14 Summary

15 During the execution of working memory tasks, task-relevant information is processed 16 by local circuits across multiple brain regions. How this multi-area computation is 17 conducted by the brain remains largely unknown. To explore such mechanisms in 18 spatial working memory, we constructed a neural network model involving 19 parvalbumin-positive, somatostatin-positive and vasoactive intestinal polypeptide-20 positive interneurons in the hippocampal CA1 and the superficial and deep layers of 21 medial entorhinal cortex (MEC). Our model is based on a hypothesis that cholinergic 22 modulations differently regulate information flows across CA1 and MEC at memory 23 encoding, maintenance and recall during delayed nonmatching-to-place tasks. In the 24 model, theta oscillation coordinates the proper timing of interactions between these 25 regions. Furthermore, the model predicts that MEC is engaged in decoding as well as 26 encoding spatial memory, which we confirmed by experimental data analysis. Thus, 27 our model accounts for the neurobiological characteristics of the cross-area 28 information routing underlying working memory tasks.

34 Introduction

Spatial navigation is a fundamental cognitive function that requires the processing of spatial memory by the hippocampus and entorhinal cortex. During a spatial navigation task, spatial information relevant to the task has to be encoded into, maintained in and recalled from spatial working memory at behaviorally adequate times. How these operations are coordinated by the cortico-hippocampal neural circuits during a spatial working memory task has yet to be explored.

41

42 A spatial working memory task is processed by several cortical areas such as the medial prefrontal cortex (mPFC) (Benchenane et al., 2010; Jones & Wilson, 2005; Spellman et 43 44 al., 2015), medial entorhinal cortex (MEC)(Suh, Rivest, Nakashiba, Tominaga, & 45 Tonegawa, 2011; Yamamoto, Suh, Takeuchi, & Tonegawa, 2014) and the hippocampal 46 area CA1 (Benchenane et al., 2010). These anatomically connected areas (Eichenbaum, 47 2017; Swanson & Cowan, 1977; Witter, Wouterlood, Naber, & Van Haeften, 2000) are 48 thought to mutually communicate information necessary to accomplish the task. 49 Importantly, the degree of functional importance of different inter-area connections 50 varies during the task. This is indicated by the fact that the impairment of these 51 connections at different behavioral phases differentially influences task performance 52 (Spellman et al., 2015; Suh et al., 2011; Yamamoto et al., 2014). For instance, in a 53 delayed nonmatching to place task (DNMP), the maintenance of spatial memory during 54 a delay period does not require synaptic connections from the layer 3 of the MEC 55 (MECIII) to CA1, but these connections are necessary for memory recall (Yamamoto et 56 al., 2014). Connections from CA1 to the mPFC play a crucial role in memory encoding 57 but not in memory recall (Spellman et al., 2015). These results indicate that information 58 flows via the hippocampal circuit are not static but are dynamically regulated depending 59 on the behavioral demands.

60

Dynamic information routing across multiple areas is thought to reflect in coherence in
neuronal activity between different areas (Spellman et al., 2015; Yamamoto et al., 2014),
which leads to the hypothesis called "communication through coherence" (Fries, 2015).

Many theoretical (Akam & Kullmann, 2010; Buehlmann & Deco, 2010; Palmigiano,
Geisel, Wolf, & Battaglia, 2017; Vogels & Abbott, 2005; Yang, Murray, & Wang, 2016)
and experimental (Letzkus, Wolff, & Lüthi, 2015; Womelsdorf, Valiante, Sahin, Miller, &
Tiesinga, 2014) studies have explored the gating functions for this dynamic processing.
However, how the computations installed at multiple cortical areas are integrated to
execute a spatial working memory task including different cognitive stages (encoding,
maintenance, and decoding) remains largely unclear.

71

72 Here, we elucidated the underlying mechanisms of multi-area dynamic information 73 processing during DNMP tasks. We hypothesize that acetylcholine (ACh) controls spatial 74 information flows in the entorhinal-hippocampal circuit according to different cognitive 75 demands. Indeed, ACh is involved in diverse cognitive functions (Hasselmo & Sarter, 76 2010; Parikh, Kozak, Martinez, & Sarter, 2007) including fear conditioning (Letzkus et al., 77 2011; Pi et al., 2013), sensory discrimination (Hangya, Ranade, Lorenc, & Kepecs, 2015; 78 Pinto et al., 2013), associative memory (Sabec, Wonnacott, Warburton, & Bashir, 2018), 79 and spatial (Croxson, Kyriazis, & Baxter, 2011; Okada, Nishizawa, Kobayashi, Sakata, & 80 Kobayashi, 2015) and non-spatial working memory tasks (Furey, Pietrini, & Haxby, 2000; 81 Hasselmo, 2006; McGaughy, Koene, Eichenbaum, & Hasselmo, 2005).

82

83 To test the hypothesis, we constructed a biologically plausible model of the entorhinal-84 hippocampal circuit consisting of MECIII, CA1 and MEC layer V (MECV) with ACh 85 projections from the medium septum and numerically simulated a DNMP task on a T 86 maze. We show that the cholinergic modulation of disinhibitory circuit in CA1 and a 87 calcium-dependent cation current in MEC is crucial for coordinating the encoding, 88 maintenance and retrieval modes of the MECIII-CA1-MECV circuit. The model 89 successfully reproduces theta phase preferences in various types of CA1 (Klausberger & 90 Somogyi, 2008) and MEC (Mizuseki, Sirota, Pastalkova, & Buzsáki, 2009) neurons. 91 Further, we demonstrate whether the inactivation of MECIII-to-CA1 input may impair 92 performance in DNMP tasks depends on the timing of inactivation, as was shown in 93 experiment (Yamamoto et al., 2014).

94

95 Our model also predicts that the same MECIII neurons encoding spatial information 96 retrieve this information later, which we confirm by analyzing experimental data of 97 single-cell and population-level activities. According to a widely accepted view, CA3-to-98 CA1 input is responsible for retrieving spatial memory (Fernández-Ruiz et al., 2017; S. J. 99 Middleton & McHugh, 2016). However, a few studies suggested that MECIII-to-CA1 100 input is engaged in the recall of spatial memory (Suh et al., 2011; Yamamoto et al., 2014), 101 and our model supports the latter view.

102

103 Results

104 Hippocampus-entorhinal cortex circuit model

105 To clarify the circuit mechanisms to control flexibly spatial information in the 106 hippocampus and MEC, we built an inter-areal cortical network model (Figure 1A, see 107 Supplemental materials for details). The network comprises three main areas CA1, MEC 108 layer 3 (MECIII) and layer 5 (MECV), and includes additional areas CA3, MEC layer 2 109 (MECII) and the medial septum (MS) as external inputs. These external inputs oscillate 110 at theta frequency (10Hz) and entrain the main circuit to theta-frequency oscillation. 111 CA3 neurons encode the current location of model rat and transfer the location 112 information to CA1. All main areas have excitatory (E) and parvalbumin (PV)-positive 113 interneurons. In addition to these neurons, the model CA1 has somatostatin (SOM)-114 positive oriens-lacunosum moleculare (OLM) and vasoactive intestinal polypeptide (VIP) 115 neurons. We built synaptic connections in our model based on anatomical observations 116 (Gonzalez-Sulser et al., 2014; Unal, Joshi, Viney, Kis, & Somogyi, 2015; Witter et al., 117 2000). In addition, we assumed that E neurons in MECII project to PV neurons in MECIII, 118 as previously suggested (Mizuseki et al., 2009).

119

Acetylcholine (ACh) is known to modulate activity of VIP neurons (Albuquerque, Pereira,
Alkondon, & Rogers, 2009) and the conductance of calcium-sensitive non-specific cation
current (CAN) in MECV excitatory cells (Fransen, Alonso, & Hasselmo, 2002; Fransén,
Tahvildari, Egorov, Hasselmo, & Alonso, 2006). The concentration of ACh ([ACh]) is

Figure 1

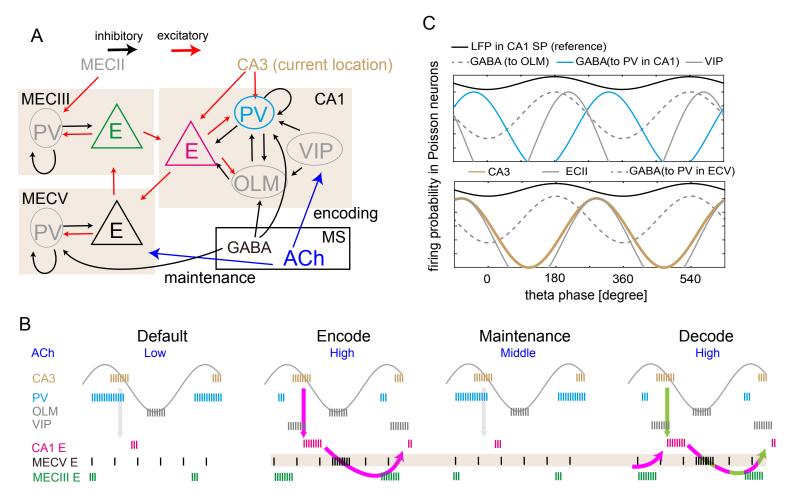

Figure 1. Entorhinal-hippocampal network model (A) Connectivity of the network model is shown. (B) Schematic image of the proposed mechanisms of spatial working memory. Vertical lines represent spikes of each neuron. Sinusoidal curve indicates theta oscillation in the CA1 stratum pyramidale (SP) layer. As described in C, this theta oscillation was used for a reference frame to measure the preferred phases of neuronal firing in our model. See the main text for details. (C) Theta-modulated firing probabilities of input neurons are shown during the sample-center run. The preferred firing phases were determined with respect to a reference theta oscillation (black) reported in the CA1 SP.

124 generally thought to change in a diffusive and tonic manner on slow timescales of 125 minutes or hours. However, recent studies have revealed that [ACh] undergoes rapid 126 phasic changes on sub-second and second timescales (Parikh et al., 2007; Teles-Grilo 127 Ruivo et al., 2017; H. Zhang, Lin, & Nicolelis, 2010). In this study, we assumed that [ACh] 128 varies in correlation with cognitive demands, i.e., [ACh] is high, slightly lowered and 129 again high during encoding, maintenance and recalling of working memory, respectively. 130 In contrast, the default concentration of Ach is low (Figure 1B). In reality, these 131 cholinergic modulations may be induced by MS (Newman, Gupta, Climer, Monaghan, & 132 Hasselmo, 2012; Okada et al., 2015; H. Zhang et al., 2010), but cholinergic neurons in 133 MS were not explicitly modeled in the present study. Under this model setting, we 134 tested the hypothesis that ACh controls information flow across the entorhinal-135 hippocampal loop circuit in the different cognitive stages of a DNMP task. In particular, 136 we proposed and explored the possibility that [Ach] regulates the disinhibition of CA1 E 137 neurons and the calcium dynamics in MECV E neurons to enable the flexible processing 138 of spatial working memory.

139

140 Before showing the details of our network model, we schematically explain the 141 mechanisms of spatial working memory which we intend to propose in this study (Figure 142 1B). In the default stage (before encoding), [ACh] is low and activity of PV is high enough 143 to inhibit activity of CA1 E neurons and the flow of information on the current location 144 from CA3 to CA1 (shaded arrow in the panel of default stage). In the encoding stage, 145 [ACh] is set higher and consequently VIP neurons are activated, which in turn inhibits 146 CA1 PV neurons to enable the transfer of location information into CA1. Thus, the 147 location information is stored in the CA1-MECV-MECIII loop circuit (magenta arrows in 148 the panel of encode stage). Next, in the maintenance stage, [ACh] is at a middle level 149 and PV neuron activity is again high, blocking the re-entry of location information into 150 CA1. Despite this blockade, however, the spatial information is maintained by the 151 activation of calcium-dependent cation current in MECV E neurons without spike 152 generation. We assume that the current remains activated at the modest level of [ACh]. 153 Finally, in the decoding stage, [ACh] is high again and information on the current location

is loaded from CA3 to CA1 (green arrow). It is noted that information on the previous
location maintained in MECV is also re-loaded from MECIII to CA1. Therefore, CA1
exhibits both current and previous position-encoding activities in the decoding stage.

157

158 The core circuits of the present network model consist of E, PV and OLM neurons, which 159 were modeled as Hodgkin-Huxley-type conductance-based neurons according to 160 previous models (S. Middleton et al., 2008; Rotstein, Oppermann, White, & Kopell, 2006; 161 Wang & Buzsáki, 1996; Wulff et al., 2009). VIP neurons were modeled as Poisson firing 162 neurons with a probability density of spikes and their outputs reflect the modulatory 163 effect of ACh. We described CA3 E neurons projecting to CA1, MECII E neurons 164 projecting to MECIII, and GABAergic neurons in MS projecting to CA1 and MECV as 165 external Poisson spike trains. As shown in Figure 1C, the firing probabilities of these 166 neurons were modulated at the theta-band frequency (10 Hz) to induce theta rhythmic 167 activities in the core circuits. The relative preferred theta phases of the external inputs 168 were chosen such that the preferred phases of various model neurons are consistent 169 with experimental observations (Klausberger & Somogyi, 2008; Mizuseki et al., 2009). 170 Furthermore, the relative phases between these inputs and theta oscillation in CA1 are 171 experimentally known, from which we can define the theta phase of the local field 172 potential (LFP) to be observed in the stratum pyramidale (SP) of CA1. This LFP oscillation 173 was used as a reference to measure the degree of agreement between the preferred 174 phases of model neurons and experimental observations. The preferred phases of 175 GABAergic neurons in MS were dependent on their target neuron types (ECV PV, CA1 176 PV and CA1 OLM). In experiment, GABAergic neurons projecting to OLM and those 177 projecting to PV in CA1 have different preferred phases (Borhegyi, 2004).

178

Given these settings of external theta-rhythmic sources, in a default stage the resultant firing of all neurons in CA1, MECIII and MECV showed theta-rhythmic patterns and their preferred phases are consistent with experimental observations (Figure S1): E and OLM neurons in CA1 showed preferred phases around the troughs of theta oscillation, whereas PV neurons around the peaks (Klausberger & Somogyi, 2008). In MECIII, E and

Figure S1

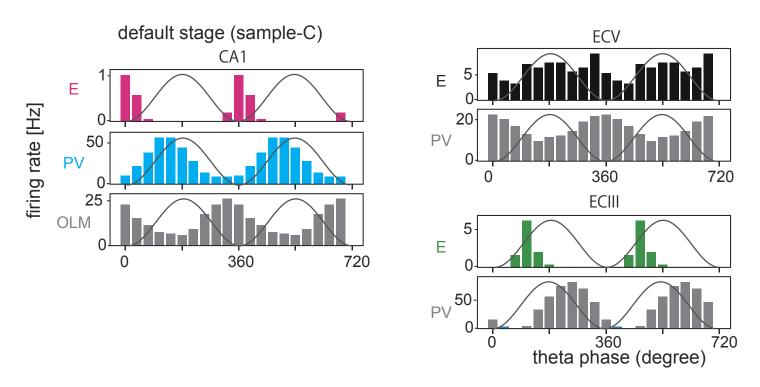

Figure S1 (related to Figure 1). Activity of various types of neuron during task. Preferred phases of various neuron types during the sample-C period. The firing rates were calculated by numerical simulations for excitatory and inhibitory neurons in the entorhinal-hippocampal circuit. The reference theta oscillation presumed in the SP layer of CA1 is also shown (solid lines).

PV neurons fired preferentially around the peaks and troughs of theta oscillation, respectively (Mizuseki et al., 2009). In MECV, PV neurons preferred the troughs, but E neurons did not show strong phase preferences (Mizuseki et al., 2009). Thus, the model neurons show biologically plausible theta-phase locking activity.

188

189 Encoding and recalling of spatial information in the circuit model

190 The central question of this study is to clarify how spatial information is encoded, 191 maintained and recalled in the entorhinal-hippocampal circuits. Before studying this 192 problem, we, first, asked whether our model can replicate the task-related activities 193 reported in previous experiments. In particular, we considered a DNMP task on a T-maze 194 (Yamamoto et al., 2014). In this experiment, one arm of the T-maze was closed during a 195 sample run and the mouse was forced to choose another arm. After a delay period, the 196 mouse was set to a test run in which both arms were open and the mouse had to choose 197 the arm opposite to the one chosen in the preceding sample run (that is, if the mouse 198 chose the right arm in the sample run, it had to choose the left arm in the test run). For 199 a successful test run, the mouse had to remember the previously chosen arm. This task 200 requires at least two types of memory, namely, rule-based memory and spatial working 201 memory. The former memory is thought to be encoded in the prefrontal cortex 202 (Durstewitz, Vittoz, Floresco, & Seamans, 2010; Guise & Shapiro, 2017; Preston & 203 Eichenbaum, 2013). However, in this study we did not model the prefrontal circuits and 204 focused on the processing of spatial working memory in the entorhinal-hippocampal 205 circuits.

206

Figure 2A shows the organization of sample and test runs in our model together with the connectivity patterns between the neural ensembles encoding different locations on the maze. We monitored the activity of sample runs along the center arm (sample-C) and left arm (sample-L), and that of test runs at the home position (delay) and center arm (test-C) up to the junction (decision point) of the T-maze. For the sake of simplicity, we implemented four subgroups L, R, C and H of place cells in CA3, each of which encoded the current position of the model mouse on the left, right, center arms and at

Figure 2

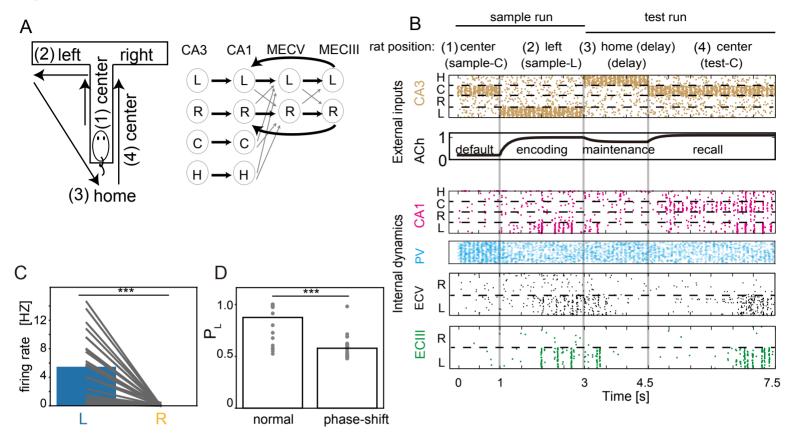

Figure 2. Performance of the model for a DNMP task (A) Left; Schematic illustrations of task periods during the sample and test trials of the DNMP T-maze task: (1) center in the sample trials (sample-C), (2) left in the sample trials (sample-L), (3) home (delay), (4) center in the test trials (test-C) periods. Right; Synaptic connectivity is shown between the neuron subgroups encoding the specific locations of the maze (left, right, center arms and home position). Connections (bold) are stronger within the loop circuit of MECV, MECIII and CA1 than other modest connections (solid). (B) Raster plots of E neurons in different cortical areas are shown together with the time evolution of ACh concentration. (C) The average firing rates of MECIII L and R subgroups were calculated for the test-C period in 25 runs of simulations (black lines, five different networks with five different initial conditions). Unless otherwise stated, average firing rates were evaluated in a similar fashion throughout this study. (D) Probability of left choice (P_L) and average of P_L was calculated in the normal and phase-shift conditions. Gray dots show P_L of different networks for different initial conditions. Chance level is 0.5.

214 the home position, respectively. For instance, neurons belonging to the subgroup L were 215 given a higher firing probability when the model mouse traveled across the left arm 216 (Figure 2B; also see "Neuron models" in Materials and methods). Accordingly, E neurons 217 in CA1 were also divided into four subgroups L, R, C, and H, each of which was strongly 218 projected to by the corresponding subgroup in CA3. In contrast, MECIII and MECV had 219 two subgroups denoted as L and R and these subgroups were assumed to form closed 220 loop circuits with the corresponding CA1 subgroups. In the present study, C and H 221 subgroups are not necessary in MEC and we omitted these parts for the sake of 222 simplicity. The other positions on the maze that are not shown in Figure 2A were not 223 modeled.

224

Below, without loss of generality, we consider the case that the mouse chooses the left arm in every sample trial. Accordingly, we define task performance as the probability of Left choice, P_L , which is estimated as $P_L = e^{-r_L}/(e^{-r_L} + e^{-r_R})$, where r_L and r_R are the spike rates of the L and R subgroups, respectively, during the test-C period. Note that P_L can be written as a function of $r_L - r_R$. The larger the difference in the spike rates, the more robust the memory encoding.

231

232 In experiment, coherence between MECIII and CA1 increased in the high-gamma band 233 (60-120Hz) as the animal approached the junction point on the T-maze (Yamamoto et 234 al., 2014). The result indicates that high-gamma oscillation plays an active role in the 235 decision making, presumably in reading out stored locations from working memory. 236 However, the task performance of the animal was also highly correlated with theta-237 phase-locked firing in MECIII. In addition, as shown later, our model successfully 238 performs working memory tasks without gamma oscillation. We speculate that high-239 gamma oscillation nested in theta oscillation may either help the downstream areas 240 (responsible for the generation of behavioral outputs) to correctly read out the stored 241 locations from the entorhinal-hippocampal circuit or mediate top-down signals to shift 242 the status of the entorhinal-hippocampal circuit from the maintenance mode to the 243 readout mode. In this study, we focus on spatial information processing within CA1 and

244 MEC, and will not model any process arising outside of the entorhinal-hippocampal 245 circuit.

246

247 Implications of preferred theta phases in coordinating activities in the CA1-MECV-

248 MECIII loop circuit

249 In Figure 2B, we show activities of E neurons in CA3, CA1, MECV and MECIII together 250 with [ACh] during (1) sample-C, (2) sample-L, (3) home (delay) and (4) test-C runs. 251 Depending on the mouse's position, the corresponding subgroup was activated in CA3 252 according to the given firing probability. During the sample-L run, [ACh] was set to 253 increase, which disinhibited CA1 PV neurons and accordingly strongly activated the CA1-254 MECV-MECIII loop circuit of the L subgroups to encode a choice memory in MECIII. Then, 255 in the delay period, [ACh] was set to decrease slightly, which strongly suppressed neural 256 activities in all L subgroups including the CA1 subgroup L. We note that a similar 257 suppression arose in experiment as if spatial memory had not been maintained during 258 delay periods (Yamamoto et al., 2014). During the test-C run, the CA1 subgroup C was 259 activated driven by the CA3 subgroup C. Importantly, as the model mouse approached 260 to the decision point, the subgroups L were gradually reactivated in the loop circuit to 261 retrieve the memory of the previous choice. This activation-suppression-reactivation 262 pattern is clearly seen in the firing rate of MECIII neurons. Average firing rates during the test-C period were significantly different ($p=3.071 \times 10^{-6}$, t test on two related 263 264 samples) between the subgroups L and R in MECIII (Figure 2C), implying that the network 265 model successfully recalled the stored spatial memory.

266

The successful encoding of memory required theta-phase-locking of neural firing along the CA1-MECV-MECIII loop circuit. As mentioned previously, the theta phases of external sources (i.e., CA3, MECII and MS) entrain neurons in these areas in theta-phaselocked firing with the preferred phases that are consistent with experimental observations. In the normal situation, MECIII PV neurons are activated by input from MECII at the troughs of theta oscillation and consequently MECIII E neurons tend to fire at the peaks. Then, CA1 E neurons are strongly activated in a non-linear manner (Bittner

et al., 2015; Takahashi & Magee, 2009) by near-coincident inputs from MECIII and CA3:
spikes from CA3 arriving at CA1 just after spikes from MECIII activate CA1 E neurons
much stronger than those from CA3 arriving at otherwise timing (see Materials and
methods).

278

279 The theta phases of inputs from the different sources were tuned such that they are 280 consistent with experimental observations (Figure 1C). Is this coordination of theta 281 phases necessary for successful working memory function? To examine this, we shifted 282 the preferred phases of MECII neurons by 180 degrees from the troughs to the peaks of 283 the reference theta oscillation of CA1 LFP (Figure S2A). Figure S2B shows the phase 284 preferences of CA3, CA1 E, CA1 PV, and MECIII E neurons after this change. MECIII PV 285 neurons dramatically reduced spikes at the descending phases of theta oscillation, 286 which shifted the firing of MECIII E neurons to the troughs of theta oscillation. 287 Consequently, the peak activities of MECIII and CA3 were separated by about one half 288 of theta cycle and did not coincidently innervate CA1. The timing deviation impaired the 289 encoding of spatial information into the loop circuit, as indicated by significantly 290 reduced rate differences between L and R subgroups (Figure S2C, p= 2.679x10⁻¹⁶, t test 291 on two related samples), resulting in a degraded task performance (Figure 2D, p= 2.334 292 $x10^{-8}$, t test on two related samples). Thus, the specific coordination of the preferred 293 theta phases of MECIII and CA3 neurons is crucial for the working memory operation of 294 the entorhinal-hippocampal circuit.

295

296 The role of disinhibition in regulating the activity of the CA1-MECV-MECIII loop circuit 297 We show that the ACh-mediated disinhibitory mechanisms regulate cross-area 298 communications within the entorhinal-hippocampal circuit during different task periods. 299 We first analyzed how activity of CA1 E neurons is regulated by [ACh]. We consider the 300 default stage (i.e., 0 to 1 sec in Figure 2B) in which [ACh] is low (Figure 3A). In this stage, 301 output from VIP neurons is weakened and, consequently, PV and OLM neurons are 302 strongly activated around the peaks and the troughs of theta oscillation, respectively 303 (Figure 3B). Accordingly, CA1 E neurons rarely fire around the peaks and troughs (but

Figure S2

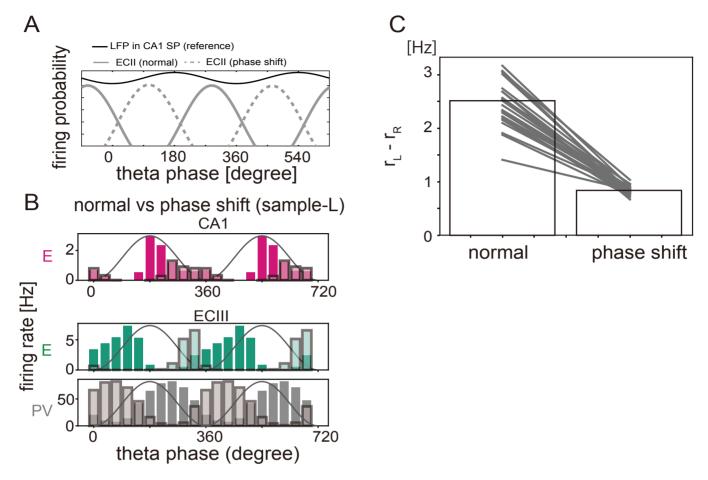

Figure S2 (related to Figure 2). (A) Theta-modulated firing probabilities of ECII neurons for the normal and preferred phase shift conditions are shown. (B) Modulations of spike counts by theta oscillation are shown for CA1 E, MECIII E and MECIII PV neurons during the sample-L period. Neuronal activities in the normal and preferred phase shift conditions of theta oscillation are shown with dark and light colors, respectively. (C) Differences in the firing rate between the L and R subgroups of CA1 E neurons were calculated during the sample-L period and compared between the normal and the phase shift conditions. Simulation results for the same initial conditions are connected with lines.

Figure 3

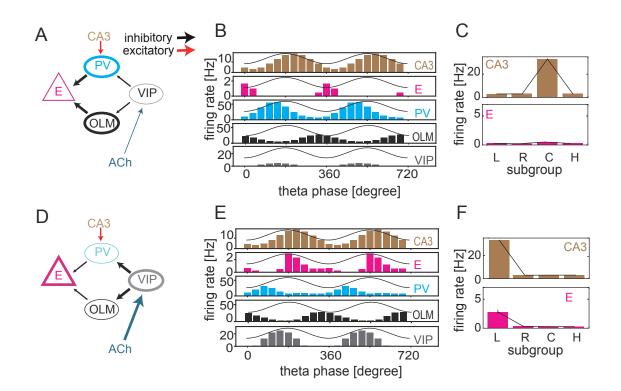

Figure 3. Gating of CA3-to-CA1 signaling by disinhibition mechanism. (A) The operation mode of disinhibitory circuit is schematically illustrated in low [ACh] states. (B) Theta phase preferences of spikes during the sample-C period are shown for CA1 neurons including all subgroups. Only for VIP neurons, the firing rate normalized by [ACh], which corresponds to output from VIP neurons to other inhibitory neurons (see the Materials and methods), is plotted. Solid curves show the reference theta oscillation. (C) Average firing rates of the L, R, C and H subgroups in CA3 and CA1 are shown during the sample-C period. Error bars indicate s.d. (D) The operation mode of disinhibitory circuit in high [ACh] states. (E, F) Similar to (B) and (C) during the sample-L period.

304 they can generate a small number of spikes driven by external noise after the troughs 305 of theta oscillation at which inputs from both PV and OLM are weakened: see Figure S1). 306 In contrast, during the epochs of high [ACh] (Figure 3D, the sample-L period: the test-C 307 period also corresponds to the high [ACh] epoch, but will be discussed later), CA1 E 308 neurons show strong activation immediately after the peaks of theta oscillation because 309 PV neurons are suppressed around the peak (Figure 3E). OLM neurons are also 310 suppressed, but their inhibitory effect on E-neuron firing around the peak is relatively 311 weak since the preferred phase of OLM neurons is the trough of theta (spikes around 312 the peak in Figure 3E are less than those in Figure 3B). Thus, [ACh] regulates the activity 313 of CA1 E neurons. Also, the cholinergic modulation advances the preferred phase of CA1 314 E neurons from the troughs to the peaks of theta oscillation. Later, we will examine the 315 model's prediction in experimental data.

316

317 Next, we asked if Information on the current position of the mouse can be selectively 318 transferred from CA3 to CA1 by [ACh]. Although, throughout the task, CA1 E neurons 319 constantly receive position information from CA3, a certain mechanism is required to 320 transfer CA3 position information to CA1 neurons selectively during encoding epoch (in 321 the sample-L period, see the CA1 L subgroups in Figure 2B). We found that ACh-induced 322 disinhibition provides this mechanism: at the sample-C period [ACh] is low and the 323 sensitivity of CA1 E neurons to CA3 input remains low, consequently the position 324 information is not transferred to CA1 (Figure 3C); at the sample-L period [ACh] is 325 increased and accordingly the sensitivity is also enhanced, resulting in an information 326 transfer (Figure 3F).

327

The disinhibition mechanism further explains why the blockade of MECIII-to-CA1 connections impaired task performance in experiment (Yamamoto et al., 2014). When the model mouse is sampling left or right arm, the disinhibition mechanism enables the activation of the corresponding subgroups in the CA1-ECV-ECIII loop: highly activated CA1 neurons activate MECV E neurons, which in turn activate MECIII E neurons. MECIIIto-CA1 projections further activate CA1 E neurons, thus completing a positive feedback

loop within the activated subgroups. However, the blockade of MECIII-to-CA1
 connections reduces neural activity in CA1 and hence in MECIII, disabling the storage of
 the current position.

337

338 To confirm the crucial roles of disinhibition (i.e., VIP-PV-E and VIP-OLM-E connections) 339 in the working memory task, we studied two cases. In the first case, PV neurons were 340 inactivated in CA1 during the entire trial period without changing the other conditions 341 (Figure S3A). Due to the lack of inhibition from PV neurons, CA1 E neurons were strongly 342 activated at any ACh concentration. In the encoding epoch, E neurons exhibited higher 343 activity in the L subgroup than in the R subgroup in both CA1 (Figure S3B) and ECIII 344 (Figure S3C, 1 to 3 sec). However, after this epoch E neurons immediately lost selectivity 345 to spatial information because they were too strongly activated in both subgroups. 346 During some intervals firing rate was higher in the L subgroup than in the R subgroup, 347 but it was opposite during other intervals (Figure S3C, after 3 sec). Thus, the spatial 348 information recalled randomly varied from trial to trial, and working memory 349 performance was unreliable (Figure S3D).

350

351 In the second case, the cholinergic modulation of PV neurons (but not that of OLM 352 neurons) was terminated during the entire trial period. In this case, PV neurons were 353 not inactivated even at high [ACh] (Figure S3E) and the encoding of spatial information 354 into CA1 was largely impaired (Figure S3F). Consequently, spatial information could not 355 be stably maintained in MECIII (Figure S3G) and probability of left choice, P_L , was 356 significantly decreased (Figure S3H, p=1.542x10⁻⁹, t test on two related samples). Thus, 357 in both cases, spatial information in CA3 was not successfully transferred into the CA1-358 MECV-MECIII loop circuit.

359

360 **Covert activation by calcium dynamics**

361 An unexpected experimental finding was that neural activities in MECIII were strongly 362 suppressed during delay periods (Yamamoto et al., 2014). This observation challenges 363 our hypothesis that either MECV or MECIII, or both, serve for working memory in the

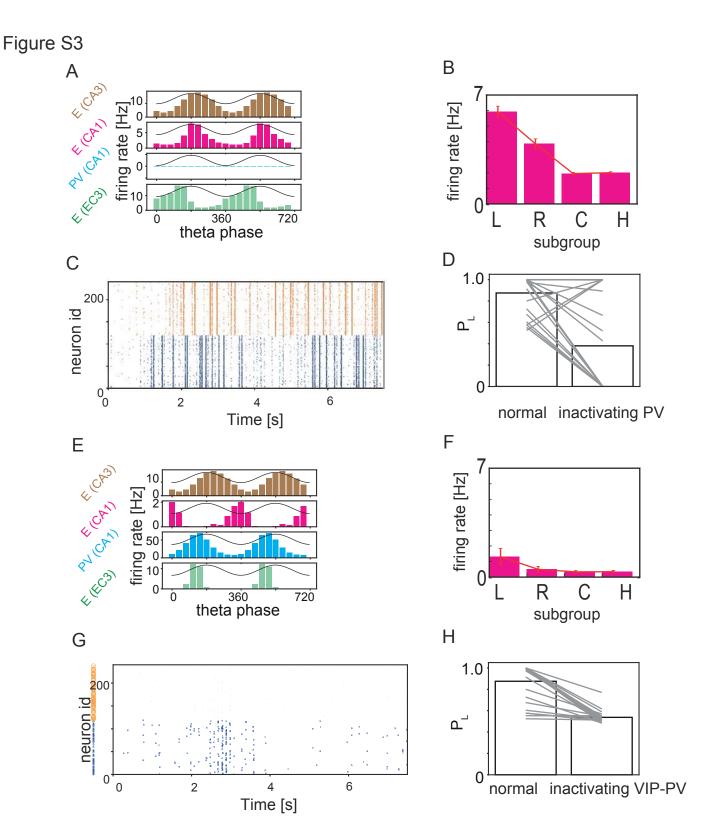

Figure S3 (related to Figure 3). Effect of inactivation of disinhibition mechanism. (A) Firing rates of CA1, CA3 and MECIII neurons during sample-L periods are shown. During the simulations, CA1 PV neurons were inactivated. Solid curves indicate the reference theta oscillation. (B) Average firing rates of CA1 E neurons in different subgroups are plotted during sample-L periods in the same inactivating condition. (C) Raster plots are shown for the L (blue) and R (orange) subgroups of MECIII E neurons. (D) Probability of left choice P_L is plotted in the normal and inactivating conditions. Lines connect two data points obtained from simulations of a normal network and its impaired version with the same initial conditions. (E, F, G, H) same as (A) to (D), but for the network models with disabled VIP-to-CA1 PV connections.

spatial decision making task, raising the question about how the entorhinalhippocampal circuit recalls the encoded spatial information after the delay periods. To explore the underlying circuit mechanisms of memory recall, we implemented calciumsensitive non-specific cation current (CAN current in Materials and methods) in our cortical neuron models.

369

370 The CAN current was originally proposed to explain persistent activity of single cortical 371 neurons in MECV (Fransen et al., 2002; Fransén et al., 2006), and a similar persistent 372 activity was later shown in the layer V of various cortical areas (Rahman & Berger, 2011). 373 The CAN current is activated in the presence of ACh with the intensity depending on the 374 activation rate of high conductance channels, $r_{\rm H}$. The conductance $r_{\rm H}$ increases in time 375 when the calcium concentration $[Ca^{2+}]$ is beyond a critical value d_P and decreases when 376 $[Ca^{2+}]$ is below another critical value d_D . Because $d_D < d_P$, a hysteresis effect or bistability 377 appears for $d_{\rm D} < [{\rm Ca}^{2+}] < d_{\rm P}$. Thus, once $[{\rm Ca}^{2+}]$ exceeds $d_{\rm P}$, the value of $r_{\rm H}$ remains high 378 until [Ca²⁺] again decreases below $d_{\rm D}$ (Figure 4A). Neurons with high $r_{\rm H}$ respond to input more sensitively than those with low $r_{\rm H}$ and, thus, memory of previous high activity is 379 380 stored in $r_{\rm H}$ through calcium dynamics.

381

382 In the sample-L period, an increased activity of the CA1 subgroup L enhanced spike firing 383 of MECV E neurons in the subgroup L (Figure 4B). During the enhanced firing, [Ca²⁺] was 384 elevated in these neurons by calcium influx through the voltage-dependent calcium 385 channel. This increase of [Ca²⁺] occurred only in the MECV subgroup L but not in the 386 MECV subgroup R (Figure 4C). After the sample-L period, [ACh] was decreased and, 387 consequently, the CAN current was also decreased. Because lowering [ACh] decreased 388 the output of VIP neurons, that of PV neurons was increased and consequently that of 389 CA1 E neurons was suppressed. Thus, the changes in neural activity resulted in a 390 decreased firing rate of MECV E neurons. Nevertheless, the fraction of high conductance 391 state remained high in the subgroup L (but not in the subgroup R) of MECV E neurons 392 (Figure 4C).

393

Figure 4

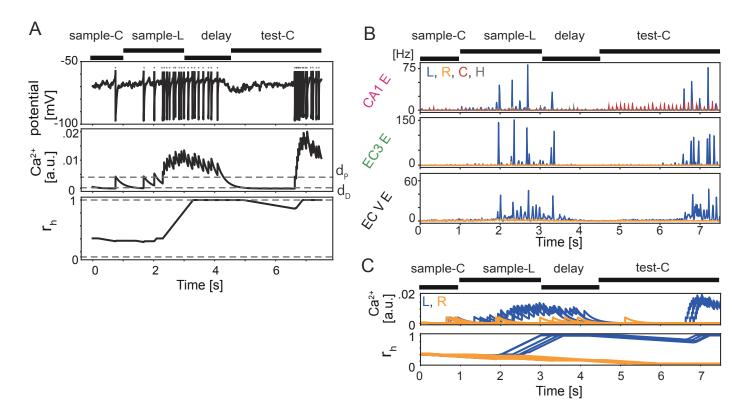

Figure 4. Role of CAN current in memory encoding and maintenance. (A) Single trial evolution of the membrane potential (top), [Ca2+] (middle) and the ratio of high conductance state of CAN channels r_h (bottom) are plotted in an MECV excitatory neuron. Dots above the membrane potential represent spikes. Broken lines denote two threshold values, dP and dD, in the middle panel and the upper and lower critical values of the high conductance ratio in the bottom panel (See Materials and methods). (B) Firing rates are shown for E neurons in CA1, MECIII and MECV. Colors indicate different neuron subgroups. (C) Time evolution of [Ca2+] (top) and rh (bottom) are plotted for randomly-chosen five MECV E neurons belonging to L (blue) or R (orange) subgroup during the same trial as in B.

394 The CAN current plays a crucial role in the maintenance of working memory. To explain 395 this, we divided the test-C period into early and late periods: in the early period CA1 396 neurons were selectively activated in the subgroup C but not in the subgroup L (and 397 subgroup R); in the late period they were strongly activated in the subgroup L (Figure 398 4B). During the test-C period, [ACh] was again increased, so was the activity of CA1 E 399 neurons through the disinhibition mechanism. Although MECV neurons in both 400 subgroups L and R received synaptic input from the CA1 subgroup C, MECV neurons 401 were selectively activated in the subgroup L because the high conductance rate 402 remained high in these neurons. The activity of the MECV subgroup L neurons gradually 403 increased in the early test-C period, and eventually became sufficiently strong to 404 activate MECIII subgroup L neurons. Accordingly, the test-C period entered the late 405 period and the spatial information stored in MECV could be decoded by CA1 neurons. 406 The onset time of the late period depends on the realization of neural networks and 407 initial conditions. Thus, the covert activation of CAN current enables the retrieval of 408 persistent activity in the MECV subgroup L neurons for the decoding of spatial 409 information in the test-C period.

410

411 Comparison of MECIII neural activity between the model and experiment

412 We compared the responses of our model with those of the mouse entorhinal-413 hippocampal circuit. For this comparison, we analyzed E neuron activity in MECIII after 414 dividing each of the sample-L, delay and test-C periods into early and late portions, 415 respectively. As in experiment (Yamamoto et al., 2014), we first quantified the intensity 416 of theta oscillation in these task periods by computing periodicity index (Materials and 417 methods). As shown in Figure 5A, this index was high during the late sample-L, early 418 delay, and late test-C periods, but it was low during delay period (i.e., late delay and 419 early test-C periods). Periodicity index exhibited similar task period-dependence in the 420 model and experiment (c.f. Figure 5C and Figure S5 in (Yamamoto et al., 2014)).

421

We next analyzed how the blockade of MECIII-to-CA1 projection affects the behavior ofour model in different task periods. In the experiment, this blockade significantly

Figure 5

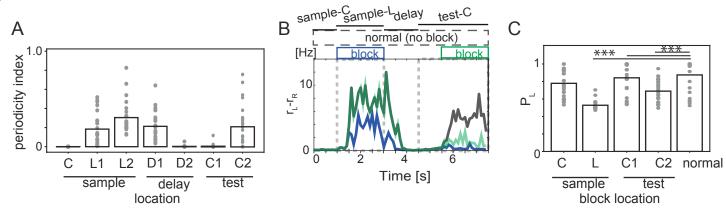

Figure 5. Blockade of MECIII-to-CA1 connections during sample-L and late test-C periods. (A) Periodicity index (Yamamoto et al., 2014) was calculated for the activity of MECIII E neurons (Materials and methods). The labels L, D, C refer to sample-L, delay, test-C periods, respectively, and the numbers 1 and 2 label the early and late portions, respectively, of these periods. (B) Average differences in firing rate between the L and R subgroups of MECIII E neurons were calculated under the blockade of MECIII-to-CA1 connections: normal condition (black); the blockade during sample-L periods (blue); the blockade during late test-C periods (green). In each condition, the differences were averaged over five networks and five initial states. By definition, green and black lines overlap with one another before the blockade. Boxes above the traces indicate the periods of blockade. (C) P_L were calculated for different periods of the blockade.

424 impaired working memory performance of the mouse. When MECIII-to-CA1 projection 425 was blocked during the encoding epoch (sample-L period), MECIII activity and the firing 426 rate difference between L and R subgroups were suppressed during both sample-L and 427 the subsequent late test-C periods (Figure 5B, blue), meaning that task performance was 428 impaired. When the blockade was during the recall epoch (late test-C, 5.5-7.5 s), the 429 inter-subgroup difference was reduced and task performance was also impaired (green 430 line in Figure 5B). In contrast, when the blockade was imposed during sample-C (3-4.5 431 s) or early test-C period (4.5-6 s), MECIII activity was not greatly affected (Figure S4). 432 Figure 5C summarizes the resultant task performance of the model. In three of the four 433 conditions (blockade in sample-C, early and late test-C), results were well consistent 434 with experimental observations (c.f., Figure 6F in (Yamamoto et al., 2014)). In addition, 435 our model predicts that the blockade in sample-L period significantly impairs working 436 memory performance (p=3.175x10⁻¹⁰), suggesting that the CA1-MECV-MECIII loop 437 circuit maintains neural activity in the MECIII and plays a pivotal role in the spatial 438 working memory task. This prediction should be experimentally validated.

439

440 Experimental validation of period-dependent preferred theta phases

441 Our model predicts that CA1 E neurons shift their preferred theta phases from the 442 troughs to the peaks when [ACh] is high (Figures 3B and 3E). In Figure 6A, we present 443 the phase preference of CA1 E neurons during sample-C, sample-L, delay, early test-444 center (test-C1) and late test-center (test-C2) periods of the DNMP task. Their spikes 445 preferred the troughs of theta oscillation during sample-C periods but, owing to the 446 disinhibitory mechanism, the preferred phase was shifted to the peaks during sample-L 447 periods. When the model mouse returned to the home position (delay period), [ACh] 448 was decreased to reactivate PV neurons in CA1, which reduced the sensitivity of CA1 to 449 inputs from MECIII and CA3 and selectively suppressed spike generation at the peaks of 450 theta oscillation (but not at the troughs). In test-C1 periods, [ACh] was again increased 451 to allow the activation of CAN current (Figure 4C), which shifted the preferred phase to 452 the descending phase of theta oscillation. During test-C2 periods, our model predicts a

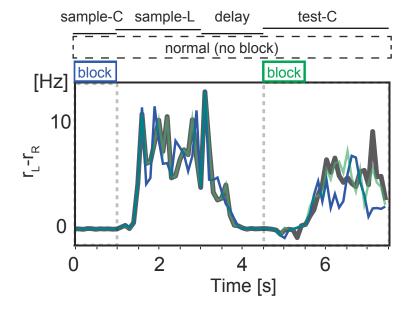

Figure S4

Figure S4 (related to Figure 5). Blockade of MECIII-to-CA1 connections during sample-C and test-C periods. Connections from MECIII to CA1 were blocked during sample-C (blue) and early test-C (green) periods. Differences in firing rate between the L and R subgroups of MECIII E neurons are shown in the same manner as in Figure 5B. Similar evolutions are also shown in the normal condition (black).

Figure 6

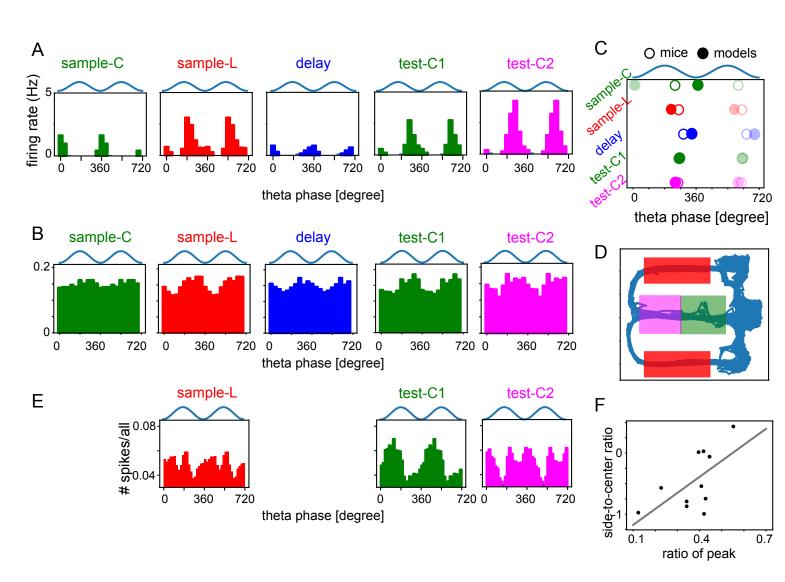

Figure 6. Preferred theta phases in model networks and rodents. (A) Phase preferences are shown for CA1 E neurons in model networks during given task periods (top). (B) Phase preference curves of CA1 neurons were calculated for data obtained in (Yamamoto et al., 2014). (C) Preferred theta phases of the models (filled circles) and mice (empty circles) were averaged over multiple theta cycles during given task periods. The same average phases are shown for two theta cycles (one in darker colors and one in light colors) for the clarity of the plots. (D) Schematic illustration of the figure-eight maze used in (Fernández-Ruiz et al., 2017; Mizuseki et al., 2013). Colored rectangles indicate early-center, late-center, and reward periods from which data were resampled. (E) Phase preference curves of CA1 excitatory neurons were calculated by using the data of (Mizuseki et al., 2013). For comparison, we divided the task periods of center arm and reward arm into early and late epochs. (F) Correlation between the ratios of spikes at the peaks and the side-to-center ratio is plotted.

453 progressive advance of preferred theta phase in CA1 due to an enhanced synaptic drive454 by MECIII.

455

456 We confirmed these predictions in the data of a DNMP task in T-maze (Yamamoto et al., 457 2014). Figure 6B shows the distributions of preferred phases of spikes in mouse CA1 458 during different task periods, i.e., sample-C, sample-L (corresponding to the reward arm), 459 delay, test-C1, and test-C2 periods (see Materials and methods). In mice, spikes were 460 generally not modulated by theta oscillation as strongly as in the model. In particular, 461 oscillatory modulations were weak in sample-C periods. Nonetheless, the preferred 462 theta phases in the various task periods are well consistent between mice and models. 463 The average preferred phase, which was computed as $\bar{\theta} = \arg(\Sigma_k \exp(i\theta_k))$ with k 464 being the index of spikes for all neurons and *i* being imaginary unit, is delayed during 465 delay periods compared to other task periods in both mice and models (Figure 6C). In 466 contrast, our model predicts that the preferred phase is progressively advanced during 467 test-C2 (i.e., late test-center) period due to an increased synaptic drive by MECIII (Figure 468 4B).

469

470 Next, we asked whether preferred theta phase behaves similarly in an alternating figure-471 eight task (Mizuseki, Sirota, Pastalkova, Diba, & Buzsaki, 2013). We were particularly 472 interested in examining the hypothesized role of cholinergic control of working memory 473 function. In the alternating figure-eight task, rats were trained to alternately change the 474 turn direction at a junction point of an eight-shape maze, meaning that the rats had to 475 remember the turn direction of the preceding run. This task is similar to the previous 476 DNMP task, but one difference is that sample and test trials are not clearly separated in 477 the alternating figure-eight task. Nevertheless, we may correlate the behavioral epochs 478 of the two tasks to each other. When rats traverse the center arm, they had to retrieve 479 memory of the preceding choice to prepare for the next choice. Therefore, traveling 480 along the center arm may correspond to test-C period in the DNMP task. Then, we can 481 define three distinct areas on the eight-shape maze (Figure 6D): early center, late center

and reward arms, which may correspond to test-C1, test-C2 and sample-L periods,respectively. Below, we follow these rules.

484

485 Figure 6E shows the preferred phases of excitatory neurons in the deep layer of CA1. It 486 has been reported that for some unknown reason these neurons only exhibit phase 487 shifts in early trials (Fernández-Ruiz et al., 2017; Mizuseki et al., 2013). Therefore, we 488 only used data of initial ten trials in the following analyses. On the early center arm (test-489 C1 period), neurons fired more frequently around the troughs of theta oscillation than 490 the peaks. However, on the late center arm (test-C2 period), neurons fired slightly more 491 often at the peaks, generating two peaks per theta cycle in the spike density distribution. 492 On the reward arm (sample-L period), neurons fired most frequently at the peaks, which 493 is consistent with the previous study (Fernández-Ruiz et al., 2017). These results seem to 494 be consistent with the model's prediction that the preferred firing phase of CA1 neurons 495 changes from the troughs to the peaks of theta oscillation during the epochs of high 496 [ACh]: in the alternating figure-eight task, high level of attention, or high [ACh], is likely 497 to be required on the reward arm (for encoding reward information) and the late center 498 arm (for recalling the previous choice).

499

500 Finally, we explored single-cell-level behavior in (Mizuseki et al., 2013) to provide further 501 support for our prediction: cells spiking on the side arms (cells in L or R subgroup in the 502 model) are likely to spike on the late center arm at the peaks of theta oscillation. 503 Therefore, we computed two ratios for 11 cells which showed high activation on the late 504 center arm (See Materials and methods for details): the number ratio of spikes 505 generated around the peaks (90° to 270°) to spikes generated on the late center arm; 506 the number ratio of spikes generated on the side arms to spikes generated on the late 507 center arm (side-to-center ratio). The values of the two ratios are significantly correlated (Figure 6F: r=0.62 and p=0.042, t-test), suggesting that cells strongly activated on the 508 509 side arms are also highly likely to fire around the theta peaks. This result strongly 510 supports the prediction of our model.

511 Task performance depends on acetylcholine concentrations in the model

512 In our model, two ACh-regulated mechanisms, that is, disinhibitory circuit in CA1 and 513 CAN current in MECV excitatory cells, play crucial roles in encoding, maintenance and 514 recall epochs of working memory tasks. Therefore, we examined whether these core 515 mechanisms work robustly when [ACh] is changed. We changed the default levels of 516 [ACh] with other parameter values unchanged. Lowering the default [ACh], which 517 weakens disinhibition, during the encoding epoch (sample-L) disenabled the CA1 L and 518 R subgroups to exhibit large enough activity differences to encode spatial information 519 in the CA1-MECV-MECIII loop circuit (Figure 7A, blue). Task performance was severely 520 impaired, contrasting to intact performance at higher default [ACh] levels (Figure 7B, 521 left). Lower default [ACh] levels during delay period had almost no effects on task 522 performance (Figure 7B, center). Finally, lower default [ACh] levels during the recall 523 epoch (test-C2) eliminated the reactivation of the subgroup L (Figure 7A, green) and task 524 performance was severely impaired (Figure 7B, right), but performance remained intact 525 at higher [ACh] levels. These results show that default [ACh] levels should be sufficiently 526 high during the encoding and recall epochs, but fine tuning of [ACh] is unnecessary.

527

Next, we explored whether theta-phase-locked firing has anything to do with the success of the working memory task. To this end, we compared the theta preference of CA1 neurons during the test-C2 period between successful and failure trials in both models and mice (Figure 7C). [ACh] was at the default levels. In both models and mice, neurons preferentially fired around the peaks of theta oscillation in success trails, but firing phases were somewhat delayed in failure trials.

534

535

536 Discussion

537

In this study, we developed a model comprising MECV, MECIII and CA1 to explore how
these local circuits process and communicate information with each other regulated by
ACh during DNMP tasks. In our model, changes in the ACh concentration control cortical

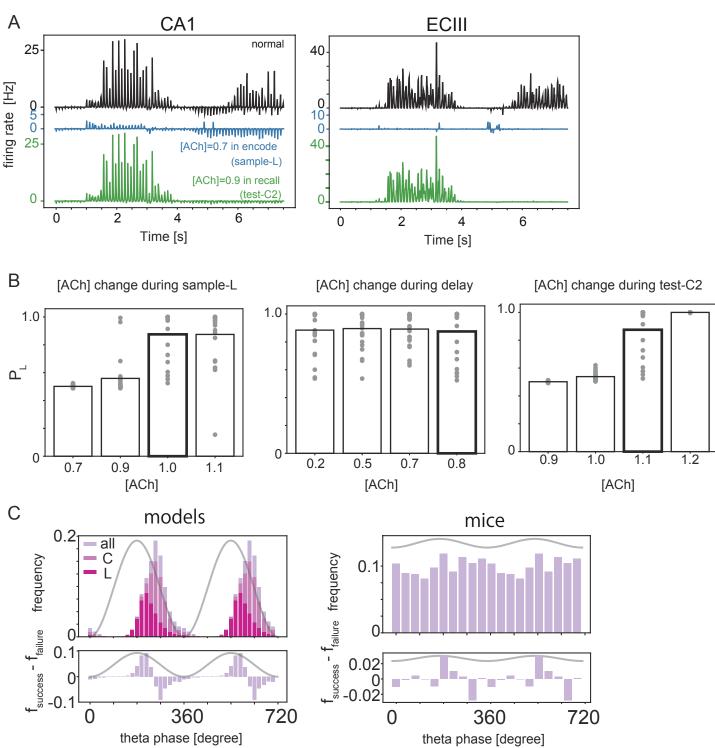

Figure 7. Cholinergic modulations in the network model. (A) In CA1 (left) and MECIII (right), differences in firing rate between the subgroups L and R were calculated at the normal (black) and reduced levels of [ACh] during encoding (sample-C, blue) and recall (test-C2, green) epochs. (B) Probability of left choice averaged over different networks and initial conditions are shown at different levels of [ACh] during sample-L (left), delay (center) and test-C2 (right) periods. Thick lines indicate results for the default [ACh] levels. (C) Frequency of spikes in CA1 excitatory neurons during test-C2 periods (top) are shown in the model (left) and mice (right). In the model, [ACh] was set to the normal level and spike counts are shown separately for the subgroups L and C. Only the total spike count is shown for mice. Bottom panels show the differences in firing rate between successful and failure trials.

disinhibitory systems and calcium-dependent cationic current to perform different cognitive functions in DNMP tasks. With the ACh modulations, our model successfully replicates the various features of neural activity observed in MECIII and CA1 (Yamamoto et al., 2014). In particular, the model predicts that CA1 neurons change their preferred theta phases depending on cognitive demands, which was also supported by experimental data (Fernández-Ruiz et al., 2017; Mizuseki et al., 2013; Yamamoto et al., 2014).

548

549 Relevance of MEC-CA1 loop to spatial working memory tasks

550 The hippocampal area CA1 is a central locus for spatial information processing, and 551 stores the concurrent position of the rodent (O'Keefe & Dostrovsky, 1971) as well as 552 retrospective and prospective representations of position information (Dragoi & Buzsáki, 553 2006; Ferbinteanu & Shapiro, 2003; Foster & Wilson, 2006; Gupta, van der Meer, 554 Touretzky, & Redish, 2010; Pastalkova, Itskov, Amarasingham, & Buzsaki, 2008; Zheng, 555 Bieri, Hsiao, & Colgin, 2016). Focusing on the CA1-MECV-MECIII loop circuit involved in 556 spatial working memory (van Strien, Cappaert, & Witter, 2009; Witter et al., 2000), we 557 demonstrated how the spatial information of the selected arm is encoded in CA1 during 558 a sample trial (Figure 3), maintained in MECV during delay period, and transferred to 559 MECIII and reloaded on CA1 for decision making (Figure 4). Several studies found that 560 connections from MECIII to CA1 are crucial for the success of spatial working memory 561 tasks (Suh et al., 2011; Yamamoto et al., 2014). Our model demonstrated this role of 562 MECIII-to-CA1 connections in spatial working memory, predicting their crucial 563 contribution to memory encoding by the entorhinal-hippocampal loop circuit. The 564 predicted operation of the loop circuit should be tested experimentally.

565

566 Sequence of spikes with theta phase precession, that is, "theta sequence" (Ferbinteanu 567 & Shapiro, 2003; S. J. Middleton & McHugh, 2016; Pfeiffer & Foster, 2013; Schlesiger et 568 al., 2015; Zheng et al., 2016), has been observed in the hippocampus and the MEC during 569 cognitive tasks requiring episodic memory. The blockade of MECIII-to-CA1 connections 570 causes modulation of theta activity in MECIII (Suh et al., 2011; Yamamoto et al., 2014).

571 Similarly, inactivation of the MEC disrupts the temporal organization of spikes and 572 impairs information maintenance (Robinson et al., 2017). These results imply that the 573 temporal coordination of theta-phase-locked neuronal firing along the CA1-MECV-574 MECIII loop circuit is crucial for the success of spatial working memory tasks. We showed 575 an example case in which the disruption of this temporal coordination in MECIII led to a 576 significant increase of failure trials (Figure S2A, B).

577

578 Our model assumes that [ACh] changes in time during a working memory task and 579 predicts that these changes shift the preferred theta phase in CA1 E neurons: higher 580 [ACh] advances the preferred phase towards the peak of theta oscillation (Figure 6). 581 Specifically, the model predicts that phase advances occur during the encoding epoch in 582 sample trials (i.e., on the reward arm) and during the recall epoch in test trials (i.e., on 583 the center arm). We validated this prediction with the results of two experiments 584 (Fernández-Ruiz et al., 2017; Mizuseki et al., 2013; Yamamoto et al., 2014). Phase 585 advances in the encoding epoch have been known previously and can be accounted for 586 by temporal separation between CA3 input and MECIII input to CA1 (Colgin et al., 2009; 587 Cutsuridis, Cobb, & Graham, 2010; Hasselmo, Bodelón, & Wyble, 2002; Lasztóczi & 588 Klausberger, 2016; Milstein et al., 2015). Input from CA3 preferentially arrives at CA1 on 589 the descending phase of theta oscillation of LFP (Klausberger & Somogyi, 2008) whereas 590 input from MECIII arrives at the peaks of theta oscillation (Fernández-Ruiz et al., 2017; 591 Hasselmo et al., 2002; Mizuseki et al., 2009). Because MECIII input, which presumably 592 carries sensory information, seems to dominate CA3 input during encoding 593 (Hasselmo2002), CA1 neurons likely fire at the peaks rather than the troughs of theta 594 oscillation (Fernández-Ruiz et al., 2017).

595

596 Phase advances on the later central arm (i.e., in the recall epoch) represent a novel 597 finding of this study. CA1 neurons were previously shown to fire at the troughs of theta 598 oscillation during memory recall (Fernández-Ruiz et al., 2017), and this was consistent 599 with the view that CA3 input dominates MECIII input during this epoch. Challenging the 600 conventional view, our model predicts that CA1 neurons retrieve spatial memory from

the MECIII, hence firing at the peaks of theta oscillation. Possibly consistent with this prediction, if we divide the center arm into early and late portions in (Mizuseki et al., 2009), preferred theta phases show a second (and advanced) peak in the late portion of recall epoch (Figure 6D). This peak was absent in the previous analysis (Fernández-Ruiz et al., 2017) because the center arm was treated as a single entity. The consistency between the model and experiment requires further clarification.

607

608 Reflection of cognitive demands on the MEC-CA1 loop circuit through ACh

609 ACh is involved with several cognitive functions such as sensory discrimination (Hangya 610 et al., 2015; Pinto et al., 2013), associative learning (Sabec et al., 2018), and spatial 611 (Croxson et al., 2011; Okada et al., 2015) and non-spatial working memory (Furey et al., 612 2000; Hasselmo & Stern, 2006; McGaughy et al., 2005). In correlation with cognitive 613 states, ACh concentration changes to modulate activity of the specific types of neurons 614 (Muñoz, Tremblay, Levenstein, & Rudy, 2017; Womelsdorf et al., 2014) through 615 muscarinic and nicotinic receptors (Parikh et al., 2007; Teles-Grilo Ruivo et al., 2017; H. 616 Zhang et al., 2010). In associative learning, ACh was suggested to facilitate MECIII-to-617 CA1 input during the encoding epoch and CA3-to-CA1 input during the decoding epoch 618 (Hasselmo, 2006). We propose a novel role and mechanism of ACh for the functions of 619 the entorhinal-hippocampal loop circuit according to the cognitive demands arising 620 during a spatial working memory task, namely, memory encoding, maintenance and 621 recall. Consistent with the proposal of our model (Figure 2B), it has recently been shown 622 in a DNMP task (Teles-Grilo Ruivo et al., 2017) that [ACh] is significantly higher on the 623 reward arm than in other positions in both sample and test trials, that on the center arm 624 [ACh] tends to be larger in test trials than in sample trials, and that [ACh] is low in delay 625 periods (c.f., Figure 7B).

626

We assumed that a change in cognitive demands is reflected in a phasic change in [ACh] on the timescale of seconds. However, [ACh] is thought to change in a diffusive and tonic manner on much slower timescales of minutes or hours. Importantly, recent studies have revealed that [ACh] undergoes phasic changes at sub-second and second

631 timescales (Parikh et al., 2007; Teles-Grilo Ruivo et al., 2017; H. Zhang et al., 2010), and 632 such a phasic change in [ACh] is associated with reward or aversive signals (Hangya et 633 al., 2015). Further, task performance is correlated with slower tonic increases in [ACh] 634 during the task period (Parikh et al., 2007), but uncorrelated with phasic changes in 635 [ACh] in the reward arm (Teles-Grilo Ruivo et al., 2017). In our model, task performance 636 saturates above a certain level of [ACh] in the reward arm (Left panel in Figure 7B). Our 637 results suggest that the tonic level of [Ach] expresses an overall bias during each trial 638 and a phasic increase in [Ach] gives a more elaborate modulation reflecting a specific 639 cognitive demand.

640

641 Dynamic processing across multiple areas

642 Coherence in neural activity between different cortical areas varies with the cognitive 643 state of the brain (Benchenane et al., 2010; Fries, 2015). Furthermore, disruption of a 644 cortico-cortical interaction at different behavioral states can impair task performance 645 differently (Spellman et al., 2015; Yamamoto et al., 2014). These results imply that 646 information flows between cortical areas are differentially routed according to the 647 demand of the on-going cognitive process through the dynamical regulation of 648 corticocortical coherence. Theoretical studies have proposed several mechanisms of 649 information routing based on a balance control between excitatory and inhibitory 650 synaptic inputs (Vogels & Abbott, 2009), disinhibitory circuits (Yang et al., 2016), 651 spontaneous bursts (Palmigiano et al., 2017), and band-pass filtering by a feed-forward 652 inhibitory circuit (Akam & Kullmann, 2010). While these studies focused on the circuit 653 mechanisms of information routing, we addressed how such mechanisms are integrated 654 to perform a spatial working memory task through different cognitive demands 655 (Benchenane et al., 2010; Spellman et al., 2015; Yamamoto et al., 2014). We 656 demonstrated that cholinergic inputs coordinate the encoding and recall functions by modulating the cortical disinhibitory circuit and Ca²⁺-dependent cationic channels in 657 658 excitatory cells.

659

660 Accumulating evidence suggests that disinhibitory circuits play a crucial role in various 661 cognitive tasks such as fear conditioning (Letzkus et al., 2011; Pi et al., 2013) and sensory 662 discrimination (Hangya et al., 2015; Pinto et al., 2013). The dominant interneuron types 663 of the disinhibitory circuits are VIP, SOM and PV inhibitory neurons (Donato, Rompani, 664 & Caroni, 2013; Francavilla et al., 2018; Kamigaki & Dan, 2017; S. Zhang et al., 2014). 665 Among these neurons, VIP neurons express muscarinic receptors and are depolarized 666 by cholinergic input (Bell, Bell, & McQuiston, 2014) and are thought to project more 667 strongly to SOM neurons than to PV neurons in cortical areas (Kamigaki & Dan, 2017; S. 668 Zhang et al., 2014). However, some studies suggest stronger cholinergic modulations of 669 PV neurons in the hippocampus (Donato et al., 2013; Francavilla et al., 2018). As 670 explained below, the cholinergic modulation of OLM neurons also does not strongly 671 influence the firing of CA1 E neurons. Therefore, in this study we mainly analyzed the 672 effect of PV neurons on neural circuit functions. In line with our model's prediction 673 (Figure S3), optogenetic inhibition of PV neurons impairs performance in spatial working 674 memory (A. J. Murray et al., 2011).

675

676 PV neurons which preferentially fire in the descending phase of theta oscillation 677 (Klausberger & Somogyi, 2008) to weaken the effect of CA3-to-CA1 input. In contrast, 678 SOM (OLM in CA1) neurons preferably spike at the troughs of theta oscillation 679 (Klausberger & Somogyi, 2008; Royer et al., 2012) much earlier than the CA3 input. In 680 our model, excitatory MECIII input innervates CA1 preferentially at the theta peaks but 681 rarely at the theta troughs. Therefore, the ACh-induced suppression of OLM neurons 682 does not also enhance the effect of MECIII input on excitatory neuron firing in CA1, 683 making OLM neurons less effective than PV neurons in modulating the CA1 activity. In 684 rats, however, the actual spikes delivered by the MECIII are distributed broadly over a 685 theta cycle (Mizuseki et al., 2009), implying that the suppression of PV and SOM neurons 686 can induce a complex modulatory effect in CA1 pyramidal neurons. Our model predicts 687 that the inactivation of PV or VIP neurons (in this case both PV and SOM are released 688 from the inhibition by VIP neurons) impairs task performance in different ways (Figure 689 S3). This prediction needs to be confirmed by experiments.

690

691 **Covert memory state for maintenance of information**

692 Recent studies showed that dynamically evolving neuronal activity can maintain 693 information during a delay period in working memory tasks (J. D. Murray et al., 2017; 694 Stokes, 2015; Wolff, Jochim, Akyürek, & Stokes, 2017). In the DNMP task we studied 695 (Yamamoto et al., 2014), theta phase-locked firing of MECIII neurons was correlated 696 with the success of the task. Nevertheless, this neuronal activity temporarily vanished 697 during a delay period, implying that a non-spiking activity maintains information on the 698 previous choice. We hypothesized that the conductance of a specific ionic channel, i.e., 699 calcium-dependent cationic current, remains in an elevated state to preserve spatial 700 information during delay period. This elevated state is not accompanied by neuronal 701 firing, hence is consistent with experimental observations. This mechanism was 702 originally proposed to account for persistent activity of isolated single neurons (Fransen 703 et al., 2002; Fransén et al., 2006) and suggested to be engaged in temporal association 704 memory (Kitamura et al., 2014). Our model demonstrates that the same mechanism can 705 generate a covert memory state necessary in spatial working memory. This and other 706 mechanisms of covert memory state, for instance, short-term synaptic plasticity 707 (Mongillo, Barak, & Tsodyks, 2008), are not mutually exclusive. However, our 708 mechanism has an important advantage that working memory maintenance is turned 709 on and off by cholinergic modulation depending on the cognitive demand. Thus, our 710 results suggest that neuromodulators are crucial for the flexible control of memory 711 processing by the brain.

712

713 Limitation of the model

First, while our model indicates that a success in spatial working memory tasks requires the adequate preferred theta phases of MEC and hippocampal neurons, experimental results suggest an active role of high-gamma oscillation (60-120 Hz) in working memory tasks (Yamamoto et al., 2014). In our model, theta-phase-locked neuronal firing is sufficient for successful information transfers along the MECIII-CA1-MECV loop circuit and gamma oscillation was not modeled. We speculate that gamma oscillation may

significantly facilitate the decoding of information stored in the entorhinal-hippocampal
circuit from its outside. The role of gamma oscillation in spatial working memory needs
to be further explored.

723

724 Secondly, we did not model any mechanism to translate the decoded information into 725 a correct choice behavior under a given rule of decision making (e.g., the alternative of 726 left or right turn). The mPFC is projected to by CA1 and projects back to it via reuniens 727 (Dolleman-Van Der Weel & Witter, 1996; Ito, Zhang, Witter, Moser, & Moser, 2015), and 728 is engaged in spatial working memory (Bolkan et al., 2017; Jones & Wilson, 2005; 729 Spellman et al., 2015). Furthermore, some mPFC neurons exhibit rule-related activities. 730 However, the delay-period activity of mPFC neurons is specific to neither previous nor 731 present location in a DNMP task (Bolkan2017) and the rule-related activities are not 732 location-specific (Durstewitz et al., 2010; Guise & Shapiro, 2017; Preston & Eichenbaum, 733 2013). Where and how decision rules are processed and how spatial working memory 734 and rule-related activities are integrated are open to future studies.

735

736 Materials and methods

737

738 Neuron models

739 Our model has two classes of neurons: i) Poisson neurons; ii) Hodgkin-Huxley type (HH)740 neurons.

741 i) Poisson neurons

There are four types of theta-oscillating neurons (excitatory neurons in CA3 and MECII, VIP neurons in CA1 and GABAergic neurons in MS) and noise neurons. Other types of neurons, that is, excitatory (E) neurons, fast spiking (PV) neurons and OLM neurons in CA1, E and PV neurons in MECIII and E and PV neurons in MECV, are modeled as HH neurons. 40 excitatory and 40 inhibitory noise neurons project to all HH neurons. Firing rates of noise neurons are different depending on the cortical areas modeled: 35 [Hz] in CA1 and in MECIII and 30 [Hz] in MECV.

For theta-oscillating Poisson neurons, we described the theta-oscillating (10Hz) probability of spiking per unit time $P_x(t_1 < t < t_1 + \Delta t)$ (x=E in CA3 and MECII, VIP in CA1, GABA in MS) as

752
$$P_x(t_1 < t < t_1 + \Delta t) = \left(\Theta(A_x\left(\sin\left(2\pi\left(\frac{t}{T} - \theta_x\right)\right) + B_x\right)) + C_x\right)\Delta t,$$

where $\Theta(s) = s$ when s>0 or otherwise 0. T = 100 ms and $\Delta t = 0.02$ ms is the step size of our numerical simulation. A_x and B_x are the amplitude and preferred phase of oscillating firing rate, respectively, and θ_x is the preferred phase of theta oscillation for the neuron type x, whereas C_x is the amplitude of background noise for inactive subgroups outside of their place fields. We set the preferred phases based on previous experimental studies (Borhegyi, 2004; Klausberger & Somogyi, 2008; Mizuseki et al., 2009) as follows:

760

761 *x* = E in CA3:

CA3 neurons in the model are divided into four groups according to their spatial preferences (Figure 2 and Circuit structure in Materials and methods). Their firing patterns are changed depending on the present location of the model rat. When the model rat is in Center (0 < t < 1000 ms, sample-C and $4500 \le t < 7500$ ms, test-C), sample-Left ($1000 \le t < 3000$ ms) and Home ($3000 \le t < 4500$ ms) positions, Center, Left, and Home subgroups are activated, respectively.

768 $A_x = 30 \, [\text{Hz}], B_x = 1, C_x = 0 \, [\text{Hz}], \theta_x = -0.2$

- 769 for neurons in an active subgroup, and
- 770 $A_x = 0 \, [\text{Hz}], C_x = 3 \, [\text{Hz}]$
- 771 for neurons in inactive subgroups.
- 772

773 *x* = ECII:

774 During the entire trial period, we set the parameters as 775 $A_x = 5 \text{ [Hz]}, B_x = 0.6, C_x = 0 \text{ [Hz]}, \theta_x = -0.2$ 776 777 x = GABAergic in MS:778 Three groups exist in the model, those projecting to PV in CA1, to OLM in CA1 and to PV 779 in MECV. The preferred theta phase of MECV PV-projecting GABAergic neurons is the 780 same as that of CA1 OLM-projecting GABAergic neurons, 781 $A_x = 5[Hz], B_x = 0.8, C_x = 0[Hz], \theta_x = -0.1,$ 782 whereas the preferred phases of CA1 PV-projecting neurons are different from the 783 above ones (Borhegyi, 2004) and given by 784 $A_x = 5[\text{Hz}], B_x = 2.0, C_x = 0[\text{Hz}], \theta_x = -0.5.$ 785 786 x=VIP: 787 During the entire trial period, we set the parameters as 788 $A_x = 20[Hz], B_x = 0.3, C_x = 0[Hz], \theta_x = -0.4.$ 789 790 Finally, we set a reference theta oscillation in CA1 SP as 791 $A_x = 1, \theta_x = 0.5, B_x = 0, C_x = 0,$ which is a virtual oscillatory component used only for determining the relative oscillation 792 793 phases of other brain regions to theta oscillation in CA1 SP, but not for numerically 794 simulating the network model. 795 796 ii) HH neurons 797 In our model, there are seven types of neurons; E, PV and OLM in CA1, and E and PV in 798 MECV and MECIII. PV neurons are modeled identically in all areas (Wang & Buzsáki, 799 1996). In the following equations, I_i is synaptic input from other neurons as described 800 in Circuit structure in Materials and methods. Dynamics of each type of neurons is 801 described below. 802 803 a) Excitatory neurons in CA1 804 We modeled excitatory neurons in CA1 based on (Wulff et al., 2009). We additionally 805 included an afterhyperpolarization (AHP) and h currents in the model for generating a 806 weak subthreshold oscillation of the membrane potentials through interplay between 807 AHP (S. Middleton et al., 2008) and h current (Rotstein et al., 2006). $V_{Na} = 50[mV], V_K = -100.0[mV], V_{AHP} = -100.0[mV], V_h = -20.0[mV], V_L$ 808 809 = -67.0[mV] $g_{Na} = 100.0[mS/cm^2], g_K = 80.0[mS/cm^2], g_{AHP} = 0.2[mS/cm^2], g_h$ 810 811 $= 0.1[mS/cm^{2}], g_{L} = 0.1[mS/cm^{2}]$ 812 $C = 1 \left[\mu S / cm^2 \right], I_{cnst} = -0.1 \left[\mu A / cm^2 \right]$

813
$$C \frac{dV_i}{dt}$$

814

$$C \frac{dV_i}{dt} = g_{Na} m_{\infty} (V)^3 h (V_{Na} - V_i) + g_K n^4 (V_K - V_i) + g_{AHP} w (V_{AHP} - V_i) + g_h (0.65hf + 0.35hs) (V_h - V_i) + g_L (V_L - V_i) + I_i + I_{const}$$

815 The channel variable h is determined as

816 $h = \max(1 - 1.25n, 0).$

817 Other channel variables evolve according to

818
$$\frac{dx}{dt} = \frac{x_{\infty}(V) - x}{\tau_{\chi}(V)},$$

- 819 where x = m, n, w, hf and hs. Among these variables, m and n are determined by 820
- $x_{\infty}(V) = \frac{\alpha_{\chi}(V)}{\alpha_{\chi}(V) + \beta_{\chi}(V)}$ 821

822
$$\tau_x(V) = 1/(\alpha_x(V) + \beta_x(V)),$$

823 where x stands for either m or n, and

824
$$\alpha_m(V) = -0.32(V + 54)/(\exp(-0.25 * (V + 54)) - 1)$$

825
$$\beta_m(V) = 0.28(V+27)/(\exp(0.2*(V+27))-1),$$

826
$$\alpha_n(V) = -0.032(V+52)/(\exp(-0.2*(V+52)) - 1),$$

827
$$\beta_n(V) = 0.5 \exp(-0.025(V+57))$$

Other variables are determined by 828

829
$$w_{\infty}(V) = \frac{1}{\exp(-0.1(V+41)) + 1}$$

830
$$\tau_w(V) = \frac{500}{3.3 \exp(0.05(V+41)) + \exp(-0.05(V+41))}$$

$$hf_{\infty}(V) = \frac{1/(1 + \exp\left(\frac{V + 79.2}{9.78}\right))}{0.51}$$

832
$$\tau_{hf}(V) = \frac{0.01}{\exp((V - 1.7)/10) + \exp(-(V + 340)/52)} + 1$$

833
$$hs_{\infty}(V) = 1/\left(1 + \exp\left(\frac{V+2.83}{15.9}\right)\right)^{50}$$

834
$$\tau_{hs}(V) = \frac{5.6}{\exp(\frac{V-1.7}{14}) + \exp(\frac{-(V+260)}{43})} + 1.$$

835

~~~

#### 836 b) PV in CA1, MECIII, MECV

837 We modeled PV neurons in CA1 as well as those in MECIII and MECV as described in 838 (Wang & Buzsáki, 1996).

839 
$$V_{Na} = 55[mV], V_K = -90.0[mV], V_L = -65.0[mV]$$
  
840  $g_{Na} = 35.0[mS/cm^2], g_K = 9.0[mS/cm^2], g_L = 0.1[mS/cm^2]$ 

$$C = 1 \left[ \mu F / cm^2 \right]$$

842 
$$C\frac{dV_i}{dt} = g_{Na}m_{\infty}(V)^3h(V_{Na} - V_i) + g_K n^4(V_K - V_i) + g_L(V_L - V_i) + I_i$$

843 
$$\frac{dx}{dt} = \frac{x_{\infty}(V) - x}{\tau_x(V)}$$

844 
$$x_{\infty}(V) = \frac{\alpha_x(V)}{\alpha_x(V) + \beta_x(V)}$$

845 
$$\tau_x(V) = 1/(\alpha_x(V) + \beta_x(V)),$$

846 where the index 
$$x = n$$
,  $h$  and  $m$ .

847  
848  

$$\alpha_m(V) = 0.1(V+35)/(1-\exp(-0.1(V+35)))$$
  
848  
 $\beta_m(V) = 4\exp(-\frac{V+57}{40})$ 

849 
$$\alpha_n(V) = 0.01(V + 34)/(1 - \exp(-(V + 34)))$$

$$u_n(V) = 0.01(V + 54)/(1 + 0.01)$$

$$\rho_n(v) = 0.125 \exp(-(v + 44)/80)$$

851 
$$\alpha_h(V) = 0.07 \exp(-(V + 58)/20)$$

852 
$$\beta_h(V) = 1/(\exp(-0.1(V+28))+1)$$

853

854 c) OLM in CA1:

855 We modeled OLM neurons as described in (Wulff et al., 2009). 856  $V_{Na} = 60[mV], V_{K} = -100.0[mV], V_{I} = -70.0[mV], V_{A} = -90.0[mV], V_{h}$ 

857 
$$= -32.0[mV]$$

858 
$$g_{Na} = 40.0[mS/cm^2], g_K = 23.0[mS/cm^2], g_A = 16.0[mS/cm^2], g_h$$
  
859  $= 6.0[mS/cm^2], g_L = 0.05[mS/cm^2]$ 

0 
$$C = 1.3[\mu S/cm^2], I_{cnst} = 0.2[\mu A/cm^2]$$

861 
$$C\frac{dV_i}{dt} = g_{Na}m^3h(V_{Na} - V_i) + g_Kn^4(V_K - V_i) + g_Aab(V_A - V_i) + g_hr(V_h - V_i)$$

$$862 \qquad \qquad + g_L(V_L - V_i) + I_i + I_{cnst}$$

863 
$$\frac{dx}{dt} = \frac{x_{\infty}(V) - x}{\tau_{\chi}(V)},$$
 (Eq.2)

where x = m, h, n, a, b and r. The channel variables are determined by 865

866 
$$x_{\infty}(V) = \frac{\alpha_x(V)}{\alpha_x(V) + \beta_x(V)},$$

867 
$$\tau_x(V) = \frac{1}{\alpha_x(V) + \beta_x(V)}.$$
  
868 for *m*, *h* and *n* with

869 
$$\alpha_m(V) = -\frac{0.1(V+38)}{\exp\left(-\frac{V+38}{10}\right) - 1}$$

870 
$$\beta_m(V) = 4\exp\left(-\frac{V+65}{18}\right)$$

871 
$$\alpha_h(V) = 0.07 \exp\left(-\frac{V+63}{20}\right)$$

872 
$$\beta_h(V) = 1/(\exp(-0.1(V+33)) + 1)$$

873 
$$\alpha_n(V) = \frac{0.018(V-25)}{1-\exp\left(-\frac{V-25}{25}\right)}$$

874 
$$\beta_n(V) = \frac{0.0036(V-35)}{\exp\left(\frac{V-35}{12}\right) - 1}$$

For 
$$x = a$$
, b and r, variables in Eq.2 are determined by

876 
$$a_{\infty}(V) = 1/(1 + \exp(-(V + 14)/16.6))$$
  
877  $\tau_a(V) = 5$ 

77 
$$\tau_a(V) = 5$$

878 
$$b_{\infty}(V) = 1/(1 + \exp((V + 71)/7.3))$$

879 
$$\tau_b(V) = 1/(\frac{0.000009}{\exp\left(\frac{V-26}{18.5}\right)} + \frac{0.014}{0.2 + \exp\left(-\frac{V+70}{11}\right)})$$

$$\exp\left(\frac{-18.5}{18.5}\right) = 0.2 + \exp\left(-\frac{-11}{11}\right)$$
880 
$$r_{\infty}(V) = 1/(1 + \exp\left((V + 84)/10.2\right))$$

881 
$$\tau_r(V) = 1/(\exp(-14.59 - 0.086V) + \exp(-1.87 + 0.0701V))$$

882

888 889 890

#### 883 d) Excitatory neurons in MECIII

884 We modeled excitatory neurons in MECIII based on an excitatory neuron model of MECII 885 (S. Middleton et al., 2008), with some modifications of parameter values. These neurons 886 have an AHP current in addition to the standard sodium, potassium and leak currents. 887 The model is described as

$$V_{Na} = 50[mV], V_{K} = -90.0[mV], V_{AHP} = -100.0[mV], V_{L} = -65.0[mV]$$
  

$$g_{Na} = 100.0[mS/cm^{2}], g_{K} = 80.0[mS/cm^{2}], g_{AHP} = 0.3[mS/cm^{2}]$$
  

$$g_{L} = 0.5[mS/cm^{2}], C = 1.0[\mu F/cm^{2}].$$

891 
$$C \frac{dV_i}{dt} = g_{Na}m^3h(V_{Na} - V_i) + g_Kn^4(V_K - V_i) + g_{AHP}w(V_{AHP} - V_i) + g_L(V_L - V_i) + I_i$$
  
892 
$$\frac{dx}{dt} = \alpha_x(V)(1 - x) - \beta_x(V)x,$$

894 
$$\alpha_m(V) = -0.32(V + 54)/(\exp(-0.25 * (V + 54)) - 1)$$

895 
$$\beta_m(V) = 0.28(V+27)/(\exp(0.2*(V+27)) - 1)$$

896 
$$\alpha_n(V) = -0.032(V + 52)/(\exp(-0.2 * (V + 52)) - 1)$$

897 
$$\beta_n(V) = 0.5 \exp(-0.025(V +$$

898 
$$\alpha_h(V) = 0.128 \exp(-(V+50)/18)$$

899 
$$\beta_h(V) = 4.0/\exp(-0.2(V+27)+1)$$

900 The channel variable w is determined by

901 
$$\frac{dw}{dt} = (w_{\infty}(V) - w)/\tau_{w}(V),$$
  
902  $w_{\infty}(V) = \frac{1}{\exp(-0.1(V + 41)) + 1}$ 

903 
$$\tau_{\infty}(V) = \frac{500}{3.3 \exp(0.05(V+41)) + \exp(-0.05(V+41))}$$

57))

913

920

### 905 e) Excitatory neurons in MECV

906 Excitatory neurons in MECV are modeled based on (Egorov, Hamam, Fransen, Hasselmo, 907 & Alonso, 2002; Fransén et al., 2006) with simplification of conductance of nonspecific 908 calcium-sensitive cationic,  $g_{CAN}$  (see Disinhibitory system in Materials and methods). Ca 909 flux is regulated through CaL channel.

910 
$$V_{Na} = 50[mV], V_K = -100[mV], V_{CAN} = -20[mV], V_{Ca} = 140[mV], V_L = -65[mV]$$
  
911  $g_{Na} = 100.0[mS/cm^2], g_K = 80.0[mS/cm^2], g_{AHP} = 0.05[mS/cm^2],$ 

911 
$$g_{Na} = 100.0[mS/cm^2], g_K = 80.0[mS/cm^2], g_{AHP} = 0.05[mS/cm^2],$$
  
912  $g_{K,C} = 195[mS/cm^2], g_M = 3.5[mS/cm^2], g_{CaL} = 0.15[mS/cm^2],$ 

$$g_{Na,p} = 0.2[mS/cm^2], g_{K,A} = 0.5[mS/cm^2], g_L = 0.5[mS/cm^2],$$

 $C = 1.0[\mu F / cm^2]$ 

915 
$$C \frac{dV_i}{dt} = g_{Na}m^3h(V_{Na} - V_i) + g_K n^4(V_K - V_i) + g_{AHP}w(V_{AHP} - V_i) + g_M s_M(V_K - V_i)$$

916 
$$V_i$$
) +  $g_{Na,p} s_{Na,p} h_{Na,p} (V_{Na} - V_i) + g_{K,A} s_{K,A} h_{K,A} (V_K - V_i) + g_{CAN}(t) s_{CAN} (V_{CAN} - V_i) + g_{CAN}(t) s_{CAN} (V_{CAN} - V_i) + g_{CAN}(t) s_{CAN}(t) s_{CAN} (V_{CAN} - V_i) + g_{CAN}(t) s_{CAN}(t) s$ 

917 
$$V_i$$
) +  $g_{K,C} s_{KC} (V_K - V_i)$  + + $g_{CaL} s_{CaL} (V_{Ca} - V_i)$  +  $I_i$  (Eq.3)

In addition to voltage dynamics, concentration of Ca<sup>2+</sup>, [Ca<sup>2+</sup>], in a neuron is modeled
 according to:

$$\frac{d[Ca^{2+}]}{dt} = \kappa I_{CaL} - [Ca^{2+}]/\tau_{Ca}$$

921 Here,  $\kappa = 0.5181937[Fd^{-1}]$  and  $\tau_{Ca} = 250[ms]$ .

922 The standard current of sodium and potassium in Eq.3 are exactly same as in excitatory
 923 neurons in MECIII. AHP, KA, KC, M, Na<sub>p</sub> and CaL currents follow the standard activation 924 inactivation forms:

925 
$$\frac{dx}{dt} = \alpha_x(V)(1-x) - \beta_x(V)x$$

926  $x = w(= AHP), s_M(= M), s_{K,A}, h_{K,A}, s_{K,C} (= KC), s_{CaL}(= CaL).$ 

927  $\alpha$  and  $\beta$  of each current are according to the following equations.:

928 
$$\alpha_{AHP}(V) = \begin{cases} \min(2.4([Ca^{2+}] - 15), 15) & \text{for } [Ca^{2+}] > 15\\ 0.2[Ca^{2+}] & \text{otherwise} \end{cases}$$

929 
$$\beta_{AHP}(V) = 1$$

930 
$$\alpha_{CaL}(C) = \frac{1.6}{1 + \exp(-0.072(V - 65))}$$

931 
$$\beta_{CaL}(V) = \frac{0.02(V - 51.1)}{\exp(0.2(V - 51.1)) - 1}$$

932 
$$\alpha_{KC}(V) = \begin{cases} \frac{\exp(0.053782V - 0.66835)}{18.975} & \text{for } V < 50\\ 2\exp\left(\frac{6.5 - V}{27}\right) & \text{otherwise} \end{cases}$$

$$\left(\frac{-27}{27}\right)$$
 otherwise  $(6.5 - V)$ 

933 
$$\beta_{KC}(V) = \begin{cases} 2 \exp\left(\frac{6.5 - V}{27}\right) - \alpha_{KC} & \text{for } V < 50\\ 0 & \text{otherwise} \end{cases}$$

934 
$$\alpha_{s_{KA}}(V) = \frac{0.02(V - 13.1)}{1 - \exp(0.1(13.1 - V))}$$

935 
$$\beta_{s_{KA}}(V) = \frac{0.175(V - 40.1)}{\exp(0.1(V - 40.1)) - 1}$$

936 
$$\alpha_{h_{KA}}(V) = 0.0016\exp(-(V+13)/18)$$

937 
$$\beta_{h_{KA}}(V) = 0.05/(1 + 0.2\exp(10.1 - V))$$

938 Variables for M, Na<sub>p</sub> and CAN channels follow the form:

939  $\frac{dx}{dt} = \frac{x_{\infty}(V) - x}{\tau_{\chi}(V)},$ 

940 where 
$$x = s_{Na,p}$$
,  $h_{Na,p}$ ,  $s_M (= M)$ ,  $s_{CAN} (= CAN)$ .  $x_{\infty}$  and  $\tau_x$  for each variable are

941 according to

942 
$$s_{M,\infty}(V) = 1/(1 + \exp(-V + 35)/5)$$
  
1000

943 
$$\tau_M(V) = \frac{1}{3.3 \exp((V+35)/40) + \exp(-(V+35)/20)}$$

944 
$$s_{Na,p\infty}(V) = 1/(1 + \exp\left(-\frac{V + 16N}{4.4}\right))$$

945 
$$\tau_{s_{Nap}}(V) = \frac{1}{\left(\frac{0.091(V+38)}{1-\exp\left(\frac{V+38}{5}\right)} - \frac{0.062(V+38)}{1-\exp\left(\frac{V+38}{5}\right)}\right)}$$

946 
$$h_{Na,p\infty}(V) = \frac{1}{1 + \exp\left(-\frac{V + 48.8}{9.98}\right)}$$

947 
$$\tau_{h_{Na},p}(V) = \frac{1}{-\frac{0.00000288(V-49.1)}{1-\exp\left(-\frac{V-49.1}{4.63}\right)} + -\frac{0.00000694(V+44.7)}{1-\exp\left(-\frac{V+44.7}{2.63}\right)}}$$

948 
$$s_{CAN,\infty}(V) = 48 \times \frac{10^2 [Ca^{2+}]^2}{48 \times 10^2 [Ca^{2+}]^2 + 0.03}$$

949 
$$\tau_{s_{CAN}}(V) = 1/(48 \times 10^2 [Ca^{2+}]^2).$$

950

- 951
- 952

# 953 Synaptic Inputs

954 Synaptic input  $I_i$  to neuron *i* includes excitatory  $I_i^E$  and inhibitory  $I_i^I$  currents. Only in CA1 955 neurons, OLM currents, which are from OLM neurons, are modeled as another type of 956 inhibitory currents based on (Wulff et al., 2009).

957 
$$I_i(t) = I_i^E + I_i^I = g_i^E(V_E - V) + g_i^I(V_I - V) + g_i^{OLM}(V_i - V)$$

958 
$$g_i^{E,I,OLM}(t) = \sum_k \int_0^t G_{ik} \sum_s \alpha^{E,I,OLM}(t' - t_k^s - d_{ik}) dt'$$
 (Eq.4),

959 where k is index of pre-synaptic neuron. For the excitatory current, k corresponds to 960 index of excitatory neurons in all cortical areas and excitatory noise neurons projecting 961 to post-synaptic neuron *i*. For the inhibitory currents, k corresponds to index of 962 inhibitory neurons (PV, OLM, VIP, GABA) in all cortical areas and inhibitory noise neurons 963 projecting to post-synaptic neuron i. Connections G among these neurons are described 964 in Circuit model in Materials and Methods. s is index of spikes in k neuron.  $d_{ik}$  is 965 transduction time lag. When neurons i and k are within a same area, d is chosen 966 randomly from (0,2) ms, while d is chosen from (10,15) ms for neurons in different areas. 967 Double exponential functions,  $\alpha$ , are described as:

968 
$$\alpha^{E,I,OLM}(t) = (e^{-\frac{t}{\tau^r_{E,I,OLM}}} - e^{-\frac{t}{\tau^d_{E,I,OLM}}})/(\tau^r_{E,I,OLM} - \tau^d_{E,I,OLM})$$
 (Eq.5)

969 Rise time constant  $t^r$  is 0.05,0.07 and 2.0 ms for E, I, and OLM, respectively, while decay 970 time constant  $t^d$  is 5.3, 9.1 and 22.0 ms for E, I, and OLM, respectively.

- 971
- 972

# 973 Circuit structure

- Our model has three cortical areas (Figure1A) and external oscillating neurons in MECII,
  CA3 and MS. excitatory neurons in each cortical area are divided into two or four
  subgroups (Table1). CA1 has four groups denoted as Left (L), Right (R), Center (C) and
  Home (H). MECIII and MECV have two groups denoted as L and R.
- 978

|     | CA1   | ECIII | ECV   | CA3   |
|-----|-------|-------|-------|-------|
| E   | 120x4 | 120x2 | 200x2 | 120x4 |
| PV  | 240   | 160   | 120   |       |
| OLM | 240   |       |       |       |

979 Table1: number of neurons in each are

980 981

In addition, a model has 240 VIP neurons in CA1, 120 excitatory neurons in MECII and
360 GABAergic neurons in MS. The GABAergic neurons are divided into three groups
projecting to different types of neuron each of which has 120 neurons; groups to OLM,
to PV in CA1 and to PV in MECV.

986 Structure of a circuit is given by a matrix *G* in Eq. 4, which represents efficacy of synaptic

987 connections. Connection between presynaptic neuron j and postsynaptic neuron I,  $G_{ij}$ 988 is determined by

989 
$$G_{ij} = \begin{cases} G_{XY}^{AB} / \rho_{XY}^{AB} N_Y^B & \text{with probability } \rho_{XY}^{AB} \\ 0 & \text{otherwise} \end{cases}$$
(Eq.6),

- 990 where X and Y are neuron types that *i* and *j* neurons belong to, respectively. A and B
- 991 refer subgroups (L,R,C,and H) that *i* and *j* neurons belong to, respectively. Because only
- 992 excitatory neurons in each area are divided as the subgroups, A and B are neglected for
- 993 other types of neurons.  $N_Y$  is the number of type Y neurons. If the type Y neurons are
- 994 divided into the subgroup,  $N^{B}_{Y}$  indicates the number of type Y neurons in subgroup B. G
- 995 and  $\rho$  for each connection are as follows:
- 996
- 997 i) Connection from noise neurons
- 998 Connections G from noise neurons to the neurons in cortical areas are shown in Table2.
- 999 A postsynaptic neuron receives inputs from 40 excitatory and 40 inhibitory neurons 1000  $(\rho_{XY} = 1, N_{XY} = 40).$
- 1001
- 1002
  - Table2 Connection  $G_{XY}$  from noise neurons to each type of neurons.

| Post-synaptic X          | CA1 |    | ECIII |    | ECV |    |    |
|--------------------------|-----|----|-------|----|-----|----|----|
| Pre-synaptic Y           | E   | PV | OLM   | E  | PV  | E  | PV |
| Excitatory noise neurons | .32 | .8 | 3.2   | .8 | .2  | .2 | .4 |
| Inhibitory noise neurons | .6  | .2 | .4    | .6 | .8  | .2 | .6 |

 $G_{XY} = 0.4$ 

 $\rho_{XY} = 1$ 

1003 1004

1007

1005 ii) Connection from excitatory neurons in MECII, MS and CA3

1006 a) connection from excitatory neurons in MECII to PV in MECIII

1008 1009 b) from GABAergic neurons in MS

.... . . . . . .

| 1010 | to PV in MECV           |                                            |
|------|-------------------------|--------------------------------------------|
| 1011 |                         | $G_{XY} = 0.1$                             |
| 1012 | to PV in CA1            |                                            |
| 1013 |                         | $G_{XY} = 3.7$                             |
| 1014 | to OLM in CA1           |                                            |
| 1015 |                         | $G_{XY} = 3.7$                             |
| 1016 | For all connections,    |                                            |
| 1017 |                         | $ \rho_{XY} = 1 $                          |
| 1018 | c) from CA3 to E in CA1 |                                            |
| 1019 | for $A \neq B$          |                                            |
| 1020 |                         | $G_{XY}^{AB}=0$ , $ ho_{XY}^{AB}=0$        |
| 1021 | For $A = B$             |                                            |
| 1022 |                         | $G_{XY}^{AB}=2.0\xi$ , $ ho_{XY}^{AB}=0.3$ |
|      |                         |                                            |

| 1023 | here, $\xi$ is chosen randomly from (0,1).                                            |
|------|---------------------------------------------------------------------------------------|
| 1024 | d) from CA3 to PV in CA1                                                              |
| 1025 | $G_{XY} = 0.1 \ \rho_{XY} = 0.5.$                                                     |
| 1026 | e) from VIP to PV and OLM in CA1                                                      |
| 1027 | Efficacy of these connections is modified by [ACh] (Tremblay, Lee, & Rudy, 2016) as   |
| 1028 | follows:                                                                              |
| 1029 | For X=PV,                                                                             |
| 1030 | $G_{XY} = 0.012[Ach], \rho_{XY} = 1$                                                  |
| 1031 | For X=OLM,                                                                            |
| 1032 | $G_{XY} = 0.02[Ach], \  ho_{XY} = 1$                                                  |
| 1033 | f) Connections between E neurons within the same cortical areas                       |
| 1034 | For $A \neq B$                                                                        |
| 1035 | $G_{XY}^{AB} = 0.01, \rho = 0.025$ (in MECIII)                                        |
| 1036 | $G_{XY}^{AB} = 0, \rho = 0$ (in MECV)                                                 |
| 1037 | For $A = B$                                                                           |
| 1038 | $G_{XY}^{AB} = 14.4, \rho = 0.15$ (in MECIII)                                         |
| 1039 | $G_{XY}^{AB} = 0.216,  ho = 0.03$ (in MECV)                                           |
| 1040 | There is no connection between excitatory neurons in CA1 in our model.                |
| 1041 |                                                                                       |
| 1042 | g) Connection between neurons within the same cortical areas (except E-E connections) |
| 1043 | There is no connection between OLMs(Wulff et al., 2009). Connections from OLM to E    |
| 1044 | neurons in CA1 are described in h), since OLM is observed to be attached on proximal  |
| 1045 | dendrite of excitatory neurons in CA1 and regulate inputs from MECIII.                |
| 1046 |                                                                                       |
| 1047 | Other connections within cortical areas are shown in Table 3.                         |
| 1048 |                                                                                       |
| 1049 | Table 3: connection parameters in CA1, MECIII, MECV                                   |
|      |                                                                                       |

|                 | CA1  |      |       |        |       |        |

1084

1085 Disinhibitory system and modulated conductance of nonspecific calcium-sensitive 1086 cationic (CAN) current through ACh.

1087 We assume that concentration of ACh represents cognitive states and changes1088 dependent of current locations:

$$1089 \qquad [ACh] = \begin{cases} 0.2 \text{ for } t < 1[s] \text{ (a rat on sample-C)} \\ 1 - 0.8 \exp\left(-\frac{t - T_{LS}}{200}\right) \text{ for } 1[s] \le t < 3[s] \text{ (a rat on sample-L)} \\ 0.8 - 0.2 \exp\left(-\frac{t - T_H}{200}\right) \text{ for } 3[s] \le t < 4.5[s] \text{ (a rat on sample-L)} \\ 1.1 - 0.3 \exp\left(-\frac{t - T_{CT}}{200}\right) \text{ for } 4.5[s] \le t \text{ (a rat on test-C)} \end{cases}$$

1090 [ACh] modifies neural behavior in a circuit in two pathways. Efficacy of connections from 1091 VIP is modified with [ACh] (Circuit structure in Materials and methods) as well as 1092 conductance of  $I_{CAN}$ . A channel of  $I_{CAN}$  takes high and low conductance states 1093 alternatively. Maximum conductance  $g_{CAN}$  is determined by [ACh] and ratio of high 1094 conductance state  $r_{\rm h}$ .  $r_{\rm h}$  is dependent on history of [Ca2+] and [ACh] (Fransén et al., 1095 2006) as follows:

1096 
$$g_{CAN}(t) = 0.5[Ach]r_{\rm h}(t)$$

1097 
$$r_{\rm h}(t + \Delta t) = \begin{cases} r_{\rm h}(t) + 0.6\Delta t \text{ for } [Ca^{2+}] > 0.004 \\ r_{\rm h}(t) - 0.08\Delta t \text{ for } [Ca^{2+}] < 0.0003 \\ r_{\rm h}(t) & \text{otherwise} \end{cases}$$

1098 We also set upper and lower bounds for  $r_{\rm h}$  at 1 and 0.12, respectively.

# 1101 Periodicity analysis

1102 Neural activity in the model oscillates driven by external theta rhythm (10Hz). We 1103 evaluated how strongly neurons oscillate in the theta rhythm by calculating an 1104 autocorrelation function R(t) (Yamamoto et al., 2014). Periodicity index is defined as 1105  $\max_{50ms < t < 200ms} R(t)$ .

- 1106
- 1107

### 1108 Experimental data in rodents

Spiking activities and LFP data in CA1 are obtained from previously published data in (Yamamoto et al., 2014) for Figures 6B and 7C and that in (Mizuseki et al., 2013) for Figures 6D and 6E. Experiments were approved by the Institutional Animal Care and Use Committee of Rutgers University. All procedures for animal care and use were performed in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals. Detailed conditions on data recording are described in these papers.

- 1116
- 1117 LFP activities were band-pass filtered (6-12Hz) as theta wave and instantaneous phase
- of the filtered theta wave were derived from Hilbert transform. For spiking activities,we dropped a part of spikes to analyzed as follows:
- 1120 Spiking activities in (Yamamoto et al., 2014) were recorded with the silicon linear probes 1121 and were analyzed as multi-unit activities. In this paper, however, we roughly distinguish 1122 putative excitatory neurons from inhibitory ones in order to show clear theta preference. 1123 According to (Mizuseki et al., 2009), we sorted spikes by trough to peak latency. Due to 1124 short length of single spike profile in the data, we cannot identify baseline before spike 1125 and consequently cannot compute peak amplitude asymmetry. We assigned spikes with 1126 the latency larger than 0.5ms to putative excitatory neurons. For Figure 6B, we have the 1127 sorted spikes in three out of five rats because spikes of the rest two rats do not show 1128 clear theta preference due to small number of spikes.
- 1129 activities in (Mizuseki et al., For spiking 2013), we used sessions 1130 "ec014.12","ec014.16","ec014.17","ec014.27","ec014.28","ec013.44","ec013.46","ec0 1131 16.30". Because phase shift in the side arm was observed only in deeper neurons in 1132 (Fernández-Ruiz et al., 2017), we only used spikes of deeper neurons according to 1133 (Mizuseki, Diba, Pastalkova, & Buzsáki, 2011).
- 1134

# 1135 Calculations of the ratio of spikes at the peaks in theta and the side-to-center ratio

1136 In Figure 6F, we used the same neurons in Figure 6E (see Experimental data in rodents). 1137 Further, we filtered these neurons by two criteria: i) number of spikes in the later 1138 center arm are larger than 50; ii) the ratio of spikes in the later center arm to total spikes 1139 is larger than 5%. To exclude place cells representing the earlier center arm and junction 1140 of T-maze (since these cells are likely to spike at the peaks in theta oscillation in the later 1141 center arm), we further excluded the cells that spike in the later center arm less 1142 frequently than at the earlier center arm or at the junction. Eleven neurons remained. 1143 For these neurons, we calculated the ratio in number of spikes around the peaks (90-1144 270 degree) to all spikes in the later center arm. We call this quantity the ratio of spikes 1145 at the peaks. We also calculated the ratio of average number of spikes emitted in the

- 1146 later center arm to that of average number of spikes emitted in the side arms. We call
- 1147 this quantity the side-to-center ratio.
