OYSTERS AND EELGRASS: POTENTIAL PARTNERS IN A HIGH PCO₂ OCEAN

Maya L. Groner, Colleen A. Burge, Ruth Cox, Natalie D. Rivlin, Mo Turner, Kathryn L. Van Alstyne, Sandy Wyllie-Echeverria, John Bucci, Philip Staudigel, and Carolyn S. Friedman

Ocean acidification (OA) threatens calcifying organisms such as the Pacific oyster, *Crassostrea gigas*. In contrast, eelgrass, *Zostera marina*, can benefit from the increase in available carbon for photosynthesis found at a lower seawater pH. Seagrasses can remove dissolved inorganic carbon from OA environments, creating local daytime pH refugia. Pacific oysters may improve the health of eelgrass by filtering out pathogens such as *Labyrinthula zosterae*, which causes eelgrass wasting disease (EWD). Using a laboratory experiment, we found that co-culture of eelgrass with oysters reduced the severity of EWD. EWD was also reduced in more acidic waters, which negatively affect oyster growth.
