18 **ABSTRACT**

19   The protein kinase PINK1 and ubiquitin ligase Parkin promote removal of damaged
20 mitochondria via a feed-forward mechanism involving ubiquitin (Ub) phosphorylation, Parkin
21 activation, and ubiquitylation of mitochondrial outer membrane proteins to support
22 recruitment of mitophagy receptors. The ubiquitin ligase substrate receptor FBXO7/PARK15
23 is mutated in an early-onset parkinsonian-pyramidal syndrome. Previous studies have
24 proposed a role for FBXO7 in promoting Parkin-dependent mitophagy. Here, we
25 systematically examine the involvement of FBXO7 in depolarization-dependent mitophagy in
26 the well-established HeLa and induced-neurons cell systems. We find that FBXO7[-/-] cells
27 have no demonstrable defect in: 1) kinetics of pUb accumulation, 2) pUb puncta on
28 mitochondria by super-resolution imaging, 3) recruitment of Parkin and autophagy
29 machinery to damaged mitochondria, 4) mitophagic flux, and 5) mitochondrial clearance as
30 quantified by global proteomics. Moreover, global proteomics of neurogenesis in the
31 absence of FBXO7 reveals no obvious alterations in mitochondria or other organelles. These
32 results argue against a general role for FBXO7 in Parkin-dependent mitophagy and point to
33 the need for additional studies to define how FBXO7 mutations promote parkinsonian-
34 pyramidal syndrome.

35

36

37 **INTRODUCTION**

38   Organelle quality control underlies cellular health and is often defective in disease
39 and pathological states. Arguably the best understood such quality control pathway is
40 mitophagy, wherein damaged or supernumerary mitochondria are targeted for removal from
41 the cell via selective autophagy (Goodall *et al*, 2022; Harper *et al*, 2018; McWilliams & Muqit,
42 2017; Pickrell & Youle, 2015). In this process, individual organelles are marked for
43 sequestration within a double-membrane vesicle called an autophagosome, which then
44 fuses with a lysosome to facilitate degradation of the organelle by resident lysosomal
45 hydrolases (Dikic & Elazar, 2018; Stolz *et al*, 2014). Multiple forms of mitophagy have been
46 reported, which differ in the types of regulatory mechanisms involved in marking the
47 organelle for degradation, but these fall into two primary types – ubiquitin-dependent and
48 ubiquitin-independent (Harper *et al.*, 2018; Pickrell & Youle, 2015). Our understanding of
49 ubiquitin-dependent mitophagy has been advanced by the discovery of a signalling pathway
50 composed of the PINK1 protein kinase and the Parkin (also called PRKN) ubiquitin (Ub) E3
51 ligase, which marks damaged mitochondria for elimination (Narendra *et al*, 2008). Parkin
52 and PINK1 are both mutated in early-onset recessive forms of Parkinson's disease and
53 understanding how these enzymes work has been a major focus of the field (Ng *et al*, 2021;
54 Pickrell & Youle, 2015).

55 In healthy mitochondria, PINK1 is imported into the mitochondrial translocon and
56 rapidly processed for degradation (Jin *et al*, 2010; Yamano & Youle, 2013). In response to
57 mitochondrial damage – such as depolarization, accumulation of mitochondrial misfolded
58 proteins, or defects in mitochondrial fusion – PINK1 is stabilized on the mitochondrial outer
59 membrane (MOM) in association with the translocon (Lazarou *et al*, 2012), where it can
60 phosphorylate Ser65 on Ub already conjugated to proteins on the MOM (Kane *et al*, 2014;
61 Kazlauskaite *et al*, 2015; Koyano *et al*, 2014; Ordureau *et al*, 2014; Wauer *et al*, 2015).
62 Accumulation of phospho S65-Ub (referred to henceforth as pUb) on the MOM promotes
63 recruitment of Parkin – a pUb-binding protein – thereby facilitating phosphorylation of Parkin
64 on S65 of its N-terminal Ub-like (UBL) domain and activation of its Ub ligase activity
65 (Gladkova *et al*, 2018; Kane *et al.*, 2014; Kazlauskaite *et al.*, 2015; Ordureau *et al.*, 2014;
66 Sauve *et al*, 2018; Wauer *et al.*, 2015). Parkin then ubiquitylates numerous MOM proteins,
67 resulting in both the accumulation of additional pUb and further MOM protein ubiquitylation
68 (Antico *et al*, 2021; Bingol *et al*, 2014; Ordureau *et al*, 2020; Sarraf *et al*, 2013). MOM
69 ubiquitylation then promotes recruitment of selective autophagy cargo receptors including
70 OPTN, CALCOCO2 (also called NDP52), and SQSTM1 (also called p62) to facilitate the
71 assembly of an autophagosome around the ubiquitylated organelle (Evans & Holzbaur,
72 2020; Heo *et al*, 2015; Lazarou *et al*, 2015; Wong & Holzbaur, 2014). Thus, PINK1, Parkin,
73 and pUb function in a positive feedback loop to promote selective ubiquitylation and
74 elimination of the damaged organelle (Goodall *et al.*, 2022).

75 Previous work (Burchell *et al*, 2013) concluded that FBXO7, the product of an early-
76 onset parkinsonian-pyramidal syndrome risk gene also designated as *PARK15* (Di Fonzo *et*
77 *al*, 2009; Houlden & Singleton, 2012; Paisan-Ruiz *et al*, 2010), is a positive modulator of
78 Parkin-dependent mitophagy (**Supplemental Figure 1A**). FBXO7 is a member of the F-box
79 family of proteins, which assemble with SKP1, CUL1, and RBX1 to form a modular SCF Ub
80 ligase complex wherein the F-box protein to binds substrates (Jin *et al*, 2004). FBXO7 is
81 characterized by an N-terminal UBL domain, a central FP domain with structural similarity to
82 a domain in the proteasome inhibitory factor PI31/PSMF1, followed by the F-box motif, and
83 a C-terminal proline rich region (Kirk *et al*, 2008). Patient mutations in FBXO7 are found in
84 multiple regions of the protein (Di Fonzo *et al.*, 2009; Houlden & Singleton, 2012; Paisan-
85 Ruiz *et al.*, 2010). Initial studies on FBXO7 proposed a functional interaction with the
86 Parkin/PINK1 pathway and concluded that FBXO7 functions as a positive regulator of
87 mitophagy through direct interaction with Parkin and with PINK1 (Burchell *et al.*, 2013).
88 Depletion of FBXO7 by siRNA in cell lines was reported to reduce depolarization-dependent
89 loss in mitochondria based on immunoblotting of matrix proteins and likewise to reduce
90 depolarization-dependent ubiquitylation of MFN1, a substrate of Parkin (Burchell *et al.*,
91 2013). However, studies that further substantiate a functional link between FBXO7 and

92   mitophagy are lacking, although FBXO7 depletion has recently been reported to alter

93   mitochondrial dynamics (Al Rawi *et al*, 2022).

94   Given the strong genetic association of FBOX7/PARK15 with Parkinson's Disease

95   (Houlden & Singleton, 2012) and major advances in our understanding of Parkin-dependent

96   mitophagy (Goodall *et al.*, 2022) since initial links between FBXO7 and mitophagy were

97   reported, we set out to elucidate how FBXO7 might function within the positive feedback

98   loop to promote mitophagy (**Supplemental Figure 1A**). Relevant advances include the

99   identification of pUb as a sentinel response to PINK1/Parkin activation (Kane *et al.*, 2014;

100   Kazlauskaite *et al.*, 2015; Koyano *et al.*, 2014; Ordureau *et al.*, 2014; Wauer *et al.*, 2015),

101   the development of highly quantitative mitophagic flux assays using a mitochondrially

102   localized Keima fluorescent reporter protein (Katayama *et al*, 2011; Lazarou *et al.*, 2015),

103   and the development of genetically tractable iNeuron systems for functional analysis of the

104   Parkin pathway in neuronal cell types (Ordureau *et al.*, 2020; Ordureau *et al*, 2018).

105   Unexpectedly, we find no evidence of a role for FBXO7 in the kinetics of depolarization-

106   dependent pUb accumulation, or mitophagic flux in either iNeurons or the conventional HeLa

107   cell used extensively to examine Parkin and PINK1-dependent mitophagy (Narendra *et al.*,

108   2008). Moreover, global proteomics of FBXO7$^{-/-}$ HeLa cells undergoing mitophagy revealed

109   no defect in mitochondrial elimination by autophagy. Taken together with previous studies

110   that failed to verify Parkin-FBXO7 interactions during mitophagy (Sarraf *et al.*, 2013), these

111   data indicate that FBXO7 does not play a general role as a positive modulator of Parkin and

112   PINK1-dependent mitophagy in HeLa and iNeuron systems. This work suggests that

113   elucidation of FBXO7 biochemical functions is needed to understand how it might contribute

114   to suppression of early-onset parkinsonian-pyramidal syndrome.

115

116   **RESULTS**

117   ***A tool kit for functional analysis of cells lacking FBXO7***

118   To test if FBXO7 is a pivotal amplifier of the PINK1/Parkin pathway, we employed

119   CRISPR-Cas9-based gene editing to generated knockouts for FBXO7 in HeLa HFT/TO-

120   PRKN cells (Ordureau *et al*, 2015) and confirmed insertion of a frameshift mutation by

121   sequencing and immunoblotting (**Supplemental Figure 1 B-D**). HeLa HFT/TO-PRKN cells

122   contain a DOX-inducible PRKN cassette allowing regulated expression of Parkin to facilitate

123   an analysis of mitophagic flux in response to mitochondrial damage (Ordureau *et al.*, 2015).

124   Three independent FBXO7$^{-/-}$ clones were identified (clones 27, 41 and 45) (**Supplemental**

125   **Figure 1C,D**). In parallel, we generated two independent human ES cell clones lacking

126   FBXO7 via CRISPR-Cas9 (clones 52 and 89) (**Supplemental Figure 1B,E,F**). Here, an ES

127   cell line harbouring a DOX inducible NGN2 gene was used, allowing for conversion of these

128   cells to cortical-like iNeurons over a two week or greater time course (Ordureau *et al.*, 2020;

129 Zhang *et al*, 2013). We have previously demonstrated that iNeurons derived from these cells

130 exhibit Parkin and PINK1-dependent mitophagic flux in response to mitochondrial damage

131 (Ordureau *et al.*, 2020). Both clones displayed normal karyotypes and the absence of

132 FBXO7 was verified using MiSeq sequencing (**Supplemental Figure 1F,G**).

133

134 ***Robust depolarization-dependent Ub phosphorylation by PINK1 in cells lacking***

135 ***FBXO7***

136   The earliest known event in Parkin-dependent mitophagy is accumulation of PINK1

137 on the mitochondrial outer membrane followed by rapid S65 phosphorylation of pre-existing

138 Ub linked with mitochondrial proteins (**Supplemental Figure 1A**), as has been worked out in

139 detail using the well-validated HeLa cell system with ectopically expressed Parkin (Kane *et*

140 *al.*, 2014; Lazarou *et al.*, 2012; Narendra *et al*, 2010; Yamano & Youle, 2013). In the

141 presence of Parkin, Ub phosphorylation is enhanced as a result of increased Ub conjugation

142 to mitochondrial proteins, thereby providing additional substrate molecules for

143 phosphorylation by PINK1 (Kane *et al.*, 2014; Koyano *et al.*, 2014; Ordureau *et al.*, 2014). To

144 examine pUb accumulation in the context of HeLa cells lacking FBXO7, we induced Parkin

145 expression (16 h) and then depolarized mitochondria for 1 or 6 h with antimycin

146 A/Oligomycin A (AO), which inhibit Complex III and Complex IV activity in the electron

147 transport chain, respectively. As expected, control HeLa cells display time-dependent

148 accumulation of pUb as measured by immunoblotting, but the absence of FBXO7 had no

149 impact on the extent of pUb accumulation, as assessed in all three FBXO7$^{-/-}$ cell lines in

150 biological triplicate analyses (**Figure 1A,B**).

151   Similarly, we assessed depolarization-dependent pUb accumulation in the iNeuron

152 system. control or FBXO7$^{-/-}$ ES cells were converted to day 12 iNeurons and depolarized

153 with AO in duplicate (**Figure 1C**). pUb was detected by immunoblotting at 6 and 24 h and

154 was indistinguishable between WT and two independent FBXO7$^{-/-}$ clones (**Figure 1D**).

155 Taken together, these data do not support a universal role for FBXO7 in promoting the

156 earliest step in mitophagy signalling – PINK1-dependent Ub phosphorylation – in the HeLa

157 cell system or iNeurons.

158

159 ***Super-resolution imaging of pUb formation independent of FBXO7***

160   While depolarization-dependent Ub phosphorylation was not impaired, we

161 considered the possibility that the organization of pUb on damaged mitochondria might be

162 altered in cells lacking FBXO7. To our knowledge, super-resolution microscopy has not been

163 used to examine the kinetics and spatial properties of pUb accumulation in response to

164 depolarization. We therefore optimized conditions to monitor pUb via volumetric 3D-SIM

165 super-resolution microscopy in both HeLa and iNeuron systems (see **EXPERIMENTAL**

166   **MATERIALS AND METHODS**). After AO treatment of HeLa cells for 1, 3 or 6 h, the

167   mitochondria matrix protein HSP60 and pUb were examined by super-resolution imaging. In

168   control cells at 1 h, fragmented mitochondria were often proximal to pUb foci with an

169   average volume of 5.71 μm^3, which were not observed in cells lacking PINK1 (**Figure 2A-C,**

170   **Supplemental Figure 2A,B**). The volume of pUb increased ~8-fold over 6 h (47.88 μm^3),

171   consistent with the known feed-forward response (**Figure 2B, Supplemental Figure 2A**). At

172   6 h of AO treatment, we observed a near complete coating of mitochondrial fragments with

173   pUb, as quantified by the significant increase in pUb object volume (**Figure 2B,C,**

174   **Supplemental Figure 2A**). Consistent with analysis of pUb by immunoblotting, two FBXO7[-/-]

175   clones did not show any significant differences in pUb recruitment, volume or overall

176   morphological differences compared to control cells, indicating that FBXO7 is not required

177   for the feed-forward amplification of PINK1/Parkin mitophagy after AO-treatment (**Figure 2A-**

178   **C**). Analogous super-resolution experiments in day 12 iNeurons with 0.5, 1, and 3 h of AO

179   revealed similar results, with no obvious effect of FBXO7 deletion on pUb recruitment,

180   volume or overall morphology when compared to WT iNeurons (**Figure 2D-F,**

181   **Supplemental Figure 3A**). As expected (Ordureau *et al.*, 2020; Ordureau *et al.*, 2018),

182   iNeurons lacking PINK1 did not accumulate pUb (**Figure 2D,E**). These results were also

183   confirmed in iNeurons treated with AO for 1 or 6 h using conventional immunofluorescence

184   and image analysis of HSP60 and pUb co-localization (**Figure 2G,H**). To ensure that kinetic

185   effects were not obscured by overt depolarization, we reduced the concentrations of AO

186   used by 10-fold, but again no defect in pUb recruitment to mitochondria was observed

187   (**Supplemental Figure 3B,C**). These data indicate that the absence of FBXO7 does not

188   alter the ability of PINK1-dependent pUb foci to accumulate on damaged mitochondria in

189   either HeLa or iNeuron systems.

190

191   ***Parkin and autophagy regulator recruitment in FBXO7[-/-] cells***

192   Parkin recruitment depends upon the accumulation of pUb on damaged mitochondria

193   (**Supplemental Figure 1A**) (Okatsu *et al*, 2015). Given that the existing model for FBXO7 in

194   Parkin-dependent mitophagy posited that Parkin and FBXO7 physically interact and that

195   FBXO7 promotes Parkin function (Burchell *et al.*, 2013), we directly tested whether FBXO7

196   is required for Parkin recruitment to mitochondria using the HeLa cell system. Control or

197   FBXO7[-/-] cells were stably transduced with a lentivirus expressing GFP-Parkin and subjected

198   to imaging with or without depolarization with AO (**Supplemental Figure 4A**). We used

199   CellProfiler (Stirling *et al*, 2021) to analyse the characteristics of GFP-Parkin and

200   mitochondria and their relationship to each other. By segmenting out cytosolic and

201   mitochondrially-localized Parkin, we could quantify alterations in Parkin abundance within

202   the mitochondrial mask as a measure of Parkin-translocation (**Supplemental Figure 4B**).

203   Our expectation was that a requirement for FBXO7 in Parkin recruitment would result in
204   reduced Parkin intensity within the mitochondrial mask in response to depolarization. First,
205   we tested whether mitochondrial morphology (mitochondrial integrated density [==mtIntDen]
206   as proxy, stained with HSP60) is changing after AO-treatment on a single-cell level. Under
207   fed conditions, control and three FBXO7$^{-/-}$ clones displayed comparable mtIntDen.
208   Depolarization by AO led to the expected mitochondrial fragmentation and clustering, thus
209   causing an increase in local HSP60 signal and a right-shift in mtIntDen (**Supplemental**
210   **Figure 4C, top panel**). This shift was also observed to a similar extend in FBXO7$^{-/-}$ cells.
211   Thus, both control and FBXO7$^{-/-}$ cells robustly respond to AO-induced mitophagy. Next, we
212   tested if Parkin intensities are increasing on mitochondria on an "organelle object" level. As
213   expected, mtIntDen did shift to the right after AO-treatment, in line with previous
214   experiments. Parkin signal was comparable between the genotypes under fed conditions,
215   and increased in intensity after AO-treatment, consistent with Parkin accumulation inside the
216   mitochondrial area (**Supplemental Figure 4C, lower panel**). This Parkin shift was observed
217   in both control and FBXO7$^{-/-}$ cell lines, arguing that FBXO7 is not universally required for
218   Parkin recruitment to damaged mitochondria.

219   Mitochondrial ubiquitylation by Parkin promotes recruitment of downstream
220   autophagy machinery, including the FIP200-ULK1 complex and Ub-bind autophagy
221   adaptors, ultimately leading to the formation of an autophagosome (Heo *et al.*, 2015;
222   Lazarou *et al.*, 2015; Ravenhill *et al*, 2019; Vargas *et al*, 2019). Lipidation of LC3 is
223   associated with autophagosome formation and is thought to contribute to recruitment of
224   autophagy receptors. As expected, depolarization of Parkin-expressing HeLa cells resulted
225   in recruitment of both p62 and FIP200 to mitochondria in a manner that dependent on
226   PINK1, as revealed by immunostaining and confocal imaging (**Supplemental Figure 4D**).
227   However, FBXO7$^{-/-}$ cells were as proficient as control cells in recruitment of p62 or FIP200
228   after 3 h or 16 h or AO-induced mitophagy (**Supplemental Figure 4D-G**). Previous studies
229   using siRNAs targeting FBXO7 also reported that LC3 lipidation in response to mitochondrial
230   depolarization is defective compared with non-depleted cells (Burchell *et al.*, 2013).
231   However, all three FBXO7$^{-/-}$ HeLa cell clones underwent depolarization-dependent LC3
232   lipidation to similar extents, consistent with a functional Parkin pathway (**Supplemental**
233   **Figure 4H,I**). Taken together, these data indicate that FBXO7 is not universally required to
234   promote either Parkin-dependent recruitment to damaged mitochondria or subsequent steps
235   that depend upon Ub chain assembly on mitochondria such as recruitment of autophagy
236   machinery and initiation of LC3 lipidation.

237   Additionally, we have not able to reproduce a previously reported association
238   between overexpressed FBXO7 and PINK1 (Huang *et al*, 2020) in either HEK293T or
239   HCT116 cells. Briefly, as part of our BioPlex project (Huttlin *et al*, 2021), we ectopically

240   expressed PINK1-HA and performed interaction proteomics. While we identified the known
241   protein kinase chaperone HSP90 subunits in association with PINK1, we did not detect
242   FBXO7 (**Supplemental Figure 4J, left panel; Supplemental Table S1**). Likewise, FBXO7
243   associated reciprocally with members of the CUL1-SKP1-RBX1, the COP9/Signalosome,
244   and both core particle and regulatory subunits of the proteasome in HEK293T and/or
245   HCT116 cells, as expected (Bader *et al*, 2011; Liu *et al*, 2019; Vingill *et al*, 2016), but neither
246   PINK or Parkin were detected (**Supplemental Figure 4J,K; Supplemental Table S2**)
247   (Huttlin *et al.*, 2021) (see **METHODS**). These results are consistent with our previous Parkin
248   interaction proteomics experiments that failed to demonstrate an interaction with FBXO7
249   during mitophagy induction (Sarraf *et al.*, 2013).
250

251   ### *Mitophagic flux in FBXO7$^{-/-}$ cells*

252   A significant advance has been the development of mitophagy reporters, which
253   cumulatively measure flux of mitochondrial turnover through to the final stages of mitophagy:
254   the fusion of mitochondria-laden autophagosomes with lysosomes (Lazarou *et al.*, 2015).
255   mKeima is a fluorescent protein that undergoes a pH-dependent Stokes shift, and delivery of
256   a Keima-tagged cargo from the cytoplasm to the acidic interior of the lysosome can be
257   monitored by measuring the ratio of emission at 620 nm with maximal excitation at 440 nm
258   or 586 nm under neutral or acidic conditions, respectively, by flow cytometry or microscopy
259   (**Figure 3A**). To monitor differences in mitophagic flux upon deletion of FBXO7, we
260   employed mtKeima, an mKeima protein targeted to the mitochondrial with a COX8-matrix
261   targeting sequence (Ordureau *et al.*, 2020).

262   In Parkin-expressing HeLa cells, the ratio of acidic-Keima (measured with excitation
263   at 561 nm and emission 620 nm) to neutral Keima (ex. 405 nm, em. 603 nm) increases as
264   cells are treated with AO (**Figure 3B, Supplemental Figure 4L**). This mitophagic flux is
265   PINK1-dependent as deletion of PINK1 abolishes this shift (**Figure 3B, Supplemental**
266   **Figure 4L**). As expected, there is little flux without depolarization with AO, and inhibition of
267   the lysosomal V-ATPase with BafilomycinA1 (BafA) restores the mtKeima acidic:neutral ratio
268   to levels similar to that seen fed cells (**Supplemental Figure 4L**). In three FBXO7$^{-/-}$ clones,
269   AO-dependent mitophagic flux is similar to control cells with increasing flux observed with
270   increasing length of AO treatment (**Figures 3B; Supplemental Figure 4L**). We validated the
271   mtKeima flux results using the mitochondrial DNA clearance assay (Heo *et al.*, 2015;
272   Lazarou *et al.*, 2015). Staining for mtDNA foci per cell after 24 h AO treatment in control and
273   FBXO7$^{-/-}$ HeLa cells showed a significant decrease in mtDNA number in all samples (**Figure**
274   **3G**). The remaining mtDNA levels were indistinguishable between control and FBXO7$^{-/-}$ cells
275   (**Figure 3G**).

276   We also measured mtKeima foci and flux in control and FBXO7$^{-/-}$ iNeurons at day 12
277   of differentiation (**Figure 3C-E**). As with HeLa cells, red-shifted mtKeima foci increased ~2-
278   fold after 6 h AO treatment in control and FBXO7$^{-/-}$ cells (**Figure 3C,D**). Using flow
279   cytometry, mitophagic flux (normalized to BafA) after 6 and 24 h AO treatment was
280   comparable between control and FBXO7$^{-/-}$ iNeurons, and was absent in PINK1$^{-/-}$ cells
281   (**Figure 3E**). Additionally, we investigated mtDNA turnover in d12 control and two
282   independent FBXO7$^{-/-}$ iNeuron clones. Within 6 or 24 h of depolarization of iNeurons, we
283   observed a reduction in the number of mitochondrial DNA/cell, and the effect was
284   independent of the presence or absence of FBXO7 (**Figure 3F,G**). Taken together, these
285   data indicate that FBXO7 is not universally required for depolarization-dependent mitophagic
286   flux in either the HeLa or iNeuron systems.
287
288   ***Proteomic analysis of HeLa cells lacking FBXO7 during mitophagy***
289   As an alternative to mtKeima for measuring mitophagic flux, we examined the total
290   proteome of depolarized HeLa cells with the expectation that in control HeLa cells,
291   mitochondrial turnover would result in bulk loss of the mitochondrial proteome in depolarized
292   cells. Thus, control or FBXO7$^{-/-}$ HeLa cells expressing Parkin were depolarized for 16 h in
293   triplicate and total cell extracts subjected to 18-plex Tandem Mass Tagging (TMT)-based
294   proteomics (**Figure 4A, Supplemental Table S3,S4**) (Li *et al*, 2021). Replicates were highly
295   correlated, with correlation coefficients greater that 0.95 and Principal Component Analysis
296   (PCA) revealed tight clustering of replicates, with the major feature separating the samples
297   being AO-treatment (**Supplemental Figure 5A,B**). Through hierarchical clustering
298   (**Supplemental Figure 5C**), we identified major alterations in the abundance of mitochondria
299   in response to depolarization (**Figure 4B, Supplemental Figure 5D-I**). Indeed, the majority
300   of proteins annotated as mitochondrial were found to have reduced levels in control cells in
301   response to depolarization, as indicated in the overlap of mitochondrial proteins on the
302   volcano plots for the ~8000 proteins quantified (leftward skew of red dots in **Figure 4B**, left
303   panel). Importantly, the patterns of protein abundance were indistinguishable from control for
304   two independent FBXO7$^{-/-}$ cell lines, with leftward skew of mitochondrial proteins in the
305   volcano plot (**Figure 4B,C**). Proteins with altered abundance were enriched for mitochondrial
306   matrix, inner membrane, outer membrane and oxidative phosphorylation categories,
307   consistent with autophagy of entire organelles (**Figure 4C**). The behaviour of other
308   organelles and large protein complexes were similar for both control and FBXO7$^{-/-}$ cells
309   (**Figure 4C**). Moreover, both FBXO7 clones displayed similar behaviour to each other and to
310   the control, as indicated by correlation analysis (Pearson's R=0.82, 0.86 and 0.74,
311   respectively) (**Figure 4D,E**). These results are consistent with the absence of a discernible
312   alteration in depolarization-dependent mitophagic flux in cells lacking FBXO7. A previous

313 report proposed that depletion of FBXO7 resulted in accumulation of PINK1 proteins levels

314 under basal conditions (Huang *et al.*, 2020), but in our experiments, PINK1 levels in the two

315 FBXO7$^{-/-}$ clones were unaffected based on TMT intensities (**Figure 4F**).

316

317 ***Proteomic analysis of human ES cells lacking FBXO7 during neurogenesis***

318 As an initial unbiased approach to examining FBXO7 function in iNeurons, we

319 performed 18-plex TMT proteomics on control and two clones of FBXO7$^{-/-}$ cells at day 0, 4

320 and d12 of differentiation (**Figure 5A, Supplemental Table S5-S8**). We have previously

321 demonstrated dramatic remodelling of mitochondria around day 4 of differentiation to

322 support a switch from glycolysis to oxidative phosphorylation, which is accompanied by

323 BNIP3L-dependent mitophagy of a fraction of mitochondria (Ordureau *et al*, 2021). From the

324 ~6000 proteins quantified across all replicates and conditions, we found strong

325 correspondence of control and FBXO7$^{-/-}$ cells, with PC1 being drive by differentiation

326 (**Supplemental Figure 6A,B**). FBXO7 itself was expressed at comparable levels across the

327 time course but was not detected in FBXO7$^{-/-}$ iNeurons, as expected (**Supplemental Figure**

328 **6C**). Remarkably, the abundance of the proteome was largely immune to the loss of FBXO7

329 at both day 4 and day 12 of differentiation (**Figure 5B-D, Supplemental Figure 6D**).

330 Moreover, the abundance of mitochondrial proteins (including inner and out membrane and

331 OXPHOS components) were unchanged relative to control cells at day 4 or 12 of

332 differentiation (**Figure 5B, Supplemental Figure 6D**).

333 Recent reports have directly linked L250P mutations in the dimerization domain of

334 FBXO7 to MiD49/MiD51, a core adapter protein involved in mitochondrial fission (Al Rawi *et*

335 *al.*, 2022). Indeed, DNM1L-mediated mitochondrial fission has been previously indicated in

336 the efficient scission of damaged parts of mitochondria and protection of the remaining

337 healthy mitochondrial network (Burman *et al*, 2017). Cells expressing FBXO7^{L250P} were

338 found to have reduced levels of proteasome subunits as well (Al Rawi *et al.*, 2022). Our

339 proteomic data from iNeurons indicates no alterations in the abundance of proteasome

340 subunits or mitochondrial fission and fusion machinery (DNM1L, MFF, and MiD51) in

341 iNeurons lacking FBXO7 (**Figure 5C,E**). To test if loss of FBXO7 causes in morphological

342 changes in the mitochondrial network, we stained day 12 iNeurons with for the matrix marker

343 HSP60 prior to image analysis (**Figure 5F,G**). However, we observed no significant

344 alterations in the number of mitochondria/cell or the mean mitochondrial length in control or

345 FBXO7$^{-/-}$ iNeurons. The mean mitochondrial circularity was slightly reduced in FBXO7$^{-/-}$

346 iNeurons treated with AO for 3h (**Figure 5F**). Analogous analyses of mitochondria and

347 fission/fusion proteins also did not reveal significant alterations in response to loss of FBXO7

348 in two independent clones of HeLa cells (**Figure 5H,I**). However, there was a ~10%

349 decrease in the abundance of proteasome subunits in HeLa cells lacking FBXO7 in the

350   absence of depolarization, but an increase after mitophagy induction (**Supplemental Figure**
351   **5E, Figure 4C**). If this response is a compensatory mechanism of the knockout cell line to
352   cope with cytotoxic insults is an intriguing idea. Last, we examined whether FBXO7$^{-/-}$ is
353   required for the maintenance of the mitochondrial organelle pool during differentiation.
354   Previous work has shown significant metabolic rewiring during the differentiation from hESC
355   to iNeurons, including a switch from glycolysis to oxidative phosphorylation as the cells main
356   energy source (Ordureau *et al.*, 2021). Since this switch is accompanied by increased
357   mitophagy, we set out to see if the absence of FBXO7 would lead to accumulation of
358   mitochondria and/or impair differentiation. FBXO7$^{-/-}$ cells did not display obvious differences
359   in the abundance of mitochondrial proteins, when normalized to day 0 (**Figure 5B,**
360   **Supplemental Figure 6D**). Likewise, other abundance of other organelles was unchanged
361   (**Figure 5C**). Finally, neither differentiation markers or autophagy proteins displayed obvious
362   changes in control versus the two FBXO7$^{-/-}$ clones as measured by TMT-proteomics and
363   displayed using a T^2-statstic (Ordureau *et al.*, 2021) (**Supplemental Figure 7A-F**).
364
365   **DISCUSSION**
366   Despite strong genetic evidence linking mutations in FBXO7 with parkinsonian-
367   pyramidal syndrome (Di Fonzo *et al.*, 2009; Houlden & Singleton, 2012; Paisan-Ruiz *et al.*,
368   2010), our understanding of the cellular roles of FBXO7 are limited. An early study reported
369   biochemical links between FBXO7 and Parkin/PINK1-dependent mitophagy in fibroblasts
370   and SH-SY5Y cells, including interaction of overexpressed FBXO7 with both PINK1 and
371   Parkin (Burchell *et al.*, 2013). Using siRNA to deplete FBXO7, it was also concluded that
372   FBXO7 promotes Parkin's ability to ubiquitylate the outer mitochondrial membrane substrate
373   MFN1 and also promotes clearance of mitochondria by autophagy. These biochemical and
374   physiological results led to the conclusion that FBXO7 functions as a biochemical amplifier
375   of Parkin/PINK1-deepndent mitophagy (Burchell *et al.*, 2013). However, follow-up studies
376   have been limited, and the field has experienced dramatic advances in the understanding of
377   the biochemical roles of Parkin and PINK1 in promoting mitochondrial clearance by
378   autophagy, thereby providing the tools to examine potential roles of FBXO7 in the pathway.
379   With these tools, we set out to define where in the pathway FBXO7 might operate to
380   promote mitophagy. However, in both the HeLa cells with overexpressed Parkin and
381   iNeurons with a fully endogenous Parkin/PINK1 pathway, we failed to validate a role for
382   FBXO7 in any of several steps in the pathway, including pUb accumulation, Parkin
383   recruitment to the mitochondrial outer membrane, recruitment of autophagy machinery,
384   mitophagic flux as measured by mtKeima, and mitochondrial proteome degradation. The
385   finding that deletion of FBXO7 has no obvious effect on the pathway with either endogenous
386   or overexpressed Parkin in iNeurons and HeLa cells indicates that FBXO7 does not play a

387　general or universally required role in the pathway. A previous study largely based on

388　overexpression concluded that FBXO7 may bind and regulate PINK1 levels, with <2-fold

389　increases in PINK1 by immunoblotting in FBXO7-depleted cells (Huang *et al.*, 2020).

390　However, our quantitative proteomics experiments (**Figure 4**) indicated that deletion of

391　FBXO7 has no effect on PINK1 abundance, consistent with the finding that pUb

392　accumulation in response to depolarization is unaffected in FBXO7$^{-/-}$ cells. Moreover, our

393　previous interaction proteomics experiments failed to identify either PINK1 in association

394　with overexpressed FBXO7 (Huttlin *et al.*, 2021) or FBXO7 in association with

395　overexpressed Parkin (Sarraf *et al.*, 2013). Thus, our functional and biochemical results do

396　not support a biochemical linkage between FBXO7 and the PINK1-Parkin pathway.

397　　　　In order to broadly examine FBXO7$^{-/-}$ iNeurons for pathways that are affected, we

398　performed global proteomic analysis during neurogenesis *in vitro*. However, we did not

399　observe any alterations in pathways linked with mitochondria, or other quality control

400　pathways, although a reduction in the abundance of alcohol dehydrogenase enzymes

401　among a small number of other proteins, was observed. Whether these signatures are

402　related to FBXO7 function remains to be examined. While a recent study linked the L250P

403　mutation in the dimerization domain of FBXO7 with alterations in proteins associated with

404　mitochondrial fusion and fission (Al Rawi *et al.*, 2022), we did not observe alterations in

405　either the abundance of these proteins (MiD51, MFF, FIS1) nor did we observe changes in

406　mitochondrial morphology in either HeLa cells or iNeurons lacking FBXO7.

407　　　　An apparent ortholog of FBXO7 was identified in *Drosophila* – referred to as

408　*nutcracker*, *ntc* – and shown to associate with components of the core particle of the

409　proteasome, as well as with DmPI31 (Bader *et al.*, 2011). Association of human FBXO7 with

410　proteasome components and PI31(also called PSMF1) have also been observed in both

411　focused studies and in our previous interaction proteomic studies (Al Rawi *et al.*, 2022;

412　Huttlin *et al.*, 2021; Vingill *et al.*, 2016). In this context, PI31/DmPI31 and FBXO7/*ntc* have

413　been proposed to functionally link proteasome trafficking via dynein motors in neuronal

414　processes (Liu *et al.*, 2019). Our interaction proteomics analysis has also confirmed

415　association of FBXO7 with PSMF1, CRL, COP9/Signalosome, and proteasome core

416　subunits (**Supplemental Figure 4J,K**). Further studies are required to elucidate the

417　relationship between FBXO7 and parkinsonian-pyramidal syndrome, to understand any

418　functional relationships between FBXO7 and other Parkinson's disease risk alleles, and to

419　examine whether FBXO7's physical association with the proteasome is linked with disease.

(**A**) Hierarchical clustering and correlation plots of control and FBXO7[-/-] c52 (top) or c89 (bottom) at indicated days of differentiation in the experiment outlined in **Figure 5A.** (**B**) PCA analysis of whole cell proteomic samples from control and FBXO7[-/-] cells. Triplicates for each timepoint and genotype were used. (**C**) FBXO7 peptide abundance in control and FBXO7[-/-] cells at indicated days of differentiation. (**D**) Violin plots [$\log_2$ (control / FBXO7[-/-])] for FBXO7[-/-] c89 cells depicting alterations in the abundance of mitochondrial proteins.
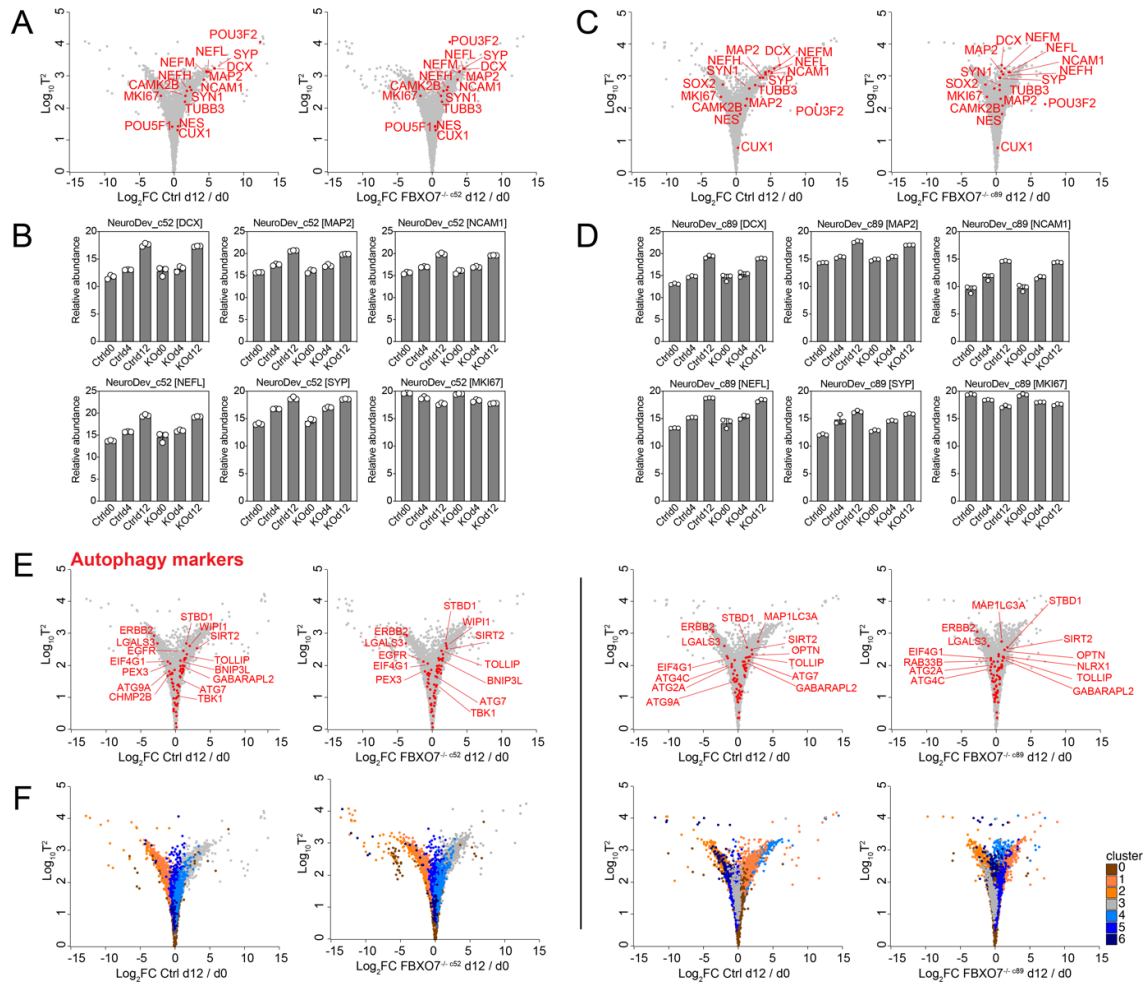

Supplemental Figure 7. Comparison of human ES cell neurogenesis with or without FBXO7. (**A**) Hotelling plots (Log$_{10}$ T^2 statistic versus Log$_2$ FC day 12/day 0) of control (left panel) or FBXO7$^{-/-}$ c52 hES cells undergoing differentiation. Selected neurogenesis factors are indicated. (**B**) The relative abundance of selected proteins is shown in the lower histograms at day 0, 4 and 12 of differentiation. (**C,D**) Hotelling plots similar to **A,B** for control and FBXO7$^{-/-}$ c89. (**E**) Patterns of changes in the abundance of autophagy proteins in control (left panel) and FBXO7$^{-/-}$ (right panel) day 12 iNeurons relative to day 0 cells displayed on a Hotelling plot. (**F**) Cluster analysis of control and FBXO7$^{-/-}$ cells comparing day 12 of differentiation to day 0. Individual clusters are displayed on Hotelling plots for each genotype.

EXPERIMENTAL MATERIALS AND METHODS

All details and catalogue numbers can be found in the **Materials Table (Supplemental Table S9).** Protocols associated with this work can be found on protocols.io (dx.doi.org/10.17504/protocols.io.kxygx99pwg8j/v1)

Cloning and plasmid generation

The construction of lentiviral expression constructs used in this study have been previously described: pHAGE-mt-mKeima in (Heo *et al.*, 2015), PB-mt-mKeimaXL (Ordureau *et al.*, 2021) and pHAGE-GFP-Parkin in (Ordureau *et al.*, 2018).

Cell culture, generation of lentiviral stable cell lines.

HeLa Flip-In T-Rex (HFT) expressing doxycycline-inducible WT-Parkin (HeLa HFT/TO-PRKN-WT) cells (Heo *et al.*, 2015) and HEK293T were maintained in Dulbecco's modified Eagles medium (DMEM), supplemented with 10% vol/vol fetal bovine serum (FBS), 5% vol/vol penicillin-streptomycin (P/S), 5% vol/vol GlutaMAX and 5% vol/vol Non-essential amino acids (NEAA) at 37°C, 5% O_2.

Stable cell lines were generated using lentivirus generated from HEK293T cells. pHAGE-mt-mKeima or pHAGE-eGFP-Parkin were co-transfected in HEK293T cells together with the lentiviral vectors pSpax2 and pMD2.1 using Lipofectaime LTX reagent (Thermo Fisher Scientific, 15338100), according to manufacturer's instructions. Virus was harvested, filtered (0.45 µm) and added 8µg/ml polybrene and target cells infected for 18 h. Antibiotic selection was performed using 1 µg/ml puromycin or FACS sorting and cells verified using immunoblotting or fluorescence microscopy.

If not stated otherwise, Parkin expression in HeLa HFT/TO-PRKN was induced using 2 µg/ml doxycycline o/n, and subsequent mitophagy induced using Antimycin A / Oligomycin A (==AO) for the indicated times.

H9 ES cells harboring the mitochondrial mt-mKeima flux reporter (Ordureau *et al.*, 2020) were generated by electroporation of 1×10^6 cells with 2.5 µg of pAC150-PiggyBac-matrix-mKeima^{XL} along with 2.5 µg of pCMV-HypBAC-PiggyBac-Helper, as described (Ordureau *et al.*, 2020). The cells were selected and maintained in E8 medium supplemented with 50 µg/ml Hygromycin and Hygromycin was kept in the medium during differentiation to iNeurons.

Gene-Editing and iNeuron differentiation

Generation of HeLa HFT cells lacking FBXO7$^{-/-}$ was facilitated using CRISPR/Cas9 with target sites determined using CHOPCHOP (Labun *et al*, 2019). Guide RNAs were ligated into the px459 plasmid (Addgene plasmid # 62988) and cells transfected using Lipofectaime LTX reagent (Thermo Fisher Scientific, 15338100), according to manufacturer's instructions. Two days post-transfection, single GFP positive cells were sorted into 96-well dishes containing 300µl full growth medium (composition as described above). Single cells were allowed to grow into colonies, then duplicated for MiSeq analysis and maintenance. Knockout candidates were confirmed by Western blot on whole cell lysates. The sgRNAs were generated using *GeneArt Precision gRNA Synthesis Kit* (Thermo Fisher Scientific) according to the manufacturer's instruction and purified using RNeasy Mini Kit (Qiagen). The sgRNA target sequence: ACCGATTCACTACAGAGCAT.

The PINK1$^{-/-}$ H9 cells used here, wherein sequences in exon 1 were deleted using CRISPR-Cas9 to create a null allele, were reported previously (Ordureau *et al.*, 2018). To generate FBXO7$^{-/-}$ H9 ES or HeLa cells, 0.6 µg sgRNA was incubated with 3 µg SpCas9 protein for 10 minutes at room temperature and electroporated into 2×10^5 WT H9 cells using Neon transfection system (Thermo Fisher Scientific). Mutants were identified by Illumina MiSeq and further confirmed by Western blotting. For introduction of TRE3G-NGN2 into the AAVS1 site, a donor plasmid pAAVS1-TRE3G-NGN2 was generated by replacing the EGFP sequence with N-terminal flag-tagged human NGN2 cDNA sequence in plasmid pAAVS1-TRE3G-EGFP (Addgene plasmid # 52343). Five micrograms of pAAVS1-TRE3G-NGN2, 2.5 µg hCas9 (Addgene plasmid # 41815), and 2.5 µg gRNA_AAVS1-T2 (Addgene plasmid #

714   41818) were electroporated into $1x10^6$ H9 cells. The cells were treated with 0.25 µg/ml
715   Puromycin for 7 days and surviving colonies were expanded and subjected to genotyping.
716   Human ES cells (H9, WiCell Institute) were cultured in E8 medium (Chen *et al*, 2011)
717   on Matrigel-coated tissue culture plates with daily medium change. Cells were passaged
718   every 4-5 days with 0.5 mM EDTA in 1× DPBS (Thermo Fisher Scientific). SpCas9 and
719   AsCas12a/AsCpf1 expression plasmids pET-NLS-Cas9-6xHis (Addgene plasmid # 62934)
720   and modified pDEST-his-AsCpf1-EC, generated by deleting the MBP sequence from
721   plasmid pDEST-hisMBP-AsCpf1-EC (Addgene plasmid # 79007), were transformed into
722   *Rosetta™(DE3)pLysS* Competent Cells (Novagen), respectively, for expression. SpCas9
723   and AsCas12a/AsCpf1 proteins were purified as described elsewhere (Hur *et al*, 2016; Zuris
724   *et al*, 2015). Briefly, cells expressing SpCas9 [0.5 mM isopropylthio-β-galactoside, 14-hour
725   induction] were lysed in FastBreak buffer (Promega, Inc) and the NaCl concentration
726   adjusted to 500 mM. Extracts were centrifuged at 38,000g for 10 min at 4^oC and the
727   supernatant incubated with Ni-NTA resin for 1 hour. The resin was washed extensively with
728   50 mM Tris pH8.0, 500 mM NaCl, 10% glycerol, 20 mM imidazole, and 2 mM TCEP prior to
729   elution with this buffer supplemented with 400 mM imidazole. Proteins were diluted two
730   volumes/volume in PBS and fractionated on a Heparin-Sepharose column using a 0.1 to 1.0
731   M NaCl gradient. Cas9-containing fractions were stored in PBS, 20% glycerol, 2 mM TCEP
732   at -80^oC. AsCpf1 expression was induced similarly, and cells pelleted by centrifugation. Cells
733   were lysed by sonication in 50 mM HEPES pH7, 200 mM NaCl, 5 mM $MgCl_2$, 1 mM DTT,
734   and 10 mM imidazole supplemented with lysozyme (1 mg/ml) and protease inhibitors (Roche
735   complete, EDTA-free). After centrifugation (16,000g for 30 min), the supernatant was
736   incubated with Ni-NTA resin, the resin washed with 2M NaCl, and bound proteins eluted with
737   250 mM imidazole, and buffer exchanged into lysis buffer lacking $MgCl_2$ and imidazole prior
738   to storage at -80^oC.
739   For human ES cell conversion to iNeurons, cells were expanded and plated at
740     $2x10^4/cm^2$ on Matrigel-coated tissue plates in DMEM/F12 supplemented with 1x N2, 1x
741   NEAA (Thermo Fisher Scientific), human Brain-derived neurotrophic factor (BDNF, 10 ng/ml,
742   PeproTech), human Neurotrophin-3 (NT-3, 10 ng/ml, PeproTech), mouse laminin (0.2 µg/ml,
743   Cultrex), Y-27632 (10 µM, PeproTech) and Doxycycline (2 µg/ml, Alfa Aesar) on Day 0. On
744   Day 1, Y-27632 was withdrawn. On Day 2, medium was replaced with Neurobasal medium
745   supplemented with 1x B27 and 1x Glutamax (Thermo Fisher Scientific) containing BDNF,
746   NT-3 and 1 µg/ml Doxycycline. Starting on Day 4, half of the medium was replaced every
747   other day thereafter. On Day 7, the cells were treated with Accutase (Thermo Fisher
748   Scientific) and plated at $3-4x10^4/cm^2$ on Matrigel-coated tissue plates. Doxycycline was
749   withdrawn on Day 10.
750
751   *Immunoblotting*
752   At the indicated times, ES cells, iNeurons or HeLa cells were washed on ice in 1x PBS,
753   harvested and pellet wash with 1x PBS and resuspended in 8 M urea buffer (8 M urea, 150
754   mM TRIS pH 7.4, 50 mM NaCl, PhosSTOP phosphatase inhibitor cocktail). Resuspended
755   cell lysates were sonicated for 10 seconds and debris pelleted at 13,000 rpm for 10 min.
756   Protein concentration was determined by BCA assay according to manufacturer's
757   instructions (Thermo Fisher Scientific, 23227). Indicated amounts of proteins were
758   resuspended in 1xLDS + 100 mM DTT and boiled for 10 minutes at 85°C. Equal amount of
759   protein and volume were loaded run on 4%-20% Bis-Tris, 8% Tris NuPAGE gels for 5
760   minutes at 100V, 5 min at 150 V and then run at 200 V for the required time. Gels were
761   transferred via wet transfer system onto PDVF membranes for immunoblotting.
762   Chemiluminescence and colorimetric images were acquired using a BioRad ChemiDoc MP
763   imaging system. Images from Western Blots were exported and analysed using Image Lab
764   and ImageJ/FiJi (Schindelin *et al*, 2012).
765
766
767
768

769
770
771 *PROTEOMICS*
772 *Proteomics – general sample preparation*
773 Sample preparation of proteomic analysis of whole-cell extract from HeLa, hESC, NPC and
774 iNeurons was performed according to previously published studies (Ordureau *et al.*, 2021;
775 Ordureau *et al.*, 2020). Cells were harvested on ice and plates were washed twice with 1x
776 PBS and detached in 1x PBS using cell scraper. After pelleting at 2000 rpm for 5 min at 4°C,
777 cells were washed 2x with 1x PBS and resuspended in 8 M urea buffer (composition stated
778 above). After sonification for 10 seconds, resuspended cells were pelleted for 10 min at
779 13000 rpm. Protein concentration was determined using BCA kit (Thermo Fisher Scientific,
780 23227).
781   Unless otherwise noted, proteomics and data analysis was performed as described
782 (Ordureau *et al.*, 2021; Ordureau *et al.*, 2020). Briefly, protein extracts (100 µg) were
783 subjected to disulfide bond reduction with 5 mM TCEP (room temperature, 10 min) and
784 alkylation with 25 mM chloroacetamide (room temperature, 20 min). Methanol–chloroform
785 precipitation was performed prior to protease digestion. In brief, four parts of neat methanol
786 were added to each sample and vortexed, one part chloroform was then added to the
787 sample and vortexed, and finally three parts water was added to the sample and vortexed.
788 The sample was centrifuged at 6,000 rpm for 2 min at room temperature and subsequently
789 washed twice with 100% methanol. Samples were resuspended in 100 mM EPPS pH8.5
790 containing 0.1% RapiGest and digested at 37 °C for 8h with Trypsin at a 100:1 protein-to-
791 protease ratio. Samples were acidified with 1% Formic Acid for 15 min and subjected to C18
792 solid-phase extraction (SPE) (Sep-Pak, Waters).
793
794 *Proteomics – quantitative proteomics using TMT*
795 Tandem mass tag labeling of each sample (50 mg peptide input) was performed by adding 5
796 uL of the 25 ng/mL stock of TMTpro reagent along with acetonitrile to achieve a final
797 acetonitrile concentration of approximately 30% (v/v). Following incubation at room
798 temperature for 1 h, the reaction was quenched with hydroxylamine to a final concentration
799 of 0.5% (v/v) for 15 min. The TMTpro- labeled samples were pooled together at a 1:1 ratio.
800 The sample was vacuum centrifuged to near dryness, and following reconstitution in 1% FA,
801 samples were desalted using C18 solid-phase extraction (SPE) (50 mg, Sep-Pak, Waters),
802 according to manufacturer protocol.
803   Dried TMTpro-labeled peptides (~300 ug) were resuspended in 10 mM NH_4HCO_3 pH
804 8.0 and fractionated using basic pH reverse phase HPLC (Wang *et al*, 2011). Briefly,
805 samples were offline fractionated over a 90 min run, into 96 fractions by high pH reverse-
806 phase HPLC (Agilent LC1260) through an Aeris peptide xb-c18 column (Phenomenex; 250
807 mm x 3.6 mm) with mobile phase A containing 5 % acetonitrile and 10 mM NH_4HCO_3 in LC-
808 MS grade H_2O, and mobile phase B containing 90 % acetonitrile and 10 mM NH_4HCO_3 in
809 LC-MS grade H_2O (both pH 8.0). The 96 resulting fractions were then pooled in a non-
810 continuous manner into 24 fractions (as outlined in Figure S5 of (Paulo *et al*, 2016)) and sets
811 of 12 fractions (even or odd numbers) were used for subsequent mass spectrometry
812 analysis. Fractions were vacuum centrifuged to near dryness. Each consolidated fraction
813 was desalted via StageTip, dried again via vacuum centrifugation, and reconstituted in 5 %
814 acetonitrile, 1 % formic acid for LC-MS/MS processing.
815   TMT proteomics samples were subjected to analysis using a Orbitrap Fusion Lumos
816 Tribrid mass spectrometer (Thermo Fisher Scientific, San Jose, CA) online with Proxeon
817 EASY-nLC1200 liquid chromatography (Thermo Scientific). Peptides were resuspended in 5
818 % ACN/5 % FA and 10 % of the samples were loaded on a 35 cm analytical column (100mm
819 inner diameter) packed in-house with Accurcore150 resin (150 Å, 2.6 mm, Thermo Fisher
820 Scientific, San Jose, CA) for LC-MS analysis. Peptide separation was performed with a
821 gradient of acetonitrile (ACN, 0.1% FA) from 3-13 % (0-83 min) and 13-28 % (80-83 min)
822 during a 90 min run.

823　　　　For the HeLa TMTpro proteomic samples, LC-hrMS/MS was combined with 3
824　optimized CV parameters on the FAIMS Pro Interface to reduced precursor ion interference
825　(Schweppe *et al*, 2019). Data-dependent acquisition (DDA) was performed by selecting the
826　most abundant precursors from each CV's (-40/-60/-80) MS^1 scans for hrMS/MS over a 1-
827　1.5s duty cycle (1s/1.5s/1s respectively). The MS^1 scan parameters include a 400-1,600 m/z
828　mass range at 60,000 resolution (at 200 Th) with 4 x 10^5 automated gain control (AGC) (100
829　%), and a maximum injection time (max IT) of 50 ms. Precursors (z=2-5) were isolated with
830　0.7 Th (quadrupole), fragmented with high energy C-trap dissociation (HCD) at 36
831　normalized collision energy (NCE), and subjected to hrMS/MS on the Orbitrap at 50,000
832　resolution (at 200 Th), 120 ms max IT, fixed first mass 110 Th, and 1.0 x 10^5 AGC (200%).
833　Precursors were placed on 90 s dynamic exclusion (+/- 10 ppm) to prevent redundant
834　sampling.
835　　　　In the iNeuron TMTpro experiments, the same FAIMS and MS^1 parameters were
836　implemented (with 1.25 s duty cycle/CV for DDA) with the Multi-Notch SPS-MS3 acquisition
837　method (McAlister *et al*, 2014), to further reduce ion interference in TMT reporter
838　quantification (Paulo *et al.*, 2016). Most abundant precursors (with 120 s dynamic exclusion
839　+/- 10 ppm) were selected from MS^1 scans, isolated using the quadrupole (0.6 Th isolation),
840　fragmented with collision-induced dissociation (CID) at 35 NCE, and subjected to MS/MS in
841　the ion trap (turbo scan speed, 35 ms max IT, 1.0 x 10^4 AGC). Using Real Time Search
842　analysis software (Erickson *et al*, 2019; Schweppe *et al*, 2020), a synchronous-precursor-
843　selection (SPS) API-MS^3 scan was collected on the top 10 most intense b- or y-ions from the
844　matched peptide identification (determined by an online search of its respective MS/MS
845　scan). MS^3 scans were performed on the Orbitrap (AGC 2.0 x 10^5; NCE 55; max IT 250 ms,
846　50,000 resolution at 200 Th). To increase quantitative sampling (MS^3 scans) of proteins
847　during each mass spectrometry injection, a 2 peptide per protein per sample closeout was
848　set. This ensures no more than two peptide-spectrum matches per protein (that pass quality
849　filters) are subjected to MS^3 scans, reducing redundant protein MS sampling and potentially
850　increasing proteome depth (Schweppe *et al.*, 2020).
851
852　*Proteomics Data Analysis*
853　Mass spectrometry raw data were converted to mzXML and monoisotopic peaks were
854　reassigned using Monocle (Rad *et al*, 2021). Mass spectra were database searched using
855　Sequest algorithm (2019.01 rev. 5; (Eng *et al*, 1994)) against the Human Reference
856　Proteome Uniprot database (2019-01 SwissProt entries only; UniProt Consortium, 2015)
857　appended with sequences of common contaminates and reverse sequences of proteins as
858　decoys, for target-decoy competition (Elias & Gygi, 2007). Sequest search parameters
859　include: 50 ppm precursor tolerance, 0.9 Da product ion tolerance, trypsin endopeptidase
860　specificity (C-terminal to [KR], 2 max missed cleavages), static modifications on peptide N-
861　terminus and lysines with TMTpro tags (+304.207 Da) and carbamidomethylation on
862　cysteines (57.021 Da), and variable modification of oxidation on methionines (+15.995 Da).
863　Peptide-spectrum matches were filtered at 2% false discovery rate (FDR) using linear
864　discriminant analysis (Huttlin *et al*, 2010), based on XCorr, DeltaCn, missed cleavages,
865　peptide length, precursor mass accurracy, fraction of matched product ions, charge state,
866　and number of modifications per peptide (additionally restricting PSM Xcorr >1 and peptide
867　length>6). Following a 2% protein FDR filter (Savitski *et al*, 2015), PSMs reporter ion
868　intensities were quantified (most intense centroid within 0.003 Da of theoretical TMT reporter
869　mass), filtered based on a precursor isolation specificity > 0.5, and filtered by a summed
870　signal-to-noise across TMT channels > 100.
871　　　　Protein quantification was performed via the summation (weighted average) of its
872　constituent PSMs' reporter intensities and TMT channels were normalized for protein input
873　to total TMT channel intensity across all quantified PSMs (adjusted to median total TMT
874　intensity for the TMT channels) (Plubell *et al*, 2017). Log$_2$ normalized summed protein
875　reporter intensities were compared using a Student's t-test and p-values were corrected for
876　multiple hypotheses using the Benjamini-Hochberg adjustment (Benjamini & Hochberg,
877　1995). Resultant q-values and mean log$_2$ fold changes between conditions were used to

878 generate volcano plots. Hotelling T^2 analysis was performed using the normalized summed
879 protein reporter ion intensities and the timecourse (v. 1.66.0; (Tai, 2022)) package in R.
880   The annotation list for the subcellular localization of organellar protein markers was
881 derived from previously published high confidence HeLa dataset ((Itzhak *et al*, 2016); "high"
882 & "very high" confidence) and additional manual entries (Ordureau *et al.*, 2021). MitoCharta
883 3.0 (Rath *et al*, 2021) was used for mitochondrial annotation, whereas annotations for
884 ribosome and autophagy components were used from previous studies (An *et al*, 2020).
885 Transcription factor and neuronal development markers were based on previously published
886 databases and publications (Lambert *et al*, 2018; Ordureau *et al.*, 2021). Figures were
887 generated using a combination of Excel, R (v.4.2.0) in RStudio (2022.07.01 Build 554),
888 Perseus (v1.6.5 (Tyanova & Cox, 2018)), GraphPad Prism (v9.1.0), and Adobe Illustrator
889 (26.2.1).
890
891 The **Supplemental Data Table S3-8** contains the quantified proteins as well as associated
892 TMT reporter ratio to control channels used for quantitative analysis.
893
894 *Interaction Proteomic Analysis*
895 For interaction analysis of FBXO7 and PINK1, interaction proteomics data from the Bioplex
896 Interactome (Huttlin *et al.*, 2021) was extracted for HEK293T and HCT116 samples
897 (**Supplemental Table S1,2**). The number of replicates in which a peptide-spectral match
898 (PSM) mapped to PINK1's or FBXO7's the Bioplex 3.0 interactomes was plotted via a
899 network diagram in R. (packages to add from R include (igraph 1.3.1, tidygraph 1.2.1, and
900 ggraph 2.0.5).
901
902 *MICROSCOPY*
903 Macros and pipelines used in this work can be found on GitHub
904 (https://github.com/harperlaboratory/FBXO7.git) or
905 Zenodo (https://doi.org/10.5281/zenodo.7258918).
906
907 *Live-cell confocal microscopy for mitophagic flux analysis over differentiation (mt-mKeima^{XL})*
908 For quantitative Keima-flux analysis (Ordureau *et al.*, 2020), hESC were seeded on day 4 of
909 differentiation into 6-well 1.5 high performance glass bottom plates (Cellvis, P06-1.5H-N)
910 and further differentiated in the vessel for the indicated times until reaching appropriate
911 confluency and imaged. iNeurons were imaged using a Yokogawa CSU-W1 spinning disk
912 confocal on a Nikon Eclipse Ti-E motorized microscope. The system is equipped with a
913 Tokai Hit stage top incubator and imaging was performed at 37°C, 5% CO_2 and 95%
914 humidity under a Nikon Plan Apo 60×/1.40 N.A immersion oil objective lens. For ratiometic
915 imaging, mtKeimaXL were excited in sequential manner with a Nikon LUN-F XL solid state
916 laser combiner ([laser line – laser power]: 445 - 80mW, 561 - 65mW]) using a
917 Semrock Di01-T445/515/561 dichroic mirror. Fluorescence emissions were collected
918 through a Chroma ET605/52m [for 445 nm] and a 568 Chroma ET605/52m [for 561 nm],
919 filters, respectively (Chroma Technologies). Confocal images were acquired with a
920 Hamamatsu ORCA-Fusion BT CMOS camera (6.5 μm^2 photodiode, 16-bit) camera and NIS-
921 Elements image acquisition software. Consistent laser intensity and exposure time were
922 applied to all the samples, and brightness and contrast were adjusted equally by applying
923 the same minimum and maximum display values in ImageJ/FiJi (Schindelin *et al.*, 2012).
924 Image quantification was performed in ImageJ/FiJi using custom-written batch-macros.
925   In brief, raw confocal images of mitochondrial targeted mt-mKeima^{XL} were divided
926 [ex:561/ex:445] resulting in a ratiometic image of only acidic Keima-puncta. These signals
927 were subjected to background subtraction (rolling kernel size 25, sliding paraboloid) and
928 converted to binary objects. The "Analyze Particles..." command (pixel size exclusion: 0.5-∞,
929 exclude edge objects) was used to measure foci-abundance and other morphological
930 parameters. Results for each image-stack saved as .csv files, together with the original
931 ratiometic .tiff file for QC purposes. Unless stated otherwise all images represent z-

932   projections. Statistical analysis and plotting of microscopy data was performed in Prism
933   (v9.1.0, GraphPad).

934
935
936
937

938   *Immunocytochemical analysis*
939   iNeurons or HeLa cells were fixed with warm 4% paraformaldehyde (Electron Microscopy
940   Science, #15710, purified, EM grade) in PBS at 37°C for 30 min and permeabilized with
941   0.5% Triton X-100 in PBS for 15 minutes at room temperature. After three washes with
942   0.02% Tween20 in PBS (PBST), cells were blocked for 10 min in 3% BSA-1xPBS at room
943   temperature and washed again three times in PBST. Cells were incubated for 3h in primary
944   antibodies in 3% BSA-1xPBS and washed three times with PBST. Secondary antibodies
945   (Thermo Scientific, 1:400 in 3% BSA-1xPBS) where applied for 1h at room temperature.
946   Alexa Fluor 633 Phalloidin (Thermo Fisher, 1:200, A22284) was added with secondary
947   antibodies to label F-actin. To stain nuclei, Hoechst33342 (1:10000) was added for 5 min to
948   cells in PBST and final three washes performed before mounting in Vectashield (Vector
949   Laboratories, H-1000-10). Primary and secondary antibodies used in this study can be found
950   in the **Materials Table (Supplemental Table S9).**

951

952   *Fixed-cell microscopy – general acquisition parameters*
953   Immunofluorescently labelled Hela or iNeurons (antibodies indicated in figures and figure
954   legends and details in **Materials Table, (Supplemental Table S9)**) were imaged at room
955   temperature using a Yokogawa CSU-W1 spinning disk confocal on a Nikon Eclipse Ti-E
956   motorized microscope equipped with a Nikon Plan Apochromat 40×/0.40 N.A air-objective
957   lens, Nikon Apochromat 60×/1.42 N.A oil-objective lens and a Plan Apochromat 100×/1.45
958   N.A oil-objective lens. Signals of 405/488/568/647 fluorophores were excited in sequential
959   manner with a Nikon LUN-F XL solid state laser combiner ([laser line – laser power]: 405 -
960   80mW, 488 - 80mW, 561 - 65mW, 640nm - 60mW]) using a Semrock Di01-
961   T405/488/568/647 dichroic mirror. Fluorescence emissions were collected with
962   Chroma ET455/50m [405 nm], 488 Chroma ET525/50m [488 nm], 568 Chroma ET605/52m
963   [561 nm], 633 Chroma ET705/72m [640 nm] filters, respectively (Chroma Technologies).
964   Confocal images were acquired with a Hamamatsu ORCA-Fusion BT CMOS camera (6.5
965   μm^2 photodiode, 16-bit) camera and NIS-Elements image acquisition software. Consistent
966   laser intensity and exposure time were applied to all the samples, and brightness and
967   contrast were adjusted equally by applying the same minimum and maximum display values
968   in ImageJ/FiJi (Schindelin *et al.*, 2012).

969

970   *Microscopy-based mitochondrial morphology measurements in iNeurons*
971   For quantitative measurement of mitochondrial morphology in d12 iNeurons under fed or
972   mitophagy conditions, HeLa cells were seeded on 6-well 1.5 high performance glass bottom
973   plates (Cellvis, P06-1.5H-N) and mitophagy induced for the indicated time durations.
974   Alternatively, hESC were seeded on day 4 of differentiation into 6-well 1.5 high performance
975   glass bottom plates (Cellvis, P06-1.5H-N) and differentiated in the vessel into iNeurons and
976   mitophagy induced for the indicated time durations. Cells were fixed and stained as
977   described above. Z-stacks were acquired with a Nikon Plan Apo 100×/1.45 N.A oil-objective
978   lens and with the parameters stated above. Image quantification was performed in
979   ImageJ/FiJi using custom-written batch-macros.
980   Statistical analysis and plotting of microscopy data was performed in Prism (v9.1.0,
981   GraphPad). Primary and secondary antibodies used in this study can be found in the
982   **Materials Table (Supplemental Table 9)**.

983

984   *Microscopy-based mtDNA turnover measurements in HeLa and iNeurons*
985   For quantitative measurement of mtDNA turnover after AO-induced mitophagy, HeLa cells
986   were seeded on 6-well 1.5 high performance glass bottom plates (Cellvis, P06-1.5H-N) and

987 mitophagy induced for the indicated time durations. Alternatively, hESC were seeded on day
988 4 of differentiation into 6-well 1.5 high performance glass bottom plates (Cellvis, P06-1.5H-
989 N) and differentiated in the vessel into iNeurons and mitophagy induced for the indicated
990 time durations. Cells were fixed and stained as described above, but primary antibody
991 incubation with aDNA (1:200) was performed overnight. Z-stacks were acquired with a Nikon
992 Plan Apo 100×/1.45 N.A oil-objective lens and with the parameters stated above. Image
993 quantification was performed in ImageJ/FiJi using custom-written batch-macros. In brief,
994 both aDNA and nuclear signals were converted to binary files and the nuclear signal
995 subtracted from the aDNA signal, resulting in an image stack containing only the mtDNA
996 intensities. The "Analyze Particles..." command (pixel size exclusion: 0.05-3, exclude edge
997 objects) was used to measure morphological features and results for each image-stack
998 saved as .csv files, together with the analyzed binary-mask overlay .tiff file for QC purposes.
999 Number of mtDNA signals were normalized to cell number found in the same image stack.
1000 Statistical analysis and plotting of microscopy data was performed in Prism (v9.1.0,
1001 GraphPad).   Primary and secondary antibodies used in this study can be found in the
1002 **Materials Table (Supplemental Table S9)**.

1003

1004 *Microscopy-based measurements of p62 recruitment in HeLa*
1005 For quantitative measurement of p62 recruitment to mitochondria, HeLa control and
1006 knockout cells were seed in 1.5 high performance glass bottom plates and doxycycline
1007 added over night to induce Parkin expression. Mitophagy was induced using Oligomycin A /
1008 Antimycin A for 16h in full DMEM in presence of doxycycline. Cells were fixed and stained
1009 as stated above and imaged using a Nikon Plan Apo 60×/1.42 N.A air-objective lens and
1010 with the parameters stated above. 8 μM z-stacks were taken for each selected field of view.
1011 Image quantification was performed in ImageJ/FiJi using custom-written batch-
1012 macros. The p62 channel was filtered (Gaussian Blue, sigma =2) and converted into binary
1013 files using the Intermodes thresholding method. p62 spots were counted using the "Analyze
1014 Particles..." function (pizel size exclusion: 0.1-30, exclude edge objects) and results for each
1015 image-stack saved as .csv files, together with the analyzed binary-mask overlay .tiff file for
1016 QC purposes. The DAPI channel was used to count nuclei for per cell normalization.
1017 Statistical analysis and plotting of microscopy data was performed in Prism (v9.1.0,
1018 GraphPad).   Primary and secondary antibodies used in this study can be found in the
1019 **Materials Table (Supplemental Table S9).**

1020

1021 *Microscopy-based pUb-coverage measurements of mitochondria in iNeurons*
1022 For quantitative measurement of pUb coverage over mitochondria AO-induced mitophagy,
1023 hESC were seeded on day 4 of differentiation into 6-well 1.5 high performance glass bottom
1024 plates (Cellvis, P06-1.5H-N) and differentiated in the vessel into iNeurons and mitophagy
1025 induced for the indicated time durations. Cells were fixed and stained as described above,
1026 using anti-HSP60 to label mitochondria and anti-pUb (Ser65) to label pUb. 3-5 10 μm thick
1027 z-stacks per replicate per sample were acquired using a Nikon Plan Apo 60×/1.42 N.A air-
1028 objective lens and with the parameters stated above.
1029 Image quantification was performed in ImageJ/FiJi using custom-written batch-
1030 macros. In brief, mitochondrial signal was filtered (Gaussian Blur, sigma=2), converted into
1031 binary files and holes in the resulting mask filled. pUb channel was thresholded into a binary
1032 file (Triangle method); these masks were measured using the "Analyze Particles..."
1033 command (pixel size exclusion: 0.5-∞, exclude edge objects) and results for each image-
1034 stack saved as .csv files, together with the analyzed binary-mask overlay .tiff file for QC
1035 purposes. % of mitochondrial pUb coverage was calculated and normalized to [t]=6h AO.
1036 Statistical analysis and plotting of microscopy data was performed in Prism (v9.1.0,
1037 GraphPad).   Primary and secondary antibodies used in this study can be found in the
1038 **Materials Table (Supplemental Table S9).**

1039

1040 *Microscopy-based evaluation of Parkin translocation and mitophagy in FBXO7$^{-/-}$ cell lines*

1041   For quantitative measurement of Parkin translocation kinetics in FBXO7$^{-/-}$ cell lines, stable
1042   HeLa cell lines expressing GFP-Parkin were created. WT and knockout cell lines were
1043   seeded into 12-well 1.5 high performance glass bottom plates (Cellvis, P12-1.5H-N) two
1044   days prior to experimental manipulation. Mitophagy was induced as described above using
1045   Antimycin A / Oligomycin A for 1h. Treated and control (fed) cells were fixed as described
1046   above, stained for mitochondria (HSP60), Parkin (GFP) and DNA (SpyDNA-555) and 8µm z-
1047   stacks were acquired with a Nikon Plan Apo 60×/1.42 N.A oil-objective lens and with the
1048   parameters stated above. For quantitate single-cell analysis, a total of ~240 randomly xy-
1049   marked stacks were acquired, and MIPs used for subsequent analysis. CellProfiler (Stirling
1050   *et al.*, 2021) was used for the quantitative analysis of single-cells and mitochondrial objects
1051   (segmentation and analysis pipelines can be found on GitHub). Plotting of microscopy data
1052   was performed in Prism (v9.1.0, GraphPad) and R using the following libraries: tidyverse,
1053   dplyr, tibble, viridis, ggplot2, ggridges, ggsci. Primary and secondary antibodies used in this
1054   study can be found in the **Materials Table (Supplemental Table S9)**.

1055
1056   *Immunocytochemical sample preparation for 3D-SIM*
1057   Sample preparation and SIM acquisition guidelines from (Kraus *et al*, 2017) were used as a
1058   basis for the super-resolution analysis of pUb spreading after mitophagy induction. iNeurons
1059   or HeLa cells were seeded on 18x18 mm Marienfeld Precision cover glasses thickness No.
1060   1.5H (tol. ± 5 µm). Cover glasses were coated, if necessary, for hESC / iNeuron culture as
1061   described above. After experimental manipulation, cells were fixed with warm
1062   paraformaldehyde 3% Glutaraldehyde 0.35% in 0.1M Sodium Cacodylate, pH 7.4 (Electron
1063   Microscopy Science) at 37°C for 30 min and permeabilized with 0.5% Triton X-100 in PBS
1064   for 15 minutes at room temperature. After three washes with 0.02% Tween20 in PBS
1065   (PBST), cells were blocked for 10 min in 3% BSA-1xPBS at room temperature and washed
1066   again three times in PBST. iNeurons were incubated overnight in primary antibodies in 3%
1067   BSA-1xPBS and washed three times with PBST. Secondary antibodies (Thermo Scientific,
1068   1:400 in 3% BSA-1xPBS) where applied for 1 h at room temperature. To stain nuclei, DAPI
1069   was added for 5 min to cells in PBST, washed three times for 5 min in 1xPBST before a
1070   post-fixation in 4% paraformaldehyde was performed. After 2 washes in PBST, coverslips
1071   were washed once in 1xPBS and mounted in Vectashield (Vector Laboratories, H-1000-10)
1072   on glass slides. Primary and secondary antibodies used in this study can be found in the
1073   **Materials Table (Supplemental Table S9)**.

1074
1075   *3D-SIM microscopy – acquisition parameters*
1076   3D-SIM microscopy was performed on a DeltaVision OMX v4 using an Olympus 60x / 1.42
1077   Plan Apo oil objective (Olympus, Japan). The instrument is equipped with 405 nm, 445 nm,
1078   488 nm, 514 nm, 568 nm and 642 nm laser lines (all >= 100 mW) and images were recorded
1079   on a front-illuminated sCMOS (PCO Photonics, USA) in 512x512px image size mode, 1x
1080   binning, 125 nm z-stepping and with 15 raw images taken per z-plane (5 phase-shifts, 3
1081   angles). Raw image data was computationally reconstructed using CUDA-accelerated 3D-
1082   SIM reconstruction code (https://github.com/scopetools/cudasirecon) based on (Gustafsson
1083   *et al*, 2008). Optimal optical transfer function (OTF) was determined via an in-house build
1084   software, developed by Talley Lambert from the NIC / CBMF (GitHub:
1085   https://github.com/tlambert03/otfsearch, all channels were registered to the 528nm output
1086   channel, Wiener filter: 0.002, background: 90).

1087
1088   *3D-SIM microscopy – pUb – mitochondria 3D renderings & analysis*
1089   3D renderings of 3D-SIM images were performed in UCSF Chimera X
1090   (https://www.cgl.ucsf.edu/chimerax/) using 32-bit .tiff image stacks. Image channels were
1091   sequentially imported and visualized as surfaces using the "Volume Viewer" tool. Surface
1092   representations were cleaned up using the "High dust" command, based on size filtering
1093   thresholding.
1094   3D-analysis of HeLa and iNeuron datasets from 3D-SIM datasets was performed
1095   using Imaris (Oxford Instruments, v9.7). After converting all multi-color .tiff to native .ims

1096 files, import into Imaris Arena and global background subtraction, mitochondrial and pUb
1097 objects were segmented from seeds (XY starting diameter: 0.08 μm == pixel size of images),
1098 segmented based on automatic thresholding with local background subtraction and splitting
1099 of touching objects (0.4μm). Objects were piped into Imaris Vantage module for further
1100 analysis. In Vantage, nearest neighbour distances of pUb to pUb and between pUb and
1101 mitochondria, as well as volume of segmented objects were computed. This pipeline was
1102 tested on WT control cells and then applied for batch processing on all other genotype to
1103 allow for unbiased segmentation and analysis. On average, 10 cells were analysed per
1104 genotype per condition (121 total) for HeLa cells, and 12 cells (139 total) for iNeurons.
1105   Unless stated otherwise, all images depicted in figures are maximum-intensity
1106 projections.
1107
1108 *Flow cytometry-based measurement of mitophagic flux*
1109 HeLa HFT/TO-PRKN cells of the indicated genotype (control, PINK1$^{-/-}$, FBXO7 $^{-/-}$) expressing
1110 mtKeima (Heo *et al.*, 2015) were seeded into 12-well dishes. Upon reaching 60%
1111 confluency, 2 μg/ml doxycycline was added to induce Parkin expression for at least eight
1112 hours before depolarization of mitochondria. Following Parkin induction, cells were treated
1113 with Antimycin A (0.5 μM) and Oligomycin (0.5 μM) for the indicated number of hours.
1114 Bafilomycin A (25 nM, Sigma-Aldrich, B1793)-treated samples were treated for three hours.
1115 Control cells were fed three hours before experimental manipulation. To harvest cells for
1116 analysis, each well was washed with 1 mL PBS then treated with 100 μL of 0.25% trypsin for
1117 3 min at room temperature, resuspended in 300 μL of DMEM with 10% FBS. 200 μL of each
1118 sample was transferred to a flat-bottom 96-well plate for analysis by flow cytometry.
1119   hESCs were seeded at day 4 into coated 6-well dishes and differentiated. At day 12,
1120 mitophagy was induced with Antimycin A (0.5 μM) and Oligomycin (0.5 μM) or Bafilomycin A
1121 (25 nM, Sigma-Aldrich, B1793) for the indicated number of hours. Control cells were fed 2h
1122 before experimental manipulation. Cells were dissociated from the wells using Accutase and
1123 resuspended in 600 μL ND2 medium + 10 μM Y27632 and filtered through a cell strainer cap
1124 tube (Corning, 352235).
1125   Analysis of a population of at least 10,000 cells was performed on an Attune NxT
1126 (Thermo Fisher Scientific) detecting neutral mtKeima signal with excitation at 445 nm and
1127 emission 603 nm with a 48 nm bandpass and acidic mtKeima with 561 nm excitation and
1128 emission 620 nm and a 15 nm band pass. mtKeima ratio was analysed as previously
1129 described (An & Harper, 2018). Briefly, acidic:neutral Keima ratios were measured by gating
1130 a population of well-behaved single cells using forward and side scatter, followed by
1131 calculation of acidic:neutral mtKeima ratio on a per-cell basis in FlowJo Software (FlowJo,
1132 LLC).
1133
1134 **QUANTIFICATION AND STATISTICAL ANALYSIS**
1135 Unless stated otherwise all quantitative experiments were performed in triplicate and
1136 average with S.E.M. or S.D. as indicated in legends reported.
