1) General Experimental Considerations

All glassware was oven dried and cooled under an inert atmosphere of N₂ before usage. Triethoxonium hexachloroantimonate was purchased from Sigma-Aldrich and stored at -30 °C in an MBraun glovebox filled with N₂. All other manipulations were performed under standard Schlenk technique under an N₂ atmosphere. [8]Cycloparaphenylene (**1**) and [12]Cycloparaphenylene were synthesized as described in the literature.^{1,2} Dichloromethane and toluene were dried by filtration through alumina according to the methods described by Grubbs.³ Anhydrous pentane was purchased from Sigma-Aldrich.

Optical spectra were recorded in screw-top quartz cuvettes using a Shimadzu UV-3600 UV-vis-NIR spectrophotometer under ambient conditions. Spectroelectrochemistry experiments were performed using a honeycomb spectroelectrochemical cell (Pine Instruments) connected to an AUTOLAB PGSTAT 10 potentiostat (Eco Chemie), using 0.1 M *n*-Bu₄NPF₆ in dichloromethane as solvent. UV-Vis spectra were recorded on a Cary 4000 spectrophotometer (Agilent) under ambient conditions with the electrochemical cell inserted into a quartz cuvette. Differential potential voltammetry experiments were performed on a Princeton Applied Research Potentiostat/Galvanostat Model 273 running M270/250 Electrochemical Software (Princeton Applied Research) with a glassy carbon working electrode, platinum counter electrode and silver wire reference electrode. Measurements were conducted in 0.1 M *n*-Bu₄NPF₆ in dichloromethane in an MBraun glovebox filled with N₂. Cyclic voltammetry experiments were performed using an CH Instruments 1200B potentiostat running CH Instruments software. Measurements were conducted in degassed 0.1 M *n*-Bu₄NPF₆ in dichloromethane under an N₂ atmosphere with a glassy carbon working electrode, platinum counter electrode and Ag/AgCl reference electrode. The ferrocene/ferrocenium couple was used as an internal reference for all electrochemical experiments. *n*-Bu₄NPF₆ was recrystallized from EtOH before use. X-band EPR spectra were recorded on a Bruker ELEXSYS-II E500 CW-EPR equipped with a cryo-cooled cavity using a flame-sealed capillary tube containing a dichloromethane solution of sample placed inside a quartz EPR tube. Spectra were collected with a 100 kHz modulation frequency and 1 G modulation amplitude.

Synthesis of **1**⁺

To a 20 mL glass vial with a septum screwcap and stirbar was added triethyloxonium hexachloroantimonate (24 mg, 0.054 mmol) in a glovebox. The vial was sealed, removed from the glovebox and placed under a stream of N₂. To the vial was then added dichloromethane (1 mL) and the gold solution was cooled to 0 °C. Then, a bright yellow dichloromethane solution (6 mL) of **1** (21 mg, 0.034 mmol) was added via cannula and the reaction mixture immediately darkened to brown/orange. The solution was stirred at 0 °C for 3 h, then cooled to -50 °C whereupon anhydrous pentane (10 mL) was added to precipitate out a dark purple solid. The

solvent was removed via cannula under N₂ pressure and the solid was washed with an additional aliquot of pentane (10 mL). The solid was redissolved in dichloromethane (5 mL) and the process (precipitation then washing) was repeated two additional times (three times total). The dark purple solid was then washed with toluene (10 mL) and pentane (3 x 10 mL), then dried under vacuum to afford highly pure **1**⁺ (22 mg, 69%). UV-vis-NIR (CH₂Cl₂): 535 ($\epsilon = 0.81 (\pm 0.03) \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$), 1115 ($\epsilon = 1.03 (\pm 0.03) \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$) nm

2) Optoelectronic Characterization:

The binding constant, K_{dimer} , for (**1**)₂⁺ was determined by gradually titrating a dichloromethane solution ($8.2 \times 10^{-3} \text{ M}$) of **1** into a cuvette containing a dichloromethane solution of **1**⁺ ($1.0 \times 10^{-4} \text{ M}$). After each aliquot of **1** was added, a spectrum was recorded, carefully noting the absorption at 1747 nm. From these data, a Benesi-Hildebrand plot was constructed (Figure 4 in main text). The data extracted from the plot is summarized below in Table S1 based on the Benesi-Hildebrand equation (Eq 1 in main text).

Table S1. Data extracted from UV-vis-NIR spectrum (Figure 3 in main text) used to construct a Benesi-Hildebrand plot (Figure 4 in main text)

Total Volume of 1 Added (μL)	$1/[\mathbf{1}]$	$[\mathbf{1}^+]/A_{1747}$
39	18503.58423	8.5153E-5
44	16487.4552	8.14598E-5
49	13554.90388	7.2748E-5
54	12455.19713	7.07127E-5
59	11524.67604	6.72664E-5
69	10035.84229	6.25136E-5
74	9431.00358	5.96417E-5
79	8897.32237	5.79812E-5
89	7998.49085	5.65055E-5
99	7270.86534	5.40988E-5
109	6669.78339	5.2892E-5
119	6164.87455	5.10385E-5
129	5734.76703	4.99444E-5
149	5041.04521	4.82196E-5
169	4505.88838	4.71776E-5

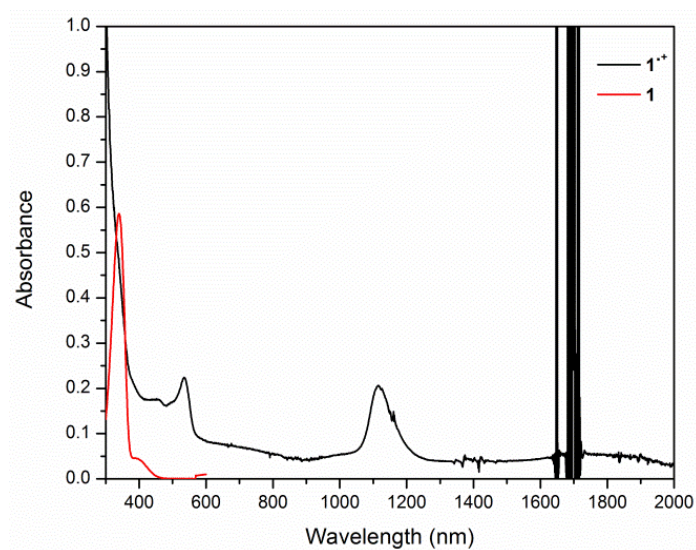

Figure S1. UV-vis-NIR spectrum of 1^{+} (2.7×10^{-4} M) and 1 (6.4×10^{-6} M). The absence of an absorption at 340 nm and a CR band in the NIR confirms the purity of 1^{+} .

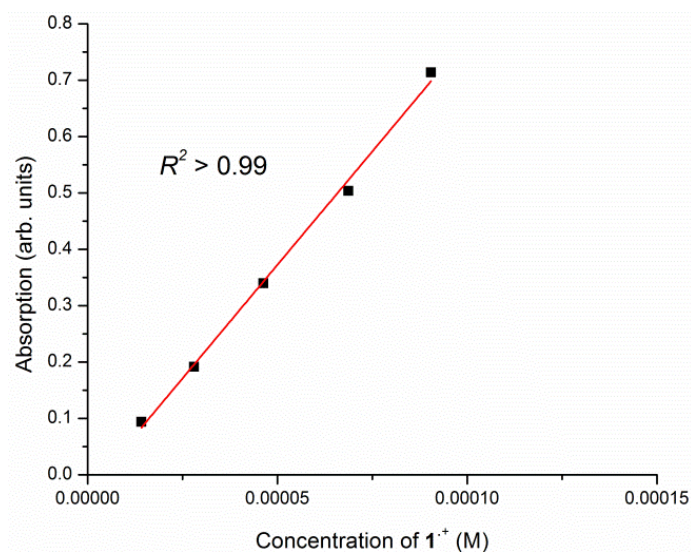

Figure S2. Beer-Lambert plot of 1^{+} at 535 nm ($\epsilon = 0.81 (\pm 0.03) \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$)

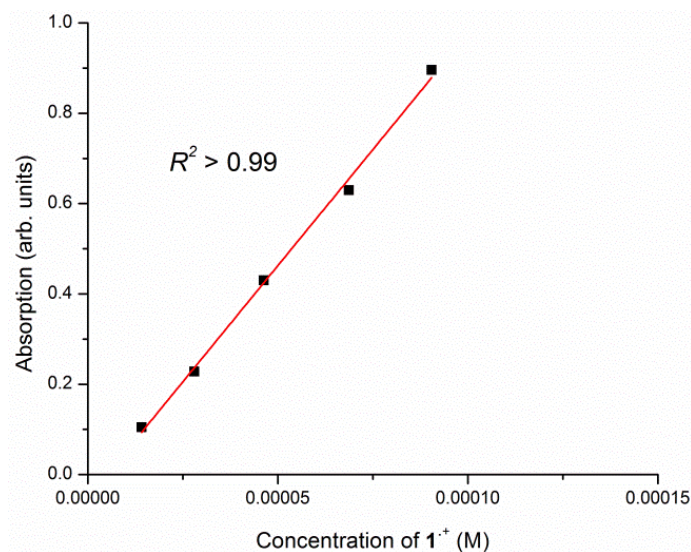

Figure S3. Beer-Lambert plot of 1^+ at 1115 nm ($\epsilon = 1.03 (\pm 0.03) \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$).

Cyclic voltammetry of **1** ($1 \times 10^{-3} \text{ M}$) was performed at increasing scan rates (25 mV/s \rightarrow 700 mV/s). At a scan rate of 50 mV/s, $E_{1/2}^{\text{ox}} = 0.68 \text{ V}$ (vs. Fc/Fc $^+$). The addition of 1 equivalent of ferrocene revealed nearly identical integrated oxidation peak areas for the two species, confirming that **1** is oxidized to 1^+ via a one-electron process.

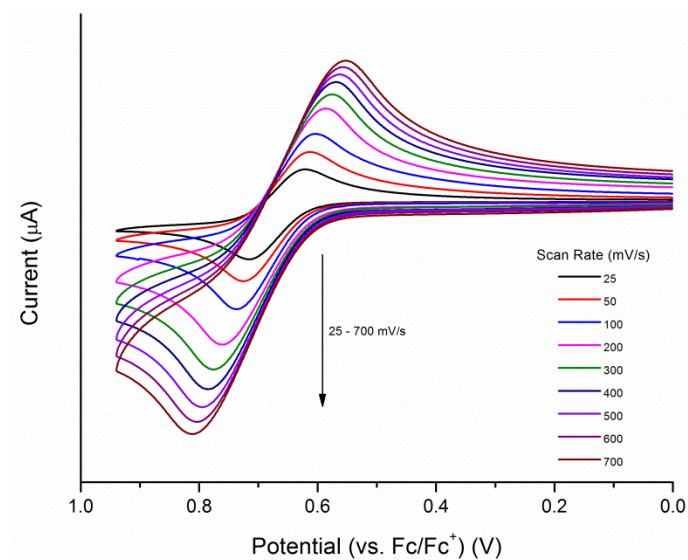

Figure S4. Cyclic voltammograms of **1** ($1 \times 10^{-3} \text{ M}$) at increasing scan rates (25 mV/s \rightarrow 700 mV/s) (0.1 M *n*-Bu $_4$ PF $_6$ in CH $_2$ Cl $_2$)

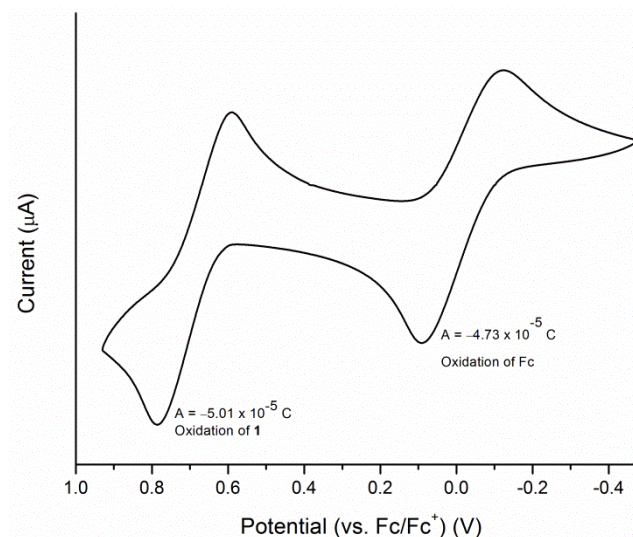

Figure S5. Cyclic voltammogram of **1** (1×10^{-3} M) containing 1 equivalent of ferrocene (0.1 M $n\text{-Bu}_4\text{PF}_6$ in CH_2Cl_2 , scan rate = 50 mV/s). $A_1 / A_{\text{Fc}} = 1.06$.

Differential potential voltammetry was used to achieve maximum sensitivity in current changes and confirmed that the single wave in the cyclic voltammogram corresponds to a single electron oxidation process.

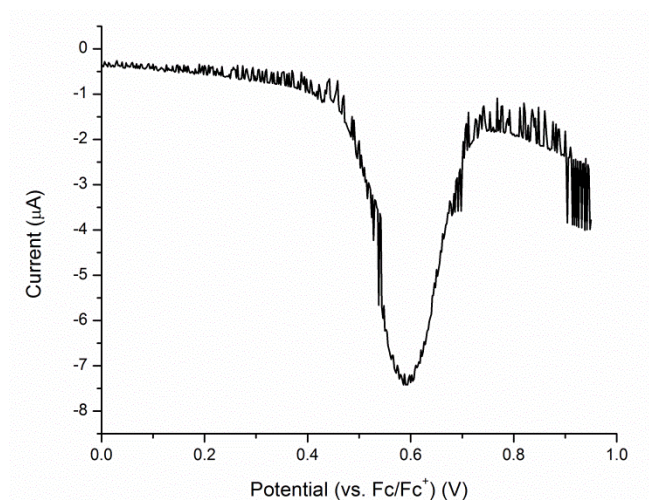

Figure S6. Differential pulse voltammogram of radical cation **1**⁺ (0.1 M $n\text{-Bu}_4\text{PF}_6$ in CH_2Cl_2) (pulse height = 25 mV, scan increment = 2 mV)

Spectroelectrochemistry experiments were performed in order to probe the behavior of neutral **1** close to its oxidation potential. Thus, based on the cyclic voltammogram (Figure S4), a constant potential of 0.8 V was applied for minutes 0 – 8. The potential was then increased to 0.9 V for another two minutes (minutes 8 – 10). At each time point, a UV-vis spectrum was recorded, showing a gradual increase in absorption at 535 nm (radical cation **1**^{•+}) and a gradual decrease in absorption at 340 nm (neutral **1**). An isosbestic point was also observed at 368 nm, suggesting direct oxidation from **1** to radical cation **1**^{•+}.

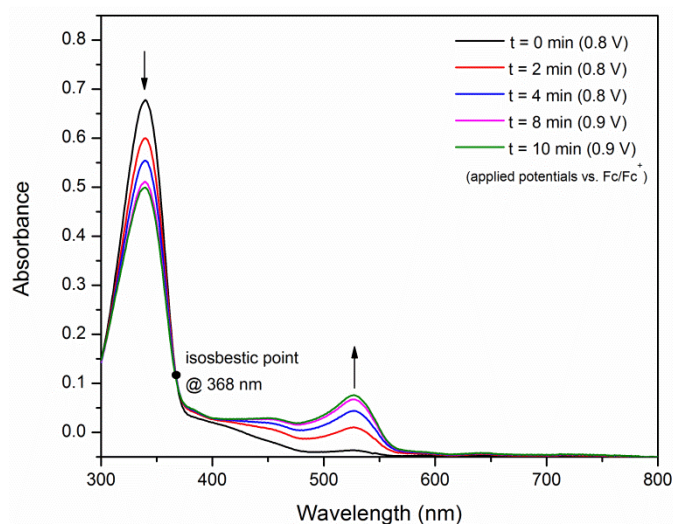

Figure S7. UV-vis spectrum (in CH₂Cl₂) depicting the gradual oxidation over time of neutral **1** to radical cation **1**^{•+} with an applied potential. Applied potentials are all relative to the Fc/Fc⁺ couple for consistency when referring to cyclic voltammogram (Figure S4)

3) EPR Spectra:

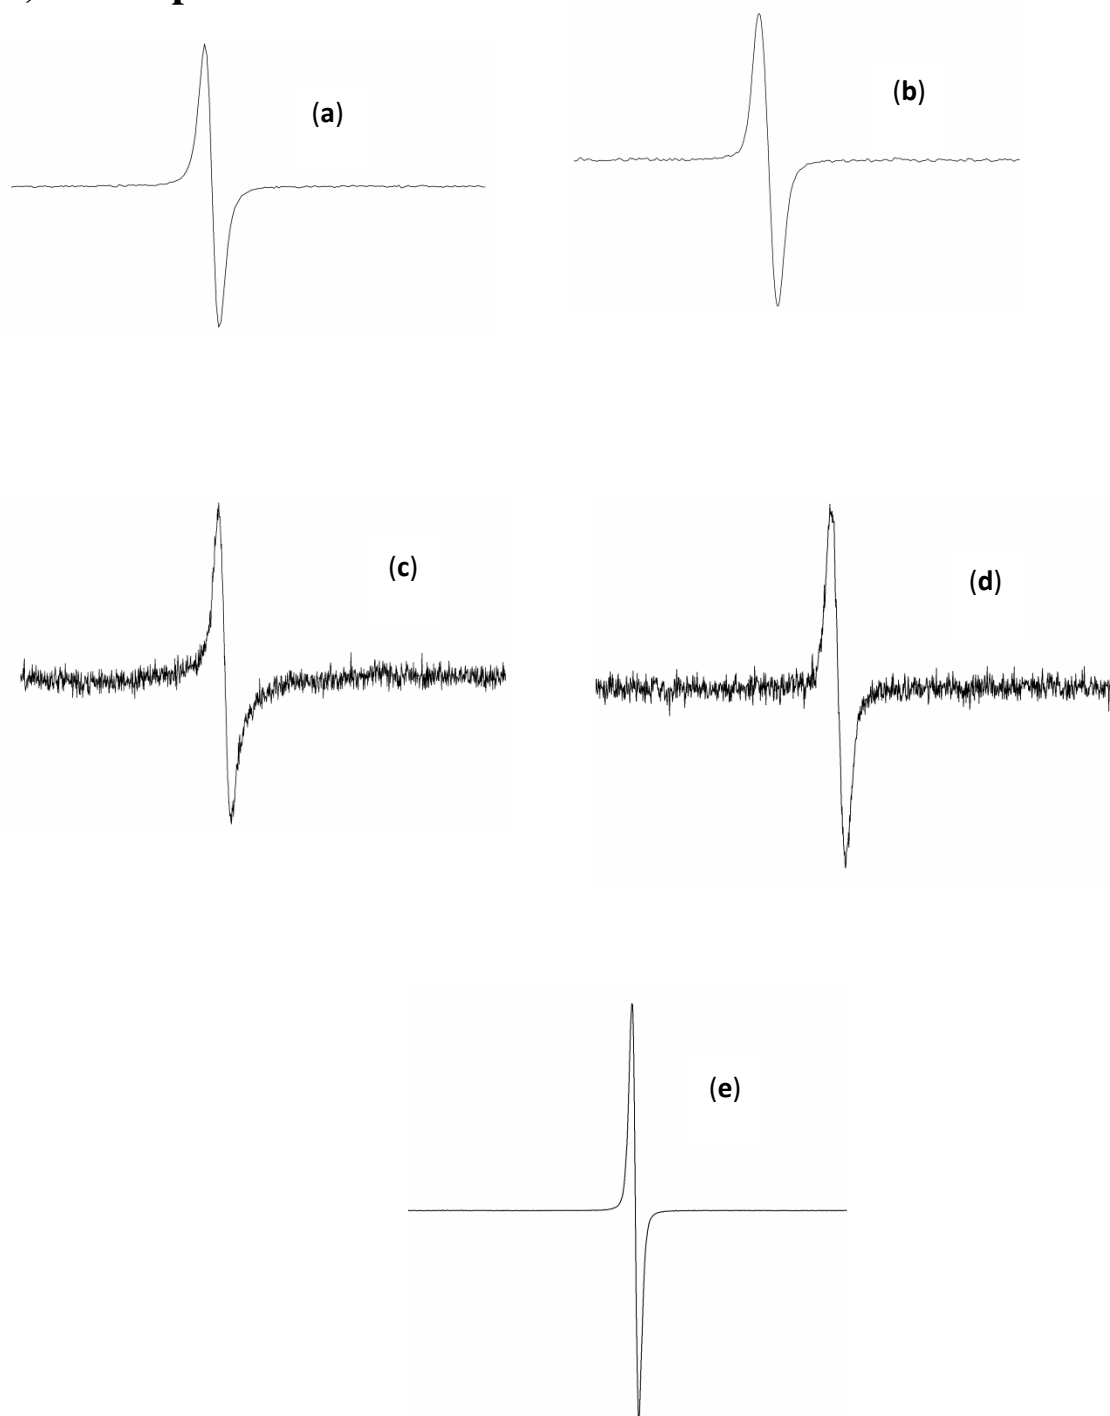

Figure S8. X-band EPR spectra of 1^{+} (10^{-3} M) recorded at: (a) 293 K. (b) 167 K. (c) 8 K. (d) 8 K (10^{-5} M) (e) 293 K (after 5 equiv oxidant)

Table S2. Parameters associated with the five EPR spectra of $\mathbf{1}^+$ shown in Figure S4

	a	b	c	d	e
Frequency (GHz)	9.389310	9.388179	9.389615	9.389778	9.867088
<i>g</i>	2.007	2.006	2.007	2.008	2.007

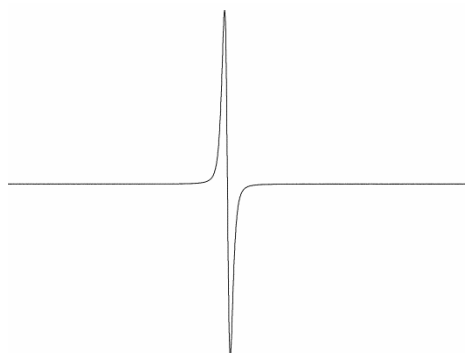

Figure S9. X-band EPR spectrum of charge-resonance dimer $(\mathbf{1})_2^{+\cdot}$ in CH_2Cl_2 after the completion of titration experiments (Frequency = 9.389929 GHz, $g = 2.007$ G)

Figure S10. Control X-band EPR spectra (CH_2Cl_2) of (a) triethyloxonium hexachloroantimonate and (b) [8]Cycloparaphenylene $\mathbf{1}$ from 3000 – 4000 G. The absence of signal confirms that the experimentally observed signals come from $\mathbf{1}^+$ and $(\mathbf{1})_2^{+\cdot}$.

4) Oxidation of [12]CPP

To a 20 mL glass vial with a septum screwcap and stirbar was added triethyloxonium hexachloroantimonate (240 mg, 0.55 mmol) in a glovebox. The vial was sealed, removed from the glovebox and placed under a stream of N₂. To the vial was then added dichloromethane (2 mL) and the gold solution was cooled to 0 °C. Then, a dichloromethane solution (5 mL) of [12]CPP (25 mg, 0.027 mmol) was added via cannula and the reaction mixture immediately darkened to dark blue. The solution was stirred at 0 °C for 3 h, then warmed to room temperature for another 14 h. The solution was then cooled to -50 °C whereupon anhydrous pentane (10 mL) was added to precipitate out a dark blue solid. The solvent was removed via cannula under N₂ pressure and the solid was washed with an addition aliquot of pentane (10 mL). The solid was redissolved in dichloromethane (5 mL) and the process (precipitation then washing) was repeated two additional times (three times total). The dark purple solid was then washed with toluene (2 x 10 mL) and pentane (3 x 10 mL), then dried under vacuum to afford 33 mg of a dark blue solid. The compound is EPR active ($g = 2.006$) and has a broad absorption in the near-IR region, which is reminiscent of a charge-resonance dimer.

The dark blue solid was dissolved to a final concentration of 0.78 mg/mL in CH₂Cl₂. To 2.4 mL of this solution was added 0.15 mL of neutral [12]CPP (1.9 mM in CH₂Cl₂) in three separate aliquots (3 x 0.05 mL). A UV-vis-NIR spectrum was recorded after each increment. Figure S11 shows bands increasing in intensity at 585 nm and beyond 2000 nm in the NIR.

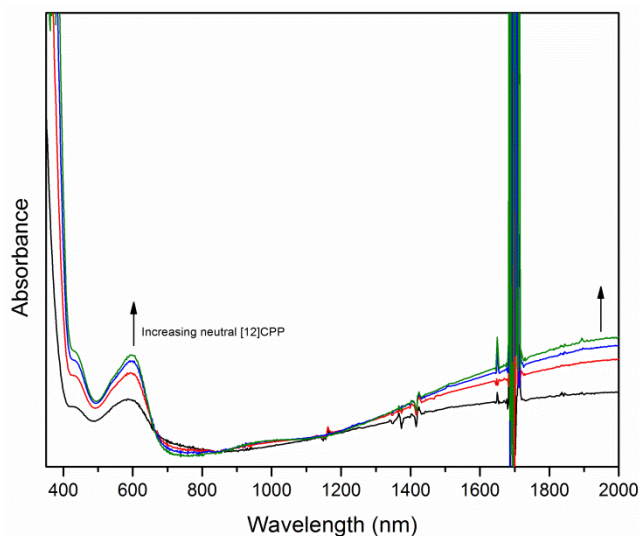

Figure S11. UV-vis-NIR spectra after the oxidation of [12]CPP (with increasing concentrations of neutral [12]CPP added)

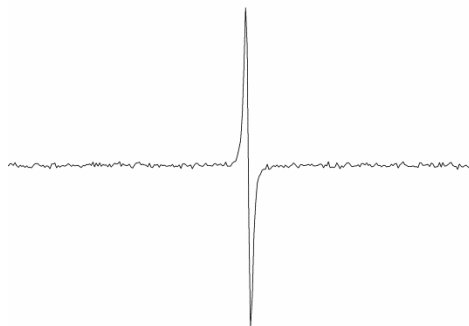

Figure S12. X-band EPR spectrum of $([12]\text{CPP})_2^{\cdot+}$ after optical titration experiments (CH_2Cl_2)
(Frequency = 9.857404 GHz, $g = 2.006$)

5) Computational Details:

All calculations were carried out with the Gaussian 09 package.⁴ Calculations performed on **1** and **1⁺** used the B3LYP exchange-correlation functional⁵ and a polarized 6-31G(d,p) basis set⁶ using default SCF convergence criteria (density matrix converged to at least 10^{-8}) and the default DFT integration grid (75 radial and 302 angular quadrature points). Calculations performed on the four [*n*]CPP charge-resonance dimers used the long-range corrected hybrid ω B97x functional⁷ with an empirical dispersion term (ω B97xD).⁸ Calculations performed on the hypothetical **1²⁺** dication species were performed at the RB3LYP/6-31G(d) level of theory (closed-shell singlet) or UB3LYP/6-31G(d) level of theory (open-shell singlet and triplet). All excited state calculations (TD-DFT) were performed on fully optimized structures. The fully optimized structures were confirmed to be true minima by vibrational analysis.

Figure S13. Spin density distribution of **1⁺** calculated at the UB3LYP/6-31G(d,p) level of theory showing complete delocalization of positive spin (blue).

Theoretical Study of [n]CPP Charge-Resonance Dimer Binding Energies

For each value of “*n*”, the geometries of the neutral monomer ([*n*]CPP) and radical cation monomer ([*n*]CPP)⁺ were minimized. The energy of the charge-resonance complex was then minimized using the same level of theory. The binding energy was calculated by subtracting the sum of the energies of the two monomers from the energy of the charge-resonance dimer.

Table S5. Energies (in Hartress) of the components making up four charge-resonance [*n*]cycloparaphenylene dimers (([*n*]CPP)₂⁺) (*n* = 6, 8, 10, 12). Calculations were done at the UωB97xD/6-31G(d,p) level of theory.

<i>n</i>	Neutral Monomer	Radical Cation Monomer	Charge-Resonance Dimer	Binding Energy
6	-1385.75873228	-1385.51883903	-2771.29690059	-0.01932928

Theoretical Investigations of a 1^{2+} Dication

In order to probe the predicted absorption spectrum of the 1^{2+} dication (arising from an oxidation of the radical cation $1^{+\cdot}$ or over-oxidation of neutral **1**), the ground-state energies of the closed-shell singlet (R), open-shell singlet (U) and triplet (T) were calculated. It was found that the ground-state energies of the closed-shell singlet and the open-shell singlet are nearly equal and have predicted absorptions at 922 nm, which are inconsistent with the experimentally determined values from the oxidation of **1** (H = HOMO, L = LUMO).

Table S6. Difference in ground-state energies between the three configurations of 1^{2+}

	Energy (kcal/mol)
$\Delta U-R$	0.01
$\Delta T-R$	7.49
$\Delta T-U$	7.50

Table S7. Predicted absorptions for 1^{2+} (closed-shell singlet) via TD-DFT calculations (RB3LYP/6-31G(d))
