Supporting Information

4 **ABSTRACT:** The linkage of molecular components into functional heterogeneous  
5 framework materials has revolutionized modern materials chemistry. Here, we use this  
6 principle to design polyoxometalate-based frameworks as high affinity adsorbents for  
7 drugs of abuse, leading to their application in solid-phase extraction analysis. The  
8 frameworks are assembled by the reaction of a Keggin-type polyanion,  $[\text{SiW}_{12}\text{O}_{40}]^{4-}$ ,  
9 with lanthanoids Dy(III), La(III), Nd(III), and Sm(III) and the multidentate linking  
10 ligand 1,10-phenanthroline-2,9-dicarboxylic acid ( $\text{H}_2\text{PDA}$ ). Their reaction leads to the  
11 formation of crystalline 1D coordination polymers. Because of the charge mismatch  
12 between the lanthanoids (+3) and the dodecasilicotungstate ( $-4$ ), we observe  
13 incorporation of the  $\text{PDA}^{2-}$  ligands into crystalline materials, leading to four  
14 polyoxometalate-based frameworks where Keggin-type heteropolyanions are linked  
15 by cationic  $\{\text{Ln}_n(\text{PDA})_n\}$  groups ( $\text{Ln} = \text{Dy}$  (1), La (2), Nd (3), and Sm (4)).  
16 Structural analysis of the polyoxometalate-based frameworks suggested that they might

17 be suitable for surface binding of common drugs of abuse via supramolecular interactions. To this end, they were used for the  
18 extraction and quantitative determination of four model drugs of abuse (amphetamine, methamphetamine, codeine, and morphine)  
19 by using micro-solid-phase extraction ( $\text{D-}\mu\text{SPE}$ ) and high-performance liquid chromatography (HPLC). The method showed wide  
20 linear ranges, low limits of detection ( $0.1\text{--}0.3 \text{ ng mL}^{-1}$ ), high precision, and satisfactory spiked recoveries. Our results demonstrate  
21 that polyoxometalate-based frameworks are suitable sorbents in  $\text{D-}\mu\text{SPE}$  for molecules containing amine functionalities. The  
22 modular design of these networks could in the future be used to expand and tune their substrate binding behavior.

## 1. INTRODUCTION

23 The past decade has seen tremendous progress in the  
24 development and use of crystalline framework materials that  
25 contain polyoxometalates either as anionic guests within the  
26 framework pores or as structural building block within the  
27 framework itself.<sup>1–3</sup> Structural analysis of these polyoxometalate-based frameworks suggested their use in applications such as  
28 sequestration and extraction.<sup>4</sup> The synthesis or “self-assembly”  
29 of materials of this type can be achieved by using a variety of  
30 protocols and componentry, including, the use of preformed  
31 POM precursors or the generation of the polyanion *in situ*.  
32 Linkage of the POM by using one or more of the following (e.g.,  
33 transition metals, lanthanoids, main group elements, and organic  
34 linkers) enables the merging of the component properties and  
35 can offer a facile route to crystalline POM-based materials for  
36 technologically relevant applications.<sup>5,6</sup> In recent years, POMs  
37 have been incorporated into organic–inorganic frameworks as  
38 guests or templates to construct novel hybrid materials that have  
39 attracted considerable scientific attention in the fields of  
40 environmental remediation, pollutant removal, and extraction  
41 methods.<sup>4,7–9</sup> This merging of organic and inorganic  
42 componentry has led to new properties such as large pores  
43 with high specific surface area, opening new opportunities in  
44 separation and adsorption technologies.<sup>4,10–13</sup>

46 Herein, we report the synthesis and characterization of four  
47 1D framework materials together with their application as solid  
48 sorbents for the extraction of four model drugs of abuse  
49 (amphetamine, methamphetamine, codeine, and morphine)  
50 from hair samples using dispersive micro-solid-phase extraction  
51 ( $\text{D-}\mu\text{SPE}$ ). This concept based on the well-documented  
52 observation that organic molecules can interact and bind to  
53 POMs by electrostatics, hydrogen bonding, or multiple weak  
54 (e.g., van der Waals or dispersion) interactions is well  
55 documented.<sup>14</sup>

56 We propose that this concept can be harnessed for the binding  
57 of analytes, e.g., pharmaceuticals or drugs, which feature a  
58 positive charge (e.g., when protonated) or hydrogen-bonding  
59 site, so that the cationic analyte binds by electrostatic, dipolar,  
60 and/or hydrogen-bonding interactions to the anionic POM  
61 surface sites.<sup>5,6,15,16</sup> Prime examples for suitable substrates are  
62 opiates and amphetamines which are widely abused drugs and

63 contain amines with high pK<sub>a</sub> values and are therefore easily  
64 protonated (Table 1). Quantitative analysis of these kinds of  
65 drugs relies on hair analysis as a convenient method of drug  
66 monitoring. Compared with the determination of drugs in the  
67 blood and urine, hair analysis has advantages such as simple  
68 sample preservation, noninvasive sample collection, and long-  
69 term stability of the analyte in hair.<sup>17,18</sup> Disadvantages include  
70 external contamination (particularly important for smoked  
71 drugs), low concentration of analytes, complex matrices, and the  
72 limited sample size, resulting in the need for substantial sample  
73 treatment prior to analysis.<sup>19–21</sup> To this end, dispersive micro-  
74 solid-phase extraction (D-μSPE) has emerged as a powerful  
75 miniaturization concept based on solid-phase extraction (SPE)  
76 techniques. D-μSPE exhibits significant advantages over tradi-  
77 tional SPE with respect to short extraction time, simple  
78 procedure, and low sample and solvent consumption.<sup>22–28</sup>  
79 Given the importance of the analyte–adsorbent interactions, the

design of advanced adsorbents for the detection of pharma-  
80 ceuticals and in particular frequently abused substances is a  
81 current research focus.

82 Here, we propose the use of POMs embedded in hybrid  
83 organic–inorganic frameworks as suitable binding sites to  
84 extract and preconcentrate highly basic drugs of abuse, enabling  
85 their facile subsequent analysis by D-μSPE and high-perform-  
86 ance liquid chromatography (HPLC). POMs are polyanionic  
87 molecular metal oxide clusters, formed by the acid-driven  
88 condensation of small metal oxo precursors in aqueous  
89 solution.<sup>29,30</sup> The prime POM prototype is the plenary Keggin  
90 anion, [X<sup>n+</sup>M<sub>12</sub>O<sub>40</sub>]<sup>(8–n)-</sup> (X: e.g., B, Si, P; M: e.g., Mo, W),  
91 whose versatile chemistry has been explored in a variety of  
92 fields.<sup>31</sup> POMs are currently used in a wide range of applications  
93 and are therefore of general scientific interest across numerous  
94 fields of research including biochemistry, magnetism, nano-  
95 structured materials, energy conversion/storage, and cataly- 96

97 sis.<sup>32–41</sup> This work is based on the recent report by some of us  
98 that Keggin anions can be linked into framework materials by  
99 using lanthanide cations and organic phenanthroline dicarbox-  
100 ylate ligands.<sup>44</sup>

## 2. EXPERIMENTAL SECTION

101 **Materials and Instruments.** All chemicals were purchased  
102 commercially (reagent grade) and were used without further  
103 purification, except for 1,10-phenanthroline-2,9-dicarbaldehyde diox-  
104 ime ( $H_2P$ phendox or PDOX) which was synthesized according to a  
105 reported procedure.<sup>42,43</sup> The drugs including amphetamine, meth-  
106 amphetamine, codeine, and morphine were obtained from Sigma-  
107 Aldrich (St. Louis, MO) (see Table 1). Standardized stock solutions  
108 were prepared at 10 ng mL<sup>-1</sup> levels in HPLC-grade methanol and  
109 stored at 4 °C. The analysis solutions were obtained by appropriate  
110 dilution of the stock standard solutions with deionized water. Hair  
111 samples were cut as close as possible to the scalp in the posterior apex  
112 with a scissors. Drug-free hair was obtained from healthy volunteers  
113 with no known exposure to drugs of abuse. The drug-containing hair  
114 samples were received from Ebnesina Hospital (Mashhad, Iran).  
115 Elemental analyses (CHN) were performed by using a Thermo  
116 Finnigan Flash-1112EA microanalyzer. The IR spectra were recorded in  
117 the range 4000–400 cm<sup>-1</sup> on a Buck 500 IR spectrometer with the  
118 sample prepared as a pressed KBr pellet. A summary of the  
119 crystallographic data and the structure refinements are provided in  
120 Table 2. Chromatographic separations were performed with a Knauer  
121 HPLC instrument equipped with a UV detector. The target analytes  
122 were separated by using an ODS3 column (4.6 mm ID × 250 mm  
123 length, 5 μm particle diameter). The mobile phase (flow rate of 1.0 mL  
124 min<sup>-1</sup>) was a mixture of 0.05 M aqueous phosphate buffer (pH 4) and  
125 acetonitrile (30:70 v/v) with isocratic elution. The wavelength of the  
126 UV detector was set to 210 nm.

127 **Synthesis and Characterization.** *Synthesis of Hybrid 1.* The  
128 synthetic procedure and structure of **1** were reported previously by  
129 some of us.<sup>44</sup> Anal. Calcd for C<sub>42</sub>H<sub>60</sub>N<sub>6</sub>NaO<sub>82</sub>SiDy<sub>3</sub>W<sub>12</sub>: C, 11.13; H,

148 S11d).

149 *Synthesis of Hybrid 4.* This hybrid framework was prepared similarly  
150 to **1**, except that Sm(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O (56 mg, 0.125 mmol) was used  
151 instead of Dy(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O. Yellow needle crystals were obtained in  
152 52% yield (based on W). Anal. Calcd for  
153 C<sub>56</sub>H<sub>82</sub>N<sub>12</sub>Na<sub>2</sub>O<sub>158</sub>Si<sub>2</sub>Sm<sub>6</sub>W<sub>24</sub>: C, 7.58; H, 0.92; N, 1.90; Na, 0.52; Si,  
154 0.63; Sm, 10.15; W, 49.53%. Found: C, 7.65; H, 0.95; N, 1.94; Na, 0.58;  
155 Si, 0.66; Sm, 10.25; W, 50.20%. IR (KBr pellet, cm<sup>-1</sup>): 3412, 1613,  
156 1564, 1466, 1389, 1308, 965, 914, 794, 712 (Figure S11e).

157 **Hair Samples.** The hair specimen was washed with methanol,  
158 acetone, and deionized water to remove contamination on the hair  
159 surface. After drying, the hair was cut into very fine pieces, weighed  
160 (~50 mg), and digested in methanol at 55 °C for 5 h. The extracted  
161 compounds were filtered, then dried under a stream of nitrogen gas, and  
162 finally redissolved in 5.0 mL of deionized water. Also, for spiking the

hair samples, the appropriate amounts of standard solutions of target  
drugs were added to the pretreated hair samples.

**Extraction Procedure.** 5.0 mL of the pretreated hair sample  
containing a certain amount of target drugs was adjusted to pH 5  
(phosphate buffer) and then placed in a glass vial. 30 mg of the  
adsorbent (1–4) was added to the sample and sonicated for 5 min.  
Then, the mixture was centrifuged and the supernatant discarded.  
Thereafter, the adsorbed analytes were eluted with 200 μL of 20%  
ammonia in acetonitrile under sonication, for 2 min. After centrifuging  
the solution, the desorption solvent was transferred to another vial and  
dried by a gentle flow of nitrogen gas. Then, the residue was redissolved  
in 20 μL of acetonitrile solvent and analyzed by HPLC.

## 3. RESULTS AND DISCUSSION

**Synthesis.** The synthesis of the polyoxometalate-based  
frameworks was achieved by the hydrothermal reaction of  
lanthanide salts, organic ligands, and H<sub>4</sub>[SiW<sub>12</sub>O<sub>40</sub>]·xH<sub>2</sub>O. See  
the Experimental Section for details. Control of solution pH  
(between pH 3.0–3.5) and temperature (130 °C) is key to  
obtaining the hybrid materials reported herein. The reactions  
gave crystalline products suitable for structure determination  
using single-crystal X-ray diffraction (SCXRD) analysis. Powder  
X-ray diffraction further demonstrated the bulk purity of **1–4**.

**Structure Description of 1–4.** SCXRD data, data  
collection, and structure refinement details are summarized in  
Table 2. Diffraction data of the polyoxometalate-based frame-  
works were collected on an Agilent SuperNova single-crystal X-  
ray diffractometer with graphite-monochromated Cu Kα  
radiation (λ ~ 1.54 Å) at 130 K (Table 2). The structures for  
**1–4** were solved by direct methods using the program SHELXS  
and refined by full-matrix least-squares methods on F<sup>2</sup> using  
SHELXL. Note that compound **1** had been reported previously  
by some of us.<sup>44</sup> Multiscan absorption correction was applied.  
Crystallographic details can be found in the CIF files. The CIF  
files are available free of charge from the Cambridge Crystallo-  
graphic Data Centre CCDC.

Structural analysis of the SCXRD data indicates **1–4** all  
contain the silicotungstate Keggin polyanion [SiW<sub>12</sub>O<sub>40</sub>]<sup>4-</sup>  
(hereafter: W<sub>12</sub>). The crystal structure of **1** is described in a  
previous publication.<sup>44</sup> It is worth mentioning that the range of  
the Ln–O distances are consistent with effects of the lanthanide  
contraction (ionic radius: La<sup>3+</sup> > Nd<sup>3+</sup> > Sm<sup>3+</sup> > Dy<sup>3+</sup>).  
Moreover, in all four polyoxometalate-based frameworks, we  
observe distinct Ln–O distances: Ln–O(H<sub>2</sub>O) > Ln–O<sub>terminal</sub> >  
Ln–O<sub>PDA</sub>, highlighting different bonding strengths in the order  
O<sub>PDA</sub> > O<sub>t</sub> > O(H<sub>2</sub>O).

The hybrid frameworks are formed by linkages between the  
PDA<sup>2-</sup> ligands Ln(III) ions and Keggin polyanions in  
tetradentate chelating-bridging coordination mode, resulting  
in 1D zigzag Ln–PDA complex chains, namely, –Ln1(PDA)–  
Ln2–Ln1(PDA)–. The zigzag Ln–PDA complex chains are  
joined together by the coordination of [La<sub>2</sub>(PDA)<sub>2</sub>] units in **2**  
and **3** and [Na<sub>2</sub>La<sub>2</sub>(PDA)<sub>2</sub>] units in **4**.

**Hybrid 2.** A view of the asymmetric unit of **2** is presented in  
Figure S4. Hybrid **2** crystallized in the monoclinic space group  
Pc. As shown in Figures S5 and S6, the compound can be  
described as a 1D coordination polymer based on two Keggin  
polyanions, [SiW<sub>12</sub>O<sub>40</sub>]<sup>4-</sup>, four [La(PDA)]<sup>+</sup> fragments, and two  
La(III) which represent 1D chainlike architecture. The  
polyanions [SiW<sub>12</sub>O<sub>40</sub>]<sup>4-</sup> act as monodentate ligands and  
coordinate to a [La(PDA)]<sup>+</sup> fragment via a terminal oxo ligand.  
The host metal–organic cations are constructed from PDA<sup>2-</sup>  
ligands and La(III) centers with slightly different local  
coordination environments. Each La atom is coordinated with

**Figure 1.** Mixed polyhedral, ball and stick representation of **2** along the crystallographic *c*-axis (top and bottom right) and *a*-axis (bottom left) without polyanions for clarity. C, black; H, white; N, blue; La, teal; O, red; Si, gray; W, orange.

**Figure 2.** Mixed polyhedral, ball and stick representation of **4**. C, black; H, white; N, blue; Na, pink; O, red; Si, gray; Sm, maroon; W, orange.

225 different coordination modes that are shown in **Figure 1**. Two  
 226 nine-coordinated La(III) atoms (La3 and La4) are linked by two  
 227 PDA<sup>2-</sup> ligands through O<sub>1</sub>,O<sub>2</sub>-bridging mode to generate a  
 228 [La<sub>2</sub>(PDA)<sub>2</sub>] unit. In addition, adjacent [La<sub>2</sub>(PDA)<sub>2</sub>] units  
 229 are linked by two other La(III) atoms through carboxylate oxygen  
 230 atoms from PDA<sup>2-</sup> to form the host cation. La2 is coordinated to  
 231 two nitrogen and two carboxylate oxygen atoms from PDA<sup>2-</sup>  
 232 and five oxygen atoms from coordinated water molecules. Also,  
 233 La1 is connected to two carboxylate oxygen atoms from PDA<sup>2-</sup>  
 234 and six oxygen atoms from coordinated water molecules. Finally,  
 235 La3 and La4 are linked by the same coordination mode. They  
 236 are coordinated to two nitrogen and three carboxylate oxygen  
 237 atoms from two different PDA<sup>2-</sup> ligands and oxygen atoms from  
 238 coordinated water molecules.

239 **Hybrid 3.** The host–guest assemblies in **2** and **3** are similar.  
 240 As shown in **Figure S7**, the asymmetric unit of **3** is composed of  
 241 one Keggin anion, two crystallographically independent PDA<sup>2-</sup>  
 242 ligands, three crystallographically unique Nd<sup>3+</sup> ions, and  
 243 numbers of coordinated and uncoordinated water molecules.

A remarkable feature of **3** is that each Keggin cluster connects to 244  
 one Nd(III) ion (**Figure S9**). In **3**, crystallographically 245  
 independent Nd3, Nd1, and Nd2 are 8-, 9-, and 10-coordinated, 246  
 displaying distorted square antiprism, distorted monocapped 247  
 square antiprism, and distorted dicapped square antiprism 248  
 coordination geometry, respectively. It should be noted that in 249  
 both polyoxometalate-based frameworks the 1D chain is 250  
 stacked. The metal–organic fragment in **3** is a supramolecular 251  
 isomer of that in **2**, and the basic Nd(III)-PDA<sup>2-</sup> unit is 252  
 [Nd<sub>2</sub>(PDA)<sub>2</sub>]. The [Nd<sub>2</sub>(PDA)<sub>2</sub>] units are further connected 253  
 by other PDA<sup>2-</sup> ligands and La(III) atoms. It is interesting to 254  
 note that a chain presents a wave-shaped single strand viewed 255  
 along the crystallographic *b*-axis (**Figure S8**). In addition, Nd– 256  
 (O)<sub>2</sub>–Nd is a direct ligand bridge which links the chains. 257

**Hybrid 4.** **4** is structurally closely related to **3** and crystallizes 258  
 in a monoclinic crystal system with the space group P2<sub>1</sub>/c. The 259  
 asymmetric unit **4** is composed of one W<sub>12</sub> cluster, two 260  
 crystallographically independent PDA<sup>2-</sup> ligands, three crystallo- 261  
 graphically unique Sm<sup>3+</sup> ions, two Na<sup>+</sup> ions, and numbers of 262

263 coordinated and uncoordinated water molecules (Figure S9).  
 264 Crystal structure analysis reveals that compound 4 consists of  
 265 three main parts:  $[\text{SiW}_{12}\text{O}_{40}]^{4-}$  polyoxoanion,  
 266  $\{\text{Na}_2\text{Sm}_2(\text{PDA})_2\}$  groups, and Sm3–Sm2(PDA)–Sm3 linear  
 267 chains. In compound 4, crystallographically independent Sm1,  
 268 Sm2, and Sm3 are all 11-coordinated, displaying a distorted  
 269 monocapped pentagonal antiprism coordination geometry. As  
 270 shown in Figure 2, there are three types of Sm ions (Sm1, Sm2,  
 271 and Sm3) in 4: Sm1 is linked with other Sm1 atoms through two  
 272 bridging oxygen and three nitrogen atoms from  $\text{PDA}^{2-}$ ,  $\text{Na}^+$  ion  
 273 from NaOH, a terminal oxygen atom from POM, and other  
 274 oxygen atoms from coordination  $\text{H}_2\text{O}$  molecules. The Sm2  
 275 atom displays 11-coordination geometry established by three  
 276 nitrogen atoms (N4, N5, and N6), two carboxylate oxygen  
 277 atoms (O51 and O53) from  $\text{PDA}^{2-}$ , and the other oxygen atoms  
 278 from coordinated water molecules. The last type of Sm(III)  
 279 (Sm3) ions is connected to two carboxylate oxygen atoms (O54  
 280 and O52) from  $\text{PDA}^{2-}$  to construct PDA–Sm3–PDA linear  
 281 chains,  $\text{Na}^+$  ion from NaOH, and the other oxygen atoms from  
 282 coordinated water molecules (Figure 2 and Figure S10).

283 **Drug Adsorption Experiments for Ln-Functionalized**  
 284 **Polyoxotungstates–Organic Frameworks.** As outlined in  
 285 the Introduction, the organic–inorganic nature of 1–4 led us to  
 286 propose them as suitable adsorbents for organic drug molecules.  
 287 To this end, we explored the extraction performance of the four  
 288 polyoxometalate-based frameworks toward four model drugs of  
 289 abuse (i.e., amphetamine, methamphetamine, codeine, and  
 290 morphine) in hair samples. As all analytes tested feature basic  
 291 amine groups, their protonation degree can be controlled by the  
 292 solution pH. We propose that this introduction of a cationic  
 293 charge allows increased interactions of the model drugs with the  
 294 adsorbent surface. To this end, we quantitatively explored the  
 295 extraction performance of 1–4 (Figure 3). As can be seen in

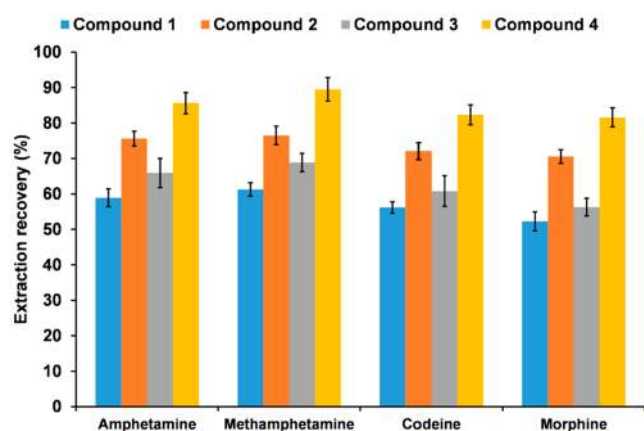

Figure 3. Extraction efficiency of 1–4 for the D- $\mu$ SPE of the target drugs.

296 Figure 3, the order of the extraction efficiency for the D- $\mu$ SPE of  
 297 the target drugs is as follows: 4 > 2 > 3 > 1 (Figure 3). Notably,  
 298 despite their different structures, the extraction recoveries (i.e.,  
 299 binding affinity of the drugs to the framework materials) are all  
 300 in a similar range. We suggest that this could be related to the  
 301 fact that all drugs have similar  $\text{pK}_a$  values (Table 1) and that  
 302 electrostatic interactions rather than specific structural features  
 303 control the binding of the substrate to the framework.

304 Based on this initial finding, the Sm-containing 4 was used for  
 305 more detailed extraction analyses. To investigate the best  
 306 condition for the extraction of target drugs, several parameters

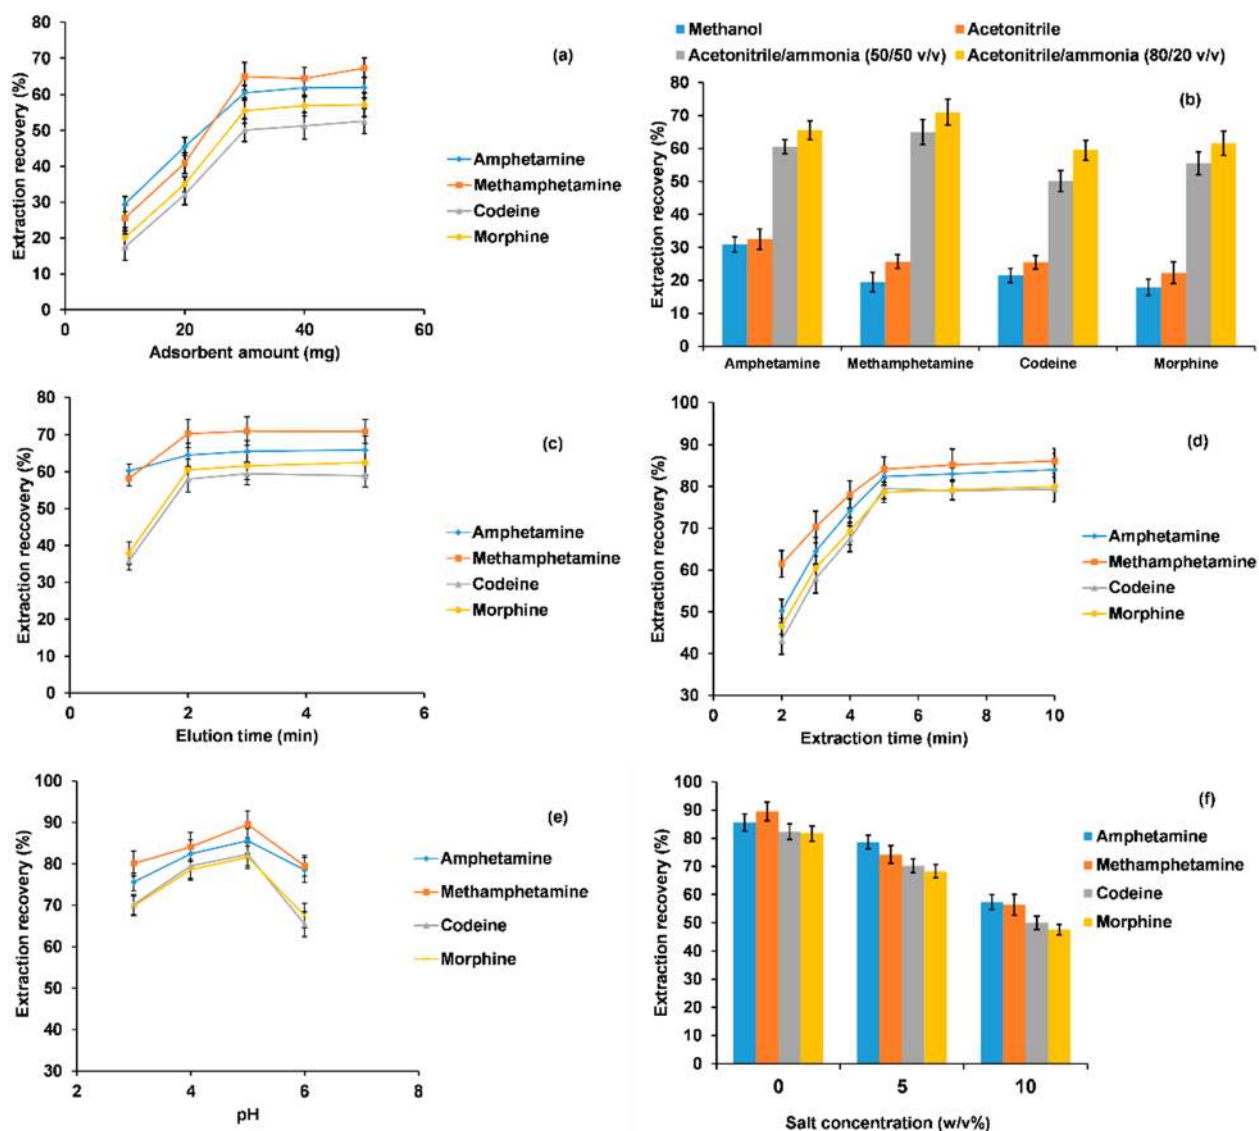

such as the amount of adsorbent (10–50 mg), desorption 307  
 conditions (eluent, eluent volume, and elution time), extraction 308  
 time (1–7 min), pH (3–6), and salt effect (0–10% w/v) were 309  
 studied. The general trends are that higher amount of adsorbent 310  
 and longer elution/extraction times result in higher recoveries. 311  
 With respect to pH value, we suggest that two trends could lead 312  
 to the data observed in Figure 4e: at high pH values, the analytes 313 f4  
 are less protonated, thereby lowering the binding affinity to the 314  
 frameworks. At low pH, surface protonation of the frameworks 315  
 could become possible, thereby lowering electrostatic inter- 316  
 actions with the analyte. A similar argument can be made for the 317  
 effects of NaCl addition: we suggest that the presence of NaCl 318  
 introduces competing  $\text{Na}^+$  cations which can also bind to the 319  
 framework surface. In addition, solution interactions between 320  
 the analytes and the NaCl ions are possible. In addition, 321  
 modification of the ionic strength of the solvent can lead to an 322  
 increased solubility of the analytes and therefore reduce their 323  
 binding to the framework materials. The following experimental 324  
 conditions yielded the best results: (a) 30 mg of the adsorbents 325  
 (Figure 4a); (b) eluent, acetonitrile/ammonia (80/20 v/v) 326  
 (Figure 4b); (c) volume of the eluent, 200  $\mu\text{L}$ ; (d) elution time, 327  
 2 min (Figure 4c); (e) extraction time, 5 min (Figure 4d); (f) 328  
 sample pH, 5 (Figure 4e), and without addition of NaCl (Figure 329  
 4f). 330

**Method Validation.** Under optimized conditions, we then 331  
 examined the linearity, the lower limit of detection (LOD), 332  
 precision, and extraction recovery (%) of the D- $\mu$ SPE-HPLC- 333  
 UV method (Table 3). The calibration curve for HPLC-UV 334 f3  
 analysis was acquired by using different drug concentrations 335  
 solution. The good linearity was achieved for all of the analytes, 336  
 with correlation coefficients ( $r$ ) higher than 0.9959, in the range 337  
 0.3–300  $\text{ng mL}^{-1}$  (0.7–300  $\text{ng mL}^{-1}$  for amphetamine, 0.3– 338  
 300  $\text{ng mL}^{-1}$  methamphetamine, and 1.0–200  $\text{ng mL}^{-1}$  for 339  
 codeine and morphine). The LOD was defined as the lowest 340  
 concentration at which a signal-to-noise ratio of 3 ( $S/N = 3$ ) was 341  
 observed which ranged from 0.1 to 0.3  $\text{ng mL}^{-1}$ . The 342  
 repeatability of the method was investigated in hair samples at 343  
 two concentration levels (5.0 and 50  $\text{ng mL}^{-1}$ ). As shown in 344  
 Table 3, the relative standard deviation (RSD) was in the range 345  
 4.1–5.5%, which is satisfactory. The extraction recoveries 346  
 obtained were in the range 78.6–84.1%. 347

**Analysis of Real Samples.** To assess the applicability of the 348  
 proposed method, the D- $\mu$ SPE-HPLC-UV method was applied 349  
 to extract and determine of amphetamine, methamphetamine, 350  
 codeine, and morphine in the hair of drug abusers. Real hair 351  
 samples of drug abusers were obtained from a Hospital in 352  
 Mashhad, Iran. Five hair samples were collected and analyzed by 353  
 the D- $\mu$ SPE-HPLC-UV method. These samples were further 354  
 confirmed by LC-MS. The results from each sample are listed in 355  
 Table S1. To investigate the effect of the matrix, the relative 356  
 recovery of the method was studied by spiking of the target 357  
 analytes at two concentration levels (5.0 and 50  $\text{ng mL}^{-1}$ ) to 358  
 each real sample. As shown in Table S1, the relative recoveries 359  
 were in the range 93.4–98.2% with an RSD of 5.9–7.3%. Note 360  
 that at this stage we do not observe a clear correlation between 361  
 adsorptive properties and crystal structure polymorph of 362  
 polyoxometalate-based frameworks 1–4, and further (kinetic) 363  
 binding studies are required to gain more insights into the role of 364  
 the exact structure on the substrate binding properties. 365

#### 4. CONCLUSION

In this work, we report the first example of the use of 366  
 polyoxometalate-based modular organic–inorganic frameworks 367

**Figure 4.** Effects of (a) adsorbent amount, (b) eluent, (c) elution time, (d) extraction time, (e) pH of sample, and (f) effect of NaCl concentration on the extraction performance.

**Table 3. Analytical Figures of Merit of the D- $\mu$ SPE Method of the Drugs of Abuse**

analyte	linear range (ng mL <sup>-1</sup> )	LOD (ng mL <sup>-1</sup> )	correlation coeff ( <i>r</i> )	ER (%)	precision	
					5.0 ng mL <sup>-1</sup>	50 ng mL <sup>-1</sup>
amphetamine	0.7–300	0.2	0.9975	85.6	5.1	4.7
methamphetamine	0.3–300	0.1	0.9966	89.5	4.9	4.4
codeine	1.0–200	0.3	0.9988	82.3	4.5	4.1
morphine	1.0–200	0.3	0.9959	81.6	5.5	4.9

368 for the extraction and quantitative analysis of drugs of abuse.  
 369 Four 1D coordination polymers based on Keggin-type  
 370 heteropolytungstates linked by lanthanoids (Dy, Sm, La, and  
 371 Nd) and organic PDA<sup>2-</sup> ligands were synthesized and used as  
 372 adsorbents for the D- $\mu$ SPE extraction and adsorption of four  
 373 drugs of abuse (amphetamine, methamphetamine, codeine, and  
 374 morphine). We report high extraction efficiency, wide linear  
 375 range, and low limits of detection, making this an intriguing new  
 376 application field for polyoxometalate-based heterogeneous  
 377 materials, even when by using complex sample matrices. Future  
 378 work will explore in more detail the interaction between the

POM and the drug molecules and will assess and optimize the  
 materials for usage under “real-life” conditions.
