4 **ABSTRACT**  
5  
6

7 Local stakeholders at the important but vulnerable Centre Hills forest reserve on Montserrat  
8 consider that the continued presence of feral livestock (particularly goats and pigs) may lead to  
9 widespread replacement of the reserve’s native vegetation by invasive alien trees (Java plum and  
10 guava), and consequent negative impacts on native animal species. Since 2009, a hunting  
11 programme to control the feral livestock has been in operation. However long-term funding is  
12 not assured. Here, we estimate the effect of feral livestock control on ecosystem services  
13 provided by the forest to evaluate whether the biodiversity conservation rationale for  
14 continuation of the control programme is supported by an economic case. A new practical tool  
15 (TESSA – Toolkit for Ecosystem Service Site-based Assessment) was employed to measure and  
16 compare ecosystem service provision between two states of the reserve (i.e. presence and  
17 absence of feral livestock control) to estimate the net consequences of the hunting programme on  
18 ecosystem services provided by the forest. Based on this we estimate that cessation of feral  
19 livestock management would substantially reduce the net benefits provided by the site, including  
20 a 46% reduction in nature-based tourism (from \$419,000 to \$228,000) and 36% reduction in  
21 harvested wild meat (from \$205,000 to \$132,000). The overall net benefit generated from annual  
22 ecosystem service flows associated with livestock control in the reserve, minus the management  
23 cost, was \$214,000 per year. We conclude that continued feral livestock control is important for  
24 maintaining the current level of ecosystem services provided by the reserve.

4 **1 INTRODUCTION**  
5  
6  
7

8 3 Invasive Alien Species (IAS) pose serious threats to biodiversity, especially on islands  
9  
10 4 (McGeoch et al. 2010; Peh 2010; Simberloff 2011). For example, IAS can dominate plant  
11 5 communities, especially after catastrophic disturbance events such as hurricanes and volcanic  
12 6 eruptions (e.g. Schmitz et al. 1997; Mack et al. 2000; Corlett 2010). Increasingly, there is also  
13 7 concern that IAS may impact ecological functions and processes, and hence the ecosystem  
14 8 services provided to people (Vitousek and Walker 1989; Pyšek et al. 2008). While impacts are  
15 9 variable, potentially even including enhancement of some services (Schlaepfer et al. 2011; Vila  
16 10 et al. 2011), there is clear potential for considerable detrimental impacts to services (e.g. de  
17 11 Lange et al. 2010; Hickman et al. 2010). For example, functional changes in forest structure  
18 12 caused by invasive trees can alter above-ground and below-ground carbon pool sizes, and hence  
19 13 an ecosystem's capacity for carbon sequestration, while foraging and travelling patterns of  
20 14 invasive mammals can lead to habitat alteration by increasing soil erosion that can in turn lead to  
21 15 watershed degradation (Vtorov 1993; Nogueira-Filho et al. 2009). To date, there are many  
22 16 accounts of ecosystem services negatively affected by IAS (e.g. Martin et al. 2009; Asner et al.  
23 17 2010; Pejchar and Mooney 2009) but only one study deals specifically with the consequences for  
24 18 ecosystem services of controlling IAS. De Lange and van Wilgen (2010) assessed the impacts of  
25 19 IAS management—using biological control—on ecosystem services. We add to this by explicitly  
26 20 assessing the effect of feral livestock control on ecosystem services provided by a forest reserve  
27 21 in Montserrat.

41  
42  
43  
44 23 IAS are an environmental problem on Montserrat, a U.K. overseas territory (UKOT) of 10,200  
45 24 ha located in the Lesser Antilles in the Caribbean (16°45'N 62°12'W). Montserrat has a moist  
46 25 tropical climate with natural climax vegetation distributed along altitudinal gradients, ranging  
47 26 from xerophytic scrub to evergreen rainforest and elfin woodland (Holliday 2009). However, a  
48 27 considerable proportion of these habitats has been converted or modified by human clearance for  
49 28 agriculture or development, and was altered by volcanic eruptions in 1995-1997. Much of the  
50 29 southern part of the island remains dominated by recent volcanic deposits (Fig. 1) and this  
51 30 formerly settled area is now designated as a formal 'exclusion zone' for humans, because of the  
52 31 risk of further eruptions. Due to net emigration since the volcanic eruptions, the human  
53  
54  
55

57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 1 population of Montserrat now numbers about 5,000, a decrease from 10,200 people before the  
5  
6 2 volcanic eruptions (United Nations Statistics Division, 2013). The Centre Hills Reserve  
7  
8 3 (hereafter ‘the reserve’; Fig. 1) is now the largest intact forest area remaining on Montserrat, and  
9  
10 4 the last stronghold for the island's endemic flora and fauna (Allcorn et al. 2012).

11 5  
12  
13 6 After the destruction of the capital, Plymouth, and the disruption of the economy in the south, the  
14  
15 7 human population now live in the northern, undeveloped half of the island near the reserve. The  
16  
17 8 reserve is therefore under pressure from development to replace housing, business infrastructure  
18  
19 9 and agricultural land lost as a result of volcanic activity. Moreover, the reserve harbours  
20  
21 10 problematic invasive alien mammals – mainly feral pigs (*Sus scrofa*) and goats (*Capra hircus*) –  
22  
23 11 whose populations have risen sharply since the volcanic eruptions because of the release of  
24  
25 12 livestock by evacuated owners, along with recruitment to the feral populations from free-range  
26  
27 13 livestock farms. The forest within the human exclusion zone on the south end of the island now  
28  
29 14 represents a reservoir from which these mammals can disperse into the reserve.

30 15  
31  
32 16 Several ecological impacts of the feral livestock are being experienced on Montserrat (see  
33  
34 17 Dawson et al. 2011). First, predation by invasive pigs threatens the last stronghold of the  
35  
36 18 Critically Endangered (IUCN Red List 2013) mountain chicken (*Leptodactylus fallax*), a large  
37  
38 19 frog whose population has already declined drastically due to infection by the chytrid fungus  
39  
40 20 (García et al. 2009). Second, clearing of the understorey vegetation by foraging livestock  
41  
42 21 indirectly affects the native bird species occupying the forest understorey. More specifically,  
43  
44 22 consumption of the native lobster claw plant (*Heliconia caribaea*) causes the loss of nests of the  
45  
46 23 Critically Endangered Montserrat oriole (*Icterus oberi*), a charismatic, endemic bird species  
47  
48 24 which is one of the attractions for nature-based tourism on the island (Allcorn et al. 2012; Opper  
49  
50 25 et al. in press).

51 26  
52 27 Lastly, feral livestock activities reduce the abundance of native plant species (which evolved in  
53  
54 28 their absence) and enhance conditions for the invasive alien plants Java plum (*Syzygium cumini*)  
55  
56 29 and guava (*Psidium guajava*) (Nogueira-Filho et al. 2009). These fast-growing species (which  
57  
58 30 require only a few years to mature and reproduce) have already formed dense canopies within  
59  
60 31 the Centre Hills and at the periphery of the reserve (mainly in the volcanic exclusion zone), their

1 establishment apparently aided over the last decade by feral livestock (pers. obs., James Daly).  
2 Pigs are the main seed dispersers of these plants (see Global Invasive Species Database,  
3 [www.issg.org](http://www.issg.org)); hurricanes aid their establishment by creating gaps in the forests, and the goats  
4 further help by opening up the understorey of the native vegetation. The saplings of both  
5 invasive plant species are not eaten by the livestock, as their leaves have low palatability and  
6 digestibility (Smith 1991; Kibria et al. 1994). These species have already naturalised in some  
7 Pacific islands where they are considered as “dominant invaders” because they spread rapidly  
8 forming dense stands and causing severe impact on native plants (Meyer 2000).

9  
10 Since July 2009, the Montserrat Department of Environment (DOE) has implemented an  
11 invasive animal management strategy. This involves permitted trapping and hunting with  
12 firearms (in both the reserve and nearby parts of the exclusion zone), educating livestock owners  
13 in the surrounding area about better animal management practices, and improving a livestock  
14 tagging and registration scheme. A preliminary assessment of these measures indicated that they  
15 are effective in reducing the feral livestock populations in the reserve (Dawson et al. 2011).  
16 However, the impact of this feral livestock management programme on the ecosystem services  
17 the reserve provides to people was unknown. For example, while the reduction of the feral  
18 livestock might help to maintain the endemic population of Montserrat Oriole, and thus sustain  
19 the nature-based tourism, it was not clear if it reduces the supply of wild meat. Furthermore, the  
20 future funding of this programme is not assured. Given the lack of knowledge on the wider  
21 socio-economic benefits of reducing feral livestock numbers, information about its net economic  
22 consequences would help to decide if the costly programme should be continued. Given evidence  
23 that the reserve generates substantial ecosystem services (van Beukering et al. 2008), we  
24 examined how cessation of feral livestock management might affect the delivery of the most  
25 important of these benefits. Specifically, we used a newly developed rapid assessment tool  
26 (TESSA – Toolkit for Ecosystem Service Site-based Assessment (Peh et al. 2013a); available at  
27 <http://www.birdlife.org/datazone/info/estoolkit> and described in Peh et al. 2013b) to estimate the  
28 net impact of livestock control on carbon storage, nature-based tourism and the provision of  
29 harvested wild meat derived from the reserve.

1  
2  
3  
4 1 TESSA was chosen over other tools (e.g. Integrated Valuation of Ecosystem Services and  
5 Tradeoffs [InVest; Tallis et al. 2013], and Assessment and Research Infrastructure for Ecosystem  
6 Services [ARIES; Bagstad et al. 2011], etc.) because it enabled the personnel at DOE to collect  
7 high resolution site-scale data that is relevant to the decisions affecting the site without the need  
8 for specialist technical knowledge on modelling approaches and using GIS software, intensive  
9 field work or substantial investment of resources; these practical features are currently lacking in  
10 alternative methods (Peh et al. 2013b). Therefore, TESSA was the most appropriate tool to use in  
11 this relatively rapid and inexpensive study, by non-experts from a governmental department  
12 (Montserrat DOE).

## 11 **METHODS**

### 13 **Study area**

15 The reserve, located in the central region of Montserrat (Fig. 1), is one of four hill ranges  
16 modified from six old volcanic cones (MacGregor 1938). The reserve covers 1,130 ha and rises  
17 to 741 m (van Beukering et al. 2008). The soils are primarily volcanic in origin, comprised  
18 mostly of clay and sandy loam (van Beukering et al. 2008). The area has a distinct wet season  
19 from July to December, and a dry season from February to May. The annual rainfall average in  
20 this region is 1,475-2,000 mm, with large annual and seasonal variations depending on the  
21 number and severity of tropical storms affecting the region (Barclay et al. 2006). Forest in the  
22 reserve was legally protected in 2000, with new environmental legislation currently pending.  
23 Two-thirds of the area is privately-owned and one-third is government-owned. A network of  
24 springs across the Centre Hills provides the island population with drinking water. The extraction  
25 and distribution of water are overseen by Montserrat Utilities Ltd.

27 The reserve is mostly forested, consisting of several vegetation types: (1) dry forest (102 ha); (2)  
28 mesic forest (635 ha); (3) wet forest (381 ha); and (4) elfin shrub-woodland (8 ha; Fig. 1). Dry  
29 forest occurs at the lowest elevation of the reserve, where precipitation is also comparatively  
30 low. The common plant species in this forest type are *Cedrela odorata*, *Chiococca alba*,  
31 *Guaiacum officinale* and *Hymenaea courbaril*. At higher elevation, dry forest is replaced by

1 mesic forest, with a more developed understorey shrub layer, with species including *Begonia*  
2 *oblique*, *Heliconia caribaea*, *Inga laurina* and the endemic shrub *Rondeletia buxifolia*. Wet  
3 forest occurs on steeper slopes above 500 m. Its characteristic flora includes palms, tree ferns  
4 and the trees *Asplundia insignis*, *Phyllanthus mimosoides* and *Podocarpus coriacetus*. On the  
5 highest peaks and ridges elfin woodland grows, comprising shrubby vegetation dominated by  
6 *Wercklea tulipiflora*. Besides the endemic globally threatened Montserrat Oriole and mountain  
7 chicken, the reserve also supports an extremely rare lizard called the Montserrat galliwasp  
8 (*Diploglossus montisserrati*). These unique animals that inhabit the reserve are the main  
9 attractants for the people visiting the island.

## 11 **Assessing ecosystem services**

13 We used the TESSA toolkit (Peh et al. 2013a, b) to compare ecosystem service provision  
14 between two states of the reserve. TESSA brings together a selection of accessible, low-cost  
15 methods to identify the important ecosystem services provided by a site, and to evaluate the  
16 magnitude and distribution of the benefits that people get from them now, compared with those  
17 expected under alternative land-uses.

19 The counterfactual, alternative state is a description of how the future (we assume the next 10 –  
20 20 years) may plausibly develop. Comparing service provision between states is more useful to  
21 decision-makers than quantifying the gross benefits from the current state (Balmford et al. 2011),  
22 as it sheds light on the net consequences of decisions. Here we compare (1) the current state, in  
23 which feral livestock populations are reduced via active management, and (2) a plausible  
24 alternative state, identified through discussion with local stakeholders, in which feral livestock  
25 control is absent, leading to higher livestock densities and impacts on native flora and fauna.

27 As TESSA is designed for rapidly comparing service delivery between two states, it does not  
28 have the resolution to describe changes in service provision through time. Therefore we did not  
29 consider in detail the timeline of the feral livestock invasion without the feral control  
30 programme, nor discount rates into the future. However, the current feral livestock management  
31 team (including experts from the UK Animal Health & Veterinary Laboratory and The Royal

1  
2  
3  
4 1 Society for the Protection of Birds) and the forestry team from the Montserrat Department of  
5  
6 2 Environment expected that the lack of control would lead—over the next 10 to 15 years—to Java  
7  
8 3 plum-dominated stands (which can thrive in wet conditions) replacing the mesic forest, wet  
9  
10 4 forest, and elfin woodland, and guava-dominated stands (which can tolerate drier conditions)  
11  
12 5 replace the dry forest (for habitat description of both invasive plant species, see: Global Invasive  
13  
14 6 Species Database, <http://www.issg.org/database>; also see Meyer (2000) for specific case studies  
15  
16 7 in the Pacific). Based on these expectations, the alternative state of the site we assessed involved  
17  
18 8 the replacement of a combined area of 1024 ha of mesic forest, wet forest and elfin woodland by  
19  
20 9 Java plum-dominated forest, and the replacement of 102 ha of dry forest by guava-dominated  
21  
22 10 forest. Based on field observations in this study,  $83 \pm 11\%$  (mean  $\pm$  95% confidence intervals,  
23  
24 11 based on 12 stands) of the stems in the forest invaded by Java plums belonged to the invasive  
25  
26 12 species, while 96 % of the stems (based on one stand) in the forest invaded by Guava were the  
27  
28 13 invasive species. Therefore these realistic estimates represented the level of dominance by these  
29  
30 14 invasive species under the alternative state.  
31  
32 15

33  
34 16 Working with stakeholders, we used TESSA's rapid appraisal protocol to identify all services  
35  
36 17 provided by the site of interest. Users of the forest will recognise and value different services.  
37  
38 18 The range of services identified was also guided by a previous economic assessment of the  
39  
40 19 ecosystem services generated by the Centre Hills (van Beukering et al. 2008). A workshop of  
41  
42 20 stakeholders in March 2011 then further assessed and identified those services that are (1)  
43  
44 21 important in either biophysical, social or economic terms; (2) sensitive to feral livestock  
45  
46 22 invasions; and (3) amenable to rapid quantification using TESSA. These were: global climate  
47  
48 23 regulation (through carbon storage and greenhouse gas fluxes), nature-based tourism,  
49  
50 24 provisioning of harvested wild meat from feral livestock and water provisioning. The ecosystem  
51  
52 25 services identified by van Beukering et al. (2008) matched this suite of services, except that our  
53  
54 26 list did not include the harvesting of mountain chicken, fruits and crayfish. This is because  
55  
56 27 mountain chickens are now rare in Montserrat and the collection of fruits and crayfish in the  
57  
58 28 reserve is now carried out infrequently, as a leisure activity, by a single individual.  
59  
60 29

61  
62 30 By quantifying these services for both states, we estimated the overall annual value for each  
63  
64 31 state, subtracted that of the current state from that of the alternative state, and hence derived an  
65

1  
2  
3  
4 1 estimate for the net economic consequences of cessation of feral livestock control. All economic  
5  
6 2 values in this study were converted from East Caribbean dollars (EC\$) to US dollars using the  
7  
8 3 2011 average exchange rate (EC\$2.70 = \$1).  
9  
10 4

11 5 *Global climate regulation* – To estimate the storage of carbon (C) in above-ground biomass  
12 6 (AGB), we used a combination of field data collection (in June 2011) and reference to the  
13 7 Intergovernmental Panel on Climate Change (IPCC) tier 1 database (IPCC 2006). The reserve  
14 8 was first stratified by vegetation type: dry forest, mesic forest, wet forest, and elfin shrub-  
15 9 woodland. We estimated the C stock in the above-ground biomass of elfin shrub-woodland from  
16 10 Table 4.12 in the IPCC (2006) tier 1 database. In each of the three other vegetation types we  
17 11 randomly located six 5m x 100 m transects, at least 200 m apart and accessed by narrow walking  
18 12 trails. Along each transect, we measured diameter at breast height, D (cm) of all trees  $\geq 10$  cm  
19 13 and estimated the height, H (cm) of all mature palms. Tree measurement followed standard  
20 14 protocols (Phillips et al. 2009) and AGB (Mg) was estimated using the following regression  
21 15 models derived from Brown (1997):  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32

$$33 \quad \text{AGB}_{\text{wet}} = 21.297 - 6.953 \times D + 0.740 \times D^2 \quad (1)$$

$$34 \quad \text{AGB}_{\text{mesic}} = \exp(-2.289 + 2.649 \times \ln D - 0.021 \times \ln D^2) \quad (2)$$

$$35 \quad \text{AGB}_{\text{dry}} = 0.2035 \times D^{2.3196} \quad (3)$$

36  
37  
38  
39  
40  
41 21 The AGB of palms was estimated as in Delaney and Roshetko (1999):  
42  
43  
44

$$45 \quad \text{AGB}_{\text{palm}} = 4.5 + 7.7 \times H \quad (4)$$

46  
47  
48 25 The above equations are widely accepted and commonly used in the literature (e.g. Pearson et al.  
49 26 2005). The amount of above-ground C stored in trees and palms was assumed to be 50 % of the  
50 27 AGB (Chave et al. 2005). We determined the sample size requirements for each forest type  
51 28 based on the pilot results, in order to attain a precision level of  $\pm 10\%$ . As a result in total we  
52 29 measured 13 transects in the wet forest, 14 transects in the mesic forest and 8 in dry forest. As  
53 30 the reserve is legally protected, we assumed there was no loss of C stocks due to human  
54 31 disturbance such as wood harvesting. Although the reserve is subject to occasional hurricane-  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 1 force winds, we did not take into account the C loss due to storm damage because we assumed  
5  
6 2 that direct effects of strong winds on the tree-covered reserve were minimal (see van Bloem et al.  
7  
8 3 2006; Imbert and Portecop 2008).

9  
10 4  
11 5 To estimate carbon storage under the alternative stage we measured diameter at breast height of  
12  
13 6 all trees  $\geq 10$  cm within all the accessible Java plum stands and all trees of the only guava stand  
14  
15 7 on the island (most of the stands of these exotic species are in the volcanic exclusion zone, and  
16  
17 8 therefore not accessible). We estimated their carbon storage capacity using the following  
18  
19 9 regression model (Delaney and Roshetko 1999):

$$10 \quad \text{AGB}_{\text{invasive}} = \exp(-2.134 + 2.53 \times \ln D) \quad (5)$$

11  
12  
13 13 In all, we measured 12 monodominant Java plum stands of a total of 0.30 ha and one guava stand  
14  
15 14 of 0.11 ha.

16  
17 16 Below-ground biomass carbon stock was estimated using a below-ground biomass: above-  
18  
19 17 ground biomass ratios for particular vegetation types (IPCC 2006). Estimates of litter and dead  
20  
21 18 wood C stocks were drawn from Anderson-Teixeira and Delucia (2011). Estimates of mineral  
22  
23 19 soil C were derived from the IPCC (2006) tier 1 database. The total carbon stock of each state  
24  
25 20 was then the summation for each habitat type of all the following components: above-ground C,  
26  
27 21 below-ground C, litter C, dead wood C and mineral soil C.

28  
29 22  
30 23 Greenhouse gas (which consisted of carbon dioxide, methane and nitrous oxide) sequestration  
31  
32 24 rates of the tree species in the two alternative states of the forest were determined by reference to  
33  
34 25 Anderson-Teixeira and Delucia (2011). However, this provides no information on variation was  
35  
36 26 provided between different species in these tropical forest communities, so we assumed the  
37  
38 27 greenhouse gas sequestration rate in the two states to be constant.

39  
40 28  
41 29 *Nature-based tourism* – The opportunity to view rare endemic species such as Montserrat oriole  
42  
43 30 and to walk in the cloud-shrouded tropical forest attracts international tourists to the reserve. The  
44  
45 31 annual value of this nature-based tourism was estimated from an international visitor

1  
2  
3  
4 1 questionnaire survey at the airport, conducted in April and May 2011 (for the interview questions  
5  
6 2 see Appendix 1) and the 2009 records of tourist numbers from the Montserrat Tourism Board  
7  
8 3 (which has the record for one year only). The airport is the main gateway to the island for  
9  
10 4 international visitors. Based on variance in expenditure reported in the first ten interviews, we  
11  
12 5 used power analysis to calculate that the minimum sample size needed to estimate expenditure to  
13  
14 6 a precision level of  $\pm 20\%$  was 52 interviews. The tourism revenue from a tourist to the reserve  
15  
16 7 was estimated as the mean expenditure per day spent on a trip to the island –including the costs  
17  
18 8 of air travel to Montserrat, accommodation, car rental and meals – multiplied by the number of  
19  
20 9 days spent at the reserve. The annual expenditure on visiting the reserve was derived by  
21  
22 10 multiplying the mean expenditure per day per tourist by the total number of tourists to the island  
23  
24 11 in 2009. In the questionnaire, for the tourists who had visited the reserve, we asked if they would  
25  
26 12 come to the reserve if the area remained forested but its unique biodiversity had disappeared (see  
27  
28 13 Appendix 1). The likelihood of all unique species becoming extinct is high under the alternative  
29  
30 14 state because they are classified as either endangered (e.g. Montserrat Oriole) or critically  
31  
32 15 endangered (mountain chicken) due to their limited distributions and small populations, and the  
33  
34 16 known threats from IAS. To establish an estimate of the value of tourism under the alternative  
35  
36 17 state, the percentage of tourists who would visit the alternative state was multiplied by the  
37  
38 18 estimated current annual expenditure on visiting the reserve. As the approach used was a  
39  
40 19 simplified version of the Travel-Cost Method (TCM), we did not collect enough information on  
41  
42 20 characteristics (e.g. income) of interviewed people to run a full TCM analysis. Despite having  
43  
44 21 relatively robust estimates of tourist expenditures, i.e. costs (for travel, accommodation, food,  
45  
46 22 etc.) incurred by each tourist in travelling to the reserve for recreational purposes, we  
47  
48 23 acknowledge that this approach is an incomplete measure of the economic value of nature-based  
49  
50 24 tourism because our estimate was less than the maximum amount that the tourists may have been  
51  
52 25 prepared to pay (Well 1997).

53  
54 26  
55 27 *Harvested wild meat*– Hunting feral animals provides an important supply of meat for the island.  
56  
57 28 We looked at two sources – private hunting, and official DOE hunts. We gathered anonymous  
58  
59 29 data from four hunters (27% of the total hunting population; 3 DOE, 1 non-DOE) on the quantity  
60  
61 30 of meat (broken down by species) which they privately collected from the reserve (i.e. excluding  
62  
63 31 the meat collected during the official hunting trips for the Department) in the six months to June  
64  
65

1  
2  
3  
4 1 2011, on the proportion they sold, and on the capital costs of their hunting activities. To deduce  
5  
6 2 the value of harvested feral meat for the alternative state, we asked the DOE hunters to estimate  
7  
8 3 the amount of meat they would have collected in the past six months if they had received no  
9  
10 4 income for DOE hunting and were prevented from accessing the exclusion zone (as they had  
11  
12 5 been before the DOE began feral animal control; for the questionnaire see Appendix 2). We  
13  
14 6 assumed that the hunting effort of the non-DOE hunters would be the same under the two states.  
15  
16 7

17 8 Data on the number of animals shot and amount of meat collected from the reserve and the  
18  
19 9 exclusion zone during official DOE hunting trips was obtained from records of 27 May 2010 to  
20  
21 10 16 February 2011. Meat acquired during the official DOE trips was not sold for profit, but was  
22  
23 11 provided to the community (e.g. to nursing homes and prison facilities). This benefit would only  
24  
25 12 be obtained under the control programme and not in the alternative state, and we assumed that its  
26  
27 13 value was equal to that of the meat which was sold.  
28  
29 14

30 15 *Water provisioning*– Montserrat's water supply is sourced from nine springs, situated across the  
31  
32 16 Centre Hills reserve, which feed immediately into pipes and a network of 18 tank reservoirs.  
33  
34 17 About 55 million litres of water were extracted and used by the island population per month from  
35  
36 18 2001 to 2006 (van Beukering et al. 2008). The reserve forest is important for the protection of  
37  
38 19 the watershed and associated erosion risks. However, increases in feral mammal numbers are not  
39  
40 20 likely to impact this water provisioning service because the springs and reservoirs are fenced off  
41  
42 21 and protected by concrete structures to prevent water contamination. It is possible that the  
43  
44 22 eventual change in tree species composition, with replacement of native species by alien species,  
45  
46 23 will affect hydrological parameters such as the amount of rainfall intercepted, evapotranspiration  
47  
48 24 rates and throughfall kinetic energy, and hence erosion risk (e.g. Geissler et al. 2013). However,  
49  
50 25 measurement of such parameters was beyond the scope of this study and it is not possible to state  
51  
52 26 in which direction effects might be observed. In light of this we conservatively assume that feral  
53  
54 27 animal control had no net benefit for water provisioning by the reserve.  
55  
56 28  
57 29

## 57 30 **RESULTS**

58  
59 31  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 1 *Global climate regulation* – We estimated the mean above-ground C stock in the reserve to be  
5  
6 2  $106.3 \pm 16.4$  (95% confidence interval) Mg C ha<sup>-1</sup> for wet forest,  $186.1 \pm 32.6$  Mg C ha<sup>-1</sup> for  
7  
8 3 mesic forest,  $40.4 \pm 14.5$  Mg C ha<sup>-1</sup> for dry forest,  $134.9 \pm 43.5$  Mg C ha<sup>-1</sup> for Java plum stands  
9  
10 4 and  $18.8 \pm 5.0$  Mg C ha<sup>-1</sup> for guava stands. The total carbon stock (across the five pools of  
11  
12 5 carbon) of the reserve was estimated to be 341,000 Mg under the current state, whereas that  
13  
14 6 under the alternative state was 302,000 Mg (Table 1). Hence the carbon stock loss that is avoided  
15  
16 7 under the current state was calculated to be 39,000 Mg (Table 1). At a carbon price of \$83.61 per  
17  
18 8 tonne (US Government; Greenspan Bell and Callan 2011), this benefit of avoided carbon loss  
19  
20 9 was estimated at \$3,240,000. However, we acknowledge that our estimates of carbon stocks for  
21  
22 10 the current and alternative states were subject to wide nominal errors (Table 1); this highlights  
23  
24 11 the importance of using local field data wherever possible in such assessments as the uncertainty  
25  
26 12 derives mainly from using IPCC values. Although carbon stock might decline with no control of  
27  
28 13 IAS, the broad estimate ranges do not indicate the significance of the change (Table 1).  
29  
30 14 Therefore we conservatively assume there was no benefit of avoided carbon loss under the  
31  
32 15 current state.

33  
34 17 Given the resolution of available data, we assume no change in carbon sequestration rates  
35  
36 18 following the spread of invasive plants. Increases in abundance of ungulates (i.e. goats, sheep  
37  
38 19 and cattle) in the reserve will lead to increased methane emissions but, without an assessment of  
39  
40 20 absolute livestock numbers in the reserve, we are not able to quantify the potential change in  
41  
42 21 methane emissions that might occur if feral animal control ceased.

43  
44 23 *Nature-based tourism* – We interviewed a total of 95 international visitors at the airport  
45  
46 24 departure hall. Based on this survey, 37.2% of the international tourists on Montserrat had visited  
47  
48 25 the reserve during their stay. We estimated their mean expenditure on visiting the reserve to be  
49  
50 26  $\$178.35 \pm 43.09$  per person. There were a total number of 6311 visitors on Montserrat in 2009.  
51  
52 27 Therefore, we estimated that 2350 international tourists visited the reserve in 2009, and their  
53  
54 28 total annual expenditure on their visits was \$419,000. Only 54.3% of the respondents indicated  
55  
56 29 that they would visit the reserve under the alternative state; this would therefore generate a total  
57  
58 30 annual expenditure of \$228,000. Therefore our estimate of the decrease in value associated with  
59  
60 31 the loss of native fauna at the reserve was \$192,000 per year (Table 2).

1  
2  
3  
4 1  
5  
6 2 *Harvested wild meats*– We found that 15 hunters harvest feral livestock from the reserve on a  
7 3 regular basis and sell meat from these private trips into the island market. Five of these hunters  
8 4 were also members of the DOE hunting team, for which they received a salary. Unfortunately,  
9 5 we were not able to interview all hunters about their level of activity, because their income was  
10 6 regarded as a sensitive topic. The sample size of the hunter survey was therefore only four, but it  
11 7 constituted over a quarter of the hunter population on the island. Information obtained from the  
12 8 sole non-DOE hunter in the sample was assumed to be representative of the other nine non-DOE  
13 9 hunters. The market prices obtained for the beef, pork, mutton and goat were US\$0.9, \$1.5, \$1.3  
14 10 and \$1.3 per kg, respectively. The assessment of the total annual net profit from feral animal  
15 11 hunting took account of the sale price of the meat harvested, and capital costs (e.g. tools,  
16 12 maintenance of hunting dogs and meat cutting fees) (Table3). Under the feral livestock  
17 13 management scheme, the total annual profit from both private and official hunting trips – was  
18 14 calculated to be \$205,000. Under the alternative state, without the DOE hunting programme, the  
19 15 total annual profit was estimated to be 36% lower, totalling \$132,000 (Table 2).  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33

34 17 *Feral livestock management cost* – The current management programme entails reduction of  
35 18 feral livestock populations in and around the reserve, monitoring the populations using a network  
36 19 of infra-red game cameras and implementing a tagging and registration scheme for non-feral  
37 20 livestock. The programme was funded by a UK Overseas Territories Environment Programme  
38 21 (OTEP) fund of \$101,000 (based on a mean 2011 exchange rate of £0.6235:US\$1) for two years,  
39 22 starting in March 2011. Since early 2013, it has been continued through a further grant from the  
40 23 European Commission ‘BEST’ fund. The cost of feral livestock management was therefore  
41 24 estimated at \$50,500 per year; this covers wages for hunters, allowances for dogs, transport,  
42 25 hunting equipment, project management, financial assistance to owners for better livestock  
43 26 practices, staff training and DOE overheads.  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53

54 28 *Net economic consequences of continuation of feral livestock management* – The overall net  
55 29 benefit generated from annual ecosystem service flows (nature-based tourism and harvested feral  
56 30 livestock) associated with livestock control in the reserve, minus the management cost, was  
57 31 \$214,000 per year (Table2). According to our estimates, cessation of feral livestock control  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 1 would reduce benefits to both local people (through harvested wild meat) and global  
5  
6 2 beneficiaries (via nature-based tourism and carbon storage) (Table 4). The cessation of feral  
7  
8 3 livestock control would likely cause the decline or disappearance of native species in the reserve.  
9  
10 4 Consequently, global stakeholders such as the foreign investors who own the restaurants and  
11  
12 5 hotels on the island, as well as the locals who hold jobs in service and supply industries, would  
13  
14 6 suffer from reduced incomes from tourism. Local communities would lose out through a reduced  
15  
16 7 supply of wild meat.  
17  
18 8

## 19 9 **DISCUSSION**

20  
21 10

22  
23 11 Many studies have estimated values of ecosystem services at a national or regional level (e.g.  
24  
25 12 Pimentel et al. 2000; Zavaleta 2000) but fewer have performed this kind of assessment at a local  
26  
27 13 scale to yield results to inform local decision-making. As far as we know, this is the first  
28  
29 14 ecosystem service assessment addressing a decision concerning IAS control. We found that  
30  
31 15 cessation of the feral livestock management in Montserrat could reduce the net benefits provided  
32  
33 16 to people by the Centre Hills Reserve, including a potential 11% reduction in carbon storage,  
34  
35 17 46% reduction in tourism (due to the loss of native species) and 36% reduction in large mammal  
36  
37 18 hunting. In total, unmanaged feral livestock could cause a loss of service flows of \$265,000 per  
38  
39 19 year – a value that is about 5 times the cost of feral livestock management. This study thus  
40  
41 20 suggests that evaluating ecosystem services can provide novel and important information to help  
42  
43 21 guide decisions about feral livestock management.  
44  
45 22

46  
47 23 This study extends and updates a previous evaluation of the economic value of the reserve (van  
48  
49 24 Beukering et al. 2008) in several ways. Firstly, the previous study used IPCC look-up table data  
50  
51 25 to calculate that 621 Mg of carbon could be lost per year, assuming an annual loss of 2.8ha  
52  
53 26 (0.25%) of the forest. Our results suggest the potential for invasive animals to have a further  
54  
55 27 impact on carbon stock by changing the tree community, even without forest loss. This impact  
56  
57 28 has also been seen with the highly invasive tree *Morella faya*, in Hawaii, which decreased AGB  
58  
59 29 in woodland-savanna ecosystems (Asner et al. 2010). Secondly, the previous study estimated that  
60  
61 30 32% of people’s motivation for visiting Montserrat could be attributed to activities related to the  
62  
63 31 reserve bringing US\$7.5-9.3 million per year (c. 25% GDP) since 2000 (van Beukering et al.  
64  
65

1  
2  
3  
4 1 2008). We estimated that the total value of tourism at the reserve was \$419,000 per year,  
5  
6 2 dropping by 46% to \$228,000 if the anticipated ecosystem changes occurred.  
7  
8 3

9  
10 4 Finally, van Beukering et al. (2008) estimated the value of harvested wild goods (including  
11 5 timber, crayfish and even the endemic mountain chicken frog) at \$158,000 per year, with a large  
12 6 proportion (81%) derived from pig hunting (based on information from two hunters). We found  
13 7 that the feral livestock management programme, which has influenced the private hunting  
14 8 behaviour of hunters, has led to an increase in the total value of wild harvested mammal meat to  
15 9 an estimated total of \$205,000, largely by allowing access to the exclusion zone. Without the  
16 10 feral animal control programme, and assuming continued lack of private access to the exclusion  
17 11 zone, the value of wild harvested meat would reduce by over a third.

13 Determining the most suitable approach for dealing with the feral livestock (e.g. control versus  
14 eradication) is not simple (Myers et al 2000). The current control program in Montserrat is  
15 aiming at area-specific suppression of the feral livestock population, as eradication is not  
16 possible due to inaccessibility of most of the exclusion zone. Interestingly, our results also imply  
17 that the current feral livestock control approach may be more economically beneficial than  
18 eradication as it yields meat worth \$205,000/yr for local consumption. However, our analysis of  
19 benefits from hunting feral meat did not involve any consideration of the population dynamics of  
20 the feral livestock. Although hunting drastically reduces feral livestock activity in and around the  
21 reserve, it has little impact on the feral livestock population as the exclusion zone – harbouring  
22 most of the feral livestock – occupies a considerable area and is largely inaccessible. In the  
23 absence of the control programme, however, it is unlikely that the total off-take of meat could  
24 remain the same or increase because there are limitations among the Montserrat population in  
25 terms of technical capacity (e.g. use of traditional hunting methods is less efficient than use of  
26 firearms during IAS control), physical capacity (the work is arduous and hence generally  
27 unattractive) and local knowledge of the physical environment required for successful hunting in  
28 Montserrat's hilly terrain.  
29

30 To reflect differences in the uncertainty associated with our estimates for each services, we used  
31 a simple scale of ‘high’, ‘medium’ and ‘low’ to assess the degree of confidence , as

1 recommended by TESSA (Table 4). Based on these standards, our confidence is ‘low’ for our  
2 estimates of carbon stocks between the two alternative states. This is because our estimations  
3 using imperfect allometric relationships and published look-up tables have wide nominal errors.  
4 We therefore did not include the net carbon stock benefit in the estimate of the net values of all  
5 services resulting from continuation of IAS control programme (Table 2). Nevertheless, it is  
6 worth mentioning that a critical component of valuing carbon stock is the choice of carbon  
7 prices. These prices – adjusted to a 2011 baseline using the International Monetary Fund’s  
8 inflation rates (<http://www.imf.org/external/pubs/ft/weo/2012/01/weodata/weorept.aspx>) – range  
9 from \$22.75 per tonne C (Verified Emission Reductions; Peters-Stanley et al. 2011), to \$56.18  
10 per tonne C (EU’s Emission Trading Scheme; Point Carbon 2011), \$118.09 per tonne C (Tol  
11 2010), \$319.33 per tonne C (UK Government; Greenspan Bell and Callan 2011) and \$348.13 per  
12 tonne C (Stern et al. 2006). Hence, the net carbon stock benefit is highly sensitive to a chosen  
13 carbon price.

14  
15 The distribution of economic impacts is a further complicating factor. For instance, the livestock  
16 management programme is counted as a “cost” of \$50,500/yr, which includes wages, financial  
17 assistance to livestock owners, and other expenses which are indeed a cost to taxpayers or  
18 funding agencies, but are actually a benefit to island residents and others employed by the  
19 programme. It is debatable therefore whether, say, hunters’ wages should be counted on the red  
20 side of the ledger while revenue from the sale of livestock meat is counted on the black.  
21 Likewise, the economic benefits from the tourism industry would likely not accrue to the same  
22 individuals or institutions who would incur the costs associated with livestock control.

23  
24 Admittedly, a full life cycle of cost-and-benefit analysis, which is beyond the scope of this  
25 assessment, is needed for the most informed decisions. We also did not consider time horizons  
26 and discount rates since this study—in contrast with alternative methods based on modelled  
27 scenarios of projections into the future—was a comparison between two different states of the  
28 reserve as ‘snapshots’ in time for which real data were collected. We therefore recognise that we  
29 did not consider the long-term change in delivery of services. Nevertheless, a simple assessment  
30 of benefits based on realistic estimates derived from the reserve enabled us to draw some useful  
31 and highly relevant conclusions for the decision context of this case study. Stakeholders at the

1  
2  
3  
4 1 reserve now have an idea how the net benefit from the feral livestock control programme  
5  
6 2 compares with the costs of such a programme.  
7  
8 3

9  
10 4 This study suggests that the feral livestock management programme in Montserrat should  
11  
12 5 continue for economic, as well as conservation reasons. Indeed, the community of Montserrat  
13  
14 6 recognise the threat of invasive species to the biodiversity and services of the reserve and, on  
15  
16 7 average, is willing to pay \$58 per household per year (in 2008 US\$) for the control of invasive  
17  
18 8 species (van Beukering et al. 2008). However, feral livestock management programmes are often  
19  
20 9 inadequately funded (Campbell and Long 2009). Despite the recognition of its importance by the  
21  
22 10 population of Montserrat and international conservationists, the Centre Hills management  
23  
24 11 scheme is currently funded only until 2015. Continued financing is essential to help protect this  
25  
26 12 reserve. The economic case for its continuation suggests that it may be timely to develop an  
27  
28 13 ecosystem service-based scheme to underpin the financial requirements of long term  
29  
30 14 conservation of the reserve, using combinations of private and public financing mechanisms that  
31  
32 15 have been explored, for instance, for reserves in Costa Rica (Bernard et al. 2009).  
33

34 16  
35 17 In assessing who might pay for feral livestock control, it is important to consider how the  
36  
37 18 benefits might be captured. For some services this will prove difficult. For instance, the  
38  
39 19 relatively small size of the potential carbon stock change in the forest reserve and the complexity  
40  
41 20 of the monitoring methods that would need to be developed might make it a relatively  
42  
43 21 unattractive prospect for the formal carbon market, although possibilities might exist to engage  
44  
45 22 in the voluntary carbon offsetting market. Tourism will continue to be important for the  
46  
47 23 Montserrat economy, but new mechanisms will be required to ensure that the resulting benefits  
48  
49 24 from nature tourism are equitably distributed among those who play a role in keeping these  
50  
51 25 services available, whether local communities, civil society organisations, business or  
52  
53 26 government. Some form of modest tourism or green visitor exit tax might offer the best  
54  
55 27 opportunity for sustainable finance. Lessons learned from schemes in other Caribbean UK  
56  
57 28 Overseas Territories indicate that a very robust mechanism for distribution of green tax revenue  
58  
59 29 needs to be in place from the outset of any proposed scheme.

**Appendix 1.** Interview questions for tourists at the department hall of the airport on Montserrat.

Interview date:

Number of people in the travel group:

1. Have you visited the Centre Hills during your stay in Montserrat?

Yes – Please complete the rest of the questionnaire.

No – End of the survey.

2. How many days will you spend away from home whilst on this trip?

N.B. This should also include the days you spend elsewhere outside Montserrat, for example other Caribbean islands, if there are any.

Answer: \_\_\_\_\_

3. In total, how much money will you spend during your whole stay in this trip?  
(per person, or for the whole group)

N.B. A) This should include your spend on travel (air, ferry, etc), accommodation, food, local transport, tour guide, etc.

B) This should include your spend elsewhere outside Montserrat, for example other Caribbean islands, if there are any.

Answer: \_\_\_\_\_ (per person/for the whole group\*)

\* delete where appropriate

4. How many days have you spent at the Centre Hills during your trip?

Answer: \_\_\_\_\_

5. Would you come to the Centre Hills for these activities if the Central Hills remain forested, but the unique animals of Montserrat (e.g., Montserrat Oriole) have disappeared?

Answer: Yes / No\*

\*delete where appropriate.

**Appendix 2.** Interview questions for hunters on Montserrat.

Interview date:

1. How much meat (in terms of lbs) - for your own use and sale - did you collect from the Centre Hills in the past six months?  
(NB. Do not include the meat collected from DOE hunting trips)

Answer: \_\_\_\_\_

2. What percentage of the meat is from pig, goat, sheep and cattle?

Pig \_\_\_\_\_ %

Goat \_\_\_\_\_ %

Sheep \_\_\_\_\_ %

Cattle \_\_\_\_\_ %

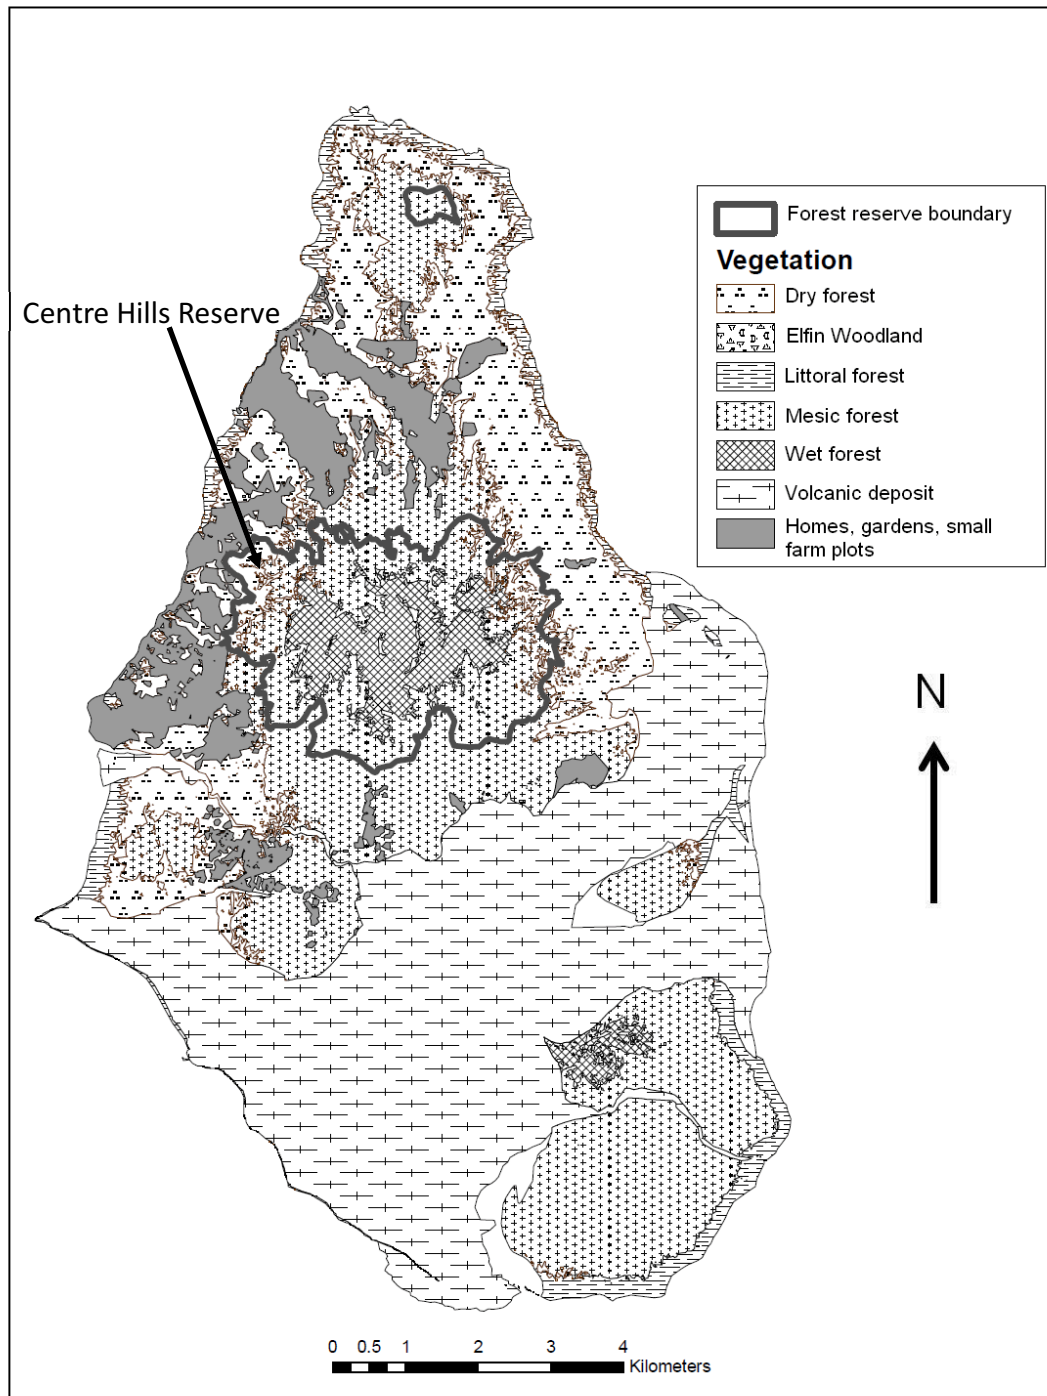

3. Would your answer to Q1 change if there is no additional income from DOE hunting trips? If yes, what is the estimated amount of meat you would have collected for the past six months? \*\*

Answer: \_\_\_\_\_

\*\* Question for the Department of Environment hunters only

Figure 1

**Table 1.** Estimates of carbon stored in live above-ground biomass (tree  $\geq 10$  cm diameter in breast height), below-ground biomass, litter, dead wood and soil of various habitat types in the current state (A; feral livestock control) and the most plausible alternative state (B; no feral livestock control) of the Centre Hills reserve. The above-ground carbon storage in living biomass for wet forest, mesic forest, dry forest, Java plum stand and guava stand were measured using data collected on site. The estimates of carbon stocks in the above-ground biomass of elfin woodland and soil were drawn from the IPCC (2006) tier 1 database. The estimates of below-ground biomass carbon stocks for all habitats were calculated using habitat-specific below-ground biomass to above-ground biomass ratios (CF) (IPCC 2006). The estimates of carbon stock for litter and dead wood were taken from Anderson-Teixeira and Delucia (2010).

#### A. Control

Habitat type	Area (ha)	Above-ground C		Below-ground C		Litter C		Dead wood C		Soil C		Total*
		Mg (Mg/ha)	Mg	CF	Mg	Mg (Mg/ha)	Mg	Mg (Mg/ha)	Mg	Mg (Mg/ha)	Mg	
Wet forest	381	106.3	40500.3	0.37	14985.1	10	3810	20	7620	130	49530	116445 (53021-179870)
Mesic forest	635	186.1	118173.5	0.24	28361.6	10	6350	20	12700	70	44450	210035 (127216-292854)
Dry forest	102	40.4	4120.8	0.28	1153.8	10	1020	20	2040	50	5100	13435 (4198-22672)
Elfin woodland	8	35.0	280.0	0.40	112.0	6	48	0	0	80	640	1080 (422-1738)
<b>Total</b>	<b>1126**</b>		<b>163074.6</b>		<b>44612.5</b>		<b>11228</b>		<b>22360</b>		<b>99720</b>	<b>340995 (184856-497134)</b>

\* Totals figures are rounded to nearest integer and are mean and, in parentheses, the potential range (maximum-minimum). Errors vary between carbon stocks. For soil, the IPCC guidelines suggest a nominal error of  $\pm 90\%$ . No errors are given for litter or dead wood, so we assume 90%. As stated in the methods, above-ground carbon (and hence below ground carbon) is calculated to a precision of 10%

\*\* Of the total reserve area of 1130ha, 4 ha are small water bodies.

#### B. No control

Habitat type	Area (ha)	Above-ground C		Below-ground C		Litter C		Dead wood C		Soil C		Total
		Mg (Mg/ha)	Mg	CF	Mg	Mg (Mg/ha)	Mg	Mg (Mg/ha)	Mg	Mg (Mg/ha)	Mg	
Java plum forest	1024	134.9	138137.6	0.20	27627.5	10	10240	20	20480	Varies	94620	291105 (140757-488420)
Guava forest	102	18.8	1917.6	0.56	1073.9	10	1020	20	2040	50	5100	11151 (2744-18830)
<b>Total</b>	<b>1126</b>		<b>140055.2</b>		<b>28701.4</b>		<b>11260</b>		<b>22520</b>		<b>99720</b>	<b>302257 (143502-507250)</b>

**Table 2.** Net values of all services (for which economic values were available) resulting from continuation of Montserrat's invasive alien mammal control programme.

	Control	No control	Difference
<b>Service (flow) (\$ yr<sup>-1</sup>)</b>			
Nature-based tourism	419,049	227,509	191,540
Harvested wild meat	204,834	131,844	72,990
Feral livestock management cost	-50,410		-50,410
<b>Net annual benefit</b>	<b>573,473</b>	<b>359,353</b>	<b>214,120</b>
<b>Net annual benefit per hectare</b>	<b>507</b>	<b>318</b>	<b>189</b>

**Table 3.** (a) The estimated total value (US\$ per year) under the current state (feral livestock control) and the most plausible alternative state (no feral livestock control), assuming meat collected during the official DOE trips would have received the market price. The prices of the wild meat are: pig, US\$3.33/lb; goat: US\$2.78/lb; sheep: US\$2.78/lb; and cattle: US\$2.04/lb. (b) Capital costs associated with hunting of 15 hunters. (c) Summary. CH = DOE hunter in Centre Hills, EZ = DOE hunter in exclusion zone. DOE = DOE hunter on private trip, Non-DOE = non-DOE hunter on private trip. Cutting fee based on a charge of US\$ 0.19 lb/yr.

(a)

	Control				No control	
	Official DOE hunting trip		Private hunting trip in CH			
	CH	EZ	DOE	Non-DOE	DOE	Non-DOE
Pig	0	1279	4218	26640	41958	26640
Goat	12619	28950	1390	0	4170	0
Sheep	427	2075	463	0	1390	0
Cattle	0	79432	4216	65280	6936	65280
Total	13046	111736	10287	91920	54454	91920

(b)

Capital Cost (US\$/yr)	Control	No control
Cutting fee	18366	10741
Dog	750	750
Dog maintenance	2639	2639
Machete	400	400
Total	22155	14530

(c)

	CH	EZ	Total	Total minus capital costs
Control	115253	111736	226989	204834
No control	146374	0	146374	131844

**Table 4.** Magnitude of change in delivery of different services in the alternative state (cessation of invasive alien mammal control), shown for beneficiaries at the local (Montserratian only), national (includes new immigrants from nearby islands) and global scale (includes foreign investors who owned the restaurants and hotels on the island). “↓” indicates decrease, “=” indicates no change and number of symbols indicates relative magnitude of change. Categories of level of confidence are based on the classification scheme provided in Peh et al. (2013a).

Ecosystem service	Location of beneficiaries			Level of confidence
	Local	National	Global	
<i>Change in annual flows</i>				
Greenhouse gas sequestration	=	=	=	Medium
Nature-based tourism	=	=	↓↓	Medium
Harvested wild Meat	↓	=	=	Low
Water provision	=	=	=	Low
<i>Change in stock</i>				
Carbon storage	=	=	↓	Low
