2008

Introduction

Previous work

Our  
contribution

## Regular encryption

- Encryption:

$m$  – message

$$c = \text{Enc}(m, r)$$

- Decryption:

$$m = \text{Dec}(c)$$

# Coercion in regular encryption scheme

SOFSEM  
2008

Introduction

Our  
contribution

## In case of coercion one can ...

- refuse presenting the key (key is lost or forgotten)
- reveal a fake parameters  $r'$  instead  $r$ , such that  $Enc(m, r) = Enc(m_f, r')$  and  $m_f$  is “legal”.

# Idea of the solution due to Canetti et al.

## Translucent set

Family  $\mathcal{S}_t$  is called *translucent set* if

- $\mathcal{S}_t \subset \{0, 1\}^t$  and  $|\mathcal{S}_t| < 2^{t-k}$ , for sufficiently large  $k(t)$ .
- It is easy to find random element  $x \in \mathcal{S}_t$
- Given  $x \in \{0, 1\}^t$  and trapdoor information  $d$  it is easy to check if  $x \in \mathcal{S}_t$
- Without  $d$  it is not computationally feasible to decide if  $x \in \mathcal{S}_t$

## Translucent set: construction

$f$ - one way permutation,  $B$  – hard core-predicate

$$\mathcal{S}_t = \{x = x_0 || b_1 || \dots || b_k \in \{0, 1\}^{s+k} \mid (\forall_{i \leq k}) B(f^{-i}(x_0) = b_i)\}$$

## Encryption

### Encryption:

- $S \in S_t, R$  – randomly chosen from  $\{0, 1\}^t$
- To encrypt 0 (resp. 1) odd (resp. even) number  $i \in 1 \dots n$  is chosen.
- Ciphertext of single bit consist of  $i$   $S$ -elements followed by  $n - i$   $R$ -elements.

**Decryption:** Parity of  $S$ -elements points if the ciphertext encodes 1 or 0.

# Scheme of Canetti al.

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Opening single bit

**Honest Opening:** The Sender reveals the real random choices used during encoding.

**Dishonest Opening:** Parity is changed - single  $S$ -element is claimed to be randomly chosen  $R$ .

# Scheme of Canetti al.

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Opening single bit

**Honest Opening:** The Sender reveals the real random choices used during encoding.

**Dishonest Opening:** Parity is changed - single  $S$ -element is claimed to be randomly chosen  $R$ .

- Scheme provides sender-deniability
- More effective modifications of the basic scheme were presented

# Nested construction based on Canetti et al.'s protocol

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Motivation

- Coercer knows that the deniable encryption scheme is used. So the coercer can demand the “true” message.
- Idea: to reveal faked  $m_f$ , on the second demand reveal also “slightly banned”  $m'_f$ , but the real message  $m$  is hidden in a deeper layer.

# Nested construction

SOFSEM  
2008

Introduction

Our  
contribution

## Nested translucent sets

Let  $t = s + 2k$ . Represent each  $x \in \{0, 1\}^{t+2k}$  as

$$x = x_0 || b_1^* || \dots || b_k^* || b_1 || \dots || b_k,$$

where  $x_0 \in \{0, 1\}^s$  is followed by  $2k$  bits. Then we define translucent sets as:

$$\mathcal{S}_t^* = \{x = x_0 || b_1^* || \dots || b_k^* || b_1 || \dots || b_k | (\forall_i \leq k) B(f^{*-1}(x_0) = b_i^*)\}$$

and

$$\mathcal{S}_t = \{x_0 || b_1^* \dots || b_k^* || b_1 || \dots || b_k | (\forall_i \leq k) B(f^{-1}(x_0 || b_1^* \dots || b_k^*) = b_i)\}$$

## Russian dolls - like encryption

- at the price of bandwidth of the information channel we can embedded more than two layers of deniability,
- hierarchy of “banned” messages- coercer does not know where the bottom is.

# Postponed One-Time Pad

SOFSEM  
2008

Introduction

Previous work

contribution

## Outline

- shared key, provides sender (sender-and-receiver) deniability
- very efficient (size of the ciphertext, computational complexity)
- on principle, can be built on the top of any encryption scheme
- allows to deny  $d$  consecutive encrypted message

# Postponed One-Time Pad, basic version

contribution

## Preliminaries

Global parameters:

- $\mathfrak{K} = \mathbb{F}_{2^{128}}$
- $E : \mathfrak{K} \rightarrow \mathfrak{K}$ , encryption scheme
- $a_1, a_2, F(a_1)$  global parameters from  $\mathfrak{K}$

Secret information shared by the sender and the receiver:

- $R : \mathfrak{K} \rightarrow \mathfrak{K}$ , random polynomial
- $b \in \mathfrak{K}$

# Postponed One-Time Pad, basic version

2008

Introduction

Previous work

Our  
contribution

## Encryption

In order to send message  $m_i$  sender computes:

- 1  $E(m_i)$  - regular ciphertext of  $m_i$ ,
- 2  $b := R(b)$ ,
- 3  $F_i$  – straight line determined by  $(a_1, F(a_1)), (b, E(m))$ ,
- 4 the ciphertext  $F_i(a_2)$  is sent to the receiver.

# Postponed One-Time Pad, basic version

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Encryption

In order to send message  $m_i$  sender computes:

- 1  $E(m_i)$  - regular ciphertext of  $m_i$ ,
- 2  $b := R(b)$ ,
- 3  $F_i$  – straight line determined by  $(a_1, F(a_1))$ ,  $(b, E(m))$ ,
- 4 the ciphertext  $F_i(a_2)$  is sent to the receiver.

## Decryption

Since the receiver can get actual value of  $b$ , he can find  $F_i(b)$  and then  $m_i = E^{-1}(F(b))$

## Dishonest opening -idea

For any set  $d$  of messages  $m_{f,1}, m_{f,2}, \dots, m_{f,d}$  it is easy to reconstruct a polynomial  $R_f$  such that gives results that are coherent with previously sent values and decryption procedure gives  $m_{f,1}, m_{f,2}, \dots, m_{f,d}$ .

## Dishonest opening -idea

For any set  $d$  of messages  $m_{f,1}, m_{f,2}, \dots, m_{f,d}$  it is easy to reconstruct a polynomial  $R_f$  such that gives results that are coherent with previously sent values and decryption procedure gives  $m_{f,1}, m_{f,2}, \dots, m_{f,d}$ .

Details of this scheme are described in the paper

# ElGamal -based deniable encryption

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Idea

- Scheme perfectly mimics regular ElGamal encryption scheme.
- Sender and receiver share a secret key of regular ElGamal scheme.
- Fake message  $m_f$  must be fixed in advance.
- Board band subliminal channel

# ElGamal -based deniable encryption

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Idea

- Scheme perfectly mimics regular ElGamal encryption scheme.
- Sender and receiver share a secret key of regular ElGamal scheme.
- Fake message  $m_f$  must be fixed in advance.
- Board band subliminal channel

## Preliminaries

- Public parameters –  $0 < x < p - 1$  is a private key, public key is  $y = g^x$ .
- Sender and receiver share a secret  $s$  and the receiver reveals his secret key  $x$  to the sender.

# ElGamal -based deniable encryption

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Encryption

- $k = \text{HASH}(s || m_f)$  is computed

$$\alpha := g^k \cdot m,$$

$$\beta := (y^k \cdot m^x) \cdot m_f.$$

# ElGamal -based deniable encryption

SOFSEM  
2008

Introduction

Previous work

Our  
contribution

## Decryption

Having  $s$  and  $x$  one can easily retrieve  $m$

$$\frac{\beta}{\alpha^x} = \frac{y^k \cdot m^x \cdot m_f}{g^{kx} \cdot m^x} = m_f .$$

$$k \quad \quad \quad := \quad \quad \quad \text{HASH}(s || m_f)$$

$$m \quad \quad \quad := \quad \quad \quad \beta(g)^{-k}$$

## Faked decryption

Receiver can reveal  $x$ . The attacker can check that this message is in fact a regular, valid ElGamal encryption of the message  $m_f$
