SUMMARY

The predicted pitching moment characteristics of the X-29A aircraft are presented for angles of attack from 0 to 20° and Mach numbers of 0.2, 0.6, 0.9, 1.2, and 1.5 for altitudes of sea level, 4572 m (15,000 ft), 9144 m (30,000 ft), and 12,192 m (40,000 ft). These data are for both rigid and flexible aircraft and for the full range of control-surface positions. The characteristics were extracted from a nonlinear, symmetric, flexibilized wind tunnel data base.

INTRODUCTION

The X-29A is a single-seat fighter-type research aircraft powered by a single General Electric F404-GE-400 engine and is designed to fly to supersonic speeds. The X-29A was constructed with parts from many existing aircraft in an effort to reduce cost. An F-5A forward fuselage, an F-16 main landing gear, and F-16 flight control actuators were incorporated into the X-29A aircraft.

The X-29A aircraft is a radical design that incorporates several emerging and unproven technologies. Thick composite wing covers on a thin supercritical forward-swept wing with aeroelastic tailoring are used to control structural divergence. The aircraft is approximately 35 percent statically unstable longitudinally and is controllable by a digital fly-by-wire flight control system.

The predicted pitching moment characteristics of the X-29A aircraft are presented for angles of attack from 0 to 20°, and Mach numbers of 0.2 at sea level, 0.6 at 4572 m (15,000 ft), 0.9 and 1.2 at 9144 m (30,000 ft), and 1.5 at 12,192 m (40,000 ft). These data are for both rigid and flexible aircraft over the full range of control-surface positions. The characteristics were extracted from a nonlinear, symmetric, flexibilized wind tunnel data base given in reference 1. The original wind tunnel data may be found in reference 2.

A brief description of the aircraft is presented in the appendix. An overview of the X-29A flight research program is given in reference 3.

This report presents the flexible and rigid pitching moment characteristics of the X-29A aircraft and is a summary update of reference 4. It is an important source of information due to the highly statically unstable configuration of the aircraft.

NOMENCLATURE

CL	lift coefficient
CM	pitching moment coefficient
CM-DF F/R	flexible/rigid ratio of the pitching moment due to wing flap deflection
DC	canard position, trailing-edge down, positive, deg

DF wing flap position, trailing-edge down, positive, deg
DS strake flap position, trailing-edge down, positive, deg
H pressure altitude, m (ft)

DISCUSSION AND RESULTS

The predicted pitching moment characteristics presented were calculated for a center-of-gravity position of fuselage station 11.46 m (451.0 in), waterline 1.64 m (64.6 in). The angle of attack was varied from 0° to 20° in 4° increments to attain the desired variation in lift coefficient. Lateral control surface positions and sideslip angle were zero. The data were calculated for both flexible and rigid aircraft (figs. 1 to 10).

Mach Effects

At lower Mach numbers, the aircraft displays a high degree of static pitch instability, nominally 35 percent. At supersonic speeds, the aerodynamic center moves aft until the aircraft becomes statically stable near Mach 1.5. This is because the aircraft center of pressure shifts with increasing Mach, which results in increased static pitch stability.

Above Mach 1.3, the aerodynamic data base is linearly extrapolated from wind tunnel data.

Flexibility Effects

Flexibility effects are known to be a function of dynamic pressure and angle of attack. Rigid data presented are referenced to zero dynamic pressure. There appears to be a reduction in lift coefficient due to flexibility at low altitudes and Mach numbers, and an increase at higher altitudes and Mach numbers. There is a slight overall increase in pitching moment. From the specific altitudes and Mach numbers, dynamic pressure effects can be inferred. There is a slight overall increase (destabilizing) in pitching moment coefficient due to flexibility. These characteristics are shown by a slight increase in pitching moment, with a small reduction in lift.

Canard Control Effectiveness

Figures 1(a) to 2(e) show the effect of canard position with varying lift coefficient (angle of attack) on the predicted flexible and rigid longitudinal static stability.

In figure 1(a), canard flow separation is seen as a reduction in canard pitching moment contribution at low altitude and at Mach 0.2. This occurs when the canard

local angle of attack (excluding upwash effects) is in excess of 20° and less than -30° . The net effect is that the aircraft approaches neutral static stability at these conditions. As shown in figures 1(b) and 1(c), canard separation occurs at reduced local angles of attack as Mach number increases to 0.6 and 0.9. This effect is characteristic of thin, sharp leading-edge, low aspect-ratio airfoils (similar to an F-104 wing). Loss of lift and canard control effectiveness is attributed to canard flow separation occurring at relatively low local angles of attack, which in turn causes a net increase in static pitch stability.

As shown in figure 2(c), flexible and rigid canard effectiveness is constant at Mach 0.9 for negative canard deflections beginning at -30° due to a constant flexible canard increment below Mach 1.05. This results in identical data for the -30° and -60° canard deflections. Because of a linear flexible canard increment beginning at Mach 1.05, rigid canard effectiveness is constant at Mach 1.2 for negative canard deflections beginning at -20° and positive deflections beginning at 10° . As shown in figure 2(d), this results in identical data for the -20° , -30° , and -60° canard deflections and identical data for the 10 and 30° canard deflections. Comparisons of figures 1 and 2 show little flexibility effect on canard control effectiveness.

Flap Control Effectiveness

Figures 3(a) to 8(e) show the effect of flap position with varying lift coefficient (angle of attack), at 20° , 0° , and -20° canard deflection, on the predicted flexible and rigid longitudinal static stability.

Flap control effectiveness is a function of flap deflection and angle of attack. A slight reduction in the lift coefficient and pitching moment contribution with positive flap deflection is seen at lower angles of attack. At higher angles of attack, there is a greater reduction in flap control effectiveness. The pitching moment producing capability of the flap is approximately 50 percent of the canard capability.

Variation in flap position has an effect on static pitch stability at higher angles of attack. An apparent increase in upwash with positive flap deflection at Mach 0.6 and 0.9 enhances canard flow separation, thereby increasing static stability. A reduction in the canard local angle of attack delays the flap-induced canard flow separation.

Flexibility effects are known to be a function of dynamic pressure and flap deflection. Comparisons of the rigid and flexible coefficients illustrate the small effect of flexibility on flap effectiveness at low altitude and Mach number conditions corresponding to low dynamic pressure. At higher Mach number conditions (higher corresponding dynamic pressures), flexibility effects become stronger except at higher flap deflections where the effects are not modeled. As shown in figure 11, this causes a reduction in flap control effectiveness.

Strake Control Effectiveness

Figures 9(a) to 10(e) show the effect of strake position with varying lift coefficient (angle of attack) on the predicted flexible and rigid longitudinal static

stability. The strake pitch control effectiveness is less than the canard or the flap, but it appears to be very nearly linear to 20° angle of attack with little variation due to flexibility. Variation in strake position seems to have minimal effect on static pitch stability.

CONCLUDING REMARKS

At low Mach numbers, the aircraft is approximately 35 percent statically unstable. The aircraft becomes slightly stable near Mach 1.5. This is because the aircraft center of pressure shifts aft with increasing Mach, which results in increased static pitch stability.

Flexibility effects were inferred to be a function of dynamic pressure and angle of attack. These characteristics are shown by a slight increase in pitching moment, with a small reduction in lift. Canard and strake control-surface effectiveness does not appear to be sensitive to flexibility, but flap effectiveness is reduced slightly.

The canard is the most powerful pitch control surface with almost twice the pitching moment producing capability of the flap. The strake is the least effective pitch control surface but maintains a nearly linear control effectiveness beyond 20° angle of attack. The flap is the most effective lifting surface, followed by the canard and the strake.

The canard is sensitive to changes in local angle of attack due to the thin surface and the sharp leading edge combined with a low aspect ratio. Loss of lift and canard control effectiveness is attributed to canard flow separation that occurs at relatively low local angles of attack causing a net increase in static pitch stability.

Static pitch stability appears to be a function of flap position at higher angles of attack. This may be due to a flap-induced canard stall or a canard-influenced wingtip stall. Reducing the canard local angle of attack tends to delay the change in pitch stability.

APPENDIX — AIRCRAFT DESCRIPTION

The X-29A is a single-seat fighter-type aircraft (figs. 12 and 13) with a closely coupled canard immediately ahead of a thin supercritical forward-swept wing. The wing leading edge is fixed, with full-span variable camber trailing-edge flaperons (fig. 14) to maximize the lift/drag ratio and to provide lateral control. An aft-body strake flap provides the aircraft with three-surface longitudinal control. Additional physical characteristics are presented in table 1.

15. Supplementary Notes					
16. Abstract <p style="text-align: center;">The predicted pitching moment characteristics of the X-29A aircraft are presented for angles of attack from 0 to 20° and Mach numbers of 0.2, 0.6, 0.9, 1.2, and 1.5 for altitudes of sea level, 4572 m (15,000 ft), 9144 m (30,000 ft), and 12,192 m (40,000 ft). These data are for both rigid and flexible aircraft and for the full range of control-surface positions. The characteristics were extracted from a non-linear, symmetric, flexibilized wind tunnel data base.</p>
