

Pricing American Perpetual Warrants by Linear Programming*

Robert J. Vanderbei[†]
Mustafa Ç. Pinar[‡]

Abstract. A warrant is an option that entitles the holder to purchase shares of a common stock at some prespecified price during a specified interval. The problem of pricing a perpetual warrant (with no specified interval) of the American type (that can be exercised any time) is one of the earliest contingent claim pricing problems in mathematical economics. The problem was first solved by Samuelson and McKean in 1965 under the assumption of a geometric Brownian motion of the stock price process. It is a well-documented exercise in stochastic processes and continuous-time finance curricula. The present paper offers a solution to this time-honored problem from an optimization point of view using linear programming duality under a simple random walk assumption for the stock price process, thus enabling a classroom exposition of the problem in graduate courses on linear programming without assuming a background in stochastic processes.

Key words. pricing, perpetual warrant, American option, linear programming, duality, dynamic programming, harmonic functions, second-order difference equations

I. Introduction. A *warrant* is an option that entitles the holder to buy shares of a common stock at some prespecified price (referred to as the “exercise price”) during a specified interval. A *perpetual warrant* is a warrant that does not have an expiration date. An *American perpetual warrant* (which can also be called a perpetual American option) can be exercised at any time. The problem of pricing an American perpetual warrant is to determine the fair price that an investor should be willing to pay to acquire it. It is a fundamental problem in the fields of financial economics and mathematical finance. The explicit solution for the pricing of warrants was given by McKean (in the appendix of [12]) under the assumption of a geometric Brownian motion model for the stock price process, upon a question posed by Samuelson [12] in 1965. A textbook coverage of the solution is given in *An Introduction to Stochastic Processes* by Kao [10], in Example 7.1.3, which is in turn based on Karlin and Taylor

[11]. Chen [3] gives a solution for finite-time warrants. A recent account of the subject along with developments after 1965 can be found in [13].

In this note, we offer a solution based on linear programming duality, after assuming that the stock price behaves as a simple random walk. The purpose is to offer yet another application where the well-developed machinery of linear programming can be brought to bear upon a time-honored problem of financial economics in a classroom setting which does not require a background in stochastic calculus and continuous-time finance. On the other hand, the paper can also serve researchers in optimization and mathematical programming seeking an introduction to the field of mathematical finance. Another interesting feature of the solution methodology is the connection to the theory of harmonic functions as treated in the excellent book by Dynkin and Yushkevich [6]. On several occasions, concepts familiar to the student of harmonic functions appear in simple forms in our elementary analysis where we try to refer the reader each time to an appropriate source.

Let X_n denote the share price of the stock at a time n periods into the future. Obviously, X_n is a random variable, and the collection of these random variables over time is a stochastic process. Let us assume that X_n is a random walk with absorption at 0 on the state space $E = \{j\Delta x : j = 0, 1, 2, \dots\}$, where Δx is a fixed small positive real number. That is, if the current stock price is $x \in E$, then the price at the next period will be either $x + \Delta x$ or $x - \Delta x$ with probabilities p and $q = 1 - p$, respectively. This model of stock price movements is close to reality in that stock prices usually move by small amounts over sufficiently short periods of time.

In order to figure out how to price the warrant, one must answer the question, what is the expected value, in today's dollars, of the warrant? Naturally, the seller of the warrant should assume that the buyer will employ an optimal strategy for exercising the warrant. If at some future date, the stock price X_n is larger than the exercise price S , then the holder of the warrant can buy the stock for S dollars and immediately sell it for X_n dollars and realize a gain of $X_n - S$ dollars. Hence, the payoff at time n of the warrant is $h(X_n) = X_n - S$. If the warrant holder exercises the option at some time τ (possibly random, but not clairvoyant), then the expected present value would be

$$\mathbb{E}_x \alpha^\tau h(X_\tau).$$

Here we have introduced a *discount factor* α (a number slightly less than one). This discount factor accounts for the fact that future dollars are worth less than present dollars. Specifically, α gives today's value of tomorrow's dollar. The optimal strategy is then determined by maximizing over all nonclairvoyant random times τ :

$$v(x) = \max_{\tau} \mathbb{E}_x \alpha^\tau h(X_\tau).$$

The function v is called the *value function*. It tells both the buyer and the seller of the warrant everything they need to know. To the seller, the "fair" price for the warrant is $v(x)$ if the current stock price is x . Since zero payoff can be obtained with the strategy $\tau = +\infty$, the function v is nonnegative.

In each period, the holder of the warrant observes the current price x of the stock and decides either to exercise the warrant or to keep the warrant for one more period. The optimal choice between exercising the warrant and holding it for one more period depends on the relative magnitudes of the payoff $h(x)$ and the expected warrant value one time step ahead, i.e., $\alpha(pv(x + \Delta x) + qv(x - \Delta x))$. By "the principle of dynamic

programming”¹ $v(x)$ must satisfy the equation

$$v(x) = \max\{h(x), \alpha(pv(x + \Delta x) + qv(x - \Delta x))\}$$

for all $x \in E \setminus \{0\}$, and the boundary condition $v(0) = 0$. This equation characterizes the optimal strategy for the buyer of the warrant. The state space can be partitioned into two sets: the set of states x where $v(x) > h(x)$ and those where $v(x) = h(x)$. The first set is called the “continuation region” and the second the “exercise region” [5]. The buyer should not exercise the option at times n when X_n is in the continuation region, that is, when $v(X_n) > h(X_n)$. In fact, the buyer should exercise the warrant as soon as $v(X_n) = h(X_n)$.

Based on the implicit equation above, it is shown in probability courses (see, e.g., [6, Chapter 3, pp. 106–107] or [4, Chapter 7, pp. 212–213]) that v can be uniquely characterized as the smallest (in the L^1 sense) function that satisfies these inequalities:

$$\begin{aligned} v(x) &\geq 0, & x \in E, \\ v(x) &\geq h(x), & x \in E, \\ v(x) &\geq \alpha(pv(x + \Delta x) + qv(x - \Delta x)), & x \in E \setminus \{0\}. \end{aligned}$$

Clearly, when the price of the stock price x is less than S there is no incentive to exercise the option—the warrant holder would lose money needlessly. Hence, we can redefine the warrant payoff function as $f(x) = (x - S)^+$ and replace the first two set of inequalities above by the single set of inequalities $v(x) \geq f(x)$ for all $x \in E$. Recalling the discreteness of our model’s state space, we can formulate an infinite-dimensional linear programming problem

$$\begin{aligned} \text{minimize} \quad & \sum_{j=0}^{\infty} v_j \\ \text{subject to} \quad & v_j \geq f_j, & j = 0, 1, 2, \dots, \\ & v_j \geq \alpha(pv_{j+1} + qv_{j-1}), & j = 1, 2, \dots, \end{aligned}$$

where $x_j = j\Delta x$, $v_j = v(x_j)$, and $f_j = f(x_j)$.

Let v_j^* , $j = 0, 1, \dots$, denote the optimal solution to this linear programming problem. Figure 1 gives an illustration of $v^*(x)$ and $f(x)$ corresponding to the case where $\alpha = 0.999$, $p = 0.5$, $\Delta x = 0.1$, and $S = 9$. From the original real-world description of the problem and Figure 1, it appears that the optimal strategy for exercising the warrant would be not to exercise when the stock price is below some threshold and then exercise as soon as the stock price hits the threshold value. In other words, it seems reasonable to conjecture that under some mild assumptions which we shall list below

¹The principle of dynamic programming, a.k.a. the principle of optimality, states, “An optimal policy has the property that whatever the initial state and the initial decision are, the remaining decision must constitute an optimal policy with regard to the state resulting from the initial decision.” See Bellman and Dreyfus [1].

Fig. 1 Plot of $v^*(x)$ and $f(x)$ corresponding to the case where $\alpha = 0.999$, $p = 0.50$, $\Delta x = 0.1$, and $S = 9$. In this case, $j^* = 112$ and therefore $x_{j^*} = 11.2$.

there exists an optimal solution with the structure

$$\begin{aligned} v_0^* &= f_0, \\ v_j^* &= \alpha(pv_{j+1}^* + qv_{j-1}^*) > f_j, & 0 < j < j^*, \\ v_j^* &= f_j > \alpha(pv_{j+1}^* + qv_{j-1}^*), & j^* \leq j, \end{aligned}$$

for some appropriately chosen j^* .

Our guess is indeed correct. Indeed, if we let

$$\xi_- = \frac{-1 - \sqrt{1 - 4\alpha^2 pq}}{-2\alpha p}, \quad \xi_+ = \frac{-1 + \sqrt{1 - 4\alpha^2 pq}}{-2\alpha p}$$

and assume that

1. $\alpha p \leq 1/2$ and $\alpha q \leq 1/2$,
2. $S = j_S \Delta x$ for some integer j_S , and
3. $f_{j_S+1}(\xi_+^{j_S} - \xi_-^{j_S}) / (\xi_+^{j_S+1} - \xi_-^{j_S+1}) > f_{j_S}$,

we can then give a closed-form formula for j^* and the optimal values of v_j :

$$(1.1) \quad j^* = \max \left\{ k : f_k \frac{\xi_+^{k-1} - \xi_-^{k-1}}{\xi_+^k - \xi_-^k} > f_{k-1} \right\},$$

$$(1.2) \quad v_j = \begin{cases} 0, & j = 0, \\ f_{j^*} \frac{\xi_+^j - \xi_-^j}{\xi_+^{j^*} - \xi_-^{j^*}}, & 0 < j < j^*, \\ f_j, & j^* \leq j. \end{cases}$$

In the problem instance of Figure 1, the optimal choice of j^* is 112. In Figures 2 and 3, we show the consequences of choosing j^* too small or too large for the same problem

Fig. 2 Plot of $v'(j)$, $v^*(j)$, and $f(j)$ when $j' = 102$ and $j^* = 112$.

instance. Suppose we were unable to correctly determine the optimal exercise point j^* . That is, we assume that j' determines the boundary continuation and exercise regions but that $j' \neq j^*$. In this case, the expected payoff $v'(j)$ is given by

$$v'(j) = \begin{cases} 0, & j = 0, \\ f_{j'} \frac{\xi_+^j - \xi_-^j}{\xi_+^{j'} - \xi_-^{j'}}, & 0 < j < j', \\ f_j, & j' \leq j. \end{cases}$$

If we set $j' = 102$, then we obtain the plot shown in Figure 2. When we set $j' = 122$ the resulting plot is as shown in Figure 3. In both cases the v -curves are below the optimal v -curve obtained with the optimal choice j^* . In the first case, the v values violate some of the inequalities $v_j \geq \alpha(pv_{j+1} + qv_{j-1})$, and in the second case, some of the inequalities $v_j \geq f_j$ are violated. In the case of Figure 2, the holder of the option erroneously underestimates the value of the warrant. This underestimation leads to an exercise of the warrant at a share price where it is in fact still advantageous to defer exercise. In the case of Figure 3, the incorrect valuation induces the holder to defer exercise at stock prices where it is in fact optimal to exercise, thereby foregoing income that could earn risk-free interest during the delay.

A function v^* defined on $0 < j < j^*$ satisfying $v_j^* = \alpha(pv_{j+1}^* + qv_{j-1}^*)$ is known as an α -harmonic function. A function v^* defined for all $j \geq j^*$ and satisfying $v_j^* > \alpha(pv_{j+1}^* + qv_{j-1}^*)$ is called an α -superharmonic function. For such definitions, the reader is directed to the opening chapter of [6].

Fig. 3 Plot of $v'(j)$, $v^*(j)$, and $f(j)$ when $j' = 122$ and $j^* = 112$.

In the rest of this paper, we shall give a step-by-step derivation of the closed-form formulae (1.1)–(1.2) and demonstrate the correctness of our guess at the solution using linear programming duality and elementary techniques for the solution of second-order difference (differential) equations. For a review of the fundamental results of linear programming, our desktop reference is the textbook [14]. For a coverage of difference equations that is suitable for our purposes, the reader can consult [9].

The plan is as follows. We first lay out the primal and dual linear programming problems, and use the complementary slackness property of optimal solutions to linear programs to simplify the claimed form of the equations leading to an optimal solution into a pair of second-order difference equations. We compute solutions to these second-order difference equations and show how these solutions satisfy various inequalities defining the primal and dual problems. Along the way, we discover the few mild assumptions that need to be made for our guess to be correct.

2. Primal Problem. Let us restate the primal linear programming problem:

$$\begin{aligned}
 & \text{minimize} && \sum_{j=0}^{\infty} v_j \\
 & \text{subject to} && v_j \geq f_j, && j \geq 0, \\
 & && v_j \geq \alpha(pv_{j+1} + qv_{j-1}), && j \geq 1.
 \end{aligned}$$

3. Dual Problem. Duality theory plays a fundamental role in linear programming. The basic idea is that associated with every linear programming problem, there is another linear programming problem, which is called the dual to the first problem (and therefore the first problem is called the primal). The two most important results are the so-called weak and strong duality theorems. The *weak duality theorem* says that

for any set of values for the dual problem that satisfy the constraints of the dual problem, the value of the dual objective function evaluated with those values provides a (lower) bound on the optimal value to the primal problem.

The *strong duality theorem* goes further and says that

the optimal value of the dual objective function equals the optimal value of the primal objective function.

One of the corollaries of the strong duality theorem gives us a so-called *certificate of optimality*. This corollary says that

if one can exhibit values for the primal problem that satisfy the primal constraints and values for the dual problem that satisfy the dual constraints and if these primal and dual values satisfy an easy-to-check property called complementarity, then the primal values are optimal for the primal problem (and the dual values are optimal for the dual problem).

This corollary is extremely useful in that it reduces an optimization problem to a problem of simply checking that a few conditions are satisfied. This is how we shall use duality in what follows. See Chapter 5 of [2] or Chapter 5 of [14] for details on duality theory.

The dual problem is obtained by the following procedure. First, a Lagrangian function is constructed using a nonnegative Lagrange (or dual) multiplier value for each constraint. The Lagrangian function is then minimized with respect to the primal variables. The resulting function value constitutes a lower bound to the optimal value of the primal problem. Then maximizing this bound over all permissible choices of Lagrange multipliers gives the dual problem.

In our case the dual problem is

$$\begin{aligned}
 &\text{maximize} && \sum_{j=0}^{\infty} f_j y_j \\
 &\text{subject to} && y_0 - \alpha q z_1 = 1, \\
 &&& y_1 + z_1 - \alpha q z_2 = 1, \\
 &&& y_j - \alpha p z_{j-1} + z_j - \alpha q z_{j+1} = 1, \quad j \geq 2, \\
 &&& y_j \geq 0, && j \geq 0, \\
 &&& z_j \geq 0, && j \geq 1.
 \end{aligned}$$

To see that this is correct, we shall derive the dual problem using the aforementioned procedure. Using nonnegative multipliers $y_j, j = 0, 1, \dots$, for the first set of inequalities in the primal problem, and nonnegative multipliers $z_j, j = 1, 2, \dots$, for the second set of inequalities, we obtain the Lagrangian function

$$L(\mathbf{v}, \mathbf{y}, \mathbf{z}) = \sum_{j=0}^{\infty} v_j + \sum_{j=0}^{\infty} y_j (f_j - v_j) + \sum_{j=1}^{\infty} z_j (\alpha p v_{j+1} + \alpha q v_{j-1} - v_j),$$

where we denote the sequences v_j , y_j , and z_j by \mathbf{v} , \mathbf{y} , and \mathbf{z} , respectively. To obtain the dual function, $g(\mathbf{y}, \mathbf{z})$ say, we have to minimize $L(\mathbf{v}, \mathbf{y}, \mathbf{z})$ over the unrestricted variables v_j ; i.e., we have

$$g(\mathbf{y}, \mathbf{z}) = \min_{\mathbf{v}} L(\mathbf{v}, \mathbf{y}, \mathbf{z}).$$

We can rewrite this minimization problem as

$$g(\mathbf{y}, \mathbf{z}) = \sum_{j=0}^{\infty} f_j y_j + \min_{\mathbf{v}} \left\{ \sum_{j=0}^{\infty} y_j (f_j - v_j) + \sum_{j=1}^{\infty} z_j (\alpha p v_{j+1} + \alpha q v_{j-1} - v_j) \right\}.$$

The minimization over each v_j can be performed separately. For v_0 we have

$$\min_{v_0} v_0 (1 - y_0 + \alpha q z_1).$$

Since v_0 is unrestricted, we need to make the term in parentheses zero to obtain a finite minimum (equal to zero), which gives the first equation of the dual problem. Similarly, for v_1 we have

$$\min_{v_1} v_1 (1 - y_1 - z_1 + \alpha q z_2),$$

which yields the second equation of the dual problem. Finally, for v_j , $j \geq 2$, we perform the minimizations again separately to obtain the third set of equations in the dual problem.

4. Statement of Claim. Let v_j denote the optimal primal solution and y_j and z_j the optimal dual solution (i.e., we are dropping the usual “stars” that denote optimality). Suppose, as claimed, that there exists a j^* such that

$$\begin{aligned} v_0 &= f_0, \\ v_j &= \alpha(pv_{j+1} + qv_{j-1}) > f_j && \text{for } 0 < j < j^*, \\ v_j &= f_j > \alpha(pv_{j+1} + qv_{j-1}) && \text{for } j^* \leq j. \end{aligned}$$

Now we are interested in solving the equations

$$(4.1) \quad v_0 = f_0,$$

$$(4.2) \quad v_j = \alpha(pv_{j+1} + qv_{j-1}) \quad \text{for } 0 < j < j^*,$$

$$(4.3) \quad v_j = f_j \quad \text{for } j^* \leq j.$$

5. Invoke Complementarity. Another useful property in linear programming is the complementarity theorem; see, e.g., [14, pp. 67–68]. In our particular case, it states that any optimal solution v_j to the primal problem and any optimal solutions y_j and z_j to the dual problem satisfy

$$(5.1) \quad z_j (\alpha p v_{j+1} + \alpha q v_{j-1} - v_j) = 0, \quad j \geq 1,$$

$$(5.2) \quad y_j (f_j - v_j) = 0, \quad j \geq 0.$$

Hence, complementarity equations (5.1) and (5.2) imply that

$$(5.3) \quad z_j = 0, \quad j \geq j^*,$$

$$(5.4) \quad y_j = 0, \quad 0 < j < j^*.$$

Since any optimal solution to the dual problem is also feasible (i.e., it satisfies all the equations of the dual problem) using (5.3), we have

$$\begin{aligned} y_{j^*} - \alpha p z_{j^*-1} &= 1, \\ y_j &= 1, \quad j > j^*. \end{aligned}$$

Similarly, using (5.4) we obtain

$$\begin{aligned} z_1 - \alpha q z_2 &= 1, \\ -\alpha p z_{j-1} + z_j - \alpha q z_{j+1} &= 1, \quad 1 < j < j^*. \end{aligned}$$

6. Second-Order Difference Equations. The problem of solving (4.1)–(4.3) from the primal problem and the equations defining the dual problem has therefore been reduced to a pair of second-order difference equations with Dirichlet boundary conditions (i.e., boundary conditions that involve a known function) [9]. The first difference equation (for the primal) is

$$(6.1) \quad v_j - \alpha(pv_{j+1} + qv_{j-1}) = 0, \quad 0 < j < j^*,$$

$$(6.2) \quad v_0 = 0,$$

$$(6.3) \quad v_{j^*} = f_{j^*},$$

and the second one (for the dual) is

$$(6.4) \quad z_j - \alpha(pz_{j-1} + qz_{j+1}) = 1, \quad 0 < j < j^*,$$

$$(6.5) \quad z_0 = 0,$$

$$(6.6) \quad z_{j^*} = 0.$$

Note that in (6.2) we used the fact that $f_0 = 0$, and in (6.4) we have added a new variable, z_0 , which is just fixed to zero (by (6.5)). In this way we consolidate the difference equation for z_j to a more elegant form.

7. Solve the Difference Equations. First, we solve (6.1) for v_j . Suppose that $v_j = \xi^j$ for some positive real number ξ . Substituting into the difference equation, we get $\xi^j - \alpha(p\xi^{j+1} + q\xi^{j-1}) = 0$. Dividing by ξ^{j-1} , we get a quadratic equation $-\alpha p \xi^2 + \xi - \alpha q = 0$ with the two roots

$$\xi_- = \frac{-1 - \sqrt{1 - 4\alpha^2 pq}}{-2\alpha p}, \quad \xi_+ = \frac{-1 + \sqrt{1 - 4\alpha^2 pq}}{-2\alpha p},$$

where we used ξ_- to denote the larger root, which is greater than one, and ξ_+ for the smaller root, which is strictly between zero and one (these properties hold if and only if $\alpha < 1$). The general solution to the difference equation is therefore $v_j = c_+ \xi_+^j + c_- \xi_-^j$. Using the first boundary condition (6.2) and the second boundary condition (6.3), we obtain

$$(7.1) \quad v_j = f_{j^*} \frac{\xi_+^j - \xi_-^j}{\xi_+^{j^*} - \xi_-^{j^*}}, \quad 0 < j < j^*.$$

Now, we solve for z_j in (6.4). For a particular solution, we choose $z_j \equiv c$. Substituting into the difference equation, we get $c = 1/(1 - \alpha)$. The general solution, which is the sum of the particular and the homogeneous solutions (the homogeneous equation is identical to (6.1) except for the interchange of p and q), is given by $z_j = \frac{1}{1-\alpha} + c_+\zeta_+^j + c_-\zeta_-^j$, where

$$\zeta_+ = 1/\xi_- = \frac{-1 + \sqrt{1 - 4\alpha^2 pq}}{-2\alpha q},$$

$$\zeta_- = 1/\xi_+ = \frac{-1 - \sqrt{1 - 4\alpha^2 pq}}{-2\alpha q}.$$

Using the boundary conditions to eliminate the two undetermined constants, we get

$$z_j = \left(1 - \frac{\zeta_-^{j^*} - 1}{\zeta_-^{j^*} - \zeta_+^{j^*}} \zeta_+^j - \frac{\zeta_+^{j^*} - 1}{\zeta_+^{j^*} - \zeta_-^{j^*}} \zeta_-^j \right) / (1 - \alpha), \quad 0 < j < j^*.$$

To summarize, we have

$$v_j = \begin{cases} 0, & j = 0, \\ f_{j^*} \frac{\xi_+^j - \xi_-^j}{\xi_+^{j^*} - \xi_-^{j^*}}, & 0 < j < j^*, \\ f_j, & j^* \leq j, \end{cases}$$

$$z_j = \begin{cases} \left(1 - \frac{\zeta_-^{j^*} - 1}{\zeta_-^{j^*} - \zeta_+^{j^*}} \zeta_+^j - \frac{\zeta_+^{j^*} - 1}{\zeta_+^{j^*} - \zeta_-^{j^*}} \zeta_-^j \right) / (1 - \alpha), & 0 < j < j^*, \\ 0, & j^* \leq j, \end{cases}$$

$$y_j = \begin{cases} 1 + \alpha q z_1, & j = 0, \\ 0, & 0 < j < j^*, \\ 1 + \alpha p z_{j^*-1}, & j = j^*, \\ 1, & j^* < j. \end{cases}$$

In Figure 4 we illustrate the behavior of optimal dual variables y and z for the sample problem illustrated by Figure 1.

8. Check the Inequalities. All that remains is to show that the various inequalities are satisfied:

$$(8.1) \quad y_j \geq 0, \quad j \geq 0,$$

$$(8.2) \quad z_j \geq 0, \quad j \geq 1,$$

$$(8.3) \quad v_j \geq f_j, \quad j \geq 0,$$

$$(8.4) \quad v_j \geq \alpha(pv_{j+1} + qv_{j-1}), \quad j \geq 1.$$

8.1. Inequalities (8.2). Inequalities (8.2) follow trivially for $j \geq j^*$ from the formula given above for z_j . To check them for $j < j^*$, we do a proof by contradiction. So, suppose that $z_j < 0$ for some $0 < j < j^*$. Then there exists a k at which z_k is negative and a local minimum:

$$z_k \leq z_{k-1} \quad \text{and} \quad z_k \leq z_{k+1}.$$

Fig. 4 Plot of optimal values of y and z corresponding to the case where $\alpha = 0.999$, $p = 0.5$, $\Delta x = 0.1$, $S = 9$, $j^* = 112$, and $x_{j^*} = 11.2$.

The reasoning leading to this property is as follows. If j itself is the index of a local minimum, there is nothing else to prove. Otherwise, there are two possibilities: we have either $z_{j+1} > z_j > z_{j-1}$ or $z_{j-1} > z_j > z_{j+1}$. In the first case we have either $z_{j-2} \geq z_{j-1}$, in which case z_{j-1} is a local minimum, or $z_{j-2} < z_{j-1}$. If the latter occurs, we can repeat the same argument with the triple $j-3, j-2, j-1$, and we find either z_{j-2} to be a local minimum or $z_{j-3} < z_{j-2} < z_{j-1}$. Continuing in this fashion we are bound to encounter a local minimum either at $z_1 < 0$ (since $z_0 = 0$) or earlier. In the second case, the reasoning is identical and yields a local minimum either at $z_{j^*-1} < 0$ (since $z_{j^*} = 0$) or earlier.

On the other hand, as a consequence of the above observation we also have

$$\begin{aligned} z_k &= 1 + \alpha(pz_{k-1} + qz_{k+1}) \\ &\geq 1 + \alpha(pz_k + qz_k) \\ &= 1 + \alpha z_k. \end{aligned}$$

Rearranging, we get $z_k \geq 1/(1 - \alpha) > 0$, which contradicts the assumption that z_k is negative. Hence, inequalities (8.2) hold for all j . This is a simple example of a *minimum principle* as one encounters in harmonic analysis; see, e.g., [7, 8]. For continuously differentiable functions, the local version of the principle states that any nonconstant harmonic function defined over a domain (in \mathbb{R}^n) not containing $+\infty$ as an interior point cannot attain a local minimum and maximum over the domain in question. Under further technical conditions, according to the global version of the minimum/maximum principle, the largest and the smallest values of a harmonic function on a domain are attained only at the points of the boundary of the domain. For superharmonic functions, which are of interest here since z is an α -superharmonic (discrete) function, the following minimum principle is well known. Let u be a superharmonic function in some domain D in \mathbb{R}^n . If, for any boundary point $\eta \in \partial D$ and

any $\epsilon > 0$, there is a neighborhood $V = V(\eta)$ such that $u(x) > -\epsilon$ in $D \cap V$, then either $u > 0$ or $u \equiv 0$ in D .

In our simpler, discrete setting the above analysis gave an analogue of the minimum principle for an α -superharmonic function z solving (6.4)–(6.6). We have established that the function z is nonnegative for all values of j between 0 and j^* . Furthermore, it is immediate to check that we cannot have a local minimum value equal to zero for $1 < j < j^* - 1$; i.e., $z_j = 0$ with $z_{j-1} > 0$, $z_{j+1} > 0$ is impossible. It is also obvious that z cannot be identically zero. Therefore, the (global) minimum value is zero and attained only at the two boundary points, i.e., $j = 0$ and $j = j^*$, which is also observed in the right plot of Figure 4 (recall that $z_0 = 0$ by (6.5)). In the terminology of [6], z is an instance of an *excessive function*.

8.2. Inequalities (8.1). These follow trivially from inequalities (8.2) and the formula for y_j .

8.3. Inequalities (8.4). These hold trivially for $j < j^*$. They also hold trivially for $j > j^*$, provided we assume that $\alpha p \leq 1/2$ and $\alpha q \leq 1/2$. *We need to make an additional assumption!* To see this, let $j = j^* + k$, $k = 1, 2, \dots$, and assume $\alpha p \leq 1/2$ and $\alpha q \leq 1/2$. Then

$$\begin{aligned} \alpha p v_{j^*+k+1} + \alpha q v_{j^*+k-1} &= \alpha p f_{j^*+k+1} + \alpha q f_{j^*+k-1} \\ &\leq \frac{1}{2} f_{j^*+k+1} + \frac{1}{2} f_{j^*+k-1} \\ &= \frac{1}{2} (f_{j^*} + (k+1)\Delta x) + \frac{1}{2} (f_{j^*} + (k-1)\Delta x) \\ &= f_{j^*} + k\Delta x \\ &= f_{j^*+k} \\ &= v_{j^*+k}. \end{aligned}$$

The one just given suffices but is not necessary (the example of Figure 5 shows that the condition is not necessary). A necessary and sufficient condition is obtained by recalling that $v_j = f_j - S$ for $j > j^*$ (even for this we need to check that $x_{j^*} > S$). It is easy to see after some simple algebraic manipulation that for $j = j^* + k$ and $k = 1, 2, \dots$, we have

$$\alpha p v_{j^*+k+1} + \alpha q v_{j^*+k-1} \leq v_{j^*+k}$$

if and only if

$$(1 - \alpha) f_{j^*} \geq \alpha \Delta x (p - q) + k(\alpha - 1) \Delta x.$$

Since $k(\alpha - 1)\Delta x$ is negative ($\alpha < 1$), the left-hand side is maximized at $k = 1$. Hence, (8.4) holds with $v_j = f_j$ if and only if

$$(8.5) \quad (1 - \alpha) f_{j^*} \geq \alpha \Delta x (p - q) + (\alpha - 1) \Delta x.$$

Since this condition is somewhat more tedious to check (it requires the computation of f_{j^*}) we use the simpler sufficient conditions $\alpha p \leq 1/2$, $\alpha q \leq 1/2$.

We shall come back to inequality (8.4) for $j = j^*$ after we consider inequalities (8.3).

8.4. Inequalities (8.3). For $j \geq j^*$, these are trivial. Furthermore, it follows immediately from (7.1) that $v_j \geq 0$ for all j (note that the roots ξ_+, ξ_- satisfy $\xi_- > 1$ and $0 < \xi_+ < 1$, provided that $\alpha < 1$). Hence, we just need to check that $v_j \geq x_j - S$ for $j < j^*$. In order to have these inequalities hold for $j < j^*$, we need to pick

$$j^* \in K := \left\{ k : f_k \frac{\xi_+^{k-1} - \xi_-^{k-1}}{\xi_+^k - \xi_-^k} > f_{k-1} \right\}.$$

Of course, we need to assume that K is nonempty. Clearly no k for which $x_k < S$ can belong to the set (because both f_k and f_{k-1} vanish). For convenience, then, we assume that $S \in E$ —that is, $S = j_S \Delta x$ for some j_S . In that case, we assume that $k = j_S + 1$ belongs to the set K , i.e.,

$$f_{j_S+1} \frac{\xi_+^{j_S} - \xi_-^{j_S}}{\xi_+^{j_S+1} - \xi_-^{j_S+1}} > f_{j_S}.$$

Notice that K is a set with a finite number of elements. To see this, it suffices to observe that for $k \in K$ we have

$$\frac{\xi_+^{k-1} - \xi_-^{k-1}}{\xi_+^k - \xi_-^{k-1}\xi_-} > \frac{f_{k-1}}{f_k},$$

and hence the left-hand side behaves as $1/\xi_-$ and the right-hand side as 1 for large k , which implies that k cannot grow without bound since $\xi_- > 1$. Let $h_j = x_j - S$. With such a choice and the assumption that $j^* \in K$, we have that $v_{j^*} = h_{j^*}$ and $v_{j^*-1} > h_{j^*-1}$. Suppose that $v_{j'} < h_{j'}$ for some $j' < j^*$. Then the sequence $u_j := v_j - h_j$ must have a local maximum at some point, say k , strictly between j' and j^* . That is, $u_k > u_{k-1}$ and $u_k > u_{k+1}$. However, we also have

$$\begin{aligned} u_k &= v_k - h_k \\ &= \alpha(pv_{k+1} + qv_{k-1}) - \frac{1}{2}(h_{k+1} + h_{k-1}) \\ &\leq \frac{1}{2}(v_{k+1} + v_{k-1}) - \frac{1}{2}(h_{k+1} + h_{k-1}) \\ &= \frac{1}{2}(u_{k+1} + u_{k-1}) \\ &< u_k. \end{aligned}$$

Clearly this is impossible. Hence, u_j cannot have a local maximum, and therefore v_j cannot dip below h_j .

8.5. Inequality (8.4) with $j = j^*$. Finally, to get inequality (8.4) for $j = j^*$, we need to assume that $j^* + 1 \notin K$. That is,

$$(8.6) \quad f_{j^*+1} \frac{\xi_+^{j^*} - \xi_-^{j^*}}{\xi_+^{j^*+1} - \xi_-^{j^*+1}} \leq f_{j^*}.$$

To see why, let w_j denote the solution to the difference equation

$$\begin{aligned} w_j - \alpha(pw_{j+1} + qw_{j-1}) &= 0, & 0 < j, \\ w_0 &= 0, \\ w_{j^*} &= f_{j^*}. \end{aligned}$$

This is the same as (6.1)–(6.3) but extended to all j . Clearly we have $v_{j^*} = w_{j^*}$ and $v_{j^*-1} = w_{j^*-1}$. Hence, (8.4) at j^* will hold if and only if $v_{j^*+1} \leq w_{j^*+1}$:

$$f_{j^*+1} = v_{j^*+1} \leq w_{j^*+1} = f_{j^*} \frac{\xi_+^{j^*+1} - \xi_-^{j^*+1}}{\xi_+^{j^*} - \xi_-^{j^*}}.$$

The resulting inequality is clearly equivalent to (8.6).

A natural consequence of our analysis above is that j^* should be chosen as

$$j^* := \max \left\{ k : f_k \frac{\xi_+^{k-1} - \xi_-^{k-1}}{\xi_+^k - \xi_-^k} > f_{k-1} \right\}.$$

9. Summary. The claimed result holds, provided we make the assumptions that

1. $\alpha p \leq 1/2$ and $\alpha q \leq 1/2$,
2. $S = j_S \Delta x$ for some integer j_S , and
3. $f_{j_S+1} (\xi_+^{j_S} - \xi_-^{j_S}) / (\xi_+^{j_S+1} - \xi_-^{j_S+1}) > f_{j_S}$.

With these assumptions, the optimal choice of j^* is

$$j^* := \max \left\{ k : f_k \frac{\xi_+^{k-1} - \xi_-^{k-1}}{\xi_+^k - \xi_-^k} > f_{k-1} \right\}.$$

The result of the present paper holds even if the assumption $\alpha p \leq 1/2$ is violated. Such a case is illustrated in Figure 5, where $\alpha p > 1/2$. However, in this case, the

Fig. 5 Plot of $v^*(x)$ and $f(x)$ corresponding to the case where $\alpha = 0.999$, $p = 0.51$, $\Delta x = 0.1$, and $S = 9$. In this case, $j^* = 124$ and therefore $x_{j^*} = 12.4$.

necessary and sufficient condition (8.5) holds. Low interest rates (i.e., α values very close to one) and an upward-biased ($p > 1/2$) stock movement model may easily induce a violation of the assumed upper bound of $1/2$ on αp . Such cases certainly make sense economically. The more involved necessary and sufficient condition (8.5) can be checked for these cases, provided that assumptions 2 and 3 of section 1 hold.

We conclude the paper with two exercise suggestions. The analysis and results presented here remain valid if, for the stock price,

- (a) we use a Markov chain model with absorption at zero, where at each step the stock price moves up by Δx with probability p , and moves down by Δx with probability q (with $p + q < 1$), and does not change with probability $1 - (p + q)$ (this is a model closer to reality for the movement of stock prices over a short time interval); and
- (b) we use a *geometric random walk* model where the stock price at the next period becomes $x\lambda$ with probability p , and x/λ with probability $1 - p$, where $\lambda > 1$ and the current price is x .

We provide some guidelines and hints below on the extension of our analysis to these two cases.

For case (a), the analysis and results hold with a slight modification in the valuation formula. Adjusting the second set of constraints in our original linear programming model, and rearranging the terms of this constraint, one can see that an almost identical model solves the valuation problem at hand, and only the right-hand side of the second constraint set is subject to change. This feature leads to a change in the structure of the difference equations in our original problem, which in turn leads to a slight change in the roots of the difference equation. The formulae for v , y , and z retain the same form except for a slight change in the specified roots.

Case (b) is slightly more involved in that the state space is constructed from some initial price, and consequently one deals with the state space $E^m = \{X_0^m \lambda^j : j \in \mathbb{Z}\}$, where X_0^m is the initial stock price. The value function should now tend to zero when $j \rightarrow -\infty$, whereas in the problem treated in the previous sections we had $v(0) = 0$. The key to the solution lies in using this modified boundary condition to obtain a particular solution to the second-order difference equations of section 7.
