#### Abstract

We study a natural probabilistic model for motif discovery that has been used to experimentally test the quality of motif discovery programs. In this model, there are $k$ background sequences, and each character in a background sequence is a random character from an alphabet $\Sigma$. A motif $G=g_{1} g_{2} \cdots g_{m}$ is a string of $m$ characters. Each background sequence is implanted into a probabilistically generated approximate copy of $G$. For an approximate copy $b_{1} b_{2} \cdots b_{m}$ of $G$, every character $b_{i}$ is probabilistically generated such that the probability for $b_{i} \neq g_{i}$ is at most $\alpha$. In this paper, we give the first analytical proof that multiple background sequences do help with finding subtle and faint motifs. This work is a theoretical approach with a rigorous probabilistic analysis. We develop an algorithm that under the probabilistic model can find the implanted motif with high probability when the number of background sequences is reasonably large. Specifically, we prove that for $\alpha<0.1771$ and any constant $x \geq 8$, there exist constants $t_{0}, \delta_{0}, \delta_{1}>0$ such that if the length of the motif is at least $\delta_{0} \log n$, the alphabet has at least $t_{0}$ characters, and there are at least $\delta_{1} \log n_{0}$ input sequences, then in $O\left(n^{3}\right)$ time our algorithm finds the motif with probability at least $1-\frac{1}{2 x}$, where $n$ is the longest length of any input sequence and $n_{0} \leq n$ is an upper bound for the length of the motif.

1. Introduction. Motif discovery is an important problem in computational biology and computer science. For instance, it has applications to coding theory [3, 5], locating binding sites and conserved regions in unaligned sequences [7, 11, 18, 19], genetic drug target identification [10], designing genetic probes [10], and universal polymerase chain reaction (PCR) primer design $[2,10,14,17]$.

This paper focuses on the application of motif discovery to finding conserved regions in a set of DNA, RNA, or protein sequences. Such conserved regions may represent common biological functions or structures. Many performance measures have been proposed for motif discovery. Let $C$ be a set of $0-1$ sequences of length $n$. The covering radius of $C$ is the smallest integer $r$ such that each vector in $\{0,1\}^{n}$ is at a Hamming distance at most $r$ from a string in $C$. The decision problem associated with the covering radius for a set of binary sequences is NP-complete [3].

[^0]The similar closest string and substring problems were proved to be NP-hard [3, 10]. Some approximation algorithms have been proposed. Li, Ma, and Wang [13] gave an approximation scheme for the closest string and substring problems. The related consensus patterns problem is as follows: given $n$ sequences $s_{1}, \cdots, s_{n}$, find a region of length $L$ in each $s_{i}$ and a string $s$ of length $L$ so that the total Hamming distance from $s$ to these regions is minimized. Approximation algorithms for the consensus patterns problem were reported in [12]. Furthermore, a number of heuristics and programs have been developed $[1,8,9,16,20]$.

In many applications, motifs are faint and may not be apparent when only two sequences are compared but may become clearer when more sequences are compared at the same time [6]. For this reason, it has been conjectured that comparing more sequences at the same time can help with identifying faint motifs. In this work, we give the first analytical proof for this conjecture. This is a theoretical approach with a rigorous probabilistic analysis.

We study a natural probabilistic model for motif discovery. In this model, there are $k$ background sequences, and each character in the background sequence is a random character from an alphabet $\Sigma$. A motif $G=g_{1} g_{2} \cdots g_{m}$ is a string of $m$ characters. Each background sequence is implanted into a probabilistically generated approximate copy of $G$. For an approximate copy $b_{1} b_{2} \cdots b_{m}$ of $G$, every character $b_{i}$ is probabilistically generated such that the probability for $b_{i} \neq g_{i}$, which is called a mutation, is at most $\alpha$. This model was first proposed in [16] and has been widely used to experimentally test motif discovery programs $[1,8,9,20]$. We note that a mutation in our model converts a character $g_{i}$ in the motif into a different character $b_{i}$ with no further probability restriction than the upper bound of $\alpha$. In particular, a character $g_{i}$ in the motif may become any character $b_{i}$ in $\Sigma-\left\{g_{i}\right\}$ with unequal probabilities.

We design an algorithm that for a reasonably large $k$ can discover the implanted motif with high probability. Specifically, we prove that for $\alpha<0.1771$ and any constant $x \geq 8$, there exist constants $t_{0}, \delta_{0}, \delta_{1}>0$ such that if the length of the motif is at least $\delta_{0} \log n$, the alphabet has at least $t_{0}$ characters, and there are at least $\delta_{1} \log n_{0}$ input sequences, then in $O\left(n^{3}\right)$ time the algorithm finds the motif with success probability at least $1-\frac{1}{2^{x}}$, where $n$ is the longest length of any input sequence and $n_{0} \leq n$ is an upper bound for the length of the motif. When $x$ is considered as a parameter of order $O(\log n)$, the parameters $t_{0}, \delta_{0}, \delta_{1}$ do not depend on $x$. We also show some lower bounds that imply that our conditions for the length of the motif and the number of input sequences are tight to within a constant multiplicative factor. This algorithm's time complexity depends on the length of input sequences but is independent of the number of the input sequences. This is because for a fixed $x, \Theta(\log n)$ sequences are sufficient to guarantee the probability of at least $1-\frac{1}{2^{x}}$ to discover the motif. In contrast to the NP-hardness of other variants of the common substring problem, motif discovery is solvable in $O\left(n^{3}\right)$ time in this probabilistic model.

Our algorithm is a deterministic algorithm that has provable high probability to return the exact motif. The only source of randomness for the algorithm is the randomness in the input sequences. The algorithm extracts similar consecutive regions among multiple sequences while tolerating noises. The algorithm needs the motif to be long enough, but does not need to have the length of the motif as an input.

In section 2, we elaborate on our model of sequence generation and discuss some basics. We give a brief description of our main algorithm, Find-Noisy-Motif, in sec-
tion 3. We set up some parameters and constants for the algorithm in section 4.1. The entire Find-Noisy-Motif is described in section 4.2. We analyze Algorithm Find-Noisy-Motif in section 5. Two lower bounds are presented in section 6 . We conclude the paper with an open problem in section 7 .
2. Notation and the model of sequence generation. For a set $A,|A|$ denotes the number of elements in $A . \Sigma$ is an alphabet with $|\Sigma|=t \geq 2$. For an integer $n \geq 0, \Sigma^{n}$ is the set of sequences of length $n$ with characters from $\Sigma$. For a sequence $S=a_{1} a_{2} \cdots a_{n}, S[i]$ denotes the character $a_{i}$, and $S[i, j]$ denotes the substring $a_{i} \cdots a_{j}$ for $1 \leq i \leq j \leq n .|S|$ denotes the length of the sequence $S$. We use $\emptyset$ to represent the empty sequence, which has length 0 .

Let $G=g_{1} g_{2} \cdots g_{m}$ be a fixed sequence of $m$ characters. $G$ is the motif to be discovered by our algorithm. A $\Theta_{\alpha}(n, G)$-sequence is defined to be a sequence $S$ of the form $S=a_{1} \cdots a_{n_{1}} b_{1} \cdots b_{m} a_{n_{1}+1} \cdots a_{n_{2}}$, where $n_{2}+m \leq n$, each $a_{i}$ has probability $\frac{1}{t}$ to be $\pi$ for each $\pi \in \Sigma$, and $b_{i}$ has probability at most $\alpha$ not equal to $g_{i}$ for $1 \leq i \leq m$, where $m=|G| . \aleph(S)$ denotes the motif region $b_{1} \cdots b_{m}$ of $S$. The motif region of $S$ may start at a probabilistic, arbitrary, or worst-case position in $S$. Also, a mutation may convert a character $g_{i}$ in the motif into an arbitrary or worst-case different character $b_{i}$ subject only to the restriction that $g_{i}$ will mutate with probability at most $\alpha$.

For two sequences $S_{1}=a_{1} \cdots a_{m}$ and $S_{2}=b_{1} \cdots b_{m}$ of the same length, let $\operatorname{diff}\left(S_{1}, S_{2}\right)=\frac{\mid\left\{i \mid a_{i} \neq b_{i} \text { for } i=1, \ldots, m\right\} \mid}{m}$, i.e., the ratio of difference between the two sequences.

Definition 2.1. For two intervals $\left[i_{1}, j_{1}\right]$ and $\left[i_{2}, j_{2}\right]$, define $\operatorname{shift}\left(\left[i_{1}, j_{1}\right],\left[i_{2}, j_{2}\right]\right)=$ $\min \left(\left|i_{1}-i_{2}\right|,\left|j_{1}-j_{2}\right|\right)$.

The analysis of our algorithm employs the Chernoff bound [15] and Corollary 2.3 below, which can be derived from that bound (see [13]).

Theorem 2.2 (see [15]). Let $X_{1}, \cdots, X_{n}$ be $n$ independent random 0-1 variables, where $X_{i}$ takes 1 with probability $p_{i}$. Let $X=\sum_{i=1}^{n} X_{i}$, and let $\mu=E[X]$. Then for any $\delta>0$,
(i) $\operatorname{Pr}(X<(1-\delta) \mu)<e^{-\frac{1}{2} \mu \delta^{2}}$, and
(ii) $\operatorname{Pr}(X>(1+\delta) \mu)<\left[\frac{e^{\delta}}{(1+\delta)^{(1+\delta)}}\right]^{\mu}$.

Corollary 2.3 (see [13]). Let $X_{1}, \cdots, X_{n}$ be $n$ independent random 0-1 variables and $X=\sum_{i=1}^{n} X_{i}$.
(i) If $X_{i}$ takes 1 with probability at most $p$, then for any $\frac{1}{3}>\epsilon>0, \operatorname{Pr}(X>$ $p n+\epsilon n)<e^{-\frac{1}{3} n \epsilon^{2}}$.
(ii) If $X_{i}$ takes 1 with probability at least $p$, then for any $\frac{1}{3}>\epsilon>0, \operatorname{Pr}(X<$ $p n-\epsilon n)<e^{-\frac{1}{2} n \epsilon^{2}}$.
3. A sketch of Algorithm Find-Noisy-Motif. Our Algorithm Find-NoisyMotif has two phases. The first phase exploits the fact that with high probability, the motif areas in some sequences conserve the first and last characters. Furthermore, the middle areas of the motif change with a small ratio. We will select enough pairs of $\Theta_{\alpha}(n, G)$-sequences $S^{\prime}$ and $S^{\prime \prime}$ and find their substrings $G^{\prime}$ and $G^{\prime \prime}$, respectively, such that $G^{\prime}$ and $G^{\prime \prime}$ match at their left- and rightmost characters. Furthermore, $G^{\prime}$ and $G^{\prime \prime}$ have only a relatively small difference in the middle areas. For each such pair $S^{\prime}$ and $S^{\prime \prime}$, the substring $G^{\prime \prime}$ of $S^{\prime \prime}$ is extracted.

During the second phase, a new set of $\Theta_{\alpha}(n, G)$-sequences $S_{1}, S_{2}, \cdots, S_{k_{2}}$ will be used. For each $G^{\prime \prime}$ extracted from a pair of sequences in the first phase, it is used to match a substring $G_{i}$ of $S_{i}$ for $i=1,2, \ldots, k_{2}$. Assume that $G_{1}, \cdots, G_{k_{2}}$ are derived

Fig. 1. The motif regions of $S_{1}, S_{2}$, and $S_{3}$ are not aligned.

Fig. 2. $S_{1}, S_{2}$, and $S_{3}$ have their motif in the same column region.
from matching $G^{\prime \prime}$ to all sequences $S_{1}, S_{2}, \cdots, S_{k_{2}}$. Some $G_{i}$ may be the empty sequence if $G^{\prime \prime}$ cannot match well to any substring of $S_{i}$. If $G^{\prime \prime}$ has the same length as that of motif $G$ and is very similar to $G$, then the number of nonempty sequences among $G_{1}, \cdots, G_{k_{2}}$ is much larger than $\frac{k_{2}}{2}$ and the $i$ th character $G[i]$ of $G$ can be recovered by voting on $G_{1}[i], \cdots, G_{k_{2}}[i]$. In other words, $G[i]$ is the character that appears more than $\frac{k_{2}}{2}$ times in $G_{1}[i], \cdots, G_{k_{2}}[i]$. We prove that with high probability such a $G^{\prime \prime}$ exists. The rearrangement of $S_{1}, \cdots, S_{k_{2}}$ from Figure 1 to Figure 2 illustrates how we recover the motif via voting.

On the other hand, if $\left|G^{\prime \prime}\right|>|G|$ or $G^{\prime \prime}$ does not match $G$ well, then we can prove that the number of nonempty sequences among $G_{1}, \cdots, G_{k_{2}}$ is less than $\frac{k_{2}}{2}$. Furthermore, if $\left|G^{\prime \prime}\right|<|G|, G^{\prime \prime}$ will be dropped since with high probability there exists a candidate $G_{0}$ with a good voting performance and the algorithm returns the result from the longest one. Our algorithm's time complexity depends on the length of the input sequences but is independent of the number of the input sequences. This is because for a fixed $x, \Theta(\log n)$ sequences are sufficient to guarantee that with probability at least $1-\frac{1}{2^{x}}$ the motif will be discovered. Additional sequences can improve the success probability but are not needed for the high probability guarantee.
4. Algorithm Find-Noisy-Motif. In this section, we detail Algorithm Find-Noisy-Motif. The algorithm can find any hidden motif $G$ in $O\left(n^{3}\right)$ time and with high success probability. It requires that the size of the alphabet is larger than a fixed constant. The performance of the algorithm is stated in the main theorem, Theorem 4.1. The proof of Theorem 4.1 is given in section 5.4.

Theorem 4.1. Assume that the mutation probability upper bound $\alpha$ is less than 0.1771. Then there exist constants $t_{0}, \delta_{0}$, and $\delta_{1}$ such that if the size $t$ of the alphabet $\Sigma$ is at least $t_{0}$ and the length of the motif $G$ is at least $\delta_{0} \log n$, then, given $k$ independent $\Theta_{\alpha}(n, G)$-sequences with $k \geq \delta_{1} \log n_{0}$, Algorithm Find-Noisy-Motif outputs $G$ with probability at least $1-\frac{1}{2^{x}}$ and runs in $O\left(n^{3}\right)$ time, where $n$ is the longest length of any input sequences and $n_{0} \leq n$ is a given upper bound for the length of $G$.

Some parameters and constants will be used in Algorithm Find-Noisy-Motif . In section 4.1, we give a list of assignments for some such parameters and constants. The description of Algorithm Find-Noisy-Motif is given in section 4.2. The analysis of the algorithm is given in sections 5.2-5.4.
4.1. Parameters. Multiple parameters affect the performance of the main algorithm, Find-Noisy-Motif; we list them below and discuss some useful inequalities.

- Let $x$ be any constant at least 8 . The parameter $x$ controls the failure probability of Find-Noisy-Motif to be at most $\frac{1}{2^{x}}$. We will prove that Find-NoisyMotif has probability at least $1-\frac{1}{2^{x}}$ to output the exact correct motif $G$.
- Let $\alpha$ be any constant with $0 \leq \alpha<0.1771$. Note that

$$
\begin{equation*}
(1-\alpha)^{2}-\alpha>\frac{1}{2} \tag{1}
\end{equation*}
$$

The parameter $\alpha$ is the upper bound for the mutation probability of each character in the motif region.

- Let $\eta=\frac{1}{6}$. The algorithm has five cases in which it may fail. In order to keep the total failure probability at most $\frac{1}{2^{x}}$, we ensure that each such case has failure probability at most $\frac{\eta}{2^{x}}$. As at most five cases can fail, the total failure probability is bounded by $5 \cdot \frac{\eta}{2^{x}}<\frac{1}{2^{x}}$.
- Let $\rho_{0}=\frac{1}{24}$. We will design a function $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ to output $\aleph\left(S_{2}\right)$ with probability greater than a fixed constant. This parameter controls the probability that Extract $\left(S_{1}, S_{2}\right)$ derives a substring of $S_{2}$ without overlap with the motif region $\aleph\left(S_{2}\right)$ in $S_{2}$. It also affects the selection of $d$, a lower bound of the motif length.
- Let $\epsilon>0$ be any constant such that

$$
\begin{equation*}
(1-\alpha)^{2}-\alpha-3 \epsilon>\frac{1}{2} \tag{2}
\end{equation*}
$$

In order to find the motif, we often extract one of two similar substrings from two input sequences. The parameter $\epsilon$ controls the similarity of two substrings (see diff $\left(S_{1}, S_{2}\right)$ in section 2 ) and appears in the probability that is derived from the Chernoff bound (see Corollary 2.3). The existence of $\epsilon$ follows from inequality (1). It also affects the selection of some other parameters.

- Let $n$ be the largest length of an input sequence with $n \geq 3$. Let parameter $n_{0} \in[d, n]$ be a given upper bound on the length of the motif $G$ that will be discovered by Algorithm Find-Noisy-Motif. If $n_{0}$ is unknown, we just let $n_{0}=n$.
- Select a constant $\delta_{0}>0$, and let $d=\delta_{0} \log n$ such that

$$
\begin{equation*}
n^{2} e^{-d} \leq \frac{\eta}{2^{x}} \tag{3}
\end{equation*}
$$

and

$$
\begin{equation*}
n^{2} e^{-\frac{\varepsilon^{2}}{3} d} \leq \rho_{0} \tag{4}
\end{equation*}
$$

To satisfy inequalities (3) and (4) above, select

$$
\delta_{0}=\max \left\{\left(2\left(1+\ln \left(\frac{\eta}{2^{x}}\right)\right)\right) / \ln 2,\left(\frac{6}{\epsilon^{2}}\left(1+\ln \rho_{0}\right)\right) / \ln 2\right\}
$$

Note that $\delta_{0}$ is a constant since both $\eta$ and $x$ are fixed. We require that the length of the motif $G$ is at least $d$ as stated in Theorem 4.1.
The motif $G$ is a pattern unknown to Algorithm Find-Noisy-Motif. Find-NoisyMotif will attempt to recover $G$ from a series of $\Theta_{\alpha}(n, G)$-sequences generated by the probabilistic model in section 2 , which is controlled by the parameters $\alpha, n$, and G. The source of randomness for Find-Noisy-Motif comes entirely from the input sequences.

Recall that a sequence $S$ is generated as follows: (1) Generate a sequence $S^{\prime}$ with $n-|G|$ characters, in which each character is a random character in $\Sigma$. (2) Generate $G^{\prime}$ such that with probability at most $\alpha, G^{\prime}[i] \neq G[i] . \quad G^{\prime}[i] \neq G[i]$ represents a mutation. A mutation may create an arbitrary or worst-case $G^{\prime}[i]$, with no probability restriction except that the mutation occurs with probability at most $\alpha$. (3) Insert $G^{\prime}$, which serves as the motif region $\aleph(S)$ of $S$, into any arbitrary or worst-case position of $S^{\prime}$.

Let $Z_{0}$ be a set of $k_{1}$ pairs of random $\Theta_{\alpha}(n, G)$-sequences $\left(S_{1}^{\prime}, S_{1}^{\prime \prime}\right), \cdots,\left(S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}\right)$. Let $Z_{1}$ be the set of $\Theta_{\alpha}(n, G)$-sequences $\left\{S_{1}^{\prime}, S_{1}^{\prime \prime}, \cdots, S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}\right\}$ in the $k_{1}$ pairs of sequences in $Z_{0}$. Let $Z_{2}$ be a set of $k_{2}$ sequences that will be used in the second phase of Algorithm Find-Noisy-Motif. Let $k=2 k_{1}+k_{2}$ be the total number of $\Theta_{\alpha}(n, G)$ sequences that are used as the input to Find-Noisy-Motif. Both parameters $k_{1}$ and $k_{2}$ are determined later (see Definition 4.2).
4.2. Description of Algorithm Find-Noisy-Motif. The algorithm is detailed in this section. Before presenting the algorithm, we define some constants and notions.

Definition 4.2.

1. Select any constant $r_{0}>0$ such that

$$
\begin{equation*}
(1-\alpha)^{2}-\alpha-3 \epsilon-2 r_{0}>\frac{1}{2} . \tag{5}
\end{equation*}
$$

The constant $r_{0}$ will be used to select the constants $v$ (which is defined below) and $t_{0}$ (which is the lower bound of the size of the alphabet and is defined in Definition 5.1). The existence of $r_{0}$ follows from inequality (2).
2. Let $v$ be the least integer that satisfies the following inequalities:

$$
\begin{align*}
1 & \leq v  \tag{6}\\
(1-\alpha)^{2}-\frac{2 c^{v}}{1-c}-\alpha-3 \epsilon-2 r_{0} & >\frac{1}{2}  \tag{7}\\
\frac{2 c_{2} v^{3} c^{v}}{1-c} & <\rho_{0}  \tag{8}\\
\frac{2 c^{v}}{1-c} & <\frac{r_{0}}{2}  \tag{9}\\
\frac{2 c^{v}}{1-c} & <\rho_{0} \tag{10}
\end{align*}
$$

where $c=e^{-\frac{\epsilon^{2}}{3}}$. Note that the existence of $v$ for inequality (7) follows from inequality (5).

The function $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ tries to find $\aleph\left(S_{2}\right)$ by matching $\aleph\left(S_{1}\right)$ and $\aleph\left(S_{2}\right)$ without shifting $\left(\aleph\left(S_{1}\right)[i]\right.$ is aligned to $\left.\aleph\left(S_{2}\right)[i]\right)$. The parameter $v$ is a threshold for the number of characters shifted when matching two motifs from two input sequences (there is one shift if $\aleph\left(S_{1}\right)[i]$ is aligned to $\left.\aleph\left(S_{2}\right)[i+1]\right)$. For the case where the number of shifts is more than $v$, the Chernoff bound is used to show that the probability is small enough. For the case where the number of shifts is less than $v$ but at least 1, the probability is still small due to the assumption that the size of the alphabet is large enough.
3. The number $k_{1}$ is selected such that

$$
\begin{equation*}
\left(1-\frac{1}{12}\right)^{k_{1}} \leq \frac{\eta}{2^{x}} \tag{11}
\end{equation*}
$$

Note that $k_{1}=O(1)$ is a constant independent of the length of the input sequences since both $\eta$ and $x$ are constants.
The parameter $k_{1}$ is the number of pairs of input sequences $\left(S_{1}, S_{1}^{\prime}\right), \cdots,\left(S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}\right)$ used to extract the motif candidates in the subroutine Phase-One of Find-Noisy-Motif.
4. Select a constant $\delta_{1}>0$, and let $k_{2}=\delta_{1} \log n_{0}-2 k_{1}$ so that

$$
\begin{equation*}
n_{0} k_{2} e^{-\frac{\epsilon^{2}}{3} k_{2}} \leq \frac{\eta}{2^{x}} \tag{12}
\end{equation*}
$$

and

$$
\begin{equation*}
k_{1} e^{-\frac{\epsilon^{2}}{3} k_{2}} \leq \frac{\eta}{2^{x}} \tag{13}
\end{equation*}
$$

The parameter $k_{2}$ is the number of input sequences used in the subroutine Phase-Two of Find-Noisy-Motif. The candidates for the motif from PhaseOne are used to match the motif regions of the $k_{2}$ sequences in Phase-Two. The original motif $G$ is recovered via voting on the $k_{2}$ substrings.
Definition 4.3.

1. Let $\beta=2 \alpha+2 \epsilon$. The parameter $\beta$ controls the similarity between $\aleph(S)$ and the original motif $G$ (see Lemma 5.8).
2. Two sequences $X_{1}$ and $X_{2}$ are left matched if (1) $\left|X_{1}\right|=\left|X_{2}\right|$, (2) $X_{1}[1]=$ $X_{2}[1]$, and $(3) \operatorname{diff}\left(X_{1}[1, i], X_{2}[1, i]\right) \leq \beta$ for all integers $i$, $v \leq i \leq\left|X_{1}\right|$.
3. Two sequences $X_{1}$ and $X_{2}$ are right matched if $X_{1}^{R}$ and $X_{2}^{R}$ are left matched, where $X^{R}=a_{n} \cdots a_{1}$ is the inverse sequence of $X=a_{1} \cdots a_{n}$.
4. Two sequences $X_{1}$ and $X_{2}$ are matched if $X_{1}$ and $X_{2}$ are both left and right matched.
Algorithm Find-Noisy-Motif has two phases. The two phases are organized as subroutines Phase-One and Phase-Two, respectively. The input to Phase-One is $k_{1}$ pairs of $\Theta_{\alpha}(n, G)$-sequences collected in the set $Z_{0}$. The input to Phase-Two consists of $k_{2} \Theta_{\alpha}(n, G)$-sequences collected in the set $Z_{2}$ and the output from Phase-One. All the $\Theta_{\alpha}(n, G)$-sequences are independent $\Theta_{\alpha}(n, G)$-sequences. Recall that $k_{1}$ is constant, $k_{2}=O\left(\log n_{0}\right)$, and $n_{0}(\leq n)$ is an upper bound for the length of the motif $G$ as discussed in Definition 4.2 and section 4.1. Algorithm Find-Noisy-Motif is deterministic, and its probabilistic performance is based on the randomness of those sequences in both $Z_{0}$ and $Z_{2}$ and the independence in generating them.

The subroutine LoadInputSequences() below generates the input sequences for Find-Noisy-Motif using the probabilistic model in section 2.

## LoadInputSequences() <br> Steps:

Independently generate $2 k_{1} \Theta_{\alpha}(n, G)$-sequences $S_{1}^{\prime}, S_{1}^{\prime \prime}, \cdots, S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}$, and let $Z_{0}=\left\{\left(S_{1}^{\prime}, S_{1}^{\prime \prime}\right),\left(S_{2}^{\prime}, S_{2}^{\prime \prime}\right), \cdots,\left(S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}\right)\right\}$.
Independently generate $k_{2} \Theta_{\alpha}(n, G)$-sequences $S_{1}, \cdots, S_{k_{2}}$, and let $Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}$.
Return $\left(Z_{0}, Z_{2}\right)$;

## End of LoadInputSequences

The function Extract $\left(S_{1}, S_{2}\right)$ below extracts the longest similar region between two sequences $S_{1}$ and $S_{2}$.

Function Extract $\left(S_{1}, S_{2}\right)$
Input: a pair of $\Theta_{\alpha}(n, G)$-sequences $S_{1}$ and $S_{2}$.
Output: a substring of $S_{2}$ which is similar to a substring of $S_{1}$.
Steps:
for $h=\min \left(\left|S_{1}\right|,\left|S_{2}\right|\right)$ to $d$ (recall from section 4.1 that $|G| \geq d$ )
for $i=1$ to $\left|S_{1}\right|$
for $j=1$ to $\left|S_{2}\right|$
let $i^{\prime}=i+h-1$ and $j^{\prime}=j+h-1$;
if $S_{1}\left[i, i^{\prime}\right]$ and $S_{2}\left[j, j^{\prime}\right]$ are matched (see Definition 4.3), then return $S_{2}\left[j, j^{\prime}\right]$ and end this function;
return $\emptyset$ (output the empty sequence when there is no match found);

## End of Extract

The following function is Phase-One of Algorithm Find-Noisy-Motif.
Phase-One ( $Z_{0}$ )
Input: $Z_{0}=\left\{\left(S_{1}^{\prime}, S_{1}^{\prime \prime}\right),\left(S_{2}^{\prime}, S_{2}^{\prime \prime}\right), \cdots,\left(S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}\right)\right\}$, a set of pairs of sequences generated at step 1 of Find-Noisy-Motif.

Output: a set $W$ that contains a similar region of each pair in $Z_{0}$.

## Steps:

let $W=\emptyset$ (empty set);
for each pair of sequences $\left(S^{\prime}, S^{\prime \prime}\right) \in Z_{0}$
let $G^{\prime \prime}=\operatorname{Extract}\left(S^{\prime}, S^{\prime \prime}\right)$ and put $G^{\prime \prime}$ into $W$;
return $W$, which will be used in Phase-Two;

## End of Phase-One

After a set $W$ of motif candidates is produced from Phase-One of Find-NoisyMotif, we use this function $\operatorname{Match}\left(G^{\prime \prime}, S_{i}\right)$ below to match this set with the set $Z_{2}$ of input sequences to recover the hidden motif by voting.

Function Match $\left(G^{\prime \prime}, S_{i}\right)$
Input: a motif candidate $G^{\prime \prime}$, which is returned from the function Extract(), and a sequence $S_{i}$ from the group $Z_{2}$.

Output: either a substring $G_{i}$ of $S_{i}$ of the same length as $G^{\prime \prime}$ or an empty sequence, where $G_{i}$ will be considered as the motif region $\aleph\left(S_{i}\right)$ of $S_{i}$ if it is not empty and the empty sequence means the failure in extracting the motif region $\aleph\left(S_{i}\right)$ of $S_{i}$.

## Steps:

find a substring $G_{i}$ of $S_{i}$ with $\left|G^{\prime \prime}\right|=\left|G_{i}\right|$ such that
$G^{\prime \prime}$ and $G_{i}$ are matched (see Definition 4.3);
if such a $G_{i}$ does not exist, let $G_{i}=\emptyset$ (empty string);
Output $G_{i}$;

## End of Match

The function $\operatorname{Vote}\left(G_{1}, G_{2}, \cdots, G_{k^{\prime}}\right)$ below generates another sequence $G^{\prime}$ by voting, where $G^{\prime}[i]$ is the most frequent character among $G_{1}[i], G_{2}[i], \cdots, G_{k^{\prime}}[i]$.

Function $\operatorname{Vote}\left(G_{1}, G_{2}, \cdots, G_{k^{\prime}}\right)$
Input: sequences $G_{1}, G_{2}, \cdots, G_{k^{\prime}}$ of the same length with $k^{\prime} \leq k_{2}$.
Output: a sequence $G^{\prime}$, which is derived by voting on every position of the input sequences.

## Steps:

let $m=\left|G_{1}\right|$;
for each $j=1, \ldots, m$
if strictly more than $\frac{k_{2}}{2}$ characters from $G_{1}[j], \cdots, G_{k^{\prime}}[j]$ are the
same character $a$,
then let $a_{j}=a$
else return "failure" and end this function;
return $G^{\prime}=a_{1} \cdots a_{m} ;$

## End of Vote

The following function performs Phase-Two of Algorithm Find-Noisy-Motif. It uses the motif candidates for the motif derived in Phase-One to extract the motif regions of the set $Z_{2}$ of input sequences and recovers the motif by voting.

Phase-Two $\left(Z_{2}, W\right)$
Input: $Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}$ as defined before and $W$ from Phase-One.
Output: $G^{\prime}$, which is a recovery of motif $G$.

## Steps:

for each $G^{\prime \prime} \in W$, let $G_{i}=\operatorname{Match}\left(G^{\prime \prime}, S_{i}\right)$ for $i=1, \ldots, k_{2}$.
If the number of nonempty sequences in $G_{1}, \cdots, G_{k_{2}}$ is at least $\left(Q_{0}-2 R-2 \epsilon\right) k_{2}$,
then output $G^{\prime}=\operatorname{Vote}\left(G_{1}, G_{2}, \cdots, G_{k_{2}}\right)$ (which will be proved to be identical to $G$ with probability at least $\left.1-\frac{1}{2^{x}}\right)$ and end Phase-Two. return "failure".

## End of Phase-Two

The entire main algorithm is described as follows:

## Algorithm Find-Noisy-Motif

## Steps:

$\left(Z_{0}, Z_{2}\right)=$ LoadInputSequences () ;
$W=$ Phase-One $\left(Z_{0}\right)$;
Phase-Two $\left(Z_{2}, W\right)$;

## End of Algorithm Find-Noisy-Motif

5. Analysis of Algorithm Find-Noisy-Motif. Section 5.1 gives an overview of the analysis of Find-Noisy-Motif. Section 5.2 analyzes Phase-One. Section 5.3 analyzes Phase-Two. Section 5.4 gives an overall analysis of Algorithm Find-NoisyMotif and proves the main theorem, Theorem 4.1.
5.1. Overview of the algorithm analysis. Phase-One derives $k_{1}$ motif candidates via $G_{1}^{\prime \prime}=\operatorname{Extract}\left(S_{1}^{\prime}, S_{1}^{\prime \prime}\right), \cdots, G_{k_{1}}^{\prime \prime}=\operatorname{Extract}\left(S_{k_{1}}^{\prime}, S_{k_{1}}^{\prime \prime}\right)$. Lemmas 5.2, 5.3, 5.5, and 5.6 show that the probability is small for Phase-One returning a substring not from the motif region of an input sequence in Phase-One. Lemma 5.8 shows that each $\Theta_{\alpha}(n, G)$-sequence $S$ has its motif region $\aleph(S)$ similar to the motif with high probability. In expecting $\operatorname{Extract}\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)$ to return the motif region $\aleph\left(S_{i}^{\prime \prime}\right)$, we compare the similarity between $S_{i}^{\prime}$ and $S_{i}^{\prime \prime}$ in order to detect the location of $\aleph\left(S_{i}^{\prime \prime}\right)$ in $S_{i}^{\prime \prime}$. If the two substrings are $\aleph\left(S_{i}^{\prime}\right)$ and $\aleph\left(S_{i}^{\prime \prime}\right)$, there is much similarity between them, and $\aleph\left(S_{i}^{\prime \prime}\right)$
is found in $S_{i}^{\prime \prime}$. Otherwise, they have high similarity only with a small probability according to Lemmas $5.2,5.3,5.5$, and 5.6.

After showing that the probability is small for Phase-One returning a nonmotif region, we prove Lemma 5.9 to give an $\Omega(1)$ probability lower bound that a motif region $\aleph\left(S_{i}^{\prime \prime}\right)$ of $S_{i}^{\prime \prime}$ is returned via $\operatorname{Extract}\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)$. Finally, the analysis of PhaseOne will show that one of those $G_{1}^{\prime \prime}, \cdots, G_{k_{1}}^{\prime \prime}$ has the same length as $G$ and is very similar to the true motif $G$ with high probability. The number $k_{1}$ of pairs amplifies the success probability exponentially, as shown in Lemma 5.10. Now assume that $G_{0}$ is a relatively accurate motif produced by Phase-One.

Phase-Two uses such $G_{0}$ to detect the motif region $\aleph\left(S_{i}\right)$ for each $S_{i}$ of the $k_{2}$ input sequences $S_{1}, \cdots, S_{k_{2}}$ via pattern matching between $G_{0}$ and a substring in $S_{i}$. This generates $G_{1}, \cdots, G_{k_{2}}$. Lemma 5.13 shows that $G_{i}$ is $\aleph\left(S_{i}\right)$ for most of $i=1, \ldots, k_{2}$. Therefore, $G[i]$ can be recovered via voting on $G_{1}[i], \cdots, G_{k_{2}}[i]$, as shown in Lemma 5.14.

Our main theorem about the correctness and complexity of the algorithm is Theorem 4.1. It combines the analyses for Phase-One and Phase-Two. If a $G_{i}^{\prime \prime}$ produced by Phase-One is longer than $G$, it will be dropped during the voting. If $G_{i}^{\prime \prime}$ is shorter than $G$, it will be also dropped since there $G_{0}$ is longer and has a better voting consensus than $G_{i}^{\prime \prime}$.
5.2. Analysis of Phase-One of Find-Noisy-Motif. Lemma 5.2 shows that with only a small probability, a sequence can match a random sequence. It will be used to prove that when two substrings in two $\Theta_{\alpha}(n, G)$-sequences are similar, they are likely to coincide with the motif regions in the two $\Theta_{\alpha}(n, G)$-sequences, respectively.

Definition 5.1. Let $t_{0}$ be any positive constant such that

$$
\begin{align*}
\frac{2(v-1)}{t_{0}} & \leq \frac{r_{0}}{2}  \tag{14}\\
\frac{c_{2} v^{3}}{t_{0}} & \leq \rho_{0} \tag{15}
\end{align*}
$$

and

$$
\begin{equation*}
\frac{t_{0}-1}{t_{0}}-\beta>\epsilon \tag{16}
\end{equation*}
$$

The parameter $t_{0}$ is used as a required lower bound of alphabet size. In the remainder of this paper, we always assume the alphabet size $t$ is at least $t_{0}$.

Lemma 5.2. Assume that $X_{1}$ and $X_{2}$ are two independent sequences of the same length and that every character of $X_{2}$ is a random character from $\Sigma$. Then the following hold:
(i) If $1 \leq\left|X_{1}\right|=\left|X_{2}\right|<v$, then the probability that $X_{1}$ and $X_{2}$ are matched is $\leq \frac{1}{t}$, where $t=|\Sigma|$.
(ii) If $v \leq\left|X_{1}\right|=\left|X_{2}\right|$, then the probability for $\operatorname{diff}\left(X_{1}, X_{2}\right) \leq \beta$ is at most $e^{-\frac{\epsilon^{2}\left|X_{1}\right|}{3}}$.
Proof. The two statements are proved as follows.
Statement (i). For every character $X_{2}[j]$ with $1 \leq j<v$, the probability is $\frac{1}{t}$ that $X_{2}[j]=X_{1}[j]$.

Statement (ii). For every character $X_{2}[j]$ with $1 \leq j \leq\left|X_{2}\right|$, the probability is $\frac{1}{t}$ for $X_{2}[j]=X_{1}[j]$. The expected number of positions where the two sequences $X_{1}$ and $X_{2}$ differ is $\frac{t-1}{t}\left|X_{1}\right|$. Since $\beta=\frac{t-1}{t}-\left(\frac{t-1}{t}-\beta\right)$, the probability for $\operatorname{diff}\left(X_{1}, X_{2}\right) \leq \beta$
is at most $e^{-\frac{\left(\frac{t-1}{t}-\beta\right)^{2}}{3}}\left|X_{1}\right| \leq e^{-\frac{\epsilon^{2}}{3}\left|X_{1}\right|}$ by inequality (16), Corollary 2.3 , and the fact that $t \geq t_{0}$ (see Definition 5.1).

Function Extract $\left(S_{1}, S_{2}\right)$ returns a substring of $S_{2}$. We expect that $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ is the motif region $\aleph\left(S_{2}\right)$ in $S_{2}$. Lemma 5.3 shows that with a small probability, the region for Extract $\left(S_{1}, S_{2}\right)$ in $S_{2}$ does not overlap the motif region $\aleph\left(S_{2}\right)$ of $S_{2}$.

Lemma 5.3. With probability at most $\rho_{0}$, Extract $\left(S_{1}, S_{2}\right)$ and $\aleph\left(S_{2}\right)$ are not overlapping substrings of $S_{2}$. In other words, with probability at most $\rho_{0},\left[j, j^{\prime}\right] \cap$ $\left[f, f^{\prime}\right]=\emptyset$, where $\operatorname{Extract}\left(S_{1}, S_{2}\right)=S_{2}\left[j, j^{\prime}\right]$ and $\aleph\left(S_{2}\right)=S_{2}\left[f, f^{\prime}\right]$.

Proof. Assume that $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ returns $M=S_{2}\left[j, j^{\prime}\right]=\operatorname{Extract}\left(S_{1}, S_{2}\right)$ such that $S_{2}\left[j, j^{\prime}\right]$ matches $S_{1}\left[i, i^{\prime}\right]$. Assume that $\aleph\left(S_{2}\right)=S_{2}\left[f, f^{\prime}\right]$. Further, assume that $M$ and $\aleph\left(S_{2}\right)$ have no overlap in $S_{2}$; i.e., $\left[j, j^{\prime}\right] \cap\left[f, f^{\prime}\right]=\emptyset$. For the condition $\operatorname{diff}\left(S_{1}\left[i, i^{\prime}\right], S_{2}\left[j, j^{\prime}\right]\right) \leq \beta$, the probability is at most $e^{-\frac{\epsilon^{2} d}{3}}$ by Lemma 5.2 (notice that the length of $M$ is at least $d$ according to Extract()). The probability of $M$ and $\aleph\left(S_{2}\right)$ not overlapping for all possible $\left[j, j^{\prime}\right]$ is at most $n^{2} \cdot e^{-\frac{\epsilon^{2} d}{3}} \leq \rho_{0}$ by inequality (4).

In order to show that $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ can be used to effectively find a motif region in $S_{2}$, we give Lemma 5.5 to show that with only small probability, the region of $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ in $S_{2}$ may shift far from the motif region $\aleph\left(S_{2}\right)$.

Definition 5.4. The constant $z$ is selected so that

$$
\begin{equation*}
z \geq v \tag{17}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{4 e^{-\frac{\epsilon^{2}}{3} z}}{1-e^{-\frac{\epsilon^{2}}{3}}} \leq \rho_{0} \tag{18}
\end{equation*}
$$

The parameter $z$ is a threshold for controlling the shift in the analysis of PhaseOne of Find-Noisy-Motif. See Lemma 5.5 and Definition 2.1.

Lemma 5.5. The probability is at most $H_{1}=2 \rho_{0}$ that for a pair of sequences $\left(S_{1}, S_{2}\right)$ from $Z_{0}$, shift $\left(\left[i_{2}, j_{2}\right],\left[i_{2}^{\prime}, j_{2}^{\prime}\right]\right) \geq z$ and $\left|S_{2}\left[i_{2}, j_{2}\right]\right| \geq|G|$, where $S_{2}\left[i_{2}, j_{2}\right]=$ $\operatorname{Extract}\left(S_{1}, S_{2}\right), \aleph\left[S_{2}\right]=S_{2}\left[i_{2}^{\prime}, j_{2}^{\prime}\right]$, and $z$ is as defined in Definition 5.4.

Proof. Assume that $M=S_{2}\left[i_{2}, j_{2}\right]=\operatorname{Extract}\left(S_{1}, S_{2}\right)$ is the matched sequence. By Lemma 5.3 , the probability is at most $\rho_{0}$ that $M$ does not intersect $\aleph\left(S_{2}\right)$.

Notice that $M=S_{2}\left[i_{2}, j_{2}\right]$ is a substring of $S_{2}$ according to the function Extract(). Assume that $M^{\prime}=S_{1}\left[i_{1}, j_{1}\right]$ is the substring of $S_{1}$ such that $M^{\prime}$ and $M$ are matched in the function $\operatorname{Extract}\left(S_{1}, S_{2}\right)$. If shift $\left(\left[i_{2}, j_{2}\right],\left[i_{2}^{\prime}, j_{2}^{\prime}\right]\right)=w \geq v$ and $|M| \geq|G|=\left|\aleph\left(S_{2}\right)\right|$, then $M$ contains a substring $N$ of length $w$ outside $\aleph\left(S_{2}\right)$ and $N$ is either a prefix or a suffix of $M$. Every character of $N$ is outside $\aleph\left(S_{2}\right)$ and is a random character that has the probability $\frac{1}{t}$ to be equal to any character in $\Sigma$. By symmetry, we assume without loss of generality that $N$ is a prefix of $M$. Then $M=N N_{1}$ and $M^{\prime}=N^{\prime} N_{1}^{\prime}$, where $N^{\prime}$ and $N$ have the same length and have a difference ratio at most $\beta$ according to the conditions in Definition 4.3. By Lemma 5.2 , the probability is at most $e^{-\frac{\epsilon^{2}}{3} w}$ that $N^{\prime}$ and $N$ have the same length and have a difference of ratio at most $\beta$.

Therefore, the probability is at most $4 e^{-\frac{\epsilon^{2}}{3} w}$ that $\operatorname{shift}\left(\left[i_{2}, j_{2}\right],\left[i_{2}^{\prime}, j_{2}^{\prime}\right]\right)=w$. The probability for $\operatorname{shift}\left(\left[i_{2}, j_{2}\right],\left[i_{2}^{\prime}, j_{2}^{\prime}\right]\right) \geq z$ is at most

$$
4 \sum_{w=z}^{\infty} e^{-\frac{\epsilon^{2}}{3} w}=\frac{4 e^{-\frac{\epsilon^{2}}{3} z}}{1-e^{-\frac{\epsilon^{2}}{3}}}=\frac{4 c^{z}}{1-c}
$$

Copyright © by SIAM. Unauthorized reproduction of this article is prohibited.
(recall $c=e^{-\frac{\epsilon^{2}}{3}}$ from Definition 4.2). Therefore, the total probability that shift ( $\left[i_{2}, j_{2}\right]$, $\left.\left[i_{2}^{\prime}, j_{2}^{\prime}\right]\right) \geq z$ is at most $H_{1}=\rho_{0}+\frac{c^{z}}{1-c} \leq 2 \rho_{0}$ by inequality (18).

Lemma 5.6 will be used to give an upper bound in probability analysis. It is derived by standard methods in calculus.

Lemma 5.6. Assume that $0<a<1$ and $j$ is a positive integer.
(i) $\sum_{i=j}^{\infty} i a^{i}=\frac{j a^{j}-(j-1) a^{j+1}}{(1-a)^{2}}<\frac{j a^{j}}{(1-a)^{2}}$.
(ii) $\sum_{i=j}^{\infty} i^{2} a^{i}=a^{j}\left(\frac{\left(j^{2}-(j-1)(j+1) a\right)(1-a)-(j-(j-1) a) 2(-a)}{(1-a)^{3}}\right)<\frac{2 j^{2} a^{j}}{(1-a)^{3}}$.

Proof. Let $\theta$ be a negative parameter.
Statement (i). Let $f(y)=\sum_{i=j}^{\infty} e^{\theta i y}$. Therefore, we have the derivative $f^{\prime}(y)=$ $\theta \sum_{i=j}^{\infty} i e^{\theta i y}$. Alternatively, using the closed form $f(y)=\frac{e^{\theta j y}}{1-e^{\theta y}}$, we have

$$
\begin{align*}
f^{\prime}(y) & =\frac{\theta j e^{\theta j y}\left(1-e^{\theta y}\right)-e^{\theta j y}\left(-\theta e^{\theta y}\right)}{\left(1-e^{\theta y}\right)^{2}}  \tag{19}\\
& =\frac{\theta j e^{\theta j y}-\theta(j-1) e^{\theta(j+1) y}}{\left(1-e^{\theta y}\right)^{2}} \tag{20}
\end{align*}
$$

Let $\theta=\ln a$ and $y=1$. We have $\sum_{i=j}^{\infty} i a^{i}=\frac{j a^{j}-(j-1) a^{j+1}}{(1-a)^{2}}<\frac{j a^{j}}{(1-a)^{2}}$.
Statement (ii). By equality (20),

$$
\begin{aligned}
f^{\prime \prime}(y) & =\left(\frac{\theta j e^{\theta j y}-\theta(j-1) e^{\theta(j+1) y}}{\left(1-e^{\theta y}\right)^{2}}\right)^{\prime} \\
& =\frac{\left(\theta^{2} j^{2} e^{\theta j y}-\theta^{2}(j-1)(j+1) e^{\theta(j+1) y}\right)\left(1-e^{\theta y}\right)^{2}-\left(\theta j e^{\theta j y}-\theta(j-1) e^{\theta(j+1) y}\right) 2\left(-\theta e^{\theta y}\right)\left(1-e^{\theta y}\right)}{\left(1-e^{\theta y}\right)^{4}} \\
& =\theta^{2}\left(\frac{\left(j^{2} e^{\theta j y}-(j-1)(j+1) e^{\theta(j+1) y}\right)\left(1-e^{\theta y}\right)-\left(j e^{\theta j y}-(j-1) e^{\theta(j+1) y}\right) 2\left(-e^{\theta y}\right)}{\left(1-e^{\theta y}\right)^{3}}\right) \\
& =\theta^{2} e^{\theta j y}\left(\frac{\left(j^{2}-(j-1)(j+1) e^{\theta y}\right)\left(1-e^{\theta y}\right)-\left(j-(j-1) e^{\theta y}\right) 2\left(-e^{\theta y}\right)}{\left(1-e^{\theta y}\right)^{3}}\right) .
\end{aligned}
$$

We also have $f^{\prime \prime}(y)=\theta^{2} \sum_{i=j}^{\infty} i^{2} e^{\theta i y}$. Let $\theta=\ln a$ and $y=1$. We have

$$
\begin{aligned}
\sum_{i=j}^{\infty} i^{2} a^{i} & =a^{j}\left(\frac{\left(j^{2}-(j-1)(j+1) a\right)(1-a)-(j-(j-1) a) 2(-a)}{(1-a)^{3}}\right) \\
& <\frac{\left(j^{2}(1-a)+2 j a\right) a^{j}}{(1-a)^{3}} \\
& <\frac{2 j^{2} a^{j}}{(1-a)^{3}} .
\end{aligned}
$$

Lemma 5.8 below shows that with high probability, many prefixes and suffixes of the motif region in a $\Theta_{\alpha}(n, G)$-sequence do not change much. We define

$$
\begin{equation*}
Q_{0}=(1-\alpha)^{2}-\frac{2 c^{v}}{1-c} \tag{21}
\end{equation*}
$$

The parameter $Q_{0}$ is used in Lemma 5.8 to give a lower bound on the probability that for a $\Theta_{\alpha}(n, G)$-sequence $S$, its $\aleph(S)$ will be similar enough to the original motif $G$ according to the conditions in Lemma 5.8.

Definition 5.7. We say that a $\Theta_{\alpha}(n, G)$-sequence $S$ contains a stable motif region $\aleph(S)$ if the following conditions hold: (1) $G^{\prime}[1]=G[1] ;(2) G^{\prime}[m]=G[m] ;$ (3) $\operatorname{diff}\left(G^{\prime}[1, h], G[1, h]\right) \leq \frac{\beta}{2}$ for all $h=v, v+1, \ldots, m$; and (4) $\operatorname{diff}\left(G^{\prime}[m-h, m], G[m-\right.$
$h, m]) \leq \frac{\beta}{2}$ for $h=v-1, v+1, \ldots, m-1$, where $G^{\prime}=\aleph(S), c=e^{-\frac{\epsilon^{2}}{3}}$, and $m=|G|$ as defined in Definition 4.2 and section 2.

Lemma 5.8. With probability at least $Q_{0}, a \Theta_{\alpha}(n, G)$-sequence $S$ contains a stable motif region.

Proof. The probability is $(1-\alpha)^{2}$ to satisfy conditions (1) and (2) in Definition 5.7. Consider condition (3). Since every character of $\aleph(S)[1, m]$ (notice that $m=|G|$ ) has probability at most $\alpha$ to mutate, by Corollary 2.3 the probability is at most $e^{-\frac{1}{3} \epsilon^{2} r}$ that $\operatorname{diff}\left(G[1, h], G^{\prime}[1, h]\right)>\frac{\beta}{2}=\alpha+\epsilon$. Let $V_{3}=\sum_{r=v}^{\infty} e^{-\frac{1}{3} \epsilon^{2} r}=\frac{c^{v}}{1-c}$, where $c=e^{-\frac{1}{3} \epsilon^{2}}$ as defined in Definition 4.2. Therefore, the probability is at most $V_{3}$ that $\operatorname{diff}\left(G[1, h], G^{\prime}[1, h]\right)>\frac{\beta}{2}=\alpha+\epsilon$ for some $h \in\{v, v+1, \cdots, m\}$. Similarly we define $V_{4}=\sum_{r=v}^{\infty} e^{-\frac{1}{3} \epsilon^{2} r} \leq \frac{c^{v}}{1-c}$. The probability is at most $V_{4}$ that $\operatorname{diff}\left(G[m-h, m], G^{\prime}[m-\right.$ $h, m])>\frac{\beta}{2}=\alpha+\epsilon$ for some $h \in\{v, v+1, \cdots, m\}$. In sum, the probability that $S$ contains a stable motif region is at least $(1-\alpha)^{2}-V_{3}-V_{4}=(1-\alpha)^{2}-\frac{2 c^{v}}{1-c}=Q_{0}$.

Lemma 5.9 below gives a lower bound for the probability that $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ returns the motif region $\aleph\left(S_{2}\right)$ of $S_{2}$, and that the motif region $\aleph\left(S_{2}\right)$ of $S_{2}$ does not differ much from the original motif $G$.

Define constants

$$
\begin{equation*}
c_{1}=\frac{2}{(1-c)^{4}} \tag{22}
\end{equation*}
$$

and

$$
\begin{equation*}
c_{2}=20 c_{1} \tag{23}
\end{equation*}
$$

Lemma 5.9. Given two independently generated $\Theta_{\alpha}(n, G)$-sequences $S_{1}$ and $S_{2}$, the probability is at least $Q_{1}=Q_{0}^{2}-H_{2}-H_{1} \geq Q_{0}^{2}-4 \rho_{0}$ that $\operatorname{Extract}\left(S_{1}, S_{2}\right)$ returns $\aleph\left(S_{2}\right)$, and $\aleph\left(S_{2}\right)$ contains a stable motif region, where $H_{1}$ is defined in Lemma 5.5, $H_{2}=c_{2} v^{3}\left(\frac{1}{t}+c^{v}\right)$, and $c_{2}$ is a constant defined in (23).

Proof. Let $M_{1}$ be the substring of $S_{1}$ that matches the substring of $M_{2}$ of $S_{2}$, let $M_{2}=\operatorname{Extract}\left(S_{1}, S_{2}\right)$, and let $h=\left|M_{1}\right|=\left|M_{2}\right|$. Assume $M_{1}=S_{1}\left[i_{1}, j_{1}\right]$ and $M_{2}=S_{2}\left[i_{2}, j_{2}\right]$. For two random $\Theta_{\alpha}(n, G)$-sequences $S_{1}$ and $S_{2}$, their motif regions $\aleph\left(S_{1}\right)$ and $\aleph\left(S_{2}\right)$ can match well with probability at least $Q_{0}^{2}$ by Lemma 5.8. We can assume that in the function Extract $\left(S_{1}, S_{2}\right)$, we consider only the variable $h \geq$ $\left|\aleph\left(S_{1}\right)\right|=\left|\aleph\left(S_{2}\right)\right|$. If $h<\left|\aleph\left(S_{1}\right)\right|=\left|\aleph\left(S_{2}\right)\right|$ happens, then $\aleph\left(S_{1}\right)$ and $\aleph\left(S_{2}\right)$ cannot match well.

Define $P_{L, R}\left(w_{1}, w_{2}, s\right)$ to be the probability that the following three conditions are satisfied.

Condition (1). There are $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the left side of $M_{1}$. In other words, $S_{1}\left[i_{1}+w_{1}\right]$ is the first character of $\aleph\left(S_{1}\right)$, and the $w_{1}$ characters $S_{1}\left[i_{1}, i_{1}+w_{1}-1\right]$ are outside the region $\aleph\left(S_{1}\right)$.

Condition (2). There are $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ in the right region of $M_{2}$. In other words, $M_{2}=S_{2}\left[i_{2}, j_{2}\right], S_{1}\left[j_{2}-w_{2}\right]$ is the last character of $\aleph\left(S_{2}\right)$, and the $w_{2}$ characters $S_{2}\left[j_{2}-w_{2}+1, j_{2}\right]$ are outside the region $\aleph\left(S_{2}\right)$.

Condition (3). The position of the first character of $\aleph\left(S_{1}\right)$ in $M_{1}$ and the position of the first character of $\aleph\left(S_{2}\right)$ in $M_{2}$ have shift $s$. In other words, if $S_{1}\left[t_{1}\right]$ is the first character of $\aleph\left(S_{1}\right)$ in $S_{1}$ and $S_{2}\left[t_{2}\right]$ is the first character of $\aleph\left(S_{2}\right)$ in $S_{2}$, then $s=\left|\left(t_{1}-i_{1}\right)-\left(t_{2}-i_{2}\right)\right|$. See Figure 3 for an illustration.

In a similar way, we define the probabilities $P_{L, L}\left(w_{1}, w_{2}, s\right), P_{R, L}\left(w_{1}, w_{2}, s\right)$, and $P_{R, R}\left(w_{1}, w_{2}, s\right)$. In other words, for $P_{A, B}\left(w_{1}, w_{2}, s\right)$ with $A, B \in\{L, R\}, A=L$ (or $A=R)$ represents the case that there are $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the left

Fig. 3. $M_{1}$ and $M_{2}$ for Case 1 of the proof of Lemma 5.9.
(respectively, right) side of $M_{1}$, and $B=L$ (or $B=R$ ) represents the case that there are $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ on the left (respectively, right) side of $M_{2}$. Furthermore, the parameter $s$ indicates the shift defined in Condition (3) above.

By Lemma 5.5 , with probability at most $H_{1}, \operatorname{shift}\left(\left[i_{2}, j_{2}\right],\left[i_{2}^{\prime}, j_{2}^{\prime}\right]\right) \geq z$, where $M=S_{2}\left[i_{2}, j_{2}\right]$ and $\aleph\left(S_{2}\right)=S_{2}\left[i_{2}^{\prime}, j_{2}^{\prime}\right]$. Therefore, the probability is at least $1-H_{1}$ that if $\left|M_{2}\right| \geq|G|$, then most parts of $M_{2}$ are in the region $\aleph\left(S_{2}\right)$ (recall that $\left.z=O(1)\right)$.

The probabilistic analysis below has 10 cases. Case $a . b$ is the $b$ th subcase of Case $a$. Case $a . b . c$ is the $c$ th subcase of Case $a . b$. We use $P_{a}, P_{a . b}$, and $P_{a . b . c}$ to denote the probabilities of Cases $a, a . b$, and $a . b . c$, respectively.

Case 1. $0 \leq w_{2}<w_{1}, M_{1}$ has $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the left side of $M_{1}$, the last character of $\aleph\left(S_{2}\right)$ is in $M_{2}$, and $M_{2}$ has $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ on the right side outside $M_{2}$. See Figure 3 .

We consider only the cases where $s=1,2, \ldots, w_{1}+w_{2}$ and $M_{2}$ has fewer than $w_{1}$ characters outside $\aleph\left(S_{2}\right)$ on the left side. The cases where $M_{2}$ has at least $w_{1}$ characters outside $\aleph\left(S_{2}\right)$ are covered by Cases 5 and 9 .

If $s>w_{1}+w_{2}$, the matched region will be shorter than that of $\aleph\left(S_{2}\right)$. If $s \leq w_{1}$, the first character of $\aleph\left(S_{2}\right)$ is in $M_{2}$, and this case is included in Case 4. Therefore, we consider only the range $w_{1}+1 \leq s \leq w_{1}+w_{2}$. For an upper bound for the probability of Case 1, we compute $P_{1}=\sum_{w_{2}=0}^{\infty} \sum_{w_{1}=w_{2}+1}^{\infty} \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right)$. There are some subcases.

- Case 1.1. $0 \leq w_{2}<v$.

Case 1.1.1. $0 \leq w_{2}<w_{1}<v$.
By Lemma 5.2, $P_{L, R}\left(w_{1}, w_{2}, s\right) \leq \frac{1}{t}$ for fixed $w_{1}, w_{2}$, and $s . \sum_{s=1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}\right.$, $\left.w_{2}, s\right) \leq \frac{2 v}{t}$ for a fixed $w_{1}$ and all $s=w_{1}+1, \ldots, w_{1}+w_{2}$. Then

$$
\sum_{w_{1}=w_{2}+1}^{v-1} \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq \frac{2 v^{2}}{t}
$$

Case 1.1.2. $v \leq w_{1}$.
By Lemma 5.2, $P_{L, R}\left(w_{1}, w_{2}, s\right) \leq e^{-\frac{\epsilon^{2}}{3} w_{1}}$ for a fixed $w_{1}$ and a fixed $s$. $\sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq w_{2} e^{-\frac{\epsilon^{2}}{3} w_{1}} . \quad \sum_{w_{1}=v}^{\infty} \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq$ $\sum_{w_{1}=v}^{\infty} w_{2} e^{-\frac{\epsilon^{2}}{3} w_{1}}=w_{2} \frac{c^{v}}{1-c}$.
Combining Cases 1.1.1 and 1.1.2, we have

$$
\begin{aligned}
P_{1.1} & =\sum_{w_{2}=0}^{v-1} \sum_{w_{1}=w_{2}+1}^{\infty} \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \\
& \leq \sum_{w_{2}=0}^{v-1}\left(\frac{2 v^{2}}{t}+\frac{c^{v} w_{2}}{1-c}\right)<\frac{2 v^{3}}{t}+\frac{v^{2} c^{v}}{2(1-c)} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)
\end{aligned}
$$

Fig. 4. $M_{1}$ and $M_{2}$ for Case 2 of the proof of Lemma 5.9.

- Case 1.2. $v \leq w_{2}$.

Assume that $v \leq w_{2}<w_{1}$. By Lemma 5.2, $P_{L, R}\left(w_{1}, w_{2}, s\right) \leq e^{-\frac{\epsilon^{2}}{3} w_{1}}$ for fixed $w_{1}, w_{2}$, and $s . \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq w_{2} e^{-\frac{\epsilon^{2}}{3} w_{1}}$ for fixed $w_{1}$ and $w_{2} . \sum_{w_{1}=w_{2}+1}^{\infty} \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq \sum_{w_{1}=w_{2}+1}^{\infty} w_{2} e^{-\frac{\epsilon^{2}}{3} w_{1}}=w_{2} \frac{c^{w_{2}+1}}{1-c}$.
Therefore, by Lemma 5.6, $P_{1.2}=\sum_{w_{2}=v}^{\infty} \sum_{w_{1}=w_{2}+1}^{\infty} \sum_{s=w_{1}+1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right)$ $\leq \sum_{w_{2}=v}^{\infty} w_{2} \frac{c^{w_{2}+1}}{1-c} \leq \frac{v c^{v+1}}{(1-c)^{3}} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.
Therefore, we have derived a probability bound for Case 1: $P_{1}=P_{1.1}+P_{1.2} \leq$ $2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 2. $0 \leq w_{2}<w_{1}$, the last character of $\aleph\left(S_{2}\right)$ is in $M_{2}, M_{2}$ has $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ in the right side of the matched region, and $M_{1}$ has $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ in the right side of the matched region. See Figure 4.

For a probability upper bound of Case 2, we compute

$$
P_{2}=\sum_{w_{2}=1}^{\infty} \sum_{w_{1}=w_{2}+1}^{\infty} P_{R, R}\left(w_{1}, w_{2}, w_{1}-w_{2}\right)
$$

There are some subcases.

- Case 2.1. $0 \leq w_{2}<v$.

Case 2.1.1. $0 \leq w_{2}<w_{1}<v$.
By Lemma 5.2, $P_{R, R}\left(w_{1}, w_{2}, s\right) \leq \frac{1}{t}$ for fixed $w_{1}, w_{2}$ and $s=w_{1}-w_{2}$. The total probability of Case 2.1.1 for a fixed $w_{2}$ and all $w_{1}$ with $w_{2}<w_{1} \leq v$ is at most $\frac{\left(v-w_{2}-1\right)}{t}$.
Case 2.1.2. $v \leq w_{1}$.
By Lemma 5.2, $P_{R, R}\left(w_{1}, w_{2}, s\right) \leq e^{-\frac{\epsilon^{2}}{3} w_{1}}$ for a fixed $w_{1}$ and a fixed $s=w_{1}-$ $w_{2}$. We have $\sum_{w_{1}=v}^{\infty} P_{R, R}\left(w_{1}, w_{2}, s\right)=\sum_{w_{1}=v}^{\infty} e^{-\frac{\epsilon^{2}}{3} w_{1}}=\frac{c^{v}}{1-c}$ for all $w_{1} \geq v$. Therefore, $P_{2.1}=\sum_{w_{2}=0}^{v-1} \sum_{w_{1}=w_{2}+1}^{\infty} P_{R, R}\left(w_{1}, w_{2}, w_{1}-w_{2}\right) \leq \sum_{w_{2}=1}^{v-1}\left(\frac{\left(v-w_{2}-1\right)}{t}\right.$ $\left.+\frac{c^{v}}{1-c}\right)<\frac{v^{2}}{2 t}+\frac{v c^{v}}{1-c} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

- Case 2.2. $v \leq w_{2}$.

Assume $v \leq w_{2}<w_{1}$. By Lemma 5.2, for a fixed $w_{1}$ and a fixed $s=w_{1}-w_{2}$, the probability for Case 2.2 is at most $P_{R, R}\left(w_{1}, w_{2}, s\right) \leq e^{-\frac{\epsilon^{2}}{3} w_{1}}$. The probability for Case 2.2 for all $w_{1}>w_{2}$ is at most $\sum_{w_{1}=w_{2}+1}^{\infty} e^{-\frac{\epsilon^{2}}{3} w_{1}}=\frac{c^{w_{2}+1}}{1-c}$. Therefore, $P_{2.2}=\sum_{w_{2}=v}^{\infty} \sum_{w_{1}=w_{2}+1}^{\infty} P_{R, R}\left(w_{1}, w_{2}, w_{1}-w_{2}\right) \leq \sum_{w_{2}=v}^{\infty}\left(\frac{c^{w_{2}+1}}{1-c}\right)<$ $\frac{c^{v+1}}{(1-c)^{2}} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.
Therefore, the probability for Case 2 is upper bounded as $P_{2}=P_{2.1}+P_{2.2} \leq$ $2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 3. $0 \leq w_{2}<w_{1}, M_{1}$ has $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the right side of $M_{1}$, the last character of $\aleph\left(S_{2}\right)$ is in $M_{2}$, and $M_{2}$ has $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ on the left side of $M_{2}$.

For a probability upper bound of Case 3 , we compute

$$
P_{3}=\sum_{w_{2}=0}^{\infty} \sum_{w_{1}=w_{2}+1}^{\infty} \sum_{s=1}^{\infty} P_{R, L}\left(w_{1}, w_{2}, s\right) .
$$

This case has the same analysis and probability as Case 1. Therefore, we have $P_{3}=$ $P_{1} \leq 2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 4. $0 \leq w_{2}<w_{1}, S_{1}$ has $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the left side of $M_{1}$, and $S_{2}$ has $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ on the left side $M_{2}$.

For a probability upper bound of Case 4 , we compute

$$
P_{4}=\sum_{w_{2}=1}^{\infty} \sum_{w_{1}=w_{2}+1}^{\infty} P_{L, L}\left(w_{1}, w_{2}, w_{1}-w_{2}\right) .
$$

This case has the same analysis and probability as Case 2. Therefore, we have $P_{4}=$ $P_{2} \leq 2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 5. $1 \leq w_{1}=w_{2}$, and the left sides of both $M_{1}$ and $M_{2}$ have the same number $w_{2}$ of characters outside $\aleph\left(S_{1}\right)$ and $\aleph\left(S_{2}\right)$, respectively.

For a probability upper bound of Case 5 , we compute $P_{5}=\sum_{w_{2}=1}^{\infty} P_{L, L}\left(w_{2}, w_{2}, 0\right)$. There are two subcases.

- Case 5.1. $1 \leq w_{2}<v$. By Lemma 5.2 , the probability for this case is at most $\frac{1}{t}$ for a fixed $w_{2}$. The total probability for this case for $1 \leq w_{2}<v$ is $P_{5.1} \leq \frac{v}{t}$.
- Case 5.2. $v \leq w_{2}$. By Lemma 5.2, the probability for this case is at most $e^{-\frac{\epsilon^{2}}{3} w_{2}}$ for a fixed $w_{2}$. The total probability for this case for $v \leq w_{2}$ is $P_{5.2} \leq \sum_{w_{2}=v}^{\infty} e^{-\frac{\epsilon^{2}}{3} w_{2}}=\frac{c^{v}}{1-c}$.
The total probability bound for Case 5 is upper bounded as $P_{5}=P_{5.1}+P_{5.2} \leq$ $\frac{v}{t}+\frac{c^{v}}{1-c} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 6. $1 \leq w_{1}=w_{2}$, and the right sides of both $M_{1}$ and $M_{2}$ have the same number $w_{2}$ of characters outside $\aleph\left(S_{1}\right)$ and $\aleph\left(S_{2}\right)$, respectively.

For the probability upper bound of Case 6 , we compute $P_{6}=\sum_{w_{2}=1}^{\infty} P_{R, R}\left(w_{2}, w_{2}, 0\right)$. This case has the same analysis and probability as Case 5. Therefore, $P_{6}=P_{5} \leq$ $c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 7. $0 \leq w_{1}<w_{2}$, the first character of $\aleph\left(S_{1}\right)$ is in $M_{1}, M_{1}$ has $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the left side of $M_{1}$, and $M_{2}$ has $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ on the right side of $M_{2}$.

We have only $s=1,2, \ldots, w_{1}+w_{2}$. For a probability upper bound of Case 7 , we compute $\sum_{w_{2}=0}^{\infty} \sum_{w_{1}=1}^{w_{2}-1} \sum_{s=1}^{\infty} P_{L, R}\left(w_{1}, w_{2}, s\right)$.

- Case 7.1. $0 \leq w_{2}<v$.

By Lemma 5.2, $P_{L, R}\left(w_{1}, w_{2}, s\right) \leq \frac{1}{t}$ for fixed $w_{1}, w_{2}$, and $s$. The total probability for this case for all $w_{1}$ with $0 \leq w_{1} \leq w_{2}$ is at most $\frac{w_{1}+w_{2}}{t}$. The probability is at most $\frac{2 w_{2}^{2}}{t}$ for all $w_{1}$ with $0 \leq w_{1}<w_{2}$. Therefore, $P_{7.1} \leq$ $\sum_{w_{2}=0}^{v-1} \sum_{w_{1}=0}^{w_{2}-1} \sum_{s=1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq \sum_{w_{2}=0}^{v-1}\left(\frac{2 w_{2}^{2}}{t}\right)<\frac{2 v^{3}}{t} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

- Case 7.2. $v \leq w_{2}$.

By Lemma 5.2, $P_{L, R}\left(w_{1}, w_{2}, s\right) \leq e^{-\frac{\varepsilon^{2}}{3} w_{2}}$ for a fixed $w_{2}$ and a fixed $s$. The total probability for this case for fixed $w_{1}$ and $w_{2}$, and variable $s=1, \ldots, w_{1}+w_{2}$
is $\sum_{s=1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2} s\right) \leq\left(w_{1}+w_{2}\right) e^{-\frac{\epsilon^{2}}{3} w_{2}}$. The total probability for this case for all $w_{2} \geq v$ is at most $P_{7}=\sum_{w_{1}=0}^{w_{2}-1}\left(w_{1}+w_{2}\right) e^{-\frac{\epsilon^{2}}{3} w_{2}}=\frac{2 w_{2}^{2} c^{w_{2}}}{1-c}$. Therefore, $P_{7.2} \leq \sum_{w_{2}=v}^{\infty} \sum_{w_{1}=0}^{w_{2}-1} \sum_{s=1}^{w_{1}+w_{2}} P_{L, R}\left(w_{1}, w_{2}, s\right) \leq \sum_{w_{2}=v}^{\infty}\left(\frac{2 w_{2}^{2} c^{w_{2}}}{1-c}\right)<$ $\frac{2}{(1-c)} \frac{2 v^{2} c^{v}}{(1-c)^{3}}=\frac{4 v^{2} c^{v}}{(1-c)^{4}} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$ (by Lemma 5.6).
In summary, the probability for Case 7 is upper bounded as $P_{7}=P_{7.1}+P_{7.2} \leq$ $2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 8. $0 \leq w_{1}<w_{2}$, the last character of $\aleph\left(S_{1}\right)$ is in $M_{1}$, there are $w_{1}$ characters on the right side of $M_{1}$ and outside its $\aleph\left(S_{1}\right)$, and $M_{2}$ has $w_{2}$ characters on the right side of $M_{2}$ and outside its $\aleph\left(S_{2}\right)$.

For a probability upper bound of Case 8 , we compute

$$
P_{8}=\sum_{w_{2}=1}^{\infty} \sum_{w_{1}=0}^{w_{2}-1} P_{R, R}\left(w_{1}, w_{2}, w_{2}-w_{1}\right)
$$

There are two subcases.

- Case 8.1. $0<w_{2}<v$.

By Lemma 5.2, the probability for this case for a fixed $w_{1}$ and a fixed $s=$ $w_{2}-w_{1}$ is at most $\frac{1}{t}$. The total probability for this case for all $w_{1}$ with $0 \leq$ $w_{1} \leq w_{2}-1$ is at most $\frac{w_{2}}{t}$. Therefore, $P_{8.1}=\sum_{w_{2}=1}^{v-1} \sum_{w_{1}=0}^{w_{2}-1} P_{R, R}\left(w_{1}, w_{2}, w_{2}-\right.$ $\left.w_{1}\right) \leq \sum_{w_{2}=1}^{v-1} \frac{w_{2}}{t}=\frac{v^{2}}{t} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

- Case 8.2. $v \leq w_{2}$.

By Lemma 5.2, $P_{L, R}\left(w_{1}, w_{2}, s\right) \leq e^{-\frac{\epsilon^{2}}{3} w_{2}}$ for a fixed $w_{2}$ and a fixed $s=$ $w_{2}-w_{1}$. The total probability for this case for all $0 \leq w_{1} \leq w_{2}-1$ is at most $\sum_{w_{1}=0}^{w_{2}-1} e^{-\frac{\varepsilon^{2}}{3} w_{2}}=\frac{w_{2} c^{w_{2}}}{1-c}$. Therefore, $P_{8.2}=\sum_{w_{2}=v}^{\infty} \sum_{w_{1}=0}^{w_{2}-1} P_{R, R}\left(w_{1}, w_{2}, w_{2}-\right.$ $\left.w_{1}\right) \leq \sum_{w_{2}=v}^{\infty} \frac{w_{2} w_{2}}{1-c} \leq \frac{v c^{v}}{(1-c)^{3}} \leq c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$ by Lemma 5.6.
We have $P_{8}=P_{8.1}+P_{8.2}=O\left(v^{2}\left(\frac{1}{t}+c^{v}\right)\right) \leq 2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.
Case $9.0 \leq w_{1}<w_{2}$, the last character of $\aleph\left(S_{1}\right)$ is in $M_{1}, S_{1}$ has $w_{1}$ characters outside $\aleph\left(S_{1}\right)$ on the right side of $M_{1}$, and $S_{2}$ has $w_{2}$ characters outside $\aleph\left(S_{2}\right)$ on the left side outside $M_{2}$.

For a probability upper bound of Case 9 , we compute

$$
P_{9}=\sum_{w_{2}=1}^{\infty} \sum_{w_{1}=0}^{w_{2}-1} \sum_{s=1}^{\infty} P_{R, L}\left(w_{1}, w_{2}, s\right)
$$

This case has the same analysis and probability as Case 7. Therefore, we have $P_{9}=$ $P_{7} \leq 2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

Case 10. $0 \leq w_{1}<w_{2}$, the first character of $\aleph\left(S_{1}\right)$ is in $M_{1}, M_{1}$ has $w_{1}$ characters on the left side of $M_{1}$ outside $\aleph\left(S_{1}\right)$, and $M_{2}$ has $w_{2}$ characters on the left side of $M_{2}$ outside $\aleph\left(S_{2}\right)$.

For a probability upper bound of Case 10 , we compute

$$
P_{10}=\sum_{w_{2}=1}^{\infty} \sum_{w_{1}=0}^{w_{2}-1} P_{L, L}\left(w_{1}, w_{2}, w_{2}-w_{1}\right)
$$

This case has the same analysis and probability as Case 8. Therefore, we have $P_{10}=$ $P_{8}=O\left(v^{2}\left(\frac{1}{t}+c^{v}\right)\right) \leq 2 c_{1} \cdot v^{3}\left(\frac{1}{t}+c^{v}\right)$.

The total probability for $w_{2} \geq 1$ is at most $H_{2}=\sum_{i=1}^{10} P_{i} \leq c_{2}\left(v^{3}\left(\frac{1}{t}+c^{v}\right)\right)$. Therefore, we have a constant $c_{2}>0$ such that $H_{2} \leq c_{2}\left(v^{3}\left(\frac{1}{t}+c^{v}\right)\right) \leq 2 \rho_{0}$ by inequalities (8) and (15). Lemma 5.9 follows from the fact that $S_{2}$ has probability at least $Q_{0}^{2}$ for $\aleph\left(S_{2}\right)$ to match $\aleph\left(S_{1}\right)$ well, and probability $H_{2}+H_{1} \leq 4 \rho_{0}$ for a bad match (i.e., $M_{2} \neq \aleph\left(S_{2}\right)$ ).

Lemma 5.10. With probability at most $\frac{\eta}{2^{x}}$, the set $W$ outputted by Phase-One does not contain $G_{0}$ such that $G_{0}=\operatorname{Extract}\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)=\aleph\left(S_{i}^{\prime \prime}\right)$ and $S_{i}^{\prime \prime}$ contains a stable motif region (see Definition 5.7).

Proof. By inequality (7) and equality (21), we have $Q_{0} \geq \frac{1}{2}$. By Lemma 5.9 and $\rho_{0}=\frac{1}{24}$ defined in section 4.1, we have $Q_{1} \geq Q_{0}^{2}-4 \rho_{0} \geq \frac{1}{12}$. Since the number $k_{1}$ is selected to be large enough that $\left(1-Q_{1}\right)^{k_{1}} \leq \frac{\eta}{2^{x}}$ (see inequality (11)), the probability is at most $\left(1-Q_{1}\right)^{k_{1}} \leq \frac{\eta}{2^{x}}$ (by Lemma 5.9) such that there is no $i$ with $1 \leq i \leq$ $k_{1}$ such that both $S_{i}^{\prime}$ and $S_{i}^{\prime \prime}$ have stable motif regions and Extract $\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)$ returns $\aleph\left(S_{i}^{\prime \prime}\right)$.

Definition 5.11. Assume that $\aleph\left(S_{i}^{\prime \prime}\right)$ is a stable motif region as described in Lemma 5.10 and that $\operatorname{Extract}\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)=\aleph\left(S_{i}^{\prime \prime}\right)$ for some $1 \leq i \leq k_{1}$. Define $G_{0}=$ $\operatorname{Extract}\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)=\aleph\left(S_{i}^{\prime \prime}\right)$.
5.3. Analysis of Phase-Two of Algorithm Find-Noisy-Motif. Lemma 5.12 below shows that with small probability, the input $Z_{1}$ (which is the set of sequences used to form the sequence pairs of $Z_{0}$ and is generated by LoadInputSequence) contains a sequence whose motif region has many mutations.

Lemma 5.12. With probability at most $2 k_{1} e^{-\frac{\epsilon^{2}}{3} d}$, at least one sequence $S$ in $Z_{1}$ mutates at more than $\frac{\beta}{2}|G|$ characters in its motif region $\aleph(S)$.

Proof. Every character in the $\aleph(S)$ region has probability at most $\alpha$ to mutate. Recall that $|\aleph(S)|=|G| \geq d$. By Corollary 2.3, with probability at most $e^{-\frac{\epsilon^{2}}{3}|G|} \leq$ $e^{-\frac{\epsilon^{2}}{3} d}$, a sequence $S$ in $Z_{1}$ has more than $(\alpha+\epsilon)|G|=\frac{\beta}{2}|G|$ mutations (recall the setting for $\beta$ in Definition 4.3). Since there are $2 k_{1}$ sequences in $Z_{1}$, the total probability is at most $2 k_{1} e^{-\frac{\varepsilon^{2}}{3} d}$ that at least one sequence $S$ in $Z_{1}$ mutates at more than $\frac{\beta}{2}|G|$ characters in its motif region $\aleph(S)$.

Lemma 5.13 below shows that with high probability, Phase-Two of Algorithm Find-Noisy-Motif extracts the correct motif regions from the sequences in $Z_{1}$.

Let $R=2\left(\frac{v-1}{t}+\frac{c^{v}}{1-c}\right)$ as defined in Lemma 5.13. Combining inequalities (7), (9), (14), equation (21), and the definition of $R$, we have

$$
\begin{equation*}
Q_{0}-\alpha-3 \epsilon-2 R>\frac{1}{2} \tag{24}
\end{equation*}
$$

Recall that Phase-One uses Extract $\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)$ to obtain a motif candidate $G^{\prime \prime}$. Then Phase-Two uses $G^{\prime \prime}$ to match with $\aleph(S)$ in another sequences $S$. The parameter $R$ is used as a small probability that the matched region between $G^{\prime \prime}$ and $S$ is not in $\aleph(S)$. See Lemma 5.13 for more details.

Lemma 5.13.
(i) Assume that $G^{\prime \prime}=\operatorname{Extract}\left(S_{i}^{\prime}, S_{i}^{\prime \prime}\right)$ with $|G| \leq\left|G^{\prime \prime}\right|$. Let $S$ be a $\Theta_{\alpha}(n, G)$ sequence with $M=\operatorname{Match}\left(G^{\prime \prime}, S\right)$, and let $w_{0}$ be the number of characters of $M$ that are not in the region $\aleph(S)$. Then the probability is at most $R=$ $2\left(\frac{v-1}{t}+\frac{c^{v}}{1-c}\right)$ that $w_{0} \geq 1$.
(ii) The probability is at least $Q_{0}-R$ that, given a $\Theta_{\alpha}(n, G)$-sequence $S, \aleph(S)=$ $\operatorname{Match}\left(G_{0}, S\right)$.

Fig. 5. $G^{\prime \prime}$ and $M$ for Lemma 5.13.

Proof. Assume $w_{0} \geq 1$. Let $w$ be the number of characters outside $\aleph(S)$ on the left side of $M$, and let $w^{\prime}$ be the number of characters outside $\mathcal{\aleph}(S)$ on the right side of $M$. Clearly, $w_{0}=w+w^{\prime}$. Since $w_{0} \geq 1$, either $w \geq 1$ or $w^{\prime} \geq 1$. See Figure 5 . Without loss of generality, we assume $w \geq 1$.

Statement (i). There are two cases.
Case (a). $1 \leq w<v$. By Lemma 5.2, the probability for this case for a fixed $w$ is at most $\frac{1}{t}$. Thus, the total probability for this case is at most $\frac{(v-1)}{t}$.

Case (b). $v \leq w$. By Lemma 5.2, the probability for this case for a fixed $w$ is at most $e^{-\frac{\epsilon^{2}}{3} w}$. The total probability for this case is at most $\sum_{w=v}^{\infty} e^{-\frac{\epsilon^{2}}{3} w}=\frac{c^{v}}{1-c}$.

The probability analysis is similar when $w^{\prime} \geq 1$. Therefore, the probability for $w_{0} \geq 1$ is at most $R=2\left(\frac{v-1}{t}+\frac{c^{v}}{1-c}\right)$.

Statement (ii). By Lemma 5.8, with probability at least $Q_{0}, S$ contains a stable motif region. By statement (i) of this lemma, we have probability at least $Q_{0}-R$ that, given a random $\Theta_{\alpha}(n, G)$-sequence, $S, \aleph(S)=\operatorname{Match}\left(G_{0}, S\right)$.

Lemma 5.14 below shows that we can use $G^{\prime}$ to extract most of the motif regions for the sequences in $Z_{2}$ if $G^{\prime}=G_{0}$ (recall that $G_{0}$ is close to the original motif $G$ as defined in Definition 5.11).

Lemma 5.14. Assume that $\left|G^{\prime}\right| \geq|G|$ and $G_{i}=\operatorname{Match}\left(G^{\prime}, S_{i}\right)$ for $S_{i} \in Z_{2}=$ $\left\{S_{1}, \cdots, S_{k_{2}}\right\}$ and $i=1, \ldots, k_{2}$ (recall that each sequence $G_{i}$ is either an empty sequence or a sequence of length $\left.\left|G^{\prime}\right|\right)$.
(i) If $G^{\prime}=G_{0}$, then the probability is at least $1-e^{-\frac{\epsilon^{2} k_{2}}{3}}$ that there are more than $\left(Q_{0}-R-\epsilon\right) k_{2}$ sequences $G_{i}$ with $G_{i}=\aleph\left(S_{i}\right)$.
(ii) The probability is at least $1-e^{-\frac{\epsilon^{2} k_{2}}{3}}$ that for every $G^{\prime}, \mid\left\{i \mid G_{i} \neq \aleph\left(S_{i}\right), i=\right.$ $\left.1, \ldots, k_{2}\right\} \mid \leq(R+\epsilon) k_{2}$.
Proof. Recall that sequence $G_{0}$ is selected according to Definition 5.11. When $G^{\prime}$ is fixed, $G_{i}=\aleph\left(S_{i}\right)=\operatorname{Match}\left(G^{\prime}, S_{i}\right)$ and $G_{j}=\aleph\left(S_{j}\right)=\operatorname{Match}\left(G^{\prime}, S_{j}\right)$ are two independent events due to the independence of $S_{i}$ and $S_{j}$. Thus, we can apply Chernoff bounds in the proof below.

Statement (i). By Lemma 5.13, for every $S_{i} \in Z_{2}$, the probability is at least $Q_{0}-R$ that $G_{i}=\aleph\left(S_{i}\right)$. By Corollary 2.3, the probability is at most $e^{-\frac{\epsilon^{2} k_{2}}{3}}$ that there are fewer than $\left(Q_{0}-R-\epsilon\right) k_{2}$ sequences $G_{i}$ with $G_{i}=\aleph\left(S_{i}\right)$.

Statement (ii). By Lemma 5.13, the probability is at most $R$ that $G_{i} \neq \aleph\left(S_{i}\right)$. By Corollary 2.3, with probability at most $e^{\frac{\epsilon^{2} k_{2}}{3}},\left|\left\{i \mid G_{i} \neq \aleph\left(S_{i}\right), i=1, \ldots, k_{2}\right\}\right|>$ $(R+\epsilon) k_{2}$.

### 5.4. Proof of the main theorem. We now give the proof of Theorem 4.1.

Proof. The parameters $\alpha, \delta_{0}, \delta_{1}$, and $t_{0}$ are set as before. By Lemma 5.9, with probability at least $Q_{1}$, a pair $\left(S^{\prime}, S^{\prime \prime}\right)$ from $Z_{0}$ gives that Extract $\left(S^{\prime}, S^{\prime \prime}\right)=\aleph\left(S^{\prime \prime}\right)$ and that $\aleph\left(S^{\prime \prime}\right)$ satisfies the conditions of Definition 5.7 . The probability is at most $\left(1-Q_{1}\right)^{k_{1}} \leq \frac{\eta}{2^{x}}$ (by inequality (11)) that the following statement (a) is false.

Statement (a). There exist sequences $\left(S^{\prime}, S^{\prime \prime}\right) \in Z_{0}$ such that $\operatorname{Extract}\left(S^{\prime}, S^{\prime \prime}\right)=$ $\aleph\left(S^{\prime \prime}\right)$ and $S^{\prime \prime}$ contains a stable motif region (see Definition 5.7 and Lemma 5.8).

As we select $G_{0}$ according to Definition $5.11, G_{0}=\operatorname{Extract}\left(S^{\prime}, S^{\prime \prime}\right)=\aleph\left(S^{\prime \prime}\right)$ (we use the pair $\left(S^{\prime}, S^{\prime \prime}\right)$ to represent the pair $\left(S_{1}, S_{2}\right)$ of $Z_{0}$ right after Lemma 5.9). By Lemma 5.14, the probability is at most $e^{-\frac{\epsilon^{2}}{3} k_{2}} \leq \frac{\eta}{2^{x}}$ (by inequality (12)) that the following statement (b) is false.

Statement (b). $\mid\left\{i \mid \operatorname{Match}\left(G_{0}, S_{i}\right)=\aleph\left(S_{i}\right)\right.$ for $\left.S_{i} \in Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid \geq$ $\left(Q_{0}-R-\epsilon\right) k_{2}$.

Suppose $G^{\prime \prime}$ is one of the sequences in $W$ returned by Phase-One of Algorithm Find-Noisy-Motif. If $\left|G^{\prime \prime}\right|>|G|$, then $M=\operatorname{Extract}\left(G^{\prime \prime}, S\right)$ has $w_{0} \geq 1$ (see Lemma 5.13). By Lemma 5.13, the probability is at most $R$ that Extract $\left(G^{\prime \prime}, S\right)$ is not empty. By Corollary 2.3, the probability is at most $e^{-\frac{\epsilon^{2}}{3} k_{2}}$ that $\mid\left\{i \mid \operatorname{Match}\left(G^{\prime \prime}, S_{i}\right) \neq \emptyset\right.$ for $\left.S_{i} \in Z_{2}\right\} \mid \geq(R+\epsilon) k_{2}$. Since Phase-One of Algorithm Find-Noisy-Motif returns at most $k_{1}$ sequences in $W$ (because $Z_{0}$ has only $k_{1}$ pairs), the probability is at most $k_{1} e^{-\frac{\epsilon^{2}}{3} k_{2}} \leq \frac{\eta}{2^{x}}$ (by inequality (13)) that the following statement (c) is false.

Statement (c). $\mid\left\{i \mid \operatorname{Match}\left(G^{\prime \prime}, S_{i}\right) \neq \emptyset\right.$ for $\left.S_{i} \in Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid \leq(R+\epsilon) k_{2}$ for every $G^{\prime \prime} \in W$ with $\left|G^{\prime \prime}\right|>|G|$.

Let $G_{1}$ be any of the longest sequences returned by $\operatorname{Extract}\left(S_{1}^{\prime}, S_{2}^{\prime}\right)$ such that $\mid\left\{i \mid \operatorname{Match}\left(G_{1}, S_{i}\right) \neq \emptyset\right.$ for $\left.S_{i} \in Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid \geq\left(Q_{0}-R-\epsilon\right) k_{2}>(R+\epsilon) k_{2}$ (by inequality (24)). If statements (a), (b), and (c) are all true, then $\left|G_{1}\right|=|G|$. By Lemma 5.14, the probability is at most $e^{-\frac{\epsilon^{2} k_{2}}{3}}$ that $\mid\left\{i \mid \operatorname{Match}\left(G_{1}, S_{i}\right)=\aleph\left(S_{i}\right)\right.$ for $\left.S_{i} \in Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid<\left(Q_{0}-R-\epsilon-R-\epsilon\right) k_{2}=\left(Q_{0}-2 R-2 \epsilon\right) k_{2}$. Therefore, the probability is at most $k_{1} e^{-\frac{\epsilon^{2} k_{2}}{3}} \leq \frac{\eta}{2^{x}}$ that the following statement (d) is false.

Statement (d). $\mid\left\{i \mid \operatorname{Match}\left(G_{1}, S_{i}\right) \neq \aleph\left(S_{i}\right)\right.$ for $\left.S_{i} \in Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid \geq$ $\left(Q_{0}-2 R-2 \epsilon\right) k_{2}$ for every longest $G_{1}$ that satisfies $\mid\left\{i \mid \operatorname{Match}\left(G_{1}, S_{i}\right) \neq \emptyset\right.$ for $S_{i} \in$ $\left.Z_{2}=\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid \geq\left(Q_{0}-R-\epsilon\right) k_{2}$.

For a fixed $j$ with $1 \leq j \leq\left|G_{1}\right|=|G|$ and $k_{2}$ sequences in $Z_{2}$, by Corollary 2.3, with probability at most $e^{-\frac{\epsilon^{2} k_{2}}{3}}$, there are more than $(\alpha+\epsilon) k_{2}$ mutated characters $\aleph\left(S_{i}\right)[j]\left(i=1, \ldots, k_{2}\right)$. Thus, the probability is at most $n_{0} e^{-\frac{\epsilon^{2} k_{2}}{3}} \leq \frac{\eta}{2^{x}}$ (by inequality (12)) that the following statement (e) is false.

Statement (e). For every $j$ with $1 \leq j \leq\left|G_{1}\right|, \mid\left\{i \mid \aleph\left(S_{i}\right)[j] \neq G[i]\right.$ for $S_{i} \in Z_{2}=$ $\left.\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \mid \leq(\alpha+\epsilon) k_{2}$.

We have probability at most $5 \cdot \frac{\eta}{2^{x}} \leq \frac{1}{2^{x}}$ that at least one of statements (a)-(e) does not hold. In other words, we have probability at least $1-\frac{1}{2^{x}}$ that statements (a)-(e) are all true. Now we assume that statements (a)-(e) all hold.

Therefore, by inequality (24), $\left(Q_{0}-2 R-2 \epsilon-\alpha-\epsilon\right) k_{2}>\frac{k_{2}}{2}$. For each $j$ with $1 \leq j \leq\left|G_{1}\right|=|G|$, we have $\mid\left\{i \mid \operatorname{Extract}\left(G_{1}, S_{i}\right)[j]=G[j]\right.$ for $S_{i} \in Z_{2}=$ $\left.\left\{S_{1}, \cdots, S_{k_{2}}\right\}\right\} \left\lvert\, \geq\left(Q_{0}-2 R-2 \epsilon-\alpha-\epsilon\right) k_{2}>\frac{k_{2}}{2}\right.$. Therefore, $G$ can be recovered by voting.

The running time of Phase-One is $O\left(k_{1} n^{3}\right)$, and the running time of Phase-Two is $O\left(k_{1} k_{2} n^{2}\right)$. The total time complexity for Find-Noisy-Motif is $O\left(n^{3}\right)$ since $k_{1}$ is constant for some fixed $x$ and $k_{2}=O(\log n)$.

Since the length upper bound of motif $G$ is no more than the length of an input
sequence $\left(n_{0} \leq n\right)$, we have the following simplified result, which does not involve $n_{0}$.
Theorem 5.15. Assume that the mutation probability upper bound $\alpha$ is less than 0.1771. There exist constants $t_{0}, \delta_{0}$, and $\delta_{1}$ such that if the size $t$ of the alphabet $\Sigma$ is at least $t_{0}$ and the length of the motif $G$ is at least $\delta_{0} \log n$, then, given $k \Theta_{\alpha}(n, G)$ sequences with $k \geq \delta_{1} \log n$, Algorithm Find-Noisy-Motif outputs $G$ with probability at least $1-\frac{1}{2^{x}}$ and runs in $O\left(n^{3}\right)$ time.

Proof. Set $n_{0}=n$ and apply Theorem 4.1.
6. Lower bounds on the parameters of motif discovery. In this section, we show some lower bounds for the length of the motif and the number of input sequences that are needed to recover the motif with high probability. Theorems 6.1 and 6.2 together show that the requirements for the motif length and the number of input sequences for Find-Noisy-Motif in the main theorem, Theorem 4.1, are optimal to within a multiplicative constant factor.
6.1. Lower bound for the motif length. Theorem 6.1 shows that when the motif is short relative to the lengths of input sequences, it is impossible to recover the motif with a small number $O(\log n)$ of sequences.

Theorem 6.1. Assume that constant $\epsilon>0$ and the alphabet has constant number $t$ characters. There is a constant $\delta>0$ such that with probability at least $1-o(1)$, given $n^{1-\epsilon}$ input $\Theta_{\alpha}(n, G)$-sequences $S_{1}, \cdots, S_{n^{1-\epsilon}}$, every sequence of length $m_{0}=\lceil\delta \log n\rceil$ is a substring of each $S_{i}$ for $i=1,2, \ldots, n^{1-\epsilon}$.

Proof. We assume that $n$ is sufficiently large. Assume that the length of the motif is $m_{0}=\lceil\delta \log n\rceil \leq 2 \delta \log n$ for a small constant $\delta>0$ such that $\delta \log t<\epsilon / 8$. Thus, $t^{m_{0}} \leq 2^{(\log t)(2 \delta \log n)}<2^{\frac{\epsilon}{4} \log n}$. Let $S$ be a $\Theta_{\alpha}(n, G)$-sequence. We partition a substring $S^{\prime}$ of length $n / 3$ of $S$ such that $S^{\prime}$ does not intersect the motif region $\aleph(S)$ into $n^{\prime}=\left\lfloor\frac{\frac{n}{3}}{m_{0}}\right\rfloor>\frac{n}{6 \delta \log n}$ blocks of size $m_{0}$ each. The probability that a pattern $G^{\prime}$ of length $m_{0}$ does not occur in these $n^{\prime}$ blocks is $\left(1-\frac{1}{\left.t^{m}\right)^{n^{\prime}}}<2^{\frac{-n^{\prime}}{m^{m 0}}}<2^{-\frac{n}{6 \delta \log n} \frac{1}{2^{\frac{c}{4} \log n}}}<\right.$ $2^{-\frac{n}{2^{\frac{e}{3} \log n}}} \leq 2^{-n^{1-\frac{\epsilon}{3}}}$ for large $n$. The probability that at least one of those $t^{m_{0}}$ patterns does not occur in $S$ is at most $t^{m_{0}}\left(1-\frac{1}{t^{m_{0}}}\right)^{n^{\prime}}<2^{\frac{\epsilon}{4} \log n} 2^{-n^{1-\frac{\epsilon}{3}}}<2^{-n^{1-\frac{\epsilon}{2}}}$.

The probability is at least $1-2^{-n^{1-\frac{\epsilon}{2}}}$ that the above sequence $S^{\prime}$ contains all the sequences of length $m_{0}$ as its sequences. If the number of input sequences is $k=n^{1-\epsilon}$, then the probability is at least $\left(1-2^{-n^{1-\frac{\epsilon}{2}}}\right)^{k}=1-o(1)$ that each of the $k$ input sequences of length $n$ contains all sequences of length $m_{0}$ as its substrings.
6.2. Lower bound for sample complexity. We consider the lower bound for the number of sequences needed for recovering the motif. Theorem 6.2 shows that if the number of input sequences is $o(\log n)$, then it is impossible to recover the motif correctly.

Theorem 6.2. There exists a constant $\delta$ such that no algorithm can recover the exact motif $G$ with at most $\delta \log n \Theta_{\alpha}(n, G)$-sequences.

Proof. Assume that the motif region occupies each input sequence entirely. Thus, every character in the input sequence has probability $\alpha$ to mutate. We assume that $\alpha$ is a positive constant. Assume that we have $k$ sequences $S_{1}, \cdots, S_{k}$. For a fixed $i$ with $1 \leq i \leq n$, the probability that all the characters $S_{1}[i], \cdots, S_{k}[i]$ mutate is $\alpha^{k}$. Therefore, the probability is $1-\left(1-\alpha^{k}\right)^{n}$ that for some $i$ with $1 \leq i \leq n$, all the $i$ th characters $S_{1}[i], \cdots, S_{k}[i]$ mutate. Note that $1-\left(1-\alpha^{k}\right)^{n}$ is very close to 1 when $k<\delta \log n$. When there is an $i$ such that all characters $S_{1}[i], \cdots, S_{k}[i]$ mutate, it is impossible to recover the $i$ th character of the motif.
7. Conclusions. We have proved that if the mutation probability upper bound $\alpha$ is less than 0.1771 , there exist constants $t_{0}>0, \delta_{0}>0$, and $\delta_{1}>0$ such that if the length of the motif is $n_{0}>\delta_{0} \log n$ and the alphabet has at least $t_{0}$ characters, then there exists an $O\left(n^{3}\right)$-time algorithm that, given at least $\delta_{1} \log n_{0}$ input sequences, can find the motif with high probability, where $n$ is the longest length of any input sequence. Very recently, we have also shown [4] that for any alphabet $\Sigma$ with $|\Sigma| \geq 2$, for every motif $G \in \Sigma^{\rho}-\Psi_{\rho, h, \epsilon}(\Sigma)$, where $\Psi_{\rho, h, \epsilon}(\Sigma)$ is a small subset of $\Sigma^{\rho}$ with $\frac{\left|\Psi_{\rho, h, \epsilon}(\Sigma)\right|}{\left|\Sigma^{\rho}\right|} \leq 2^{-\Theta\left(\epsilon^{2} h\right)}$, if $G$ has length at least $c_{0} \log n$, it can be recovered with $O(n \log n)$ sequences with high probability. This second algorithm is applicable to DNA motif discovery. An interesting open problem is whether there exists an algorithm to recover all the motifs for an alphabet of four characters.

Acknowledgments. We thank Miklós Csürös and Manan Sanghi for helpful discussions. We are also grateful to Andrew Wei Xu, David Sankoff, and anonymous referees for providing comments to help us improve the presentation of this paper.
