Abstract: In this paper we will demonstrate how productivity and improvement rate of urban organizational units (called also Decision Making Units - DMU's) may be assessed when measured along several time periods. The assessment and subsequent ranking of cities is achieved by means of the Data Envelopment Analysis (DEA) methodology to determine DMU's efficiency for each period, the Cross Efficiency ranking method to rank DMU's and the Malmquist Index approach which measures changes in productivity relative to a base period. The above combined methodology will be applied to a case study of 70 Israeli cities in years 2006, 2007 and 2008.

Key words: Data Envelopment Analysis (DEA); Malmquist Index; ranking methods

1. Introduction

Banks, insurance companies, widespread food chains, police stations, etc., are organizations that have several branches and subunits (Decision Making Units - DMUs). Such organizations are often interested in assessing the productivity of their DMU's in two main aspects: 1) Relative efficiency of each DMU per every time period; 2) General improvement trends among DMU's. The importance of this assessment boils down to first know better relative productivity of each DMU as compared to other structural units, and in addition to be aware of improvement trends characteristic of every DMU. Profound knowledge of the above parameters enables decision makers in the regarded organizations to assess better specific performance of each division unit as well as their timely changes, thus contributing to a broader managerial view on every DMU within the organization. In our application we assume that cities are subunits of the organization, and therefore their relative productivities and their improvement trends should be estimated.

Relative efficiency of each DMU (productivity assessment) for every time period may be investigated by means of the DEA methodology (the so-called CCR or BCC models) which have been primarily suggested by Charnes, Cooper and Rhodes (CCR) in 1978 and subsequently developed and expanded by Banker, Charnes and Cooper (BCC) in 1984. The CCR model calculates the Technical and Scale Efficiency (TSE) while BCC determines Technical Efficiency (TE). In addition to that, productivity assessment may be facilitated by means of conventional ranking methods, like the Super Efficiency method (SE) developed by Anderson and Peterson (1993), the Cross Efficiency method (CE) introduced by Sexton et al. (1994), the bi-criteria method for efficient DMU ranking suggested by Hadad and Friedman (2004), as well as a combination of the AHP method (Analytical Hierarchic Process) and the DEA methodology described by Sinuany-Stern et al. (2000). A comprehensive review of contemporary ranking methods can be found in a study by Adler et al. (2002).

In recent years, a variety of scientific papers tackling the problem of productivity assessment by means of DEA and ranking methods, have been published and are available to the broad scientific community. Among others, one should mention Sueyoshi (1992) who measured the industrial performance of 35 Chinese cities by means of Data Envelopment Analysis, Doyle and Green (1994) who ranked 20 universities in the UK; Hadad, et al. (2009), to carry out comparative efficiency assessment and ranking of public defence authority in Israel; Malul, et al. (2009), measuring and ranking of economic, environmental and social efficiency of countries; Hadad, et al. (2007), measuring efficiency of restaurants; Hadad, et al. (2004), evaluating hotel advertisements efficiency using DEA; Hadad, et al. (2004), ranking fish farms.

Relative improvement trend for each DMU may be assessed when comparing productivities determined for every pair of consecutive time periods, or by means of Malmquist Index approach primarily suggested by Caves, et al. (1982) and subsequently developed by Fare, et al. (1985) and Fare, et al. (1994). This method investigates the improvement measure of each DMU during every pair of consecutive time periods. Should the amount of time periods exceed 2, the procedure boils down to determining improvement levels for consecutive time periods with subsequently calculating the mean geometrical product for all values obtained during the regarded complex time period (Coelli, (1996)). Practical implementation of the Malmquist Index approach have been demonstrated by Barros (2006) who investigated relative efficiency of 33 police stations in Lisbon during

2001-2002. In his research, Barros also estimates the total productivity change of the Lisbon Police Force.

In the present paper, we will demonstrate joint implementation of the DEA methodology, the Cross Efficiency ranking method and the Malmquist Index approach for productivity assessment of 70 Israeli cities between 2006-2008. The cities will be estimated every year separately upon a variety of parameters which we will regard as inputs or outputs. In addition, we will verify existence of positive correlation between the productivity ratios calculated by means of the Cross Efficiency method versus the Malmquist Index approach.

Our paper is organized in the following way. The next section introduces the presentation and formulation of DEA procedures, which will be employed in the analysis and the Super Efficiency. The third section presents the Malmquist Index approach. Part four illustrates how to evaluate city advertisements' efficiency using the models that have been described in sections two and three. Finally, the findings are presented along with conclusions and recommendations for future research.

2. Data Envelopment Analysis and Cross Efficiency

2.1. Data Envelopment Analysis

DEA is a procedure designed to measure the relative efficiency in situations when there are multiple inputs and multiple outputs and no obvious objective how to aggregate both inputs and outputs into a meaningful index of productive efficiency DEA was developed by Charnes Cooper and Rhodes (CCR) (1978). The method provides a mechanism for measuring the efficiency of each Decision-Making Unit (DMU).

The efficiency in CCR model is termed Technical and Scale Efficiency (TSE) and the relative efficiency of a DMU is defined as the ratio of its total weighted output to its total weighted input. The BCC model, named after Banker, Charnes and Cooper (1984) allow the production function to exhibit non-constant return to scale (Banker and Chang 1995)) whiles the CCR model imposes the additional assumption of constant returns to scale on the production function.

The formulation of CCR model for unit k is:

$$\begin{aligned} \text{Maximize } h_k &= \sum_{r=1}^s U_r^k Y_{rk} \\ \text{subject to} \\ \sum_{r=1}^s U_r^k Y_{rj} - \sum_{i=1}^m V_i^k X_{ij} &\leq 0 \quad \text{for } j=1,2,..,n, \\ \sum_{i=1}^m V_i^k X_{ik} &= 1, \\ U_r^k &\geq \varepsilon > 0 \quad r=1,2,..,s, \\ V_i^k &\geq \varepsilon > 0 \quad i=1,2,..,m. \end{aligned} \tag{1}$$

where ε is defined as an infinitesimal constant (a non-Archimedean quantity).

2.2. The Cross Efficiency

The Cross Evaluation matrix was first developed by Sexton et al. (1994). This method calculated the efficiency score of each unit n times using the optimal weights evaluated by each run. The results of all the DEA cross efficiency are summarized in a matrix as given in (2)

$$h_{kj} = \frac{\sum_{r=1}^s U_r^k Y_{rj}}{\sum_{i=1}^m V_i^k X_{ij}}, \quad j = 1, 2, \dots, n, \quad k = 1, 2, \dots, n. \quad (2)$$

Thus h_{kj} represents the score given to unit j by the optimal weights of unit k . The elements in the diagonal h_{kk} represent the standard DEA scores h_k . The Cross Efficiency ranking method utilized the matrix h_{kj} for ranking the units one scale.

Ranking of DMUs is thus based on the average cross efficiency score being calculated as

$$h_k = \frac{\sum_{j=1}^n h_{kj}}{n}.$$

3. The Malmquist Index Approach

To investigate improvement of productivity, Fare et al. (1994) have demonstrated that DEA methodology may be applied to assess Malmquist Total Factor Productivity (TFP) index numbers. As a matter of fact, Malmquist index is an approach enabling relative measurement of productivity changes between consecutive periods of time (e.g., a year). Those productivity changes may be broken down to structural elements depending on technical efficiency enhancement as well as technology changes and progress. The Malmquist DEA approach determines efficiency level in a certain year relatively to the previous one, thus enabling evaluation of productivity improvement between the two consecutive periods.

The Malmquist TFP index measures efficiency in each period t related to the base period s in terms of productivity improvement. Fare et al. (1994) specifies an output based Malmquist productivity change index:

$$m_0(y_s, x_s, y_t, x_t) = \left[\frac{d_0^s(y_t, x_t)}{d_0^s(y_s, x_s)} \times \frac{d_0^t(y_t, x_t)}{d_0^t(y_s, x_s)} \right]^{\frac{1}{2}} \quad (3)$$

where the notations $d_0^s(y_t, x_t)$, $d_0^t(y_t, x_t)$, $d_0^s(y_s, x_s)$, $d_0^t(y_s, x_s)$ are distance functions and x , y are the output and input vector.

An equivalent way of writing this would be

$$m_0(y_s, x_s, y_t, x_t) = \frac{d_0^t(y_t, x_t)}{d_0^s(y_s, x_s)} \left[\frac{d_0^s(y_t, x_t)}{d_0^s(y_t, x_t)} \times \frac{d_0^t(y_s, x_s)}{d_0^t(y_s, x_s)} \right]^{\frac{1}{2}}. \quad (4)$$

The above equation can be broken into two parts, namely the efficiency change component and the technical change component:

$$\text{Efficiency change} = \frac{d_0^t(y_t, x_t)}{d_0^s(y_s, x_s)} \quad (5)$$

and

$$\text{Technical change} = \left[\frac{d_0^s(y_t, x_t)}{d_0^s(y_t, x_t)} \times \frac{d_0^t(y_s, x_s)}{d_0^t(y_s, x_s)} \right]^{\frac{1}{2}} \quad (6)$$

The Malmquist productivity change index may be determined as the result of solving 4 linear programming problems as listed below:

$$\begin{cases} d_0^s(y_t, x_t) = \min \theta \\ \text{subject to} \\ -y_{ot} + Y_s \lambda \geq 0 \\ \theta x_{0t} - X_s \lambda \geq 0 \\ \lambda \geq 0 \end{cases} \quad (7)$$

$$\begin{cases} d_0^s(y_s, x_s) = \min \theta \\ \text{subject to} \\ -y_{os} + Y_s \lambda \geq 0 \\ \theta x_{0s} - X_s \lambda \geq 0 \\ \lambda \geq 0 \end{cases} \quad (8)$$

$$\begin{cases} d_0^t(y_t, x_t) = \min \theta \\ \text{subject to} \\ -y_{os} + Y_s \lambda \geq 0 \\ \theta x_{0s} - X_s \lambda \geq 0 \\ \lambda \geq 0 \end{cases} \quad (9)$$

$$\begin{cases} d_0^t(y_t, x_t) = \min \theta \\ \text{subject to} \\ -y_{ot} + Y_t \lambda \geq 0 \\ \theta x_{0t} - X_t \lambda \geq 0 \\ \lambda \geq 0 \end{cases} \quad (10)$$

In (7-10), θ is a scalar, λ is a vector that representative the constants. The value of θ will be the efficiency score for the i -th DMU. It will satisfy θ less than or equal to 1, with a value of 1 indicating a point on the frontier and hence a technically efficient DMU. These four LPs must be solved for each DMU in the sample.

4. The Case Study on Israeli Cities

4.1. Determining DMUs

In order to proceed with the DEA procedure one has to determine first Decision Making Units (DMUs). In our research, we decided to determine DMUs as Israeli cities comprising a total of 10,000 inhabitants at least. The latter data has been adopted from the Central Bureau Statistics database published in 2006, 2007, 2008.

4.2. Selection of outputs and inputs

An important issue in employing DEA is the selection of inputs and outputs. In order to calculate the efficiency and the score of each city entering this study the following outputs and inputs have been implemented:

Inputs

X_1 - negative emigration percentage - the ratio between citizens that left the city to the total number of inhabitants (negative emigration ratio);

X_2 - percentage of unemployed citizens and obtaining minimal income insurance;

X_3 - percentage of deceased throughout the year;

X_4 - average number of schoolchildren in a classroom;

X_5 - average number of apartments per citizen;

X_6 - average spending by the local authority per citizen (in thousands NIS per citizen).

Outputs

Y_1 - positive immigration percentage - the ratio between citizens that joint the city to the total number of inhabitants (positive immigration ratio);

Y_2 - average monthly income per citizen (in thousands NIS per month);

Y_3 - percentage of successfully graduating from the city school system that complied with university entrance requirements;

Y_4 - average number of private vehicles per citizen;

Y_5 - average city income per citizen (including donations from the state).

We will demonstrate the regarded procedure for Year 2008. The data on 70 cities with 5 outputs and 6 inputs are given in Table 1:

Table 1. The numerical data for 2008

Table 3. 10 top ranked Israeli cities

City	Cross Efficiency					Malmquist productivity		
	2008	2007	2006	Mean	Rank	2006-2007	2007-2008	Mean*
Raanana	0.9631	0.9093	0.9432	0.939	1	0.791	0.612	0.695
Ramat-Hasharon	0.9001	0.9564	0.9233	0.927	2	0.779	0.601	0.684
Ness-Ziona	0.9108	0.9168	0.9268	0.918	3	0.843	0.603	0.713
Rishon Lezion	0.9341	0.9419	0.8739	0.917	4	0.847	0.611	0.720
Herzliya	0.8883	0.9334	0.913	0.912	5	0.833	0.615	0.716
Yavne	0.915	0.9477	0.8557	0.906	6	0.784	0.592	0.681
Tel-Aviv	0.8686	0.9401	0.9029	0.904	7	0.82	0.616	0.711
Hod-Hasharon	0.9233	0.8963	0.8867	0.902	8	0.849	0.644	0.740
Petah-Tikva	0.9157	0.9086	0.8788	0.901	9	0.846	0.653	0.743

City	Cross Efficiency					Malmquist productivity		
	2008	2007	2006	Mean	Rank	2006-2007	2007-2008	Mean*
Kfar-Saba	0.8421	0.893	0.9577	0.898	10	0.914	0.679	0.788

- Note that according to the Cross Efficiency method results Raanana, Ramat-Hasharon and Ness-Ziona turned out to be ranked first. The common feature of these cities is their geographical position in the centre of the country and along the sea coast line.

Table 4. 10 bottom ranked Israeli cities

City	Cross Efficiency					Malmquist productivity		
	2008	2007	2006	Mean	Rank	2006-2007	2007-2008	Mean*
Qalansuwa	0.7304	0.7151	0.7688	0.738	61	0.949	0.667	0.796
Arad	0.8106	0.7346	0.6671	0.737	62	0.783	0.624	0.699
Ofakim	0.7228	0.7201	0.7491	0.731	63	0.723	0.57	0.642
Ramla	0.7926	0.6538	0.7399	0.729	64	0.672	0.546	0.606
Kiryat-Mal'achy	0.6894	0.7275	0.7591	0.725	65	0.63	0.533	0.580
Zfat	0.7006	0.6958	0.7388	0.712	66	0.659	0.571	0.613
Qiryat-Yam	0.7454	0.7074	0.6776	0.71	67	0.672	0.565	0.616
Beit-Shean	0.6782	0.6852	0.717	0.693	68	0.696	0.504	0.592
Beitar-Illit	0.6603	0.542	0.7139	0.639	69	1.018	0.669	0.826
Taibe	0.7184	0.4331	0.7628	0.638	70	0.552	0.844	0.682

- Note that bottom ranked cities listed in Table 4 belong generally to the northern and southern outskirts of the country.

5. Conclusions and Future Research

In this paper we intended to demonstrate an important application area of the DEA methodology enabling relative effectively assessment of DMUs in conjunction with the CE method to carry out fully ranking for the same, all this compared with the Malmquist productivity index capable of evaluating relative improvement of each DMU per every pair of consecutive time periods. These methods have been applied to evaluating 70 Israeli cities within years 2006, 2007 and 2008. The results obtained which have been reported in the present study may lead to the following conclusions:

- No correlation whatsoever has been identified between the ranking position of the city and its relative improvement through years. As a matter of fact, the majority of cities investigated in our research show actually worsening rather than improvement, no matter whether being ranked at the top of the list or close to the bottom.
- Ranking positions obtained as well as improvement rates refer of cause to the set of input / output criteria chosen for the research. A different choice of input / output criteria might cause other results, accordingly.

- There is no consistency within the ranking obtained on the basis of existing ranking methods. The substance of the ranking method is important for obtaining specific ranking results whatsoever.
- No correlation whatsoever has been identified between the size of the city (number of inhabitants) and its ranking / relative improvement through years. In other words, one cannot claim those features to be size dependent.

Ranking and improvement as reflected in our research relate to a broad spectrum of instances such as: education, health care, the local authority's municipal spending, etc. We suggest further research to be undertaken to estimate ranking of cities according to each criterion separately, while calculating relative weights for every criterion chosen. Then, efficiency score and ranking position for every participating city might be re-calculated with reference to the established weights. In addition, further investigation has to be undertaken as to specific reasons for cities' productivity worsening as detected in the framework of the current research.
