Introduction

Psychosomatic medicine in Germany is not a synonym for consultation-liaison psychiatry but represents a comprehensive field [1] as well as a specialized medical discipline [2]. As a consequence, psychosomatic medicine in Germany has a larger institutional basis than in any other country. Like elsewhere, the German psychosomatic approach was originally rooted in the tradition of applying psychoanalysis to medicine – Franz Alexander was probably this method's most influential psychoanalyst. The fate of his primarily psychogenetic model was tied, as it was in Germany (Alexander Mitscherlich), to the rise and decline of psychoanalysis and psychoanalytic concepts like the specific conflict. German psychosomatic medicine, however, has another root, which was an independent forerunner of current models for bio-psychosocial medicine [3]. The so-called integrative psychosomatic medicine, as developed in internal medicine (Thure von Uexküll) and neurology (Viktor von Weizsäcker), conceptualized the interactions of mind, body, and environment in a different 'enactive and embodied' way: body and bodily symptoms are not mere manifestations of the 'theatre of the soul'. The body and its sensorimotor and other activities shape the mind as much as the other way round [4].

In Germany, psychosomatic medicine is not a subspecialty of psychiatry, although it has clear connections in terms of shared models, methods, and overlapping care for patients. At some places, most prominently in Heidelberg and Tübingen, departments of psychosomatic medicine are part of overarching departments for internal medicine. The institutional independence of psychosomatic medicine in Germany is largely due to German psychiatry resisting the integration of psychotherapy as a core method. Hence, psychosomatic medicine developed independently as an institutional and academic basis for psychotherapy in medicine and later for integrated care models.

The clinical core competency of German psychosomatic medicine is centered on integrated care for the following disorders: somatoform/functional disorders, eating disorders, somatopsychic disorders (including psycho-oncology, psychocardiology, neuropsychosomatics, and psychodiabetology), and psychotraumatology. An overlap with psychiatry exists in the fields of depressive, anxiety, and personality disorders.

The following presents a brief overview of the current state of institutionalization, research, and teaching in the field of German psychosomatic medicine.

Psychosomatic Facilities and Structure

The first psychosomatic inpatient hospital was opened in Berlin in 1927. Since then, numerous hospitals and departments developed specifically to address psychosomatic issues have been established across Germany. Actual data show that there are a total of 223 institutions covering more than 10,000 inpatient beds, with a mean duration of stay of 40 days. Of note, the number of inpatient beds in Germany nearly tripled this millennium. There has also been a steep increase of psychosomatic day-patient facilities in recent years.

The current types of psychosomatic hospital facilities are as follows:

- 1 Hospitals for psychosomatic medicine with a superregional coverage area. The hospitals often include specialized subunits (for example, eating disorders, PTSD, and chronic pain) comprising more than 200 beds.
- 2 Departments of psychosomatic medicine at general hospitals providing regional coverage. The departments administer a consultation-liaison service for the entire hospital but have limited inpatient facilities (9–36 beds).
- 3 Departments of psychosomatic medicine and psychotherapy as academic institutions at university hospitals. These departments are responsible for patient care (20–70 beds), teaching, and research (fig. 1).
- 4 Departments of psychosomatic medicine that are part of a psychiatric hospital (20–30 beds).
- 5 Consultation-liaison services for psychosomatic medicine at general and university hospitals (without own treatment unit).

Health insurance (public or private) covers treatment costs from a budget separate from the one for psychiatry. Costs for psychosomatic care are based on length of treatment rather than on the diagnosis-related group. This re-funding system will probably change in the next few years.

Aside from the health insurance-covered hospital sector, there is a separate system of rehabilitation centers in Germany, which target the clinical areas of cardiology, oncology, neurology, orthopedics, and psychosomatic medicine. Their particular focus is on work-related aspects of disability prevention. Pension insurance covers the costs for these centers. There are 141 centers for psychosomatic medicine in this system, which provide about 16,000 additional inpatient beds with average treatment duration of 37 days [for more details, see 5].

Psychosomatic inpatient and day-patient treatment programs are mostly combined multimodal therapy pro-

grams, combining psychotherapy in individual and group formats, oriented on treatment guidelines and best practice experiences. Very often, psychodynamic and cognitive-behavioral approaches are both used in a coherent overall framework. Based on the leading diagnosis, additional therapies, for example stress reduction techniques, physiotherapy, body psychotherapy, and creative therapies (art and/or music therapy) are often part of the combined treatment package. Problems in the interpersonal and psychosocial field are the major focus of family/partner-oriented treatments often supplemented by psychosocial skills training. As part of the new reimbursement system, the dosage of psychotherapy is monitored as a key input factor.

Effectiveness of Integrated Care in German Psychosomatic Medicine

Multimodal inpatient care in hospital departments for psychosomatic medicine has been shown to be effective in numerous naturalistic studies – RCTs are hardly possible to design to test such a complex intervention. A recent systematic review and meta-analysis on these studies [6] revealed a medium within-group effect size of $g = 0.72$ for symptom change and 0.35 for change of interpersonal problems. However, there are now multisite RCTs in Germany, investigating the setting effects of day- and inpatient psychosomatic treatment in patients with a depressive disorder [7, 8].

The majority of psychosomatic departments and hospitals take part in stringent quality assurance programs in order to monitor their treatment programs and to provide transparency to the patients. In addition, registries were introduced in respective regions and states to provide outcome data on basic factors, for example duration of treatment, leading diagnosis, and number of comorbid disorders [9].

Stages of Training and Specialization

In 1993, the General Assembly of German Physicians voted for a three-level approach and, thus, a differentiated and stepped-care qualification training process for specializing in psychosomatic medicine and psychotherapy:

- 1 Psychosomatic basic care or ‘Psychosomatische Grundversorgung’ includes an 80-hour training comprising theoretical and clinical instruction, communi-

Fig. 1. Structure of an academic psychosomatic department (PSM) in Germany. C-L = Consultation-liaison; PSM = psychosomatics.

cation training with psychosomatic patients, and reflection of the doctor-patient relationship. All clinically practicing medical specialists can enroll in this training. Psychosomatic basic care is also an integral part of specialist training in general medicine and gynecology. About 35,000 general practitioners and 12,000 gynecologists have obtained this qualification [10].

- 2 A postgraduate degree in psychotherapy for those already holding a specialization degree (about 18,000 with an additional qualification in psychotherapy) [11]. The training is extra-occupational and conveys basic psychotherapeutic skills (120 h of supervised psychotherapy, 120 h of theoretical input, and personal therapy).
- 3 A 5-year specialization in psychosomatic medicine and psychotherapy (including 1 year each of internal medicine and psychiatry). This training comprises 1,500 h of supervised psychotherapy, 240 h of theoretical input, and personal therapy in both individual and group settings. The main emphasis is on the specialized psychotherapeutic and integrated psychosomatic treatment of patients with mental, psychoso-

matic, somatopsychic, and stress disorders (for more details, see table 1). Among physicians who practice psychotherapy in Germany, a specialist in psychosomatic medicine and psychotherapy has received the most intensive psychotherapeutic training. Thus, he or she is the most qualified expert within the medical psychotherapeutic and psychosomatic care fields (5,000 specialists of psychosomatic medicine and psychotherapy) [11]. Additionally, there are about 11,000 psychiatrists and 5,600 neurologists [12]. In the outpatient sector, there are 3,058 specialists in psychosomatic medicine and psychotherapy as well as 3,900 specialists in psychiatry and psychotherapy, 1,972 neurologists, and 10,269 medical specialists with an additional psychotherapy certification (out of these, 3,493 are practicing mainly psychotherapy), summarizing a total of 21,312 medical trained doctors with a certification in psychotherapy (2014) [13] and a total of 16,664 psychologists with a specialization in psychotherapy [10]. In Germany, only medical doctors and psychologists are allowed to practice psychotherapy for adults.

Table 1. Synopsis of the specialization curriculum in psychosomatic medicine in Germany

Specialization in psychosomatic medicine and psychotherapy
At least 5 years of full-time clinical training [3 years in psychosomatic medicine, 1 year in psychiatry, and 1 year in an additional clinical discipline (e.g. internal medicine), including theoretical, technical, and clinical training as well as supervision and personal therapy (see below)]
In total, 240 h of theory in psychosomatic medicine and psychotherapy [e.g. basics in psychodynamic-oriented psychotherapy (PDT) and CBT, psychopathology, psycho-diagnostic tests]
In total, 1,500 h of psychotherapeutic treatment have to be conducted alternatively in (a) PDT or (b) CBT, including individual or group-based supervision of at least every 4th session
<i>PDT-oriented track</i>
6 individual psychotherapies of 50–120 h/patient
6 individual psychotherapies of 25–50 h/patient
4 focal, short-term therapies of 5–25 h/patient
2 couple therapies over a minimum of 10 sessions/couple
2 family therapies of 5–25 sessions/family
100 h of group psychotherapy (group size 6–9 patients)
150 h of psychodynamic-oriented personal psychotherapy and 70 h of personal psychodynamic-oriented group psychotherapy
<i>CBT-oriented track</i>
10 long-term individual CBT psychotherapies of 50 sessions/patient
10 short-term CBT-oriented psychotherapies with a total of 200 h
4 couple and/or family therapies
6 group psychotherapies
70 × 2 h of CBT-oriented personal therapy in individual or group format
In addition, each trainee has to be trained in as follows: at least 32 h of stress reduction and relaxation techniques (e.g. autogenic training), 10 cases of psycho-education in somatically ill patients, 35 × 2 h of Balint groups or interactional group supervision, and 20 documented consultation-liaison cases

Psychosomatic Medicine in Academic Teaching and Research

In 1970, psychosomatic medicine became an obligatory subject in the medical school curriculum at the 37 official medical schools in Germany. Building on this advancement, the majority of the medical schools ($n = 26$) then decided to establish entire departments of psychosomatic medicine. The curricula of these departments not only cover the topic of psychosomatic medicine – its disorders, diagnostic techniques, and treatment methods – but department members have actively created and implemented communication skills training as part of a competency-based medical curriculum. The departments have also been involved in the development, implementation, and evaluation of state-of-the-art teaching formats and continue to play an active role in the international medical education community [14–16].

In the first 2 decades following the nationwide introduction of psychosomatic medical departments in 1970, conducting empirical research was not a high priority.

Providing proper instruction was more pressing, and most chairs and professors were psychotherapeutic clinicians and theoreticians rather than empirical researchers. In 1986, the German Council of Science and Humanities (the central science advisory board to the government) criticized the state of research in the field of psychosomatic medicine. Since this wake-up call, things have changed gradually, but profoundly. Today, German psychosomatic medicine plays an active role in all areas of medical investigation – funded by federal and other third parties – be it clinical, health care, public health, or basic research.

Clinical Research

A particular strength of clinical research in psychosomatic medicine is the conceptualization, implementation, and evaluation of manualized disorder-oriented brief psychotherapies tested and demonstrated in different psychosomatic and mental disorders (e.g. the AN-TOP study in anorexia nervosa [17, 18], the SPIRR-CAD study in depressed patients with coronary heart disease [19] and chronic heart failure [20], the PISO and SPE-

CIAL studies in somatoform disorders [21, 22], the SOPHONET study in social phobia [23], the DAD study in diabetes [24, 25], and RCTs in depression [7, 26] and personality disorders [27]). Psycho-oncology is a fast-growing field of research interest in psychosomatic medicine, ranging from diagnostic to intervention studies [28–30]. While many of these therapies are psychodynamic [31, 32], the scope of treatment development is much broader and also covers CBT-oriented therapy and neuropsychologically informed treatment approaches. Most of these multisite RCTs were designed, implemented, and evaluated according to stringent and robust regulatory rules conforming to good clinical practice. In recent years, the psychotherapy community has worked to modernize web-based health treatments by developing and testing approaches that apply digital media (Interbed, Base, Restart [33–35]).

Health Care and Public Health Research

Health care research in psychosomatic medicine has a traditional, but by no means exclusive, focus on psycho-oncology. Typical topics include developing screening instruments [29], assessing the need for psycho-oncological support for patients and caregivers [36], and evaluating naturalistic interventions [37]. Another example of psychosomatic-based health care research is a trans-sectoral networking initiative in the large city of Hamburg, which brought together more than 60 partners from the government and the research, health care, and health industries (Psychnet [38]). In cooperation with other academic partners, the local university's Department of Psychosomatic Medicine coordinates and evaluates screening, networking, and therapeutic interventions in patients with eating and somatoform disorders [39].

Developing and coordinating evidence-based national guidelines on topics relevant to psychosomatic medicine, such as functional/somatoform or eating disorders, has been an important undertaking in recent years [22, 40–44]. Researchers of psychosomatic medicine have also participated in several population-based cohorts in Germany (e.g. the Gutenberg Health Study in Mainz [45], the KORA study in Augsburg, and the ESTHER study in Heidelberg [46]). The studies provide epidemiological data on the interaction of different psychological, social, immunological, and other risk factors in the etiology and course of diabetes and cardiovascular and other chronic diseases. In a research world increasingly dominated by purely (systems) biological perspectives, these bio-psycho-social approaches are an important antidote against an all too strong reductionism.

Basic Science

In German psychosomatic research, there is a long tradition of basic science-related research [47], especially in the areas of mechanism-oriented [48], psychophysiological [49], life event-related, and stress-related research [49]. Contrarily, interest and expertise in animal-based or wet laboratory-based research is relatively recent. In the last decade, though, there has been a steep increase in the number of institutions with expertise in the field of neuroscience-related research paradigms, including neurocognitive [50] and neuroimaging approaches [51] and neuroimmunology [52]. Psychosomatic medicine research also plays a crucial role in national and international collaborative research networks, for example on nutrition medicine and eating disorders [50, 53–56], placebo and nocebo effects (DFG-funded research unit FOR 1328 [57–59]), and neural control of intestinal functions (NeuroGut in EU FP7 [44, 59, 60]).

Conceptual Work

Adapting bio-psycho-social concepts to modern medicine requires conceptual work. German psychosomatic medicine has contributed to two interdisciplinary European Union Marie Curie Training Networks (DISCOS and TESIS), where neuroscientists, psychologists, psychiatrists, and philosophers worked on translating current concepts of embodiment and enaction to clinical approaches to 'disorders of the embodied self' [61].

Organizations and National Congress

There are two major psychosomatic medicine societies in Germany, which closely collaborate and share offices in Berlin. The first is the German College of Psychosomatic Medicine (DKPM) founded in 1974 by Thure von Uexküll and associates. It is an interdisciplinary scientific professional association for doctors, psychologists, and other professions (e.g. art therapists) and has about 450 members. Supported by the Swiss-based Carus Foundation, it runs and promotes postgraduate research-based training and advancement in all areas of psychosomatic medicine [62]. It has strong ties to other European, American, and Asian societies in the field of psychosomatic medicine. The second, the German Society for Psychosomatic Medicine and Medical Psychotherapy (DGPM), founded in 1992, is the medical association for the field of psychosomatic medicine and psychotherapy. It has about 1,300 members. Both organizations have their own Journal Citation Reports-listed journals (DKPM: Psychother

Psychosom Med Psychol, Thieme publisher; DGPM: Z Psychosom Med, Hogrefe publisher).

Together, both societies (DGPM and DKPM) organize the annual conference on psychosomatic medicine and psychotherapy at the end of March each year at the Free University in Berlin. Over the last years an average of 1,100 participants and around 450 papers were presented in symposia or poster sessions including an English/international track. As a consequence, this conference is the biggest on psychosomatic medicine in Europe and the world and is not sponsored by the pharmaceutical sector [for recent discussion, see 63].

To conclude: combining its two traditions, German psychosomatic medicine has developed well over the last decades, benefitting from its institutional independence.

Clinically, disorder-oriented psychotherapy is a core method integrated with other modes of therapy; as a conceptual base for empirical research, nonreductionist accounts of the interactions of (sick) persons with their environment are most important. Therefore, the German model of psychosomatic medicine is a strong advocate for psychotherapy in medicine and thus more than ever a strong partner for a bio-psycho-social medicine in the 21st century [64].

Acknowledgment

The authors want to dedicate this editorial to our colleague, friend, and teacher Prof. Peter Hahn, Heidelberg, who just turned 85 years.
