

Abstract

The microexplosion evolution phenomenon of single droplets of water in pure diesel emulsion under Leidenfrost effect has been studied. The tested emulsions were stabilized with a blend of commercial surfactants with three different water contents of 9%, 12% and 15%. A high speed camera synchronized with backlight technique was used to capture the evolution of microexplosion and puffing. Three different droplet diameters of approximately 2.6mm, 2mm and 0.2mm were analysed. It was found that the tendency of microexplosion and puffing frequency was influenced by the droplet diameter. Coalescence was the dominating factor in inducing microexplosion in bigger droplets. It was observed that the child droplets ejected from the parent droplet undergoes further puffing processes. The size of the secondary droplets after microexplosion were also found to be slightly influenced by the parent droplet size. The waiting time for microexplosion and puffing were compared for different droplets size.

Keywords

Microexplosion, Leidenfrost Effect, Coalescence, Surfactant, Sauter Mean Diameter (SMD)

Introduction

In spite of their preferable advantages, diesel engines are one of the foremost pollution contributors to the environment (Basha and Anand, 2011, Brijesh et al., 2015). One way to combat these drawbacks of compression ignition (CI) engines can be overcome by fuel based solutions, which can be readily adapted to the existing engines without any modifications. Emulsified fuels are considered as one of the conceivable alternative fuels for reducing the engine exhaust emissions (Abu-Zaid, 2004, Armas et al., 2005, Park et al., 2000, Yahaya Khan et al., 2014). The most noticeable effects of such fuels are the secondary atomization occurring during the combustion process. The volatility difference between the base fuel and the dispersed water droplets (i.e) results in superheating of the water which is achieved before

1
2
3 the base fuel and rapid vapour expansion which leads to a violent microexplosion of the
4 emulsified droplets (Watanabe et al., 2010) . The presence of water aids to reduce the
5 combustion temperature, therefore reducing NO_x. The microexplosion phenomena results in
6 the formation of smaller droplets with very high surface-to-volume ratio which results in
7 better mixing with air leading to more complete combustion and lower particulate matter
8 (PM) emissions.

11
12
13
14
15
16
17

18 The microexplosion phenomenon is often quoted for countering the engine exhaust emissions
19 (i.e.) reducing PM and NO_x simultaneously. Therefore, understanding the microexplosion
20 phenomena can help to increase the efficiency of alternative fuels, in particular with water in
21 diesel emulsions. Usage of suspended droplets on thermocouple or quartz fiber has been
22 studied previously to record the temperature history of the heated emulsion droplets,(i.e)
23 emulsion of pyrolysis oil in diesel oil (Calabria et al., 2007) , n-dodecane and n-tetradecane in
24 water emulsion (Tsue et al., 1996), kerosene and water emulsion (Watanabe et al., 2009),
25 commercial diesel and water emulsion (Califano et al., 2014), and diesel- bio diesel-ethanol
26 blends (Avulapati et al., 2016). One of the main demerits in these type of techniques is that
27 the presence of thermocouple or the fiber wire results in the heterogeneous bubble nucleation
28 on the surface of the wire (Watanabe et al., 2010). A 50μm diameter R-type thermocouple
29 was used in their study. On the other hand Mura (Mura et al., 2014) concluded that the
30 presence of 76.2μm diameter K-type thermocouple did not dominate the microexplosion
31 process. However, the size, geometry and of heat transfer to the thermocouple from the
32 droplet and its effect on the microexplosion evolution is still unclear.

51 Also, prior studies confirmed that the microexplosion does not always occur (Califano et al.,
52 2014, Khan et al., 2014, Yahaya Khan et al., 2016). The droplet diameters considered for the
53 purpose of visualization of the microexplosion evolution were different among the studies.

Emulsion fuels with the parent droplet size, studied previously by the other researchers for the development of microexplosion phenomenon are highlighted in the Table 1. This experimental work investigates the evolution of microexplosion phenomenon of water in pure diesel emulsion droplets. Breakup characterisation studies of child droplets are scarce and are limited to base fuels other than pure diesel (Avulapati et al., 2016). Such characteristics are also studied here by analyzing the primary and secondary droplet sizes in order to fill in this gap in the knowledge base. The droplets sizes studied in this experiment are within the comparable range of other researchers, so as to compare the present results with their works.

Materials and methods

Emulsion preparation and stability

The Water in Diesel Emulsions (WiDE) used in this study was blended at 1500rpm for 15 minutes using overhead stirrer. Mixtures of commercial surfactants Span-80 with an HLB value of 4.3 and an HLB of 11 for TWEEN 85 were used as emulsifier. Surfactants are necessary to lower the interfacial tension between the diesel and water to form a stable emulsion. The base fuel used was pure diesel without any additives. The emulsions were

1
2
3 stabilized with 15% of surfactant concentration to the water content. The preparation matrix
4
5 for the WiDE is shown in Table 2. All the prepared emulsions were found to be stable for
6
7 almost 30 days. This was due to the dosage of surfactant blend being sufficient to the overall
8
9 surface of the dispersed compound to be completely covered by the surfactant molecules
10
11 (Abdul Karim et al.).
12

13
14 A Hydrophilic-Lipophilic Balance (HLB) value of 9 was used for stabilizing all the
15
16 emulsions. It was obtained by mixing the two surfactants by the following equation
17

$$18 \quad \% A = 100 * (x - HLB_B) / (HLB_A - HLB_B) \quad (1)$$

19
20
21 Where

22
23 HLB_A = HLB value of surfactant A

24
25 HLB_B = HLB value of surfactant B

26
27 x = Required HLB value

28
29 $\% A$ = Quantity of surfactant A required

30
31 $\% B$ = Quantity of surfactant B required (i.e) ($\% B = 100 - \% A$)

42 **Experimental Setup**

43
44 Schematic diagram of the experimental setup for the evolution of microexplosion
45
46 visualization is shown in Figure 1. The basic principle of the setup is same as that of Mura
47
48 (Mura et al., 2012). A PHANTOM MIRO M310 high speed camera was used for image
49
50 capturing. The image acquisition rate was set at 8000 fps for larger droplets and 10000 fps
51
52 with a resolution of 640X480 for droplets with the smallest diameter. A polished flat
53
54 aluminum plate with a small concave dint was used to place the droplet and the base plate
55
56
57
58
59
60

1
2
3 temperature was maintained at 500 +/- 2°C using a ceramic heater to obtain the Leidenfrost
4
5 effect. The temperature was maintained throughout the experiment by a digital temperature
6
7 controller. The water droplets distribution images were captured by using a digital microscope
8
9 with a magnification of 1000X and the Sauter mean diameter of dispersed water droplets were
10
11 calculated by post processing the images obtained. The light source used for backlight
12
13 illumination purpose was of single LED type and was synchronized with the exposure time of
14
15 the high speed camera. Also, a light source with 12 high power LEDs was used for direct
16
17 image recording to observe the phase changes and internal features of the droplet during the
18
19 evolution of microexplosion. The recording speed was set at 2000 fps with a resolution of
20
21 510X510 pixels. The images were post processed using the phantom camera control software
22
23 for measurements and calculating the waiting time of microexplosion. Approximately 2.6 mm
24
25 and 2 mm sized droplets diameters of water in pure diesel emulsion (WiDE) were generated
26
27 using a syringe of 0.8mm and 0.4mm orifice diameter needles. Due to the limitations in the
28
29 generation of smaller droplets. A single bigger emulsion droplet of diameter 2.6mm was made
30
31 to fall on the heated aluminium plate from a height, which results in immediate shattering of
32
33 bigger droplet in to numerous smaller droplets of diameter approximately 0.2mm. It should be
34
35 noted that if the created smaller droplets are not formed of emulsions it will not develop
36
37 microexplosion. On the other hand if the droplets are formed only with pure diesel it will not
38
39 under go microexplosion phenomenon, instead it will only evaporate (Khan et al., 2014). Each
40
41 emulsion sample was tested three times under same testing conditions to ascertain the
42
43 behaviour. The high speed camera was set to start recording the events as soon as the droplet
44
45 touched the hot plate. This was achieved by the pre-trigger option available with camera
46
47 control software. This facilitated the identification of the exact starting time during post
48
49 processing of the captured images.

Results and discussion

The water droplet distribution in the emulsions was captured using a digital microscope with a magnification of 1000X as shown in Figure 2. The water droplet diameter measurements were made using the Motic Image plus 2.0 software.

[Insert Figure -2]

The sizes of the measured droplets were expressed in terms of Sauter Mean Diameter (SMD) (D_{32}) as follow:

$$D_{32} = \frac{\sum_i (n_i \times D_i^3)}{\sum_i (n_i \times D_i^2)} \quad (2)$$

Where D_i is the diameter of the droplet and n_i is the total number of droplets having the same diameter. The size distribution of water droplets of the samples are depicted in Figure 3. It is clear from Figure 3 that WiDE-1 had a wide range of distributed water droplet diameters even with sizes of 7.6 to 8.4 μm . Whereas, WiDE-2 had 0.8 to 1.2 μm and WiDE-3 had 0.8 to 1.4 μm diameter droplets which were more densely populated.

For the same surfactant dosage, the SMD of WiDE-1 was around 6 μm , 3.34 μm for WiDE-2 and 3.65 μm WiDE-3 as shown in Figure 4. In the case of WiDE-1, a uneven size distribution of a wide range droplet diameters were present. Whereas, the difference between the droplet diameters for WiDE-2 and WiDE-3 were very small. According to Mura, in his studies on microexplosion of water in sunflower oil, the uneven distribution of bigger droplets leads to faster coalescence and eventually microexplodes. (Mura et al., 2012).

[Insert Figure -3]

[Insert Figure -4]

[Insert Table -3]

1
2
3 Physical properties of the prepared emulsions are tabulated in the Table 3. The density of the
4
5 emulsions was found to be almost the same for all the WiDE samples and the viscosity was
6
7 increasing with increasing water content. The surface tension of WiDE-1 was lower compared
8
9 to the other two samples.
10

11 **Microexplosion evolution of WiDE with bigger parent droplet**

12
13
14 The evolution of WiDE Ø2.6 mm (approx.) size droplets is shown in Figure 5. Since no
15
16 significant changes in the emulsion phase were observed in the early part of the experiment
17
18 after the placing of the droplet on the surface, the image sequence shown is from 2 seconds
19
20 onwards and was captured using the direct image recording.
21
22

23
24 [Insert Figure -5]
25
26
27

28
29 [Insert Figure -6]
30

31
32 The rate of coalescence to form larger dispersed water droplets was found to be more
33
34 dominant (as highlighted in Figure 6) in the emulsion WiDE-1 with 9% water, hence more
35
36 readily exploded when compared to the other two WiDE samples. The size of the
37
38 coalescenced water droplets was in the range of 650 µm to 1000 µm for WiDE-1, 69 µm to 37
39
40 µm for WiDE-2 and it was between 37 µm to 105 µm in case of WiDE-3. The phase change
41
42 for all the WiDE with Ø2.6mm is shown in Figure 6 for selected times. It is clear from these
43
44 images that the coalescence is more dominant in case of WiDE-1 than the other two
45
46 emulsions. Also, the coalescence leading to phase change occurred earlier than the other
47
48 WiDE emulsions. As shown in Figure 3, WiDE-1 contains a wide range of different sized
49
50 dispersed water droplets compared to the other two WiDE samples. This non uniform
51
52 distribution of water droplets led to a higher coalescence rate and hence resulted in
53
54 microexplosion. Whereas, the other two WiDE samples had narrow sized distributed water
55
56
57
58
59
60

1
2
3 droplets, with a minimum difference in the values of the SMD, did not undergo intensive
4
5 coalescence resulting in only phase change with no microexplosion. Similar behaviour was
6
7 observed for all the three trials.
8
9

10
11
12 [Insert Figure -7]
13

14
15
16
17 [Insert Figure -8]
18

19 The sequence of evolution of the $\text{Ø}2.0$ mm is shown in Figure 7. The images shown are from
20
21 0 second and with a time interval of 0.5 seconds. Similar behaviour occurred in the case of
22
23 droplets with $\text{Ø}2.0$ mm (approx.) in which WiDE-1 developed microexplosion whereas the
24
25 other two emulsions did not. The secondary droplets after microexplosion from WiDE-1 are
26
27 shown in Figure 8. Further observation of the secondary droplets from a $\text{Ø}2.6$ mm parent
28
29 droplet were in the average size of $\text{Ø}0.22$ mm with a standard deviation of 0.181 and the
30
31 secondary droplets from the $\text{Ø}2.0$ mm parent droplet were around $\text{Ø}0.19$ mm with a standard
32
33 deviation of 0.112. From these observations implies that the size of the secondary droplets is
34
35 slightly influenced by the size of the parent droplet itself. However, more tests has to be
36
37 performed to confirm this precisely.
38
39
40
41
42
43

44 [Insert Figure -9]
45

46 [Insert Figure -10]
47
48

49 Figures 9 and 10 depict the changes in the diameter of the parent droplet at half second time
50
51 interval. For both cases there were no significant changes in the droplet diameter up to 1.5 s,
52
53 due to the fact that the droplet might not had enough heating energy. As the time increases the
54
55 droplet diameter started increasing due to vapour expansion inside the droplet. As the pressure
56
57
58
59
60

1
2
3 built up in the droplet and reached a particular point water leaves the droplets in a very fine
4 mist (Ochoterena et al., 2010). Puffing is the ejection of the inner content of the emulsified
5 droplet without the complete shattering of the parent droplet. At the end of every puffing
6 (resulting in ejection of larger child droplets) the diameter of the parent droplet dropped and
7 underwent further vapour expansion and its diameter increased as shown in the graph. The
8 time taken for initial puffing and the puffing frequency of Ø2.0 mm and Ø2.6 mm WiDE
9 droplets are shown in Figure 11.

10
11
12 The time taken for initial puffing was found to increase with increasing water content in the
13 case of Ø2.6 mm droplet diameter whereas no such trend was observed in the case of Ø2.0
14 mm diameter droplets. However, it is clear from the Figure 11 that the time taken for the
15 initial puffing was considerably less in the case of smaller droplet of WiDE.

16
17
18
19
20
21
22
23
24
25
26
27
28 [Insert Figure -11]

29
30 As far as the puffing frequency is concerned, it was comparatively higher for the Ø2.6 mm
31 droplet than the Ø 2.0 mm. Notably, WiDE-3 with 15% water content exhibited maximum
32 puffing frequency irrespective of the droplet diameters. It was found that the parent droplet
33 size played an important role in the puffing frequency with the larger parent droplets
34 producing high puffing frequencies.

35
36
37 As highlighted in the Figure 12, the child droplets ejected from the parent droplet during
38 puffing was observed to undergo further puffing. The ejected child droplet was about Ø0.568
39 mm. The child droplet was ejected at 1.590s from the parent droplet and the puffing time for
40 the child droplet was at 1.5921s.

41
42
43
44
45
46
47
48
49
50
51 [Insert Figure -12]

52
53
54 **Microexplosion and puffing behaviour of smaller WiDE droplets**

1
2
3 The microexplosion evolutions of the smaller droplets of $\text{Ø}0.2$ mm to $\text{Ø}0.3$ mm are discussed
4
5 in this section. These droplets were generated by dropping a larger droplet from a height onto
6
7 the hot plate which resulted in the production of smaller droplets.
8

9
10 [Insert Figure -13]

11
12 Since it was not possible to control the size or the movement of the droplets generated this
13
14 way, only selected droplets which underwent microexplosion were considered for analysis
15
16 excluding bouncing droplets. These images were captured at 10000 fps. The microexplosion
17
18 behaviour of smaller droplets of WiDE-1, 2 and 3 are shown in Figure 13.
19

20
21 [Insert Table - 4]

22
23 [Insert Figure -14]

24
25
26 The waiting times of the parent droplets and the size of the secondary droplets after
27
28 microexplosion are shown in Table 4. The secondary droplets created after microexplosion of
29
30 parent droplets were between $1/3$ and $1/10$ of the size of the parent droplets. Figure 14 shows
31
32 the instantaneous images of a puffing sequence of WiDE-2, which was observed with the
33
34 smaller parent droplet of $\text{Ø}0.2$ mm and resulted in child droplets of $\text{Ø}0.135$ mm and $\text{Ø}0.138$
35
36 mm. The duration of puffing was 0.002 s. As shown in Figure 14, the diameter of the parent
37
38 droplet increased due to vapour expansion and resulted in the puffing of child droplets. The
39
40 ejected child droplets were observed to undergo further puffing processes as shown.
41
42
43
44

45 46 **Conclusions**

47
48 Water in pure diesel emulsion (WiDE) with different parent droplet sizes were visualized for
49
50 the microexplosion evolution and the outcomes of the observation are summarised as follows;
51

- 52
53 • Coalescence and the size of the coalescenced water droplet was the dominant factor in
54
55 inducing the microexplosion phenomenon in the case of large droplets.
56

- Puffing frequency of the WiDE droplets was found to be a function of the parent droplet size.
- The child droplets ejected during puffing of parent droplets underwent further puffing processes.
- Unlike the large diameter droplets, the small sized ($\varnothing 0.2$ mm) WiDE droplets developed microexplosion irrespective of their water content.
- The size of the child droplets after microexplosion was almost less than 1/10 of the size of the parent droplet for large droplets ($\varnothing 2.6$ and $\varnothing 2.0$ mm) and between 1/3 and 1/10 of the size of the smaller parent droplet. The present testing conditions implies that the size of the secondary droplets is slightly influenced by the size of the parent droplet itself. However, further tests has to be performed to confirm this precisely.

Acknowledgements

The authors wish to thank the Universiti Teknologi PETRONAS for the financial and facility support for the study. The authors express their gratitude to Firmansyah and Ezrann Zharif for their technical assistance in conducting the experiments.

Table Caption

Table 1. Droplet sizes and emulsion fuels on previous studies

Table 2. The preparation matrix for the WiDE

Table 3. Physical properties of WiDE

Table 4. Waiting time of smaller droplets of WiDE

Table 1

Reference	Emulsion fuels used	Parent droplet diameter (mm)
(Ocampo-Barrera et al., 2001)	Heavy fuel oil/water	0.83
(Tanaka et al., 2006)	n-dodecane + n-tetradecane + n-hexadecane + water	2
(Watanabe et al., 2009)	kerosene/water	0.7-1.3
(Morozumi and Saito, 2010)	n-hexadecane/water	1.5-1.8
(Suzuki et al., 2011)	kerosene/water	0.85-0.99
(Tarlet et al., 2014)	sunflower oil/water	0.15-0.45
(Califano et al., 2014)	commercial diesel/water	0.7-1.1
(Mura et al., 2014)	sunflower oil/water	1

Table 2

Volume of surfactant	Sample ID	Amount of H ₂ O (ml)	Volume (ml)	
			Diesel	Surfactant
15% from H ₂ O				
	WiDE-1	9	89.65	1.35
	WIDE-2	12	86.20	1.8
	WIDE-3	15	82.75	2.25

Table 3

Sample ID	Density @ 20°C (g/m ³)	Viscosity @ 40°C (m pas)	Surface tension @ 20°C (mN/m)
Pure diesel	0.84376	2.7396	-----
WiDE-1	0.86109	3.4223	27.47
WiDE-2	0.86052	3.6863	32.27
WiDE-3	0.87140	4.6791	31.11

Table 4

Sample ID	Droplet diameter (mm)	Microexplosion time (s)	Average diameter of secondary droplets after microexplosion (mm)
WiDE-1	0.17	0.196	0.053
WiDE-2	0.23	0.152	0.031
WiDE-3	0.30	0.233	0.030
