

QUANTITATIVE THEOREMS ON LINEAR APPROXIMATION PROCESSES OF CONVOLUTION OPERATORS IN BANACH SPACES

TOSHIHIKO NISHISHIRAHÔ

(Received November 29, 1979)

1. Introduction. Let X be an arbitrary (real or complex) Banach space with norm $\|\cdot\|_X$ and let $B[X]$ denote the Banach algebra of all bounded linear operators of X into itself with the usual operator norm $\|\cdot\|_{B[X]}$. Here we are concerned with linear approximation processes on X defined as follows:

DEFINITION 1. Let $\{L_{n,\lambda}; n \in N, \lambda \in A\}$ be a family of operators in $B[X]$, where N denotes the set of all natural numbers and A is an arbitrary index set. The family $\{L_{n,\lambda}\}$ is said to be a linear approximation process on X if for every $f \in X$,

$$\lim_{n \rightarrow \infty} \|L_{n,\lambda}(f) - f\|_X = 0 \quad \text{uniformly in } \lambda \in A.$$

In this note we would like to study the direct problem of approximation by particular linear approximation processes $\{L_{n,\lambda}; n \in N, \lambda \in A\}$, $L_{n,\lambda}$ being of convolution type in connection with families of strongly continuous operators in $B[X]$. That is, we estimate the degree of convergence of $L_{n,\lambda}(f)$ to f (in the sense of our Definition 1) by a modulus of continuity of f , which can be defined in a natural way (cf. [9; p. 204]). We also study the multiplier type operators in connection with Fourier series expansions corresponding to a total, fundamental sequence of mutually orthogonal projections in $B[X]$ (cf. [3]).

The results obtained in this paper yield applications to the almost convergence of sequences of operators in $B[X]$. For the basic properties of almost convergent sequences of real numbers, see [7] (cf. [6], [8], [10]). We also give applications to the approximation problem in homogeneous Banach spaces due to Katznelson [5] (cf. [9, p. 206]), which are more than the Banach spaces $L^p_{2\pi}$, $1 \leq p < \infty$, and $C_{2\pi}$ of all 2π -periodic, p th power Lebesgue integrable functions f with the norm

$$\|f\|_p = \left\{ (1/2\pi) \int_{-\pi}^{\pi} |f(t)|^p dt \right\}^{1/p},$$

and of all 2π -periodic continuous functions f with the norm

$$\|f\|_\infty = \max\{|f(t)|; |t| \leq \pi\},$$

respectively. An excellent source for references and a systematic treatment on approximation by convolution integral operators in $L^p_{2\pi}$, $1 \leq p < \infty$, and $C_{2\pi}$ can be found in the books of Butzer and Nessel [2] and DeVore [4].

2. Approximate identities for convolution operators. Let R denote the set of all real numbers and let $\mathcal{T} = \{T_t; t \in R\}$ be a family of operators in $B[X]$ with $T_0 = I$, the identity operator, such that for each $f \in X$ the map $t \rightarrow T_t(f)$ is strongly continuous. Therefore, the uniform boundedness principle implies that

$$M_{\mathcal{T}} = \sup\{\|T_t\|_{B[X]}; |t| \leq \pi\}$$

is finite. The convolution of f in X with k in $L^1_{2\pi}$ is the element $k*f$ in X given by

$$k*f = (1/2\pi) \int_{-\pi}^{\pi} k(t)T_t(f)dt,$$

which exists as a Bochner integral (cf. [9; pp. 201-202]).

Let $k \in L^1_{2\pi}$ and $P \in B[X]$. Then the relation

$$(k*P)(f) = k*(P(f)) \quad (f \in X)$$

determines a convolution operator $k*P$ on X . Note that $k*P$ belongs to $B[X]$ and

$$\|k*P\|_{B[X]} \leq M_{\mathcal{T}} \|k\|_1 \|P\|_{B[X]},$$

and moreover, if $PT_t = T_tP$ for each $t \in R$, then $P(k*I) = (k*I)P$. In many cases we deal with linear approximation processes on X which can be generated via convolution operators of the form $k*I$, k being a non-negative or even function in $L^1_{2\pi}$.

In connection with convergence theorems we give the following standard definition.

DEFINITION 2. An approximate identity (for convolution) is a family $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ of elements in $L^1_{2\pi}$ such that

$$(1) \quad \sup\{\|k_{n,\lambda}\|_1; n \in N, \lambda \in A\} < \infty,$$

$$(2) \quad \lim_{n \rightarrow \infty} (1/2\pi) \int_{-\pi}^{\pi} k_{n,\lambda}(t)dt = 1 \quad \text{uniformly in } \lambda \in A$$

and

$$(3) \quad \lim_{n \rightarrow \infty} \int_{\delta \leq |t| \leq \pi} |k_{n,\lambda}(t)|dt = 0 \quad \text{uniformly in } \lambda \in A$$

for any fixed δ satisfying $0 < \delta < \pi$.

LEMMA 1. Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be an approximate identity and let Φ be a continuous X -valued function on $[-\pi, \pi]$. Then

$$\lim_{n \rightarrow \infty} (1/2\pi) \int_{-\pi}^{\pi} k_{n,\lambda}(t) \Phi(t) dt = \Phi(0) \quad \text{uniformly in } \lambda \in A.$$

We omit the proof, which is elementary ([cf. [5; Chapter I, Lemma 2.2)]. As an immediate consequence of Lemma 1, we have the following.

PROPOSITION 1. Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be an approximate identity. Then the family $\{k_{n,\lambda} * I; n \in N, \lambda \in A\}$ is a linear approximation process on X .

PROOF. Let f be an arbitrary element in X and take $\Phi(t) = T_t(f)$ in Lemma 1.

COROLLARY 1. Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be a family of non-negative functions in $L^1_{2\pi}$ satisfying (2) with Fourier series expansions

$$k_{n,\lambda}(t) \sim \sum_{j=-\infty}^{\infty} \hat{k}_{n,\lambda}(j) e^{tj} \quad (n \in N, \lambda \in A),$$

where

$$\hat{k}_{n,\lambda}(j) = (1/2\pi) \int_{-\pi}^{\pi} k_{n,\lambda}(t) e^{-tj} dt.$$

Suppose that $\lim_{n \rightarrow \infty} \{\hat{k}_{n,\lambda}(0) - \text{Re}(\hat{k}_{n,\lambda}(1))\} = 0$ uniformly in $\lambda \in A$, where $\text{Re}(\hat{k}_{n,\lambda}(1))$ denotes the real part of $\hat{k}_{n,\lambda}(1)$. Then the family $\{k_{n,\lambda} * I; n \in N, \lambda \in A\}$ is a linear approximation process on X .

PROOF. Let $0 < \delta < \pi$. Then we have

$$\int_{\delta \leq |t| \leq \pi} k_{n,\lambda}(t) dt \leq 2\pi \{\hat{k}_{n,\lambda}(0) - \text{Re}(\hat{k}_{n,\lambda}(1))\} / (1 - \cos \delta)$$

for all $n \in N$ and for all $\lambda \in A$. Therefore, the desired assertion follows from Proposition 1.

REMARK 1. Let $\{L_p; p \in N\}$ be a sequence of operators in $B[X]$ and let $f, g \in X$. In view of the concept of almost convergence of sequences of real numbers due to Lorentz [7], we say that the sequence $\{L_p(f); p \in N\}$ is almost convergent to g in X if

$$\lim_{n \rightarrow \infty} \left\| (1/n) \sum_{p=m}^{m+n-1} L_p(f) - g \right\|_X = 0 \quad \text{uniformly in } m = 1, 2, \dots$$

(cf. [6], [8], [10]). Let

$$(4) \quad L_{n,m} = (1/n) \sum_{p=m}^{m+n-1} L_p \quad (m, n = 1, 2, \dots).$$

Then the family $\{L_{n,m}; n \in N, m \in N\}$ is a linear approximation process on X if and only if for each $f \in X$, the sequence $\{L_p(f); p \in N\}$ is almost convergent to f in X .

REMARK 2. Let $\{k_p; p \in N\}$ be a sequence of functions in $L^1_{2\pi}$ having Fourier series expansions

$$k_p(t) \sim \sum_{j=-\infty}^{\infty} \hat{k}_p(j) e^{ij t} \quad (p \in N),$$

and let

$$(5) \quad k_{n,m} = (1/n) \sum_{p=m}^{m+n-1} k_p \quad (m, n = 1, 2, \dots).$$

Applying Proposition 1 and Corollary 1, we have the following:

(i) If the family $\{k_{n,m}; n \in N, m \in N\}$ is an approximate identity, then for each $f \in X$, the sequence $\{k_p * f; p \in N\}$ is almost convergent to f in X .

(ii) If each function k_p is non-negative and if $\{\hat{k}_p(0); p \in N\}$ and $\{\hat{k}_p(0) - \text{Re}(\hat{k}_p(1)); p \in N\}$ are almost convergent respectively to one and zero, then $\{k_p * f; p \in N\}$ is almost convergent to f for each $f \in X$.

3. **A quantitative theorem.** In order to recast Corollary 1 in a quantitative form we shall need the following additional assumption upon the family $\mathcal{T} = \{T_t; t \in R\}$:

(\mathcal{T} -1) There exists a constant $C_{\mathcal{T}} \geq 1$, independent of f, s and t , such that

$$(6) \quad \|T_s(f) - T_t(f)\|_X \leq C_{\mathcal{T}} \|T_{s-t}(f) - f\|_X$$

for all $s, t \in R$ and for all $f \in X$.

REMARK 3. If $\mathcal{T} = \{T_t; t \in R\}$ is a uniformly bounded strongly continuous group of operators in $B[X]$ (for the fundamentals of semi-group theory, see [1]), then (6) holds with $C_{\mathcal{T}} = \sup\{\|T_t\|_{B[X]}; t \in R\}$. If in addition each T_t is isometric, then $\|T_s(f) - T_t(f)\|_X = \|T_{s-t}(f) - f\|_X$.

We now introduce a modulus of continuity of elements in X associated with the family \mathcal{T} (cf. [9; p. 204]).

DEFINITION 3. Suppose \mathcal{T} satisfies (\mathcal{T} -1) and let $f \in X$. For $\delta \geq 0$ we define the modulus of continuity of f associated with \mathcal{T} by

$$\omega_{\mathcal{T}}(X; f, \delta) = \sup\{\|T_t(f) - f\|_X; |t| \leq \delta\}.$$

The modulus of continuity has the following fundamental properties:

LEMMA 2. Suppose \mathcal{T} satisfies (\mathcal{T} -1) and let $f \in X$.

- (i) $\omega_{\mathcal{S}}(X; f, \delta)$ is a non-decreasing function of δ on $[0, \infty)$ and $\omega_{\mathcal{S}}(X; f, 0) = 0$.
- (ii) $\omega_{\mathcal{S}}(X; f, \eta\delta) \leq (1 + \eta C_{\mathcal{S}})\omega_{\mathcal{S}}(X; f, \delta)$ for each $\eta, \delta \geq 0$.
- (iii) $\lim_{\delta \rightarrow 0^+} \omega_{\mathcal{S}}(X; f, \delta) = 0$.

PROOF. The parts (i) and (iii) are obvious by the definition and the strong continuity of the map $t \rightarrow T_t(f)$ at $t = 0$. Condition (\mathcal{S} -1) yields that

$$\omega_{\mathcal{S}}(X; f, \delta + \eta) \leq C_{\mathcal{S}}\omega_{\mathcal{S}}(X; f, \delta) + \omega_{\mathcal{S}}(X; f, \eta).$$

Hence by induction on n we have

$$\omega_{\mathcal{S}}(X; f, n\delta) \leq \{1 + (n - 1)C_{\mathcal{S}}\}\omega_{\mathcal{S}}(X; f, \delta) \quad (n \in N),$$

from which the part (ii) follows.

LEMMA 3. Let k be a non-negative function in $L^1_{2\pi}$ with its Fourier series expansion

$$k(t) \sim \sum_{j=-\infty}^{\infty} \hat{k}(j)e^{ijt}.$$

Then we have

$$(1/2\pi) \int_{-\pi}^{\pi} |t|k(t)dt \leq \pi\{(1/2)(\hat{k}(0) - \operatorname{Re}\hat{k}(1))\}^{1/2}\{\hat{k}(0)\}^{1/2}$$

and

$$(1/2\pi) \int_{-\pi}^{\pi} t^2k(t)dt \leq (\pi^2/2)\{\hat{k}(0) - \operatorname{Re}\hat{k}(1)\}.$$

The proof follows by elementary computations using the inequality $2x/\pi \leq \sin x$ ($0 \leq x \leq \pi/2$) and Hölder's inequality (cf. [2; Lemma 1.5.7]).

LEMMA 4. Suppose that \mathcal{S} satisfies (\mathcal{S} -1). Let k be a non-negative function in $L^1_{2\pi}$, and $f \in X$. Then we have

$$(7) \quad \|k * f - \hat{k}(0)f\|_X \leq \{\hat{k}(0)\}^{1/2}\omega_{\mathcal{S}}(X; f, \delta)[\{\hat{k}(0)\}^{1/2} + (\pi C_{\mathcal{S}}/\delta)\{(1/2)(\hat{k}(0) - \operatorname{Re}\hat{k}(1))\}^{1/2}]$$

for each $\delta > 0$.

PROOF. We have

$$k * f - \hat{k}(0)f = (1/2\pi) \int_{-\pi}^{\pi} k(t)\{T_t(f) - f\}dt,$$

which implies

$$\|k * f - \hat{k}(0)f\|_X \leq (1/2\pi) \int_{-\pi}^{\pi} k(t)\|T_t(f) - f\|_X dt$$

$$\leq (1/2\pi) \int_{-\pi}^{\pi} k(t)\omega_{\mathcal{S}}(X; f, |t|)dt .$$

Therefore it follows from the part (ii) of Lemma 2 that

$$\|k * f - \hat{k}(0)f\|_X \leq \omega_{\mathcal{S}}(X; f, \delta)(1/2\pi) \int_{-\pi}^{\pi} \{1 + (|t|C_{\mathcal{S}}/\delta)\}k(t)dt ,$$

which implies (7) by Lemma 3. The proof of the lemma is complete.

Given a family $\{L_{n,\lambda}; n \in N, \lambda \in A\}$ of operators in $B[X]$, let

$$\|A_n(f) - f\|_X = \sup\{\|L_{n,\lambda}(f) - f\|_X; \lambda \in A\} \quad (n \in N, f \in X) .$$

Note that $\{L_{n,\lambda}\}$ is a linear approximation process on X if and only if $\lim_{n \rightarrow \infty} \|A_n(f) - f\|_X = 0$ for every $f \in X$.

We are now in a position to recast Corollary 1 in a quantitative form as follows.

THEOREM 1. *Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be a family of non-negative functions in $L_{2\pi}^1$ such that for each $n \in N$*

$$(8) \quad \alpha_n = \sup\{(\hat{k}_{n,\lambda}(0))^{1/2}; \lambda \in A\}$$

*is finite. Suppose that $\mathcal{S} = \{T_i; t \in R\}$ satisfies (\mathcal{S} -1). Then for the family $\{k_{n,\lambda} * I; n \in N, \lambda \in A\}$ we have*

$$(9) \quad \|A_n(f) - f\|_X \leq \|f\|_X \gamma_n + \{\alpha_n + (1/2)^{1/2} \pi C_{\mathcal{S}}\} \alpha_n \omega_{\mathcal{S}}(X; f, \beta_n)$$

for all $n \in N$ and for all $f \in X$, where

$$(10) \quad \beta_n = \sup\{[\hat{k}_{n,\lambda}(0) - \text{Re}(\hat{k}_{n,\lambda}(1))]^{1/2}; \lambda \in A\}$$

and

$$(11) \quad \gamma_n = \sup\{|\hat{k}_{n,\lambda}(0) - 1|; \lambda \in A\} .$$

In particular, if $\hat{k}_{n,\lambda}(0) = 1$ for all $n \in N$ and for all $\lambda \in A$, then (9) reduces to

$$(12) \quad \|A_n(f) - f\|_X \leq \{1 + (1/2)^{1/2} \pi C_{\mathcal{S}}\} \omega_{\mathcal{S}}(X; f, \beta_n) .$$

PROOF. Taking $k = k_{n,\lambda}$ in Lemma 4, we have

$$(13) \quad \|k_{n,\lambda} * f - \hat{k}_{n,\lambda}(0)f\|_X \leq \alpha_n \{\alpha_n + (1/2)^{1/2} \pi C_{\mathcal{S}}(\beta_n/\delta)\} \omega_{\mathcal{S}}(X; f, \delta) .$$

If $\beta_n > 0$, take $\delta = \beta_n$ in (13). Then the inequality

$$(14) \quad \|k_{n,\lambda} * f - f\|_X \leq \|k_{n,\lambda} * f - \hat{k}_{n,\lambda}(0)f\|_X + |\hat{k}_{n,\lambda}(0) - 1| \|f\|_X$$

implies (9). If $\beta_n = 0$, then (13) reduces to

$$\|k_{n,\lambda} * f - \hat{k}_{n,\lambda}(0)f\|_X \leq \alpha_n^2 \omega_{\mathcal{S}}(X; f, \delta) .$$

Letting $\delta \rightarrow 0+$, we have $k_{n,\lambda} * f = \hat{k}_{n,\lambda}(0)f$ by (iii) of Lemma 2. Thus

(14) reduces to

$$\|k_{n,\lambda} * f - f\|_X = |\hat{k}_{n,\lambda}(0) - 1| \|f\|_X,$$

which implies (9), and the proof of the theorem is complete.

In connection with even functions we shall need the following condition (\mathcal{S} -2) instead of (\mathcal{S} -1):

(\mathcal{S} -2) For every $s, t, u \in R$ and for every $f \in X$,

$$(15) \quad \|T_s(f) + T_t(f) - 2T_u(f)\|_X = \|T_{s-u}(f) + T_{t-u}(f) - 2f\|_X.$$

REMARK 4. (\mathcal{S} -2) already implies (\mathcal{S} -1) with $C_{\mathcal{S}} = 1$;

$$\|T_s(f) - T_t(f)\|_X = \|T_{s-t}(f) - f\|_X \quad (f \in X, s, t \in R).$$

If $\mathcal{S} = \{T_t; t \in R\}$ is a strongly continuous group of isometric operators in $B[X]$, then (\mathcal{S} -2) always holds.

DEFINITION 4. Suppose \mathcal{S} satisfies (\mathcal{S} -2) and let $f \in X$. For $\delta \geq 0$ we define the generalized modulus of continuity of f associated with \mathcal{S} by

$$\omega_{\mathcal{S}}^*(X; f, \delta) = \sup\{\|T_t(f) + T_{-t}(f) - 2f\|_X; 0 \leq t \leq \delta\}.$$

LEMMA 5. Suppose \mathcal{S} satisfies (\mathcal{S} -2) and let $f \in X$.

(i) $\omega_{\mathcal{S}}^*(X; f, \delta)$ is a non-decreasing function of δ on $[0, \infty)$ and $\omega_{\mathcal{S}}^*(X; f, 0) = 0$.

(ii) $\omega_{\mathcal{S}}^*(X; f, \eta\delta) \leq (1 + \eta)^2 \omega_{\mathcal{S}}^*(X; f, \delta)$ for each $\eta, \delta \geq 0$.

(iii) $\omega_{\mathcal{S}}^*(X; f, \delta) \leq 2\omega_{\mathcal{S}}(X; f, \delta)$ for each $\delta \geq 0$. Thus in particular, $\lim_{\delta \rightarrow 0+} \omega_{\mathcal{S}}^*(X; f, \delta) = 0$.

PROOF. The parts (i) and (iii) are obvious by definition and the part (iii) of Lemma 2. Condition (\mathcal{S} -2) yields that $\omega_{\mathcal{S}}^*(X; f, n\delta) \leq n^2 \omega_{\mathcal{S}}^*(X; f, \delta)$ ($n \in N$), from which the part (ii) follows.

LEMMA 6. Suppose that \mathcal{S} satisfies (\mathcal{S} -2). Let k be a non-negative, even function in $L_{2\pi}^1$, and $f \in X$. Then we have

$$(16) \quad \|k * f - \hat{k}(0)f\|_X \leq \omega_{\mathcal{S}}^*(X; f, \delta) [(\pi^2/4)(\hat{k}(0) - \hat{k}(1))(1/\delta^2) + (1/2)(\hat{k}(0))^{1/2}\{(\hat{k}(0))^{1/2} + 2^{1/2}\pi(\hat{k}(0) - \hat{k}(1))^{1/2}/\delta\}]$$

for each $\delta > 0$.

PROOF. Since k is even and positive, we have

$$k * f - \hat{k}(0)f = (1/2\pi) \int_0^\pi k(t) \{T_t(f) + T_{-t}(f) - 2f\} dt,$$

and so

$$\begin{aligned} \|k * f - \hat{k}(0)f\|_X &\leq (1/2\pi) \int_0^\pi k(t) \|T_t(f) + T_{-t}(f) - 2f\|_X dt \\ &\leq (1/2\pi) \int_0^\pi k(t) \omega_{\mathcal{F}}^*(X; f, t) dt . \end{aligned}$$

Therefore it follows from the part (ii) of Lemma 5 that

$$\|k * f - \hat{k}(0)f\|_X \leq (1/2\pi) \omega_{\mathcal{F}}^*(X; f, \delta) \int_0^\pi (1 + t/\delta)^2 k(t) dt ,$$

which implies (16) by Lemma 3.

THEOREM 2. *Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be a family of non-negative, even functions in $L^1_{2\pi}$ such that for each $n \in N$, α_n defined by (8) is finite. Suppose that $\mathcal{F} = \{T_t; t \in R\}$ satisfies (\mathcal{F} -2). Then for the family $\{k_{n,\lambda} * I; n \in N, \lambda \in A\}$ we have*

$$(17) \quad \| |A_n(f) - f| \|_X \leq \|f\|_X \gamma_n + (1/2) \{ \pi^2/2 + \alpha_n (2^{1/2} \pi + \alpha_n) \} \omega_{\mathcal{F}}^*(X; f, \beta_n)$$

for all $n \in N$ and for all $f \in X$, where α_n, β_n and γ_n are numbers defined by (8), (10) and (11), respectively. In particular, if $\hat{k}_{n,\lambda}(0) = 1$ for all $n \in N$ and for all $\lambda \in A$, then (17) reduces to

$$(18) \quad \| |A_n(f) - f| \|_X \leq (1/2) (1 + 2^{-1/2} \pi)^2 \omega_{\mathcal{F}}^*(X; f, \beta_n) .$$

PROOF. In view of Lemma 6 the proof is essentially similar to that of Theorem 1, and so we omit the details.

COROLLARY 2. *Let $\{k_p; p \in N\}$ be a sequence of functions in $L^1_{2\pi}$, and let $\{k_{n,m}; n \in N, m \in N\}$ be the family of functions defined by (5) such that for each $n \in N$, α_n defined by (8) is finite. Then the following statements hold:*

(i) *Suppose that $\mathcal{F} = \{T_t; t \in R\}$ satisfies (\mathcal{F} -1) and each k_p is non-negative. Then for the family $\{k_{n,m} * I; n \in N, m \in N\}$, (9) holds for all $n \in N$ and for all $f \in X$. If in addition $\hat{k}_p(0) = 1$ for each $p \in N$, then (12) holds for all $n \in N$ and for all $f \in X$.*

(ii) *Suppose that $\mathcal{F} = \{T_t; t \in R\}$ satisfies (\mathcal{F} -2) and each k_p is non-negative and even. Then for the family $\{k_{n,m} * I; n \in N, m \in N\}$, (17) holds for all $n \in N$ and for all $f \in X$. If in addition $\hat{k}_p(0) = 1$ for each $p \in N$, then (18) holds for all $n \in N$ and for all $f \in X$.*

REMARK 5. Let $\{k_p; p \in N\}$ be a sequence of non-negative, even functions in $L^1_{2\pi}$ with Fourier series expansions

$$k_p(t) \sim 1 + 2 \sum_{j=1}^\infty a_p(j) \cos jt \quad (p \in N) .$$

Suppose that $\mathcal{F} = \{T_t; t \in R\}$ satisfies (\mathcal{F} -2) and there exists a constant

$C > 0$ such that $1 - a_p(1) \leq C/p$ for all $p \in N$. Then the latter statement of the part (ii) of Corollary 2 implies that

$$(19) \quad |||A_n(f) - f|||_X \leq (1/2)(1 + 2^{-1/2}\pi)^2 \omega_{\mathcal{F}}^*(X; f, \{C(\gamma + \log(n + 1))/n\}^{1/2})$$

for all $n \in N$ and for all $f \in X$, where γ is Euler's constant:

$$\gamma = \lim_{p \rightarrow \infty} \left(\sum_{j=1}^p (1/j) - \log p \right) = 0.5772156649015328 \dots$$

We mention some concrete examples of non-negative, even functions $k_p, p \in N$.

(1°) $k_p(t) = 1 + 2 \sum_{j=1}^p \{1 - j/(p + 1)\} \cos jt$, the Fejér kernel (in this case, $C = 1$).

(2°) $k_p(t) = 1 + 2 \sum_{j=1}^p \{(p!)^2 / ((p - j)! (p + j)!)\} \cos jt$, the de La Vallée Poussin kernel (in this case, $C = 1$).

(3°) $k_p(t) = \{3/(p(2p^2 + 1))\} \{(\sin(pt/2))/\sin(t/2)\}^4$, the Jackson kernel (in this case, $C = 3/2$).

(4°) $k_p(t) = 1 + 2 \sum_{j=1}^p a_p(j) \cos jt$ with

$$a_p(j) = \{(p - j + 3) \sin((j + 1)\pi/(p + 2)) - (p - j + 1) \sin((j - 1)\pi/(p + 2))\} \{2(p + 2) \sin(\pi/(p + 2))\}^{-1},$$

the Fejér-Korovkin kernel (in this case, $C = \pi$, cf. [2; pp. 79-80]).

DEFINITION 5. Suppose $\mathcal{F} = \{T_t; t \in R\}$ satisfies (\mathcal{F} -1). An element $f \in X$ is said to satisfy the Lipschitz condition with constant M and exponent α , or to belong to the class $\text{Lip}_{\mathcal{F}}(X; \alpha)_M, M > 0, \alpha > 0$, if $\omega_{\mathcal{F}}(X; f, \delta) \leq M\delta^\alpha$ for all $\delta \geq 0$. Further, we let $\text{Lip}_{\mathcal{F}}(X; \alpha) = \bigcup \{\text{Lip}_{\mathcal{F}}(X; \alpha)_M; M > 0\}$.

DEFINITION 6. Suppose $\mathcal{F} = \{T_t; t \in R\}$ satisfies (\mathcal{F} -2). An element $f \in X$ is said to satisfy the generalized Lipschitz condition with constant M and exponent α , or to belong to the class $\text{Lip}_{\mathcal{F}}^*(X; \alpha)_M, M > 0, \alpha > 0$, if $\omega_{\mathcal{F}}^*(X; f, \delta) \leq M\delta^\alpha$ for all $\delta \geq 0$. Further, we let $\text{Lip}_{\mathcal{F}}^*(X; \alpha) = \bigcup \{\text{Lip}_{\mathcal{F}}^*(X; \alpha)_M; M > 0\}$.

REMARK 6. Under the hypotheses of Theorem 1, if f belongs to $\text{Lip}_{\mathcal{F}}(X; \alpha)_M$, then (12) implies that

$$|||A_n(f) - f|||_X \leq M\{1 + (1/2)^{1/2}\pi C_{\mathcal{F}}\} \beta_n^\alpha$$

for all $n \in N$. Under the hypotheses of Theorem 2, if f belongs to $\text{Lip}_{\mathcal{F}}^*(X; \alpha)_M$, then (18) implies that

$$|||A_n(f) - f|||_X \leq (M/2)(1 + 2^{-1/2}\pi)^2 \beta_n^\alpha$$

for all $n \in N$. In particular under the hypotheses of Remark 5, if f belongs to $\text{Lip}_{\mathcal{S}}^*(X; \alpha)_M$, then (19) implies that

$$\|A_n(f) - f\|_X \leq (M/2)(1 + 2^{-1/2}\pi)^2 \{C(\gamma + \log(n + 1))/n\}^{\alpha/2}$$

for all $n \in N$.

THEOREM 3. *Let $\mathcal{S} = \{T_t; t \in R\}$ be a uniformly bounded strongly continuous group of operators in $B[X]$, having G as its infinitesimal generator with domain $D(G)$ and M as its bound. Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be a family of non-negative, even functions in $L_{2\pi}^1$ such that for each $n \in N$, α_n defined by (8) is finite. Then for the family $\{k_{n,\lambda} * I; n \in N, \lambda \in A\}$ we have*

$$(20) \quad \|A_n(f) - f\|_X \leq \|f\|_X \gamma_n + 2^{-1/2}\pi \|G(f)\|_X \alpha_n \beta_n \\ + 2^{-1/2}\pi \{1 + M(2^{-3/2}\pi)\} \beta_n \omega_{\mathcal{S}}(X; G(f), \beta_n)$$

for all $n \in N$ and for all $f \in D(G)$, where α_n , β_n and γ_n are numbers defined by (8), (10) and (11), respectively. In particular, if $\hat{k}_{n,\lambda}(0) = 1$ for all $n \in N$ and for all $\lambda \in A$, then (20) reduces to

$$(21) \quad \|A_n(f) - f\|_X \leq 2^{-1/2}\pi \|G(f)\|_X \beta_n \\ + 2^{-1/2}\pi \{1 + M(2^{-3/2}\pi)\} \beta_n \omega_{\mathcal{S}}(X; G(f), \beta_n).$$

PROOF. Let k be a non-negative, even function in $L_{2\pi}^1$, and $f \in D(G)$. Then we have

$$(22) \quad \|k * f - \hat{k}(0)f\|_X \leq 2^{-1/2}\pi \{\hat{k}(0)(\hat{k}(0) - \hat{k}(1))\}^{1/2} \|G(f)\|_X \\ + 2^{-1/2}\pi \{\hat{k}(0) - \hat{k}(1)\}^{1/2} [1 + M(2^{-3/2}\pi/\delta)] \{\hat{k}(0) \\ - \hat{k}(1)\}^{1/2} \omega_{\mathcal{S}}(X; G(f), \delta)$$

for each $\delta > 0$. Indeed,

$$k * f - \hat{k}(0)f = (1/2\pi) \left\{ \int_0^\pi k(t)(T_t(f) - f)dt + \int_0^\pi k(t)(T_{-t}(f) - f)dt \right\} \\ = g + h,$$

say. Since

$$T_t(f) - f = \int_0^t T_u(G(f))du \quad (t > 0),$$

we have

$$\|g\|_X \leq \left\{ (1/2\pi) \int_0^\pi tk(t)dt \right\} \|G(f)\|_X \\ + (1/2\pi) \int_0^\pi k(t) \left\{ \int_0^t \|T_u(G(f)) - G(f)\| du \right\} dt.$$

The second integral is, by virtue of the part (ii) of Lemma 2, majorized by

$$\begin{aligned} & (1/2\pi) \int_0^\pi k(t) \left\{ \int_0^t (1 + (M/\delta)u) \omega_{\mathcal{S}}(X; G(f), \delta) du \right\} dt \\ & = \omega_{\mathcal{S}}(X; G(f), \delta) (1/2\pi) \int_0^\pi tk(t) \{1 + (M/2\delta)t\} dt . \end{aligned}$$

In a similar manner, we obtain the same estimate for $\|h\|_x$, and consequently

$$\begin{aligned} \|k*f - \hat{k}(0)f\|_x & \leq \left\{ (1/\pi) \int_0^\pi tk(t) dt \right\} \|G(f)\|_x \\ & + \left[(1/\pi) \int_0^\pi tk(t) \{1 + (M/2\delta)t\} dt \right] \omega_{\mathcal{S}}(X; G(f), \delta) . \end{aligned}$$

This, in virtue of Lemma 3, proves the desired estimate (22).

Taking $k = k_{n,\lambda}$ in (22), we finish the proof exactly as that of Theorem 1.

REMARK 7. Let $\{k_p; p \in N\}$ and $\mathcal{S} = \{T_t; t \in R\}$ be as in Remark 5 and Theorem 3, respectively. Then (21) reduces to

$$\begin{aligned} (23) \quad \|A_n(f) - f\|_x & \leq 2^{-1/2}\pi \|G(f)\|_x \{C(\gamma + \log(n + 1))/n\}^{1/2} \\ & + 2^{-1/2}\pi \{1 + M(2^{-3/2}\pi)\} \{C(\gamma + \log(n + 1))/n\}^{1/2} \\ & \times \omega_{\mathcal{S}}(X; f, \{C(\gamma + \log(n + 1))/n\}^{1/2}) \end{aligned}$$

for all $n \in N$ and for all $f \in D(G)$. In particular, if $f \in D(G)$ belongs to $\text{Lip}_{\mathcal{S}}(X; \alpha)_K$, then (23) implies that $\|A_n(f) - f\|_x \leq 2^{-1/2}\pi \|G(f)\|_x \{C(\gamma + \log(n + 1))/n\}^{1/2} + 2^{-1/2}\pi K \{1 + M(2^{-3/2}\pi)\} \{C(\gamma + \log(n + 1))/n\}^{(1+\alpha)/2}$ for all $n \in N$.

4. Multiplier operators. In this section we would like to discuss certain families $\{T_t; t \in R\}$ of multiplier operators. Let Z denote the set of all integers, and let $\{P_j\}_{j \in Z}$ be a sequence of projections in $B[X]$ satisfying the following properties:

(i) The projections P_j are mutually orthogonal, i.e., for all $j, m \in Z$ there holds $P_j P_m = \delta_{j,m} P_m$, $\delta_{j,m}$ being Kronecker's symbol.

(ii) The sequence $\{P_j\}$ is total, i.e., $P_j(f) = 0$ for all $j \in Z$ implies $f = 0$.

(iii) The sequence $\{P_j\}$ is fundamental, i.e., the linear subspace of X spanned by the ranges $P_j(X)$, $j \in Z$, is 'dense in X . Then for each $f \in X$ the series $\sum_{j=-\infty}^{\infty} P_j(f)$ is called the (formal) Fourier series expansion

sion of f (with respect to $\{P_j\}$), and the following notation is used (cf. [3]):

$$(24) \quad f \sim \sum_{j=-\infty}^{\infty} P_j(f).$$

Let \mathcal{S} denote the set of all sequences $a = \{a_j\}_{j \in Z}$ of scalars. An element $a \in \mathcal{S}$ is called a multiplier sequence for X (corresponding to $\{P_j\}$) if for each $f \in X$ there exists an element $f_a \in X$ such that $a_j P_j(f) = P_j(f_a)$ for all $j \in Z$, thus

$$(25) \quad f_a \sim \sum_{j=-\infty}^{\infty} a_j P_j(f).$$

Note that f_a is uniquely determined by f , since $\{P_j\}$ is total and so the map $f \rightarrow f_a$ defines a bounded linear operator of X into itself by the closed graph theorem. An element $T \in B[X]$ is called a multiplier operator on X if it permits an expansion of type (25).

REMARK 8. The expansion (24) represents a slight generalization of the concept of Fourier series in a Banach space X associated with a fundamental, total, biorthogonal system $\{f_j, f_j^*\}_{j \in Z}$. Here $\{f_j\}_{j \in Z}$ and $\{f_j^*\}_{j \in Z}$ are sequences of elements in X and X^* (the dual space of X), respectively, such that the linear subspace of X spanned by $\{f_j\}$ is dense in X (fundamental), $f_j^*(f) = 0$ for all $j \in Z$ implies $f = 0$ (total), and $f_j^*(f_m) = \delta_{j,m}$ for all $j, m \in Z$ (biorthogonal). Then (24) and (25) read

$$f \sim \sum_{j=-\infty}^{\infty} f_j^*(f) f_j, \quad T(f) \sim \sum_{j=-\infty}^{\infty} a_j f_j^*(f) f_j,$$

respectively.

The following proposition shows that if $\mathcal{S} = \{T_t; t \in R\}$ is generated via multiplier operators on X with associated multiplier sequences of exponential type, then every convolution operator $k * I$ with $k \in L_{2\pi}^1$ is a multiplier operator on X .

PROPOSITION 2. Let $\mathcal{S} = \{T_t; t \in R\}$ be a family of operators in $B[X]$ such that $\sup\{\|T_t\|_{B[X]}; t \in R\}$ is finite and

$$(26) \quad T_t(f) \sim \sum_{j=-\infty}^{\infty} \exp(a_j t) P_j(f) \quad (t \in R, f \in X),$$

where $a = \{a_j\}$ is a sequence in \mathcal{S} . Then \mathcal{S} is a strongly continuous group of operators in $B[X]$, and with each $k \in L_{2\pi}^1$ the convolution operator $k * I$ on X is a multiplier operator on X with associated multiplier sequence $c = \{c_j\}_{j \in Z} \in \mathcal{S}$ defined by

$$c_j = (1/2\pi) \int_{-\pi}^{\pi} k(t) \exp(a_j t) dt, \quad j \in Z,$$

thus

$$(27) \quad k * f \sim \sum_{j=-\infty}^{\infty} c_j P_j(f)$$

for every $f \in X$. Furthermore, the infinitesimal generator G of \mathcal{S} with domain $D(G)$ satisfies

$$(28) \quad G(f) \sim \sum_{j=-\infty}^{\infty} a_j P_j(f)$$

for all $f \in D(G)$. If, furthermore, with the n th Cesàro mean operator σ_n defined by

$$\sigma_n = \sum_{j=-n}^n \{1 - |j|/(n + 1)\} P_j,$$

the sequence $\{\sigma_n\}$ is uniformly bounded, i.e.,

$$(29) \quad \sup\{\|\sigma_n\|_{B[X]}; n = 0, 1, 2, \dots\} < \infty,$$

then

$$(30) \quad D(G) = \left\{ f \in X; g \sim \sum_{j=-\infty}^{\infty} a_j P_j(f) \text{ for some } g \in X \right\}.$$

PROOF. Since $\{P_j\}$ is total, the expansion (26) implies that \mathcal{S} forms a group of operators in $B[X]$. We have

$$\lim_{t \rightarrow s} \|T_t(h) - T_s(h)\|_X = \lim_{t \rightarrow s} |\exp(a_j t) - \exp(a_j s)| \|h\|_X = 0$$

for every $h \in P_j(X)$, $j \in Z$, and so the map $t \rightarrow T_t(f)$ is strongly continuous for each $f \in X$, since $\{P_j\}$ is fundamental and \mathcal{S} is uniformly bounded. Let $k \in L^1_{2\pi}$ and $f \in X$. Then we have, for all $j \in Z$,

$$P_j(k * f) = (1/2\pi) \int_{-\pi}^{\pi} k(t) P_j(T_t(f)) dt = (1/2\pi) \int_{-\pi}^{\pi} k(t) \exp(a_j t) P_j(f) dt = c_j P_j(f),$$

which implies (27), and so the first assertion of the proposition is proved.

Suppose now that f belongs to $D(G)$. Then for each $j \in Z$ we have

$$P_j(G(f)) = \lim_{t \rightarrow 0} (1/t) P_j(T_t(f) - f) = \lim_{t \rightarrow 0} (1/t) \{ \exp(a_j t) - 1 \} P_j(f) = a_j P_j(f),$$

which implies (28), and therefore $D(G)$ is contained in the set on the right-hand side of (30). Suppose next that (29) is satisfied. Let f be an element of X such that

$$g \sim \sum_{j=-\infty}^{\infty} a_j P_j(f)$$

for some $g \in X$. Then $\sigma_n(g) = G(\sigma_n(f))$ for all $n \in N$. Since $\{P_j\}$ is fundamental, (29) implies that $\lim_{n \rightarrow \infty} \|\sigma_n(h) - h\|_X = 0$ whenever h belongs to X . Thus we have

$$\lim_{n \rightarrow \infty} \|\sigma_n(f) - f\|_X = 0 \quad \text{and} \quad \lim_{n \rightarrow \infty} \|G(\sigma_n(f)) - g\|_X = 0,$$

which imply that $f \in D(G)$ and $G(f) = g$, since G is a closed operator. This proves (30), and the proof of the proposition is complete.

REMARK 9. Condition (29) is a standard one in the study of multiplier sequences and summation processes of Fourier series expansions in Banach spaces (cf. [3]). For the particular sequence $\{a_j\}_{j \in Z} = \{-ij\}_{j \in Z}$, (27) reduces to

$$k * f \sim \sum_{j=-\infty}^{\infty} \hat{k}(j) P_j(f).$$

In view of Remarks 3 and 4 and Proposition 2, we have the following theorem in which the convolution operators in question have Fourier series expansions of the form (27).

THEOREM 4. Let $\mathcal{S} = \{T_t; t \in R\}$ be a family of multiplier operators on X with Fourier series expansions (26). Then the following statements hold.

(i) Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be as in Theorem 1. Suppose that $M = \sup\{\|T_t\|_{B[X]}; t \in R\}$ is finite. Then for all $n \in N, \lambda \in A$ and for all $f \in X$

$$(31) \quad k_{n,\lambda} * f \sim \sum_{j=-\infty}^{\infty} c_{n,\lambda}(j) P_j(f),$$

where

$$c_{n,\lambda}(j) = (1/2\pi) \int_{-\pi}^{\pi} k_{n,\lambda}(t) \exp(a_j t) dt$$

and furthermore, (9) holds with $C_{\mathcal{S}} = M$.

(ii) Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be as in Theorem 2. Suppose that $\|T_t(f)\|_X = \|f\|_X$ for all $t \in R$ and for all $f \in X$. Then for all $n \in N, \lambda \in A$ and for all $f \in X$, (31) holds and furthermore, (17) holds.

(iii) Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be as in Theorem 3. Suppose that $M = \sup\{\|T_t\|_{B[X]}; t \in R\}$ is finite. Then for every $n \in N, \lambda \in A$ and for every $f \in X$, (31) holds and furthermore, (20) holds.

5. Homogeneous Banach subspaces of $L^1_{2\pi}$. In this section we apply the results obtained in the preceding section to homogeneous Banach subspaces of $L^1_{2\pi}$. Let X be a linear subspace of $L^1_{2\pi}$. X is called a homogeneous Banach subspace of $L^1_{2\pi}$ if it is a Banach space with norm $\|\cdot\|_X$ which satisfies the following properties (cf. [5; p. 14], [9; p. 206]):

(H-1) There exists a constant $C > 0$ such that $\|f\|_1 \leq C\|f\|_X$ for all $f \in X$.

(H-2) For each $f \in X$ and $t \in R$, $T_t(f)$ belongs to X and $\|T_t(f)\|_X = \|f\|_X$, where T_t is the translation operator, i.e.,

$$T_t(f)(u) = f(u - t), \quad u \in R.$$

(H-3) For each $f \in X$, the map $t \rightarrow T_t(f)$ is a continuous X -valued function on R .

Examples of homogeneous Banach subspaces of $L^1_{2\pi}$ are the following:

- (1°) $L^p_{2\pi}$, $1 \leq p < \infty$ (note that (H-3) is not satisfied when $X = L^\infty_{2\pi}$).
- (2°) $C_{2\pi}$.
- (3°) $C^{(n)}_{2\pi}$ = the linear subspace of $C_{2\pi}$ of all n -times continuously differentiable functions f with norm

$$\|f\|_{C^{(n)}_{2\pi}} = \sum_{j=0}^n (1/j!) \|f^{(j)}\|_\infty.$$

(4°) $AC_{2\pi}$ = the linear subspace of $L^1_{2\pi}$ of all 2π -periodic absolutely continuous functions f with norm

$$\|f\|_{AC_{2\pi}} = \|f\|_1 + \|f'\|_1.$$

(5°) $0 < \alpha < 1$, $\text{lip}^\alpha_{2\pi}$ = the linear subspace of $C_{2\pi}$ consisting of all functions f for which

$$F(f) = \sup\{|f(t+h) - f(t)|/|h|^\alpha; h \neq 0, t \in R\} < \infty$$

and

$$\lim_{h \rightarrow 0} (\sup\{|f(t+h) - f(t)|/|h|^\alpha; t \in R\}) = 0,$$

with norm

$$\|f\|_{\text{lip}^\alpha_{2\pi}} = \|f\|_\infty + F(f).$$

(6°) $D(L)$ = the domain in $L^1_{2\pi}$ of a closed operator L with range in $L^1_{2\pi}$ such that for each $t \in R$, T_t commutes with L , with norm

$$\|f\|_{D(L)} = \|f\|_1 + \|L(f)\|_1.$$

Now let X be a homogeneous Banach subspace of $L^1_{2\pi}$ with norm $\|\cdot\|_X$. Recall that $\mathcal{T} = \{T_t; t \in R\}$ is the family of translation operators.

Therefore, we have

$$\omega_{\mathcal{F}}(X; f, \delta) = \sup\{\|f(\cdot - t) - f(\cdot)\|_X; |t| \leq \delta\}$$

and

$$\omega_{\mathcal{F}}^*(X; f, \delta) = \sup\{\|f(\cdot + t) + f(\cdot - t) - 2f(\cdot)\|_X; 0 \leq t \leq \delta\},$$

respectively.

Let $k \in L^1_{2\pi}$ and $f \in X$. Then

$$(32) \quad (k * f)(u) = (1/2\pi) \int_{-\pi}^{\pi} k(t)f(u - t)dt .$$

Defining the sequence $\{P_j\}_{j \in \mathbb{Z}}$ by $P_j(f)(t) = \hat{f}(j)e^{ijt}$, it is obvious that $\{P_j\}$ is a total, fundamental sequence of mutually orthogonal projections in $B[X]$ since $\lim_{n \rightarrow \infty} \|\sigma_n(g) - g\|_X = 0$, whenever g belongs to X by virtue of Theorems 2.11 and 2.12 of [5; Chapter I]. Furthermore, we have

$$T_t(f) \sim \sum_{j=-\infty}^{\infty} e^{-ijt} P_j(f), \quad t \in R$$

and

$$k * f \sim \sum_{j=-\infty}^{\infty} \hat{k}(j) P_j(f) .$$

Consequently, under the above setting all the results obtained in the preceding sections are applicable to homogeneous Banach subspaces X . In particular, the result corresponding to the part (ii) of Corollary 2 extends Theorem 7 of Mohapatra [8] for the real Banach space $C_{2\pi}$ to the more general homogeneous Banach subspaces of $L^1_{2\pi}$ and yields the better estimate of the degree of almost convergence.

Finally, for homogeneous Banach subspaces X of $L^1_{2\pi}$ we recast Corollary 1 in connection with the test function class $\{u_0, u_1, u_2\}$, where $u_0(t) = 1$, $u_1(t) = \cos t$ and $u_2(t) = \sin t$ for all $t \in R$.

THEOREM 5. *Let $\{k_{n,\lambda}; n \in N, \lambda \in A\}$ be a family of non-negative functions in $L^1_{2\pi}$. Suppose that for $j = 1, 2$ and for each $f \in X$, $u_j f$ belongs to X and $\|u_j f\|_X \leq \|f\|_X$, and $\|u_0\|_X = 1$. Then the following three statements are equivalent:*

(i) *For every $f \in X$,*

$$\lim_{n \rightarrow \infty} \|k_{n,\lambda} * f - f\|_X = 0 \quad \text{uniformly in } \lambda \in A;$$

(ii) *For $j = 0, 1, 2$,*

$$(33) \quad \lim_{n \rightarrow \infty} \|k_{n,\lambda} * u_j - u_j\|_X = 0 \quad \text{uniformly in } \lambda \in A;$$

(iii) $\lim_{n \rightarrow \infty} \hat{k}_{n,\lambda}(0) = 1$ *uniformly in $\lambda \in A$*

and

$$(34) \quad \lim_{n \rightarrow \infty} \{\widehat{k}_{n,\lambda}(0) - \operatorname{Re}(\widehat{k}_{n,\lambda}(1))\} = 0 \quad \text{uniformly in } \lambda \in A .$$

PROOF. It is clear that (i) implies (ii) since u_0, u_1 and u_2 belong to X . Suppose that (ii) is valid. In view of the general formula (32) we have

$$\{\widehat{k}_{n,\lambda}(0) - \operatorname{Re}(\widehat{k}_{n,\lambda}(1))\}u_0 = k_{n,\lambda} * u_0 - u_1 k_{n,\lambda} * u_1 - u_2 k_{n,\lambda} * u_2 ,$$

which implies

$\widehat{k}_{n,\lambda}(0) - \operatorname{Re}(\widehat{k}_{n,\lambda}(1)) \leq \|k_{n,\lambda} * u_0 - u_0\|_X + \|k_{n,\lambda} * u_1 - u_1\|_X + \|k_{n,\lambda} * u_2 - u_2\|_X$, since $\|u_1 f\|_X \leq \|f\|_X$, $\|u_2 f\|_X \leq \|f\|_X$ whenever f belongs to X , and $\|u_0\|_X = 1$. Thus letting n tend to infinity in the above inequality, we have (34). For $j = 0$, (33) is equivalent to

$$\lim_{n \rightarrow \infty} \widehat{k}_{n,\lambda}(0) = 1 \quad \text{uniformly in } \lambda \in A ,$$

and therefore (iii) holds. It follows from Corollary 1 that (ii) implies (i), and the theorem is proved.

We close with the following remark.

REMARK 10. The equivalence of (i) and (ii) in Theorem 5 extends Theorem 5 of King and Swetits [6] for sequences of positive convolution integral operators on $C_{2\pi}$ to the more general homogeneous Banach subspaces of $L^1_{2\pi}$.
