#### Abstract

We study queues in tandem with customer deadlines and retrials. We first consider a 2-queue Markovian system with blocking at the second queue, analyze it, and derive its stability condition. We then study a non-Markovian setting and derive the stability condition for an approximating diffusion, showing its similarity to the former condition. In the Markovian setting, we use probability generating functions and matrix analytic techniques. In the diffusion setting, we consider expectations of the first hitting times of compact sets.

## 1 Introduction

In this paper we study a system of queues in tandem with customer deadlines and retrials. Networks of queues in tandem or more elaborate topologies have long been the subject of many articles in the literature (e.g., the famous Jackson network [13, 14]). Tandem queues with finite buffers and blocking, causing retrials, have recently been studied and applied to Internet data traffic (see, for eaxample, [6, 7]). There is also a vast literature on retrial queues (e.g., [3, 9, 11, 30] and references therein). Queues

[^0]with impatient customers and abandonments have also been studied; see, for example, [1, 31]. Many authors have also recently studied many-server queues with abandonments [2, 12, 19, 20].

We are motivated by a scenario in which data packets are being sent through several routers. Each packet has a deadline time by which it must arrive at its final destination. If the packet is still in the system when its deadline expires, then it is removed from the system and in its place a new packet is entered into the system. The new packet is assigned a new deadline time as well.

Consequently, we consider a system comprised of two queues in tandem, where the first queue has an unlimited buffer capacity and the second queue has a finite buffer capacity. Each arriving job (customer) carries with it a deadline time such that if its processing at the first queue does not start by the time its deadline expires, the job is fed back to the end of the queue. Upon completion of service at the first queue, the job proceeds to the second queue. If it is blocked there, because the buffer is full, the job is fed back to the end of the first queue. The same applies if the job is admitted to the second queue but its waiting time there exceeds its deadline.

We first study a Markovian system with two queues in tandem and with exponential deadlines in each queue. We use both a Probability Generating Function (PGF) approach, as well as Matrix Geometric analysis. We obtain the condition for stability and give it a probabilistic interpretation. Based on this interpretation, we consider a more general 2-queue system with general arrival and service processes and apply a diffusion approximation to obtain the stability condition of the system.

The structure of the paper is as follows. The Markovian model is presented in Sect. 2. Balance equations are derived in Sect. 3. PGFs are applied in Sect. 4, while the calculation of the so-called 'boundary probabilities' is discussed in Sect. 5. A theorem on the roots of a polynomial related to the set of PGFs is presented, from which the stability condition of the system is derived. Marginal probabilities are discussed in Sect. 6. The Matrix Geometric method is used in Sect. 7 and a stability condition is obtained. It is shown that this condition is equivalent to the stability condition derived in Sect. 5. A probabilistic interpretation is discussed in Sect. 8. In Sect. 9 we consider the non-Markovian setting and present a diffusion approximation in Sect. 10. In Sect. 11 we present a stability result regarding our diffusion approximation, and the subsequent proof may be found in Sects. 12 and 13.

## 2 The model

We consider a system comprised of two Markovian queues in tandem. The first queue $\left(Q_{1}\right)$ is an unlimited-buffer $M / M / 1$-type queue with homogeneous Poisson arrivals at rate $\lambda$. The service time for each individual customer at station 1 is exponentially distributed with mean $1 / \mu_{1}$. Each customer in $Q_{1}$ has a deadline on her waiting time. If service does not start before the customer's deadline runs out, the customer reneges from her position in the waiting line and goes to the end of the queue, activating a new deadline, independent of the previous deadlines. We assume that the deadline time is a random variable, exponentially distributed, with mean $1 / \gamma$. Upon completion of service in $Q_{1}$, a customer immediately moves to queue $2\left(Q_{2}\right)$, which is a limitedbuffer $\cdot / M / 1 / N$ queue with service rate $\mu_{2}$. Here again, there is a deadline on a

Fig. 1 Two queues in tandem with deadlines, blocking, and retrials
customer's queueing time. However, if the deadline, exponentially distributed with mean $1 / \gamma$, expires before the customer starts service in $Q_{2}$, the customer moves all the way back to the end of the first queue, $Q_{1}$. Moreover, when a customer completes service in $Q_{1}$ and finds that there are $N$ customers present in $Q_{2}$ ( $N-1$ waiting and one being served), she is fedback all the way to the end of the first queue. The system is depicted in Fig. 1.

Our aim is to analyze this "deadline-with-blocking and retrials" system, find its steady-state 2-dimensional distribution function, reveal the system's stability condition, and give it a probabilistic interpretation.

## 3 Balance equations

Consider the system in steady state. Let $L_{i}$ denote the total number of customers (waiting and being served) in $Q_{i}$ for $i=1,2$. Then $\left(L_{1}, L_{2}\right)$ is a Markov process with transition-rate diagram as depicted in Fig. 2. In this section we derive the balance equations for ( $L_{1}, L_{2}$ ) in stationarity.

Define the steady-state probabilities of the system's states

$$
P_{m n}=P\left(L_{1}=m, L_{2}=n\right) \quad m=0,1,2, \ldots ; n=0,1, \ldots, N .
$$

Then, we can write the balance equations as follows:
(i) For $L_{2}=0$,

$$
\begin{align*}
& L_{1}=0: \quad \lambda P_{00}=\mu_{2} P_{01} ;  \tag{1}\\
& L_{1}=m: \quad\left(\lambda+\mu_{1}\right) P_{m 0}=\mu_{2} P_{m 1}+\lambda P_{m-1,0} \quad(m=1,2,3, \ldots), \tag{2}
\end{align*}
$$

(ii) For $L_{2}=n(1 \leq n \leq N-1)$,

$$
\begin{align*}
L_{1}=0: & \left(\lambda+\mu_{2}+(n-1) \gamma\right) P_{0 n}=\mu_{2} P_{0, n+1}+\mu_{1} P_{1, n-1}  \tag{3}\\
L_{1}=m: \quad & \left(\lambda+\mu_{2}+(n-1) \gamma+\mu_{1}\right) P_{m n} \\
& =\mu_{2} P_{m, n+1}+\mu_{1} P_{m+1, n-1}+n \gamma P_{m-1, n+1}+\lambda P_{m-1, n} \\
& m \geq 1 \tag{4}
\end{align*}
$$

Fig. 2 Transition-rate diagram for $\left(L_{1}, L_{2}\right)$
(iii) For $L_{2}=N$,

$$
\begin{align*}
L_{1}=0: & \left(\lambda+\mu_{2}+(N-1) \gamma\right) P_{0 N}=\mu_{1} P_{1, N-1} ;  \tag{5}\\
L_{1}=m: \quad & \left(\lambda+\mu_{2}+(N-1) \gamma\right) P_{m N}=\mu_{1} P_{m+1, N-1}++\lambda P_{m-1, N} \\
& (m \geq 1) . \tag{6}
\end{align*}
$$

## 4 Generating functions

Define $N+1$ probability generating functions (PGFs) as follows:

$$
G_{n}(z)=\sum_{m=0}^{\infty} P_{m n} z^{m}, \quad 0 \leq n \leq N
$$

Then, for $L_{2}=0$, multiplying each equation in (2) by $z^{m}$ and summing all resulting equations, including (1), leads to

$$
\lambda G_{0}(z)+\mu_{1}\left(G_{0}(z)-P_{00}\right)=\mu_{2} G_{1}(z)+\lambda z G_{0}(z)
$$

Arranging terms we have

$$
\begin{equation*}
\left[\lambda(1-z)+\mu_{1}\right] G_{0}(z)-\mu_{2} G_{1}(z)=\mu_{1} P_{00} \tag{7}
\end{equation*}
$$

Similarly, for $L_{2}=n(1 \leq n \leq N-1)$, using (3) and (4) results in

$$
\begin{aligned}
{[\lambda} & \left.+\mu_{2}+(n-1) \gamma\right] G_{n}(z)+\mu_{1}\left[G_{n}(z)-P_{0 n}\right] \\
& =\mu_{2} G_{n+1}(z)+\frac{\mu_{1}}{z}\left[G_{n-1}(z)-P_{0, n-1}\right]+n \gamma z G_{n+1}(z)+\lambda z G_{n}(z)
\end{aligned}
$$

Arranging terms we get

$$
\begin{align*}
& z\left[\lambda(1-z)+\mu_{1}+\mu_{2}+(n-1) \gamma\right] G_{n}(z)-\mu_{1} G_{n-1}(z)-z\left[\mu_{2}+n \gamma z\right] G_{n+1}(z) \\
& \quad=\mu_{1} z P_{0, n}-\mu_{1} P_{0, n-1} \quad(1 \leq n \leq N-1) \tag{8}
\end{align*}
$$

Finally, for $L_{2}=N$, considering (5) and (6), we obtain

$$
\left[\lambda+\mu_{2}+(N-1) \gamma\right] G_{N}(z)=\frac{\mu_{1}}{z}\left[G_{N-1}(z)-P_{0, N-1}\right]+\lambda z G_{N}(z)
$$

or

$$
\begin{equation*}
z\left[\lambda(1-z)+\mu_{2}+(N-1) \gamma\right] G_{N}(z)-\mu_{1} G_{N-1}(z)=-\mu_{1} P_{0, N-1} \tag{9}
\end{equation*}
$$

Equations (7), (8), and (9) define a linear set of equations in the unknown PGFs $G_{0}(z), G_{1}(z), \ldots, G_{N}(z)$, depending on the $N$ unknown boundary probabilities $P_{00}, P_{01}, \ldots, P_{0, N-1}$.

## 5 Solving for the boundary probabilities $P_{00}, P_{01}, \ldots, P_{0, N-1}$

Define the $(N+1)$-dimensional column vector $\underline{G}(z)=\left(G_{0}(z), G_{1}(z), \ldots, G_{N}(z)\right)^{T}$, and the column vector

$$
\underline{b}(z)=\mu_{1}\left[P_{00}, z P_{01}-P_{00}, z P_{02}-P_{01}, \ldots, z P_{0, N-1}-P_{0, N-2},-P_{0, N-1}\right] .
$$

Then, (7), (8), and (9) can be written in a matrix form as

$$
\begin{equation*}
A(z) \underline{G}(z)=\underline{b}(z), \tag{10}
\end{equation*}
$$

where the $(N+1)$-dimensional square matrix $A(z)$ is given by
with

$$
\alpha_{n}(z)=z\left[\lambda(1-z)+\mu_{1}+\mu_{2}+(n-1) \gamma\right], \quad 1 \leq n \leq N-1
$$

and

$$
\beta_{n}(z)=\mu_{2}+n \gamma z, \quad n=0,1,2, \ldots, N-1 .
$$

By Cramer's rule, each generating function can be calculated as

$$
\begin{equation*}
G_{n}(z)=\frac{\left|A_{n}(z)\right|}{|A(z)|}, \quad n=0,1,2, \ldots, N \tag{11}
\end{equation*}
$$

where $A_{n}(z)$ is obtained from $A(z)$ by replacing its $n$th column with the RHS vector $b(z)$ of (10), and $|A(z)|$ is the determinant of the matrix $A(z)$.

Thus, if we know the $N$ unknown boundary probabilities appearing in the vector $\underline{b}(z)$, each generating function $G_{n}(z), n=0,1,2, \ldots, N$, is fully determined by (11). Now, since $G_{n}(z)$ is analytic within $-1 \leq z \leq 1$, if there is a root $\hat{z}$ in that interval such that $|A(\hat{z})|=0$, then the same root applies to $A_{n}(z)$ so that $\left|A_{n}(\hat{z})\right|=0$ as well. Moreover, $\left|A_{n}(\hat{z})\right|=0$ gives an equation involving the $N$ unknown boundary probabilities appearing in $\underline{b}(z)$. In order to solve for those $N$ probabilities, we claim the following.

Theorem 5.1 For any $\lambda>0, \mu_{1} \geq 0, \mu_{2} \geq 0, \gamma \geq 0$, and $N=2 k-1$ or $N=2 k$, where $k=1,2,3, \ldots$, the determinant $|A(z)|$ is a polynomial of degree $2 N+1$, possessing the following roots:
(i) a root of multiplicity $k$ at $z_{0}=0$;
(ii) $N-k-1$ distinct roots in the open interval $(0,1)$;
(iii) a single root at $z_{*}=1$;
(iv) $N$ roots in the open interval $(1, \infty)$; and
(v) another root as follows: If the condition

$$
\lambda>\mu_{1}\left(1+\sum_{k=1}^{N-1} \frac{\mu_{1}^{k}}{\prod_{j=1}^{k}\left(\mu_{2}+j \gamma\right)}\right)\left(1+\sum_{k=1}^{N} \frac{\mu_{1}^{k}}{\prod_{j=0}^{k-1}\left(\mu_{2}+j \gamma\right)}\right)^{-1}
$$

holds, then this root falls in the open interval $(0,1)$. If

$$
\begin{equation*}
\lambda<\mu_{1}\left(1+\sum_{k=1}^{N-1} \frac{\mu_{1}^{k}}{\prod_{j=1}^{k}\left(\mu_{2}+j \gamma\right)}\right)\left(1+\sum_{k=1}^{N} \frac{\mu_{1}^{k}}{\prod_{j=0}^{k-1}\left(\mu_{2}+j \gamma\right)}\right)^{-1} \tag{12}
\end{equation*}
$$

this root falls in the open interval $(1, \infty)$. In the case

$$
\lambda=\mu_{1}\left(1+\sum_{k=1}^{N-1} \frac{\mu_{1}^{k}}{\prod_{j=1}^{k}\left(\mu_{2}+j \gamma\right)}\right)\left(1+\sum_{k=1}^{N} \frac{\mu_{1}^{k}}{\prod_{j=0}^{k-1}\left(\mu_{2}+j \gamma\right)}\right)^{-1}
$$

this root is simply $z=1$.
Proof The line of reasoning of the tedious proof is similar to the proofs given in [18] and [23], and therefore will be omitted.

Now, if (12) holds, we have $k_{N}$ roots at $z_{0}=0$ and $N-k_{N}-1$ roots in $(0,1)$ for a total of $N-1$ roots in $[0,1)$. Each root yields an equation involving the $N$ unknown probabilities. Together with (1), we have $N$ equations determining the probabilities in $\underline{b}(z)$, as needed.

It follows that condition (12) is the condition for stability of the system, namely for $\left(L_{1}, L_{2}\right)$ to be positive recurrent. If condition (12) is reversed, we have an extra root, yielding another equation in the unknown probabilities, leading to an unsolved set of equations; i.e., $\left(L_{1}, L_{2}\right)$ is transient. If (12) is an equality, then $\left(L_{1}, L_{2}\right)$ is null-recurrent. In the sections that follow, we provide a meaningful probabilistic (and intuitive) interpretation of the condition (12).

## 6 Marginal probabilities

Define the marginal probabilities for $L_{2}$ :

$$
P_{\bullet n}=P\left(L_{2}=n\right)=\sum_{m=0}^{\infty} P_{m n}, \quad n=0,1,2, \ldots, N
$$

Then, by setting $z=1$ in (7), (8), and (9) we get respectively

$$
\begin{equation*}
\mu_{1} P_{\bullet 0}-\mu_{2} P_{\bullet}=\mu_{1} P_{00}, \tag{13}
\end{equation*}
$$

$$
\begin{align*}
& \left(\mu_{1}+\mu_{2}+(n-1) \gamma\right) P_{\bullet n}-\mu_{1} P_{\bullet}, n-1-\left(\mu_{2}+n \gamma\right) P_{\bullet, n+1}=\mu_{1}\left(P_{0 n}-P_{0, n-1}\right) \\
& \quad(1 \leq n \leq N-1),  \tag{14}\\
& \left(\mu_{2}+(N-1) \gamma\right) P_{\bullet N}-\mu_{1} P_{\bullet, N-1}=-\mu_{1} P_{0, N-1} . \tag{15}
\end{align*}
$$

Adding (13) to (14) for $n=1$ yields

$$
\mu_{1}\left(P_{\bullet 1}-P_{01}\right)=\left(\mu_{2}+\gamma\right) P_{\bullet 2} .
$$

Continuing, we obtain

$$
\begin{equation*}
\mu_{1}\left(P_{\bullet n}-P_{0 n}\right)=\left(\mu_{2}+n \gamma\right) P_{\bullet, n+1} \quad(0 \leq n \leq N-1) . \tag{16}
\end{equation*}
$$

Now, once the boundary probabilities ( $P_{00}, P_{01}, \ldots, P_{0, N-1}$ ) are determined, the set of (16) together with the normalizing condition

$$
\sum_{n=0}^{N} P_{\bullet}=1
$$

provide a unique solution to the marginal probabilities $\left\{P_{\bullet}\right\}$.
Remark Equations (16) can also be obtained by considering horizontal 'cuts' in Fig. 2 between "levels" $L_{2}=n$ and $L_{2}=n+1(n=0,1,2, \ldots, N-1)$.

Define now the marginal probabilities for $L_{1}=m$ :

$$
p_{m \bullet}=\sum_{n=0}^{N} P_{m n}, \quad m=0,1,2, \ldots .
$$

Then, by taking vertical 'cuts' between columns $m$ and $m+1$ in Fig. 2, we get

$$
\begin{equation*}
\lambda P_{m \bullet}+\gamma \sum_{n=1}^{N}(n-1) P_{m n}=\mu_{1} P_{m+1, \bullet}, \quad m=0,1,2, \ldots \tag{17}
\end{equation*}
$$

Summing (17) over $m$ yields

$$
\lambda+\gamma \sum_{n=1}^{N}(n-1) P_{\bullet}=\mu_{1}\left(1-P_{0 \bullet}\right)
$$

That is,

$$
\begin{equation*}
\lambda+\gamma E\left[\tilde{Q}_{2}\right]=\mu_{1}\left(1-P_{0 \bullet}\right), \tag{18}
\end{equation*}
$$

where $E\left[\tilde{Q}_{2}\right]$ denotes the mean queue size (customers waiting for service to start) of $Q_{2}$. In (18), the LHS gives the total effective arrival rate to the server at $Q_{1}$, composed of the original rate $\lambda$ and the feedback customers that didn't meet their deadline in $Q_{2}$ (the feedback customers from $Q_{1}$ do not affect $L_{1}$ as they renege
before their service starts). This effective arrival rate equals the effective service rate at $Q_{1}$, being $\mu_{1}\left(1-P_{0}\right)$. Finally, once $P_{0 \bullet}$ is determined, $E\left[\tilde{Q}_{2}\right]$ is easily calculated, and $\gamma E\left[\tilde{Q}_{2}\right]$ gives the rate of customers not meeting their deadline in $Q_{2}$.

## 7 Matrix geometric method

Consider again the state space $\{m, n\}$ denoting $m$ customers in $Q_{1}$ and $n$ customers in $Q_{2}, m \geq 0,0 \leq n \leq N$. When $L_{2}=n$, we say that the system is in level, or in phase, $n$. We construct a quasi birth-and-death (QBD) process with generator $Q$, satisfying

$$
\underline{P} Q=\underline{0},
$$

where

$$
\underline{P}=\left(\underline{P}_{0}, \underline{P}_{1}, \underline{P}_{2}, \ldots\right)
$$

with

$$
\underline{P}_{m}=\left(P_{m 0}, P_{m 1}, \ldots, P_{m N}\right), \quad m=0,1,2, \ldots
$$

$\underline{P}_{m}$ denotes the $(N+1)$-dimensional vector of probabilities that the system is in state $m$ and level $n(n=0,1,2, \ldots, N)$. The generator $Q$ is given by

$$
Q=\left(\begin{array}{ccccccc}
A_{1}^{0} & A_{0} & 0 & \cdots & \cdots & \cdots & \cdots \\
A_{2} & A_{1} & A_{0} & 0 & \cdots & \cdots & \cdots \\
0 & A_{2} & A_{1} & A_{0} & 0 & \cdots & \cdots \\
\vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \cdots \\
\vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots
\end{array}\right),
$$

where the $(N+1) \times(N+1)$ square matrices $A_{1}^{0}, A_{0}^{0}, A_{2}, A_{1}$, and $A_{0}$ are given by

$$
\left.\left.\begin{array}{l}
A_{1}^{0}=\left(\begin{array}{ccccccc}
-\lambda & 0 & & 0 & 0 & \cdots & 0 \\
\mu_{2} & -\left(\lambda+\mu_{2}\right) & 0 & 0 & \cdots & 0 & 0 \\
0 & \mu_{2} & -\left(\lambda+\mu_{2}+\gamma\right) & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \ddots & \ddots & \vdots & \vdots \\
0 & 0 & & 0 & \cdots & \cdots & \mu_{2}
\end{array}\right]-\left(\lambda+\mu_{2}+(N-1) \gamma\right)
\end{array}\right), \begin{array}{ccccccc}
\lambda & 0 & 0 & \cdots & \cdots & 0 & 0 \\
0 & \lambda & 0 & \cdots & \cdots & 0 & 0 \\
0 & \gamma & \lambda & \ddots & \cdots & 0 & 0 \\
\vdots & \ddots & \ddots & \ddots & \ddots & \vdots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \lambda & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & (N-2) \gamma & \lambda & 0 \\
0 & 0 & 0 & \cdots & 0 & (N-1) \gamma & \lambda
\end{array}\right), \quad .
$$

$$
A_{2}=\left(\begin{array}{cccccc}
0 & \mu_{1} & 0 & \cdots & 0 & 0 \\
0 & 0 & \mu_{1} & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 0 & \mu_{1} \\
0 & 0 & 0 & \cdots & 0 & 0
\end{array}\right)
$$

and

$$
A_{1}=\left(\begin{array}{ccccccc}
-\left(\lambda+\mu_{1}\right) & 0 & 0 & \cdots & 0 & 0 & 0 \\
\mu_{2} & a_{0} & 0 & \cdots & 0 & 0 & 0 \\
0 & \mu_{2} & a_{1} & \cdots & 0 & 0 & 0 \\
0 & 0 & \mu_{2} & a_{2} & 0 & 0 & 0 \\
0 & 0 & 0 & \ddots & \ddots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \mu_{2} & a_{N-2} & 0 \\
0 & 0 & 0 & \cdots & 0 & \mu_{2} & -\left(\lambda+\mu_{2}+(N-1) \gamma\right)
\end{array}\right)
$$

with $a_{n}=-\left(\lambda+\mu_{1}+\mu_{2}+n \gamma\right), n=0,1,2, \ldots, N-2$.
Consider now the matrix $A=A_{0}+A_{1}+A_{2}$, which is given by

$$
A=\left(\begin{array}{cccccc}
-\mu_{1} & \mu_{1} & 0 & 0 & \cdots & \\
\mu_{2} & -\left(\mu_{1}+\mu_{2}\right) & \mu_{1} & 0 & \cdots & \\
0 & \left(\mu_{2}+\gamma\right) & -\left(\mu_{1}+\mu_{2}+\gamma\right) & \mu_{1} & \cdots & \\
\vdots & \vdots & \ddots & \ddots & \vdots & \\
\vdots & \vdots & \vdots & \ddots & \ddots & \\
\vdots & \vdots & \vdots & \vdots & \ddots & \\
0 & 0 & 0 & 0 & \cdots & \\
0 & 0 & 0 & 0 & \cdots & \\
& 0 & & 0 & & 0 \\
& 0 & 0 & & 0 \\
& 0 & \vdots & & \vdots \\
& \vdots & \vdots & & \vdots \\
& \ddots & & & & \vdots \\
& & & & & \\
& \left(\mu_{2}+(N-2) \gamma\right) & -\left(\mu_{1}+\mu_{2}+(N-2) \gamma\right) & \mu_{1} \\
0 & \left(\mu_{2}+(N-1) \gamma\right) & -\left(\mu_{2}+(N-1) \gamma\right)
\end{array}\right) .
$$

The matrix $A$ represents the generator of a limited-buffer $M / M / 1 / N+M$-type queue with constant arrival rate $\mu_{1}$, service rate $\mu_{2}$, and individual reneging (abandonment) rate $\gamma$ such that, if the number of customers present is $L=j$, the instantaneous departure rate from the system $A$ is $\mu_{2}+(j-1) \gamma$. This system is depicted in Fig. 3.

Fig. 3 The system given by the generator $A$

This queue has a stationary distribution function $\underline{\pi}=\left(\pi_{0}, \pi_{1}, \ldots, \pi_{N}\right)$, where $\pi_{k}=P(L=k), k=0,1,2, \ldots, N$. We have

$$
\underline{\pi} A=\underline{0} \quad \text { and } \quad \underline{\pi} \cdot \underline{e}=1, \quad \text { where } \underline{e}=(1,1, \ldots, 1)^{T} .
$$

We readily obtain

$$
\pi_{0}=\left[1+\sum_{k=1}^{N} \frac{\mu_{1}^{k}}{\prod_{j=0}^{k-1}\left(\mu_{2}+j \gamma\right)}\right]^{-1}
$$

and

$$
\pi_{k}=\frac{\mu_{1}^{k}}{\prod_{j=0}^{k-1}\left(\mu_{2}+j \gamma\right)} \pi_{0}, \quad k=1,2, \ldots, N .
$$

The stability condition for the QBD process with the generator $Q$ is given by (see [22])

$$
\begin{equation*}
\underline{\pi} A_{0} \underline{e}<\underline{\pi} A_{2} \underline{e} . \tag{19}
\end{equation*}
$$

Now, denoting by $L_{q}(A)$ the queue size in the system represented by the matrix $A$, we have

$$
\underline{\pi} A_{0} \underline{e}=\lambda+\gamma \sum_{k=2}^{N}(k-1) \pi_{k}=\lambda+\gamma E\left[L_{q}(A)\right]
$$

and

$$
\underline{\pi} A_{2} \underline{e}=\mu_{1}\left(1-\pi_{N}\right) .
$$

Thus, the stability condition (19) for the QBD process $Q$ is

$$
\begin{equation*}
\lambda+\gamma E\left[L_{q}(A)\right]<\mu_{1}\left(1-\pi_{N}\right) . \tag{20}
\end{equation*}
$$

We remark that it can be shown, following tedious algebraic calculations, that condition (20) is exactly condition (12) given in Theorem 5.1.

If $N=1, E\left[L_{q}(A)\right]=0, \pi_{0}=\mu_{2} /\left(\mu_{1}+\mu_{2}\right)$, and $\pi_{1}=\mu_{1} /\left(\mu_{1}+\mu_{2}\right)$. Thus, condition (20) translates into

$$
\lambda<\frac{\mu_{1} \mu_{2}}{\mu_{1}+\mu_{2}}
$$

independent of $\gamma$. If $\mu_{1}=\mu_{2}$, then condition (20) is further reduced to $\lambda<\mu_{1} / 2$. Finally, the steady-state probability vectors $\underline{P}_{m}$ are given by

$$
\begin{aligned}
\underline{P}_{0} A_{1}^{0}+\underline{P}_{1} A_{2} & =\underline{0}, \\
\underline{P}_{0} A_{0}^{0}+\underline{P}_{1} A_{1}+\underline{P}_{2} A_{2} & =\underline{0} \\
\underline{P}_{m-1} A_{0}+\underline{P}_{m} A_{1}+\underline{P}_{m+1} A_{2} & \underline{0}, \quad m=2,3, \ldots
\end{aligned}
$$

with

$$
\underline{P}_{m}=\underline{P}_{m-1} R=\underline{P}_{1} R^{m-1} \quad(m \geq 2) .
$$

The matrix $R$ is the minimal non-negative solution of the matrix equation

$$
A_{0}+R A_{1}+R^{2} A_{2}=0
$$

The normalizing condition is

$$
\begin{aligned}
\sum_{m=0}^{\infty} \underline{P}_{m} \underline{e} & =\underline{P}_{0} \underline{e}+\sum_{m=1}^{\infty} \underline{P}_{m} \underline{e} \\
& =\left(\underline{P}_{0}+\underline{P}_{1} \sum_{m=0}^{\infty} R^{m}\right) \underline{e} \\
& =\left(\underline{P}_{0}+\underline{P}_{1}(I-R)^{-1}\right) \underline{e} \\
& =1 .
\end{aligned}
$$

Now, the mean number of customers in the first queue, $Q_{1}$, is given by

$$
E\left[L_{1}\right]=\sum_{m=1}^{\infty} m \underline{P}_{m} \underline{e}=\underline{P}_{1} \sum_{m=1}^{\infty} m R^{m-1} \underline{e}=\underline{P}_{1}(I-R)^{-2} \cdot \underline{e} .
$$

## 8 Probabilistic interpretation

We now provide a probabilistic interpretation for the stability conditions (12) and (20). As indicated, these conditions can be shown to be equivalent to one another. We begin with an explanation of sufficiency. Consider the right-hand side of (20). Here $\mu_{1}\left(1-\pi_{N}\right)$ represents the maximum possible rate at which customers may be processed at station 1. Next, consider the left-hand side of (20). In particular, consider $\gamma E\left[L_{q}(A)\right]$. This represents the maximum possible rate at which customers may abandon from station 2 back to station 1 . We say total maximum since in the generator $A$ we assume that customers arrive at station 2 at the maximum possible rate $\mu_{1}$. The maximum possible rate at which customers can arrive at station 1 is therefore $\lambda+\gamma E\left[L_{q}(A)\right]$, and so if this is less than $\mu_{1}\left(1-\pi_{N}\right)$, the system will be stable.

Suppose, on the other hand, that the inequality (20) is reversed and that initially at time zero there are a large number of customers at station 1 . While processing this initial set of customers, the departure rate from station 1 will be $\mu_{1}$. Moreover, up until the final customer is processed, the departure process will behave as a Poisson process with rate $\mu_{1}$. This will then cause station 2 to behave as the process described by the generator $A$ and consequently customers will abandon back to station one at approximately rate $\gamma E\left[L_{q}(A)\right]$. Thus, if $\lambda+\gamma E\left[L_{q}(A)\right]>\mu_{1}\left(1-\pi_{N}\right)$, station 1 will not be able to finish processing its initial set of customers before receiving an additional round of customers. In fact, the number of customers at station 1 will grow larger while it is processing its initial set customers and so the system will be unstable.

The type of reasoning used above is made rigorous in the following section where we provide an approximating stability condition for the non-Markovian setting.

## 9 Non-Markovian setting

We now consider the system depicted in Fig. 1 but with general interarrival and service time distributions and with unlimited buffer space at station two $(N=\infty)$. We suppose that the external arrival process to the system $(A(t), t \geq 0)$ is a renewal process where

$$
A(t)=\max \left\{n: \sum_{i=1}^{n} u_{i} \leq \lambda t\right\},
$$

where $\left\{u_{i}, i \geq 1\right\}$ is an i.i.d. sequence of random variables with mean one and variance $a_{1}$ and that $\lambda>0$. We also assume that the number of customers served by station $i, i=1,2$, in its first $t$ units of processing time is given by

$$
S_{i}(t)=\max \left\{n: \sum_{i=1}^{n} v_{i} \leq \mu_{i} t\right\}
$$

where $\left\{v_{i}, i \geq 1\right\}$ is an i.i.d. sequence of random variables with mean one and variance $b_{i}$ and $\mu_{i}>0$. Finally, we assume that customers abandon station 2 according to an exponential distribution and return to station 1 at a Poissonian rate $\gamma$.

Unlike the exact stability condition for the Markovian case given by (12) and (20), the exact stability condition in this non-Markovian setting appears to be difficult to determine. However, the type of network described above falls into the class of networks referred to as generalized Jackson networks in [25]. In particular, Theorem 1 of [25] provides a heavy-traffic diffusion approximation to the queue length process for this network. Our approach therefore is to first use Theorem 1 of [25] in order determine the proper heavy-traffic diffusion approximation for this system and then to determine the stability condition for the diffusion approximation.

## 10 Diffusion approximation

As in Sect. 3, let $\left(L_{1}, L_{2}\right)=\left(\left(L_{1}(t), L_{2}(t)\right), t \geq 0\right)$ be the two-dimensional process representing the number of customers present at stations 1 and 2 , respectively, at
time $t$. Our main result in this section is to show that $\left(L_{1}, L_{2}\right)$ may be approximated by a two-dimensional diffusion approximation known as a reflected OrnsteinUhlenbeck ( $\mathrm{RO}-\mathrm{U}$ ) process. We therefore first provide the following definition of a one-dimensional RO-U process and then provide the analogous definition of a twodimensional RO-U process. Let $\theta, \gamma \in \mathbb{R}$ and $\sigma \in \mathbb{R}_{+}$.

Definition 1 A one-dimensional $\mathrm{RO}-\mathrm{U}$ process confined to $\mathbb{R}_{+}$with parameters $(\theta, \sigma, \gamma)$ and initial position $Z(0) \in \mathbb{R}_{+}$is defined to be the process $Z=(Z(t)$, $t \geq 0) \in D\left([0, \infty), \mathbb{R}_{+}\right)$satisfying

$$
Z(t)=Z(0)+B(t)+\theta t-\int_{0}^{t} \gamma Z(s) d s+Y(t), \quad t \geq 0
$$

where $B=(B(t), t \geq 0)$ is a one-dimensional Brownian motion with infinitesimal variance $\sigma^{2}, Z(t) \in \mathbb{R}_{+}$for $t \geq 0$, and $Y=(Y(t), t \geq 0) \in D\left([0, \infty), \mathbb{R}_{+}\right)$is such that

1. $Y(0)=0$,
2. $Y=(Y(t), t \geq 0)$ is non-decreasing,
3. $\int_{0}^{\infty} 1\{Z(s)>0\} d Y(s)=0$.

As shown in Proposition 2 of [25], there will always be a unique, strong solution $Z$ in Definition 1 above.

Next, we provide the definition of a two-dimensional RO-U process. Let $\theta \in \mathbb{R}^{2}$ and let $C, M, \Gamma \in \mathbb{R}^{2 \times 2}$, where $C$ is a variance-covariance matrix.

Definition 2 A two-dimensional RO-U process confined to $\mathbb{R}_{+}^{2}$ with parameters $(\theta, C, M, \Gamma)$ and initial position $Z(0) \in \mathbb{R}_{+}^{2}$ is defined to be the process $Z=$ $(Z(t), t \geq 0) \in D\left([0, \infty), \mathbb{R}_{+}^{2}\right)$ satisfying in vector notation

$$
Z(t)=Z(0)+B(t)+\theta t-\int_{0}^{t} \Gamma Z(s) d s+M Y(t), \quad t \geq 0
$$

where $B=(B(t), t \geq 0)$ is a two-dimensional Brownian motion with variancecovariance matrix $C, \bar{Z}(t) \in \mathbb{R}_{+}^{2}$ for $t \geq 0$, and $Y=(Y(t), t \geq 0) \in D\left([0, \infty), \mathbb{R}_{+}^{2}\right)$ is such that for each $i=1,2$,

1. $Y_{i}(0)=0$,
2. $Y_{i}=\left(Y_{i}(t), t \geq 0\right)$ is non-decreasing,
3. $\int_{0}^{\infty} 1\left\{Z_{i}(s)>0\right\} d Y_{i}(s)=0$.

We remark that, as is shown in Proposition 2 of [25], when the matrix $M$ has positive diagonal elements, non-positive off-diagonal elements and a non-negative inverse, then there exists a unique, strong solution $Z$ in Definition 2 above.

We now introduce the heavy-traffic regime of [25] in which ( $L_{1}, L_{2}$ ) may be approximated by a two-dimensional RO-U. We consider a sequence of systems indexed by $n \geq 1$. For the $n$th system, we denote the system parameters by $\lambda^{n}, \mu_{1}^{n}, \mu_{2}^{n}$, and

Fig. 4 The state space and directions of reflection for $\tilde{L}$

$\gamma^{n}$ and we assume that as $n \rightarrow \infty$,

$$
\begin{equation*}
n^{-1} \lambda^{n} \rightarrow \lambda, \quad n^{-1} \mu_{1}^{n} \rightarrow \mu_{1}, \quad n^{-1} \mu_{2}^{n} \rightarrow \mu_{2} \tag{21}
\end{equation*}
$$

and

$$
\begin{equation*}
\sqrt{n}\left(n^{-1} \lambda^{n}-n^{-1} \mu_{1}^{n}\right) \rightarrow \theta_{1}, \quad \sqrt{n}\left(n^{-1} \mu_{1}^{n}-n^{-1} \mu_{2}^{n}\right) \rightarrow \theta_{2}, \tag{22}
\end{equation*}
$$

for some $\left(\theta_{1}, \theta_{2}\right) \in \mathbb{R}^{2}$. We also assume that

$$
\begin{equation*}
\gamma^{n}=\gamma, \quad n \geq 1 . \tag{23}
\end{equation*}
$$

Now, for each $n \geq 1$, let $\left(L_{1}^{n}, L_{2}^{n}\right)$ be the two-dimensional process representing the number of customers present at stations 1 and 2, respectively, at time $t$ in the $n$th system and let $\left(\tilde{L}_{1}^{n}, \tilde{L}_{2}^{n}\right)=(1 / \sqrt{n})\left(L_{1}^{n}, L_{2}^{n}\right)$ be the diffusion scaled queue length process. The following is then a direct result of Theorem 1 of [25].

Proposition 1 Under assumptions (21)-(23), if $\left(\tilde{L}_{1}^{n}(0), \tilde{L}_{2}^{n}(0)\right) \Rightarrow\left(\tilde{L}_{1}(0), \tilde{L}_{2}(0)\right)$ as $n \rightarrow \infty$, then $\left(\tilde{L}_{1}^{n}, \tilde{L}_{2}^{n}\right) \Rightarrow \tilde{L}=\left(\tilde{L}_{1}, \tilde{L}_{2}\right)$ as $n \rightarrow \infty$, where $\left(\tilde{L}_{1}, \tilde{L}_{2}\right)$ is a twodimensional $R O-U$ process confined to $\mathbb{R}_{+}^{2}$ with parameters $(\theta, C, M, \Gamma)$ and initial position $\left(\tilde{L}_{1}(0), \tilde{L}_{2}(0)\right)$, where $\theta=\left(\theta_{1}, \theta_{2}\right)$,
$C=\left[\begin{array}{cc}\lambda a_{1}+\mu_{1} b_{1} & -\mu_{1} b_{1} \\ -\mu_{1} b_{1} & \mu_{1} b_{1}+\mu_{2} b_{2}\end{array}\right], \quad M=\left[\begin{array}{cc}1 & 0 \\ -1 & 1\end{array}\right], \quad$ and $\quad \Gamma=\left[\begin{array}{cc}0 & \gamma \\ 0 & -\gamma\end{array}\right]$.
We remark that the matrix $M$ given above satisfies the criteria for uniqueness of the RO-U given by Proposition 2 of [25] and hence the above limit is unique in law. One may also consult Fig. 4 below for a depiction of the state-space and directions of reflection for $\tilde{L}$.

## 11 Stability condition for RO-U approximation

The following is our main result of this section. It provides a necessary and sufficient condition for the limit process $\tilde{L}=\left(\tilde{L}_{1}, \tilde{L}_{2}\right)$ in Proposition 1 to be positive recurrent. Let $\mathcal{N}\left(\mu, \sigma^{2}\right)$ be a normal random variable with mean $\mu$ and variance $\sigma^{2}$.

Theorem 11.1 The limit process $\tilde{L}$ in Proposition 1 is positive recurrent if and only if

$$
\begin{equation*}
\gamma \cdot E\left[\mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right) \left\lvert\, \mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right)>0\right.\right]<-\theta_{1} . \tag{24}
\end{equation*}
$$

We remark that the probabilistic interpretation of condition (24) is similar to that of (20) for the Markovian setting in Sect. 8. In particular, we make the following observations. The quantity on the left-hand side of (24), after multiplying by $\sqrt{n}$, approximately represents the maximum possible steady-state rate of abandonment from station 2 in the $n$th system, assuming that station 1 is never idle. That is, we approximately have

$$
\begin{equation*}
\gamma \frac{E\left[L_{2}^{n}(\infty)\right]}{\sqrt{n}}<\gamma \cdot E\left[\mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right) \left\lvert\, \mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right)>0\right.\right] . \tag{25}
\end{equation*}
$$

On the other hand, by (22),

$$
\begin{equation*}
\theta_{1} \approx \frac{\lambda^{n}}{\sqrt{n}}-\frac{\mu_{1}^{n}}{\sqrt{n}} \tag{26}
\end{equation*}
$$

Thus, using (25) and (26), one sees that (24) is approximately the same as the condition

$$
\lambda^{n}+\gamma E\left[L_{2}^{n}(\infty)\right]<\mu_{1}^{n},
$$

which is similar to (20).

## 12 Proof of necessity

In this section we provide the proof of the necessity of (24) in order for $\tilde{L}$ to be positive recurrent. In Sect. 13 we provide the proof of sufficiency.

Proof of necessity of condition (24) Let $\hat{L}_{2}$ be a $\left(\theta_{2}, \mu_{1} b_{1}+\mu_{2} b_{2}, 1, \gamma\right) 1-\mathrm{d}$ RO-U confined to $\mathbb{R}_{+}$, with initial condition $\hat{L}_{2}(0)$. In other words, $\hat{L}_{2}$ is given by the unique, strong solution to

$$
\begin{equation*}
\hat{L}_{2}(t)=\hat{L}_{2}(0)+\tilde{X}_{2}(t)+\theta_{2} t-\gamma \int_{0}^{t} \hat{L}_{2}(s) d s+\hat{Y}_{2}(t) \tag{27}
\end{equation*}
$$

for $t \geq 0$, where $\tilde{X}_{2}=\left(\tilde{X}_{2}(t), t \geq 0\right)$ is a Brownian motion with infinitesimal variance $\mu_{1} b_{1}+\mu_{2} b_{2}$ and $\hat{Y}_{2}$ satisfies Conditions $1-3$ of Definition 1 . Since $\gamma>0$, it is well known (see, for instance, [27]) that $\hat{L}_{2}(t) \Rightarrow \hat{L}_{2}(\infty)$ as $t \rightarrow \infty$, where $\hat{L}_{2}(\infty)$ is distributed as

$$
\mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right) \left\lvert\, \mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right)>0 .\right.
$$

That is, $\hat{L}_{2}(\infty)$ is distributed as a normal random variable conditioned to be positive.

Now note that one may view $\hat{L}_{2}$ as a regenerative process with regeneration point 0 . In particular, let $\delta>0$ and set

$$
\vartheta(\delta)=\inf \left\{t>0: \hat{L}_{2}(t)=\delta\right\} \quad \text { and } \quad \beta_{0}(\delta)=\inf \left\{t>\vartheta(\delta): \hat{L}_{2}(t)=0\right\}
$$

and define $\beta_{0}(\delta)$ to be a regeneration cycle started from 0 . By Theorem 2 of [27], it follows that $\mathbb{E}\left[\vartheta(\delta) \mid \hat{L}_{2}(0)=0\right]<\infty$. Next, let $\vartheta(0)=\inf \left\{t>0: \hat{L}_{2}(t)=0\right\}$. By Proposition 4 of [27], the fact that $\hat{L}_{2}$ is a strong Markov process and the $P$-a.s. continuity of the sample-paths of $\hat{L}_{2}$, one has that

$$
\mathbb{E}\left[\beta_{0}(\delta)-\vartheta(\delta) \mid \hat{L}_{2}(0)=0\right]=\mathbb{E}\left[\vartheta(0) \mid \hat{L}_{2}(0)=\delta\right]<\infty .
$$

Hence, $\mathbb{E}\left[\beta_{0}(\delta)-\vartheta(\delta) \mid \hat{L}_{2}(0)=0\right]<\infty$ and so $\hat{L}_{2}$ has finite expected regeneration times. Next note, again using the fact that $\hat{L}_{2}$ is a strong Markov process and the $P$-a.s. continuity of the sample-paths of $\hat{L}_{2}$, that

$$
\begin{align*}
& E\left[\int_{0}^{\beta_{0}(\delta)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=0\right] \\
& \quad=E\left[\int_{0}^{\vartheta(\delta)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=0\right]+E\left[\int_{0}^{\vartheta(0)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=\delta\right] \\
& \quad \leq \delta E\left[\vartheta(\delta) \mid \hat{L}_{2}(0)=0\right]+E\left[\int_{0}^{\vartheta(0)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=\delta\right] . \tag{28}
\end{align*}
$$

By Theorem 2 of [27], $\delta E\left[\vartheta(\delta) \mid \hat{L}_{2}(0)=0\right]<\infty$. Next, by the definition of $\hat{L}_{2}$ in (27), the fact that $\vartheta(0)$ is a stopping time and the optional sampling theorem [16], it follows that

$$
\begin{aligned}
0= & \delta+\theta_{2} E\left[\vartheta(0) \mid \hat{L}_{2}(0)=\delta\right]-\gamma E\left[\int_{0}^{\vartheta(0)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=\delta\right] \\
& +E\left[\hat{Y}_{2}(\vartheta(0)) \mid \hat{L}_{2}(0)=\delta\right] .
\end{aligned}
$$

By Condition 3 of Definition 1,

$$
E\left[\hat{Y}_{2}(\vartheta(0)) \mid \hat{L}_{2}(0)=\delta\right]=0 .
$$

Moreover, by Proposition 4 of [27], $E\left[\vartheta(0) \mid \hat{L}_{2}(0)=\delta\right]<\infty$, so that

$$
E\left[\int_{0}^{\vartheta(0)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=\delta\right]<\infty
$$

which, by (28), implies

$$
E\left[\int_{0}^{\beta_{0}(\delta)} \hat{L}_{2}(u) d u \mid \hat{L}_{2}(0)=0\right]<\infty
$$

Now let

$$
\begin{equation*}
\kappa=E\left[\mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right) \left\lvert\, \mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right)>0\right.\right] . \tag{29}
\end{equation*}
$$

It then follows by Theorem 3.1 of [4] that for each $z_{2} \geq 0$,

$$
\begin{equation*}
P\left(\left.\lim _{t \rightarrow \infty} \frac{1}{t} \int_{0}^{t} \hat{L}_{2}(s) d s=\kappa \right\rvert\, \hat{L}_{2}(0)=z_{2}\right) \tag{30}
\end{equation*}
$$

equals one.
Now assume that condition (24) does not hold (assume that the inequality is reversed) and let $\varepsilon, \delta>0$ be such that $\varepsilon<1$ and that there exists a $v_{\varepsilon, \delta}$ such that

$$
\begin{equation*}
P\left(\gamma \int_{0}^{u} \hat{L}_{2}(s) d s>\left(-\theta_{1}+\delta\right) u \text { for } u \geq v_{\delta, \varepsilon} \mid \hat{L}_{2}(0)=z_{2}\right)>1-\varepsilon . \tag{31}
\end{equation*}
$$

Such a triplet ( $\varepsilon, \delta, v_{\delta, \varepsilon}$ ) may always be found by virtue of (30) and the assumption that the inequality in (24) is reversed.

Next, let $\tilde{X}_{1}=\left(\tilde{X}_{1}(t), t \geq 0\right)$ be a Brownian motion with infinitesimal variance $\lambda a_{1}+\mu_{1} b_{1}$ and note that by the strong law of large numbers for Brownian motion [15]

$$
P\left(\lim _{t \rightarrow \infty} \frac{\tilde{X}_{1}(t)}{t}=0\right)=1 .
$$

Thus, there exists a $w_{\varepsilon, \delta}$ such that

$$
\begin{equation*}
P\left(\tilde{X}_{1}(u)>-\frac{\delta}{2} u \text { for } u \geq w_{\delta, \varepsilon}\right)>1-\varepsilon . \tag{32}
\end{equation*}
$$

Finally, let $z_{1}>0$ be sufficiently large such that

$$
\begin{equation*}
P\left(\inf _{0 \leq u \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}} \tilde{X}_{1}(u)+\theta_{1} u>-z_{1} / 2\right)>1-\varepsilon . \tag{33}
\end{equation*}
$$

Now note that by Proposition 1 and by Definition 2, $\left(\tilde{L}_{1}, \tilde{L}_{2}\right)$ may be written as the unique, strong solution to the stochastic differential equation

$$
\begin{align*}
& \tilde{L}_{1}(t)=\tilde{L}_{1}(0)+\tilde{X}_{1}(t)+\theta_{1} t+\gamma \int_{0}^{t} \tilde{L}_{2}(s) d s+\tilde{Y}_{1}(t),  \tag{34}\\
& \tilde{L}_{2}(t)=\tilde{L}_{2}(0)+\tilde{X}_{2}(t)+\theta_{2} t-\gamma \int_{0}^{t} \tilde{L}_{2}(s) d s-\tilde{Y}_{1}(t)+\check{Y}_{2}(t), \tag{35}
\end{align*}
$$

for $t \geq 0$, subject to $\left(\tilde{L}_{1}(t), \tilde{L}_{2}(t)\right) \in \mathbb{R}_{+}^{2}$ and $\left(\tilde{Y}_{1}, \tilde{Y}_{2}\right)$ adhering to Conditions $1-3$ of Definition 2 . It will also be assumed that ( $\tilde{L}_{1}, \tilde{L}_{2}$ ) is defined on the same probability space as $\hat{L}_{2}$ in (27). In particular, the process $\tilde{X}_{2}$ is shared by both $\left(\tilde{L}_{1}, \tilde{L}_{2}\right)$ and $\hat{L}_{2}$.

Now let $z_{1}, z_{2}$ be as defined above and fix $\left(\tilde{L}_{1}(0), \tilde{L}_{2}(0)\right)=\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$. Next, define the set

$$
\begin{aligned}
\Xi= & \left\{\gamma \int_{0}^{u} \hat{L}_{2}(s) d s>\left(-\theta_{1}+\delta\right) u \text { for } u \geq v_{\delta, \varepsilon}\right\} \\
& \cap\left\{\tilde{X}_{1}(u)>-\frac{\delta}{2} u \text { for } u \geq w_{\delta, \varepsilon}\right\} \\
& \cap\left\{\inf _{0 \leq u \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}} \tilde{X}_{1}(u)+\theta_{1} u>-z_{1} / 2\right\} .
\end{aligned}
$$

By (31), (32), and (33), it is clear that $\mathbb{P}(\Xi)>1-3 \varepsilon$. Moreover, we claim that on the set $\Xi$ one has that

$$
\begin{equation*}
\tilde{L}_{1}(t)=z_{1}+\tilde{X}_{1}(t)+\theta_{1} t+\gamma \int_{0}^{t} \hat{L}_{2}(s) d s \tag{36}
\end{equation*}
$$

for $t \geq 0$. By the definition of $\Xi$, this implies that on $\Xi$ one has that for $u \geq$ $v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$,

$$
\tilde{L}_{1}(u)>z_{1}+\frac{\delta}{2} u \rightarrow \infty \quad \text { as } u \rightarrow \infty .
$$

Thus,

$$
\mathbb{P}\left(\lim _{u \rightarrow \infty} \tilde{L}_{1}(u)=\infty \mid\left(\tilde{L}_{1}(0), \tilde{L}_{2}(0)\right)=\left(z_{1}, z_{2}\right)\right)>1-3 \varepsilon
$$

which implies that ( $\tilde{L}_{1}, \tilde{L}_{2}$ ) cannot be positive recurrent as desired.
In order to complete the proof, it now suffices to show that (36) holds. First note that by the definition of $\Xi$,

$$
\Xi \subseteq\left\{\inf _{0 \leq u \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}} \tilde{X}_{1}(u)+\theta_{1} u>-z_{1} / 2\right\},
$$

and so it follows by (34) and the positivity of $\gamma$ that on $\Xi$ one has $\tilde{L}_{1}(t)>0$ for $0 \leq t \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$. By Condition 3 of Definition 2, this then implies that $\tilde{Y}_{1}(t)=0$ for $0 \leq t \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$, which, by (27) and (34), implies that $\tilde{L}_{2}(t)=\hat{L}_{2}(t)$ for $0 \leq$ $t \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$. Thus, (36) holds on $\Xi$ for $0 \leq t \leq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$. Next, note that

$$
\Xi \subseteq\left\{\gamma \int_{0}^{u} \hat{L}_{2}(s) d s>\left(-\theta_{1}+\delta\right) u \text { for } u \geq v_{\delta, \varepsilon}\right\} \cap\left\{\tilde{X}_{1}(u)>-\frac{\delta}{2} u \text { for } u \geq w_{\delta, \varepsilon}\right\} .
$$

Thus, on $\Xi$, one has that for $u>v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$,

$$
\begin{equation*}
z_{1}+\tilde{X}_{1}(u)+\theta_{1} u+\gamma \int_{0}^{u} \hat{L}_{2}(s) d s>z_{1}+\frac{\delta}{2} u>0 . \tag{37}
\end{equation*}
$$

We now claim that (37) implies that $\tilde{Y}_{1}(u)=0$ for $u>v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$, which, using (27), (34), and (35), implies (36) on $\Xi$ for $t \geq v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$, thus completing the proof.

Suppose that $\tilde{Y}_{1}(u)>0$ for some $u>v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$. By Condition 3 of Definition 2, this necessarily implies that $\tilde{L}_{1}(u)=0$ for some $u>v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$. However, since $\hat{L}_{2}(u)=\tilde{L}_{2}(u)$ up until the first time that $\tilde{L}_{1}$ hits zero, by (34) this then implies that

$$
\begin{equation*}
z_{1}+\tilde{X}_{1}(u)+\theta_{1} u+\gamma \int_{0}^{u} \hat{L}_{2}(s) d s=0 \tag{38}
\end{equation*}
$$

for some $u>v_{\varepsilon, \delta} \vee w_{\varepsilon, \delta}$. However, (38) is in direct contradiction to (37), which completes the proof.

## 13 Proof of sufficiency

In this section we provide the proof of the sufficiency of condition (24). For each $z=\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$, let $\tilde{L}^{z}=\left(\tilde{L}_{1}^{z}, \tilde{L}_{2}^{z}\right)$ be the limit process in Proposition 1 started from $z$. That is, $\tilde{L}^{z}$ is the unique, strong solution to the stochastic differential equation

$$
\begin{align*}
& \tilde{L}_{1}^{z}(t)=z_{1}+\tilde{X}_{1}(t)+\theta_{1} t+\gamma \int_{0}^{t} \tilde{L}_{2}^{z}(s) d s+\tilde{Y}_{1}^{z}(t)  \tag{39}\\
& \tilde{L}_{2}^{z}(t)=z_{2}+\tilde{X}_{2}(t)+\theta_{2} t-\gamma \int_{0}^{t} \tilde{L}_{2}^{z}(s) d s-\tilde{Y}_{1}^{z}(t)+\tilde{Y}_{2}^{z}(t) \tag{40}
\end{align*}
$$

for $t \geq 0$, subject to $\left(\tilde{L}_{1}^{z}(t), \tilde{L}_{2}^{z}(t)\right) \in \mathbb{R}_{+}^{2}$ and $\left(\tilde{Y}_{1}^{z}, \tilde{Y}_{2}^{z}\right)$ adhering to Conditions $1-3$ of Definition 2. All relevant quantities in (39)-(40) are superscripted by $z$ in order to emphasize their dependence on the initial state $z$. Note also that it is not necessary to superscript $\tilde{X}$ since $\tilde{X}$ is always a Brownian motion started at the origin.

Next, for each $z=\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$, define the norm $|z|=\left|z_{1}\right|+\left|z_{2}\right|$ and, for each $\varepsilon>0$, let $\mathcal{B}_{\varepsilon}$ be the compact set

$$
\mathcal{B}_{\varepsilon}=\left\{z \in \mathbb{R}_{+}^{2}:|z| \leq \varepsilon\right\} .
$$

Let us also define the stopping time

$$
\tau_{\varepsilon}^{z}=\inf \left\{t \geq 0: \tilde{L}^{z}(t) \in \mathcal{B}_{\varepsilon}\right\} .
$$

Our main result in this section is the following.
Proposition 2 If (24) holds, then there exists a $\kappa>0$ such that for each $z \in \mathbb{R}_{+}^{2}$, $\mathbb{E}\left[\tau_{\kappa}^{z}\right]<\infty$. Moreover, for each compact set $\mathcal{C} \subset \mathbb{R}_{+}^{2}$,

$$
\sup _{z \in \mathcal{C}} \mathbb{E}\left[\tau_{\kappa}^{z}\right]<\infty
$$

Using a standard argument such as that provided by the proof of Theorem 4.1 of [5], one may then show that Proposition 2 implies Theorem 11.1. The details are omitted in the present paper.

The proof of Proposition 2 relies on the following critical lemma whose proof we postpone for the moment.

Lemma 1 If (24) holds, then there exists a $\delta>0$ such that

$$
\mathbb{E}\left[\frac{1}{|z|} \cdot\left|\tilde{L}^{z}(|z| \delta)\right|\right] \rightarrow 0 \quad \text { as } z \rightarrow \infty
$$

Given Lemma 1, Proposition 2 may now be proven in a manner similar to the proof of Theorem 3.1 of [10]. The details are as follows.

Proof of Proposition 2 We follow the proof of Theorem 3.1 of [10]. Let $0<\varepsilon<1$ and note that by Lemma 1 there exists a $\kappa \geq 1$ such that

$$
\mathbb{E}\left[\frac{1}{|z|} \cdot\left|\tilde{L}^{z}(|z| \delta)\right|\right] \leq 1-\varepsilon
$$

for all $z \in \mathbb{R}_{+}^{2}$ such that $|z| \geq \kappa$. Moreover, following the same reasoning as in the proof of Lemma 1, there exists a $b>0$ such that

$$
\begin{equation*}
\sup _{z \in \mathcal{B}_{\kappa}} \mathbb{E}\left[\left|\tilde{L}^{z}(|z| \delta)\right|\right] \leq b \tag{41}
\end{equation*}
$$

Thus, we may write

$$
\begin{equation*}
\mathbb{E}\left[\left|\tilde{L}^{z}(|z| \delta)\right|\right] \leq(1-\varepsilon)|z|+b 1\left\{z \in \mathcal{B}_{\kappa}\right\} . \tag{42}
\end{equation*}
$$

Now let $n(z)=|z| \delta$ if $z \notin \mathcal{B}_{\kappa}$ and let $n(z)=\delta$ if $z \in \mathcal{B}_{\kappa}$. Note that $n(z) \geq \delta$ for all $z \in \mathbb{R}_{+}^{2}$ and so it follows from (41) and (42) that

$$
\mathbb{E}\left[\left|\tilde{L}^{z}(n(z))\right|\right] \leq(1-\varepsilon)|z|+b 1\left\{z \in \mathcal{B}_{\kappa}\right\} \leq|z|-\frac{\varepsilon}{\delta} n(z)+\tilde{b} 1\left\{z \in \mathcal{B}_{\kappa}\right\}
$$

for some $\tilde{b}>0$ and all $z \in \mathbb{R}_{+}^{2}$. Therefore, proceeding exactly as in the proof of Theorem 2.1(ii) of [21], it follows that for each $z \in \mathbb{R}_{+}^{2}$,

$$
\mathbb{E}\left[\tau_{\kappa}^{z}\right] \leq \frac{\delta}{\varepsilon}(|z|+\tilde{b})<\infty,
$$

which completes the proof.
The remainder of this section is now dedicated to proving Lemma 1. Our approach is to first study a coupled process which on a sample-path basis is $P$-a.s. larger than $\tilde{L}^{z}$. For each $z=\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$, let $\hat{L}^{z}=\left(\left(\hat{L}_{1}^{z}(t), \hat{L}_{2}^{z}(t)\right), t \geq 0\right)$ be the solution to the stochastic differential equation

$$
\begin{align*}
& \hat{L}_{1}^{z}(t)=z_{1}+\tilde{X}_{1}(t)+\theta_{1} t+\gamma \int_{0}^{t} \hat{L}_{2}^{z}(s) d s+\hat{Y}_{1}^{z}(t)  \tag{43}\\
& \hat{L}_{2}^{z}(t)=z_{2}+\tilde{X}_{2}(t)+\theta_{2} t-\gamma \int_{0}^{t} \hat{L}_{2}^{z}(s) d s+\hat{Y}_{2}^{z}(t) \tag{44}
\end{align*}
$$

for $t \geq 0$, subject to $\left(\hat{L}_{1}^{z}(t), \hat{L}_{2}^{z}(t)\right) \in \mathbb{R}_{+}^{2}$ and $\left(\hat{Y}_{1}^{z}, \hat{Y}_{2}^{z}\right)$ adhering to Conditions $1-3$ of Definition 2 . Note that the process $\tilde{X}$ is the same for both $\tilde{L}^{z}$ and $\hat{L}^{z}$, implying that $\tilde{L}^{z}$ and $\hat{L}^{z}$ are defined on the same probability space.

The following is our first result and it shows that $\hat{L}^{z}$ dominates $\tilde{L}^{z}$ on a samplepath basis. We assume in the proofs that follow that $e=(t, t \geq 0)$ is the identity process.

Lemma 2 For each $\left(y_{1}, y_{2}\right),\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$ such that $y_{1} \leq z_{1}$ and $y_{2} \leq z_{2}, \tilde{L}_{1}^{y}(t) \leq$ $\hat{L}_{1}^{z}(t)$ and $\tilde{L}_{2}^{y}(t) \leq \hat{L}_{2}^{z}(t)$ for $t \geq 0, P$-a.s.

Proof Let $\left(y_{1}, y_{2}\right),\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$ be such that $y_{1} \leq z_{1}$ and $y_{2} \leq z_{2}$. Then, by (40), (44) and the fact that $\tilde{Y}_{1}^{y}$ is a non-decreasing process, it follows by Proposition 2.2 of [26] that $\tilde{L}_{2}^{y}(t) \leq \hat{L}_{2}^{z}(t), P$-a.s., for each $t \geq 0$.

Next, note that from (39) and Condition 1-3 of Definition 2, we may write

$$
\begin{equation*}
\tilde{L}_{1}^{y}=\Psi\left(y_{1}+\tilde{X}_{1}+\theta_{1} e+\gamma \int_{0}^{e} \tilde{L}_{2}^{y}(s) d s\right) \tag{45}
\end{equation*}
$$

where $\Psi: D([0, \infty), \mathbb{R}) \mapsto D([0, \infty), \mathbb{R})$ is the standard one-dimensional regulator map [28] and, from (43) and Conditions 1-3 of Definition 2, we may write

$$
\begin{equation*}
\hat{L}_{1}^{z}=\Psi\left(z_{1}+\tilde{X}_{1}+\theta_{1} e+\gamma \int_{0}^{e} \hat{L}_{2}^{z}(s) d s\right) . \tag{46}
\end{equation*}
$$

From the first portion of the proof $\hat{L}_{2}^{z}(t) \geq \tilde{L}_{2}^{y}(t) \geq 0, P$-a.s., which implies that for each $t \geq 0$,

$$
\begin{equation*}
\gamma \int_{0}^{t} \hat{L}_{2}^{z}(s) d s \geq \gamma \int_{0}^{t} \tilde{L}_{2}^{y}(s) d s \tag{47}
\end{equation*}
$$

$P$-a.s.. Thus, using (45), (46), (47) and the fact that $y_{1} \leq z_{1}$, it follows by standard monotonicity results for $\Psi$ that for each $t \geq 0, \tilde{L}_{1}^{y}(t) \leq \hat{L}_{1}^{z}(t), P$-a.s. This completes the proof.

We now study the process $\hat{L}^{z}$. Recall that for a generic vector $z=\left(z_{1}, z_{2}\right) \in \mathbb{R}_{+}^{2}$, we define $|z|=\left|z_{1}\right|+\left|z_{2}\right|$. Also, in the next result we assume that $z=\left(z_{1}, z_{1}\right)$ where $z_{1} \in \mathbb{R}_{+}$.

Lemma 3 If (24) holds, then there exists a $\delta>0$ such that for each $\varepsilon>0$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{1}{|z|} \cdot\left|\hat{L}^{z}(|z| \delta)\right|>\varepsilon\right) \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{48}
\end{equation*}
$$

Proof In order to show (48), we show that there exists a $\delta>0$ such that for each $\varepsilon>0$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{1}{|z|} \cdot\left|\hat{L}_{1}^{z}(|z| \delta)\right|>\varepsilon\right) \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{49}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbb{P}\left(\frac{1}{|z|} \cdot\left|\hat{L}_{2}^{z}(|z| \delta)\right|>\varepsilon\right) \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{50}
\end{equation*}
$$

Let $\delta>0$ and $z=\left(z_{1}, z_{1}\right) \in \mathbb{R}_{+}^{2}$. By (43), after some algebra we may write

$$
\frac{1}{|z|} \hat{L}_{2}^{z}(|z| \delta)=\frac{1}{2}+\frac{\tilde{X}_{2}(|z| \delta)}{|z|}+\theta_{2} \delta-\gamma \int_{0}^{\delta} \hat{L}_{2}^{z}(|z| s) d s+\frac{1}{|z|} \cdot \hat{Y}_{2}^{z}(|z| \delta) .
$$

Since $\hat{Y}_{2}^{z}$ satisfies Conditions 1-3 of Definition 2, it then follows that we may write

$$
\begin{equation*}
\frac{1}{|z|} \hat{L}_{2}^{z}(|z| \delta)=\Psi\left(\frac{1}{2}+\frac{\tilde{X}_{2}(|z| e)}{|z|}+\theta_{2} e-\gamma \int_{0}^{e} \hat{L}_{2}^{z}(|z| s) d s\right)(\delta) \tag{51}
\end{equation*}
$$

where $\Psi: D([0, \infty), \mathbb{R}) \mapsto D([0, \infty), \mathbb{R})$ is the standard one-dimensional regulator map [28], which is well known to be continuous.

Next, let $c=\theta_{2} / \gamma$ and set

$$
\tau_{c, 0}^{z}=\inf \left\{t \geq 0: \hat{L}_{2}^{z}(t)=c \vee 0\right\} .
$$

Since $\hat{L}_{2}^{z}(t) \geq 0$ for each $t \geq 0$, we then have, for each $t \geq 0$,

$$
\begin{align*}
\gamma \int_{0}^{t} \hat{L}_{2}^{z}(|z| s) d s & =\frac{\gamma}{|z|} \int_{0}^{|z| t} \hat{L}_{2}^{z}(s) d s \\
& =\frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z} \wedge|z| t} \hat{L}_{2}^{z}(s) d s+\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s \\
& \geq \frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s . \tag{52}
\end{align*}
$$

Thus, using (51) and (52), it follows by standard monotonicity results for the map $\Psi$ that

$$
\begin{equation*}
\frac{1}{|z|} \hat{L}_{2}^{z}(|z| \delta) \leq \Psi\left(\frac{1}{2}+\frac{\tilde{X}_{2}(|z| e)}{|z|}+\theta_{2} e-\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| e}^{|z| e} \hat{L}_{2}^{z}(s) d s\right)(\delta) . \tag{53}
\end{equation*}
$$

Now recall the definition of $\kappa$ in (29) and note that $\kappa>\min \left\{0, \theta_{2} / \gamma\right\}$. We then claim that

$$
\begin{equation*}
\frac{1}{2}+\frac{\tilde{X}_{2}(|z| e)}{|z|}+\theta_{2} e-\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| e}^{|z| e} \hat{L}_{2}^{z}(s) d s \Rightarrow \frac{1}{2}+\theta_{2} e-\gamma \kappa e . \tag{54}
\end{equation*}
$$

Using Doob's martingale inequality [15], it is straightforward to show that

$$
\frac{\tilde{X}_{2}(|z| e)}{|z|} \Rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty
$$

Therefore, in order to show (54), it remains to show that

$$
\begin{equation*}
\frac{1}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| e}^{|z| e} \hat{L}_{2}(s) d s \Rightarrow \kappa e \quad \text { as } z_{1} \rightarrow \infty \tag{55}
\end{equation*}
$$

However, note that since

$$
\frac{1}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| e}^{|z| e} \hat{L}_{2}(s) d s
$$

is a non-decreasing process, in order to show (55) it suffices to show that for each $t \geq 0$,

$$
\begin{equation*}
\frac{1}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}(s) d s \Rightarrow \kappa t \quad \text { as } z_{1} \rightarrow \infty \tag{56}
\end{equation*}
$$

We begin by evaluating $\mathbb{E}\left[\tau_{c, 0}^{z}\right]$. Suppose first that $c \geq 0$ and that $z_{1}$ is sufficiently large so that $z_{1} \geq c$. That is, $0 \leq c \leq z_{1}$. It then follows that $\tau_{c, 0}^{z}$ is equal in law the the first hitting time of $c$ by an unreflected $\mathrm{O}-\mathrm{U}$ process started at the level $z_{1}$. Using the representation for the distribution of $\tau_{c, 0}^{z}$ found in [24], one may write

$$
\begin{equation*}
\mathbb{E}\left[\tau_{c, 0}^{z}\right]=\int_{0}^{\infty} t \cdot \frac{|\xi|}{\sqrt{2 \pi}}\left(\frac{\gamma}{\sinh (\gamma t)}\right)^{3 / 2} \exp \left(-\frac{\gamma \xi^{2} e^{-\gamma t}}{2 \sinh (\gamma t)}+\frac{\gamma t}{2}\right) d t \tag{57}
\end{equation*}
$$

where

$$
\begin{equation*}
\xi=\frac{z_{1}}{\mu_{1} b_{1}+\mu_{2} b_{2}}-\frac{\theta_{2}}{\gamma\left(\mu_{1} b_{1}+\mu_{2} b_{2}\right)} . \tag{58}
\end{equation*}
$$

Using (57) and (58), it is then straightforward to show that

$$
\begin{equation*}
\frac{\mathbb{E}\left[\tau_{c, 0}^{z}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{59}
\end{equation*}
$$

Now suppose that $c<0$ and let $\tilde{\tau}_{c}^{z}$ be equal in law to the first hitting time of $c$ by an unreflected $\mathrm{O}-\mathrm{U}$ process started at the level $z_{1}$. Recall also that for $z_{1} \geq c, \tau_{c, 0}^{z}$ is equal in the law to the first hitting time of an unreflected $\mathrm{O}-\mathrm{U}$ process to the level $c \vee 0$. Thus, $\tau_{c, 0}^{z} \leq_{\mathrm{st}} \tilde{\tau}_{c}^{z}$. Moreover, formula (57) continues to hold for $c<0$ and so

$$
\begin{equation*}
\frac{\mathbb{E}\left[\tau_{c, 0}^{z}\right]}{|z|} \leq \frac{\mathbb{E}\left[\tilde{\tau}_{c}^{z}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{60}
\end{equation*}
$$

Next note that using straightforward algebra, for each $t \geq 0$ we may write

$$
\begin{align*}
& \frac{1}{|z| t} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s \\
& \quad=\left(1-\left(\frac{\tau_{c, 0}^{z}}{|z| t} \wedge 1\right)\right) \cdot \frac{1}{|z| t-\tau_{c, 0}^{z} \wedge|z| t} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s . \tag{61}
\end{align*}
$$

Equations (59) and (60) and the fact that $\tau_{c, 0}^{z} \geq 0$ imply that

$$
\begin{equation*}
\left(1-\left(\frac{\tau_{c, 0}^{z}}{|z| t} \wedge 1\right)\right) \Rightarrow 1 \quad \text { as } z_{1} \rightarrow \infty \tag{62}
\end{equation*}
$$

and also that, for each $b>0$,

$$
\begin{equation*}
P\left(|z| t-\tau_{c, 0}^{z} \wedge|z| t>b\right) \rightarrow 1 \quad \text { as } z_{1} \rightarrow \infty \tag{63}
\end{equation*}
$$

Recall next by [27] that $\hat{L}_{2}^{z}(t) \Rightarrow \tilde{L}_{2}^{z}(\infty)$ as $t \rightarrow \infty$, where $\hat{L}_{2}^{z}(\infty)$ has the distribution

$$
\mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right) \left\lvert\, \mathcal{N}\left(\frac{\theta_{2}}{\gamma}, \frac{\mu_{1} b_{1}+\mu_{2} b_{2}}{2 \gamma}\right)>0 .\right.
$$

Thus, since $\hat{L}_{2}^{z}$ is a strong Markov process and $\tau_{c, 0}^{z}$ is a stopping time for $\hat{L}_{2}^{z}$, (63) and Theorem 3.1 of [4] may be used to show that

$$
\begin{equation*}
\frac{1}{|z| t-\tau_{c, 0}^{z} \wedge|z| t} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s \Rightarrow \kappa \quad \text { as } z_{1} \rightarrow \infty \tag{64}
\end{equation*}
$$

Equations (61), (62), and (64) now imply (55), which implies (54).
Now note that by (51), (54) and the continuous mapping theorem [8],

$$
\begin{aligned}
& \Psi\left(\frac{1}{2}+\frac{\tilde{X}_{2}(|z| e)}{|z|}+\theta_{2} e-\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| e}^{|z| e} \hat{L}_{2}^{z}(s) d s\right)(\delta) \\
& \quad \Rightarrow \Psi\left(\frac{1}{2}+\theta_{2} e-\gamma \kappa e\right)(\delta), \quad \delta \geq 0
\end{aligned}
$$

However, since $\kappa>\min \left\{0, \theta_{2} / \gamma\right\}$, it follows that $(1 / 2)+\theta_{2} e-\gamma \kappa e$ is a strictly decreasing, linear process and so we may select $\delta_{2}$ large enough so that $\Psi(1 / 2+$ $\left.\theta_{2} e-\gamma \kappa e\right)(\delta)=0$ for $\delta \geq \delta_{2}$. Using (53), this then implies (50).

We next proceed to show that (49) holds. Our proof is similar to the proof of (50) above. Using (43), for each $\delta>0$ we may write

$$
\begin{equation*}
\frac{1}{|z|} \hat{L}_{1}^{z}(|z| \delta)=\Psi\left(\frac{1}{2}+\frac{\tilde{X}_{1}(|z| e)}{|z|}+\theta_{1} e+\gamma \int_{0}^{e} \hat{L}_{2}^{z}(|z| s) d s\right)(\delta) \tag{65}
\end{equation*}
$$

where $\Psi: D([0, \infty), \mathbb{R}) \mapsto D([0, \infty), \mathbb{R})$ is the standard one-dimensional regulator map, which is a continuous map [28]. Next note that since $\hat{L}_{2}^{z}(t) \geq 0$ for each $t \geq 0$, it follows that for each $t \geq 0$ we may write

$$
\begin{align*}
\gamma \int_{0}^{t} \hat{L}_{2}^{z}(|z| s) d s & =\frac{\gamma}{|z|} \int_{0}^{|z| t} \hat{L}_{2}^{z}(s) d s \\
& =\frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z} \wedge|z| t} \hat{L}_{2}^{z}(s) d s+\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s \\
& \leq \frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z}} \hat{L}_{2}^{z}(s) d s+\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s \tag{66}
\end{align*}
$$

Thus, using (65) it follows by standard monotonicity results for the map $\Psi$ that

$$
\begin{align*}
& \frac{1}{|z|} \hat{L}_{1}^{z}(|z| \delta) \\
& \quad \leq \Psi\left(\frac{1}{2}+\frac{\tilde{X}_{1}(|z| e)}{|z|}+\theta_{1} e+\frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z}} \hat{L}_{2}^{z}(s) d s+\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s\right)(\delta) \tag{67}
\end{align*}
$$

We now show that

$$
\begin{equation*}
\frac{1}{2}+\frac{\tilde{X}_{1}(|z| e)}{|z|}+\theta_{1} e+\frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z}} \hat{L}_{2}^{z}(s) d s+\frac{\gamma}{|z|} \int_{\tau_{c, 0}^{z} \wedge|z| t}^{|z| t} \hat{L}_{2}^{z}(s) d s \Rightarrow 1+\theta_{1} e-\gamma \kappa e \tag{68}
\end{equation*}
$$

as $z_{1} \rightarrow \infty$. As in the proof of (50), using Doob's martingale inequality [15] and (61), in order to show (68), it now suffices to show that

$$
\begin{equation*}
\frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z}} \hat{L}_{2}^{z}(s) d s \Rightarrow \frac{1}{2} \quad \text { as } z_{1} \rightarrow \infty \tag{69}
\end{equation*}
$$

Note that by Conditions 1-3 of Definition 2, $\hat{Y}_{2}^{z}\left(\tau_{c, 0}^{z}\right)=0, P$-a.s. Hence, by [15], we obtain

$$
\frac{\gamma}{|z|} \int_{0}^{\tau_{c, 0}^{z}} \hat{L}_{2}^{z}(s) d s=\frac{1}{2}+\frac{\tilde{X}_{2}\left(\tau_{c, 0}^{z}\right)}{|z|}+\theta_{2} \frac{\tau_{c, 0}^{z}}{|z|}-\frac{c \vee 0}{|z|}
$$

By (59) and (60),

$$
\begin{equation*}
\frac{\mathbb{E}\left[\tau_{c, 0}^{z}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{70}
\end{equation*}
$$

Using Theorem 3.3.28 of [15], (70) then implies

$$
\frac{\tilde{X}_{2}\left(\tau_{c, 0}^{z}\right)}{|z|} \Rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty
$$

Moreover, since $\tau_{c, 0}^{z} \geq 0$, (70) also implies that $\tau_{c, 0}^{z}| | z \mid \Rightarrow 0$ as $z_{1} \rightarrow \infty$. Finally, clearly $(c \vee 0) /|z| \rightarrow 0$ as $z_{1} \rightarrow \infty$. It now follows that (69) holds, which implies (68).

Now note that by assumption (24), $1+\theta_{1} e-\gamma \kappa e$ is a decreasing process and so there exists a $\delta_{1}>0$ such that

$$
\Psi\left(1+\theta_{1} e-\gamma \kappa e\right)(\delta)=0,
$$

for all $\delta \geq \delta_{1}$. Thus, it follows as in the proof of (50), using (67), (68), and the continuous mapping theorem [8], that (49) holds, which completes the proof.

We now strengthen the result of Lemma 3 by upgrading the convergence in (48) to convergence in expectation. We assume in the following that $z=\left(z_{1}, z_{1}\right)$ where $z_{1} \in \mathbb{R}$.

Lemma 4 If (24) holds, then there exists a $\delta>0$ such that

$$
\begin{equation*}
\mathbb{E}\left[\frac{1}{|z|} \cdot\left|\hat{L}^{z}(|z| \delta)\right|\right] \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{71}
\end{equation*}
$$

Proof By Lemma 3 and (3.18) of [8], it suffices to show the uniform integrability condition

$$
\sup _{z_{1}>0} \mathbb{E}\left[\left(\frac{1}{|z|} \cdot\left|\hat{L}^{z}(|z| \delta)\right|\right)^{2}\right]<\infty .
$$

However, note that since

$$
\begin{aligned}
\left(\frac{1}{|z|} \cdot\left|\hat{L}^{z}(|z| \delta)\right|\right)^{2} & =\left(\frac{1}{|z|}\right)^{2}\left(\left|\hat{L}_{1}^{z}(|z| \delta)\right|+\left|\hat{L}_{2}(|z| \delta)\right|\right)^{2} \\
& \leq 4 \cdot\left(\frac{1}{|z|}\right)^{2}\left(\left|\hat{L}_{1}^{z}(|z| \delta)\right|^{2}+\left|\tilde{L}_{2}^{z}(|z| \delta)\right|^{2}\right)
\end{aligned}
$$

it suffices to show both

$$
\begin{equation*}
\sup _{z_{1}>0} \mathbb{E}\left[\left(\frac{1}{|z|}\left|\hat{L}_{1}^{z}(|z| \delta)\right|\right)^{2}\right]<\infty \tag{72}
\end{equation*}
$$

and

$$
\begin{equation*}
\sup _{z_{1}>0} \mathbb{E}\left[\left(\frac{1}{|z|}\left|\hat{L}_{2}^{z}(|z| \delta)\right|\right)^{2}\right]<\infty \tag{73}
\end{equation*}
$$

We begin with (73). As in the proof of Lemma 3, define the hitting time of the origin by $\hat{L}_{2}^{z}$,

$$
\tau_{0}^{z}=\inf \left\{t \geq 0: \hat{L}_{2}^{z}(t)=0\right\}
$$

Next, recall that $\hat{L}_{2}^{z}$ possess the strong Markov property and note that $\tau_{0}^{z}$ is a stopping time for $\hat{L}_{2}^{z}$ and so

$$
\begin{align*}
& \mathbb{E}\left[\left(\hat{L}_{2}^{z}(|z| \delta)\right)^{2}\right] \\
& \quad=\mathbb{E}\left[\left(\hat{L}_{2}^{z}(|z| \delta)\right)^{2} 1\left\{\tau_{0}^{z} \leq|z| \delta\right\}\right]+\mathbb{E}\left[\left(\hat{L}_{2}^{z}(|z| \delta)\right)^{2} 1\left\{\tau_{0}^{z}>|z| \delta\right\}\right] \\
& \quad=\int_{0}^{|z| \delta} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] P\left(\tau_{0}^{z} \in d s\right)+\mathbb{E}\left[\left(\hat{L}_{2}^{z}(|z| \delta)\right)^{2} 1\left\{\tau_{0}^{z}>|z| \delta\right\}\right] \tag{74}
\end{align*}
$$

We treat each term on the right-hand side of the final equality above separately. We begin with the integral term. As in the proof of Lemma 3, let $c=\gamma / \theta_{2}$ and set

$$
\tau_{c, 0}^{z}=\inf \left\{t \geq 0: \hat{L}_{2}^{z}(t)=c \vee 0\right\}
$$

If $c<0$, then $\tau_{c, 0}^{z}=\tau_{0}^{z}$ and so, as in the proof of Lemma 3, it follows that

$$
\begin{equation*}
\frac{\mathbb{E}\left[\tau_{0}^{z}\right]}{|z|}=\frac{\mathbb{E}\left[\tau_{c, z}^{0}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{75}
\end{equation*}
$$

On the other hand, suppose that $c>0$. By [29], $\mathbb{E}\left[\tau_{0}^{c}\right]<\infty$. Thus, since $\hat{L}_{2}^{z}$ is a strong Markov process and since $\tau_{c, 0}^{z}$ is a stopping time, it follows using (59) in the proof of Lemma 3 that for $z_{1} \geq c$,

$$
\begin{equation*}
\frac{\mathbb{E}\left[\tau_{0}^{z}\right]}{|z|}=\frac{\mathbb{E}\left[\tau_{c, 0}^{z}\right]}{|z|}+\frac{\mathbb{E}\left[\tau_{0}^{c}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{76}
\end{equation*}
$$

In summary, by (75) and (76),

$$
\begin{equation*}
\frac{\mathbb{E}\left[\tau_{0}^{z}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{77}
\end{equation*}
$$

which, since $\tau_{z}^{0} \geq 0$, also implies that

$$
\begin{equation*}
\frac{\tau_{0}^{z}}{|z|} \Rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{78}
\end{equation*}
$$

Now consider the integral term

$$
\int_{0}^{|z| \delta} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] P\left(\tau_{0}^{z} \in d s\right)
$$

By Proposition 3.3 of [26],

$$
\begin{equation*}
\mathbb{E}\left[\left(\hat{L}_{2}^{0}(t)\right)^{2}\right] \rightarrow \mathbb{E}\left[\left(\hat{L}_{2}(\infty)\right)^{2}\right]<\infty \quad \text { as } t \rightarrow \infty \tag{79}
\end{equation*}
$$

We now claim using (78) and (79) that

$$
\begin{equation*}
\int_{0}^{|z| \delta} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] \mathbb{P}\left(\tau_{0}^{z} \in d s\right) \rightarrow \mathbb{E}\left[\left(\hat{L}_{2}(\infty)\right)^{2}\right] \quad \text { as } z_{1} \rightarrow \infty \tag{80}
\end{equation*}
$$

In order to see this, first let $0<\delta^{\prime}<\delta$ and write

$$
\begin{align*}
& \int_{0}^{|z| \delta} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] \mathbb{P}\left(\tau_{0}^{z} \in d s\right) \\
& =\int_{0}^{|z| \delta^{\prime}} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] \mathbb{P}\left(\tau_{0}^{z} \in d s\right) \\
& \quad+\int_{|z| \delta^{\prime}}^{|z| \delta} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] \mathbb{P}\left(\tau_{0}^{z} \in d s\right) . \tag{81}
\end{align*}
$$

We now treat each of the integral terms on the right-hand side of (81) separately. For the first term, note that since $0<\delta^{\prime}<\delta$, we find by (79) that

$$
\begin{equation*}
\sup _{0 \leq s \leq|z| \delta^{\prime}}\left|\mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right]-\mathbb{E}\left[\left(\hat{L}_{2}(\infty)\right)^{2}\right]\right| \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{82}
\end{equation*}
$$

Next, by (78) it follows that $P\left(\tau_{0}^{z}<|z| \delta^{\prime}\right) \rightarrow 1$ as $z_{1} \rightarrow \infty$. Hence, using (82) one has

$$
\begin{equation*}
\int_{0}^{|z| \delta^{\prime}} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] \mathbb{P}\left(\tau_{0}^{z} \in d s\right) \rightarrow \mathbb{E}\left[\left(\hat{L}_{2}(\infty)\right)^{2}\right] \quad \text { as } z_{1} \rightarrow \infty \tag{83}
\end{equation*}
$$

Regarding the second integral term on the right-hand side of (81), note first by (79) and the continuity of the function $\left(\mathbb{E}\left[\left(\hat{L}_{2}^{0}(t)\right)^{2}\right], t \geq 0\right)$ that

$$
\sup _{t \geq 0} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(t)\right)^{2}\right]<\infty
$$

Hence, since by (78) it follows that $P\left(\tau_{0}^{z}>|z| \delta^{\prime}\right) \rightarrow 0$ as $z_{1} \rightarrow \infty$, one has

$$
\begin{equation*}
\int_{|z| \delta^{\prime}}^{|z| \delta} \mathbb{E}\left[\left(\hat{L}_{2}^{0}(|z| \delta-s)\right)^{2}\right] \mathbb{P}\left(\tau_{0}^{z} \in d s\right) \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{84}
\end{equation*}
$$

Equations (83) and (84) now imply (80).
Next, consider $\mathbb{E}\left[\left(\hat{L}_{2}^{z}(|z| \delta)\right)^{2} 1\left\{\tau_{0}>|z| \delta\right\}\right]$. First note the equality

$$
\begin{equation*}
\mathbb{E}\left[\left(\hat{L}_{2}^{z}(|z| \delta)\right)^{2} 1\left\{\tau_{0}^{z}>|z| \delta\right\}\right]=\mathbb{E}\left[\left(\check{L}_{2}^{z}(|z| \delta)\right)^{2} 1\left\{\tilde{\tau}_{0}^{z}>|z| \delta\right\}\right], \tag{85}
\end{equation*}
$$

where $\check{L}_{2}^{z}$ is an unreflected $\mathrm{O}-\mathrm{U}$ process started at $z_{1}$ and $\check{\tau}_{0}^{z}$ is its first hitting time of zero. That is, $\check{L}_{2}$ is the unique, strong solution to

$$
\begin{equation*}
\check{L}_{2}^{z}(t)=z_{1}+\tilde{X}_{2}(t)+\theta_{2} t-\gamma \int_{0}^{t} \check{L}_{2}^{z}(s) d s, \quad t \geq 0 \tag{86}
\end{equation*}
$$

and

$$
\begin{equation*}
\check{\tau}_{0}^{z}=\inf \left\{t \geq 0: \check{L}_{2}^{z}(t)=0\right\} . \tag{87}
\end{equation*}
$$

Using the explicit form of the solution to (86) (see, for instance, [15]), it is straightforward to show that for each $\delta>0$,

$$
\begin{equation*}
\mathbb{E}\left[\left(\check{L}_{2}^{z}(\delta|z|)\right)^{2}\right] \rightarrow \mathbb{E}\left[\left(\check{L}_{2}(\infty)\right)^{2}\right]<\infty \quad \text { as } z_{1} \rightarrow \infty \tag{88}
\end{equation*}
$$

Next, note that since $\check{\tau}_{0}^{z}$ is equal in distribution to $\tau_{0}^{z}$, it follows using (77) that

$$
\frac{\mathbb{E}\left[\check{\tau}_{0}^{z}\right]}{|z|}=\frac{\mathbb{E}\left[\tau_{0}^{z}\right]}{|z|} \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty
$$

which, since $\check{\tau}_{0}^{z} \geq 0, P$-a.s., implies that

$$
\begin{equation*}
\frac{\check{\tau}_{0}^{z}}{|z|} \Rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{89}
\end{equation*}
$$

Now note that we may write

$$
\begin{equation*}
\mathbb{E}\left[\left(\check{L}_{2}^{z}(\delta|z|)\right)^{2}\right]=\mathbb{E}\left[\left(\check{L}_{2}^{z}(\delta|z|)\right)^{2} 1\left\{\check{\tau}_{0}^{z} \leq \delta|z|\right\}\right]+\mathbb{E}\left[\left(\check{L}_{2}^{z}(\delta|z|)\right)^{2} 1\left\{\check{\tau}_{0}^{z}>\delta|z|\right\}\right] \tag{90}
\end{equation*}
$$

However, by (88) and (89),

$$
\begin{equation*}
\mathbb{E}\left[\left(\check{L}_{2}^{z}(\delta|z|)\right)^{2} 1\left\{\check{\tau}_{0}^{z} \leq \delta|z|\right\}\right] \rightarrow \mathbb{E}\left[\left(\check{L}_{2}(\infty)\right)^{2}\right]<\infty \quad \text { as } z_{1} \rightarrow \infty \tag{91}
\end{equation*}
$$

Thus, by (90),

$$
\begin{equation*}
\mathbb{E}\left[\left(\check{L}_{2}^{z}(\delta z)\right)^{2} 1\left\{\check{\tau}_{0}>\delta z\right\}\right] \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty \tag{92}
\end{equation*}
$$

Using (74), (80), (85), and (92), it now follows that (73) holds.
Next, consider (72). First note that by the basic inequality

$$
\begin{equation*}
\left(x_{1}+\cdots+x_{I}\right)^{2} \leq I^{2}\left(x_{1}^{2}+\cdots+x_{I}^{2}\right) \tag{93}
\end{equation*}
$$

and (43), it follows that for each $\delta>0$,

$$
\begin{align*}
\frac{1}{5^{2}} & \left(\frac{1}{|z|} \cdot \hat{L}_{1}(|z| \delta)\right)^{2} \\
\leq & \frac{1}{4}+\left(\frac{\tilde{X}_{1}(|z| \delta)}{|z|}\right)^{2}+\theta_{1}^{2} \delta^{2}+\gamma^{2}\left(\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \hat{L}_{2}^{z}(s) d s\right)^{2} \\
& +\left(\frac{\hat{Y}_{1}^{z}(|z| \delta)}{|z|}\right)^{2} . \tag{94}
\end{align*}
$$

Now note that

$$
\mathbb{E}\left[\left(\frac{\tilde{X}_{1}(|z| \delta)}{|z|}\right)^{2}\right]=\frac{\delta^{2}}{|z|}\left(\lambda a_{1}+\mu_{1} b_{1}\right) \rightarrow 0 \quad \text { as } z_{1} \rightarrow \infty
$$

Next, using (43) and the explicit solution to the one-sided regulator map $\Psi$, one has that

$$
\begin{align*}
\frac{\tilde{Y}_{1}^{z}(|z| \delta)}{|z|} & =-\sup _{0 \leq s \leq|z| \delta} \min \left\{0,\left(\frac{1}{2}+\frac{\tilde{X}_{1}(s)}{|z|}+\theta_{1} \frac{s}{|z|}+\frac{\gamma}{|z|} \int_{0}^{s} \hat{L}_{2}^{z}(s) d s\right)\right\} \\
& \leq-\sup _{0 \leq s \leq|z| \delta} \min \left\{0,\left(\frac{1}{2}+\frac{\tilde{X}_{1}(s)}{|z|}+\theta \frac{s}{|z|}\right)\right\} \\
& \leq \frac{1}{2}+\theta \delta+\sup _{0 \leq s \leq|z| \delta}\left|\frac{\tilde{X}_{1}(s)}{|z|}\right| \tag{95}
\end{align*}
$$

Using the expression for the distribution of the running maximum of Brownian motion [15], it is straightforward to show that

$$
\sup _{z_{1}>0} E\left[\sup _{0 \leq s \leq|z| \delta}\left|\frac{\tilde{X}_{1}(s)}{|z|}\right|^{2}\right]<\infty
$$

and so from (95) it follows that

$$
\sup _{z_{1}>0} \mathbb{E}\left[\left(\frac{\tilde{Y}_{1}^{z}(|z| \delta)}{|z|}\right)^{2}\right]<\infty
$$

Hence, by (94), in order to complete the proof it suffices to show that

$$
\begin{equation*}
\sup _{z_{1}>0} \mathbb{E}\left[\left(\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \hat{L}_{2}^{z}(s) d s\right)^{2}\right]<\infty \tag{96}
\end{equation*}
$$

First note that

$$
\begin{align*}
\mathbb{E} & {\left[\left(\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \hat{L}_{2}^{z}(s) d s\right)^{2}\right] } \\
& =\mathbb{E}\left[\frac{1}{|z|^{2}} \cdot \int_{0}^{|z| \delta} \int_{0}^{|z| \delta} \hat{L}_{2}^{z}(s) \hat{L}_{2}^{z}(u) d s d u\right] \\
& =\frac{1}{|z|^{2}} \cdot \int_{0}^{|z| \delta} \int_{0}^{|z| \delta} \mathbb{E}\left[\hat{L}_{2}^{z}(s) \hat{L}_{2}^{z}(u)\right] d s d u . \tag{97}
\end{align*}
$$

Next, by the Cauchy-Schwartz inequality [17],

$$
\mathbb{E}\left[\hat{L}_{2}^{z}(s) \hat{L}_{2}^{z}(u)\right] \leq \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2}\right]} \cdot \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(u)\right)^{2}\right]}
$$

Substituting into (97), one then obtains

$$
\begin{equation*}
\mathbb{E}\left[\left(\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \hat{L}_{2}^{z}(s) d s\right)^{2}\right] \leq\left(\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2}\right]} d s\right)^{2} \tag{98}
\end{equation*}
$$

Now note that

$$
\begin{aligned}
\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2}\right] & =\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z} \leq s\right\}\right]+\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z}>s\right\}\right] \\
& =\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z} \leq s\right\}\right]+\mathbb{E}\left[\left(\check{L}_{2}^{z}(s)\right)^{2} 1\left\{\check{\tau}_{0}^{z}>s\right\}\right] \\
& \leq \mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z} \leq s\right\}\right]+\mathbb{E}\left[\left(\check{L}_{2}^{z}(s)\right)^{2}\right],
\end{aligned}
$$

where $\check{L}_{2}^{z}$ is the unreflected O-U process given by (86) and $\check{\tau}_{0}^{z}=\inf \{t \geq 0$ : $\left.\check{L}_{2}^{z}(t)=0\right\}$ as in (87). Thus,

$$
\sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2}\right]} \leq \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z} \leq s\right\}\right]}+\sqrt{\mathbb{E}\left[\left(\check{L}_{2}^{z}(s)\right)^{2}\right]}
$$

and so by (98),

$$
\begin{align*}
\sqrt{\mathbb{E}\left[\left(\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \hat{L}_{2}^{z}(s) d s\right)^{2}\right]} \leq & \frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z} \leq s\right\}\right]} d s \\
& +\frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \sqrt{\mathbb{E}\left[\left(\check{L}_{2}^{z}(s)\right)^{2}\right]} d s \tag{99}
\end{align*}
$$

Now consider each of the terms on the right-hand side of (99). Conditioning on $\tau_{0}^{z}$ as in (74) and using (79), it follows that

$$
\sup _{z_{1}, s \geq 0} \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right)^{2} 1\left\{\tau_{0}^{z} \leq s\right\}\right]}<\infty
$$

from which one obtains

$$
\begin{equation*}
\sup _{z_{1} \geq 0} \frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \sqrt{\mathbb{E}\left[\left(\hat{L}_{2}^{z}(s)\right) 1\left\{\tau_{0}^{z} \leq s\right\}\right]} d s<\infty \tag{100}
\end{equation*}
$$

Now note that the explicit solution for $\hat{L}_{2}^{z}$ (see, for instance, [15]) is given by

$$
\begin{equation*}
\hat{L}_{2}^{z}(t)=z_{1} e^{-\gamma t}+\frac{\theta_{2}}{\gamma}\left(1-e^{-\gamma t}\right)+\int_{0}^{t} e^{\gamma(s-t)} d \tilde{X}_{2}(s) \tag{101}
\end{equation*}
$$

Squaring both sides of (101), using the basic inequality (93) (with $I=3$ ) and noting that $\gamma>0$, one then obtains

$$
\begin{equation*}
\left(\hat{L}_{2}^{z}(t)\right)^{2} \leq 9 z_{1}^{2} e^{-2 \gamma t}+9\left(\frac{\theta_{2}}{\gamma}\right)^{2}+9\left(\int_{0}^{t} e^{\gamma(s-t)} d \tilde{X}_{2}(s)\right)^{2} \tag{102}
\end{equation*}
$$

Hence, taking expectations on both sides of (102) and using the Ito isometry [15] it follows that

$$
\begin{align*}
E\left[\left(\hat{L}_{2}^{z}(t)\right)^{2}\right] & \leq 9 z_{1}^{2} e^{-2 \gamma t}+9\left(\frac{\theta_{2}}{\gamma}\right)^{2}+9\left(\mu_{1} b_{1}+\mu_{2} b_{2}\right)^{2} \int_{0}^{t} e^{2 \gamma(s-t)} d s \\
& \leq 9 z_{1}^{2} e^{-2 \gamma t}+9\left(\frac{\theta_{2}}{\gamma}\right)^{2}+9 \frac{\left(\mu_{1} b_{1}+\mu_{2} b_{2}\right)^{2}}{2 \gamma} \tag{103}
\end{align*}
$$

Now taking square roots on both sides of (103) and using the triangle inequality, one obtains

$$
\sqrt{\mathbb{E}\left[\left(\check{L}_{2}^{z}(s)\right)^{2}\right]} \leq \kappa_{1} z_{1} e^{-\kappa_{2} s}+\kappa_{3},
$$

where

$$
\kappa_{1}=\sqrt{9}, \quad \kappa_{2}=\gamma, \quad \text { and } \quad \kappa_{3}=\sqrt{9\left(\left(\frac{\theta_{2}}{\gamma}\right)^{2}+\frac{\left(\mu_{1} b_{1}+\mu_{2} b_{2}\right)^{2}}{2 \gamma}\right)} .
$$

Hence, since $\kappa_{1}, \kappa_{2}$, and $\kappa_{3}$ are independent of $z$, it follows that

$$
\begin{align*}
\sup _{z_{1}>0} \frac{1}{|z|} \cdot \int_{0}^{|z| \delta} \sqrt{\mathbb{E}\left[\left(\check{L}_{2}^{z}(s)\right)^{2}\right]} d s & \leq \sup _{z_{1}>0} \frac{1}{|z|} \cdot \int_{0}^{|z| \delta}\left(\kappa_{1} z_{1} e^{-\kappa_{2} s}+\kappa_{3}\right) d s \\
& =\kappa_{1} / \kappa_{2}+\delta \kappa_{3} \\
& <\infty \tag{104}
\end{align*}
$$

Equations (99), (100), and (104) now show (96), which completes the proof.
We are now in a position to provide the proof of Lemma 1.

Proof of Lemma 1 Note that by the definition of the norm $|z|=\left|z_{1}\right|+\left|z_{2}\right|$, it suffices to prove that

$$
\begin{equation*}
\mathbb{E}\left[\frac{1}{|z|} \cdot\left|\tilde{L}_{1}^{z}(|z| \delta)\right|\right] \rightarrow 0 \quad \text { as } z \rightarrow \infty \tag{105}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbb{E}\left[\frac{1}{|z|} \cdot\left|\tilde{L}_{2}^{z}(|z| \delta)\right|\right] \rightarrow 0 \quad \text { as } z \rightarrow \infty \tag{106}
\end{equation*}
$$

Suppose that $|z|=\varepsilon$. Then, by the definition of the norm $|\cdot|, z_{1}, z_{2} \leq \varepsilon$ and so, by Lemma $2, \tilde{L}_{1}^{z}(t) \leq \tilde{L}_{1}^{x}(t)$ and $\tilde{L}_{2}^{z}(t) \leq \tilde{L}_{2}^{x}(t)$ for $t \geq 0$, where $x=(\varepsilon, \varepsilon)$. Thus, $\tilde{L}_{1}^{z}(2|z| \delta) \leq \tilde{L}_{1}^{x}(|x| \delta)$ and $\tilde{L}_{2}^{z}(2|z| \delta) \leq \tilde{L}_{2}^{x}(|x| \delta)$ for each $\delta>0$, and (105) and (106) now follow by Lemma 4.

Acknowledgements The authors would like to thank Jim Dai for bringing this problem to their attention. We thank Efrat Perel for providing the details of Theorem 5.1.
