Abstract: Reactions of the aryl complexes $\operatorname{Rh}(\operatorname{aryl})\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{PiPr}_{2}\right)_{2}\right]\right\}(\mathbf{1}$; aryl $=3,5-$ $\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{a}), \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{c}), 3-\mathrm{FC}_{6} \mathrm{H}_{4}$ (d); $\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}=9,9$-dimethyl-4,5-bis(diisopropylphosphino)xanthene) with $\mathrm{O}_{2}, \mathrm{CO}$, and $\mathrm{MeO}_{2} \mathrm{CC}_{\mathrm{C}}=\mathrm{CCO}_{2} \mathrm{Me}$ have been performed. Under 1 atm of $\mathrm{O}_{2}$, the pentane solutions of complexes 1 afford the dinuclear peroxide derivatives $\left[\operatorname{Rh}(\operatorname{aryl})\left\{\kappa^{2}-\mathrm{P}, \mathrm{P}-\mathrm{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right) 2\right\}\right]_{2}\left(\mu-\mathrm{O}_{2}\right)_{2}(\mathbf{2 a}-\mathbf{d})$ as yellow solids. In solution these species are unstable. In dichloromethane, at room temperature they are transformed into the dioxygen adducts $\mathrm{Rh}(\operatorname{aryl})\left(\eta^{2}-\mathrm{O}_{2}\right)\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ (3a-d), as a result of the rupture of the double peroxide bridge and the reduction of the metal center. Complex $\mathbf{3 b}$ decomposes in benzene, at $50^{\circ} \mathrm{C}$, to give diphosphine oxide, phenol and biphenyl. Complexes $\mathbf{1}$ react with CO to give the square-planar mono carbonyl derivatives $\operatorname{Rh}(\operatorname{aryl})(\mathrm{CO})\left\{\mathrm{\kappa}^{2}-\mathrm{P}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right) 2\right]\right\}$ (4a-d), which under carbon monoxide atmosphere evolve to benzoyl species $\mathrm{Rh}\{\mathrm{C}(\mathrm{O}) \operatorname{aryl}\}(\mathrm{CO})\left\{\mathrm{\kappa}^{2}-\mathrm{P}, \mathrm{P}-\right.$ [xant( $\left.\left.\left.\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ (5a-d), resulting from the migratory insertion of CO into the Rh -aryl bond and the coordination of a second CO molecule. The transformation is reversible; under vacuum, complexes 5 regenerate the precursors $\mathbf{4}$. The addition of the activated alkyne to complexes $\mathbf{1 b}$ and 1d initially leads to the $\pi$-alkyne intermediates $\operatorname{Rh}(\operatorname{aryl})\left\{\eta^{2}-\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \equiv \mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right)\right\}\left\{\kappa^{3}-\right.$ $\left.\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{P}} \mathrm{Pr}_{2}\right)_{2}\right]\right\} \quad(\mathbf{6 b}, \quad \mathbf{6 d})$ which evolve to the alkenyl derivatives $\operatorname{Rh}\{(E)-$ $\left.\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right)=\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \operatorname{ary}\right\}\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}\right]\right\} \quad(7 \mathbf{b}, 7 \mathbf{d})$. The diphosphine adapts its coordination mode to the stability requirements of the different complexes, coordinating cis- $\mathrm{k}^{2}$ $\mathrm{P}, \mathrm{P}$ in complexes $\mathbf{2}$, fac- $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ in compounds $\mathbf{3}$, trans $-\kappa^{2}-\mathrm{P}, \mathrm{P}$ in the mono carbonyl derivatives 4 and 5, and mer- $\mathrm{K}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ in products 6 and 7.

Key words: Rhodium; pincer ligand; peroxide; carbonyl; aryl

## Introduction

Square-planar rhodium(I) aryl complexes of general formula $\mathrm{L}_{3} \mathrm{Rh}$-aryl are stabilized with three phosphines, ${ }^{1}$ bulky carbenes, ${ }^{2}$ or bulky substituents at the ortho positions of the coordinated aryl group. ${ }^{3}$ From an electronic point of view, the carbonyl ligand ${ }^{4}$ and fluorine substituents at the aryl group ${ }^{1 \mathrm{ce}, ; 2 \mathrm{a}, \mathrm{b} ; 4 \mathrm{c} ; 5}$ also appear to increase the stability of these compounds. As a consequence of the limited number of species isolated, the studies on stoichiometric reactivity are very scarce, being focused on the protolytic cleavage of the $\mathrm{Rh}-\mathrm{C}$ bond $^{4 \mathrm{a}}$ and insertion reactions into the latter of cumulenes, ${ }^{1 \mathrm{a}}$ aldehydes, ${ }^{4 \mathrm{~b}}$ ketones, ${ }^{6}$ alkynones, ${ }^{6 \mathrm{a}}{ }^{\text {amines }}{ }^{6 \mathrm{Ga}, 7}$ and nitriles. ${ }^{6 b}$

Two families of pincer ligands have been mainly used to stabilize square-planar complexes of formula $\mathrm{L}_{3} \mathrm{Rh}$-aryl: P,N,P-ligands based on 2,6-bis(dialkylphosphinomethyl)pyridines ${ }^{8}$ and flexible P,O,P-groups. ${ }^{9}$ The deprotonation of one of the $\mathrm{CH}_{2}$ arms of the first ones gives rise to the dearomatization of the pyridine ring. This facilitates processes of activation of aromatic C-H bonds, which leads to rhodium(I)-aryl derivatives regenerating the initial ligand (Scheme 1 ). ${ }^{8 e, f, \mathrm{f}, \mathrm{j}}$ On the other hand, it has been shown that the hydride complex $\operatorname{RhH}\left\{\mathrm{K}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ (xant $\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}=9,9$-dimethyl-4,5-bis-(diisopropylphosphino)xanthene) oxidatively adds aromatic $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{Cl}$ bonds to give the rhodium(III) species $\mathrm{RhH}_{2}(\operatorname{aryl})\left\{\mathrm{\kappa}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{P}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ and $\operatorname{RhH}(\operatorname{aryl}) \mathrm{Cl}\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$. In spite of the trans disposition of the hydrides in the first ones and the hydride and chloride in the second ones, the flexibility of the $\mathrm{P}, \mathrm{O}, \mathrm{P}$ ligand allows the reductive elimination of $\mathrm{H}_{2}$ and HCl , respectively, which leads to a wide variety of squareplanar $\operatorname{Rh}(\operatorname{ary})\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ complexes (Scheme 2). ${ }^{\text {9ac,d }}$ Both families show interesting catalytic uses; P,N,P-rhodium(I)-aryl derivatives promote the catalytic deuteration of arenes, ${ }^{8 c, \mathrm{~d}}$ in addition to cross-coupling of aryl iodides with $\mathrm{sp}^{2}$ and $\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}$ bonds, ${ }^{8 \mathrm{~h}}$ whereas the
$\mathrm{P}, \mathrm{O}, \mathrm{P}$-aryl complexes $\operatorname{Rh}(\operatorname{aryl})\left\{\mathrm{K}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ are the key intermediates in the direct borylation of arenes ${ }^{9 \mathrm{aa}}$ and in the decyanative borylation of aryl nitriles. ${ }^{9 b}$ These uses indicate that square-planar $\mathrm{L}_{3} \mathrm{Rh}$-aryl complexes bearing $\mathrm{L}_{3}$-pincer ligands can play a notable role in the direct functionalization of arenes. ${ }^{10}$
[Insert Scheme 1 here]
[Insert Scheme 2 here]

Our interest in the chemistry of platinum group metal complexes with $\mathrm{P}, \mathrm{O}, \mathrm{P}-$ pincer ligands ${ }^{9 \mathrm{a}-}$ ${ }^{\mathrm{c} ; 11}$ and in the direct functionalization of hydrocarbons ${ }^{12}$ prompted us to study model reactions of complexes $\operatorname{Rh}(\operatorname{aryl})\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ with three different molecules: oxygen, carbon monoxide, and dimethyl acetylenedicarboxylate. These reactions are relevant by their connection with three catalytic processes for the direct functionalization of arenes: oxidation to phenols, ${ }^{13}$ carbonylation to benzaldehydes, ${ }^{14}$ and vinylation to styrenes. ${ }^{15}$ This paper shows the interaction of these molecules with the metal center of the aryl complexes, the influence of the molecules coordination in the coordination mode of the diphosphine, and their ability to insert into the Rharyl bond.

## Results and discussion

## Reactions with molecular oxygen

The unsaturated rhodium center of the aryl complexes $\operatorname{Rh}(\operatorname{aryl})\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}(\mathbf{1}$; aryl $\left.=3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{a}), \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{c}), 3-\mathrm{FC}_{6} \mathrm{H}_{4}(\mathbf{d})\right)$ coordinates molecular oxygen. Stirring of pentane solutions of $\mathbf{1}$ under 1 atm of this gas, or exposed to air, at room temperature
affords yellow solids of formula $\left[\operatorname{Rh}(\operatorname{aryl})\left(\mathrm{O}_{2}\right)\left\{\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right\}\right] \times$ (2), according to their $\mathrm{C}, \mathrm{H}$ elemental analysis, in almost quantitative yield (87-93\%).

The X-ray diffraction analysis structure (Figure 1) of the 3,5- $\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}$-derivative 2a reveals that these compounds are dinuclear species $(x=2)$, which have an inversion center. Two oxygen molecules bond the rhodium centers of two $\operatorname{Rh}(\operatorname{aryl})\left\{\operatorname{xant}\left(\mathrm{P}^{\mathrm{P}} \mathrm{Pr}_{2}\right)_{2}\right\}$ metal fragments, forming a double $\mu-\kappa^{1}: \eta^{2}$ peroxide bridge $(O(1)-O(2)=O(1 A)-O(2 A)=1.442(5) \AA)$. The coordination of the oxygen molecules to the rhodium centers is asymmetric displaying three different metaloxygen bond lengths: $\mathrm{Rh}-\mathrm{O}(1)=\mathrm{Rh}(\mathrm{A})-\mathrm{O}(1 \mathrm{~A})=1.988(4) \AA, \mathrm{Rh}(\mathrm{A})-\mathrm{O}(2)=\mathrm{Rh}-\mathrm{O}(2 \mathrm{~A})=$ $2.024(4) \AA$, and $\mathrm{Rh}-\mathrm{O}(2)=\mathrm{Rh}(\mathrm{A})-\mathrm{O}(2 \mathrm{~A})=2.439(3) \AA$. The dimeric nature of these species is noticeable, since comparable reactions usually lead to mononuclear derivatives. The Cambridge Structural Database (2019 version; update 3) contains 51 structures bearing the $\mathrm{RhO}_{2}$ unit. From them, 48 correspond to mononuclear species, 36 are peroxide derivatives $(1.41-1.46 \AA)^{16,17}$ and 12 are dioxygen adducts (1.27-1.39 $\AA) ;^{17,18}$ a structure related to that shown in Figure 1 has been previously reported only in three cases: $\left[\mathrm{RhCl}\left(\mathrm{PPh}_{3}\right)_{2}\right]_{2}\left(\mu-\mathrm{O}_{2}\right)_{2},{ }^{19}\left[\mathrm{Rh}\left(\mathrm{PhBP}_{3}\right)\right]_{2}\left(\mu-\mathrm{O}_{2}\right)_{2}\left(\mathrm{PhBP}_{3}=\right.$ $\operatorname{tris}\left(\text { methylenediphenylphosphane)phenylborate), }{ }^{20} \text { and }\left[\operatorname{Rh}\left\{(E)-\mathrm{CF}=\mathrm{CF}^{(\mathrm{CF}} 3\right)\right\}\left(\mathrm{PEt}_{3}\right)_{2}\right]_{2}\left(\mu-\mathrm{O}_{2}\right)_{2} .{ }^{21}$ This dimeric structure is rare not only in the rhodium chemistry, but also for the platinum group metals. As far as we know, the palladium complex $\left[\operatorname{Pd}\left(\kappa^{2}-\mathrm{Tp}^{\mathrm{iPr} 2}\right)(\mathrm{py})\right]_{2}\left(\mu-\mathrm{O}_{2}\right)\left(\mathrm{Tp}^{\mathrm{iPr} 2}=\right.$ hydridotris(3,5-diisopropylpyrazolyl)borate) is the other precedent, between the remaining platinum group metals, although it only bears a single peroxide bridge. ${ }^{22}$
[Insert Figure 1 here]

The structure shown in Figure 1 also reveals that during the oxidation of complexes $\mathbf{1}$ (Scheme 3), the coordination mode of the diphosphine changes from mer- $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ to cis- $\kappa^{2}-\mathrm{P}, \mathrm{P}$,
decreasing the P-Rh-P angle to $103.59(5)^{\circ}$. The change prevents the steric hindrance that the isopropyl substituents should undergo in a mer- $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ coordination of the diphosphine in a dimeric structure. A similar phenomenon has been previously observed during the formation of the dinuclear cation $\left[\left(\mathrm{Os}(\mathrm{H} \cdots \mathrm{H})\left\{\mathrm{K}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right\}\right)_{2}(\mu-\mathrm{Cl})_{2}\right]^{2+}$, which contains a faccoordinated $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ diphosphine. The flexibility of the xanthene linker certainly favors the change. ${ }^{23}$
[Insert Scheme 3 here]

The coordination polyhedron around the rhodium atoms of these $\left[\operatorname{Rh}(\operatorname{aryl})\left\{\kappa^{2}-\mathrm{P}, \mathrm{P}-\right.\right.$ $\left.\left.\operatorname{xant}\left(\mathrm{PiPr}_{2}\right)_{2}\right\}\right]_{2}\left(\mu-\mathrm{O}_{2}\right)_{2}\left(\mathbf{2}\right.$; aryl $=3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}$ (a), $\mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{c}), 3-\mathrm{FC}_{6} \mathrm{H}_{4}$ (d)) complexes can be rationalized as the distorted octahedron expected for rhodium(III) centers, with the oxygen atoms disposed fac, and the aryl group situated pseudo-trans to the longest Rh-O bond $\left(\mathrm{C}(1)-\mathrm{Rh}-\mathrm{O}(2)=\mathrm{C}(1 \mathrm{~A})-\mathrm{Rh}(\mathrm{A})-\mathrm{O}(2 \mathrm{~A})=132.37(17)^{\circ}\right)$.

The double bridge is broken in solution at room temperature (Scheme 4). The cleavage is strongly supported by ${ }^{1} \mathrm{H}$ NMR Diffusion-ordered spectroscopy ( ${ }^{1} \mathrm{H}$-DOSY) experiments in dichloromethane. Pulse field gradient (PFG) NMR is a method for measuring diffusion rates of molecules in solution, which depends on their size and hydrodynamic volume. ${ }^{24}$ Table 1 shows that the diffusion coefficients obtained from the dichloromethane solutions of $\mathbf{2 b} \mathbf{- d}$ and the respective calculated hydrodynamic radii are similar to those of the corresponding precursors 1bd. The rupture also occurs in other solvents such as acetonitrile. The electrotrospray HRM spectra of 2a-d in the latter display molecular peaks corresponding to monomeric species; i.e., a half of the expected ones for the dinuclear complexes. This is in contrast to that observed for the
previously reported compounds $\left[\mathrm{Rh}\left(\mathrm{PhBP}_{3}\right)\right]_{2}\left(\mu-\mathrm{O}_{2}\right)_{2}$ and $\left[\mathrm{Rh}\left\{(E)-\mathrm{CF}=\mathrm{CF}\left(\mathrm{CF}_{3}\right)\right\}\left(\mathrm{PEt}_{3}\right)_{2}\right]_{2}(\mu-$ $\left.\mathrm{O}_{2}\right)_{2}$, which kept their dinuclear structure in solution. ${ }^{20,21}$
[Insert Scheme 4 here]

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra in dichloromethane solutions of the four oxidized species display doublets at about 40 ppm , suggesting equivalent $\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}$ groups, which is not consistent with the structure shown in Figure 1. Furthermore, the values of P-Rh coupling constants between 147 and 155 Hz are outside the range of Rh-P coupling constants observed for rhodium(III) complexes bearing the $\operatorname{xant}\left(\mathrm{PiPr}_{2}\right)_{2}$ diphosphine $(86-132 \mathrm{~Hz}),{ }^{9 \text { a-c; } 25}$ while they lie in that reported for the derivatives of rhodium(I) with this diphosphine $(140-198 \mathrm{~Hz}){ }^{9 \mathrm{a}, \mathrm{c} ; 25 \mathrm{a}, \mathrm{b} ; 26}$ This reveals that the rupture of the double peroxide bridge produces the reduction of the metal centers, which must imply a peroxide-to-dioxo transformation. According to this, the IR spectra in $\mathrm{CCl}_{4}$ contain a characteristic dioxo $v(\mathrm{O}-\mathrm{O})$ band ${ }^{17 \mathrm{a}}$ at $1064 \mathrm{~cm}^{-1}$, which is absent in solid state.

The equivalence of the $\mathrm{PiPr}_{2}$ groups along with the presence of four doublet of doublets between 1.4 and 0.8 ppm , corresponding to the methyl groups of the isopropyl substituents, in the ${ }^{1} \mathrm{H}$ NMR spectra point out a fac- $\mathrm{K}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ coordination of the diphosphine. ${ }^{27}$ So, the coordination polyhedron of the oxidized species in solution appears to be a trigonal bipyramid ${ }^{28}$ with the oxygen atom of the diphosphine and the phenyl group in apical positions, while the dioxygen ligand and the phosphorous atoms should lie in the equatorial plane. ${ }^{29}$ On the basis of this structure, the reduction process can be understood as a sequential rupture of the $\mathrm{Rh}-\mathrm{O}$ bonds following an inverse relationship to their strength.

The dinuclear complexes $\mathbf{2 a - d}$ are stable in the solid state, under argon, at room temperature for long time. In contrast, the mononuclear species $\operatorname{Rh}(\operatorname{aryl})\left(\eta^{2}-\mathrm{O}_{2}\right)\left\{\mathrm{\kappa}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}\right]\right\}(\mathbf{3}$;
aryl $\left.=3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{a}), \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{c}), 3-\mathrm{FC}_{6} \mathrm{H}_{3}(\mathbf{d})\right)$ are scarcely stable, in dichloromethane or benzene, under argon. At $50{ }^{\circ} \mathrm{C}$, in benzene, complex 3b quantitatively decomposes after 22 h , to give diphosphine dioxide, phenol, biphenyl, and other unidentified products. Under one oxygen atmosphere, the decomposition is faster, being completed in about 5 h.

## Reactions with Carbon Monoxide

Complexes 1 also add carbon monoxide. Stirring of the red pentane solutions of these compounds, under 1 atm of the gas, for a few minutes or seconds initially affords yellow solutions from which yellow solids were isolated. They are consistent with the formula $\operatorname{Rh}(\operatorname{ary})(\mathrm{CO})\left\{\operatorname{xant}\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}\right\}$ (4), according to the C,H elemental analysis and their electrospray HRM spectra. For the solid resulting from the 1d precursor, suitable crystals for X-ray diffraction analysis were obtained. Figure 2 shows a view of the molecule of the new compound 4d. Without doubt, a feature to be mentioned of the structure is the unusual trans- $\mathrm{K}^{2}-\mathrm{P}, \mathrm{P}$ coordination of the diphosphine, which is strongly supported by the long separation between its oxygen atom and the rhodium center of $2.683 \AA$ and the angle $\mathrm{P}(1)-\mathrm{Rh}-\mathrm{P}(1 \mathrm{~A})$ of $149.37(10)^{\circ}$. Thus, the geometry around the rhodium atom is almost square planar, with the phenyl ligand disposed trans to the carbonyl group $\left(\mathrm{C}(1)-\mathrm{Rh}-\mathrm{C}(7)=161.2(5)^{\circ}\right)$. The coordination trans- $\mathrm{K}^{2}-\mathrm{P}, \mathrm{P}$ is unprecedented for the $\operatorname{xant}\left(\mathrm{P}^{\mathrm{P}} \mathrm{Pr}_{2}\right)_{2}$ ligand, in the rhodium chemistry. Previously, it has been observed in the palladium complexes trans- $\mathrm{Pd}(\mathrm{Ph})(\mathrm{X})\left\{\mathrm{\kappa}^{2}-\mathrm{P}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}\left(\mathrm{R}=\mathrm{Br}, \mathrm{CF}_{3}\right)^{30}$ and in the nickel-napthyl compounds trans- $\mathrm{Ni}(\mathrm{Np})(\mathrm{X})\left\{\mathrm{K}^{2}-\mathrm{P}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr} 2\right)_{2}\right]\right\}\left(\mathrm{X}=\mathrm{F}, \mathrm{CF}_{3}\right) .{ }^{31}$

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR, and IR spectra of the yellow solids are consistent with the structure shown in Figure 2 and strongly support the formation of complexes $\operatorname{Rh}(\operatorname{aryl})(\mathrm{CO})\left\{\kappa^{2}-\right.$ $\left.\mathrm{P}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\} \quad\left(4 ;\right.$ aryl $=3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}$ (a), $\mathrm{C}_{6} \mathrm{H}_{5}$ (b), $3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{3}$ (c), 3- $\mathrm{FC}_{6} \mathrm{H}_{3}$ (d)), according to Scheme 5. In agreement with the equivalence of the $\mathrm{P}^{\mathrm{i}} \operatorname{Pr}_{2}$ groups the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra show a doublet between 39 and 41 ppm with a P-Rh coupling constant in the range 158167 Hz , which as previously mentioned is characteristic for $\mathrm{Rh}(\mathrm{I})$ species. In accordance with the mutually trans disposition of the ${ }^{1} \operatorname{Pr}_{2}$ groups, the ${ }^{1} \mathrm{H}$ NMR spectra contain the doublets of virtual triplets expected for the methyl groups of the isopropyl substituents, in the region 1.50 0.20 ppm . In the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra, the CO-resonance appears as a doublet $\left({ }^{1} \mathrm{~J} \mathrm{C}-\mathrm{Rh} \sim 58 \mathrm{~Hz}\right)$ of triplets $\left({ }^{2}{ }^{\mathrm{JC}-\mathrm{P}} \sim 14 \mathrm{~Hz}\right)$ at about 201 ppm , whereas the signal corresponding to metalated carbon atom of the aryl ligand is observed between 172 and 161 ppm , also as a doublet of triplets but with C-Rh and C-P coupling constants between 24 and 28 Hz and about 14 Hz , respectively. The IR spectra display a strong $v(\mathrm{CO})$ band between 1960 and $1910 \mathrm{~cm}^{-1}$.
[Insert Scheme 5 here]

Complexes 4 were obtained in high yield $(70-83 \%)$ as pure yellow solids. ${ }^{32}$ The substitution of the oxygen atom of the diphosphine by carbon monoxide should take place through the fivecoordinate intermediates $\mathbf{A}$ (Scheme 5), resulting from the coordination of a carbonyl ligand to the metal center of the precursors $\mathbf{1}$. The flexibility of the xanthene linker facilitates the replacement.

Complexes 4 rapidly evolve to the monocarbonyl-benzoyl species $\mathrm{Rh}\{\mathrm{C}(\mathrm{O}) \operatorname{aryl}\}(\mathrm{CO})\left\{\mathrm{\kappa}^{2}-\mathrm{P}, \mathrm{P}-\right.$ $\left.\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}\left(\mathbf{5} ; \operatorname{aryl}=3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{a}), \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{c}), 3-\mathrm{FC}_{6} \mathrm{H}_{3}(\mathbf{d})\right)$, when carbon monoxide is bubbled through their toluene solutions (Scheme 5). The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\},{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$

NMR, and IR spectra of these compounds support a square-planar arrangement of ligands around the metal center, which resembles that of complexes 4 , with the benzoyl group at the position of the aryl ligand. In agreement with complexes 4, the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra contain a doublet ( $\mathrm{J}_{\mathrm{P} \text { - }}$ $\mathrm{Rh}=170-180 \mathrm{~Hz})$ at about 43 ppm , whereas four doublets of virtual triplets due to the methyl groups of the isopropyl substituents of the diphosphine are observed in the ${ }^{1} \mathrm{H}$ NMR spectra, between 1.50 and 0.50 ppm . In the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra, the benzoyl ligand generates two characteristic signals: one of them due to the carbonyl group, which appears at about 258 ppm , and the other one corresponding to the OCC-carbon atom, which is observed in the region of 150 ppm , shifted by about 20 ppm towards higher field with regard to the RhC -signal of the respective counterparts 4. The chemical shift of the carbonyl resonance ( $\sim 202 \mathrm{ppm}$ ) is very similar to that observed for the precursors. As expected, the IR spectra contains two $v(\mathrm{CO})$ bands; that due to carbonyl ligand appears in the range $1950-1930 \mathrm{~cm}^{-1}$, whereas the band corresponding to the benzoyl group is observed in the region of $1700 \mathrm{~cm}^{-1}$.

The carbonylation of complexes $\mathbf{4}$ to give the derivatives 5 is reversible. Under vacuum, complexes 5 regenerate compounds $\mathbf{4}$. This along with the low basicity of the metal center of the $\operatorname{Rh}(\mathrm{I})\left\{\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right\}$ species ${ }^{25 a \mathrm{~b} ; ; 33}$ suggests that the transformation implies the migratory insertion of the carbonyl ligand into the Rh -aryl bond and the subsequent coordination of a second carbon monoxide molecule ${ }^{33}$ (Scheme 5). Because of the mutually trans disposition of the aryl ligand and the carbonyl group in complexes 4, the regeneration of intermediates $\mathbf{A}$ by re-coordination of the oxygen atom of the diphosphine is necessary for the migratory insertion to take place. The aryl migration should afford square-planar benzoyl intermediates $\mathbf{B}$, related to complexes $\mathbf{1}$, bearing coordinated the oxygen atom of the diphosphine. Like complexes 1, these intermediates
could undergo the substitution of the oxygen atom of the xanthene linker by the new carbonyl ligand, to give complexes $\mathbf{5}$, through the five-coordinate species $\mathbf{C}$.

A few examples of rhodium(I)-benzoyl derivatives stabilized by P,N,P-pincer ligands have been reported. ${ }^{8 g, \mathrm{i}}$ They were also formed by CO insertion into a $\mathrm{Rh}(\mathrm{I})-\mathrm{Ph}$ bond. However, there are significant differences with regard to the carbonylation shown in Scheme 5, which seems to be related to the differences in flexibility of the linkers between the $\mathrm{PR}_{2}$ groups of the $\mathrm{P}, \mathrm{O}, \mathrm{P}$ and P,N,P diphosphines. Thus, in contrast to $\operatorname{xant}\left(\mathrm{P}^{\mathrm{i} P r} 2\right) 2$, the rigidity of the $\mathrm{P}, \mathrm{N}, \mathrm{P}$ diphosphines prevents square-planar species similar to complexes $\mathbf{4}$ and 5, bearing an additional carbonyl ligand, although the formation of the benzoyl moiety also appears to take place through fivecoordinate intermediates similar to $\mathbf{A}$. Shimon, Milstein and co-workers have reported the formation of a $(\mathrm{P}, \mathrm{N}, \mathrm{P}) \mathrm{Rh}\{\mathrm{C}(\mathrm{O}) \mathrm{Ph}\}$ derivative, by irradiation of a benzene solution of a P,N,Pdearomatized monocarbonyl precursor. The cooperation of the dearomatized pincer appears to be necessary to promote the C-H bond activation of benzene, which affords a five-coordinate monocarbonyl-aryl key intermediate ${ }^{8 g}$; i. e., a P,N,P-counterpart of the intermediates A shown in Scheme 5. Huang and co-workers have recently replaced the $\mathrm{CH}_{2}$ arms of the classical P,N,Ppincers by NH units to prepare a benzoyl derivative related to that of the group of Shimon and Milstein, by means of the introduction of carbon monoxide into a benzene solution of the phenyl precursor. Intermediates have not been proposed in this case. ${ }^{8 \mathrm{i}}$

## Reactions with Dimethyl Acetylenedicarboxylate

The aryl complexes $\mathbf{1}$ also react with this activated alkyne. The addition of 1.0 equiv of dimethyl acetylenedicarboxylate to toluene solutions of $\mathbf{1 b}$ and $\mathbf{1 d}$ initially leads to the $\pi$-alkyne complexes $\mathrm{Rh}(\operatorname{aryl})\left\{\eta^{2}-\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \equiv \mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right)\right\}\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\mathrm{xant}\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}\right\} \quad\left(\mathbf{6} ; \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3-\mathrm{FC}_{6} \mathrm{H}_{3}\right.$
(d)). At $-20{ }^{\circ} \mathrm{C}$, the $3-\mathrm{FC}_{6} \mathrm{H}_{3}$-derivative $\mathbf{6 d}$ precipitated from the toluene solutions to afford an orange solid. Its IR spectrum shows a $v(\mathrm{C} \equiv \mathrm{C})$ band at $1759 \mathrm{~cm}^{-1}$, which strongly supports the coordination of the alkyne to the rhodium center. ${ }^{35}$ However, the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of these compounds do not clarify the multiplicity of the coordinated C-C bond. At room temperature, the spectra contain a doublet at 26.7 ppm for $\mathbf{6 b}$ and at 31.8 ppm for $\mathbf{6 d}$; the values of the $\mathrm{P}-\mathrm{Rh}$ coupling constants of 145 and 133 Hz , respectively, lie in the undefined region between rhodium(I) and rhodium(III). In the ${ }^{1} \mathrm{H}$ NMR spectra, the most noticeable feature is the presence of four doublets of virtual triplets between 1.50 and 0.5 ppm , which are consistent with the trans disposition of the equivalent ${ }^{i}{ }^{1} \mathrm{Pr}_{2}$ groups of the diphosphine. Complexes 6 are unstable and rapidly evolve to the alkenyl derivatives $\operatorname{Rh}\left\{(E)-\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right)=\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{Aryl}\right\}\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\right.$ $\left.\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right\}\left(7 ; \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3-\mathrm{FC}_{6} \mathrm{H}_{4}(\mathbf{d})\right)$, as a result of the syn-insertion of the $\mathrm{C}-\mathrm{C}$ triple bond of the alkyne into the rhodium-aryl bond (Scheme 6).

## [Insert Scheme 6 here]

Complexes 7 were isolated as orange solids in high yields (70\% (b) and $75 \%$ (d)). Their formation was confirmed by means of the structure of X-ray diffraction analysis of 7b. Figure 3 shows a view of the molecule. In contrast to complexes 2 and 4, the diphosphine coordinates mer- $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ with $\mathrm{P}(1)-\mathrm{Rh}-\mathrm{P}(2), \mathrm{P}(1)-\mathrm{Rh}-\mathrm{O}(5)$, and $\mathrm{P}(2)-\mathrm{Rh}-\mathrm{O}(5)$ angles of $159.33(4)^{\mathrm{o}}$, $81.57(7)^{\circ}$, and $81.89(7)^{\circ}$, respectively. Thus, the coordination around the metal center can be described as square-planar with the alkenyl ligand disposed trans to the oxygen atom of the diphosphine $\left(\mathrm{C}(1)-\mathrm{Rh}-\mathrm{O}(5)=177.64(12)^{\circ}\right)$. The C -donor ligand displays $E$-stereochemistry, with $\mathrm{Rh}-\mathrm{C}(1)$ and $\mathrm{C}(1)-\mathrm{C}(2)$ bond lengths of $1.976(4)$ and $1.372(5) \AA$, respectively, which compare well with those reported for other rhodium-alkenyl complexes. ${ }^{26,36}$ The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of 7b and 7d are consistent with the structure shown in Figure 3. As expected for
equivalent $\mathrm{P}^{1} \mathrm{Pr}_{2}$ groups, the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra show at about 37 ppm a doublet with a $\mathrm{P}-\mathrm{Rh}$ coupling constant of about 166 Hz , which agrees with the +1 oxidation state of the metal center. In the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra, the $\mathrm{RhC} a$-resonance of the alkenyl ligand appears as a doublet $\left({ }^{1}{ }^{\mathrm{J} C}\right.$ $\mathrm{Rh} \sim 42 \mathrm{~Hz}$ ) of triplets ( ${ }^{2} J_{\mathrm{C}-\mathrm{P}} \sim 24 \mathrm{~Hz}$ ) at 179.0 ppm for $7 \mathbf{b}$ and at 182.4 ppm for $7 \mathbf{d}$, whereas the alkenyl-C $\beta$ atom gives rise to a singlet at about 128 ppm .
[Insert Figure 3 here]

It should be also mentioned that the alkenyl ligand of complexes 7 is stable in benzene solution, at $70^{\circ} \mathrm{C}$, under argon. After one week, under these conditions, the complexes were recovered unchanged. The alkenyl ligand does not undergo E-Z isomerization nor $\mathrm{C}-\mathrm{H}$ bond activation on any substituent, in contrast to that observed for the previously reported $\operatorname{Rh}($ alkenyl $)\left\{\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{PiPr}_{2}\right)_{2}\right]\right\}$ complexes. ${ }^{26}$

## Conclusion

This study has revealed that the metal center of the square-planar complexes $\operatorname{Rh}(\operatorname{ary})\left\{\kappa^{3}\right.$ $\left.\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ coordinates molecular oxygen, carbon monoxide, and dimethyl acetylenedicarboxylate to subsequently promote transformations, involving these small molecules and ligands of the original metal coordination sphere; mainly the aryl group but also $\operatorname{xant}\left(\mathrm{P}^{\mathrm{i} P r}\right)_{2}$, which is oxidized in the case of dioxygen. The diphosphine plays the main role in these processes. As a consequence of the flexibility of the xanthene linker between the $\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}$ groups, the diphosphine has the ability of adapting its coordination mode to the stability requirements of the reaction products; cis- $\kappa^{2}-\mathrm{P}, \mathrm{P}$ in the dinuclear peroxide complexes $\mathbf{2}$, trans $-\kappa^{2}-$ $\mathrm{P}, \mathrm{P}$ in the carbonyl derivatives $\mathbf{4}$ or mer- $\mathrm{K}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ in the alkenyl compounds 7 ; in addition to favor intermediates key for the development of particular reaction pathways. As a proof of
concept of the latter, Scheme 5 shows that the coordination of the diphosphine oxygen atom provides mer $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ intermediates $\mathbf{A}$, which are the key for the insertion of the CO group into the Rh-aryl bond. In addition, Scheme 4 exposes that the $f a c-\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}$ coordination of the diphosphine stabilizes the dioxygen adducts $\mathbf{3}$, which are intermediates in the diphosphine oxidation and the formation of phenol and biphenyl. This provides a marked personality to the chemistry of the $\operatorname{Rh}\left\{\operatorname{xant}\left(\mathrm{P}^{i} \mathrm{Pr}_{2}\right)_{2}\right\}$ unit, which differentiates it from that of the $\operatorname{Rh}(\mathrm{P}, \mathrm{N}, \mathrm{P})$ systems. For instance, the dinuclear peroxide complexes 2, the mononuclear dioxygen derivatives 3, or the square-planar mono carbonyl compounds $\mathbf{4}$ and $\mathbf{5}$ have not precedent in the chemistry of the $\mathrm{Rh}(\mathrm{P}, \mathrm{N}, \mathrm{P})$ pincer-complexes and, more relevant, due to geometric constraints their preparation appears to be not possible.

## Experimental

## General

All reactions were carried out with exclusion of air using Schlenk-tube techniques or in a drybox. Instrumental methods and X-ray details are given in the Supplementary Data file. In the NMR spectra the chemical shifts (in ppm) are referenced to residual solvent peaks ( $\left.{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\right)$, or external $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}\left({ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}\right)$. Coupling constants $J$ and $N$ are given in hertz. $\operatorname{Rh}(\operatorname{aryl})\left\{\mathrm{\kappa}^{3}-\right.$ $\left.\mathrm{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i} P r}\right)_{2}\right]\right\}\left(\mathbf{1}\right.$; aryl $\left.=3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{a}), \mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{b}), 3,5-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathbf{c}), 3-\mathrm{FC}_{6} \mathrm{H}_{4}(\mathbf{d})\right)$ were prepared by the published methods. ${ }^{9 \mathrm{c}}$

## Reaction of $\mathbf{R h}\left(\mathbf{3 , 5 - M e} \mathbf{M}_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right)\left\{\mathbf{\kappa}^{\mathbf{3}} \mathbf{- P}, \mathbf{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{PiPr}_{2}\right)_{2}\right]\right\}$ (1a) with Oxygen

Complex 1a ( $100 \mathrm{mg}, 0.15 \mathrm{mmol}$ ) was dissolved in pentane $(5 \mathrm{~mL})$ and the resulting mixture was stirred during 10 min at room temperature under an oxygen atmosphere, during which time
the formation of a yellow precipitate was observed. The yellow solid (2a) thus formed was washed with pentane ( $3 \times 1 \mathrm{~mL}$ ) and dried in vacuo. Yield: $92 \mathrm{mg}(88 \%)$. ## Reaction of $\operatorname{Rh}\left(\mathbf{3}, 5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right)\left\{\kappa^{3}-\mathbf{P}, \mathrm{O}, \mathrm{P}-\left[\operatorname{xant}\left(\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}\right)_{2}\right]\right\}$ (1a) with CO: Formation of  [xant( $\left.\left.\left.\mathbf{P i P r}_{2}\right)_{2}\right]\right\}(\mathbf{5 b})$

A solution of complex $\mathbf{1 a}(50 \mathrm{mg}, 0.07 \mathrm{mmol})$ in pentane $(5 \mathrm{~mL})$ was exposed to a CO atmosphere. The color of the solution immediately changes to yellow. Its evaporation to dryness yielded a yellow solid. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum shows a mixture of $\mathbf{4 a}$ and $\mathbf{5 a}$ in a molar
ratio of 65:35. Bubbling CO through toluene solutions of the solid affords 5a. Under vacuum, the mixture of $\mathbf{4 a}$ and $\mathbf{5 a}$ is regenerated.

Spectroscopic data for 4a: ${ }^{1} \mathrm{H}$ NMR ( 400.13 MHz , toluene- $\left.d_{8}, 298 \mathrm{~K}\right): \delta 7.23\left(\mathrm{~d}, J_{\mathrm{H}-\mathrm{H}}=7.3, J_{\mathrm{H}-}\right.$ $\mathrm{H}^{2}=1.9,2 \mathrm{H}, \mathrm{CH}$-arom POP $), 7.12(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}$-arom POP $), 7.0-6.9(\mathrm{~m}, 4 \mathrm{H}, 2 \mathrm{CH} \mathrm{POP}+2$ o-CH $\left.3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right), 6.56\left(\mathrm{~s}, p-\mathrm{CH} 3,5-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right), 2.23\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.59(\mathrm{~s}, 6 \mathrm{H}, 3,5-$ $\left.\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right), 1.33\left(\mathrm{dvt},{ }^{3} \mathrm{~J}_{\mathrm{H}-\mathrm{H}}=8.1, N=17.0,6 \mathrm{H}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.31\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right), 1.23\left(\mathrm{dvt},{ }^{3} \mathrm{~J}_{\mathrm{H}-\mathrm{H}}=\right.$ $\left.7.0, N=16.7,6 H, \operatorname{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.18(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH} 3), 0.92\left(\mathrm{dvt},{ }^{3} \mathrm{~J}_{\mathrm{H}-\mathrm{H}}=6.3, N=12.4,6 \mathrm{H}\right.$, $\left.\operatorname{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 0.29\left(\mathrm{dvt},{ }^{3} \mathrm{~J}_{\mathrm{H}-\mathrm{H}}=7.0, N=13.9,6 \mathrm{H}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right) .{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-apt NMR $(100.63 \mathrm{MHz}$, toluene- $\left.d_{8}, 263 \mathrm{~K}\right): \delta 201.5\left(\mathrm{dt},{ }^{1} \mathrm{~J}_{\mathrm{C}-\mathrm{Rh}}=58.2,{ }^{2} J_{\mathrm{C}-\mathrm{P}}=14.5, \mathrm{Rh}-\mathrm{CO}\right), 161.8\left(\mathrm{dt},{ }^{1} J_{\mathrm{C}-\mathrm{Rh}}=24.1,{ }^{2} J_{\mathrm{C}-\mathrm{P}}\right.$ $=13.5, \mathrm{Rh}-\mathrm{C}), 155.3(\mathrm{vt}, N=9.1, \mathrm{C}$-arom POP), $138.7(\mathrm{~s}, \mathrm{CH} \mathrm{Ph}), 133.7(\mathrm{vt}, N=4.0, \mathrm{C}$-arom POP), 133.3 (s, C Ph), 131.2, 125.9, 123.6 (all s, CH-arom POP), 121.2 (s, CH Ph), 119.5 (vt, $N$ $=30.4$, C-arom POP $), 35.5\left(\mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 33.1\left(\mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 31.4\left(\mathrm{vt}, N=24.0, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 25.0$ $\left(\mathrm{vt}, \mathrm{N}=19.1, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 23.1\left(\mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right), 19.4\left(\mathrm{vt}, N=15.9, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 19.2$ (s, $\left.\operatorname{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 18.1\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 17.4\left(\mathrm{~s}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right) .{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(161.98 \mathrm{MHz}\right.$, toluene- $\mathrm{d}_{8}, 298$ $\mathrm{K}): \delta 39.2\left(\mathrm{~d},{ }^{1} \mathrm{~J}_{\mathrm{P}-\mathrm{Rh}}=166.8\right)$. ## Supplementary Data.

Supplementary data (General information, crystallographic data, and IR and NMR spectra) are available with the article through the journal Web site.

## Accession codes

CCDC 1959849, 1959850 and 1959851 contain the crystallographic data for this paper. These data can be obtained, free of charge, via http://www.ccdc.cam.ac.uk/products/csd/request/ (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, U.K. (Fax: 44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk)).

## Acknowledgements

Financial support from the MINECO of Spain (Project CTQ2017-82935-P (AEI/FEDER, UE)), Gobierno de Aragón (Group E06_17R and project LMP148_18), FEDER, and the European Social Fund is acknowledged. L.A.d.1.H. thanks the MECD for her FPU contract (FPU17/04813).

(27) A mer- $\kappa^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-$ coordination should give rise to doublets of virtual triplets.
(28) A square-planar pyramid with a fac- $\mathrm{k}^{3}-\mathrm{P}, \mathrm{O}, \mathrm{P}-$ coordination of the diphosphine does not allow equivalent $\mathrm{P}^{\mathrm{i}} \mathrm{Pr}_{2}$ groups.
(29) In principle, a similar structure with the dioxygen ligand disposed trans to the oxygen atom of the diphosphine could be also possible. However, it is little probable because in such disposition the three oxygen atoms of the molecule should compete by the same metal orbital.

(32) The carbonylation of $\mathbf{4 a}$ to give $\mathbf{5 a}$ is so fast that prevented isolation of $\mathbf{4 a}$ in pure form. As a consequence a mixture of $\mathbf{4 a}$ and $\mathbf{5 a}$ in a ratio $65: 35$ was obtained (see Experimental).
