depend on electron density and the Lyman- α escape probability. The regimes of temperature and particle density for which Case B is valid are discussed. Newly Summary. The relative intensities of H1 and He11 recombination lines are calculated, including full collisional effects, for a considerably larger range of of Baker & Menzel is assumed, and tables of line opacities are also presented to enable the assumption of negligible optical depth in all but the Lyman series to be checked. Collisional excitation of the n = 3 levels from both n = 1 and n = 2 states is considered, and is found to invalidate Case B theory in some conditions which calculated collision strengths for the n=1, 2 and 3 states of He⁺ are tabulated. temperature, density and principal quantum numbers than before. Case B

1 Introduction

numbers larger than previously considered. Moreover, in many of these objects, such as Wolf-Rayet stars, for which accurate infrared line measures can be obtained, the relevant temperatures and densities lie outside the ranges covered by existing tabulations. For the higher densities, particularly, collisional effects are very much more important than in previous recombination calculations and therefore have to be treated more accurately and completely. In view of the higher densities considered here, we limit our calculations to Case B of Baker & £ order to interpret these observations, which can be uniquely useful because of the relative simplicity of the physical process controlling the formation of infrared recombination lines, it is necessary to have theoretical line intensities for transitions involving levels with quantum lines can be observed in many types of astronomical objects at ever-increasing wavelengths. In With the increasing sensitivity and resolution available to infrared spectroscopy, recombination Menzel (1938) for which the Lyman lines are taken to be optically thick. In the Case

approximation, it is assumed that all other lines are optically thin. Since this assumption may be invalid at the higher densities, we tabulate a factor for every transition from which the line opacity can be easily calculated. In a standard Case B calculation, the effect of collisional excitations from n=1 and n=2 states collisional excitation from the n=2 states may become important. In this paper we restrict is ignored. The range of densities of interest for Wolf-Rayet stars includes a regime in which subsequent paper will give the results of extended Case B calculations at the higher densities. 4 ourselves to densities for which the standard Case B assumptions are valid.

our The recombination of a high-density plasma has been treated previously by a number of authors. The connection between the so-called collisional-radiative recombination theory of Bates, Kingston & McWhirter (1962) and the approach used by Brocklehurst (1970, 1971) and by ourselves is shown by Burgess & Summers (1976) and Summers (1977). Our Case B theory is identical to the 'depopulated n=2' case treated by Summers (1977), apart from numerical results are essentially identical to those of Summers (1977) in the few cases where our choice of collisional cross-sections and method of solution. As discussed below, comparison can be made, although the goals of his paper are very different from ours.

3.5≤ In this paper we give extensive results for the recombination lines of H1 and He11, with the upper and lower principal quantum numbers up to 50 and 29, respectively. For H1 we cover log $T_e \le 5$ and $2 \le \log N_e \le 13$. Our results are largely an extension of those of Brocklehurst (1971). In Section 2 we give a brief description of the method of calculation and outline the most important differences from the work of Brocklehurst. Section 3 contains a detailed comparison of the rates for the various atomic processes and of the numerical methods with those used by Brocklehurst. In Section 4, we discuss the breakdown of Case B theory caused by collisional transitions from levels with n=1 and n=2 to higher levels, and derive conditions parameterized by the Lyman alpha escape probability under which these effects can be neglected. The resulting relative intensities and opacity factors, which are tabulated in full on microfiche, are the temperature and density ranges $3 \le \log T_e \le 4.5$ and $2 \le \log N_e \le 10$, while for HeII, discussed in Section 5.

2 Formulation

In the determination of the level populations, N_{nl} , of hydrogenic systems, we follow the approach of Brocklehurst (1970, 1971), and make use of the computer program used in the latter work with a number of modifications and improvements. It is convenient to introduce the departure coefficients b_{nl} defined in terms of the Saha–Boltzmann populations by

$$\frac{N_{nl}}{N_{\rm e}N_{\rm +}} = \frac{\omega_{nl}}{2\omega_{\rm +}} \left(\frac{h^2}{2\pi m k T_{\rm e}}\right)^{3/2} \exp(x_{nl}) b_{nl}, \tag{1}$$

by Seaton & Storey (1976). This program differs from that used by Brocklehurst (1970) mainly in the treatment of energy-changing collisional processes and in its generality with respect to the charge of the hydrogenic ion. In the second stage of the calculation, the values of b_n from the first stage are used to start an iterative solution for the b_{nl} . Brocklehurst (1971) defined a value of $kT_{\rm e}$, and E_{nl} is the ionization energy of the state. To calculate b_{nl} we use a two-stage process. In the first stage, values of b_n are calculated assuming that the *l*-sublevels have populations proportional to (2l+1), so that $b_{nl}=b_n$. A matrix condensation method is used to reduce the infinite set of linear equations describing the departure coefficients b_n to a finite set. The calculation of the b_n is carried out using a program that has been described by Storey (1972) and where N_e and N_+ are the densities of electrons and recombining ions, respectively, $x_{nl} = E_{nl}/N_e$

of solving the n linear equations describing the populations of the nl substates, making explicit allowance for the $l \rightarrow l \pm 1$ collision processes. The iteration begins with $n = n_c$ and ends with n = 3The value of $n=n_c$ necessary to ensure $b_{nl}=b_n$ depends on ion charge, particle density and electron temperature; our method of determining n_c is discussed below. In the second stage energy-changing collisional processes. There are also some differences in the numerical methods used to evaluate the infinite sums of radiative rates. In the calculation of b_n , Brocklehurst incorporated all energy-changing collision processes, whereas in the calculation of b_{nl} , only those Although collisions, this inconsistency in the treatment of collisions in the two stages of the calculation led to difficulties in matching the values of b_{nl} and b_n at $n = n_c$ (Brocklehurst 1971). These difficulties become worse at densities larger than those considered by Brocklehurst. In the calculations described here, all electron-induced energy-changing collisional processes are incorporated, both in the calculation of b_n and the subsequent calculation of b_{nl} . In addition, the same cross-sections and the same $= n_c$ above which it is assumed that $b_{nl} = b_n$. For $n \le n_c$, values of b_{nl} at each *n* are calculated by for a Case B calculation. A few such iterations are normally sufficient for adequate convergence. calculation, the main differences from Brocklehurst (1971) are again in the treatment transitions were included in which the principal quantum number changed by ± 1 . $|\Delta n| = 1$ dominate in the total rate for energy-changing numerical methods are used in both stages. transitions with

3 Atomic rate coefficients and numerical methods

3.1 CALCULATION OF b_n

We describe the atomic processes included in the calculation of b_n and compare our methods with those of Brocklehurst (1970):

3.1.1 Bound-bound radiative transitions

As in Brocklehurst (1970).

3.1.2 Radiative recombination

As in Brocklehurst (1970)

3.1.3 Bound-bound collisional transitions

Brocklehurst (1970) used a mixture of impact-parameter, correspondence principle, and binary encounter cross-sections for these transitions. Here, the fits to various classical and semi-classical A more complete background to these cross-sections is given by Percival & Richards (1975) Richards (1978) are used. results of Percival &

3.1.4 Collisional ionization and three-body recombination

equation 37). Burgess & Summers (1976) have added a contribution allowing for distant Using the formulae of Summers (1979), we find that the maximum contribution to the collision rate from this logarithmic, quantal part of the cross-sections is 4 per cent for the n = 3 state of He⁺ at 100 000 K. The quantal contribution declines rapidly as n increases and electron temperature We use the symmetrized binary encounter ionization cross-section of Burgess & Percival (1968, collisions, calculated in the impact-parameter approximation (Burgess 1964; Summers 1979).

the binary encounter result for H at low energies. We exclude this modification since it is only of We therefore neglect this term in the cross-section. Binary-encounter ionization importance at energies, and for states, for which collisional ionization is an unimportant process in the conditions considered here. Brocklehurst (1970) does not specify how he calculated the rates for these processes, but it seems likely that he also used a binary encounter method, which is suitable for large energy transfers. Rate coefficients for three-body recombination are obtained cross-sections are also discussed by Percival & Richards (1975), who introduce a modification to from those for collisional ionization using the principle of detailed balance. decreases.

3.1.5 Numerical methods

Ś Summers (1969). A description of the method is given by Brocklehurst (1970) and by Burgess We employ the matrix condensation technique first applied to this problem by Burgess & Summers (1976)

In summary, our calculations of b_n and those of Brocklehurst (1970) differ only in the choice of cross-sections for energy-changing collisional processes.

3.2 CALCULATION OF b_{nl}

3.2.1 Bound-bound radiative transitions

recursion relations to generate the functions in order to avoid cancellation difficulties (see for series expansions. We use the same method for low principal quantum numbers ($n \le 200$), but for we use Brocklehurst (1971) evaluates transition probabilities directly from the expression of Gordon (1929) in terms of the hypergeometric functions $_{2}F_{1}$. He calculates these functions directly from higher values, which are required in our modified treatment of the cascade problem, example, van Regemorter et al. 1979).

3.2.2 Radiative recombination

As in Brocklehurst (1971).

3.2.3 l-changing collisions

As in Brocklehurst (1971), we use the semi-classical impact-parameter treatment for degenerate states developed by Pengelly & Seaton (1964). In this approach, a weak and a strong coupling region of incident particle impact parameter, r_p , are defined. The boundary of these two regions, $r_{\rm p} = r_{\rm s}$, is defined by

$$\sum_{V=1+1}^{P} P_{nl,\,nl'} = \frac{1}{2},\tag{1}$$

ନ

where $P_{nl,nl'}(E, r_p)$ is the probability of a transition from $nl \rightarrow nl'$ at an incident energy E, and impact parameter r_p . The cross-section for collisions out of *nl* is then given by

$$Q_{nl} = \sum_{l'=l+1} Q_{nl,\ nl'} = \int_{r_s}^{r_u} 2\pi r \sum_{l'=l+1} P_{nl,\ nl'} dr + \frac{1}{2}\pi r_s^2,$$
(3)

ъ $P_{nl,nl'}$ is directly proportional to the oscillator strength of the transition, $f_{nl,nl'}$. In Brocklehurst's transition is 1/2, and r_u is an upper cut-off, discussed by Brocklehurst (1971). The probability where it has been assumed that in the strong coupling region the average probability of

804

oscillations by making the additional assumption that even in the strong coupling region, the of $C_{nl,nl'}$ are obtained from these two recursions, and a mean is taken. This procedure leads to distribution of electron velocities. Individual rate coefficients $C_{nl,nl'}$ are then obtained by recursion and detailed balancing arguments, starting both at l=0 and at l=n-1. Different values oscillations in the behaviour of $C_{nl,nl'}$ as a function of l of a few per cent. We avoid these Maxwellian cross-section is proportional to the oscillator strength, so that for all impact parameters, ಡ C_{nl} are calculated by integrating the Q_{nl} over approach, rate coefficients

$$\frac{Q_{nl,nl'}}{Q_{nl}} = \frac{f_{nl,nl'}}{\Sigma_{l'=l\pm 1}f_{nl,nl'}}.$$
(4)

Brocklehurst's method, but vary smoothly with *l*. In practice, $C_{nl,nl+1}$ is calculated and $C_{nl+1,nl}$ is obtained from detailed balance considerations. In the calculation of the rate coefficients for these The $C_{nl,nl'}$ obtained with this assumption differ by at most a few per cent from those obtained by collisions we have included the effects of electrons, protons and He⁺ ions. The assumed abundances are discussed in Section 4.

3.2.4 Energy-changing collisions

among the nearly degenerate *l*-states for a given value of n are always much larger than for n-changing collisions, the precise *l*-dependence of the $nl \rightarrow n'l \pm 1$ cross-sections is not of primary importance. Moreover, the dominant contribution comes from transitions with $|\Delta n|=1$. Consequently, for transitions with $|\Delta n| = 1$ we have assumed that the excitation cross-section, Q, We use the cross-sections described in Section 3.1.3 above. As the collision rates for $\Delta l = l'$ dominate, we consider only those transitions. Because the collision rates at incident energy E is $-l = \pm 1$

$$Q_{nl,n\pm 1l'}(E) = \frac{f_{nl,n\pm 1l\pm 1}}{f_{n,n\pm 1}} Q_{n,n\pm 1}(E), \qquad \Delta l = \pm 1$$

= 0. \Delta L_{n,n\pm 1} = 0.

 $\widehat{\mathbf{S}}$

where f stands for absorption oscillator strength. This assumption is based on the Coulomb-Bethe approximation for collisional excitation. For transitions with $|\Delta n| > 1$ we use the simpler approximation,

$$Q_{nl,n'l+\Delta l}(E) = Q_{nn'}(E), \qquad \Delta l = \pm 1$$

=0,
$$\Delta l \neq \pm 1.$$
 (6)

largest radiative decay rate for that value of n. Calculations show this to be true for those values of important. To summarize, Brocklehurst (1971) included only $|\Delta n|=1$ transitions, which were calculated by the impact-parameter method. We employ the cross-sections of Percival &rapid *l*-changing collisions with $\Delta n = 0$ to correctly distribute population among the *l*-substates for each n. In order for this to occur, the rate of l-changing collisions for a given n must exceed the n for which n-changing collisions are important. Calculations were also made with the cruder approximation of equation (6) for all values of $|\Delta n|$. The resulting values of b_{nl} differ by no more This is an additional confirmation that the exact *l*-dependence of the $n \rightarrow n'$ collision rates is not These assumptions maintain the correct total number of $n \rightarrow n'$ transitions, and rely on the very than 0.2 per cent from the final values obtained using equation (5) for the $|\Delta n| = 1$ transitions. Richards (1978) with the assumptions of equations (5) and (6) and with no restriction on $|\Delta n|$. Collisional ionization and three-body recombination

As in equation (6) we assume that the ionization cross-section at incident electron energy E, is independent of the angular momentum of the bound level,

$$\sigma_{nl}(E) = \sigma_n(E).$$

The three-body For $\sigma(E)$ we use the binary encounter result of Burgess & Percival (1968). recombination rate is obtained as in Section 3.1.4.

6

3.2.6 Numerical methods

improvement in accuracy over Brocklehurst's approach, but arise from our desire to use, as far as integration in the variable $1/n^{2}$ is used. Again the same method is used in both stages of the that $b_{nl} = b_n$ for $n_c < n \le 300$. For higher n he assumed $b_n = 1$. In our calculation, $b_{nl} = b_n$ for all $n > n_c$. To obtain the total radiative cascade rate to a given level, nl, Brocklehurst sums the first few terms and then makes a two-term fit to the quantity $n^{\prime3}A(n^{\prime}l^{\prime} \rightarrow nl) b_{n^{\prime}l^{\prime}}$ where A is the transition probability from some higher state n'l' to nl. This quantity is slowly varying as a function of $1/n^{\prime 2}$. The fit is then integrated analytically. We replace this latter procedure with five-point Gaussian integration in the variable $1/n^{\prime 2}$. These changes do not represent a great is possible, the same techniques in the first-stage calculation of b_n as in the subsequent calculation of b_{nl} . The infinite sums of collisional rates are obtained in a similar way, by summing the first few terms and carrying out a numerical integration for the remainder. In this case a 16-point Gaussian Brocklehurst (1971). The differences lie in the treatment of the radiative cascade and collisional contributions to the populations of each sublevel *nl*. In Brocklehurst's treatment it was assumed As outlined in Section 2, the iterative method of evaluation of b_{nl} is similar to that used by calculation.

4 Collisional excitation of higher levels from n=1 and n=2

collisional transitions from n=1 and 2 may make an appreciable contribution to the populations with $n \ge 3$ and thus invalidate these calculations. Thus it is imperative both that explicit conditions be derived under which these collisional transitions are negligible and that the users of our tables The 'Case B' theory used here is based on the assumption that the level populations for $n \ge 3$ are independent of those of levels 1 and 2, which are not, of course, evaluated explicitly. However, at the higher densities and temperatures considered in this paper it is possible that upward take these limits seriously.

The rate at which an (n, l) level is populated by direct recombination and by radiative and collisional transitions from all levels with larger principal quantum numbers is given in terms of an effective recombination rate constant \overline{a}_{nl} , which is defined by

$$N_{\rm e}N_{+}\overline{\alpha}_{nl} = N_{\rm e}N_{+}(\alpha_{nl} + N_{\rm e}\beta_{nl}) + \sum_{n'=n+1}^{N} \sum_{l'=l+1}^{N} N_{n'l'}(A_{n'l',nl} + N_{\rm e}C_{n'l',nl}),$$
(8)

8

where α_{nl} and β_{nl} are the direct radiative and three-body recombination rate coefficients, $A_{n'l',nl}$ (n, l) transition. From Tables 1 and 2, which give values of $\overline{\alpha}_{nl}$ for n=2 and 3 in hydrogen and ionized helium, respectively, at selected values of N_e and T_e , it is clear that these coefficients are smoothly decreasing functions of temperature and are almost independent of density. Rate coefficients for electron-induced transitions between levels with n=1, 2 and 3 are required for both H and He⁺. We discuss these rate coefficients in the Appendix. The Appendix contains the is the Einstein coefficient and $C_{n'l',nl}$ is the collisional rate coefficient for the (n', l')-

results of a new close-coupling and distorted-wave calculation of collision strengths for He⁺ + e, which provides rates for the $1 \rightarrow 3$ and $2 \rightarrow 3$ transitions substantially more accurate than those currently in the literature.

4.1 $1 \rightarrow 2$ and $1 \rightarrow 3$ collisional transitions

which ensures that collisional transitions from the ground state are negligible. The population of ground-state population is determined by the balance of ionizing and recombining mechanisms, and consequently its value in any particular circumstance cannot be obtained from recombination theory alone. However, we can derive a limiting value for the degree of ionization level (n, l) will be unaffected by collisions from n=1 if The

$$\mathsf{V}_{\mathsf{I}s}\mathsf{N}_{\mathsf{e}}C_{\mathsf{I}s,\,\mathfrak{n}!} \ll \mathsf{N}_{\mathsf{e}}\mathsf{N}_{+}\overline{\alpha}_{\mathfrak{n}!}.$$

(10)We define a critical degree of ionization $(N_{1s}/N_{+})_{nl}^{crit}$, such that the total rate of collisional population of the (n, l) level is a small fraction, p, of the population rate from higher states, by $(N_{1s}/N_+)_{nl}^{\text{crit}} \equiv p \overline{\alpha}_{nl}/C_{1s,nl}.$

As this quantity depends strongly on temperature, but less strongly on density, we give in Table 3 for p = 0.1 values of $(N_{1s}/N_+)_{nl}^{crit}$ for one density only, $N_0 = 10^6$ for H and $N_e = 10^8$ for He⁺. If, in a particular situation, collisional excitation of n = 2 is important, but not that of higher levels, then the tabulated Case B results will still be valid providing collisional $2 \rightarrow 3$ transitions are negligible; this issue is discussed in the next Section 4.2. On the other hand, if collisional excitation of n=3 from the ground state is significant, then $1s \rightarrow nl$ collisions are probably simply contaminating level populations for all levels, and the results of this paper are inapplicable.

$$(N_{1s}B_{1s,2p} - N_{2p}B_{2p,1s})\overline{J} = N_{2p}A_{2p,1s}(1-\beta), \qquad 0 \le \beta \le 1, \tag{14}$$

gives which, when substituted into equation (12)

$$N_{+}\overline{\alpha}_{2p} + N_{2s}C_{2s,2p} + N_{1s}C_{1s,2p} = N_{2p}[N_{e}^{-1}A_{2p,1s}\beta + C_{2p,1s} + C_{2p,2s} + C(2p)].$$
(12')

Denning

$$R_{s} \equiv N_{e}^{-1} A_{2q} + C_{s}, \qquad C_{s} \equiv C_{2s,1s} + C(2s), \qquad (15a)$$

$$R_{p} \equiv N_{c}^{-1} A_{2p,1s} \beta + C_{p}, \qquad C_{p} \equiv C_{2p,1s} + C(2p), \qquad (15b)$$

$$C \equiv C_{2p,2s} = \frac{1}{3} S_{2s,2p}, \qquad (15c)$$

$$C = C_{2p, 2s} = \frac{1}{3}C_{2s, 2p},$$

we can solve equations (11) and (12') to obtain

$$V_{2p} = \{N_{+}[\overline{\alpha}_{2p}(R_{s}+3C)+3C\overline{\alpha}_{2s}]+N_{1s}C_{1s},2_{p}(R_{s}+C)\}D^{-1}$$
(16a)

$$I_{2s} = \{N_+[\vec{a}_{2p}C + \vec{a}_{2s}(R_p + C)] + N_{1s}C_{1s, 2s}(R_p + C)\} D^{-1},$$
(16b)

where

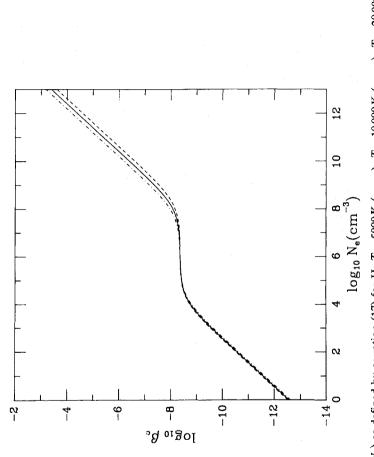

$$D = R_p R_s + C(R_s + 3R_p).$$
(16c)

value The 2s and 2p level populations are largest for a given electron density when the terms in D some critical less than β for occurs this small; sufficiently become B that involve

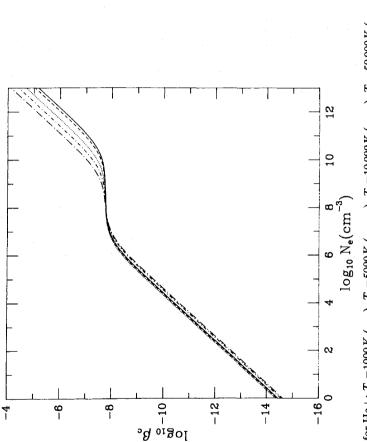

Substituting equations (15a, b) into equation (16c) and collecting terms proportional to β , we find $\beta_{\rm c}(N_{\rm e}).$

(17)

H108..422.2AANM7801

at the highest densities it is not strongly temperature-dependent. Simple approximate forms of β_c for each of the distinct density regions apparent in the figures can readily be found from sufficient conditions for their validity, these results, for For H and He⁺, this quantity is plotted versus N_e in Figs 1 and 2 for various temperatures; except regions (1), (2) and (3) in order of increasing density, are (17). Together with the equation

$$\beta_{c}^{(1)} = N_{e}C/A_{2p,1s}, \qquad A_{2q} \gg 3N_{e}C \gg N_{e} \max(C_{s}, C_{p})$$
 (18a)

$$\beta_{\rm c}^{(2)} = A_{2q}/3A_{2p,1s}, \qquad 3N_{\rm e}C \gg A_{2q} \gg N_{\rm e} \max(C_s, c_p)$$
(18b)

$$S_{c}^{(3)} = N_{e}(3C_{p} + C_{s})/3A_{2p,1s}, \qquad 3N_{e}C \gg N_{e}\max(C_{s}, C_{p}) \gg A_{2q}.$$
(18c)

For $\beta_c^{(2)}$ we have the exact value 4.4×10⁻⁹ Z² and for $\beta_c^{(1)}$, an order of magnitude estimate of $2 \times 10^{-13} N_e Z^{-4}$. In regions (1) and (2) the dominant mechanism for depopulating the 2p level is collisional transitions to 2s followed by two-quantum decay, while in region (3), it is collisions to higher levels.

The denominator D in equations (16) can be written in the form

$$D = [R_s(C + C_p) + 3 C C_p][1 + (\beta/\beta_c)].$$
(19)

The only other occurrence of β in equations (16) is in the combination $R_p + C$, which can be written as

$$R_{p} + C = C \left\{ 1 + (\beta/\beta_{c}) [R_{s}/(R_{s} + C)] \right\} + C_{p} [1 + (\beta/\beta_{c})].$$
⁽²⁰⁾

Lyman lines for which the dominant loss mechanism is emission in other lines. The probability of respectively. Hence Case B is relatively easy to achieve for the higher Lyman lines, but not for Thus the populations of the n = 2 levels are manifestly independent of β when $\beta \ll \beta_c$; thus one can set $\beta = 0$ which is the condition for strict radiative detailed balance in Lyman α . For $N_e \approx 10^8$ we see that β_c is sufficiently large for the $\beta = 0$ limit to be attained in real astrophysical systems. In contrast, for lower densities the $\beta = 1$ limit is probably appropriate, as the condition $\beta \ll \beta_c$ is likely never to be satisfied in reality in this case. This situation is in marked contrast to that for the higher re-emission into a line of another series is approximately 0.04, 0.16 and 0.18 for n=3, 4 and 5, Lyman α .

For $2 \rightarrow 3$ collisions to be negligible, we require

$$V_{2s}C_{2s,3l} + N_{2p}C_{2p,3l} \leq N_{+}\overline{\alpha}_{3l}, \qquad l=0,1,2.$$
(21)

to the criteria of the previous section. We now define a critical electron density N_e^c for the ъ Let us first assume that the terms in equations (16) containing N_{1s} are negligible, according E. n=3 levels such that the total rate of collisional population of the n=3 states from n=2small fraction, p, of the population rate from all higher states. That is

$$N_{e}^{c} \sum_{ll'} N_{2l} C_{2l,3l'} = p N_{e}^{c} N_{+} \sum_{l} \overline{a}_{3l},$$
(22)

where N_{2l} depends parametrically on N_c^c . In general equation (22) is quadratic in N_c^c , although it becomes linear for $\beta = 0$. To avoid unnecessary algebraic complexity, we restrict our attention to regions (2) and (3), for which the condition $3N_eC \leq A_{2q}$ is valid. if, in addition

$$\beta \leqslant 3N_{\rm e}C/A_{2p,1s} \approx 5 \times 10^{-13} N_{\rm e} Z^{-4}, \tag{23}$$

then equations (16) take the form

$$N_{2l} = (2l+1) N_{\rm e} N_{+} \bar{\alpha}_{2} / (A_{2q} + 3A_{2p,1s}\beta + \gamma N_{\rm e}),$$
(24)

By adding the statistical equilibrium equations for $2s$ and $2p$ similar to equations (16) to the usual Case B equations, an 'extended Case B' can be obtained, which accounts for collisional effects involving the $n=2$ levels, except those arising from the ground state. Although a subsequent paper will contain relative intensities of recombination lines at higher densities using this more general treatment, we note here that collisional transitions to higher levels will be important in driving the level populations to their LTE values as the density increases above the critical density. When the $1s \rightarrow 2l$ collisional ransid be reduced. In this case the critical densities the inequalities (21) are satisfied will ranidly be reduced. and relative number of ions causing l-changing collisional transitions, are given in Table 5. We assume throughout that N(He)/N(H) = 0.1. As He II recombination lines formed under rather different sets of conditions are observed in different types of objects, such as planetary nebulae and Wolf-Rayet stars, we have made trial calculations for HeII which reflect the ionic abundances in these two classes of object. The 'PN' calculations were carried out with the of He²⁺ and electrons, so that $N(\text{He}^{2+}) = N(\text{He}) = 0.5 N_{\text{e}}$. Comparing the PN and WR results at $N_e = 10^9$ and $T_e = 20\,000\,\text{K}$, we find that the maximum difference for any line-intensity ratio is Absolute emissivities in the lines differ by at most 6 per cent. The difference between the PN and WR models decreases with increasing electron density. In view of these relatively small differences, we tabulate results only for the PN model. Results are given for all transitions between pairs of upper and lower principal quantum numbers $n_{\rm u}$ and $n_{\rm i}$, respectively, in the values of the Lyman α escape probabilities $\beta \gg \beta_c$, where β_c is given by Figs 1 and 2. The species abundances given in Table 5. The 'WR' calculation assumes that the plasma is composed entirely about 12 per cent, which occurs in comparing lines in the infrared with lines in the ultraviolet. ranges $n_{\rm u} = 3(1)30(5)50$ and $n_l = 2(1)29$.

For each ion and each pair of parameters (T_e, N_e) we give both the relative intensities and the opacity factors, as defined below. In Tables 6 and 7 we reproduce the tabular material from the fiche for the case of H at $N_e = 10^4 \text{ cm}^{-3}$ and $T_e = 10^4 \text{ K}$. At the top of each table appears the identification of the spectrum, the values of T_e and N_e and of the parameter NC. The second line contains the value of the total recombination coefficient α_B for the ion, the effective recombination coefficient for the reference transition 4-3 or 4-2 as indicated, the power in the reference transition in erg cm⁻³ s⁻¹, and finally the coefficients \bar{a}_{2s} and \bar{a}_{2p} defined by equation (8). The main body of the upper part of the table gives the energy in each transition $n_{\rm u}$ to n_l relative to unit energy in a reference transition, which is 4-2 for H_I and 4-3 for He⁺

The lower part of the table contains, for each transition, the opacity factor $\Omega_{n,n'}$ defined as

$$\Omega_{n,n'} = \frac{e^2 \sqrt{\pi}}{mc \Delta_{n,n'}} \sum_{l=0}^{n-1} \left(\frac{N_{nl}}{N_e N_+} \right) f_{nln'l'}^{abs} \left(1 - \frac{b_{n'l'} \exp(x_{n'})}{b_{nl} \exp(x_n)} \right) \qquad n' > n,$$
(29)

where $\Delta_{nn'}$ is the Doppler width in frequency units for the transition, $x_n = E_n/kT_e$, and b_{nl} are the ratios of the level populations to their LTE values. The line centre optical depth corresponding to a path length of $L \operatorname{cm}$ is then

$$\tau_{m'} = N_{\rm e} N_+ \Omega_{m'} L. \tag{30}$$

Note that for many transitions $\Omega_{nn'} < 0$, which indicates population inversions and the potential for maser action in those transitions. The theory used in these calculations assumes that $|\tau_{nn'}| \ll 1$ for n' > n > 1. When using the tabulated line intensities for an $n' \rightarrow n$ transition in a particular astrophysical context, it is necessary to confirm that the optical depth given by equation (30) is small in all transitions, especially those involving states below n, n'. In this paper we do not calculate populations for n=2 states and consequently the opacities in the Balmer lines are unknown. However, by using the estimates of 2s and 2p level populations given by equations (16), these quantities can be calculated from equation (29). The stimulated emission factor can be ignored.

(31)Interpolation of the tables of relative intensities to intermediate values of electron temperature can be readily carried out by assuming that the variation with temperature has a power-law form, $I(N_{\rm e}, T_{\rm e}, n', n) = A(N_{\rm e}, n', n) t^{eta},$

where $t = 10^{-4} T_e(K)$ and $A(N_e, n^*, n)$ and β are constants. A similar procedure may be used to interpolate in n' for n' > 30,

$$I(N_{\rm e}, T_{\rm e}, n', n) = B(N_{\rm e}, T_{\rm e}, n) n' \gamma,$$
(32)

where $B(N_e, T_e, n)$ and γ are constants. Variations with electron density are generally sufficiently weak that linear interpolation suffices.

COMPARISON WITH PREVIOUS CALCULATIONS 5.2

expect that these rates have an error of less than 1 per cent in our calculation. A similar degree of In the calculation of b_n and $b_{n'}$ for hydrogenic ions, the rate coefficients for *radiative* processes are in principle known exactly, and in practice can be determined to any desired level of accuracy. We accuracy is obtained in numerical methods. The rates for collisional processes are far less well known, but the values of the b-coefficients are somewhat less sensitive to these processes. It is therefore of interest to compare our values of b_n and b_{nl} with those from other calculations with a different choice of collisional rate coefficients. We do, however, consider that the cross-sections of Percival & Richards (1978), used in our calculations, are the best currently available. In the first stage calculation of b_n we can compare our results with those of Brocklehurst (1970), who tabulates b_n for H for $40 \le n \le 300$. We have made comparisons for $\log N_e = 3, 4, 5$ and $T_e = 5 \times 10^3$, 10^4 and 2×10^4 K. The largest differences are 2.8 per cent for $T_e = 5 \times 10^3$ K, 1.2 per cent for = 10^4 K for electron densities of 10^4 cm⁻³ and 1.5×10^4 cm⁻³ in order to simulate by means of a density variation of 50 per cent a change in the collision rates of the same amount, which is probably a reasonable error estimate for these rates. The result of this 50 per cent change in density is to change the values of b_n by a maximum of 2.5 per cent. This largest change is at n = 50 $T_e = 10^4$ K and 0.4 per cent for $T_e = 2 \times 10^4$ K. In a trial calculation, we obtained values of b_n at where $b_n = 0.87$ and energy-changing collisional processes are becoming dominant. We conclude that the differences between our results and those of Brocklehurst (1970) most probably arise $T_{\rm e}$:

We can also make limited comparisons of our b_n for H and those of Summers (1977). We compared at $\log N_e = 4$, $T_e = 10^4$ K and $\log N_e = 5$, $T_e = 2 \times 10^4$ K. Summers tabulates b_{nl} for $n \le 35$ and b_n for $n \ge 40$. For $n \ge 40$, we find maximum differences of 2 per cent between our results and those of Summers. Summers' treatment of energy-changing collisions differs from ours in that he used the semi-empirical method of van Regemorter (1962) for transitions with $|\Delta n|$ large. For the important $|\Delta n|=1$ transitions and for other neighbouring states (Summers 1977) Summers used the impact parameter method (Seaton 1962; Burgess 1964), consistent with the cross-sections of Percival & Richards (1978) used in this work. Again the although now the differences are in the opposite sense to those with respect to Brocklehurst (1970). For $n \le 35$, differences between our b_{nl} and those of Summers are again less than 2 per cent with the exception of the 3d and 4d states, where differences of up to 4 per cent exist. These larger differences are unexpected, in that the populations of such low-lying states depend uses an interpolation method that samples in both n and l. The most probable explanation for the magnitude of the difference is consistent with probable uncertainties in the collision rates, primarily on radiative processes, the rates for which are known to high precision. Summers (1977) disagreement for the 3d and 4d states is his rather sparse choice of n states at low n in the matrix from the different choice of cross-sections for the energy-changing collision rates. condensation scheme (Summers 1986, personal communication).

Our results for the relative intensities and effective recombination coefficients can be

additional transitions in He⁺. Brocklehurst (1971) tabulates relative line intensities for the Balmer series of H and the Pickering series of He⁺. The largest difference between our results and those of Brocklehurst (1971) occur when the principal quantum number of the upper state, n, Differences of up to 5 per cent are found for these transitions in the H spectrum, although for smaller values of n, the agreement is generally better than 1 per cent. The larger discrepancies for solutions for b_n and b_{nl} at $n = n_c$. In He⁺, differences from Brocklehurst's line intensities are generally larger, in the range 1-3 per cent, increasing with principal quantum number and compared with those of Brocklehurst (1971) for H and He⁺, and with those of Seaton (1978) for is greater than n_c , the boundary between the b_n and b_{nl} calculations in Brocklehurst's work. $n > n_c$ are almost certainly due to the difficulties encountered by Brocklehurst in matching the decreasing with rising electron temperature.

from the zero-density calculations of Pengelly (1964) and the density-dependent calculations of We find slightly larger differences when comparing with the work of Seaton (1978), who obtained relative line intensities for He⁺ $n \rightarrow 2$ and $n \rightarrow 3$ series. These intensities were derived Brocklehurst (1971) by using scaling laws. We differ from Seaton by a maximum of 6 per cent, with an average difference of 3 per cent.

 $4 \rightarrow 2$ and He⁺ $4 \rightarrow 3$ transitions at a few temperature and densities. We reproduce his results for Brocklehurst (1971) also tabulates values for the effective recombination coefficients for the H these quantities to within 1 per cent for all cases.

Appendix: Rate coefficients for electron induced transitions in H and He^+

Consider two atomic states i and j. The collision strength $\Omega(i, j)$ for excitation from i to j is related to the cross-section σ_{ij} by

$$\sigma_{ij} = \frac{\Omega(i,j)}{E_i \omega_i} \pi a_0^2, \tag{A1}$$

where ω_i is the statistical weight of the initial state, E_i is the energy of the incident electron relative to the initial state and a_0 is the Bohr radius. The rate coefficient for excitation from i to j, q_{ij} , may be written

$$q_{ij} = 8.629 \times 10^{-6} \frac{Y(i, j, T_e)}{\omega_i T_e^{1/2}} \exp\left(-\Delta E_{ij}/k T_e\right) \operatorname{cm}^3 \mathrm{s}^{-1},$$
(A2)

where ΔE_{ij} is the energy of the transition and $Y(i, j, T_e)$ is an effective collision strength, obtained by averaging $\Omega(i, j)$ over a Maxwellian distribution of electron velocities,

8

$$Y(i,j,T_{\rm e}) = \int_0^{} \Omega(i,j,E_j) \exp\left(-E_j/kT_{\rm e}\right) d(E_j/kT_{\rm e}).$$
(A3)

We require values of Y for transitions between the n = 1, 2 and 3 states of H and He⁺. We give the sources of this information below.

A.1 HYDROGEN $1 \rightarrow 2$ and $1 \rightarrow 3$

We use the effective collision strengths of Aggarwal (1983), who makes the fit

(**A**4)

 $\Upsilon(T_{\rm e}) = A + B T_{\rm e} + C T_{\rm e}^2 + D T_{\rm e}^3$

and tabulates A, B, C, D for each transition. For $1s \rightarrow 2s$ and $1s \rightarrow 2p$, Aggarwal uses the collision \rightarrow 3 transitions he uses the work of Hata, Morgan & McDowell (1980), Syms et al. (1975) and Callaway & McDowell (1983). strengths recommended by Callaway & McDowell (1983). For the 1

A.2 HYDROGEN 2→3

We average the collision strengths of Hata *et al.* (1980) over energy to obtain $\overline{\Omega}(2l, 3l')$. We then assume $Y(2l, 3l', T_e) = \overline{\Omega}(2l, 3l')$. Since the data of Hata *et al.* are restricted to energies within

about 0.04 Ryd of the n=2 threshold, there are considerable uncertainties in the rates derived, particularly at higher temperatures.

A.3 He⁺

is smaller for lower energies. The distorted-wave calculations have been extended to $L_{\text{max}} = 23$ for $E_1 = 6$ Ryd and to $L_{\text{max}} = 20$ for the other energies. For the two highest energies, a correction for $L > L_{\text{max}}$ has been calculated using the observation that the collision strengths are declining in a $L \ge L_{\text{max}}$ (Burgess 1974), are not possible in this case due to the persistence of strong coupling among the n = 3 states. The corrections for $L \ge L_{\text{max}}$ are, in any case, small (≤ 3 per cent). For the described by Eissner & Seaton (1972). Comparison of collision strengths calculated using the two methods, at $E_1 = 6$ Ryd and L = 12 shows that the agreement is good with the exception of the $2s \rightarrow 3p$ and $2s \rightarrow 3d$ transitions, where the difference is 13 per cent in both cases. This difference is due to strong coupling between the channels based on the n=3 states, which is not correctly treated in the unitarized distorted-wave method. The use of the distorted-wave method for L>12implies a maximum uncertainty from this source of 4 per cent for these two transitions. The error geometric progression with increasing L. More accurate calculations of the collision strengths for We have carried out a six-state calculation (1s, 2s, 2p, 3s, 3p, 3d) of collision strengths for He⁺ in the energy region above the n=3 threshold. We define E_1 to be the energy (in Ryd) of , and L to be the total orbital angular momentum of the He⁺ + e^- system. We calculate collision strengths at the energies $E_1 = 3.57, 3.8,$ 4.0, 4.41, 5.0 and 6.0 Ryd, for $L \le 23$. For $0 \le L \le 12$ we have used the close-coupling code IMPACT (Crees, Seaton & Wilson 1978), and for $13 \le L \le 23$, the unitarized distorted-wave method lower energies, such corrections are negligible (<1 per cent). the incident electron relative to the ground state of He⁺,

calculations exist for energies between the n=2 and n=3 thresholds and for the $1s \rightarrow 2s$ and $1s \rightarrow 2p$ collision strengths at intermediate energies. We adopt the following values for these Our calculated inelastic scattering collision strengths are given in Table A1. More elaborate transitions

Linear interpolation of calculation of Morgan (1980) $\Omega = 0.147.$ $3.24 < E_1 \le 3.556$ $3.0 \le E_1 \le 3.24$ $1_S \rightarrow 2_S$

 $3.556 < E_1 \le 4.0$ $\Omega = 0.127$.

Linear interpolation of calculation of Wakid & Callaway (1980). Fit from Callaway (1983). $4.0 < E_1 \le 4.5$ $4.5 < E_1 \le \infty$

Linear interpolation of calculation of Morgan (1980). $\Omega = 0.279 + 0.357(E_1 - 3).$ $\Omega = 0.262 + 0.311(E_1 - 3).$ $3.24 < E_1 \le 3.556$ $3.556 < E_1 \le 4.0$ $3.0 \le E_1 \le 3.24$ $\rightarrow 2p$ Ś

Fit from Callaway (1983)

 $4.0 < E_1 \leq \infty$

increases too rapidly with increasing energy due to unaccounted for open channels. The choice of region 3.24 $< E_1 \le 3.556$ we use the results of the calculation by Burke & Taylor (1969) who use a three-state close coupling expansion with correlation terms. These results contain considerable resonance structure. The value of $\Omega(1s, 2s) = 0.147$ in this energy region is a simple mean of their results, whereas the linear relation for $\Omega(1s, 2p)$ is a least-squares fit to their results, this form being chosen to reflect the shape of the experimental curve of Daschenko et al. (1974) in this energy region. Between the n=3 threshold and the ionization limit, $3.556 < E_1 \le 4.0$, we are guided by our own six-state close-coupling calculation. We consider that this calculation gives the most reliable result for the collision strengths immediately above the n=3 threshold, but that it $\Omega(1s, 2s) = 0.127$ in this energy region gives a good match with the results of Wakid & Callaway (1980) at the ionization limit, whereas the linear behaviour of $\Omega(1s, 2p)$ is chosen to connect the six-state close-coupling result at the n=3 threshold with the Callaway (1983) fit at the ionization The calculation of Morgan (1980) is the most elaborate in the near-threshold region. In the energy limit.

Using the above values for $\Omega(1s, 2s)$ and $\Omega(1s, 2p)$ and the remainder from Table A1, effective collision strengths $Y(T_e)$ have been calculated (equation A3) and fitted to the form,

 $Y(t) = a + bt + ct^2 + dt^3$

(Y2)

They are valid for where $t=10^{-4} T_{\rm e}({\rm K})$. The fitted parameters are tabulated in Table A2. $0 \le t \le 10$.

Table A2. Parameters for the fit to the He⁺ + e^- effective collision strengths, $Y(t) = a + bt + ct^2\lambda + dt^3$; 0≤1≤10.
