Technology and Director*

## AUTHORITY

This document has been developed by the National Institute of Standards and Technology (NIST) in furtherance of its statutory responsibilities under the Federal Information Security Management Act (FISMA) of 2002, Public Law 107-347.

NIST is responsible for developing standards and guidelines, including minimum requirements, for providing adequate information security for all agency operations and assets, but such standards and guidelines **shall not** apply to national security systems.

This Recommendation has been prepared for use by federal agencies. It may be used by nongovernmental organizations on a voluntary basis and is not subject to copyright. (Attribution would be appreciated by NIST.)

Nothing in this document should be taken to contradict standards and guidelines made mandatory and binding on federal agencies by the Secretary of Commerce under statutory authority. Nor should this recommendation be interpreted as altering or superseding the existing authorities of the Secretary of Commerce, Director of the OMB, or any other Federal official.

Conformance testing for implementations of this Recommendation will be conducted within the framework of the Cryptographic Algorithm Validation Program (CAVP) and the Cryptographic Algorithm Module Program (CMVP). The requirements of this Recommendation are indicated by the word “**shall**.” Some of these requirements may be out-of-scope for CAVP or CMVP validation testing, and thus are the responsibility of entities using, implementing, installing or configuring applications that incorporate this Recommendation.

### **Acknowledgements**

The authors wish to thank their colleagues, who reviewed drafts of this document and contributed to its development. The authors also gratefully acknowledge and appreciate the many comments from the public and private sectors whose thoughtful and constructive comments improved the quality and usefulness of this publication.

**Abstract**

This publication specifies the Triple Data Encryption Algorithm (TDEA), including its primary component cryptographic engine, the Data Encryption Algorithm (DEA). When implemented in an SP 800-38-series-compliant mode of operation and in a FIPS 140-2-compliant cryptographic module, TDEA may be used by Federal organizations to protect sensitive unclassified data. Protection of data during transmission or while in storage may be necessary to maintain the confidentiality and integrity of the information represented by the data. This Recommendation defines the mathematical steps required to cryptographically protect data using TDEA and to subsequently process such protected data. TDEA is made available for use by Federal agencies within the context of a total security program consisting of physical security procedures, good information management practices, and computer system/network access controls.

Key words: block cipher, computer security, cryptography, data encryption algorithm, security, triple data encryption algorithm.

## Foreward

The Triple Data Encryption Algorithm (TDEA) is an **approved** cryptographic algorithm as required by Federal Information Processing Standard (FIPS) 140-2, *Security Requirements for Cryptographic Modules*. TDEA specifies both the DEA cryptographic engine employed by TDEA and the TDEA algorithm itself.

This Recommendation provides a description of a mathematical algorithm for cryptographically protecting binary coded information (e.g., using encryption and authentication). The algorithm described in this recommendation specifies cryptographic operations that are based on a binary number called a key.

Authorized users of computer data cryptographically protected using TDEA must have the key that was used to protect the data in order to process the protected data. The cryptographic algorithm specified in this Recommendation is assumed to be commonly known among its users. The cryptographic security of the data depends on the security provided for the key used to protect the data.

Data that is determined by a responsible authority to be sensitive, data that has a high value, or data that represents a high value should be cryptographically protected if it is vulnerable to unauthorized disclosure or undetected modification during transmission or while in storage. A risk analysis should be performed under the direction of a responsible authority to determine potential threats. The costs of providing cryptographic protection using this Recommendation, as well as of alternative methods for providing this protection, should be projected. A responsible authority then should make a decision, based on these analyses, whether or not to use cryptographic protection and this recommendation.

DEA was originally specified in FIPS 46, *The Data Encryption Standard*, which became effective July 1977. It was reaffirmed in 1983, 1988, 1993, and 1999. The DEA has now been withdrawn. The use of DEA is permitted only as a component function of TDEA. This Recommendation applies to all Federal agencies, contractors of Federal agencies, or other organizations that process information (using a computer or telecommunications system) on behalf of the Federal Government to accomplish a Federal function. Each Federal agency or department may issue internal directives for the use of this recommendation by their operating units based on their data security requirement determinations.

With the withdrawal of the FIPS 46-3 standard (i.e., the final revision of FIPS 46), implementations of the DEA function are no longer authorized for protection of Federal government information.

Note: Through the year 2030<sup>1</sup>, Triple DES (TDEA) and the FIPS 197 Advanced Encryption Standard (AES) will coexist as **approved** algorithms – thus, allowing for a gradual transition to AES. (The AES is another symmetric-based encryption standard approved by NIST.)

Implementations of the algorithm specified in this Recommendation may be covered by U.S. and foreign patents. Certain cryptographic devices and technical data regarding them are subject to Federal export controls. Exports of cryptographic modules implementing this algorithm and technical data regarding them must comply with these Federal regulations and be licensed by the Bureau of Export Administration of the U.S. Department of Commerce. Applicable Federal government export controls are specified in Title 15, Code of Federal Regulations (CFR) Part 740.17; Title 15, CFR Part 742; and Title 15, CFR Part 774, Category 5, Part 2.

---

<sup>1</sup> TDEA with Keying Option 2 (see Section 3) is **approved** for the protection of Federal government information only through the period of time specified in SP 800-131A. Recommendations regarding the use of Option 2 are contained in SP 800-57, Part 1.

**SPECIFICATIONS FOR THE**  
**TRIPLE DATA ENCRYPTION ALGORITHM (TDEA) BLOCK CIPHER**

## **1. INTRODUCTION**

This Recommendation specifies the Triple Data Encryption Algorithm (TDEA) block cipher. The TDEA block cipher includes a Data Encryption Algorithm (DEA) cryptographic engine (specified in Section 2) that is implemented as a component of TDEA (specified in Section 3). TDEA functions incorporating the DEA cryptographic engine **shall** be designed in such a way that they may be used in a computer system, storage facility, or network to provide cryptographic protection to binary coded data. The method of implementation will depend on the application and environment. TDEA implementations **shall** be subject to being tested and validated as accurately performing the transformations specified in the TDEA algorithm and in NIST Special Publication (SP) 800-38<sup>2</sup>.

### **1.1 Applications**

Cryptography is utilized in various applications and environments. The specific utilization of encryption and the implementation of TDEA<sup>3</sup> will be based on many factors particular to the computer system and its associated components. In general, cryptography is used to protect data while it is being communicated between two points or while it is stored in a medium vulnerable to physical theft or technical intrusion (e.g., hacker attacks). In the first case, the key must be available by the sender and receiver simultaneously during communication. In the second case, the key must be maintained and accessible for the duration of the storage period. NIST Special Publications (SP) 800-133 provides **approved** methods for generating cryptographic keys<sup>4</sup>, and SP 800-57, Part 1<sup>5</sup>, provides recommendations for managing cryptographic keys, including the keys used by the algorithm specified in this Recommendation.

---

<sup>2</sup> SP 800-38: *Recommendation for Block Cipher Modes of Operation - Methods and Techniques*.

<sup>3</sup> And the cryptographic engine that forms the basis for TDEA.

<sup>4</sup> SP 800-133: *Recommendation for Cryptographic Key Generation*.

<sup>5</sup> SP 800-57, Part 1: *Recommendation for Key Management: General*.

## **1.2 Modes of Using the TDEA**

SP 800-38 describes modes of operation for the TDEA block cipher described in this Recommendation. These modes of operation are **approved** for the protection of Federal government information.

## **1.3 Organization**

Section 2 of this Recommendation describes the DEA cryptographic engine employed by TDEA.

Section 3 of the Recommendation describes the basic TDEA algorithm.

Appendices are provided for DEA primitives, examples of encryption and decryption using the TDEA block cipher operation; a glossary of terms; a list of references; a list of requirements for entities installing, configuring and using TDEA; and a list of version changes.

## 2. DATA ENCRYPTION ALGORITHM CRYPTOGRAPHIC ENGINE

The DEA cryptographic engine is used by TDEA to cryptographically protect (e.g., encrypt) blocks of data consisting of 64 bits under the control of a 64-bit key<sup>6</sup>. Subsequent processing of the protected data (e.g., decryption) is accomplished using the same key as was used to protect the data. Each 64-bit key **shall** contain 56 bits that are randomly generated and used directly by the algorithm as key bits. The other eight bits, which are not used by the algorithm, may be used for error detection. The eight error-detecting bits are set to make the parity of each 8-bit byte of the key odd. That is, there is an odd number of "1"s in each 8-bit byte<sup>7</sup>.

During each application of the DEA engine, a block is subjected to an initial permutation **IP**, then to a complex key-dependent computation and finally to a permutation that is the inverse of the initial permutation, **IP**<sup>-1</sup>. The key-dependent computation can be simply defined in terms of a function **f** and a function **KS**, called the key schedule. The DEA engine can be run in two directions - as a forward transformation<sup>8</sup> and as an inverse transformation<sup>9</sup>. The two directions differ only by the order in which the bits of the key are used.

Descriptions of the forward and inverse transformations are provided below, followed by a definition of the function **f** in terms of primitive functions called by the selection functions **S<sub>i</sub>**, and the permutation function **P**. Values for **S<sub>i</sub>**, **P** and **KS** of the engine are contained in Appendix A.

The following notation is convenient: Given two blocks **L** and **R** of bits, **LR** denotes the block consisting of the bits of **L** followed by the bits of **R**. Since concatenation is associative, **B<sub>1</sub>B<sub>2</sub>...B<sub>8</sub>**, for example, denotes the block consisting of the bits of byte **B<sub>1</sub>** followed by the bits of byte **B<sub>2</sub>**...followed by the bits of byte **B<sub>8</sub>**.

### 2.1 DEA Forward Transformation

A sketch of the forward transformation is given in **Figure 1**.

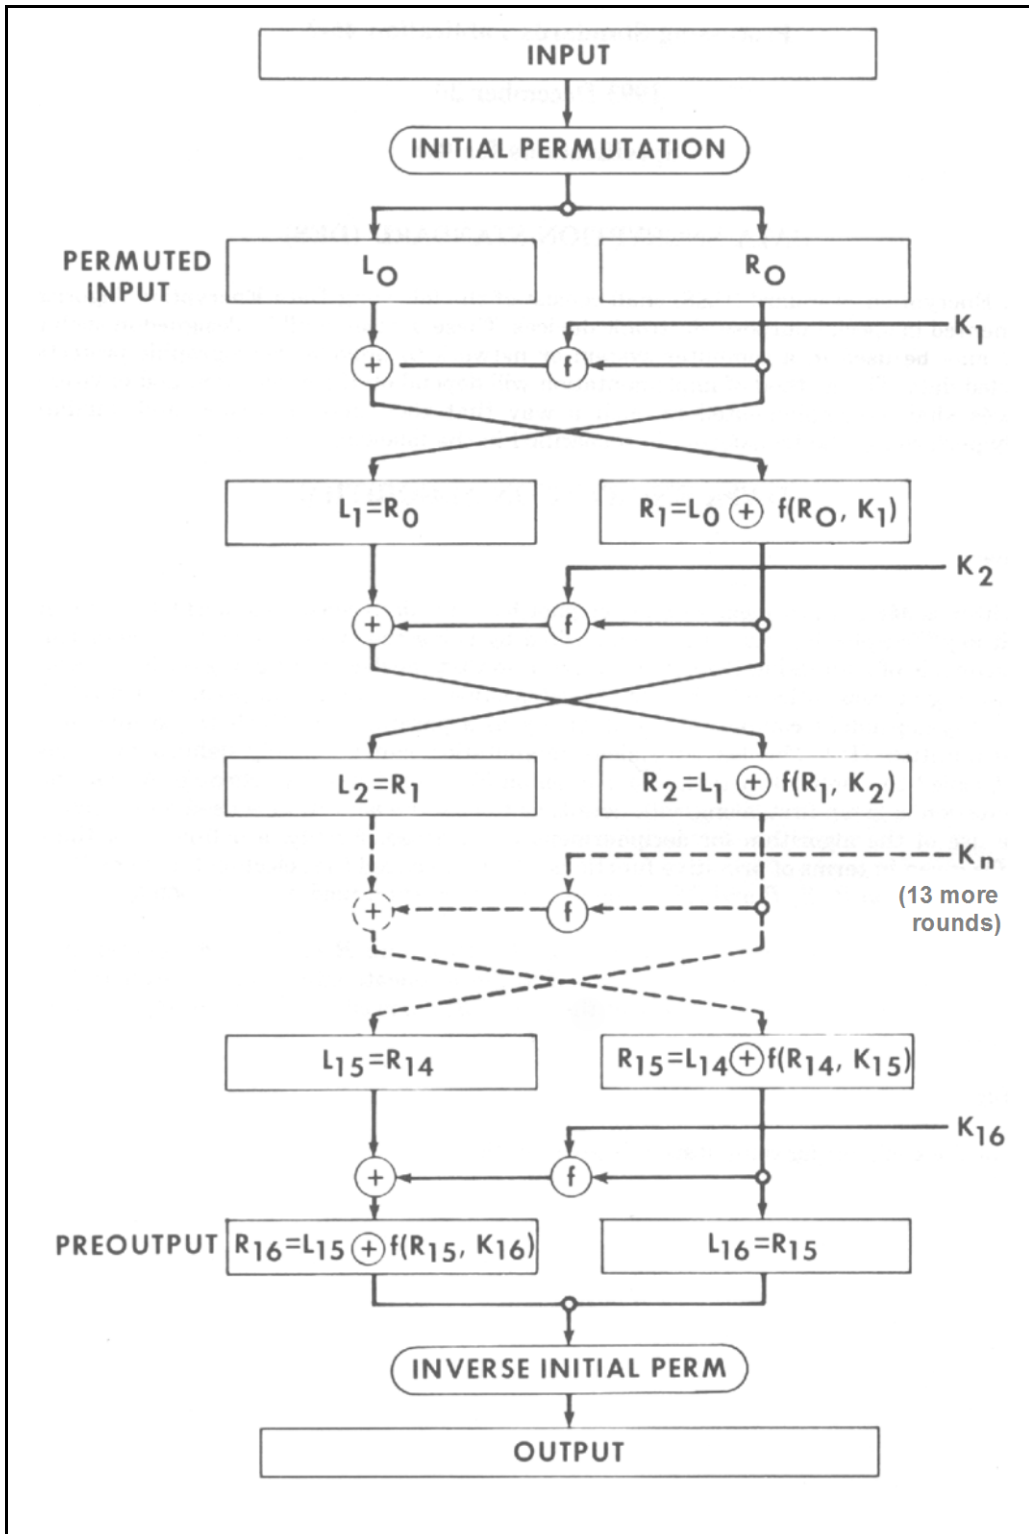

---

<sup>6</sup> Blocks are composed of bits numbered from left to right, i.e., the left-most bit of a block is bit one.

<sup>7</sup> Sometimes keys are generated in an encrypted form. A random 64-bit number is generated and defined to be the cipher formed by the encryption of a key using a key-encrypting key. In this case the parity bits of the encrypted key cannot be set until after the key is decrypted.

<sup>8</sup> Often called "encryption."

<sup>9</sup> Often called "decryption."

**Figure 1. Forward Transformation of the DEA Cryptographic Engine**

The 64 bits of the input block for the forward transformation are first subjected to the following permutation, called the initial permutation **IP**:

<u><i>IP</i></u>							
58	50	42	34	26	18	10	2
60	52	44	36	28	20	12	4
62	54	46	38	30	22	14	6
64	56	48	40	32	24	16	8
57	49	41	33	25	17	9	1
59	51	43	35	27	19	11	3
61	53	45	37	29	21	13	5
63	55	47	39	31	23	15	7

That is, the permuted input has bit 58 of the input as its first bit, bit 50 as its second bit, and so on, with bit 7 as its last bit. The permuted input block is then the input to a complex key-dependent computation that is described below. The output of that computation, called the preoutput, is then subjected to the following permutation that is the inverse of the initial permutation:

<u><i>IP<sup>-1</sup></i></u>							
40	8	48	16	56	24	64	32
39	7	47	15	55	23	63	31
38	6	46	14	54	22	62	30
37	5	45	13	53	21	61	29
36	4	44	12	52	20	60	28
35	3	43	11	51	19	59	27
34	2	42	10	50	18	58	26
33	1	41	9	49	17	57	25

That is, the output of the algorithm has bit 40 of the preoutput block as its first bit, bit 8 as its second bit, and so on, until bit 25 of the preoutput block is the last bit of the output.

The key-dependent computation that uses the permuted input block as its input to produce the preoutput block consists, except for a final interchange of blocks, of 16 iterations of a calculation that is described below in terms of the function  $f$ . This function operates on two blocks, one of 32 bits and one of 48 bits, to produce a block of 32 bits.

Let the 64 bits of the input block to an iteration consist of a 32-bit block  $L$ , followed by a 32-bit block  $R$ . Using the notation defined above, the input block is then  $LR$ .

Let  $K$  be a block of 48 bits chosen from the 64-bit key. Then the output  $L'R'$  of an iteration with input  $LR$  is defined by:

$$(1) \quad \begin{aligned} L' &= R \\ R' &= L \oplus f(R, K) \end{aligned}$$

where  $\oplus$  denotes bit-by-bit addition modulo 2 (also known as exclusive-or or XOR).

As remarked before, the input of the first iteration of the calculation is the permuted input block. If  $L'R'$  is the output of the 16th iteration, then  $R'L'$  is the preoutput block. At each iteration, a different block  $K$  of key bits is chosen from the 64-bit key designated by **KEY**.

With more notation, the iterations of the computation can be described in more detail. Let  $KS$  be a function that takes an integer  $n$  in the range from 1 to 16 and a 64-bit block **KEY** as input. The output of  $KS$  is a 48-bit block  $K_n$  that is a permuted selection of bits from **KEY**. That is:

$$(2) \quad K_n = KS(n, \mathbf{KEY})$$

with  $K_n$  determined by the bits in 48 distinct bit positions of **KEY**.  $KS$  is called the key schedule because the block  $K$  used in the  $n$ 'th iteration of (1) is the block  $K_n$  determined by (2).

As before, let the permuted input block be  $LR$ . Finally, let  $L_{()}$  and  $R_{()}$  be respectively  $L$  and  $R$ , and let  $L_n$  and  $R_n$  be respectively  $L'$  and  $R'$  of (1) when  $L$  and  $R$  are respectively  $L_{n-1}$  and  $R_{n-1}$ , and  $K$  is  $K_n$ ; that is, when  $n$  is in the range from 1 to 16,

$$(3) \quad \begin{aligned} L_n &= R_{n-1} \\ R_n &= L_{n-1} \oplus f(R_{n-1}, K_n) \end{aligned}$$

The preoutput block is then  $R_{16}L_{16}$ .

The key schedule  $KS$  of the algorithm is described in detail in Appendix A. The key schedule produces the 16  $K_n$  that are required for the algorithm.

## 2.2 DEA Inverse Transformation

The permutation  $IP^{-1}$  applied to the preoutput block is the inverse of the initial permutation  $IP$

$$(4) \quad \begin{aligned} R &= L' \\ L &= R' \oplus f(L', K) \end{aligned}$$

Consequently, to apply the inverse transformation, it is only necessary to apply the *very same algorithm to a block of the protected data produced by the forward transformation*, taking care that at each iteration of the computation, *the same block of key bits  $K$  is used during the inverse transformation as was used during the forward transformation*.

Using the notation of the previous section, this can be expressed by the equations:

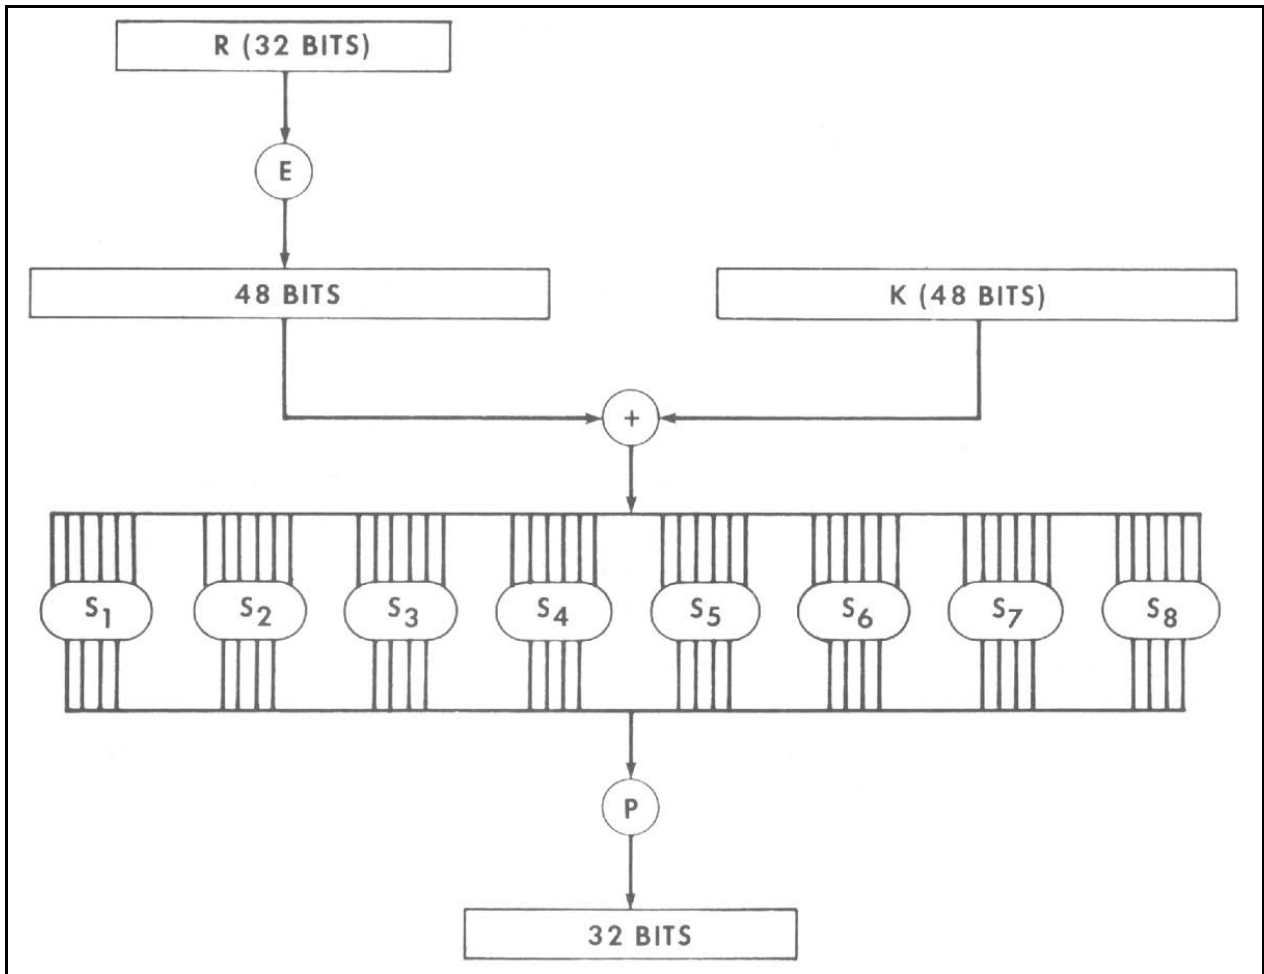

$$(5) \quad \begin{aligned} R_{n-1} &= L_n \\ L_{n-1} &= R_n \oplus f(L_n, K_n) \end{aligned}$$

where  $R_{16}L_{16}$  is the permuted input block for the inverse transformation, and  $L_0R_0$  is the preoutput block. That is, for the inverse transformation with  $R_{16}L_{16}$  as the permuted input,  $K_{16}$  is used in the first iteration,  $K_{15}$  in the second, and so on, with  $K_1$  used in the 16th iteration.

### 2.3 The Function $f$

A sketch of the calculation of  $f(R, K)$  is given in **Figure 2**.

Let  $E$  denote a function that takes a block of 32 bits as input and yields a block of 48 bits as output. Let  $E$  be such that the 48 bits of its output, written as 8 blocks of 6 bits each, are obtained by selecting the bits in its inputs in order according to Table 1:

**Figure 2.** Calculation of  $f(R, K)$

Table 1:  $E$  BIT-SELECTION TABLE

32	1	2	3	4	5
4	5	6	7	8	9
8	9	10	11	12	13
12	13	14	15	16	17

16	17	18	19	20	21
20	21	22	23	24	25
24	25	26	27	28	29
28	29	30	31	32	1

Thus, the first three bits of  $E(\mathbf{R})$  are the bits in positions 32, 1 and 2 of  $\mathbf{R}$ , while the last 2 bits of  $E(\mathbf{R})$  are the bits in positions 32 and 1.

Each of the unique selection functions  $S_1, S_2, \dots, S_8$ , takes a 6-bit block as input and yields a 4-bit block as output and is illustrated by using Table 2. Table 2 contains  $S_1$ :

**Table 2:  $S_1$**

		Column Number															
Row	No.	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	0	14	4	13	1	2	15	11	8	3	10	6	12	5	9	0	7
	1	0	15	7	4	14	2	13	1	10	6	12	11	9	5	3	8
	2	4	1	14	8	13	6	2	11	15	12	9	7	3	10	5	0
	3	15	12	8	2	4	9	1	7	5	11	3	14	10	0	6	13

If  $S_1$  is the function defined in this table, and  $\mathbf{B}$  is a block of 6 bits, then  $S_1(\mathbf{B})$  is determined as follows: The first and last bits of  $\mathbf{B}$  represent, in base 2, a number in the range 0 to 3. Let that number be  $i$ . The middle 4 bits of  $\mathbf{B}$  represent, in base 2, a number in the range 0 to 15. Let that number be  $j$ . Using the table, look up the number in the  $i$ 'th row and  $j$ 'th column. It is a number in the range 0 to 15 and is uniquely represented by a 4-bit block. That block is the output  $S_1(\mathbf{B})$  of  $S_1$  for the input  $\mathbf{B}$ . For example, for input 011011, the row is 01 (i.e., row 1), and the column is determined by 1101 (i.e., column 13). The number 5 appears in row 1, column 13, so the output is 0101.

Selection functions  $S_1, S_2, \dots, S_8$  of the algorithm appear in Appendix A.

The permutation function  $P$  yields a 32-bit output from a 32-bit input by permuting the bits of the input block. Such a function is defined by Table 3:

**Table 3:  $P$**

16	7	20	21
29	12	28	17
1	15	23	26

5	18	31	10
2	8	24	14
32	27	3	9
19	13	30	6
22	11	4	25

The output  $P(L)$  for the function  $P$  defined by this table is obtained from the input  $L$  by taking the 16th bit of  $L$  as the first bit of  $P(L)$ , the 7th bit as the second bit of  $P(L)$ , and so on until the 25th bit of  $L$  is taken as the 32nd bit of  $P(L)$ . The permutation function  $P$  of the algorithm is repeated in Appendix A.

Now let  $S_1, \dots, S_8$  be eight distinct selection functions, let  $P$  be the permutation function, and let  $E$  be the function defined above.

To define  $f(R, K)$ , let  $B_1, \dots, B_8$  be blocks of 6 bits each for which

$$(6) \quad B_1 B_2 \dots B_8 = K \oplus E(R)$$

The block  $f(R, K)$  is then defined to be

$$(7) \quad P(S_1(B_1)S_2(B_2)\dots S_8(B_8))$$

Thus,  $K \oplus E(R)$  is first divided into the 8 blocks as indicated in (6). Then each  $B_i$  is taken as an input to  $S_i$  and the 8 blocks  $S_1(B_1), S_2(B_2), \dots, S_8(B_8)$  of 4 bits each are consolidated into a single block of 32 bits, which forms the input to  $P$ . The result (7) is then the output of the function  $f$  for the inputs  $R$  and  $K$ .

### 3. TRIPLE DATA ENCRYPTION ALGORITHM

#### 3.1 Basic TDEA Forward and Inverse Cipher Operations

In this Recommendation, each TDEA forward and inverse cipher operation is a compound operation of the DEA forward and inverse transformations specified in Section 2.

A TDEA key consists of three keys for the cryptographic engine (**Key**<sub>1</sub>, **Key**<sub>2</sub> and **Key**<sub>3</sub>); the three keys are also referred to as a key bundle (**KEY**). Two options for the selection of the keys in a key bundle are **approved**. Option 1, the preferred option, employs three unique keys (i.e. **Key**<sub>1</sub>, **Key**<sub>2</sub> and **Key**<sub>3</sub>, where **Key**<sub>1</sub> ≠ **Key**<sub>2</sub>, **Key**<sub>2</sub> ≠ **Key**<sub>3</sub>, and **Key**<sub>3</sub> ≠ **Key**<sub>1</sub>). Option 2 employs two unique keys and a third key that is the same as the first key (i.e. **Key**<sub>1</sub>, **Key**<sub>2</sub> and **Key**<sub>3</sub>, where **Key**<sub>1</sub> ≠ **Key**<sub>2</sub> and **Key**<sub>3</sub> = **Key**<sub>1</sub>). A key bundle **shall not** consist of three identical keys.

Let  $F_{KeyX}(d)$  and  $I_{KeyY}(d)$ , respectively, represent the DEA forward and inverse transformations on data  $d$  using key bundle **KEY**. The following operations are used:

1. TDEA forward cipher operation: the transformation of a 64-bit block  $d$  into a 64-bit block  $O$  that is defined as follows:

$$O = F_{Key3}(I_{Key2}(F_{Key1}(d))).$$

2. TDEA inverse cipher operation: the transformation of a 64-bit block  $d$  into a 64-bit block  $O$  that is defined as follows:

$$O = I_{Key1}(F_{Key2}(I_{Key3}(d))).$$

#### 3.2 TDEA Keying Options

This Recommendation specifies the following keying options for a TDEA key bundle (**Key**<sub>1</sub>, **Key**<sub>2</sub>, **Key**<sub>3</sub>)

1. Keying Option 1: **Key**<sub>1</sub>, **Key**<sub>2</sub> and **Key**<sub>3</sub> are unique keys (i.e., **Key**<sub>1</sub> ≠ **Key**<sub>2</sub>, **Key**<sub>2</sub> ≠ **Key**<sub>3</sub>, and **Key**<sub>3</sub> ≠ **Key**<sub>1</sub>);
2. Keying Option 2: **K**<sub>1</sub> and **K**<sub>2</sub> are unique keys (i.e., **Key**<sub>1</sub> ≠ **Key**<sub>2</sub>, and **Key**<sub>3</sub> = **Key**<sub>1</sub>).

#### 3.3 TDEA Modes of Operation

TDEA **shall** be implemented using one or more of the modes of operation specified in SP 800-38. These modes of operation are **approved** for the protection of Federal government sensitive, but unclassified information. Each of the modes employs the TDEA forward or inverse cipher operations as defined in Section 3.1. Note that the TDEA block cipher **shall** be used to provide cryptographic security only when used in an **approved** mode of operation.

#### 3.4 Keys

The TDEA keys **shall** be managed in accordance with SP 800-57, Part 1. SP 800-57, Part 1 also specifies time frames during which the TDEA keying options may be used.

### 3.4.1 Key Requirements

For all TDEA modes of operation, three cryptographic keys (**Key<sub>1</sub>**, **Key<sub>2</sub>**, **Key<sub>3</sub>**) define a TDEA key bundle. The bundle and the individual keys **shall**:

- a. be kept secret;
- b. be generated using an **approved** method<sup>10</sup> that is based on the output of an **approved** random bit generator<sup>11</sup>;
- c. be independent of other key bundles;
- d. have integrity whereby each key in the bundle has not been altered in an unauthorized manner since the time it was generated, transmitted, or stored by an authorized entity;
- e. be used in the appropriate order as specified by the particular mode;
- f. be considered a fixed quantity in which an individual key cannot be manipulated while leaving the other two keys unchanged; and cannot be unbundled except for its designated purpose.

### 3.4.2 Weak Keys

There are a few keys that are considered weak for the DEA cryptographic engine. The use of weak keys can reduce the effective security afforded by TDEA and should be avoided. Keys that are considered weak are (in hexadecimal format):

- 01010101 01010101
- FEF EFEFE FEF EFEFE
- E0E0E0E0 F1F1F1F1
- 1F1F1F1F 0E0E0E0E

Note that the weak keys listed above and the semi-weak keys and the possibly weak keys listed below are expressed with odd parity, which is indicated in the rightmost bit of each byte.

Some pairs of keys encrypt plaintext to identical ciphertext and also should be avoided. These semi-weak keys are (in hexadecimal format):

- 011F011F010E010E and 1F011F010E010E01
- 01E001E001F101F1 and E001E001F101F101
- 01FE01FE01FE01FE and FE01FE01FE01FE01
- 1FE01FE00EF10EF1 and E01FE01FF10EF10E
- 1FFE1FFE0EFE0EFE and FE1FFE1FFE0EFE0E

---

### 3.5 Usage Guidance

The security of TDEA is affected by the number of blocks processed with one key bundle. One key bundle **shall not** be used to process more than  $2^{32}$  64-bit data blocks when the keys conform to Keying Option 1 (see Section 3.2). When Keying Option 2 is used, the keys **shall not** be used to process more than  $2^{20}$  blocks (see SP 800-131A).

## APPENDIX A: PRIMITIVE FUNCTIONS FOR THE DATA ENCRYPTION ALGORITHM

The choice of the primitive functions  $KS$ ,  $S_1, \dots, S_8$  and  $P$  is critical to the strength of the transformations resulting from the algorithm. The tables below specify the functions  $S_1, \dots, S_8$  and  $P$ . For the interpretation of the tables describing these functions, see the discussion in Section 2.

The primitive functions  $S_1, \dots, S_8$  are:

### $S_1$

14	4	13	1	2	15	11	8	3	10	6	12	5	9	0	7
0	15	7	4	14	2	13	1	10	6	12	11	9	5	3	8
4	1	14	8	13	6	2	11	15	12	9	7	3	10	5	0
15	12	8	2	4	9	1	7	5	11	3	14	10	0	6	13

### $S_2$

15	1	8	14	6	11	3	4	9	7	2	13	12	0	5	10
3	13	4	7	15	2	8	14	12	0	1	10	6	9	11	5
0	14	7	11	10	4	13	1	5	8	12	6	9	3	2	15
13	8	10	1	3	15	4	2	11	6	7	12	0	5	14	9

### $S_3$

10	0	9	14	6	3	15	5	1	13	12	7	11	4	2	8
13	7	0	9	3	4	6	10	2	8	5	14	12	11	15	1
13	6	4	9	8	15	3	0	11	1	2	12	5	10	14	7
1	10	13	0	6	9	8	7	4	15	14	3	11	5	2	12

### $S_4$

7	13	14	3	0	6	9	10	1	2	8	5	11	12	4	15
13	8	11	5	6	15	0	3	4	7	2	12	1	10	14	9
10	6	9	0	12	11	7	13	15	1	3	14	5	2	8	4
3	15	0	6	10	1	13	8	9	4	5	11	12	7	2	14

### $S_5$

2	12	4	1	7	10	11	6	8	5	3	15	13	0	14	9
14	11	2	12	4	7	13	1	5	0	15	10	3	9	8	6

4 2 1 11 10 13 7 8 15 9 12 5 6 3 0 14  
 11 8 12 7 1 14 2 13 6 15 0 9 10 4 5 3

S<sub>6</sub>

12 1 10 15 9 2 6 8 0 13 3 4 14 7 5 11  
 10 15 4 2 7 12 9 5 6 1 13 14 0 11 3 8  
 9 14 15 5 2 8 12 3 7 0 4 10 1 13 11 6  
 4 3 2 12 9 5 15 10 11 14 1 7 6 0 8 13

S<sub>7</sub>

4 11 2 14 15 0 8 13 3 12 9 7 5 10 6 1  
 13 0 11 7 4 9 1 10 14 3 5 12 2 15 8 6  
 1 4 11 13 12 3 7 14 10 15 6 8 0 5 9 2  
 6 11 13 8 1 4 10 7 9 5 0 15 14 2 3 12

S<sub>8</sub>

13 2 8 4 6 15 11 1 10 9 3 14 5 0 12 7  
 1 15 13 8 10 3 7 4 12 5 6 11 0 14 9 2  
 7 11 4 1 9 12 14 2 0 6 10 13 15 3 5 8  
 2 1 14 7 4 10 8 13 15 12 9 0 3 5 6 11

The primitive function **P** is:

16	7	20	21
29	12	28	17
1	15	23	26
5	18	31	10
2	8	24	14
32	27	3	9
19	13	30	6
22	11	4	25

Recall that  $\mathbf{K}_n$ , for  $1 \leq n \leq 16$ , is the block of 48 bits of the algorithm in (2). Hence, to describe  $\mathbf{KS}$ , it is sufficient to describe the calculation of  $\mathbf{K}_n$  from a key ( $\mathbf{Key}_i$ ) of the key bundle for  $n = 1, 2, \dots, 16$ . That calculation is illustrated in Figure 4. To complete the definition of  $\mathbf{KS}$ , it is therefore sufficient to describe the two permuted choices, as well as the schedule of left shifts. One bit in each 8-bit byte of  $\mathbf{Key}_i$  may be utilized for error detection in key generation,

distribution and storage. Bits 8, 16,..., 64 are for use in assuring that each byte is of odd parity. (Note that these eight parity bits have no effect on the operation of the algorithm.)

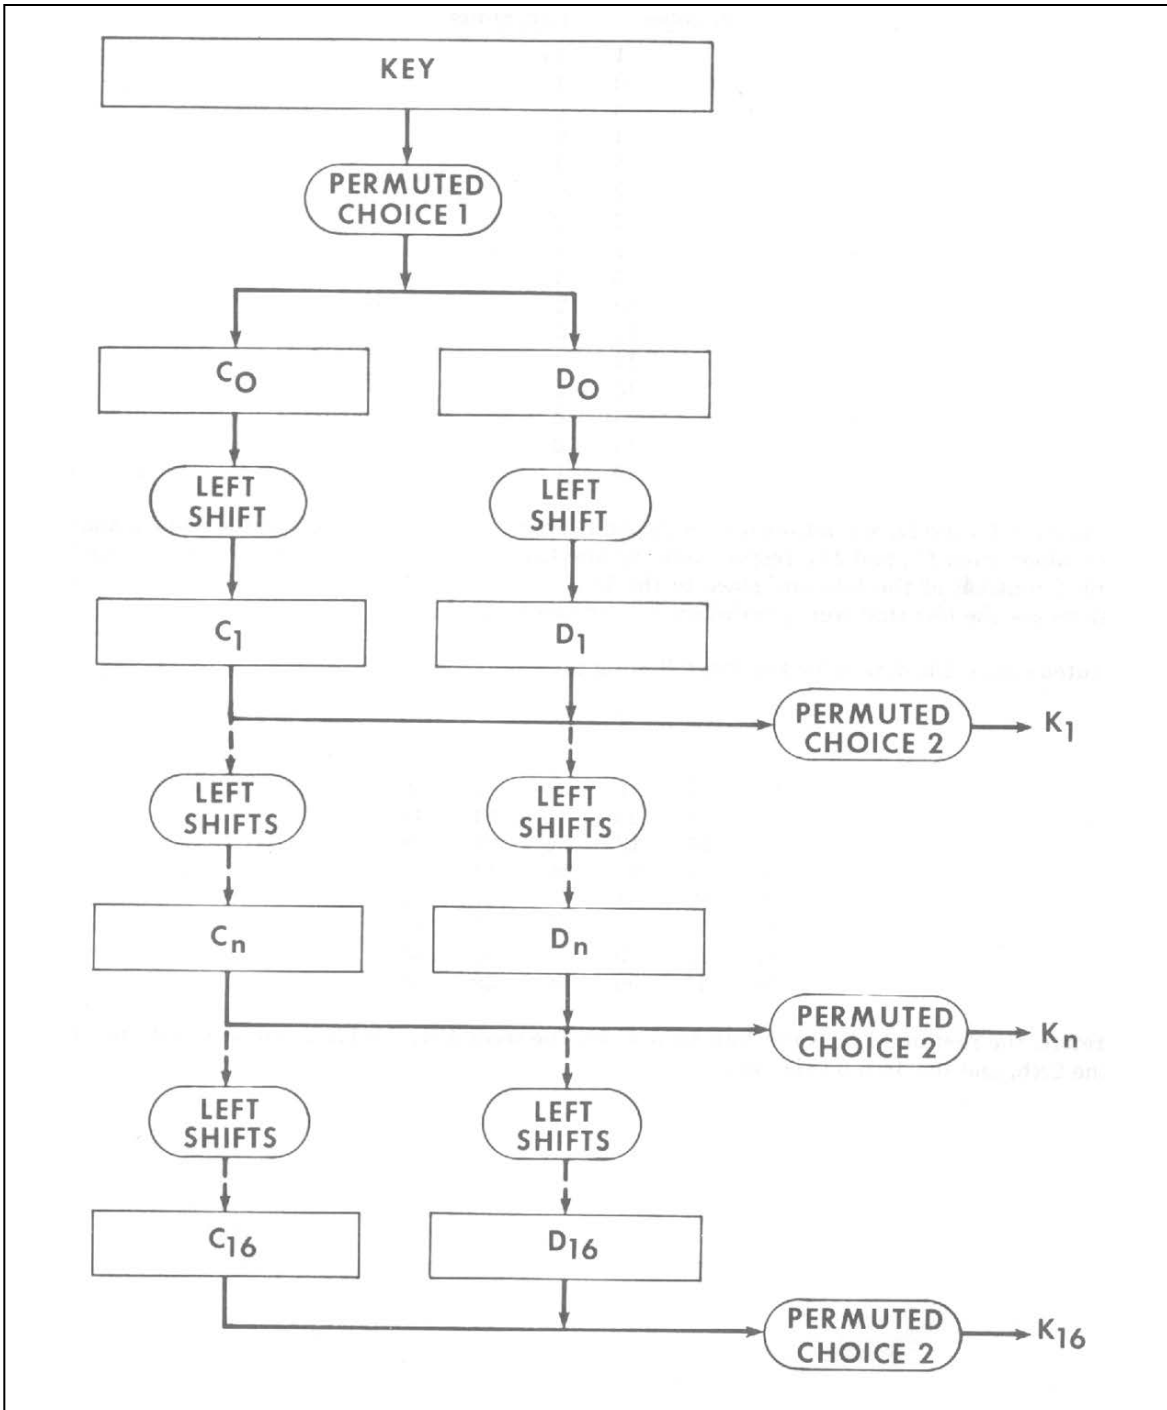

Figure 4: Key Schedule Calculation

Permuted choice 1 is determined by the following table:

<u><b>PC-1</b></u>						
57	49	41	33	25	17	9
1	58	50	42	34	26	18
10	2	59	51	43	35	27
19	11	3	60	52	44	36
63	55	47	39	31	23	15
7	62	54	46	38	30	22
14	6	61	53	45	37	29
21	13	5	28	20	12	4

The table has been divided into two parts, with the first part determining how the bits of  $C_{()}$  are chosen, and the second part determining how the bits of  $D_{()}$  are chosen. The bits of  $Key_i$  are numbered 1 through 64. The bits of  $C_{()}$  are respectively bits 57, 49, 41, ..., 44 and 36 of  $Key_i$ , with the bits of  $D_{()}$  being bits 63, 55, 47, ..., 12 and 4 of  $Key_i$ .

With  $C_{()}$  and  $D_{()}$  defined, the blocks  $C_n$  and  $D_n$  are obtained from the blocks  $C_{n-1}$  and  $D_{n-1}$ , respectively, for  $n = 1, 2, \dots, 16$ , by adhering to the following schedule of left shifts of the individual blocks:

<i>Iteration</i>	<i>Number of</i>
<i>Number</i>	<i>Left Shifts</i>
1	1
2	1
3	2
4	2
5	2
6	2
7	2
8	2
9	1
10	2
11	2
12	2

13	2
14	2
15	2
16	1

For example,  $C_3$  and  $D_3$  are obtained from  $C_2$  and  $D_2$ , respectively, by two left shifts, and  $C_{16}$  and  $D_{16}$  are obtained from  $C_{15}$  and  $D_{15}$ , respectively, by one left shift. In all cases, by a single left shift is meant a rotation of the bits one place to the left, so that after one left shift the bits in the 28 positions are the bits that were previously in positions 2, 3, ..., 28, 1.

Permuted choice 2 is determined by the following table:

<u>PC-2</u>					
14	17	11	24	1	5
3	28	15	6	21	10
23	19	12	4	26	8
16	7	27	20	13	2
41	52	31	37	47	55
30	40	51	45	33	48
44	49	39	56	34	53
46	42	50	36	29	32

Therefore, the first bit of  $K_n$  is the 14<sup>th</sup> bit of  $C_nD_n$ , the second bit of  $K_n$  is the 17<sup>th</sup> bit of  $C_nD_n$ , and so on, with the 47<sup>th</sup> bit of  $K_n$  as the 29<sup>th</sup> bit of  $C_nD_n$ , and the 48<sup>th</sup> bit of  $K_n$  as the 32<sup>nd</sup> bit of  $C_nD_n$ .

## APPENDIX B: EXAMPLE OF TDEA FORWARD AND INVERSE CIPHER OPERATIONS

This Appendix presents an example that may be used when implementing the TDEA forward and inverse cipher operations. Appendices B.1 and B.2 provide an example of TDEA forward and inverse cipher operations in the Electronic Codebook (ECB) mode as specified in SP 800-38A.

In this example, all keys, plaintext and ciphertext are expressed in hexadecimal. The example uses three independent keys (Keying Option 1), which are:

$$Key_1 = 0123456789ABCDEF$$

$$Key_2 = 23456789ABCDEF01$$

$$Key_3 = 456789ABCDEF0123$$

The plaintext for the example is selected from the ASCII encoding of the phrase “The quick brown fox jumped over the lazy dog’s back”. The example employs the first 24 characters of the phrase (i.e., The quick brown fox jump).

The ASCII encoding of the above phrase is segmented as follows:

P <sub>1</sub>	“The quic”	5468652071756663
P <sub>2</sub>	“k brown ”	6B2062726F776E20
P <sub>3</sub>	“fox jump”	666F78206A756D70

### B.1 TDEA Block Cipher Forward Cipher Operations - ECB Mode

In the example below, the input and output of the DEA cryptographic engine are given sequentially. At step 1, the input to DEA<sub>1</sub> is P<sub>1</sub>, and the output of DEA<sub>1</sub> is “A28E91724C4BBA31”. At step 2, the input to DEA<sub>2</sub> is the output of DEA<sub>1</sub>, and the output of DEA<sub>2</sub> is “5A2EA7F983A2F53F”. At step 3, the input to DEA<sub>3</sub> is the output of DEA<sub>2</sub>, and the output of DEA<sub>3</sub> is “A826FD8CE53B855F”. The output of DEA<sub>3</sub> is the ciphertext C<sub>1</sub>.

$$P_1 = \text{“The quic”} = 5468652071756663$$

Transformation and key used	Input	Output
DEA <sub>1</sub> - F <sub>Key1</sub>	5468652071756663	A28E91724C4BBA31
DEA <sub>2</sub> - I <sub>Key2</sub>	A28E91724C4BBA31	5A2EA7F983A2F53F
DEA <sub>3</sub> - F <sub>Key3</sub>	5A2EA7F983A2F53F	A826FD8CE53B855F

$C_1 = A826FD8CE53B855F$

During the second TDEA operation, the input is  $P_2$ , and the output after the three steps is ciphertext  $C_2$ .

$P_2 = \text{“k brown”} = 6B2062726F776E20$

Transformation and key used	Input	Output
$DEA_1 - F_{Key1}$	6B2062726F776E20	167E47EC24F71D63
$DEA_2 - I_{Key2}$	167E47EC24F71D63	EA141A7DD69701F0
$DEA_3 - F_{Key3}$	EA141A7DD69701F0	CCE21C8112256FE6

$C_2 = CCE21C8112256FE6$

During the third TDEA operation, the input is  $P_3$ , and the output after the three steps is ciphertext  $C_3$ .

$P_3 = \text{“fox jump”} = 666F78206A756D70$

Transformation and key used	Input	Output
$DEA_1 - F_{Key1}$	666F78206A756D70	2C1A917234425365
$DEA_2 - I_{Key2}$	2C1A917234425365	8059EE8212E22A79
$DEA_3 - F_{Key3}$	8059EE8212E22A79	68D5C05DD9B6B900

$C_3 = 68D5C05DD9B6B900$

The resulting ciphertext is the concatenation of  $C_1$ ,  $C_2$  and  $C_3$  (i.e.,  $A826FD8CE53B855F CCE21C8112256FE6 68D5C05DD9B6B900$ ).

### **B.2 TDEA Block Cipher Inverse Cipher Operation - ECB Mode**

During inverse cipher operations in the ECB mode, the ciphertext  $C_1$ ,  $C_2$  and  $C_3$  from Appendix B.1 are fed into the TDEA to produce the plaintext  $P_1$ ,  $P_2$  and  $P_3$ . The output of  $DEA_3$  becomes the input to  $DEA_2$ , and the output of  $DEA_2$  becomes the input to  $DEA_1$ .

$C_1 = A826FD8CE53B855F$

Transformation and key used	Input	Output
-----------------------------	-------	--------

$DEA_3 - I_{Key3}$	A826FD8CE53B855F	5A2EA7F983A2F53F
$DEA_2 - F_{Key2}$	5A2EA7F983A2F53F	A28E91724C4BBA31
$DEA_1 - I_{Key1}$	A28E91724C4BBA31	5468652071756663

$P_1 = 5468652071756663 = \text{“The quic”}$ .

$C_2 = CCE21C8112256FE6$

<b>Transformation and key used</b>	<b>Input</b>	<b>Output</b>
$DEA_3 - I_{Key3}$	CCE21C8112256FE6	EA141A7DD69701F0
$DEA_2 - F_{Key2}$	EA141A7DD69701F0	167E47EC24F71D63
$DEA_1 - I_{Key1}$	167E47EC24F71D63	6B2062726F776E20

$P_2 = 6B2062726F776E20 = \text{“k brown”}$ .

$C_3 = 68D5C05DD9B6B900$

<b>Transformation and key used</b>	<b>Input</b>	<b>Output</b>
$DEA_3 - I_{Key3}$	68D5C05DD9B6B900	8059EE8212E22A79
$DEA_2 - F_{Key2}$	8059EE8212E22A79	2C1A917234425365
$DEA_1 - I_{Key1}$	2C1A917234425365	666F78206A756D70

$P_3 = 666F78206A756D70 = \text{“fox jump”}$ .

The plaintext is the ASCII encoding of “The quick brown fox jump”.

**APPENDIX C: GLOSSARY**

Approved	FIPS-approved or NIST-recommended: an algorithm or technique that is either 1) specified in a FIPS or NIST Recommendation, or 2) adopted in a FIPS or NIST Recommendation.
Authentication	Provides assurance of the authenticity and, therefore, the integrity of data.
Bit	A binary digit having a value of zero or one.
Block	In this Recommendation, a binary string, for example, a plaintext or a ciphertext, is segmented with a given length. Each segment is called a block. Data is processed block by block, from left to right.
Block Cipher Algorithm	A family of functions and their inverses that is parameterized by a cryptographic key; the function maps bit strings of a fixed length to bit strings of the same length.
Byte	A group of eight bits that is treated either as a single entity or as an array of eight individual bits.
Ciphertext	Encrypted (enciphered) data.
Cryptographic Key	A parameter that determines the transformation using DEA and TDEA forward and inverse operations.
Data Encryption Algorithm	The DEA cryptographic engine that is used by the Triple Data Encryption Algorithm (TDEA).
Decryption	The process of transforming ciphertext into plaintext.
Encryption	The process of transforming plaintext into ciphertext.
Exclusive-OR	The bit-by-bit modulo 2 addition of binary vectors of equal length.
FIPS	Federal Information Processing Standard.
Forward Cipher Operation/Forward Transformation	One of the two functions of the block cipher algorithm that is determined by the choice of a cryptographic key. The term “forward cipher operation” is used for TDEA, while the term “forward transformation” is used for DEA.

Inverse Cipher Operation/Inverse Transformation	The block cipher algorithm function that is the inverse of the forward cipher function. The term “inverse cipher operation” is used for TDEA, while the term “inverse transformation” is used for DEA.
Key	See cryptographic key.
Key Bundle	The three cryptographic keys ( $Key_1$ , $Key_2$ , $Key_3$ ) that are used with a TDEA mode.
Plaintext	Intelligible data that has meaning and can be read or acted upon without the application of decryption. Also known as cleartext.

## APPENDIX E: CONFORMANCE REQUIREMENTS FOR INSTALLATION, CONFIGURATION AND USE

Conformance to many of the requirements in this Recommendation are the responsibility of entities installing, configuring or using applications or protocols that incorporate this Recommendation. These requirements include the following:

Section	Requirement
1	TDEA functions incorporating the DEA cryptographic engine <b>shall</b> be designed in such a way that they may be used in a computer system, storage facility, or network to provide cryptographic protection to binary coded data.
2	Each 64-bit key <b>shall</b> contain 56 bits that are randomly generated and used directly by the algorithm as key bits.
3.1	A key bundle <b>shall not</b> consist of three identical keys.
3.3	Note that the TDEA block cipher <b>shall</b> be used to provide cryptographic security only when used in an <b>approved</b> mode of operation.
3.4	The TDEA keys <b>shall</b> be managed in accordance with NIST Special Publication (SP) 800-57, Part 1.
3.4	The following specifications for keys <b>shall</b> be met in implementing the TDEA modes of operation.
3.4.1	The bundle and the individual keys <b>shall</b> : <ul style="list-style-type: none"> <li>a. be kept secret;</li> <li>b. be generated using an <b>approved</b> method<sup>12</sup> that is based on the output of an <b>approved</b> random bit generator<sup>13</sup>;</li> <li>c. be independent of other key bundles;</li> <li>d. have integrity whereby each key in the bundle has not been altered in an unauthorized manner since the time it was generated, transmitted, or stored by an authorized source;</li> <li>e. be used in the appropriate order as specified by the particular mode;</li> <li>f. be considered a fixed quantity in which an individual key cannot be manipulated while leaving the other two keys unchanged; and cannot be unbundled except for its designated purpose.</li> </ul>
3.5	One key bundle <b>shall not</b> be used to process more than $2^{32}$ 64-bit data blocks when the keys conform to Keying Option 1
3.5	When Keying Option 2 is used, the keys <b>shall not</b> be used to process more than $2^{20}$ blocks (see [SP 800-131A]).

<sup>12</sup> See SP 800-133.

<sup>13</sup> See SP 800-90 and FIPS 140-2, Annex C.

## APPENDIX F: CHANGES

Version 1.1 modified the list of weak keys in Section 3.4.2, correcting the third and fourth weak keys in the list. In addition, a note was inserted that the actual values of the parity bits were ignored when listing the weak and semi-weak keys.

In version 1.2, the following non-editorial modifications have been made:

1. The authority section was updated, primarily to include a paragraph about validation testing.
2. References to American National Standard X9.52, *Triple Data Encryption Algorithm Modes Of Operation*, have been removed, since the standard was withdrawn.
3. Various parts of SP 800-38 have been referenced: SP 800-90 and FIPS 140-2, Annex C, have been referenced for random bit generators; SP 800-131A has been referenced for the transition away from two-key TDEA; and SP 800-133 has been referenced for key generation.
4. The previous Section 1.1, *Basis*, was removed, since the information is provided in the Authority section.
5. The previous Section 1.2, *Applicability*, was removed.
6. In Table 3 of Section 2.3, the third entry in the first row was corrected to be “20.”
7. In Section 3.1, the relationship of the acceptable keys used for TDEA has been further clarified.
8. In Section 3.5, the “should not” in the statement “One key bundle should not be used to process more than  $2^{32}$  64-bit data blocks when the keys conform to Keying Option 1...” has been changed to “**shall not.**”
9. In Section 3.4.1, line 2, the “must” was changed to “**shall.**”
10. In Section 3.5, guidance for the use of Keying Options 1 and 2 was further clarified. In addition, the “should not” in the statement “One key bundle should not be used to process more than  $2^{32}$  64-bit data blocks when the keys conform to Keying Option 1...” has been changed to “**shall not.**”
11. In Appendix D, additional references were provided for SP 800-131A and SP 800-133.
12. Appendix E was added to identify requirements that are the responsibility of entities that install, configure or use applications or protocols that incorporate TDEA.
