## The problem

$$\min_{x \in \mathsf{R}^n} f(x) \tag{1}$$

- $f: \mathbb{R}^n \to \mathbb{R}$  nonlinear, twice-continuously differentiable and bounded below
- No convexity assumption
- (1) results from the discretization of some infinite-dimensional problem on a relatively fine grid for instance (*n* large)

 $\longrightarrow$  Iterative search of a first-order critical point  $x_*$  (s.t.  $\nabla f(x_*) = 0$ )

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

## Basic trust-region algorithm

### <u>At iteration k</u> (at $x_k$ ):

- 1 Define a local model  $m_k(x_k + s)$  of f around  $x_k$  (Taylor's model)
- 2 Compute a candidate step  $s_k$  that (approximately) solves

ſ	$minimize_{s\in \mathbf{R}^n}$	$m_k(x_k+s)$
ĺ	subject to	$\ s\  \leq \Delta_k$

3 Compute  $f(x_k + s_k)$  and  $\rho_k = \frac{f(x_k) - f(x_k + s_k)}{m_k(x_k) - m_k(x_k + s_k)}$ 

0 Update the iterate  $x_k$  and the trust-region radius  $\Delta_k$ 

$$x_{k+1} = \begin{cases} x_k + s_k & \text{if } \rho_k \ge \eta_1 \\ x_k & \text{if } \rho_k < \eta_1 \end{cases} \quad \Delta_{k+1} = \begin{cases} \max(\alpha_2 \|s_k\|, \ \Delta_k) & \text{if } \rho_k \ge \eta_2 \\ \Delta_k & \text{if } \rho_k \in [\eta_1, \eta_2) \\ \alpha_1 \|s_k\| & \text{if } \rho_k < \eta_1 \end{cases}$$

where  $0 < \eta_1 \leq \eta_2 < 1$  and  $0 < \alpha_1 < 1 < \alpha_2$ 

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients Model construction The recursive algorithm

## The minimum surface problem

$$\min_{v} \int_{0}^{1} \int_{0}^{1} \left( 1 + (\partial_{x}v)^{2} + (\partial_{y}v)^{2} \right)^{\frac{1}{2}} dx dy$$

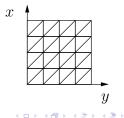

with the boundary conditions:

 $\rightarrow$  Discretization using a finite element basis

$$\left\{ \begin{array}{ll} f(x), & y=0, & 0 \leq x \leq 1 \\ 0, & x=0, & 0 \leq y \leq 1 \\ f(x), & y=1, & 0 \leq x \leq 1 \\ 0, & x=1, & 0 \leq y \leq 1 \end{array} \right.$$

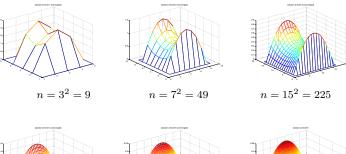

where

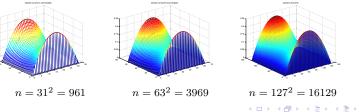

$$f(x) = x * (1 - x)$$

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients Model construction The recursive algorithm

## The solution at different levels

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work Main algorithmic ingredients

## The framework

### Assume that

- we know a collection of functions  $\{f_i\}_{i=0}^r$  s.t.  $f_i: \mathbb{R}^{n_i} \to \mathbb{R} \in \mathcal{C}^2$  and  $n_i > n_{i-1}$
- $n_r = n$  and  $f_r(x) = f(x)$  for all  $x \in \mathbb{R}^n$

such that, for each  $i = 1, \ldots, r$ 

- $f_i$  is "more costly" to minimize than  $f_{i-1}$
- there exist full-rank linear operators:

 $\left. \begin{array}{l} R_i: \mathsf{R}^{n_i} \to \mathsf{R}^{n_{i-1}} \text{ (the restriction)} \\ P_i: \mathsf{R}^{n_{i-1}} \to \mathsf{R}^{n_i} \text{ (the prolongation)} \end{array} \right\} \text{ such that } \sigma_i P_i = R_i^T \quad (\sigma_i = \|P_i\|^{-1}) \end{array}$ 

#### Terminology

- a particular i is referred to as a level
- a subscript i is used to denote a quantity corresponding to the i-th level

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients Model construction The recursive algorithm

## The idea

 $\rightarrow$  If more than two levels are available (r > 1), do this recursively

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients Model construction The recursive algorithm

## Additional ingredients

- Construction of the coarse local models: first-order coherence
- Use of the coarse local models: coarsening condition
- Trust-region constraint preservation

<ロト < 同ト < 三ト

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients **Model construction** The recursive algorithm

### Construction of the coarse models

At a given iteration (i, k) with current iterate  $x_{i,k}$ 

• Restrict  $x_{i,k}$  to create the starting iterate  $x_{i-1,0}$  at level i-1

 $x_{i-1,0} = R_i x_{i,k}$ 

• Define the lower level model  $h_{i-1}$  around  $x_{i-1,0}$ 

$$h_{i-1}(x_{i-1,0} + s_{i-1}) \stackrel{\text{def}}{=} f_{i-1}(x_{i-1,0} + s_{i-1}) + v_{i-1}^T s_{i-1}$$

where

$$v_{i-1} = R_i \nabla h_i(x_{i,k}) - \nabla f_{i-1}(x_{i-1,0})$$

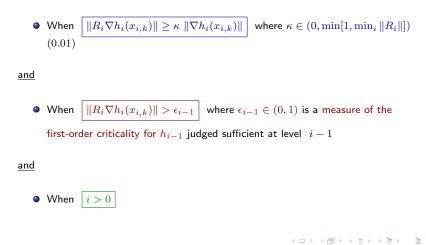

so that

$$\nabla h_{i-1}(x_{i-1,0}) = R_i \nabla h_i(x_{i,k})$$

Coherence of first-order information

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients **Model construction** The recursive algorithm

## Use of the coarse models

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients **Model construction** The recursive algorithm

## Choosing a model

Assume that we enter level i and want to (locally) minimize  $h_i$  starting from  $x_{i,0}$ 

At iteration  $\boldsymbol{k}$  of this minimization

• Choose a local model of 
$$h_i$$
 at  $x_{i,k}$ :   
the coarse model
the coarse model

• Compute a candidate step  $s_{i,k}$  that generates a decrease on this model within

 $\mathcal{B}_{i,k} = \{s_i \mid \|s_i\|_i \le \Delta_{i,k}\}$ 

where  $\Delta_{i,k} > 0$  and  $\|\cdot\|_i$  is a level-dependent norm

< ロ > < 同 > < 三 > < 三 > 、

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients **Model construction** The recursive algorithm

# Using Taylor's model

The step  $s_{i,k}$  is computed such that it approximately solves

$$\begin{split} & \text{minimize}_{s_i \in \mathbb{R}^{n_i}} \quad m_{i,k}(x_{i,k}+s_i) = h_i(x_{i,k}) + g_{i,k}^T s_i + \frac{1}{2} \; s_i^T H_{i,k} s_i \\ & \text{subject to} \qquad \qquad \|s_i\|_i \leq \Delta_{i,k} \end{split}$$

where  $g_{i,k} \stackrel{\text{def}}{=} \nabla h_i(x_{i,k})$  and  $H_{i,k} \approx \nabla^2 h_i(x_{i,k})$ 

The decrease of  $m_{i,k}$  is understood in its usual meaning for trust-region methods, i.e.,  $s_{i,k}$  must satisfy the "sufficient decrease" condition:

$$m_{i,k}(x_{i,k}) - m_{i,k}(x_{i,k} + s_{i,k}) \ge \kappa_{\text{red}} \|g_{i,k}\| \min\left[\frac{\|g_{i,k}\|}{1 + \|H_{i,k}\|}, \, \Delta_{i,k}\right]$$

for some  $\kappa_{\text{red}} \in (0, 1)$ 

< ロ > < 同 > < 回 > < 回 >

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients **Model construction** The recursive algorithm

## Using the coarse model

Defining the level-dependent norm  $\|\cdot\|_{i-1}$  by

$$\|\cdot\|_r = \|\cdot\|_2$$
 and  $\|s_{i-1}\|_{i-1} = \|P_i s_{i-1}\|_i$  for  $i = 1, \dots, r$ 

then the lower level subproblem consists in approximately solving

$$\begin{cases} \text{minimize}_{s_{i-1} \in \mathbb{R}^{n_{i-1}}} & h_{i-1}(x_{i-1,0} + s_{i-1}) \\\\ \text{subject to} & \|s_{i-1}\|_{i-1} \leq \boxed{\Delta_{i,k}} \end{cases}$$

yielding a point  $x_{i-1,*}$  such that

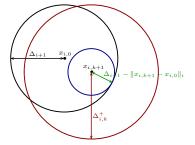

$$h_{i-1}(x_{i-1,*}) < h_{i-1}(x_{i-1,0})$$

and a corresponding step  $x_{i-1,*} - x_{i-1,0}$  which is brought back to level i

$$s_{i,k} = P_i(x_{i-1,*} - x_{i-1,0})$$

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients **Model construction** The recursive algorithm

## Preserving the trust-region constraint

Trust-region radius update:

$$\Delta_{i,k+1} = \min\left[\Delta_{i,k}^{+}, \, \Delta_{i+1} - \|x_{i,k+1} - x_{i,0}\|_{i}\right]$$
where

$$\Delta_{i,k}^{+} = \begin{cases} \max[\alpha_{2} \| s_{i,k} \|, \Delta_{i,k}] & \text{if } \rho_{i,k} \ge \eta_{2} \\ \Delta_{i,k} & \text{if } \rho_{i,k} \in [\eta_{1}, \eta_{2}) \\ \alpha_{1} \| s_{i,k} \| & \text{if } \rho_{i,k} < \eta_{1} \end{cases}$$

< □ > < 同 > < 三 >

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients Model construction The recursive algorithm

Algorithm RMTR(i,  $x_{i,0}$ , $g_{i,0}$ ,  $\Delta_{i+1}$ )

(First call with arguments  $r,\,x_{r,0},\,\nabla f_r(x_{r,0})$  and  $\infty)$ 

Step 0: Initialization

- Compute  $v_i$  and  $h_i(x_{i,0})$
- Set  $\Delta_{i,0} = \Delta_{i+1}$  (or some  $\Delta_r^s$  if i = r) and k = 0

Step 1: Model choice

• If i = 0 or if  $||R_i g_{i,k}|| < 0.01 ||g_{i,k}||$  or if  $||R_i g_{i,k}|| \le \epsilon_{i-1}$ , go to Step 3

• Otherwise, choose to go to Step 2 (recursive step) or to Step 3 (Taylor step)

#### Step 2: Recursive step computation

• Call Algorithm RMTR(i - 1,  $R_i x_{i,k}$ ,  $R_i g_{i,k}$ ,  $\Delta_{i,k}$ ), yielding an approximate solution

$$\begin{array}{c} x_{i-1,*} \quad \text{of} \\ \\ \left\{ \begin{array}{l} \text{minimize}_{s_{i-1} \in \mathsf{R}^{n_{i-1}}} & h_{i-1}(R_i x_{i,k} + s_{i-1}) \\ \text{subject to} & \|s_{i-1}\|_{i-1} \leq \underline{\Delta}_{i,k} \end{array} \right.$$

• Define 
$$s_{i,k} = P_i(x_{i-1,*} - R_i x_{i,k})$$
  
• Set  $\delta_{i,k} = h_{i-1}(R_i x_{i,k}) - h_{i-1}(x_{i-1,*})$  and go to Step 4

### Step 3: Taylor step computation

• Choose  $H_{i,k}$  and compute  $s_{i,k} \in \mathbb{R}^{n_i}$  that approximately solves

$$\begin{array}{ll} \text{minimize}_{s_i \in \mathbb{R}^{n_i}} & m_{i,k}(x_{i,k} + s_i) = h_i(x_{i,k}) + g_{i,k}^T s_i + \frac{1}{2} \ s_i^T H_{i,k} s_i \\ \text{subject to} & \|s_i\|_i \leq \boxed{\Delta_{i,k}} \end{array}$$

• Set 
$$\delta_{i,k} = m_{i,k}(x_{i,k}) - m_{i,k}(x_{i,k} + s_{i,k})$$
 and go to Step 4

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

э

First-order convergence results A practical recursive algorithm Second-order convergence Numerical experience Ongoing work The context Motivation Main algorithmic ingredients Model construction The recursive algorithm

### Step 4: Acceptance of the trial point

• Compute  $h_i(x_{i,k} + s_{i,k})$  and  $\rho_{i,k} = \frac{h_i(x_{i,k}) - h_i(x_{i,k} + s_{i,k})}{\delta_{i,k}}$ • Define  $x_{i,k+1} = \begin{cases} x_{i,k} + s_{i,k} & \text{if } \rho_{i,k} \ge \eta_1 \\ x_{i,k} & \text{if } \rho_{i,k} < \eta_1 \end{cases}$  (successful iteration)

### Step 5: Termination

• Compute 
$$g_{i,k+1}$$
  
• If  $\|g_{i,k+1}\|_{\infty} \leq \underline{\epsilon_i}$  or  $\|x_{i,k+1} - x_{i,0}\|_i > (1 - \varepsilon)\Delta_{i+1}$   
return with  $x_{i,*} = x_{i,k+1}$ 

### Step 6: Trust-region radius update

• Set  $\Delta_{i,k}^{+} = \begin{cases} \max[\alpha_{2} \| s_{i,k} \|, \Delta_{i,k}] & \text{if } \rho_{i,k} \ge \eta_{2} \text{ (very successful iteration)} \\ \Delta_{i,k} & \text{if } \rho_{i,k} \in [\eta_{1}, \eta_{2}) \\ \alpha_{1} \| s_{i,k} \| & \text{if } \rho_{i,k} < \eta_{1} \end{cases}$ • Set  $\Delta_{i,k+1} = \min \left[ \Delta_{i,k}^{+}, \Delta_{i+1} - \| x_{i,k+1} - x_{i,0} \|_{i} \right]$ • Increment k by one and go to Step 1

< 17 >

< ∃ >

In short In more details

## Global convergence and complexity

Based on the trust-region technology:

- Uses the sufficient decrease argument (imposed in Taylor's iterations)
- Plus the coarsening condition  $(||R_i g_{i,k}|| \ge 0.01 ||g_{i,k}||)$

Main results:

- Convergence to first-order critical points at all levels
- Weak upper bound  $(\mathcal{O}(1/\epsilon_r^2))$  on the number of iterations to achieve a given accuracy

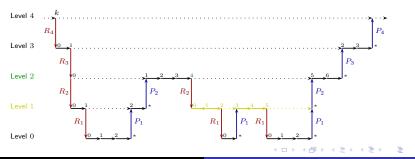

In short In more details

## Minimization sequence

If iteration (i, k) is a recursive iteration:

a minimization sequence at level i - 1 initiated at iteration (i, k)

denotes all successive iterations at level i-1 until a return is made to level i

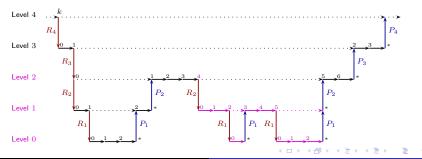

Gratton, Sartenaer, Toint Recursive Multilevel Optimization

In short In more details

The set  $\mathcal{R}(i,k)$ 

At iteration (i, k) we associate the set:

 $\mathcal{R}(i,k) \stackrel{\mathrm{def}}{=} \{(j,\ell) \mid \text{iteration } (j,\ell) \text{ occurs within iteration } (i,k) \}$ 

Gratton, Sartenaer, Toint Recursive Multilevel Optimization

In short In more details

## Key results

### Consider the set

$$\mathcal{V}(i,k) \stackrel{\mathrm{def}}{=} \{ \ (j,\ell) \in \mathcal{R}(i,k) \mid \underbrace{\delta_{j,\ell} \geq c \|g_{i,k}\| \Delta_{j,\ell}}_{\text{"sufficient decrease"}} \} \quad c \in (0,1)$$

### If $x_{i,k}$ is non-critical and $\Delta_{i,k}$ is small enough

then: •  $\mathcal{V}(i,k) = \mathcal{R}(i,k)$ 

- The total number of iterations in  $\mathcal{R}(i,k)$  is finite
- All iterations  $(j, \ell) \in \mathcal{R}(i, k)$  are very successful
- $\Delta_{i,k}^+ \ge \Delta_{i,k}$

Because we impose nonzero tolerances  $\epsilon_i$  on the gradient norms

- then: Each minimization sequence contains at least one successful iteration
  - All the trust-region radii are bounded away from zero

イロト イポト イヨト イヨト

In short In more details

## Complexity result

### Furthemore:

- The number of iterations at each level is finite
- Algorithm RMTR needs at most

$$\frac{f(x_{r,0}) - f_{\text{low}}}{\theta(\epsilon_{min})}$$

successful Taylor iterations at any level to obtain an iterate  $x_{r,k}$  such that

$$\|g_{r,k}\| \le \epsilon_r$$

where

- $\epsilon_{min} = \min_{i=0,\dots,r} \epsilon_i$
- $f_{\text{low}}$  is a known lower bound on f
- $\theta(\epsilon) = \mathcal{O}(\epsilon^2)$  for small values of  $\epsilon$  (can be estimated)

э

In short In more details

This complexity bound in  $1/\epsilon^2$  for small  $\epsilon$ :

- is in terms of iteration numbers, thus only implicitly accounts for the cost of computing a Taylor step
- is only modified by a constant factor if all iterations (successful and unsucessful) are considered
- thus gives a worst case upper bound on the number of function and gradient evaluations
- is of the same order as the corresponding bound for the pure gradient method (not surprising since based on the "sufficient decrease" condition)
- involves the number of successful Taylor iterations summed up on all levels, meaning that successful such iterations at cheap low levels decrease the number of necessary expensive ones at higher levels
- does not depend on the problem dimension but on the properties of the problem and of the algorithm

In short In more details

## Global convergence result

If Algorithm RMTR is called at the uppermost level with  $\epsilon_r = 0$ , then:

$$\lim_{k\to\infty}\|g_{r,k}\|=0$$

If the trust region becomes asymptotically inactive at all levels and all  $\epsilon_i$  are driven to zero, then each minimization sequence becomes infinite and:

$$\lim_{k\to\infty}\|g_{i,k}\|=0$$

for every level  $i = 0, \ldots, r$ 

Image: Image:

In short In more details

### Two comments

"Premature" termination does not affect the convergence results at the upper level provided each minimization sequence contains at least one successful iteration

#### One can:

- Stop a minimization sequence after a preset number of successful iterations
- Use fixed lower-iterations patterns like the V or W cycles in multigrid methods

We did not use the form of the lower levels functions  $\{f_i\}_{i=0}^{r-1}$ 

One can:

• Choose  $f_i = 0$  for i = 0, ..., r - 1, which implies that the lower level model  $h_{i-1}(x_{i-1,0} + s_{i-1})$  reduces to the linear model  $(R_i g_{i,k})^T s_{i-1}$

э

Iteration types Models Recursion forms Other issues

- Start the first SCM smoothing cycle by minimizing along the largest gradient component (enough to ensure sufficient decrease)
- While inside the trust region, perform (at most *p*) SCM smoothing cycles (reasonable cost)
- If the step lies outside the trust region, apply a variant of the dogleg strategy (very rare in practice)
- If negative curvature is encountered during a cycle:
  - Remember the step to the trust-region boundary which produces the largest model reduction during the cycle (stop the SCM smoothing)
  - Select the final step as that giving the maximum reduction

(日)

Iteration types Models Recursion forms Other issues

#### Second-order and Galerkin models

At level i - 1 (model for level i):

First-order coherence

$$h_{i-1}(x_{i-1,0} + s_{i-1}) = f_{i-1}(x_{i-1,0} + s_{i-1}) + v_{i-1}^T s_{i-1}$$

with 
$$x_{i-1,0} = R_i x_{i,k}$$
 and  $v_{i-1} = R_i g_{i,k} - \nabla f_{i-1}(x_{i-1,0})$ 

$$\Rightarrow \quad g_{i-1,0} = \nabla h_{i-1}(x_{i-1,0}) = R_i g_{i,k}$$

<u>Second-order coherence</u> (more costly)

$$h_{i-1}(x_{i-1,0} + s_{i-1}) = f_{i-1}(x_{i-1,0} + s_{i-1}) + v_{i-1}^T s_{i-1} + \frac{1}{2}s_{i-1}^T W_{i-1}s_{i-1}$$

with  $W_{i-1} = R_i H_{i,k} P_i - \nabla^2 f_{i-1}(x_{i-1,0})$ 

$$\Rightarrow \ \nabla^2 h_{i-1}(x_{i-1,0}) = R_i H_{i,k} P_i$$

# Recursion forms

Example of recursion with 5 levels (r = 4)

Iteration types Models Recursion forms Other issues

## Free and fixed form recursions

Because:

• The convergence properties of Algorithm RMTR still hold if the minimization at lower levels (i = 0, ..., r - 1) is stopped after the first successful iteration

⇒ Flexibility that allows different recursion patterns

 Alternance of successful SCM smoothing iterations with recursive or TCG successful iterations (at all levels but the coarsest) is very fruitful

 $\Rightarrow$  This alternance is imposed for each recursion form

• TCG iterations are much more expensive than recursive iterations

 $\Rightarrow$  A recursive iteration is always attempted whenever allowed (i.e., when i > 0 and  $||R_i g_{i,k}|| \ge 0.01 ||g_{i,k}||$  and  $||R_i g_{i,k}|| > \epsilon_{i-1}$ )

Iteration types Models Recursion forms Other issues

Free form recursion

 The minimization at each level is stopped when the termination condition on the gradient norm or on the step size is satisfied (Step 5 of Algorithm RMTR)

 Alternance of successful SCM smoothing iterations with recursive (or TCG) iterations is imposed

Convergence to weak minimizers

Convergence to second-order critical points requires the eigen-point condition

If  $\tau_{i,k}$  (the smallest eigenvalue of  $H_{i,k}$ ) is negative, then  $m_{i,k}(x_{i,k}) - m_{i,k}(x_{i,k} + s_{i,k}) \ge \kappa_{\text{eip}} |\tau_{i,k}| \min[\tau_{i,k}^2, \Delta_{i,k}^2]$ where  $\kappa_{\text{eip}} \in (0, \frac{1}{2})$ 

 $\longrightarrow$  Too costly to impose a posteriori on recursive iterations

• The SCM smoothing technique limits its exploration of the model's curvature to the coordinate axes and thus only guarantees

If  $\mu_{i,k}$  (the most negative diagonal element of  $H_{i,k}$ ) is negative, then

 $m_{i,k}(x_{i,k}) - m_{i,k}(x_{i,k} + s_{i,k}) \ge \frac{1}{2} |\mu_{i,k}| \Delta_{i,k}^2$ 

Image: A math a math

- → Asymptotic positive curvature:

Test problems Performance of Algorithm RMTR

## Comparison of three algorithms

- AF ("All on Finest"): standard Newton trust-region algorithm (with TCG as subproblem solver) applied at the finest level
- MR ("Mesh Refinement"): discretized problems solved in turn from the coarsest level to the finest one, using the same standard Newton trust-region method

(Starting point at level i + 1 obtained by prolongating the solution at level i)

• FM ("Full Multilevel"): Algorithm RMTR

• □ > • □ > • □ > • □ > •

Test problems Performance of Algorithm RMTR

# The default full multilevel (FM) algorithm

- Newton quadratic model at the finest level
- Galerkin models  $(f_i = 0)$  at coarse levels
- W-form recursion performed at each level
- Recursive iteration always attempted when allowed
- A single smoothing cycle allowed at SCM smoothing iterations

Test problems Performance of Algorithm RMTR

## Comparison of computational kernels

For the quadratic problems:

 Number of smoothing cycles (FM) vs number of matrix-vector products (AF, MR)

For the non-quadratic problems:

- Number of smoothing cycles (FM) vs number of matrix-vector products (MR)
- Number of f, g, and H evaluations

Test problems Performance of Algorithm RMTR

## Time performance of computational kernels

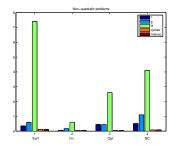

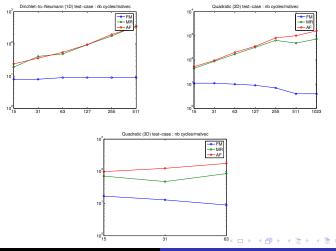

Image: A mathematical states and a mathem

Test problems Performance of Algorithm RMTR

### Performance results on quadratic problems

Gratton, Sartenaer, Toint Recursive Multilevel Optimization

Test problems Performance of Algorithm RMTR

# $\underbrace{ On \ quadratic \ problems:}_{mesh \ size \ and \ dimension} \text{ the number of smoothing cycles is fairly independent of the }$

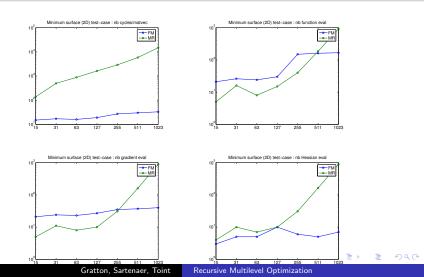

- → Similar behaviour as the linear multigrid approach
- $\longrightarrow$  The trust-region machinery introduced in the multigrid setting does not alter the property

イロト イポト イヨト イヨト

Test problems Performance of Algorithm RMTR

## Performance results on Surf

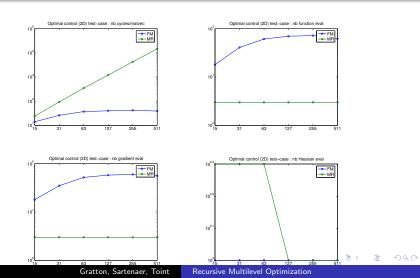

Test problems Performance of Algorithm RMTR

## Performance results on Inv

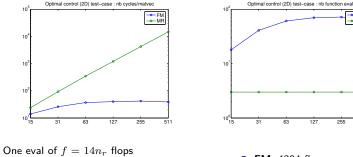

Test problems Performance of Algorithm RMTR

### Performance results on Opt

Performance of Algorithm RMTR

## Operations counts for Opt (at the finest level)

۰ One eval of  $q = 56n_r$  flops

۲

One cycle/matyec =  $10n_r$  flops ۰

FM: 4394 flops MR: 148470 flops

A - A - A

FM

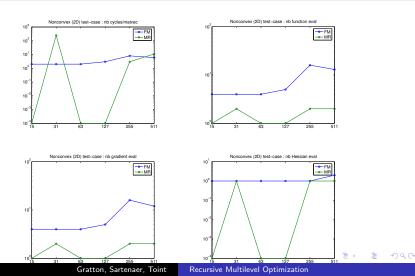

MB

255

MR much more expensive than FM because the gain in the number of smoothing cycles is much superior to the loss in f and q evaluations

Test problems Performance of Algorithm RMTR

## Performance results on NC

Test problems Performance of Algorithm RMTR

### Comparison of algorithmic variants

→ Sensibility investigation of **FM** 

- W2: two smoothing cycles per SCM smoothing iteration instead of one
- W3: three smoothing cycles per SCM smoothing iteration instead of one
- V1: V-form recursions instead of W-form recursions
- F1: free form recursions instead of W-form recursions
- LMOD: first-order coherent model rather than Galerkin model ( $f_i = 0$ )
- QMOD: second-order coherent model rather than Galerkin model ( $f_i = 0$ )
  - LINT: linear rather than cubic interpolation in the initialization phase

Test problems Performance of Algorithm RMTR

### Current comparative conclusions

 $\longrightarrow$  Encouraging !

- Algorithm RMTR (default version FM) is more efficient than mesh refinement (MR) for large instances
- Pure quadratic recursion (Galerkin model) is very efficient
- W-form and free form recursions are most efficient

• □ ▶ • • □ ▶ • □ ▶

An  $\ell_\infty$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

(日)

## Outline

- 1 A recursive multilevel trust-region algorithm
- Pirst-order convergence results
- 3 A practical recursive algorithm
- 4 Second-order convergence
- 5 Numerical experience

6 Ongoing work

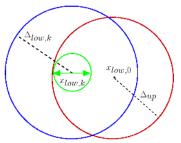

An  $\ell_{\infty}$  version (with M. Weber)

Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

## A (more natural) $\ell_{\infty}$ version

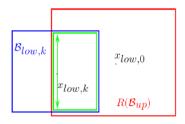

#### RMTR

- 2-norm criticality measure
- good results, but annoying trust region scaling problem (recursion)

#### $RMTR-\infty$

- $\infty$ -norm (bound constraints)
- new criticality measure
- new possibilities for step length

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos an

Constrained problems (with M. Mouffe et al.)

#### $\infty$ -norm in trust regions

- Possibility for asymmetric trust regions (more freedom)
- In lower levels, can be represented as a bound constrained subproblem
- We will impose that the lower level steps must remain inside the restriction of the upper level trust region: If

$$\mathcal{B}_{up} = \{x \,|\, l_{up} \le x \le u_{up}\}$$

then

$$\mathcal{B}_{low} = \mathcal{R}\mathcal{B}_{up} = \{x \mid \mathcal{R}l_{up} \le x \le \mathcal{R}u_{up}\}$$

• The step  $s_{up} = Ps_{low}$  will not necessarily be inside the upper level trust region! But: If  $\Delta_{up} = \operatorname{radius}(\mathcal{B}_{up})$ , then

$$\|s_{up}\|_{\infty} \leq \|P\|_{\infty} \|R\|_{\infty} \Delta_{up}.$$

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber Constrained problems (with M. Mouffe et al.)

## A new Criticality Measure

- Each lower level subproblem is constrained by the restriction of the upper level trust region; we can consider the lower level subproblem as a bound constrained optimization problem.
- Instead of evaluating  $g_{\text{low}}$  to check criticality, we will look at

$$\chi(x_{\mathsf{low}}) = |\min_{\substack{d \in \mathcal{RB}_{\mathsf{up}} \\ \|d\| \le 1}} \langle g_{\mathsf{low}}, d \rangle|.$$

We only use recursion if:

$$\chi_{low} \geq \kappa_\chi \chi_{up}$$

• We have found a solution to the current level *i* if

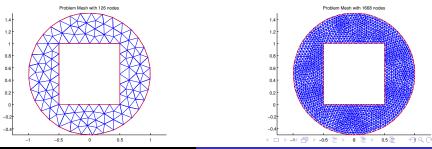

$$\chi < \epsilon_i^{\chi}.$$

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

## Algebraic multigrid

No need for predefined grids; lower level information is obtained automatically through a preprocessing phase which can be expensive (but usually the resolution phase is faster for a single system).

- Problem definition
- 2 Choice of smoothing operator (smooth error detection)
- 3 Construction of intergrid operators and subgrids.

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

(日)

## P-multigrid

Need an initial grid (not necessarily uniform); Construct the finer grids by using higher level polynomials.

- Choice of the basis: shape functions, hierarchical basis, ... with different degrees at each level
- Same number of nodes for each level
- Construction of the intergrid operators that have to interpolate correctly the basis

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

イロト イポト イヨト イヨト

### Bound constrained problems

 $\begin{array}{ll} \mbox{minimize} & f(x) \\ \mbox{subject to} & x \geq 0, \end{array}$ 

Issues:

- Restriction of bound constraints \u2272 bounds!
- Fast active set identification
- Bound compatible smoothing operator
- Criticality measure

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

イロト イポト イヨト イヨト

## Equality constrained problems

 $\begin{array}{ll} \mbox{minimize} & f(x) \\ \mbox{subject to} & c(x) = 0, \end{array}$ 

Issues:

- Error in the adjoint equation
- Inexactly tangential steps
- Iterative solvers
- (Filters?)

An  $\ell_{\infty}$  version (with M. Weber) Multigrid enhancements (with D. Tomanos and M. Weber) Constrained problems (with M. Mouffe et al.)

## Perspectives

- More numerical experiments
- Hessian approximation schemes
- Combination with non-monotone techniques, filter methods, ...
- Real applications in data assimilation ....
- ... and much more !
