# Register Allocation by Puzzle Solving 

Fernando Magno Quintão Pereira Jens Palsberg<br>UCLA Computer Science Department<br>University of California, Los Angeles<br>\{fernando, palsberg\}@cs.ucla.edu

#### Abstract

We show that register allocation can be viewed as solving a collection of puzzles. We model the register file as a puzzle board and the program variables as puzzle pieces; pre-coloring and register aliasing fit in naturally. For architectures such as x86, SPARC V8, and StrongARM, we can solve the puzzles in polynomial time, and we have augmented the puzzle solver with a simple heuristic for spilling. For SPEC CPU2000, the compilation time of our implementation is as fast as that of the extended version of linear scan used by LLVM, which is the JIT compiler in the openGL stack of Mac OS 10.5. Our implementation produces x 86 code that is of similar quality to the code produced by the slower, state-of-the-art iterated register coalescing of George and Appel with the extensions proposed by Smith, Ramsey, and Holloway in 2004.

## 1. Introduction

Researchers and compiler writers have used a variety of abstractions to model register allocation, including graph coloring [18, 37], integer linear programming [2, 21], partitioned Boolean quadratic optimization [36, 24], and multi-commodity network flow [27]. These abstractions represent different tradeoffs between compilation speed and quality of the produced code. For example, linear scan [34] is a simple algorithm based on the coloring of interval graphs that produces code of reasonable quality with fast compilation time; iterated register coalescing [18] is a more complicated algorithm that, although slower, tends to produce code of better quality than linear scan. Finally, the Appel-George algorithm [2] achieves optimal spilling, with respect to a cost model, in worstcase exponential time via integer linear programming.

In this paper we introduce a new abstraction: register allocation by puzzle solving. We model the register file as a puzzle board and the program variables as puzzle pieces. The result is a collection of puzzles with one puzzle per instruction in the intermediate representation of the source program. We will show that puzzles are easy to use, that we can solve them efficiently, and that they produce code that is competitive with state-of-the-art algorithms. Specifically, we will show how for architectures such as x86, SPARC V8, and StrongARM we can solve each puzzle in linear time in the number of registers, how we can extend the puzzle solver with a simple heuristic for spilling, and how pre-coloring and register aliasing fit in naturally. Pre-colored variables are vari-
ables that have been assigned to particular registers before register allocation begins; two register names alias [37] when an assignment to one register name can affect the value of the other.

We have implemented a puzzle-based register allocator. Our register allocator has four steps:

1. transform the program into an elementary program (using the technique described in Section 2.2);
2. transform the elementary program into a collection of puzzles (using the technique described in Section 2.2);
3. do puzzle solving, spilling, and coalescing (using the techniques described in Sections 3 and 4); and finally
4. transform the elementary program and the register allocation result into assembly code (by implementing $\varphi$-functions, $\pi$ functions, and parallel copies using the technique described by Hack et al. [23]).
For SPEC CPU2000, our implementation is as fast as the extended version of linear scan used by LLVM, which is the JIT compiler in the openGL stack of Mac OS 10.5. We compare the x86 code produced by gcc, our puzzle solver, the version of linear scan used by LLVM [15], the iterated register coalescing algorithm of George and Appel [18] with the extensions proposed by Smith, Ramsey, and Holloway [37], and the partitioned Boolean quadratic optimization algorithm [24]. The puzzle solver produces code that is, on average, faster than the code produced by extended linear scan, and of similar quality to the code produced by iterated register coalescing. Unsurprisingly, the exponential-time Boolean optimization algorithm produces the fastest code.

In the following section we define our puzzles and in Section 3 we show how to solve them. In Section 4 we present our approach to spilling and coalescing, and in Section 5 we discuss some optimizations in the puzzle solver. We give our experimental results in Section 6, and we discuss related work in Section 7. Finally, Section 8 concludes the paper.

## 2. Puzzles

A puzzle consists of a board and a set of pieces. Pieces cannot overlap on the board, and a subset of the pieces are already placed on the board. The challenge is to fit the remaining pieces on the board.

We will now explain how to map a register file to a puzzle board and how to map program variables to puzzle pieces. Every resulting puzzle will be of one of the three types illustrated in Figure 1 or a hybrid.

### 2.1 From Register File to Puzzle Board

The bank of registers in the target architecture determines the shape of the puzzle board. Every puzzle board has a number of separate areas that each is divided into two rows of squares. We will explain

Figure 1. Three types of puzzles.
in Section 2.2 why an area has exactly two rows. The register file may support aliasing and that determines the number of columns in each area, the valid shapes of the pieces, and the rules for placing the pieces on the board. We distinguish three types of puzzles: type0 , type-1 and type-2, where the board of a type-i puzzle has $2^{i}$ columns.

Type-0 puzzles. The bank of registers used in PowerPC and the bank of integer registers used in ARM are simple cases because they do not support register aliasing. Figure 2(a) shows the puzzle board for PowerPC. Every area has just one column that corresponds to one of the 32 registers. Both PowerPC and ARM give a type-0 puzzle for which the pieces are of the three kinds shown in Figure 1. We can place an X-piece on any square in the upper row, we can place a Z-piece on any square in the lower row, and we can place a Y-piece on any column. It is straightforward to see that we can solve a type- 0 puzzle in linear time in the number of areas by first placing all the Y-pieces on the board and then placing all the X-pieces and Z-pieces on the board.

Type-1 puzzles. Floating point registers in SPARC V8 and ARM support register aliasing in that two 32-bit single precision floating point registers can be combined to hold a 64 -bit double precision value. Figure 2(b) shows the puzzle board for the floating point registers of SPARC V8. Every area has two columns that correspond to two registers that can be combined. For example, SPARC V8 does not allow registers F1 and F2 to be combined; thus, their columns are in separate areas. Both SPARC V8 and ARM give a type-1 puzzle for which the pieces are of the six kinds shown in Figure 1. We define the size of a piece as the number of squares that it occupies on the board. We can place a size-1 X-piece on any square in the upper row, a size-2 X-piece on the two upper squares of any area, a size-1 Z-piece on any square in the lower row, a size-2 Z-piece on the two lower squares of any area, a size-2 Y-piece on any column, and a size-4 Y-piece on any area. Section 3 explains how to solve a type-1 puzzle in linear time in the number of areas.

Type-2 puzzles. SPARC V9 [40, pp 36-40] supports two levels of register aliasing: first, two 32 -bit floating-point registers can be combined to hold a single 64 -bit value; then, two of these $64-$ bit registers can be combined yet again to hold a 128 -bit value. Figure 2(c) shows the puzzle board for the floating point registers of SPARC V9. Every area has four columns corresponding to four registers that can be combined. SPARC V9 gives a type-2 puzzle for which the pieces are of the nine kinds shown in Figure 1. The rules for placing the pieces on the board are a straightforward extension of the rules for type-1 puzzles. Importantly, we can place a size-2 X-piece on either the first two squares in the upper row of an area, or on the last two squares in the upper row of an area. A similar

-SPARC V8, 16 double precision floating point registers -1

Figure 2. Examples of register banks mapped into puzzle boards.

Figure 3. General purpose registers of the x 86 architecture
rule applies to size-2 Z-pieces. Solving type-2 puzzles remains an open problem.

Hybrid puzzles. The x86 gives a hybrid of type-0 and type1 puzzles. Figure 3 shows the integer-register file of the x86, and Figure 2(d) shows the corresponding puzzle board. The registers AX, BX, CX, DX give a type-1 puzzle, while the registers EBP, ESI, EDI, ESP give a type-0 puzzle. We treat the EAX, EBX, ECX, EDX registers as special cases of the $\mathrm{AX}, \mathrm{BX}, \mathrm{CX}, \mathrm{DX}$ registers; values in EAX, EBX, ECX, EDX take up to 32 bits rather than 16 bits. Notice that x86 does not give a type-2 puzzle because even though we can fit four 8 -bit values into a 32 -bit register, x86 does not provide register names for the upper 16-bit portion of that register. For a hybrid of type- 1 and type- 0 puzzles, we first solve the type- 0 puzzles and then the type-1 puzzles.

The floating point registers of SPARC V9 give a hybrid of a type-2 and a type-1 puzzle because only half of the registers can be combined into quad precision registers.

### 2.2 From Program Variables to Puzzle Pieces

We map program variables to puzzle pieces in a two-step process: first we convert a source program into an elementary program and then we map the elementary program into puzzle pieces.

From a source program to an elementary program. We can convert an ordinary program into an elementary program in three

Figure 4. (a) Original program. (b) Elementary program.
steps. First, we transform the source program to static single assignment (SSA) form [14]. We use a variation of SSA-form in which every basic block begins with a $\varphi$-function that renames the variables that are live coming in to the basic block. Second, we transform the SSA-form program into static single information (SSI) form [1]. In a program in SSI form, every basic block ends with a $\pi$-function that renames the variables that are live going out of the basic block. (The name $\pi$-assignment was coined by Bodik et al. [5]. It was originally called $\sigma$-function in [1], and switch operators in [25].) Finally, we transform the SSI-form program into an elementary program by inserting a parallel copy between each pair of consecutive instructions in a basic block. The parallel copy renames the variables that are live at that point. Appel and George used the idea of inserting parallel copies everywhere in their ILPbased approach to register allocation [2]; they called it optimal liverange splitting. In summary, in an elementary program, every basic block begins with a $\varphi$-function, has a parallel copy between each consecutive pair of instructions, and ends with a $\pi$-function. Figure 4(a) shows a program, and Figure 4(b) gives the corresponding elementary program. In this paper we adopt the convention that lower case letters denote variables that can be stored into a single register, and upper case letters denote variables that must be stored into a pair of registers.

Ananian [1] gave a polynomial time algorithm for constructing SSI form directly from a source program; we can perform the remaining step of inserting parallel copies in polynomial time as well.

|  | $\begin{gathered} p_{x}:(C, d, E, f, g)=\left(C^{\prime}, d^{\prime}, E^{\prime}, f^{\prime}\right) \\ A, b=C, d, E \\ p_{x+1}:\left(A^{\prime \prime}, b^{\prime \prime}, E^{\prime \prime}, f^{\prime \prime}, g^{\prime \prime}\right)=(A, b, E, f) \end{gathered}$ |
| :---: | :---: |
|  |  |
| $\begin{aligned} & \mathscr{U} \\ & \underset{\sim}{0} \end{aligned}$ |  |

Figure 5. Mapping program variables into puzzle pieces.

From an elementary program to puzzle pieces. A program point [2] is a point between any pair of consecutive instructions. For example, the program points in Figure 4(b) are $p_{0}, \ldots, p_{11}$. The collection of program points where a variable $v$ is alive constitutes its live range. The live ranges of programs in elementary form contain at most two program points. A variable $v$ is said to be live-in at instruction $i$ if its live range contains a program point that precedes $i$; $v$ is live-out at $i$ if $v$ 's live range contains a program point that succeeds $i$. For each instruction $i$ in an elementary program we create a puzzle that has one piece for each variable that is live in or live out at $i$ (or both). The live ranges that end in the middle become X-pieces; the live ranges that begin in the middle become Z-pieces; and the long live ranges become Y-pieces. Figure 5 gives an example of a program fragment that uses six variables, and it shows their live ranges and the resulting puzzles.

We can now explain why each area of a puzzle board has exactly two rows. We can assign a register both to one live range that ends in the middle and to one live range that begins in the middle. We model that by placing an X-piece in the upper row and a Z-piece right below in the lower row. However, if we assign a register to a long live range, then we cannot assign that register to any other live range. We model that by placing with a Y-piece, which spans both rows.

The sizes of the pieces are given by the types of the variables. For example, for x 86 , an 8 -bit variable with a live range that ends in the middle becomes a size-1 X-piece, while a 16 or 32-bit variable with a live range that ends in the middle becomes a size-2 X-piece. Similarly, an 8-bit variable with a live range that begins in the middle becomes a size-1 Z-piece. while a 16 or 32-bit variable with a live range that ends in the middle becomes a size-2 Z-piece. An 8bit variable with a long live range becomes a size-2 Y-piece, while a 16 -bit variable with a long live range becomes a size- 4 Y -piece.

### 2.3 Register Allocation and Puzzle Solving are Equivalent

The core register allocation problem, also known as spill-free register allocation, is: given a program $P$ and a number $K$ of available registers, can each of the variables of $P$ be mapped to one of the $K$ registers such that variables with interfering live ranges are assigned to different registers?

In case some of the variables are pre-colored, we call the problem spill-free register allocation with pre-coloring.
Theorem 1. (Equivalence) Spill-free register allocation with pre-coloring for an elementary program is equivalent to solving a collection of puzzles.

Figure 6. Padding: (a) puzzle board, (b) pieces before padding, (c) pieces after padding. The new pieces are marked with stripes.

## Proof. See Appendix A.

Figure 9(a) shows the puzzles produced for the program in Figure 4 (b).

## 3. Solving Type-1 Puzzles

Figure 8 shows our algorithm for solving type-1 puzzles. Our algorithmic notation is visual rather than textual. The goal of this section is to explain how the algorithm works and to point out several subtleties. We will do that in two steps. First we will define a visual language of puzzle solving programs that includes the program in Figure 8. After explaining the semantics of the whole language, we then focus on the program in Figure 8 and explain how seemingly innocent changes to the program would make it incorrect.

We will study puzzle-solving programs that work by completing one area at a time. To enable that approach, we may have to pad a puzzle before the solution process begins. If a puzzle has a set of pieces with a total area that is less than the total area of the puzzle board, then a strategy that completes one area at a time may get stuck unnecessarily because of a lack of pieces. So, we pad such puzzles by adding size-1 X-pieces and size-1 Z-pieces, until these two properties are met: (i) the total area of the X-pieces equals the total area of the Z-pieces; (ii) the total area of all the pieces is $4 K$, where $K$ is the number of areas on the board. Note that total area includes also pre-colored squares. Figure 6 illustrates padding. It is straightforward to see that a puzzle is solvable if and only if its padded version is solvable. For simplicity, the puzzles in Figure 9 are not padded.

### 3.1 A Visual Language of Puzzle Solving Programs

We say that an area is complete when all four of its squares are covered by pieces; dually, an area is empty when none of its four squares are covered by pieces.

The grammar in Figure 7 defines a visual language for programming puzzle solvers: a program is a sequence of statements, and a statement is either a rule $r$ or a conditional statement $r: s$. We now informally explain the meaning of rules, statements, and programs.

Rules. A rule explains how to complete an area. We write a rule as a two-by-two diagram with two facets: a pattern, that is, dark areas which show the squares (if any) that have to be filled in already for the rule to apply; and a strategy, that is, a description of how to complete the area, including which pieces to use and where to put them. We say that the pattern of a rule matches an area $a$ if the pattern is the same as the already-filled-in squares of $a$. For a rule $r$ and an area $a$ where the pattern of $r$ matches $a$,

- the application of $r$ to $a$ succeeds, if the pieces needed by the strategy of $r$ are available; the result is that the pieces needed by the strategy of $r$ are placed in $a$;
- the application of $r$ to $a$ fails otherwise.

For example, the rule

Figure 7. A visual language for programming puzzle solvers.

has a pattern consisting of just one square-namely, the square in the top-right corner, and a strategy consisting of taking one size-1 X-piece and one size-2 Z-piece and placing the X-piece in the topleft corner and placing the Z-piece in the bottom row. If we apply the rule to the area

and one size-1 X-piece and one size-2 Z-piece are available, then the result is that the two pieces are placed in the area, and the rule succeeds. Otherwise, if one or both of the two needed pieces are not available, then the rule fails. We cannot apply the rule to the area

because the pattern of the rule does not match the area.
Statements. For a statement that is simply a rule $r$, we have explained above how to apply $r$ to an area $a$ where the pattern of $r$ matches $a$. For a conditional statement $r: s$, we require all the rules in $r: s$ to have the same pattern, which we call the pattern of $r: s$. For a conditional statement $r: s$ and an area $a$ where the pattern of $r: s$ matches $a$, the application of $r: s$ to $a$ proceeds by first applying $r$ to $a$; if that application succeeds, then $r: s$ succeeds (and $s$ is ignored); otherwise the result of $r: s$ is the application of $s$ to $a$.

Programs. The execution of a program $s_{1} \ldots s_{n}$ on a puzzle $\mathcal{P}$ proceeds as follows:

- For each $i$ from 1 to $n$ :

Figure 8. Our puzzle solving program

- For each area $a$ of $\mathcal{P}$ such that the pattern of $s_{i}$ matches $a$ :
$-\operatorname{apply} s_{i}$ to $a$
- if the application of $s_{i}$ to $a$ failed, then terminate the entire execution and report failure
Example. Let us consider in detail the execution of the program

on the puzzle

The first statement has a pattern which matches only the first area of the puzzle. So, we apply the first statement to the first area, which succeeds and results in the following puzzle.

The second statement has a pattern which matches only the second area of the puzzle. So, we apply the second statement to the second area. The second statement is a conditional statement, so we first apply the first rule of the second statement. That rule fails because the pieces needed by the strategy of that rule are not available. We then move on to apply the second rule of the second statement. That rule succeeds and completes the puzzle.

Time Complexity. It is straightforward to implement the application of a rule to an area in constant time. A program executes $O(1)$ rules on each area of a board. So, the execution of a program on a board with $K$ areas takes $O(K)$ time.

### 3.2 Our Puzzle Solving Program

Figure 8 shows our puzzle solving program, which has 15 numbered statements. Notice that the 15 statements have pairwise different patterns; each statement completes the areas with a particular pattern. While our program may appear simple and straightforward, the ordering of the statements and the ordering of the rules in conditional statements are in several cases crucial for correctness. We will discuss four such subtleties.

First, it is imperative that in statement 7 our program prefers a size-2 X-piece over two size-1 X-pieces. Suppose we replace statement 7 with a statement $7^{\prime}$ which swaps the order of the two rules in statement 7. The application of statement $7^{\prime}$ can take us from a solvable puzzle to an unsolvable puzzle, for example:

Because statement 7 prefers a size-2 X-piece over two size-1 X -pieces, the example is impossible. Notice that our program also prefers the size-2 pieces over the size-1 pieces in statements 8-15; and it prefers a size-4 Y-piece over two size-2 Y-pieces in statement 15 ; all for reasons similar to our analysis of statement 7 .

Second, it is critical that statements $7-10$ come before statements 11-14. Suppose we swap the order of the two subsequences of statements. The application of rule 11 can now take us from a solvable puzzle to an unsolvable puzzle, for example:

Notice that the example uses an area in which two squares are filled in. Because statements $7-10$ come before statements 11-14, the example is impossible.

Third, it is crucial that statements $11-14$ come before statement 15. Suppose we swap the order such that statement 15 comes before statements $11-14$. The application of rule 15 can now take us from a solvable puzzle to an unsolvable puzzle, for example:

Notice that the example uses an area in which one square is filled in. Because statements 11-14 come before statement 15, the example is impossible.

Fourth, it is essential that in statement 11, the rules come in exactly the order given in our program. Suppose we replace statement 11 with a statement $11^{\prime}$ which swaps the order of the first two rules of statement 11. The application of statement $11^{\prime}$ an take us from a solvable puzzle to an unsolvable puzzle, for example:

When we use the statement 11 given in our program, this situation cannot occur. Notice that our program makes a similar choice in statements 12-14; all for reasons similar to our analysis of statement 11.

THEOREM 2. (Correctness) A type-1 puzzle is solvable if and only if our program succeeds on the puzzle.

Proof. See Appendix B.

Figure 9. (a) The puzzles produced for the program given in Figure 4(b). (b) An example solution. (c) The final program.

For an elementary program $P$, we generate $|P|$ puzzles, each of which we can solve in linear time in the number of registers. So, we have Corollary 3.

Corollary 3. (Complexity) Spill-free register allocation with pre-coloring for an elementary program $P$ and $2 K$ registers is solvable in $O(|P| \times K)$ time.

A solution for the collection of puzzles in Figure 9(a) is shown in Figure 9 (b).

## 4. Spilling and Coalescing

We now present our approach to spilling and coalescing. Figure 10 shows the combined step of puzzle solving, spilling, and coalescing.

Spilling. If the polynomial-time algorithm of Theorem 3 succeeds, then all the variables in the program from which the puzzles were generated can be placed in registers. However, the algorithm may fail, implying that the need for registers exceeds the number of available registers. In that situation, the register allocator faces the task of choosing which variables will be placed in registers and which variables will be spilled, that is, placed in memory. The goal is to spill as few variables as possible.

We use a simple spilling heuristic. The heuristic is based on the observation that when we convert a program $P$ into elementary form, each of $P$ 's variables is represented by a family of variables in the elementary program. For example, the variable $c$ in Figure 4(a) is represented by the family of variables $\left\{c_{23}, c_{3}, c_{4}, c_{67}, c_{7}, c_{8}, c_{9}\right\}$ in Figure 4(b). When we spill a variable in an elementary program, we choose to simultaneously spill all the variables in its family and thereby reduce the number of pieces in many puzzles at the same time. The problem of register allocation with pre-coloring and spilling of families of variables is to perform register allocation with pre-coloring while spilling as few families of variables as possible.

Theorem 4. (Hardness) Register allocation with pre-coloring and spilling of families of variables for an elementary program is $N P$-complete.
Proof. See Appendix C.

- $S$ = empty
- For each puzzle $p$, in a pre-order traversal of the dominator tree of the program:
- while $p$ is not solvable:
- choose and remove a piece $s$ from $p$, and for every puzzle $p^{\prime}$ that contains a variable $s^{\prime}$ in the family of $s$, remove $s^{\prime}$ from $p^{\prime}$.
- $S^{\prime}$ = a solution of $p$, guided by $S$
- $S=S^{\prime}$

Figure 10. Register allocation with spilling and local coalescing

Theorem 4 justifies our use of a spilling heuristic rather than an algorithm that solves the problem optimally. Figure 10 contains a while-loop that implements the heuristic; a more detailed version of this code is given in Appendix D. It is straightforward to see that the heuristic visits each puzzle once, that it always terminates, and that when it terminates, all puzzles have been solved.

When we choose and remove a piece $s$ from a puzzle $p$, we use the "furthest-first" strategy of Belady [3] that was later used by Poletto and Sarkar [34] in linear-scan register allocation. The furthest-first strategy spills a family of variables whose live ranges extend the furthest.

The total number of puzzles that will be solved during a run of our heuristic is bounded by $|\mathcal{P}|+|\mathcal{F}|$, where $|\mathcal{P}|$ denotes the number of puzzles and $|\mathcal{F}|$ denotes the number of families of variables, that is, the number of variables in the source program.

Coalescing. Traditionally, the task of register coalescing is to assign the same register to the variables $x, y$ in a copy statement $x=y$, thereby avoiding the generation of code for that statement. An elementary program contains many parallel copy statements and therefore many opportunities for a form of register coalescing. We use an approach that we call local coalescing. The goal of local coalescing is to allocate variables in the same family to the same register, as much as possible. Local coalescing traverses the dominator tree of the elementary program in pre-order and solves each puzzle guided by the solution to the previous puzzle, as shown
in Figure 10. In Figure 9(b), the numbers next to each puzzle denote the order in which the puzzles were solved.

The pre-ordering has the good property that every time a puzzle corresponding to statement $i$ is solved, all the families of variables that are defined at program points that dominate $i$ have already been given at least one location. The puzzle solver can then try to assign to the piece that represents variable $v$ the same register that was assigned to other variables in $v$ 's family. For instance, in Figure 4(b), when solving the puzzle formed by variables $\left\{A_{3}, c_{3}\right\}$, the puzzle solver tries to match the registers assigned to $A_{2}$ and $A_{3}$. This optimization is possible because $A_{2}$ is defined at a program point that dominates the definition site of $A_{3}$, and thus is visited before.

During the traversal of the dominator tree, the physical location of each live variable is kept in a vector. If a spilled variable is reloaded when solving a puzzle, it stays in registers until another puzzle, possibly many instructions after the reloading point, forces it to be evicted again, in a way similar to the second-chance allocation described by Traub et al. [39].

Figure 9(c) shows the assembly code produced by the puzzle solver for our running example. We have highlighted the instructions used to implement parallel copies. The x86 instruction cxhg swaps the contents of two registers.

## 5. Optimizations

We now describe three optimizations that we have found useful in our implementation of register allocation by puzzle solving for $x 86$.

Size of the intermediate representation. An elementary program has many more variable names than an ordinary program; fortunately, we do not have to keep any of these extra names. Our solver uses only one puzzle board at any time: given an instruction $i$, variables alive before and after $i$ are renamed when the solver builds the puzzle that represents $i$. Once the puzzle is solved, we use its solution to rewrite $i$ and we discard the extra names. The parallel copy between two consecutive instructions $i_{1}$ and $i_{2}$ in the same basic block can be implemented right after the puzzle representing $i_{2}$ is solved.

Critical Edges and Conventional SSA-form. Before solving puzzles, our algorithm performs two transformations in the target control flow graph that, although not essential to the correctness of our allocator, greatly simplify the elimination of $\varphi$-functions and $\pi$-functions. The first transformation, commonly described in compiler text books, removes critical edges from the control flow graph. These are edges between a basic block with multiple successors and a basic block with multiple predecessors [8]. The second transformation converts the target program into a variation of SSA-form called Conventional SSA-form (CSSA) [38]. Programs in this form have the following property: if two variables $v_{1}$ and $v_{2}$ are related by a parallel copy, e.g: $\left(\ldots, v_{1}, \ldots\right)=\left(\ldots, v_{2}, \ldots\right)$, then the live ranges of $v_{1}$ and $v_{2}$ do not overlap. Hence, if these variables are spilled, the register allocator can assign them to the same memory slot. A fast algorithms to perform the SSA-to-CSSA conversion is given in [11]. These two transformations are enough to handle the 'swap' and 'lost-copy' problems pointed out by Briggs et al. [8].

Implementing $\varphi$-functions and $\pi$-functions. The allocator maintains a table with the solution of the first and last puzzles solved in each basic block. These solutions are used to guide the elimination of $\varphi$-functions and $\pi$-functions. During the implementation of parallel copies, the ability to swap register values is important [7]. Some architectures, such as x86, provide instructions to swap the values in registers. In systems where this is not the case, swaps can be performed using xor instructions.

## 6. Experimental Results

Experimental platform. We have implemented our register allocator in the LLVM compiler framework [28], version 1.9. LLVM is the JIT compiler in the openGL stack of Mac OS 10.5. Our tests are executed on a 32 -bit x $86 \operatorname{Intel}(\mathrm{R}) \mathrm{Xeon}(\mathrm{TM})$, with a 3.06 GHz cpu clock, 3 GB of free memory and 512 KB L1 cache running Red Hat Linux 3.3.3-7.

Benchmark characteristics. The LLVM distribution provides a broad variety of benchmarks: our implementation has compiled and run over 1.3 million lines of C code. LLVM 1.9 and our puzzle solver pass the same suite of benchmarks. In this section we will present measurements based on the SPEC CPU2000 benchmarks. Some characteristics of these benchmarks are given in Figure 11. All the figures use short names for the benchmarks; the full names are given in Figure 11. We order these benchmarks by the number of non-empty puzzles that they produce, which is given in Figure 6.

Puzzle characteristics. Figure 12 counts the types of puzzles generated from SPEC CPU2000. A total of $3.45 \%$ of the puzzles have pieces of different sizes plus pre-colored areas so they exercise all aspects of the puzzle solver. Most of the puzzles are simpler: $5.18 \%$ of them are empty, i.e., have no pieces; $58.16 \%$ have only pieces of the same size, and $83.66 \%$ have an empty board with no pre-colored areas.

As we show in Figure 6, 94.6\% of the nonempty puzzles in SPEC CPU2000 can be solved in the first try. When this is not the case, our spilling heuristic allows for solving a puzzle multiple times with a decreasing number of pieces until a solution is found. Figure 6 reports the average number of times that the puzzle solver had to be called per nonempty puzzle. On average, we solve each nonempty puzzle 1.05 times.

Three other register allocators. We compare our puzzle solver with three other register allocators, all implemented in LLVM 1.9 and all compiling and running the same benchmark suite of 1.3 million lines of C code. The first is LLVM's default algorithm, which is an industrial-strength version of linear scan that uses extensions by Wimmer et al. [41] and Evlogimenos [15]. The algorithm does aggressive coalescing before register allocation and handles holes in live ranges by filling them with other variables whenever possible. We use ELS (Extended Linear Scan) to denote this register allocator.

The second register allocator is the iterated register coalescing of George and Appel [18] with extensions by Smith, Ramsey, and

Figure 13. Number of calls to the puzzle solver per nonempty puzzle. \#puzzles: number of nonempty puzzles. avg and max: average and maximum number of times the puzzle solver was used per puzzle. once: number of puzzles for which the puzzle solver was used only once.

Holloway [37] for handling register aliasing. We use EIRC (Extended Iterated Register Coalescing) to denote this register allocator.

The third register allocator is based on partitioned Boolean quadratic programming (PBQP) [36]. The algorithm runs in worstcase exponential time and does optimal spilling with respect to a set of Boolean constraints generated from the program text. We use this algorithm to gauge the potential for how good a register allocator can be. Lang Hames and Bernhard Scholz produced the implementations of EIRC and PBQP that we are using.

Stack size comparison. The top half of Figure 14 compares the maximum amount of space that each assembly program reserves on its call stack. The stack size gives an estimate of how many different variables are being spilled by each allocator. The puzzle solver and extended linear scan (LLVM's default) tend to spill more variables than the other two algorithms.

Figure 14. In both charts, the bars are relative to the puzzle solver; shorter bars are better for the other algorithms. Stack size: Comparison of the maximum amount of bytes reserved on the stack. Number of memory accesses: Comparison of the total static number of load and store instructions inserted by each register allocator.

Spill-code comparison. The bottom half of Figure 14 compares the number of load/store instructions in the assembly code. The puzzle solver inserts marginally fewer memory-access instructions than PBQP, $1.2 \%$ fewer memory-access instructions than EIRC, and $9.6 \%$ fewer memory-access instructions than extended linear scan (LLVM's default). Note that although the puzzle solver spills more variables than the other allocators, it removes only part of the live range of a spilled variable.

Run-time comparison. Figure 15 compares the run time of the code produced by each allocator. Each bar shows the average of five runs of each benchmark; smaller is better. The base line is the run time of the code when compiled with gcc -O3 version 3.3.3. Note that the four allocators that we use (the puzzle solver, extended linear scan (LLVM's default), EIRC and PBQP) are implemented in LLVM, while we use gcc, an entirely different compiler, only for reference purposes. Considering all the benchmarks, the four allocators produce faster code than gcc; the fractions are: puzzle solver 0.944 , extended linear scan (LLVM's default) 0.991, EIRC 0.954 and PBQP 0.929. If we remove the floating point benchmarks, i.e., msa , amp, art, eqk, then gcc -O3 is faster. The fractions are: puzzle Solver 1.015, extended linear scan (LLVM's default) 1.059, EIRC 1.025 and PBQP 1.008. We conclude that the puzzle solver produces better code that the other polynomial-time allocators, but worse code than the exponential-time allocator.

Compile-time comparison. Figure 16 compares the register allocation time and the total compilation time of the puzzle solver and extended linear scan (LLVM's default). On average, extended linear scan (LLVM's default) is less than $1 \%$ faster than the puzzle solver. The total compilation time of LLVM with the default allocator is less than 3\% faster than the total compilation time of LLVM with the puzzle solver. We note that LLVM is industrial-strength and highly tuned software, in contrast to our puzzle solver.

We omit the compilation times of EIRC and PBQP because the implementations that we have are research artifacts that have not been optimized to run fast. Instead, we gauge the relative compilation speeds from statements in previous papers. The experiments

Figure 15. Comparison of the running time of the code produced with our algorithm and other allocators. The bars are relative to gcc -O3; shorter bars are better.

Figure 16. Comparison between compilation time of the puzzle solver and extended linear scan (LLVM's default algorithm). The bars are relative to the puzzle solver; shorter bars are better for extended linear scan.
shown in [24] suggest that the compilation time of PBQP is between two and four times the compilation time of extended iterated register coalescing. The extensions proposed by Smith et al. [37] can be implemented in way that add less than $5 \%$ to the compilation time of a graph-coloring allocator. Timing comparisons between graph coloring and linear scan (the core of LLVM's algorithm) span a wide spectrum. The original linear scan paper [34] suggests that graph coloring is about twice as slow as linear scan, while Traub et al. [39] gives an slowdown of up to 3.5 x for large programs, and Sarkar and Barik [35] suggests a 20x slowdown. From these observations we conclude that extended linear scan (LLVM's default) and our puzzle solver are approximately equally fast and that both are significantly faster than the other allocators.

## 7. Related Work

Register allocation is equivalent to graph coloring. We now discuss work on relating programs to graphs and on complexity results for variations of graph coloring. Figure 19 summarizes most of the results.

Register allocation and graphs. The intersection graph of the live ranges of a program is called interference graph. Figure 17 shows the interference graph of the elementary program in Figure 4(b). Any graph can be the interference graph of a gen-

Figure 17. Interference graph of the program in Figure 4(b).

Figure 18. Elementary graphs and other intersection graphs. RDVgraphs are intersection graphs of directed lines on a tree [32].
eral program [12]. SSA-form programs have chordal interference graphs [6, 9, 23], and the interference graphs of SSI-form programs are interval graphs [10]. We call the interference graph of an elementary program an elementary graph [33]. Each connected component of an elementary graph is a clique substitution of $P_{3}$, the simple path with three nodes. We construct a clique substitution of $P_{3}$ by replacing each node of $P_{3}$ by a clique, and connecting all the nodes of adjacent cliques.

Elementary graphs are a proper subset of interval graphs, which are contained in the class of chordal graphs. Figure 18 illustrates these inclusions. Elementary graphs are also Trivially Perfect Graphs [19], as we show in the proof of Lemma 8, given in an Appendix. In a trivially perfect graph, the size of the maximal independent set equals the size of the number of maximal cliques.

Spill-free Register Allocation. Spill-free register allocation is NP-complete for general programs [12] because coloring general graphs is NP-complete. However, this problem has a polynomial time solution for SSA-form programs [6, 9, 23] because chordal graphs can be colored in polynomial time [4]. This result assumes an architecture in which all the registers have the same size.

Aligned 1-2-Coloring. Register allocation for architectures with type-1 aliasing is modeled by the aligned 1-2-coloring problem. In this case, we are given a graph in which vertices are assigned a weight of either 1 or 2 . Colors are represented by numbers, e.g: $0,1, \ldots, 2 K-1$, and we say that the two numbers $2 i, 2 i+1$ are aligned. We define an aligned 1-2-coloring to be a coloring that assigns each weight-two vertex two aligned colors. The problem of finding an optimal 1-2-aligned coloring is NP-complete even for interval graphs [29].

Pre-coloring Extension. Register allocation with pre-coloring is equivalent to the pre-coloring extension problem for graphs. In this problem we are given a graph $G$, an integer $K$ and a partial function $\varphi$ that associates some vertices of $G$ to colors. The challenge is to extend $\varphi$ to a total function $\varphi^{\prime}$ such that (1) $\varphi^{\prime}$ is a proper coloring of $G$ and (2) $\varphi^{\prime}$ uses less than $K$ colors. Precoloring extension is NP-complete for interval graphs [4] and even for unit interval graphs [31].

Aligned 1-2-coloring Extension. The combination of 1-2aligned coloring and pre-coloring extension is called aligned 1 2 -coloring extension. We show in the proof of Lemma 16, given

|  | Class of graphs |  |  |  |

in an Appendix, that this problem, when restricted to elementary graphs, is equivalent to solving type-1 puzzles; thus, it has a polynomial time solution.

## 8. Conclusion

In this paper we have introduced register allocation by puzzle solving. We have shown that our puzzle-based allocator runs as fast as the algorithm used in a industrial-strength JIT compiler and that it produces code that is competitive with state-of-the-art algorithms. A compiler writer can easily model a register file as a puzzle board, and straightforwardly transform a source program into elementary form and then into puzzle pieces. For a compiler that already uses SSA-form as an intermediate representation, the extra step to elementary form is small. Our puzzle solver works for architectures such as x86, SPARC V8, ARM, and PowerPC. Puzzle solving for SPARC V9 (type-2 puzzles) remains an open problem.

## Acknowledgments

Fernando Pereira was sponsored by the Brazilian Ministry of Education under grant number 218603-9. We thank Lang Hames and Bernhard Scholz for providing us with their implementations of EIRC and PBQP. We thank João Dias, Glenn Holloway, Ayee Kannan Goundan, Stephen Kou, Jonathan Lee, Todd Millstein, Norman Ramsey, and Ben Titzer for helpful comments on a draft of the paper.

## A. Proof of Theorem 1

We will prove Theorem 1 for register banks that give type-1 puzzles. Theorem 1 states:
(Equivalence) Spill-free register allocation with precoloring for an elementary program is equivalent to solving a collection of puzzles.

In Section A. 1 we define three key concepts that we use in the proof, namely aligned 1-2-coloring extension, clique substitution of $P_{3}$, and elementary graph. In Section A. 2 we state four key lemmas and show that they imply Theorem 1. Finally, in four separate subsections, we prove the four lemmas.

## A. 1 Definitions

We first state again a graph-coloring problem that we mentioned in Section 7, namely aligned 1-2-coloring extension.

## Aligned 1-2-COLORING EXTENSION

Instance: a number of colors $2 K$, a weighted graph $G$, and a partial aligned 1-2-coloring $\varphi$ of $G$. Problem: Extend $\varphi$ to an aligned 1-2-coloring of $G$.

We use the notation $(2 K, G, \varphi)$ to denote an instance of the aligned 1-2-coloring extension problem. For a vertex $v$ of $G$, if $v \in \operatorname{dom}(\varphi)$, then we say that $v$ is pre-colored.

Next we define the notion of a clique substitution of $P_{3}$. Let $H_{0}$ be a graph with $n$ vertices $v_{1}, v_{2}, \ldots, v_{n}$ and let $H_{1}, H_{2}$, $\ldots, H_{n}$ be $n$ disjoint graphs. The composition graph [20] $H=$ $H_{0}\left[H_{1}, H_{2}, \ldots, H_{n}\right]$ is formed as follows: for all $1 \leq i, j \leq n$, replace vertex $v_{i}$ in $H_{0}$ with the graph $H_{i}$ and make each vertex of $H_{i}$ adjacent to each vertex of $H_{j}$ whenever $v_{i}$ is adjacent to $v_{j}$ in $H_{0}$. Figure 20 shows an example of composition graph.
$P_{3}$ is the path with three nodes, e.g., $(\{x, y, z\},\{x y, y z\})$. We define a clique substitution of $P_{3}$ as $P_{X, Y, Z}=P_{3}\left[K_{X}, K_{Y}, K_{Z}\right]$, where each $K_{S}$ is a complete graph with $|S|$ nodes.

Definition 5. A graph $G$ is an elementary graph if and only if every connected component of $G$ is a clique substitution of $P_{3}$.

Figure 20. Example of a composition graph (taken from [20]).

## A. 2 Structure of the Proof

We will prove the following four lemmas.

- Lemma 6: Spill-free register allocation with pre-coloring for an elementary program $P$ is equivalent to the aligned 1-2-coloring extension problem for the interference graph of $P$.
- Lemma 13: An elementary program has an elementary interference graph.
- Lemma 15: An elementary graph is the interference graph of an elementary program.
- Lemma 16: Aligned 1-2-coloring extension for a clique substitution of $P_{3}$ is equivalent to puzzle solving.

We can now prove Theorem 1:
Proof. From Lemmas 6, 13, and 15 we have that spill-free register allocation with pre-coloring for an elementary program is equivalent to aligned 1-2-coloring extension for elementary graphs. From Lemma 16 we have that aligned 1-2-coloring extension for elementary graphs is equivalent to solving a collection of puzzles.

## A. 3 From register allocation to coloring

Lemma 6. Spill-free register allocation with pre-coloring for an elementary program $P$ is equivalent to the aligned 1-2-coloring extension problem for the interference graph of $P$.

Proof. Chaitin et al. [12] have shown that spill-free register allocation for a program $P$ is equivalent to coloring the interference graph of $P$, where each color represents one physical register. To extend the spill-free register allocation to an architecture with a type-1 register bank, we assign weights to each variable in the interference graph, so that variables that fit in one register are assigned weight 1 , and variables that fit in a register-pair are assigned weight 2 . To include pre-coloring, we define $\varphi(v)=r$, if vertex $v$ represents a pre-colored variable, and color $r$ represents the register assigned to this variable. Otherwise, we let $\varphi(v)$ be undefined.

## A. 4 Elementary programs and graphs

We will show in three steps that an elementary program has an elementary interference graph. We first give a characterization of clique substitutions of $P_{3}$ (Lemma 8). Then we show that a graph $G$ is an elementary graph if and only if $G$ has an elementary interval representation (Lemma 10). Finally we show that the inter-
ference graph of an elementary program has an elementary interval representation and therefore is an elementary graph (Lemma 13).

## A.4.1 A Characterization of Clique Substitutions of $P_{3}$

We will give a characterization of a clique substitution of $P_{3}$ in terms of forbidden induced subgraphs. Given a graph $G=(V, E)$, we say that $H=\left(V^{\prime}, E^{\prime}\right)$ is an induced subgraph of $G$ if $V^{\prime} \subseteq V$ and, given two vertices $v$ and $u$ in $V^{\prime}, u v \in E^{\prime}$ if, and only if, $u v \in E$. Given a graph $F$, we say that $G$ is $F$-free if none of its induced subgraphs is isomorphic to $F$. In this case we say that $F$ is a forbidden subgraph of $G$. Some classes of graphs can be characterized in terms of forbidden subgraphs, that is, a set of graphs that cannot be induced in any of the graphs in that class. In this section we show that any graph $P_{X, Y, Z}$ has three forbidden subgraphs: (i) $P_{4}$, the simple path with four nodes; (ii) $C_{4}$, the cycle with four nodes, and (iii) $3 K_{1}$, the graph formed by three unconnected nodes. These graphs are illustrated in Figure 21, along with the bipartite graph $K_{3,1}$, known as the claw. The claw is important because it is used to characterize many classes of graphs. For example, the interval graphs that do not contain any induced copy of the claw constitute the class of the unit interval graphs [20, p. 187]. A key step of our proof of Lemma 10 shows that elementary graphs are claw-free.

Figure 21. Some special graphs.

We start our characterization by describing the class of the Trivially Perfect Graphs [19]. In a trivially perfect graph, the size of the maximal independent set equals the size of the number of maximal cliques.
THEOREM 7. (Golumbic [19]) A graph $G$ is trivially perfect if and only if $G$ contains no induced subgraph isomorphic to $C_{4}$ or $P_{4}$.

The next lemma characterizes $P_{X, Y, Z}$ in terms of forbidden subgraphs.

Lemma 8. A graph $G$ is a clique substitution of $P_{3}$ if and only if $G$ contains no induced subgraph isomorphic to $C_{4}, P_{4}$, or $3 K_{1}$.

Proof. $(\Rightarrow)$ Let $G$ be a clique substitution of $P_{3}$, and let $G$ be of the form $P_{X, Y, Z}$. Let us first show that $G$ is trivially perfect. Note that $G$ contains either one or two maximal cliques. If $G$ contains one maximal clique, we have that $G$ is of the form $P_{\emptyset, Y, \emptyset}$, and the maximal independent set has size 1 . If $G$ contains two maximal cliques, those cliques must be $X \cup Y$ and $X \cup Z$. In this case, the maximal independent set has two vertices, namely an element of $X-Y$ and an element of $Z-Y$. So, $G$ is trivially perfect, hence, by Theorem 7, $G$ does not contain either $C_{4}$ nor $P_{4}$ as induced subgraphs. Moreover, the maximum independent set of $G$ has size one or two; therefore, $G$ cannot contain an induced $3 K_{1}$.
$(\Leftarrow)$ If $G$ is $C_{4}$-free and $P_{4}$-free, then $G$ is trivially perfect, by Theorem 7. Because $G$ is $3 K_{1}$-free, its maximal independent set has either one or two nodes. If $G$ is unconnected, we have that $G$ consists of two unconnected cliques; thus, $G=P_{X, \emptyset, Y}$. If $G$ is connected, it can have either one or two maximal cliques. In the first case, we have that $G=P_{\emptyset, Y, \emptyset}$. In the second, let these maximal cliques be $C_{1}$ and $C_{2}$. We have that $G=P_{C_{1}-C_{2}, C_{1} \cap C_{2}, C_{2}-C_{1}}$.

## A.4.2 A Characterization of Elementary Graphs

We recall the definitions of an intersection graph and an interval graph [20, p.9]. Let $\mathcal{S}$ be a family of nonempty sets. The intersection graph of $\mathcal{S}$ is obtained by representing each set in $\mathcal{S}$ by a vertex and connecting two vertices by an edge if and only if their corresponding sets intersect. An interval graph is an intersection graph of a family of subintervals of an interval of the real numbers.

A rooted tree is a directed tree with exactly one node of indegree zero; this node is called root. Notice that there is a path from the root to any other vertex of a rooted tree. The intersection graph of a family of directed vertex paths in a rooted tree is called $a$ rooted directed vertex path graph, or RDV [32]. A polynomial time algorithm for recognizing RDV graphs was described in [17]. The family of RDV graphs includes the interval graphs, and is included in the class of chordal graphs. An example of RDV graph is given in Figure 22.

Figure 22. (a) Directed tree $T$. (b) Paths on $T$. (c) Corresponding RDV graph.

Following the notation in [17], we let $L=\left\{\overline{v_{1}}, \ldots, \overline{v_{n}}\right\}$ denote a set of $n$ directed paths in a rooted tree $T$. The RDV graph that corresponds to $L$ is $G=\left(\left\{v_{1}, \ldots, v_{n}\right\}, E\right)$, where $v_{i} v_{j} \in E$ if and only if $\overline{v_{i}} \cap \overline{v_{j}} \neq \emptyset$. We call $L$ the path representation of $G$. Because $T$ is a rooted tree, each interval $\bar{v}$ has a well-defined start point $\operatorname{begin}(\bar{v})$, and a well-defined end point $\operatorname{end}(\bar{v}): \operatorname{begin}(\bar{v})$ is the point of $\bar{v}$ closest to the root of $T$, and end $(\bar{v})$ is the point of $\bar{v}$ farthest from the root.

Given a connected graph $G=(V, E)$, the distance between two vertices $\{u, v\} \subseteq V$ is the number of edges in the shortest path connecting $u$ to $v$. The diameter of $G$ is the maximal distance between any two pairs of vertices of $G$. A key step in the proof of Lemma 10 below (Claim 3) shows that the diameter of any connected component of an elementary graph is at most 2.

We define elementary interval representation as follows:
Definition 9. A graph $G$ has an elementary interval representation if:

1. $G$ is a $R D V$ graph.
2. If $u v \in E$, then $\operatorname{begin}(\bar{u})=\operatorname{begin}(\bar{v})$, or $\operatorname{end}(\bar{u})=\operatorname{end}(\bar{v})$.
3. If $u v \in E$, then $\bar{u} \subseteq \bar{v}$ or $\bar{v} \subseteq \bar{u}$.

Lemma 10 shows that any elementary graph has an elementary interval representation.

Lemma 10. A graph $G$ is an elementary graph if, and only if, $G$ has an elementary interval representation.
Proof. $(\Leftarrow)$ We first prove six properties of $G$ :

- Claim 1: If $a, b, c \in V, a b \in E, b c \in E$ and $a c \notin E$, then we have $(\bar{a} \cup \bar{c}) \subseteq \bar{b}$ in any path representation of $G$.
- Claim 2: $G$ is $P_{4}$-free.
- Claim 3: Let $C=\left(V_{C}, E_{C}\right)$ be a connected component of $G$. Given $a, b \in V_{C}$ such that $a b \notin E_{C}$, then $\exists v$ such that $a v \in E_{C}$ and $b v \in E_{C}$.
- Claim 4: $G$ is claw-free.
- Claim 5: Every connected component of $G$ is $3 K_{1}$-free.
- Claim 6: $G$ is $C_{4}$-free.

Proof of Claim 1. Let us first show that $\bar{b} \nsubseteq \bar{a}$. If $\bar{b} \subseteq \bar{a}$, then, from $a c \notin E$ we would have $b c \notin E$, which is a contradiction. Given that $a b \in E$ and $\bar{b} \nsubseteq \bar{a}$ we have that $\bar{a} \subseteq \bar{b}$. By symmetry, we have that $\bar{c} \subseteq \bar{b}$. We conclude that $(\bar{a} \cup \bar{c}) \subseteq \bar{b}$.

Proof of Claim 2. Assume $G$ contains four vertices $x, y, z$ and $w$ that induce the path $\{x y, y z, z w\}$ in $G$. From Claim 1 we have $(\bar{x} \cup \bar{z}) \subseteq \bar{y}$; in particular, $\bar{z} \subseteq \bar{y}$. Similarly we have $(\bar{y} \cup \bar{w}) \subseteq \bar{z}$; in particular, $\bar{y} \subseteq \bar{z}$. So, $\bar{y}=\bar{z}$. From $z w \in E$ and $\bar{y}=\bar{z}$, we have $y w \in E$, contradicting that the set $\{x, y, z, w\}$ induces a path in $G$.

Proof of Claim 3. From Claim 2 we have that $G$ is $P_{4}$-free, so any minimal-length path between two connected vertices contains either one or two edges. We have $a, b \in V_{C}$ so $a, b$ are connected, and we have $a b \notin E_{C}$, so we must have a minimal-length path $\{a v, v b\}$ for some vertex $v$.

Proof of Claim 4. Let $L$ be $G$ 's directed path representation. Suppose $G$ contains four vertices $x, y, z, w$ that induce the claw $\{x y, x z, x w\}$. Without loss of generality, we assume $\operatorname{begin}(\bar{x})=$ $\operatorname{begin}(\bar{y})$. Because $G$ is an RDV-graph, we must have end $(\bar{x})=$ $\operatorname{end}(\bar{z})$. However, $x$ and $w$ interfere, yet, $w$ cannot share the starting point with $x$, or it would interfere with $y$, nor can $w$ share its end point with $x$, or it would interfere with $z$. So, the claw is impossible.

Proof of Claim 5. Let $C=\left(V_{C}, E_{C}\right)$ be a connected component of $G$. Assume, for the sake of contradiction, that there are three vertices $\{a, b, c\} \in V_{C}$ such that $a b \notin E_{C}, a c \notin E_{C}$ and $b c \notin E_{C}$. From Claim 3 we have that there exists a vertex $v_{a b}$ that is adjacent to $a$ and $b$. Likewise, we know that there exists a vertex $v_{b c}$ that is adjacent to $b$ and $c$. From Claim 1 we have that in any path representation of $G$, $(\bar{a} \cup \bar{b}) \subseteq \overline{v_{a b}}$. We also know that $(\bar{b} \cup \bar{c}) \subseteq \overline{v_{b c}}$. Therefore, $\bar{b} \subseteq\left(\overline{v_{a b}} \cap \overline{v_{b c}}\right)$, so $v_{a b} v_{b c} \in E_{C}$, hence either $\overline{v_{a b}} \subseteq \overline{v_{b c}}$ or $\overline{v_{b c}} \subseteq \overline{v_{a b}}$. If the first case holds, $\left\{a, b, c, v_{b c}\right\}$ induces a claw in $G$, which is impossible, given Claim 4. In the second case, $\left\{a, b, c, v_{a b}\right\}$ induces a claw.

Proof of Claim 6. By definition, RDV graphs are chordal graphs, which are $C_{4}$ free.

Finally, we prove that every connected component of $G$ is a clique substitution of $P_{3}$. By Lemma 8, a minimal characterization of clique substitutions of $P_{3}$ in terms of forbidden subgraphs consists of $C_{4}, P_{4}$, and $3 K_{1}$. $G$ is $C_{4}$-free, from Claim 6, and $G$ is $P_{4}$-free, from Claim 2. Any connected component of $G$ is $3 K_{1}$ free, from Claim 5.
$(\Rightarrow)$ Let $G$ be a graph with $K$ connected components, each of which is a clique substitution of $P_{3}$. Let $P_{X, Y, Z}$ be one of $G$ 's connected components. We first prove that $P_{X, Y, Z}$ has an elementary interval representation. Let $T$ be a rooted tree isomorphic to $P_{4}=(\{a, b, c, d\},\{a b, b c, c d\})$, and let $a$ be its root. We build an elementary graph $G_{P}$, isomorphic to $P_{X, Y, Z}$ using intervals on $T$. We let $\overrightarrow{v_{1} v_{2} \ldots v_{n}}$ denote the directed path that starts at node $v_{1}$ and ends at node $v_{n}$. We build an elementary interval representation of $P_{X, Y, Z}$ as follows: for any $x \in X$, we let $\bar{x}=\overrightarrow{a b}$. For any
$y \in Y$, we let $\bar{y}=\overrightarrow{a b c d}$. And for any $z \in Z$, we let $\bar{z}=\overrightarrow{c d}$. It is straightforward to show that the interval representation meets the requirements of Definition 9 .

Let us then show that $G$ has an elementary interval representation. For each connected component $C_{i}, 1 \leq i \leq K$ of $G$, let $T_{i}$ be the rooted tree that underlies its directed path representation, and let $\operatorname{root}_{i}$ be its root. Build a rooted tree $T$ as $\operatorname{root} \cup T_{i}, 1 \leq i \leq K$, where root is a new node not in any $T_{i}$, and let root be adjacent to each $\operatorname{root}_{i} \in T_{i}$. The directed paths on each branch of $T$ meet the requirements in Lemma 10 and thus constitute an elementary interval representation.

Lemma 10 has a straightforward corollary that justifies one of the inclusions in Figure 18.

## Corollary 11. An elementary graph is a unit interval graph.

Proof. Let us first show that a clique substitution of $P_{3}$ is a unit interval graph. Let $i$ be an integer. Given $P_{X, Y, Z}$, we define a unit interval graph $I$ in the following way. For any $x \in X-Y$, let $\bar{x}=[i, i+3]$; for any $y \in(Y-(X \cup Z))$, let $\bar{y}=[i+2, i+5]$; and for any $z \in Z-Y$, let $\bar{z}=[i+4, i+7]$. Those intervals represent $P_{X, Y, Z}$ and constitute a unit interval graph.

By the definition of elementary graphs we have that every connected component of $G$ is a clique substitution of $P_{3}$. From each connected component $G$ we can build a unit interval graph and then assemble them all into one unit interval graph that represents $G$.

## A.4.3 An elementary program has an elementary interference graph

Elementary programs were first introduced in Section 2.2. In that section we described how elementary programs could be obtained from ordinary programs via live range splitting and renaming of variables; we now give a formal definition of elementary programs.

Program points and live ranges have been defined in Section 2.2. We denote the live range of a variable $v$ by $L R(v)$, and we let $\operatorname{def}(v)$ be the instruction that defines $v$. A program $P$ is strict [11] if every path in the control-flow graph of $P$ from the start node to a use of a variable $v$ passes through one of the definitions of $v$. A program $P$ is simple if $P$ is a strict program in SSA-form and for any variable $v$ of $P, L R(v)$ contains at most one program point outside the basic block that contains $\operatorname{def}(v)$. For a variable $v$ defined in a basic block $B$ in a simple program, we define $\operatorname{kill}(v)$ to be either the unique instruction outside $B$ that uses $B$, or, if $v$ is used only in $B$, the last instruction in $B$ that uses $v$. Notice that because $P$ is simple, $L R(v)$ consists of the program points on the unique path from $\operatorname{def}(v)$ to $\operatorname{kill}(v)$. Elementary programs are defined as follows:

Definition 12. A program produced by the grammar in Figure 23 is in elementary form if, and only if, it has the following properties:

1. $P_{e}$ is a simple program;
2. if two variables $u, v$ of $P_{e}$ interfere, then either $\operatorname{def}(u)=$ $\operatorname{def}(v)$, or $\operatorname{kill}(u)=\operatorname{kill}(v)$; and
3. if two variables $u, v$ of $P_{e}$ interfere, then either $L R(u) \subseteq$ $L R(v)$, or $L R(v) \subseteq L R(u)$.
We can produce an elementary program from a strict program:

- insert $\varphi$-functions at the beginning of basic blocks with multiple predecessors;
- insert $\pi$-functions at the end of basic blocks with multiple successors;
- insert parallel copies between consecutive instruction in the same basic block; and

| $P$ | $::=$ | $S\left(L \varphi(m, n) i^{*} \pi(p, q)\right)^{*} E$ |
| ---: | :--- | :--- |
| $L$ | $::=$ | $L_{\text {start }}, L_{1}, L_{2}, \ldots, L_{\text {end }}$ |
| $v$ | $:==$ | $v_{1}, v_{2}, \ldots$ |
| $r$ | $::=$ | $\mathrm{AX}, \mathrm{AH}, \mathrm{AL}, \mathrm{BX}, \ldots$ |
| $o$ | $::=$ | $\bullet$ |
|  | $\mid$ | $v$ |
| $S$ | $::=$ | $L_{\text {start }}: \pi(p, q)$ |
| $E$ | $::=$ | $L_{\text {end }}: \operatorname{halt}$ |
| $i$ | $::=$ | $o=o$ |
|  | $\mid=$ | $V(n)=V(n)$ |
| $\pi(p, q)$ | $::=$ | $M(p, q)=\pi V(q)$ |
| $\varphi(n, m)$ | $::=$ | $V(n)=\varphi M(m, n)$ |
| $V(n)$ | $::=$ | $\left(o_{1}, \ldots, o_{n}\right)$ |
| $M(m, n)$ | $::=$ | $V_{1}(n): L_{1}, . ., V_{m}(n): L_{m}$ |

Figure 23. The grammar of elementary programs.

- rename variables at every opportunity given by the $\varphi$-functions, $\pi$-functions, and parallel copies.

An elementary program $P$ generated by the grammar 23 is a sequence of basic blocks. A basic block, which is named by a label $L$, is a sequence of instructions, starting with a $\varphi$-function and ending with a $\pi$-function. We assume that a program $P$ has two special basic blocks: $L_{\text {start }}$ and $L_{\text {end }}$, which are, respectively, the first and last basic blocks to be visited during $P$ 's execution. Ordinary instructions either define, or use, one operand, as in $r_{1}=$ $v_{1}$. An instruction such as $v_{1}=\bullet$ defines one variable but does not use a variable or register. Parallel copies are represented as $\left(v_{1}, \ldots, v_{n}\right)=\left(v_{1}^{\prime}, \ldots, v_{n}^{\prime}\right)$.

In order to split the live range of variables, elementary programs use $\varphi$-functions and $\pi$-functions. $\varphi$-functions are an abstraction used in SSA-form to join the live ranges of variables. An assignment such as:
$\left(v_{1}, \ldots, v_{n}\right)=\varphi\left[\left(v_{11}, \ldots, v_{n 1}\right): L_{1}, \ldots\left(v_{1 m}, \ldots, v_{n m}\right): L_{m}\right]$ contains $n \varphi$-functions such as $v_{i} \leftarrow \varphi\left(v_{i 1}: L_{1}, \ldots, v_{i m}: L_{m}\right)$. The $\varphi$ symbol works as a multiplexer. It will assign to each $v_{i}$ the value in $v_{i j}$, where $j$ is determined by $L_{j}$, the basic block last visited before reaching the $\varphi$ assignment. Notice that these assignments happen in parallel, that is, all the variables $v_{1 i}, \ldots, v_{n i}$ are simultaneously copied into the variables $v_{1}, \ldots, v_{n}$.

The $\pi$-functions were introduced in [25] with the name of swicth nodes. The name $\pi$-node was established in [5]. The $\pi$ nodes, or $\pi$-functions, as we will call them, are the dual of $\varphi$ functions. Whereas the latter has the functionality of a variable multiplexer, the former is analogous to a demultiplexer, that performs a parallel assignment depending on the execution path taken. Consider, for instance, the assignment below:
$\left[\left(v_{11}, \ldots, v_{n 1}\right): L_{1}, \ldots\left(v_{1 m}, \ldots, v_{n m}\right): L_{m}\right]=\pi\left(v_{1}, \ldots, v_{n}\right)$
which represents $m \pi$-nodes such as $\left(v_{i 1}: L_{1}, \ldots, v_{i m}: L_{m}\right) \leftarrow$ $\pi\left(v_{i}\right)$. This instruction has the effect of assigning to each variable $v_{i j}: L_{j}$ the value in $v_{i}$ if control flows into block $L_{j}$. Notice that variables alive in different branches of a basic block are given different names by the $\pi$-function that ends that basic block.
Lemma 13. An elementary program has an elementary interference graph.

Proof. Let $P$ be an elementary program, let $G=(V, E)$ be $P$ 's interference graph, and let $T_{P}$ be $P$ 's dominator tree. We first prove that for any variable $v, L R(v)$ determines a directed path in $T_{P}$. Recall that $L R(v)$ consists of the vertices on the unique path from

Figure 24. An elementary program representing a clique substitution of $P_{3}$.
$\operatorname{def}(v)$ to $\operatorname{kill}(v)$. Those vertices are all in the same basic block, possibly except $\operatorname{kill}(v)$. So every vertex on that path dominates the later vertices on the path, hence $L R(v)$ determines a directed path in $T_{P}$. So, $G$ is an RDV-graph. Given a variable $v$, we let $\operatorname{begin}(L R(v))=\operatorname{def}(v)$, and we let $\operatorname{end}(L R(v))=\operatorname{kill}(v)$. The second and third requirements in Lemma 10 follow immediately from the second and third requirements in Definition 12.

## A. 5 An elementary graph is the interference graph of an elementary program

In this section we show in two steps that any elementary graph is the interference graph of some elementary program.

LEMMA 14. A clique substitution of $P_{3}$ is the interference graph of an instruction sequence.

Proof. Let $G=P_{X, Y, Z}$ be a clique substitution of $P_{3}$. Let $m=$ $|X|, n=|Y|$ and $p=|Z|$. We build a sequence of $2(m+n+p)$ instructions $i_{1}, \ldots i_{2(m+n+p)}$ that use $m+n+p$ variables, such that each instruction either defines or uses one variable:

| $i_{j}$ | $v_{j}$ | $=\bullet$ | for $j \in 1 . . n$ |
| :--- | ---: | :--- | :--- |
| $i_{n+j}$ | $v_{n+j}$ | $=\bullet$ | for $j \in 1 . . m$ |
| $i_{n+m+j}$ | $\bullet$ | $=v_{n+j}$ | for $j \in 1 . . m$ |
| $i_{n+2 m+j}$ | $v_{n+m+j}$ | $=\bullet$ | for $j \in 1 . . p$ |
| $i_{n+2 m+p+j}$ | $\bullet$ | $=v_{n+m+j}$ | for $j \in 1 . . p$ |
| $i_{n+2 m+2 p+j}$ | $\bullet$ | $=v_{j}$ | for $j \in 1 . . n$ |

Figure 24 illustrates the instructions. It is straightforward to show that $P_{X, Y, Z}$ is the interference graph of the instruction sequence.

Lemma 15. An elementary graph is the interference graph of an elementary program.
Proof. Let $G$ be an elementary graph and let $C_{1}, \ldots, C_{n}$ be the connected components of $G$. Each $C_{i}$ is a clique substitution of $P_{3}$ so from Lemma 14 we have that each $C_{i}$ is the interference graph of an instruction sequence $s_{i}$. We build an elementary program $P$ with $n+2$ basic blocks: $B_{\text {start }}, B_{1}, \ldots, B_{n}, B_{\text {end }}$, such that $B_{\text {start }}$ contains a single jump to $B_{1}$, each $B_{i}$ consists of $s_{i}$ followed by a single jump to $B_{i+1}$, for $1 \leq i \leq n-1$, and $B_{n}$ consists of $s_{n}$ followed by a single jump to $B_{\text {end }}$. The interference graph of the constructed program is $G$.

Figure 25. Example of padding. Square nodes represent vertices of weight two, and the other nodes represent vertices of weight one.

## A. 6 From Aligned 1-2-coloring to Puzzle Solving

We now show that aligned 1-2-coloring extension for clique substitutions of $P_{3}$ and puzzle solving are equivalent under linear-time reductions. Our proof is in two steps: first we show how to simplify the aligned 1-2-coloring extension problem by padding a graph, and then we show how to map a graph to a puzzle.

Padding of puzzles has been defined in Section 3. A similar concept applies to clique substitutions of $P_{3}$. We say that a graph $P_{X, Y, Z}$ is $2 K$-balanced, if (1) the weight of $X$ equals the weight of $Z$, and (2) the weight $X \cup Y$ is $2 K$. We pad $P_{X, Y, Z}$ by letting $X^{\prime}, Z^{\prime}$ be sets of fresh vertices of weight one such that the padded graph $P_{\left(X \cup X^{\prime}\right), Y,\left(Z \cup Z^{\prime}\right)}$ is $2 K$-balanced. It is straightforward to see that padding executes in linear time. Figure 25 shows an example of padding. The original graph has two maximal cliques: $K_{X} \cup K_{Y}$ with weight 5 and $K_{Y} \cup K_{Z}$ with weight 4 . We use square nodes to denote vertices of weight two. After the padding, each maximal clique of the resulting graph has weight 6 .

It is straightforward to see that for any partial aligned 1-2coloring $\varphi$ whose domain is a subset of $X \cup Y \cup Z$, we have that $\left(2 K, P_{X, Y, Z}, \varphi\right)$ is solvable if and only if $\left(2 K, P_{\left(X \cup X^{\prime}\right), Y,\left(Z \cup Z^{\prime}\right)}, \varphi\right)$ is solvable.

We now define a bijection $\mathcal{F}$ from the aligned 1-2-coloring extension problem for 2 K -balanced clique substitutions of $P_{3}$ to puzzle solving. We will view a board with $K$ areas as a 2 -dimensional $2 \times 2 K$ table, in which the $i$ 'th area consists of the squares with indices $(1,2 i),(1,2 i+1),(2,2 i)$ and $(2,2 i+1)$.

Let $(2 K, G, \varphi)$ be an instance of the aligned 1-2-coloring extension problem, where $G$ is a $2 K$-balanced clique substitution of $P_{3}$. We define a puzzle $\mathcal{F}(2 K, G, \varphi)$ with $K$ areas and the following pieces:

- $\forall v \in X$, weight of $v$ is one: a size-1 X-piece. If $\varphi(v)$ is defined and $\varphi(v)=i$, then the piece is placed on the square $(1, i)$, otherwise the piece is off the board.
- $\forall v \in X$, weight of $v$ is two: a size-2 X-piece. If $\varphi(v)$ is defined and $\varphi(v)=\{2 i, 2 i+1\}$, then the piece is placed on the upper row of area $i$, otherwise the piece is off the board.
- $\forall v \in Y$, weight of $v$ is one: a size-2 Y-piece. If $\varphi(v)$ is defined and $\varphi(v)=i$, then the piece is placed on the squares $(1, i)$ and $(2, i)$, otherwise the piece is off the board.
- $\forall v \in Y$, weight of $v$ is two: a size-4 Y-piece. If $\varphi(v)$ is defined and $\varphi(v)=\{2 i, 2 i+1\}$, then the piece is placed on area $i$. otherwise the piece is off the board.
- $\forall v \in Z$, weight of $v$ is one: a size-1 Z-piece. If $\varphi(v)$ is defined and $\varphi(v)=i$, then the piece is placed on the square $(2, i)$, otherwise the piece is off the board.
- $\forall v \in Z$, weight of $v$ is two: a size-2 Z-piece. If $\varphi(v)$ is defined and $\varphi(v)=\{2 i, 2 i+1\}$, then the piece is placed on the lower row of area $i$, otherwise the piece is off the board.

Given that $\varphi$ is a partial aligned 1-2-coloring of $G$, we have that the pieces on the board don't overlap. Given that $G$ is $2 K$-balanced, we
have that the pieces have a total size of $4 K$ and that the total size of the X -pieces is equal to the total size of the Z-pieces.

It is straightforward to see that $\mathcal{F}$ is injective and surjective, so $\mathcal{F}$ is a bijection. It is also straightforward to see that $\mathcal{F}$ and $\mathcal{F}^{-1}$ both execute in $O(K)$ time.

Lemma 16. Aligned 1-2-coloring extension for a clique substitution of $P_{3}$ is equivalent to puzzle solving.

Proof. First we reduce aligned 1-2-coloring extension to puzzle solving. Let $(2 K, G, \varphi)$ be an instance of the aligned 1-2-coloring extension problem where $G$ is a clique substitution of $P_{3}$. Via the linear-time operation of padding, we can assume that $G$ is $2 K$ balanced. Use the linear-time reduction $\mathcal{F}$ to construct a puzzle $\mathcal{F}(2 K, G, \varphi)$. Suppose $(2 K, G, \varphi)$ has a solution. The solution extends $\varphi$ to an aligned 1-2-coloring of $G$, and we can then use $\mathcal{F}$ to place all the pieces on the board. Conversely, suppose $\mathcal{F}(2 K, G, \varphi)$ has a solution. The solution places the remaining pieces on the board, and we can then use $\mathcal{F}^{-1}$ to define an aligned 1-2-coloring of $G$ which extends $\varphi$.

Second we reduce puzzle solving to aligned 1-2-coloring. Let $\mathcal{P}$ be a puzzle and use the linear-time reduction $\mathcal{F}^{-1}$ to construct an instance of the aligned 1-2-coloring extension problem $\mathcal{F}^{-1}(\mathcal{P})=$ $(2 K, G, \varphi)$, where $G$ is a clique substitution of $P_{3}$. Suppose $\mathcal{P}$ has a solution. The solution places all pieces on the board, and we can then use $\mathcal{F}^{-1}$ to define an aligned 1-2-coloring of $G$ which extends $\varphi$. Conversely suppose $\mathcal{F}^{-1}(\mathcal{P})$ has a solution. The solution extends $\varphi$ to an aligned 1-2-coloring of $G$, and we can then use $\mathcal{F}$ to place all the pieces on the board.

## B. Proof of Theorem 2

Theorem 2 states:
(Correctness) A type-1 puzzle is solvable if and only if our program succeeds on the puzzle.

We first show that an application of a rule from the algorithm given in Figure 8 preserves solvability of a puzzles.

Lemma 17. (Preservation) Let $\mathcal{P}$ be a puzzle and let $i \in\{1, \ldots, 15\}$ be the number of a statement in our program. For $i \in\{11,12,13,14\}$, suppose every area of $\mathcal{P}$ is either complete, empty, or has just one square already filled in. For $i=15$, suppose every area of $\mathcal{P}$ is either complete or empty. Let a be an area of $\mathcal{P}$ such that the pattern of statement $i$ matches $a$. If $\mathcal{P}$ is solvable, then the application of statement $i$ to a succeeds and results in a solvable puzzle.

Proof. We begin by outlining the proof technique that we will use for each $i \in\{1, \ldots, 15\}$. Notice that statement $i$ contains a rule for each possible strategy that can be used to complete $a$. Let $\mathcal{S}$ be a solution of $\mathcal{P}$. Given that $\mathcal{S}$ completes $a$, it is straightforward to see that the application of statement $i$ to $a$ succeeds, although possibly using a different strategy than $\mathcal{S}$. Let $\mathcal{P}^{\prime}$ be the result of the application of statement $i$ to $a$. To see that $\mathcal{P}^{\prime}$ is a solvable puzzle, we do a case analysis on (1) the strategy used by $\mathcal{S}$ to complete $a$ and (2) the strategy used by statement $i$ to complete $a$. For each case of (1), we analyze the possible cases of (2), and we show that one can rearrange $\mathcal{S}$ into $\mathcal{S}^{\prime}$ such that $\mathcal{S}^{\prime}$ is a solution of $\mathcal{P}^{\prime}$. Let us now do the case analysis itself. If statement $i$ is a conditional statement, then we will use $i . n$ to denote the $n^{\text {th }}$ rule used in statement $i$.
$i=1$. The area $a$ can be completed in just one way. So, $\mathcal{S}$ uses the same strategy as statement 1 to complete $a$, hence $\mathcal{S}$ is a solution of $\mathcal{P}^{\prime}$.
$i \in\{2,3,4,5\}$. The proof is similar to the proof for $i=1$, we omit the details.
$i=7$. The area $a$ can be completed in two ways. If $\mathcal{S}$ uses the strategy of rule 7.1 to complete $a$, then statement 7 uses that
strategy, too, hence $\mathcal{S}$ is a solution of the resulting puzzle. If $\mathcal{S}$ uses the strategy of rule 7.2 to complete $a$, we have two cases. Either statement 7 uses the strategy of rule 7.2 , too, in which case $\mathcal{S}$ is a solution of $\mathcal{P}^{\prime}$. Otherwise, statement 7 uses the strategy of rule 7.1 , in which case we can create $\mathcal{S}^{\prime}$ from $\mathcal{S}$ in the following way. We swap the two size-2 X-pieces used by $\mathcal{S}$ to complete $a$, with the size-2 X-piece used by statement 7 to complete $a$. To illustrate the swap, here are excerpts of $\mathcal{P}, \mathcal{S}, \mathcal{P}^{\prime}, \mathcal{S}^{\prime}$ for a representative $\mathcal{P}$.

It is straightforward to see that $\mathcal{S}^{\prime}$ is a solution of $\mathcal{P}^{\prime}$.
$i \in\{8,9,10\}$. The proof is similar to the proof for $i=7$, we omit the details.
$i=11$. The area $a$ can be completed in three ways. If $\mathcal{S}$ uses the strategy of rule 11.1 or of rule 11.3 to complete $a$, the proof proceeds in a manner similar to the proof for $i=7$, we omit the details. If $\mathcal{S}$ uses the strategy of rule 11.2 to complete $a$, we have two cases. Either statement 11 uses the strategy of rule 11.2, too, in which case $\mathcal{S}$ is a solution of $\mathcal{P}^{\prime}$. Otherwise, statement 11 uses the strategy of rule 11.1, and now we have several of subcases of $\mathcal{S}$. Because of the assumption that all areas of $\mathcal{P}$ are either complete, empty, or has just one square already filled in, the following subcase is the most difficult; the other subcases are easier and omitted. Here are excerpts of $\mathcal{P}, \mathcal{S}, \mathcal{P}^{\prime}, \mathcal{S}^{\prime}$.

It is straightforward to see that $\mathcal{S}^{\prime}$ is a solution of $\mathcal{P}^{\prime}$.
$i \in\{12,13,14\}$. The proof is similar to the proof for $i=11$, we omit the details.
$i=15$. The proof is similar to the proof for $i=11$, with a total of 28 subcases. All the subcases turn out to be easy because of the assumption that all areas of $\mathcal{P}$ are either complete or empty. We omit the details.

## We can now prove Theorem 2 (Correctness).

Proof. Suppose first that $\mathcal{P}$ is a solvable puzzle. We must show that our program succeeds on $\mathcal{P}$, that is, all the 15 statements succeed. From Lemma 17 and induction on the statement number we have that indeed all 15 statements succeed.

Conversely, suppose $\mathcal{P}$ is a puzzle and that our program succeeds on $\mathcal{P}$. Statements $1-4$ complete all areas with three squares already filled in. Statements $5-10$ complete all areas with two squares already filled in. Statements $11-14$ complete all areas with one square already filled in. Statement 15 completes all areas with
no squares already filled in. So, when our program succeeds on $\mathcal{P}$, the result is a solution to the puzzle.

As a collary we get the following complexity result.
Lemma 18. The aligned 1-2-coloring extension problem for an elementary graph $G$ is solvable in $O(C \times K)$, where $C$ is the number of connected components of $G$, and $2 K$ is the number of colors.

Proof. Let $(2 K, G, \varphi)$ be an instance of the aligned 1-2-coloring extension problem for which $G$ is an elementary graph. We first list the connected components of $G$ in linear time [13]. All the connected components of $G$ are clique substitutions of $P_{3}$. Next, for each connected component, we have from Lemma 16 that we can reduce the aligned 1-2-coloring extension problem to a puzzle solving problem in linear time. Finally, we run our linear-time puzzle solving program on each of those puzzles (Theorem 2). The aligned 1-2-coloring extension problem is solvable if and only if all those puzzles are solvable. The total running time is $O(C \times K)$.

## C. Proof of Theorem 4

## Theorem 4 (Hardness) states:

Register allocation with pre-coloring and spilling of families of variables for an elementary program is NPcomplete.

We reduce this problem to the maximal K-colorable subgraph of a chordal graph, which was proved to be NP-complete by Yannakakis and Gavril [42]. The key step is to show that any chordal graph is the interference graph of a program in SSA form. We first define a convenient representation of chordal graphs. Suppose we have a tree $T$ and a family $V$ of subtrees of $T$. We say that $(T, V)$ is a program-like decomposition if for for all $\sigma \in V$ we have that (1) the root of $\sigma$ has one successor. (2) each leaf of $\sigma$ has zero or one successor, (3) each vertex of $T$ is the root of at most one element of $V$, (4) a vertex of $T$ is the leaf of at most one element of $V$, in which case it is not the root of any subtree, and (5) each element of $V$ contains at least one edge. For each subtree $\sigma \in V$, we identify $\operatorname{root}_{\sigma}$ as the vertex of $\sigma$ that is closest to the root of $T$.

In order to prove that any chordal graph has a program like decomposition, we rely on the concept of nice tree decomposition [30]. Given a nice tree $T$, for each vertex $x \in T$ we denote by $K_{x}$ the union of all the subtrees that touch $x$. T satisfies the following properties: (1) Every node $x$ has at most two children. (2) If $x \in T$ has two children, $y, z \in T$, then $K_{x}=K_{y}=K_{z}$. In this case, $x$ is called a joint vertex. (3) If $x \in T$ has only one child, $y \in T$, then $K_{x}=K_{y} \cup\{u\}$, or $K_{x}=K_{y} \backslash\{u\}$. (4) If $x \in T$ has no children, then $K_{x}$ is reached by at most one subtree, and $x$ is called a leaf node. Figure 26 (b) shows a nice tree decomposition produced for the graph in Figure 26 (a). The program like decomposition is given in Figure 26 (c).
Lemma 19. A graph is chordal if and only if it has a program like tree decomposition.

Proof. $\Leftarrow$ : immediate.
$\Rightarrow$ : A graph is chordal if and only if it has a nice tree decomposition [30]. Given a chordal graph, and its nice tree decomposition, we build a program like decomposition as follows:
(1) the only nodes that have more than one successor are the joint nodes. If a joint node $v$ is the root of a subtree, replicate $v$. Let $v^{\prime}$ be the replicated node. Add the predecessor of $v$ as the predecessor of $v^{\prime}$, and let the unique predecessor of $v$ be $v^{\prime}$. Now, $v^{\prime}$ is the root of any subtree that contains $v$.
(2) this is in accordance to the definition of nice tree, for joint nodes are never leaves of subtrees.
(3) If there is $v \in T$ such that $v$ is the root of $\sigma_{x}, \sigma_{y} \in V$, then replicate $v$. Let $v^{\prime}$ be the replicated node in such a way that $K_{v^{\prime}}=K_{v} \backslash\{x\}$. Add the predecessor of $v$ as the predecessor of $v^{\prime}$, and let the unique predecessor of $v$ be $v^{\prime}$. Now, $v^{\prime}$ is the root of any subtree that reaches $v$, other than $\sigma_{y}$.
(4) If there is $v \in T$ such that $v$ is the leaf of $\sigma_{x}, \sigma_{y} \in V$, then replicate $v$. Let $v^{\prime}$ be the replicated node in such a way that $K_{v^{\prime}}=K_{v} \backslash\{x\}$. Add the sucessor of $v$ as the successor of $v^{\prime}$, and let the unique successor of $v$ be $v^{\prime}$. Now, $v^{\prime}$ is the leaf of any subtree that reaches $v$, except $\sigma_{y}$.
(5) If there is a subtree that only spans one node, replicate that node as was done in (1).

We next define simple notions of statement and program that are suitable for this paper. We use $v$ to range over program variables. A statement is defined by the grammar:

| (Statement) $s$ | $::=$$v=$ (definition of $v)$ <br> $=v$ (use of $v)$ <br>  skip |  |
| :---: | :---: | :---: |

A program is a tree-structured flow chart of a particular simple form: a program is a pair $(T, \ell)$ where $T$ is a finite tree, $\ell$ maps each vertex of $T$ with zero or one successor to a statement, and each variable $v$ is defined exactly once and the definition of $v$ dominates all uses of $v$. Notice that a program is in strict SSA form.

The interference graph of a program $(T, \ell)$ is an intersection graph of a family of subtrees $V$ of $T$. The family of subtrees consists of one subtree, called the live range, per variable $v$ in the program; the live range is the subtree of the finite tree induced by the set of paths from each use of $v$ to the definition of $v$. Notice that a live range consists of both vertices and edges (and not, as is more standard, edges only). That causes no problem here because we don't allow a live range to end in the same node as another live range begins.

From a chordal graph $G$ presented as a finite tree $T$ and a program-like family of subtrees $V$, we construct a program $P_{G}=$ $(T, \ell)$, where for each subtree $\sigma \in V$, we define $\ell\left(\operatorname{root}_{\sigma}\right)$ tobe " $v_{\sigma}=$ ", and for each subtree $\sigma \in V$, and a leaf $n$ of $\sigma$, we define $\ell(n)$ tobe " $=v_{\sigma}^{\prime \prime}$. Figure 26(d) shows the program that corresponds to the tree in Figure 26 (c).

Lemma 20. $G$ is the interference graph of $P_{G}$.
Proof. For all $\sigma \in V$, the live range of $v_{\sigma}$ in $P$ is $\sigma$.
In Section 4 we introduced families of variables in an elementary program. This concept is formally defined as:

Definition 21. Let $P_{s}$ to be a strict program, and let $P_{e}$ to be the corresponding elementary program. Given a variable $v \in P_{s}$, the set $Q_{v}$ of all the variables in $P_{e}$ produced from the renaming of $v$ is called the family of variables $v$.

We emphasize that the union of the live ranges of all the variables in a family $Q_{v}$ is topologically equivalent to the live range of $v$. We state this fact as Lemma 22.

Lemma 22. Let $P_{s}$ be a strict program, and let $P_{e}$ be the elementary program derived from $P_{s}$. Let $v$ and $u$ be two variables of $P_{s}$, and let $Q_{v}$ and $Q_{u}$ be the corresponding families of variables in $P_{e}$. The variables $v$ and $u$ interfere if, and only if, there exists $v^{\prime} \in Q_{v}$ and $u^{\prime} \in Q_{u}$ such that $v^{\prime}$ and $u^{\prime}$ interfere.

THEOREM 23. The maximal aligned 1-2-coloring extension problem for elementary graphs is NP-complete.

Proof. The problem of finding the maximum induced subgraph of a chordal graph that is $K$ colorable is NP-complete [42]. We combine this result with Lemmas 20 and 22 for the proof of this theorem.

The proof of Theorem 4 is a corollary of Theorem 23:
Proof. Follows from Theorem 23.

## D. Pseudocode

The algorithm given in Figure 27 is an expansion of the program presented in Figure 10. Important characteristics of our register assignment phase are:

- the size of the intermediate representation is kept small, i.e, at any moment the register allocator keeps at most one puzzle board in memory;
- the solution of a puzzle is guided by the solution of the last puzzle solved;
- parallel copies between two consecutive instructions $i_{1}$ and $i_{2}$ in the same basic block can be implemented after the puzzle for $i_{2}$ is solved. To implement a parallel copy means to insert copies/swaps to transfer a solution found to $i_{1}$ to $i_{2}$;
- we record the locations of variables at the beginning and at the end of each basic block in tables called Head and Tail. These recordings guide the elimination of $\varphi$-functions and $\pi$ functions.
The variable $L$ in Figure 27 is a mapping of registers to variables. For instance, $L[v]=r$ denotes that register $r$ is holding the value of variable $v$.

Once all the basic blocks have been visited, our register allocator procedes to implement $\varphi$-functions and $\pi$-functions. We use basically the technique described by Hack et al. [22]; however, the presence of aliasing complicates the algorithm. We are currently writing a technical report describing the subtleties of SSAelimination after register allocation.

Figure 26. A chordal graph represented as a program.

- $S=$ empty;
- $L=$ undefined for all registers;
- For each basic block $b$, in a pre-order traversal of the dominator tree of the program:
- For each instruction $i \in b$ :

1. if $i$ is the first instruction of $b$ :
$-\operatorname{Head}[b]=L$;
2. Let $p$ be a puzzle build from live-in, live-out and variables in $i$.
3. while $p$ is not solvable:

- choose and remove a piece $v$ from $p$; assign a memory address to $v$;

4. $S^{\prime}:=$ a solution of $p$, guided by S .
5. Update $L$ with the variables that $S$ places on the board.
6. if there is instruction $i^{\prime} \in b$ that precedes $i$ :

- implement the parallel copy between $i^{\prime}$ and $i$ using $S$ and $S^{\prime}$.

7. $S=S^{\prime}$;
8. if $i$ is the last instruction of $b$ :
$-\operatorname{Tail}[b]=L ;$

Figure 27. The color assignment pass.
