

# MINUTES OF THE 49th GENERAL ASSEMBLY OF THE EUROPEAN ASSOCIATION FOR THE STUDY OF DIABETES

held in the Pi i Sunyer Hall, Fira de Barcelona, Barcelona, Spain on Thursday 26 September, 2013 at 18:30

**Present:**

|                                |                             |
|--------------------------------|-----------------------------|
| <b>Dr. Andrew J.M. Boulton</b> | <b>(President)</b>          |
| <b>Dr. Stefano Del Prato</b>   | <b>(Vice President)</b>     |
| <b>Dr. Bernard Thorens</b>     | <b>(Vice President)</b>     |
| <b>Dr. Michael Roden</b>       | <b>(Honorary Treasurer)</b> |
| <b>Dr. Mark Walker</b>         | <b>(Honorary Secretary)</b> |
| <b>Dr. Cees J. Tack</b>        | <b>(Chair, PGEC)</b>        |
| <b>Dr. Viktor Jörgens</b>      | <b>(Executive Director)</b> |
| <b>Dr. Monika Grüsser</b>      | <b>(Vice Director)</b>      |
| <b>and 51 members</b>          |                             |

The President, Dr. Boulton, welcomed everyone to the 49th General Assembly. He asked those present to stand in memory of the following members, who had passed away: Drs. Georg Eisenbarth, John Hutton, Harry Keen, Carol Lurie, Irina G. Obrosova, Samuel Rahbar, Jean-Louis Richard, Richard Rubin and Patrick Vexiau.

## 1. MINUTES 48th GENERAL ASSEMBLY 2012

Since there were no comments, the minutes were unanimously approved and officially signed as a correct record.

## 2. REPORTS

### a) President

The President's report to the members on the activities of EASD was given in the President's Address before the Minkowski Lecture. It is available under: <http://www.easdvirtualmeeting.org/resources/6926>

The President announced the Claude Bernard Lecturer 2014: Dr. Domenico Accili.

The President announced the Medical Devices in Diabetology meeting on 26/27 February 2014. He said better post-marketing surveillance was required and the Swedish project of regulating pumps would be looked at.

The President expressed his thanks to all partners. Dr. Boulton reported that as expected the EASD Annual Meeting in Barcelona was doing very well and the number of delegates attending had slightly increased. Dr. Boulton

thanked all members of the EASD Office and the Executive Committee for their commitment and hard work.

### b) Honorary Treasurer

i) Result of tax audit 2008-2010/actions to be taken  
In autumn 2012 for the second time, a control of the EASD by the Inland Revenue took place. These controls will always occur every three years due to the large turnover of the Association. In August 2013, EASD received the draft conclusion of this tax control. The non-profit status of the EASD is beyond all question; the main issue is the question of the taxation of the income from industry exhibition and symposia. EASD itself does not handle the industry exhibition and the symposia organized by third parties; these activities are taken care of by a professional congress organizer which is actually Interplan in Munich. In common with other medical associations in Germany, EASD has a contract, in our case with Interplan, giving them permission to organize these activities on their own responsibility without interfering with EASD concerning the organization and the fund raising. The basis of this collaboration is a loan contract and the income from such a loan contract is considered to be tax free. This legal and taxation construction is the basis of a healthy financial situation of German academic medical societies. The Düsseldorf tax authorities questioned this regulation and even asked their superiors for comments. In August 2013, they came up with the opinion that all incomes of EASD from these loan contracts, starting with 2008, are considered by the Inland Revenue as a taxable income. Taking into account corporation and local business tax, the result is that a total of Euro 5.4 million will likely have to be paid at the beginning of 2014. Following the advice of legal and

taxation advisors, EASD will oppose this decision and will eventually go to court. Nevertheless, this amount will be paid in advance to avoid the potential addition of interest on this sum should we elect to await the outcome of our appeal and should this be negative.

As we allowed for this potential outcome last year, no transfers have been carried forward from EASD to EFSD resulting in a reserve of Euro 5.2 million being kept on the accounts which is more than usual. Now EASD, following the income from the last Annual Meetings, will be able to cover the taxation imposed, but the Association will nevertheless have a hard time to finance its activities in the first six months of 2014 until a substantial income from the Meeting in Vienna has occurred.

The final decision regarding these matters will be made by the Düsseldorf Inland Revenue and their report could reach EASD at the beginning of 2014.

Following the advice from a specialist lawyer in Bonn, it was unanimously decided that when requested, the current tax bill of Euro 5.4 million should be paid; after that, we will challenge the decision in court. It was also unanimously decided to seek further advice from the lawyer concerning the way forward.

Dr. Roden explained that with the possibility of this tax invoice in mind, EASD had made no financial transfer to EFSD in 2012, resulting in EASD having enough funds to pay the tax bill. However, this will necessitate making savings in the first half of 2014 until an income has been received from the Annual Meeting in Vienna. Such savings could include reducing the costs of the Annual Meeting by no longer printing a Provisional Programme and no longer funding a Welcome and Farewell party. The decision had already been made to increase registration fees moderately.

Dr. Boulton thanked the Honorary Treasurer for his report and asked if there were any questions. Dr. Lenzen asked if there were any plans to relocate EASD. Dr. Boulton said that there were no relocation plans at that time.

### c) Honorary Auditors

The President asked the Honorary Auditor, Dr. Peter Diem, for his report. Dr. Diem confirmed that the accounts had been checked carefully by Dr. Luis Gardete-Correia and were in perfect order. Dr. Boulton asked for the vote to accept the accounts.

The Honorary Treasurer was unanimously discharged (35 votes in favour and 6 abstentions).

### d) Honorary Secretary

The Honorary Secretary reported that 2321 abstracts had been received for the Annual Meeting in Barcelona. Of these, 1360 were accepted: 264 oral presentations and 1096 poster presentations. The main countries submitting abstracts are the United States, the United Kingdom, Japan and Germany. The palm questionnaire rating the 48th Annual meeting in Berlin gave excellent feedback on the venue facilities, the scientific programme, the Prize Lectures, the EASD symposia, the oral presentations and abstracts, the poster presentations, the Industry symposia and the Associations' Village. The Rising Star Symposium continues to identify promising and innovative young researchers in Europe.

The Honorary Secretary concluded by reporting that the Programme Committee for 2014 had been appointed and had had its first meeting during the Annual Meeting in Barcelona. It would then meet in May 2014 to select the abstracts on an anonymous basis for the Annual Meeting in 2014.

Dr. Walker closed his report by thanking all those who had forwarded ideas for the scientific programme and all members of the EASD staff, in particular Mrs. H. Goliberzuch and Mrs. M. Toledo, for their outstanding help and support with the organisation of the EASD Annual Meetings.

Dr. Boulton thanked Dr. Walker for his diligence and asked if there were any questions. There were no further comments.

### e) Editor-in-Chief, Diabetologia

In the absence of Dr. Juleen Zierath, Editor-in-Chief, Diabetologia, the President reported the following information:

The Committee on Publication Ethics had put together ethical guidelines for peer-reviewers. From July 2013, all papers returned for revision underwent plagiarism detection. Springer is as yet unable to check images for possible manipulation, but are aware such a service is of high priority for the journal. The Scientific Integrity Panel (SIP) set up a policy outlining what is expected of authors and how to deal with cases of misconduct which was published on the Diabetologia website in April 2013. Mr. Tony Kirby, a former press officer with the Lancet, has helped to publicise papers by issuing press releases.

In total, 1,990 articles were submitted to Diabetologia in 2012 and 17% were published. The proportion of papers triaged increased to 63% in the first half of 2013. On average, papers are triaged in 3 days and peer-reviewed in 30 days.

Dr. Boulton expressed his thanks to Dr. Zierath in her absence for her co-operation and hard work. Thanks were also expressed to the team in Bristol, especially to Dr. Judy Naylor, and the outgoing associate editors.

#### f) Chair, Postgraduate Education Committee

Dr. Tack reported on the courses that had taken place in 2012 and 2013: Almaty/Kazakhstan, Lviv/Ukraine and Kazan/Russia. Dr. Tack said all courses in 2012 and 2013 had been very successful and had attracted delegates from many of the countries neighbouring the one where the course was held. Dr. Tack said a course was being planned in Budapest/Hungary in November 2014 and additional courses will be agreed upon with the incoming PGEC Chair.

Dr. Boulton thanked Dr. Tack for his co-operation and commitment to postgraduate education.

#### g) Chair, Extra-European Postgraduate Activities

Dr. Czupryniak reported that a course had successfully been organised in Dubai/United Arab Emirates in 2012. In August 2013, a course was held in India when 4 cities (Chennai, Ahmedabad, Lucknow and Chandigarh) were visited. The main Extra-European course in collaboration with IDF and ADA in 2013 will take place in Sri Lanka in November. Also in November, another course will be held in the Gulf Region (Oman).

Dr. Czupryniak brought his report to an end by thanking Dr. Boulton for his support and the EASD team for their help in organising the courses.

Dr. Boulton thanked Dr. Czupryniak for his co-operation and hard work.

### 3. ELECTIONS

#### Honorary Secretary (2013-2016)

The election of Dr. Per-Henrik Groop was unanimously approved with 40 votes.

#### Chair, PGEC (2013-2016)

The election of Dr. Leszek Czupryniak was unanimously approved with 41 votes and 1 abstention.

#### Council Members (2014 - 2017)

The election of Drs. Bo Ahrén, Sehnaz Karadeniz, Michele Solimena, Nicholas Tentolouris was unanimously approved with 37 votes each and 4 abstentions.

#### Editor-in-Chief, Diabetologia (2013-2015) extension of office

The election of extension of office of Dr. Juleen Zierath was unanimously approved with 41 votes.

### 4. STUDY GROUPS

#### i) Non-Alcoholic Fatty Liver Disease (NAFLD) Study Group

The General Assembly was informed of the decision by the Executive Committee and Council to endorse the initiation of this EASD Study Group.

#### ii) EASD Diabetes and Cancer Study Group

The General Assembly was informed of the decision by the Executive Committee and Council to endorse the initiation of this EASD Study Group.

#### iii) Gluco-Incretin Biology and Clinical Applications Study Group

The General Assembly was informed of the decision by the Executive Committee and Council to endorse the initiation of this EASD Study Group.

#### iv) Metabolic Imaging Study Group

The General Assembly was informed of the decision by the Executive Committee and Council to endorse the initiation of this EASD Study Group.

### 5. HONORARY MEMBERSHIP

The nomination of Drs. Anthony Cerami, Willy Malaisse, John D. Ward was unanimously approved. Dr. Boulton thanked them for their outstanding contribution to diabetes research.

### 6. ANY OTHER BUSINESS

Dr. Boulton reported that from January 2014 only an electronic version of the journal would be available for members. He added that this was the correct way forward both economically and ecologically. He said this would not affect re-prints which would continue to be available. An email will be sent to all members informing them of this situation and a monthly email will be sent with the table of contents for each month's journal.

The President thanked Dr. Walker, retiring Honorary Secretary, and Dr. Cees Tack, retiring Chair of the PGEC, for their friendly collaboration and diligence during their term of office. He also expressed his sincere gratitude to the Local Organising Committee for their outstanding contribution to the organisation of the 49th EASD Annual Meeting. He warmly thanked Dr. Jörgens, Dr. Grüsser and the EASD team in Düsseldorf for their dedicated work.

Dr. Boulton brought the General Assembly to a close at 19:25.

# Agenda for the 50th General Assembly of the European Association for the Study of Diabetes

to be held in the Randle Hall at Messe Wien Exhibition & Congress Center, Vienna, Austria  
on Tuesday, 16 September 2014 at 18:30

## 1. Minutes of the 49th General Assembly, Barcelona, Spain 2013

## 2. Reports

- |  |                         |
|--|-------------------------|
| a) President                               | Andrew J.M. Boulton     |
| i) Membership fees 2016                    |                         |
| ii) Retirement Executive Director          |                         |
| b) Honorary Treasurer                      | Michael Roden           |
| c) Honorary Auditors                       | Peter Diem              |
|  | Luis M. Gardete-Correia |
| d) Honorary Secretary                      | Per-Henrik Groop        |
| e) Editor-in-Chief, Diabetologia           | Juleen Zierath          |
| f) Chair, Postgraduate Education Committee | Leszek Czupryniak       |

## 3. POSITIONS

To be elected for retiring member(s):

### 3.1 Elections

- |   |  |
|---|--|
| a) President Extension of office (2014-2015)          | Andrew JM Boulton                      |
| b) President (2015-2018)                              | Andrew JM Boulton                      |
| c) Vice President (2014-2017)                         | Stefano Del Prato                      |
| d) Honorary Treasurer Extension of office (2014-2016) | Michael Roden                          |
| d) Honorary Auditors (2014-2017)                      | Peter Diem and Luis M. Gardete-Correia |
| e) Council Members (2015-2018)                        | Henning Beck-Nielsen                   |
|   | Svitlana Bolgarskaya                   |
|   | Anna Novials                           |
|   | Raimund Weitgasser                     |

## 4. Study Groups

- a) Reactive Metabolites in Diabetes Study Group

## 5. Honorary Membership

## 6. Any other business

# 50th EASD Annual Meeting of the European Association for the Study of Diabetes

Vienna, Austria, 15 – 19 September 2014

## Abstracts

### Index of Oral Presentations

- OP 01 SGLT2 inhibitors: new outcome studies
- OP 02 Nephropathy: biomarkers and infections
- OP 03 Evolving tools in education
- OP 04 Brown adipose tissue
- OP 05 Factors driving islet cell development
- OP 06 Novel mechanism of glucose tolerance
- OP 07 GLP-1 analogues: clinical efficacy
- OP 08 Matters of the heart
- OP 09 Diabetic retinopathy
- OP 10 Entero-pancreatic endocrinology
- OP 11 Lifestyle factors and prediction of type 2 diabetes
- OP 12 The many faces of advanced glycation
- OP 13 Clinical studies with GLP-1 analogues
- OP 14 Weight regulation and obesity
- OP 15 Diabetic nephropathy: epidemiology and genetics
- OP 16 Mechanisms of cardiovascular disease
- OP 17 Intra- and inter-islet cell signalling
- OP 18 Novel genes for type 2 diabetes and its complications
- OP 19 Insulin: clinical decision making
- OP 20 Novel compounds on the horizon
- OP 21 Physiological adaptation to bariatric surgery
- OP 22 Neuropathy: mechanisms and outcomes
- OP 23 Novel regulators of insulin and glucagon secretion
- OP 24 Genes and biomarkers for type 2 diabetes
- OP 25 Novel insulin formulations and combinations
- OP 26 Pregnancy and diabetes
- OP 27 Protecting the periphery
- OP 28 Ectopic lipids and type 2 diabetes
- OP 29 Autoimmune diabetes
- OP 30 Integrative physiology
- OP 31 GLP-1 analogues: non-glycaemic endpoints
- OP 32 Complications: expect the unexpected
- OP 33 Device utilisation and outcomes
- OP 34 Novel approaches for beta cell protection
- OP 35 Hypertension in diabetes
- OP 36 Molecular mechanisms of insulin action in vitro
- OP 37 Metformin: new insights into an old drug
- OP 38 Novelty in risk prediction
- OP 39 Inflammation in obesity and type 2 diabetes
- OP 40 Translational immunology of type 1 diabetes
- OP 41 The human methylome in diabetes
- OP 42 Liver metabolism
- OP 43 GLP-1 analogues: novel formulations
- OP 44 Diabetes and cancer
- OP 45 Diabetic foot: mechanisms of wound healing

- OP 46 New approaches and clinical outcomes of islet or pancreas transplantation
- OP 47 Pharmacogenetics and disease progression
- OP 48 Novel targets for anti-inflammatory therapies

### Index of Poster Sessions

- PS 001 Pragmatic prediction and prevention of type 2 diabetes
- PS 002 Aetiological epidemiological studies of type 2 diabetes
- PS 003 Type 1 diabetes: epidemiology
- PS 004 Epidemiology of obesity and ectopic fat
- PS 005 Descriptive epidemiology of diabetes
- PS 006 Epidemiology of diabetes: comorbidities and complications
- PS 007 Pharmaco-epidemiology
- PS 008 Type 1 diabetes: genes and biomarkers
- PS 009 Old genes, new phenotypes
- PS 010 Genomics and epigenetics of type 2 diabetes
- PS 011 New and old genes for monogenic diabetes
- PS 012 Monogenic diabetes across the world
- PS 013 Islet gene expression in type 2 diabetes
- PS 014 Beta cell proliferation and differentiation
- PS 015 Metabolic coupling in insulin secretion
- PS 016 Modulation of islet function through cell surface receptors
- PS 017 Transgenic animal models of type 1 and type 2 diabetes
- PS 018 Control of insulin exocytosis
- PS 019 Cytokine-induced beta cell death
- PS 020 Clinical immunology of type 1 diabetes
- PS 021 Measuring and preserving insulin secretion in type 1 diabetes
- PS 022 Beta cell ER stress and apoptosis
- PS 023 Mechanisms of lipotoxicity
- PS 024 Islet and pancreas transplantation
- PS 025 Hypoglycaemia rates and their economic burden
- PS 026 Insulin secretion in animal models
- PS 027 Determinants of insulin secretion in humans
- PS 028 Insulin secretion in diabetes
- PS 029 Gut hormones
- PS 030 Gut endocrinology in vivo
- PS 031 Gut hormone action
- PS 032 Novel approaches for identifying and targeting determinants of glucose tolerance
- PS 033 Determinants of insulin sensitivity and glycaemic control
- PS 034 Glucose uptake and glucose action

- PS 035 Mechanisms of insulin action in non-human models
- PS 036 Mechanisms of insulin resistance in vivo
- PS 037 Mechanisms of insulin action and inter-organ cross-talk
- PS 038 Insulin resistance and adipose tissue
- PS 039 Glucagon
- PS 040 Exercise physiology I
- PS 041 Exercise physiology II
- PS 042 Consequences of hypoglycaemia
- PS 043 Nocturnal and drug-induced hypoglycaemia
- PS 044 Endocrine control of glucose tolerance

- PS 093 Gestational diabetes mellitus management
- PS 094 Pregnancy outcomes in gestational diabetes mellitus
- PS 095 Postpartum outcomes
- PS 096 Pregnancy in type 1 diabetes
- PS 097 Neuropathy: biomarkers and mechanisms
- PS 098 Mechanisms and outcomes of neuropathy
- PS 099 Diabetic foot: prevention and treatment
- PS 100 Management of foot ulcers
- PS 101 Diabetic eye disease
- PS 102 Mechanisms of microangiopathy: experimental
- PS 103 Mechanisms of nephropathy: experimental
- PS 104 Nephropathy: genes and mechanisms
- PS 105 Diabetic nephropathy: clinical
- PS 106 Clinical: hypertension in diabetes
- PS 107 Predicting complications I
- PS 108 Predicting complications II
- PS 109 Predicting complications III
- PS 110 Biomarkers and complications I
- PS 111 Biomarkers and complications II
- PS 112 Clinical observations in children
- PS 113 Clinical observations in children and women
- PS 114 Clinical observations in type 2 diabetes
- PS 115 Liver
- PS 116 Vascular calcification
- PS 117 Vascular dysfunction
- PS 118 Advanced glycation
- PS 119 Metabolism and complications
- PS 120 Animal models of complications I
- PS 121 Animal models of complications II

## OP 01 SGLT2 inhibitors: new outcome studies

1

### Fixed dose combinations of empagliflozin/linagliptin for 52 weeks as add-on to metformin in subjects with type 2 diabetes

S. Patel<sup>1</sup>, R. DeFronzo<sup>2</sup>, A. Lewin<sup>3</sup>, D. Liu<sup>4</sup>, R. Kaste<sup>4</sup>, H.J. Woerle<sup>5</sup>, U.C. Broedl<sup>5</sup>;

<sup>1</sup>Boehringer Ingelheim Ltd., Bracknell, Berkshire, UK, <sup>2</sup>University of Texas Health Sciences, San Antonio, USA, <sup>3</sup>National Research Institute, Los Angeles, USA, <sup>4</sup>Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, USA, <sup>5</sup>Boehringer Ingelheim, Ingelheim, Germany.

**Background and aims:** A randomized, double-blind, parallel group Phase III study evaluated the efficacy and safety of fixed dose combinations (FDCs) of empagliflozin/linagliptin (EMPA/LINA) as add-on to metformin in subjects with type 2 diabetes (T2DM).

**Materials and methods:** Subjects were randomized to EMPA 25 mg/LINA 5 mg (n=137), EMPA 10 mg/LINA 5 mg (n=136), EMPA 25 mg (n=141), EMPA 10 mg (n=140), or LINA 5 mg (n=132) as add-on to stable-dose metformin for 52 weeks. Primary analysis was at week 24. Exploratory endpoints at week 52 were changes from baseline in HbA1c, body weight, systolic and diastolic blood pressure (SBP and DBP), and percentage of subjects with baseline HbA1c  $\geq 7\%$  who reached HbA1c  $< 7\%$ . Efficacy was evaluated in 674 subjects (mean [SD] age 56.2 [10.2] years; weight 86.2 [18.7] kg; BMI 31.0 [5.5] kg/m<sup>2</sup>; HbA1c 7.98 [0.85] %).

**Results:** Compared with LINA 5 mg and their respective EMPA monotherapies, both EMPA/LINA FDCs led to significant reductions in HbA1c and higher percentages of subjects with HbA1c  $< 7\%$  at week 52 (Table). Compared with LINA 5 mg, body weight was reduced with EMPA 25 mg/LINA 5 mg (difference: -3.2 kg [95% CI 4.2, 2.2];  $p < 0.001$ ) and EMPA 10 mg/LINA 5 mg (difference: 2.8 kg [95% CI 3.8, 1.7];  $p < 0.05$ ). The FDCs did not reduce body weight compared with their respective EMPA monotherapies. Changes from baseline in SBP and DBP were 0.3 mmHg and -0.6 mmHg, respectively, with LINA 5 mg. EMPA and FDCs reduced SBP from baseline by 2.8 to 3.6 mmHg and DBP by 1.8 to 2.2 mmHg. Adverse events (AEs) were reported in 71.5%, 69.1%, 73.0%, 68.6% and 68.9% of subjects on EMPA 25 mg/LINA 5 mg, EMPA 10 mg/LINA 5 mg, EMPA 25 mg, EMPA 10 mg and LINA 5 mg, respectively, over 52 weeks. Confirmed hypoglycaemic AEs (glucose  $\leq 70$  mg/dL and/or requiring assistance) were reported in 3.6%, 2.2%, 3.5%, 1.4% and 2.3% of subjects on EMPA 25 mg/LINA 5 mg, EMPA 10 mg/LINA 5 mg, EMPA 25 mg, EMPA 10 mg and LINA 5 mg, respectively; none required assistance. AEs consistent with urinary tract infection were reported in 10.2%, 9.6%, 13.5%, 11.4% and 15.2% of subjects on EMPA 25 mg/LINA 5 mg, EMPA 10 mg/LINA 5 mg, EMPA 25 mg, EMPA 10 mg and LINA 5 mg, respectively, and AEs consistent with genital infection were reported in 2.2%, 5.9%, 8.5%, 7.9% and 2.3% of subjects in these groups, respectively.

**Conclusion:** As add-on to stable-dose metformin in subjects with T2DM, FDCs of EMPA 25 mg/LINA 5 mg and EMPA 10 mg/LINA 5 mg for 52 weeks significantly reduced HbA1c compared with LINA 5 mg and compared with the respective EMPA monotherapies. The FDCs were well tolerated, with overall safety profiles similar to those known for the individual components.

### Empagliflozin compared with glimepiride as add-on to metformin for 2 years in patients with type 2 diabetes

M. Ridderstråle<sup>1</sup>, K.R. Andersen<sup>2</sup>, C. Zeller<sup>3</sup>, G. Kim<sup>4</sup>, H.J. Woerle<sup>4</sup>, U.C. Broedl<sup>4</sup>;

<sup>1</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>2</sup>Boehringer Ingelheim Norway KS, Asker, Norway, <sup>3</sup>Boehringer Ingelheim, Biberach, <sup>4</sup>Boehringer Ingelheim, Ingelheim, Germany.

**Background and aims:** We performed a Phase III trial, EMPA-REG H2H-SU<sup>TM</sup>, to compare the efficacy and safety of empagliflozin (EMPA) and glimepiride (GLIM) as add-on to metformin (MET) in patients with type 2 diabetes (T2DM).

**Materials and methods:** Patients were randomized and treated double-blind with EMPA 25 mg (n=765) or GLIM 1-4 mg (n=780) for 104 weeks (mean [SD] age 55.9 [10.4] years; BMI 30.1 [5.3] kg/m<sup>2</sup>). The primary endpoint was change from baseline in HbA1c. Key secondary endpoints were change from baseline in weight, occurrence of confirmed hypoglycaemic adverse events (AEs; plasma glucose  $\leq 70$  mg/dL and/or requiring assistance) and changes from baseline in systolic and diastolic blood pressure (SBP and DBP).

**Results:** At week 104, EMPA significantly reduced HbA1c versus GLIM (Table). Confirmed hypoglycaemic AEs were reported in 2.5% of patients on EMPA and 24.2% on GLIM (adjusted risk ratio: 0.102 [95% CI 0.065, 0.162];  $p < 0.001$ ); no patients on EMPA and 2 on GLIM required assistance. EMPA significantly reduced weight and SBP versus GLIM (Table). At week 104, adjusted mean (SE) change from baseline in DBP was 1.8 (0.3) mmHg with EMPA compared with 0.9 (0.3) mmHg with GLIM (difference versus GLIM: -2.7 mmHg [95% CI 3.4, 1.9];  $p < 0.001$ ). AEs were reported in 86.4% and 86.3% of patients on EMPA and GLIM, respectively. AEs consistent with urinary tract infection were reported in 13.7% and 13.1% of patients, and AEs consistent with genital infection were reported in 11.8% and 2.2% of patients, on EMPA and GLIM, respectively.

**Conclusion:** This large and long-term trial showed that EMPA 25 mg for 104 weeks as add-on to MET was well tolerated and led to a greater HbA1c

reduction, weight loss and BP reduction with a low risk of hypoglycaemia compared with GLIM.

#### Energy balance following sodium-glucose co-transporter-2 (SGLT2) inhibition

G. Ferrannini<sup>1</sup>, T. Hach<sup>2</sup>, S. Crowe<sup>2</sup>, E. Ferrannini<sup>1</sup>;

<sup>1</sup>University of Pisa, Italy, <sup>2</sup>Boehringer Ingelheim, Ingelheim, Germany.

**Background and aims:** SGLT2 inhibitors lower glycaemia by inducing urinary glucose excretion (UGE), with the attendant calorie loss. Evidence suggests that the resulting weight loss (WL) is less than expected from UGE.

**Materials and methods:** To quantify this phenomenon we analysed data from 86 type 2 diabetic (T2D) patients (39 women, age = 58 ± 9 years, BMI = 29.8 ± 4.5 kg/m<sup>2</sup>, HbA<sub>1c</sub> = 7.8 ± 0.8%, FPG = 169 ± 41 mg/dL, eGFR = 89 ± 19 ml·min<sup>-1</sup>·1.73m<sup>2</sup>, μ ± SD), the per-protocol completers cohort of a clinical trial who received empagliflozin (25 mg/day) for 90 weeks with frequent (n=11) assessments of body weight, eGFR, and FPG. Time-dependent glucose filtration was calculated as the product of eGFR and FPG, time-dependent UGE was estimated by assuming - from previous direct measurements - a quasi-linear relationship between fractional UGE and glycaemia. The relation of calorie-to-weight changes was estimated using a mathematical model (<http://bwsimulator.niddk.nih.gov>) that simulates the time-course of WL for a given change in calorie balance.

**Results:** At week 90, WL averaged -3.2 ± 4.2 kg (range -17.0 to +5.5); over 90 weeks, UGE averaged 54 ± 15 g/day (fractional UGE = 45 ± 4%). The observed WL corresponded to a calorie deficit of -78 ± 103 kcal/day. On the other hand, the observed calorie loss (-217 ± 59 kcal/day) predicted a WL of -8.7 ± 2.4 kg (range -4.0 to -15.3 kg) over 90 weeks. Thus, patients lost only 38 ± 53% of the WL predicted by their glycosuria. As previous studies showed that empagliflozin does not affect either resting or meal-induced energy expenditure, patients likely increased their energy intake (by an estimated +138 ± 116 kcal/day). This excess calorie intake was inversely related to baseline BMI (partial  $r = -0.33$ ,  $p < 0.01$ ) and positively to baseline eGFR (partial  $r = 0.30$ ,  $p < 0.01$ ).

**Conclusion:** Chronic glycosuria elicits an adaptive increase in energy intake, particularly in leaner patients with preserved renal function. Combining SGLT2 inhibition with strategies to maintain energy intake or curb appetite is expected to be associated with major WL.

#### Randomised, double-blind trial of dual add-on saxagliptin plus dapagliflozin vs saxagliptin or dapagliflozin add-on alone in poorly controlled type 2 diabetes on metformin

L. Hansen<sup>1</sup>, P. Zee<sup>1</sup>, Y. Li<sup>2</sup>, W. Cook<sup>2</sup>, B. Hirshberg<sup>2</sup>, N. Iqbal<sup>1</sup>, J. Rosenstock<sup>3</sup>;  
<sup>1</sup>Bristol-Myers Squibb, Princeton, <sup>2</sup>AstraZeneca, Wilmington,  
<sup>3</sup>Dallas Diabetes and Endocrine Center, USA.

**Background and aims:** SGLT2 and DPP-4 inhibitors have complementary mechanisms of action that can potentially improve glucose control with weight loss and a low risk of hypoglycaemia. We compared the efficacy and safety of dual add-on of saxagliptin (SAXA) and dapagliflozin (DAPA) with SAXA and DAPA alone in patients with type 2 diabetes mellitus (T2DM) poorly controlled with metformin.

**Materials and methods:** In this 24-week, multicenter, randomized, double-blind, active-controlled trial, adults with T2DM and A1C ≥8.0% and ≤12.0%, received SAXA 5 mg and DAPA 10 mg once daily compared with SAXA and placebo (PBO) or DAPA and PBO on background of metformin XR ≥1500 mg/d. The primary end point was the adjusted mean change in A1C from baseline to week 24. Safety and tolerability assessments included adverse events (AEs) and hypoglycaemia.

**Results:** A total of 534 patients were randomized. Mean ± SD A1C at baseline in SAXA+DAPA, SAXA+PBO, and DAPA+PBO groups was 8.9 ± 1.2%, 9.0 ± 1.1%, and 8.9 ± 1.2%, respectively. Adjusted mean reduction from baseline in A1C was -1.47% in SAXA+DAPA compared with -0.88% in SAXA+PBO (difference -0.59%; 95% CI [-0.81, -0.37];  $P < 0.0001$ ) and -1.20% in DAPA+PBO (difference -0.27%; 95% CI [-0.48, -0.05];  $P < 0.02$ ). The adjusted mean proportion of patients achieving A1C <7% was 41% in SAXA+DAPA compared with 18% in SAXA+PBO (difference of 23%; 95% CI [15, 32]) and 22% in DAPA+PBO (difference of 19%; 95% CI [10, 28]). AEs occurred in 48.6%, 52.8%, and 48.6% of patients in the SAXA+DAPA, SAXA+PBO, and DAPA+PBO groups, respectively. Urinary and genital infections occurred with the expected frequency previously reported. Incidence of hypoglycaemia was 1.1%, 0.6%, and 1.1%, respectively with no episodes of major hypoglycaemia.

**Conclusion:** This first report of triple therapy, adding a well-tolerated combination of DPP-4 and SGLT2 inhibitors to background metformin therapy in patients with T2DM poorly controlled with metformin, demonstrated that the dual add-on combination of SAXA and DAPA had greater improvements in glucose control than each component alone. More than 40% of poorly controlled T2DM patients receiving SAXA+DAPA achieved an A1C goal of <7%, with weight loss similar to DAPA alone and with very low hypoglycaemia risk.

#### Long-term efficacy and safety of canagliflozin in older patients with type 2 diabetes mellitus over 104 weeks

K. Stenlöf<sup>1</sup>, B. Bode<sup>2</sup>, S. Harris<sup>3</sup>, D. Sullivan<sup>4</sup>, A. Fung<sup>4</sup>, K. Usiskin<sup>4</sup>;  
<sup>1</sup>Clinical Trial Center, Sahlgrenska University Hospital, Gothenburg, Sweden, <sup>2</sup>Atlanta Diabetes Associates, USA, <sup>3</sup>University of Western Ontario, London, Canada, <sup>4</sup>Janssen Research & Development, LLC, Raritan, USA.

**Background and aims:** Canagliflozin (CANA), a sodium glucose co-transporter 2 (SGLT2) inhibitor developed for the treatment of type 2 diabetes mellitus (T2DM), lowers plasma glucose by increasing urinary glucose excretion. This randomised, double-blind, Phase 3 study assessed the long-term efficacy and safety of CANA in older patients with T2DM over 104 weeks.

**Materials and methods:** Patients aged 55 to 80 years (N = 714) with T2DM inadequately controlled on a stable antihyperglycaemic agent (AHA) regimen received CANA 100 or 300 mg or placebo (PBO) during a 26-week core period followed by a 78-week extension (n = 624 [87%]). Efficacy endpoints were evaluated at 104 weeks and safety was assessed by adverse event (AE) reports.

**Results:** Mean baseline characteristics were similar across groups (age, 63.6 years; HbA1c, 7.7%; fasting plasma glucose [FPG], 8.7 mmol/L; BMI, 31.6 kg/m<sup>2</sup>; estimated glomerular filtration rate [eGFR], 77.5 mL/min/1.73 m<sup>2</sup>). At 104 weeks, CANA 100 and 300 mg reduced HbA1c, FPG, body weight, and systolic blood pressure (BP), with small increases in high-density lipoprotein cholesterol (HDL-C) and low-density lipoprotein cholesterol (LDL-C) compared with PBO (Table). Over 104 weeks, overall AE rates were 88.0%, 89.8%, and 86.1% with CANA 100 and 300 mg and PBO, respectively; AE-related

discontinuation rates were 4.6%, 10.2%, and 6.8%, and serious AE rates were similar across groups. CANA 100 and 300 mg were associated with a higher incidence than PBO of urinary tract infections (14.5%, 16.5%, 10.1%) and genital mycotic infections in females (23.9%, 18.7%, 4.3%) and males (5.6%, 10.9%, 1.4%). Incidences of osmotic diuresis-related AEs (eg, pollakiuria [increased urine frequency] and thirst; 9.1%, 12.3%, 5.5%) and AEs related to reduced intravascular volume (eg, postural dizziness and orthostatic hypotension; 5.4%, 5.9%, 1.7%) were higher with CANA 100 and 300 mg than PBO, but these AEs led to few discontinuations. The incidence of documented hypoglycaemia ( $\leq 3.9$  mmol/L) was modestly higher with CANA 100 and 300 mg than PBO in patients on an AHA associated with hypoglycaemia (54.1%, 61.0%, 48.9%) as well as those on an AHA not associated with hypoglycaemia (18.3%, 10.9%, 6.6%); severe hypoglycaemia rates were low across groups.

**Conclusion:** CANA 100 and 300 mg improved glycaemic control, reduced body weight and BP, and were generally well tolerated in older patients with T2DM over 104 weeks, consistent with 26-week results; the AE profile was consistent with that seen in a broad range of CANA-treated patients.

**Table. Summary of Efficacy Endpoints at Week 104 (mITT, LOCF)**

| Parameter   | CANA 100 mg          | CANA 300 mg          | PBO         |

### Safety of dapagliflozin in patients with type 2 diabetes mellitus and hypertension inadequately controlled by a renin-angiotensin system blocker with/without a second agent

T.A. Mansfield<sup>1</sup>, M.A. Weber<sup>2</sup>, J.F. List<sup>1</sup>, A. Ptaszynska<sup>1</sup>;

<sup>1</sup>Bristol-Myers Squibb, Princeton, <sup>2</sup>SUNY Downstate College of Medicine, New York, USA.

**Background and aims:** Hypertension is common in patients with type 2 diabetes mellitus (T2DM) and is often treated with an ACE inhibitor (ACEi) or an angiotensin receptor blocker (ARB) plus other antihypertensive (AHT) agents if needed. Dapagliflozin inhibits renal glucose reabsorption causing glucosuria, weight loss, diuresis and decreased BP. Dapagliflozin significantly reduced HbA<sub>1c</sub> and seated and ambulatory systolic BP versus placebo in clinical studies of patients with T2DM and hypertension. Here we describe key safety data from these studies.

**Materials and methods:** In two, randomized, double-blind, 12-week studies, patients with T2DM and inadequate glycaemic control (HbA<sub>1c</sub> 7.0–10.5%) and BP (seated systolic BP / diastolic BP: 140–164 / 85–104 mmHg) receiving an ACEi or an ARB (Study 1) plus a 2nd AHT drug (Study 2) were randomized to dapagliflozin 10 mg or placebo over 12 weeks. Preliminary efficacy results have been previously presented.

**Results:** In Study 1, 613 patients on an ACEi or ARB were randomized to treatment. In Study 2, 449 patients on an ACEi or ARB plus a 2nd AHT drug were randomized to treatment. In each study, similar proportions of dapagliflozin and placebo experienced adverse events (AEs), with few serious AEs reported. In Study 1 and 2, fewer dapagliflozin (1.0 and 0.4%, respectively) versus placebo (1.3 and 1.8%) patients withdrew due to an AE. Few hypoglycaemic events occurred (3.3 and 5.8% with dapagliflozin vs 1.3 and 2.7% with placebo), none of which led to discontinuation. No serious BP related safety issues were noted; one orthostatic hypotension AE occurred with dapagliflozin in Study 1. Serum uric acid decreased with dapagliflozin but there was no effect on serum sodium, potassium, or calcium, despite its diuretic effect (Table).

**Conclusion:** Dapagliflozin had a good safety profile over 12 weeks when used in combination with an ACEi or ARB ± 1AHT in patients with T2DM and inadequately controlled hypertension.

### Uric acid serum level affects serum level of cystatin C, independently of GFR, in patients with type 2 diabetes

F. Iliadis<sup>1</sup>, T. Didangelos<sup>1</sup>, A. Ntemka<sup>1</sup>, C. Margaritidis<sup>1</sup>, A. Zantidis<sup>1</sup>, E. Moralidis<sup>2</sup>, A. Makedou<sup>3</sup>, A. Gotzamani-Psarakou<sup>2</sup>, D. Grekas<sup>1</sup>, A. Hatzitolios<sup>1</sup>;

<sup>1</sup>First Propedeutic Department of Internal Medicine, <sup>2</sup>Laboratory of Nuclear Medicine, Medical School, <sup>3</sup>Laboratory of Lipids, 2nd Paediatric Department, AXEPA Hospital, Aristotle University of Thessaloniki, Greece.

**Background and aims:** Cystatin C has been reported to be a reliable marker of GFR in both type 1 and type 2 diabetic patients with mild-to-moderate CKD (stages 2-3). Recently, elevated serum level of cystatin C has also been identified as a significant prognostic indicator for the development of cardiovascular disease in people with diabetes. However, there are limited data on factors, other than GFR, that influence its serum concentration, especially in adult patients with type 2 diabetes. The aim of our study was to identify such factors.

**Materials and methods:** In this cross-sectional study, 560 consecutive type 2 diabetic patients (252 men, 308 women), aged 65.0±10.0 years (mean±SD) were recruited from our outpatient diabetic clinic. All participants were Europeans. GFR was measured using 51Cr-EDTA (mGFR). Serum cystatin C was related to several clinical and biochemical parameters. Multivariate analysis was performed in order to identify factors independently associated with cystatin C serum level beyond mGFR. SPSS 18.0 was used for statistical analysis. A value of  $p < 0.01$  was considered to indicate statistical significance.

**Results:** Cystatin C was significantly correlated with mGFR ( $r = -0.590$ ;  $p < 0.001$ ), age ( $r = 0.365$ ;  $p < 0.001$ ), ACR-albumin creatinine ratio ( $r = 0.159$ ;  $p = 0.001$ ), uric acid ( $r = 0.299$ ;  $p < 0.001$ ), albumin ( $r = -0.206$ ;  $p < 0.001$ ) and Hb ( $r = -0.230$ ;  $p < 0.001$ ). There were no significant relationships between serum cystatin C levels and other variables (diabetes duration, sex, glucose-lowering therapy, BMI, fasting glucose, HbA1c, liver function tests, lipid profile, thyroid function tests, white blood cells, electrolytes and hsCRP). However, in standard multiple regression analysis, only mGFR ( $B = -0.008$ ;  $p < 0.001$ ) and uric acid ( $B = 0.040$ ;  $p = 0.008$ ) were independent predictors of cystatin C level.

**Conclusion:** In adult patients with type 2 diabetes, uric acid serum level seems to affect cystatin C serum level independently of GFR. Hence, uric acid level should be considered when cystatin C based equations for GFR estimation are used.

Clinical Trial Registration Number: NCT01215994

### Associations of serum bicarbonate with renal and cardiovascular outcome in patients with diabetic nephropathy

E. Schutte<sup>1</sup>, H.J. Lambers Heerspink<sup>2</sup>, H.L. Lutgers<sup>3</sup>, S.J.L. Bakker<sup>1</sup>, B.H.R. Wolffenbuttel<sup>3</sup>, K. Umanath<sup>4</sup>, D. de Zeeuw<sup>2</sup>, R.T. Gansevoort<sup>1</sup>;

<sup>1</sup>Nephrology, <sup>2</sup>Clinical Pharmacology, <sup>3</sup>Endocrinology, UMC Groningen, Netherlands, <sup>4</sup>Nephrology and Hypertension, Henry Ford Hospital, Detroit, USA.

**Background and aims:** Low serum bicarbonate, one of the metabolic complications of impaired renal function, has been reported to be an independent predictor of renal function decline and mortality. To date, no study has investigated this association in patients with diabetic nephropathy (DN), whereas it has been suggested that acid-base balance is different in subjects with DM versus non-DM. We therefore investigated the association of serum bicarbonate with renal and cardiovascular (CV) outcome in specifically type 2 DM patients with DN.

**Materials and methods:** Post-hoc analysis of the RENAAL and IDNT trials, both randomised controlled trials (RCTs) investigating the effect of angiotensin receptor blockers on renal and CV outcomes in patients with DN due to type 2 DM. DN was defined as urinary albumin-to-creatinine ratio (UACR)  $\geq 300$  mg/g or proteinuria  $\geq 900$  mg/d. Serum bicarbonate was measured as total  $\text{CO}_2$ . Linear regression analysis was used to examine baseline factors associated with serum bicarbonate concentration. In addition, Cox regression models were built to examine the longitudinal associations of serum bicarbonate with renal outcomes (incidence of end-stage renal disease (ESRD), the

combined endpoint ESRD or doubling of serum creatinine (DSCR)) and CV outcome (incidence of fatal/non-fatal stroke/myocardial infarction). Serum bicarbonate concentration was studied as continuous variable and stratified in quartiles to allow assessment of non-linear associations.

**Results:** We included 2628 patients (mean age  $60 \pm 7$  (SD) years, 65% male, 61% white) with mean estimated GFR (eGFR)  $44 \pm 16$  mL/min/1.73m<sup>2</sup> and median UACR of 1366 mg/g (interquartile range 682 - 2653). Mean serum bicarbonate level was  $24.3 \pm 3.7$  mEq/L and 602 patients had serum bicarbonate levels  $< 21$  mEq/L. Multivariate linear regression analyses showed significant associations of serum bicarbonate with age, diuretic use, total cholesterol, potassium, chloride, phosphate and albuminuria (all  $p < 0.05$ ), and particularly with eGFR ( $p < 0.001$ ). During follow-up for  $2.8 \pm 1.0$  years, 948 (36%) patients developed ESRD, 731 (28%) ESRD or DSCR, and 457 (17%) a CV event. Cox regression analysis showed that serum bicarbonate had a negative association with incident ESRD (HR 0.91 [95% CI 0.90-0.93],  $P < 0.001$ ) and with the incidence of the combined endpoint of ESRD or DSCR (HR 0.94 [0.92-0.96],  $P < 0.001$ ). These associations were independent of traditional risk factors for renal and CV disease, but lost significance when adjusting for baseline eGFR. Analysis of bicarbonate quartiles showed similar results for the lowest bicarbonate quartile ( $< 21$  mEq/L) versus the quartile with normal bicarbonate levels (24-26 mEq/L). No associations were found between serum bicarbonate and CV outcome in any model. Of note, in these RCTs no interaction was found between treatment allocation and bicarbonate versus any of the three outcomes.

**Conclusion:** In this cohort of type 2 DM patients with diabetic nephropathy, serum bicarbonate was not independently associated with renal or CV endpoints. This finding suggests that the predictive value of serum bicarbonate for adverse outcomes differs between diabetic and non-diabetic patients.

9

### Association between 3 biomarkers and kidney complications in type 2 diabetic patients

P. Saulnier<sup>1,2</sup>, E. Gand<sup>3</sup>, G. Velho<sup>4</sup>, K. Mohammadi<sup>4,5</sup>, P. Sosner<sup>6</sup>, P. Zaoui<sup>7</sup>, M. Fraty<sup>3</sup>, S. Ragot<sup>1</sup>, M. Marre<sup>4,5</sup>, R. Roussel<sup>4,5</sup>, S. Hadjadj<sup>8,9</sup>;

<sup>1</sup>CIC1402 Inserm, CHU, Poitiers, <sup>2</sup>INSERM, Cic1402, <sup>3</sup>pole DUNE, CHU, Poitiers, <sup>4</sup>U695, INSERM, Paris, <sup>5</sup>Diabetology, Endocrinology and Nutrition, AP-HP, Paris, <sup>6</sup>Cardiology, CHU, Poitiers, <sup>7</sup>Nephrology, CHU, Grenoble, <sup>8</sup>Endocrinology, Diabetes, Metabolic diseases, CHU, Poitiers, <sup>9</sup>Cic1402, INSERM, Poitiers, France.

**Background and aims:** We aimed to explore the predictors of severe renal complications in type 2 diabetes in a multi-biomarker approach. Three peptides recently reported as associated with cardiovascular or renal complications of diabetes in the literature were considered: the mid-regional part of pro-ADM (MR-proADM) which is a surrogate marker of adrenomedullin, ultrasensible copeptin (usCT-proAVP) which is a surrogate marker for arginine vasopressin release and soluble Tumor Necrosis Factor receptor 1 (sTNFr1) which is a marker of the TNF pathway.

**Materials and methods:** A total of 1,408 T2D patients without history of renal replacement and GFR  $> 15$  mL/min at baseline were prospectively followed in a mono-center hospital-based cohort in middle-western part of France. Median duration of follow up was 70 months (8,365 patient.years). The three peptides were measured on the same baseline plasma sample. Renal events were defined as sustained doubling of serum creatinine levels or renal replacement therapy during follow-up. Events were adjudicated by an independent adjudication committee.

**Results:** During follow up 82 patients yielded a renal event (9.9 for 1,000 patient.years). The median (interquartile range) MR-proADM, usCT-proAVP and TNFR1s plasma concentrations were 0.73 (0.36) nmol/L, 6.57 (7.68) pmol/L and 1843 (770) pg/L respectively.

In univariate analysis, MR-proADM, usCT-proAVP and TNFR1s were significantly associated with risk of renal event ( $p < 0.0001$  for all). Hazard ratio (HR) [95%CI] were 1.17 [1.15-1.20], 1.02 [1.02-1.03] and 1.11 [1.09-1.12] for an increase of 0.1 nmol/L MR-proADM, 1 pmol/L usCT-proAVP and 100 pg/L TNFR1s respectively. Kaplan Meier survival curves according to quartiles groups of biomarkers are presented in Figure. MR-proADM, usCT-proAVP and TNFR1s were significantly inter-correlated (Spearman test, all  $p < 0.0001$ ). When considering together all three biomarkers, only MR-proADM and TNFR1s remained significant predictors of renal event. After adjustment on age, sex and baseline eGFR, adjusted HR [95%CI] were 1.12 [1.07-1.17] and 1.05 [1.02-1.07] for an increase of 0.1 nmol/L and 100 pg/L of MR-proADM and TNFR1s, respectively.

**Conclusion:** High levels of MR-proADM and sTNFR1 were independently associated with an increased risk of renal event in patients with type 2 diabetes. With this approach, usCT-proAVP did not carry additional information regarding of renal event when adjusting on these 2 biomarkers.

**Figure. Kaplan-Meier survival curves without renal event according to biomarkers quartiles (patient with eGFR<15ml/min and without ESRD n=1408)**

### Lipoprotein(a) predicts new onset of chronic kidney disease in patients with type 2 diabetes mellitus: a ten-year follow-up study

J.-S. Yun<sup>1</sup>, K.-H. Song<sup>1</sup>, Y.-M. Park<sup>2</sup>, S.-H. Ko<sup>1</sup>, Y.-B. Ahn<sup>1</sup>;

<sup>1</sup>Internal Medicine, <sup>2</sup>Preventive Medicine, The Catholic University of Korea, Seoul, Republic of Korea

**Background and aims:** We investigated factors that might influence the development of chronic kidney disease (CKD) in patients with type 2 diabetes. **Materials and methods:** From January 2000 to December 2002, a total of 1,367 patients with type 2 diabetes without CKD (estimated glomerular filtration rate [eGFR]  $\geq 60$  ml/min/1.73m<sup>2</sup>) were consecutively enrolled. Patients were divided into two groups according to their baseline serum Lp(a) levels (Lp(a)  $>30$ mg/dL vs Lp(a)  $\leq 30$ mg/dL). The estimated GFR was measured annually, and new onset CKD was defined as eGFR  $< 60$  ml/min/1.73m<sup>2</sup> using a Modification of the Diet in Renal Disease formula. We used a Cox proportional hazard regression analysis to test associations between new onset CKD and potential explanatory variables.

**Results:** Of the 1,367 patients who were enrolled in this study, 904 (66.1%) completed the follow-up evaluation. The median follow-up time was 9.8 years. The mean age was  $56.0 \pm 10.3$  years, and the duration of diabetes was  $8.5 \pm 6.9$  years. The baseline eGFR was  $98.3 \pm 25.6$  ml/min/1.73m<sup>2</sup>. During the follow-up period, 234 patients (25.9%) progressed to chronic kidney disease. The patients in the CKD group were older ( $P < 0.001$ ), had hypertension ( $P < 0.001$ ), a longer duration of diabetes ( $P < 0.001$ ), higher baseline A1C levels (Lp(a)  $>30$ mg/dL vs Lp(a)  $\leq 30$ mg/dL: hazard ratio 3.4; 95% CI 2.50 - 4.54;  $P < 0.001$ ) after adjusting for sex, age, diabetic duration, mean A1C, albuminuria, treatment of insulin, ACE inhibitor/ARB and lipid lowering agents.

**Conclusion:** In conclusion, the development of CKD from normal renal function was independently associated with serum Lp(a) level in patients with type 2 diabetes.

## 11

### Lipidomic biomarkers associated with and predictive of rapid progression of renal disease in type 2 diabetes

M. Colombo<sup>1</sup>, H.C. Looker<sup>2</sup>, B. Farran<sup>2</sup>, F. Agakov<sup>3</sup>, P.E. Sanders<sup>4</sup>, M.S. Kuo<sup>4</sup>, M.K. Thomas<sup>4</sup>, P. McKeigue<sup>1</sup>, H.M. Colhoun<sup>5</sup>, on behalf of the SUMMIT Investigators;

<sup>1</sup>Centre for Population Health Sciences, University of Edinburgh, UK, <sup>2</sup>Population Health Sciences, University of Dundee, UK, <sup>3</sup>Pharmatics Ltd, Edinburgh, UK, <sup>4</sup>Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, USA, <sup>5</sup>Population Health Sciences, University of Dundee, UK.

**Background and aims:** To identify lipidomic biomarkers associated with and/or predictive of rapid progression of nephropathy in subjects with type-2 diabetes mellitus.

**Materials and methods:** 288 serum samples (134 cases and 154 controls) from the Genetics of Diabetes Audit and Research Tayside Study (Go-Darts) study were selected based on changes in eGFR following baseline sampling. All cases and controls had a baseline eGFR of 30-60ml/min with cases losing  $>40\%$  of baseline eGFR over a maximum follow-up of 3.5 years, whilst controls lost a maximum of 5% baseline eGFR after  $>3.5$  years follow-up. 221

lipid species, belonging to 9 lipid classes, were measured using a mass spectrometry platform. We assessed the association with the rapid eGFR loss with individual lipid species, the sum of the lipid class and ratios of individual lipids to the sum of lipid class, by univariate tests and using predictive selection models. We applied two complementary approaches to biomarker selection: forward selection using logistic regression, and sparse logistic regression with the L1 (LASSO) regularization penalty, with models adjusted for standard clinical covariates including age, sex, diabetes duration, baseline eGFR, albuminuria, HbA1c and use of ACE Inhibitors or ARBs. Model performance was assessed using Area Under the Receiver Operating Characteristic curve (AUROC) from cross-validated models.

**Results:** A model limited to clinical covariates only had an AUROC of 0.695. A class-by-class analysis of lipids reveals that the most predictive associations are with the Phosphatidylcholines lipids (PC) (AUROC = 0.739 with forward selection, 0.764 with LASSO-regularized selection). Other lipid classes which help improving predictions are Sphingomyelins (SPM) (AUROC = 0.724 and 0.726). Among the Phosphatidylcholines PC26.6 was inversely associated with progression in univariate analysis (Odds Ratio 0.66, 95% Confidence Interval 0.49, 0.86,  $p < 0.001$ ).

**Conclusion:** Circulating serum phosphatidylcholines are associated with rapid eGFR loss in patients with diabetes and significantly improve its prediction. The mechanism underlying association warrants further investigation.

### Epidemiology of urinary tract infections in type 2 diabetes mellitus patients and associated healthcare cost

T. Wilke<sup>1</sup>, A. Groth<sup>2</sup>, B. Böttger<sup>2</sup>, S. Müller<sup>2</sup>, A. Fuchs<sup>3</sup>, S. Yu<sup>4</sup>, M. Botteman<sup>5</sup>, U. Maywald<sup>3</sup>;

<sup>1</sup>Pharmerit / IPAM Wismar, <sup>2</sup>IPAM Wismar, <sup>3</sup>AOK Plus, Dresden, Germany, <sup>4</sup>Merck Sharp & Dohme Co., Whitehouse Station, USA, <sup>5</sup>Pharmerit International, Bethesda, USA.

**Background and aims:** Urinary tract infections (UTIs) are considered to be the most common bacterial infection in diabetes mellitus type 2 (T2DM) patients (pts). This study aims to assess the incidence of UTIs, identify predictors of UTI event risk, and describe the associated treatment costs in T2DM pts.

**Materials and methods:** This was a retrospective database analysis of the German sickness fund covering Year 2010-12. Patient inclusion criteria were documented continuous insurance from 2010-12 and documented  $\geq 1$  inpatient or  $\geq 2$  outpatient T2DM diagnoses. To be included as an UTI case, the UTI diagnoses had to be coded after a T2DM diagnosis. A UTI diagnosis was interpreted as incident if no prior UTI diagnosis was documented. If a prior UTI was documented, such a diagnosis was interpreted as recurrent only if it was not documented in the same or following quarter as the prior UTI AND documented by either a different physician and/or associated with antibiotics use. UTI event rates were calculated per 1,000-patient-years. Logistic regressions were used to evaluate the association between pts characteristics and the risk of UTI within the whole sample and within a subsample of pts with available HbA1C/BMI data. Costs included UTI-related antibiotics use, outpatient and inpatient treatment. Cost was analysed descriptively.

**Results:** There were 456,827 T2DM pts meeting the inclusion criteria. Median age was 75.5 years; 43.8% were male. In the first observation year (2010), 60.8% of the prevalent T2DM pts received antidiabetic therapy (OAD: 76.1%; insulin: 40.5%). Average Charlson comorbidity index (CCI) was 7.29. In the observation period 2010-12, 89,024 pts (19.5%) had  $\geq 1$  UTI, and 28,393 patients (6.2%) with  $\geq 2$  UTI. The event rate was 120 cases/1,000 patient-years. An inpatient admission occurred in 3.7% of the observed UTI events. In the multivariate analysis, the following variables, among others, predicted the risk to experience  $\geq 1$  event (OR; all with  $p < 0.001$ ) in 2012: age 77-83 years and  $> 83$  years vs.  $\leq 62$  years (1.46/1.58), female gender (1.66), previous UTI in 2010/11 (3.20), and other non-UTI infections in 2010/11 (1.74). Variables were mainly associated with the risk to experience  $\geq 2$  UTI in 2012: age 72-77, 77-83 years and  $> 83$  years vs.  $\leq 62$  years (1.38/1.51/1.65), female gender (1.32), previous UTI in 2010/11 (5.13), other non-UTI infections in 2010/11 (1.63), and CCI  $> 8$  (1.67). In the subgroup with laboratory data available (217,022 pts), a higher UTI risk in 2012 was additionally associated with a mean HbA1C of 9.5-10.0  $> 10.0\%$  vs. 7.0-7.5 in 2011 (1.31/1.33;  $p < 0.001$ ). The most commonly prescribed antibiotic for outpatients was ciprofloxacin (48.8%). Mean (SD), and median costs per UTI case were 193.28 € (802.85 €) and 68.94 € respectively (inpatient: 50.5%; outpatient: 43.6%; medication/other: 5.9%).

**Conclusion:** Among a real-life T2DM cohort from 2010–12, UTI event risk was very high compared to previous studies which reported event rates 47–60 cases/1,000 patient years. This may be due to the older and more comorbid sample which reflects a real life cohort of T2DM patients in Germany. Age, female gender, health status and previous infections are the greatest risk factors associated with the UTI event risk.

#### Internet intervention designed to identify and reduce risk of diabetic driving mishaps, a randomised clinical trial

D.J. Cox<sup>1</sup>, L. Gonder-Frederick<sup>1</sup>, L.M. Ritterband<sup>1</sup>, B. Kovatchev<sup>1</sup>, K. Ingersoll<sup>1</sup>, H. Singh<sup>1</sup>, D. Ford<sup>1</sup>, K. Schmidt<sup>2</sup>, T. Banton<sup>1</sup>;

<sup>1</sup>Psychiatry & Neurobehavioral Sciences,

<sup>2</sup>Psychology, University of Virginia, Charlottesville, USA.

**Background and aims:** While driving mishaps are more common among those who have Type 1 Diabetes (T1D), in part due to extreme blood glucose (BG), this increased risk is believed to be restricted to a subgroup of drivers who are more vulnerable to moderate hypoglycaemia. We tested the hypotheses that an interactive internet intervention, DiabetesDriving.com (DD.com), could: 1) identify high-risk drivers, and 2) aid high-risk drivers to diminish their risk by better anticipating, preventing, detecting, and treating extreme BG while driving.

**Materials and methods:** 1739 drivers with T1D from all 50 US states who registered for DD.com were screened for inclusion criteria, and for High or Low risk for future driving mishaps based on the Risk Assessment for Diabetic Drivers (RADD). 379 High-Risk drivers were randomized to Routine Care (RC), DD.com, or DD.com + Motivational Interviews administered once before and once after DD.com. 122 Low Risk drivers were assigned to RC. DD.com was administered during months 1–2. During months 3–14, all participants completed monthly on-line driving diaries in which the frequency of the following driving mishaps was reported: Severe hypoglycaemia while driving, Loss of vehicle control without hitting anything, Collisions, Being stopped by the police while driving, Automatic driving due to extreme BG, Unintentional stops while driving, and Requiring assistance from someone else while driving due to extreme BG.

**Results:** Analyses of partial data (4,036 diaries) indicate High-Risk RC drivers reported more than twice as many driving mishaps/month than Low-Risk RC drivers (0.54 vs 0.21 mishaps/month,  $p < 0.001$ ). Both DD.com groups reported similar numbers of mishaps/month (0.31 and 0.29), significantly fewer than for the High-Risk RC participants ( $p < 0.001$ ). DD.com participants who answered “yes” to the question, “Do you use continuous glucose monitoring (CGM)?” reported a similar frequency of driving mishaps to those who said “no” ( $p = 0.68$ ), but this may be because the CGM users had significantly greater driving risk (RADD scores) than the non-CGM users ( $p = 0.026$ ).

**Conclusion:** Results indicate: 1) Diabetes-related driving mishaps are relatively high frequency events for high-risk routine care individuals, 2) RADD can identify T1D drivers at-risk for future mishaps, 3) DD.com can reduce, and possibly prevent, future driving mishaps of T1D drivers at high risk for mishaps, and 4) the additional costs of MI cannot be justified in this particular situation.

### 14

#### Effects of peer support in type 2 diabetes patients on diabetes related distress, self efficacy and well being: a randomised controlled trial

L. de Vries<sup>1</sup>, A.A. van der Heijden<sup>1</sup>, C.A. Baan<sup>2</sup>, J.M. Dekker<sup>1</sup>, M. Rijken<sup>3</sup>, G. Rutten<sup>4</sup>, G. Nijpels<sup>1</sup>;

<sup>1</sup>The EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, <sup>2</sup>RIVM, Bilthoven, <sup>3</sup>Nivel, Netherlands Institute for Health Services Research, Utrecht, <sup>4</sup>UMCU, Utrecht, Netherlands.

**Background and aims:** Many type 2 diabetes mellitus patients face difficulties self-managing their illness, which can lead to high levels of diabetes-related distress. Diabetes distress may be decreased by peer support, as peers understand and have dealt with similar problems, and can help motivate each other. However, a recent systematic review concluded that evidence of benefits of peer support in patients with type 2 diabetes mellitus were inconsistent. The primary aim of this study was to investigate the effectiveness of a group-based, peer support program on diabetes-related distress, well-being and diabetes-specific self-management in type 2 diabetes patients.

**Materials and methods:** A parallel group randomised controlled trial of a six session group-based peer support intervention, delivered by peer leaders and group psychotherapists, compared with one educational meeting on diabetes. Duration of the intervention was six months. Patients with a type 2 diabetes

duration of three years or more and between 50 and 70 years of age, recruited via their general practitioner, were randomised to receive the peer support intervention (n=101) or one educational meeting (n=132). Outcomes were measured one month before, and 6, and 12 months after baseline by means of self-reported questionnaires (PAID; WHO-5; diabetes specific CIDS). Baseline characteristics between intervention and control group were compared and multilevel linear regression models were performed on complete cases to investigate the effect of the intervention on diabetes-related distress (n=118), psychological well-being (n=116) and diabetes-specific self-management (n=107) (Mlwin2.22). Unadjusted analysis as well as analysis adjusted for differences in baseline characteristics are presented.

**Results:** Mean age of the study participants was 64 years (SD: 5) in both the control and intervention group. More men were randomised to the intervention group (69.3%) and more participants were lower educated (60.4%). Other characteristics did not differ between the two groups at baseline. No effects were seen for diabetes-related distress or well-being. However, the intervention group showed an increase in diabetes-specific self-management after 6 months of follow-up ( $\beta=4.6$ ; 95% CI: -5.4 to 14.6) and between baseline and 12 months of follow-up ( $\beta=5.1$ ; 95% CI: 1.2 to 9.0). Adjustment for differences in sex and educational level between intervention and control group at baseline slightly increased the differences in effects after 6 months ( $\beta=6.5$ ; 95% CI: -2.8 to 15.7) and after 12 months ( $\beta=7.0$ ; 95% CI: 3.01 to 11.02).

**Conclusion:** Results of this study indicate that a group-based, peer support program had no effect on diabetes distress nor on well-being but a modest beneficial effect on diabetes-specific self-management in type 2 diabetes patients was seen, which sustained for at least six months after the last peer group session.

### The efficacy of a new education and treatment programme (PRIMAS) for people with type 1 diabetes in daily routine and RCT: a health care research trial

N. Hermanns, N. Bergis-Jurgan, D. Ehrmann, T. Haak;  
Research Institute of Diabetes Academy Mergentheim (FIDAM),  
Bad Mergentheim, Germany.

**Background and aims:** It's a common result of health care research that efficacy of treatments assessed in randomized trials (RCT) is superior to efficacy of these treatments in routine care. We evaluated if a new education and teaching programme for type 1 diabetes patients (PRIMAS) had a similar efficacy in daily routine than in the RCT.

**Materials and methods:** In this health care research trial (HCRT) 255 people with type 1 diabetes from 42 diabetologists practices participated (age  $43 \pm 14$  yrs.; 54% male gender; diabetes duration  $13 \pm 12$  years; HbA1c  $8.1 \pm 1.4\%$ ). Participants took part in the education and treatment programme (PRIMAS), which consisted of 12 lessons. The outcomes were assessed 6 months after the education programme was finished. In both trials HbA1c was assessed in a central laboratory. Patients also completed a Hypoglycaemia Awareness Questionnaire, the Center of Epidemiological Studies-Depression Scale (CESD), the Diabetes Distress Scale (DDS), the Diabetes Self-efficacy Scale and the Empowerment Scale. Central outcomes were the difference in HbA1c reduction between the RCT and this health care research trial. Secondary outcomes were improvements of the hypoglycaemia awareness score, depressive symptoms, diabetes related distress, self-efficacy and empowerment.

**Results:** HbA1c showed an equivalent improvement in RCT and HCRT ( $-0.36 \pm 1.1$  vs.  $-0.39 \pm 1.2$  percentage points,  $\Delta 0.03$  95% CI -0.27 to 0.33 percentage points,  $p=.827$ ). The confidence interval of HbA1c-differences was beneath the 0.4 % non-inferiority threshold as defined by the ADA. Similar results were obtained regarding the hypoglycaemia unawareness score (RCT  $-0.52 \pm 1.42$  vs. HCRT  $-0.36 \pm 1.36$ ,  $p=.375$ ), for depressive symptoms score (RCT  $-1.18 \pm 7.93$  vs. HCRT  $-1.85 \pm 8.49$ ,  $p=.542$ ), for diabetes distress score (RCT  $-0.32 \pm 0.76$  vs. HCRT  $-0.18 \pm 0.66$ ,  $p=.180$ ) for self-efficacy score (RCT  $+1.39 \pm 3.56$  vs. HCRT  $-1.11 \pm 5.88$ ,  $p=.631$ ) and for empowerment score (RCT  $+2.61 \pm 5.93$  vs. HCRT  $-2.34 \pm 7.01$ ,  $p=.752$ ).

**Conclusion:** The PRIMAS diabetes education and treatment programme had similar effects under routine care conditions than observed in a RCT. Thus, PRIMAS can contribute to an improvement of routine health care in people with type 1 diabetes.

### Effects of a patient-oriented decision aid for prioritising treatment goals in diabetes, a randomised controlled trial

P. Denig<sup>1,2</sup>, J. Schuling<sup>3,2</sup>, F.M. Haaijer-Ruskamp<sup>1,2</sup>, J. Voorham<sup>1,2</sup>;

<sup>1</sup>Clinical Pharmacy and Pharmacology, University Medical Center

Groningen, <sup>2</sup>University of Groningen, <sup>3</sup>General Practice, University Medical Center Groningen, Netherlands.

**Background and aims:** Decision aids (DA) can encourage patient-provider discussions about disease management by presenting available treatment options and expected outcomes for the individual patient. The newest generation DA for diabetes patients and providers prioritise between clinical domains to guide treatment decisions. Our aim was to assess the effects of such a patient-oriented DA in comparison to usual care on shared goal-setting and treatment decisions.

**Materials and methods:** We conducted a randomised controlled trial including 18 general practices in the north of the Netherlands. Four presentation formats of the DA were compared to usual care. Practices were randomly allocated to a computer-screen or printed version of the aid. Within each practice, patients were randomised to receiving either the short or extended version of the aid or usual care. Effects on patient empowerment for making shared decisions about treatment goals (primary outcome), smoking status, prescribing of glucose-regulating, blood pressure-regulating, lipid-regulating and albuminuria-regulating drugs (secondary outcomes) were tested in intention-to-treat and per-protocol analyses. Data were collected through structured questionnaires and automated data extraction from electronic health records in 6 months before and after the intervention.

**Results:** Of 665 eligible patients with type 2 diabetes being  $\leq 65$  years at time of diagnosis, 344 consented to participate; 225 were allocated to the intervention groups and 119 to the usual care group. The mean empowerment score increased 0.1 on a 5-point scale in the overall intervention group. This effect was not significantly different from the control group in the intention-to-treat analysis but was significant in the per-protocol analysis (n=103 patients, who received the DA as planned vs 119 control patients,  $p=0.031$ ). Lipid-regulating drug treatment was intensified in 24% of intervention and 11% of control patients with elevated cholesterol levels, which was a significant difference in the intention-to-treat ( $p=0.041$ ) as well as the per-protocol analysis ( $p=0.038$ ). No significant changes were seen for the other drug treatments or in smoking status.

**Conclusion:** Our study showed that a patient-oriented treatment DA can lead to improved drug treatment and has potential for increasing patient empowerment, provided it is used as intended. The effects of the DA may have been limited due to its single use within the setting of this randomised trial.

### Health economic implications of education-based flexible insulin therapy versus conventional or technology-based approaches in type 1 diabetes

H. Zulewski<sup>1</sup>, M. Brändle<sup>2</sup>, A.-E. Minder<sup>1</sup>, B. Hunt<sup>3</sup>, W.J. Valentine<sup>3</sup>;

<sup>1</sup>University Hospital Basel, <sup>2</sup>Kantonsspital St. Gallen,

<sup>3</sup>Ossian Health Economics and Communications, Basel, Switzerland.

**Background and aims:** To estimate the long-term clinical and cost outcomes associated with flexible intensive insulin therapy (FIT) in relation to standard management and a continuous subcutaneous insulin infusion with continuous glucose monitoring (CGM-CSII) for patients with type 1 diabetes in Switzerland.

**Materials and methods:** Evaluation of a long-term cost-effectiveness model with parameters estimated from three landmark type 1 diabetes trials: The Basel FIT study, STAR 3 and EDIC, with clinical outcomes extrapolated using the published and validated CORE Diabetes Model. Main outcome measures included life expectancy, quality-adjusted life expectancy, incidence of diabetes-related complications, direct costs, and incremental cost-effectiveness ratios (ICERs).

**Results:** FIT and CGM-CSII were associated with clinical benefits over standard management, improving life expectancy (14.43 years and 14.20 years versus 14.07 years) and quality-adjusted life expectancy (10.14 quality-adjusted life years [QALYs], and 9.97 QALYs versus 9.75 QALYs). Improvements were driven by reduced incidences of diabetes-related complications and severe hypoglycaemic events, as a result of improved glycaemic control

over standard management. FIT was associated with reduced direct medical costs over standard management (CHF 186,373 versus CHF 192,588), and therefore was considered to dominate standard management. Costs were higher in the CGM-CSII (CHF 245,983) arm as a result of increased costs of CSII pumps and CGM consumables, with an ICER of CHF 248,602 per QALY gained versus standard management.

**Conclusion:** The education-based approach of FIT and the technology-based approach of CGM-CSII are both likely to produce improvements in clinical outcomes, but the high cost of CGM-CSII represents a barrier to its use, particularly compared to the cost savings associated with FIT. Investment of physician time in patient education may be more cost-effective than investment in CGM-CSII technology, in terms of optimizing management of patients with type 1 diabetes in Switzerland.

### Effects of multidisciplinary and structured education programme on glycaemic control during transition of young adults with type 1 diabetes

A. Da Porto, E. Tommasi, S. Cum, E. Del Forno, E. Caroli, E. Manca, A. Petrucco, R. Candido;  
Diabetes Unit, ASS I Triestina, Trieste, Italy.

**Background and aims:** The transition from pediatric to adult diabetes care represents a high risk period for a person with diabetes. Prior studies highlight the risk of gaps in medical follow-up and adverse diabetes related outcomes in emerging adults, including poor glycaemic control, appearance of long term diabetes complications and early mortality. Very little is known about the specific aspects of transitions process, in particular about the role of structured education during transition. Aim of our study was to evaluate the relationship between multidisciplinary structured education during transition and post-transition glycaemic control.

**Materials and methods:** We evaluated baseline clinical characteristics, glycaemic control, glycaemic variability, hypoglycaemia frequency and their variation one year after multidisciplinary structured education program in 55 young adults with type 1 diabetes who have done transition process. Data for Glycaemic variability (SD of average glucose) and hypoglycaemia frequency were obtained from the analysis of glycaemic samples from personal blood glucose meters during a period of 90 days. Multidisciplinary structured education was done at the first visit (and carried on during the following months) by Diabetologist, Dietician and Nurse with particular attention to CHO counting, hypoglycaemia correction and modulation of insulin therapy during exercise. Every 2 months correct use of CHO count or adherence to constant CHO diet were verified by dietician. Descriptive statistics were presented as means and SD or proportions. Chi square test was used to compare proportions. Multivariate logistic regression model was used to verify the association between correct management of CHO and glycaemic control at 1 year (variable included: age, sex,  $\Delta$  Hb1c  $\Delta$  glycaemic variability,  $\Delta$  hypoglycaemic frequency).

**Results:** Average population age was 27,8 $\pm$ 10,1 years with mean diabetes duration of 17,3 $\pm$ 9,9 years. Average transition GAP from the last pediatric diabetes visit and first adult visit was 6, 24 $\pm$ 9, 12 months. At the first visit to adult center mean Hb1c was 7, 9 $\pm$ 1, 2% , on average worsen of 0,32  $\pm$ 1,8% during transition GAP. Glycaemic variability was 83,1 $\pm$ 23 mg/dl and hypoglycaemic frequency was 12,6  $\pm$ 8,2%. Only 23,6% of patients correctly apply CHO counting and 11% employ constant CHO diet at baseline. Education was accepted by 85% of patients. One year later 34,6% of patients correctly apply CHO counting and 25,2% employ constant CHO diet (p 0,014 and 0,037 vs baseline). Hb1c and glycaemic variability decreased significantly from baseline (-0,72 $\pm$ 0,65% p 0,009 and - 12% p 0,041 respectively) . Hypoglycaemia frequency decreased not significantly (-2% p 0,124). Correct CHO management was associated to reduction of Hb1c (r 0,293 p 0,012) less glycaemic variability (r - 0,366 p =0,021) and lower hypoglycaemia frequency (r - 0,534 p 0,032) after 12 months in univariate model but loose statistical relevance in multivariate one. Baseline Hb1c was the only predictor of glycaemic control after 12 months of follow-up (R =0,0659 p 0,0001).

**Conclusion:** In our study sample age of transition and transition GAP was high, during transition GAP glycaemic control worsen. A multidisciplinary structured education during transition, if accepted by patient , lead to a better CHO management that is associated to a better posttransition glycaemic control.

## OP 04 Brown adipose tissue

### 19

#### Impaired brown adipose tissue fatty acid metabolism in obese subjects

T. Saari<sup>1</sup>, J. Raiko<sup>1</sup>, T. Niemi<sup>2</sup>, M. Taittonen<sup>3</sup>, J. Laine<sup>4</sup>, N. Savisto<sup>1</sup>, M. Haaparanta-Solin<sup>1</sup>, P. Nuutila<sup>1</sup>, K. Virtanen<sup>1</sup>;  
<sup>1</sup>Turku PET Centre, <sup>2</sup>Department of Plastic and General Surgery, <sup>3</sup>Department of Anesthesiology, <sup>4</sup>Department of Pathology, Turku University Hospital, Finland.

**Background and aims:** Brown adipose tissue (BAT) activation is commonly found during cold exposure: BAT glucose uptake and blood flow are increased in cold conditions. Obese subjects have a blunted glucose metabolism in BAT. The role of fatty acid metabolism in BAT function is uncertain. The aim of this study was to quantify NEFA uptake using PET-CT in lean and obese subjects during cold exposure and in room temperature (RT), and to measure the differences in NEFA uptakes between lean and obese subjects.

**Materials and methods:** NEFA uptake was quantified in lean (n=12, 5F/7M, ages: 34.4 $\pm$ 11.8 years, BMI: 24.1 $\pm$ 1.4 kg/m<sup>2</sup>) and obese subjects (n=9, 4F/5M, ages: 45.7 $\pm$ 5.8 years, BMI 32.6 $\pm$ 4.4 kg/m<sup>2</sup>) using 18F-FTHA, a palmitate analog. Each subject was imaged twice, once at RT and once during cold exposure. Cold exposure was started 2 hours before the imaging session. Tissue specific NEFA uptakes were calculated for supraclavicular adipose deposits, deltoid muscles and subcutaneous white adipose tissue (WAT). A biopsy was performed to confirm the existence of BAT in the supraclavicular area. Subjects were grouped to BAT positive (BAT+) and BAT negative (BAT-) groups based on their biopsy result. Biopsy site was determined from CT images.

**Results:** Three lean subjects (2F/1M) had biopsy proven BAT. They had 7-fold higher NEFA uptake during cold compared to obese- subjects (5.56 $\pm$ 1.15 vs. 0.74 $\pm$ 0.26  $\mu$ mol/100g/min, P=0.01) and 4-fold compared to lean BAT- subjects (1.43 $\pm$ 1.00  $\mu$ mol/100g/min, P=0.02 vs. BAT+). Cold exposure increased BAT NEFA uptake in BAT+ subjects 3-fold compared to RT (P=0.02). BAT+ subjects had higher BAT NEFA uptake in RT compared to obese subjects (1.69 $\pm$ 0.57 vs. 0.57 $\pm$ 0.55  $\mu$ mol/100g/min, P=0.01). BAT FA uptake in cold was higher in lean BAT- subjects compared to all obese subjects (P=0.01). Lean and obese groups had similar muscle and WAT NEFA uptakes in cold and RT.

**Conclusion:** Cold stimulation increases NEFA uptake of BAT, but not skeletal muscles or WAT. All subjects who had functionally active BAT were lean, and all lean subjects had higher tissue activity during cold exposure in the supraclavicular area compared to the obese subjects. BAT+ subjects had increased BAT NEFA uptake in RT. This would suggest that BAT takes in NEFA even without cold exposure. These results suggest that obese subjects have an impaired NEFA uptake in the supraclavicular area, typical BAT region.

### 20

#### Cold exposure increases the oxygen uptake rate of brown adipose tissue in humans

M. U Din<sup>1</sup>, J. Raiko<sup>1</sup>, T. Saari<sup>1</sup>, T. Tolvanen<sup>1</sup>, V. Oikonen<sup>1</sup>, J. Teuhon<sup>1</sup>, H. Sipilä<sup>1</sup>, N. Savisto<sup>1</sup>, P. Nuutila<sup>1,2</sup>, K.A. Virtanen<sup>1</sup>;  
<sup>1</sup>Turku PET Centre, Turku University Hospital and University of Turku, <sup>2</sup>Turku University Hospital, Department of Endocrinology, Finland.

**Background and aims:** Brown adipose tissue (BAT) activity has been suggested to have direct relation with insulin sensitivity and inverse association with obesity. BAT is more active during cold environment as it produces heat by the oxidation of glucose and fatty acids, a phenomenon known as non-shivering thermogenesis. Oxygen uptake rate can be a marker of BAT thermogenic potential as an indicator of oxidative metabolism. In our present study we aimed to determine whether cold exposure increases the oxygen uptake rate in BAT and how much BAT oxygen uptake rate is associated with blood flow and NEFA uptake rate during cold.

**Materials and methods:** Healthy lean and obese study subjects (n = 8, age: 34.5  $\pm$  11.0 years, BMI range: 23.2 - 31.1 kg/m<sup>2</sup>) of both genders (3F/5M) were studied at two different scanning sessions, 1) at room temperature (RT) and 2) with acute cold exposure, using PET-CT. Radioactive oxygen [<sup>15</sup>O]O<sub>2</sub>, [<sup>15</sup>O]H<sub>2</sub>O and [<sup>18</sup>F]FTHA were given for the measurements of oxygen uptake rate, blood flow and NEFA uptake rate of BAT, respectively. Indirect calorimetry was performed to assess the differences in whole body energy expendi-

ture between RT and cold environment. Data was compared with two tailed T-test and correlation analysis were performed with Pearson's correlations.

**Results:** Cold exposure increased oxygen uptake rate by 22.4 % (from 2.21 ± 0.68 to 2.85 ± 0.59 ml/100g/min, P = 0.001) in 16 BAT regions within 8 subjects, while oxygen uptake tended to be higher during RT in deltoid muscle (2.55 ± 1.52 vs. 3.13 ± 1.85 ml/100g/min, cold vs. RT, P = 0.06); however, no significant difference was found in white adipose tissue (1.76 ± 0.21 vs. 1.78 ± 0.19 ml/100g/min, cold vs. RT, P = 0.76). Cold exposure also tended to increase whole body energy expenditure (from: 7.07 ± 1.10 to 8.24 ± 2.43 MJ/24h, P = 0.09). During cold exposure, oxygen uptake rate correlated with blood flow (r = 0.51, P = 0.05) and NEFA uptake rate in BAT (r = 0.76, P = 0.01, n = 5).

**Conclusion:** High oxygen demand during cold in brown adipose tissue is most likely due to increased oxidation of available substrates (either glucose or fatty acids) for thermogenesis. Positive correlation between NEFA and oxygen uptakes suggests that NEFAs that enter brown adipocytes during cold also undergo β-oxidation within mitochondria.

Loss of sympathetic drive may explain loss of brown adipose tissue activity in elderly but not in obese males

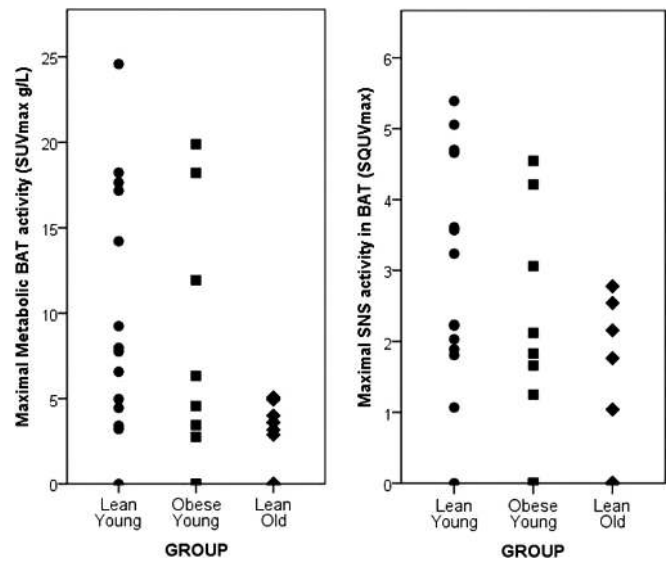

L. Bähler, H.J. Verberne, W.M. Admiraal, M.R. Soeters, J.B.L. Hoekstra, F. Holleman; Academic Medical Center, Amsterdam, Netherlands.

**Background and aims:** Metabolically active brown adipose tissue (BAT) could facilitate weight loss by increasing energy expenditure. Cold is a potent stimulator of BAT, activating BAT primarily through the sympathetic nervous system (SNS). Old or obese individuals have less metabolic BAT activity than lean and young, but the role of the SNS in this decrease is unknown. We determined whether the lower metabolic BAT activity can be explained by a lower SNS response to cold.

**Materials and methods:** We studied 10 young obese (26 [21-31] years, BMI 32 [31-39] kg/m<sup>2</sup>), 10 old lean (55 [51-60] years, BMI 23 [22-25] kg/m<sup>2</sup>) and 14 young lean (26 [21-28] years, BMI 22 [21-23] kg/m<sup>2</sup>) males. Metabolic BAT activity was measured as maximal standardised uptake value and volume (SUVmax, SUVvol) on 18F-Fluorodeoxyglucose positron emission tomography CT (FDG). SNS activity was measured as semiquantitative uptake values of 123I-metaiodobenzylguanidine (MIBG) on single photon emission computed tomography scans, with the mediastinum as reference region. Scans were made after an overnight fast and 2 hours of cold exposure.

**Results:** Metabolic BAT activity and volume were different between young vs old (median [IQR] SUVmax (g/L) 7.9[4.2-17.3] vs 3.0[0.0-4.2] p<0.05, SUVvol (cm3) 124.8[10.9-333.8] vs 4.3[0.0-12.3] p<0.05) but unexpectedly, not for lean vs obese (SUVmax (g/L) 7.9[4.2-17.3] vs 4.0[0.0-13.5] p=0.2, SUVvol (cm3) 124.8[10.9-333.8] vs 11.8[0.0-190.2] p=0.2). HOMA-IR differed between lean and obese (p<0.01) but not for young vs old. There was no correlation between HOMA-IR and either SUVmax or SUVvol. There were no differences in the SNS activity in BAT between lean and obese males (p=0.2) but for young and old males this was borderline significant (p=0.06) We confirmed the strong positive correlation between BAT activity measured with FDG and MIBG in the whole group (spearman correlation ρ=0.76, p<0.01), which we previously showed.

**Conclusion:** We conclude that loss of sympathetic drive may explain the loss of BAT activity in elderly but not in obese males.

22

Seasonal variation in temperature influences acute brown adipose tissue activation

J.W.T. Deelen, L. Bähler, J.B.L. Hoekstra, H. Verberne, F. Holleman; Academic Medical Center, Amsterdam, Netherlands.

**Background and aims:** Brown adipose tissue(BAT) has gained a lot of interest because of its capacity to convert calories into heat. Retrospective data on diagnostic 18F-Fluorodeoxyglucose-(FDG)-Positron-Emission-Tomography-(PET)-CT scans, in warm temperatures, show increased BAT activity during the winter months as compared to the summer months. Indeed, cold has been shown to be the strongest activator of BAT activity so far. Besides seasonal changes in BAT activity on diagnostic 18F-FDG-PET-CT scans, there is also an acute BAT activation after direct cold exposure. The magnitude of this acute effect might still be influenced by seasonal temperatures through preconditioning of BAT. Indeed, frequent exposure to cold has been shown to increase BAT activity and volume. The aim of this study was to evaluate the seasonal effect of BAT in subjects exposed to acute cold.

**Materials and methods:** 18F-FDG-PET-CT scans of 63 consecutive subjects were included. These subjects participated in BAT research in the Academic Medical Center between January 2010 and December 2013. All subjects were cold exposed at 16-17 °C in an air cooled room, after an overnight fast. Temperature data (24 hours, 1 week, 2 weeks and 4 weeks before the scan) were collected from the national weather institute. Correlations between BAT activity (i.e. maximal and mean standardised uptake value(SUVmax and SUVmean) and volume) and outdoor temperature (OT) were calculated by the Spearman's correlation coefficient.

**Results:** Forty-nine subjects were BAT positive. The BAT positive subjects were significantly younger (median age 25 IQR[21.1-29.4] vs 29.5 [23.5-51.8] years, p<0.05) and leaner (median BMI 22.6 [21.3-23.7] vs 26.2 [23.3-32.6] kg/m<sup>2</sup>, p<0.05) as compared to the BAT negative subjects. One week and 4 weeks prior to the scan the OT was significantly lower in the BAT positive group compared to the BAT negative group: 10.0 °C ([4.6-16.4] vs 17.1 [9.1-17.6] °C, p<0.01 ) and 10.6 °C ([7.7-16.3] vs 16.5 [10.3-17.0] °C, p<0.05). However, 24 hours and 2 weeks prior to the scan there were no significant differences in OT between the BAT positive and BAT negative subjects. There was a strong negative correlation for both the maximal BAT activity as well as BAT volume and outdoor temperature for all different time points (24 hours, 1 week, 2 weeks and 4 weeks before the scan all p<0.01).

**Conclusion:** These data confirm the strong negative correlation between outside temperature and BAT activity and volume. In addition the data show that BAT activation by acute cold is largely influenced by outside temperatures. It seems therefore advisable to study BAT activity during periods of relative cold.

| Correlation Coefficients | SUVmax          | SUVmean         | BAT Volume      |
|--------------------------|-----------------|-----------------|-----------------|
| Temp 24 hours            | -0.45 [p<0.001] | -0.46 [p<0.001] | -0.43 [p<0.001] |
| Temp 1 week              | -.50 [p<0.001]  | -0.52 [p<0.001] | -0.45 [p<0.001] |
| Temp 2 weeks             | -0.45 [p<0.001] | -0.47 [p<0.001] | -0.41 [p<0.001] |
| Temp 4 weeks             | -0.46 [p<0.001] | -0.49 [p<0.001] | -0.44 [p<0.001] |

Table 1. Spearman correlation coefficients between maximal BAT activity(SUVmax), mean BAT activity (SUVmean) BAT volume and Temperature data in the hours or week(s) before the scan.

## 23

**Brown adipose tissue activity associates with insulin sensitivity and liver adiposity independently of visceral fat mass in healthy adults**J.R.H. Raiko<sup>1</sup>, T. Saari<sup>1</sup>, V. Saunavaara<sup>1</sup>, R. Parkkola<sup>2</sup>, P. Nuutila<sup>1,3</sup>, K. Virtanen<sup>1</sup>;<sup>1</sup>Turku PET Centre, University of Turku, <sup>2</sup>Department of Radiology, Tampere University Hospital, <sup>3</sup>Department of Endocrinology, Turku University Hospital, Finland.

**Background and aims:** Brown adipose tissue (BAT) activity associates with insulin sensitivity and inversely with obesity. However, it remains unclear if the association between BAT and insulin sensitivity is mediated by low intra-abdominal adipose tissue mass and low liver adiposity in subjects with active BAT. In this study, we examined associations between BAT activity during cold exposure and glycaemic control, whole body insulin sensitivity, intra-abdominal adipose tissue mass and liver adiposity.

**Materials and methods:** 22 healthy adult subjects (M/F: 8/14, 41.0 ± 8.3 years, BMI 27.3 ± 5.3 kg/m<sup>2</sup>) underwent positron emission tomography with [<sup>15</sup>O]-H<sub>2</sub>O to measure BAT perfusion and [<sup>18</sup>F]-FTHA to measure NEFA uptake in the supraclavicular BAT depot during cold exposure. Cold exposure had started two hours prior to and continued during the PET imaging. Whole body insulin sensitivity (hyperinsulinemic euglycemic clamp) and HbA<sub>1c</sub> were measured. MRI imaging was used for the measurement of intra-abdominal adipose tissue volume and liver adiposity was adjusted with MR spectroscopy.

**Results:** Cold-induced NEFA uptake in BAT was 2.25±1.75 μmol/100g/min and perfusion was 22.0±27.0 ml/100g/min. HbA<sub>1c</sub> was 5.4±0.4%, M value was 6.8±3.2 mg/kg/min, visceral adipose mass was 3.3±2.0 kg and liver fat content was 5.7±6.9%. NEFA uptake in BAT correlated with whole body insulin sensitivity ( $r = 0.50$ ,  $P = 0.02$ ), intra-abdominal fat mass ( $r = -0.43$ ,  $P = 0.04$ ) and liver adiposity ( $r = -0.47$ ,  $P = 0.04$ ). Cold-induced BAT perfusion correlated with HbA<sub>1c</sub> ( $r = -0.57$ ,  $P = 0.01$ ). These associations (perfusion vs. HbA<sub>1c</sub> and NEFA uptake vs. whole body insulin sensitivity) were independent of intra-abdominal fat volume or liver adiposity ( $P$  always < 0.05). Associations between NEFA uptake and liver adiposity were also independent of intra-abdominal adipose tissue volume ( $P = 0.03$ ).

**Conclusion:** These results show that cold-induced BAT activity is associated with glycaemic control and insulin sensitivity independently of visceral adipose tissue mass and liver adiposity in health. Subjects with high BAT activity might have lower visceral fat mass due to increased energy expenditure. Additionally, BAT NEFA uptake might prevent fat accumulation in liver in visceral obesity. Although, liver fat content and visceral obesity correlate inversely with BAT activity, BAT may associate with insulin sensitivity via a separate mechanism. These may include yet unrecognized BAT-derived cytokines affecting muscle metabolism.

**Inorganic nitrate promotes the browning of white adipose tissue through the nitrate-nitrite-nitric oxide pathway**L.D. Roberts<sup>1</sup>, T. Ashmore<sup>2</sup>, A.O. Kotwica<sup>2</sup>, S.A. Murfitt<sup>3</sup>, B.O. Fernandez<sup>4</sup>, M. Feelisch<sup>4</sup>, A.J. Murray<sup>2</sup>, J.L. Griffin<sup>1</sup>;<sup>1</sup>Medical Research Council - Human Nutrition Research, University of Cambridge, <sup>2</sup>Physiology, Development and Neuroscience, University of Cambridge, <sup>3</sup>Biochemistry, University of Cambridge, <sup>4</sup>Faculty of Medicine, Clinical & Experimental Sciences, University of Southampton, UK.

**Background and aims:** Inorganic nitrate is considered an oxidation end-product of nitric oxide with little biological activity. However, recent studies demonstrate that dietary nitrate, largely derived from green leafy vegetables, modulates mitochondrial function in man and is effective in reversing features of the metabolic syndrome in mice. The role of nitrate in white adipose tissue (WAT) function remains poorly characterized. The development of a brown-like phenotype in white adipocytes (“beige” or “brite” cells), a process known as “browning”, includes the induction of thermogenesis, the dissipation of chemical energy as heat. Activation of the browning response in WAT may represent a process underlying the altered systemic energy balance observed with nitrate treatment.

**Materials and methods:** Wistar rats were treated with 0.35 mM, 0.7 mM or 1.4 mM sodium nitrate (NaNO<sub>3</sub>) in drinking water for 18 days ( $n = 6$ /group). Nitrate induced browning of WAT was assessed using both RT qPCR and mass spectrometry based metabolomics. In vitro browning of primary

adipocytes treated with 25 μM, 50 μM and 500 μM NaNO<sub>3</sub> was analysed using respirometry, metabolomics, stable-isotope labelling techniques and RT qPCR. The mechanism of nitrate induced browning was defined in primary white adipocytes using pharmacological inhibitors of nitric oxide (NO), guanylate cyclase and protein kinase G (PKG). The effect of hypoxia on nitrate induced browning of WAT was determined in vivo in Wistar rats and in vitro using primary adipocytes.

**Results:** Nitrate dose-dependently increased the expression of brown-adipocyte specific genes in WAT of nitrate treated rats (UCP-1, CIDEA, PGC-1α, CYCS, CPT1, ACADvl, Two-way ANOVA, Control vs. 0.35 mM NaNO<sub>3</sub>  $P \leq 0.01$ , Control vs. 0.7 mM NaNO<sub>3</sub>  $P \leq 0.0001$ , Control vs. 1.4 mM NaNO<sub>3</sub>  $P \leq 0.001$ ). Metabolomic analysis demonstrated that treatment with nitrate also decreased the total triacylglycerol content within WAT (0.95-fold, 0.35 mM NaNO<sub>3</sub>; 0.94-fold, 0.7 mM NaNO<sub>3</sub>; 0.98-fold, 1.4 mM NaNO<sub>3</sub>; ANOVA, Control vs. 0.35 mM  $P \leq 0.01$ , Control vs. 0.7 mM  $P \leq 0.01$ ). These findings were reproduced in vitro using primary white adipocytes treated with nitrate and analysed using RT qPCR, stable isotope labelling and metabolomics, and were accompanied by an increase in oxygen consumption, assessed by respirometry (Control 4.2 nmoles O<sub>2</sub>/min/106 cells, 50 μM NaNO<sub>3</sub> 6.6 nmoles O<sub>2</sub>/min/106 cells, 500 μM NaNO<sub>3</sub> 7.7 nmoles O<sub>2</sub>/min/106 cells, ANOVA,  $P = 0.02$ ). Using pharmacological inhibitor assays in primary white adipocytes, nitrate was found to induce these phenotypic changes in WAT independently of NO synthase, through the recently identified xanthine oxidoreductase catalysed nitrate-nitrite-NO pathway and downstream cGMP/PKG signalling. Furthermore, the nitrate induced browning of WAT, both in vitro and in vivo, was enhanced in hypoxia.

**Conclusion:** Since beige/brite cells exhibit anti-diabetic and anti-obesity effects and WAT from obese individuals is characterized by hypoxia, nitrate may be an effective means of targeting the induction of browning to white adipocytes located in obese and hypoxic adipose depots to treat the metabolic syndrome.

### G1 lengthening promotes pancreatic progenitor cell differentiation in mouse embryonic development

N.A.J. Krentz, M. Tang, A. Watanabe, F.C. Lynn;  
University of British Columbia, Vancouver, Canada.

**Background and aims:** Cellular-based therapies for diabetes mellitus, such as the differentiation of human embryonic stem cells (hESCs), require an in-depth understanding of pancreatic development. During early pancreatic development, the Pdx1+Cpa1+ tip multipotent progenitor cells give rise to all three cell types of the pancreas, exocrine, endocrine and ductal cells, while the trunk Pdx1+Cpa1- cells give rise to endocrine or ductal cells only. The process that regulates the proliferation and differentiation of these progenitor populations is not fully known. There is evidence during neurogenesis that the length of the G1 phase of the cell cycle can directly influence the differentiation of neural precursors. Thus, we hypothesize that the cell cycle length regulates pancreas organogenesis.

**Materials and methods:** Pregnant CD-1 mice (P12.5) were injected with the thymidine analog 5'Ethynyl-2'-deoxyuridine (EdU) every 1.5 hours starting at 9 am. Embryos were collected at evenly spaced intervals from 9:30 am to 8 pm. The number of Pdx1+Cpa1+ and Pdx1+Cpa1- cells labelled with EdU was determined using immunofluorescence and confocal microscopy (n>4). The lengths of the G1, S and G2/M phases were determined mathematically from the length of time required to label all dividing cells, the number of cells labeled at time 0, and the proportion of dividing cells.

**Results:** We determined that the G1 length of multipotent progenitor cells at E12.5 was 3.6 hours while the bi-potent trunk cells had a G1 length of 5.8 hours. We did not find any significant change in the lengths of either the S or G2/M phases of the cell cycle. Consistent with findings in neural development, the difference in total cell cycle length of these two progenitor populations at E12.5 was largely due to a lengthening of the G1 phase. Intriguingly, the maximal proportion of EdU labeled cells or the growth fraction was significantly different (p<0.05; n=17) between multipotent and bi-potent progenitor cells with 90% and 66% EdU+, respectively. Preliminary data suggests that the majority of non-dividing Pdx1+ cells are still located within the pancreatic epithelium, express other progenitor cell markers such as Sox9 and Nkx6.1, and are Ki67+. These results suggest that there is a population of progenitor cells that are still in the cell cycle but are not dividing. As it has been previously shown that Ngn3 expression in endocrine progenitors inhibits proliferation by activation of Cdkn1a we also examined whether Ngn3 cells are labelled with EdU. Consistent with these results, we did not find a meaningful population of Ngn3+EdU+ cells.

**Conclusion:** These results support the 'cell cycle length hypothesis' from neurogenesis and suggest that G1 lengthening is important for pancreatic progenitor cell differentiation. Understanding this process may give novel insight into pancreatic development and inform studies aiming to produce mature beta cells from hESCs for diabetes treatment.

### Up-regulation of MafA drives embryonic progenitor-derived insulin-producing cells towards maturation and functional improvement both in vitro and in vivo

G. Li<sup>1</sup>, S. Shao<sup>1</sup>, J. Zhang<sup>1</sup>, W. Nishimura<sup>2</sup>, A. Sharma<sup>2</sup>, Y.-M. Bee<sup>3</sup>;  
<sup>1</sup>Clinical Research, Singapore General Hospital, Singapore, <sup>2</sup>Joslin Diabetes Center, Boston, USA, <sup>3</sup>Endocrinology, Singapore General Hospital, Singapore.

**Background and aims:** Shortage in pancreas donors has impeded transplantation therapy for insulin-dependent diabetes. Our previous work has generated insulin-producing cells from mouse embryonic stem cells and embryos-derived progenitor cells, which could secrete insulin upon glucose stimulation and correct hyperglycaemia after transplantation into diabetic animals. However, these cells failed to function completely alike the adult  $\beta$ -cells and revealed features of immaturity. It is known that MafA (v-maf musculoaponeurotic fibrosarcoma oncogene homolog A) acts as a master transcription factor in regulating  $\beta$ -cell development and glucose responsive-

ness, but its expression is significantly lower in our insulin-producing cells. This study aimed to investigate if up-regulation of MafA could improve the function of these cells.

**Materials and methods:** MafA-expressing lentivirus was used to transduce mouse embryonic progenitor-derived insulin-producing (MEPI)-1 cells, followed by evaluations of cell functions both in vitro and in vivo.

**Results:** MafA levels in MEPI-1 cells could be significantly elevated near to that in isolated adult islets by the lentivirus. Insulin production was augmented by 50% and the expression of many genes (e.g. insulin, GLP-1 receptor, Glut2, glucokinase, Kir6.2 and Nkx6.1) important for  $\beta$ -cell development and function was significantly enhanced. These cells also exhibited higher extents of glucose metabolism, membrane potential depolarization and intracellular Ca<sup>2+</sup> concentration rise, indicating more active signaling events upon glucose stimulation. Particularly, MafA up-regulation markedly improved glucose-stimulated insulin secretion by reducing basal insulin release and shifting the dose-response curve of insulin secretion upon glucose stimulation more close to the physiological pattern. When transplanted into streptozotocin-induced diabetic mice, MafA-upregulated MEPI-1 cells were able to correct hyperglycaemia for a longer term and reduce the hypoglycaemic incidences. In addition, MafA up-regulation slowed down MEPI-1 cell growth both in vitro and in vivo, and arrested the cells at G1 phase, which might be due to the observed elevation of expression of p27, an important cell cycle inhibitor.

**Conclusion:** Up-regulation of MafA levels in MEPI-1 cells enhances expression of the  $\beta$ -cell relevant gene profile, increases insulin biosynthesis, improves stimulated insulin secretion by augmenting signaling cascade, slows cell growth, ameliorates their in vivo capability of correcting hyperglycaemia in diabetic animals. These findings indicate that MafA can promote maturation of embryonic stem cell-derived insulin-producing cells, enabling them to achieve better correction of hyperglycaemia for treatment of type 1 diabetes.

### Elucidating the role of Menin during islet cell development in the human foetal pancreas

J. Li<sup>1</sup>, J.L. Dubrick<sup>1</sup>, G.F. Fellows<sup>2</sup>, C.G. Goodyer<sup>3</sup>, R. Wang<sup>1</sup>;  
<sup>1</sup>Physiology & Pharmacology, Western University, <sup>2</sup>Obstetrics and Gynaecology, Western University, London, <sup>3</sup>Pediatrics, McGill University, Montreal, Canada.

**Background and aims:** The transcription factor, Menin, a tumour suppressor encoded by the Men1 gene, has recently been implicated as necessary for murine pancreatic development, suggesting a dual functionality: (1) to promote endocrine (including progenitor) differentiation via Ngn3 expression during development; and (2) to suppress proliferation and insulin hypersecretion in the adult pancreas. Most studies of Menin in the human have focused on its neoplastic role in the adult pancreas; however, knowledge of Menin's function during human fetal pancreatic development is limited. In the present study, the expression pattern and functional role of Menin was examined in the early to mid-gestation human fetal endocrine pancreas.

**Materials and methods:** The presence of Menin in the human fetal (8-21 weeks fetal age) pancreas was characterized by quantitative RT-PCR, western blotting and immunohistological approaches. Isolated human fetal islet-epithelial cell clusters (15-18 weeks) were treated with either MEN1 siRNA or MEN1 overexpression vector.

**Results:** Immunostaining revealed strong nuclear Menin (nMenin) expression within pancreatic cells from 8 to 21 weeks of fetal age that paralleled Menin mRNA and protein expression patterns. nMenin+ cells co-localized with transcription factors (PDX-1, SOX9, NGN3) that are critical for maintenance of the progenitor pool and endocrine differentiation. A high proportion of Ki67+ cells contained nMenin signals at 8-16 weeks but this decreased significantly at 18-21 weeks of development; the proliferative capacity of nMenin+ cells was reduced in parallel. Knockdown of MEN1 in human fetal islet-epithelial cells significantly increased apoptosis, reduced proliferation and decreased SOX9, NKX2.2 and NKX6.1 expression levels. Overexpression of MEN1 had opposite results: a significant increase in cell proliferation and insulin mRNA, suggesting that Menin plays a positive role in the developing human fetal pancreas.

**Conclusion:** We have investigated the expression and potential function of MEN1 in the early to mid-gestation human fetal pancreas. Functional knock-down and overexpression studies both suggest that Menin promotes human fetal pancreatic cell survival and proliferation, maintains the islet progenitor pool and regulates islet differentiation, very different from its anti-tumorigenic role in the adult pancreas.

## 28

### SOX9 and WNT signalling during human foetal pancreatic development

R. Wang<sup>1</sup>, J.A. Belo<sup>1</sup>, J. Li<sup>1</sup>, G.F. Fellows<sup>2</sup>, C.G. Goodyer<sup>3</sup>;

<sup>1</sup>Physiology & Pharmacology, Western University, <sup>2</sup>Obstetrics and Gynaecology, Western University, London, <sup>3</sup>Pediatrics, McGill University, Montreal, Canada.

**Background and aims:** Regulation of pancreatic progenitor proliferation and differentiation is crucial when generating an appropriate beta-cell mass. SOX9 is an important factor in pancreatic progenitor maintenance as well as endocrine differentiation; however, the signaling pathways that regulate expression of SOX9 remain unclear. A study of murine duodenal epithelium demonstrated that Wnt signaling regulated progenitor expansion and differentiation in addition to Sox9 expression. In the present study, the co-localization and inter-relationship between SOX9 and Wnt/ $\beta$ -catenin factors and their targets in the developing human pancreas were examined.

**Materials and methods:** Human fetal pancreata (8-21 weeks fetal age) were examined for SOX9 and Wnt signaling molecules using immunofluorescence, western blot and qRT-PCR approaches. Isolated human fetal (18-21 week) islet-epithelial cell clusters were also treated with or without recombinant WNT3A in a dose- and time-dependent fashion. In addition, cells were treated with either a GSK3 $\beta$  inhibitor (I-Akp) or a Wnt signaling inhibitor (FZD8-CRD).

**Results:** Half of the SOX9+ cells expressed WNT3A at 8-12 weeks but the numbers decreased with age ( $p < 0.05$ - $0.01$ ); in contrast, FZD and  $\beta$ -catenin expression in SOX9+ cells remained stable. The majority of insulin+ cells expressed WNT3A, FZD and  $\beta$ -catenin throughout this developmental period. To examine WNT signalling, isolated human fetal (18-21 week) islet-epithelial cell clusters were treated with rWNT3A or vehicle. Cells treated with WNT3A showed a dose-related increase in  $\beta$ -catenin localization. In addition, a significant increase in SOX9 and ISL1 expression as well as the number of insulin+ cells was observed in the WNT3A treated group after 48h of culture ( $p < 0.01$  vs. controls), but no significant effect on the glucagon+ cell number. Cell proliferation studies using Ki67 labeling showed a transient increase in cell proliferation at 4h of culture but no changes in proliferative capacity at 24 and 48h. Similar results were observed when the cells were treated with a GSK3 $\beta$  inhibitor. Furthermore, these effects of WNT3A on human islet-epithelial cell differentiation could be partially blocked by co-treatment with FZD8-CRD, a Wnt signaling inhibitor, suggesting that WNT3A induces SOX9 expression and beta cell differentiation through both FZD and non-FZD pathways.

**Conclusion:** These data indicate an active role for WNT signalling during endocrine cell differentiation in the early to mid-gestation human fetal pancreas. SOX9+ progenitors express WNT3A, FZD and  $\beta$ -catenin, suggesting that the WNT pathway may be involved in maintenance and differentiation of these cells. The present data provide evidence for a role of Wnt/ $\beta$ -catenin and SOX9 in determination of insulin cells by regulating proliferation versus differentiation.

### Changes in microRNAs profile underline the dedifferentiation process of in vitro cultured human pancreatic islet cells

G. Sebastiani<sup>1</sup>, G. Ventriglia<sup>1</sup>, L. Nigi<sup>1</sup>, M. Valentini<sup>1</sup>, L. Marselli<sup>2</sup>, P. Marchetti<sup>2</sup>, F. Dotta<sup>1</sup>;

<sup>1</sup>University of Siena and Umberto di Mario Foundation,

<sup>2</sup>University of Pisa, Italy.

**Background and aims:** Beta-cell dedifferentiation has recently been identified as a mechanism of beta-cell dysfunction both in type1 and type2 diabetes. Upon metabolic or inflammatory stress, beta-cells undergo a specific phenotypic re-arrangement which on one side protects them from apoptosis and, on the other, elicits functional impairment. Previously, we have set up

a model of in vitro de-differentiation of human native islets (HI) that, when cultured in appropriate conditions, undergo an epithelial-mesenchymal like transition process (EMT), generating human pancreatic islet-derived mesenchymal cells (hPIDM). MicroRNAs (miRNAs) are smallRNAs, which regulate gene expression. MiRNAs have been demonstrated to control several biological processes including stemness and cell differentiation. MiRNAs have also been proposed to contribute to the development of many disorders including diabetes. Here, we aimed at characterizing the miRNA expression profile during human pancreatic islet cell dedifferentiation process.

**Materials and methods:** Human native islets were collected from 3 multiorgan donors and cultured for 15 days. De-differentiated proliferating hPIDM cells were collected and total RNA was extracted from human islets and from hPIDM cells. Expression of 768 miRNAs was evaluated using Taqman Human miRNAs panel A and B arrays. MiRNA prediction target analysis followed by gene ontology classification was performed using Targetscan and DAVID 6.7. MiRNA target genes expression levels on 3 different human native islets preparations and 3 hPIDM cells samples were evaluated with Taqman plates by using Real Time PCR. Data and statistical analysis was performed using expression suite software

**Results:** Among 768 miRNAs analyzed, 335 and 331 miRNAs were detected in HI and in hPIDM cells respectively. Following dedifferentiation, 110 miRNAs resulted significantly decreased and 13 increased in hPIDM cells vs native human islets. Upregulated miRNAs included miR-100, miR-337-3p, miR-214, miR-199a-3p and -5p, miR-137, miR-708, miR-99a and miR-302s. To gain insights into the molecular pathways potentially regulated by these miRNAs, we looked at the predicted targets genes. Using Targetscan, we extrapolated a list of 196 genes predicted as targets of the 13 upregulated miRNAs. In order to classify the predicted genes we used the algorithm DAVID 6.7 which allowed us to perform a gene ontology analysis. We identified 11 functional categories with a significant p-value. Among these categories, most genes belonged to cell-cell adhesion mechanisms and to differentiation process; By analyzing the expression levels of a selection of these predicted target genes in HI and hPIDM, we observed a major downregulation of 44 genes during EMT, in line with the inverse expression levels of targeting miRNAs

**Conclusion:** We detected a specific miRNA signature of in-vitro dedifferentiated human pancreatic islet-derived mesenchymal cells. We specifically identified 13 miRNAs strongly upregulated during this process, which may indeed function as regulators of those genes controlling mesenchymal-like phenotype acquisition. Using a bioinformatic approach we uncovered a putative specific role for these miRNAs in exploiting several functions by regulating the expression of genes involved in cell-adhesion, cell-cell contact, morphogenesis and in mesenchymal-like phenotype acquisition.

## 30

### Transcriptome profiling by RNAseq of single human islet cells reveals unique features of individual alpha and beta cells

M. Garieri, C. Borel, P. Ribaux, S.E. Antonarakis, E.T. Dermitzakis, P.A. Halban;

Genetic Medicine and Development, University of Geneva, Switzerland.

**Background and aims:** Deep coverage RNA sequencing (RNAseq) allows for the detailed description of transcriptomes. Typically this is performed on pure or mixed cell populations and the data offer no insight into the transcriptome signature or true identity of individual cells, or cell-to-cell variability in gene expression. To understand the unique features of individual human islet cells, we have now captured single cells and analysed them by RNAseq.

**Materials and methods:** Human islets isolated from 2 healthy donors (samples C1, C2) and 2 with type 2 diabetes (D1, D2) were dissociated (accutase) and single cells captured and processed in 96-well microfluidic plates (Fluidigm C1 Single-Cell Auto Prep System). We RNA sequenced 288 single cells with Illumina HiSeq2000 (100 base pairs, paired-end reads), with an average of 36.6 million total reads. mRNA levels are expressed as Reads Per Kilobase per Million mapped (RPKM).

**Results:** After quality control, 275 cells were analysed. Of these, 123 were considered beta cells (defined as RPKM INS (insulin)  $> 100$ , GCG (glucagon), PPY (pancreatic polypeptide) and SST (somatostatin)  $< 100$ ). The number of beta/total cells for each donor was: C1: 42/68; C2: 50/81; D1: 14/63; D2: 17/63. In these cells, INS was highly expressed, but with considerable inter-cellular variability (RPKM range for C1: 1040-52410; C2: 167-104500; D1: 293-35930; D2: 316-22440). Interestingly, there was expression of GCG in all beta cells (range 1-75 RPKM), albeit at much lower levels than in the 48

captured alpha cells (RPKM GCG >100, INS, PPY and SST <100) with RPKM range C1: 68530-175400, C2: 36670-188100; D1: 110-90340; D2: 5752-59780. Similarly, there was low INS expression in all alpha cells (range 6-89 RPKM). Analysis of empty wells indicated that this low-grade expression was not due to contamination. There is considerable interest in islet cell plasticity, particularly possible alpha-to-beta cell trans-differentiation. We identified a total of 53 mixed phenotype "alpha-beta" cells (RPKM INS and GCG >100, PPY and SST <100) distributed as: C1: 6; C2: 10; D1: 25; D2: 12 cells, with INS 107-70790 and GCG 115-136500 RPKM. The ratio INS/GCG also varied: 0.004-119 (C1), 0.12-471 (C2), 0.009-222 (D1), 0.003-2.20 (D2). It has not yet been possible to determine whether the GLP-1 receptor (GLP1R) is expressed in human alpha as well as beta cells, yet this is of great clinical interest. Just 19 of the 123 beta cells expressed detectable levels of GLP1R (C1: 6/42 cells, 0.03-79.4 RPKM; C2: 7/50, 0.03-14.5; D1: 3/14, 0.04-70.9; D2: 3/17, 0.03-0.49), whereas no alpha cells expressed any detectable GLP1R.

**Conclusion:** We have for the first time analysed gene expression in single human islet cells. There is remarkable intercellular variability in INS and GCG expression that may reflect beta and alpha cell functional heterogeneity. Intriguingly, the regulation of expression of these two genes is not absolute, with low expression of INS in alpha and GCG in beta cells. There were several "alpha-beta" cells in all preparations, possibly representing cells in transition from one type to another. GLP1R was expressed in some but not all human beta cells, but was not detectable in any of the alpha cells. Inability to detect GLP1R expression could in theory be due to inadequate sequencing depth but in any event indicates extremely low levels of mRNA in all alpha and many beta cells that may not translate to physiologically meaningful protein levels.

## OP 06 Novel mechanism of glucose tolerance

**Brain natriuretic peptide prevents diet-induced obesity and glucose intolerance in mice**

M. Coue, P.-M. Badin, I.K. Vila, K. Louche, M.-A. Marques, D. Langin, C. Moro;

Institute of Metabolic and Cardiovascular Diseases, Inserm UMR1048, Toulouse, France.

**Background and aims:** Growing evidences indicate that natriuretic peptides (NPs) and downstream cyclic GMP-dependent signaling play an important role in the regulation of energy metabolism. Recent studies have highlighted relationships between reduced circulating NPs levels, obesity and the risk of type 2 diabetes (T2D). The present work aimed to demonstrate the pathophysiological link between NPs deficiency and metabolic disturbances in different mouse models of obesity and T2D.

**Materials and methods:** We first measured natriuretic peptides receptor (NPRA and NPRC) protein expression by western blot in genetic obese/diabetic mice (db/db versus db/+). We next investigated the effect of continuous delivery of Brain-NP (BNP) via intraperitoneal osmotic mini-pumps for 4 weeks in db/db and high fat diet (60% kcal)-fed mice. Metabolic parameters such as body weight, body composition, insulin and glucose tolerance were examined.

**Results:** NPRA/NPRC protein ratio (NPs biologically active receptor/clearance receptor) was dramatically down-regulated in skeletal muscles, liver and white and brown adipose tissue in db/db mice compared to db/+ mice ( $p=0.0001$ ). More interesting, chronic BNP infusion improved glycaemic control reflected by reduced HbA1c (-15%,  $p=0.01$ ) in db/db mice, and prevented body weight gain (-45%,  $p=0.004$ ) and improved glucose tolerance ( $p=0.02$ ) in HFD-fed mice compared to saline-treated mice. This better metabolic profile was accompanied by increased palmitate oxidation in skeletal muscle ( $p=0.04$ ) and reduced lipotoxicity reflected by reduced intramyocellular content of C18-diacylglycerols (-15%,  $p=0.08$ ) and total ceramides (-17%,  $p<0.05$ ).

**Conclusion:** Collectively, our data indicate that obesity is associated with a reduced biological activity of NPs in several metabolic organs such as skeletal muscles that may contribute to the development of T2D. Increasing plasma NPs levels improves glycaemic control and glucose tolerance in obese/diabetic mice. Some of these beneficial effects may be driven by improved lipid oxidative capacity and reduced lipotoxic lipid pressure in skeletal muscle. **Insulin is dispensable for the glucose lowering action of leptin in mice with streptozotocin-induced diabetes and congenital insulin deficiency**

U.H. Neumann, H.C. Denroche, M. Mojibian, T.J. Kieffer;

Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

**Background and aims:** It is widely believed that insulin is the only hormone capable of normalizing the catabolic consequences of type 1 diabetes. However, it has been shown that the hormone leptin can reverse hyperglycaemia in streptozotocin (STZ)-induced diabetes in the absence of insulin therapy. All previous reports of leptin treatment in insulin deficient rodents used chemical or immune mediated  $\beta$ -cell destruction, where insulin depletion is incomplete. Since leptin enhances insulin sensitivity, we sought to definitively determine whether leptin can reverse hyperglycaemia independently of insulin.

**Materials and methods:** To determine the effect of insulin receptor antagonism on leptin action, STZ-treated mice were implanted with a pump delivering either vehicle or 20  $\mu\text{g/day}$  leptin or an insulin pellet to control fasting blood glucose. Fasted mice were administered an i.p. injection of vehicle or 25 nmol/kg of the insulin receptor antagonist S961 alone (day 5) or preceding an oral glucose gavage (day 7), and subsequent glucose homeostasis was assessed. In addition, we tested whether leptin treatment in mice with con-

genital insulin deficiency could extend lifespan and reverse hyperglycaemia. *Ins1<sup>-/-</sup>Ins2<sup>-/-</sup>* (InsKO) mice were maintained on twice daily insulin injections until 14 days of age then transplanted with ~100–150 islets into the anterior chamber of the eye. At ~10 weeks of age InsKO mice were treated daily with an i.p. injection of 10 µg/day PEG-ylated leptin or vehicle and vehicle treated *Ins1<sup>-/-</sup>Ins2<sup>+/-</sup>* (Het) littermates were used as controls. On day 4 of treatment the transplanted eye was enucleated to render the mice entirely insulin deficient. Survival, body weight, and fed and fasting blood glucose were assessed. **Results:** In STZ-treated mice both leptin and insulin treatment reduced fasting blood glucose by day 2 compared to vehicle treated controls (22.6±0.7 mM STZ-vehicle, 10.8±2.0 mM STZ-leptin, 12.5±2.0 mM STZ-insulin). Injection of S961 increased blood glucose in the insulin treated mice after 2 hours (17.9±4.5 mM STZ-insulin + S961, 4.8±0.5 mM STZ-insulin + vehicle,  $P<0.05$ ) however this dramatic elevation was not observed in the leptin treated group (7.7±2.7 mM STZ-leptin + S961, 4.7±1.1 mM STZ-leptin + vehicle). Similarly, after an oral glucose load the difference in area under the curve was substantially larger in the insulin treated mice (3592±206 STZ-insulin + S961, 737±92 STZ-insulin + vehicle,  $P<0.05$ ) than the leptin treated mice (2530±354 STZ-leptin + S961, 2042±337 STZ-leptin + vehicle). In our complementary model the majority of vehicle treated InsKO mice reached humane endpoint in less than 24 hours after ceasing insulin treatment; however, leptin treatment in InsKO mice prolonged survival for up to 3 weeks. On day 11 of leptin treatment fed blood glucose levels were dramatically elevated in leptin treated InsKO mice compared to Het controls (>33.3 mM vs 10.5±0.7 mM) yet upon 6 hour fasting leptin treated InsKO mice reached dangerously low blood glucose levels compared to Het controls (2.2±0.1 mM vs 4.0±0.3 mM,  $P<0.05$ ), and hyperglycaemia rapidly returned upon 1 hour of re-feeding.

**Conclusion:** Insulin receptor antagonism and congenital insulin deficiency do not prevent leptin-mediated normalization of fasting glycaemia or survival, suggesting that leptin can act independently of insulin to improve diabetic symptoms in type 1 diabetes.

### Importance of ceramide transporter CERT in the development of muscle insulin resistance

R. Mahfouz<sup>1</sup>, D. Berkeš<sup>2</sup>, F. Foufelle<sup>1</sup>, P. Ferré<sup>1</sup>, E. Hajdúch<sup>1</sup>;

<sup>1</sup>INSERM, Paris, France,

<sup>2</sup>Department of Organic Chemistry, Bratislava, Slovakia.

**Background and aims:** Accumulation of fatty acids (FA) in muscle cells, a situation that can be observed in obesity, is accompanied by a decrease of insulin sensitivity. FA are metabolized into a lipid derivative called ceramide and studies show that accumulation of ceramide in cells plays a central role in the development of muscle insulin resistance. In physiological condition, ceramide is produced at the endoplasmic reticulum (ER), and transported from the ER to the Golgi, where it is converted to sphingomyelin. The ceramide transporter CERT has been identified as a key factor for the ER-to-Golgi trafficking of ceramide. We tested the hypothesis that a reduction of the activity/expression of CERT could contribute to the accumulation of ceramide in the ER and in the development of insulin resistance in muscle cells.

**Materials and methods:** We quantified expression of CERT in various insulin resistance models (i) *in vitro* in C2C12 and human myotubes treated with palmitate and in diabetic patient myotubes and (ii) *in vivo* in muscle from ob/ob mice as well as mice fed a high fat diet. To figure out whether CERT plays an important role in maintaining insulin sensitivity in muscle cells, we inhibited its expression using siRNA or a CERT chemical inhibitor (HPA-12).

**Results:** CERT protein expression was decreased in all insulin resistance models. We demonstrated that the decrease in CERT expression observed in the presence of FA excess was not related to the activation of ER stress, action of ceramide produced from palmitate itself or degradation via the proteasome, but through caspase cleavage. In addition, we also showed a protein kinase D dependent hyperphosphorylation on serine residue of CERT in response to palmitate, indicating a decrease of its activity. We further confirmed the involvement of a reduction in CERT expression on insulin sensitivity in muscle cells after either artificially inhibiting CERT expression with a siRNA or inhibiting its activity with the HPA-12 inhibitor. In opposite, inhibition of caspase activity prevented ceramide-induced insulin resistance in muscle cells.

**Conclusion:** Altogether, these results demonstrate the importance of a normal traffic of ceramide from the ER to the Golgi to preserve muscle cell insulin sensitivity and the importance of CERT expression in this process.

### Myeloid Sirt1 regulation macrophage infiltration and insulin sensitivity in mice fed a high-fat diet

S. Ka<sup>1</sup>, M. Song<sup>1</sup>, E. Bae<sup>2</sup>, B. Park<sup>1</sup>;

<sup>1</sup>Department of Biochemistry, Chonbuk National University, Jeonju,

<sup>2</sup>College of Pharmacy, Woosuk University, Wanju, Republic of Korea

**Background and aims:** Inflammation is an important factor in the development of insulin resistance. Sirt1, a class 3 histone/protein deacetylase, has anti-inflammatory functions. Myeloid-specific Sirt1 deletion promotes macrophage infiltration into insulin-sensitive organs and aggravates tissue inflammation. In this study, we investigated how Sirt1 regulates macrophage locomotion in response to metabolic stresses.

**Materials and methods:** Myeloid-specific Sirt1-deleted mice (mS1KO) and wild type littermates were fed a 60% calorie high-fat diet (HFD) for 16 weeks. Tissue inflammation and metabolic phenotypes were compared. Bone marrow macrophages from wild type or mS1KO mice were used in *in vitro* chemotaxis assays and macrophage polarization studies.

**Results:** Sirt1 deletion did not alter body weight gain or food intake. However, mS1KO mice fed a HFD exhibited impaired glucose tolerance with reduced insulin secretion and insulin sensitivity. Consistent with these results, mS1KO pancreatic islets displayed decreased mass with profound apoptotic cell damage and increased macrophage infiltration and tissue inflammation. Liver and adipose tissue from mS1KO mice also showed greater accumulation of macrophages and tissue inflammation. *In vitro* results showed that myeloid Sirt1 deletion stimulated proinflammatory M1-like macrophage polarization of bone marrow macrophages and augmented the migration potential of macrophages toward chemoattractants. The latter effect was mediated by increased expression and activation of nuclear factor κB/focal adhesion kinase and mitogen-activated protein kinase pathways.

**Conclusion:** Taken together, our results suggested that myeloid Sirt1 is crucial for macrophage migration and the development of HFD-induced inflammation and metabolic derangements.

### The effects of obesity and insulin resistance on serum NMR metabolic profile during an oral glucose tolerance test: a twin study

J. Rämö<sup>1</sup>, S. Kaye<sup>1</sup>, L.H. Bogl<sup>2</sup>, N. Matikainen<sup>3</sup>, A. Hakkarainen<sup>4</sup>,

J. Lundbom<sup>4</sup>, N. Lundbom<sup>4</sup>, A. Rissanen<sup>5</sup>, J. Kaprio<sup>2,6</sup>, K. Pietiläinen<sup>1,6</sup>;

<sup>1</sup>Research Programs Unit, Diabetes and Obesity, University of Helsinki,

<sup>2</sup>Department of Public Health, Hjelt Institute, University of Helsinki,

<sup>3</sup>Department of Endocrinology, Helsinki University Central Hospital,

<sup>4</sup>Helsinki Medical Imaging Center, University of Helsinki,

<sup>5</sup>Department of Psychiatry, Helsinki University Central Hospital,

<sup>6</sup>FIMM, Institute for Molecular Medicine, Helsinki, Finland.

**Background and aims:** Untargeted metabolic profiling has shown that obesity and insulin resistance (IR) are associated with differences in the levels of many circulating metabolites. Notably, the levels of low molecular weight metabolites (LMWMs) and fatty acids predict future risk of diabetes in healthy individuals. Recent studies have also revealed significant metabolic changes in response to an oral glucose tolerance test (OGTT). Obesity and IR are associated with the magnitudes of these changes, but their relative importances are unknown. In this study, we measured a novel panel of metabolites, including lipoprotein fractions, during an OGTT in healthy young twins discordant for BMI, to control for genetic effects and to compare the effects of acquired obesity and IR on the dynamic metabolic profile.

**Materials and methods:** 31 rare MZ twin pairs discordant for obesity (Within-pair BMI difference BMI >3kg/m<sup>2</sup>), along with 119 MZ and DZ control pairs, were identified from cohorts of 22–32-year-old Finnish twins. Their serum was analyzed with Nuclear Magnetic Resonance (NMR) at 4 timepoints (0/30/60/120min) during an OGTT. Based on a 50 percentile cut point for the difference of HOMA index within the discordant pairs, the twins were divided into two groups, indicating whether or not the heavier twins' acquired obesity was accompanied by IR. This allowed analyses of metabolite profiles during the OGTT in unhealthy and healthy obese co-twins as compared with their lean twin pair members.

**Results:** Glucose ingestion resulted in a significant alteration in the levels of 12 out of 51 measured lipoprotein subclasses, 7 out of 24 lipids and 17 out of 21 LMWMs (Multiple-corrected  $P<0.05$ ). There was a late fall in VLDL triglyceride content, most evident in larger fractions (-0.14 SD units,  $P=8.5e-12$ ). The diameter of VLDL particles decreased (-0.34 SD units,  $P=6.2e-06$ ) and

that of LDL particles increased (0.12 SD units,  $P=0.008$ ). Cholesterol content in very large HDL particles decreased (-0.36 SD units,  $P=3.12e-6$ ) but rose in medium-sized particles (0.19 SD units,  $P=0.016$ ). Healthy obese MZ co-twins (without IR) had lower HDL cholesterol levels throughout the OGTT, especially in large HDL and HDL2 ( $P<3.8e-04$ ). In contrast, unhealthy obese co-twins (with IR) showed changes in 32 out of 96 metabolites (corrected  $P<0.05$ ), including lipoproteins, fatty acids and LMWMs. These include three recently discovered risk markers for all-cause mortality:  $\alpha$ -acid glycoprotein, citrate and VLDL size.

**Conclusion:** Ingestion of pure glucose results in considerable change in the lipoprotein, lipid and LMWM profiles. Some lipoprotein changes can be explained by increased hepatic synthesis, but others may be indicative of novel actions of insulin. Acquired obesity primarily affects HDL composition, whereas an accompanied insulin resistance results in widespread changes in the metabolic profile both in the fasting state and during a glucose challenge. *Supported by: AOF, NNF, HUHFR, DRF, FFCR*

## OP 07 GLP-1 analogues: clinical efficacy

### 37

**Efficacy and safety of liraglutide vs placebo when added to basal insulin analogues in subjects with type 2 diabetes (LIRA-ADD2BASAL): a randomised, placebo-controlled trial**

J. Lahtela<sup>1</sup>, A. Ahmann<sup>2</sup>, H. Rodbard<sup>3</sup>, J. Rosenstock<sup>4</sup>, L. de Loreda<sup>5</sup>, K. Tornøe<sup>6</sup>, A. Boopalan<sup>7</sup>, M. Nauck<sup>8</sup>;

<sup>1</sup>Tampere University Hospital, Finland, <sup>2</sup>Oregon Health & Science University, Portland, USA, <sup>3</sup>Endocrine and Metabolic Consultants, Rockville, USA, <sup>4</sup>Dallas Diabetes and Endocrine Center, Dallas, USA, <sup>5</sup>Hospital Privado Centro Médico de Córdoba S.A., Córdoba, Argentina, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>Novo Nordisk, Bangalore, India, <sup>8</sup>Diabeteszentrum, Bad Lauterberg, Germany.

**Background and aims:** This trial aimed to establish the superior efficacy and acceptable safety of liraglutide (LIRA) vs. placebo (PLAC) added to pre-existing basal insulin analogue  $\pm$  metformin in subjects with inadequately controlled type 2 diabetes.

**Materials and methods:** Subjects with type 2 diabetes, age 18-80 years, BMI 20-45 kg/m<sup>2</sup>, HbA1c 7.0-10.0% and on stable insulin analogue dose  $\geq 20$  U/day  $\pm$  stable metformin  $\geq 1500$  mg/day were eligible for participation. In a multi-centre, multi-national, double-blind, parallel-group design, subjects were randomised 1:1 to receive once daily LIRA 1.8 mg or PLAC added to pre-existing treatment for 26 weeks. Following randomisation, insulin adjustments above the pre-trial dose were not allowed. The primary endpoint was the change in HbA1c from baseline to Week 26.

**Results:** A total of 451 subjects were randomised (226 LIRA; 225 PLAC). All subjects but 1 (LIRA, not exposed) were included in the analysis. Mean baseline characteristics were similar between the two groups (LIRA;PLAC): HbA1c 8.2;8.3%, BMI 32.3;32.2 kg/m<sup>2</sup>, diabetes duration 12.1 years and insulin dose 48.3;45.9 U (geometric mean 40.5 U for both groups). After 26 weeks of treatment, subjects taking LIRA had a greater decrease in HbA1c from baseline than PLAC, and more LIRA subjects reached HbA1c  $<7.0\%$  and HbA1c  $\leq 6.5\%$  using a lower mean estimated daily dose of basal insulin analogue compared to PLAC (35.8 U vs. 40.0 U; see Table). Subjects taking LIRA also achieved greater decreases from baseline in fasting plasma glucose (FPG), incremental post-prandial self-measured plasma glucose (SMPG), body weight, systolic blood pressure and lipids. Nausea and vomiting occurred more frequently with LIRA than PLAC (22.2% vs. 3.1% and 8.9% vs. 0.9%, respectively). Minor hypoglycaemia (plasma glucose  $<3.1$  mmol/L) occurred in 18.2% and 12.4% of LIRA and PLAC subjects, respectively. No severe hypoglycaemic events (requiring assistance of another person to actively administer resuscitative actions) were reported during this trial.

**Conclusion:** The addition of LIRA to basal insulin analogues ± metformin significantly improved glycaemic control, which can be attributed to the effect of LIRA on both FPG and post-prandial glucose levels. Additionally, LIRA induced greater weight loss and a reduction in systolic blood pressure and selected lipids compared to PLAC. Typical gastrointestinal symptoms and minor hypoglycaemia were more frequent with LIRA than PLAC. No severe hypoglycaemic events were reported during this trial.

### Efficacy and safety of once weekly dulaglutide vs insulin glargine in combination with metformin and glimepiride in type 2 diabetes patients (AWARD-2)

F. Giorgino<sup>1</sup>, M. Benroubi<sup>2</sup>, J.-H. Sun<sup>3</sup>, A.G. Zimmermann<sup>4</sup>, V. Pechtner<sup>5</sup>;

<sup>1</sup>Endocrinology & Metabolic Diseases, University of Bari, Italy,

<sup>2</sup>Evangelismos-Polyclinic, Athens, Greece, <sup>3</sup>Chang Gung Memorial Hospital, Taoyuan Hsien, Taiwan, <sup>4</sup>Eli Lilly and Company, Indianapolis, USA,

<sup>5</sup>Eli Lilly and Company, Neuilly-Sur-Seine Cedex, France.

**Background and aims:** This Phase 3, 78-week, parallel-arm, open-label (double-blinded to dulaglutide [DU] doses) study compared two doses of the once weekly GLP-1 receptor agonist DU with insulin glargine titrated to fasting glucose target, in patients with type 2 diabetes inadequately controlled with maximally tolerated doses of metformin and glimepiride. Metformin and glimepiride were to be continued throughout the study.

**Materials and methods:** Patients (N = 807; mean baseline characteristics: age 57 years; duration of diabetes 9.1 years; HbA<sub>1c</sub> 8.1%; body weight 86.3 kg; BMI 31.6 kg/m<sup>2</sup>) were randomised (1:1:1) to once weekly DU 1.5 mg, DU 0.75 mg, or once daily insulin glargine. The primary objective was to demonstrate DU 1.5 mg was noninferior (margin 0.4%) to insulin glargine for HbA<sub>1c</sub> change from baseline at 52 weeks. Additional analyses were carried out at 52 and 78 weeks.

**Results:** At 52 weeks, DU 1.5 mg was superior and DU 0.75 mg was noninferior to insulin glargine on HbA<sub>1c</sub> change from baseline. The mean insulin glargine dose was 29.4 U. Body weight decreased with both DU doses and increased with insulin glargine. Over the 52-week period, the mean rate of documented symptomatic hypoglycaemia (≤3.9 mmol/L) was 2.0, 2.0, and 3.3 events/patient/year for DU 1.5 mg, DU 0.75 mg, and insulin glargine, respectively. At 78 weeks, HbA<sub>1c</sub>, body weight, and hypoglycaemia results were similar to 52 weeks, and the mean insulin glargine dose was 31.4 U. Through 78 weeks, four events of severe hypoglycaemia occurred: 2 in patients treated with DU 1.5 mg and 2 in patients treated with insulin glargine. Nausea and diarrhoea were more common with DU 1.5 mg (15.4% and 10.6%) and DU 0.75 mg (7.7% and 9.2%) versus insulin glargine (1.5% and 5.7%) through 78 weeks.

**Conclusion:** DU 1.5 mg demonstrated superior and DU 0.75 mg noninferior glycaemic control compared with insulin glargine, and this was associated with weight loss, reduced incidence of hypoglycaemia, and an acceptable safety profile.

### Liraglutide 3.0 mg for weight management in obese/overweight adults with type 2 diabetes: SCALE diabetes 56-week randomised, double-blind, placebo-controlled trial

M.J. Davies<sup>1</sup>, R. Bergenstal<sup>2</sup>, B. Bode<sup>3</sup>, R. Kushner<sup>4</sup>, A. Lewin<sup>5</sup>, T.V. Skjoth<sup>6</sup>, C.B. Jensen<sup>6</sup>, R. DeFronzo<sup>7</sup>;

<sup>1</sup>University Hospitals of Leicester, UK, <sup>2</sup>Park Nicollet Institute, St Louis Park, USA, <sup>3</sup>Atlanta Diabetes Associates, USA, <sup>4</sup>Northwestern University, Chicago, USA, <sup>5</sup>National Research Institute, Los Angeles, USA, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>Texas Diabetes Institute, San Antonio, USA.

**Background and aims:** Liraglutide at doses up to 1.8 mg is approved for the treatment of T2D. This study investigated the efficacy and safety of liraglutide 3.0 mg and 1.8 mg, as adjunct to diet and exercise, for weight management in obese/overweight adults with T2D.

**Materials and methods:** In this 56-week, randomised, double-blind, placebo-controlled trial, adults with T2D (on diet and exercise alone or with 1-3 oral antidiabetic drugs [OADs], HbA<sub>1c</sub> 7-10%, BMI ≥27.0 kg/m<sup>2</sup>) were randomised 2:1:1 to receive liraglutide 3.0 mg, 1.8 mg or placebo. All subjects received diet (500 kcal/day deficit) and exercise instruction.

**Results:** 846 individuals were randomised: age 54.9 (18.0-82.0) years, 50% male, BMI 37.1 (27.0-67.6) kg/m<sup>2</sup>, HbA<sub>1c</sub> 7.9% (6.4-10.3%), fasting plasma glucose (FPG) 8.8 (4.2-17.3) mmol/L, T2D for 7.3 (0.2-36.5) years, 11.5% on diet and exercise, 57.3% on metformin only, 31.2% on combination OADs. Liraglutide 3.0 mg and 1.8 mg were superior to placebo, and 3.0 mg was superior to 1.8 mg on mean and categorical weight loss at week 56 (Table). Liraglutide 3.0 mg also achieved superior glycaemic control vs. placebo and liraglutide 1.8 mg (change in HbA<sub>1c</sub> and FPG, proportion reaching HbA<sub>1c</sub> ≤6.5%, and [vs. placebo only] postprandial plasma glucose [PG] increment; Table). The safety profiles with liraglutide 3.0 mg and 1.8 mg were similar, although gastrointestinal disorders were more frequent with 3.0 mg (65% of individuals) than 1.8 mg (56%) and placebo (39%). No cases of pancreatitis were reported during the trial. An increase in mean serum lipase activity was seen with liraglutide 1.8 mg and 3.0 mg; the increase was not dose-dependent and few individuals (7.7% and 9.8% on liraglutide 1.8 mg and 3.0 mg, respectively, vs. 6.3% on placebo) had levels ≥3 times the upper normal range at any time during treatment. Rates of documented symptomatic hypoglycaemia (PG <3.9 mmol/L) were 0.87, 0.95 and 0.31 events per patient year for liraglutide 3.0 mg, 1.8 mg and placebo, respectively; in all groups, hypoglycaemia rates were greater for subjects on a sulphonylurea (SU) compared with those not on SU. Eight severe hypoglycaemic events were reported (5 events in 3 subjects [0.7%] with liraglutide 3.0 mg; 3 events in 2 subjects [1.0%] with liraglutide 1.8 mg); all subjects affected were receiving background SU therapy.

**Conclusion:** Liraglutide 3.0 mg, as adjunct to diet and exercise, was efficacious and well-tolerated for weight management over 56 weeks in obese/overweight individuals with T2D.

### Efficacy and safety of once weekly dulaglutide versus once daily liraglutide in type 2 diabetes (AWARD6)

S. Tofe Povedano<sup>1</sup>, K.M. Dungan<sup>2</sup>, T. Forst<sup>3</sup>, J.G. González González<sup>4</sup>, C. Atisso<sup>5</sup>, W. Sealls<sup>5</sup>, J.L. Fahrback<sup>5</sup>;

<sup>1</sup>Endocrinología, Clínica Juameda, Palma de Mallorca, Spain, <sup>2</sup>The Ohio State University, Columbus, USA, <sup>3</sup>Profil Mainz GmbH & Co. KG, Mainz, Germany, <sup>4</sup>Universidad Autónoma de Nuevo León, Monterrey, Mexico, <sup>5</sup>Eli Lilly and Company, Indianapolis, USA.

**Background and aims:** This Phase 3, randomised, open-label, parallel-arm 26-week (wk) study compared the efficacy and safety of once weekly dulaglutide (DU) 1.5 mg, a long-acting GLP-1 receptor agonist, with once daily liraglutide (LIRA) 1.8 mg in metformin-treated (≥1500 mg) patients with type 2 diabetes.

**Materials and methods:** Patients (N=599; mean baseline age, 57 years; HbA<sub>1c</sub>, 8.1 %; weight 94.1 kg) were randomised to DU 1.5 mg or LIRA 1.8 mg in a 1:1 ratio. The primary objective was HbA<sub>1c</sub> change from baseline at 26 wks tested for noninferiority (margin 0.4%); DU 1.5 mg vs LIRA 1.8 mg.

**Results:** DU 1.5 mg was noninferior to LIRA 1.8 mg at 26 wks as measured by HbA<sub>1c</sub> change from baseline (between-group HbA<sub>1c</sub> change -0.06; 95% CI [-0.19, 0.07]) (Table 1). While both groups experienced significant weight reduction, LIRA-treated patients demonstrated a 0.71 kg greater weight reduction than DU-treated patients (p=0.01). The most common treatment-emergent gastrointestinal adverse events for DU 1.5 mg and LIRA 1.8 mg, respectively, were nausea (20.4%, 18.0%), diarrhoea (12.0%, 12.0%), dyspepsia (8.0%, 6.0%), and vomiting (7.0%, 8.3%). Patients who discontinued study and/or study drug due to gastrointestinal adverse events were similar (DU 1.5 mg [3.0%], LIRA 1.8 mg [4.3%]). Rates of hypoglycaemia (≤3.9 mmol/L ± symptoms) were 0.34 events/pt/yr (DU 1.5 mg) and 0.52 (LIRA 1.8 mg) events/pt/yr. No severe hypoglycaemia was reported.

**Conclusion:** Once weekly DU 1.5 mg demonstrated noninferior glycaemic control compared to once daily LIRA 1.8 mg with a similar safety and tolerability profile.

| Efficacy Measures (26 wk, ITT)                                   | DU 1.5 mg (N=299)         | LIRA 1.8 mg (N=300) |

### Harmony 1 year 3 Results: albiglutide vs placebo in patients with type 2 diabetes mellitus not controlled on pioglitazone (pio) ± metformin (met) C.M. Perkins<sup>1</sup>, B.W. Bode<sup>2</sup>, M.W. Stewart<sup>3</sup>, D.T. Cirkel<sup>4</sup>, F. Yang<sup>3</sup>, C.R. Perry<sup>3</sup>, P.D. Ambery<sup>5</sup>;

<sup>1</sup>PPD, Morrisville, <sup>2</sup>Atlanta Diabetes Associates, <sup>3</sup>GlaxoSmithKline, King of Prussia, USA, <sup>4</sup>GlaxoSmithKline, Stevenage, <sup>5</sup>MedImmune, Cambridge, UK.

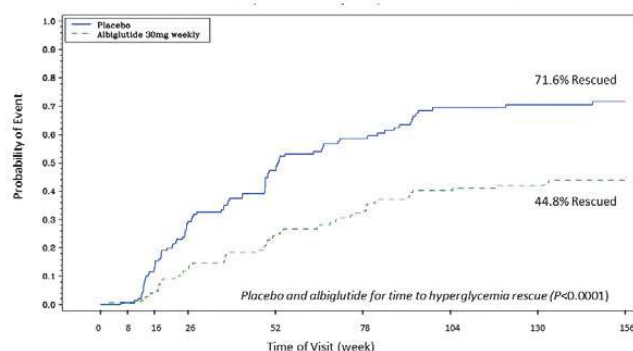

**Background and aims:** This 3 year (y), randomized, double-blind, placebo (Pbo) controlled study evaluated efficacy & safety of once weekly GLP-1 receptor agonist albiglutide 30 mg vs Pbo in patients (pts) inadequately controlled (A1c 53-85.8 mmol/mol [7-10%]) on Pio ± Met.

**Materials and methods:** Pts could continue if hyperglycaemic rescue was needed. Primary endpoint (PE) was A1c change from baseline at week 52.

**Results:** Baseline demographics were similar between groups; mean A1c 65 mmol/mol (8.1%); age 55 y; 80% on Pio + Met. PE showed Albi superior to Pbo (treatment difference: -8.2 mmol/mol [-0.75%], P<0.0001). Glycaemic reduction with Albi was maintained for 3 y: fewer Albi pts required rescue compared to Pbo pts: 45% vs 72%; P<0.0001. In pts completing 3 y of treatment, A1c reduction was durable to wk 156 without rescue (n=54/26 for Albi/Pbo: -9.5 mmol/mol [-0.87%] Albi, -5.5 mmol/mol [-0.50%] Pbo) and with rescue n=89/83, -9.8 mmol/mol [-0.90%] Albi, -3.0 mmol/mol [-0.27%] Pbo). FPG changes were similar to A1c. Change in weight at 3 y was -0.16kg Albi and 1.50kg Pbo. Through wk 156, adverse events (% pts) of nausea and vomiting were low and comparable between Albi/Pbo (12.0%/11.9% and 5.3%/4.0%) while diarrhea was higher with Albi (14.7% vs 10.6%). Injection site reactions were higher for Albi (18.0%) vs Pbo (8.6%). Incidence of pre-rescue documented symptomatic (≤3.88 mmol/L [70 mg/dL]) and severe hypoglycaemia was low: 3.3%/1.3% for Albi and 2.0%/0% for Pbo.

**Conclusion:** Albi combination therapy resulted in durable glycaemic improvement with good tolerability.

### Better glycaemic control and less weight gain with once weekly dulaglutide vs bedtime insulin glargine, both combined with thrice daily lispro, in type 2 diabetes (AWARD-4)

J. Zende<sup>1</sup>, L. Blonde<sup>2</sup>, J. Rosenstock<sup>3</sup>, V. Woo<sup>4</sup>, J. Gross<sup>5</sup>, H. Jiang<sup>6</sup>, Z. Milicevic<sup>7</sup>;

<sup>1</sup>Endocrine and Diabetes Center, University of Orebro, Sweden, <sup>2</sup>Ochsner Medical Center, New Orleans, <sup>3</sup>Dallas Diabetes and Endocrine Center, Dallas, USA, <sup>4</sup>University of Manitoba, Winnipeg, Canada, <sup>5</sup>Federal University of Rio Grande do Sul, Porto Alegre, Brazil, <sup>6</sup>Eli Lilly and Company, Indianapolis, USA, <sup>7</sup>Eli Lilly and Company, Vienna, Austria.

**Background and aims:** This 52 week, parallel-arm, open-label, phase 3 study compared two doses of the once weekly GLP-1 receptor agonist dulaglutide (DU) versus bedtime insulin glargine, all combined with pre-meal insulin lispro with or without metformin, in patients with type 2 diabetes mellitus inadequately controlled on conventional insulin therapy. Insulin glargine and insulin lispro were titrated to attempt to reach glycaemic targets.

**Materials and methods:** Patients (N = 884; mean baseline characteristics: age 59.4 years; duration of diabetes 12.7 years; HbA<sub>1c</sub> 8.5%; body weight 91.1 kg; BMI 32.5 kg/m<sup>2</sup>; total daily insulin dose 56 U) were randomised (1:1:1) to once weekly DU 1.5 mg, DU 0.75 mg, or bedtime insulin glargine titrated-to-target. The primary objective was to compare the change in HbA<sub>1c</sub> from baseline of DU 1.5 mg with insulin glargine at 26 weeks for noninferiority (margin 0.4%) and if met, then superiority was tested.

**Results:** At 26 and 52 weeks, both DU doses were statistically superior to insulin glargine for HbA<sub>1c</sub> change from baseline. Insulin glargine was associated with greater fasting serum glucose reduction compared with both DU doses. The mean prandial insulin doses at 26 weeks were 93 U for DU 1.5 mg, 97 U for DU 0.75 mg, and 68 U for insulin glargine. The insulin glargine dose was 65 U. Similar insulin doses were observed at 52 weeks. Body weight decreased with DU 1.5 mg and increased with DU 0.75 mg and insulin glargine at 52 weeks. The rate of documented symptomatic hypoglycaemia ( $\leq 3.9$  mmol/L) at 52 weeks was 31.0, 35.0, and 39.9 events/patient/year for DU 1.5 mg, DU 0.75 mg, and insulin glargine, respectively. The number of severe hypoglycaemia events was 11 for DU 1.5 mg, 15 for DU 0.75 mg, and 22 for insulin glargine. Nausea, diarrhoea, and vomiting were more common with DU 1.5 mg (25.8%, 16.6%, and 12.2%, respectively) and DU 0.75 mg (17.7%, 15.7%, and 10.6%) versus insulin glargine (3.4%, 6.1%, and 1.7%).

**Conclusion:** DU compared to insulin glargine, both combined with insulin lispro, resulted in better glycaemic control, less body weight gain, no increased risk of hypoglycaemia, and more common reporting of gastrointestinal adverse events.

#### Does diabetes affect the efficacy of dual antiplatelet therapy in patients with acute coronary syndromes?

M. Samos<sup>1</sup>, L. Duraj<sup>2</sup>, M. Fedor<sup>2</sup>, F. Kovar<sup>1</sup>, P. Galajda<sup>1</sup>, J. Fedorova<sup>3</sup>, J. Stasko<sup>1</sup>, T. Bolek<sup>1</sup>, M. Mekan<sup>1</sup>, P. Kubisz<sup>1</sup>, M. Mekan<sup>1</sup>;

<sup>1</sup>Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava,

<sup>2</sup>Department of Hematology and Blood Transfusion, Jessenius Faculty of

Medicine in Martin, Comenius University in Bratislava, <sup>3</sup>HemoMedika,

Center of Thrombosis and Hemostasis, Martin, Slovakia.

**Background and aims:** Diabetes is a strong, independent risk factor of acute coronary syndromes (ACS). Diabetes aggravates the course of ACS and increases the risk of its complications. Recently, there is growing amount of data about failure in antiplatelet response, which is specifically associated with insulin resistance and diabetes. This incomplete antiplatelet response may contribute to a worse prognosis of ACS in diabetic patients. The aim of this study was to clarify the impact of presence of diabetes on the efficacy of dual antiplatelet therapy given in standard doses in patients with ACS.

**Materials and methods:** 82 patients with ACS (53 men, 29 women, mean age 65 years) were enrolled in this preliminary prospective observational study. Patients were treated with aspirin loading dose (400 mg) and ADP receptor antagonist loading dose: in 62 patients clopidogrel (600 mg) and in 20 patients prasugrel (60 mg) was used. 21 patients had diabetes. Coronary angiography and percutaneous coronary intervention of culprit coronary lesion was subsequently performed. Light transmission aggregometry (LTA) with specific inducers and VASP phosphorylation assessment was chosen for antiplatelet therapy efficacy testing. Samples were taken after first maintenance dose administration (sample 1) and on 30th day from loading dose administration (sample2).

**Results:** Mean LTA measured platelet reactivity was 32.7±18.9% in sample1 and 28.4±14.4% in sample2 respectively. No significant difference in antiplatelet response on ADP receptor antagonist (ADP-RA) between diabetic and non-diabetic patients was found (sample1: 30.7±19.8% versus 33.5±18.8%; sample2: 28.4±12.1% versus 28.4±15.7%). Totally 38 non-responders on ADP-RA were identified; ADP-RA unresponsiveness was not associated with the presence of diabetes. Prasugrel therapy generally showed better platelet inhibition than clopidogrel administration (sample1: 22.8±13.7% versus 35.8±19.3%, p<0.01; sample2: 20.0±9.9% versus 33.1±14.6%, p<0.05).

**Conclusion:** ADP-RA therapy unresponsiveness was frequently (46.3%) identified in ACS patients undergoing coronary angiography. However, diabetes was not connected with higher platelet reactivity or higher prevalence of ADP-RA non-response in this study. Prasugrel showed significantly better platelet inhibition than clopidogrel and thus prasugrel therapy should be preferred not only in diabetic ACS patients. Laboratory monitoring of antiplatelet therapy efficacy may help identify patients with inadequate antiplatelet response.

#### Impact of diabetes mellitus on long-term prognosis in patients with ischaemic heart failure: a report from the Swedish Heart Failure Registry (S-HFR)

A. Norhammar<sup>1</sup>, I. Johansson<sup>1</sup>, M. Edner<sup>1</sup>, P. Näsman<sup>2</sup>, U. Dahlström<sup>3,4</sup>, L. Rydén<sup>1</sup>;

<sup>1</sup>Cardiology Unit, Department of medicine Solna, Karolinska Institutet, Stockholm, <sup>2</sup>Centre for Safety Research, KTH Royal Institute of Technology, Stockholm, <sup>3</sup>Division of Cardiovascular Medicine, Department of Medicine and Health Sciences, Linköping University, <sup>4</sup>Department of Cardiology UHL, County Council of Östergötland, Linköping, Sweden.

**Background and aims:** Patients with diabetes are at increased risk of developing heart failure. In an everyday life setting, we investigated the impact of diabetes on long-term prognosis in patients with heart failure of ischemic origin.

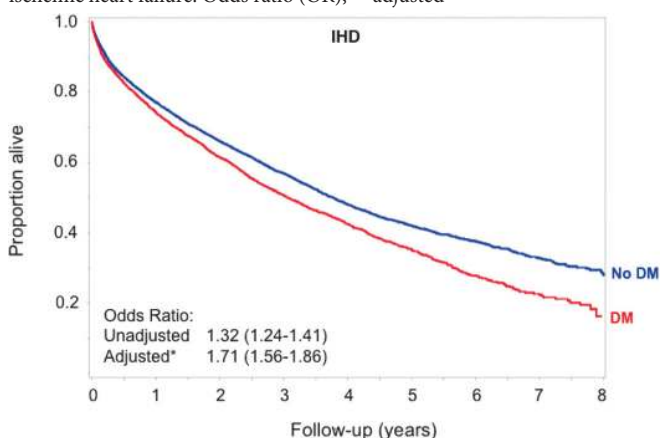

**Materials and methods:** Patients clinically judged to have ischemic heart failure, of whom 50% were previously revascularised with (n=5265) and without (n=12 408) type 2 diabetes, included in the Swedish Heart Failure Registry (S-HFR) 2003-2011 were followed for mortality until 30 September

2011 (median 22.5 months). Differences in background characteristics were adjusted for in a logistic regression model.

**Results:** Patients with diabetes were younger (75 vs. 77 years) and more often had preserved renal function (>60 ml/min; 44 vs. 38%), however hypertension was more common in those with diabetes (59 vs. 45%). EF did not differ, 17% in both groups had an EF  $\geq$ 50%, however those with diabetes had more of severe heart failure symptoms (NYHA III-IV; 53 vs. 46%). Among those with diabetes, 88% received beta-blockade, 61% ACE inhibitors, 67% Statins and 71% Aspirin. Kaplan-Meier curves of mortality are presented in Figure 1. The unadjusted and adjusted\* ORs (95% CI) for mortality were 1.32 (1.24-1.41) and 1.71 (1.56-1.86). In those revascularised (50%), unadjusted and adjusted\* ORs for mortality were 1.52 (1.39-1.67) and 1.63 (1.45-1.84).

**Conclusion:** Diabetes is an independent predictor of long-term mortality in patients with ischemic heart failure. Revascularisation did not abolish the impact of diabetes. The use of anti-ischemic secondary preventive treatment seemed somewhat low considering all patients were classified to have ischemic heart disease \* Adjusted for gender, age, duration of heart failure, weight, blood pressure, hypertension, atrial fibrillation, pulmonary disease, EF class, revascularisation, eGFR class, Hb class and pharmacological treatment. Figure 1. Kaplan Meyer-curve showing long-term survival by diabetes (DM) in patients with ischemic heart failure. Odds ratio (OR), \*=adjusted

### Impact of diabetes mellitus on long-term prognosis in patients with preserved heart failure: a report from the Swedish Heart Failure Registry (S-HFR)

I. Johansson<sup>1</sup>, M. Edner<sup>1</sup>, L. Rydén<sup>1</sup>, P. Näsman<sup>2</sup>, U. Dahlström<sup>3,4</sup>, A. Norhammar<sup>1</sup>;

<sup>1</sup>Cardiology Unit, Department of medicine, Karolinska Institutet, Karolinska University Hospital Solna, Stockholm, <sup>2</sup>Centre for Safety Research, KTH Royal Institute of Technology, Stockholm, <sup>3</sup>Division of Cardiovascular Medicine, Department of Medicine and Health Sciences, Linköping University, Linköping, <sup>4</sup>Department of Cardiology UHL, County Council of Östergötland, Linköping, Sweden.

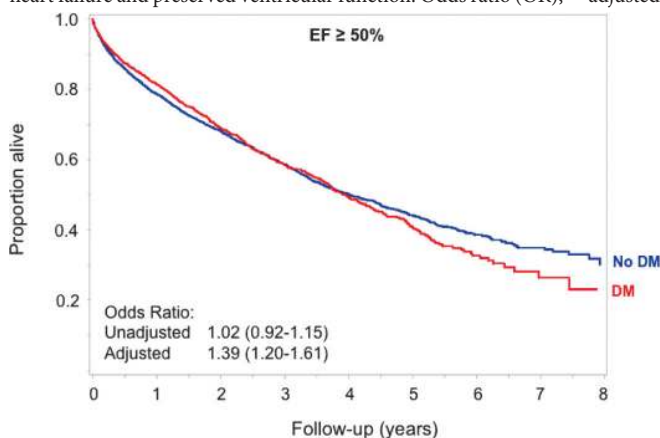

**Background and aims:** Patients with diabetes are at increased risk for developing heart failure. We investigated the impact of diabetes on long-term prognosis in patients with heart failure and preserved left ventricular function from an everyday life perspective.

**Materials and methods:** Patients with EF  $\geq$ 50%, with (n=1658) and without (n=5047) type 2 diabetes included in the Swedish Heart Failure Registry (S-HFR) 2003-2011 were followed for mortality until 30 September 2011 (median 22.5 months). Differences in background characteristics were adjusted for in a logistic regression model.

**Results:** Patients with diabetes were younger (76 vs. 78 years), more often had known ischemic heart disease (47 vs. 36%), hypertension (68 vs. 52%), and more often had preserved renal function (eGFR > 60ml/min, 45 vs. 38%). NYHA classes III and IV were somewhat more common in those with diabetes (44 vs. 39%). Kaplan-Meier curves for mortality are presented in Figure 1. The unadjusted and adjusted\* ORs (95% CI) for mortality were 1.02 (0.92-1.15) and 1.39 (1.20-1.61).

**Conclusion:** Our data support that diabetes is an independent predictor of mortality in patients with heart failure and preserved left ventricular function. As much as 50% of patients with preserved left ventricular function had

reported ischemic heart disease, which questions the concept of a pure diabetic cardiomyopathy. \* Adjusted for gender, age, duration of heart failure, weight, blood pressure (systolic and diastolic), ischemic heart disease, hypertension, atrial fibrillation, pulmonary disease, revascularisation, eGFR class, Hb class, ACE inhibitors, ARBs, beta-blockers, mineralocorticoid receptor antagonists, diuretics, digitalis, nitrates, statins and antithrombotic agents. Figure: Kaplan-Meier curve showing survival by diabetes in patients with heart failure and preserved ventricular function. Odds ratio (OR), \*=adjusted

## 46

### Methylglyoxal-induced endothelial dysfunction has a role in the development of heart failure in a mouse model of type 1 diabetes

B. Vulesevic<sup>1</sup>, B. McNeill<sup>1</sup>, F. Giacco<sup>2</sup>, M. Brownlee<sup>2</sup>, R. Milne<sup>3</sup>, E. Suuronen<sup>1</sup>;

<sup>1</sup>Cardiac Surgery, University of Ottawa Heart Institute, Ottawa, Canada,

<sup>2</sup>Diabetes Research Center, Albert Einstein College of Medicine,

Bronx, USA, <sup>3</sup>Diabetes and Atherosclerosis Laboratory, University of Ottawa Heart Institute, Canada.

**Background and aims:** Diabetes mellitus increases the risk of heart failure independent of coronary artery disease or hypertension. Endothelial dysfunction (ED) and inflammation, both common in diabetes, are partly caused by the accumulation of methylglyoxal (MG), the primary substrate of the enzyme glyoxalase 1 (GLO1). We have generated transgenic mice that carry the human GLO1 transgene under the control of the preproendothelin promoter. Using this mouse model we examined if the over-expression of GLO1 could reduce MG-induced ED and prevent the development of heart failure caused by streptozotocin (STZ)-induced hyperglycaemia.

**Materials and methods:** GLO1 transgenic mice and their wildtype (WT) littermates were treated with STZ (WT-diabetic and GLO1-diabetic mice) or vehicle (WT-control and GLO1-control mice). GLO1 activity was measured in endothelial cells (ECs) and cardiomyocytes isolated from the hearts. Eight weeks after STZ treatment, blood serum levels of the ED markers E-selectin, ICAM and VCAM were determined by ELISA. Heart function was assessed using echocardiography. Protein expression of the receptor for advanced glycation end products (RAGE) and neurogulin in the heart was determined by western blot. Apoptosis, detected by TUNEL assay, and capillary numbers, expressed by number of CD31+ cells were determined by immunohistochemistry. QPCR for the Bcl-2 pro-survival gene was done on ECs collected from the digested hearts.

**Results:** Increased GLO1 activity was confirmed to be 5.6-fold greater in aortic endothelial cells (ECs) of GLO1-mice compared to their WT littermates. Also, the over-expression and increased activity of GLO1 in the heart was restricted to ECs, and not observed in cardiomyocytes. Eight weeks post-STZ elevated serum levels of all 3 ED markers was observed in WT-diabetic mice compared to all other groups (E-selectin  $\geq$ 1.3-fold, VCAM  $\geq$ 1.1-fold, and ICAM  $\geq$ 6.7-fold;  $p \leq 0.04$ ). RAGE levels were significantly higher in hearts of WT-diabetic mice compared to all other groups ( $\geq$ 1.8-fold,  $p \leq 0.03$ ). The WT-diabetic group had lower left ventricular ejection fraction (EF; 43.6%) and fractional shortening (FS; 28.6%), compared to the other 3 groups ( $\geq$ 67.5% (EF) and  $\geq$ 42.7% (FS);  $p \leq 0.01$ ). The number of CD31+ ECs in WT-diabetic hearts was reduced by 46% compared to both non-diabetic groups and GLO1-diabetic mice ( $p = 0.03$ ). Apoptotic cells were more numerous in the hearts of WT-diabetic mice (0.44% of cells), compared to non-diabetic WT (0.03%) and GLO1-diabetic mice (0.07%;  $p \leq 0.04$ ). The reduced number of

ECs seen in WT-diabetic mice may also be involved in the 3-fold reduction of neurotrophin-3, an EC-produced protein that supports cardiomyocyte survival ( $p=0.04$ ). The improved survival of ECs in GLO1-diabetic mice may be related to the preserved mRNA levels of Bcl-2, which can be modified by MG. Bcl-2 was down-regulated 2-fold in WT-diabetic ECs compared to the other groups ( $p=0.04$ ).

**Conclusion:** Taken together, these results suggest that increased GLO1 activity in ECs reduced ED, cell death and inflammation, and preserved cardiac function, despite high blood glucose levels.

### A relationship of asymptomatic coronary artery disease and type 2 diabetes in acute ischaemic stroke patients; cerebral angiography and coronary angiography study

H. Kwon, J. Lim, J. Shin, J. Son, S. Lee, S. Kim, S. Yoo;

Division of Endocrinology and Metabolism, Department of Internal Medicine, The Catholic University of Korea, Bucheon, Republic of Korea

**Background and aims:** Stroke and coronary artery disease (CAD) share similar atherosclerosis risk factors such as smoking, hypertension, dyslipidaemia, and diabetes. CAD is considered the leading cause of mortality and morbidity in patients with ischemic stroke. However, data about the prevalence of CAD in the patients with acute ischemic stroke remains limited. Furthermore, characteristics of CAD in patients with diabetes are asymptomatic onset and multiple vessels involvement. But it remains unclear whether the impact of diabetes on CAD is different in ischemic stroke. The aim of this study was to determine the relation of type 2 diabetes and acute ischemic stroke to the presence and extent of asymptomatic CAD by coronary angiography.

**Materials and methods:** Acute ischemic stroke patients without known CAD were enrolled between October 2008 and September 2013 in our hospital. Patients with high Framingham Risk Score (FRS; a 10 year-risk of coronary heart disease  $\geq 20\%$ ) underwent cerebral angiography and coronary angiography at the same time. We analyzed the coronary angiography and other classic atherosclerosis risk factors in 187 patients retrospectively. The patients were divided into diabetes group and non-diabetes group, and the data was assessed according to the following classifications: (1) presence of coronary artery stenosis, (2) presence of significant stenosis ( $\geq 50\%$ ), (3) presence of multiple coronary artery stenosis ( $\geq 2$  vessels), and (4) presence of significant multiple coronary artery stenosis ( $\geq 2$  vessels). We calculated the prevalence of CAD with 95% confidence intervals. All data was analyzed after adjusting classic atherosclerosis risk factors such as age, sex, hypertension and history of past stroke.  $P$  value  $< 0.05$  was considered to be statistically significant.

**Results:** Mean age was  $64.5 \pm 10.9$  years and 126 patients (67.4%) were male. 59 patients (M:F 35:24) had type 2 diabetes, 128 patients (M:F 91:37) had no history of diabetes. A total of 129 patients (69%; 48 with diabetes, 81 without diabetes) had hypertension ( $p$ -value  $< 0.008$ ). Past stroke history was shown in 12 patients with diabetes, 15 patients without diabetes ( $p$ -value 0.15). The prevalence of coronary artery stenosis was 93% ( $n=55$ ) in the diabetes group, 82% ( $n=105$ ) in the non-diabetes group ( $p$ -value 0.08). 31 patients (52.5%) had significant stenosis in the diabetes group, 49 patients (38.2%) had it in the non-diabetes group ( $p$ -value 0.019). Multiple coronary artery stenosis was shown in 42 patients (71%) with diabetes, 72 patients (56%) without diabetes ( $p$ -value 0.04). The prevalence of significant multiple stenosis was 28.8% ( $n=17$ ) in the diabetes group, 20.3% ( $n=26$ ) in the non-diabetes group ( $p$ -value 0.019). In the diabetes group, the patients had high FRS ( $40.9\% \pm 8.59$ ) and had a tendency of both intracranial and extracranial stenosis in cerebral angiography ( $n=29$ ). The characteristics of coronary artery stenosis did not seem to correlate with the severity or location of cerebral artery stenosis.

**Conclusion:** This study shows that type 2 diabetes with acute ischemic stroke was strongly associated with asymptomatic and severe coronary artery disease. We suggest that assertive evaluation about asymptomatic CAD might be considered in type 2 diabetic patients with acute ischemic stroke.

## 48

### Cardiac $^{82}\text{Rb}$ -PET/CT reveals microvascular dysfunction in asymptomatic patients with type 2 diabetes

T.W. Hansen<sup>1</sup>, B.J. von Scholten<sup>1</sup>, P. Hasbak<sup>2</sup>, T.E. Christensen<sup>2</sup>, A.A. Ghotbi<sup>2</sup>, A. Kjaer<sup>2</sup>, P. Rossing<sup>1,3</sup>;

<sup>1</sup>Steno Diabetes Center, Gentofte, <sup>2</sup>Department of Clinical Physiology, Nuclear Medicine & PET and Cluster for Molecular Imaging, Rigshospitalet, Copenhagen, <sup>3</sup>University of, Copenhagen and Aarhus, Denmark.

**Background and aims:** Type 2 diabetes (T2DM) is commonly accompanied by asymptomatic coronary artery disease. Coronary flow reserve (CFR; CFR = stress divided by rest coronary blood flow) and coronary calcium score (CCS) represent different aspects of atherosclerosis. CFR is a measure of vasodilator function and reflects physiologic changes of vascular smooth muscle as well as endothelial function and detects coronary microvascular dysfunction. CCS is an anatomic measure of atherosclerosis. Cardiac  $^{82}\text{Rb}$  positron emission tomography (PET)/computed tomography (CT) allows for simultaneous non-invasive assessment of both CFR and CCS. We aimed 1) to gain information of the prevalence and predictors of reduced CFR and high levels of CCS in T2DM patients free of overt CV disease (with or without albuminuria) while comparing them to non-diabetic controls, and 2) to determine the association between CFR and CCS.

**Materials and methods:** Cross-sectional study of 60 T2DM patients stratified by normoalbuminuria ( $< 30\text{mg}/24\text{h}$ ) ( $n=30$ ; age (mean  $\pm$  SD)  $60.9 \pm 10.1$  years; 40% women) and albuminuria ( $\geq 30\text{mg}/24\text{h}$ ) ( $n=30$ ;  $65.6 \pm 4.8$  years; 27% women) randomly selected from our outpatient clinic and 30 non-diabetic controls ( $59.8 \pm 9.9$  years; 40% women) undergoing quantitative rest and pharmacologic stress  $^{82}\text{Rb}$  PET/CT and comprehensive assessment of other cardiovascular risk factors.

**Results:** In controls, normoalbuminuric, and albuminuric patients the CFR was  $3.0 \pm 0.8$ ,  $2.6 \pm 0.8$ , and  $2.0 \pm 0.5$  ( $P < 0.001$ ); frequency of reduced CFR ( $< 2.5$ ) was 16.7, 40.0, and 83.3% ( $P < 0.001$ ); and CCS (median [IQR]) was 0 [0-81], 36 [1-325], and 370 [152-1025] ( $P < 0.001$ ), respectively. After adjustment for age, gender, body mass index, 24-h systolic blood pressure, heart rate, cholesterol, and smoking the level of CFR remained significant higher ( $P=0.023$ ) and CCS significant lower ( $P=0.020$ ) in normoalbuminuric vs. albuminuric patients. Moreover, the frequency of reduced CFR remained significant lower in normoalbuminuric vs. albuminuric patients ( $P=0.001$ ) and in controls vs. albuminuric patients ( $P < 0.001$ ). The univariate association between CFR and CCS was significant in control subjects ( $R^2 = 0.23$ ;  $P=0.007$ ), but not in normoalbuminuric or albuminuric patients ( $R^2 \leq 0.10$ ;  $P \geq 0.09$ ). Multivariate linear regression analysis (including variables as above and additionally urine albumin excretion (UAER) and  $\text{HbA}_{1c}$ ) was used to identify variables independently associated with CFR and CCS in the three groups. Lower CFR was significantly related to higher CCS, UAER, age, heart rate, lower  $\text{HbA}_{1c}$ , and male gender ( $P \leq 0.047$ ) in albuminuric patients; and to female gender ( $P=0.024$ ) in normoalbuminuric patients. Higher CCS was significantly related to lower CFR and UAER ( $P \leq 0.048$ ) in albuminuric patients; and to higher  $\text{HbA}_{1c}$  in controls ( $P=0.033$ ).

**Conclusion:** In T2DM patients free of overt cardiovascular disease the prevalence of coronary microvascular dysfunction was high, especially with concomitant albuminuria. This was not explained by elevated CCS ("atherosclerosis") and prospective studies are needed to show the prognostic significance.

## OP 09 Diabetic retinopathy

49

### Validation of model to estimate risk of progression of diabetic retinopathy using screening and clinical data in 3 cohorts

I.M. Stratton<sup>1</sup>, S.J. Aldington<sup>1</sup>, R. Cragg<sup>2</sup>, T. Gazis<sup>3</sup>, G. Russell<sup>4</sup>, C. Connor<sup>5</sup>, S. Sivaprasad<sup>6</sup>, P.H. Scanlon<sup>1</sup>;

<sup>1</sup>Gloucestershire Diabetic Retinopathy Research Group, Gloucestershire Hospitals, Cheltenham, <sup>2</sup>Nottingham Diabetic Retinopathy Service, Nottingham University Hospitals NHS Trust, <sup>3</sup>Diabetes and Endocrinology, Nottingham University Hospitals NHS Trust, <sup>4</sup>Health Intelligence Ltd, Sandbach, <sup>5</sup>Diabetic Eye Screening Programme for Lambeth, Southwark and Lewisham, Guy's and St Thomas NHS Foundation Trust, London, <sup>6</sup>Ophthalmology, King's College Hospital NHS Foundation Trust, London, UK.

**Background and aims:** Diabetic retinopathy (DR) is a microvascular complication of diabetes and can lead to vision loss and blindness. Annual screening with 2 field digital retinal imaging after mydriasis is recommended by the UK National Screening Committee. This is becoming difficult to achieve because of resource limitations and increasing numbers of people with diabetes. We have developed and validated a model to estimate risk of progression to sight threatening DR (STDR) using results from one screening episode, HbA<sub>1c</sub> in twelve months prior to screening and duration of diabetes in one English screening programme. We know that grading protocols differ between screening programmes and rates of DR are affected by duration of diabetes, ethnicity, deprivation and diabetic control. Here we examine the performance of the model in 3 more English programmes.

**Materials and methods:** Data were obtained from 3 English screening programmes and data for a subset of patients was extracted from primary care. Patients free of STDR were categorised into those with No DR, those with mild non proliferative DR (NPDR) in one eye and those with Mild NPDR in both eyes. Using the risk estimation algorithm the risk score in those free of STDR was estimated and progression to STDR in quintiles of risk obtained.

**Results:** The programmes had 8632, 1084 and 1377 people respectively. There were few non White Caucasian patients in the first 2 programmes but 30% of those in the third programme were of African or Afro-Caribbean ethnicity. Duration of diabetes was 6 (2 to 11) (median (25th to 75th centile)), 2.9 (0.6 to 6.2) and 3.6 (1.4 to 6.8) years, HbA<sub>1c</sub> 56 (48 to 66), 53 (46 to 53) and 52 (45 to 64), follow-up from date of index screening 2.9 (2.1 to 3.0), 4.2 (2.2 to 5.3) and 4.1 (2.1 to 6.9) years. In the first programme the rate of progression to STDR in the lowest risk quintile was 4.1 per 1000 patient years and in highest quintile 74.0 per 1000 patient years, in the second programme 2.4 and 79.2 respectively and in the third programme 1.7 and 49.0 respectively. Area under the ROC curve was 0.82, 0.87, and 0.77.

**Conclusion:** Within each of the three programmes examined the risk model discriminates well between those with very low and with high risk of progression to STDR. The algorithm would be suitable for calculation of personalised screening intervals. Further validation in other screening programmes and ethnic groups is required.

### Importance of using HbA<sub>1c</sub> data of total diabetes duration in studying the relation between HbA<sub>1c</sub> value and retinopathy in type 1 diabetes

A. Hirose<sup>1</sup>, S. Kitano<sup>1</sup>, Y. Uchigata<sup>2</sup>;

<sup>1</sup>Diabetic Ophthalmology, Diabetes Center,

<sup>2</sup>Diabetes Center, Tokyo Women's Medical University, Japan.

**Background and aims:** Glycaemic memory, in which past glycaemia could affect future retinopathy, is a potential issue in studying the relation between glycosylated haemoglobin A1c (HbA1c) value and retinopathy. We have

demonstrated that mean HbA1c value (mA1C) covering total diabetes duration, which might reflect the full effect of glycaemic memory, could substantially predict retinopathy, but the longer the period without HbA1c data following diabetes onset in simulation, the less accurate the prediction in our type 1 diabetes mellitus (T1DM) patients. To confirm the importance of using HbA1c data of total diabetes duration, we examined the relation between mA1C and retinopathy in the public data of DCCT/Epidemiology of Diabetes Interventions and Complications (EDIC) studies.

**Materials and methods:** From the primary prevention cohort, we included T1DM patients with the shortest diabetes duration ( $\leq 12$  months) at DCCT baseline. We developed a window which we named 'half-yearly visit (HYV)' to calculate the mA1C and to determine the retinopathy steps of the final Early Treatment Diabetic Retinopathy Study (ETDRS) severity scale for persons. HbA1c values of an even number of quarterly visits (QVs) were applied to those of HYVs: for example, the value of QV00 (DCCT baseline) to HYV00, QV02 to HYV01, and so on during DCCT. During EDIC, HbA1c values were applied to the corresponding HYVs according to their data collection dates from DCCT baseline: for example,  $11.75 \leq X < 12.25$  years' data to HYV24 (12 years from DCCT baseline). Missing values were estimated by time-weighted averaging from the preceding and the succeeding HYV values. An mA1C at HYV24 (mA1C(HYV24)) was calculated by supposing that each patient had a diabetes duration of one year at HYV00 and had kept the same HbA1c value of HYV00 during that period. We also calculated simulated mA1C(24HYV) s by masking HbA1c data for periods of 3, 6, and 9 years following diabetes onset, that is, by averaging HbA1c values from HYV05, HYV11, and HYV17 to HYV24, respectively. Retinopathy was defined as positive if a patient's ETDRS step was 4 or above at HYV24; otherwise it was considered negative. The Wilcoxon rank-sum test was performed. Two-sided  $P < 0.05$  was considered significant.

**Results:** Of the 55 cases who fulfilled the criteria, 40 cases (mean duration 10.9, range 8-12 months) had retinopathy data at HYV24. The 40 values of mA1C(HYV24) were well-divided between the retinopathy-positive and -negative groups ( $P = 0.0003$ ). In simulated cases of mA1C(HYV24) masked during periods of 3, 6, and 9 years, the differences seemed to lessen gradually between the two groups ( $P = 0.0009, 0.0145$  and  $0.180$ , respectively), and there was no significant difference in mA1C(HYV24) masked for 9 years. It seemed that the longer the period without HbA1c data following onset in simulation, the less difference between the two groups. This could be explained by the difference of the transitions of the mean HbA1c values in each HYV between the two groups over the course of 12 DCCT/EDIC years. In the earlier period (HYV01 to HYV18), these values were higher in the retinopathy-positive group ( $P < 0.05$  for each HYV), but gradually decreased until there was no significant difference between groups (HYV19 to HYV24).

**Conclusion:** It is important to consider using HbA1c data of total diabetes duration in studying the relation between HbA1c value and retinopathy in T1DM patients.

51

### Genetic variation of SLC19A3 is associated to diabetic retinopathy and nephropathy in type 1 diabetes

K. Toppila<sup>1</sup>, M. Porta<sup>2</sup>, N. Sandholm<sup>1</sup>, C. Forsblom<sup>1,3</sup>, L. Borio<sup>2</sup>, E. Beltramo<sup>2</sup>, I. Hietala<sup>1,4</sup>, M. Hosseini<sup>5,6</sup>, A.D. Paterson<sup>5</sup>, P.-H. Groop<sup>1,3</sup>;

<sup>1</sup>Folkhälsan Research Center, Helsinki, Finland, <sup>2</sup>Dept Medical Sciences, University of Turin, Italy, <sup>3</sup>Div Nephrology, Dept Medicine, Helsinki University Central Hospital, Finland, <sup>4</sup>Dept Ophthalmology, Helsinki University Central Hospital, Finland, <sup>5</sup>Inst Medical Science, University of Toronto, Canada, <sup>6</sup>Program in Genetics and Genome Biology, Hospital for Sick Children, Toronto, Canada.

**Background and aims:** Diabetes duration, glycaemic control and blood pressure control are the strongest known risk factors for the development of diabetic microangiopathy. Thiamine (Vitamin B1) regulates intracellular glucose management at different levels and has been shown to correct high glucose-induced abnormalities by reducing reactive oxygen species production. Thiamine and its derivative benfotiamin have also been shown to reduce progression of retinopathy and nephropathy in animals with experimental diabetes. According to our hypothesis, patients who are prone to develop diabetic retinopathy and/or nephropathy may have impaired ability to achieve sufficiently high intracellular thiamine levels. This might be particularly damaging in insulin independent tissues that are more exposed to hyperglycaemia because they cannot regulate glucose inflow, such as retinal capillary endothelium and pericytes, the neuroretina, renal podocytes and mesangium. The aim of this study was to test if mutations in thiamine trans-

porters hTHTR1 and hTHTR2 (coded by *SLC19A2* and *SLC19A3*, respectively), and/or their transcription factors Sp1 and Sp2 (coded by *SP1* and *SP2*), are associated with proliferative diabetic retinopathy (PDR) and/or diabetic nephropathy (DN).

**Materials and methods:** The patient population consisted of 1568 cases with PDR, and 217 controls with no/mild retinopathy from the Finnish Diabetic Nephropathy (FinnDiane) Study. PDR was defined as ETDRS-score of 53 or worse or scattered laser treatment. Controls were required to have minimal diabetes duration of 20 years, maximal ETDRS-score of 30 on altered ETDRS-scale (corresponding to mild retinopathy) and no laser treatment. We chose HapMapII imputed SNPs from all four candidate genes and 10kb up and downstream of them (n=134). Logistic regression adjusted for sex, age, diabetes duration, and first ten genetic principal components were used for statistical calculations. In addition, association was tested between patient groups with different states of DN, and intersection of classes with both severe PDR and end-stage renal disease (ESRD) (n=369) vs. normo/microalbuminuric controls with no/mild retinopathy (n=190).

**Results:** Two SNPs, rs12694743 and rs6713116, showed association with PDR (rs12694743: OR = 1.91, CI95% = 1.62–2.19,  $P = 1.02 \times 10^{-5}$ ; rs6713116: OR = 2.34, CI95% = 1.97–2.72,  $P = 9.10 \times 10^{-6}$ ). Both SNPs are located in intronic regions of *SLC19A3*. The signal was also noticeable in DN phenotypes, but was not significant after correcting for multiple testing. In analysis of intersection of extreme phenotypes the signal was amplified (rs12694743: OR = 3.18, CI95% = 2.76–3.60,  $P = 7.51 \times 10^{-8}$ ; rs6713116: OR = 3.87, CI95% = 3.33–4.40,  $P = 7.49 \times 10^{-7}$ ) providing proof of association not only with retinopathy, but both retinopathy and nephropathy. Replications in DCCT/EDIC and WESRD cohorts are ongoing.

**Conclusion:** The results of this study suggest that mutations in *SLC19A3* may increase susceptibility to PDR and especially to the combined phenotype of PDR and ESRD.

## 52

### Microvesicles derived from mesenchymal stem cells in diabetic-like conditions increase permeability in a retinal blood-barrier model

A. Mazzeo, E. Beltramo, T. Lopatina, M. Porta;  
Dept of Medical Sciences, University of Turin, Italy.

**Background and aims:** Loss of pericytes in the early phases of diabetic retinopathy may disrupt their stable association with endothelial cells (EC), leading to EC proliferation and, eventually, angiogenesis. Microvesicles (MV) are small membrane particles derived from different cells which contain biologically active proteins and RNA and are known to promote phenotypic changes in target cells. MV derived from injured cells may induce dedifferentiation of pericytes, allowing their detachment from vessels. We have previously shown that MV derived from mesenchymal stem cells (MSC), but not from EC, induce pericyte detachment and that diabetic-like conditions (high glucose and hypoxia) play a synergistic role in this destabilizing influence. This study aimed at evaluating whether MV produced by MSC in hypoxia and/or high glucose are able to influence the retinal blood-barrier permeability and to explore the possible role of matrix metalloproteases (MMP) in MV-induced pericyte detachment.

**Materials and methods:** We used commercially available human microvascular EC (HMEC) and MSC from bone marrow, while human retinal pericytes (HRP) had been previously immortalized in our laboratory. A blood-barrier model was established by seeding HMEC on the porous membrane of transwell inserts, letting them adhere for 24 hrs and then adding HRP into the same insert. MV were extracted from the supernatant of MSC cultured in 1) physiological conditions (NG) 2) hypoxia (hypo) 3) high glucose (HG) 4) HG + hypo. These MV were subsequently added to the confluent HMEC/HRP co-cultures. After 2 hrs of MV exposure, FITC was added into the upper chamber and fluorescence measured in the lower chamber of the inserts after another 30', 1, 2, 3, 4 and 24h. MMP expression in both MV and supernatants of HRP exposed to MV was evaluated by Zimography. Results were confirmed by pre-treatment of MV with batimastat, a MMP inhibitor, and subsequent exposure of HRP to them.

**Results:** Permeability of EC-HRP co-cultures was increased by exposure to MSC-derived MV obtained in all the above conditions, the highest percentage increase occurring after 6h of total exposure to MV (2h pre-treatment + 4h FITC): NG-MV  $134.42 \pm 17.46\%$  ( $p < 0.05$  vs control without MV), HG-MV  $128.07 \pm 3.81\%$  ( $p = 0.000$ ), NG+hypo-MV  $119.87 \pm 15.56\%$  ( $p < 0.05$ ), HG+hypo-MV  $134.60 \pm 15.21\%$  ( $p < 0.05$ ). MSC-derived MV expressed MMP-2 and MMP-9. The same MMPs were expressed by HRP following 24h exposure to MV, MMP-2 to a much higher degree. HRP number decreased after 4h incubation with untreated MV ( $75.81 \pm 9.22\%$ ,  $p < 0.05$  vs control), while pre-incubation of MV with batimastat completely reverted their effect on pericyte detachment.

**Conclusion:** MSC-derived MV may play a role in vessel destabilization and increase of retinal blood-barrier permeability during the early stages of retinopathy. This effect may be mediated by increased MMP expression.

### Fenofibrate prevents the disruption of the outer blood retina barrier through downregulation of NF- $\kappa$ B activity

M. Garcia-Ramírez<sup>1,2</sup>, C. Hernández<sup>1,2</sup>, X. Palomer<sup>2,3</sup>,  
M. Vázquez-Carrera<sup>2,3</sup>, R. Simó<sup>1,2</sup>;

<sup>1</sup>Diabetes and Metabolism Research Unit, Vall d'Hebron Research Institute. Universitat Autònoma de Barcelona, <sup>2</sup>Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Madrid, <sup>3</sup>Department of Pharmacology and Therapeutic Chemistry and Institute of Biomedicine of the University of Barcelona (IBUB), Faculty of Pharmacy, University of Barcelona, Spain.

**Background and aims:** There is clinical evidence that fenofibrate, a PPAR $\alpha$  agonist, arrests the progression of diabetic macular edema (DME). However, the underlying mechanisms of this beneficial effect remain to be elucidated. We previously reported that fenofibric acid (FA), the active metabolite of fenofibrate, prevents the disorganization of tight junction proteins and the hyperpermeability provoked by the diabetic milieu in the retinal pigment epithelium (RPE). The aim of the present study was to evaluate whether this effect is mediated by inhibiting the proinflammatory transcription factor NF- $\kappa$ B, as well as the expression of several proinflammatory cytokines involved in the pathogenesis of DME.

**Materials and methods:** Human RPE were cultured under standard conditions and under conditions leading to the disruption of the monolayer (IL-1 $\beta$  (10 ng/mL)). The effect of FA, QNZ (a NF- $\kappa$ B inhibitor), WY14643 (a PPAR $\alpha$  agonist), and MK-886 (a PPAR $\alpha$  antagonist) in preventing the disruption of the monolayer was determined by dextran permeability and immunohistochemistry analyses. The effect of FA on NF- $\kappa$ B activity was assessed by EMSA and by NF- $\kappa$ B/p65 nuclear translocation analyses. The expression of cytokines (IL-6, IL-8, MCP-1) was measured by RT-PCR.

**Results:** FA prevented RPE monolayer disruption, and the consequent hyperpermeability induced by IL-1 $\beta$ , through inhibition of NF- $\kappa$ B activity. This effect was due to PPAR $\alpha$  activation and was associated with a significant downregulation of the expression of proinflammatory cytokines.

**Conclusion:** Our findings suggest that the anti-inflammatory effects of FA through inhibition of NF- $\kappa$ B activity play a key role in the beneficial effect of fenofibrate for treating DME.

**Diabetic macular oedema and diabetic retinopathy: treatment outcomes with aflibercept do not depend on systemic diabetes control**

C. Metzger, for the VIVID-DME/VISTA-DME Study Investigators;  
Bayer HealthCare Pharmaceuticals, Berlin, Germany.

**Background and aims:** Diabetic macular edema (DME) is a major cause of vision loss in patients with diabetic retinopathy resulting from poorly controlled diabetes mellitus. Vascular endothelial growth factor plays a key role in the pathogenesis of DME.

**Materials and methods:** Two similarly designed Phase 3 trials, VIVID-DME and VISTA-DME, evaluated the efficacy and safety of intravitreal aflibercept (IVT-AFL) injection for the treatment of DME. These trials randomised 872 patients with DME 1:1:1 to receive either IVT-AFL 2 mg every 4 weeks plus sham laser (2q4), IVT-AFL 2 mg every 8 weeks following 5 initial monthly doses plus sham laser (2q8), or macular laser photocoagulation plus sham IVT treatment. The primary efficacy endpoint was the mean change in best-corrected visual acuity (BCVA) from baseline at Week 52. An exploratory analysis examined BCVA and diabetic retinopathy severity score (DRSS) outcomes in subgroups of patients in these studies with baseline haemoglobin A1c (HbA1c) levels  $\leq 8\%$  and  $> 8\%$ .

**Results:** Overall, 65% and 35% of patients had HbA1c  $\leq 8\%$  and  $> 8\%$  at baseline, respectively. The mean change in BCVA from baseline to Week 52 in the 2q4 and 2q8 groups versus the laser group was +12.3 and +10.9 versus +1.1 letters ( $P < 0.0001$ ) in patients with baseline HbA1c  $\leq 8\%$ , and +10.4 and +10.3 versus -0.3 letters ( $P < 0.0001$ ) in patients with baseline HbA1c  $> 8\%$ , respectively. The proportion of patients in the 2q4 and 2q8 groups versus the laser group with  $\geq 2$ -step improvement in DRSS score at Week 52 was 34.7% and 29.8% versus 12.3% ( $P \leq 0.0001$ ) in patients with baseline HbA1c  $\leq 8\%$ , and 33.3% and 26.5% versus 11.4% ( $P < 0.03$ ) in patients with baseline HbA1c  $> 8\%$ , respectively. The overall incidence of ocular and nonocular adverse events and serious adverse events, including the Anti-Platelet Trialists' Collaboration-defined arterial thromboembolic events, was similar across treatment groups in the total patient population.

**Conclusion:** These findings suggest that the improvements achieved with IVT-AFL 2q4 and 2q8 over laser in vision and DRSS were robust and similar in patients with variable systemic disease control at baseline (HbA1c levels  $\leq 8\%$  and  $> 8\%$ ). Furthermore, the DRSS improvement indicates an effect of IVT-AFL not only on DME, but also on the underlying diabetic retinopathy. *Clinical Trial Registration Number: NCT01331681, NCT01363440*

**Severely disrupted islet function in mice with global deletion of GLP-1 and GIP receptors**

B. Omar, B. Ahrén;  
Clinical Sciences, Lund University, Sweden.

**Background and aims:** The incretin hormones glucagon like peptide 1 (GLP-1) and glucose dependent insulinotropic polypeptide (GIP) potentiate glucose stimulated insulin secretion. Both incretin hormones promote proliferation of pancreatic beta cells and prevent beta cell apoptosis. Incretins have also long been known to mediate the majority of insulin secretion during a meal or oral glucose challenge, however a role for the endogenous and basal incretin hormones in the long term regulation of beta cell function has not been characterized. We have therefore evaluated the role of basal incretin hormones on islet function by using mice with targeted disruption of both incretin hormone receptors.

**Materials and methods:** Double incretin receptor knockout (DIRKO) mice with global deletion of both the GLP-1 receptor and GIP receptor genes were used to study the effect of chronic deficiency of incretin action on beta cell function ex vivo and in vivo. Ex vivo insulin secretion was determined in static batch incubations of isolated islets from wild type and DIRKO mice with stimulatory glucose concentrations (16 mmol/l). In vivo insulin secretion was assessed by hyperglycaemic clamp in which, after a 20 minute baseline, mice were given a bolus injection of glucose (0.35mg/kg) together with infusion of 30% glucose in saline and clamped at a target blood glucose concentration of 16.7 mmol/l. The steady state period was between 20 and 105 minutes. Plasma insulin was measured at multiple time points throughout the steady state period. Insulin sensitivity from the clamp was determined by the insulin sensitivity index, calculated as the mean glucose infusion rate during the last 40 minutes of the steady state period divided by the mean plasma insulin concentration for the same period.

**Results:** Insulin secretion was markedly lower in islets from DIRKO mice compared to islets from wild type mice during static incubation of isolated islets with stimulatory glucose (16.7 mmol/l) ( $395 \pm 80$  vs  $1171 \pm 131$  pmol/islet/hour,  $p = 0.02$ ). In order to specifically study beta cell function in vivo, hyperglycaemic clamp experiments were performed in which mice were clamped with a target blood glucose concentration of 16.7 mmol/l. This target was closely achieved in both wild-type and DIRKO mice ( $17.0 \pm 0.3$  vs  $17.1 \pm 0.2$  mmol/l). Insulin secretion during the hyperglycaemic clamp was severely impaired in DIRKO mice compared to control mice. The acute insulin response (AIR) was blunted in DIRKO mice compared to controls ( $199 \pm 88$  vs  $540 \pm 108$  pmol/l,  $p = 0.005$ ). The total area under the insulin secretion curve (AUC) during the steady state period was significantly lower in DIRKO mice compared to wild-type mice ( $25.5 \pm 1.8$  vs  $37.0 \pm 3.6$  nmol/l\*min,  $p = 0.008$ ). Insulin sensitivity, derived from clamp data, was not significantly different between wild-type and DIRKO mice ( $0.029 \pm 0.004$  vs  $0.036 \pm 0.005$  mg glucose/kg/min/pmol insulin).

**Conclusion:** Normal islet function is heavily dependent on both incretin hormones, whereas insulin sensitivity is not altered by genetic deletion of incretin hormone receptors

### GIP contributes to the protection from hypoglycaemia of DPP-4 inhibition

S. Malmgren, B. Ahrén;

Department of Clinical Sciences in Lund, Lund University, Sweden.

**Background and aims:** Intensive glucose lowering therapies in type 2 diabetes (T2D) increases the risk of hypoglycaemia, which is associated with acute unpleasant consequences and increased long-term risk for cardiovascular diseases. A major defence mechanism to combat hypoglycaemia is glucagon counter-regulation; however, this mechanism is commonly compromised in persons with T2D. Therefore, there is a need to develop glucose-lowering therapies which sustain the endogenous counter-regulations to hypoglycaemia. Inhibition of dipeptidyl peptidase-4 (DPP-4) prevents the regulatory inactivation of the incretin hormones and is a glucose-lowering therapy in T2D with low risk for hypoglycaemia. We have previously shown that DPP-4 inhibition protects from insulin-induced hypoglycaemia in mice. The aim of the present study is to examine the mechanisms behind this protection and particularly the contribution of the incretin hormone glucose-dependent insulinotropic polypeptide (GIP).

**Materials and methods:** Anesthetized C57BL/6 mice were infused with 15 mU/kg/min of insulin and variable rates of glucose to target a steady state blood glucose of 2.5 mmol/L between minute 60 and 90 of the hyperinsulinemic hypoglycaemic clamp. To explore GIP in the endogenous defence against hypoglycaemia we performed hypoglycaemic clamps in GIPR<sup>-/-</sup> mice lacking the GIP receptor (n=5) or wild type (wt) counterparts (n=7). To further explore the effect of GIP, wt mice were infused with synthetic GIP (50 pmol/kg/min) during hypoglycaemic clamp (n=10). Glucose, insulin and glucagon levels were measured and glucose infusion rate (GIR) during the clamp was estimated. To explore the relationship of GIP expression to glucagon secretion in humans, correlation analysis was performed in islet gene expression and secretion data from isolated human islets from 69 individuals. Values are presented as Mean±S.E and statistical significance assessed using Student's *t*-test.

**Results:** GIPR<sup>-/-</sup> mice required increased GIR compared to matched wt animals to maintain blood glucose during the clamp (6.0±1.2 vs. 2.5±0.5 mg/kg/min; p=0.03). Both wt and GIPR<sup>-/-</sup> mice had similar increases in endpoint glucagon after 90 minutes of clamp compared to baseline levels (2.3±0.5-

fold and 1.7±0.2-fold respectively; p=0.50). During GIP infusion, GIR was reduced to 4.2±0.9 compared to 6.9±0.8 mg/kg/min (p=0.040) in animals infused with saline. This was accompanied by a tendency towards an increase in glucagon levels at 60 (11.5±2.0 vs 6.2±1.9 pg/mL; p=0.072) and 90 (17.5±4.0 vs 8.6±2.1 pg/mL; p=0.062) minutes of the clamp. Clamp insulin levels did not differ between groups. In human islets, there was a significant positive correlation between GIP expression and glucagon secretion at 1 mM of glucose (rho=0.345, p=0.004).

**Conclusion:** GIPR<sup>-/-</sup> mice were more sensitive to insulin-induced hypoglycaemia while GIP infusion during clamp protects wt mice from hypoglycaemia. Results from glucagon measurements suggests that GIP infusion protects from hypoglycaemia via increases in glucagon levels but also raise the possibility of glucagon independent mechanisms further explaining the protective mechanism of DPP-4 inhibition. Furthermore, the positive GIP expression correlation with increased glucagon secretion in human islets suggests relevance in humans. Based on these findings we conclude that GIP is a protective factor from hypoglycaemia and suggest that it contributes to the low risk of hypoglycaemia that can be seen with diabetes treatment using DPP-4 inhibition, thus elevating GIP levels.

### Altered enteroendocrine expression of glucagon and somatostatin in the gut of patients with type 2 diabetes compared with healthy matched controls

T. Jorsal<sup>1,2</sup>, N.A. Rhee<sup>1,2</sup>, J. Pedersen<sup>1,2</sup>, S.L. Jepsen<sup>2</sup>, C.D. Wahlgren<sup>2</sup>, B. Mortensen<sup>1,2</sup>, P. Vilman<sup>3,4</sup>, H. Hassan<sup>3,4</sup>, J.W. Hendel<sup>3,4</sup>, S.S. Poulsen<sup>2</sup>, J.J. Holst<sup>2</sup>, T. Vilsbøll<sup>1</sup>, F.K. Knop<sup>1,2</sup>;

<sup>1</sup>Diabetes Research Division, Department of Medicine, Gentofte Hospital, University of Copenhagen, Hellerup, <sup>2</sup>Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, <sup>3</sup>Unit of Enteroscopy, Department of Medicine, Gentofte Hospital, University of Copenhagen, Hellerup, <sup>4</sup>Endoscopy Unit, Department of Gastroenterology, Herlev Hospital, University of Copenhagen, Herlev, Denmark.

**Background and aims:** Hormones secreted from enteroendocrine cells in the gut play a crucial role in regulation of whole-body glucose metabolism. Little is known about the distribution of these enteroendocrine cells along the intestinal tract, and it is currently unknown whether the distribution and/or phenotype of these cells is altered in type 2 diabetes (T2D). We aimed to evaluate the expression of products from enteroendocrine D, K and L cells, respectively, along the entire length of the small and large intestines in patients with T2D and in healthy control subjects

**Materials and methods:** We used double-balloon enteroscopy (DBE) to collect mucosal gut biopsies. The study involved 12 subjects diagnosed with T2D and 12 age and BMI-matched non-diabetic controls. All subjects underwent antegrade and retrograde DBE. Biopsies were collected from every 30 cm from pylorus to the ileocecal valve and from 6 specific sites in colon. RNA was isolated and analysed for expression of glucagon (*GCG*), peptide YY (*PYY*), glucose-dependent insulinotropic polypeptide (*GIP*) and somatostatin (*SST*). **Results:** Expression of markers for L cells (*GCG*, *PYY*) and K cells (*GIP*) showed significantly higher expression of L cell genes in the distal versus the proximal parts of the small intestine and significantly higher expression of the K cell marker (*GIP*) in the proximal part of the small intestine. Expression of the L cell marker (*GCG*) was significantly higher in the proximal small intestine in subjects with T2D compared to healthy controls (337% (113%;1002%) p<0.05). Expression of the D cell marker (*SST*) was significantly lower in the distal part of the small intestine in T2D subjects compared with healthy controls (21% (5%;27%) p<0.05).

**Conclusion:** Using DBE, we managed to collect biopsies along the entire length of the small and large intestines in patients with T2D and non-diabetic controls. Our results confirm the notion of higher expression of the L cell marker (*GCG*) distally, and higher expression of the K cell product (*GIP*) proximally in the small intestine. Importantly, we also show that intestinal expression of *GCG* and *SST* is altered in patients with T2D, a finding that might prove relevant in future prevention and treatment of the disease.

**Role of the somatostatin in the control of glucagon secretion by glucose and  $K_{ATP}$  channel blockers**

A. Gómez-Ruiz, K.B. Lai, H.-Y. Chae, N. Antoine, P. Gilon;  
Pôle d'endocrinologie, diabète et nutrition, Université catholique de Louvain, Brussels, Belgium.

**Background and aims:** It is well established that glucose (G) inhibits glucagon release by pancreatic  $\alpha$ -cells. However, it has sometimes been reported that high concentrations of the sugar ( $>20$ mM) stimulate glucagon secretion. The mechanisms behind these effects are unknown. In particular, it is still unclear whether G controls glucagon release by modulating  $K_{ATP}$  channels of  $\alpha$ - and non- $\alpha$ -cells within the islet and whether somatostatin (SST) released from  $\delta$ -cells is involved in the control of glucagon release. In the present study, we evaluated the role of SST in the control of glucagon secretion by various G concentrations and  $K_{ATP}$  channel blockers.

**Materials and methods:** The effects of G and  $K_{ATP}$  channel modulators were tested on glucagon secretion of control islets and islets devoid of SST paracrine influence (islets pre-treated for 24h with 200ng/ml pertussis toxin (PTX) or from  $Sst^{-/-}$  mice). Unless indicated, all the experiments were performed in the presence of a 6 mM mixture of amino acids (Mix AA: 2 mM alanine, 2 mM glutamine and 2 mM arginine).

**Results:** The role of SST in the control of glucagon secretion by various G concentrations (0, 1, 2, 5, 7, 15 and 30 mM) was first evaluated in incubation experiments with control islets or islets preincubated with PTX to remove the paracrine influence of SST. In control islets, G dose-dependently inhibited glucagon secretion with a maximal effect obtained already at around 7 mM. In PTX-pre-treated islets, glucagon secretion was larger at all G concentrations and the dose-response relationship for G-regulated glucagon secretion displayed a U-shape reflecting an inhibition of glucagon release at G concentrations up to 7 mM followed by a progressive decrease of the glucagonostatic effect at G concentrations  $>7$  mM. Perfusion experiments with islets of  $Sst^{+/+}$  or  $Sst^{-/-}$  mice confirmed these results. Thus increasing the G concentration of the medium from 1 to 7 or 30 mM equally inhibited glucagon release of  $Sst^{+/+}$  islets, whereas G7 inhibited glucagon release more potently than G30 in  $Sst^{-/-}$  islets. Moreover, increasing the G concentration of the perfusion medium from 7 to 30 mM did not affect glucagon release of  $Sst^{+/+}$  islets, whereas it stimulated that of  $Sst^{-/-}$  islets. These results suggest that SST is partially involved in the glucagonostatic effect of high G concentrations. We next studied the role of SST in the control of glucagon secretion by tolbutamide (Tolb, a  $K_{ATP}$  channel blocker). In  $Sst^{+/+}$  islet, Tolb (500  $\mu$ M) did not affect glucagon release at G1 and slightly stimulated it at G7. By contrast, in  $Sst^{-/-}$  islets, Tolb stimulated glucagon secretion both at G1 and G7. The glucagonotropic effect of Tolb in  $Sst^{-/-}$  islets was much more evident in the absence of Mix AA. It is unrelated to Epac2 activation because a much lower concentration of Tolb (10  $\mu$ M) and gli-clazide (10  $\mu$ M) which do not activate Epac2 also strongly stimulated glucagon release of  $Sst^{-/-}$  islets perfused with G7 and without MixAA.

**Conclusion:** G dose-dependently inhibits glucagon release of control islets. This inhibition is independent of SST for intermediate G concentrations (0-7 mM) but starts to involve SST for G concentrations  $>7$  mM. Pharmacological closure of  $K_{ATP}$  channels controls glucagon secretion by two mechanisms: a direct stimulation of  $\alpha$ -cells (independent of Epac2 activation and observed in the absence of SST influence) and an indirect inhibition via SST released from  $\delta$ -cells.

## 59

**Effect of glucose and free fatty acid on PC1/3-PC2 expression in pancreatic alpha cell**

V. Sancho Barnez, R. Lupi, V. Garau, S. Del Guerra, D. Lucchesi, A. Dardano, L. Giusti, R. Miccoli, G. Penno, S. Del Prato;  
Endocrinology and Metabolism, University of Pisa, Italy.

**Background and aims:** An intra-islet incretin system has been recently suggested to operate through modulation of the expression and activity of pro-convertase 1/3 and 2 (PC1/3, PC2) in pancreatic alpha-cell accounting for local release of GLP-1. Little is known, whether this alpha-cell activity can be affected by the metabolic alterations occurring in type 2 diabetes, such as hyperglycaemia, hyperlipidemia or hyperglucagonemia.

**Materials and methods:** AlphaTC1/6 cells from a mice pancreatic cell line were incubated in the presence of two glucose (G) concentration (5.5 and 16.7 mM) for 16 h with or without free fatty acid (FA, 2:1 palmitate:oleate,

0.5 mM), IL6 (200 ng/ml) or glucagon (GLU: 250 pg/ml). GLP-1 secretion was measured by ELISA and expression of PC1/3 and PC2 by RT-PCR and western blot; cell viability was determined by MTT method, Reactive Oxygen Species generation (ROS) by H2DCFDA fluorescence and apoptosis by Annexin staining and Propidium Iodide (PI) fluorescence.

**Results:** Upon 16.7G incubation, GLP-1 secretion (total and active) was significantly increased (130 $\pm$ 9% and 158 $\pm$ 19%, respectively,  $p<0.04$ , all vs 5.5G) in parallel with a significant increment in PC1/3 expression (RNA: 1.37 $\pm$ 0.06 folds and protein: 138 $\pm$ 10%, both  $p<0.02$ ), a slight increase in cell viability (116 $\pm$ 3%,  $p<0.001$ ) and ROS generation (118 $\pm$ 5%,  $p<0.001$ ) and by a decrement in PC2 expression (RNA: 0.51 $\pm$ 0.06,  $p<0.05$ ) with no change in cell apoptosis (105 $\pm$ 4%). No change was observed upon incubation with mannitol. When cells were incubated at 5.5G + FA, also an increment in GLP-1 secretion (173 $\pm$ 21%,  $p<0.02$ ) and PC1/3 expression was observed (RNA: 2.07 $\pm$ 0.24 folds,  $p<0.006$ ) together an increment in ROS generation (132 $\pm$ 8%,  $p<0.002$ ), a decrement in cell viability (47 $\pm$ 2%,  $p<0.001$ ), and a modest increment in apoptosis (Annexin: 115 $\pm$ 5%,  $p<0.03$ ; PI: 109 $\pm$ 5%). When incubated with 16.7G + FA, the increment in GLP-1 secretion was reduced to basal (107 $\pm$ 6% vs. 5.5G), accompanied by an increment in apoptosis (Annexin: 152 $\pm$ 11%,  $p<0.001$ ; PI: 142 $\pm$ 9%,  $p<0.001$ ) and ROS generation (139 $\pm$ 9%,  $p<0.001$ ). This was also observed with IL6 (GLP-1 secretion: 5.5G + IL6: 156 $\pm$ 12% vs. 16.7G + IL6: 111 $\pm$ 25%; PC1/3: 5.5G + IL6: 2.78 $\pm$ 1.04 vs 16.7G + IL6: 6.56 $\pm$ 1.37), but in this case, no modification in ROS generation or apoptosis was observed when compared to 16.7G. The presence of GLU did not modify any of the parameters studied.

**Conclusion:** These data suggest that under hyperglycaemic, hyperlipidaemic or inflammatory conditions, alpha cells can increase expression PC1/3 and activate GLP-1 secretion, which may contribute protecting both alpha and beta-cells from glucose and lipotoxicity, while this effect seems to be lost in the presence of both pathophysiological conditions.

## 60

**Gp130 receptor signalling mediates alpha cell dysfunction in a rodent model of type 2 diabetes**

S.Z.W. Chow<sup>1</sup>, M. Speck<sup>1</sup>, P. Yoganathan<sup>1</sup>, D. Nackiewicz<sup>1</sup>, A. Hansen<sup>2</sup>, M. Ladefoged<sup>3</sup>, B. Rabe<sup>3</sup>, S. Rose-John<sup>3</sup>, P.J. Voshol<sup>4</sup>, F.C. Lynn<sup>1</sup>, P.L. Herrera<sup>5</sup>, W. Muller<sup>6</sup>, H. Ellingsgaard<sup>7</sup>, J.A. Ehses<sup>1</sup>;  
<sup>1</sup>Surgery, University of British Columbia, Vancouver, Canada, <sup>2</sup>Novo Nordisk, Malov, Denmark, <sup>3</sup>University of Kiel, Germany, <sup>4</sup>University of Cambridge, UK, <sup>5</sup>University of Geneva, Switzerland, <sup>6</sup>University of Manchester, UK, <sup>7</sup>University of Copenhagen, Denmark.

**Background and aims:** Dysregulated glucagon secretion accompanies islet inflammation in type 2 diabetes. We recently discovered that IL-6 stimulates glucagon secretion from human and rodent islets. IL-6 family cytokines require the gp130 receptor to signal. In this study we elucidated the effects of a cell gp130 receptor signaling on glycaemic control in type 2 diabetes.

**Materials and methods:** IL6 family cytokines were analyzed in islets in two rodent models of T2D. Gp130 receptor signalling was assessed in primary  $\alpha$  cells. Furthermore, a cell specific gp130 knock out (agp130KO) mice were generated and subjected to streptozotocin (STZ) alone, high fat diet (HFD) alone, and STZ plus HFD to study how a cell dysfunction contributes to glycaemic control. Glucose tolerance tests, insulin tolerance tests, and hyperinsulinemic-euglycemic clamps were performed to assess a cell function,  $\beta$  cell function, and insulin sensitivity.

**Results:** IL-6 family cytokines were elevated in islets in rodent models of this disease. Gp130 receptor activation induced STAT3 phosphorylation in primary  $\alpha$  cells and stimulated glucagon secretion. agp130KO mice showed no differences in glycaemic control, a cell function or a cell mass. However, when subjected to STZ alone agp130KO mice showed improved glucose tolerance. Further, when subjected to STZ plus HFD to induce islet inflammation and pathophysiology modelling type 2 diabetes, agp130KO mice had reduced fasting glycaemia, improved glucose tolerance, reduced fasting insulin, and improved a cell function despite decreased fasting GLP-1 levels. Hyperinsulinemic-euglycemic clamps revealed no differences in insulin sensitivity.

**Conclusion:** We conclude that during T2D, activation of a cell gp130 receptor signaling causes impaired  $\alpha$  cell function, promoting hyperglycaemia. Despite decreased systemic GLP-1 levels in agp130KO mice (likely due to receptor deletion in L cells), activation of a cell gp130 receptor signalling in a setting of reduced  $\beta$  cell mass and HFD-induced insulin resistance had detrimental effects on normal  $\alpha$  cell function and glycaemic control. Antagonism of a cell gp130 receptor signaling may be useful for the treatment of T2D.

### Trajectories of glycaemic traits in south Asians and whites before diabetes diagnosis: a longitudinal analysis from the Whitehall II study

A.G. Tabák<sup>1,2</sup>, E.J. Brunner<sup>2</sup>, D.R. Witte<sup>3</sup>, K. Faerch<sup>4</sup>, D. Vistisen<sup>4</sup>, S. Ikehara<sup>5</sup>, M. Kivimäki<sup>3</sup>, A. Hulmán<sup>6</sup>;

<sup>1</sup>1st Department of Medicine, Semmelweis University, Faculty of Medicine, Budapest, Hungary, <sup>2</sup>Department of Epidemiology and Public Health, University College London, UK, <sup>3</sup>Centre de Recherche Public de la Santé, Strassen, Luxembourg, <sup>4</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>5</sup>Osaka University, Japan, <sup>6</sup>University of Szeged, Hungary.

**Background and aims:** An increased risk of type 2 diabetes among south Asians compared to whites is well established. Most of the literature suggests that this is related to lower insulin sensitivity among south Asians however the role of insulin secretion is rarely assessed. Therefore, we aimed to investigate ethnic differences in trajectories of fasting (FPG) and 2-h post-load plasma glucose (2hPG), log-transformed homeostasis model assessment insulin sensitivity (HOMA-S) and secretion (HOMA-B) prior to the diagnosis of type 2 diabetes.

**Materials and methods:** We analysed trajectories of glycaemic traits before the diagnosis of diabetes by fitting mixed-effects models to longitudinal data (with up to 4 repeat measures within individuals) from 101 south Asian and 764 white participants of the Whitehall II study, who developed type 2 diabetes during follow-up between 1992 and 2009.

**Results:** South Asians had an almost 4 times increased risk of incident diabetes compared to whites during follow-up (26.4% vs 10.2%,  $P < 0.001$ ). According to age and sex-adjusted mixed-effects models, South Asians had a faster increasing FPG trajectory before diagnosis (slope difference: 0.34 mmol/l per decade, 95% CI: 0.05, 0.64;  $P = 0.022$ ) and 0.36 mmol/l (95% CI: 0.10, 0.63;  $P = 0.007$ ) higher FPG levels at diagnosis than whites. There were no differences in 2hPG trajectories between the two ethnic groups. South Asians had significantly lower HOMA-S already 15 years before diagnosis and the difference increased even further until diagnosis (difference at diagnosis: 0.30, 95% CI: 0.14, 0.46;  $P < 0.001$ ). HOMA-B trajectories had different quadratic characteristics ( $P = 0.04$  for ethnicity  $\times$  time<sup>2</sup> interaction). It increased in both ethnicities until 7 years before diagnosis however the increase was faster in whites, while it followed a similar decreasing trajectory thereafter until diagnosis. Differences in FPG and HOMA-B trajectories were robust to adjustment for measures of obesity and lifestyle measures.

**Conclusion:** Insulin sensitivity falls more rapidly among south Asians than whites. In contrast to whites, who could increase insulin secretion up to 7 years before diagnosis, this compensatory mechanism is can be hardly seen in south Asians, hence a more rapidly increasing FPG trajectory develops prior to the diagnosis of diabetes. These findings extend our prior observation of inadequate  $\beta$ -cell compensation with aging in healthy south Asians.

### Food sources of fat may clarify the earlier inconsistent role of dietary fat intake for incidence of type 2 diabetes

U. Ericson<sup>1</sup>, S. Hellstrand<sup>1</sup>, L. Brunkwall<sup>1</sup>, E. Sonestedt<sup>1</sup>, P. Wallström<sup>2</sup>, B. Gullberg<sup>2</sup>, E. Wirfält<sup>2</sup>, M. Orho-Melander<sup>1</sup>;

<sup>1</sup>Department of Clinical sciences in Malmö, Diabetes and Cardiovascular disease, Genetic Epidemiology, Lund University Diabetes Center (LUDC), <sup>2</sup>Department of Clinical sciences in Malmö, Nutrition Epidemiology, Lund University, Malmö, Sweden.

**Background and aims:** Dietary fats could affect glucose metabolism and insulin sensitivity and may thereby have a crucial role in the development of type 2 diabetes (T2D). Studies have indicated that replacing saturated fat with monounsaturated and polyunsaturated fats might be favorable in the prevention of T2D. In line with this, plant sources of fat have been suggested to be a better choice compared with animal sources. Indeed, high intakes of red meat and meat products show positive associations with risk of T2D. Nevertheless, several epidemiological studies have indicated that a high intake of dairy products may be protective. Subsequently, the importance of dietary fat content and food sources of fat remains to be clarified. Our aim was to exam-

ine intakes of main dietary fat sources, classified according to fat content, in relation to incident T2D.

**Materials and methods:** In total 26 930 individuals (60% women), 45–74 years, from the population-based Malmö Diet and Cancer cohort, were included. Dietary data was collected with a modified diet history method. During 14 years follow-up, 2860 incident T2D cases were identified. Cox proportional hazards regression model was used to estimate hazard ratios (HR) of diabetes incidence in quintiles of energy adjusted dietary intakes. The multivariate model included adjustments for age, sex, season, diet assessment method version, total energy intake, BMI, leisure time physical activity, smoking, alcohol consumption and education.

**Results:** High intake of high-fat dairy products was associated with lower incidence of T2D (HR for the highest (median=8 portions/day) compared with the lowest (median=1 portion/day) intake quintile: 0.77; 95% CI: 0.68–0.87;  $P$  for trend  $< 0.001$ ). Concerning intakes of specific high-fat dairy foods, cream and high-fat fermented milk were inversely associated with risk of T2D ( $P < 0.01$ ). High intake of low-fat dairy products was associated with increased risk ( $P$  for trend=0.01), but this association disappeared after additional adjustment for protein intake ( $P$  for trend=0.37). High intakes of meat and meat products were, regardless of fat content associated with increased risk (HR: 1.09; CI: 0.97–1.24;  $P$  for trend=0.04 and HR: 1.25; 95% CI: 1.11–1.41;  $P$  for trend  $< 0.001$ , for high- and low-fat meat respectively)(median intakes in the highest quintiles=90, 80 g/day).

**Conclusion:** Our observations may contribute to clarifying previous findings regarding dietary fats and their food sources in relation to T2D. The decreased risk at high intakes of high-fat dairy products, but not of low-fat dairy products, indicate that dairy fat, at least partly, explains observed protective associations between dairy intake and T2D. Meat intake was associated with increased risk independently of fat content.

### Movement during sedentary time is associated with metabolic outcomes

J.D. van der Berg<sup>1</sup>, H. Bosma<sup>1</sup>, P. Caserotti<sup>2</sup>, G. Eiriksdottir<sup>3</sup>, N.Y. Arnardottir<sup>3,4</sup>, R.J. Brychta<sup>5</sup>, K.Y. Chen<sup>5</sup>, T. Sveinsson<sup>4</sup>, E. Johannsson<sup>6</sup>, L.J. Launer<sup>7</sup>, V. Gudnason<sup>3,8</sup>, P.V. Jonsson<sup>9,10</sup>, C.D.A. Stehouwer<sup>11</sup>, T.B. Harris<sup>7</sup>, A. Koster<sup>1</sup>;

<sup>1</sup>Social Medicine/CAPHRI School for Public Health and Primary Care, Maastricht University, Netherlands, <sup>2</sup>Institute of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark, <sup>3</sup>Icelandic Heart Association, Kopavogur, <sup>4</sup>Research Center of Movement Science, University of Iceland, Reykjavik, Iceland, <sup>5</sup>Diabetes Endocrinology and Obesity Branch, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, USA, <sup>6</sup>Center for Sport and Health Sciences, Iceland University of Education, Laugarvatn, Iceland, <sup>7</sup>Laboratory of Epidemiology and Population Sciences, Intramural Research Program, National Institute on Aging, Bethesda, USA, <sup>8</sup>University of Iceland, <sup>9</sup>Faculty of Medicine, University of Iceland, <sup>10</sup>Department of Geriatrics, Landspítali National University Hospital, Reykjavik, Iceland, <sup>11</sup>Department of Internal Medicine/Cardiovascular Research Institute Maastricht (CARIM), Maastricht University Medical Centre, Netherlands.

**Background and aims:** Studies have shown that more sedentary time is associated with adverse health effects including metabolic syndrome, type 2 diabetes, cardiovascular diseases, and increased mortality risk. Next to total amount of sedentary time other aspects of sedentary behaviour, such as the pattern in which sedentary time is accumulated, have been associated with health outcomes. During sedentary time the degree of movement of the upper body can differ between individuals and this could be another relevant aspect of sedentary behaviour. Whether movement during sedentary time is meaningful for health outcomes is not clear and therefore this study aims to examine the association between movement during sedentary time and metabolic outcomes.

**Materials and methods:** 631 participants (aged 73–98 years) of the AGESII-Reykjavik Study wore a triaxial accelerometer (ActiGraph GT3X) for 7 consecutive days. Movement during sedentary time was defined as any activity in the anteroposterior and/or mediolateral axes with an intensity  $\geq 100$  counts per minute (cpm), during sedentary time ( $< 100$  cpm in the vertical axis). Metabolic outcomes included body mass index (BMI), waist circumference (WC), levels of HDL-cholesterol (HDL), triglycerides (TG), fasting glucose (FG) and C-reactive protein (CRP).

**Results:** Linear regression analysis showed that compared with those who had the most minutes with movements during sedentary time, participants with fewer movement minutes (quartiles 3, 2, 1) had a higher BMI ( $B=1.43$ ;  $B=1.97$ ;  $B=3.38$ ; all  $p<0.05$ ) and an up to 8.3 cm larger WC ( $B=4.66$ ;  $B=5.25$ ;  $B=8.30$ ; all  $p<0.05$ ) after adjusting for demographic and health factors, sedentary time, and MVPA. Fewer movement minutes were also associated with lower levels of HDL (Q3  $B=-0.11$ ; Q1  $B=-0.13$ ; all  $p<0.05$ ) and higher TG levels ( $B=1.10$ ;  $B=1.09$ ;  $B=1.10$ ; all  $p<0.05$ , back transformed from log scale), but not with FG and CRP.

**Conclusion:** Movement during sedentary time was associated with metabolic outcomes; an up to 3.4 kg/m<sup>2</sup> higher BMI and 8.3 cm larger WC was seen in participants with less movement minutes. These findings suggest that movement during sedentary time could be a relevant aspect of sedentary behaviour.

### Association of restrictive ventilatory dysfunction with development of prediabetes and type 2 diabetes in Koreans

C.-H. Kim<sup>1</sup>, E.-H. Kim<sup>2</sup>, S.-J. Bae<sup>2</sup>, H.-K. Kim<sup>2</sup>;

<sup>1</sup>Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Kyeonggi-do, <sup>2</sup>Health Promotion Center, Asan Medical Center, Seoul, Republic of Korea

**Background and aims:** Accumulating evidence have suggested that reduced lung function, especially restrictive pattern, is associated with insulin resistance and type 2 diabetes. However, the causal direction between reduced lung function and type 2 diabetes remains unclear and there is a paucity of longitudinal studies in Asian populations. We investigated whether restrictive ventilatory dysfunction is a predictor for development of prediabetes and type 2 diabetes in Koreans.

**Materials and methods:** We analyzed the clinical and laboratory data of 17,144 Korean adults (age 20–79 years, 37.8% women) who underwent routine medical check-ups in 2008 (baseline) and again in 2012–13 (follow up) with a median 4.9-year (range 3.0–5.9 years) interval. Patients who had diabetes at baseline were excluded. Results of spirometry were categorized into three groups; normal ( $FEV_1/FVC \geq 0.70$ ,  $FVC \geq 80\%$  predicted), obstructive ventilatory dysfunction (OVD;  $FEV_1/FVC < 0.70$ ), and restrictive ventilatory dysfunction (RVD;  $FVC < 80\%$  predicted,  $FEV_1/FVC \geq 0.70$ ). At baseline, 1518 subjects (9.4%) had RVD and 770 (4.8%) had OVD. Prediabetes was defined as fasting plasma glucose 5.6–6.9 mmol/l or HbA1c 39–46 mmol/mol [5.7–6.4%].

**Results:** Subjects with RVD had higher age, body mass index (BMI), waist circumference, systolic and diastolic blood pressure, and fasting glucose level at baseline compared to those with normal ventilatory function. Among the 16,195 participants who did not have diabetes at baseline, a total of 640 subjects (4.0%) developed type 2 diabetes during the follow-up period. Compared to subjects with normal ventilatory function, the subjects with RVD had a higher incidence of type 2 diabetes (3.7% vs. 6.3%,  $P<0.001$ ) but subjects with OVD did not (3.7% vs. 4.8%,  $P=0.119$ ). On multiple logistic regression analysis, the OR of type 2 diabetes in subjects with RVD was significantly increased (1.47 [1.16–1.87],  $P=0.001$ ) after adjusting for age, sex, exercise, drinking, smoking, and blood pressure. However, further adjustment for BMI, waist circumference, and baseline glucose level attenuated the OR to become insignificant (1.17 [0.90–1.52],  $P=0.251$ ). Since subjects with RVD already had higher prevalence of prediabetes at baseline, we confined the analysis to subjects with normal fasting glucose and HbA1c levels at baseline. Among those 9461 participants, a total of 2288 subjects (24.2%) developed prediabetes and 37 (0.4%) developed type 2 diabetes during the follow-up. The OR of progression to prediabetes or diabetes in subjects with RVD was 1.30 (1.12–1.51,  $P=0.001$ ) after controlling age, sex, exercise, drinking, smoking, and blood pressure. The OR remained significantly increased after further adjustment for BMI, waist circumference, and baseline glucose level (1.26 [1.07–1.47],  $P=0.004$ ).

**Conclusion:** Our results indicate that restrictive, but not obstructive, ventilatory dysfunction is independently associated with development of prediabetes and may precede the development of type 2 diabetes.

## 65

### Lifestyle factors and genetic predisposition to obesity in people from Pakistan: the PROMIS study

S. Ahmad<sup>1</sup>, W. Zhao<sup>2</sup>, F. Renstrom<sup>1</sup>, A. Rasheed<sup>3</sup>, D. Rader<sup>2</sup>, P.W. Franks<sup>1,4</sup>, J. Danesh<sup>5</sup>, D. Saleheen<sup>2,3</sup>;

<sup>1</sup>Genetic and Molecular Epidemiology (GAME) Unit, Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden, <sup>2</sup>Genetic and Molecular Epidemiology (GAME) Unit, Department of Clinical Sciences, Malmö, Sweden, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, USA, <sup>3</sup>Center for Non-Communicable Diseases Pakistan, Karachi, Pakistan, <sup>4</sup>Department of Nutrition, Harvard School of Public Health, Boston, USA, <sup>5</sup>Department of Public Health and Primary Care, University of Cambridge, UK.

**Background and aims:** Most complex trait genetics studies have focused on populations of European ancestry. However, conducting such studies in South Asians is important because their lifestyles are becoming increasingly westernized, their genetic architecture is somewhat distinct from Europeans, and the burden of complex diseases is growing rapidly. In 14,786 adults ( $N=7,354$  with myocardial infarction (MI)) from the Pakistan Risk of Myocardial Infarction Study (PROMIS) we tested if: a) 31 loci, established in Europeans to predispose to higher BMI, also do so in Pakistanis, and b) physical activity, smoking and cooking oil type modify the effects of these loci.

**Materials and methods:** A genetic risk score (GRS) comprised of 31 BMI-susceptibility loci was calculated by summing the BMI-associated alleles at each variant. Physical activity, smoking, and cooking oil type were assessed using self-administered questionnaires. Generalized linear models and logistic regression were used to examine associations and interactions (SNP\*lifestyle factor), with BMI as the outcome. Analyses were adjusted for age, age<sup>2</sup>, sex, MI (yes/no), and population substructure.

**Results:** In the total sample, each additional GRS risk allele was positively associated with BMI (0.07 (SE=0.1) kg/m<sup>2</sup>/risk allele;  $P<0.0001$ ). In interaction analyses, physical activity modified the effect of the GRS on BMI in the total sample ( $P_{\text{interaction}}=0.009$ ); the BMI-raising allele was associated with 0.11 (SE=0.02) kg/m<sup>2</sup> higher BMI in inactivity participants ( $P<0.0001$ ), whereas the GRS effect in moderately and in very physically active participants was 0.07 (SE=0.01;  $P<0.0001$ ), and 0.02 (SE=0.03;  $P=0.59$ ) kg/m<sup>2</sup> per allele respectively. Although the interaction effect estimates were essentially the same in cases and controls as in the full sample, the tests of interaction were not statistically significant by case/control strata ( $P_{\text{interaction}}=0.07$  and 0.08 respectively), possibly because of the smaller sample sizes (Fig. 1). In individual SNP analyses, the rs2815752 NEGR1 variant modified the association of physical activity with BMI in the total sample ( $P_{\text{interaction}}=0.002$ ), and in controls ( $P_{\text{interaction}}=0.035$ ) and cases ( $P_{\text{interaction}}=0.035$ ) separately.

**Conclusion:** Physical activity may modify the genetic predisposition to obesity in Pakistanis, the latter observation being consistent with earlier reports in European ancestry populations.

Figure 1 Forest plot shows the interaction of GRS x exposure (physical activity, dietary oil type and smoking) on BMI in total sample, control and cases in PROMIS study.

**Effect of lifestyle modification on the prevention of type 2 diabetes and impaired glucose tolerance in a young healthy urban South Asian population**

J. Karalliedde<sup>1</sup>, M. Wijesuriya<sup>2</sup>, L. Vasantharajah<sup>2</sup>, M. Gulliford<sup>3</sup>, G. Viberti<sup>1</sup>, L. Gnudi<sup>3</sup>;

<sup>1</sup>Diabetes, King's College London, UK, <sup>2</sup>Diabetes, Diabetes Association of Sri Lanka, Colombo, Sri Lanka, <sup>3</sup>King's College London, UK.

**Background and aims:** There is an increasing incidence of type 2 diabetes mellitus (T2DM) and related cardiovascular disease (CVD) in young South Asian subjects. Several studies have confirmed that lifestyle modification (LSM) is very effective in preventing T2DM in older subjects with impaired glucose tolerance (IGT). The effect of LSM on the prevention of cardio-metabolic disease in young healthy urban South Asian subjects is unknown.

**Materials and methods:** A randomised controlled clinical trial to compare an intensive 3-monthly LSM (I-LSM) with a less-intensive 12 monthly LSM (LI-LSM) for a primary composite cardio-metabolic endpoint of new onset T2DM, IGT, impaired fasting glycaemia, hypertension, initiation of lipid lowering therapy and cardio-renal disease in subjects aged 5 to 40 years with at least 2 of the following risk factors: raised body mass index, raised waist circumference (WC), first degree family history of T2DM and physical inactivity. A cluster sampling strategy was used to select a representative sample of healthy at risk subjects with two or more of the above risk factors. We randomised 4606 subjects of whom 3,685 (48% males) qualified for analyses. The study was performed at a single centre in Colombo, Sri Lanka between 2010 to 2013. Intervention: Each subject received LSM advice aimed at reducing weight, improving diet and increasing physical activity 3 monthly (I-LSM) or 12 monthly (LI-LSM) for 4 years.

**Results:** There were no significant baseline differences in anthropometric, clinical and demographic measures between groups [I-LSM (n=1807, mean  $\pm$  SD age, 22.4 $\pm$ 10 yrs.) and LI-LSM (n=1878 age, 22.4 $\pm$ 9.8 yrs)]. The cumulative incidence of the primary end point after 4 years was n=270 in I-LSM vs. n=302 in LI-LSM, a 9% (95% CI 1.0% to 16%) relative risk reduction (RRR), which was independent of baseline age, gender, p=0.02. Similarly there was a significant 26% RRR (95% CI 2% to 44%) in new onset T2DM p=0.04, and 18% RRR (95% CI 7% to 28%) in new onset IGT p=0.002. I-LSM did not significantly reduce the other components of the primary composite endpoint.

**Conclusion:** Our results demonstrate for the first time that in a young healthy but at risk South Asian population intensive LSM significantly reduces the development of T2DM, IGT and a composite endpoint of cardio-metabolic disease. These results highlight the importance of intervening early with lifestyle modification to prevent and reduce the burden of T2DM in young at risk subjects.

**OP 12 The many faces of advanced glycation**

## 67

**Exogenous and endogenous hydrogen sulfide protects the cardiomyocyte cell line H9c2 from methylglyoxal-mediated damage**

T. Ghela<sup>1</sup>, J.G. Mabley<sup>2</sup>;

<sup>1</sup>Brighton and Sussex Medical School,

<sup>2</sup>School of Pharmacy & Biomolecular Sciences, University of Brighton, UK.

**Background and aims:** Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound, has been implicated as a mediator of diabetic cardiovascular complications. MGO has already been shown to cause endothelial cell dysfunction as well as cardiomyocyte contractile dysfunction via increased cellular oxidative stress. Hydrogen sulfide is a gaseous transmitter found in the vasculature and synthesised from the amino acid L-cysteine. Hydrogen sulfide has been demonstrated to have a protective role in the vasculature acting as a vasodilator and protecting cells from increased oxidative stress. Hydrogen sulfide has already been shown to protect endothelial cells from MGO-mediated damage. The aim of this study is to investigate whether hydrogen sulfide generated exogenously by a chemical donor or endogenously from L-cysteine is also able to protect cardiomyocytes from MGO-mediated dysfunction.

**Materials and methods:** The cardiomyocyte cell line H9c2 was exposed to increasing concentrations of MGO (0.1-1 mM) for 24h prior to measuring cell viability and apoptosis. In a second series of experiments H9c2 cells were exposed to MGO 0.6 and 0.8 mM in combination with 0.25 or 0.5 mM sodium hydrogen sulfide or L-cysteine. Cell viability was determined using the MTT assay and cell death by propidium iodide/Hoechst staining. Endoplasmic Reticulum (ER) stress by Western blotting for CHOP.

**Results:** Methylglyoxal dose-dependently reduced H9c2 cell viability. MGO 0.6 and 0.8 mM reduced cell viability to 55 $\pm$ 3% and 47 $\pm$ 2% respectively, sodium hydrogen sulfide protected against this loss of cell viability with 0.25 mM returning viability to 65 $\pm$ 5% and 57 $\pm$ 4% and 0.5 mM returning viability to 70 $\pm$ 4% and 63 $\pm$ 3% respectively (p<0.05 vs. MGO alone). Similarly L-cysteine also protected against the MGO-mediated loss of cell viability with 0.25 mM returning viability to 79 $\pm$ 5% and 61 $\pm$ 3% and 0.5 mM returning viability to 106 $\pm$ 5% and 92 $\pm$ 3% respectively (p<0.05 vs MGO alone). To determine if this protection by L-cysteine was mediated by endogenous synthesis of hydrogen sulfide we used an inhibitor of the synthesizing enzyme cystathionine-gamma-lyase, DL-propargylglycine (PAG) 10 mM, pretreating the cells for 2h prior to treatment with MGO and L-cysteine. In the absence of PAG 0.25 and 0.5 mM L-cysteine protected against MGO 0.8 mM; increasing viability by 9 $\pm$ 2% and 49 $\pm$ 2% respectively but following PAG pretreatment this protection was reduced to -0.7 $\pm$ 0.4% and 27 $\pm$ 2% (p<0.05). MGO was found to increase apoptosis levels in H9c2 cells by a mechanism independent of ER stress. MGO also increases H9c2 cell necrosis levels. Again both sodium hydrogen sulfide and L-cysteine protected against this MGO-mediated increase in apoptosis and necrosis.

**Conclusion:** Hydrogen sulfide generated either directly from a chemical donor or indirectly from the endogenous substrate L-cysteine provided significant protection against MGO-mediated decrease in H9c2 cell viability and increased necrosis and apoptosis. This data suggests that not only will hydrogen sulfide protect endothelial cells but will also directly protect cardiomyocytes from methylglyoxal-mediated damage. These data suggest that hydrogen sulfide donors or therapies designed to increase endogenous production of hydrogen sulfide may be useful in reducing diabetic cardiovascular complications.

## 68

**Metabolic modelling of methylglyoxal formation, metabolism and AGE formation in vascular endothelial cells in model hyperglycaemia in vitro**

P.J. Thornalley, Z. Irshad, M. Xue, N. Rabbani;

Warwick Medical School, Division of Metabolic and Vascular Health, University of Warwick, Coventry, UK.

**Background and aims:** Methylglyoxal (MG) is a reactive dicarbonyl, glucose-derived metabolite and precursor of quantitatively major advanced glycation endproducts (AGEs). Increased MG-derived AGEs in vascular endothelial cells likely contributes to endothelial cell dysfunction and the development

of vascular complications of diabetes. Glyoxalase1 (Glo1) and glyoxalase 2 (Glo2) of the cytoplasmic glyoxalase system metabolises MG and prevents AGE formation. The aim of this investigation was to produce a mathematical model of MG concentration and related AGE formation in human vascular endothelial cells in vitro from experimental measurements of glucose metabolism and activities of Glo1 and Glo2 in normal glucose concentration and also high glucose concentration to model hyperglycaemia. The model is then validated by experimental measurement of cellular MG and AGEs. Exposure to increased AGEs may thereby be predicted for a given level of hyperglycaemia and the level of pharmacological induction of Glo1 induction required to prevent increased AGEs predicted.

**Materials and methods:** Human microvascular endothelial HMEC-1 cells were incubated in MCDB131 media with 10% serum containing low glucose or high Glucose (5 mM, LG and 30 mM, HG, respectively) for 6 days at 37°C. Similar experiments were performed with human aortic endothelial cells (HAECs) in primary culture with 5 mM or 20 mM glucose. Rate of glucose consumption, activities of Glo1 and glyoxalase 2, cellular and medium concentrations of MG, flux of MG (measured as the surrogate accumulation of D-lactate), D-lactate metabolism and cell protein content and flux of the major MG-derived AGE, hydroimidazolone MG-H1 were determined. Single and two compartment models of MG metabolism by the glyoxalase system and AGE formation were constructed using the COPASI programme.

**Results:** Incubation of HMEC-1 cells in HG produced a progressive decrease in Glo1 activity of 31% after 6 days. The rate of glucose metabolism was increased 70% and the flux of formation of MG was increased 66%. A mathematical model taking into account flux of MG formation, reversible binding of MG to GSH and protein thiols, metabolism by Glo1 and rate of MG glycation predicted an increase in cellular MG concentration and related AGEs in HG of 134%. Experimental validation produced similar results: increased in MG content of cells (pmol/106 cells) of 114% (LG,  $2.08 \pm 1.15$ ; HG,  $4.76 \pm 0.38$ ,  $P < 0.02$ ) and increased flux of formation of the major MG-derived AGE, MG-H1, of 102% in HG ( $P < 0.05$ ). Similar effects were found for HAECs. This can be corrected by a 3-fold induction of Glo1 expression which is achieved by small molecule Glo1 inducers.

**Conclusion:** MG-derived AGE formation in human vascular endothelial cells in vitro are increased in model hyperglycaemia by synergistic effects of increased formation of MG from increased anaerobic glycolysis and decreased metabolism of MG by decreased Glo1 activity. Correction of increased MG and AGE formation in hyperglycaemia is likely within the pharmacological capability of Glo1 inducers currently under investigation.

## 69

### Intracellular accumulation of methylglyoxal alters the collagen expression profile of L6 myoblasts

B. Goldstein, Y. Mattern, D. Tschoepe, B. Stratmann;  
Diabetes Center, Heart und Diabetes Center NRW, Bad Oeynhausen, Germany.

**Background and aims:** We have previously shown that down-regulation of the Methylglyoxal (MG) detoxifying glyoxalase system by siRNA mediated knockdown of (GLO1) results in impaired endocytosis of the transmembrane GLUT4 transporter leading to a prolonged and exaggerated cellular glucose influx. The consequences of this finding were analysed with special focus on the expression of extracellular matrix components in ratL6 myoblasts stably overexpressing the GLUT4 transporter.

**Materials and methods:** Detection of proteins and mRNA expression levels were carried out by western blot and quantitative real time PCR (qRT-PCR) analysis following intracellular accumulation of MG by siRNA mediated knockdown of Glo1 under hyperglycaemic conditions. mRNA levels and protein levels were determined 72 hrs after knockdown of Glo1. Normo- and hyperglycaemic controls were prepared following the same incubation time.

**Results:** The fibrillous collagens-1, -3, and -5 were significantly up-regulated on the mRNA-level ( $p < 0.0005$  vs. scrambled control), the increase in collagen-1 expression was also demonstrated on the protein level ( $p < 0.05$  vs. scrambled control), whereas for collagen-5 the increased expression was not detected on the protein level. For collagen-4 an increased mRNA expression was already detected following hyperglycaemia ( $p < 0.05$  vs. normoglycaemia), which was more pronounced following Glo1 knockdown ( $p < 0.0005$  vs. scrambled control). Regarding regulators of extracellular matrix turnover MMP-9 was significantly up-regulated ( $p < 0.001$  vs. scrambled control) on mRNA level, but not on protein level. A reduced expression of the cross-linking enzyme PLOD2 ( $p < 0.0005$  vs. scrambled control) and a slightly but non-significantly increased LEPREL2 were detected on protein level. DPSYL2,

which is of influence in cytoskeletal remodeling, is up-regulated on mRNA and protein level ( $p < 0.0005$  vs. scrambled control,  $p < 0.05$  vs. hyperglycaemia, respectively).

**Conclusion:** The results of this experimental research further elucidate the effect of exaggerated glucose influx after MG induced prolonged GLUT4 presence in the cell membrane on the cytoskeleton and extracellular matrix. The impact of expression of fibrillous and basal lamina associated collagens may account for the observations commonly detected in myofibrosis.

## 70

### Synergistic hepatotoxic effects with a combination of methylglyoxal and palmitic acid

T.L. Walter<sup>1</sup>, J.G. Mabley<sup>2</sup>;  
<sup>1</sup>Brighton and Sussex Medical School, <sup>2</sup>School of Pharmacy & Biomolecular Sciences, University of Brighton, Brighton, UK.

**Background and aims:** Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound, has been implicated as a central mediator of diabetic complications. Recently diabetes has been found to be an independent risk factor for development of liver disease including non-alcoholic fatty liver disease (NAFLD). Hepatocyte exposure to MGO or the saturated fatty acid, palmitic acid (PA) results in a loss of cell viability, increase in apoptosis and increased inflammation as demonstrated by IL-8 release. The aim of this study was therefore to determine if a combination of methylglyoxal and palmitic acid can synergistically damage hepatocytes and increase inflammation.

**Materials and methods:** The human hepatocyte cell line, HepG2, was exposed to MGO (0.6 mM) in combination with PA (3 or 10  $\mu$ M) for 24h. Cell viability was determined using the MTT assay and cell death by propidium iodide/Hoechst staining. Inflammation was assessed by IL-8 release and Endoplasmic Reticulum (ER) stress by Western blotting for CHOP.

**Results:** Hepatocytes exposed to a combination of MGO and PA had a lower cell viability and increased levels of apoptosis as compared to exposure to either component alone. Exposure to MGO 0.6 in combination with PA 3  $\mu$ M decreased cell viability to  $78 \pm 3\%$  as compared to  $81 \pm 1\%$  and  $98 \pm 2\%$  for MGO and PA alone ( $p < 0.05$ ), and also increased apoptosis from  $0.3 \pm 0.05\%$  to  $2.3 \pm 0.2\%$  as compared to  $0.7 \pm 0.1\%$  and  $0.9 \pm 0.1\%$  for MGO and PA alone ( $p < 0.05$ ). Exposure to MGO 0.6 in combination with PA 10  $\mu$ M decreased cell viability to  $74 \pm 1\%$  as compared to  $81 \pm 1\%$  and  $97 \pm 2\%$  for MGO and PA alone ( $p < 0.05$ ), and also increased apoptosis to  $3.9 \pm 0.1\%$  as compared to  $0.7 \pm 0.1\%$  and  $1.5 \pm 0.5\%$  for MGO and PA alone ( $p < 0.05$ ). The increase in apoptosis may be accounted for by increased ER stress in response to the combination of MGO and PA as compared to that seen with PA alone. However, no such synergy was seen with inflammation only an additive effect was observed with IL-8 release increased by  $49 \pm 13$  and  $46 \pm 8\%$  with the combination of MGO 0.6 mM and PA 3 or 10  $\mu$ M respectively. Whereas IL-8 increased by  $30 \pm 5\%$  with MGO 0.6 mM and  $13 \pm 6$  and  $8 \pm 7\%$  for PA 3 and 10  $\mu$ M when applied alone.

**Conclusion:** The synergistic effects of methylglyoxal and with relatively low physiological concentrations of palmitic acid on hepatocyte viability and apoptosis as well as the additive effects on inflammation may increase the risk of hepatotoxic effects being observed in diabetics. This may also account for the increased risk diabetics have of developing liver diseases such as NAFLD and strategies to not only lower saturated fatty acid levels but also methylglyoxal levels may prove effective in preventing these complications.

## 71

### The effect of hypertriglyceridaemia and metformin on reactive dicarbonyls in heart and kidney in a model of metabolic syndrome

H. Malinska, J. Trnovska, V. Škop, L. Kazdova;  
Center for Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague<sup>4</sup>, Czech Republic.

**Background and aims:** Biogenesis of reactive dicarbonyls is related to glycaemic and lipid status in diabetes and higher plasma levels of methylglyoxal are observed in diabetic patients. Excessive generation of dicarbonyls leads to production of advanced glycation end products (AGE), activates inflammatory pathway, increases oxidative stress and can play a key role in the development of diabetic vascular complications. Dicarbonyls determination could be early biomarker risk for these complications. Metformin, the most widely prescribed glucose- and lipid-lowering agent for treatment of type 2 diabetes, has also been proposed as a scavenger of methylglyoxal. However its effect on

individual dicarbonyls metabolism in tissue is not fully clarified. In our study we analyzed level of individual reactive dicarbonyls - methylglyoxal (MG), glyoxal (GL) and 3-deoxyglucosone (3-DG) in relation to lipid disorders and after metformin administration in non-obese rats with hereditary hypertriglyceridemia (HHTg rats).

**Materials and methods:** Adult Wistar rats (controls) and HHTg rats, which exhibit genetic fixed hypertriglyceridemia, tissue insulin resistance, impaired glucose tolerance, hyperinsulinemia and ectopic lipid accumulation, were fed a standard laboratory diet with or without metformin (300mg/kg b.wt.) for 4 weeks. The concentration of dicarbonyls were determined by derivatisation with 1,2-diamino-4,5-dimethoxy-benzene and HPLC-method with fluorescence detection.

**Results:** Compared with controls, HHTg rats exhibited markedly elevated serum levels of triacylglycerol ( $4.05 \pm 0.39$  vs  $1.88 \pm 0.23$  mmol/l,  $p < 0.001$ ), FFA ( $0.97 \pm 0.19$  vs  $0.47 \pm 0.13$  mmol/l,  $p < 0.01$ ) and hepatic triglycerides accumulation ( $13.87 \pm 2.23$  vs  $4.32 \pm 0.70$   $\mu$ mol/g,  $p < 0.001$ ). In HHTg rats we observed markedly increased serum level of MG ( $p < 0.01$ ). Concentrations of individual reactive dicarbonyls in myocardium (MG:  $14.99 \pm 0.78$  vs  $8.66 \pm 1.28$  nmol/mg,  $p < 0.001$ ; GL:  $3.53 \pm 0.51$  vs  $1.22 \pm 0.42$  nmol/mg,  $p < 0.01$ ; 3-DG:  $3.46 \pm 0.46$  vs  $1.61 \pm 0.39$  nmol/mg,  $p < 0.01$ ) and kidney cortex (MG:  $6.14 \pm 0.59$  vs  $3.45 \pm 0.39$  nmol/mg,  $p < 0.01$ ) were significantly elevated in HHTg rats compared to controls. Metformin treatment was associated with significantly reduced level of reactive dicarbonyls in myocardium (MG:  $p < 0.05$ , GL:  $p < 0.05$ , 3-DG:  $p < 0.01$ ), when compared to untreated HHTg rats. There were no significant effects of metformin on dicarbonyls concentration in kidney cortex.

**Conclusion:** Results indicate that chronically elevated hypertriglyceridemia and FFA was associated with increased levels of methylglyoxal in serum and with markedly elevated reactive carbonyls in heart and kidney. Beneficial effect of metformin administration on reactive dicarbonyls in heart could contribute to cardioprotective effect of metformin.

### Association between decreased serum level of sRAGE, RAGE Gly82ser polymorphism and diabetic patients with mild cognitive impairment

P. Wang, R. Huang, W. Xia, H. Sun, R. Cai, S. Wang;

Affiliated ZhongDa Hospital of Southeast University, Nanjing, China.

**Background and aims:** The incidence of mild cognitive impairment (MCI) is much higher in type 2 diabetes mellitus (T2DM). As the receptor for advanced glycation end products (AGEs) and  $\text{A}\beta$ , RAGE was involved both in chronic complications of T2DM and Alzheimer's disease. The aim of this study was to investigate the association of the serum level of sRAGE which acts as a decoy receptor of RAGE, the Gly82ser polymorphism in RAGE gene and T2DM with MCI.

**Materials and methods:** A total of 109 type 2 diabetic patients, 52 subjects met the MCI diagnostic criteria proposed by the MCI Working Group of the European Consortium on Alzheimer's Disease, and 57 matched type 2 diabetic patients, were enrolled into our study. Participants were evaluated using an extensive assessment of cognitive function, serum level of sRAGE was measured by enzyme-linked immunosorbent assay, and RAGE Gly82ser polymorphism was determined by PCR-RFLP.

**Results:** The serum level of sRAGE in the MCI patients with T2DM (median [interquartile range] =  $0.86 [0.42-1.20]$  ng/ml) was significantly lower than those matched T2DM without MCI ( $0.86 [0.42-1.20]$  ng/ml,  $p < 0.001$ ), even in the heterozygote group ( $0.87, 0.42$  ng/ml,  $p < 0.001$ ). It seems the 82S allele was associated with an elevated risk of MCI, the odds ratio (OR) of GS+SS is ( $1.476 [0.680-3.202]$ ), but without statistics significance because of the limitation of population size.

**Conclusion:** T2DM with MCI showed a lower serum concentration of sRAGE, and sRAGE may be a potential marker and preventive measures for MCI, especially in T2DM patients. The RAGE gene Gly82ser polymorphism may play a role in MCI with T2DM, but still need more research with larger population size.

Table Serum level of sRAGE (ng/ml) in MCI and normal control patients with T2DM, Median (interquartile range)

| Group                | Total           | Genotype        |                 |                 | p-value <sup>b</sup> |
|----------------------|-----------------|-----------------|-----------------|-----------------|----------------------|
|                      |                 | GG              | GS              | SS              |                      |
| Total                | 0.53(0.39-0.98) | 0.78(0.43-1.20) | 0.53(0.38-0.92) | 0.37(0.23-0.41) | 0.012                |
| Non-MCI              | 0.86(0.42-1.20) | 0.95(0.43-1.95) | 0.87(0.65-1.10) | 0.41*           | 0.071                |
| MCI                  | 0.44(0.36-0.65) | 0.47(0.41-1.01) | 0.42(0.36-0.51) | 0.35*           | 0.117                |

### Liraglutide 3.0 mg reduces the prevalence of prediabetes and delays onset of type 2 diabetes in overweight/obese adults: the SCALE obesity and prediabetes trial

X. Pi-Sunyer<sup>1</sup>, K. Fujioka<sup>2</sup>, C. Le Roux<sup>3</sup>, A. Astrup<sup>4</sup>, F. Greenway<sup>5</sup>, A. Halpern<sup>6</sup>, M. Krempf<sup>7</sup>, D.C.W. Lau<sup>8</sup>, R. Violante Ortiz<sup>9</sup>, C.B. Jensen<sup>10</sup>, S.K. Lillioe<sup>10</sup>, J.P.H. Wilding<sup>11</sup>;

<sup>1</sup>Division of Endocrinology, Diabetes and Nutrition, St. Luke's-Roosevelt Hospital Center, New York, USA, <sup>2</sup>Scripps Clinic, La Jolla, USA, <sup>3</sup>University College Dublin, Ireland, <sup>4</sup>University of Copenhagen, Denmark, <sup>5</sup>Louisiana State University, Baton Rouge, USA, <sup>6</sup>University of São Paulo Medical School, Brazil, <sup>7</sup>Université de Nantes, France, <sup>8</sup>University of Calgary, Canada, <sup>9</sup>Instituto Mexicano del Seguro Social, Ciudad Madero, Mexico, <sup>10</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>11</sup>University of Liverpool, UK.

**Background and aims:** This trial investigated the effects of liraglutide 3.0 mg, as adjunct to diet and exercise, on weight loss, prediabetes prevalence and onset of T2D (ADA 2010) over 56 weeks. The effects of liraglutide 3.0 mg cessation were investigated in a subsequent 12 week re-randomised period.

**Materials and methods:** Adults (BMI  $\geq 27$  kg/m<sup>2</sup> +  $\geq 1$  comorbidity or  $\geq 30$  kg/m<sup>2</sup>) were advised on a 500 kcal/day deficit diet and exercise programme and randomised 2:1 to once daily sc liraglutide 3.0 mg (n=2487) or placebo (n=1244). Randomisation was stratified by prediabetes status (ADA 2010). At week 56, individuals without prediabetes on liraglutide 3.0 mg were re-randomised 1:1 to liraglutide 3.0 mg or placebo (diet and exercise continued).

**Results:** Baseline characteristics: age 45.1 yr, 78.5% female, body weight 106.2 kg, BMI 38.3 kg/m<sup>2</sup>, 61.2% with prediabetes. At week 56, individuals on liraglutide 3.0 had lost 8.0% weight compared to 2.6% with placebo (estimated treatment difference [ETD] -5.4%,  $p < 0.0001$ , LSmeans, full analysis set-LOCF, ANCOVA). Liraglutide 3.0 mg improved fasting and post-load glycaemia compared to placebo (ETD FPG -0.38 mmol/L, PG [OGTT, area under curve] -2.02 h\*mmol/L, HbA1c 0.23%-points;  $p < 0.0001$  for all). Of those with prediabetes at screening, more had reverted to normoglycaemia on liraglutide 3.0 mg (69.7%) vs placebo (32.1%) at week 56. Likewise, of those with normoglycaemia at screening, more had progressed to prediabetes on placebo (19.9%) vs liraglutide 3.0 mg (6.9%) at week 56 (Fig). Few individuals developed T2D during treatment, but significantly more on placebo than on liraglutide 3.0 mg developed T2D (n=14, 1.3 events/100 patient years of exposure [PYE] vs n=4, 0.2 events/100 PYE;  $p = 0.0003$ ). From week 56 to 68, individuals re-randomised from liraglutide 3.0 mg to placebo regained more weight (2.9%) vs those staying on liraglutide 3.0 mg (0.7%) (ETD 2.2%,  $p < 0.0001$ ), and more individuals progressed to prediabetes on placebo (from 8.0% to 22.4%, observed means) than on liraglutide 3.0 mg (from 9.1% to 8.6%) ( $p < 0.0001$ ). None developed T2D.

**Conclusion:** Consistent with the effects on body weight and glycaemia, liraglutide 3.0 mg, as adjunct to diet and exercise, was superior to placebo in reducing the prevalence of prediabetes and T2D after 56 weeks. Continued treatment was required to sustain these effects.

**Figure:** Proportion of subjects with prediabetes at week 56 by baseline prediabetes status

### Effect of exenatide on postprandial cerebral and liver glucose metabolism: a double-blind randomised clinical trial

G. Daniele<sup>1</sup>, P. Iozzo<sup>2</sup>, M. Molina-Wilkins<sup>1</sup>, J. Lancaster<sup>1</sup>, D. Ciociaro<sup>2</sup>, C. Triplitt<sup>1</sup>, E. Cersosimo<sup>1</sup>, D. Tripathy<sup>1</sup>, P. Fox<sup>1</sup>, N. Musi<sup>1</sup>, R.A. DeFronzo<sup>1</sup>, A. Gastaldello<sup>1,2</sup>;

<sup>1</sup>University of Texas Health Science Center, San Antonio, USA,

<sup>2</sup>Institute of Clinical Physiology, Pisa, Italy.

**Background and aims:** The main effect of GLP-1 receptor (GLP-1R) agonists is on insulin secretion. However, since GLP-1Rs have been found in the brain it has been hypothesized that GLP-1R agonists (GLP-1RA) could improve brain glucose metabolism. We have also shown that GLP-1Rs are present in human livers and that GLP-1 injection during pancreatic clamp can reduce hepatic glucose production. The aims of the study were to evaluate the effects of a single injection of GLP-1RA Exenatide (EX) on cerebral as well as hepatic and peripheral glucose metabolism.

**Materials and methods:** We studied 15 male subjects with increased postprandial glucose (n=12 IGT and n=3 newly diagnosed type 2 diabetics, age=56±8 y, BMI=29±1 kg/m<sup>2</sup>, HbA1c=5.7±0.1%). Each subject underwent 2 oral glucose tests (OGTT 75 g), with double blind injection of EX (5 mcg) or placebo (PLC) 30 min before OGTT; 6,6-2H-glucose was infused for 4h (2h before and 2h during OGTT) and U-13C-glucose was added to oral glucose to assess glucose absorption (RaOr), production (EGP), total rate of glucose appearance (Ra) and disposal (Rd). Brain and liver glucose uptake were measured by PET following injection of 18FDG (5mCi) at t=0 and acquiring images 1h into the OGTT.

**Results:** EX delayed gastric emptying (RaOr-0-60min=12.1±3.2 vs. 34.5±3.1 μmol/min·kg). Insulin response was lower in EX vs PLC (mean Insulin-0-60min 17.5±3.2 vs. 24.7±3.8 mU/l) as a consequence of lower glucose excursion (mean glucose0-60min 107±6 vs. 138±8 mg/dl, all  $p < 0.02$ ). Despite whole body glucose Rd was comparable in EX and PLC (Rd-0-60min 10.6±0.8 vs. 11.1±0.7 μmol/min·kg), in EX we observed lower liver uptake when corrected for glucose concentrations (0.17±0.02 vs. 0.25±0.04 μmol/min·ml,  $p = 0.047$ ) but higher when expressed as percent of RaOr ( $p < 0.005$ ). Cerebral glucose metabolic rate (CMR) was increased after EX (0.18±0.01 vs. 0.12±0.01 μmol/min·ml;  $p = 0.02$ ). Brain areas with the highest CMR were: Thalamus (0.23±0.02 μmol/min·ml), Occipital (0.24±0.02 μmol/min·ml) and Frontal lobes (0.19±0.02 μmol/min·ml), (all  $p < 0.004$ ). However, in the Hypothalamus EX reduced the CMR from 0.13±0.02 to 0.09±0.01 μmol/min·ml

( $p=0.003$ ). Total glucose CMR was inversely correlated with RaOr ( $r=-0.63$ ;  $p<0.0005$ ).

**Conclusion:** EX increased CMR in multiple areas of the brain but reduced glucose uptake in the hypothalamus. Liver glucose uptake accounted for a higher percentage of RaOr in EX. These results implicate a role of both brain and liver in the regulation of glucose metabolism by EX.

### Impact of baseline gastric emptying on effects of lixisenatide and liraglutide in type 2 diabetes mellitus (T2DM) as add-on to insulin glargine

B.A. Menge<sup>1</sup>, C. Kapitza<sup>2</sup>, A. Hincelin-Méry<sup>3</sup>, C. Roy-Duval<sup>3</sup>, A. Delfolie<sup>3</sup>, H.-V. Coester<sup>4</sup>, T. Forst<sup>4</sup>, J.J. Meier<sup>1</sup>;

<sup>1</sup>St Josef Hospital, Bochum, <sup>2</sup>Profil Institute, Neuss, Germany,

<sup>3</sup>Sanofi R&D, Chilly-Mazarin, France, <sup>4</sup>Profil Institute, Mainz, Germany.

**Background and aims:** Lixisenatide (LIXI) and liraglutide (LIRA), both once-daily glucagon-like peptide-1 receptor agonists (GLP-1 RAs), were administered as add-on to insulin glargine in patients with type 2 diabetes mellitus (T2DM) for 8 wks. Here we explore whether baseline (BL) gastric emptying (GE) is a potential factor influencing the efficacy of LIXI and LIRA. **Materials and methods:** Patients were randomized 1:1:1 to once-daily s.c. LIXI 20 µg or LIRA 1.2 or 1.8 mg as add-on to insulin glargine for 8 wks. Patients fasted overnight for 10 h before a standardized <sup>13</sup>C-labelled breakfast on Days -4 and 55 (281 kcal; 16% protein, 62% fat, 24% carbohydrate including 91 mg <sup>13</sup>C-octanoic acid mixed with egg). <sup>13</sup>C-octanoic acid breath samples were collected 30 min before breakfast (just before GLP-1 RA administration at Wk 8), every 15 min after breakfast for 2 h, then every 30 min for the next 3 h (total 15 samples). Breath samples were centrally analyzed for <sup>13</sup>CO<sub>2</sub> by isotope-selective non-dispersive infrared spectrometry. Time for retention of <sup>13</sup>C to decline to 50% ( $t_{1/2}$ ) and time at which % of the <sup>13</sup>C dose excreted/unit time reached its peak ( $t_{lag}$ ) were assessed. All patients from the pharmacodynamic population were grouped into BL GE  $t_{1/2}$  tertiles (T) for analysis of 8-wk outcomes: T1 92–150 min, T2 151–170 min, T3 171–334 min. Statistical analyses were performed using a linear model (ANOVA) with Bonferroni adjustment for tertile analyses.

**Results:** Mean (SD) BL  $t_{1/2}$  and  $t_{lag}$  were 169.48 (41.07) and 113.46 (26.50) min for LIXI ( $n=46$ ), 161.70 (23.40) and 111.23 (19.70) min for LIRA 1.2 mg ( $n=44$ ) and 164.30 (27.13) and 109.61 (20.84) min for LIRA 1.8 mg ( $n=46$ ). Least squares (LS) mean changes in GE  $t_{1/2}$  and  $t_{lag}$  were 453.56 and 175.56 min with LIXI ( $p<0.0001$  for both vs BL), 175.31 and 70.10 min with LIRA 1.2 mg, and 130.49 and 48.85 min with LIRA 1.8 mg ( $p<0.05$  for all changes with LIRA vs BL). The study showed a significantly greater delay in GE with LIXI vs LIRA ( $p<0.0001$ ) and significantly greater reductions in the AUC for postprandial glucose (AUC PPG)<sub>00:30-04:30 h</sub> with LIXI ( $p<0.0001$ ). There were no significant differences in reductions in AUC PPG<sub>00:30-04:30 h</sub> and HbA<sub>1c</sub> by BL  $t_{1/2}$  tertile in the LIXI and LIRA groups (Table). Patients with faster BL GE experienced greater GE  $t_{lag}$  delay with LIXI (LS mean  $t_{lag}$  difference [SE] in T1 vs T3: 165.33 [44.22] min;  $p=0.0009$ ).

**Conclusion:** LIXI delayed GE significantly more than LIRA. BL GE  $t_{1/2}$  did not predict treatment response (AUC PPG<sub>00:30-04:30 h</sub> or HbA<sub>1c</sub>) with LIXI or LIRA. Delay in GE with LIXI was less pronounced in patients with slower BL GE, suggesting that risk of aggravating pre-existing GE disturbances with GLP-1 RAs is low.

| Parameter                                 | LIXI 20 µg  |             |              | LIRA 1.2 mg |             |             | LIRA 1.8 mg |              |              |

### Effect of liraglutide 3.0 mg cessation on efficacy and safety/tolerability after 56 weeks' treatment in obese/overweight adults with type 2 diabetes: SCALE diabetes

R. DeFronzo<sup>1</sup>, R. Bergenstal<sup>2</sup>, B. Bode<sup>3</sup>, R. Kushner<sup>4</sup>, A. Lewin<sup>5</sup>, T.V. Skjoth<sup>6</sup>, C.B. Jensen<sup>6</sup>, M. Davies<sup>7</sup>;

<sup>1</sup>Diabetes Division, Department of Medicine, University of Texas School of Medicine at San Antonio, <sup>2</sup>Park Nicollet Institute, St Louis Park,

<sup>3</sup>Atlanta Diabetes Associates, <sup>4</sup>Northwestern University, Chicago,

<sup>5</sup>National Research Institute, Los Angeles, USA, <sup>6</sup>Novo Nordisk A/S,

Søborg, Denmark, <sup>7</sup>University of Leicester, UK.

**Background and aims:** This was a 56-wk randomised, double-blind, placebo-controlled trial to evaluate the effect of liraglutide on weight loss induction and maintenance and glycaemic control in overweight/obese subjects with T2D. Present data are from a 12-wk follow-up period, which assessed efficacy and safety after treatment cessation.

**Materials and methods:** Individuals were randomised 2:1:1 to liraglutide 3.0 mg, 1.8 mg or placebo (PBO), as adjunct to diet and exercise (D&E) for 56 wks. Those who completed 56 wks' treatment entered the 12-wk off-treatment follow-up; D&E continued until wk 68. With exception of pulse, lipase, data are LS means (ANCOVA).

**Results:** 846 individuals (age 54.9 years, weight 105.9 kg, BMI 37.1 [27.0–67.6] kg/m<sup>2</sup>, HbA<sub>1c</sub> 7.9%, fasting plasma glucose (FPG) 8.8 mmol/l, 7.3 years of T2D) were randomised. More individuals on liraglutide (3.0 mg: 77%, 1.8 mg: 78%) vs PBO (66%) completed 56-wks' treatment. After 56 wks, liraglutide 3.0 mg and 1.8 mg led to greater reductions in body weight than PBO (-5.93% and -4.58% vs -1.96%, respectively; both  $p<0.0001$  vs PBO); weight loss was greater with 3.0 mg vs 1.8 mg ( $p=0.0024$ ). FPG reductions at wk 56 were greater with liraglutide 3.0 mg and 1.8 mg vs PBO (-1.89 and -1.40 vs -0.12 mmol/l, respectively; both  $p<0.0001$  vs PBO), and greater with 3.0 mg vs 1.8 mg ( $p=0.0061$ ). After liraglutide cessation weight re-gain was observed but weight loss from baseline (BL) to wk 68 remained greater with liraglutide 3.0 mg (4.66%) than PBO (-2.50%;  $p=0.0002$ ). There was no significant difference in weight loss between liraglutide 1.8 mg (-3.70%) and PBO, nor 3.0 mg and 1.8 mg from BL to wk 68 (Fig). FPG reverted toward PBO levels within 2 wks of treatment cessation; at wk 68, change in FPG from baseline was -0.21, -0.01 and -0.12 mmol/l for liraglutide 3.0 mg, 1.8 mg and PBO, respectively ( $p=NS$  for all pairwise comparisons). Mean lipase activity increased from BL to wk 56 with liraglutide 3.0 mg and 1.8 mg vs PBO (+15.3, +16.6 vs +3.7 U/l, respectively); at wk 68, lipase activity was similar in all treatment groups. Mean pulse increased from BL to wk 56 with liraglutide (2.0 and 2.1 vs -1.4 beats/min for liraglutide 3.0 mg, 1.8 mg and PBO, respectively) but decreased after treatment cessation (change from BL to wk 68: -1.3, -0.5 and 0.4 beats/min for liraglutide 3.0 mg, 1.8 mg and PBO). No adverse effects of treatment cessation on safety or binge eating were noted.

**Conclusion:** 12 wks after liraglutide cessation, the beneficial treatment effects on weight were reduced and effects on FPG were reversed, emphasising the need for continued treatment.

**Figure: Effect of liraglutide cessation on body weight (%)**

Data are observed means  $\pm$  standard error. Treatment comparisons are from an analysis of covariance model with treatment, country, sex, background treatment, baseline HbA<sub>1c</sub> stratum and interaction between background treatment and HbA<sub>1c</sub> stratum as fixed factors and baseline value as covariate.

### DURATION-1 extension: efficacy and tolerability of exenatide once weekly over 6 years in patients with type 2 diabetes mellitus

E. Klein<sup>1</sup>, R.R. Henry<sup>2</sup>, J. Malloy<sup>3</sup>, P. Griffin<sup>3</sup>, M. Zhou<sup>4</sup>, N. Iqbal<sup>5</sup>,  
<sup>1</sup>West Olympia Internal Medicine, Olympia, <sup>2</sup>Center for Metabolic Research, VA San Diego Healthcare System and University of California,  
<sup>3</sup>Bristol-Myers Squibb, San Diego, <sup>4</sup>Bristol-Myers Squibb, Hopewell,  
<sup>5</sup>Bristol-Myers Squibb, Princeton, USA.

**Background and aims:** In a 30-week controlled, Phase III trial (DURATION-1), exenatide once weekly (QW) exhibited greater reduction in HbA<sub>1c</sub> than exenatide twice daily (–1.9% vs –1.5%;  $P=0.002$ ), with similar weight loss, in 295 intention to treat (ITT) patients with type 2 diabetes mellitus not controlled with diet and exercise, or single or combination oral glucose-lowering therapies. Here, we report data from patients who completed 6 years of treatment, the longest assessment of the efficacy and safety of a glucagon-like peptide-1 (GLP-1) receptor agonist to date.

**Materials and methods:** In the open-ended extension of DURATION-1, all patients received exenatide QW.  
**Results:** In total, 127 patients (43%) completed 6 years of treatment; baseline characteristics of these patients were similar to the ITT population. In completers, baseline [mean  $\pm$  SD] values were: HbA<sub>1c</sub> 8.2  $\pm$  0.9%; fasting plasma glucose (FPG) 9.22  $\pm$  2.26 mmol/L; weight 101  $\pm$  17 kg; diabetes duration 7  $\pm$  6 years. Withdrawal from the extension was most often due to withdrawal of consent (23.4%), adverse events (AEs; 5.8%) or investigator decision (5.1%). Among 6 year completers, HbA<sub>1c</sub> improved significantly from baseline (least squared mean –1.6% [95% CIs –1.9, –1.4]), 45% achieved HbA<sub>1c</sub> <7.0%, and 32% achieved HbA<sub>1c</sub>  $\leq$ 6.5%. Significant improvements in FPG (–1.58 mmol/L [–2.13, –1.03]) and weight (–4.3 kg [–6.0, –2.6]) were observed, and improvements in cardiovascular markers were maintained over 6 years. Improvements in lipid levels were: total cholesterol (–0.28 mmol/L [–0.47, –0.09]); LDL cholesterol (–0.27 mmol/L [–0.42, –0.11]); HDL cholesterol (0.06 mmol/L [0.01, 0.12]); triglyceride (–0.67 mmol/L [–1.11, –0.24]). Overall, most improvements were generally observed at week 30 and main-

tained to 6 years. In the ITT population, nausea (mostly mild) was the most common AE with exenatide QW for week 0 to 30 (exposure-adjusted annual event rate [events/year of patient exposure for each period] of 0.85) but decreased over time (to 0.08 from week 30 to 6 years), as did injection site pruritus (from 0.51 to 0.02) and injection site erythema (from 0.14 to 0.01). Treatment-emergent AEs leading to withdrawal from week 30 to 6 years were infrequent (6.6%). Most common AEs leading to withdrawal were nausea and type 2 diabetes mellitus progression (loss of glucose control) ( $n=2$  each). Over 6 years, 2 pancreatitis (annual rate 0.002; 1 withdrawal), 1 pancreatic carcinoma (1 withdrawal), and 3 acute renal failure cases were reported. No major hypoglycaemia was reported. Most minor hypoglycaemia occurred with concomitant sulfonylurea use.

**Conclusion:** In the longest extension of a Phase III GLP-1 receptor agonist study reported to date, exenatide QW was associated with significant, sustained improvements in glycaemic control and weight over 6 years in patients who continued therapy, with no unexpected safety findings.

### One-year efficacy and safety of IDegLira in patients with type 2 diabetes

S.C.L. Gough<sup>1</sup>, J.B. Buse<sup>2</sup>, V.C. Woo<sup>3</sup>, H.W. Rodbard<sup>4</sup>, S. Linjawi<sup>5</sup>, P. Poulsen<sup>6</sup>, L. Korsholm<sup>6</sup>, B.W. Bode<sup>7</sup>,  
<sup>1</sup>University of Oxford, Oxford Centre for Diabetes, Endocrinology and Metabolism, UK, <sup>2</sup>University of North Carolina School of Medicine, Chapel Hill, USA, <sup>3</sup>University of Manitoba, Winnipeg, Canada, <sup>4</sup>Endocrine and Metabolic Consultants, Rockville, USA, <sup>5</sup>Coffs Endocrine & Diabetes Services, Coffs Harbour, Australia, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>Atlanta Diabetes Associates, USA.

**Background and aims:** IDegLira, a combination of insulin degludec (IDeg) and liraglutide (Lira), provided the advantages and mitigated the main side effects of each of its components in a previous 26-week trial. This 26-week extension assessed whether these benefits were sustained up to 1 year of use.

**Materials and methods:** Patients with type 2 diabetes randomized to once-daily IDegLira, IDeg or Lira (1.8 mg), plus metformin  $\pm$  pioglitazone, continued their allotted treatment in the extension. IDegLira and IDeg were titrated to a FPG of 4–5 mmol/L (72–90 mg/dL).

**Results:** Of 1663 adults randomised in the main trial (mean age: 55 yr, BMI: 31.2 kg/m<sup>2</sup>), 1311 (78.8%) entered the extension: 665 (79.7%) patients on IDegLira, 333 (80.4%) on IDeg and 313 (75.4%) on Lira. Mean HbA<sub>1c</sub> was reduced from baseline by 1.8% (IDegLira), 1.4% (IDeg) and 1.2% (Lira) to end of trial values of 6.4%, 6.9% and 7.1%, respectively; 78% of patients on IDegLira achieved an HbA<sub>1c</sub> of <7% vs. 63% for IDeg and 57% for Lira. Mean FPG was similar for IDegLira (5.7 mmol/L; 103 mg/dL) and IDeg (6.0 mmol/L; 108 mg/dL) and higher for Lira (7.3 mmol/L; 132 mg/dL). At study end, daily insulin dose was 37% lower with IDegLira (39 U) vs. IDeg (62 U). IDegLira was associated with a mean weight reduction of 0.4 kg, and had a 37% lower rate of hypoglycaemia vs. IDeg. Fewer patients had gastrointestinal adverse events with IDegLira vs. Lira (nausea: 10.3% vs. 22.3%).

**Conclusion:** The improved glycaemic control and more favourable safety profile seen for IDegLira in the extension trial supports the sustainability of IDegLira over at least 1 year of treatment.

### Genetic risk score of 31 BMI loci and substantial weight change over a period of 50 years in the Malmö Diet and Cancer Study

G. Rukh<sup>1</sup>, U. Ericson<sup>1</sup>, G. Hindy<sup>1</sup>, O. Melander<sup>1</sup>, P. Nilsson<sup>2</sup>, M. Orho-Melander<sup>1</sup>;

<sup>1</sup>Department of Clinical Sciences in Malmö, Lund University Diabetes Center (LUDC), <sup>2</sup>Department of Internal Medicine, Skåne University Hospital, Lund University, Malmö, Sweden.

**Background and aims:** Body weight gain has increasingly become a public health threat worldwide as it is associated with many metabolic abnormalities conveying an increased morbidity and mortality. Our aim was to evaluate the contribution of genetic susceptibility defined as a genetic risk score (GRS) of 31 BMI associated single nucleotide polymorphisms (SNPs) to BMI at young, middle-age and older age, and to substantial weight gain (SWG) covering a mean time period of over 50 years starting from age of 20 years in a large Swedish cohort.

**Materials and methods:** Totally, 22634 non-diabetic participants (62% females) from the population based Malmö Diet and Cancer Study (MDCS) with baseline examinations 1990–1996 (age 57±8y, BMI 26±4kg/m<sup>2</sup>) and who in a questionnaire reported weight at 20 years of age (BMI 21±3kg/m<sup>2</sup>) as well as if their weight after 20 years of age had been stable, unstable, increased or decreased. A random sample of the MDCS (N=6,103), who were alive and had not emigrated from Sweden (N=4,924) were invited to a follow-up (FU) re-examination 2007–2012. Of these, 3734 subjects attended and 2676 with information of self-reported BMI from 20y were included in this study (58% females, age 73±6y, BMI 26±4kg/m<sup>2</sup>, FU time from baseline 16.5±1.5y and from 20y of age 52.8±5.6y). SWG was defined as gaining (i) ≥10% of self-reported weight at 20y until baseline, (ii) ≥10% of baseline weight until FU and (iii) ≥10% of self-reported weight at 20y until FU. A weighted GRS based on 31 GWAS identified BMI susceptibility loci was created. Linear regression was used to analyze the associated effect sizes (β) per increasing quintile of GRS on BMI at 20 years of age, at baseline and at the end of FU. Further, we used logistic regression to analyze the risk (OR) per GRS quintile for belonging to the self-reported unstable weight group (23.7% of all individuals), and for SWG from 20 years age to baseline and to FU, and from baseline to FU. All analyses were adjusted for age, sex and FU time when applicable.

**Results:** The GRS associated with higher BMI at all ages and with highest effect size at middle-age; 20y (β 0.03±0.01, p=2.0×10<sup>-37</sup>), baseline (β 0.23±0.02, p=1.8×10<sup>-34</sup>) and FU (β 0.20±0.06, p=0.003). The GRS associated with 10% increased risk per GRS quintile for having unstable weight from 20y to baseline (OR 1.10 [1.07–1.13], p=1.1×10<sup>-9</sup>) and with 4% increased risk of SWG (OR 1.04 [1.02–1.07], p=0.002) from 20y to baseline. The risk increase was 42% for unstable weight reporters (p=4.1×10<sup>-7</sup>) and 15% for SWG (p=0.016) for individuals in the highest GRS quintile compared to lowest. In contrast to this, the GRS did not associate with SWG from 20y to end of FU (OR 0.97 [0.90–1.05], p=0.47) and it associated with 10% decreased risk of SWG from baseline to FU (OR 0.90 [0.84–0.97]; p=0.004) and 26% decreased risk comparing highest to lowest quintiles of GRS (OR 0.74 [0.55–1.01]; p=0.061).

**Conclusion:** Our data suggest that BMI GRS associates with BMI at all adult ages and with unstable weight and substantial weight gain until the later middle age. However, our results indicate inversed association with weight gain at older ages. Whether the latter can be explained by the BMI GRS accentuating the age related loss of muscle mass, other age related weight loss, age related effects on appetite regulation, or other reasons, needs to be investigated in future studies.

### Effects of genetic and environmental influences on abdominal adipose tissue compartments and hepatic lipid accumulation: a classical twin study

A.L. Jermendy<sup>1</sup>, Z.D. Drobni<sup>1</sup>, T. Horvath<sup>1</sup>, C. Celeng<sup>1</sup>, A. Panajotu<sup>1</sup>, F.I. Suhai<sup>1</sup>, A.D. Tarnoki<sup>2</sup>, D.L. Tarnoki<sup>2</sup>, B. Merkely<sup>1</sup>, P. Maurovich-Horvat<sup>1</sup>, G. Jermendy<sup>3</sup>;

<sup>1</sup>MTA-SE Lendulet Cardiovascular Imaging Research Group,

<sup>2</sup>Semmelweis University Department of Radiology and Oncotherapy,

<sup>3</sup>Bajcsy-Zsilinszky Hospital, Budapest, Hungary.

**Background and aims:** In patients with diabetes and/or obesity, accumulation of abdominal adipose tissue and non-alcoholic fatty liver disease (NAFLD) are linked to increased cardiometabolic risk. Little is known about the genetic and environmental effects on the distribution of the abdominal adipose tissue compartments and hepatic lipid accumulation. The aim of the study was to assess the magnitude of genetic and environmental impact on the size of various abdominal adipose tissue compartments and the hepatic lipid accumulation within a cohort of healthy twin pairs.

**Materials and methods:** In this classical twin study, 136 adult twin subjects (58.8% women; age: 56.8±9.3 years, weight: 77.1±17.2 kg, BMI 27.3±4.9 kg/m<sup>2</sup> [x±SD], 37 monozygotic [MZ] and 31 dizygotic [DZ] pairs) were involved. The twin pairs were investigated with a 256-slice CT-scanner. A 2 mm thick axial slice was acquired at the level of L3–L4. Subsequently a 50 mm wide axial image slab was acquired below the diaphragm. For each patient CT-based measurement of waist circumference, subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) quantification were performed. Liver and spleen attenuation was determined by calculating the average of three 300 mm<sup>2</sup> ROIs (regions of interest). Hepatic lipid accumulation was characterized by attenuation ratios (CT<sub>L/S</sub>) and ratio of ≤0.9 was assessed as sign of NAFLD. Concordance between MZ and DZ pairs was assessed by Pearson correlations. For assessing heritability of abdominal adipose tissue compartments and that of hepatic lipid accumulation, the structural equation (A-C-E) model was used.

**Results:** Comparing MZ to DZ twin pairs, no significant differences were found in age (55.9±9.7 vs. 58.2±8.8 years), in BMI (27.2±3.9 vs. 26.5±4.0 kg/m<sup>2</sup>), in waist circumference (94.0±12.9 vs. 95.4±13.1 cm), in SAT (206.0±79.9 vs. 200.9±83.1 cm<sup>2</sup>), in VAT (159.9±91.0 vs. 143.0±77.6 cm<sup>2</sup>), and in CT<sub>L/S</sub> ratio (1.1±0.2 vs 1.2±0.2); p>0.05 for all comparison. Strong correlations among BMI, SAT and VAT values were found in MZ twin pairs (r=0.63 [95% CI 0.34 - 0.84], r=0.74 [95% CI 0.54 - 0.90], r=0.60 [95% CI 0.34 - 0.79], respectively) whereas these correlations were weak or absent in DZ twin pairs (r=0.08 [95% CI -0.43 - 0.43], r=0.35 [95% CI 0.00 - 0.64], r=0.20 [95% CI -0.16 - 0.51], respectively). As for hepatic lipid accumulation, correlations among CT<sub>L/S</sub> values were absent in both MZ pairs (r=0.30, 95% CI -0.16 - 0.67) and DZ pairs (r=0.15, 95% CI -0.15 - 0.55). Using the structural equation (A-C-E) model, relatively strong heritability index was found regarding BMI (58%, 95% CI 18–85%), SAT (74%, 95% CI 43–93%) and VAT (59%, 95% CI 22–82%) whereas environmental influences predominated in hepatic lipid accumulation (additive genetic effect 30% [95% CI 0–75%], shared environmental effect 1% [95% CI 0–41%], unique environmental effect 69% [95% CI 32–100%]).

**Conclusion:** Both BMI and abdominal adipose tissue compartments (SAT and VAT) have relatively strong heritability whereas hepatic lipid accumulation (presence of NAFLD) is predominantly influenced by environmental factors.

<sup>2</sup>Departement of Radiology, VU University Medical Centre, <sup>3</sup>Departement of Psychiatry, VU University Medical Centre, Amsterdam, Netherlands.

**Background and aims:** The central nervous system (CNS) plays a major role in the regulation of feeding and maintenance of body weight. Food ingestion activates the secretion of gut-hormones, such as glucagon-like peptide-1 (GLP-1). GLP-1 has been proposed to be involved in the CNS regulation of feeding, by relaying information about the nutritional status to the CNS. We

hypothesised that endogenous GLP-1 has effects on central reward and satiety circuits in overweight individuals with diabetes and healthy, lean individuals. **Materials and methods:** We included overweight patients with type 2 diabetes (T2DM) ( $n=20$ , mean  $\pm$  SD age  $59.3 \pm 4.1$  yrs, BMI  $32.0 \pm 4.7$  kg/m<sup>2</sup>, 11 males) and age matched healthy, lean controls ( $n=20$ , mean  $\pm$  SD age  $56.3 \pm 6.2$  yrs, BMI  $22.5 \pm 1.7$  kg/m<sup>2</sup>, 10 males). Using functional MRI (fMRI), we determined the effects of blocking endogenous GLP-1 on CNS responses to visual food-cues before and after a standardized liquid meal. To block the endogenous GLP-1 effects, intravenous administration of the GLP-1 receptor antagonist exendin 9-39 (ex9-39) was used and compared to placebo infusion. During the fMRI session, subjects were presented pictures of high calorie, low calorie and non-food objects. Imaging data were analysed using SPM8 and activation contrasts were computed (food vs. non-food).

**Results:** In the fasting state, obese T2DM patients versus lean individuals showed increased brain activation in response to food pictures within left amygdala, right orbitofrontal cortex and bilateral insula. The standardized meal reduced these hyperactivations in bilateral insula in patients with T2DM. Blocking endogenous GLP-1 with ex9-39 partly prevented this meal induced reduction in brain activations. In healthy lean individuals, the standardized meal also reduced activation in the insula in response to food pictures, however to a lesser extent and only in right insula. Blocking endogenous GLP-1 with ex9-39 did not prevent this meal induced reduction in brain activations.

**Conclusion:** Patients with T2DM showed increased brain activations in response to food pictures in areas involved in reward and satiety while fasted. Intake of a meal reduced these brain responses and this effect was blunted with blockade of endogenous GLP-1. These effects could not be detected in healthy, lean individuals. The lower brain activation in response to food pictures in healthy lean individuals at baseline, may have decreased the likelihood to detect changes in these brain activation after a meal with or without blocking endogenous GLP-1. Our findings in patients with T2DM support the hypothesis that endogenous GLP-1 is involved in the regulation of central reward and satiety.

### A high fat diet during pregnancy and lactation affects the metabolic fate of Gpr-/- mice via hypothalamic insulin signalling and DNA-methylation of lipid metabolism genes

F. Keyhani Nejad<sup>1,2</sup>, F. Isken<sup>1,2</sup>, M.A. Osterhoff<sup>1,2</sup>, B. Nitz<sup>3,4</sup>, T. Ludwig<sup>4</sup>, H. Grallert<sup>3,4</sup>, A.F.H. Pfeiffer<sup>1,2</sup>, M. Kruse<sup>1,2</sup>;

<sup>1</sup>Department of Clinical Nutrition, German Institute of Human Nutrition, Nuthetal, <sup>2</sup>Department for Endocrinology, Diabetes and Nutrition, Charité – University of Medicine, Berlin, <sup>3</sup>Research Unit of Molecular Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, <sup>4</sup>Institute of Epidemiology II, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany.

**Background and aims:** Maternal high-fat (HF) feeding during intra-uterine (IU) and lactation (L) periods predisposes the offspring for obesity and impaired glucose homeostasis in mice. Inhibition of Glucose-dependent insulinotropic polypeptide (GIP) signaling in GIP receptor knockout mice (Gpr-/-) leads to protection from HF induced obesity. We reported that Gpr-/- mice exposed to HF during IU/L were no longer protected from diet induced obesity and had a decreased glucose tolerance in adulthood. We hypothesized that the metabolic programming of IU/L HF consumption triggers hypothalamic insulin resistance and promoter DNA methylation of key genes in fat metabolism and their subsequently altered gene expression in Gpr-/- mice.

**Materials and methods:** Female GIP receptor heterozygous (Gpr+/-) mice were fed either a HF (60% fat) or control (C, 10% fat) diet for 2 weeks prior to gestation and during IU/L. After weaning, male Gpr-/- and wild type (WT) offspring were kept on normal chow until the age of 25 weeks, after which all offspring were exposed to HF for the following 20 weeks. This resulted in Gpr-/- which were exposed to either a C (KO Ciu-HF) or a HF (KO HFiu-HF) diet during IU/L and a HF later in adulthood. WT mice fed a control diet during IU/L and a HF in adulthood served as controls (WT Ciu-HF). A glucose tolerance test (GTT) was performed by i.p. injection of 2 g/kg BW glucose. At 45 weeks of age, body fat content, adipocyte size and genes involved in hypothalamic insulin sensitivity and DNA-methylation of fatty acid oxidation genes in muscle were analyzed.

**Results:** Body fat content significantly increased in KO HFiu-HF compared to KO Ciu-HF ( $22.6 \pm 2.5$  g vs.  $19.5 \pm 0.8$  g, respectively;  $p<0.05$ ).

KO HFiu-HF showed significantly larger adipocytes compared to KO Ciu-HF ( $p<0.005$ ). KO HFiu-HF and WT Ciu-HF mice had significantly higher plasma glucose levels compared to KO Ciu-HF (AUC:  $3,784.5 \pm 284.9$  and  $3,836.9 \pm 180.2$  vs.  $2,829.5 \pm 256.3$  mmol/l\*min, respectively; all  $p<0.05$ ). In KO Ciu-HF hypothalamic gene expression of PI3K subunit p85 $\alpha$  was 22% down regulated compared to WT Ciu-HF mice ( $p<0.01$ ) and back up regulated 1.27 fold in KO HFiu-HF compared to KO Ciu-HF ( $p<0.05$ ). Expression levels of PPAR $\alpha$  and CPT-1 $\beta$ , the key enzymes of fatty acid oxidation, were massively increased in KO Ciu-HF compared to WT Ciu-HF mice (2.45-fold for PPAR $\alpha$  and 1.53-fold for CPT-1 $\beta$ ,  $p<0.01$ ), but then down regulated 41% for CPT-1 $\beta$  and 45.2% for PPAR $\alpha$  in KO HFiu-HF compared to KO Ciu-HF ( $p<0.05$ ) in muscle. One CpG-site of PPAR $\alpha$  and three CpG-sites of CPT-1 $\beta$  showed hypomethylation in KO Ciu-HF compared to WT Ciu-HF and KO HFiu-HF. DNA-methylation was inversely correlated with gene expression.

**Conclusion:** Consuming a HF diet during IU/L leads to reduced central insulin sensitivity and can change the offspring's epigenetic marks resulting in decreased peripheral fatty acid oxidation, which reverses the protection of diet induced obesity in Gpr-/- mice.

## 83

### Weight loss normalises lowered mu-opioid receptor availability in the morbidly obese

H.K. Karlsson<sup>1</sup>, J.J. Tuulari<sup>1</sup>, L. Tuominen<sup>1,2</sup>, H. Honka<sup>1</sup>, J. Hirvonen<sup>1,3</sup>, P. Salminen<sup>4</sup>, P. Nuutila<sup>1,5</sup>, L. Nummenmaa<sup>1,6</sup>,  
<sup>1</sup>Turku PET Centre, <sup>2</sup>Department of Psychiatry, Turku University Hospital, <sup>3</sup>Department of Radiology, Turku University Hospital, <sup>4</sup>Department of Surgery, Turku University Hospital, <sup>5</sup>Department of Endocrinology, Turku University Hospital, <sup>6</sup>Department of Biomedical Engineering & Computational Science, Aalto University School of Science, Espoo, Finland.

**Background and aims:** Neurochemical pathways involved in overeating and obesity are poorly understood. Our previous positron emission tomography (PET) studies suggest that morbidly obese versus normal-weight human subjects have lower mu-opioid receptor (MOR) availability but unaltered dopamine D2 receptor (D2R) availability in the brain. Investigating the effects of weight loss could reveal whether altered receptor availability is a state or a trait of obesity.

**Materials and methods:** We recruited 21 morbidly obese women (mean BMI 41, mean age 42), with nine having type 2 diabetes (T2DM), eligible for bariatric surgery, and measured their brain D2R availability using PET with [<sup>11</sup>C]raclopride and MOR availability with [<sup>11</sup>C]carfentanil before and six months after the bariatric surgery. 14 non-obese age-matched healthy women (mean BMI 23, mean age 45) formed the control group. Receptor availability was assessed as the binding potential (BPND). Both ROI-based statistics and statistical parametric mapping were used to compare the parametric BPND maps within subjects (pre- vs. postoperative).

**Results:** Average weight loss after surgery was 25 kg. T2DM recovered in six subjects. Weight loss normalized lowered [<sup>11</sup>C]carfentanil BPND in the morbidly obese, with on average 31 % higher MOR binding in the postoperative scan (Figure 1). Significant changes were observed in several areas implicated in reward processing, including ventral striatum, dorsal caudate, insula, amygdala, thalamus and anterior cingulate cortex ( $ps < 0.005$ ). However, weight loss did not influence [<sup>11</sup>C]raclopride binding in any brain region (Figure 1). Glycaemic status did not affect the receptor density before or after weight loss.

**Conclusion:** Endogenous opioid system plays an important role in the pathophysiology of obesity while the role of dopaminergic pathways remains questionable. Because bariatric surgery and concomitant weight loss recovers MOR availability, lowered MOR availability is a consequence of obesity and may mediate maintenance of excessive energy uptake. Understanding the opioidergic contribution to overeating is thus critical for developing new treatments for obesity.

### KBP-042 lowers body-weight and sustains weight-loss in high fat-diet rats

S.T. Hjuler, S. Gydesen, K.V. Andreassen, M.A. Karsdal, K. Henriksen; Diabetes group, Nordic Bioscience, Herlev, Denmark.

**Background and aims:** KBP-042 is a dual amylin- and calcitonin receptor agonist, with superior activity compared to salmon calcitonin. In this study we evaluated the long term potential of KBP-042 as a treatment against obesity. We evaluated body weight, adiposity, glucose tolerance and insulin action in a rat model of obesity.

**Materials and methods:** Male sprague-Dawley rats were fed a high fat-diet for ten weeks resulting in an obese and glucose intolerant phenotype. Based on body weight the rats were randomized into the treatment groups: Vehicle (saline), 0.625  $\mu\text{g}/\text{kg}$ , 1.25  $\mu\text{g}/\text{kg}$ , 2.5  $\mu\text{g}/\text{kg}$ , 5.0  $\mu\text{g}/\text{kg}$ , 10.0  $\mu\text{g}/\text{kg}$  KBP-042 s.c. once daily ( $n=10$ ), as well as pair-fed controls for the two highest concentration groups (pair-fed 10  $\mu\text{g}/\text{kg}$  and pair-fed 5  $\mu\text{g}/\text{kg}$ ) which were food restricted to match the food intake of the 10  $\mu\text{g}/\text{kg}$  and 5  $\mu\text{g}/\text{kg}$  groups.

**Results:** A dose-dependent and sustained weight-loss was obtained. For the KBP-042 10  $\mu\text{g}/\text{kg}$  group the treatment resulted in a 4.7 % weight reduction (20 % vehicle-corrected), while only a transient change in food intake. Furthermore, while the pair-fed groups did not lower body weight, they did not match the extent of their corresponding treatment group, +5.6 % and +7.1 % respectively (-5.6 % and -8.0 % vehicle-corrected). Adiposity was vastly improved after treatment with KBP-042. The visceral fat depots were significantly reduced (~40% perirenal AT:  $p<0.01$  10  $\mu\text{g}/\text{kg}$  vs. vehicle, ~33% epididymal AT  $p<0.05$  10 $\mu\text{g}/\text{kg}$  vs. vehicle), and the subcutaneous inguinal AT was significantly reduced (~35%  $p<0.05$  10 $\mu\text{g}/\text{kg}$  vs. vehicle) all depots were lowered in a dose-dependent manner. For all the depots that we measured, we observed no difference between the pair-fed groups and vehicle. The treatment groups showed improved glucose tolerance both in the oral glucose tolerance test (OGTT) (21 %  $p<0.001$  vehicle vs. 10  $\mu\text{g}/\text{kg}$  and 17 %  $p<0.001$  vehicle vs. 5  $\mu\text{g}/\text{kg}$ ) and in the intravenous glucose tolerance test (IVGTT) (10 %  $p<0.02$  vehicle vs. 10  $\mu\text{g}/\text{kg}$ ) without increasing insulin levels. Furthermore, the incretin GIP was significantly lowered after oral glucose load for the 2.5  $\mu\text{g}/\text{kg}$ , 5  $\mu\text{g}/\text{kg}$  and 10  $\mu\text{g}/\text{kg}$  groups ( $p<0.01$  vs. vehicle) while there were no changes in the pair-fed groups.

**Conclusion:** In conclusion KBP-042 induced and sustained a significant and dose-dependent weight-loss, reduced adiposity and improved the glucose tolerance in high-fat diet rats, independent of calorie-restriction. This study demonstrates KBP-042 as a therapeutic agent against obesity in an intervention model of obesity.

## OP 15 Diabetic nephropathy: epidemiology and genetics

85

### Prevalence of nonalbuminuric chronic kidney disease (CKD) is increasing in patients with type 1 diabetes mellitus

E. Russo<sup>1</sup>, G. Penno<sup>1</sup>, M. Garofolo<sup>1</sup>, D. Lucchesi<sup>1</sup>, L. Pucci<sup>2</sup>, V. Sancho Bornez<sup>1</sup>, L. Giusti<sup>1</sup>, R. Bellante<sup>1</sup>, R. Russo<sup>2</sup>, R. Miccoli<sup>1</sup>, S. Del Prato<sup>1</sup>;

<sup>1</sup>Endocrinology and Metabolism, University of Pisa,

<sup>2</sup>Institute of Agricultural Biology and Biotechnology, CNR, Pisa, Italy.

**Background and aims:** According to traditional paradigms of diabetic nephropathy, albuminuria precedes glomerular filtration rate (GFR) loss in the progression to CKD. However, even in type 1 DM (T1DM), recent findings (DCCT/EDIC) demonstrate that GFR loss may occur in normoalbuminuria. We compared prevalence of different CKD phenotypes in two cohorts of Italian T1DM subjects.

**Materials and methods:** The first cohort (C1) consisted of 777 T1DM recruited 2001–2009 at our Metabolic Unit; the second cohort (C2) consisted of 936 T1DM belonging from the EURODIAB IDDM Complications Study (they attended 9 Italian centres in 1989–1991). Eligibility criteria were the same for both cohorts. However, C2 was stratified at enrollment by sex, age (15–29, 30–44, 45–59 yrs) and duration (1–7, 8–14,  $\geq 15$  yrs). Methods employed to assess diabetic complications were similar.

**Results:** Gender distribution (M/F: 52/48% vs 51/49%) and current smokers (29.6% vs 30.4%) were similar. Due to inclusion criteria, C1 were older (40.2 $\pm$ 11.7 vs 32.1 $\pm$ 10.5) and had longer diabetes duration (19.4 $\pm$ 12.2 vs 14.4 $\pm$ 9.0 years; both  $p < 0.0001$ ). C1 had higher BMI, sBP and hypertension rate (35.2% vs 21.9%), lower total- and LDL-C (higher rate of lipid-lowering treatment: 12.9% vs 2.4%), higher HDL-C ( $p < 0.0001$  for all), with no differences in triglycerides. HbA1c was slightly lower in C1 (7.83 $\pm$ 1.17 vs 8.08 $\pm$ 1.79%,  $p = 0.0008$ ). C1 were more frequently on BP-lowering drugs (19.4% vs 9.4%) and RAS blockers (17.5% vs 6.7%, both  $p < 0.0001$ ). Prevalence of any retinopathy was similar (41.3% vs 41.2%), while proliferative retinopathy was more frequent in C1 (15.6% vs 8.8%,  $p < 0.0001$ ), with no difference in CV events (8.5% vs 9.9%). Albuminuria was more frequent in C2: rates of normo- (nA, ACR  $< 30$  mg/g), micro- (ACR 30–299) or macro- (ACR  $\geq 300$ ) were 91.6, 6.4 and 1.9% in C1, and 79.2, 14.1 and 6.7% in C2 ( $p < 0.0001$ ). Stage 1 ( $\geq 90$ ), 2 (60–89) and  $\geq 3$  ( $< 60$  ml/min/1.73m<sup>2</sup>, MDRD) eGFR were 57.3, 39.0 and 3.7% in C1, and 84.8, 13.2 and 1.9% in C2 ( $p < 0.0001$ ). In C1, 89.4% had no-CKD; 6.8% stages 1–2 and 3.7% stages  $\geq 3$  CKD; in C2, 78.6, 19.5 and 1.9%, respectively ( $p < 0.0001$ ). The albuminuric (Alb+) and non-albuminuric (Alb-) phenotypes were present in 41.4 and 58.6% of stages  $\geq 3$  in C1 vs 72.2 and 27.8% in C2 ( $p < 0.039$ ). In both cohorts, nA was splitted in “normal albuminuria” (ACR  $< 10$  mg/g) and “low-microalbuminuria” (ACR 10–29 mg/g); stages 1–2 was stratified in 2a (75–89) and 2b (60–74 ml/min/1.73m<sup>2</sup>). Also in 2b eGFR, nA was common and more frequent in C1 than C2 (88.7% vs 67.5%,  $p = 0.006$ ). Considering 2b and  $\geq 3$  CKD as a whole, nA was present in 80% of C1 and 55% of C2 ( $p = 0.001$ ); “normal albuminuria” in 60 and 29%, respectively ( $p = 0.0001$ ).

**Conclusion:** Nonalbuminuric renal function impairment is detectable in a high proportion of T1DM. Thought several factors may contribute to explain the differences in the rate nonalbuminuric CKD phenotypes between the two cohorts, the possibility of really increasing incidence of the nonalbuminuric phenotypes, likely driven by improvements in care, cannot be ruled-out.

Diabetes Unit, San Raffaele Scientific Institute, Milan, <sup>6</sup>Endocrinology and

Diabetes Unit, Ospedali Riuniti, Bergamo, <sup>7</sup>Department of Clinical and

Experimental Medicine, University of Padua, <sup>8</sup>Department of Clinical and

Biological Sciences, University of Turin, Orbassano, <sup>9</sup>Department of Internal

Medicine, University of Turin, <sup>10</sup>Department of Medical Sciences, University

of Foggia, <sup>11</sup>Department of Clinical and Molecular Medicine, La Sapienza

University, Rome, Italy.

**Background and aims:** Higher values of albumin excretion rate (AER) within the normoalbuminuric range are known to correlate with higher cardiovascular disease (CVD) and renal risk. This cross-sectional analysis was aimed at assessing the determinants of AER in normoalbuminuric subjects with type 2 diabetes from the Renal Insufficiency And Cardiovascular Events (RIACE) Italian Multicenter Study.

**Materials and methods:** The RIACE cohort consists of 15,773 patients, consecutively visiting 19 Diabetes Clinics throughout Italy in years 2007–2008. Exclusion criteria were dialysis or renal transplantation. AER was measured by immunonephelometry or immunoturbidimetry and eGFR was calculated by the MDRD study and the CKD-EPI equation. The 11,538 subjects with normoalbuminuria (73.2% of the entire cohort) were stratified in those with normal albuminuria (NA, AER  $< 10$  mg/24h;  $n = 6,023$ , 52.2%) and low albuminuria (LA, AER = 10–29 mg/24h,  $n = 5,515$ , 47.8%).

**Results:** Compared with NA subjects, LA patients were more frequently males and former or current smokers, had longer diabetes duration, higher HbA<sub>1c</sub>, diastolic blood pressure, and, in men only, BMI waist circumference, triglycerides, and LDL-cholesterol (in men only), and higher prevalence of family history of hypertension, use of antihypertensive drugs and oral hypoglycaemic agents (OHA) or insulin, hypertension, and the metabolic syndrome. Moreover, patients with LA had higher prevalence of: non-advanced (12.1% vs. 9.9%) and advanced (7.6% vs. 6.5%) retinopathy ( $p < 0.0001$ ); any CVD (21.9% vs. 17.9%,  $p < 0.0001$ ); myocardial infarction (10.6% vs. 9.3%,  $p = 0.019$ ); and coronary (15.0% vs. 12.5%,  $p < 0.0001$  in males only) and peripheral (4.7% vs. 3.6%,  $p = 0.003$  in females only) artery disease. eGFR correlated significantly with AER ( $p < 0.0001$ ), though prevalence of LA increased only from category 3b for eGFR<sub>MDRD</sub> and 3a for eGFR<sub>CKD-EPI</sub>. Logistic regression with backward variables selection showed an independent correlation of LA with age (OR = 1.018), smoking status (former, OR = 1.158; current, OR = 1.234), HbA<sub>1c</sub> (OR = 1.065), triglycerides (OR = 1.001), diastolic BP (OR = 1.010), waist circumference (OR = 1.004), use of RAS blockers (OR = 1.081) or DHP Ca-channel blockers (OR = 1.178), use of OHA (OR = 1.324), OHA+insulin (OR = 1.378), or insulin alone (OR = 1.535), and family history of hypertension (OR = 1.321).

**Conclusion:** Several factors that are potentially amenable of intervention are associated with an early increase of AER within the normoalbuminuric range in patients with type 2 diabetes from the RIACE cohort.

## Kidney injury molecule - 1 is linked to the loss of kidney function and life span, in patients with type 1 diabetes

N.M. Panduru<sup>1,2</sup>, N. Sandholm<sup>2</sup>, C. Forsblom<sup>2</sup>, V. Harjutsalo<sup>2,3</sup>, A. Bierhaus<sup>4</sup>, M. Saraheimo<sup>5</sup>, P. Humpert<sup>6</sup>, P.-H. Groop<sup>5,2</sup>;

<sup>1</sup>2nd Clinical Department - Diabetes, Nutrition and Metabolic Diseases Chair, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, <sup>2</sup>Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland, <sup>3</sup>Diabetes Prevention Unit, National Institute for Health and Welfare, Helsinki, Finland, <sup>4</sup>Department of Medicine I and Clinical Chemistry, University of Heidelberg, Germany, <sup>5</sup>Division of Nephrology - Department of Medicine, Helsinki University Central Hospital, Finland, <sup>6</sup>Stoffwechselforschungszentrum Rhein Pfalz, Mannheim, Germany.

**Background and aims:** We previously showed that kidney injury molecule 1 (KIM-1) predicts progression to ESRD, but its relation with kidney function and mortality in patients with type 1 diabetes is not very clear. The aim of this study is to investigate if KIM-1 predicts and has a causal role in the loss of kidney function or life span by a Mendelian randomisation approach.

**Materials and methods:** We enrolled at baseline 1573 patients with type 1 diabetes divided in three groups: 953 patients with normal AER, 269 patients with microalbuminuria and 350 patients with macroalbuminuria. KIM-1 was measured at baseline, by ELISA and normalized with urinary creatinine. Kidney function was evaluated by estimated GFR according to CKD-EPI formula. Life span was considered the vital time. The predictive value of KIM-1 for the loss of kidney function and life span was evaluated by linear regression. Multiple linear regression models estimated the observed effect (association) of KIM-1 on eGFR or life span. We assessed the causal effect of KIM-1 on eGFR and life span, by Instrumental variable analysis, using two stage least squares method (2SLS), with the top SNP associated with KIM-1 from our GWAS.

**Results:** In linear regression analysis KIM-1 predicted the loss of GFR in univariate analysis ( $\beta = -4.522$ ;  $P < 0.0001$ ), but not when adjusted for albumin excretion rate (AER) ( $\beta = 0.336$ ;  $P = 0.70$ ). Also KIM-1 predicted the life span in univariate linear regression analysis ( $\beta = 0.812$ ;  $p = 0.006$ ), adjusted for AER ( $\beta = 1.103$ ;  $P < 0.0001$ ), but not eGFR ( $\beta = 0.318$ ;  $P = 0.26$ ). In our GWAS the single nucleotide polymorphism - rs2036402 presented the strongest association with KIM-1 ( $p = 3.54 \times 10^{-38}$ ). The instrumental analysis (IV), showed that increased KIM-1 was associated with decreased eGFR, even after adjusting for AER ( $\beta = -5.981$ ;  $P = 0.021$ ). Furthermore, the IV analysis showed that increased KIM-1 was associated with life span even adjusted for AER ( $\beta = 1.920$ ;  $p = 0.038$ ), but not when adjusted for eGFR ( $\beta = 1.167$ ;  $p = 0.19$ ).

**Conclusion:** In summary, increased KIM-1 levels is associated with decreased eGFR in patients with type 1 diabetes. Furthermore KIM-1 is associated with life span, in the same patients and this association seems to be mediated by eGFR.

## A novel podocyte gene, R3h domain containing-like inhibits non-canonical TGF-beta signalling

T. Ishikawa<sup>1</sup>, M. Takemoto<sup>1</sup>, Y. Akimoto<sup>2</sup>, K. Yan<sup>3</sup>, S. Kenichi<sup>1</sup>, P. He<sup>1</sup>, R. Ishibashi<sup>1</sup>, Y. Maezawa<sup>1</sup>, C. Betsholtz<sup>4</sup>, K. Tryggvason<sup>5</sup>, K. Yokote<sup>1</sup>;

<sup>1</sup>Department of Clinical Cell Biology and Medicine, Chiba University Graduate School of Medicine, <sup>2</sup>Department of Anatomy, Kyorin University School of Medicine, Tokyo, <sup>3</sup>Department of Pediatrics, Kyorin University School of Medicine, Chiba, Japan, <sup>4</sup>Department Immunology, Genetics and Pathology, Rudbeck Laboratory, Uppsala University, Sweden, <sup>5</sup>Diabetes Research, Duke-NUS, Singapore.

**Background and aims:** Diabetic nephropathy (DN) is a major microvascular complication of diabetes mellitus and is one of the most common causes of end-stage renal disease. However, the molecular mechanisms underlying DN remain largely unknown. We previously identified >300 glomerulus-enriched transcripts, including R3h domain containing-like (R3hdml), through large-scale sequencing and microarray profiling of the mouse glomerular transcriptome. Therefore, the aim of this study was to analyze both the in vivo and in vitro functions of R3hdml.

**Materials and methods:** R3hdml mRNA expression was examined in mice by non-radioactive in situ hybridization, and protein expression was evalu-

ated by immunohistochemistry (IHC) or western blot (WB) analysis. Cultured murine podocytes, R3hdml knockout (R3hKO) podocytes, and human fibroblasts overexpressing R3hdml were used for in vitro analysis. The effects of transforming growth factor- $\beta$  (TGF- $\beta$ ) on R3hdml expression and function were evaluated by real-time polymerase chain reaction and WB analysis. R3hdml knockout mice were generated by homologous recombination. Diabetes was induced in mice by intraperitoneal injection of streptozotocin (STZ).

**Results:** Both R3hdml mRNA and protein were specifically expressed in glomerular podocytes. TGF- $\beta$  has been reported to play a major role in DN. Therefore, we evaluated the effects of TGF- $\beta$  on R3hdml expression and function. TGF- $\beta$  can activate not only Smad-dependent pathways but also non-Smad pathways, including the non-canonical p38 mitogen-activated protein kinase (MAPK) pathway. When human fibroblasts were treated with TGF- $\beta$ , phosphorylation of p38 MAPK (pp38MAPK) increased by  $2.26 \pm 0.15$ -fold (mean  $\pm$  SEM). On the other hand, TGF- $\beta$ -induced pp38MAPK expression was significantly (54%) reduced in human fibroblasts overexpressing R3hdml. Smad phosphorylation was independent of R3hdml, indicating that R3hdml inhibited the non-Smad pathway but not the Smad-dependent pathway. Furthermore, TGF- $\beta$  increased pp38MAPK by  $2.35 \pm 0.01$ -fold in primary cultured podocytes. TGF- $\beta$ -induced pp38MAPK was significantly higher (2.03-fold) in R3hKO podocytes than in the wild-type (WT) controls. R3hKO mice showed aberrant podocyte structure and partial thickening of the glomerular basement membrane. Furthermore, IHC revealed that pp38MAPK was increased by  $2.14 \pm 0.490$ -fold in R3hKO glomeruli compared with the WT controls. R3hdml mRNA expression in the glomeruli was increased by  $2.7 \pm 0.73$ -fold in the diabetic mice compared with the WT controls. Finally, we induced diabetes in both the WT and R3hKO mice by STZ injection and found that the prevalence of albuminuria was significantly increased in the diabetic and R3hKO mice compared with the diabetic WT controls.

**Conclusion:** We identified a novel podocyte-specific gene, R3hdml, which is regulated by TGF- $\beta$  signaling. This gene product inhibits TGF- $\beta$ -induced p38 MAPK signaling. Our results suggest that podocyte-specific therapy presents a viable option to inhibit DN in the near future.

## ABCG8 polymorphisms and renal disease in type 2 diabetic patients

F. Fumeron<sup>1</sup>, A. Nicolas<sup>1</sup>, S. Fatima<sup>1</sup>, N. Munoz-Bellili<sup>1</sup>, P.-J. Saulnier<sup>2</sup>, S. Hadjadj<sup>2,3</sup>, G. Velho<sup>1</sup>, M. Marre<sup>1,4</sup>, R. Roussel<sup>1,4</sup>;

<sup>1</sup>INSERM U1138, Centre de Recherche des Cordeliers, Paris, <sup>2</sup>Université de Poitiers, UFR de Médecine et Pharmacie, Poitiers, <sup>3</sup>INSERM, U1082, Poitiers, <sup>4</sup>Department of Diabetology, Endocrinology and Nutrition, Assistance Publique Hôpitaux de Paris, Bichat Hospital, France.

**Background and aims:** The ATP-binding cassette transporters G5 and G8 (ABCG5 and ABCG8) play an important role in the intestinal sterol absorption and biliary acid secretion. They are involved in the elimination of plant sterols. Polymorphisms of the genes coding for these transporters have been involved in absorption of sterols, cholesterol synthesis, gallstone disease, insulin resistance and cardiovascular risk. Lipid metabolism and insulin resistance are associated with diabetic nephropathy. The aim of our study was to assess the associations between two ABCG8 coding polymorphisms, T400K and D19H, and the incidence of renal events in type 2 diabetic subjects.

**Materials and methods:** First, participants were the 3,123 French type 2 diabetic subjects with micro- or macro-albuminuria from the genetic substudy of the DIABHYCAR trial. These participants had serum creatinine concentrations  $\leq 150$   $\mu\text{mol/l}$ . The drug tested against placebo was low-dose ramipril (1.25 mg/day). The mean duration of follow-up was 4 years. Renal events were defined as a doubling of serum creatinine concentration or end-stage renal disease at follow-up. This trial showed no effect of the drug on the incidence of renal events. We then used a second population (DIAB2NEPHROGENE/SURDIAGENE study) of 2,452 patients with type 2 diabetes for the purpose of replication. Polymorphisms T400K and D19H were genotyped using Kasper method. The genotyping success rate was > 98%.

**Results:** Seventy-five renal events (66 doublings of serum creatinine concentration, and 9 cases of end-stage renal failure) occurred in genotyped patients during the study. The 400K allele was significantly associated with a higher risk of incident renal event: sex and age adjusted OR 1.66, 95%CI 1.15-2.39,  $P = 0.007$ . This association was still significant after multiple additional adjustments for values at baseline (BMI, blood lipids, estimated glomerular filtration rate, urinary albumin excretion): OR 1.57, 95%CI 1.07-2.31,  $P = 0.02$ . There was a trend toward an interaction with ramipril treatment ( $P$  interaction = 0.06). The 400K allele was associated with a higher risk in the ramipril

treated group (OR 2.41, 95%CI 1.41–4.13,  $P < 0.001$ ) but not in the placebo group (OR 1.21, 95%CI 0.72–2.03). In the replication cohort, no association was found with the incidence of new renal events, but the 400K allele was associated with the prevalence of end stage renal disease at baseline (sex, age, BMI adjusted OR 1.77, 95%CI 1.01–3.10,  $P = 0.045$ ). No significant association was found between the D19H polymorphism and the risk of diabetic nephropathy.

**Conclusion:** A polymorphism of the sterol transporter ABCG8 has been associated with prevalence of end stage renal disease and with the incidence of new renal events in type 2 diabetic patients. These results described for the first time should be replicated.

## 90

### Genome-wide association studies of diabetic kidney disease

E. Ahlqvist<sup>1</sup>, H.A. Deshmukh<sup>2</sup>, N. Sandholm<sup>3,4</sup>, C. Ladenvall<sup>1</sup>, N. Van Zuydam<sup>5</sup>, M. Lajer<sup>6</sup>, L. Marcovecchio<sup>7</sup>, E. Rurali<sup>8</sup>, W.N. Rayner<sup>5</sup>;

<sup>1</sup>Department of Clinical Sciences, Lund University, Malmö, Sweden, <sup>2</sup>Ninewells Hospital and Medical School, University of Dundee, UK, <sup>3</sup>Folkhälsan Research Center, Helsinki, Finland, <sup>4</sup>Division of Nephrology, Helsinki University Central Hospital, Finland, <sup>5</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, UK, <sup>6</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>7</sup>Department of Paediatrics, University of Cambridge, UK, <sup>8</sup>Istituto di Ricerche Farmacologiche “Mario Negri”, IRCCS, Bergamo, Italy.

**Background and aims:** Diabetes mellitus is associated with devastating chronic complications including diabetic kidney disease (DKD), a leading cause of end-stage renal disease (ESRD). The risk of developing DKD is partly determined by genetic factors. In the SUMMIT consortium we performed meta-analysis of genome-wide association studies in European T1D and T2D patients to identify genetic determinants of DKD. The genetic variants regulating early stages of disease may differ from those that determine progression to severe disease. We therefore analyzed microalbuminuria (MiAU), reflecting early pathologic changes and endothelial dysfunction, and more severe DKD, i.e. macroalbuminuria (MaAU), chronic kidney disease (CKD) and ESRD, separately.

**Materials and methods:** DKD was defined as MiAU, MaAU or ESRD, whereas controls had normoalbuminuria and diabetes duration > 10 years. The study included four cohorts of T2D patients: GoDARTS (n=3240), SDR (n=1830), Steno (n=294) and MNI (n=353). We analyzed ~9.2 million single nucleotide polymorphisms (SNPs), imputed based on the 1000G (March 2012) reference panel, using logistic regression, adjusting for sex, age at onset and duration of diabetes, for five phenotypes: DKD, CKD, MiAU, MaAU+ESRD and ESRD. Meta-analyses were performed using a fixed effects model. We also performed joint analyses with four T1D studies analyzed using similar methods and phenotype definitions: FinnDiane (n=3415), Eurodiab (n=789), SDR (n=556) and Cambridge (n=396).

**Results:** In T2D, rs2206136 (OR=1.2,  $p = 2.1 \times 10^{-8}$ ) near *PLCB4* was significantly associated with CKD (3094 cases, 2906 controls). Nominal associations were also seen with DKD, MiAU and ESRD ( $p < 0.01$ ). The strongest associations for other phenotypes were rs183249293 (OR=0.42,  $p = 2.4 \times 10^{-7}$ ) for DKD (3345 cases, 2372 controls); rs2150814 (OR=0.8,  $p = 8.1 \times 10^{-8}$ ) near *GABRR1* for MiAU (1989 cases, 2238 controls); rs76262407 (OR=5.5,  $p = 1.1 \times 10^{-7}$ ) for ESRD (371 cases, 4471 controls); and rs116354014 (OR=4.5,  $p = 2.5 \times 10^{-7}$ ) for MaAU+ESRD (1339 cases, 2372 controls). In the joint T1D+T2D meta-analysis rs2331712 near *STXBP5L* reached genome-wide significance (OR=1.4,  $p = 1.9 \times 10^{-8}$ , 1184 cases, 8466 controls) for ESRD. The effect size was slightly higher in T2D (OR=1.8,  $p = 4.1 \times 10^{-6}$ ) compared to T1D (OR=1.3,  $p = 0.0008$ ). No association was seen with MiAU or CKD ( $p > 0.1$ ) suggesting an effect specifically on late stages of disease.

**Conclusion:** We have identified two new candidate loci for DKD situated near the *PLCB4* (phospholipase C, beta 4) and *STXBP5L* (syntaxin binding protein 5-like) genes. *PLCB4* has previously been shown to be differentially expressed in DKD, making it a strong candidate gene, possibly affecting disease risk via the DAG/PKC pathway.

#### Low levels of C-peptide production protect from complications and improve HbA<sub>1c</sub> control in longstanding type 1 diabetes

D.L. Faustman<sup>1</sup>, P.E. Reinhold<sup>1</sup>, S.L. Washer<sup>1</sup>, E. Hsu<sup>1</sup>, M. Zhao<sup>1</sup>, D. Burger<sup>1</sup>, H. Zheng<sup>2</sup>;

<sup>1</sup>Immunobiology Laboratory, Massachusetts General Hospital/Harvard Medical School, Charlestown, <sup>2</sup>Biostatistics, Massachusetts General Hospital/Harvard Medical School, Charlestown, USA.

**Background and aims:** Low levels of C-peptide (2.5–50 pmol/L) are produced for decades after the onset of type I diabetes, but the clinical significance is unknown. This study seeks to understand the clinical significance of extremely low levels (< 10 pmol/L) of C-peptide production.

**Materials and methods:** We evaluated the relationship between low levels of C-peptide and age of onset (n=1273), diabetes complications (n=324), HbA<sub>1c</sub> control (n=807), risk of hypoglycemia (n=331), and response to a mixed meal tolerance test (MMTT, n=9) in patients with longstanding type I diabetes. C-peptide samples were tested using a regular or ultrasensitive C-peptide ELISA kit. Hypoglycemia risk was determined using a validated survey. For the MMTT, each subject had three MMTT tests performed over a three-month period to understand biological variation in stimulated C-peptide at low ranges of basal pancreas function.

**Results:** After adjusting for disease duration, we found that extremely low levels of C-peptide were associated with risk for diabetes-related complications (e.g., nephropathy, neuropathy, cardiovascular disease) ( $p = 0.03$ ) and poorer metabolic control captured by HbA<sub>1c</sub> ( $p = 0.01$ ). There was no association between C-peptide < 10 pmol/L and risk of hypoglycemia. Even at extremely low levels of C-peptide production, beta-islet cells responded to a glucose challenge from a MMTT by secreting insulin, indicating that pancreatic function is preserved, but patients with undetectable C-peptide (< 1.5–2.5 pmol/L) did not respond to the MMTT.

**Conclusion:** Extremely low levels of C-peptide appear to have clinical significance and may be helpful in defining groups of long term diabetics who are at risk for complications or poor metabolic control.

#### Skin AGE fluorophore LW-1 predicts micro- and subclinical macrovascular complication progression in type 1 diabetes

V.M. Monnier<sup>1</sup>, W. Sun<sup>2</sup>, J.M. Lachin<sup>3</sup>, P.A. Cleary<sup>3</sup>, S. Genuth<sup>4</sup>, The DCCT/EDIC Research Group, D.R. Sell<sup>4</sup>;

<sup>1</sup>Pathology & Biochemistry, Case Western Reserve Univ, Cleveland, <sup>2</sup>Biostatistic Center, George Washington University, Washington, <sup>3</sup>Biostatistics Center, George Washington University, Washington, <sup>4</sup>Pathology, Case Western Reserve Univ, Cleveland, USA.

**Background and aims:** Skin collagen Long Wave autofluorescence (LW) is widely used as a surrogate marker for the accumulation of advanced glycation end-products (AGE). We determined the relationship between LW-1, a novel fluorescent skin collagen marker of partially known structure, with glycaemia, other collagen AGEs and the severity of complications in biopsies obtained from 216 participants at closeout of the Diabetes Control and Complications Trial (DCCT) study in 1993.

**Materials and methods:** Skin biopsy proteolytic digests were prepared as described and LW-1 content was determined by fluorescence HPLC.

**Results:** LW-1 levels increased with age and diabetes duration and when corrected for these parameters, they were significantly decreased with intensive vs. conventional diabetes therapy in both primary and secondary DCCT cohorts ( $P$  less than 0.0001). They were associated with retinopathy progression (sustained greater than 3 microaneurysms ever in DCCT) and albumin excretion rate (AER closest to biopsy > 40 mg/24 hr) ( $P = 0.0038$ ) which remained significant after adjustment for DCCT HbA<sub>1c</sub>. In EDIC, LW-1 correlated with retinopathy progression at EDIC Year 13–16, intima media thickness (IMT) at Yr 6 (n=147,  $P = 0.014$ ) and left ventricular mass (EDIC Yr 14–16) adjusted for EDIC A1c ( $P = 0.004$ ). LW-1 correlated highly ( $P$  less than 0.0001) with collagen modifications in the order glucosepane > pento-

sidine > pepsin insolubility > collagen fluorescence > MG-H1, and weaker with fructose-lysine ( $P = 0.0021$ ), and explained almost 10% of the variability in DCCT HbA1c.

**Conclusion:** LW-1 is a novel robust marker which predicts progression of retinopathy and nephropathy and future progression of IMT and LVM increase independently of the effects of HbA1c.

## 93

### Plasma levels of MMP-2, -3 and -10, and of TIMP-1 are associated with vascular complications in patients with type 1 diabetes: the EURODIAB prospective complications study

S.A. Peeters<sup>1,2</sup>, L. Engelen<sup>1,3</sup>, J. Buijs<sup>2</sup>, N. Chaturvedi<sup>4</sup>, J.H. Fuller<sup>5</sup>, C.G. Schalkwijk<sup>1,3</sup>, C.D.A. Stehouwer<sup>1,3</sup>;

<sup>1</sup>Department of Internal Medicine, Maastricht University Medical Centre, Netherlands, <sup>2</sup>Department of Internal Medicine, Atrium Medical Centre, Heerlen, Netherlands, <sup>3</sup>CARIM School for Cardiovascular Diseases, Maastricht University Medical Centre, Netherlands, <sup>4</sup>Institute of Cardiovascular Sciences, University College, London, UK, <sup>5</sup>Department of Epidemiology and Public Health, University College, London, UK.

**Background and aims:** Extracellular matrix remodeling by matrix metalloproteinases (MMPs) and tissue inhibitor of metalloproteinase (TIMP) may lead to micro- and/or macrovascular complications in type 1 diabetes. Evidence so far with regard to the associations between plasma MMPs and vascular complications is contradictory, as both positive and null associations have been described in relatively small studies. Therefore we have investigated the associations between plasma MMP-1, -2, -3, -9 and -10, and TIMP-1 on the one hand and cardiovascular disease (CVD) and microvascular complications on the other in a cohort of type 1 diabetic patients, and the extent to which such associations may be explained (i.e. mediated) by low-grade inflammation (LGI) and/or endothelial dysfunction (ED), as estimated by plasma markers.

**Materials and methods:** The study included 493 type 1 diabetic patients (39.5 ± 9.9 years old, 51% men) from the EURODIAB Prospective Complications Study. We used linear regression analyses to investigate the differences in plasma levels of MMP-1, -2, -3, -9 and -10, and of TIMP-1 between patients with vs. without CVD, albuminuria (normo, micro and macro) and retinopathy (no, non-proliferative and proliferative). All analyses were adjusted for age, sex, duration of diabetes and HbA1c and additionally for other cardiovascular risk factors and other vascular complications, as appropriate. Standardized concentrations of plasma CRP, IL-6 and TNF- $\alpha$  were averaged to compose an LGI score and standardized concentrations of plasma sV-CAM-1 and sE-selectin composed an ED score. These LGI and ED scores were then added to the fully adjusted model.

**Results:** Patients with CVD ( $n=118$ ) had significantly higher levels of TIMP-1 [ $\beta = 0.32$  SD (95%CI 0.12; 0.52)] than those without CVD ( $n=375$ ). Higher plasma levels of MMP-2, MMP-3, MMP-10 and TIMP-1 were associated with increasing levels of albuminuria ( $p$ -trends were 0.034, 0.004, 0.004 and 0.001, respectively). The severity of retinopathy was significantly associated with higher levels of MMP-2 ( $p$ -trend=0.022). MMP-1, -3, -9 and -10, and TIMP-1 were significantly and positively associated with the LGI score. MMP-2, MMP-10 and TIMP-1 were significantly and positively associated with the ED score. Nevertheless, the significant associations between plasma levels of MMPs and TIMP-1 on the one hand and CVD, albuminuria and retinopathy on the other were largely independent of LGI and ED.

**Conclusion:** In patients with type 1 diabetes, prevalent CVD, albuminuria and retinopathy were significantly associated with higher plasma levels of MMP-2, MMP-3, MMP-10 and TIMP-1, and these associations were largely independent of LGI and ED. Thus, these data support the hypothesis that extracellular matrix remodeling, by the action of MMPs and TIMP-1, is involved in vascular complications in type 1 diabetes.

### Acute glucose and insulin changes during OGTT relate to LV-myocardial deformation changes, untwisting and coronary-flow-reserve through increased arterial stiffness

F. Kousathana<sup>1</sup>, I. Ikonomidis<sup>2</sup>, G. Pavlidis<sup>2</sup>, C. Koukoulis<sup>2</sup>, M. Varoudi<sup>2</sup>, G. Matsaggouras<sup>1</sup>, H. Triantafyllidi<sup>2</sup>, J. Lekakis<sup>2</sup>, G. Dimitriadis<sup>1</sup>, V.A. Lambadiari<sup>1</sup>;

<sup>1</sup>2nd Dept of Internal Medicine, Research Institute and Diabetes Center, Attikon University Hospital, <sup>2</sup>2nd Cardiology Dept, University of Athens, Attikon Hospital, Athens, Greece.

**Background and aims:** Insulin resistance is linked to endothelial dysfunction and increased arterial stiffness. Increased Arterial stiffness may impair LV function. We investigated whether first-degree relatives of diabetic patients have similarly impaired coronary microcirculation, LV-myocardial strain and twisting with diabetic patients, as assessed after an oral glucose tolerance test (OGTT).

**Materials and methods:** In 76 subjects without known diabetes a standard 75-gr OGTT was performed. Glucose and insulin levels, pulse wave velocity (PWVa) and augmentation index (AI) (Arteriograph, Tensiomed) were measured at 0, 30, 60, 90 and 120 min after glucose load. At 0 and 120 min, we measured: a) E' and A' mitral annular velocities and their ratio E'/A' using tissue Doppler imaging, b) LV longitudinal (GLS-%), strain, systolic(LGSr) and diastolic strain rate (LGSrE), twisting (Tw -deg), peak twisting (Tw-deg/sec) velocity, and peak untwisting (unTw) velocity using speckle tracking echocardiography and c) coronary flow reserve (CFR) of the LAD after adenosine infusion using Doppler echocardiography. We assessed insulin resistance using insulin sensitivity index (ISI) which includes both insulin and glucose levels at baseline and 120 min after OGTT.

**Results:** Of the 76 subjects, 36 who were first degree relatives of diabetics had normal OGTT (relatives), 20 had normal OGTT and no family history of diabetes (normals), and 20 had abnormal OGTT (diabetics). Age, sex and BMI were similar between subgroups ( $p=ns$ ). Compared to normals, diabetics and relatives had both higher baseline PWVa ( $9.3 \pm 2$  vs.  $8.1 \pm 2$  vs.  $7.2 \pm 1.6$  m/sec.), AI ( $23 \pm 9$  vs.  $24 \pm 14$ ,  $18 \pm 15\%$ ), insulin (median 14 vs. 15 vs. 10  $\mu$ U/ml,  $p < 0.09$ ), and lower ISI ( $50 \pm 24$  vs.  $73 \pm 22$  vs.  $93 \pm 17$ ), baseline E'/A' ( $0.7 \pm 0.2$  vs.  $0.98 \pm 0.2$  vs.  $1.1 \pm 0.3$ ), LGSr ( $-0.95 \pm 0.1$  vs.  $-0.94 \pm 0.1$  vs.  $-1.1 \pm 15$  1/sec.) LGSrE ( $0.98 \pm 0.1$  vs.  $1. \pm 0.1$  vs.  $1.3 \pm 15$  1/sec,  $p < 0.05$ ) Tw ( $15 \pm 7$  vs.  $13 \pm 5$  vs.  $17 \pm 7$ ) and unTw velocity ( $-95 \pm 31$  vs.  $-94 \pm 40$  vs.  $116 \pm 36$ ) and lower CFR ( $2.7 \pm 1.1$  vs.  $2.6 \pm 0.9$  vs.  $3.0 \pm 0.6$ ) ( $p < 0.05$  for all comparisons). Compared to baseline, insulin was increased at 120min, to 87  $\mu$ U/ml (521%) in diabetics, 59  $\mu$ U/ml (293%) in relatives and 29  $\mu$ U/ml (190%) in normals ( $p < 0.05$ ). PWVa was increased at 120min to  $8.9 \pm 2$  m/s (10%) in relatives, was reduced to  $6.8 \pm 2$  m/s (6%) in normals and remained high ( $9.4 \pm 2$  m/s) in diabetics ( $p < 0.05$ ). Tw and unTw velocity at 120min, was increased to  $17 \pm 7$  (13%), and  $-105 \pm 31$  (10%) in diabetics, to  $15 \pm 5$  (15%) and  $-105 \pm 40$  (10%) in relatives and was reduced to  $13 \pm 7$  (24%) and  $-87 \pm 30$  (25%) in normals ( $p < 0.05$ ). CFR was decreased to  $2.4 \pm 0.7$  (14%) in diabetics,  $2.3 \pm 0.7$  (12%) in relatives and  $2.8 \pm 0.9$  (6%) in normals ( $p < 0.05$ ). ISI, insulin and glucose at 120 min were related with PWV, CFR, GLS, LGSr E, Tw, Tw velocity unTw velocity and E'/A' in both diabetics and relatives ( $p < 0.05$ ). At 0 and 120 min, PWV was related with the corresponding LGSr E, Tw, Tw velocity unTw velocity and E'/A' ( $p < 0.05$ )

**Conclusion:** Acute hyperglycaemia and hyperinsulinemia post OGTT are related to abnormal LV-myocardial deformation, twisting and untwisting possibly through increases in arterial stiffness and impairment of coronary microcirculatory function in first degree relatives and diabetics

**Vascular and cellular ageing in patients with type 2 diabetes mellitus**

N.V. Brailova<sup>1,2</sup>, E. Dudinskaya<sup>1</sup>, O. Tkacheva<sup>1</sup>, S. Boytsov<sup>1</sup>, I. Strazhesko<sup>1</sup>, D. Akasheva<sup>1</sup>, M. Shestakova<sup>2,3</sup>, Y. Brailov<sup>3</sup>, M. Pokrovskaya<sup>1</sup>;

<sup>1</sup>National Research Centre for Preventive Medicine,

<sup>2</sup>National Research Center for Endocrinology,

<sup>3</sup>Align Technology Inc., Moscow, Russian Federation.

**Background and aims:** It is known that glucose disturbances contribute to micro- and macrovascular complications and vascular aging. The length of telomere (TL) is considered as a biomarker for vascular and cellular aging. But the interrelation of vascular aging and cellular aging in type 2 diabetes mellitus (T2DM) and pathogenic mechanisms of this interrelation remains a challenge. The aim of our study was to determine mechanisms of TL shortening and vascular aging in patients with T2DM.

**Materials and methods:** The study group included 50 patients with T2DM in mean age 58.4±7.83 years and 156 healthy patients in mean age 57.04±7.7 years. TL and telomerase activity (TA) was assessed by quantitative polymerase chain reaction (PCR). Intima-media thickness (IMT) and plaque presence (PP) were determined by ultrasonography in both left and right carotid arteries. Arterial stiffness (AS) was appreciated by aortic pulse wave velocity (PWV) measuring by SphygmoCor (AtCor Medical). Endothelial dysfunction as assessed by flow-mediated endothelium-dependent dilation (FMV) in response to reactive hyperemia and endothelium-independent vasodilation in response to nitroglycerine (NDV). Oxidative stress was assessed by malondialdehyde measuring, inflammation was estimated by interleukin-6 (IL-6), C-reactive protein (CRP), fibrinogen measuring.

**Results:** We found in group with T2DM compared with the control group of healthy patients a greater telomere shortening (9,57 vs 9,75, p=0,0051) and TA reduction (0,33 vs 0,49, p=0,0023). Vascular aging are more pronounced in patients with T2DM, than without diabetes: PWV CPIIB 12,3 m/s vs 11,3 m/c (p=0,0032), IMT 0,93 mm vs 0,77 mm (p<0,0001), PP 2,02 vs 1,29 (p=0,0026). Patients with T2DM have worse endothelial function: FMV 9 vs 11 (p=0,0146), NDV 13 vs 16,5 (p=0,0001). With regard to lipid oxidation product and inflammatory markers we found significant differences: patients with T2DM have more increased malondialdehyde (0,08 vs 0,02, p=0,044), CRP (3,60 vs 2,35, p<0,0001), increased fibrinogen (0,30 vs 0,11, p=0,0007).

**Conclusion:** Vascular aging (AS, IMT increasing, subclinical atherosclerosis (PP), endothelial dysfunction) and cellular aging (TL, TA reduction) are more pronounced in patients with T2DM, than without diabetes. Patients with T2DM have more pronounced oxidative stress and chronic inflammation. Thus we can suppose that oxidative stress and chronic inflammation play principal role in TL shortening and vascular aging at macro, tissue and cell level.

## 96

**Arterial stiffness is not associated with skin microvascular function in individuals with or without type 2 diabetes: the Maastricht Study**

T.T. van Sloten<sup>1</sup>, A.J.H. Houben<sup>1</sup>, D.M.J. Muris<sup>1</sup>, M.T. Schram<sup>1</sup>, P.C. Dagnelie<sup>2</sup>, C. van der Kallen<sup>1</sup>, N.C. Schaper<sup>1</sup>, S.J. Sep<sup>1</sup>, A. Koster<sup>3</sup>, A.D. Protogerou<sup>1</sup>, R.M.A. Henry<sup>1</sup>, C.D.A. Stehouwer<sup>1</sup>;

<sup>1</sup>Medicine, Maastricht University Medical Centre,

<sup>2</sup>Epidemiology, Maastricht University Medical Centre,

<sup>3</sup>Social Medicine, Maastricht University Medical Centre, Netherlands.

**Background and aims:** Increased arterial stiffness leads to an increased pulsatile pressure load, which may damage the microcirculation. Individuals with type 2 diabetes (T2DM) may be particularly prone to the detrimental effects of this increased pressure load, because T2DM is associated with increased microvascular perfusion, allowing pulsatile pressure to penetrate deeply into the microcirculation. The skin enables the direct measurement of microcirculatory function both at rest and during provocative stimuli. Furthermore, the cutaneous microcirculation is considered a representative vascular bed to examine generalized microvascular phenomena. The aim of the present study was therefore to evaluate, in a large population-based cohort, the association between arterial stiffness and skin microvascular function. We additionally investigated whether any such association was stronger in individuals with as compared to those without T2DM.

**Materials and methods:** We used cross-sectional data of The Maastricht Study (for the present analysis: n=737; age 59.7 years; 45.2% women; 28.8% T2DM (by design)). The Maastricht Study is a population-based cohort study that focuses on the pathophysiology of T2DM. Arterial stiffness was determined via carotid-femoral pulse wave velocity (cfPWV, tonometry). In addition, finger skin capillaroscopy was used to determine capillary density at baseline and during post-occlusive hyperaemic response and venous congestion. Laser Doppler flowmetry was used to assess skin microvascular flow-motion.

**Results:** After adjustment for age and sex, both in individuals with and without T2DM, cfPWV was not associated with baseline capillary density, hyperaemic capillary recruitment, or capillary density during venous congestion (Table, models 1). In addition, cfPWV was not associated with microvascular flowmotion (models 1). Further adjustment for potential confounders (models 2 and 3) did not materially change these results. There was no interaction with type 2 diabetes (P for interaction, all >.13).

**Conclusion:** In the present population-based cohort study, arterial stiffness was not associated with skin microvascular function. This suggests that increased arterial stiffness does not lead to generalized microvascular dysfunction, irrespective of the presence of T2DM.

### LKB1 and AMPK regulate *Nptx2* expression and glutamate signalling in pancreatic beta cells

M.-S. Nguyen-Tu<sup>1</sup>, C. Kantor<sup>1</sup>, S. Sayers<sup>1</sup>, T.J. Pullen<sup>1</sup>, G. Sun<sup>1</sup>, M. Kone<sup>1</sup>, M. Ibberson<sup>2</sup>, J. Ferrer<sup>3</sup>, B. Thorens<sup>4</sup>, A. Swisa<sup>5</sup>, Y. Dor<sup>5</sup>, T. Hildebrandt<sup>6</sup>, I. Uphues<sup>6</sup>, G.A. Rutter<sup>1</sup>;

<sup>1</sup>Section of Cell Biology, Department of Medicine, Imperial College London, UK, <sup>2</sup>Swiss institute of Bioinformatics, University of Lausanne, Switzerland, <sup>3</sup>Endocrinology and Metabolic Medicine, Department of Medicine, Imperial College London, UK, <sup>4</sup>Center for integrative Genomics, University of Lausanne, Switzerland, <sup>5</sup>Hebrew University of Jerusalem, School of Medicine-IMRC, Israel, <sup>6</sup>Boehringer Ingelheim International GmbH, Ingelheim, Germany.

**Background and aims:** Inactivation in beta cells of the tumour suppressor Liver kinase B1 (LKB1/STK11) or the downstream enzyme AMP-activated protein kinase (AMPK) exerts dramatic effects on beta cell growth and insulin secretion. Here, we used massive parallel sequencing (RNASeq), and subsequent functional analyses, to identify gene clusters which may mediate these effects.

**Materials and methods:** Mice null for LKB1 or both AMPK catalytic ( $\alpha 1$ ,  $\alpha 2$ ) subunits were generated by Ins1Cre-mediated (beta cell-selective) deletion of *lox'd* alleles. Islets were isolated from four 12 week old mice per genotype. After 24 h culture at 11 mM glucose RNA was extracted (RNAEasy) before deep sequencing (RNASeq) on a HiSeq 2000. Cytosolic free  $Ca^{2+}$  was measured using fura-2 using an Olympus IX81 microscope with micromanipulator-controlled data capture via an Andor Zyla CMOS camera. Immunohistochemical analysis of pancreatic slices was performed using a rabbit anti-Nptx2 antibody on a Zeiss-200M microscope (Zen software), and analysed using ImageJ. Insulin secretion was measured during static incubations (30 min) at 3 or 16 mM glucose using radioimmunoassay.

**Results:** Amongst the mRNAs most strongly up-regulated by LKB1 deletion was a cluster involved with glutamate signalling, including *Nptx2*, encoding neuronal pentraxin 2 (11.2-fold, E-value <0.001), and *dlgap2*, encoding discs, large (Drosophila) homolog-associated protein 2 (11.9-fold, E<0.001). A similar degree of up-regulation was observed after AMPK deletion (19.7-fold, E<0.01 and 4.7-fold, E<0.01, respectively). LKB1 deletion increased *Nptx2* immunoreactivity in islets by 6.0-fold, p<0.01. At 3 mM glucose, cytosolic calcium increases in response to the glutamate receptor agonist kainate were significantly increased by LKB1 deletion (area under the curve, 2.1-fold, p<0.05, amplitude 43 %, p<0.01), whilst insulin secretion was increased 2.2-fold (p<0.05) at 3 but not 16 mM glucose.

**Conclusion:** LKB1 regulates glutamate receptor signalling in beta cells by a mechanism likely to involve the up-regulation of *Nptx2*, a secreted protein which binds  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors, and by *dlgap2*, which interacts with PSD-95 (encoded by DLG4) and N-methyl-D-aspartate NMDA receptors. The actions of LKB1 are likely to involve the nutrient-sensitive protein kinase AMPK, and may thus provide a novel mechanism by which glucose or other secretagogues regulate insulin secretion or beta cell survival.

### The non-canonical NF $\kappa$ B pathway as a novel player in beta cell dysfunction in diabetes

E.K. Malle<sup>1</sup>, B.M. Tan<sup>1</sup>, S.N. Walters<sup>1</sup>, N.W. Zammit<sup>1</sup>, R. Brink<sup>1</sup>, J. Cantley<sup>2</sup>, S.T. Grey<sup>1</sup>;

<sup>1</sup>Immunology, Garvan Institute of Medical Research, Sydney, Australia, <sup>2</sup>University of Oxford, UK.

**Background and aims:** We previously demonstrated that mice deficient for TRAF2 ( $\beta$ TRAF2) in their beta cells showed exacerbated glucose intolerance and an impaired first phase insulin secretion in a diet-induced obesity model.  $\beta$ TRAF2 islets also displayed dysregulated signaling as defined by hyperactivation of the non-canonical NF $\kappa$ B signaling pathway. TRAF2 is an adaptor protein that functions by recruiting the E3 ubiquitin ligases BIRC2 and

BIRC3 to the complex, which target the NF $\kappa$ B inducing kinase (NIK) for degradation thereby directly controlling the non-canonical NF $\kappa$ B pathway.

**Materials and methods:** To dissect out the function of this E3 ubiquitin ligase complex in islet biology in diabetes, we generated a beta cell specific BIRC2/3 knockout ( $\beta$ BIRC) mouse. Of note, a class of BIRC inhibitors, so-called Smac mimetics, are in Phase I and II clinical trials as anti-cancer drugs. We hypothesized that genetic ( $\beta$ BIRC mice) or drug-based (Smac mimetic) deletion of BIRC would impair beta cell function.

**Results:**  $\beta$ BIRC mice showed increased glucose intolerance on a high-fat diet (45 kcal % fat) thus phenocopying  $\beta$ TRAF2. The common molecular denominator that we found, was increased cell intrinsic NIK accumulation and processing of p100 to p52 in unstimulated  $\beta$ TRAF2 and  $\beta$ BIRC islets, indicating activation of the non-canonical NF $\kappa$ B pathway. Thus, disruption of the TRAF/BIRC E3 ligase complex derails control of non-canonical NF $\kappa$ B signaling and thereby causes beta cell dysfunction. Next, we synthesized and purified the monovalent preclinical Smac-mimetic MV1. Treatment of C57BL/6 islets with MV1 resulted in increased processing of p100 to p52 indicating activation of the non-canonical NF $\kappa$ B pathway. We then transplanted a limited and defined number of vehicle-control and MV1-treated islets into syngeneic diabetic mice and performed an i.p.GTT at day 3 and 10 post transplant. Both control and MV1-treated islets established normoglycemia at postoperative day 1-2. At day 3, MV1-treated islets showed a severe decrease in glucose tolerance compared to vehicle-treated controls. However, at day 10 there was no difference to controls, indicating that the MV1 Smac mimetic causes a transient defect in beta cell function. This raises the question whether cancer patients receiving Smac mimetics should be monitored for changes in glucose tolerance. In all models,  $\beta$ TRAF2 mice,  $\beta$ BIRC mice and MV1-treated islets, the loss of beta cell function was independent of cell death, as they maintained their islet mass.

**Conclusion:** Mice lacking TRAF2 or BIRC2/3 in beta cells exhibit severe defects in glucose homeostasis and insulin secretion in a diet-induced obesity model. At the molecular level this E3 ubiquitin ligase complex reigns in NIK activation as a non-canonical NF $\kappa$ B pathway trigger. Loss of this control circuit by either genetic deletion or treatment with an anti-cancer Smac mimetic drug precipitates a diabetes phenotype. These data define NIK activation and non-canonical NF $\kappa$ B as novel players in islet dysfunction, and commend them as potential drug targets in diabetes.

### Stimulation of insulin secretion by GPR75: identification of signalling pathways in rodent and human beta cells

Z. Hassan, B. Liu, S. Amisten, G.C. Huang, P.M. Jones, S.J. Persaud; Diabetes Research Group, Kings College London, UK.

**Background and aims:** GPR75 is an atypical chemokine receptor that is activated by the pro-inflammatory chemokine ligand 5 (CCL5). We have previously demonstrated that GPR75 mRNA is highly expressed by mouse and human islets and it localises to  $\beta$ -cells, whereas the conventional CCL5-activated chemokine receptors CCR1, 3 and 5 are expressed at very low levels in islets. We have also shown that CCL5 elevates  $[Ca^{2+}]_i$  in  $\beta$ -cells and stimulates insulin secretion, but the downstream signalling cascades and involvement of GPR75 in the stimulatory effects of CCL5 are unknown. This study therefore determined the pathways downstream of CCL5 signalling in mouse and human islets and investigated whether GPR75 activation is required for CCL5-induced insulin secretion.

**Materials and methods:** Changes in  $[Ca^{2+}]_i$  were measured by single cell microfluorimetry of Fura-2-loaded human islet cells, insulin secretion from isolated mouse and human islets was determined in static incubation experiments and quantified by radioimmunoassay, and GPR75 was down-regulated by transient transfection with GPR75 siRNAs.

**Results:** Blockade of L-type  $Ca^{2+}$  channels reduced CCL5-induced elevations in  $[Ca^{2+}]_i$  in human islets (10nM CCL5: 90 $\pm$ 15% of ATP response; +10 $\mu$ M nifedipine: 14 $\pm$ 6%, n=7-17, P<0.05), and opening of  $K_{ATP}$  channels was associated with a loss in CCL5 induced insulin secretion from mouse islets (2mM glucose: 0.19 $\pm$ 0.02ng/islet/h; +25nM CCL5: 0.31 $\pm$ 0.04, P<0.05; +25nM CCL5 +250 $\mu$ M diazoxide: 0.18 $\pm$ 0.02, P>0.2 vs 2mM glucose). Inhibition of phospholipase C in human islets also abolished the secretory response to CCL5 (20mM glucose: 0.65 $\pm$ 0.07ng/islet/h; +10nM CCL5: 1.22 $\pm$ 0.25, P<0.05; +10nM CCL5 +10 $\mu$ M U73122: 0.44 $\pm$ 0.07, P>0.2 vs 20mM glucose), as did depletion of typical isoforms of protein kinase C (PKC) by 24 hour exposure to 4 $\beta$ PMA (control: 196 $\pm$ 26% of 20mM glucose response; PKC

depleted:  $90 \pm 10\%$ ,  $n=7-8$ ,  $P<0.01$ ). Furthermore, inhibition of the calcium-calmodulin-dependent protein kinase CAMK II diminished CCL5-induced insulin secretion from human islets (20mM glucose:  $0.57 \pm 0.08$ ng/islet/h; +10nM CCL5:  $1.17 \pm 0.15$ ,  $P<0.05$ ; +10nM CCL5 +10 $\mu$ M KN62:  $0.69 \pm 0.08$ ,  $P>0.2$  vs 20mM glucose). Exposure of  $\beta$ -cells to GPR75 siRNAs for 48 hours caused  $39.6 \pm 1.4\%$  reduction in GPR75 mRNA expression and this was accompanied by decreased insulin secretion in response to CCL5 (non-coding RNAs:  $166 \pm 30\%$  of 20mM glucose response; GPR75 siRNAs:  $70 \pm 10\%$ ,  $n=6$ ,  $P<0.05$ ).

**Conclusion:** These data indicate that CCL5 activates  $\beta$ -cell GPR75 to stimulate insulin secretion from mouse and human islets, which is dependent on signal transduction cascades that include phospholipase C activation, calcium influx via L-type  $Ca^{2+}$  channels, and activation of the calcium-dependent protein kinases PKC and CaMK II. This novel role for CCL5 in improving  $\beta$ -cell function via GPR75 activation may provide a potential therapeutic target for improving insulin secretion in type 2 diabetes.

## 100

### Knockout of GPR55 impairs insulin secretion and reduces islet cell turnover

B. Liu<sup>1</sup>, S. Song<sup>1</sup>, D. Baker<sup>2</sup>, Z. Hassan<sup>1</sup>, R.L. Drynda<sup>1</sup>, J.E. Bowe<sup>1</sup>, P.M. Jones<sup>1</sup>, S.J. Persaud<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, King's College London,

<sup>2</sup>Blizard Institute, Queen Mary University of London, UK.

**Background and aims:** GPR55 is a G-protein coupled receptor (GPCR) whose activity is regulated by a range of synthetic and endogenous cannabinoids, and by lipid-derived ligands. We have previously reported that GPR55 knockout (KO) mice are more susceptible to diet-induced obesity, and the aim of the current study was to investigate the effect of GPR55 deletion on islet function *in vivo* and *in vitro* following diet-induced obesity.

**Materials and methods:** GPR55 KO mice and age-matched WT mice were fed *ad lib* either standard chow (SC, fat:protein:carbohydrate: 14%:28%:58%) or a high fat diet (HFD, 55%:16%:29%) for 19 weeks. Glucose and insulin tolerance tests were performed following a single *i.p.* administration of glucose (2g/kg body weight) or insulin (0.75U/kg body weight), and tail vein blood glucose concentrations were determined using a glucose meter. Islets isolated from WT and KO mice were lysed with acidified ethanol and insulin content was measured by radioimmunoassay. Dynamic insulin secretion was quantified by radioimmunoassay following perfusion of isolated islets. Islet caspase-3/7 activities were quantified using a luminescent assay following exposure to a cytokine cocktail (1U/ $\mu$ l IFN $\gamma$ , 1U/ $\mu$ l TNF $\alpha$ , 0.05U/ $\mu$ l IL-1 $\beta$ ). BrdU (1mg/ml) was delivered to mice in their drinking water for 7 days prior to sacrifice, and beta cell proliferation was determined by insulin and BrdU immunostaining.

**Results:** GPR55 KO mice fed a HFD for 19 weeks were glucose intolerant (glucose at  $t=30$ , KO on SC:  $20.8 \pm 1.3$ mM; KO on HFD:  $28.1 \pm 1.1$ ,  $n=6$   $P<0.01$ ) and insulin resistant (reduction in blood glucose following insulin injection, KO on SC:  $1.1 \pm 0.1$ mM; KO on HFD:  $0.3 \pm 0.4$ ,  $n=6$   $P<0.05$ ). Islets isolated from KO mice fed a HFD for 19 weeks showed a small reduction in basal insulin secretion at 2mM glucose (KO:  $0.11 \pm 0.01$ pg/islet/min; WT:  $0.15 \pm 0.03$ ,  $n=4$   $P<0.05$ ) and glucose-stimulated insulin secretion was also impaired (peak responses to 20mM glucose, KO:  $4.1 \pm 1.3$ pg/islet/min; WT:  $8.5 \pm 0.9$ ;  $P<0.05$ ). Islets from KO mice after maintenance for 19 weeks on SC showed increased cytokine-induced apoptosis (caspase 3/7 activities; luminescence, KO:  $41,692 \pm 939$ ; WT:  $29,980 \pm 457$ ;  $n=8$   $P<0.01$ ) as did islets from KO mice fed on a HFD (KO:  $55,093 \pm 2,740$ ; WT:  $38,599 \pm 564$ ;  $n=8$   $P<0.01$ ). In addition, while there was a  $3.2 \pm 0.6$ -fold increase in beta cell BrdU incorporation in pancreases of WT mice fed a HFD this compensatory increase in beta cell proliferation in response to HFD was attenuated in KO mice ( $1.2 \pm 0.2$ -fold increase in beta cell BrdU incorporation;  $n=12$ ,  $P<0.05$  vs WT). Consistent with the reduced proliferation and increased apoptosis, islets isolated from HFD-fed KO mice had lower insulin content (KO:  $134.8 \pm 2.3$ ng/islet; WT:  $166.3 \pm 4.2$ ;  $n=8$   $P<0.001$ ).

**Conclusion:** GPR55 KO mice show impaired glucose handling under conditions of diet-induced increased metabolic demand, which is associated with reduced insulin secretory capacity, increased islet cell apoptosis and insufficient compensatory increases in beta cell proliferation. These observations support GPR55 playing an important role in regulating islet function that could make it a suitable target for treating type 2 diabetes.

### IDs are novel oxidative stress-responsive genes in beta cells that regulate redox status and survival through effects on mitochondria and the NFE2L2 pathway

M. Bensellam<sup>1</sup>, M. Montgomery<sup>2</sup>, J. Luzuriaga<sup>1</sup>, J. Chan<sup>1</sup>, D.R. Laybutt<sup>1</sup>;

<sup>1</sup>Garvan Institute of Medical Research,

<sup>2</sup>University of New South Wales, Sydney, Australia.

**Background and aims:** Oxidative stress is a central mechanism of beta-cell glucotoxicity, but the underlying signaling pathways are only partially understood. Inhibitor of Differentiation (ID) proteins are transcriptional regulators induced by hyperglycaemia in islets, but the mechanisms involved and their role in beta-cells are not clear. Here we investigated: 1) whether oxidative stress regulates ID expression in beta-cells, and 2) the role of ID expression in beta-cell pathophysiology under conditions of oxidative stress.

**Materials and methods:** Fixed pancreata and isolated islets from diabetic db/db mice and their normoglycemic db/+ littermates were used to verify the expression of IDs and antioxidant genes. Insulin-secreting MIN6 beta-cells and isolated islets from Id1 and Id3-KO mice were cultured for 0-48h in the presence or absence of  $H_2O_2$  (100-300  $\mu$ M) or ribose (5-50 mM) to induce oxidative stress. RNA interference was used to silence the expression of Id1 and/or Id3 in MIN6 cells. mRNA and protein levels were measured by real-time RT-PCR, western blot and immunocytochemistry.  $H_2O_2$  levels were assessed by DCFDA probe, mitochondrial morphology by Mitotracker probe, oxygen consumption by Clark electrode and apoptosis by DNA fragmentation ELISA.

**Results:** ID1-4 expression was upregulated in the islets of diabetic db/db mice with parallel changes in the expression of multiple antioxidant genes. In MIN6 cells, ribose and  $H_2O_2$  treatment increased the mRNA levels of Id1-4 in a time- and concentration-dependent manner with parallel changes in the expression of antioxidant genes. Furthermore, immunostaining showed that ribose treatment increased ID1 and ID3 nuclear localisation. In ribose-treated cells, siRNA-mediated inhibition of Id1 and/or Id3 reduced the expression of multiple antioxidant genes, including heme oxygenase. Additive effects were observed when both isoforms were inhibited. Glutathione peroxidase activity was also reduced after Id1/3 knockdown. These effects were accompanied by  $\sim 2$ -fold increase in  $H_2O_2$  levels ( $p<0.01$ ), 18% reduction in oxygen consumption ( $p<0.01$ ) and  $\sim 2$ -fold increase in beta-cell apoptosis ( $p<0.001$ ). Furthermore, Id1/3 inhibition induced mitochondrial fragmentation similar to that observed in the presence of ribose. Similarly, ribose-induced apoptosis in islets was potentiated in Id1-KO islets and to a stronger extent in Id3-KO islets (1.6-fold;  $p<0.01$ ). Finally, under oxidative stress, Id1/3 inhibition further increased NFE2L2 nuclear localization but represses the expression of its interacting partners MafK and MafF.

**Conclusion:** We have identified IDs as a novel family of oxidative stress-responsive genes in beta-cells as well as an unexpected role for Id1 and Id3 in the modulation of redox status. Such modulation is likely to stem from the maintenance of an adequate mitochondrial adaptation and upholding of the expression of NFE2L2 interacting partners. The maintenance of an adequate mitochondrial-antioxidant response by IDs may promote beta-cell survival under conditions of oxidative stress.

### Optical interrogation of glucose-regulated beta cell connectivity

N.R. Johnston<sup>1</sup>, R.K. Mitchell<sup>1</sup>, J. Ferrer<sup>1</sup>, B. Thorens<sup>2</sup>, G.A. Rutter<sup>1</sup>, D.J. Hodson<sup>1</sup>;

<sup>1</sup>Department of Medicine, Imperial College London, UK,

<sup>2</sup>Center for Integrative Genomics, University of Lausanne, Switzerland.

**Background and aims:** The multicellular organization of beta cell dynamics produces a gain-of-function in insulin release through the generation of rhythmic and synchronous activity patterns. Here, we describe an optical silencing strategy to allow the precise and specific interrogation of the functional wiring patterns which orchestrate and pace beta cell interactivity.

**Materials and methods:** Functional multicellular calcium ( $Ca^{2+}$ ) imaging (fMCI) was used in combination with online Monte Carlo-based correlation analyses to construct the wiring patterns underlying cell-cell connectivity and hormone release. Rapid Nipkow disk microscopy allowed video rate recording at speeds in excess of 5 Hz. Beta cell-specific expression of the light-activated inward chloride ( $Cl^-$ ) channel, halorhopsin, was directed by crossing the Ins1Cre deleter strain with animals engineered to express

eNpHR3.0-EYFP following excision of a *loxP*-flanked STOP cassette. To allow user-directed single cell silencing within the field of view, a diffraction-limited 585nm laser was coupled via a fibre optic to a custom-manufactured dichroic array.

**Results:** Beta cells form a scale-free network which supports the synchronous propagation of glucose-stimulated  $\text{Ca}^{2+}$  waves by efficiently connecting distant regions of the intact islet ( $n = 12$  recordings from 5 animals) (power law fit;  $R^2 = 0.7247$ ). A typical feature of such a topology was the non-random appearance of superconnected hub cells whose firing activity repetitively preceded that of the remainder of the population. Online mapping of islet functional architecture using MATLAB routines coupled directly to the imaging setup revealed the presence of a statistically-stable hub cell population. Silencing of individual identified hubs using a pinpointing laser had catastrophic consequences for coordinated islet responses to glucose, and this could be reversed simply by ceasing illumination ( $11.5 \pm 1.8$  versus  $3.1 \pm 0.8$  % correlated cell pairs, laser OFF versus laser ON, respectively;  $P < 0.01$ ) ( $n = 8$  recordings from 4 animals). By contrast, specific silencing of non-hub or follower cells was unable to significantly perturb islet dynamics ( $7.3 \pm 1.8$  versus  $9.9 \pm 2.0$  % correlated cell pairs, laser OFF versus laser ON, respectively;  $P > 0.05$ ) ( $n = 7$  recordings from 4 animals). Further supporting a role for distinct wiring patterns in glucose-regulated islet connectivity, low-grade cytokine (IL-1 $\beta$  and IL-6) treatment resulted in a dramatic and rapid collapse in correlated cell-cell activity due to impaired hub function ( $9.6 \pm 0.9$  versus  $5.1 \pm 0.6$  % correlated cell pairs, 0 versus 4 hrs cytokine exposure, respectively;  $P < 0.01$ ) ( $n = 7$  recordings from 3 animals).

**Conclusion:** The intra-islet circuitry is dominated by superconnected hub cells which dictate population responses to glucose. Notably, these hubs are vulnerable to pro-inflammatory T2D insults and may contribute to the reduced functional beta cell mass that accompanies glucose intolerance.

## OP 18 Novel genes for type 2 diabetes and its complications

### 103

#### A common Greenlandic *TBC1D4* variant confers muscle insulin resistance and type 2 diabetes

N. Grarup<sup>1</sup>, I. Moltke<sup>2</sup>, M.E. Jørgensen<sup>3</sup>, P. Bjerregaard<sup>4</sup>, J.T. Treebak<sup>1</sup>, T.S. Korneliusen<sup>5</sup>, M.A. Andersen<sup>1</sup>, T.S. Nielsen<sup>1</sup>, N.T. Krarup<sup>1</sup>, A. Linneberg<sup>6</sup>, J. Wang<sup>7</sup>, O. Pedersen<sup>1</sup>, R. Nielsen<sup>8</sup>, A. Albrechtsen<sup>9</sup>, T. Hansen<sup>1</sup>;

<sup>1</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Denmark, <sup>2</sup>Department of Human Genetics, University of Chicago, USA, <sup>3</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>4</sup>National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark, <sup>5</sup>Centre for GeoGenetics, Natural History Museum of Denmark, University of Copenhagen, Denmark, <sup>6</sup>Research Centre for Prevention and Health, Glostrup University Hospital, Glostrup, Denmark, <sup>7</sup>BGI-Shenzhen, China, <sup>8</sup>Department of Integrative Biology, University of California, Berkeley, USA, <sup>9</sup>The Bioinformatics Centre, Department of Biology, University of Copenhagen, Denmark.

**Background and aims:** Previous studies have shown that founder populations can be valuable for genetic association studies, because they have increased levels of linkage disequilibrium and may harbor deleterious mutations of higher frequency. The same can be argued for historically small and isolated populations. Motivated by this, and by the dramatically increased prevalence of type 2 diabetes in the small Greenlandic population, we performed association mapping of four type 2 diabetes-related quantitative traits, plasma glucose and serum insulin levels at fasting and at two hours during an OGTT, in Greenlandic individuals without known diabetes.

**Materials and methods:** Discovery analyses were performed in up to 2,757 participants of the Inuit Health in Transition cohort and replication in up to 1,064 participants from the B99 cohort. Participants underwent an OGTT. Samples were genotyped by the Illumina CardioMetabochip. Association testing was done using a linear mixed model in GEMMA to control for admixture and relatedness. Exome sequencing of selected individuals was done by Agilent SureSelect capture and Illumina sequencing.

**Results:** Applying array-based genotyping and exome sequencing, we discovered a nonsense variant in *TBC1D4* with an allele frequency of 17% in the Greenlandic population. Under a recessive model, this variant strongly increases the levels of plasma glucose ( $\beta = 3.8$  mmol/L,  $P = 2.5 \times 10^{-35}$ ) and serum insulin ( $\beta = 165$  pmol/L,  $P = 1.5 \times 10^{-20}$ ) two hours after an oral glucose load, while reducing fasting plasma glucose ( $\beta = -0.18$  mmol/L,  $P = 1.1 \times 10^{-6}$ ) and fasting serum insulin ( $-8.3$  pmol/L,  $P = 0.0014$ ). Even the heterozygous carriers have an increased 2 hour plasma glucose ( $\beta = 0.43$  mmol/L,  $P = 5.3 \times 10^{-5}$ ). The same polymorphism was associated with an increased risk of type 2 diabetes risk (OR 10.3,  $P = 1.6 \times 10^{-24}$ ). All findings were replicated in the B99 cohort. Analyses of muscle biopsies from mutation carriers showed decreased mRNA and protein expression of the long muscle-specific isoform of *TBC1D4* and decreased muscle protein abundance of GLUT4 projecting a decreased insulin-stimulated glucose uptake in skeletal muscle.

**Conclusion:** We establish a single variant which imposes effect sizes several times larger than any findings of large-scale genome-wide association studies and accounts for more than 10% of all cases of type 2 diabetes in a population. This finding constitutes further proof that it is valuable to conduct genetic association studies outside the traditional setting of large homogeneous populations.

### 104

#### Fine-mapping type 2 diabetes susceptibility loci with high-density imputation

A.P. Morris<sup>1,2</sup>, T.M. Teslovich<sup>3</sup>, T. Ferreira<sup>2</sup>, A. Mahajan<sup>2</sup>, Y. Lee<sup>3</sup>, N.W. Rayner<sup>2</sup>, R. Magi<sup>4</sup>, on behalf of the DIAGRAM Consortium;

<sup>1</sup>Department of Biostatistics, University of Liverpool,

<sup>2</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, UK,

<sup>3</sup>Department of Biostatistics, University of Michigan, Ann Arbor, USA,

<sup>4</sup>Estonian Genome Centre, University of Tartu, Estonia.

**Background and aims:** Genome-wide association studies (GWAS) have been successful in identifying loci for type 2 diabetes (T2D). These loci are typi-

cally characterised by common lead SNPs with association signals that extend over large genomic intervals. Consequently, there has been limited progress in localising causal variants for T2D and establishing the functional impact of these loci in the pathogenesis of the disease. We aimed to: (i) identify multiple signals of association with T2D in established loci; (ii) assess the evidence for association with low-frequency (LF) variants, minor allele frequency (MAF) <5%, in established loci; and (iii) localise the likely causal variant(s) for each association signal.

**Materials and methods:** We combined Metachip and GWAS data from 46,168 T2D cases and 172,714 controls of European ancestry, supplemented by imputation up to the 1000 Genomes Project reference panel (March 2012 release), to facilitate fine-mapping of 39 established loci. We undertook approximate conditional analyses implemented in GCTA, using 3,298 cases and 3,708 controls from GoDARTS as reference, to identify loci with multiple signals of association with T2D at “locus-wide” significance ( $p < 10^{-5}$ ). We defined “credible sets” of SNPs that account for 99% of the probability of including the causal variant for each association signal.

**Results:** We identified five association signals mapping to the *KCNQ1* locus, three at *HNF1A*, and two each at *CDKN2A/B*, *DGKB*, *MC4R*, *GIPR* and *HNF4A*. We highlighted LF associated variants mapping near *HNF1A* (rs1800574, MAF=2.2%,  $p=4.2 \times 10^{-10}$ ), *HNF4A* (rs1800961, MAF=3.9%,  $p=1.4 \times 10^{-9}$ ), and *MC4R* (rs17066842, MAF=4.8%,  $p=2.9 \times 10^{-6}$ ), all independent ( $r^2 < 0.05$ ) of the common lead GWAS SNPs at these loci. The 99% credible set includes no more than ten variants at nine loci, with greatest refinement at *MTNR1B* (rs10830963 only), one signal at *KCNQ1* (3 SNPs map to 197bp), and *TCF7L2* (3 SNPs map to 4.3kb), and with both signals at *CDKN2A/B* each mapping to less than 1.5kb. The variants in the 99% credible sets at these nine “fine-mapped” loci are common (MAF  $\geq 5\%$ ) and predominantly non-coding, with the exception of rs13266634 (R325W) at *SLC30A8*.

**Conclusion:** Our study has provided insight into the genetic architecture of T2D and has prioritised regions for follow-up with regulatory annotation that may aid characterisation of the functional role of these GWAS loci in the pathogenesis of the disease.

## 105

### Identification of protein-coding variants associated with risk of type 2 diabetes

A. Mahajan<sup>1</sup>, C. Fuchsberger<sup>2</sup>, J. Flannick<sup>3</sup>, M. Rivas<sup>1</sup>, P. Fontanillas<sup>3</sup>, A. Morris<sup>1</sup>, T. Teslovich<sup>2</sup>, M. McCarthy<sup>1,4</sup>, for T2D-GENES and GoT2D Consortium;

<sup>1</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, UK, <sup>2</sup>University of Michigan, Ann Arbor, <sup>3</sup>Broad Institute, Cambridge, USA, <sup>4</sup>OCDEM, University of Oxford, UK.

**Background and aims:** Genome wide association studies (GWAS) have successfully identified common [minor allele frequency (MAF) >5%] genetic variants contributing to risk of type 2 diabetes (T2D). However, the impact of low-frequency (LF; MAF 0.5–5%) and rare (MAF <0.5%) variants to disease susceptibility remains widely unexplored. We evaluated the role of this class of variation to T2D predisposition, focusing on coding variants as these are enriched for functional impact and allow more direct insight into disease biology.

**Materials and methods:** We analysed: (i) exome sequence data from 12,940 individuals (6,504 T2D cases, 6,436 controls), ascertained from five major ethnic groups (European, South Asian, East Asian, Hispanic and African American); and (ii) exome-array data from additional 81,740 Europeans (29,569 T2D cases, 52,171 controls). We first performed single-variant analyses within each ethnic group, and then combined ancestry-specific association summary statistics in a trans-ethnic meta-analysis using MANTRA. We defined exome-wide significance by a  $\log_{10}$  Bayes' Factors (BF) >5. Conditional analysis was done to determine if coding variants drive the known common SNP GWAS signal, or represent statistically independent associations.

**Results:** In the combined analysis, 26 coding variants, mapping to 18 loci, were associated with T2D at exome-wide significance. All except two have MAF >5% in the ethnic group driving the association signal. Of these, seven variants at five loci (*SLC30A8*, *MACF1*, *GCKR*, *PPARG*, and *KCNJ11-ABCC8*) were confirmatory of previously-reported common coding variants driving GWAS signals. Of the remaining 19 T2D-associated coding variants, 13 also mapped to established GWAS loci but have not previously been reported to be causal. These included *PAX4* R192H (rs2233580,  $\log_{10}$ BF >6.3), a signal driven exclusively by East Asians (odds ratio=1.79[1.59–1.99], MAF ~10%). Reciprocal conditional analyses at these loci revealed the novel coding variants to be either independent of, or indistinguishable from previously report-

ed lead GWAS SNPs, and implicate several novel genes - including *RREB1*, *THADA*, and *TM6SF2* - in T2D pathogenesis. The remaining six variants, mapping to three loci, were located entirely outside known GWAS regions. These include two variants in *PAM* (D563G,  $\log_{10}$ BF=9.96) and *PP1P5K2* (S1207G,  $\log_{10}$ BF=7.47), for which a T2D-association was recently described in the Icelandic population. Three further highly-correlated coding variants at *MTMR3/ASCC2* were associated with T2D (Europeans specific signal). The *MTMR3* variant ( $\log_{10}$ BF=6.46) has the strongest residual association signal after accounting for the other variants and represents the most plausible candidate at this novel locus. The last novel locus was *FAM63A* ( $\log_{10}$ BF=5.24) and signal was driven by a LF variant. The T2D risk-allele has a MAF of 1% in Europeans, and was otherwise only detected in South Asian sequence data (11 copies,  $p=0.02$  for association).

**Conclusion:** Here we show that rare and LF coding variants of moderate to large effect are not major contributors to T2D risk. We identify 26 coding variants with exome-wide significant associations with T2D and highlight the promise of this approach to provide insight into the pathophysiology of the disease.

## 106

### Meta-analysis of birth weight genome-wide association studies identifies two novel loci extending links between early growth and adult metabolic diseases

M. Horikoshi<sup>1,2</sup>, M.N. Kooijman<sup>3</sup>, J.P. Bradfield<sup>4</sup>, D. Strachan<sup>5</sup>, N.V. Tejedor<sup>6</sup>, E. Kreiner-Møller<sup>7</sup>, P. Joshi<sup>8</sup>, V. Lindi<sup>9</sup>, N. Grarup<sup>10</sup>, S.F.A. Grant<sup>4</sup>, M.I. McCarthy<sup>1,2</sup>, I. Prokopenko<sup>11</sup>, R.M. Freathy<sup>12</sup>, A.P. Morris<sup>1,13</sup>, EGG Consortium;

<sup>1</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, <sup>2</sup>Oxford Centre for Diabetes, Endocrinology & Metabolism, UK, <sup>3</sup>Department of Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands, <sup>4</sup>Center for Applied Genomics, The Children's Hospital of Philadelphia, USA, <sup>5</sup>Population Health Research Institute, St George's, University of London, UK, <sup>6</sup>Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain, <sup>7</sup>COPSAC, the Copenhagen Prospective Studies on Asthma in Childhood; Health Sciences, University of Copenhagen, Denmark, <sup>8</sup>Centre for Population Health Sciences, University of Edinburgh, UK, <sup>9</sup>Department of Physiology, Institute of Biomedicine, University of Eastern Finland, Kuopio, Finland, <sup>10</sup>The Novo Nordisk Foundation, Center for Basic Metabolic Research, Faculty of Medical and Health Sciences, University of Copenhagen, Denmark, <sup>11</sup>Department of Genomics of Common Disease, Imperial College London, <sup>12</sup>University of Exeter Medical School, <sup>13</sup>Department of Biostatistics, University of Liverpool, UK.

**Background and aims:** Lower birth weight (BW) is associated with increased risk of future type 2 diabetes (T2D) and cardiovascular diseases. Based on HapMap 2 imputation, we previously reported 7 loci associated with BW, of which two (*ADCY5* and *CDKALI*) have been implicated in T2D and one (*ADRB1*) in hypertension. We have expanded this effort by increasing sample size and undertaking imputation up to 20.8M SNPs from the more dense 1000 Genomes Project reference panels. With these data we aimed to 1) discover novel loci; 2) assess evidence of association with low-frequency variants (minor allele frequency <5%) of larger effect sizes; and 3) fine-map established and novel loci by constructing credible sets of variants that are most likely to be causal on the basis of statistical evidence of association.

**Materials and methods:** For analysis, we considered 41,551 European singletons born at  $\geq 37$  weeks' gestation with genome-wide association (GWA) and imputation data from 17 studies. Standardized sex-specific Z-scores of BW were tested for association with each SNP assuming an additive genetic model after adjustment for gestational week where available. Association summary statistics were combined across studies using inverse-variance fixed-effects meta-analysis.

**Results:** Two novel common variant loci were detected at genome-wide significance: near *MAFB* ( $p=3.1 \times 10^{-8}$ ) and at *SREBF2* ( $p=3.9 \times 10^{-9}$ ). *MAFB* has been implicated in hyperlipidemia and *SREBF2* is involved in cholesterol biosynthesis. There was no evidence for low-frequency variants that explain common GWA signals. The 99% credible sets included fewer than 20 SNPs at 4 loci. At *ADRB1*, the credible set included just 5 variants, including G389R. We will further refine the association signals by combining with GWA studies of non-European ancestry.

**Conclusion:** Collectively, 4 of the 9 known and novel loci provide genetic links between BW and adult metabolic phenotypes such as T2D, hypertension and hyperlipidemia, highlighting complex non-linear relationships between genetic variation, early growth and later metabolic disease including T2D.

## 107

**Functional SNPs as focused gene probes: results from SUMMIT on diabetic nephropathy, coronary and lower extremity artery disease**

D. Ziemek<sup>1</sup>, E. Fauman<sup>2</sup>, N.R. Van Zuydam<sup>3</sup>, N.W. Rayner<sup>3</sup>, C.L. Hyde<sup>2</sup>, N. Sandholm<sup>4</sup>, C. Forsblom<sup>4</sup>, E. Ahlquist<sup>5</sup>, C. Ladenvall<sup>5</sup>, SUMMIT Consortium;

<sup>1</sup>Pfizer, Berlin, Germany, <sup>2</sup>Pfizer, Cambridge, USA, <sup>3</sup>OCDEM and WTCHG, University of Oxford, UK, <sup>4</sup>FINNDIANE, Folkhalsan Institute of Genetics, University of Helsinki, Finland, <sup>5</sup>Diabetes Center, Lund University, Sweden.

**Background and aims:** Diabetic nephropathy (DN), coronary (CAD) and lower extremity artery disease (LEAD) are devastating, but, at least partially, heritable complications of diabetes with a poorly understood mechanistic basis. To move towards more effective preventative and therapeutic strategies, the SUMMIT consortium has conducted large-scale genome-wide association studies. Despite large sample sizes for CAD (4009 cases and 7918 controls), LEAD (2345 cases and 8706 controls), and specific sub-phenotype interrogation in DN (5908 cases and 4965 controls), only 3 genome wide significant signals ( $p < 5 \times 10^{-8}$ ) were detected. This might imply a highly polygenic architecture of the considered phenotypes or significant noise levels in the trait definitions. At the same time, repositories such as NHGRI's GWAS catalog contain thousands of validated loci associated with a variety of traits. Each of these is likely tagging a functional alteration influencing a specific gene product. Focusing on these prior associations and their implicated genes can eliminate millions of non-functional SNPs to pinpoint variants associated with diabetic complications.

**Materials and methods:** We acquired all SNPs associated with any trait from NHGRI's GWAS catalog as well as cis-expression QTLs from the GTEx project. SNPs were pruned at a significance level of  $p < 1 \times 10^{-5}$  and reduced to lead SNPs using a p-value-dependent distance cutoff. We mapped SNPs to probable causal genes using a novel LD and distance-based algorithm that has been validated to provide an F-measure of 73% on metabolite QTLs. This resulted in a total of 11,000 SNPs associated with over 2,000 phenotypes which map to 6,500 genes. As a measure of overall signal improvement, we compared QQ-plots before and after limiting analysis to gene probe SNPs based on a Wilcoxon rank-sum test of the truncated log p-values. Finally, we computed false discovery rate estimates for all SNPs in the full and the restricted set and report variants passing an FDR cutoff of 0.3 as candidates for specific signals discovered through the method.

**Results:** We obtained significant improvements for the QQ-plots on CAD, LEAD (with various stratifications) and eGFR traits (all p-values  $< 0.01$ ). For instance, rs7173743 in the *MORF4L1* gene is associated with CAD on the background of type 2 diabetes at a q-value of 0.07 in the focused set whereas it was insignificant (q-value = 1) in the full set. When combining SUMMIT CAD data with CARDIOGRAM data, this locus reaches genome-wide significance. Other examples include rs13180 in the *IREB2* gene for LEAD in smokers (q-value  $< 0.01$ ) and rs13333226 in the *UMOD* gene (q-value  $< 0.08$ ) for eGFR.

**Conclusion:** Overall we can implicate a number of plausible loci stemming from robust prior phenotype associations in traits studied by SUMMIT on the background of diabetes. We plan to explore these results on the basis of their associated genes in pathway-based analysis to derive mechanistic insights for the traits under consideration in the SUMMIT consortium. This approach appears useful for finding novel associations for previously identified loci when the full GWAS lacks power to identify new loci achieving traditional genome-wide significance.

**Genome-wide association study for diabetic retinopathy in Japanese patients with type 2 diabetes**

M. Imamura<sup>1</sup>, A. Takahashi<sup>2</sup>, M. Kubo<sup>3</sup>, S. Maeda<sup>4</sup>;

<sup>1</sup>Laboratory for Endocrinology, Metabolism and Kidney diseases, Center for Integrative Medical Sciences, <sup>2</sup>Laboratory for Statistical Analysis, Center for Integrative Medical Sciences, <sup>3</sup>Laboratory for Genotyping Development, Center for Integrative Medical Sciences, <sup>4</sup>Laboratory for Endocrinology, Metabolism and Kidney Diseases, Riken, Center for Integrative Medical Sciences, Yokohama, Japan.

**Background and aims:** Diabetic retinopathy (DR) is one of the leading causes of blindness in Japanese adults. Several reports have shown familial aggregations of DR or advanced DR among patients with type 1 or type 2 dia-

betes, suggesting genetic susceptibility contributes to the development and/or progression of DR. Although several candidate-genes have been shown to be associated with susceptibility to DR, namely genes encoding Angiotensin-I Converting Enzyme (*ACE*), Aldose reductase (*AKR1B1*), Vascular Endothelial Growth factor A (*VEGFA*) and Erythropoietin (*EPO*), the association of these genes with DR has not reached to genome-wide significance levels ( $p$ -value  $< 5.0 \times 10^{-8}$ ) except rs1617640 in the *EPO* locus. Genome-wide association studies (GWAS) for advanced DR in European population have identified several suggestive loci with borderline association ( $p$ -value  $< 1 \times 10^{-6}$ ), however the association of these loci with DR is still inconclusive. To identify novel genetic loci associated with the susceptibility to DR, we performed GWAS for DR in Japanese patients with type 2 diabetes.

**Materials and methods:** We divided Japanese patients with type 2 diabetes, registered in BioBank Japan, into 2 groups; 1) DR cases, defined as patients having any stages of DR, and 2) controls, who did not have any sign of DR and with long duration of diabetes ( $\geq 10$  years) or with diabetic nephropathy. We examined 2 independent case-control groups (Study-1; 4,839 DR cases and 4,041 controls, Study-2; 693 DR cases and 1,524 controls) for  $\sim 7.5$  million single nucleotide polymorphisms (SNPs) from directly genotyped data (Study-1; Omni-express, Study-2; Illumina 610K) and genotype imputation using mini-MACH. Results of the 2 GWAS were combined with an inverse variance method in a fixed effect model.

**Results:** We identified 5 SNP loci associated with DR in Japanese patients with type 2 diabetes (rs8025089 on chromosome [Ch]15:  $p = 3.0 \times 10^{-7}$ , Odds ratio [OR] = 1.15, 95% confidence interval [CI], 1.09-1.22, rs12630354 on Ch3:  $p = 4.2 \times 10^{-7}$ , OR = 1.15, 95% CI, 1.09-1.22, rs2471299 on Ch7:  $p = 1.5 \times 10^{-6}$ , OR = 1.14, 95% CI, 1.08-1.20, rs2517532 on Ch6:  $p = 3.9 \times 10^{-6}$ , OR = 1.13, 95% CI, 1.08-1.19, rs4240499 on Ch10:  $p = 4.4 \times 10^{-6}$ , OR = 1.17, 95% CI, 1.10-1.26). A sub-group analysis, excluding patients with simple DR, has identified 3 loci associated with advanced DR (2,003 DR cases [Study-1] and 368 DR cases [Study-2]) ( $p < 1 \times 10^{-3}$ ). None of the association reached to genome-wide significance level ( $p < 5.0 \times 10^{-8}$ ) in this study. Regarding previously reported DR susceptible loci (*ACE*, *AKR1B1*, *VEGFA* and *EPO*), none of these loci was significantly associated with DR in the present study.

**Conclusion:** We have identified several candidate loci potentially contributing to DR susceptibility, although further studies are required to validate the association of these loci with DR.

## OP 19 Insulin: clinical decision making

109

### Clinical factors influencing the basal rate profile in subjects with type 1 diabetes treated with continuous subcutaneous insulin infusion (insulin pumps)

M. Kahle, U. Buss, A. Varnhorn, B. Nawrodt, M.A. Nauck;  
Diabeteszentrum Bad Lauterberg, Germany.

**Background and aims:** Defining an individually appropriate basal rate profile in patients with type 1 diabetes requires knowledge about the general shape of such a profile, and needs to take into account patient factors with a significant influence on (a) the total dose of insulin administered as a basal rate and (b) the circadian variation in insulin needs. We assessed these influences based on a retrospective analysis of 339 patients, in whom the adequacy of basal rates was checked by means of a 24 h fasting period.

**Materials and methods:** Laboratory-based blood glucose profiles determined during regular day and night (eating meals) and during a 24 h fasting period (6 p.m. to 6 p.m.) and basal rate profiles corrected after the fasting period were entered into our database for 339 patients with type 1 diabetes during inpatient treatment in a specialized diabetes centre (183 women, 156 men; age  $41 \pm 14$  years,  $HbA_{1c}$   $8.3 \pm 1.6$  %; BMI  $26.1 \pm 4.9$  kg/m<sup>2</sup>; diabetes duration  $20 \pm 12$  years; insulin dose  $0.55 \pm 0.20$  IU/kg body weight per day). Patients were divided according to gender, or into tertiles of age, body-mass-index, and diabetes duration. A significant influence of the characteristic in question was assessed by repeated-measures ANOVA on hourly basal rates and also expressed as a percentage of the overall 24 h basal rate for each individual hour.

**Results:** A 24 h fasting period resulted in relatively stable blood glucose values of  $6.6 \pm 2.8$  mmol/L with 11.5 % of the values  $> 9.9$  mmol/L and 11.3 % of the values  $< 3.7$  mmol/L. Basal rates after correction for low or high blood glucose values during the fasting period showed typical circadian rhythms with “dawn-” and “dusk-” phenomena and a total (mean  $\pm$  SD) basal rate of  $21.5 \pm 9.2$  IU/day. There were significant differences due to gender (more prominent dawn phenomenon in males;  $p < 0.0001$ ), age (more prominent dawn phenomenon in younger subjects;  $p = 0.036$ ), body mass index (higher overall basal rates in more obese subjects;  $p < 0.0001$ ; with no influence on the circadian distribution  $p = 1.00$ ), and diabetes duration (more prominent dawn phenomenon in those with shorter diabetes duration;  $p < 0.0001$ ).

**Conclusion:** Our large database helps define basal rate profiles for subjects with type 1 diabetes treated with continuous subcutaneous insulin infusions. It also allows to take into account clinical characteristics of the patients with a significant influence on the basal rate profile (both total amount of insulin and circadian profile) to individually predict insulin requirements during insulin pump treatment. Based on multivariate regression analysis, it may be possible to predict individual hourly basal rates with reasonable confidence intervals.

110

### Relationship of $HbA_{1c}$ with body weight change over 4 years from starting insulin therapy in people with type 2 diabetes: the CREDIT study

B. Balkau<sup>1</sup>, N. Freemantle<sup>2</sup>, F. Calvi-Gries<sup>3</sup>, V. Pilorget<sup>4</sup>, M. Vincent<sup>4</sup>, P. Home<sup>5</sup>;

<sup>1</sup>INSERM, U1018, University Paris Sud 11, UMRS 1018, Villejuif, France,

<sup>2</sup>University College London, UK, <sup>3</sup>AtlanStat, Rezé, France,

<sup>4</sup>Sanofi, Paris, France, <sup>5</sup>Newcastle University, Newcastle upon Tyne, UK.

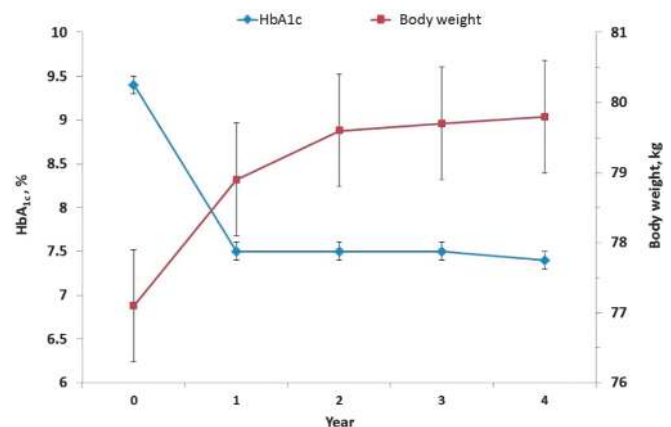

**Background and aims:** Insulin treatment is often delayed for people with type 2 diabetes; fear of weight gain and any consequences of glycaemic control can factor in that delay. Clinical trials provide some insight into this issue but have limited generalisability due to restrictions on participant selection and treatments used. Here, we examine the relationship between change in body weight and  $HbA_{1c}$  over 4 years of insulin therapy in routine clinical practice.

**Materials and methods:** CREDIT was a noninterventional study of people with type 2 diabetes beginning insulin therapy in Europe, North America, and Asia. Physicians were free to choose and adapt treatments in accordance with usual practice; data were collected from physician records. Univariate

and multivariable analyses were used to determine the relationship between change in body weight and  $HbA_{1c}$  over 4 years.

**Results:** Determinants of  $HbA_{1c}$  were studied in 1973 people with 4-year data from starting insulin; 47% were men, baseline mean age  $61 \pm 10$  (SD) years, BMI  $29.2 \pm 6.1$  kg/m<sup>2</sup>,  $10 \pm 8$  years of diabetes,  $HbA_{1c}$   $9.5 \pm 1.9$  % ( $80 \pm 21$  mmol/mol), 69% continuing oral glucose-lowering therapies. Half were started on basal insulin alone, 23% on premix insulin alone, and 15% on basal + meal-time insulin; over all insulin regimens, starting insulin dose was  $0.26 \pm 0.18$  U/kg. In the first year,  $HbA_{1c}$  declined, then remained stable (Figure), with a decrease at year 4 of  $-2.0 \pm 2.1$  % ( $-22 \pm 23$  mmol/mol). Body weight increased an average of  $1.9 \pm 4.7$  kg in the first year, but  $< 1.0$  kg over the subsequent 3 years; over the 4 years, weight increased by  $2.6 \pm 7.4$  kg. Daily insulin dose increased  $0.15 \pm 0.23$  U/kg over the first year and by  $0.27 \pm 0.31$  U/kg over the 4 years. This was accompanied by a change in insulin regimen from starting insulin to 4 years for 44% of population (30% on basal alone, 33% on basal + meal-time, and 25% on premix alone at year 4). After adjusting for region and centre, 4-year change in weight was predictive of  $HbA_{1c}$  at year 4 ( $P < 0.0001$ ), but with a small effect size: a weight gain of 2.6 kg was associated with a 0.005 %-unit (0.05 mmol/mol) higher  $HbA_{1c}$  at year 4. Other variables were associated with  $HbA_{1c}$  at year 4: baseline  $HbA_{1c}$ , BMI, age, and at 4 years, insulin dose, number of oral glucose-lowering drugs and symptomatic hypoglycaemia. Taking these variables into account, weight change remained predictive of  $HbA_{1c}$  at year 4 ( $P < 0.04$ ). Symmetrically, the odds ratio (95% CI) for an  $HbA_{1c}$  below 7.0 % vs.  $HbA_{1c} \geq 7.0$  % at year 4 following a 1.0 kg increase in weight over the 4-year period, was 0.97 (0.96, 0.99;  $P = 0.0015$ ), after adjusting for other predictive variables.

**Conclusion:** After 4 years of insulin treatment in people with type 2 diabetes, weight gain was associated with minimally higher  $HbA_{1c}$  values at year 4. These results should allay fears of weight gain having a strong impact on glycaemic control.

### The INITIATOR study: real-world treatment patterns and outcomes in patients with type 2 diabetes initiating insulin glargine or liraglutide

P.A. Levin<sup>1</sup>, W. Wei<sup>2</sup>, E. Buysman<sup>3</sup>, S. Thayer<sup>3</sup>, L. Brekke<sup>3</sup>, W.H. Crown<sup>3</sup>, M. Grabner<sup>4</sup>, X. Ke<sup>4</sup>, R.A. Quimbo<sup>4</sup>, M.J. Cziraky<sup>4</sup>, W. Hu<sup>2</sup>, R. Cuddihy<sup>2</sup>, J.W. Chu<sup>5</sup>;

<sup>1</sup>MODEL Clinical Research, Baltimore, <sup>2</sup>Sanofi US, Bridgewater,

<sup>3</sup>Optum, Eden Prairie, <sup>4</sup>HealthCore, Wilmington,

<sup>5</sup>Monterey Endocrine & Diabetes Institute, Monterey, USA.

**Background and aims:** Patients with type 2 diabetes mellitus (T2DM) not achieving glycaemic control on oral antidiabetic drugs (OADs) can initiate injectable therapy with insulin or a glucagon-like peptide-1 receptor agonist (GLP-1) analogue. As the first large real-world observational longitudinal study of T2DM patients Initiating New Injectable Treatment Introduced after Anti-diabetic Therapy with Oral-only Regimens (INITIATOR), this analysis aimed to provide a comprehensive understanding of patient characteristics, treatment patterns, and associated outcomes.

**Materials and methods:** T2DM patients from 2 of the largest US commercial health insurers who were aged  $\geq 18$  years, previously on OADs only, and initiated either insulin glargine pen (GLA) or the GLP1 analogue liraglutide (LIRA) between April 1, 2010-March 31, 2012 were included. Patients had continuous healthcare coverage during the 6 months before (baseline [BL]),

and 12 months after initiation (follow-up). Health claims and medical chart data from eligible patients were extracted by OP and HC from their respective health plans. We compared differences in BL characteristics between treatment groups and 1-year follow-up measures to BL within each group. Treatment patterns, and clinical and economic outcomes at follow-up were assessed descriptively within each health plan.

**Results:** 4,490 patients were included (45.5% women; mean age 52.7 years; mean number of OADs 2). Significant BL differences existed: GLA patients had higher comorbidity burden, higher HbA<sub>1c</sub>, lower weight, and were less often women (Table). A total of 23.8% of LIRA patients had a HbA<sub>1c</sub> level of < 7.0% and 21.4% reported 'improve weight control' as a reason for initiation. At 1 year follow-up, overall treatment persistence was 64.0% for GLA and 49.4% for LIRA patients; 3.5% of GLA patients were on twice-daily GLA. Both groups had significant HbA<sub>1c</sub> reductions. GLA patients had a slight weight gain whereas LIRA patients lost weight. Overall follow-up hypoglycaemia rates were 16% in GLA and 9% in LIRA patients; rates of severe hypoglycaemia were low. Compared with BL, LIRA patients had significant increases in total healthcare costs (OP and HC), in contrast to GLA patients who had fewer diabetes-related hospitalizations (OP only) and no increase in total healthcare costs. LIRA (OP and HC) and GLA patients (OP only) incurred higher diabetes drug costs.

**Conclusion:** These findings showed clinically relevant differences in BL characteristics and follow-up outcomes in T2DM patients initiating GLA or LIRA. This study highlights challenges in translating clinical trial findings into real-world settings, and in conducting comparative effectiveness studies where important BL group differences may exist.

### Characteristics of patients with type 2 diabetes mellitus (T2DM) on basal insulin who do not achieve glycaemic goals

S. Brunton<sup>1</sup>, L. Blonde<sup>2</sup>, P. Chava<sup>3</sup>, R. Zhou<sup>3</sup>, J. Meyers<sup>4</sup>, K. Davis<sup>4</sup>, M. Dalal<sup>5</sup>, A. DiGenio<sup>6</sup>,

<sup>1</sup>University of North Carolina, Chapel Hill,

<sup>2</sup>Ochsner Medical Center, New Orleans, <sup>3</sup>Medpace Inc., Cincinnati,

<sup>4</sup>RTI Health Solutions, Research Triangle Park, <sup>5</sup>Sanofi US, Inc., Bridgewater,

<sup>6</sup>Isis Pharmaceuticals, Inc., Carlsbad, USA.

**Background and aims:** Despite the efficacy of basal insulin therapy in individuals with T2DM, a significant number of patients may not achieve glycaemic goals. Patients taking basal insulin who reach their fasting plasma glucose (FPG) goal but not their glycated haemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) target represent an important unmet T2DM management need. This study used both randomized clinical trial (RCT) and "real-world" data to compare the baseline characteristics of T2DM patients with HbA<sub>1c</sub> ≥ 7.0% achieving FPG levels < and ≥130 mg/dL.

**Materials and methods:** Characteristics, including age, gender, BMI, and weight, of patients on basal insulin who do or do not achieve HbA<sub>1c</sub> < 7.0% were analysed using 11 pooled RCTs assessing insulin glargine (6-months follow-up) and real-world data from the GE Centricity electronic medical records (EMR) database (6- and 12-months follow-up). Patients with HbA<sub>1c</sub> ≥ 7.0% were stratified by FPG level (< 130 or ≥ 130 mg/dL).

**Results:** Patients with high HbA<sub>1c</sub> at follow-up also had high baseline HbA<sub>1c</sub> (HbA<sub>1c</sub> ≥ 7.0% vs < 7.0%: RCT, 9.1% vs 8.5%; EMR: 9.0% vs 8.1% [6-months

follow-up] and 9.0% vs 8.0% [12-months follow-up]). About 50% of the RCT patients reached HbA<sub>1c</sub> goal vs < 30% of EMR patients. Of patients with HbA<sub>1c</sub> ≥ 7.0%, about 50% (RCT) and < 30% (EMR) achieved FPG < 130 mg/dL. RCT patients tended to be younger, less obese, and weigh less vs EMR patients (mean: age 2-4 years younger; BMI ~3 kg/m<sup>2</sup> less; and weight ~6 kg less). Patients with HbA<sub>1c</sub> < 7.0% were somewhat older than those with HbA<sub>1c</sub> ≥ 7.0% (mean age in years for HbA<sub>1c</sub> < 7.0% vs ≥ 7.0%: RCT, 58.4 vs 57.7; EMR, 62.3 vs 60.2 [6-months follow-up] and 62.7 vs 59.8 [12-months follow-up]). Little difference existed in gender distribution or mean BMI for patients with HbA<sub>1c</sub> < 7.0% versus HbA<sub>1c</sub> ≥ 7.0%. For both RCT and EMR patients with HbA<sub>1c</sub> ≥ 7.0%, those with FPG < 130 mg/dL were slightly older than those with FPG ≥ 130 mg/dL (mean age for FPG < 130 vs ≥ 130 mg/dL: RCT, 58.7 vs 56.4 years; EMR, 62.3 vs 59.6 [6-months follow-up] and 62.4 vs 59.0 [12-months follow-up]). Differences were also seen in baseline insulin usage in the RCT patients, with more patients with FPG ≥ 130 mg/dL using a fast-acting insulin analogue (71.2% vs 28.9%). For both RCT and EMR patients, other demographic characteristics did not differ between the FPG groups.

**Conclusion:** We present differences in characteristics between patients on basal insulin who do or do not achieve HbA<sub>1c</sub> < 7.0%. Patients with a higher baseline HbA<sub>1c</sub> were less likely to achieve target HbA<sub>1c</sub> < 7.0% on basal insulin alone; more intensive treatment regimens may be required. A large proportion of the HbA<sub>1c</sub> > 7.0% patients were also above target for FPG at follow-up and would likely benefit from addition basal insulin titration. In patients achieving FPG < 130 mg/dL, despite above target HbA<sub>1c</sub> values, postprandial glucose (PPG) control could be used to help bring their HbA<sub>1c</sub> within recommended limits. Appropriate therapeutic choices for those not reaching HbA<sub>1c</sub> < 7.0% should be based on assessment of FPG and PPG, as well as of HbA<sub>1c</sub>. A better understanding of patient characteristics and factors involved in goal achievement might increase the numbers of patients reaching targets and reduce the time they are exposed to hyperglycaemia and its adverse consequences.

### People with type 2 diabetes with lower HbA<sub>1c</sub> using insulin experience fewer cardiovascular events and death: results from the CREDIT study

N. Freemantle<sup>1</sup>, N. Danchin<sup>2</sup>, F. Calvi-Gries<sup>3</sup>, M.-P. Dain<sup>4</sup>, M. Vincent<sup>4</sup>, P. Home<sup>5</sup>,  
<sup>1</sup>Department of Primary Care and Population Health, University College London, UK, <sup>2</sup>Universite Paris 5, <sup>3</sup>AtlasStat, Rezé, <sup>4</sup>Sanofi, Paris, France, <sup>5</sup>Institute for Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK.

**Background and aims:** CREDIT (Cardiovascular Risk Evaluation in people with Type 2 Diabetes on Insulin Therapy) was a noninterventional study designed to examine relationships between HbA<sub>1c</sub> and cardiovascular (CV) events in 2999 patients beginning insulin in real-world practice in Europe, North America, and Asia, with up to 54 months' follow-up. The study did not impact normal practice, having no intervention or formal visits-instead, data were collected from physician reports.

**Materials and methods:** Primary outcome was the composite of nonfatal stroke or myocardial infarction (MI) or CV death. Events were blindly adjudicated by an endpoints committee. Relative hazard of CV events was described with Cox proportional hazards models, including patient risk factors, and updated mean HbA<sub>1c</sub> as a time-dependent covariate. Primary outcome components were described separately. The relationship of severe and symptomatic hypoglycaemia (collected observationally for prior 6 months) to CV and all-cause mortality was examined by adding patient-level covariates to the Cox models.

**Results:** In total, 147 primary events were accrued during study follow-up. There were 60 CV deaths, 44 nonfatal MIs, and 57 nonfatal strokes, with 148 all-cause deaths. There was a significant positive relationship between updated mean HbA<sub>1c</sub> and primary outcome; hazard ratio (HR) 1.25 (95% CI: 1.12-1.40; P<0.0001). CV death (HR 1.31 [1.10-1.57]; P=0.0027) and stroke (HR 1.36 [1.17-1.59]; P<0.0001) were both strongly associated with HbA<sub>1c</sub>, but MI was not (HR 1.05 [0.83-1.32]). One or more severe hypoglycaemic episodes affected 175 participants, while 1508 experienced ≥1 symptomatic hypoglycaemic event. We found no relationship between history of severe or symptomatic hypoglycaemic events and CV or all-cause death.

**Conclusion:** Thus, as measured in the CREDIT study, ongoing poorer glucose control was associated with CV events; hypoglycaemia was not associated with CV or all-cause death.

## 114

**Intensive versus conservative glucose control in patients undergoing coronary artery bypass graft surgery (GLUCO-CABG Trial)**

D. Smiley<sup>1</sup>, S. Cardona<sup>1</sup>, F. Pasquel<sup>1</sup>, F. Farrokhi<sup>1</sup>, S. Jacobs<sup>1</sup>, L. Peng<sup>2</sup>, M. Halkos<sup>1</sup>, J.D. Puskas<sup>1</sup>, R.A. Guyton<sup>1</sup>, V. Thourani<sup>1</sup>, G.E. Umpierrez<sup>1</sup>;  
<sup>1</sup>Medicine-Division of Endocrinology, Emory University,  
<sup>2</sup>Biostatistics, Rollins School of Public Health, Atlanta, USA.

**Background and aims:** This randomized controlled trial aimed to determine whether intensive glucose control (intensive, BG target: 5.6–7.8 mmol/L) reduces perioperative complications compared to conservative glucose control (conservative, BG target: 7.8–10 mmol/L) in hyperglycaemic patients undergoing CABG.

**Materials and methods:** After ICU care, subjects were transitioned to the same treatment regimen targeting BG <7.8 mmol/L before meals during the hospital stay and 90 days post discharge. The primary outcome was differences in a composite score of hospital complications including mortality, wound infection, pneumonia, bacteremia, respiratory failure, acute renal failure, and major cardiovascular events.

**Results:** A total of 302 patients were randomized to intensive (n=151) or conservative (n=151) glucose control following a computerized insulin infusion algorithm. The groups were well balanced. The mean ICU daily BG was 7.3±0.78 mmol/L (IQR 6.9–7.7) in the intensive group and 8.6±1.1 mmol/L (IQR 7.9–9.1) in the conservative group (p=0.99), and the hospital length of stay was 11.4±11 vs. 9.5±6 days (p=0.13), respectively. In the ICU, a BG <3.9 mmol/L occurred in 8% and 2% of the intensive and conservative groups (p=0.03), with no BG <2.2 mmol/L. After ICU care, there were no differences between intensive and conservative groups in mean daily BG (7.9±1.6 mmol/L vs. 7.8 ±1.6 mmol/L), patients with hypoglycaemia (<2.2 mmol/L: 1% vs. 3%, p=0.68), or hospital readmissions (18% vs. 20%, p=0.62).

**Conclusion:** In summary, intensive control targeting a BG of 5.6–7.8 mmol/L in the ICU did not reduce perioperative complications, mortality or hospital length of stay compared to a less strict glucose target of 7.8–10 mmol/L in hyperglycaemic patients undergoing CABG surgery.

**Effect of omarigliptin, a novel once-weekly DPP-4 inhibitor, in Japanese patients with type 2 diabetes: a placebo- and sitagliptin-controlled trial**

I. Gantz<sup>1</sup>, T. Okamoto<sup>2</sup>, Y. Ito<sup>2</sup>, K. Okuyama<sup>2</sup>, S.S. Engel<sup>1</sup>;  
<sup>1</sup>Merck Sharp & Dohme Corp., Whitehouse Station, USA,  
<sup>2</sup>MSD K. K., Tokyo, Japan.

**Background and aims:** Omarigliptin (OMARI) is a potent, oral, once-weekly, dipeptidyl peptidase-4 (DPP-4) inhibitor in development for the treatment of type 2 diabetes mellitus. This is a randomized, double-blind, parallel-group, active and placebo-controlled study in monotherapy for Japanese patients with type 2 diabetes mellitus (T2DM) to assess the efficacy, safety, and tolerability of OMARI compared to placebo (PBO) and sitagliptin (SITA), a commonly used once-daily DPP-4 inhibitor.

**Materials and methods:** Patients either not on or on an oral antihyperglycemic agent (AHA) were eligible. After a diet/exercise run-in and, for patients on an AHA, a drug wash-off period, eligible patients (N = 414) were randomized (2:2:1) to OMARI 25 mg q.w., SITA 50 mg q.d. (recommended dose in Japan), or PBO for 24 weeks. The primary efficacy endpoint was the change in HbA1c from baseline at Week 24 with two co-primary hypotheses, superiority of OMARI to PBO and non-inferiority of OMARI to SITA based on the prespecified criterion of having an upper bound of the 95% confidence interval (CI) less than 0.3%.

**Results:** Treatment groups were well-balanced for baseline characteristics. At baseline, randomized patients had a mean HbA1c of 7.9, 8.0 and 8.1% in OMARI, SITA, and PBO group, respectively. Mean fasting plasma glucose (FPG) was also similar between treatment groups with 9.0, 8.8, and 9.0 mmol/L in OMARI, SITA and PBO group, respectively. At Week 24, OMARI significantly changed HbA1c by -0.80% from baseline relative to PBO (Table). The change (least squares mean, 95% CI) relative to SITA was -0.02% (-0.15, 0.12) and met the prespecified non-inferiority criterion. FPG and 2hr post meal glucose were significantly reduced from baseline with OMARI and SITA relative to PBO. OMARI was well tolerated without symptomatic hypoglycaemia and was not associated with weight gain.

**Conclusion:** In monotherapy, treatment with once-weekly OMARI provided comparable efficacy to once-daily SITA and was generally well tolerated over 24 weeks in patients with T2DM.

## 116

**Postprandial effects of the phosphodiesterase-5 (PDE-5) inhibitor tadalafil in type 2 diabetes patients: a randomised controlled trial**

L. Sjogren, J. Olausson, L. Strindberg, R. Mobini, P. Fogelstrand, L. Mattsson Hultén, P.-A. Jansson;  
 Molecular and Clinical Medicine, Medicine, Gothenburg, Sweden.

**Background and aims:** Type 2 diabetes (T2D) is characterised by postprandial hyperglycaemia and it is important to find better treatment for this metabolic aberration. One strategy may be to amplify NO signalling through PDE-5 inhibition which increases intracellular cyclic GMP levels. Previous data have shown that PDE-5 inhibition induced by tadalafil was able to im-

prove markers of insulin sensitivity in T2D patients. Here, we investigated acute metabolic and vascular effects of tadalafil in T2D patients after a mixed meal.

**Materials and methods:** We performed a randomised, double blind, placebo controlled trial, in parallel groups. Twenty-six T2D patients (Age: 40–70 (male) and 50–70 years (female); BMI: 27–40 kg/m<sup>2</sup>; HbA1c < 60 mmol/mol) were enrolled and they received either 20 mg tadalafil (n=14) or placebo (n=12) 30 min prior to a mixed meal. To assess forearm glucose uptake (FGU) and muscle capillary recruitment (PSglu), intramuscular microdialysis was combined with arterial and venous blood sampling, as well as plethysmography monitoring of forearm blood flow (FBF). Blood samples and tissue dialysates were repeatedly collected for 5 hours. We used an ANOVA and Mann-Whitney U-test for all statistical analyses. Furthermore, we performed an ad hoc analysis excluding patients on ACE-inhibitors because this family of drugs have known positive effects on glucose metabolism. Accordingly, 10 patients in the tadalafil group and 9 patients in the placebo group were evaluated in a subgroup analysis.

**Results:** The groups were comparable regarding gender, age, BMI and HbA1c. ITT analyses showed that T2D patients in the tadalafil group increased FBF ( $p < 0.05$ ), whereas this was not observed in the placebo group. Moreover, incremental area under the curve (IAUC) for FGU and IAUC for PSglu during 5 hrs after the meal were similar in the two groups. However, the ad hoc analysis showed a significant increase ( $p < 0.05$ ) for IAUC FGU as well as for IAUC PSglu ( $p < 0.05$ ) in T2D patients treated with tadalafil (n=10) compared with placebo (n=9). Finally, postprandial glucose and insulin concentrations were similar in the two groups.

**Conclusion:** In conclusion, our data suggest that tadalafil may induce positive metabolic and vascular effects in the postprandial state in type 2 diabetes patients.

### A selective GPR40 (FFAR1) agonist provides immediate and durable glucose control in rodent models of type 2 diabetes

Y. Chen;

Eli Lilly & Co, Indianapolis, USA.

**Background and aims:** LY2881835 (LY) is a high affinity, potent, and efficacious GPR40 agonist when examined in GPR40 receptor binding and cell-based assays. In addition, a statistically significant (SS) increase in glucose-dependent insulin secretion was seen when LY was examined in primary mouse, rat and human islets. The following studies were performed to 1) explore the in vivo selectivity of LY using wild type (WT), GPR40 KO-, and GPR120-KO mice plus 2) the glucose lowering properties of LY in rodent models of type 2 diabetes.

**Materials and methods:** Islets isolated from the WT, GPR40 KO- and GPR120-KO mice were treated with LY2881835. Insulin concentrations were measured after drug incubation for 90 min. LY2881835 was administered orally to the WT, GPR40 KO- and GPR120-KO mice. An OGTT was performed 60 minutes following drug administration and immediately prior to administration of the oral glucose bolus. LY2881835 was administered orally once daily to DIO or Streptozotocin (STZ)-treated DIO mice for 14 days. OGTTs were performed on days 1, or 7 and 14 with the oral glucose bolus administered at 30 or 60 minutes following drug administration.

**Results:** A statistically significant (SS) increase in Insulin secretion was seen when LY was tested in primary islets from WT and GPR120 KO mice; although, no insulin secretion was detected in primary islets from GPR40 KO mice. OGTTs performed in WT, GPR40- and GPR120-KO mice following oral administration of LY at 30 mg/kg demonstrated SS reductions in glucose AUCs in WT and GPR120 KO mice but not in GPR40-KO mice when compared to controls. These findings demonstrate that LY induces specific GPR40-mediated anti-diabetic activity when examined ex-vivo and in-vivo. To explore the activity and the durability of LY in a model of insulin resistance, LY was administered orally, at 30 mg/kg to DIO mice (a model of Insulin resistance induced by a high fat/sucrose diet) for 14 days with OGTTs performed on days 1 and 14. SS reductions in glucose AUCs were seen on days 1 and 14. A similar study was performed in STZ-treated DIO mice to explore glucose control in a model of type 2 diabetes. In this model, pancreatic insulin content was reduced ~80% due to STZ-treatment. Glucose AUCs were SS reduced during OGTTs performed on days 1, 7 and 14 compared to control mice.

**Conclusion:** These results demonstrate that LY functions as a GPR40-specific agonist mediating immediate and durable glucose control in rodent models of type 2 diabetes. The findings suggest that GPR40 agonism could benefit glucose control across the spectrum of type 2 diabetes phenotypes including those patients with insulin resistance and substantially reduced beta-cell function.

### Pramlintide-insulin fixed-dose combination: a phase 1 dose ratio-finding study in patients with type 1 diabetes mellitus

T. de Bruin<sup>1</sup>, K. Yuen<sup>2</sup>, M.C. Riddle<sup>2</sup>, K. Herrmann<sup>3</sup>, P. Martin<sup>1</sup>, O. Kolterman<sup>4</sup>, P. Ohman<sup>5</sup>;

<sup>1</sup>AstraZeneca, Wilmington, <sup>2</sup>Oregon Health & Science University, Portland, <sup>3</sup>AstraZeneca, San Diego, <sup>4</sup>Consultant, La Jolla, <sup>5</sup>AstraZeneca, Gaithersburg, USA.

**Background and aims:** Patients with type 1 diabetes mellitus (T1DM) lack secretion of both insulin and amylin, which are normally co-secreted by  $\beta$ -cells; thus, replacing both hormones may provide therapeutic advantages in optimizing glycaemic control. In treating T1DM, fixed doses (e.g. 60  $\mu$ g) of pramlintide (an analog of human amylin) are administered as adjunct to prandial insulin, irrespective of insulin dose. This phase 1 study adjusted the pramlintide dose relative to insulin and examined the effects of 3 dose ratios on postprandial glucose and glucagon for 3 hours after a standard breakfast (600 kcal, 55% carbohydrate, 15% protein, 30% fat) meal.

**Materials and methods:** Subjects in this single-blinded, 4-way, crossover study received regular insulin + placebo, pramlintide 6  $\mu$ g/U + regular insulin, 9  $\mu$ g/U + regular insulin, and 12  $\mu$ g/U + regular insulin in random order, using a 30% reduction in usual preprandial insulin dose with an allowed maximum of 10U in all treatment groups before the test meal. Adverse events were identified on non-directed questioning, laboratory values, vital signs, and physical exam.

**Results:** Of 19 subjects randomized (mean [SD] age 46.2 [15.6] years, HbA1c 7.75 [0.58] %, weight 81.5 [11.1] kg, BMI 26.4 [2.6] kg/m<sup>2</sup>), 17 completed all four treatments. Premeal fasting plasma glucose levels ranged from 7.7 (2.0) to 8.7 (2.0) mmol/L, and insulin doses from 5.1 (1.54) to 5.4 (1.28) U across all groups. Mean (SEM) postprandial incremental glucose AUC<sub>0-3h</sub> (mmol/L•h) for the pramlintide 6, 9, and 12  $\mu$ g/U + regular insulin groups were 456.6 (102.7), 476.7 (103.5), and 321.3 (99.8), respectively, versus 1142.5 (99.7) for placebo. Postprandial incremental glucagon AUC<sub>0-3h</sub> (ng/L•h) for the pramlintide 6, 9, and 12  $\mu$ g/U + regular insulin groups were 649.4 (342.5), 614.9 (345.0), and 677.7 (333.8), respectively, versus 1503.0 (334.2) for placebo. All three pramlintide dose ratios lowered incremental glucose and glucagon AUC 58–72% and 55–59%, respectively, versus placebo. No treatment-related hypoglycaemia was reported. One subject reported nausea in all 3 pramlintide dose ratios, and 1 reported abdominal pain and diarrhoea.

**Conclusion:** All three pramlintide dose ratios showed efficacy in lowering postprandial glucose and glucagon levels, and were generally well-tolerated.

## 119

### A novel chemically modified analogue of xenin-25 exhibits improved glucose-lowering and insulin-releasing actions

V.A. Gault, C.M. Martin, V. Parthasarathy, N. Irwin;

School of Biomedical Sciences, University of Ulster, Coleraine, UK.

**Background and aims:** Xenin-25 is a K-cell derived gut peptide that is co-secreted with glucose-dependent insulinotropic polypeptide (GIP) following a meal. Recent studies have shown that xenin-25 improves glucose homeostasis and possibly potentiates the biological action of GIP. However, like many regulatory gut peptides, xenin-25 is rapidly degraded by plasma enzymes following release into the circulation. The aim of the present study was to examine the biological actions of a novel analogue of xenin-25, chemically modified by substitution of naturally occurring Lys and Arg residues with Gln, namely xenin-25(Gln).

**Materials and methods:** Xenin-25 and xenin-25(Gln) were synthesised by Fmoc peptide chemistry, purified by rp-HPLC and characterised by MALDI-ToF MS. Xenin-25 and xenin-25(Gln) were incubated with murine plasma in 50 mmol/l TEA/HCl buffer (pH 7.8) at 37°C for 0, 2, 8 and 24 hours and degradation profiles analysed by rp-HPLC and MALDI-ToF MS. *In vitro* insulin-

releasing properties of xenin-25(Gln) ( $10^{-12}$  to  $10^{-6}$  mol/l) were determined in BRIN-BD11 cells ( $n=8$ ; 20 min incubation) at 5.6 and 16.7 mmol/l glucose concentrations in the absence and presence of (d-Ala<sup>2</sup>)GIP. Acute effects of xenin-25(Gln) (25 nmol/kg bw; *ip*) on plasma glucose and Insulin concentrations were examined in NIH Swiss mice fed a high fat diet (45% fat, 35% carbohydrate and 20% protein) for 140 days prior to experiment. Persistent effects of xenin-25(Gln) on blood glucose concentrations were examined in lean C57Bl/6J mice.

**Results:** Xenin-25(Gln) was resistant to plasma-mediated degradation for up to 24 hours whereas native xenin-25 was sequentially degraded by murine plasma. In BRIN-BD11 cells, xenin-25(Gln) significantly stimulated (1.5 to 2.9-fold;  $P < 0.05$  to  $P < 0.001$ ) Insulin secretion in a concentration-dependent manner at both 5.6 and 16.7 mmol/l glucose. Moreover, xenin-25(Gln) significantly augmented (1.4 to 1.7-fold;  $P < 0.05$  to  $P < 0.01$ ) the insulinotropic response of (d-Ala<sup>2</sup>)GIP *in vitro*. Acute administration of xenin-25(Gln) to high fat fed mice significantly reduced plasma glucose concentrations compared to glucose alone (56% reduction;  $P < 0.001$ ) and xenin-25 (38% reduction;  $P < 0.05$ ) treated mice. Correspondingly, the overall Insulin secretory response was significantly enhanced (3.4-fold increase;  $P < 0.05$ ) in xenin-25(Gln) treated mice compared to high fat fed mice administered glucose alone. Furthermore, xenin-25(Gln) elicited a protracted glucose-lowering effect (40% reduction;  $P < 0.001$ ) when administered 8 hours prior to a glucose load in C57Bl/6J mice.

**Conclusion:** In summary, xenin-25(Gln) represents a novel enzymatically stable analogue of xenin-25 with improved glucose-lowering and insulinotropic actions over the native peptide. As a result, xenin-25(Gln) can be positioned as a novel treatment of type 2 diabetes.

### Faster-acting insulin aspart improves postprandial glycaemia versus insulin aspart in patients with type 1 diabetes mellitus

T. Heise<sup>1</sup>, H. Haahr<sup>2</sup>, L. Jensen<sup>2</sup>, L. Erichsen<sup>2</sup>, M. Hompesch<sup>3</sup>;

<sup>1</sup>Profil, Neuss, Germany, <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark,

<sup>3</sup>Profil Institute for Clinical Research, Inc., Chula Vista, USA.

**Background and aims:** Faster-acting insulin aspart is insulin aspart (IAsp) in a new formulation containing two new excipients (nicotinamide and arginine), which result in a faster initial absorption after s. c. injection.

**Materials and methods:** In total, 36 patients with type 1 diabetes mellitus (T1DM; mean  $\pm$  standard deviation age:  $38.6 \pm 12.5$  years; haemoglobin A<sub>1c</sub>:  $7.8 \pm 0.81\%$ ) received a single dose (0.2 U/kg s. c.) of faster-acting insulin aspart formulation 'B' (FIA(B)) or IAsp immediately ( $\leq 2$  minutes) before a standardised liquid meal test (600 kcal; 67% carbohydrates, 17% protein, 16% fat; to be consumed within 8 minutes) in a randomised, crossover design.

**Results:** Compared with IAsp, FIA(B) had a faster onset of appearance, i.e., time from trial drug administration until the first time serum insulin aspart concentration was  $>30$  pmol/l (median difference [95% confidence interval (CI)]: -6.6 minutes [-8.0; -5.0]) and greater exposure during the first 2 hours with the largest difference in the first 15 minutes, whereas the overall pharmacokinetic exposure was similar between the two insulins (mean ratio [95% CI] AUC<sub>0-15 minutes</sub>: 3.14 [2.59; 3.80]; AUC<sub>0-30 minutes</sub>: 1.93 [1.64; 2.26]); AUC<sub>0-1 hour</sub>: 1.30 [1.15; 1.46]; AUC<sub>0-2 hours</sub>: 1.13 [1.03; 1.24]; AUC<sub>0-10 hours</sub>: 0.99 [0.93; 1.06]). The faster absorption led to a greater reduction in postprandial blood glucose (BG) with FIA(B) versus IAsp, indicated by lower post-meal AUC<sub>BG</sub> over 2 and 6 hours (reduction by 26% and 33%, respectively; Figure), and by lower BG values 1 and 2 hours postprandially (mean difference [95% CI] BG<sub>1 hour</sub>: -1.24 mmol/l [-2.01; -0.46]; BG<sub>2 hours</sub>: -1.45 mmol/l [-2.49; -0.42]). No safety or tolerability issues were identified; in particular, no injection site reactions were observed.

**Conclusion:** FIA(B) was absorbed faster and had an increased early exposure than insulin aspart, leading to improved postprandial glycaemic control versus insulin aspart.

**Figure:** Meal test blood glucose profile.

## OP 21 Physiological adaptation to bariatric surgery

121

**Bariatric surgery improves whole body and femoral subcutaneous adipose tissue insulin sensitivity independently of whole body weight loss**

L. Landini<sup>1,2</sup>, M. Bucci<sup>1</sup>, T. Pham<sup>1</sup>, J.C. Hannukainen<sup>1</sup>, P. Salminen<sup>3</sup>, P. Iozzo<sup>3</sup>, P. Nuutila<sup>1,4</sup>;

<sup>1</sup>Turku PET Centre, University of Turku, Finland,

<sup>2</sup>National Research Council, Pisa, Italy, <sup>3</sup>Department of Surgery,

<sup>4</sup>Department of Endocrinology, Turku University Hospital, Finland.

**Background and aims:** The effect of weight reduction by dietary treatment does not reverse adipose tissue insulin resistance, as opposed to skeletal muscle in which it makes a big improvement. To the best of our knowledge, there is no evidence of how bariatric surgery modulates femoral adipose tissue glucose uptake. We examine how bariatric surgery modifies femoral adipose tissue glucose uptake both in fasting condition and during euglycemic hyperinsulinemic clamp in severely obese patients and healthy lean subjects and we study if the changes in adipose tissue glucose uptake were related with the remission of diabetes.

**Materials and methods:** Femoral subcutaneous adipose tissue and muscle glucose uptake were studied with positron emission tomography using [<sup>18</sup>F] fluorodeoxyglucose (Figure 1) during fasting and euglycemic hyperinsulinemic clamp in 25 morbidly obese patients (BMI of 43.2±3.6 kg/m<sup>2</sup>) before and six months after the bariatric surgery. Ten age-matched lean subjects (BMI: 23.7±1.8 kg/m<sup>2</sup>) served as controls. All data are presented as mean ± SE.

**Results:** At baseline, nine patients had type 2 diabetes mellitus (T2DM) and seven had impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT). After surgery, remission of T2DM or IFG/IGT was observed in ten patients. Two patients dropped out from the study. At baseline, obese patients had impaired whole body (M value: 12.2±1.14 vs 40.3±3.00 μmol/(min\*kg), p<0.001) and tissue specific (muscle 20.0±3.24 vs 68.4±8.24 μmol/(min\*kg), p<0.001 and adipose tissue 5.8±0.54 vs 9.3±1.40, p<0.01) insulin sensitivity compared to controls. After the bariatric procedure, obese patients lost 23±6% of body weight. M value and muscle and adipose tissue glucose uptake were increased by 106±80%, p<0.001; 166±173%, p<0.001; 77±129%, p=0.03, respectively. Furthermore, adipose tissue glucose uptake normalised after surgery. There were no differences in fasting adipose tissue glucose uptake before or after surgery in obese as compared to controls. Neither the changes in whole body nor the changes in tissue specific insulin sensitivity correlated with the change in weight loss. The remission of diabetes was positively correlated with the change produced by bariatric surgery on the effect of insulin on adipose tissue glucose uptake (Spearman's correlation: R=0.54; p<0.05).

**Conclusion:** Bariatric surgery promotes the remission of T2DM and insulin resistance and this is connected with the improvement of insulin action on adipose tissue glucose uptake. Improved whole body and femoral subcutaneous adipose tissue insulin sensitivity do not relate with the whole body weight loss. Hence, insulin sensitivity may depend on the intrinsic action of the bariatric surgery.

**Meal protein uptake and systemic leucine kinetics after Roux-en-Y gastric bypass**

K.N. Bojsen-Møller<sup>1,2</sup>, S.H. Jacobsen<sup>1,2</sup>, C. Dirksen<sup>1,2</sup>, N.B. Jørgensen<sup>1,2</sup>, J.E. Jensen<sup>1</sup>, V.B. Kristiansen<sup>3</sup>, J.J. Holst<sup>4,2</sup>, G. van Hall<sup>5</sup>, S. Madsbad<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Hvidovre Hospital, <sup>2</sup>Novo Nordisk

Foundation Centre for Basic Metabolic Research, University of Copenhagen,

<sup>3</sup>Department of Surgical Gastroenterology, Hvidovre Hospital, <sup>4</sup>Department of Biomedical Sciences, University of Copenhagen, <sup>5</sup>Clinical Metabolomics

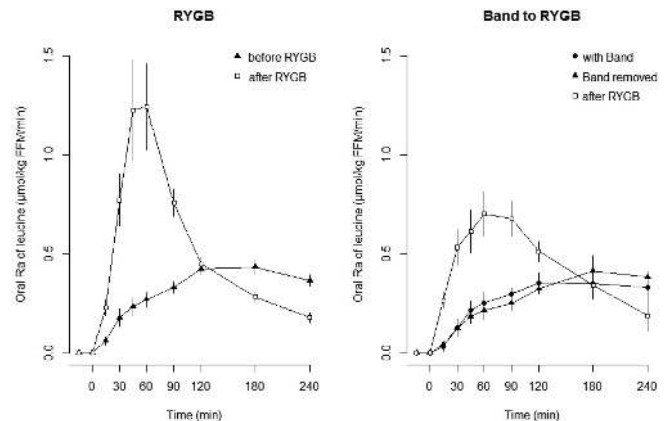

Core Facility, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Gastric emptying and glucose absorption is accelerated after Roux-en-Y gastric bypass (RYGB), but absorption kinetics of other nutrients are unknown. Exclusion of major parts of the stomach and delayed admixing of nutrients and pancreatic proteases could potentially impair protein digestion and absorption after surgery.

**Materials and methods:** Leucine kinetics was investigated after meal ingestion in 9 obese glucose tolerant subjects (BMI 39.2±1.8 kg/m<sup>2</sup> (mean±sem), HbA1c 5.3±0.1%) before and 3 months after primary RYGB. Additionally, 5 obese subjects (BMI 42.1±1.7 kg/m<sup>2</sup>, HbA1c 5.4±0.1%) who underwent conversion of gastric band to RYGB were studied with the band, after band removal and 3 months after conversion to RYGB. All received a 6 h primed-continuous infusion of [3,3,3-2H3]-leucine combined with a 4 h meal test (200 mL, semi-liquid, 394 kcal, carbohydrate 50%, fat 35% and protein 15%) containing 15.2 g of casein intrinsically labeled with [1-13C]-leucine. Fat free mass (ffm) was assessed by whole body DEXA scan.

**Results:** Plasma leucine concentration was unchanged at fasting while the postprandial leucinemia increased (iAUC: pre 4.1±0.6, 3 mo 9.5±2.0 mmol/L×min, p=0.03) but was shorter lasting after RYGB. Peak rate of appearance (Ra) of oral leucine increased (0.45 ± 0.04 vs 1.35 ± 0.22 μmol/kg ffm/min, p<0.01) and occurred earlier (173 ± 16 vs 65 ± 8 min, p<0.01) and oral recovery increased over the 4 h measured (49±4% vs 70±4%, p<0.01). Peak rate of disappearance (Rd) of leucine increased after RYGB (1.9 ± 0.07 vs 2.9 ± 0.26 μmol/kg ffm/min, p<0.01). Band removal did not change oral Ra (peak: 0.44 ± 0.06 vs 0.44 ± 0.07 μmol/kg ffm/min), oral recovery (38±4% vs 40±4%) or Rd of leucine (peak: 1.9 ± 0.2 vs 1.8 ± 0.1 μmol/kg ffm/min), but similar increases were seen after conversion to RYGB as after primary RYGB.

**Conclusion:** In conclusion, digestion and absorption of casein are dramatically changed after RYGB from slow to fast, while protein kinetics is not altered by the gastric band. Protein digestion and absorption thus seem to be accelerated rather than impaired after RYGB. Although the nutritional consequences are unknown, fast absorption could change the nutritional anabolic effect of protein potentially favoring oxidation rather than protein synthesis. These findings may have implications for our recommendation of source, quantity and frequency of protein intake after RYGB.

## 123

**Beta cell function improvements in subjects with type 2 diabetes 1 year after biliopancreatic diversion**A.C.J. Vasques<sup>1</sup>, J.C. Pareja<sup>2</sup>, M.S. Oliveira<sup>2</sup>, F.S. Novaes<sup>2</sup>, M.M.O. Lima<sup>3</sup>, É.A. Chaim<sup>3</sup>, F. Piccinini<sup>4</sup>, C. Dalla Man<sup>4</sup>, C. Cobelli<sup>4</sup>, B. Geloneze<sup>2</sup>;<sup>1</sup>Laboratory of Investigation on Metabolism and Diabetes (LIMED), School of Applied Sciences, Limeira, <sup>2</sup>Laboratory of Investigation on Metabolism and Diabetes (LIMED), Faculty of Internal Medicine, Campinas,<sup>3</sup>Department of Surgery, Faculty of Internal Medicine, Campinas, Brazil,<sup>4</sup>Department of Information Engineering, University of Padua, Italy.

**Background and aims:** Bariatric surgery is an alternative therapeutic approach for obese patients with poorly controlled type 2 diabetes (T2DM). To provide evidence for the underlying mechanisms associated with T2DM remission after biliopancreatic diversion (BPD), this study aimed to evaluate the long term effect of BPD on  $\beta$ -cell function parameters and insulin sensitivity in grade I and II obese patients with T2DM.

**Materials and methods:** Sixty-eight women were divided into three groups: 19 LeanNGT (BMI:  $23 \pm 2$  kg/m<sup>2</sup>), 18 ObeseNGT (BMI:  $35 \pm 5$  kg/m<sup>2</sup>) both with normal glucose tolerance (NGT), and 31 ObeseT2DM (BMI:  $36 \pm 4$  kg/m<sup>2</sup>). Twenty ObeseT2DM women underwent BPD and were reassessed 1 year after surgery. OGTTs and hyperglycaemic clamps were performed. Mathematical modeling, based on insulin and C-peptide serum levels, was used to analyze  $\beta$ -cell function, insulin sensitivity (IS<sub>oral</sub> and IS<sub>clamp</sub>) and delay time of  $\beta$ -cell response to a specific plasma glucose concentration. The basal (DI<sub>b</sub>), dynamic (DI<sub>d</sub>), static (DI<sub>s</sub>) and total disposition indexes (DI<sub>oral</sub> and DI<sub>clamp</sub>) represents  $\beta$ -cell function adjusted to IS and were calculated by multiplying  $\beta$ -cell responsivity indices by IS.

**Results:** After BPD, BMI (pre:  $36 \pm 4$  vs post:  $28 \pm 3$  kg/m<sup>2</sup>), fasting glycaemia (pre:  $133 \pm 38$  vs post:  $88 \pm 13$  mg/dl) and HbA1c levels (pre:  $7.2 \pm 1.3$  vs post:  $5.1 \pm 0.9\%$ ) were reduced ( $p < 0.001$ ). At baseline, IS<sub>oral</sub> and IS<sub>clamp</sub> were reduced in the obese groups compared with the LeanNGT group ( $p < 0.001$ ). After BPD, IS indexes increased approximately 6-fold. IS<sub>oral</sub> became comparable to LeanNGT, and IS<sub>clamp</sub> became increased in comparison with the LeanNGT [ $29$  (9–89) vs  $15$  (8–24) dl/kg/min per  $\mu$ U/ml,  $p < 0.01$ ], respectively. At baseline, the basal disposition index (DI<sub>basal</sub>) was reduced in the ObeseT2DM [ $67$  (44–145) dl/kg/min<sup>2</sup> per pmol/l] compared with the NGT groups [Lean:  $258$  (170–455) and Obese:  $169$  (119–326) dl/kg/min<sup>2</sup> per pmol/l;  $p < 0.001$ ]. After surgery, the DI<sub>basal</sub> increased 3-fold reaching similar levels to that of both NGT groups ( $p = 0.167$ ). At baseline, the DI<sub>d</sub>, DI<sub>s</sub> and DI<sub>oral</sub> derived from the OGTT were reduced in the ObeseT2DM compared with both NGT groups ( $p < 0.001$ ). After surgery, DI<sub>d</sub> and DI<sub>oral</sub> were similar to ObeseNGT and remained reduced compared with the LeanNGT, while the DI<sub>s</sub> was restored to the levels of both NGT groups. In the clamp test, at baseline, DI<sub>d</sub>, DI<sub>s</sub> and DI<sub>clamp</sub> of the ObeseT2DM were similar to ObeseNGT and reduced compared with the LeanNGT ( $p < 0.05$ ). After surgery, all of the DI were similar to LeanNGT levels and were increased compared with the ObeseNGT. The delay time, at baseline, was markedly increased in the ObeseT2DM compared with the NGT subjects in both dynamic tests ( $p < 0.001$ ). After BPD, the delay time was decreased (Clamp:  $100$  (80–108) vs  $29$  (8–100) min.; OGTT:  $15$  (9–74) vs  $9$  (7–10) min.;  $p < 0.05$ ) and reached similar levels to both NGT groups ( $p = 0.8$ ).

**Conclusion:** In long term, the BPD resulted in positive physiological adaptations in patients with grade I and II obesity and T2DM, with improvements in a wide range aspects of  $\beta$ -Cell function and IS which probably contributed to the improved glycaemic control.

**Restoration of beta cell function in severely obese type 2 diabetic patients after gastric bypass surgery is accompanied by improved insulin processing**E. Svehlikova<sup>1</sup>, A. Tuca<sup>1</sup>, V. Höller<sup>1</sup>, B. Obermayer-Pietsch<sup>1</sup>, O. Freisinger<sup>2</sup>, F. Tadler<sup>3</sup>, B. Ernst<sup>4</sup>, B. Wilms<sup>5</sup>, M. Thurnheer<sup>4</sup>, B. Schultes<sup>4</sup>, T.R. Pieber<sup>1</sup>;<sup>1</sup>Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, <sup>2</sup>Department of Surgery, Medical University of Graz, <sup>3</sup>Department of Surgery, Krankenhaus der Elisabethinen, Graz, Austria, <sup>4</sup>Interdisciplinary Obesity Center, eSwiss Medical & Surgical Center, St. Gallen, <sup>5</sup>Exercise Physiology Lab, Institute of Human Movement Sciences, ETH Zurich, Switzerland.

**Background and aims:** Gastric bypass surgery improves glycaemic control, but the underlying mechanisms are incompletely understood. The aim of the study was to quantify changes in beta cell function and insulin sensitivity before, early and 1 year after gastric bypass in type 2 diabetic (DM) and non-diabetic (ND) morbidly obese patients.

**Materials and methods:** Before, 8 to 21 days and 1 year after the surgery, 34 T2DM (17 with diabetes duration  $\geq 8$  years) and 21 ND patients underwent an oral glucose tolerance test (OGTT) and a botnia clamp combining an intravenous glucose tolerance test (IVGTT) with a subsequent hyperinsulinaemic-euglycaemic clamp.

**Results:** In DM patients, glucose tolerance gradually improved after the surgery, fasting insulin was decreased at 1 year ( $p < 0.001$ ). In the OGTT total insulin secretion ( $AUC_{CP}/AUC_{GLU}$ : time  $p < 0.001$ ; group  $p < 0.001$ ) as well as the early insulin response (time  $p < 0.001$ ; group  $p < 0.001$ ) displayed an early improvement in both groups followed by decline or constant values respectively. DM patients did not reach non-diabetic values, but they showed an improved C-peptide secretion pattern with a shorter time to peak C-peptide ( $p < 0.01$ ) and reduced late hyperinsulinaemia in OGTT. Insulin response to the IVGTT (AIR) did not change early after the surgery, but declined at 1 yr (time  $p < 0.001$ ; group  $p < 0.001$ ). On the contrary, proinsulin levels during OGTT successively declined after the surgery in both groups (peak proinsulin: time  $p < 0.01$ ). The proinsulin/C-peptide ratio decreased early postoperatively and remained comparable at 1 yr in both groups (time  $p < 0.001$ ). Having higher baseline values, DM group showed a greater reduction in proinsulin/C-peptide ratio compared to ND (time  $\times$  group  $p < 0.01$ ). Insulin sensitivity displayed an early increase in DM patients reaching non-diabetic values at 1 yr and a later improvement in the ND group (Glucose disposal: time  $p < 0.001$ ; group  $p < 0.001$ ). The disposition index increased in DM patients but declined in ND group (time  $\times$  group  $p < 0.01$ ; group  $p < 0.001$ ).

**Conclusion:** The progressive improvement of glucose metabolism in DM patients after gastric bypass surgery relies on both improved insulin sensitivity and beta-cell function that however does not normalize entirely. Importantly, our results on proinsulin levels provide the first and strong evidence of improved insulin processing after gastric bypass, which may represent an important mechanism of the improvement of beta cell function in DM patients after the surgery.

**Mechanisms of post-prandial hypoglycaemia after Roux-en-Y gastric bypass (RYGB) and sleeve gastrectomy (LSG)**

M. Nannipieri<sup>1</sup>, A. Belligoli<sup>2</sup>, A. Mari<sup>3</sup>, D. Moriconi<sup>1</sup>, S. Baldi<sup>4</sup>, D. Colligiani<sup>4</sup>, M. Anselmino<sup>5</sup>, M. Foletto<sup>6</sup>, E. Zabeo<sup>7</sup>, R. Vettor<sup>7</sup>, E. Ferrannini<sup>8</sup>;

<sup>1</sup>Clinical and Experimental Medicine, University of Pisa, <sup>2</sup>Medicine, University of Padua, <sup>3</sup>Biomedical Engineering, CNR of Padua, <sup>4</sup>Dpt Clinical and Experimental Medicine, University of Pisa, <sup>5</sup>Azienda Ospedaliera Universitaria Pisana, <sup>6</sup>Oncological, Surgical and Gastroenterological Sciences, University of Padua, <sup>7</sup>Medicine, University of Padua, <sup>8</sup>Dpt Clinical and Experimental Medicine, University of Pisa and CNR of Pisa, Italy.

**Background and aims:** Symptomatic hypoglycaemia (Hypo) is a well recognised complication of RYGB surgery. Data on the development of postprandial Hypo after LSG are scanty. We investigated the mechanisms of postprandial Hypo in patients undergoing RYGB or LSG.

**Materials and methods:** 32 obese non-diabetic subjects treated with RYGB and 39 with LSG received a 3-h OGTT before and 12–18 months after surgery. Hypo was defined as plasma glucose  $\leq 2.7$  mmol/L. Insulin sensitivity was assessed by OGIS index and  $\beta$ -cell function by modelling analysis of the C-peptide response to glucose load.

**Results:** Postprandial Hypo occurred in 20 of 32 RYGB patients and in 13 of 39 LSG patients. Age did not discriminate Hypo from non-Hypo (NH) subjects. Presurgery BMI was lower in RYGB-Hypo than RYGB-NH ( $43.8 \pm 5.2$  vs  $49.7 \pm 6.1$  kg/m<sup>2</sup>,  $p=0.004$ ), but not in LSG-Hypo vs LSG-NH patients. Similarly, baseline insulin sensitivity was higher in RYGB-Hypo than RYGB-NH ( $386 \pm 53$  vs  $325 \pm 44$  ml.min<sup>-1</sup>.m<sup>-2</sup>,  $p=0.004$ ), but was similar in LSG-Hypo and LSG-NH subjects. After either operation, insulin sensitivity improved ( $p<0.0001$ ) to the same extent in Hypo and NH subjects. Pre-surgery fasting glycaemia was lower in both RYGB-Hypo and LSG-Hypo compared to the respective NH group ( $5.0 \pm 0.4$  vs  $5.7 \pm 0.9$  mM,  $p<0.001$ , and  $5 \pm 0.3$  vs  $5.6 \pm 0.7$  mM,  $p<0.02$  in LSG). Similarly, before surgery mean OGTT glycaemia was lower in Hypo than NH subjects ( $6.9 \pm 0.9$  vs  $8.4 \pm 1.3$  mM,  $p=0.001$ ), as was the plasma glucose nadir ( $4.7 \pm 1.3$  vs  $6.4 \pm 1.6$  mM,  $p=0.005$ ) similarly in the two groups. Pre-surgery fasting plasma insulin and insulin secretion rate were similar at baseline in all four groups, and were similarly reduced after surgery ( $p<0.0001$ ). In contrast, total insulin secretion was reduced in NH, but not in Hypo after either intervention ( $79 \pm 23$  vs  $59 \pm 27$  and  $71 \pm 28$  vs  $72 \pm 30$  nmol.m<sup>-2</sup>,  $p<0.01$  for the timexgroup interaction).  $\beta$ -cell glucose sensitivity was negatively correlated with glucose nadir values in both surgeries ( $p=0.02$  in RYGB and  $p=0.0009$  in LSG). Likewise, insulin sensitivity was inversely correlated with the glucose nadir ( $p<0.0001$  in RYGB and  $p=0.009$  in LSG).

**Conclusion:** Baseline lower plasma glucose concentrations during an OGTT are associated with a higher risk of post-surgery reactive hypoglycaemia after both RYGB and LSG. Mechanistically, inherently higher insulin output and better  $\beta$ -cell glucose sensitivity and peripheral insulin sensitivity are responsible for postprandial Hypo in surgically weight-reduced patients.

## 126

**Inadequate eating behaviour and accelerated glucose appearance can be resolved by sensor-augmented nutrition training in patients with hypoglycaemias (NIPHS) after RYGB**

K.G. Rett<sup>1</sup>, R. Weiner<sup>2</sup>, H. Schreiweis<sup>1</sup>, I. Skudelny<sup>1</sup>, D. Wagenknecht<sup>1</sup>, E. Fischer<sup>1</sup>, K. Krieger<sup>1</sup>, E. Weitz<sup>1</sup>, C. Stier<sup>2</sup>;

<sup>1</sup>Endocrinology and Diabetes, Krankenhaus Sachsenhausen, <sup>2</sup>Bariatric Surgery, Krankenhaus Sachsenhausen, Frankfurt am Main, Germany.

**Background and aims:** Gastric bypass (RYGB) has been said to promote prudent eating by altering food preference and reducing intake of fat and sweet foods thereby contributing to the favourable effects on metabolic control and body weight. On the other hand, recent clinical and experimental data suggest accelerated appearance of oral glucose due to the anatomic alterations and metabolic reprogramming of the Roux limb. We therefore assessed both eating behavior and glucose excursions in RYGB subjects with noninsulinoma pancreatogenous hypoglycaemia syndrome (NIPHS) - a condition with high glucose variability - under real life conditions.

**Materials and methods:** In 20 patients (18 f, 2 m) who had undergone RYGB for obesity (BMI  $45.5 \pm 2.2$  kg/m<sup>2</sup>; 80% type 2 diabetes) and in whom both NIPHS and inadequate postbariatric eating behavior had been diagnosed during a week of continuous glucose monitoring (CGM; Dexcom G4, lower alarm limit: 70 mg/dl) 6–18 months after the bariatric procedure (BMI

$36.7 \pm 2.7$  kg/m<sup>2</sup>). It was our aim to modify eating behavior and dumping-like postprandial glucose excursions. During one week of sensor-augmented nutrition counseling, participants were asked to comply with defined nutrition targets ( $<30\%$  fat/ $>40\%$  carbohydrates/ $<20$ g sucrose/ $>25$ g fiber) and record nutrition and physical activity in detailed diaries.

**Results:** Daily energy intake ( $1409 \pm 135$  kcal; mean $\pm$ SEM) was hypocaloric, whereas fat consumption exceeded general recommendations both in absolute ( $64 \pm 7$ g) and relative terms (42% of daily energy intake). Carbohydrate ingestion was slightly too low both in absolute ( $131 \pm 15$ g) and relative terms (38% of daily energy intake), however 21% of the carbohydrates were consumed as sucrose (28g). Protein intake ( $69 \pm 1$ g / 20% of daily energy intake) was rather low and fiber consumption ( $13 \pm 2$ g) definitely too low. In two female subjects, one with (DM+) and one without preoperative diabetes (DM-), complete CGM-datasets before and after nutrition training have yet been compiled: Target adherence reduced glucose variability (STD) from 45 to 31 (DM-) and from 24 to 16 (DM+), respectively; time spent in hypoglycaemia (IG $<70$  mg/dl) decreased from 11 to 8.4% (DM-) and from 29 to 2.6% (DM+) of the day, respectively; time spent in hyperglycaemia (IG $>180$  mg/dl) decreased from 8.9 to 3.2% (DM-) and from 0.9 to 0% (DM+) of the day.

**Conclusion:** Inadequate postbariatric eating behavior was prevalent in symptomatic NIPHS subjects. In contrast to bariatric literature, sucrose and fat consumption were exceeding and fiber and complex carbohydrates falling short of prescribed and desirable amounts. Sensor augmented nutrition training focusing on strict adherence to adequate nutrition targets markedly reduced prandial glucose peaks, overall glucose variability and time spent  $<70$  mg/dl in two preliminary cases. We challenge the idea of RYGB-induced prudent food preference. Sensor augmented nutrition training may help to avoid sweetened food as far as possible in order to balance accelerated glucose appearance after RYGB.

## OP 22 Neuropathy: mechanisms and outcomes

### Diabetic neuropathy and urologic complications in men with type 1 diabetes in the DCCT/EDIC study

R. Pop-Busui<sup>1</sup>, B. Braffett<sup>2</sup>, J. Hotaling<sup>3</sup>, P. Cleary<sup>2</sup>, C. Martin<sup>1</sup>, R. Dunn<sup>4</sup>, H. Wessels<sup>5</sup>, A. Sarma<sup>4</sup>, DCCT/EDIC;

<sup>1</sup>Department of Internal Medicine, University of Michigan Medical School, Ann Arbor, <sup>2</sup>Department of Biostatistics, George Washington University, Rockville, <sup>3</sup>Department of Urology, University of Utah, Salt Lake City, <sup>4</sup>Department of Urology, University of Michigan Medical School, Ann Arbor, <sup>5</sup>Department of Urology, University of Washington, Seattle, USA.

**Background and aims:** Impaired genital sensory or motor function may promote sexual or urinary dysfunction, but data in persons with type 1 diabetes (T1D) are limited. We evaluated associations between diabetic peripheral neuropathy (DPN), erectile dysfunction (ED) and lower urinary tract symptoms (LUTS) in men with T1D participating in Diabetes Control and Complications Trial/Epidemiology of Diabetes Intervention and Complications (DCCT/EDIC)

**Materials and methods:** DPN was evaluated with a composite of symptoms, neurological examination and nerve conduction studies (NCS) performed at baseline and biennially during DCCT, and at years 13/14 during EDIC. Confirmed DPN was defined as NCS abnormalities in  $\geq 2$  nerves and  $\geq 2$  positive responses among symptoms, sensory signs, or reflex changes. ED was assessed using the question from the International Index of Erectile Function “Over the past 4 weeks, how would you rate your confidence that you can get and keep erection?” at EDIC year 17. Answers “very low-low” were classified as ED. LUTS was assessed by the American Urological Association Symptom Index (AUASI). AUASI scores 0–7 were defined as no LUTS, and AUASI of 8–35 as LUTS.

**Results:** ED and LUTS data were available from 635 men (mean age 52 years, mean duration 30 years, mean DCCT/EDIC A1c 7.9%). ED only was reported by 193 (30%), LUTS only by 61 (10%) and both ED and LUTS by 97 (15%) men. Men with confirmed DPN at year 13/14 were more likely to report ED (41%), LUTS (31%) or both ED and LUTS (62%) at EDIC year 17 compared to those without ED or LUTS (22%) ( $p < 0.0001$  for all). In multivariable logistic regression analysis adjusting for DCCT cohort assignment (Intensive vs. Conventional), DCCT/EDIC HbA1c, DCCT/EDIC systolic blood pressure, age, smoking and drinking status, men with confirmed DPN had 3.82 (95% CI 2.0–7.3) greater odds of having both ED and LUTS compared to those without DPN.

**Conclusion:** Men with T1D and DPN are more likely to report urologic complications than men with no DPN. The temporal relationship between DPN and ED/LUTS in this cohort is under analysis.

### Erectile dysfunction and health-related quality of life in type 1 diabetes: longitudinal follow-up of the DCCT/EDIC cohort

A.M. Jacobson<sup>1</sup>, B.H. Braffett<sup>2</sup>, P.A. Cleary<sup>2</sup>, R.L. Dunn<sup>3</sup>, S. Holt<sup>4</sup>, M.L. Larkin<sup>5</sup>, H. Wessels<sup>4</sup>, A.V. Sarma<sup>3</sup>, DCCT/EDIC Research Group; <sup>1</sup>Diabetes, Obesity and Cardiometabolic Research Center, Winthrop-University Hospital, Mineola, <sup>2</sup>Biostatistics Center, George Washington University, Rockville, <sup>3</sup>Urology, University of Michigan, Ann Arbor, <sup>4</sup>Urology, University of Washington, Seattle, <sup>5</sup>Diabetes Research Center, Massachusetts General Hospital, Boston, USA.

**Background and aims:** No longitudinal studies have examined the effects of erectile dysfunction (ED) on health-related quality of life (HRQOL) among men with type 1 diabetes (T1DM). We used biomedical information gathered as part of the Diabetes Control and Complications Trial and its follow-up the Epidemiology of Diabetes Interventions and Complications (DCCT/EDIC) study to examine the relationship.

**Materials and methods:** Assessment of ED was made annually in EDIC through a question asking “Has the patient experienced impotence since the last completed annual visit?” The Diabetes Quality of Life Scale (DQOL) (higher score, better QOL; scale 0–100), was given biannually throughout

EDIC follow-up. The cumulative effects of ED over the 17-year time-frame were examined by calculating the number of consecutive years of ED as of year 17. A multivariable regression model was built to estimate the association between ED experience and having a low DQOL score ( $\leq 25$ th percentile; DQOL = 70). Analyses were adjusted for time-weighted DCCT/EDIC HbA1c levels.

**Results:** At EDIC baseline, the 693 male subjects with ED and QOL data were on average  $35.6 \pm 6.7$  years old with a mean BMI of  $26.3 \pm 3.6$  kg/m<sup>2</sup>, diabetes duration  $13.3 \pm 4.8$  years, and DCCT/EDIC time-weighted HbA1c of  $8.1 \pm 1.3\%$ . Forty-one (6%) subjects reported ED at baseline (ED mean DQOL  $69.6 \pm 10.3$  vs. No ED  $76.9 \pm 9.2$ ;  $p < 0.0001$ ) and 232 (37%) reported ED at EDIC year 17 (ED mean DQOL  $72.6 \pm 11.2$  vs. No ED  $77.7 \pm 10.5$ ;  $p < 0.0001$ ). Among the 652 men who reported no ED at baseline, 332 (51%) went on to develop ED; 262 (79%) of the incident cases were reported at 2 or more follow-up visits. The mean DQOL at year 17 decreased with the number of consecutive years of ED (mean DQOL score for no ED  $77.7 \pm 10.5$ , 1 year of ED  $75.3 \pm 13.4$ , 2 years of ED  $71.9 \pm 9.5$ , 3 years of ED  $73.1 \pm 8.6$ , and 4 or more years of ED  $71.8 \pm 11.1$ ;  $p < 0.0001$ ). The table shows the effect of consecutive years of ED as of year 17 on the odds of a low total DQOL score at year 17 after adjusting for HbA1c. While HRQOL decreases initially with increased duration of ED, these effects start to diminish as the number of years with ED increases, suggesting some adaptation to the change in health state.

**Conclusion:** Development of ED is common in T1DM patients and is associated with decrease in health-related quality of life. The effects however are not cumulative as men may begin to cope with the change in health state.

#### Adjusted Odds Ratios (95% CI) of a Low DQOL Score ( $\leq 25$ th percentile) by ED Experience

|  | OR (95% CI)       |
|--|-------------------|
| <b>Consecutive years of ED as of year 17</b> |                   |

### Diabetic peripheral neuropathy adversely affects balance during stair ascent and descent

S.J. Brown<sup>1</sup>, J.C. Handsaker<sup>1</sup>, F.L. Bowling<sup>2</sup>, C.N. Maganaris<sup>3</sup>, A.J.M. Boulton<sup>2</sup>, N.D. Reeves<sup>1</sup>;

<sup>1</sup>Manchester Metropolitan University, <sup>2</sup>University of Manchester, <sup>3</sup>Liverpool John Moores University, UK.

**Background and aims:** Patients with diabetic peripheral neuropathy (DPN) are known to display unsteadiness during walking and as a result be at increased risk for falling. Whilst some studies have found increased postural sway during quiet standing and walking on level ground in patients with DPN, no data exist on objective measures of balance during stair walking. Walking on stairs is one of the most dangerous daily activities in terms of fall risk and this study investigated the underlying mechanisms of unsteadiness in patients with DPN during stair ascent and descent.

**Materials and methods:** Motion and force data were collected for 22 diabetes patients with DPN (PN; age:  $57 \pm 9.3$  years), 40 diabetes patients with no DPN (DM;  $57 \pm 12.8$  years), and 32 healthy controls (Ctrl;  $50 \pm 19$  years). Movement data was collected using a 10-camera 3D motion analysis system from reflective markers placed at anatomical locations on the body to calculate whole-body centre-of-mass (CoM). The centre-of-pressure (CoP) under the feet was measured using 4 force platforms mounted into the middle of a 7-step staircase, which participants ascended and descended at least 3 times. Balance was quantified by assessing the separation between the centre-of-mass and centre-of-pressure (CoM-CoP separation) in the medial-lateral plane. This parameter was expressed in terms of maximum separation and the variation in separation (standard deviation within 3 trials). Results were analysed using analysis of variation with Tukey post-hoc tests.

**Results:** During stair ascent the PN group showed significantly higher maximum CoM-CoP separation (mean [SD] PN: 13 [2], DM: 10 [3], Ctrl: 10 [3] cm;  $p < 0.01$ ) and significantly increased variation in CoM-CoP separation (mean [SD] PN: 7 [1], DM: 5 [1], Ctrl: 6 [1] cm;  $p < 0.05$ ) compared to the Ctrl group. During stair descent the PN group again showed significantly higher maximum CoM-CoP separation (mean [SD] PN: 15 [3], DM: 13 [4], Ctrl: 12

[3] cm;  $p < 0.05$ ) and significantly increased variation in CoM–CoP separation (mean [SD] PN: 8 [1], DM: 7 [1], Ctrl: 7 [1] cm;  $p < 0.01$ ) compared to the Ctrl group. The PN group also displayed a significantly wider stance width compared to the Ctrl group during stair descent only (mean [SD] PN: 17 [3], DM: 15 [3], Ctrl: 15 [2] cm;  $p < 0.05$ ). No differences in any variable were observed in the DM group compared to the Ctrl group during stair ascent or descent.

**Conclusion:** Diabetes patients with peripheral neuropathy display greater extremes in magnitude of medial-lateral sway during stair ascent and descent as well as displaying higher variability during stair ascent and descent. This indicates that patients with DPN have difficulty regulating control of balance during this challenging task. A larger and more variable medial-lateral sway means that patients with DPN are more likely to lose control of balance and experience a fall during what is known to be an activity where the risk of falls is already very high (stair walking).

## 130

### Shear forces applied to the feet during walking act for a longer duration in patients with diabetic neuropathy

N.D. Reeves<sup>1</sup>, S.J. Brown<sup>1</sup>, J.C. Handsaker<sup>1</sup>, F.L. Bowling<sup>2</sup>, A.J.M. Boulton<sup>2</sup>;

<sup>1</sup>School of Healthcare Science, Manchester Metropolitan University,

<sup>2</sup>Faculty of Medical & Human Sciences, University of Manchester, UK.

**Background and aims:** High plantar shear pressures are believed to play an important role in the development of diabetic foot ulcers, despite little supporting evidence. In-shoe plantar pressure systems can only measure vertical forces, whilst force platforms allow shear forces to be measured at the foot-ground interface. We investigated whether shear forces at the foot-ground/step interface are elevated in patients with diabetic peripheral neuropathy (DPN) during level ground and stair walking.

**Materials and methods:** Data are presented for 94 participants in three groups: patients with DPN ( $n=22$ ), patients with diabetes but no neuropathy (DM;  $n=40$ ) and non-diabetic controls (CTRL;  $n=32$ ). As participants walked at a self-selected speed, ground reaction forces acting on the feet were measured from force platforms embedded into the floor (level walkway) and steps (staircase). Data were analysed using analysis of variance and post-hoc tests.

**Results:** Peak propulsive shear forces were no different ( $P > 0.05$ ) between groups during stair ascent, but were lower in the DPN compared to the CTRL group during stair descent. The anterior-posterior shear force-time integrals were however, higher in the DPN compared to the CTRL group during both stair ascent (DPN: 0.30, DM: 0.26, CTRL: 0.23 N-s/kg;  $P < 0.01$ ) and stair descent (DPN: 0.41, DM: 0.41, CTRL: 0.33 N-s/kg;  $P < 0.01$ ). During level ground walking, peak propulsive shear forces (DPN: 1.7, DM: 2.0, CTRL: 2.1 N/kg;  $P < 0.01$ ) and anterior-posterior shear force-time integrals (DPN: 0.56, DM: 0.61, CTRL: 0.65 N-s/kg;  $P < 0.05$ ) were lower in the DPN compared to the CTRL group. During level ground and stair walking, the medio-lateral shear force-time integrals were significantly higher in the DPN compared to the CTRL group ( $P < 0.01$ ).

**Conclusion:** Our results highlight that shear ground reaction forces during level and particularly during stair walking, are applied on the feet of patients with diabetic neuropathy for longer. This longer application of shear forces to the feet may play an important role in the development of diabetic foot ulcers. Information on the specific area of the foot affected is not known from these measurements alone and warrants further investigation linked together with in-shoe plantar pressure measures.

## 131

### Increased default mode network functional connectivity in painful diabetic neuropathy

R. Gandhi<sup>1</sup>, S. Pallai<sup>1</sup>, I.D. Wilkinson<sup>2</sup>, S. Tesfaye<sup>1</sup>, D. Selvarajah<sup>3</sup>;

<sup>1</sup>Academic Department of Diabetes and Endocrinology, Sheffield Teaching Hospital NHS Foundation Trust, <sup>2</sup>Academic Department of Radiology, University of Sheffield, <sup>3</sup>Department of Human Metabolism, University of Sheffield, UK.

**Background and aims:** Painful diabetic peripheral neuropathy (Painful-DPN) is common and leads to considerable disability and a reduced quality of life. As there are no objective biomarkers of painful-DPN current treatments are less than optimal. Recent imaging studies using resting-state functional magnetic resonance imaging (rs-fMRI) have identified a network of brain structures that are active and connected during task-free paradigms, when the brain is at rest. This is called the default mode network (DMN). We therefore investigated the status of the DMN in painful DPN as a potential biomarker.

**Materials and methods:** 51 patients with type 1 diabetes (No DPN,  $n=17$ ; Painful DPN,  $n=17$  and healthy volunteers [HV],  $n=17$ ) underwent detailed clinical and neurophysiological assessments. Rs-fMRI data were acquired at 3T (Achieva, Philips Healthcare) Blood oxygen level-dependent susceptibility-weighted dynamic datasets ( $n=100$ ) were acquired over 225sec whilst the subject fixated on a visual cross. Data analysis were performed using independent components Analysis (ICA) with the FSL Multivariate Exploratory Linear Optimized Decomposition into Independent Components (FSL-MELODIC, FMRIB Oxford) tool and a previously validated dual-regression statistical approach.

**Results:** Patients with painful DPN had increased functional connectivity in the DMN areas including the cingulate gyrus, hippocampus, medial frontal cortex and precuneus, when compared to no DPN and HV subjects (TFCE, uncorrected  $p < 0.001$ ). There was no difference in DMN functional connectivity between diabetic subjects with no DPN and HV.

**Conclusion:** This preliminary study suggests abnormal functional connectivity in patients with painful DPN. These findings demonstrate that chronic pain has a widespread impact on overall brain function in diabetes, and suggest that disruptions of the DMN may underlie the cognitive and behavioral impairments accompanying chronic pain.

## 132

**Abnormal neural plasticity and cortical reorganisation in underlies the painful/painless leg**D. Selvarajah<sup>1</sup>, I.D. Wilkinson<sup>2</sup>, E. Bolan<sup>1</sup>, S. Tesfaye<sup>3</sup>;<sup>1</sup>Department of Human Metabolism, University of Sheffield, <sup>2</sup>Academic Department of Radiology, University of Sheffield, <sup>3</sup>Academic Department of Radiology, Sheffield Teaching Hospital NHS Foundation Trust, UK.

**Background and aims:** The clinical paradox of chronic painful neuropathic symptoms in patients with insensate feet (the so called 'painless/painful leg') is well recognised. Using recent advances in functional magnetic resonance imaging (fMRI) we sought to phenotype the pattern of brain activation in these patients with painful diabetic neuropathy (DN) to provide new insights into this poorly understood condition. In the present study, painful stimuli of the foot and thigh were examined in painful DN subjects with and without retained foot sensation using fMRI.

**Materials and methods:** 26 subjects (Painless DN, n=9; Painful DN sensate, n=9; Painful DN insensate, n=8) with Type 1 diabetes and 17 healthy volunteers underwent detailed clinical and neurophysiological assessments (vibration detection thresholds, sural, common peroneal and tibial nerve conduction studies using standard procedures). Painful neuropathic symptoms were assessed using the NTSS-6 questionnaire. All Painful DN subjects had severe neuropathic pain below the knees. Before fMRI heat pain was applied to the right anterior thigh (control region) and dorsum of the foot to establish a threshold of noxious thermal stimulation capable of eliciting a response of at least 7 on an 11 point Likert scale. Painful DN insensate patients were defined as those unable to perceive a noxious thermal stimulus applied to the foot at the maximum temperature setting (39.9°C). This was repeated inside the MR scanner (Acheiva 3T, Philips Healthcare) at the predetermined threshold alternating with a pain-free baseline condition in a pseudo-randomised box-car design. Images were analysed using FSL (FEAT, FMRIB, Oxford).

**Results:** Thermal noxious stimulus delivered to the foot and thigh was associated with significantly increased neuronal response in both the sensory discriminatory (left somatosensory cortex [stereotactic coordinates: -12,-44,78], left thalamus [-12,-12,4] and right midbrain [8,-18,-14]; corrected p<0.05) and emotional affective (bilateral insular cortex [-32,18,4 and 36,18,0]; corrected p<0.05) and left anterior cingulate gyrus (0,28,20) ; corrected p<0.05) components of the pain matrix in Painful DN sensate subjects when compared to Painful DN insensate and Painless DN groups. However, there was abnormal response to painful foot and thigh stimulation in the somatosensory cortex that was shifted laterally to the region which generally dominates the upper limb (foot: -62,-6,26 and thigh: -60,-10,34; corrected p<0.05) in Painful DN insensate subjects compared with HV, Painful DN sensate and Painless DN subjects. There was also significantly increased ipsilateral somatosensory cortical (foot: 64,-6,14 and thigh: 68,-10,26; corrected p<0.05) activation in subjects with Painful DN insensate subjects compared to other study cohorts.

**Conclusion:** These results suggest a novel, dynamic reorganisation of the somatosensory (S1) representation in painful DN which explains why patients with insensate feet can have intolerable pain. A further understanding of the neural plasticity and cortical reorganisation in DN may lead to the development of more effective compounds with fewer side effects.

## 133

**The mitochondrial transcription factor TFB2M plays a critical role in mitochondrial function and insulin secretion in pancreatic beta cells**L.M. Nichol<sup>1</sup>, B. Valtat<sup>1</sup>, N.-G. Larsson<sup>2</sup>, M. Abels<sup>1</sup>, N. Wierup<sup>1</sup>, H. Mulder<sup>1</sup>;<sup>1</sup>Department of Clinical Sciences, Lund University, Malmo, Sweden,<sup>2</sup>Max Planck Institute for Biology of Ageing, Cologne, Germany.

**Background and aims:** Insulin release from pancreatic  $\beta$ -cells is controlled by mitochondrial metabolism via its key role in stimulation-secretion coupling. Consequently, insulin secretion is critically dependent on mitochondrial (mt) DNA expression in these cells. Mitochondrial transcription factor B2 (TFB2M) has been newly identified to play a key role in mtDNA transcription. Its exact role in mitochondrial metabolism in  $\beta$ -cells, however, remains unknown. This study, therefore, investigated the role of TFB2M in mitochondrial function and insulin secretion both in vitro and in vivo.

**Materials and methods:** RNAi was used to knockdown (KD) Tfb2m in INS-1 832/13 cells. Mice with  $\beta$ -cell specific knockout of Tfb2m were generated using the Cre-loxP system. Blood glucose and insulin concentrations were measured weekly in non-fasted mice from 3 weeks of age. Mitochondrial gene expression in cells and  $\beta$ -Tfb2m<sup>-/-</sup> islets was determined by RT-PCR. Oxygen consumption in INS-1 832/13 cells was assessed by Seahorse XF24. Mitochondrial function in 18 days  $\beta$ -Tfb2m<sup>-/-</sup> islets was investigated by using a dye reflecting mitochondrial membrane polarization (tetramethyl-rhodamine methylester; TMRM). ATP production was determined by ATP-dependent luciferase activity in permeabilized cells. Insulin secretion from cells and isolated  $\beta$ -Tfb2m<sup>-/-</sup> islets from 18 and 35 days old mice was determined using radioimmunoassay upon stimulation with low and high glucose concentrations as well as mitochondrial fuels.  $\beta$ -cell mass was determined by immunofluorescence. Data were analysed using a 1-way ANOVA with repeated measures or a Mann Whitney test. A probability level of 5% was taken to be significant.

**Results:** Knockdown of Tfb2m in INS-1 832/13 cells resulted in decreased expression of a number of mitochondrial encoded genes including ATP synthase protein 8, cyclooxygenase 1 and NADH dehydrogenase 1 (P<0.001) and 5 (P<0.01). These cells also had impaired basal and glucose-stimulated respiration, a reduction in ATP production and content (P<0.01). In line with these findings in vitro,  $\beta$ -Tfb2m<sup>-/-</sup> mice exhibited increased plasma glucose and decreased plasma insulin concentrations (P<0.01) after weaning, prior to the onset of diabetes. This could be attributed to impaired insulin secretion from pancreatic islets in response to glucose and mitochondrial fuel (P<0.05), which was present before and persisted after weaning. Furthermore, islets from pre-weaned  $\beta$ -Tfb2m<sup>-/-</sup> mice showed altered mitochondrial function upon glucose stimulation; the maximal decrease in TMRM fluorescence intensity from baseline was reduced compared to controls (P<0.05). Loss of  $\beta$ -Tfb2m also resulted in decreased  $\beta$ -cell mass and  $\beta$ -cell area per pancreatic area (P<0.05) in these mice.

**Conclusion:** Loss of Tfb2m in pancreatic  $\beta$ -cells results in mitochondrial dysfunction and consequently impaired insulin secretion in response to metabolic stimuli. These changes precede the development of clinical indicators of type 2 diabetes (T2D). Taken together, these findings indicate that TFB2M may play a pathogenic and clinically important role in the development of T2D.

## 134

**Roles of the type 2 diabetes-associated gene products Arap1 and StarD10 in the control of insulin secretion**G.R.J. Carrat<sup>1</sup>, T.J. Pullen<sup>1</sup>, L. Marselli<sup>2</sup>, G. Meur<sup>1</sup>, P. Marchetti<sup>2</sup>, G.A. Rutter<sup>1</sup>;<sup>1</sup>Medicine, Imperial College London, UK, <sup>2</sup>Department of Clinical and Experimental Medicine, University of Pisa, Italy.

**Background and aims:** Investigation of the function of genes identified by genome-wide association studies for Type 2 diabetes (T2D) may bring a better understanding of disease aetiology and ultimately provide new therapeutic

tic targets. Recently-identified common genetic variants in the ARAP1 locus affect fasting proinsulin levels (rs11603334) and glucose-induced insulin secretion (rs1552224) in man. Here we investigate the roles of two genes implicated at this locus: ARAP1 and STAR10.

**Materials and methods:** Arap1 and StarD10 expression was silenced by siRNA and proteins overexpressed via a coding plasmid transfected by Lipofectamine 2000 (cell lines) or adenoviral infection (mouse and human islets). Total and secreted insulin were measured by radioimmunoassay.

**Results:** Expression quantitative trait loci (eQTL) analysis by qRT-PCR in human islets from 49 donors revealed increased expression of the short form of Arap1 (variant 1: Arap1v1) in the carriers of the risk variant at SNP rs1552224 ( $p < 0.02$ ). Association with StarD10 mRNA levels was not detected. Over-expression of the full-length variant of Arap1 (variant 3) in MIN6 cells exerted no apparent effect on insulin secretion in response to either 30 mM glucose (control:  $2.31 \pm 0.28$ -fold; Arap1-V3:  $2.22 \pm 0.25$ -fold; NS) or 30 mM KCl (control:  $4.24 \pm 0.48$ ; Arap1-V3:  $4.13 \pm 0.72$ ; NS). However, over-expression of Arap1v1, lacking an N-terminal inhibitory domain and thus predicted to be more active, tended to inhibit insulin secretion provoked by 30 mM glucose (control:  $4.01 \pm 0.63$ -fold; Arap1-V1:  $2.84 \pm 0.53$ -fold; NS) or 30 mM KCl (control:  $3.68 \pm 0.28$ ; Arap1-V1:  $2.90 \pm 0.32$ ;  $p = 0.083$ ). Moreover, over-expression of Arap1v1 or StarD10 in human islets reduced insulin secretion provoked by 17 mM glucose (control:  $33.39 \pm 9.95$ -fold; Arap1V1:  $19.92 \pm 3.11$ -fold; StarD10:  $15.26 \pm 1.11$ -fold) and by 30 mM KCl in the case of StarD10 (control:  $38.39 \pm 8.46$ -fold; Arap1V1:  $35.22 \pm 3.85$ -fold; StarD10:  $15.41 \pm 2.04$ -fold). In addition, Arap1v1 overexpression strongly reduced the total insulin content of human ( $54.21 \pm 0.04\%$ ;  $p < 0.0001$ ) and mouse ( $50.51 \pm 0.03\%$ ;  $p < 0.0001$ ) islets. Forced over-expression of StarD10 in MIN6 cells decreased insulin secretion provoked by 30 (versus 3.0) mM glucose (control:  $2.54 \pm 0.21$ -fold; StarD10:  $1.55 \pm 0.10$ -fold;  $p < 0.01$ ) or 30 mM KCl (control:  $5.20 \pm 0.35$ -fold, StarD10:  $2.63 \pm 0.14$ -fold;  $p < 0.0001$ ). Overexpression of StarD10 potentiated apoptosis induced by staurosporine (1  $\mu$ M) in mouse islets, assessed by TUNEL staining (control:  $1.85 \pm 0.23\%$ ; StarD10:  $4.60 \pm 0.62\%$ ;  $p < 0.0001$ ). siRNA-mediated silencing of neither gene affected insulin content or secretion.

**Conclusion:** These data indicate that Arap1, whose expression is increased in the carriers of risk alleles at SNP rs1552224, affects islet insulin content and secretion and is thus likely to mediate the effects of these alleles on diabetes susceptibility. The demonstration that StarD10 over-expression also affects insulin secretion and beta cell survival suggests that changes in the latter gene product may also contribute. However, further eQTL studies will be required to test this hypothesis in larger cohorts.

## 135

### Diazoxide as a tool to investigate metabolic amplification of insulin secretion: a reconsideration

N. Görgler, M. Willenborg, K. Schumacher, I. Rustenbeck;  
Institute of Pharmacology and Toxicology, University of Braunschweig, Germany.

**Background and aims:** Glucose-induced insulin secretion is mediated by a bifurcating pathway generating “triggering” and “amplifying” signals. The standard protocol to demonstrate the amplifying effect of glucose (and other nutrient secretagogues) is to depolarize the beta cells by raising the external  $K^+$  concentration while the  $K_{ATP}$  channels are clamped open by diazoxide to ensure the generation of the Nernst equilibrium. Any further increase in secretion which is caused by the addition of glucose is then believed to be mediated by the still incompletely understood amplifying pathway. Diazoxide, however, has been reported to have sites of action in addition to the  $K_{ATP}$  channel, which may complicate the interpretation of the observed effects.

**Materials and methods:** The membrane potential of primary mouse islet cells was measured by the patch clamp technique using the perforated patch configuration. The cytosolic  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ) was measured with the Fura technique, the mitochondrial membrane potential with rhodamine 123 and insulin granules were visualized by insulin-EGFP. Insulin secretion was quantified by batch perfusion of islets and ELISA of the fractionated efflux. The adenine nucleotide content was measured by the luciferase method after static incubation.

**Results:** To depolarize the beta cell plasma membrane a  $K^+$  concentration was used (15 mM KCl) which mimicked the slow-wave depolarization by glucose (20 mV) and raised  $[Ca^{2+}]_i$  to levels comparable to those produced by 20 mM glucose. In the presence of a substimulatory glucose concentration 15 mM  $K^+$  produced only a modest transient increase of insulin secretion. When glucose

was raised from 5 mM to 10 mM in the continuing presence of 15 mM  $K^+$  a marked increase of insulin secretion with a biphasic pattern resulted. The addition of 250  $\mu$ M diazoxide diminished the secretion down to prestimulatory levels. The abolition of the glucose-stimulated secretion by diazoxide was unexpected since  $K^+$  still depolarized the beta cell plasma membrane (by  $18 \pm 1$  mV) and since the presence of 10 mM glucose was expected to ensure the generation of amplifying signals. Compared with the presence of 10 mM glucose plus 15 mM KCl the addition of diazoxide led to a slight decrease of the ATP/ADP ratio and an equally slight increase of the ATP/AMP ratio. Measuring  $[Ca^{2+}]_i$  using the same protocol showed that the level established by the combined action of 15 mM  $K^+$  and 10 mM glucose was moderately, but significantly diminished by diazoxide. Concomitantly diazoxide had a depolarizing effect on the mitochondria, which was also visible in the TIRF mode, showing that mitochondria co-exist with secretory granules in the immediate submembrane space.

**Conclusion:** Diazoxide does not only affect insulin secretion by the opening of  $K_{ATP}$  channels. The effect on mitochondrial function may interfere with the amplifying pathway of nutrient secretagogues, the existence of which is usually demonstrated by the use of diazoxide. The interference may not even require changes in the bulk cytosol, since mitochondria could be shown to exist in the immediate submembrane space close to secretory granules.

### Elevated expression of CaV3.1 channels impairs glucose-stimulated insulin secretion through downregulation of the exocytotic machinery

J. Yu<sup>1</sup>, Y. Shi<sup>1</sup>, G. Yang<sup>1,2</sup>, L. Yu<sup>1</sup>, P.-O. Berggren<sup>1</sup>, S.-N. Yang<sup>1</sup>;  
<sup>1</sup>The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Jilin Academy of Traditional Chinese Medicine, Changchun, China.

**Background and aims:** Pancreatic  $\beta$  cells are equipped with at least seven subtypes of voltage-gated calcium (CaV) channels, including CaV1.2, CaV1.3, CaV2.1, CaV2.2, CaV2.3, CaV3.1 and CaV3.2, to conduct L-, P/Q-, N-, R- and T-type CaV currents, respectively. These CaV channels are vital to the function and survival of  $\beta$  cells. CaV3 channel-mediated T-type  $Ca^{2+}$  currents have long been recorded in  $\beta$  cells from different species including human. Enhanced T-type  $Ca^{2+}$  currents are observed in type 2 diabetic Goto-Kakizaki rat  $\beta$  cells and T-type  $Ca^{2+}$  currents, which are absent in normal mouse  $\beta$  cells, occur in nonobese diabetic mouse  $\beta$  cells. To date, it is not known whether the enhanced T-type  $Ca^{2+}$  currents and phenotypic switch of CaV3 channel expression in diabetic  $\beta$  cells are causes or consequences of the disease. The present work aimed at exploring the role of CaV3.1 channels in the pathogenesis of diabetes by elevating CaV3.1 channel expression in rat  $\beta$  cells.

**Materials and methods:** We employed multiple methods including construction of adenoviral vectors (Ad) carrying either enhanced green fluorescent protein (EGFP) or EGFP-CaV3.1, patch-clamp analysis, confocal microscopy, immunoblot assay, islet perfusion and transplantation.

**Results:** The present work began with construction of Ad-EGFP-CaV3.1 and Ad-EGFP. Subsequently, characterization of these constructs was performed in COS-7 cells, rat islet cells and intact islets. Ad-EGFP-CaV3.1 and Ad-EGFP effectively transduced COS-7 cells and rat islet cells. Strong EGFP signals were detected in both Ad-EGFP-CaV3.1- and Ad-EGFP-transduced cells whereas typical unitary and whole-cell T-type  $Ca^{2+}$  currents were only observed in Ad-EGFP-CaV3.1-transduced cells. These data verify that Ad-EGFP-CaV3.1 is expressed in COS-7 cells and rat islet cells resulting in enhanced T-type  $Ca^{2+}$  currents. Both Ad-EGFP-CaV3.1 and Ad-EGFP efficiently infected islet cells throughout the intact islet. Ad-EGFP-CaV3.1-infected islets released less insulin during exposure to 2.8 mM glucose. Importantly these islets displayed impaired first phase but intact second phase insulin secretion when perfused with 16.7 mM glucose. These observations demonstrate that elevated expression of CaV3.1 channels selectively impairs basal insulin release and first-phase glucose stimulated insulin secretion. More importantly, the relative abundance of synaptotagmin III, syntaxin 1A and SNAP-25 proteins in Ad-EGFP-CaV3.1-treated islets is lower than that in islets infected with Ad-EGFP. These results reveal that elevated expression of CaV3.1 channels downregulates syntaxin 1A, SNAP-25 and synaptotagmin III, which are critical for glucose-stimulated insulin secretion. Most importantly, a significant normalization of hyperglycaemia occurred in streptozotocin-induced diabetic rats transplanted with control islets or islets infected with Ad-EGFP into the anterior chamber of the eye, but not in those transplanted with islets transduced with Ad-EGFP-CaV3.1. These *in vivo* findings

indicate that elevated expression of CaV3.1 channels causes impaired glucose homeostasis.

**Conclusion:** Elevated expression of CaV3.1 channels impairs glucose-stimulated insulin secretion through downregulation of the exocytotic machinery and plays an important role in the pathogenesis of diabetes.

## 137

### NGF secretion from beta cells contributes to fine tuning of insulin secretion

A. Pingitore<sup>1</sup>, M.C. Caroleo<sup>2</sup>, E. Cione<sup>2</sup>, S. Persaud<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, Diabetes and Nutritional Sciences, King's College London, UK, <sup>2</sup>Pharmacy and NHS, University of Calabria, Rende, Italy.

**Background and aims:** Islet  $\beta$ -cells express a range of peptides such as nerve growth factor (NGF), which was originally identified as a signaling protein regulating neuronal survival. It is now recognised that NGF is a more complex messenger involved in controlling a broad range of homeostatic responses through binding to two trans-membrane receptors, trkA and p75NTR, both expressed in islets. The role of NGF in islet function has not been established so we investigated whether  $\beta$ -cells possess an autocrine loop through which NGF release modulates insulin secretion.

**Materials and methods:** Studies were conducted with isolated mouse islets (MI) and human islets (HI), and with MIN6 pseudoislets (PI) that were generated by growing MIN6  $\beta$ -cells on bacterial dishes for 10 days. NGF release from islets was determined by western blotting and quantified by ELISA, and insulin secretion was quantified by radioimmunoassay. The biological activity of  $\beta$ -cell-derived NGF was blocked via a NGF neutralising antibody (AbNGF) at 5 $\mu$ g/mL and trkA blockade was achieved with 5nM K252a. Immunoprecipitation studies were performed using INS-832/13  $\beta$ -cells with an anti-RhoGDI antibody followed by electrophoresis and western blotting probing with anti-p75NTR.

**Results:** NGF expression and release from islets was identified by western blotting, and a sensitive ELISA indicated that NGF was secreted from MI in a glucose-dependent manner (2mM glucose: 17.8 $\pm$ 6.1 pg/mL; 20mM glucose 56.7 $\pm$ 2.8 pg/mL). Blockade of secreted NGF action in islets and PIs with AbNGF increased insulin output at 2mM glucose (MI 381.0 $\pm$ 114.0%,  $p < 0.001$ ; HI 150.5 $\pm$ 17.5%,  $p < 0.05$ ; PI 142.6 $\pm$ 17.0%,  $p > 0.2$ ). In contrast, HI responded to K252a treatment at 2mM glucose with an elevation in insulin secretion comparable to that seen with AbNGF blockade (133.7 $\pm$ 16.2%,  $p < 0.05$ ), but trkA inhibition at 20mM glucose did not affect insulin release, suggesting that p75NTR is the receptor through which locally released NGF acts to inhibit GSIS from islets and pseudoislets. Consistent with this, over-expression of p75NTR in  $\beta$ -cells significantly inhibited GSIS (by 48.5 $\pm$ 2.5%). Furthermore, immunoprecipitation studies revealed that Rho-GDI was bound to  $\beta$ -cell p75NTR at 2mM glucose and the complex dissociated upon glucose stimulation. Impairment of NGF biological activity with AbNGF resulted in the inability of the p75NTR/Rho-GDI complex to dissociate in response to glucose. Most likely, this affects the correct cycling of Rho-GDI small GTPases, disturbing the control on granule secretion through the actin-dependent cytoskeleton remodeling.

**Conclusion:** These observations support the presence of an autocrine NGF loop in islets, whose functions go beyond the canonical survival pathways: we propose that co-release of NGF with insulin following a glucose stimulus allows the fine tuning of the  $\beta$ -cell secretory response to prevent hyper-secretion of insulin and potentially deleterious hypoglycaemia.

## 138

### Alpha-cell functionality shows gender-specific adaptations face to a nutritional insult in Wistar rats

J. de Toro-Martín<sup>1</sup>, E. Fernandez-Millan<sup>2</sup>, E. Lizárraga-Mollinedo<sup>1,2</sup>,

F. Escrivá<sup>1,2</sup>, C. Álvarez<sup>1,2</sup>;

<sup>1</sup>Department of Biochemistry and Molecular Biology II, School of Pharmacy, UCM, <sup>2</sup>Ciberdem, ISCIII, Madrid, Spain.

**Background and aims:** Nutritional rehabilitation after early food restriction has been extensively associated with the later appearance of metabolic disturbances, like type 2 diabetes, according to the thrifty phenotype hypothesis. This fact has been related with adaptations of beta-cell plasticity and function. Together with beta-cells, alpha-cells play a key role in the control of

glucose homeostasis and abnormalities in alpha-cell functionality have been also reported in patients with type 2 diabetes. In the present study we aimed to analyse the adaptations of alpha-cells face to a nutritional rehabilitation and gender-specific differences were investigated.

**Materials and methods:** The experiments were carried out in male and female Wistar rats aged of 180 days, belonging to four diet groups: control (C), fed a standard chow diet, undernourished (U), fed 35% of the daily control food intake, control high-fat (CHF) and undernourished high-fat (UHF), both fed a HFD from weaning onwards. Immunohistochemical and morphological analysis were performed to quantify alpha- and beta-cell mass, as well as the islet number and size. Functionality of alpha and beta cells was analysed in vitro by static incubation of isolated islets under different glucose concentrations (0.5, 3 and 17mM). Alpha-cell secretory capacity was studied by adding arginine (19mM) to the incubation buffer. Glucagon and insulin content were quantified in the isolated islets by RIA.

**Results:** Islets from HFD-fed rats showed increased size in both male and female rats, whereas islet density only increased in CHF female rats. Alpha-cell mass significantly increased in UHF rats, whereas no changes were observed in CHF rats. Both male and female CHF rats exhibited increased glucagon secretion under low glucose conditions (0.5mM) and a lack of suppression face to increasing glucose concentrations. Despite significantly increased islet glucagon content in both male and female UHF rats, gender-specific differences were observed regarding the islet functionality. While UHF male rats showed improved response to stimulating glucose concentrations, UHF female rats exhibited a nearly absence of alpha-cell response, similar to that shown by U rats. All populations showed increased glucagon secretion when analysed with 19mM arginine. However, UHF female islets showed the greater increase in glucagon secretion at 0.5mM (~4-fold) and a significant lack of suppression at 3mM (~3.6-fold). Despite the increased beta-cell mass shown by both CHF and UHF rats, a compromised beta-cell function was exhibited by these rats under stimulating glucose conditions (17mM), especially worsened in UHF female rats, showing also decreased insulin content.

**Conclusion:** Since glucagon release by alpha-cells is mainly regulated by glucose and a highly specific paracrine control, these results point to a defect in glucose sensitivity of alpha-cells after HFD, likely related to a deficient beta-cell-mediated paracrine control of glucagon. The worsening of these alterations in female rats evidences a gender-specific occurrence of impaired adaptations to a nutritional insult.

### A beta cell specific protein subnetwork significantly enriched for association with GLP-1 stimulated insulin secretion: a DIRECT study

V. Gudmundsdottir<sup>1</sup>, H.K. Pedersen<sup>1</sup>, L.M. 't Hart<sup>2</sup>, K. Banasik<sup>3,4</sup>, D. Boomsma<sup>5</sup>, E. de Geus<sup>5</sup>, M. Eekhoff<sup>6</sup>, M. Diamant<sup>6</sup>, M. McCarthy<sup>3,7</sup>, E. Pearson<sup>8</sup>, C. Workman<sup>1</sup>, R. Gupta<sup>1</sup>, S. Brunak<sup>1</sup>;

<sup>1</sup>Technical University of Denmark, Kgs. Lyngby, Denmark,

<sup>2</sup>Leiden University Medical Center, Netherlands, <sup>3</sup>University of Oxford, UK,

<sup>4</sup>University of Copenhagen, Denmark, <sup>5</sup>VU University Amsterdam,

<sup>6</sup>VU University Medical Center, Amsterdam, Netherlands, <sup>7</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, <sup>8</sup>University of Dundee, UK.

**Background and aims:** The heritability of insulin secretion response (ISR) during a modified hyperglycaemic clamp with glucose, glucagon-like peptide-1 (GLP-1) and arginine stimulation has been shown to be considerable ( $h^2=0.52$  to  $0.80$ ) and it is of great interest to identify genetic variants influencing these responses. Evaluating ISR with a modified hyperglycaemic clamp is not feasible in larger cohorts of sizes preferred for genome-wide association studies (GWAS). When sample sizes are small, GWAS may be complemented with systems biology approaches to aid the prioritisation of genetic variants. Within the DIRECT consortium a GWAS was performed on GLP-1 stimulated ISR and here we aimed to use data integration to add biological context to the results and facilitate variant prioritisation.

**Materials and methods:** GLP-1 stimulated ISR was measured with a modified hyperglycaemic clamp in 130 twins and sibs from the Netherlands twin register. The cohort was genotyped using the Illumina HumanCore Exome BeadChip and association analysis was performed using the QTassoc software and adjusted for age, sex, familial relationships and insulin sensitivity index. Gene-based P-values were mapped onto a  $\beta$ -cell specific protein-protein interaction (PPI) network, which was created by pruning high confidence PPIs from InWeb 3.0 using published  $\beta$ -cell RNAseq data. Connected components in the network enriched for high scoring genes were identified with the Cytoscape plugin jActiveModules. The significance of the top-scoring network was evaluated by converting the gene P-values to z-scores and estimating the probability of observing a combined z-score of same size or higher with 10,000 degree-preserved randomly sampled subnetworks from the  $\beta$ -cell PPI. Gene set enrichment analysis was performed on the top subnetwork using DAVID.

**Results:** None of the variants tested in the GWAS reached a genome-wide significance of  $P \leq 5.0E-8$ . However, the top scoring subnetwork had a significantly higher combined z-score than expected by random ( $P \leq 1.0E-4$ ). It contained 25 genes and was most strongly enriched for the Gene Ontology terms “plasma membrane part” (Padj =  $2.2E-4$ ), “cell junction” (Padj =  $3.6E-4$ ) and “cell projection” (Padj =  $4.9E-3$ ). The subnetwork contained a number of genes known to affect  $\beta$ -cell mass and function (*FOXO1*), insulin secretion (*WFS1*, *RYR2*) or to be implicated in type 2 diabetes (*MAGI2*, *CTNNA2* and *PTPRD*).

**Conclusion:** We have identified a  $\beta$ -cell PPI network enriched for genes with nominal associations with GLP-1 stimulated ISR, demonstrating how data integration can highlight biological mechanisms underlying a phenotype where GWAS results on their own may be insufficient. Furthermore, the network can be used to prioritise genetic variants to take forward for replication in independent cohorts.

### FOXA2 bound sites are enriched for type 2 diabetes risk variants

K.J. Gaulton<sup>1</sup>, A.P. Morris<sup>3</sup>, M.I. McCarthy<sup>1</sup>, the DIAGRAM consortium;

<sup>1</sup>Wellcome Trust Centre for Human Genetics, Oxford, <sup>2</sup>Department of Biostatistics, University of Liverpool, UK.

**Background and aims:** Risk variants for type 2 diabetes (T2D) are primarily non-coding and are enriched at regulatory features; however, specific causal variants and regulatory factors underlying risk variant activity are largely unknown. We aimed to integrate systematic regional genotyping data with genomic annotation to identify (i) regulatory factor binding sites broadly enriched for T2D risk and (ii) causal regulatory variants driving enriched signals.

**Materials and methods:** We used “credible sets” of SNPs that account for 99% of the probability of including the causal variant for 39 T2D association signals identified in a study of 27,116 T2D cases and 57,574 controls (MetaboChIP imputed up to 1000G). We then identified chromatin immunoprecipitation (ChIP) binding sites of 141 proteins obtained from ENCODE and several independent studies. Credible sets were tested for enrichment in the sum of posterior probabilities for variants overlapping binding sites for each factor pooled across all assayed cell types compared to variants in shuffled site locations (within 100kb). We performed enrichment tests both across all loci together and, for globally-enriched factors, at each locus individually.

**Results:** We identified significant enrichment for FOXA2 sites (assayed in pancreatic islets and HepG2 cells) across all risk loci ( $P=3 \times 10^{-4}$ ). No other factor was significantly enriched. Among individual loci, there was nominally significant enrichment ( $P < .05$ ) at 12 out of the 24 total loci containing at least one credible set variant overlapping a FOXA2 site. We identified candidate regulatory variants at 8 of these 12 loci using predictions of sequence motifs in FOXA2-bound sites. Further in silico and preliminary experimental study of allelic effects on protein binding suggests a subset are functional regulatory variants, including a variant with prior functional evidence (rs7903146 at TCF7L2).

**Conclusion:** These results identify potential causal variants at a set of known T2D risk loci and suggest that altered FOXA2 binding may be a common functional avenue for many T2D risk variants.

### The terminal complement complex C5b-9, but not the anaphylatoxin C5a, is cross-sectionally associated with fatty liver disease:

#### The CODAM study

M.M.J. van Greevenbroek<sup>1</sup>, M.F.J. Wilbrink<sup>1</sup>, E. Hertle<sup>1</sup>, N. Wlazlo<sup>2</sup>, C.J.H. van der Kallen<sup>1</sup>, E.J.M. Feskens<sup>3</sup>, C.G. Schalkwijk<sup>1</sup>, C.D.A. Stehouwer<sup>1</sup>;

<sup>1</sup>Internal Medicine (UNS<sup>50</sup> box<sup>14</sup>), Maastricht University,

<sup>2</sup>Internal Medicine (UNS<sup>50</sup> box<sup>14</sup>), Catharina Ziekenhuis, Eindhoven,

<sup>3</sup>Human Nutrition, Wageningen University, Netherlands.

**Background and aims:** The etiological mechanisms that underlie human fatty liver disease are incompletely understood. We previously showed that certain aspects of complement activation - as reflected by systemic C3a levels - were associated with human fatty liver disease. Objective: To investigate whether activation of the terminal complement pathway - as represented by C5a and soluble (s)C5b-9 - was also associated with fatty liver disease.

**Materials and methods:** Plasma C5a and sC5b-9 were measured in a cross-sectional evaluation of the Cohort on Diabetes and Atherosclerosis Maastricht (CODAM, n=508, 61% men; 59±7 yrs). As markers of fatty liver disease we used liver fat content (eLF%), estimated using a validated predictive equation, as well as liver enzymes [alanine aminotransferase (ALT), aspartate amino transferase (AST), and gamma-glutamyl transferase (GGT)], that were compiled into a standardized (std) liver enzyme (LE) score. Multiple linear regression analyses were used to investigate associations between C5a and sC5b-9 and these fatty liver disease markers. Analyses were adjusted for age, sex, impaired glucose metabolism and type 2 diabetes mellitus, cardiovascular disease, smoking, alcohol consumption, kidney function, medication, physical activity, and waist circumference. We additionally investigated whether these associations, if present, were mediated (i.e. explained) by low-grade inflammation (LGI). For this, 8 markers of LGI (TNF- $\alpha$ , CRP, IL6, IL8, serum amyloid A, ICAM1, ceruloplasmin and haptoglobin) were compiled into a std LGI score that was added to the fully adjusted regression models.

**Results:** In the fully adjusted regression models, std sC5b-9 was significantly associated with std eLF% ( $\beta=0.12$  [95%CI: 0.05;0.18]) and with the std LE-score ( $\beta=0.16$  [95%CI: 0.09;0.24]). In contrast, C5a was not significantly associated with either fatty liver disease marker. The association between sC5b-9 and the markers of fatty liver disease was for a substantial part (20-30%), but not fully, explained by LGI. In the final, mediated, regression model, sC5b-9 ( $\beta=0.08$  [95%CI: 0.01;0.14],  $\beta=0.13$  [95%CI: 0.05;0.21]) and the LGI score ( $\beta=0.14$  [95%CI: 0.07;0.21],  $\beta=0.14$  [95%CI: 0.06;0.23]) were both independently associated with eLF% and the LE-score, respectively. Similar results were obtained when analyses were restricted to those who consumed no-to-moderate amounts of alcohol (<30 g/d for men, <20g/d for women, n=400).

**Conclusion:** In the CODAM cohort, plasma levels of the anaphylatoxin C5a appeared not to be associated with fatty liver disease. In contrast, a hallmark of full complement activation - i.e. formation of the (s)C5b-9 complex - was associated with human fatty liver disease, as represented by markers of hepatic fat accumulation (eLF%) and hepatocellular injury (LE-score). These associations were only partly explained by LGI and therefore suggest a po-

tential direct involvement of terminal complement activation in the aetiology of human fatty liver disease, which deserves further investigation aiming to unravel the potential mechanisms involved.

### Novel metabolite models that distinguish impaired glucose tolerance (IGT) from normal glucose tolerance (NGT)

J.E. Cobb<sup>1</sup>, A. Eckhart<sup>1</sup>, K.-P. Adam<sup>1</sup>, R. Perichon<sup>1</sup>, J. Wulff<sup>1</sup>, M. Mitchell<sup>1</sup>, R. Elverson<sup>1</sup>, R. Wolfert<sup>1</sup>, K. Lawton<sup>1</sup>, E. Button<sup>1</sup>, Z. Li<sup>1</sup>, B. Carr<sup>2</sup>, M. Sinnott<sup>2</sup>, E. Ferrannini<sup>3</sup>;  
<sup>1</sup>Metabolon, Durham, USA, <sup>2</sup>Vhi Healthcare, Dublin, Ireland, <sup>3</sup>University of Pisa, Italy.

**Background and aims:** Metabolomic profiling studies have identified a number of metabolites where fasting levels are associated with dysglycemia and type 2 diabetes. The aim of this study was to identify metabolites and metabolite-based models that distinguish IGT from NGT in non-diabetic subjects. **Materials and methods:** Using the stable isotope dilution technique, quantitative assays were developed for a set of 23 candidate biomarker metabolites previously linked to dysglycemia. This set included:  $\alpha$ -hydroxybutyric acid (AHB), linoleoylglycerophosphocholine (LGPC), oleic acid,  $\alpha$ -ketoglutaric acid, 2-aminoadipic acid, glycine, aromatic amino acids, and the 3 branched-chain amino acids and several of their catabolites. These metabolites were measured in fasting plasma samples taken just prior to an OGTT from 1,679 non-diabetic subjects: 979 from the RISC Study 3 year follow up (11.5% have IGT) and 679 subjects from the DMVhi cohort in the DEXLIFE project (11.8% have IGT).

**Results:** Random forest decision tree analysis using subject metabolite, anthropometric, and metabolic characteristic data were generated to rank variables for their ability to distinguish IGT from NGT. The top 4 were found to be AHB, fasting glucose, LGPC, and oleic acid in RISC and fasting glucose, age, LGPC, and AHB in DMVhi. Multivariate models for estimating risk of IGT were evaluated in both cohorts using AUCs calculated from the corresponding ROC curves. AUCs generally did not increase in models having more than 7 variables. A number of 7 variable, metabolite only models were developed that had AUCs >0.80. For example, in RISC, a model consisting of AHB, glucose, LGPC, oleic acid, glycine, creatine, and 2-oxoisoleucine had an AUC of 0.825. In contrast, a model consisting of age, sex, BMI, glucose, insulin and HDL had a significantly lower ( $p=0.0001$ ) AUC of 0.731.

**Conclusion:** AHB and LGPC have been identified as metabolite markers of IGT and metabolite-based models may be useful for identifying IGT in non-diabetic subjects

### Causal effect of decreased LDL cholesterol and increased blood pressure on higher incidence of type 2 diabetes by Mendelian randomisation in the Malmö Diet and Cancer Study

G. Hindy, G. Rukh, P. Almgren, U. Ericson, O. Melander, M. Orho-Melander; Department of Clinical Sciences in Malmö, Lund University Diabetes Center, Skåne University Hospital, Lund University, Malmö, Sweden.

**Background and aims:** Obesity, dyslipidemia and hypertension associate with type 2 diabetes (T2D). However, the relationship between these traits and T2D may not be causal due to confounding and reverse causation. In the Mendelian randomization approach genetic variants are assumed to be randomly distributed, and can be used as instrumental variables to estimate causal relationships. The aim of this study was to investigate if BMI, systolic blood pressure (SBP) and lipid traits are causally associated with T2D incidence by using genetic risk scores (GRSs) of single nucleotide polymorphisms (SNPs) identified in genome wide association studies (GWAS) for these traits as instrumental variables.

**Materials and methods:** In total, 27254 non-diabetic participants (61% females) from the population based Malmö Diet and Cancer Study (MDCS), collected at baseline during 1990-1996 (age 58±8 years, BMI 26±4 kg/m<sup>2</sup>), were genotyped for SNPs associating with BMI (N=31), high density lipoprotein cholesterol (HDL, N=41), low density lipoprotein cholesterol (LDL, N=32), triglycerides (TG, N=26) and SBP (N=29). Trait-specific weighted GRSs were created using PLINK software. During a mean follow-up time of

15±4 years, 3248 incident T2D and 3977 cardiovascular disease (CVD) cases were identified. At baseline, BMI and SBP were measured for all individuals and fasting blood lipid levels were analyzed in a random sub-cohort (MDC-CC) of 5284 individuals of which 781 developed T2D and 754 CVD. COX-regression was used to analyze the association between BMI, SBP, HDL, LDL and TG, and incidence of T2D per standard deviation (SD). For Mendelian randomization, a two-stage least square regression method was used with the GRSs as instrumental variables. The predicted values for the first stage of regression of the lipid traits on their respective GRSs were estimated from MDC-CC for all MDCS. Adjustments were made for age, sex, lipid-lowering and antihypertensive medication.

**Results:** As expected, baseline levels of higher BMI, SBP, LDL and TG, and lower HDL associated with higher incidence of T2D (HR 1.83 [1.78-1.88],  $P<0.00001$ ; 1.34 [1.29-1.38],  $P=3\times 10^{-59}$ ; 1.17 [1.08-1.25],  $P=0.0004$ ; 1.23 [1.20-1.27],  $P=2\times 10^{-50}$  and 1.66 [1.51-1.82],  $P=4\times 10^{-27}$ , respectively). The instrumental variable analysis revealed causal effect of increased BMI and SBP but decreased LDL on higher incidence of T2D (HR 1.92 [1.30-2.83],  $P=0.001$ ; 1.99 [1.14-3.48],  $P=0.02$  and 1.14 [1.00-1.28],  $P=0.04$ , respectively). The instrumental variable analysis did not indicate causality between HDL or TG and incidence of T2D (0.90 [0.78-1.03],  $P=0.13$  and 1.07 [0.91-1.26],  $P=0.42$ , respectively). The instrumental variable analysis indicated a causal effect of increased SBP, LDL and TG on higher incidence of CVD (HR 1.73 [1.04-2.88],  $P=0.03$ ; 1.21 [1.08-1.36],  $P=0.001$  and 1.17 [1.01-1.36],  $P=0.04$ , respectively).

**Conclusion:** In this large prospective study the Mendelian randomization analysis indicated causal effects of increased BMI and SBP and decreased LDL on higher incidence of T2D. Our results suggest opposite causal effects of LDL on the risk of T2D and CVD, and raise the question about the potential deleterious effects of LDL lowering agents on the risk of T2D. Further, our study emphasizes the importance of weight loss and blood pressure control in prevention of T2D.

**Background and aims:** Chemerin is an adipokine proposed to link obesity and chronic inflammation of adipose tissue. Genetic factors determining chemerin release from adipose tissue are yet unknown.

**Materials and methods:** We conducted a meta-analysis of genome-wide association studies GWAS for serum chemerin in three independent cohorts from Europe (Sorbs and KORA from Germany and PPP-Botnia study from Sweden; total N=2,791). Furthermore, we measured mRNA expression of genes within the associated loci in lymphocytes and adipose tissue by quantitative RT-PCR and performed mRNA expression-genotype association studies.

**Results:** Heritability of circulating chemerin levels was 16.2%. Thirty one single nucleotide polymorphisms (SNPs) at chromosome 7 within the *RARRES2* locus reached genome-wide significance ( $p<10^{-7}$ ) in the meta-analysis (strongest evidence for association at rs7806429 with  $p=7.8\times 10^{-14}$ ,  $\beta=0.067$ ). All other SNPs within the cluster were in strong linkage disequilibrium with rs7806429 ( $r^2 >0.43$  in the Sorbs). The results in the subgroup analyses in males and females were consistent with the results in the total cohort. Although effect sizes for all genome-wide significant SNPs were

stronger in females than in males, no SNP gender interaction was observed. Furthermore, rs7806429 was associated with mRNA expression of *RARRES2* in visceral adipose tissue in women ( $p < 0.05$  after adjusting for age, sex and body mass index).

**Conclusion:** The present meta-analysis of GWAS combined with mRNA expression studies highlights the role of genetic variation in *RARRES2* in the regulation of circulating chemerin concentrations.

#### The effect of insulin degludec in combination with liraglutide and metformin in patients with type 2 diabetes requiring treatment intensification

V.R. Aroda<sup>1</sup>, T. Bailey<sup>2</sup>, B. Cariou<sup>3</sup>, S. Kumar<sup>4</sup>, L.A. Leiter<sup>5</sup>, P. Raskin<sup>6</sup>, J. Zacho<sup>7</sup>, M. Bandier<sup>7</sup>, A. Philis-Tsimikas<sup>8</sup>;

<sup>1</sup>MedStar Health Research Institute, Hyattsville, <sup>2</sup>AMCR Institute Inc., Escondido, USA, <sup>3</sup>Department of Endocrinology, Nantes University Hospital, Nantes, France, <sup>4</sup>WISDEM Centre, University Hospitals of Coventry and Warwickshire, Coventry, UK, <sup>5</sup>St Michael's Hospital, University of Toronto, Canada, <sup>6</sup>University of Texas Southwestern Medical Center at Dallas, USA, <sup>7</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>8</sup>Scripps Whittier Diabetes Institute, San Diego, USA.

**Background and aims:** Several studies have evaluated the combination of a basal insulin and a glucagon-like peptide-1 (GLP-1) analogue in addressing the multiple concomitant defects in glucose homeostasis seen in type 2 diabetes (T2D). The aim of this trial was to investigate the efficacy of insulin degludec (IDeg) compared with placebo in improving glucose control in patients with T2D, treated with liraglutide (lira) and metformin and qualifying for treatment intensification.

**Materials and methods:** In this 26-week, double-blind trial, patients with T2D who remained inadequately controlled ( $HbA_{1c}$  7–9%, inclusive) after a 15-week run-in period with initiation and intensification of liraglutide to 1.8 mg in combination with metformin ( $\geq 1500$  mg) were randomised (1:1) to addition of once-daily IDeg ( $n=174$ ) or placebo ( $n=172$ ), with dosing of both IDeg and placebo based on titration guidelines (fasting plasma glucose [FPG] target 4.0–5.0 mmol/L).

**Results:** Patient characteristics were generally similar at randomisation: mean  $HbA_{1c}$  was 7.5% (IDeg+lira) vs. 7.6% (placebo+lira), BMI 32.0 kg/m<sup>2</sup> vs. 32.4 kg/m<sup>2</sup>, duration of diabetes 9.7 years vs. 9.3 years and FPG 8.7 mmol/L vs. 9.1 mmol/L. At 26 weeks, IDeg+lira was superior to placebo+lira in improving glycaemic control in terms of  $HbA_{1c}$  (estimated treatment difference [ETD]: -0.92% [-1.10; -0.75]<sub>95%CI</sub>,  $p < 0.0001$ ) with observed mean reductions of 1.04% and 0.16%, respectively. IDeg+lira was more effective in lowering FPG than placebo+lira, ETD -2.55 mmol/L [-3.07; -2.02]<sub>95%CI</sub>,  $p < 0.0001$  with observed mean reductions of 2.60 mmol/L and 0.28 mmol/L, respectively. At 26 weeks, IDeg dose was 51 U while placebo was titrated to a dose corresponding to 105 U. During lira run-in, mean body weight in those later randomised to trial treatment decreased from 95.4 kg to 92.3 kg. After 26 weeks of treatment, patients randomised to IDeg+lira had gained on average 2.0 kg, while patients randomised to placebo+lira had an additional weight reduction of 1.3 kg during treatment. Rates (episodes per exposure-year) of confirmed hypoglycaemia were low in both groups, higher with IDeg+lira than with placebo+lira (0.57 vs. 0.12), estimated treatment ratio: 4.67 [2.07; 10.56]<sub>95%CI</sub>,  $p = 0.0002$ . Rates of nocturnal confirmed hypoglycaemic episodes were low and similar for both groups (0.05 and 0.03, respectively,  $p = NS$ ). There were no episodes of severe hypoglycaemia in either treatment arm. No safety issues were identified with IDeg+lira with respect to adverse events or standard safety parameters.

**Conclusion:** For patients with T2D treated with lira+metformin and qualifying for treatment intensification, addition of IDeg compared with placebo significantly improved glycaemic control with low rates of overall hypoglycaemia (higher with IDeg than placebo) and similar rates of nocturnal hypoglycaemia compared with placebo.

**Similar efficacy and safety with LY2963016 insulin glargine compared with insulin glargine in patients with type 1 diabetes mellitus: the ELEMENT 1 study**

R.K. Pollom<sup>1</sup>, T. Bevins<sup>2</sup>, D. Dahl<sup>3</sup>, J. Rosenstock<sup>4</sup>, W.J. Huster<sup>1</sup>, L.L. Ilag<sup>1</sup>, M.J. Prince<sup>1</sup>;

1Eli Lilly and Company, Indianapolis, 2Texas Diabetes & Endocrinology, Austin, USA, 3Gemeinschaftspraxis für Innere Medizin und Diabetologie, Hamburg, Germany, 4Dallas Diabetes and Endocrine Center, USA.

**Background and aims:** LY2963016 (LY IGLar) and insulin glargine (Sanofi-Aventis; IGLar) are both insulin glargine products, with identical amino acid sequences. Even with identical primary structure, protein-based therapeutics manufactured by distinct processes must be shown to be clinically similar.

**Materials and methods:** A 52-week, Phase 3, randomized, open-label, parallel study, with a 24-week treatment period and a 28-week extension, was undertaken to compare the efficacy and safety of LY IGLar once daily (QD) vs IGLar QD in combination with pre-meal insulin lispro thrice daily in patients with T1DM (HbA<sub>1c</sub> ≤11.0 %). LY IGLar and IGLar were administered with prefilled pen injectors. The primary aim was to test the non-inferiority (0.3% margin) of LY IGLar to IGLar as measured by change in HbA<sub>1c</sub> from baseline to 24 weeks. Testing for non-inferiority of IGLar to LY IGLar was also performed and pre-specified as a complementary hypothesis, which if met along with the primary aim, would demonstrate equivalent efficacy between LY IGLar and IGLar. Insulin doses were adjusted during the study to achieve glycemic targets (HbA<sub>1c</sub> <7%, fasting plasma-equivalent glucose ≤ 6.0 mmol/L). Safety assessments included hypoglycaemia, adverse events (AEs) and antibody responses.

**Results:** Most patients (LY IGLar, 81.3%; IGLar 87.6%) were receiving IGLar prior to randomization. Both treatment groups had within-group statistically significant (p<.001) decreases in mean HbA<sub>1c</sub> values from baseline. The change in HbA<sub>1c</sub> from baseline with LY IGLar was non-inferior to IGLar (Table). Non-inferiority of IGLar to LY IGLar was also demonstrated; thus, the criteria for equivalence in clinical efficacy between LY IGLar and IGLar were met. At 24 and 52 weeks, there were no treatment differences in secondary efficacy or safety outcomes including hypoglycaemia and treatment-emergent antibody response (Table). At 52 weeks, similar findings were seen between LY IGLar and IGLar in mean [SD] overall rates (events/patient/year) of nocturnal hypoglycaemia (LY IGLar, 16.1 [20.2]; IGLar, 17.3 [19.5], p=.250) and severe hypoglycaemia (LY IGLar, 0.1 [0.5]; IGLar, 0.1 [0.5], p=.826), and in mean [SD] weight gain (kg) (LY IGLar, 0.9 [3.3]; IGLar, 0.6 [3.7], p=.253). AE frequency was the same with LY IGLar (62%) and IGLar (62%) (p>.999).

**Conclusion:** LY IGLar compared with IGLar, used in combination with insulin lispro, provided equivalent efficacy and a similar safety profile in patients with T1DM.

Table

**Treatment intensification with IDegAsp BID vs IDeg OD plus IAsp in insulin-treated patients with type 2 diabetes: a randomised, controlled phase 3 trial**

J.G. Cooper<sup>1</sup>, T.R. Pieber<sup>2</sup>, B. Cariou<sup>3</sup>, L. Endahl<sup>4</sup>, J. Zacho<sup>4</sup>, H.W. Rodbard<sup>5</sup>;

1Stavanger University Hospital, Norway, 2Medical University of Graz, Austria, 3L'Institut du Thorax, Nantes University Hospital, France, 4Novo Nordisk A/S, Søborg, Denmark, 5Endocrine and Metabolic Consultants, Rockville, USA.

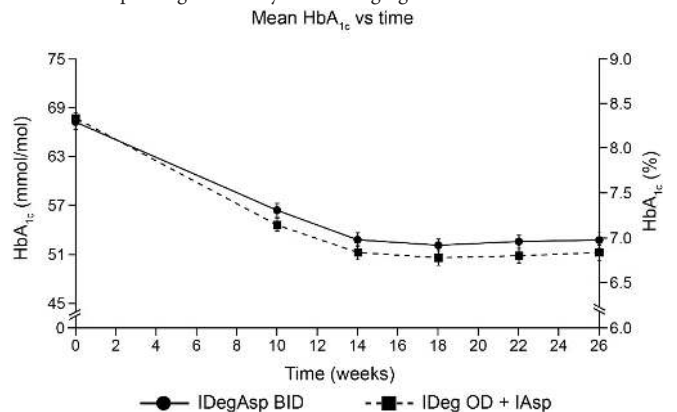

**Background and aims:** This study compared the efficacy and safety of two regimens in the management of adults with TD2M previously treated with

basal insulin and in need of insulin intensification to improve glycaemic control in the postprandial period: (1) IDegAsp (a fixed and soluble combination of 70% insulin degludec IDeg and 30% insulin aspart (IAsp), administered twice daily (BID), and (2) a basal-bolus regimen with once daily IDeg (OD) with IAsp 2-4 times daily.

**Materials and methods:** In this 26-week randomised multinational phase 3b trial, participants (mean: age 60 years, HbA<sub>1c</sub> 8.3%, duration of diabetes 13 years) previously treated with a basal insulin (insulin glargine [64%]) were randomised (1:1) to IDegAsp BID (n=138) or IDeg OD plus IAsp 2-4 times daily (n=136). IDegAsp was administered with the two main meals of the day.

**Results:** HbA<sub>1c</sub> was reduced with IDegAsp BID and IDeg OD plus IAsp regimens (to 7.0 and 6.8%, respectively; see Figure), with no significant difference between the two treatments. IDegAsp did not achieve non-inferiority, as the 95% CI exceeded the pre-defined non-inferiority limit (Estimated Treatment Difference [ETD] 0.18, 95% CI -0.04; 0.41). A significantly lower total daily insulin dose of 1.11 U/kg for IDegAsp BID vs 1.34 U/kg for IDeg OD plus IAsp (estimated ratio 0.88, 95% CI 0.78; 1.00, p<0.05) was observed. Change in body weight (LOCF analysis) at end of trial was +2.75 kg and +3.76 kg for IDegAsp BID and IDeg OD plus IAsp (ETD -1.04, 95% CI -1.99; -0.10, p<0.05). Fewer confirmed hypoglycaemia episodes (self-reported plasma glucose <3.1 mmol/L) were reported for IDegAsp BID vs IDeg OD plus IAsp (11.6 vs 13.6 events/patient year exposure [Relative Rate (RR) 0.81, 95% CI 0.61; 1.07, p=NS]). Frequency of nocturnal confirmed hypoglycaemia episodes (onset 00.01-05.59 h) was lower with IDegAsp BID vs IDeg OD plus IAsp (1.23 vs 1.55 events/patient year exposure, RR 0.80, 95% CI 0.50; 1.29, p=NS).

**Conclusion:** HbA<sub>1c</sub> was reduced with IDegAsp BID and IDeg OD plus IAsp, with no significant difference between the regimens. The 95% confidence interval for the HbA<sub>1c</sub> treatment difference did cross the pre-specified non-inferiority margin for the primary analysis (however, all pre-specified sensitivity analyses did achieve non-inferiority). IDegAsp BID was associated with significantly lower total daily insulin doses and less weight gain, with non-significant lower rates of confirmed and nocturnal confirmed hypoglycaemia episodes compared with IDeg OD plus IAsp. Thus, IDegAsp BID offers the potential for a simple alternative to basal bolus treatment in patients who require intensification of basal insulin regimens, especially where adherence to more complex regimens may be challenging.

**Glycaemic control and hypoglycaemia with new insulin glargine 300 U/mL in people with type 1 diabetes (EDITION 4)**

P.D. Home<sup>1</sup>, R.M. Bergenstal<sup>2</sup>, M.C. Riddle<sup>3</sup>, M. Ziemien<sup>4</sup>, M. Rojascki<sup>5</sup>, M. Espinasse<sup>6</sup>, G.B. Bolli<sup>7</sup>;

1Newcastle University, Newcastle upon Tyne, UK, 2International Diabetes Center at Park Nicollet, Minneapolis, 3Oregon Health & Science University, Portland, USA, 4Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany, 5Sanofi, Bridgewater, USA, 6Sanofi, Paris, France, 7University of Perugia, Italy.

**Background and aims:** EDITION 4 studied the efficacy and safety of new insulin glargine (300 U/ml; Gla-300) compared with glargine 100 U/ml (Gla-100) in people with type 1 diabetes mellitus.

**Materials and methods:** In this 6-month, multinational, multicentre, open-label study, participants (n=549, BMI 27.6 kg/m<sup>2</sup>, diabetes duration 21.0

years, HbA<sub>1c</sub> 8.1 % [65 mmol/mol]) were randomised 1:1:1 to once-daily Gla-300 or Gla-100, morning or evening, while continuing mealtime insulin. **Results:** Overall, Gla-300 was non-inferior to Gla-100 for HbA<sub>1c</sub> change from baseline (primary endpoint) (LS mean change [SE] -0.40 [0.05] % (-4.4 [0.6] mmol/mol) and -0.44 [0.05] % (-4.8 [0.6] mmol/mol); LS mean difference 0.04 [95% CI: -0.10 to 0.19] % (0.4 [-1.1 to 2.1] mmol/mol)). Event rates of confirmed ( $\leq 3.9$  mmol/l [ $\leq 70$  mg/dl]) or severe hypoglycaemia at any time of day (24 h) were similar for the two groups, while nocturnal hypoglycaemia was lower in the Gla-300 group compared with the Gla-100 group during the first 8 weeks of the study (Table). Severe hypoglycaemia was observed in 6.6% (Gla-300) and 9.5% (Gla-100) of participants. Neither glycaemic control nor hypoglycaemia differed between insulins or times for morning and evening injection groups. Total insulin dose increased to a somewhat greater extent for Gla-300 compared with Gla-100 (change from baseline +0.19 versus +0.10 U/kg). Weight gain was statistically significantly lower with Gla-300 versus Gla-100 (LS mean difference -0.56 [95% CI: -1.09 to -0.03] kg,  $p=0.037$ ). There was no difference in adverse events between the two groups. **Conclusion:** In conclusion, new insulin glargine 300 U/ml provided comparable glycaemic control versus glargine 100 U/ml, while nocturnal hypoglycaemia was less frequent during the first 8 weeks of treatment.

Table – Hypoglycaemic events per participant-year in the two insulin groups

### Recombinant human hyaluronidase pretreatment of CSII cannula sites provides comparable glycaemic control with reduced hypoglycaemia in T1DM compared to usual CSII

J.S. Skyler<sup>1</sup>, B. Bode<sup>2</sup>, I.B. Hirsch<sup>3</sup>, J.B. Buse<sup>4</sup>, S.K. Garg<sup>5</sup>, D.E. Vaughn<sup>6</sup>, X.W. Wu<sup>6</sup>, D.B. Muchmore<sup>6</sup>,  
<sup>1</sup>University of Miami, <sup>2</sup>Atlanta Diabetes Associates, <sup>3</sup>University of Washington, Seattle, <sup>4</sup>University of North Carolina, Chapel Hill, <sup>5</sup>University of Colorado Denver, Aurora, <sup>6</sup>Halozyne Therapeutics, Inc., San Diego, USA.

**Background and aims:** Recombinant human hyaluronidase (rHuPH20) is FDA-approved to increase dispersion and absorption of injected or infused drugs. In CSII, a single pretreatment of the cannula site with rHuPH20 accelerates exposure to and action of bolus doses of rapid analogs for up to 3 days of catheter use. This study was performed to characterize the clinical attributes of this treatment in an outpatient cohort of T1DM.

**Materials and methods:** 456 subjects with T1DM (age 48±13 years, BMI 28.5±5.1, screening A1C 7.8±0.7) were randomized 3:1 to CSII with rHuPH20 pretreatment or usual CSII for 6 months.

**Results:** A1C fell 0.14% from 7.69% with rHuPH20 and 0.18% from baseline 7.70% for CSII alone. The primary endpoint of A1C noninferiority (0.4% margin) was achieved with a treatment difference of 0.05% (95% CI -0.08 to 0.18) with similar % of subjects reaching A1C <7.0% (20.9% with rHuPH20 and 17.5% for CSII alone,  $p=.45$ ). Mean overall 90 min post-meal glucose excursion was 1.04 mmol/L with rHuPH20 and 1.09 mmol/L for CSII alone ( $p=.79$ ). There were fewer hypoglycemic events (HEs) with rHuPH20 than for CSII alone. The protocol specified primary HE analysis was based on SMBG-based event rates after a month of active titration following randomization; these data were derived from 261,341 individual SMBG readings. Hypoglycemia results are summarized in the table. Adverse event rates were generally comparable between treatments, although rHuPH20 pretreatment

was associated with an increased incidence of infusion site pain (typically mild transient burning) from 6.2% to 14.9%.

**Conclusion:** We conclude that pretreatment of CSII cannulas with rHuPH20 is well tolerated and results in similar glycemic control in T1DM with reduction of hypoglycaemia.

## 150

### A novel concentrated recombinant human insulin formulation with improved ultra-rapid action for continuous subcutaneous infusion therapy

R. Pohl, B.R. Wilson, M. Li, M. Guinness, P. Reddy, K. O'Brien, A. Krasner, E. De Souza;  
Biodel Inc, Danbury, USA.

**Background and aims:** BIOD-531, a U-400 formulation of recombinant human insulin, EDTA, citrate and MgSO<sub>4</sub>, is associated with an accelerated onset of action compared to Regular Human Insulin U-500 (U-500R) and Insulin Lispro Mix75/25, and has a basal duration profile in obese non-diabetic subjects and in diabetic swine. In order to assess the potential of BIOD-531 for open and closed-loop continuous subcutaneous insulin infusion (CSII) therapy, we evaluated the pharmacokinetic (PK) and pharmacodynamic (PD) profiles of BIOD-531 vs. U-500R and Insulin Lispro U-100 (Humalog, IL) following pump bolus administration and compared it to the timing of subcutaneous (sc) injection in miniature diabetic swine.

**Materials and methods:** Test formulations consisting of IL, U-500R, BIOD-531 or BIOD-530 (BIOD-531 without MgSO<sub>4</sub>) were administered using a crossover design by either Animas pump (Studies 1 and 2) or sc injection (Studies 3 and 4). On the morning of each study, miniature diabetic swine were given a sc dose (0.25 U/kg) of test formulation, followed by a meal. Blood glucose and plasma insulin were sampled from -30 to 480 min post dose. Plasma insulin was measured by an ELISA method and glucose concentration was determined by YSI. Data from each study were compared for significant differences from BIOD-531 using Students t-test.

**Results:** Key PK timing parameters ( $T_{50\%max}$ ,  $T_{max}$  and  $AUC_{0-20min}$ ) and onset of action PD parameter T-BG<sub>50%Minimum</sub> (time to 50% glucose nadir) are shown in Table below. BG<sub>Minimum</sub> is the lowest baseline subtracted glucose value or nadir. The rate of absorption and onset of action of BIOD-531 are not significantly different from IL and faster than U-500R following pump bolus and sc administration. In addition, the PK and PD profiles comparing BIOD-531 vs. IL are similar following pump bolus or sc injection.

**Conclusion:** These data suggest the potential utility of BIOD-531 as CSII therapy for insulin resistant type 2 diabetes patients who require high doses of insulin. Furthermore, BIOD-531 may be useful to help conserve space in future Artificial Pancreas systems.

| Pharmacokinetic and Pharmacodynamic Profiles of BIOD-531/530 <sup>†</sup> Vs. ## OP 26 Pregnancy and diabetes

151

### Pregestational diabetes (type 1 and 2), gestational diabetes: data from the French population in 2011

C. Billionnet<sup>1</sup>, A. Weill<sup>1</sup>, P. Ricordeau<sup>1</sup>, F. Alla<sup>1</sup>, D. Mitanchez<sup>2,3</sup>, A. Hartemann<sup>4,3</sup>, S. Jacqueminet<sup>4</sup>;

<sup>1</sup>Caisse Nationale de l'Assurance Maladie, <sup>2</sup>Néonatalogie, Hôpital Armand Trousseau, <sup>3</sup>Sorbonne Universités UPMC, <sup>4</sup>Diabétologie, Institute of Cardiometabolism and Nutrition, Hôpital Pitié-Salpêtrière, Paris, France.

**Background and aims:** Pregestational diabetes increases the risks of congenital malformations and perinatal complications. The risks incurred by newborn infants in the case of gestational diabetes (GD) are debated. There are no national data available in France except for data from multicenter cohorts. We evaluated the risks of complications according to the type of maternal diabetes from the French birth cohort in 2011.

**Materials and methods:** Data were obtained from the PMSI (French hospital discharge database) and the SNIIRAM (French national health insurance information system). All childbirths and terminations of pregnancy (TOP) after 22 weeks of gestation, due to medical reasons were selected. The mother's diabetes was identified by an algorithm based on the consumption of antidiabetics and hospitalization diagnoses before and during pregnancy. An identifier in the PMSI links mothers and infants, thus enabling analyses of associations between the mother's diabetes and outcome.

**Results:** 806 579 childbirths / TOP > 22 weeks were identified in the PMSI. The Mother - infant chaining was obtained for 474 614 births in public institutions. 1257 (0.16%) type 1 diabetes (T1D), 1896 (0.24%) type 2 diabetes (T2D) and 51 701 (6.4%) GD were identified, with a mean age respectively of 30.3, 33.3 and 32 years. In the case of T1D and T2D, the risks were respectively increased for the following complications (OR adjusted on mother's age [95%CI]): preterm birth (gestational age < 38 weeks) (6.6[5.9-7.4] and 3.7[3.3-3.9]), caesarean section (4.3[3.8-4.8] and 2.9[2.7-3.2]), preeclampsia and eclampsia (6.7 [5.6-8.2] and 3.9 [3.2-4.7]), macrosomia (birth weight (BW) > 90th percentile) (7.0 [6.1-8.0] and 3.9 [3.4-4.4]) perinatal death (2.2 [1.4-3.4] and 3.0 [2.2-4.1]), perinatal asphyxia (3.3 [2.2-5.1] and 2.5 [1.6-3.7]), respiratory distress syndrome (OR adjusted on mother's age and gestational age): 2.6 [2.0-3.4] and 1.9 [1.5-2.5]), brachial plexus trauma and/or collarbone fractures in cases of vaginal delivery (8.5 [4.9-14.8] and 2.9 [1.5-5.9]), cardiac malformations (4.4 [3.0-6.5] and 3.2 [2.2-4.7]). Data on macrosomia are respectively for DT1 and DT2: BW > 4 kg 16.7% and 13.4%; BW > 90th percentile 42.5 % (n=354) and 30.4% (n=348). In the case of GD, the risk of certain outcomes was lower: prematurity (1.35 [1.32-1.38]), caesarean section (1.46 [1.44-1.49]), preeclampsia and eclampsia (1.55 [1.46-1.65]), macrosomia (BW > 90th percentile) (1.7 [1.6-1.8]) respiratory distress syndrome (1.2 [1.1-1.3]). The risks were not increased for the others complications compared to the population without diabetes. Concerning macrosomia, 9.0% of the newborn had a BW > 4 kg in GD, and 6.6% in the absence of diabetes. 15.7% of the newborn had a BW > 90th percentile in GD and 9.4% in the absence of diabetes.

**Conclusion:** The rate of perinatal complications remains high for both types of pregestational diabetes, especially T1D. The link between gestational diabetes and macrosomia is confirmed. Some complications associated with gestational diabetes are slightly increased (caesarean section, prematurity, eclampsia, respiratory distress syndrome), others are not (brachial plexus trauma and/or collarbone fractures, death, perinatal asphyxia).

### Maternity care at a superspecialised unit for women with type 1 diabetes results in pregnancy outcome comparable to background population

M. Landin-Olsson<sup>1</sup>, H. Strevens<sup>2</sup>, D. Ursing<sup>1</sup>;

<sup>1</sup>Dept of Endocrinology, Skane University Hospital, <sup>2</sup>Dept of Obstetrics and Gynaecology Lund, Skane University Hospital, Lund University, Sweden.

**Background and aims:** Pregnancies in women with Type 1 diabetes are more often complicated by preeclampsia, prematurity, caesarean section, malformation, macrosomia, stillbirth and postnatal hypoglycaemia in the infant. The rate of complications is mainly depending on the blood glucose regulation. Our model for pregnant women with Type 1 is based on a specialised maternity unit including obstetrician, diabetologist, midwife and dietician. Women are required to take seven self monitored glucose measurements

daily, all values are sent electronically to the hospital and followed up weekly by a phone call from a diabetologist. The insulin doses are adjusted frequently to optimize glucose levels. An extra ultrasound is done late in pregnancy and if growth is rapid there is a liberality to induce labour. This study is aimed to compare outcome of pregnancy in women with Type 1 diabetes with the Swedish background women and also to evaluate if higher insulin dose could further improve outcome.

**Materials and methods:** All consecutive pregnant women with Type 1 diabetes who delivered infants during 2000-2013 (n=266) at our hospital were compared to all women in Sweden who delivered infants during the same period. Data from background population was obtained from the Swedish Medical Birth Register, which has a very high rate of ascertainment. In the next step we compared outcome in pregnancies in Type 1 diabetic women who delivered in 2000-2006 (n=1418) with those who delivered in 2007-2013 (n=148). For women in the later time period we tried to further increase insulin doses to improve metabolic regulation.

**Results:** For women with Type 1 diabetes birth weight was only 59 g higher (3566 compared to 3507), despite a shorter gestational length (37.7 vs. 39.3 weeks; p=0.001) and higher frequency of sectio (44% vs. 17%; p<0.001). The frequencies of preeclampsia, instrumental deliveries, postnatal hypoglycaemia, intensive care of infant, malformations and stillbirth were not significantly different. Women with partus 2000-06 compared to 2007-13 had equal duration of diabetes (15.5 yrs; p=ns), weighted same (69.4 vs. 71.3 kg; p=ns), body length were same (167; p=ns), they gained equal in weight during pregnancy (14.7 vs. 15.2 kg; p=ns), had equal insulin dose at start (49.7 vs. 50.6 IU; p=ns), same HbA1c at start (56 vs. 58 mmol/mol; p=) and gestational length was equal (264 vs. 265 days; p=ns). The women in the later group were treated with higher doses of insulin at the end of pregnancy (79.4 vs. 96.3 IU; p=0.001), but despite this, HbA1c were lower in the first group (40 vs. 42 mmol/mol; p=0.03) and birth weights did not differ (3619 vs. 3565 g; p=0.6). There were no differences in the frequencies of sectio (42% vs. 38%; p=ns), prematurity (19% vs. 22%; p=ns), malformations of all types (7.6% vs. 6.1%; p=ns), Apgar <7 at 5min (11.2 vs. 8.8%; p=ns), frequency of hypoglycaemia (24% vs. 19%; p=ns) or need of postnatal intensive care (47% vs. 35%; p=ns).

**Conclusion:** Pregnancy outcome in women with Type 1 diabetes was very close to results in the Swedish population. Further increase in insulin dose did not improve the results. This superspecialised maternity care for women with diabetes enables an almost normal outcome of pregnancy.

### Screening for diabetic retinopathy in pregnancy

A.M. Egan<sup>1</sup>, L. McVicker<sup>1</sup>, L. Carmody<sup>1</sup>, B. Kirwin<sup>1</sup>, F. Harney<sup>2</sup>, F. Dunne<sup>1</sup>;

<sup>1</sup>Galway Diabetes Research Centre, National University of Ireland Galway,

<sup>2</sup>Department of Ophthalmology, University Hospital Galway, Ireland.

**Background and aims:** Pregnancy is associated with progression of diabetic retinopathy and therefore frequent retinal screening to allow prompt treatment of disease is necessary. Our aims were to evaluate if our patients were receiving appropriate retinal screening during pregnancy and to assess the proportion who had progression of diabetic retinopathy. Additionally we wished to identify factors influencing screening and progression of retinopathy in our cohort.

**Materials and methods:** We identified 341 women with pregestational diabetes from the Atlantic DIP database. This cohort comprised 233 (68%) with type 1 diabetes and 108 (32%) with type 2 diabetes. Screening was deemed appropriate if it occurred at least twice during pregnancy in separate trimesters. Statistical analysis was performed using SPSS version 20.0 (IBM). Hypothesis testing was performed on the data of equal variance and normal distribution using an unpaired Student's t test. A Chi-squared analysis was used to compare sample proportions. Binary logistic regression was used to evaluate factors associated with appropriate screening and progression of retinopathy.

**Results:** Appropriate screening took place in 191 (56%) pregnancies, more commonly in women with type 1 diabetes. Women who received appropriate screening attended pre-pregnancy care (PPC) [56.5% versus 22.7% (p<0.001)] and received folic acid [69.6% versus 53.3% (p=0.002)] more frequently than those who did not. Women who received appropriate screening also had a longer duration of diabetes [11.3 ± 2.9 versus 9.3 ± 2.9 years (p=0.03)]. There was a significant difference in rates of adequate screening across the five antenatal centres participating in the Atlantic DIP study (21.6% - 71.4%, p<0.001). Modelling by logistic regression identified PPC as the only maternal factor significantly associated with re-

ceiving appropriate screening [odds ratio 4.01; CI 2.38–6.75 ( $p < 0.001$ )]. On evaluation of those patients who received appropriate screening ( $n = 191$ ), it was noted that 49 (26%) had retinopathy progression during pregnancy. Univariate analysis revealed that these women had on average, a longer duration of diabetes [ $14.4 \pm 5.7$  versus  $10.0 \pm 2.8$  years ( $p = 0.003$ )], a higher 1st trimester HbA1c [ $7.7 \pm 1.6$  versus  $7.1 \pm 1.4\%$  ( $p = 0.02$ )], a larger drop in HbA1c between the 1st and 3rd trimesters of pregnancy [ $1.4 \pm 1.3$  versus  $0.7 \pm 0.9\%$  ( $P = 0.002$ )] and a higher systolic blood pressure at the booking visit [ $128.0 \pm 17.6$  versus  $122.2 \pm 13.2$  mmHg ( $p = 0.02$ )] compared to women with no progression. Logistic regression analysis of significant factors from univariate analysis, revealed decrease in HbA1c [odds ratio 2.09; CI 1.11; 3.92 ( $p = 0.02$ )] and systolic blood pressure at booking [odds ratio 0.03; CI 1.03; 1.06 ( $P = 0.05$ )] as significant factors associated with retinopathy progression in pregnancy.

**Conclusion:** We demonstrate inadequate screening for diabetic retinopathy during pregnancy and significant variation across participating centres. Our study highlights the importance of participation in PPC as this is associated with appropriate screening in the ensuing pregnancy. As 26% of women continue to demonstrate progression of retinopathy during pregnancy, there is urgent need to ensure adherence to screening protocols. This is particularly important for women with larger reductions in HbA1c during pregnancy and higher systolic blood pressure at booking as these women are at greatest risk for progression.

### Association of stillbirth with type 2 diabetes development and future cardiovascular events in women with and without gestational diabetes: a population-based cohort study

B. Pintaudi, G. Lucisano, A. D'Etto, G. Di Vieste, V. Lepore, M. Sacco, G. De Berardis, M. Scardapane, M.C. Rossi, F. Pellegrini, G. Tognoni, A. Nicolucci, Fondazione Mario Negri Sud, S. Maria Imbaro (CH), Italy.

**Background and aims:** Women with gestational diabetes mellitus (GDM) are at increased risk for the onset of type 2 diabetes (T2DM) and cardiovascular disease in the years following pregnancy. Aim of the study was to estimate the incidence of T2DM and cardiovascular events in women with previous GDM and in those with normal glucose tolerance in pregnancy and to evaluate the role of stillbirth in differentiating the risks.

**Materials and methods:** A population-based cohort study using administrative data of 12 local health authorities in Puglia, Italy, during the index period from January 1, 2002, to December 31, 2010 was conducted. From a population-based sample of 2.1 million women we identified those with a diagnosis of GDM during the index period and they were propensity-matched on a 1-to-3 basis with women without GDM or diabetes mellitus. Characteristics that were matched were age, local health authority code, use of antihypertensive and antithrombotic agents. Main outcome measures were T2DM development and hospitalizations for cardiovascular events occurring after a pregnancy complicated by GDM and ended at term or in miscarriage.

**Results:** There were 3851 women with GDM (mean age  $37.1 \pm 5.9$  years) and 11553 matched controls without GDM. During a median follow-up of 5.4 years, the incidence rate of T2DM was of 2.1 per 1000 person-years in women without GDM, of 54.0 per 1000 person-years among women with GDM and pregnancy at term, and 115.0 per 1000 person-years among women with GDM and a pregnancy ended in stillbirth. The cumulative IRs of T2DM development showed that GDM increased the risk of T2DM by 21.7 times, while GDM complicated by stillbirth increased the risk of T2DM by 46.9 times as compared with women with a normal pregnancy. GDM and stillbirth during GDM were associated with a significantly higher risk of cardiovascular events compared with normal pregnancy (IRR, 2.4; 95% CI, 1.5 to 3.8 and IRR, 16.7; 95% CI, 3.7 to 74.7, respectively).

**Conclusion:** Pregnancy complicated by GDM and ended in stillbirth represents a decisive factor in determining the development of T2DM and future cardiovascular events. For this reason these women deserve a careful follow-up.

## 155

### Maternal obesity, glucose levels in early pregnancy, and gestational diabetes in association with cognitive and psychomotor development at 4 years of age

L. Chatzi<sup>1</sup>, V. Daraki<sup>1,2</sup>, V. Georgiou<sup>1</sup>, K. Koutra<sup>1</sup>, M. Kampouri<sup>1</sup>, A. Kyriklaki<sup>1</sup>, M. Karachaliou<sup>1</sup>, G. Chalkiadaki<sup>1</sup>, K. Sarri<sup>1</sup>, A. Pappas<sup>3</sup>, M. Vassilaki<sup>1</sup>, S. Papavasileiou<sup>2</sup>, M. Kogevas<sup>4</sup>,  
<sup>1</sup>Department of Social Medicine, Heraklion, <sup>2</sup>Clinic of Endocrinology Diabetes and Metabolic Diseases, University Hospital of Crete, Heraklion, <sup>3</sup>Diabetes Center, Venizelio Hospital, Heraklion, <sup>4</sup>National School of Public Health, Athens, Greece.

**Background and aims:** Fetal life and early infancy are critical periods for brain development. An hyperglycaemic environment in utero may programme biological regulatory mechanisms inducing delay in brain maturity and neurobehavioural abnormalities in offspring. Few studies have examined associations of maternal obesity and diabetes in pregnancy with offspring neurodevelopment, with conflicting results. The aim of this study was to assess the associations of maternal glucose and insulin levels in early pregnancy, gestational diabetes (GDM), and pre-pregnancy body mass index (BMI) with offspring cognitive and psychomotor development at 4 years of age.

**Materials and methods:** The mother-child "Rhea" study in Crete is a prospective cohort examining pregnant women (Greek and immigrants) residents at the prefecture of Heraklion that became pregnant during one year starting in February 2007. The present analysis includes seven hundred seven (707) mother-child pairs, after excluding twin pregnancies, and women with pre-gestational diabetes. Maternal fasting serum samples were collected at the time of the first major ultrasound (Mean: 12 weeks, SD: 1.5). Pregnant women were screened for GDM between 24 and 28 weeks of gestation, and GDM was defined by the criteria proposed by Carpenter and Coustan. Neurodevelopment at 4 years was assessed by means of the McCarthy Scales of Children's Abilities (MSCA). Multivariable linear regression models were used to estimate the effect of maternal glucose and insulin levels in early pregnancy, GDM, and pre-pregnancy BMI on neurodevelopmental scores at 4 years of age after adjusting for maternal age, education, parity, child sex, birth weight, breastfeeding duration and quality of assessment.

**Results:** The percentage of overweight and obese mothers prior to gestation was 21% and 12.7% respectively, while 8% women developed GDM. Maternal obesity prior to gestation was associated with reduced general cognitive (score reduction: -2.33; 95% CI: -4.57, -0.10), and perceptual development scores (score reduction: -2.87; 95% CI: -5.19, -0.55) at 4 years of age. There was also evidence of a dose-response relationship with continuous maternal BMI. Stratified analysis by child sex showed a higher reduction in girls compared to boys (general cognitive score reduction: -4.00; 95% CI: -7.25, -0.75; perceptual score reduction: -3.42; 95% CI: -6.57, -0.27,  $p$  for interaction  $< 0.01$ ). Gestational diabetes, and maternal fasting glucose and insulin levels in early pregnancy were not associated with offspring neurodevelopmental outcomes after adjustment for potential confounders.

**Conclusion:** Maternal obesity prior to gestation may contribute to reduced child cognitive development at preschool age, while GDM was not found to be significantly associated with offspring neurodevelopment. Further follow up of this cohort will allow to determine whether these findings persist into later childhood development.

### Gestational diabetes mellitus and risk for autism in offspring

A.H. Xiang<sup>1</sup>, X. Wang<sup>1</sup>, M.P. Martinez<sup>1</sup>, D. Getahun<sup>1</sup>, K.A. Page<sup>2</sup>, T.A. Buchanan<sup>2</sup>, E.S. Curry<sup>3</sup>, K.J. Coleman<sup>1</sup>,  
<sup>1</sup>Research & Evaluation, Kaiser Permanente Southern California, Pasadena, <sup>2</sup>Department of Medicine, Keck School of Medicine, Los Angeles, <sup>3</sup>Pediatrics, Kaiser Permanente Fontana Medical Center, Fontana, USA.

**Background and aims:** Pregnancies complicated by gestational diabetes mellitus (GDM) increase risks of perinatal morbidities and postnatal obesity and metabolic disorders in offspring. A few studies also suggest that maternal hyperglycaemia during pregnancy is associated with a high rate of inattention, developmental delays, and autism spectrum disorders (ASD) in offspring. The hypothesis is that hyperglycaemia may "disrupt" fetal brain development and maturation and lead to increased risks for offspring to develop neurobehavioral disorders in later life. We conducted a large population-based study

to assess the association between GDM exposure *in-utero* and development of ASD in offspring.

**Materials and methods:** This retrospective longitudinal cohort included children who were born as a singleton at 28–44 weeks gestation in hospitals from a large integrated health plan between January 1, 1995 and December 31, 2009. Children were required to have the health plan membership by age 1–2 years, when screening for developmental delays and ASD are initiated per the health plan guidelines. Children were prospectively followed from birth using electronic medical record until any one of following criteria was met: (1) a clinical diagnosis of ASD identified by ICD-9 codes 299.x, (2) >4-months of inactive health plan membership, (3) death from any cause, or (4) December 31, 2012. Children who were born to women with pre-existing diabetes were excluded. Survival analysis was used to estimate the incidence rate of ASD and Cox proportional hazard regression was used to estimate the relative risk (RR) of developing ASD associated with GDM.

**Results:** A total of 336,164 children (26,897 [8%] GDM exposed) met the cohort inclusion criteria with a median 5.5 years (range 1.0–18.0 years) of follow-up during which 4,526 children developed ASD. The incidence rate of ASD was 2.36/1000 per year (2.81/1000 for GDM and 2.32/1000 for non-GDM group, respectively). In the unadjusted analysis, the incidence of ASD in the GDM exposed group was 20% higher than that in the GDM unexposed group (RR= 1.20, 95% CI: 1.08–1.32,  $p=0.0004$ ). However, the RR was reduced to 1.06 (95% CI: 0.96–1.18,  $p=0.22$ ) after adjustment for maternal age, parity, education, household income, race/ethnicity and child gender. The greatest reduction in the RR was due to the adjustment for maternal age (from 1.20 to 1.09) as mothers who had GDM were on average 3.2 years older at delivery than mothers without GDM. Additional adjustment for child birth weight, gestational weeks at delivery and congenital abnormalities at birth, factors known to be associated with maternal hyperglycaemia, slightly reduced the RR association between GDM and ASD (to 1.04,  $p=0.46$ ). Excluding children with congenital abnormalities at birth had no impact to the results. Analysis by ASD sub-type reached similar conclusions.

**Conclusion:** Data from a large multi-ethnic and population-based clinical care system did not support significant association between GDM exposure *in-utero* and risk of development of ASD in offspring. The slightly elevated risk for ASD in offspring exposed to GDM was largely due to older age of women with GDM.

### mRNA expression profiling in perivascular and subcutaneous adipose tissue of patients with carotid artery (ACI) stenosis

D. Schleinitz<sup>1</sup>, P. Büttner<sup>2</sup>, A. Körner<sup>3</sup>, B. Gutschmann<sup>1</sup>, M. Fasold<sup>4</sup>, M. Eszlinger<sup>5</sup>, S. Rohm<sup>6</sup>, O. Richter<sup>6</sup>, G. Aust<sup>6</sup>, P. Kovacs<sup>7</sup>

<sup>1</sup>IFB Adiposity Diseases, University of Leipzig, <sup>2</sup>Cardiocenter Leipzig, Clinic for Internal Medicine and Cardiology, Department of Rhythmology R&L, University of Leipzig, <sup>3</sup>Hospital for Children and Adolescents, University Hospital Leipzig, Center for Pediatric Research, University of Leipzig, <sup>4</sup>ecSeq Bioinformatics, <sup>5</sup>Division of Endocrinology and Nephrology, University of Leipzig, <sup>6</sup>Research Laboratories, Clinic for Visceral, Transplantation, Thoracic and Vascular Surgery, University of Leipzig, <sup>7</sup>Ev. Diakonissenkrankenhaus Leipzig, Clinic for Vascular Surgery, Center for Surgery, Leipzig, Germany.

**Background and aims:** There is growing evidence for a vasoregulatory and atherosclerosis-inducing role of local fat deposits around vessels. Secreted adipokines may contribute directly or indirectly to the regulation of vessel wall homeostasis. Investigating molecular mechanisms specific for perivascular fat could therefore contribute to better understanding of its role in the pathophysiology of atherosclerosis and its sequelae such as stroke or myocardial infarction. Aim of the study was to investigate gene expression profiles in paired human samples of subcutaneous (sc) and perivascular (pv) adipose tissue (AT) and to link it to clinical and anthropometric characteristics of carotid stenosis patients.

**Materials and methods:** A RNA/cDNA bank was established from paired sc (cervical) and pv (ACI) AT samples of patients who underwent carotid endarterectomy. Tissue specific marker genes (e.g. *MYH2* for muscle, *COMP* for fibroblasts or *GPM6A* for nerve) have been measured to control for impurities of “non-adipocyte” cells. The expression median with appropriate ranges for every marker gene was set specifically for each fat depot. Sixty paired samples passed these criteria and were assayed on Illumina HT12 microarrays. *P*-values for differential expression between AT depots and phenotypic groups (e.g. symptomatic vs. asymptomatic) were calculated using background-corrected, quantile-normalized expression values and paired/standard *t*-test. To correct for multiple testing an experiment based genome wide significance level and FDR methodology were applied. Gene expression was correlated to anthropometric, metabolic and clinical parameters. Best hits underwent validation using TaqMan qPCR technology.

**Results:** We found 1100 genes with significant differential expression between sc and pv AT clearly distinguishing both AT types from each other. The top hits with >2 fold changes are represented by developmental genes like *HOX* genes, *TBX15* or *WNT5A* but also genes found to be involved in atherosclerosis (*CDKN2B*, *TRIB1*) and coronary artery disease (*PTGS2*, *CARD8*). Intra-depot comparison of e.g. symptomatic vs. asymptomatic, lean vs. obese or diabetic vs. non-diabetic patients revealed genes with nominal differences in mRNA levels, which however, correlated with anthropometric and metabolic parameters (BMI, triglycerides, cholesterol, percent stenosis).

**Conclusion:** Our data revealed fat depot-specific mRNA expression of developmental genes and genes associated with atherosclerosis or coronary artery disease, supporting the relevance of perivascular adipose tissue in the pathogenesis of atherosclerosis.

### rs196462, near *SMOC2*, is associated with lower extremity arterial disease in patients with diabetes

N.R. van Zuydam<sup>1</sup>, M. de Andrade<sup>2</sup>, E. Vlachopoulou<sup>3</sup>, V. Salomaa<sup>3</sup>, A. Paterson<sup>4</sup>, H. Colhoun<sup>5</sup>, I.J. Kullo<sup>2</sup>, GoLEAD, SUMMIT;

<sup>1</sup>University of Oxford, UK, <sup>2</sup>Division of Cardiovascular Diseases and the Gonda Vascular Center and Department of Health Sciences, The Mayo Clinic, Rochester, USA, <sup>3</sup>National Institute for Health and Welfare, Helsinki, Finland, <sup>4</sup>Hospital for Sick Kids and DCCT/EDIC, Toronto, Canada, <sup>5</sup>Medical Research Institute, University of Dundee, UK.

**Background and aims:** Lower extremity arterial disease (LEAD) is a common macrovascular complication of diabetes and the most common cause of amputations in patients with diabetes. LEAD in patients with diabetes is

often accompanied by dyslipidaemia, renal disease and neuropathy. Despite large sample sizes, previous GWA studies have identified 1 genome wide significant ( $p < 5 \times 10^{-8}$ ) signal near *CHRNA3* and another highly significant signal ( $p < 5 \times 10^{-7}$ ) in the 9p21 region. The lack of strong associations may be due to the highly polygenic architecture of LEAD, phenotypic heterogeneity or both. Based on the different risk factors contributing to LEAD in patients with and without diabetes we performed stratified analyses of LEAD in patients with and without diabetes and in smokers vs. non-smokers, irrespective of diabetes status.

**Materials and methods:** We combined summary statistics in a fixed effects meta-analysis for 2,356,286 SNPs from 4,544 LEAD cases and 30,404 LEAD controls - of which 2,345 cases and 8,706 controls were patients with diabetes and 3,535 cases and 20,212 controls were smokers. We also performed an interaction analysis of allelic effects in patients with diabetes vs. individuals without diabetes and in smokers vs. non-smokers.

**Results:** Rs196462, near *SMOC2*, was associated with LEAD in patients with diabetes at genome wide significance ( $p < 5 \times 10^{-8}$ ). Rs10743273, near *PIK3C2G*, was associated with LEAD in non-diabetic individuals and showed evidence for interaction ( $OR = 1.2$ ,  $p = 6.3 \times 10^{-4}$ ,  $phet = 6.1 \times 10^{-4}$ ). Rs2451819 ( $OR = 1.2$ ,  $p = 1.2 \times 10^{-5}$ ,  $phet = 5.9 \times 10^{-4}$ ) near *PIK3R1* and rs7084667 ( $OR = 1.3$ ,  $p = 3.2 \times 10^{-5}$ ,  $phet = 6.5 \times 10^{-4}$ ), near *SFTPD* were associated with LEAD in patients with diabetes and showed evidence for interaction. These genes play a role in insulin resistance, obesity and cardiovascular disease. The top SNP in smokers was rs1051730 ( $p = 7.2 \times 10^{-7}$ ), near *CHRNA3*, that is established for LEAD and is associated with pack years. Rs2076156 ( $OR = 2.4$ ,  $p = 1.1 \times 10^{-4}$ ,  $phet = 3.5 \times 10^{-6}$ ), near *BIK*, rs12593396 ( $OR = 1.46$ ,  $p = 4.2 \times 10^{-6}$ ,  $phet = 1.3 \times 10^{-5}$ ), near *ADAMTS7* and rs11214800 ( $OR = 1.3$ ,  $p = 2.6 \times 10^{-4}$ ,  $phet = 2.7 \times 10^{-5}$ ), near *HRT3A* were associated in LEAD in smokers and showed evidence for interaction with smoking status. The expression of *BIK* is directly affected by cigarette smoke, while SNPs near *ADAMTS7* have been shown to interact with smoking status to affect blood pressure and SNPs in *HRT3A* have been associated with smoking quantity.

**Conclusion:** Diabetes and smoking are well established risk factors for LEAD and by stratifying analyses by these risk factors we have identified a signal near *SMOC2* that appears to be specific to LEAD patients with diabetes. The interaction analysis also revealed interactions near genes that affect cardio-metabolic traits. While signals in the smoking interaction analysis did not achieve

## 159

### The association between diabetic peripheral neuropathy and peripheral artery disease

G.A. Nichols;

Kaiser Permanente Center for Health Research, Portland, USA.

**Background and aims:** Diabetic peripheral neuropathy (DPN) and peripheral artery disease (PAD) are common complications that occur more frequently in patients with type 2 diabetes than in the general population. Data on the association between these two conditions is surprisingly scant. We studied the association between DPN and PAD, including characteristics that were associated with each condition.

**Materials and methods:** We searched the electronic medical records of 37,095 members of Kaiser Permanente Northwest who had type 2 diabetes identified prior to 2013 and had complete health plan eligibility in 2012 for physician-coded ICD-9-CM diagnoses of DPN or PAD in 2010-2012. We compared demographic (age, sex, diabetes duration) and clinical characteristics (BMI, HbA<sub>1c</sub>, blood pressure, lipids, and presence of ischemic heart disease [IHD], chronic kidney disease [CKD] and heart failure [HF]) associated with the presence of one or both of these conditions. To isolate the independent association between DPN and PAD, we constructed a multiple logistic regression model that controlled for risk factors for DPN and PAD.

**Results:** Of the 37,095 type 2 diabetes patients, 24% ( $n = 9,044$ ) had DPN without PAD, 3% ( $n = 994$ ) had PAD without DPN, 4% ( $n = 1,592$ ) had both DPN and PAD, and 69% ( $n = 25,465$ ) had neither condition. The table displays characteristics of patients with neither, both, or either DPN or PAD. Among the 29% of patients with DPN ( $n = 10,636$ ), 15% had PAD compared with 4% without DPN ( $p < 0.001$ ). Nearly two-thirds of patients with PAD also had DPN, while only about one-quarter of patients without PAD had DPN (62% vs. 26%,  $p < 0.001$ ). Characteristics of patients without PAD differed markedly depending on whether DPN was present. For example, mean age of patients with DPN but no PAD was 67.3 years, compare with 59.9 years among those without DPN or PAD ( $p < 0.001$ ), and those with DPN were two to three times

more likely to have IHD, CKD or HF. However, characteristics including age, sex and presence of comorbidities were similar among patients with PAD regardless of the presence of DPN. After controlling for demographic and clinical characteristics, presence of DPN more than doubled the probability of having PAD ( $OR = 2.32$ , 95% CI 2.08-2.60).

**Conclusion:** Our results demonstrate a strong association between DPN and PAD that remained even after controlling for a number of characteristics. Although our design did not evaluate the temporal relationship between these two conditions, older age and longer duration of diabetes among PAD patients suggests that DPN may often precede PAD. Research is needed to determine whether treating DPN can reduce the risk of PAD.

|                             | Neither DPN |          |          | Both DPN and PAD |

### Clinical and ultrasonographic results of endovascular therapy in diabetic patients with critical limb ischaemia

O.N. Bondarenko, G.R. Galstyan, N.L. Ayubova, I.I. Sitkin, I.I. Dedov;

Diabetic Foot Clinic, Endocrinology Research Center, Moscow, Russian Federation.

**Background and aims:** To evaluate arterial patency and clinical outcomes after percutaneous transluminal angioplasty (PTA) in diabetic patients with critical limb ischemia (CLI).

**Materials and methods:** From September 2010 to June 2013, a prospective single-center study was conducted involving 164 diabetic patients with CLI (76(46%) men, mean age 64,1[54-68] years, mean HbA<sub>1c</sub> 7,9±1,4%, mean duration of diabetes 16,5[0,8-43] years, diabetes type 1/2 - 16/148) who underwent PTA in 193 limbs. Myocardial infarction and stroke in anamnesis were in 25(15%) and 15(9%) patients, respectively. Chronic kidney disease (CKD) 3-4 stages was in 40(24%) patients, end-stage renal disease 16(10%). Diagnosis of CLI based on recommendation of TASC II. Patency of arteries of lower extremity was evaluated by duplex ultrasound (DU) during whole follow-up period. PTA in all patients was considered technically successful in restoring continuous arterial flow to the foot of at least one crural artery without residual stenosis > 50%. Follow-up assessment during 3 years included clinical examination for wound healing (WH), limb salvage (LS) and common survival (CS).

**Results:** Peripheral arterial disease 4 category according Rutherford classification revealed in 29(15%), 5 category-in 103(53,4%), and 6 category in 61(31,6%) patients. 0-1 the degree of tissue damage according Wagner classification identified in 29 (15%) cases, W 2 - 100 (51,8%) cases, W 3-4 - 64 (33,2%) cases. Peripheral arterial disease 4-6 classes according Graziani classification was in 180 (93%) cases. Extensive tibial arterial calcification was in 123(64%) cases, in patients with residual stenosis (> 50% remaining diameter)-113 (89%). After PTA residual stenoses (>50%) in treated arteries were in 125(79,1%), thrombosis in the treated arteries - 9(5,7%), intimal dissection - 18(11,4%), incomplete stent disclosure - 3 (1,9%), incomplete capture stent area stenosis - 2(1,3%) and dislocation of the stent - 1(0,6%). Repeat PTA in the early period (30 days) was in 15 patients. Cumulative primary patency in the femoropopliteal segment was 55%, in tibial segment 25%; in patients with residual stenosis in treated arteries <50% - 21%, with residual stenosis ≥50% - 66% (Kaplan-Meier Estimates). Repeat PTA during follow-up was performed in 73(38%) cases generally, in patients with CKD 3-5 stages 18(45%). There were 10(5,2%) major amputations (log-rank,  $p < 0,05$ ), in patients with end-stage renal disease 5(2,6%); LS rate was 94%, WH rate was 98% (log-rank,  $p < 0,05$ ); CS was 81% (log-rank,  $p < 0,05$ ).

**Conclusion:** CLI in diabetic patients is characterized by having severe morphological lesions of the lower limb arteries, arterial calcification and soft tissue lesions. The high level of residual stenosis was revealed after PTA. Extremely low primary patency in diabetic patients with CLI mainly at the tibial

arteries is associated with chronic renal insufficiency and residual stenosis. Timely reintervention in diabetic patients with recurrent CLI promotes optimal WH, LS and CS.

## 161

### Optimal blood pressure targets for prevention of peripheral artery disease in patients with type 2 diabetes and hypertension

A. Hishida<sup>1</sup>, M. Tochiya<sup>2</sup>, R. Koezuka<sup>2</sup>, Y. Oohata<sup>2</sup>, T. Tamanaha<sup>2</sup>, H. Makino<sup>2</sup>, I. Kishimoto<sup>2</sup>;  
National Cerebral and Cardiovascular Center, Suita, Japan

**Background and aims:** Peripheral artery disease (PAD) is one of the macrovascular complications of diabetes, and often associated with considerable functional limitation. Although the benefits of reducing high blood pressure (BP) on the risks of cardiovascular disease and cerebral artery disease are well known, the optimal BP goal is not established. The guideline recommended BP target for patients with diabetes had recently been changed from <130/80 mmHg to <140/80 mmHg, because there have been no clear evidence showing that tight control (<130/80 mmHg) was associated with improved cardiovascular outcomes compared with <140/80 mmHg. However, previous studies did not address which goal is more appropriate for the reduction of PAD events. In this study, we retrospectively examined whether subjects with the tighter BP control were associated with better clinical outcomes with respect to PAD events in patients with type 2 diabetes mellitus and hypertension.

**Materials and methods:** Among 963 patients with type 2 diabetes and hypertension, referred to our department between January 2000 and December 2012 (633 for men, mean age 66 years, HbA1c 8.7%, mean BP 137/74 mmHg), subjects with baseline BP<140/80 mmHg were selected (n=513). Patients were categorized into two groups by their BP at baseline: Group 1, less than 130/80 mmHg and Group 2, 130/80 mmHg or higher. As a result, 262 patients (51%) were categorized into Group 1 (33% for men, mean age 66 years), and 251 patients (48%) into Group 2 (32% for men, mean age 66 years). The effect of baseline BP category on the development of PAD event was analyzed at a mean follow-up of 4.5 ± 3.1 years. Multivariable Cox regression models were performed to examine the independent association between baseline BP category and PAD events during follow-up. The PAD event was defined as angioplasty for PAD or ischemic ulcer requiring hospital care.

**Results:** Among all subjects, mean systolic and diastolic BP of Group 1 were 116 ± 7.5 mmHg and 64.8 ± 7.2 mmHg respectively, whereas those of Group 2 were 131.0 ± 14.2 mmHg and 74.5 ± 10.5 mmHg respectively. Between the two groups, there were no significant difference with respect to age, sex, smoking, HbA1c, eGFR, insulin use, previous stroke and previous myocardial infarction. However the prevalence of PAD at baseline was significantly higher in Group 2 (8.8 % in Group 1 vs. 14.7 % in Group 2, p=0.04). During follow-up, 8 patients (1.6% of total population) were hospitalized for PAD events. Kaplan-Meier estimation showed that the risk of PAD hospitalization was significantly higher in Group 2 (log-rank p=0.03). Cox regression analysis revealed that the association between baseline BP category and PAD events was significant after adjustment of age, sex, smoking, HbA1c, eGFR, insulin use, and previous stroke, myocardial infarction and PAD at baseline (p=0.04).

**Conclusion:** In patients with type 2 diabetes and hypertension, baseline BP<130/80 mmHg showed significantly lower risk of future PAD events than BP<140/80 mmHg. It is, therefore, suggested that tighter control of blood pressure could reduce the incidence of PAD events in patients with type2 diabetes and hypertension.

## 162

### Beneficial effect of multifactorial intervention on the prognosis of patients with type 2 diabetes mellitus and critical limb ischaemia/peripheral arterial disease

C. Hoebaus<sup>1</sup>, G. Schernthaner<sup>2</sup>, R. Koppensteiner<sup>1</sup>, G.-H. Schernthaner<sup>1</sup>;  
<sup>1</sup>Internal Medicine II, Medical University Vienna, <sup>2</sup>Internal Medicine II, Rudolfstiftung Vienna, Austria.

**Background and aims:** The combination of critical limb ischemia/peripheral artery disease (PAD) and diabetes mellitus type 2 (T2DM) is known for poor survival. The last major publication on successful management of such a patient population reported a 50% mortality and 25% amputation rate after six years of follow up. We have analyzed whether more recent treatment advances of T2DM and PAD in the last five years have ameliorated those detrimental effects.

**Materials and methods:** In a prospective study we enrolled 366 patients (34% female) with PAD, 38% had T2DM, 33% impaired glucose tolerance (PRE) and 29% normal glucose tolerance (NGT). As expected the patient cohort had a high cardiovascular risk factor (CRF) burden: 92% hypertension, 97% hyperlipidemia, 74% active or former smoker; Coronary heart disease (CHD) was known in 32% and carotid artery disease (CAD) in 39% of the patients. Within 6 months the target values of CRF control - LDL-Cholesterol <100 mg/dl, blood pressure (<140/80 mm Hg, HbA1c in DM <7.0%) were reached in 58%, 69% and 69%. Patients followed a strict control visit program in the center for 5 years.

**Results:** The overall survival of this cohort was 89.3% after 4.9 years. MACE (combination of death, non-fatal myocardial infarction or stroke) free survival was 84.3% and event free survival including interventional or surgical procedures due to critical limb ischemia/PAD was 68%. Patients with T2DM showed a survival of 87.8% compared to 89.3% PRE, and 95.2% NGT (p=0.161). MACE free survival was 81.3% for T2DM, 87.6% for PRE, and for 92.4% NGT (p=0.059). Additionally, event free survival was 65.5% for T2D, 71.9% for PRE, and 77.1% for NGT (p=0.155).

**Conclusion:** In summary, strict multifactorial management induced a dramatic reduction in the annual death rate (2.8 for patients with T2DM and PAD), MACE and amputation. Thus, management of such patients should be restricted to centralized centers to improve outcome for the patients.

## OP 28 Ectopic lipids and type 2 diabetes

163

### Effect of bariatric surgery on hepatic fatty acid uptake and blood flow

H.M. Immonen<sup>1</sup>, J.C. Hannukainen<sup>1</sup>, N. Kudomi<sup>2</sup>, R. Parkkola<sup>1</sup>, V. Saunavaara<sup>1</sup>, P. Iozzo<sup>3</sup>, P. Nuutila<sup>1</sup>;

<sup>1</sup>Turku PET Centre, University of Turku, Finland, <sup>2</sup>Faculty of Medicine, University of Kawaga, Japan, <sup>3</sup>Institute of Biomedical Engineering, National Research Council, Padua, Italy.

**Background and aims:** Increased delivery of free fatty acids (FFAs) to the liver plays a role in the pathogenesis of type 2 diabetes. Bariatric surgery is associated with high rates of diabetes remission, but the underlying mechanisms are not fully elucidated. Liver fatty acid uptake is crucial in understanding the mechanism of postoperative metabolic changes. This study's objective was to assess the surgery-induced changes in hepatic FFA uptake, together with quantification of hepatic perfusion and liver fat content (LFC).

**Materials and methods:** We measured hepatic FFA uptake, hepatic portal, and arterial perfusion with positron emission tomography using [18F]-FTHA and [15-O]-H<sub>2</sub>O in 22 morbidly obese subjects before and 6 months after bariatric surgery and in 14 healthy lean volunteers. LFC was quantified by MRS and liver volume by MRI.

**Results:** Baseline: Plasma FFA concentration was elevated in the obese group compared to the lean control group ( $0.67 \pm 0.22$  vs.  $0.48 \pm 0.21$  mmol/l,  $p = 0.02$ ). Liver FFA uptake, when measured per depot or per unit mass, was higher in obese subjects compared to controls (depot:  $254 \pm 67$  vs.  $107 \pm 39$   $\mu$ mol/min,  $p < 0.001$  and per unit mass:  $14.4 \pm 3.6$  vs.  $10.0 \pm 3.7$   $\mu$ mol/min/100 ml,  $p < 0.01$ , respectively). LFC in the obese group was significantly higher than in controls ( $5.7 \pm 4.7$  vs.  $1.5 \pm 1.5\%$ ,  $p < 0.01$ ), and 9 of the obese patients had liver steatosis (LFC  $\geq 5\%$ ). When obese subjects were divided into two groups, with LFC below (LFC-low) or above (LFC-high) the median of 4.4%, the LFC-high group had an increased FFA depot uptake compared to LFC-low group ( $p = 0.09$ ). When patients were grouped according to diabetic status, no difference in FFA uptake was observed. In pooled data, FFA uptake correlated with intraperitoneal fat mass ( $r = 0.40$ ,  $p = 0.02$ ). Compared to controls, both portal and arterial blood flow were higher in the obese group ( $5.2 \pm 2.1$  vs.  $3.6 \pm 1.0$  l/min,  $p = 0.01$  and  $0.34 \pm 0.16$  vs.  $0.19 \pm 0.10$  l/min,  $p < 0.001$ , respectively). At 6 months after surgery: BMI decreased from  $41 \pm 4$  kg/m<sup>2</sup> to  $32 \pm 4$  kg/m<sup>2</sup> ( $p < 0.001$ ) and the remission of diabetes was observed in 8 out of 10 patients. Plasma FFA concentration was unchanged ( $p = \text{NS}$  vs. baseline). The liver depot uptake decreased by 15% ( $p = 0.02$  vs. baseline), but remained twice as high compared to the control group ( $p < 0.001$  vs. controls). LFC was decreased by 69% ( $p = 0.001$  vs. baseline) and was now similar to that of lean controls ( $p = \text{NS}$  vs. controls). None of the subjects had liver steatosis postoperatively. Portal blood flow decreased by 55% ( $p < 0.0001$ ) and arterial flow by 76% ( $p < 0.0001$ ), and both were reduced compared to levels measured in controls ( $p < 0.05$  for both). Reduction in intraperitoneal fat mass was related to changes in LFC ( $r = 0.59$ ,  $p = 0.02$ ) and in portal blood flow ( $r = 0.69$ ,  $p = 0.001$ ). An association between the change in portal blood flow and improvement in insulin sensitivity index was observed ( $r = 0.52$ ,  $p = 0.02$ ).

**Conclusion:** Hepatic fatty acid uptake was decreased, but did not normalize to controls, when measured six months after bariatric surgery. After surgery, fatty acid uptake changes may contribute to the resolution of liver steatosis. Morbidly obese subjects showed increased portal vein blood flow, which resulted in a higher supply of fatty acids for hepatic FFA uptake. Postoperatively blood flow decreased along with the reduction in visceral fat mass and improvement in insulin sensitivity.

### High-fat diet increases autophagic flux in pancreatic beta cells in vivo

K.-Y. Chu, T.J. Biden;

Garvan Institute, Darlinghurst, Australia.

**Background and aims:** Autophagy is an important cellular survival mechanism that responds to changes in cellular nutrients, and potentially counter-regulates endoplasmic reticulum (ER) stress, previously implicated in

lipotoxic beta-cell death. Because it is extremely difficult to measure true autophagic flux in vivo, it is still unclear how high-fat feeding or fatty acids regulate autophagy in pancreatic beta-cells. Here, we used both in vivo and in vitro models to study autophagic flux; and also investigated the upstream signaling pathways triggered by fatty acids.

**Materials and methods:** For unequivocal estimation of autophagic flux, GFP-LC3 mice were fed with chow or high-fat diet for 10 weeks and then, for 5 consecutive days before sacrifice, injected with 100mg/kg chloroquine to block clearance of autophagic markers. The pancreata and livers were collected and fixed for cryosectioning. The beta-cells of the pancreatic sections were labeled with the insulin antibody, and the GFP-LC3 signaling analysed by fluorescence microscopy. Autophagic and ER stress markers were detected by western blot following acute (2h) treatment with chloroquine using both islets ex vivo from the high-fat fed mice, and mouse clonal MIN6 beta-cells treated with oleate and palmitate for 0–48h.

**Results:** Autophagic flux, assessed from the amount of GFP puncta, was increased in pancreatic acinar tissue and beta-cells after high-fat feeding and chloroquine injection. In contrast, GFP signal in the liver was markedly attenuated under identical conditions. LC3 levels in the isolated mouse islets were also increased by high-fat diet and further enhanced by chloroquine incubation ex vivo. ER stress, indicated by the markers CHOP and phospho-elf2a levels, in isolated islets was not augmented by high-fat feeding alone, but was induced by autophagic inhibition with chloroquine and further enhanced by high-fat feeding. This reveals a reciprocal relationship between ER stress and autophagy in beta-cells and suggests that autophagy is not solely secondary to ER stress in the context of lipotoxicity in vivo. In MIN6 cells, oleate increased LC3-II levels in both the presence and absence of chloroquine (indicative of enhanced flux and steady state autophagy respectively) whereas palmitate augmented the autophagic flux alone. ER stress was increased by palmitate but not oleate, which concurs with the in vivo model that lipids/fatty acids could induce autophagy without the activation of ER stress. Nevertheless, neither fatty acid modulated classical mTOR signaling illustrated by the downstream phospho-4EBP levels.

**Conclusion:** Using GFP-LC3 mice with chloroquine injection we show for the first time that beta-cells have a very low basal autophagic flux but, in contrast to liver, this is increased by high-fat feeding. This appears to act as a protective mechanism prior to the activation of ER stress, and is triggered independently of the classical mTOR pathway.

### Sphingosine kinase 1 promotes hepatic steatosis via up-regulation of PPARgamma

P. Xia<sup>1,2</sup>, J. Chen<sup>2</sup>, W. Wang<sup>1</sup>, G. McCaughan<sup>2</sup>, X. Gao<sup>1</sup>, M. Vadas<sup>2</sup>;

<sup>1</sup>Endocrinology and Metabolism, Fudan University Zhongshan Hospital, Shanghai, China, <sup>2</sup>Centenary Institute, the University of Sydney, Australia.

**Background and aims:** Sphingolipid metabolites have emerged playing key roles in the pathogenesis of metabolic diseases, including obesity, diabetes and nonalcoholic fatty liver disease (NAFLD). The current study aimed to explore the underlying mechanisms and discover a potentially druggable intermediate in the steatotic pathways associated with sphingolipid metabolites.

**Materials and methods:** We utilized pharmaceutical inhibitors or genetic means to manipulate sphingosine kinase 1 (SphK1), one of the key enzymes that control sphingolipids metabolism. Both cellular and animal models were applied in the study investigating the role of SphK1 in hepatic lipid metabolism and NAFLD development.

**Results:** A nearly 2-fold increase in the expression level of SphK1 was observed in either cellular or animal models of NAFLD, without alterations in SphK2 (another isoenzyme of SphK), suggesting a specific link of SphK1 to NAFLD. Enforced overexpression of SphK1 significantly promoted lipid accumulation in mouse primary hepatocytes, whereas loss of SphK1 gene expression inhibited the process compared with the control hepatocytes (both  $p < 0.01$ ). Moreover, SphK1 deletion resulted in a significant amelioration in histological changes of steatosis, along with a 30% reduction in hepatic contents of triglycerides and cholesterols in diet-induced obese (DIO) mice ( $p < 0.01$ ). Analysis of fatty liver-related gene expression revealed a 40% reduction of transcriptional factor peroxisome proliferator-activated receptor  $\gamma$  (PPAR $\gamma$ ) and its target genes in DIO SphK1<sup>-/-</sup> mice, in comparison with wild-type DIO mice ( $p < 0.01$ ). Accordingly, treatment with sphingosine-1-phosphate (S1P) or overexpression of SphK1 increased PPAR $\gamma$  expression by 150% ( $p < 0.01$ ) in the lipid-laden hepatocytes. Furthermore, PPAR $\gamma$  inhi-

bition by using its siRNA or antagonists markedly reduced SphK1-dependent hepatic lipid accumulation (all  $p < 0.01$ ).

**Conclusion:** SphK1 plays an important role in fatty liver development by promoting lipid accumulation and up-regulation of PPAR $\gamma$  in hepatocytes. The functional link between the SphK1 and PPAR $\gamma$  pathways in aggravating hepatic steatosis may reveal a new way to the management of NAFLD.

## 166

### Hypothalamic nitric oxide regulates insulin signalling and hepatic lipid metabolism

F.O. Martins<sup>1,2</sup>, S. Tovar<sup>3</sup>, J.G. Jones<sup>4,5</sup>, S. Perez-Sieira<sup>3</sup>, D. González-Touceda<sup>3</sup>, A. Natali<sup>6,7</sup>, C. Diéguez<sup>3</sup>, M.P. Macedo<sup>6,5</sup>; <sup>1</sup>Departamento de Fisiología, Centro de Estudios de Doenças Crónicas (CEDOC), FCM, Universidade Nova de Lisboa, <sup>2</sup>Centre for Neurosciences and Cell Biology, University of Coimbra, Portugal, <sup>3</sup>Centro de Investigación de Medicina Molecular y Enfermedades Crónicas (CIMUS), Universidad de Santiago de Compostela, Spain, <sup>4</sup>Centre for Neurosciences and Cell Biology, University of Coimbra, <sup>5</sup>Portuguese Diabetes Association (APDP-ERC), Lisbon, <sup>6</sup>Departamento de Fisiología, Centro de Estudos de Doenças Crónicas, New University of Lisbon, Portugal, <sup>7</sup>Metabolism Unit, Department of Internal Medicine, University of Pisa, Italy.

**Background and aims:** Human studies demonstrated that NO is an important regulator of insulin clearance. Whether the control of insulin clearance is solely dependent on hepatic mechanisms or also involves hypothalamic regulation is currently uncertain. Since hypothalamus is a critical regulator of energy metabolism and endocrine functions, we previously hypothesized that NO production by central/hypothalamic axis regulates insulin clearance and therefore peripheral insulin bioavailability. We found a significant inverse correlation between NO production in the paraventricular nucleus (PVN) and systemic insulin clearance. However, the metabolic consequences of PVN NO-mediated regulation of insulin clearance remain unknown, so we hypothesized that in addition to insulin clearance, it also modulates hepatic glucose and lipid metabolism.

**Materials and methods:** Male Wistar rats underwent brain surgery using a stereotaxic apparatus for implantation of the double cannulas, for nucleus specific infusion in the PVN region. After the bregma localization the following coordinates were used: AP: -1.8mm, Lat: +/- 0.4mm, DV: -8.0mm. Bolus infusion of 250ug/2uL of L-NAME (or 2uL of saline in the control animals) were performed in each side of the brain, once only in the day of the experiment. An oral glucose tolerance test (OGTT) (2g/kg) was subsequently performed. Liver was harvested and kept at -80° for protein extraction and analysis of glucose and lipid metabolism-related enzymes by immunoblotting.

**Results:** We observed that PVN NO depletion led to changes in insulin signaling as well as glucose and lipid metabolism. Regarding insulin signaling, IRS-1 and AKT expression as well as IRS-1 and AKT phosphorylation were decreased. In addition, expression of hepatic Glut 1, 2 and 4 were all significantly decreased suggesting a reduced capacity for glucose uptake by the liver. Interestingly, depletion of PVN NO levels suppressed the lipogenic enzymes (ACC, FAS, ATP citrate lyase and pATP citrate lyase), which is consistent with the observed diminished hepatic non-esterified fatty acids (NEFA) content. Meanwhile, hepatic DGAT expression was increased, possibly in response to decreased NEFA. Hepatic TG levels were not diminished by PVN-NO depletion possibly due to this compensatory DGAT upregulation.

**Conclusion:** These results support the hypothesis that increased PVN NO results in a decreased insulin clearance and a stimulation of de novo lipogenesis. This suggests that hypothalamic NO signaling has a role in regulating hepatic lipid metabolism.

### MiR-494 is regulated by exercise in obese sedentary individuals with increased risk of type 2 diabetes and modulates skeletal muscle lipid metabolism in vitro

M. Balaz<sup>1</sup>, T. Kurdiova<sup>1</sup>, M. Vician<sup>2</sup>, O. Kyselovicova<sup>3</sup>, V. Belan<sup>4</sup>, I. Jelok<sup>5</sup>, C. Wolfrum<sup>6</sup>, J. Ukropec<sup>1</sup>, B. Ukropcova<sup>1</sup>; <sup>1</sup>Diabetes laboratory, Institute of Experimental Endocrinology, <sup>2</sup>Surgery Clinic, <sup>3</sup>Faculty of Sport and Physical Education, <sup>4</sup>Radiology Clinic, <sup>5</sup>National Institute of Cardiovascular Diseases, Bratislava, Slovakia, <sup>6</sup>Institute of Food, Nutrition and Health, Schwerzenbach, Switzerland.

**Background and aims:** Exercise leads to activation of several signaling pathways which improve skeletal muscle lipid metabolism and insulin sensitivity. On the contrary, physical inactivity is associated with impaired lipid metabolism and insulin resistance. We hypothesized that miR-494 might be involved in the response of skeletal muscle to both acute and regular exercise. The aim of our study was to investigate regulation of miR-494 in skeletal muscle of sedentary overweight to obese individuals (age  $36.0 \pm 1.7$  yrs; BMI  $31.6 \pm 0.9$  kg.m<sup>-2</sup>; M/F, 8/7) with increased risk of T2D (prediabetics, n=10) who underwent a 12-week endurance (n=8) or strength (n=7) training programme. A functional study examining the role of miR-494 in regulation of lipid metabolism was performed in primary human myotubes.

**Materials and methods:** Biopsies of *m. vastus lateralis* were taken prior and after training. Effects of a single exercise bout were examined in a subpopulation of 8 individuals (M/F, 4/4). All participants underwent complex metabolic phenotyping, including an assessment of glucose tolerance (oGTT), subcutaneous and visceral adipose tissue content and distribution (MRI) and maximal aerobic capacity (bicycle ergometry). Total RNA, including miRNA, was isolated from skeletal muscle & serum and quantified with the aid of real-time PCR. *In vitro* functional studies were performed in primary human myotubes, transfected with miR-494 mimics, inhibitor or negative control.

**Results:** The 12-week training led to 19% increase of VO<sub>2</sub> max ( $p < 0.05$ ), confirming the efficiency of training intervention. Expression of miR-494 in skeletal muscle was reduced by 28% ( $p < 0.05$ ) in response to 12-week training. However, no effect of an acute exercise bout on muscle miR-494 was observed in neither sedentary nor trained individuals. Interestingly, circulating levels of miR-494 were 2.6-fold higher ( $p < 0.01$ ) after 12-week training. Overexpression of miR-494, lowered expression of FoxJ3 (-48%,  $p < 0.001$ ), PGC1 $\alpha$  (-33%,  $p < 0.001$ ), SIRT3 (-18%,  $p < 0.001$ ) and SIRT1 (-36%,  $p < 0.001$ ) and was associated with 22% reduction of mitochondrial content ( $p < 0.05$ ) and marked increase (3.6-fold,  $p < 0.001$ ) in triglyceride accumulation. Transfection of miR-494 inhibitor significantly increased expression of PGC1 $\alpha$  (+26%,  $p < 0.001$ ) and SIRT1 mRNA (+17%,  $p < 0.01$ ) and reduced lipid accumulation (-30%,  $p < 0.01$ ) in differentiated human myotubes. However, no effect of miR-494 inhibitor on mitochondrial content was observed.

**Conclusion:** Our results indicate that both skeletal muscle and circulating miR-494 levels are regulated by exercise training. In addition, our *in vitro* functional studies suggest that miR-494 might be involved in regulation of mitochondrial biogenesis and lipid storage/utilization capacity, likely by targeting the PGC1 $\alpha$  and SIRT1 pathways.

### Fatty acid composition determines the acute effects of oral fat intake on insulin sensitivity and muscle mitochondrial function in humans

C. Koliaki<sup>1</sup>, K. Kaul<sup>1</sup>, A. Boenner<sup>1</sup>, P. Nowotny<sup>1</sup>, M. Esser<sup>1</sup>, K. Tinnes<sup>1</sup>, M. Roden<sup>1,2</sup>;

<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, Leibniz Center for Diabetes Research, <sup>2</sup>Department of Endocrinology and Diabetology, Heinrich Heine University, Düsseldorf, Germany.

**Background and aims:** Intravenous administration of fat, mainly consisting of unsaturated lipids, promotes insulin resistance, which might relate to altered mitochondrial function. However, it remains unclear whether oral fat ingestion may also induce muscle and/or hepatic insulin resistance, and whether fatty acid composition might differently affect insulin sensitivity and skeletal muscle oxidative capacity. Thus, we examined in the present study the acute effects of an oral lipid challenge rich in either saturated or unsaturated lipids on insulin sensitivity and muscle mitochondrial respiration in healthy humans.

**Materials and methods:** Ten healthy lean sedentary volunteers (age 25±1 years, body mass index 24.8±0.3 kg/m<sup>2</sup>) were randomized in a cross-over manner to an oral lipid emulsion (50% fat) enriched in saturated fatty acids (SAFA: 92 g palm oil), omega-6 polyunsaturated fatty acids (PUFA: 92 g safflower oil) and water as control (CON). Skeletal muscle biopsies were performed before and 2.5 hours after interventions. Euglycemic-hyperinsulinemic clamps with infusion of deuterated glucose were initiated 6 hours after interventions to assess whole-body (M-value) and hepatic insulin sensitivity (insulin-mediated suppression of endogenous glucose production). High-resolution respirometry was applied to assess ex-vivo muscle mitochondrial respiratory capacity.

**Results:** After both SAFA and PUFA, whole-body insulin sensitivity was lower compared to CON (CON: 7.3±0.8; PUFA: 5.8±0.8; SAFA: 4.3±0.5 mg.kg<sup>-1</sup>.min<sup>-1</sup>, p<0.05), while hepatic insulin sensitivity remained unaltered (CON: 76±5; PUFA: 79±3; SAFA: 65±5%). SAFA led to greater whole-body insulin resistance than PUFA (p<0.05), and tended to reduce hepatic insulin sensitivity to a greater extent (p=0.06). Plasma incretin levels rose after both interventions without affecting however serum glucose and insulin levels. Although plasma free fatty acids (FFA) did not change upon SAFA or PUFA, the triglyceride enrichment of circulating plasma chylomicrons was markedly higher after both interventions (total AUC<sub>0-8h</sub>; CON: 84±13; PUFA: 236±52; SAFA: 280±65 % hour, p<0.05). SAFA-induced insulin resistance associated with impaired suppression of lipolysis under insulin-stimulated conditions, whereas PUFA-induced insulin resistance related to increased post-intervention plasma FFA levels (p<0.05). ADP-stimulated respiration related to β-oxidation (malate, octanoylcarnitine, ADP) was lowered in muscle after PUFA intake (before: 22.4±2.2; after: 18.8±2.5 pmol.sec<sup>-1</sup>.mg<sup>-1</sup>, p<0.05), but was not altered after SAFA intake.

**Conclusion:** Oral intake of both saturated and unsaturated fat induces acutely peripheral insulin resistance in healthy humans, which may be partly mediated by increased circulating triglyceride-rich chylomicrons contributing to muscle lipotoxicity. The underlying mechanisms are divergent depending on fatty acid composition, and may implicate adipose tissue insulin resistance in the case of saturated, and impaired skeletal muscle oxidative capacity due to FFA lipotoxicity in the case of unsaturated fat.

### Mass sequencing of the faecal virome: a study in children with early onset of islet autoimmunity

L. Kramná<sup>1</sup>, K. Holková<sup>1</sup>, S. Oikarinen<sup>2</sup>, J.-P. Pursiheimo<sup>3</sup>, M. Knip<sup>4</sup>, O. Simell<sup>5</sup>, R. Veijola<sup>6</sup>, J. Ilonen<sup>7</sup>, H. Hyöty<sup>2</sup>, O. Cinek<sup>1</sup>;

<sup>2</sup>Department of Virology, University of Tampere, <sup>3</sup>Department of

Medical Biochemistry and Genetics, University of Turku, <sup>4</sup>Department

of Paediatrics, University of Helsinki, <sup>5</sup>Department of Paediatrics, Turku

University Central Hospital, <sup>6</sup>Department of Paediatrics, University of Oulu,

<sup>7</sup>Department of Immunogenetics, University of Turku, Finland.

**Background and aims:** The search for an association between viruses and islet autoimmunity has been limited mostly to candidate virus genera and serotypes, whereas information has been very scarce about the whole virome (i.e. the complete “virus flora”). The next-generation sequencing technologies have offered a possibility to identify all prevalent viruses in a given sample. We used this technology to contrast the stool virome between children who developed very early islet autoimmunity with subsequent type 1 diabetes, and their matched peers in the Finnish prospective Diabetes Prediction and Prevention (DIPP) birth cohort.

**Materials and methods:** We conducted a case-control study nested within the DIPP cohort; nineteen cases were selected among children with the earliest onset of islet autoimmunity (mean age 15 months at first islet autoantibodies). Control children without islet autoimmunity were matched 1:1 for gender, time and place of birth and for the HLA risk. The virome was sequenced in available stool samples preceding the onset of autoimmunity by 3, 6 and 9 months. After mechanical enrichment of the virus fraction and nucleic acid extraction, we performed reverse transcription with tagged random primers, second strand synthesis, and partial amplification. Sequencing libraries were prepared using the Nextera XT protocol and sequenced on an Illumina MiSeq instrument. The resulting sequence reads were filtered, reduced in complexity using unbiased de-novo assembly, and analysed for human viruses using BLAST. Only indubitable virus infections with more than 5 reads were counted in the downstream analyses. The association was assessed using conditional logistic regression methods.

**Results:** The number of good quality sequence reads ranged from 200,000 to 1.5 million per sample, most of which belonged to multiple bacteriophages and bacteria. At least one human virus was identified in 47% samples, with 13% samples being simultaneously positive for more than one human virus. We most often observed parechoviruses (35%), bocaviruses (13%) and sapoviruses (11%), whereas enteroviruses and rhinoviruses were rare. The overall coverage of the viruses ranged from several thousand-fold in a massively replicating sapovirus to sparsely distributed numbers of reads. We noted a clustering of virus findings within the matching groups, indicating adequate matching strategies. No globally significant virus association with the development of islet autoimmunity was observed at the genus level (all P values > 0.4).

**Conclusion:** This study shows a richness of human viruses previously not appreciated in the stools of otherwise healthy Finnish children, and underlines the utility of massive parallel sequencing of the virome. Further extension of this pilot dataset will allow studies of individual virus subtypes and strains, and also of sequence contigs not matching currently known organisms.

She<sup>3</sup>, O. Simell<sup>7</sup>, A. Ziegler<sup>4</sup>, J. Krischer<sup>1</sup>, J.M. Norris<sup>8</sup>, S.M. Virtanen<sup>9</sup>, the TEDDY Study Group;

<sup>1</sup>University of South Florida, Tampa, USA, <sup>2</sup>Lund University, Malmo,

Sweden, <sup>3</sup>Medical College of Georgia, Atlanta, USA, <sup>4</sup>Diabetes Research

Institute, Munich, Germany, <sup>5</sup>Barbara Davis Center for Childhood Diabetes,

Aurora, <sup>6</sup>Pacific Northwest Diabetes Research Institute, Seattle, USA,

<sup>7</sup>University of Turku, Finland, <sup>8</sup>Colorado School of Public Health, Aurora,

USA, <sup>9</sup>National Institute for Health and Welfare, Helsinki, Finland.

**Background and aims:** It is hypothesized that probiotics can prevent adverse immunological responses to environmental exposures by supporting the

healthy gut microbiota, and thus prevent the development to type 1 diabetes associated islet autoimmunity (IA) in young children. The aim of this study was to examine the association between early probiotic use and IA.

**Materials and methods:** The Environmental Determinants of Diabetes in the Young (TEDDY) study prospectively follows 8502 children with type 1 diabetes (T1D)-associated HLA-DR-DQ alleles in Finland, Germany, Sweden and the US. Blood samples were collected every 3 months from birth to evaluate the primary outcome of IA, defined as appearance of one or more of the islet autoantibodies GADA, IAA, or IA-2A confirmed at two consecutive visits. The introduction of either probiotic supplement or infant formula containing probiotics was classified as: early introduction (at the age of <3 months), or late or no introduction (at the age of 3 months and later, or not introduced during the first 12 months). We applied time-to-event analysis to study the association between probiotic use and IA, stratifying by country and adjusting for family T1D status, HLA type, sex, exclusive breastfeeding, and mode of delivery.

**Results:** Probiotic supplementation during the first 3 months either through dietary supplements and/or infant formula was most common in Finland (35.9%). In Germany 24.0%, in Sweden 11.6% and in the US 2.2% of children were given probiotics before the age of 3 months. Probiotic supplementation before 3 months of age was associated with a decreased risk of IA, compared with probiotic supplementation after 3 months or not at all (HR 0.62; 95% CI 0.45–0.84;  $p=0.0018$ ). The country-specific hazard risk ratios for associations between the early probiotic supplementation and IA were: Finland 0.72 (95% CI 0.49–1.07;  $p=0.10$ ), Germany 0.65 (95% CI 0.26–2.55;  $p=0.37$ ), Sweden 0.42 (95% CI 0.21–0.85;  $p=0.0165$ ), and the US 0.62 (95% CI 0.15–2.50;  $p=0.50$ ).

**Conclusion:** Early probiotic supplementation may reduce the risk of IA in children who are at elevated genetic risk of T1D.

### Diabetic family history and beta cell autoimmunity in children with HLA-associated disease risk

H.T.A. Siljander<sup>1,2</sup>, R.-T. Salonsaari<sup>2</sup>, A. Hekkala<sup>3</sup>, S. Simell<sup>4</sup>, R. Veijola<sup>3</sup>, J. Ilonen<sup>5,6</sup>, O. Simell<sup>4</sup>, M. Knip<sup>1,2</sup>;

<sup>1</sup>Children's Hospital/ Scientific Laboratory, University of Helsinki and Helsinki University Central Hospital, <sup>2</sup>Department of Pediatrics, Tampere University Hospital, <sup>3</sup>Department of Pediatrics, Oulu University Hospital, <sup>4</sup>Department of Pediatrics, University of Turku, <sup>5</sup>Immunogenetics Laboratory, University of Turku, <sup>6</sup>Department of Clinical Microbiology, University of Eastern Finland, Kuopio, Finland.

**Background and aims:** We assessed the role of a positive family history for type 1 diabetes (T1D) in relation to beta-cell autoimmunity in children carrying HLA-conferred disease risk, recruited from the general population.

**Materials and methods:** Children ( $n=7410$ , 52.7% males) with ( $n=189$ , 2.6%) and without ( $n=7233$ ) T1D-affected first degree relatives (FDRs) were recruited as newborn infants from the general population, based on HLA-defined disease risk. They were observed for T1D-associated autoimmunity and progression to T1D for 13.6 years (median; range 0.9–18.6 years). In 1994–2002, the ICA assay was used for the primary autoantibody screening, after which IAA, GADA, and IA-2A were measured in seroconverted subjects, but since 2003, all four autoantibodies have been analyzed from all samples available.

**Results:** Children with T1D-affected FDRs had a higher frequency of seroconversions and multipositivity, higher levels of IAA and GADA, and progressed more often to T1D than children with no affected FDRs. The age at diagnosis was similar regardless of family background. Compared to children with no affected FDRs, the highest T1D risk was associated with paternal T1D (OR=11.9;  $p<0.001$ ), followed by maternal (OR=3.5;  $p<0.001$ ) and sibling-associated T1D (OR=3.4;  $p=0.083$ ; sib vs. maternal T1D,  $p=NS$ ). Children with T1D-affected FDRs had higher frequency of the high risk HLA genotype (DQB1\*02:0302; 30.2 vs. 21.0%,  $p=0.002$ ) than those with no family history for T1D. In the analyses of T1D-free survival in subjects who had developed at least one T1D-associated autoantibody, the 10-year progression rate since seroconversion was 66.1% (CI 47.7–84.5%) in children with paternal T1D, 37.7% (CI 12.8–62.6%) in children with maternal T1D, and 18.2% (CI 0–41.0%) in children with siblings affected by T1D (paternal vs. maternal,  $p=0.035$ ), while the rate was 15.1% (12.9–17.2%) in children with no family history for T1D (paternal vs. no FDRs,  $p<0.001$ , and maternal vs. no FDRs,  $p=0.006$ ). In the Cox regression analysis on seroconverted subjects, multipositivity (HR=7.2, CI 5.3–9.8), a positive family history for T1D (HR=2.0, CI

1.3–3.1), high risk genotype (HR=1.8, CI 1.4–2.4), young age at seroconversion (HR=0.7, CI 0.7–0.8), and higher levels of IAA (RU; HR=1.014, CI 1.007–1.021), IA-2A (RU; HR=1.010, CI 1.004–1.017), and ICA (JDFU; HR=1.004, CI 1.002–1.006) remained independent predictors of T1D.

**Conclusion:** Children with T1D-affected family members carry a higher risk for the initiation of beta-cell autoimmunity than their peers with no family history for T1D, even among children with moderate to high HLA-associated disease risk. Paternal T1D is an indicator of high risk for progression towards T1D, although the association between the high-risk HLA genotype and paternal T1D may partly explain the higher proportion of T1D observed in the offspring of affected fathers.

### A novel syndrome of early-onset type 1 diabetes and multi-organ autoimmunity caused by activating germline mutations in STAT3

S.E. Flanagan<sup>1</sup>, E. Haapaniemi<sup>2</sup>, M.A. Russell<sup>1</sup>, T.J. McDonald<sup>1</sup>, J. Barton<sup>3</sup>, N.P. Murphy<sup>4</sup>, M. Seppanen<sup>5</sup>, T. Milenkovic<sup>6</sup>, K. Heiskanen<sup>7</sup>, A. Lernmark<sup>8</sup>, T. Otonkoski<sup>7</sup>, J. Kere<sup>9,2</sup>, N.G. Morgan<sup>1</sup>, S. Ellard<sup>1</sup>, A.T. Hattersley<sup>1</sup>;

<sup>1</sup>University of Exeter Medical School, UK, <sup>2</sup>Folkhälsan Institute of Genetics, and Research Programs Unit, Molecular Neurology, University of Helsinki, Finland, <sup>3</sup>Bristol Royal Hospital for Children, Bristol, UK, <sup>4</sup>Children's University Hospital, Dublin, Ireland, <sup>5</sup>Helsinki University Central Hospital, Finland, <sup>6</sup>Institute for Mother & Child Health Care of Serbia 'Dr Vukan Cupic', Belgrade, Serbia, <sup>7</sup>Children's Hospital, Helsinki University Central Hospital and University of Helsinki, Finland, <sup>8</sup>Lund University/CRC, Skåne University Hospital SUS, Malmö, <sup>9</sup>Karolinska Institutet, Huddinge, Sweden.

**Background and aims:** Type 1 diabetes (T1D) can be a feature of the monogenic polyautoimmune disorders, Immunodysregulation, Polyendocrinopathy, Enteropathy X-linked syndrome (IPEX) and Autoimmune Polyendocrinopathy Syndrome 1 (APS1). In these conditions autoimmune disease presents very early and in IPEX syndrome T1D often occurs  $\leq 3$  months. Investigation of individuals with early onset T1D associated with multiple early-onset autoimmune features may therefore reveal novel monogenic causes of autoimmunity.

**Materials and methods:** We studied patients with early onset Type 1 diabetes (<12 months) and early-onset autoimmune disease (<5 years). Initial investigation was looking for a de novo mutation by sequencing the exome of an individual with early onset T1D, primary hypothyroidism and coeliac disease and the unaffected parents. This was followed by further testing of 24 individuals with  $\geq 2$  autoimmune disorders (diagnosed <5 years) and 64 subjects with isolated diabetes diagnosed <6 months who are aged <5 years.

**Results:** The only de novo coding pathogenic variant was, p.T716M, in STAT3 in the patient with T1D, primary hypothyroidism and coeliac disease. Sanger sequencing identified a further 4 patients (3 polyautoimmune disease, 1 PNDM) with de novo STAT3 mutations (p.K392R, p.N646K (x2), p.K658N). All substitutions affect highly conserved residues and functional studies confirmed that all mutations increased STAT3 activity in vitro. Diabetes was present in 4/5 patients, presented early (2.5 [0–43] weeks (median [range])) and was insulin treated from diagnosis. Islet autoantibodies were detected in 3/4 patients supporting a diagnosis of autoimmune-mediated T1D. Additional autoimmune conditions included enteropathy, interstitial lung disease, juvenile-onset arthritis and primary hypothyroidism. Other common features were short stature (5/5 (<2SDS)) and eczema (4/5). The young age at presentation is consistent with STAT3 mutations causing accelerated autoimmune disease.

**Conclusion:** We report germline activating STAT3 mutations are a novel cause of early onset polyautoimmunity in which T1D is a common feature. This result confirms the crucial role of STAT3 in the pathophysiology of T1D. Whilst monogenic polyautoimmune disease is rare, these conditions are important as they offer valuable insights into the biology of the immune system in T1D.

**Family history of type 1 and type 2 diabetes and the risk of LADA—results from a population-based study of incident cases**

S. Carlsson<sup>1</sup>, T. Andersson<sup>1</sup>, P.-O. Carlsson<sup>2</sup>, M. Dorkhan<sup>3</sup>, L. Groop<sup>3</sup>, J. Edwall Löfvenborg<sup>4</sup>, R. Hjort<sup>1</sup>, M. Martinell<sup>4</sup>, B. Rasouli<sup>1</sup>, P. Storm<sup>3</sup>, T. Tuomi<sup>5,6</sup>;

<sup>1</sup>Division of epidemiology, Institute of Environmental Medicine, Stockholm, Sweden, <sup>2</sup>Department of Medical Sciences, Uppsala, Sweden,

<sup>3</sup>Department of Clinical Sciences, Clinical Research Centre, Malmö,

<sup>4</sup>Department of Public Health and Caring Sciences, Uppsala, Sweden,

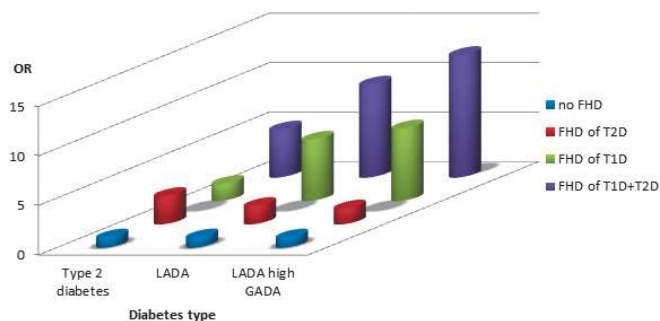

<sup>5</sup>Division of Endocrinology, Helsinki, <sup>6</sup>Research Program for Diabetes and Obesity, University of Helsinki, Finland.

**Background and aims:** LADA (latent autoimmune diabetes in adults) is suggested to be genetic mix of type 1 and type 2 diabetes, linked to HLA-DQB1 risk genotypes associated with autoimmunity as well as genes associated with type 2 diabetes, including *TCF7L2*. Family history of diabetes (FHD) encompasses both genetic and shared environmental factors and is a strong predictor of diabetes risk, although scarcely investigated in relation to LADA. Our aim was to investigate the risk of LADA in relation to family history of type 1 and type 2 diabetes.

**Materials and methods:** We used data from a population based case-control study with incident cases of adult onset ( $\geq 35$  years) diabetes, including 264 cases of LADA (Glutamic acid decarboxylase antibodies (GADA) positive ( $>10$  IU/mL) with c-peptide  $>0.3$  nmol/l, 796 cases of type 2 diabetes (GADA negative), together with 1047 controls without diabetes, randomly selected from the population. Self-reported information on diabetes in first and second degree relatives was collected and relatives with onset  $<40$  years and insulin treatment were classified as having type 1 diabetes (T1D) and otherwise as having type 2 diabetes (T2D). We estimated the odds ratio (OR) of LADA and T2D in relation to FHD, adjusted for age, sex and BMI.

**Results:** Family history of T1D (OR 6.2; 95% CI 1.8–20.8), and T2D (1.8; 95% CI 1.35–2.46) was associated with an increased risk of LADA and there were indications of a synergistically increased risk in those with a combination of T1D and T2D in the family (OR 9.39; 95% CI; 4.4–20.0). The association with FHD was even more pronounced for LADA with high GADA concentrations ( $>$ median); OR was estimated at 7.3 (95% CI 1.91–28.0) for FHD of T1D and at 12.4 (95% CI 5.5–27.9) for the combination of T1D and T2D in the family. No difference was seen for FHD of T1D in female (OR 4.0; 95% CI 1.7–9.1) vs. male relatives (OR 4.4; 95% CI 1.9–10.2). The risk of T2D was associated with FHD of T2D (OR 2.9; 95% CI 2.3–3.6) but not FHD of T1D. In LADA patients, FHD of T1D vs T2D was associated with higher GADA (197.8 vs 139.5 IU/mL,  $p=0.003$ ) but lower c-peptide (0.55 vs 0.81 nmol/l,  $p=0.009$ ) levels.

**Conclusion:** The current data add support to the view that LADA is an admixture of both T1D and T2D, also in terms of genetic risk.

**Low birth weight is associated with an increased risk of latent autoimmune diabetes in adults (LADA) and type 2 diabetes: results from ESTRID a Swedish case-control study**

R. Hjort<sup>1</sup>, P.O. Carlsson<sup>2</sup>, M. Dorkhan<sup>3</sup>, L. Groop<sup>3</sup>, M. Martinell<sup>4</sup>, B. Rasouli<sup>4</sup>, T. Toumi<sup>5</sup>, S. Carlsson<sup>1</sup>;

<sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm,

<sup>2</sup>Department of Medical Sciences, Uppsala University, <sup>3</sup>Department of Clinical Sciences in Malmö, Lund University, Malmö, <sup>4</sup>Department of Public Health and Caring Sciences, Uppsala University, Sweden, <sup>5</sup>Department of

Medicine, Helsinki University Central Hospital, Finland.

**Background and aims:** A large body of research has recognized low birth weight as a risk factor for type 2 diabetes (T2D), hypothetically as an indicator of poor nutrition of the fetus, leading to insulin resistance. Genetic factors have also been implicated, e.g. it has been suggested that effects of paternal diabetes may be mediated by effects on intrauterine environment, manifested in low birth weight of the offspring. In contrast a link between high birth weight and type 1 diabetes (T1D) has been documented. Our aim was to investigate, for the first time, the association between birth weight and LADA, a common diabetes form with features of both T1D and T2D.

**Materials and methods:** We used data from ESTRID (Epidemiological Study of Risk factors for LADA and type 2 Diabetes), a Swedish population-based study. Eligible for the analysis were 116 incident LADA cases ( $\geq$  age 35 and Glutamic Acid Decarboxylase Antibodies (GADA) positive ( $>10$  IU/mL) with c-peptide  $>0.3$  nmol/l), 298 incident T2D cases ( $\geq$  age 35 and GADA negative) and 521 disease-free controls randomly sampled from the population. Information on birth weight and covariates was based on self-report. We present Odds Ratios (OR) and 95% Confidence Intervals (CI) calculated by logistic regression and adjusted for sex, age, current BMI ( $\text{kg/m}^2$ ) and family history of diabetes (FHD) in first and second degree relatives.

**Results:** Low birth weight was associated with an increased risk for LADA as well as T2D; OR per kilogram reduction was estimated at 1.40 (CI; 1.03–1.90) and 1.39 (CI; 1.07–1.81) respectively and OR for subjects weighing less than 3 kg compared to more than 4 kg at birth was estimated at 2.06 (CI; 1.07–3.97) for LADA and 1.98 (CI; 1.16–3.40) for T2D. Further adjustments for education, physical activity, smoking and alcohol did not affect these estimates. Indications of an excess risk was seen both in those with FHD (OR 1.24, CI; 0.79–1.95) and without FHD (OR 1.59, CI; 1.04–2.43). A combination of low birth weight ( $<3$  kg) and current obesity (BMI  $\geq 30$ ) further augmented the risk; OR 3.69, CI; 1.33–10.26 (LADA) and 14.72, CI; 6.44–33.62 (T2D).

**Conclusion:** Our results suggest that low birth may also be a risk factor for LADA of the same strength as for T2D. The association appeared to be independent of family history of diabetes, which provides some support for the hypothesis that environmental rather than genetic factors explain this link. The combination of low birth weight and adult obesity appears to be a particularly strong risk factor, this being in line with the thrifty phenotype hypothesis.

### A novel mitochondrial mechanism controlling insulin secretion in obesity

M. Liesa, S.B. Sereda, L. Stiles, L. Nocito, O.S. Shirihai;  
Boston University School of Medicine, USA.

**Background and aims:** Reactive oxygen species can increase or decrease insulin secretion. However, it is unknown whether inhibiting an antioxidant system in islets can lead to improved insulin secretion without affecting their viability. Our goal is to identify whether modulating components related to heme metabolism, known to increase reactive oxygen species production but also antioxidant activity, can increase secretion without affecting viability. To this end, we studied the role of the mitochondrial transporter ATP-binding cassette B10 (ABCB10) regulating glucose stimulated insulin secretion in the context of diet-induced obesity, as ABCB10 is essential for proper heme metabolism and protection from oxidative stress.

**Materials and methods:** Obesity in mice was induced by high fat diet feeding (45% Fat, Research Diets). Mice fed hypercaloric control diet (CD, calories matched with carbohydrates) or chow diet were used as controls. Glucose tolerance tests (1g/kg I.P.) after fasting were performed and both insulin (ELISA, ALPCO) and glucose (FreeLite glucometer) were measured. Studies were carried out along BU IACUC and “Principles of laboratory animal care” (NIH). Mouse models are whole body ABCB10 +/- mice (n=10 backcrossed) and ABCB10-LoxP+/+ mice (pure) in C57Bl6J background. Islets were isolated 14–24 weeks after diet onset (weaning). Glucose stimulated insulin secretion was performed in modified DMEM by incubating islets in 2.8 mM glucose or 16.7 mM glucose for 30 minutes. Insulin in the media was measured by FRET (HTRF, CisBio). In the case of ABCB10-LoxP islets, they were transduced with Cre or Ds-Red control adenovirus at MOI 200 after isolation. Insulin was measured as in ABCB10 +/- islets. ABCB10 Real time PCR was performed using TaqMan probes.

**Results:** High fat diet and control diet feeding for 5 months had the expected effects increasing weight, fasting glucose and insulin levels, when compared to chow diet feeding. No significant differences in these parameters were detected between wild type and ABCB10 +/- mice though. However, glucose tolerance tests showed that ABCB10 +/- mice were more tolerant than wild type mice and only after high fat diet feeding. This increase in glucose tolerance was associated with higher blood insulin levels in response to glucose. In this regard, only high fat diet feeding resulted in ABCB10 +/- islets showing higher glucose stimulated insulin secretion when compared to wild type (40% increase). To address whether ABCB10 acutely regulated insulin secretion, we inactivated ABCB10 alleles after high fat diet feeding by Cre adenoviral expression in ABCB10 LoxP+/+ or LoxP+/- islets. Using this approach, we reduced ABCB10 expression by 80–90% and 40–50% respectively. We found that only after high fat feeding, glucose stimulated insulin secretion was increased in ABCB10 knock out (LoxP+/+ - Cre; ~30%) and in LoxP+/- Cre (~15%), when compared to respective DsRed transduced controls. This increase in insulin secretion was also present in ABCB10 knock out islets from chow diet mice just exposed for 24 hours to high glucose (20mM) and NEFA (palmitate 0.4 mM).

**Conclusion:** We report an unexpected role for the mitochondrial transporter ABCB10 regulating insulin secretion specifically in the context of high fat diet. We propose that lack of ABCB10 increases a reactive oxygen species-related high fat specific signal in islets that stimulates insulin secretion. In all, ABCB10 modulation could be a potential approach to improve insulin secretion specifically in the context of obesity.

### Circulating irisin is up-regulated by insulin infusion in obese, but not in lean humans, and is inversely associated with insulin sensitivity and respiratory exchange ratio

M. Straczowski<sup>1,2</sup>, A. Nikolajuk<sup>2</sup>, N. Matulewicz<sup>1</sup>, M. Stefanowicz<sup>1</sup>, M. Karczewska-Kupczewska<sup>1,3</sup>;

<sup>1</sup>Department of Metabolic Diseases, Medical University of Bialystok,

<sup>2</sup>Department of Prophylaxis of Metabolic Diseases, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn,

<sup>3</sup>Department of Metabolic Diseases, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland.

**Background and aims:** Irisin is a recently discovered myokine, with the potential to induce brown-fat-like development of white adipose tissue and to increase energy expenditure. In humans, data on the relationships of circulating irisin with insulin sensitivity and other metabolic parameters are inconsistent. The aim of the present study was to assess the associations of serum irisin with insulin sensitivity and substrate oxidation, as well as the effect of insulin infusion on circulating irisin.

**Materials and methods:** The study group consisted of 148 healthy subjects (115 males and 33 females, age between 18 and 35 years), 81 lean and 67 overweight or obese. Euglycemic hyperinsulinemic clamp and indirect calorimetry were performed. Serum irisin was measured in the baseline state and after the clamp.

**Results:** Baseline irisin was not different between lean and overweight/obese group (p=0.44). Insulin infusion resulted in an increase in serum irisin in overweight/obese (p=0.006), but not in the lean group (p=0.73). In consequence, post-clamp irisin was higher in the overweight/obese (p=0.042). Baseline irisin was related to fasting NEFAs (r=0.26, p=0.008). Post-clamp irisin was positively related to BMI, waist circumference, triglycerides and resting energy expenditure (all p<0.05) and negatively to insulin sensitivity (r=-0.20, p=0.014) and respiratory exchange ratio, both at baseline (r=-0.21, p=0.046) and during the clamp (r=-0.34, p=0.001). Concordantly with the latter finding, we observed negative association of post-clamp irisin with glucose oxidation (r=-0.26, p=0.008) and positive with lipid oxidation (r=0.37, p<0.0001) during hyperinsulinemia.

**Conclusion:** Our data show that insulin increases circulating irisin, but this effect is dependent on the presence of overweight/obesity and may represent a compensatory response to increase lipid oxidation in these conditions.

### Maternal BMI and exercise have interactive effects on brain's white and grey matter composition in elderly women

M. Buccì<sup>1</sup>, J.J. Tuulari<sup>1</sup>, J. Raiko<sup>1</sup>, V. Huovinen<sup>1</sup>, H. Lipponen<sup>1</sup>, S. Koskinen<sup>1</sup>, S. Sandboge<sup>2</sup>, J. Eriksson<sup>2,3</sup>, P. Iozzo<sup>4</sup>, L. Nummenmaa<sup>1,5</sup>, P. Nuutila<sup>1</sup>;

University of Helsinki, Finland, <sup>4</sup>National Research Council, Pisa, Italy,

<sup>5</sup>Department of Biomedical Engineering and Computational Science and Brain Research Unit, School of Science, Aalto University, Espoo, Finland.

**Background and aims:** Maternal obesity during pregnancy is a major health risk for the offspring and it may have a permanent effect on the offspring's subsequent morbidity. Cardiovascular diseases and type 2 diabetes share common early life risk factors and start from early age. Frailty is considered a precursor of ageing. Exercise training programs promote beneficial effects on health and can be effective even in elderly subjects. Nevertheless, no data is available on brain morphometric changes in frail subjects, and the effects of exercise on brain tissue composition. The object of the study was to measure the possible differences in grey (GM) and white matter (WM) density between frail offspring of obese (OOM) and lean mothers (OLM). We hypothesized that i) OOM have lower WM density compared to OLM and that ii) the OLM subjects will have higher capacity to increase WM density compared to OOM following the exercise intervention.

**Materials and methods:** 36 frail women aged 68–79 years were studied at baseline and 27 of them after four months of resistance exercise training. The participants were recruited from a large cohort from the Helsinki Birth Cohort Study (HBCS) according to the body mass index of their mothers when giving birth (16 from highest quartile and 20 from the two lowest quartiles). T1-weighted MRI images were segmented into GM and WM using SPM and

VBM8 toolbox, and compared using t tests. Data were thresholded at  $p < 0.05$ , FDR corrected at cluster level.

**Results:** WM but not GM density was higher in OLM versus OOM globally in the brain. Exercise intervention increased WM density in both OLM and OOM subjects in the cerebellum. The intervention increased WM and decreased GM density in parietal superior regions in OLM and in cuneus and precuneus regions in OOM. When comparing OLM and OOM for the changes in WM density following intervention, cerebellum of the OLM showed higher increase of WM density compared to OOM (Figure 1).

**Conclusion:** Maternal BMI during pregnancy influences brain atrophy in their offspring, especially the white matter. We show that exercise has an impact on brain morphology even in elderly women and in a brief time period. Being born to an obese mother compared to a lean or normal weight mother implies lower brain adaptability to exercise-induced changes in the WM density. These changes were more pronounced in the cerebellum region and this could have been caused by axon caliber and myelination increase in a similar way to what happens in subjects learning a new motor skill.

Figure 1. Exercise intervention differences (OLM higher than OOM) in White Matter Density

### Plasma FGF21 is released from the splanchnic circulation in response to exercise and regulated by insulin and glucagon: a human study

P. Plomgaard<sup>1</sup>, J. Hansen<sup>1</sup>, J.O. Clemmesen<sup>2</sup>, N.H. Secher<sup>3</sup>, B.K. Pedersen<sup>4</sup>,  
<sup>1</sup>Department of Clinical Biochemistry, <sup>2</sup>Department of Hepatology, Rigshospitalet, <sup>3</sup>Department of Anaesthesiology, <sup>4</sup>Center of Inflammation and Metabolism, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** FGF21 is a circulating protein that has beneficial metabolic effects. An increase in plasma FGF21 has been observed with fasting and exercise; probably secreted from the liver. However the regulation of plasma FGF21 in normal physiology is not completely understood. Aims: 1) to demonstrate that FGF21 is released from the liver in response to an acute exercise bout. 2) to investigate if glucagon and/or insulin regulates plasma FGF21 levels.

**Materials and methods:** A: Ten healthy young males performed a 2 hour exercise bout, with a hepatic vein and arterial catheter allowing drawing blood repeatedly and simultaneously before, during and after a 2 hour bicycling exercise bout at 60%  $\text{VO}_2\text{max}$ . Hepatic blood flow was determined by use of indocyanine green. B: Ten subjects underwent 4 trails resting in supine position: 1) 1 hour of glucagon infusion 2) 1 hour of glucagon combined with a co-infusion of somatostatin 3) 1 hour of somatostatin infusion, 4) 1 hour of saline infusion (control). Blood samples were obtained every hour during the 8 hour experimental day. Plasma insulin, glucagon and FGF21 was measured by immunoassays.

**Results:** The exercise study with the arterial-hepatic venous difference demonstrated a higher level of insulin and glucagon in the hepatic vein compared to the artery. During the exercise bout a decrease in plasma insulin and an increase in plasma glucagon were observed, which normalised in the recovery after the bicycling exercise. Plasma FGF21 gradually increased during the exercise bout to a 5-fold increase and rapidly returned to basal level into recovery. Calculating the arterial- hepatic vein differences revealed a net release of FGF21 at rest before the bicycling commenced. The secretion of FGF21 increased gradually during the 2 hours of bicycling and returned to baseline in the recovery. The hepatic blood flow did not change during the experiment.

In infusion study 1 (glucagon alone), plasma glucagon increased during the 1 hour infusion followed by compensatory increase in plasma insulin. In trial 2 (glucagon + somatostatin) glucagon increased similarly to trail 1, with no compensatory insulin increase. In trial 3 (somatostatin alone) both insulin and glucagon decreased, compared to trail 4 (saline), where no changes were observed. Interestingly, plasma FGF21 increased with a similar kinetics as observed with exercise, only when glucagon was infused and the compensatory insulin response was blocked by somatostatin. A delayed increase in plasma FGF21 was observed in trail 3 (somatostatin alone).

**Conclusion:** Here we present the first human data demonstrating by a direct measurement across the splanchnic organs that FGF21 is released. The liver is the most likely organ to be responsible; however contributions from other organs as the spleen, intestines or pancreas cannot be excluded. Furthermore our data demonstrate that the splanchnic circulation releases exercise-induced FGF21 in humans. Exercise increased plasma glucagon concomitantly with a decrease in insulin and simulating this condition in resting healthy men, increased plasma FGF21 with a similar kinetics as observed with exercise. These data add to the understanding of FGF21 in human physiology.

### Selective expression of ROCK1 in the liver promotes insulin resistance and hepatic steatosis in diet-induced obese mice

I.S. Lima<sup>1,2</sup>, S.-H. Lee<sup>3</sup>, M. Chung<sup>1</sup>, M.J. Kim<sup>1</sup>, M.P. Macedo<sup>2,4</sup>, Y.B. Kim<sup>1</sup>,  
<sup>1</sup>Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center - Harvard Medical School, Boston, USA, <sup>2</sup>CEDOC - Chronic Diseases Research Center, Faculdade de Ciências Médicas - Universidade Nova de Lisboa, Portugal, <sup>3</sup>Department of Internal Medicine - Division of Endocrinology and Metabolism, The Catholic University of Korea, Seoul, Republic of Korea, <sup>4</sup>Portuguese Diabetes Association - Education and Research Center (APDP-ERC), Lisboa, Portugal.

**Background and aims:** In the European Union approximately 29 million people suffer from a chronic liver condition. The prevalence of non-alcoholic fatty liver disease (NAFLD) is 2-44% in the European population and 42.6-69.5% in people with type 2 diabetes. Furthermore, over 50% of adults in the European Union are overweight or obese. Obesity is a risk factor for NAFLD and is strongly associated with insulin resistance. Our previous data showed that liver-specific deletion of Rho-kinase 1 (ROCK1) caused a significant improvement in insulin sensitivity and hepatosteatosis in obese mice induced by a high-fat diet. The current study was designed to further determine the physiological role of hepatic ROCK1 in regulating whole-body glucose and lipid metabolism.

**Materials and methods:** Mice expressing a constitutively active (CA) mutant of ROCK1 in liver were studied. These mice started a high-fat diet (HFD) at 6 weeks of age for a period of 12 weeks. Insulin sensitivity and glucose tolerance were assessed and body weight and glucose levels were also monitored. Hepatic and serum content in triglycerides and cholesterol was determined. Hematoxylin and eosin stain (H&E stain) of liver sections from control and CA-ROCK1 mice was performed. Gene expression of key molecules involved in lipid metabolism was also determined for control and CA-ROCK1 mice.

**Results:** Liver-specific CA-ROCK1 mutant mice exhibited higher body weight 2 weeks after HFD feeding ( $21.6 \pm 0.4$  g N=10 vs.  $23.6 \pm 0.6$  g N=10,  $p = 0.01$ ) and this difference was increased by the period on HFD ( $33.8 \pm 1.28$  g N=10 vs.  $39.4 \pm 1.4$  g N=10,  $p = 0.01$ ). Blood glucose was also increased after 4 weeks of HFD ( $148.0 \pm 3.7$  mg/dL N=10 vs.  $165.4 \pm 7.1$  mg/dL N=10,  $p = 0.05$ ). These mice were insulin resistant, as revealed by the failure of blood glucose levels to decrease after insulin injection (AUC  $16058 \pm 594.0$  N=6 vs.  $20581 \pm 1102$  N=10,  $p = 0.01$ ), but normal glucose tolerant. These effects were accompanied by hyperinsulinemia, increased hepatic triglycerides ( $430.2 \pm 40.7$  mg/dL N=9 vs.  $674.1 \pm 108.0$  mg/dL N=8,  $p = 0.05$ ) and serum cholesterol ( $94.2 \pm 8.4$  mg/dL N=10 vs.  $131.4 \pm 12.6$  mg/dL N=9,  $p = 0.05$ ) in the CA-ROCK1 mice. Histological analysis showed that hepatic steatosis by high-fat feeding was greatly increased in liver-specific CA-ROCK1 mutant mice compared with control mice. Moreover, activation of ROCK1 in liver caused an increase in gene expressions of key lipogenic enzymes, including FAS (fatty acid synthase) and ACC (Acetyl-CoA carboxylase). However, overexpression of hepatic CA-ROCK1 had no effect on gene expression involved in fatty acid oxidation and fatty acid uptake.

**Conclusion:** Our data demonstrate that activation of hepatic ROCK1 is sufficient to cause insulin resistance and hepatic steatosis in diet-induced obese mice, suggesting an important role for hepatic ROCK1 in regulating fuel me-

tabolism. Thus, hepatic ROCK1 could be a molecular target for the treatment of obesity and obesity-related metabolic disorders such as NAFLD.

### Prediabetes and type 2 diabetes are associated with increased content of dipeptide carnosine in human skeletal muscle

T. Kurdiova<sup>1</sup>, B. deCourten<sup>2</sup>, S. Vallova<sup>1</sup>, M. Balaz<sup>1</sup>, M. Vician<sup>3</sup>, M. Vlcek<sup>1</sup>, V. Belan<sup>4</sup>, I. Klimes<sup>1</sup>, D. Gasperikova<sup>1</sup>, W. Derave<sup>5</sup>, J. Ukropec<sup>1</sup>, B. Ukropcova<sup>1</sup>;

<sup>1</sup>Obesity section, Diabetes laboratory, Institute of Experimental Endocrinology, SAS, Bratislava, Slovakia, <sup>2</sup>Monash University, Melbourne, Australia, <sup>3</sup>Department of Surgery, Slovak Medical University, <sup>4</sup>Radiology Clinic, University Hospital, Bratislava, Slovakia, <sup>5</sup>Department of Movement and Sports Sciences, Ghent University, Belgium.

**Background and aims:** Carnosine ( $\beta$ -alanine L-histidine) is dipeptide commonly found in mammalian tissues and enriched in skeletal muscle. It has been shown to suppress many biochemical processes that accompany ageing and age related chronic diseases. Recent animal studies suggested the importance of carnosine supplementation for glycemic control and prevention of type 2 diabetes. Our aim was to analyze skeletal muscle carnosine content in middle aged (45.1 $\pm$ 1.2 years) lean healthy (BMI 24.5 $\pm$ 0.4 kg.m<sup>-2</sup>), overweight/obese (BMI 29.3 $\pm$ 0.8 kg.m<sup>-2</sup>), prediabetic (BMI 32.1 $\pm$ 0.7 kg.m<sup>-2</sup>) and type 2 diabetic (BMI 30.7 $\pm$ 0.9 kg.m<sup>-2</sup>) individuals (n=9/group).

**Materials and methods:** Metabolic phenotyping included euglycemic hyperinsulinemic clamp (insulin sensitivity), oral glucose tolerance test, MRI (abdominal adipose tissue content & distribution) and indirect calorimetry (resting energy expenditure). Physical activity was monitored with accelerometers and validated questionnaire. Samples of *m.vastus lateralis* were obtained by needle biopsy. Skeletal muscle carnosine content (HPLC) and serum CN1 carnosinase activity were determined. Mitochondrial biogenesis related genes as well as relative muscle mitochondrial content were assessed by qPCR.

**Results:** Skeletal muscle carnosine content progressively increased in patients with prediabetes (by 30%, NS) and type 2 diabetes (by 39%, p<0.05) as compared to lean individuals. It was positively associated with BMI (R=0.44, p=0.007), % body fat (R=0.35, p=0.037), abdominal subcutaneous adipose tissue content (R=0.38, p=0.024) as well as with atherogenic index (R=0.35, p=0.04), fasting and 2h glycaemia (R=0.39, p=0.02; R=0.55, p=0.002). Muscle carnosine content was inversely associated with insulin sensitivity (R=-0.42, p=0.006), percentage of high and moderate intensity ambulatory activity (R=-0.42, p=0.011) as well as with resting energy expenditure (R=-0.58, p<0.001). Associations of muscle carnosine with 2h glycaemia and resting energy expenditure were at least in part independent on BMI. Muscle carnosine levels were not related to mitochondrial content and *Pgc1 $\alpha$*  and *cytochrome C* mRNA. Serum CN1 carnosinase activity was not regulated in obesity and T2D.

**Conclusion:** We observed increased skeletal muscle carnosine content in patients with type 2 diabetes. This might represent a potential adaptive mechanism counteracting disturbances related to diabetic status.

### Effect of liraglutide 3.0/1.8 mg on body weight and cardiometabolic risk factors in overweight/obese adults with type 2 diabetes: SCALE diabetes randomised, double-blind, 56-week trial

B. Bode<sup>1</sup>, R. DeFronzo<sup>2</sup>, R. Bergenstal<sup>3</sup>, R. Kushner<sup>4</sup>, A. Lewin<sup>5</sup>, T.V. Skjoth<sup>6</sup>, C.B. Jensen<sup>6</sup>, M. Davies<sup>7</sup>;

<sup>1</sup>Atlanta Diabetes Associates, Atlanta, <sup>2</sup>Texas Diabetes Institute, San Antonio, <sup>3</sup>Park Nicollet Institute, St Louis Park, <sup>4</sup>Northwestern University, Chicago, <sup>5</sup>National Research Institute, Los Angeles, USA, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>University of Leicester, UK.

**Background and aims:** Obesity increases the risk of multiple comorbidities including type 2 diabetes mellitus (T2D) and cardiovascular (CV) disease. Weight loss of 5-10% can decrease the risk, but is difficult to achieve and maintain by lifestyle changes alone. Liraglutide at doses up to 1.8 mg is approved for treatment of T2D and is associated with weight loss in addition to glycaemic control. This study evaluated the effects of liraglutide (3.0 and 1.8 mg) as adjunct to diet and exercise on weight loss (primary endpoint) and cardiometabolic risk factors (waist circumference, glycaemia, blood pressure [BP], pulse, fasting lipids, and CV biomarkers) in overweight/obese adults with T2D.

**Materials and methods:** Subjects were randomised 2:1:1 to liraglutide 3.0 mg, 1.8 mg, or placebo for 56 weeks; all arms included a 500 kcal/day deficit diet and exercise.

**Results:** A total of 846 individuals (male 50%, mean age 54.9 years, BMI 37.1 kg/m<sup>2</sup> [27.0–67.6], HbA1c 7.9%, diabetes duration 7.3 years [0.2–36.5], 11.5% on diet and exercise, 57.3% on metformin alone, and 31.2% on combination OADs) were randomised into the trial. At week 56, least square (LS) mean weight loss was 5.9%, 4.6% and 2.0% for 3.0 mg, 1.8 mg, and placebo, respectively; 3.0 mg and 1.8 mg were superior to placebo (p<0.0001); 3.0 mg was superior to 1.8 mg (p=0.0024). Weight loss was accompanied by reductions in waist circumference of 6.0, 4.9, and 2.8 cm respectively; 3.0 mg and 1.8 mg were superior to placebo (p $\le$ 0.0004); 3.0 mg was superior to 1.8 mg (p=0.0224). HbA1c decreased by 1.32%, 1.13% and 0.38% from baseline with 3.0 mg, 1.8 mg, and placebo respectively (p<0.0001 vs. placebo; p=0.0125 for 3.0 mg vs. 1.8 mg). At baseline, systolic (S) /diastolic (D) BP and lipids were well controlled. SBP reductions were 3.0, 3.1, and 0.4 mmHg from baseline (~130 mmHg) for the 3 arms respectively; greater with 3.0 mg and 1.8 mg (p<0.05 vs. placebo), with no significant differences between treatments in DBP at week 56. Similar LS mean pulse increases of 2.0 and 2.2 beats/min occurred with liraglutide 3.0 and 1.8 mg vs. -1.5 beats/min for placebo (p<0.0001 vs. placebo) (observed means, LOCF: 2.0 and 2.1 vs. -1.4 beats/min, respectively). Liraglutide 3.0 mg reduced total cholesterol, VLDL and triglycerides (4%, 13%, 14%, p<0.05) and increased HDL (+3%, p<0.05) vs. placebo whereas 1.8 mg had no effects. Liraglutide had no significant effects on LDL and FFA. Reductions in high-sensitivity C reactive protein occurred with liraglutide 3.0 and 1.8 mg (-27% and -25% vs. placebo, p $\le$ 0.0002). Decreases in plasminogen activator inhibitor-1 (-24%, p=0.0004) and urinary albumin/creatinine ratio (-20%, p=0.0086) occurred only with liraglutide 3.0 mg vs. placebo; No treatment effects on adiponectin occurred. Fibrinogen increased by 5% vs. placebo with 3.0 mg only (p=0.046).

**Conclusion:** After 56 weeks' treatment, liraglutide 3.0 mg, as an adjunct to diet and exercise, caused significant weight loss that was associated with additional benefits for multiple cardiometabolic risk factors compared to liraglutide 1.8 mg and placebo in overweight/obese adults with T2D.

**Efficacy and safety of liraglutide versus placebo in subjects with type 2 diabetes and moderate renal impairment (LIRA-RENAL): a randomised trial**

G. Umpierrez<sup>1</sup>, S. Atkin<sup>2</sup>, S. Bain<sup>3</sup>, P. Rossing<sup>4</sup>, D. Scott<sup>5</sup>, M. Shamkhalova<sup>6</sup>, H. Bosch-Traberg<sup>7</sup>, A. Syrnén<sup>7</sup>, M. Davies<sup>8</sup>;  
<sup>1</sup>Emory University School of Medicine, Atlanta, USA, <sup>2</sup>Weill Cornell Medical College Qatar, Doha, Qatar, <sup>3</sup>Abertawe Bro Morgannwg University NHS Trust, Swansea, UK, <sup>4</sup>Diabetes, Steno Research Center, Gentofte, Denmark, <sup>5</sup>Clinical Research Development Associates, Rosedale, USA, <sup>6</sup>Endocrinology Research Centre, Moscow, Russian Federation, <sup>7</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>8</sup>University of Leicester, UK.

**Background and aims:** Renal impairment in type 2 diabetes mellitus (T2DM) limits the available glucose lowering treatment options. The rationale for this trial was to establish the efficacy and safety of liraglutide 1.8 mg as add-on to existing glucose lowering drugs and/or insulin therapy in subjects with inadequately controlled T2DM and moderate renal impairment (estimated glomerular filtration rate [eGFR] 30–59 mL/min/1.73 m<sup>2</sup>; MDRD).

**Materials and methods:** In this 26-week, double-blind, multicentre, multinational, parallel group trial, adults with T2DM and moderate renal impairment, BMI of 20–45 kg/m<sup>2</sup>, HbA1c of 7.0–10.0% and on stable diabetes medication (unchanged medication and dose for ≥90 days prior to screening) were randomised 1:1 to receive either once-daily liraglutide 1.8 mg or placebo. Liraglutide was initiated at 0.6 mg/day and incremented by 0.6 mg/day on a weekly basis to the target dose of 1.8 mg/day. The primary endpoint was change in HbA1c from baseline (BL) to Week 26 (Table).

**Results:** 279 subjects were randomised (140 to liraglutide; 139 to placebo). All subjects, except for 2 in the placebo group, were exposed to trial medication and included in the analysis. Liraglutide 1.8 mg showed superior glycaemic control relative to placebo in subjects with moderate renal impairment with a low risk of hypoglycaemia and reduced body weight (Table). The most common adverse events (AEs) were GI side effects (liraglutide 35.7%, placebo 17.5%), mostly nausea and vomiting which resolved quickly. There was a higher incidence of AE leading to withdrawals in the liraglutide group (13.6%), compared to placebo (2.9%). No deterioration in renal function was observed (eGFR change from BL: -1% liraglutide; +1% placebo p=0.36). There was an increase from baseline in amylase and lipase levels in the liraglutide group that was not seen in the placebo group. One subject with elevated lipase (>3x ULN) and amylase (>2x ULN) at baseline was diagnosed with chronic pancreatitis on Day 11 of treatment with liraglutide.

**Conclusion:** Liraglutide 1.8 mg showed superior HbA1c and weight reduction with no unexpected safety or tolerability issues including no worsening of renal function in subjects with moderate renal impairment over 26 weeks. The efficacy, low incidence of hypoglycaemia and safety of liraglutide in subjects with T2DM and moderate renal impairment was demonstrated.

<sup>1</sup>The Diabetes Unit, Hadassah Hebrew University - Medical Center, Jerusalem, Israel, <sup>2</sup>Brigham and Women's Hospital, Harvard Medical School, Boston, USA, <sup>3</sup>Hospital Italiano de Buenos Aires, Argentina, <sup>4</sup>Endocrinology Research Center, Moscow, Russian Federation, <sup>5</sup>St. Georges University of London, UK, <sup>6</sup>AstraZeneca, Wilmington, <sup>7</sup>AstraZeneca LP, Wilmington, <sup>8</sup>BMS, Princeton, USA, <sup>9</sup>The Chinese University of Hong Kong, Hong Kong.

**Background and aims:** It was previously suggested that DPP-4 inhibitors may have a protective effect on diabetic kidney disease. Herein we studied the renal outcomes of 16,492 patients (pts) with type 2 diabetes, who were prospectively followed in the SAVOR TIMI 53 trial for a median of 2.1 years. Predefined renal outcomes (safety and efficacy) were: doubling of serum creatinine, the composite of initiation of chronic dialysis, renal transplant or serum creatinine >6.0 mg/dl, reduction from baseline of albumin/creatinine ratio (ACR) and categorical changes in ACR.

**Materials and methods:** At baseline, pts were stratified into 3 groups according to renal function: normal or mild renal dysfunction (RD) [eGFR >50 mL/min; N=13,916], moderate RD [eGFR 30–50 mL/min; N=2,240], or severe RD [eGFR <30 mL/min; N=336]. Baseline categorical ACR was normal (ACR <30 mg/G) in 9,696 (58.8%) pts, microalbuminuria (ACR 30–300 mg/G) in 4,426 (26.8%) pts and macroalbuminuria (ACR >300 mg/G) in 1,638 (9.9%) pts.

**Results:** Patients assigned to saxagliptin (SAXA) vs. placebo (PLB) were more likely to improve their categorical ACR (11% vs. 9% p<0.01) and less likely to worsen their categorical ACR (13% vs. 16% p<0.01). In patients with microalbuminuria at baseline, treatment with saxagliptin was associated with greater reversal to normoalbuminuria: at 1 year, 31.3% vs. 25.7%, respectively (p<0.0001). These results were maintained for 2 years and at end of trial (EOT). At an “on treatment analysis”, the improvements in the SAXA group compared with the PLB group were observed in ACR and in all eGFR categories and at all time points (Table). Pearson correlation analysis showed that the change in albuminuria was independent of the change in HbA1c at 1 year, 2 years, and EOT (Pearson coefficients: 0.015, 0.025, and 0.033, respectively). There were no differences in the other predefined renal outcomes between the SAXA and PLB groups: doubling of serum creatinine [153 (0.92%) vs. 147 (0.89%), HR 1.04 (0.83–1.30)], the composite of initiation of chronic dialysis, renal transplant or serum creatinine >6.0 mg/dl [51 (0.31%) vs. 55 (0.33%), HR 0.90 (0.61–1.32)] or the composite end point of death and all of the above [573 (3.47%) vs. 525 (3.20%), HR 1.08 (0.96–1.22)].

**Conclusion:** In the SAVOR TIMI 53 trial, saxagliptin improved ACR and had a neutral effect on the other predefined renal outcomes. The beneficial effect of saxagliptin on albuminuria seems to be independent of its effect on glycaemia.

Mean Change from Baseline of ACR (mg/G) by eGFR Categories, Time Point and Treatment Groups (On-Treatment Analysis)

| eGFR group N (at baseline)   | Time point | Treatment group | N    | Mean change in ACR from baseline (mg/G) | Difference in mean change in ACR between SAXA and Placebo (mg/G) | 95% CI of difference in ACR between SAXA and Placebo (mg/G) | P values for difference in ACR between SAXA and Placebo |

### Liraglutide 3.0 mg reduces severity of obstructive sleep apnoea and body weight in obese individuals with moderate or severe disease: SCALE sleep apnoea trial

A. Blackman<sup>1</sup>, G. Foster<sup>2</sup>, G. Zammit<sup>3</sup>, R. Rosenberg<sup>4</sup>, L. Aronne<sup>5</sup>, T. Wadden<sup>6</sup>, B. Claudius<sup>7</sup>, C.B. Jensen<sup>7</sup>, E. Mignot<sup>8</sup>;

<sup>1</sup>Toronto Sleep Institute, MedSleep, Canada, <sup>2</sup>School of Medicine, Temple University, Philadelphia, <sup>3</sup>Clinilabs Sleep Disorders Institute, New York, <sup>4</sup>NeuroTrials Research, Atlanta, <sup>5</sup>Weill Cornell Medical College, New York, <sup>6</sup>Perelman School of Medicine, University of Pennsylvania, Philadelphia, USA, <sup>7</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>8</sup>School of Medicine, Stanford University, Palo Alto, USA.

**Background and aims:** Obesity is strongly associated with obstructive sleep apnoea (OSA) and weight loss has been shown to reduce disease severity. This randomised, double-blind, parallel-group trial compared the effects of liraglutide 3.0 mg to placebo, both as adjunct to diet (500 kcal/day deficit) and exercise, on OSA severity and body weight. The primary endpoint was change in apnoea-hypopnoea index (AHI, number of apnoea/hypopnoea events per hour of sleep) after 32 weeks (Table).

**Materials and methods:** Obese individuals without diabetes who had moderate (AHI 15–29.9 events/h) or severe (AHI  $\geq$ 30 events/h) OSA and were unwilling/unable to use continuous positive airway pressure therapy were randomised 1:1 to liraglutide 3.0 mg or placebo for 32 weeks. Of 359 randomised individuals (mean baseline age 48.5 years, males 71.9%, AHI 49.2 events/h, severe OSA 67.1%, body weight 117.6 kg, BMI 39.1 kg/m<sup>2</sup>, HbA1c 5.7%), 276 (76.9%) completed the trial.

**Results:** After 32 weeks, the reduction in AHI was significantly greater with liraglutide 3.0 mg than with placebo (-12.2 vs. -6.1 events/h,  $p=0.0150$ ) (Table). Supporting the reduction in AHI, endpoints related to oxygen saturation, polysomnographic measures of sleep quantity and efficiency, and quality of life also improved with liraglutide 3.0 mg, albeit statistically non-significantly compared to placebo. Liraglutide 3.0 mg produced significantly greater mean percentage weight loss compared to placebo (-5.7 vs. -1.6%,  $p<0.0001$ ) and enabled more individuals to reach  $\geq$ 5% and  $>$ 10% weight loss targets after 32 weeks. Post-hoc analysis showed a relationship between weight loss and change in AHI. In addition, there were significantly greater reductions in neck circumference, HbA1c and systolic blood pressure (SBP) with liraglutide 3.0 mg versus placebo. After 32 weeks, heart rate increased by about 2 beats/min with liraglutide 3.0 mg compared to placebo. The safety profile of liraglutide 3.0 mg was generally consistent with that previously seen with liraglutide in type 2 diabetes. Nausea and diarrhoea were the most common adverse events with liraglutide 3.0 mg (27% and 17% of individuals, respectively); most events were mild/moderate and transient.

**Conclusion:** As an adjunct to diet and exercise, liraglutide 3.0 mg was generally well tolerated and produced significantly greater reductions than placebo in AHI, body weight, SBP and HbA1c in obese individuals with moderate/severe OSA. The results also indicate that weight loss improves OSA-related parameters.

Table. Effects of liraglutide 3.0 mg on parameters related to OSA, body weight, glycaemia and blood pressure after 32 weeks of treatment.

### The incretin hormone GLP-1 is upregulated in critically ill ICU patients and regulates the metabolic response during acute inflammation: central role of IL-6

F. Kahles, C. Meyer, J. Möllmann, C. Leberherz, H.M. Findeisen, S. Diebold, A. Koch, F. Tacke, C. Trautwein, N. Marx, M. Lehrke; University Hospital Aachen, Germany.

**Background and aims:** Hypoglycemia predicts adverse outcome in critically ill patients including those with sepsis or myocardial infarction. The underlying mechanism for inflammation-mediated hypoglycaemia are incompletely understood. Experimental data suggest that hyperinsulinemia might play a role here and that LPS induces insulin secretion in a glucose-dependent manner. Since the incretin hormone Glucagon-like-peptide 1 (GLP-1) also causes insulin secretion, we speculated that GLP-1 may be of relevance for inflammation dependent hypoglycaemia.

**Materials and methods:** C57BL/6J, IL6 knockout (KO) and IL1 receptor KO mice were given i.p. injections of saline or lipopolysaccharides (LPS) (100 $\mu$ g/kg), IL1 $\beta$ , IL6 and TNF $\alpha$  (all 4  $\mu$ g/kg), respectively (n=6–12/ group). A total of 155 critically ill patients (112 with sepsis, 43 without sepsis) were studied prospectively upon admission to the medical intensive care unit (ICU) and compared to 134 healthy controls.

**Results:** LPS upregulated GLP-1 secretion in C57BL/6J mice with a maximal 3,4 fold increase ( $p<0,001$ ) 120 minutes post LPS injection, which was paralleled by elevated insulin ( $p<0,001$ ) and decreased glucose ( $p<0,001$ ) levels. A similar increase of serum GLP-1 and insulin was found after IL1 $\beta$  or IL6 administration. Studies in IL1-R KO - and IL6 KO mice showed that LPS dependent GLP-1 secretion was selectively dependent on IL6 but not on IL1 secretion. Consistently IL6 ( $p<0,05$ ) but not IL1 $\beta$  or LPS stimulated GLP-1 secretion from intestinal L cells in vitro. To evaluate the functional relevance of GLP-1 for glucose metabolism we inhibited its degradation by administration of the DPP4 inhibitor sitagliptin (40mg/kg), which augmented LPS-induced insulin secretion and blood glucose lowering in mice. Conversely, injection of the GLP-1 receptor antagonist exendin 9-39 (100nM/kg) markedly blunted LPS-dependent increase of serum insulin and prevented endotoxic hypoglycaemia. We next asked whether GLP-1 would also be upregulated in humans under inflammatory conditions. Indeed, critically ill patients admitted to the intensive care unit showed a 6.9 fold increase of total GLP-1 plasma levels in comparison to healthy controls (97.0 pM versus 13.9 pM;  $p<0.001$ ). Among the ICU cohort higher GLP-1 plasma concentrations were found in patients presenting with sepsis (101.1 pM versus 67.5 pM in none septic patients) and more severe disease (109 pM in patients with Apache II  $>$  10 versus 73,4 pM in patients with Apache II  $<$  10;  $p=0.002$ ). GLP-1 levels were associated with IL6 concentrations ( $p<0.001$ ) in the whole ICU cohort and with insulin ( $p<0,05$ ) in none septic ICU patients.

**Conclusion:** GLP-1 provides a new metabolic cross talk between the gut and the immune system with LPS dependent hypoglycaemia being dependent on an inflammatory cascade including IL6, GLP-1 and insulin. GLP-1 plasma concentrations are elevated in critically ill patients, correlating with disease severity.

**Saxagliptin in patients with prior heart failure - observations from the SAVOR-TIMI 53 trial**

B.M. Scirica<sup>1</sup>, E. Braunwald<sup>1</sup>, I. Raz<sup>2</sup>, O. Mosenzon<sup>2</sup>, A. Cahn<sup>2</sup>, J. Lopez-Sendon<sup>3</sup>, B. Hirshberg<sup>4</sup>, P.A. Pollack<sup>4</sup>, P. Steg<sup>5</sup>, A. Umez-Eronini<sup>1</sup>, K. Im<sup>1</sup>, D.L. Bhatt<sup>1</sup>;

<sup>1</sup>Medicine, Brigham and Women's Hospital, Boston, USA, <sup>2</sup>Medicine, Hadassah Medical Center, Jerusalem, Israel, <sup>3</sup>Hospital Universitario La Paz, Madrid, Spain, <sup>4</sup>AstraZeneca, Wilmington, USA, <sup>5</sup>Medicine, Département Hospitalo-Universitaire FIRE, INSERM U-1148, Université Paris-Diderot, and Hôpital Bichat, Paris, France.

**Background and aims:** Heart failure (HF) and T2DM frequently co-exist; however, there are limited data regarding the safety of an antihyperglycemic drugs in patients with T2DM and prior HF and thus clinical uncertainty over optimal glycaemic control strategies.

**Materials and methods:** The SAVOR-TIMI 53 trial evaluated the safety and efficacy of saxagliptin vs. placebo in 16,492 patients with T2DM, at high risk of cardiovascular disease, of whom patients with HF at baseline were a pre-specified sub-group. The 1° endpoint was CV death, MI, or ischemic stroke. The 2° endpoint included the 1° endpoint together with hospitalization for HF, unstable angina, or coronary revascularization. Median follow-up was 2.1 years. The 1° and 2° endpoints were adjudicated by a blinded events committee.

**Results:** 2,105 patients (12.8%) reported prior HF at baseline. Patients with prior HF were older and more likely to have established CV disease and renal impairment, with no difference in duration of DM or HbA1c. More patients with prior HF were on ASA, statins, B-blockers, and insulin, but fewer on metformin or sulfonylurea. There was no difference in the duration of DM and only a small difference (0.1%) in baseline HbA1c. Patients with prior HF were at double the risk for all CV events compared to patients with no prior HF. (Table) The relative effect of saxagliptin versus placebo was similar in patients with and without prior HF for the 1° and 2° endpoints. The increased risk of hospitalization for heart failure with saxagliptin was also similar regardless of prior HF, though the absolute risk difference with saxagliptin was greater in patients with prior HF. The incidence of hypoglycaemia, adverse events, and A1c reductions are presented in the Table.

**Conclusion:** Despite being at substantially increased risk of CV complications, saxagliptin neither increased nor decreased the risk of the 1° and 2° endpoints compared to placebo in patients with T2DM and prior HF. Similarly, there was no relative differential in the increased risk of hospitalization for HF with saxagliptin, though the absolute risk was greater. These data provide important information regarding the safety and efficacy of an antihyperglycemic agent in a traditionally difficult to treat population.

### A randomised clinical trial on the efficacy of an adapted bowel preparation for diabetic patients undergoing a colonoscopy

J.A. Flores-Le Roux<sup>1</sup>, M.A. Alvarez<sup>2</sup>, J.J. Chillarón<sup>1</sup>, A. Seoane<sup>2</sup>, D. Benaiges<sup>1</sup>, L. Carot<sup>2</sup>, S. Bacchiddu<sup>2</sup>, J. Pedro-Botet<sup>1</sup>;

<sup>1</sup>Endocrinology, <sup>2</sup>Gastroenterology, Hospital del Mar, Barcelona, Spain.

**Background and aims:** Need for colonoscopy is common among diabetic patients because of the high prevalence of gastrointestinal symptoms but they are more likely to have inadequately cleansed bowels which leads to a repeat procedure that will increase patients' exposure to unnecessary risk and costs. No studies have evaluated the importance of dietary recommendations before the procedure or the need for hypoglycaemic drug adjustments during preparation. A specific bowel preparation for patients with diabetes with special attention to dietary recommendations and modification of hypoglycaemic medication could facilitate patient adherence and consequently improve bowel cleansing. We evaluated the efficacy and safety of an adapted protocol for colon cleansing in diabetic patients.

**Materials and methods:** Single-blind experimental design, 80 persons with diabetes who were scheduled for colonoscopies were randomly assigned to either the experimental diabetic colon preparation (DMe) or the standard colon preparation (DMs). A group of 40 non-diabetic subjects was also included (noDM). DMe patients were instructed to follow a specific low-residues diet, with special attention to carbohydrate intake, without liquid diet the day before colonoscopy, and to modify the doses of hypoglycaemic medication prior to the procedure. DMs subjects received the standard recommendations including general information on low-residues diet and liquid diet the day before the procedure with no counselling on hypoglycaemic medication adjustments. All patients received the same medication for bowel preparation. Endoscopists blinded to the type of preparation scored the type of residual stool and the percentage of bowel wall visualized for each segment of colon and for the overall examination using the Boston score. Hypoglycaemic episodes during preparation were recorded.

**Results:** 73 diabetic patients were randomized: 37 in DMe group and 36 in the DMs group. 40 noDM subjects were also included. NoDM patients were younger (56±15 vs 68±10 years, p<0.001), less frequently male (55% vs 74%, p<0.001) and had a lower comorbidity index (1 vs 14, p=0.07) than diabetic subjects. Subjects in the DMe and DMs groups were comparable in all the analyzed characteristics (table). Overall, the noDM group had a higher Boston score than diabetic subjects (8,3±1,5 vs 7±3,2, p=0.010). DMe patients had a higher Boston score than DMs (7,6±1,5 vs 6,4±2,8, p=0.02) a lower number of non-diagnostic colonoscopies (2,8% vs 19,4%, p=0.028) which was similar to that of noDM subjects (2,7%, p=0.93).

**Conclusion:** An adapted bowel preparation protocol for diabetic patients undergoing a colonoscopy can achieve a better visualization of the colon wall, which in turn reduces the need for repeat procedures to a level equivalent to the general population.

**Dissociation pattern in resting-state default mode network connectivity in type 2 diabetes patients**

Y. Cui, Y. Jiao, S. Ju, G.-J. Teng;

Radiology, Southeast University, Nanjing, China.

**Background and aims:** Type 2 diabetes mellitus (T2DM) has been shown to be associated with an increased risk of cognitive impairment. Patients with impaired cognition often show default-mode network (DMN) disruption. This study aimed to investigate the integrity of the DMN by using independent component analysis (ICA) methods in patients with T2DM and to correlate the DMN functional connectivity (FC) changes with neurocognitive performance and clinical variables.

**Materials and methods:** The current study was approved by the local ethics committee and written informed consent was obtained from all participants. Twenty-nine T2DM patients and thirty well-matched healthy controls were included in the study and underwent resting-state functional MRI (rs-fMRI) in a 3 Tesla unit. All participants underwent a detailed battery of neuropsychological tests. Clinical parameters such plasma glucose, HbA1c, insulin resistance, BMI and cholesterol levels were also collected. A group ICA method was used to extract the DMN of all participants. Two components were identified to be related to two sub-networks of the DMN, including the anterior and posterior parts of the DMN. Z-maps of the two sub-networks were compared between the two groups and correlated with the neurocognitive performance and clinical parameters by using Pearson correlation analysis.

**Results:** Patients with T2DM showed significantly increased frontal connectivity around the medial prefrontal cortex (MPFC) in the anterior DMN (aDMN) and significantly decreased connectivity in the posterior cingulate cortex (PCC) and angular gyrus in the posterior DMN (pDMN) (Figure 1). The FC strength in aDMN was found to be negatively correlated with the score on complex-figure-test ( $r=-0.46$ ) and positively correlated with the FPG ( $r=0.44$ ). On the other hand, the FC strength in pDMN was negatively correlated with the disease duration ( $r=-0.55$ ) and the time spent on trail-making-test (part B) ( $r=-0.68$ ). These associations were independent of vascular risk factors and cerebral small vessel disease.

**Conclusion:** The current study demonstrated the dissociation between anterior and posterior DMN sub-networks in patients with T2DM. Our results highlight the important role of the DMN in the pathophysiology of T2DM-related cognitive impairment and suggest that abnormal DMN activity may be a trait associated with T2DM patients.

Fig. 1 aDMN (upper row) and pDMN (lower row) differences between T2DM patients and healthy controls ( $P < 0.05$ , AlphaSim corrected)

## 189

**Disrupted circadian arousal patterns comorbid with diabetes**M. Kadono<sup>1</sup>, G. Hasegawa<sup>2</sup>, M. Fukui<sup>3</sup>, N. Nakamura<sup>3</sup>;

<sup>1</sup>Internal Medicine, Ayabe City Hospital, <sup>2</sup>Endocrinology and Metabolism, Kyoto Second Redcross Hospital, <sup>3</sup>Endocrinology and Metabolism, Kyoto Prefectural University of Medicine, Japan.

**Background and aims:** Sleep-wake disturbances and disruptions of circadian rhythms are now recognized to be highly prevalent comorbidities in patients with medical illness. Likewise, it is supposed that circadian arousal rhythms were disrupted in parallel with metabolic and vascular vulnerability in diabetes. We aimed to explore disrupted circadian arousal patterns comorbid with diabetes.

**Materials and methods:** Ninety-one diabetic outpatients with BMI < 25 kg/m<sup>2</sup> in our diabetes clinic wore an actigraph for consecutive 7 days (men: 41, type 1 diabetes: 3, age: 68.7 ± 8.2 yrs). Patients with depression, dementia, liver cirrhosis, renal failure, blindness, and shift work were excluded. Activity recording derived from an actigraph was aggregated in hourly bins counting

the number of minutes containing any activity. Next, an average 24-hour arousal profile was calculated by averaging each corresponding hour of all recorded days. To determine several underlying circadian arousal patterns by the 24-hour arousal profiles, a principal component analysis was applied. The analysis identified three factors which explained 25.2%, 17.7%, and 19.8% of the total variance. These components were interpreted as 1) a “Daytime Arousal” factor (DA) with positive loadings of hourly activity counts of 8:00 a.m.–19:00, 2) a “Midnight Arousal” factor (MA), with positive loadings of 0:00 a.m.–4:00 a.m., and 3) a “Phase” factor (P), with positive loadings of 18:00–0:00 a.m., and inverse loadings of 4:00 a.m.–7:00 a.m.. In addition, a “Hyperarousal” (HA) factor, average total time spent awake per day, was calculated from total activity counts across a day. Last, the stepwise regression analysis was used to evaluate associations of diabetic clinical backgrounds with the circadian rhythms related measurements, DA, MA, HA and P.

**Results:** Higher age, higher BMI, higher cholesterol levels, insulin treatment were associated with lower levels of DA ( $p=0.04, 0.03, 0.01$  and  $0.02$ , respectively), while higher HbA1c and the presence of painful neuropathy was associated with higher DA ( $p=0.03$  and  $0.02$ ). Male gender and higher levels of urinary albumin excretion were associated with higher MA ( $p=0.04$  and  $0.03$ ). Similarly to DA, lower age, lower BMI, higher HbA1c, no insulin treatment, and painful neuropathy were associated with higher HA ( $p=0.05, 0.02, 0.06, 0.01$ , and  $0.02$ ). Furthermore, painful neuropathy and antilipids usage were independent predictors of delayed P ( $p=0.02$  and  $0.03$ ), while cardiovascular diseases and smoke were independent predictors of advanced P ( $p=0.04$  and  $0.01$ ).

**Conclusion:** Diabetic clinical backgrounds were associated with a variety of circadian arousal patterns and daily arousal levels. The current study suggests that high age, obesity, dyslipidemia, and insulin treatment in diabetes might reduce daily arousal levels with excessive daytime sleepiness, and that poorly controlled blood sugar and painful neuropathy in diabetes might be pathogenically associated with sleep loss resulting from short sleep or insomnia which is a 24-hour disorder of hyperarousal. Furthermore, diabetic neurovasculopathies may alter circadian arousal patterns by affecting the midnight arousal levels and circadian phase. These findings could provide a novel insight helpful for interventions for various patterns of sleep/wake disorders comorbid with diabetes.

**Sleep stages and type 2 diabetes: characterisation of electroencephalography features**A. Lecube<sup>1</sup>, O. Mestres<sup>2</sup>, A. Ciudin<sup>3</sup>, C. Zafon<sup>4</sup>, G. Sampol<sup>2</sup>, O. Romero<sup>2</sup>, F. Rius<sup>2</sup>, C. Hernández<sup>2</sup>, A. Casteràs<sup>4</sup>, A. Caixàs<sup>5</sup>, R. Simó<sup>6</sup>;

<sup>1</sup>Diabetes Research Unit Vall d’Hebron (Barcelona) and Endocrinology Department Arnau Vilanova, (Lleida), <sup>2</sup>Sleep Unit, Pneumology Department Vall d’Hebron, Barcelona, <sup>3</sup>Endocrinology Department, Diabetes Research Unit Vall d’Hebron, Barcelona, <sup>4</sup>Endocrinology Department Vall d’Hebron, Barcelona, <sup>5</sup>Endocrinology Department, Endocrinology Department Arnau Vilanova, Lleida, <sup>6</sup>Endocrinology Department Parc Taulí, Sabadell, Spain.

**Background and aims:** There is growing evidence suggesting that type 2 diabetes mellitus (T2DM) is an independent risk factor for severe nocturnal hypoxemia and sleep breathing disorders. However, it is unknown whether or not these sleep disturbances affect the structure of sleep.

**Materials and methods:** For this purpose we designed a case-control study between 28 patients with T2DM and 56 non-diabetic subjects, closely matched by age, gender, BMI, waist and neck circumferences, and smoking status. Subjects were also matched for their apnea-hypopnea index (IAH) [31.2 (1.0 to 106.3) vs 33.9 (1.2 to 109.1) events per hour,  $p=0.924$ ]. The exclusion criteria included chronic respiratory disease, neuromuscular and cerebrovascular disease, alcohol abuse, use of sedatives, and pregnancy. Examination included an electroencephalography and respiratory polysomnography, as well as oxygen saturation measures and the degree of sleepiness using the Epworth Sleepiness Scale (ESS). Studies with less than 5 hours of correct signal recording were ruled out.

**Results:** No differences in the Rapid Eye Movement (REM) Sleep (13.5 ± 8.2 vs. 12.8 ± 7.4 % of total time of sleep,  $p=0.689$ ) nor in the Non-Rapid Eye Movement (NREM) Sleep stages (stage 1: 18.6 ± 12.4 vs. 15.1 ± 13.0 %TTS,  $p=0.243$ ; stage 2: 58.1 ± 14.0 vs. 59.3 ± 12.5 %TTS,  $p=0.688$ ; stage 3: 12.5 ± 10.5 vs. 12.3 ± 10.2 %TTS,  $p=0.924$ ; stage 4: 13.8 ± 10.8 vs. 12.4 ± 10.4 %TTS,  $p=0.594$ ) were observed between subjects with and without T2DM. However, T2DM patients showed a higher number of microarousals (or brief awakenings) events than control subjects [34.1 (4.6 to 101.4) vs. 22.7 (1.3 to 93.1)

events per hour during the total time of sleep,  $p=0.023$ ]. A significant positive correlation between microarousals and the AHI was detected ( $r=0.807$ ,  $p<0.001$ ). Finally, a stepwise regression analysis showed that both the AIH and the presence (or not) of T2DM (but not gender, age, BMI, neither neck circumference) independently predicted microarousals ( $R^2=0.593$ ).

**Conclusion:** T2DM adversely affects structure of sleep, becoming an independent risk factor for higher rates of microarousals. As sleep fragmentation has been involved with increased levels of lipids and blood pressure, this increased rate of microarousals may be implicated in the progression of cardiovascular disease in T2DM.

### Diabetes is associated with increased prevalence of perinasal sinus diseases

Y. Kabeya, K. Kato, M. Okisugi, M. Tomita, T. Katsuki, Y. Oikawa, A. Shimada;  
Tokyo Saiseikai Central Hospital, Japan.

**Background and aims:** Past studies have reported that patients with diabetes are susceptible to respiratory tract infections. However, it remains unknown whether or not individuals with diabetes are more likely to have perinasal sinus diseases than those without. In the present study, we investigated the association between diabetes and perinasal sinus diseases in Japanese adults who underwent a health checkup.

**Materials and methods:** This was a cross-sectional study performed in the medical checkup unit of one general hospital in Japan. A total of 1,350 adults who underwent a medical checkup including a head MRI scan from January 2007 to December 2011 were enrolled in the study. The participants were generally healthy and asymptomatic. Information on lifestyle was obtained by a questionnaire. Anthropometric data and blood samples were collected under a fasting condition. Diabetes was defined by any of the following criteria: 1) self-reported diabetes or use of anti-diabetic medications based on the questionnaire, 2) fasting plasma glucose of  $\geq 126$  mg/dl, or 3) HbA1c of  $\geq 6.5$  %. Perinasal sinus diseases were defined as partial or complete opacification of perinasal sinuses (including mucosal thickening and small polyps) detected by a head MRI scan. The prevalence of perinasal sinus diseases in adults with diabetes and those without was calculated, which was standardized to the 1985 model population of Japan. Multiple logistic regression analysis was performed to calculate the odds ratio of having perinasal sinus diseases in adults with diabetes in relation to those without. The model was adjusted for age, sex, body mass index, waist to hip ratio, smoking status, alcohol intake and white blood cell count. In addition, the dose-response relationship was examined between HbA1c levels and the presence of perinasal sinus diseases.

**Results:** Of the 1,350 adults (mean age,  $62\pm 10$  years; 72% men), 220 diabetes cases were identified. Perinasal sinus diseases were diagnosed in 151 adults. The age-standardized prevalence of perinasal sinus diseases was 18.8% in adults with diabetes and 11.0% in those without, respectively. In the logistic regression analysis, a significant association was observed between diabetes and the presence of perinasal sinus diseases after adjustment for the confounders [odds ratio (OR) = 1.74, 95% CI = 1.12–2.71]. The odds of having perinasal sinus diseases increased with HbA1c levels. Compared with adults with HbA1c of  $<5.5\%$ , those with HbA1c of 5.5–6.5% and  $\geq 6.5\%$  were more likely to have perinasal sinus diseases with ORs of 1.32 (95% CI=0.88–1.97) and 1.86 (95% CI=1.05–3.31), respectively ( $p$  for trend = 0.03).

**Conclusion:** The present study found that perinasal sinus diseases are more common in adults with diabetes than those without. The dose-response relationship between hyperglycaemia and the presence of perinasal sinus diseases was also observed. The association was independent of known risk factors for perinasal sinus diseases. Although the clinical significance of the diseases detected by a head MRI scan remains undetermined, physicians should keep in mind the higher prevalence of perinasal sinus diseases among diabetic patients in daily practice.

## 192

### Hyponatraemia is associated with all-cause mortality in patients with type 2 diabetes (ZODIAC-46)

I.J. Riphagen<sup>1,2</sup>, S.J.J. Logtenberg<sup>1</sup>, K.H. Groenier<sup>3,4</sup>, K.J.J. van Hateren<sup>4</sup>, G. Navis<sup>1</sup>, I.P. Kema<sup>5</sup>, H.J.G. Bilo<sup>1,4</sup>, N. Kleefstra<sup>1,4</sup>, S.J.L. Bakker<sup>1,2</sup>;

<sup>1</sup>Internal Medicine, UMCG, Groningen, <sup>2</sup>Top Institute Food and Nutrition, Wageningen, <sup>3</sup>General Practice, UMCG, Groningen, <sup>4</sup>Diabetes Centre, Isala Clinics, Zwolle, <sup>5</sup>Laboratory Medicine, UMCG, Groningen, Netherlands.

**Background and aims:** Hyponatremia (i.e. plasma sodium  $<135$  mmol/L), the most prevalent electrolyte disorder in clinical practice, was found to be an independent predictor for all-cause mortality both in patients with heart failure and in the general population. Although hyponatremia appears more prevalent in diabetes, the association of hyponatremia with mortality in patients with type 2 diabetes is rarely studied. Our aim was to prospectively investigate whether plasma sodium is associated with cardiovascular (CV) and all-cause mortality in patients with type 2 diabetes.

**Materials and methods:** Patients with type 2 diabetes participating in the Zwolle Outpatient Project Integrating Available Care (ZODIAC) study were included. Cox regression analyses with restricted cubic splines were used to investigate the association of baseline plasma sodium with CV and all-cause mortality.

**Results:** We included 1,068 patients (45% male, age  $67 \pm 12$  years). Mean plasma sodium concentration was  $142.3 \pm 3.0$  mmol/L. In multivariable linear regression analyses, plasma sodium was associated with copeptin, a surrogate marker for vasopressin, urinary albumin-to-creatinine ratio (ACR), HbA1c and gender. After median follow-up for 6.5 [interquartile range: 3.1–10.2] years, 345 patients died (32%), with 145 deaths (14%) attributable to CV causes. A restricted cubic spline depicting the association of plasma sodium with all-cause mortality is shown in Figure 1. In univariable Cox regression analyses, plasma sodium levels  $<142$  mmol/L were significantly associated with all-cause mortality (Hazard Ratio [HR] 0.90;  $p=0.003$ ), but not with CV mortality (HR 0.90;  $p=0.07$ ). After adjustment for age, sex, BMI, smoking, systolic blood pressure, total cholesterol-to-HDL ratio, duration of diabetes, HbA1c, use of antihypertensive medication including diuretics and RAAS inhibitors, history of CV diseases, serum creatinine, log ACR and copeptin, the associations of plasma sodium levels  $<142$  mmol/L with all-cause mortality (HR 0.91;  $p=0.04$ ) and CV mortality (HR 0.89;  $p=0.09$ ) were essentially unchanged.

**Conclusion:** We found low plasma sodium levels to be independently associated with an increased risk for all-cause mortality in patients with type 2 diabetes. Whether hyponatremia itself leads to poor outcome or that it is a marker for (unidentified) co-morbidity severity or use of specific medications remains to be elucidated.

### Continuous intraperitoneal insulin infusion versus subcutaneous insulin for type 1 diabetes: a prospective, case-control trial proving non-inferiority

H.J.G. Bilo<sup>1</sup>, P.R. van Dijk<sup>1</sup>, S.J.J. Logtenberg<sup>1</sup>, K.H. Groenier<sup>1</sup>, H. Feenstra<sup>2</sup>, R.O.B. Gans<sup>3</sup>, N. Kleefstra<sup>1</sup>;

<sup>1</sup>Diabetes centre, Isala clinics, Zwolle, <sup>2</sup>Internal Medicine, Diaconessenhuis, Meppel, <sup>3</sup>Internal Medicine, University Medical Center Groningen, Netherlands.

**Background and aims:** Continuous intraperitoneal insulin infusion (CIPII) using an implantable pump is a last-resort treatment option for patients with type 1 diabetes mellitus (T1DM) who fail to reach acceptable glycaemic control with intensified subcutaneous (SC) insulin regimens. Aim of this study was to compare the effects of long-term CIPII with SC insulin therapy in T1DM.

**Materials and methods:** This is a 36 week, investigator initiated, prospective, open-label matched-control study. Patients were eligible if they had been treated with either CIPII or SC insulin for >4 years and had a HbA1c of  $\geq 53$  mmol/mol. CIPII treated patients were matched to SC treated patients regarding age and gender. In order to account for inequality between treatment groups, as CIPII treated patients are a selected group of patients in need of a last-resort treatment, the primary endpoint was not a superiority but a non-inferiority assessment of the difference in HbA1c between both groups. A non-inferiority margin of -5.5 mmol/mol was predefined. Secondary outcomes were clinical and biochemical parameters, quality of life (SF-36 (scores 0-100)) and treatment satisfaction (DTSQ (scores 0-36)). Analysis were performed with ANCOVA, taking baseline differences into account.

**Results:** During study, one patient withdrew consent. Subsequently 183 patients, 36% male with a mean age of 50 years (SD 1) and diabetes duration of 26 years (SD 13), of which 39 were treated with CIPII and 144 with SC insulin therapy were analyzed. Age and gender were well matched. Results are presented in table 1. HbA1c remained stable within the CIPII group while it decreased with -1.0 mmol/mol (95%CI -1.9, -0.1) in the SC group. Using ANCOVA, the difference between treatment groups was -3.0 mmol/mol (95%CI -5.0, -1.0) and met the predefined non-inferiority criterion. Besides a difference in alanine aminotransferase (ALT) concentrations between groups of 3.6 U/L (95%CI 1.2, 6.0) being higher in the CIPII group, no other differences were found. At baseline and at the end of the trial, SF-36 scores were lower among CIPII treated patients as compared patients treated with SC insulin. CIPII treated patients had lower SF-36 mental and physical component scores and higher treatment satisfaction as compared to patients treated with SC insulin at baseline and follow-up.

**Conclusion:** CIPII therapy is non-inferior to SC insulin therapy with respect to glycaemic control in the treatment of poorly controlled T1DM patients. Besides a lower ALT among SC treated patients, there are no differences in clinical and biochemical parameters. Despite a lower quality of life, treatment satisfaction is higher among CIPII treated patients. This study underlines the effectiveness of long-term CIPII therapy as last resort treatment in T1DM.

### Three to four weeks of overnight closed loop insulin delivery during free living: analysis of randomised crossover studies in adults and adolescents with type 1 diabetes

H. Thabit<sup>1</sup>, L. Leelarathna<sup>1</sup>, D. Elleri<sup>1</sup>, J.M. Allen<sup>1</sup>, A. Lubina-Solomon<sup>2</sup>, M. Stadler<sup>3</sup>, E. Walkinshaw<sup>3</sup>, A. Iqbal<sup>3</sup>, P. Choudhary<sup>3</sup>, M.E. Wilinska<sup>1</sup>, S.R. Heller<sup>2</sup>, S.A. Amiel<sup>3</sup>, M.L. Evans<sup>1</sup>, D.B. Dunger<sup>1</sup>, R. Hovorka<sup>1</sup>;

<sup>1</sup>University of Cambridge, <sup>2</sup>Academic Unit of Diabetes, Endocrinology and Metabolism, Department of Human Metabolism, University of Sheffield, <sup>3</sup>Diabetes Research Group, Kings College London, UK.

**Background and aims:** Results from single-night laboratory-based closed loop studies demonstrated improved overnight glucose control and reduced risk of hypoglycaemia in subjects with type 1 diabetes. Assessments outside hospital settings over longer periods in free living conditions are underway. We combined data collected during free-living unsupervised randomised open-label crossover studies comparing overnight closed loop and sensor augmented pump therapy.

**Materials and methods:** 40 participants with type 1 diabetes [24 adults recruited at three centres and 16 adolescents recruited at one centre (age 43±12 years, HbA1c 8.0±0.9%; mean±SD) (15.6±3.6 years, HbA1c 8.1±0.8%)] underwent training on study devices followed by two periods of sensor augmented pump therapy in combination with or without overnight closed-loop utilising a model predictive control algorithm to direct insulin delivery. The order of interventions was random; each period lasted four weeks in adults and three weeks in adolescents. Primary outcome was time when sensor glucose was in the target range between 3.9 and 8.0mmol/L. All analyses were by intention to treat.

**Results:** Closed loop was started by participants on their own volition on 866 nights (89%). The proportion of time when sensor glucose was in target range (3.9-8.0mmol/L) between midnight and 08:00 was increased by 18.5% during closed-loop compared to sensor augmented therapy (P<0.001; Table). Closed loop significantly reduced mean overnight glucose by 0.8mmol/L (P<0.001), with no difference in glycaemic variability as measured by the standard deviation of sensor glucose. Time spent above target range was reduced (P=0.001) and so was time spent in hypoglycaemia below 3.9mmol/L (P=0.014) during closed loop. Lower mean overnight glucose during closed loop was brought about by increased overnight insulin delivery (P<0.001) without changing the total daily delivery (P=0.84).

**Conclusion:** Overnight closed loop at home in adults and adolescents with type 1 diabetes is feasible, demonstrating improvements in glucose control and reducing the risk of nocturnal hypoglycaemia.

Table.

|  | Overnight closed loop (n=40) | Sensor augmented pump therapy (n=40) | P      |
|--|------------------------------|--------------------------------------|--------|
| Mean overnight glucose (mmol/l)            | 7.9±0.9                      | 8.7±1.4                              | <0.001 |
| SD of overnight glucose (mmol/l)           | 2.0±0.3                      | 1.9±0.3                              | 0.47   |
| Time spent overnight at glucose levels (%) |                              |                                      |        |

**Impact of real-time continuous glucose monitoring system usage on endothelial function in adolescents with type 1 diabetes**

**B. Głowińska-Olszewska**, M. Jamiolkowska, I. Jamiolkowska, W. Łuczynski, J. Tołwińska, A. Bossowski;  
Department of Pediatrics, Endocrinology, Diabetology with Cardiology Division, Medical University of Białystok, Poland.

**Background and aims:** Chronic hyperglycaemia and recently defined “glucose variability” in the course of diabetes are established risk factors for cardiovascular disease. Children with type 1 diabetes (T1DM) are the high - risk group of accelerated early atherosclerosis development. Real-time continuous glucose monitoring system (RT-CGMS) provides with new possibilities for the detection of excessive glycaemic fluctuations and enables the patient to react quickly to decrease these adverse phenomena. The aim of the study was to assess the usefulness of RT-CGMS as an educational tool to find and reduce glycemic variability in order to improve the parameters of endothelial function in adolescents with T1DM.

**Materials and methods:** Forty T1DM patients aged mean 14.6 years, diabetes duration: 7.4 years, mean HbA<sub>1c</sub> before the study: 9.35%, 19 boys and 21 girls were recruited. The study was based on one month continuous glucose sensors use combined with education of the patients and caregivers. Several parameters of glycemic variability (mean glucose, SD for the mean glucose, AUC>140 mg/dl, AUC<70 mg/dl, minimal and maximal glucose level) were analysed during first and last sensor use, together with brachial artery flow mediated dilatation (FMD), as a parameter of endothelial function. HbA<sub>1c</sub> was measured before the study and after 3 months follow-up. Depending on the initial value of HbA<sub>1c</sub> the group was divided into well-controlled group (with HbA<sub>1c</sub> <7.5%, mean 7.25±0.19%) and poorly controlled group (with HbA<sub>1c</sub>>7.5%, mean 9.88±1.22%). Decrease of HbA<sub>1c</sub> by at least 0.5% after 3-month follow-up was the criterion to divide the study group into improved vs. not improved. To determine the differences between the study groups for variables with normal distributions the t-Student test was applied. The t-Student test for paired variables was used to compare the variables within the respective groups at baseline and after one-month (glycaemic variability parameters and FMD). To assess correlations between study parameters Pearson correlation coefficient was used.

**Results:** In the whole group FMD improvement was found (10.9% to 16.6%, p<0.005), together with significant decrease in all studied glycaemic variability parameters. Significant HbA<sub>1c</sub> improvement was observed in 68% patients (27 children): 9.02% before vs. 8.04%, after study, P=0.001. In these patients compared to the group without improvement (10.0±1.7% vs. 10.4±1.4% after the study) we found greater increase of FMD (12% to 19%, P<0.005 vs. 8.2% to 11.3%, P=0.08) and greater decrease of the mean glucose, SD for the mean glucose, AUC>140mg/dl and maximal glucose level. In group with initial HbA<sub>1c</sub><7.5% we found greater improvement of FMD than in group with HbA<sub>1c</sub>>7.5% (16% to 28%, p<0.005 vs. 9.6 to 13.9%, P<0.005). Improvement of parameters of glycemic variability in group with HbA<sub>1c</sub><7.5% was not so evident.

**Conclusion:** RT-CGMS can be considered as a new tool that allows to improve endothelial function in type 1 adolescent diabetic patients by enabling the quick reaction to decrease glycemic variability parameters in short-time observation. Whether such approach might influence to reduce the risk of future cardiovascular disease remains to be elucidated.

**Insulin pumps (CSII) and cardiovascular diseases and mortality in the Swedish national diabetes register**

**S. Gudbjörnsdóttir**<sup>1</sup>, B. Eliasson<sup>1</sup>, A.-M. Svensson<sup>2</sup>, T. Avdic<sup>1</sup>, M. Landin-Olsson<sup>3</sup>, J. Cederholm<sup>4</sup>;

<sup>1</sup>University of Gothenburg, <sup>2</sup>National Diabetes Register, Centre of registers, Gothenburg, <sup>3</sup>University of Lund, <sup>4</sup>Department of Public Health and Caring Sciences, Uppsala, Sweden.

**Background and aims:** Insulin pump treatment (CSII) is given for improved glycemic control and quality of life. However, studies on the effect of CSII on long-term risk for cardiovascular diseases (CVD) and mortality are lacking.

**Materials and methods:** Comparison between 2136 patients with type 1 diabetes with CSII and 13,028 patients with insulin injections, from the Swedish National Diabetes Register (NDR), followed for outcomes during mean 5.9 years with 14,523 person-years.

**Results:** Baseline characteristics are given in the Table. Adjusted hazard ratios (95% confidence intervals) for fatal/nonfatal coronary heart disease and fatal/nonfatal cardiovascular disease (heart disease or stroke) were 0.95 (0.90-0.99; p=0.02), and for all-cause mortality 0.95 (0.91-1.00; p=0.03), when adjusting for age, sex, diabetes duration, baseline HbA<sub>1c</sub>, systolic blood pressure, smoker, BMI, total cholesterol, history of CVD or heart failure at Cox regression. Hazard ratio were similar in a sensitivity analysis adjusting by stratification with a propensity score including these covariates and also HDL cholesterol, cumulative albuminuria, creatinine, antihypertensive drugs, and lipid-lowering drugs. P values for covariates between the groups after adjusting with the propensity score are given in the Table. Another sensitivity analysis in a subgroup with 15,164 patients with no history of CVD or heart failure also showed similar hazard ratios.

**Conclusion:** This large prospective observational study showed risk reductions of around 5% for cardiovascular diseases and mortality with CSII compared to insulin injections in patients with type 1 diabetes followed for 6 years.

**Table. Baseline characteristics.**

**The long term effect of continuous subcutaneous insulin infusion on renal function in type 1 diabetic patients with microalbuminuria**

**R. Trevisan**<sup>1</sup>, D. Bruttomesso<sup>2</sup>, G. Lepore<sup>1</sup>, S. Costa<sup>2</sup>, P. Fioletto<sup>3</sup>, M. Vedovato<sup>3</sup>, E. Zarra<sup>4</sup>, A. Corsi<sup>1</sup>, C. Scaranna<sup>1</sup>, U. Valentini<sup>4</sup>, A. Tiengo<sup>3</sup>;  
<sup>1</sup>Department of Medicine, AO Papa Giovanni XXIII, Bergamo, <sup>2</sup>Department of Medicine, University of Padua, <sup>3</sup>Department of Medicine, University of Padua, <sup>4</sup>Department of Medicine, AO Spedali Civili, Brescia, Italy.

**Background and aims:** The purpose of the study was to investigate whether insulin pump therapy (CSII) was superior to multiple daily insulin injections (MDI) to prevent progression of albuminuria in patients with type 1 diabetes (T1DM).

**Materials and methods:** Case-control prospective study of 3 years duration. 26 T1DM patients on CSII with AER of at least 20 μg/min were matched for age (40.3 ± 9.3 vs 42.2 ± 11.1 yrs), diabetes duration (27 ± 8 vs 24 ± 10 yrs) BMI (24.4 ± 3 vs 24.7±4.2 kg/m<sup>2</sup>) and AER with 26 T1DM patients on MDI. Patients were in stable maximal RAAS blockade before entering the study. Before the study all patients received education in intensive diabetes treatment and self-care including carbohydrate counting. Patients return to the clinic every 6 months for measurement of AER, GFR (by ioexol e.v.),

urinary concentrations of 8-iso-PGF2alfa, HbA1c, 24hr blood pressure, 3 days Continuous Glucose Monitoring sensor (CGM), self monitored blood glucose profiles.

**Results:** AER decreased slightly in MDI group from a median value of 65 µg/min (31–100 IQR) to 55 (33–155) after 3 years of follow-up. AER decreased significantly ( $p < 0.01$ ) from 63 µg/min (37–154 IQR) to 18.3 (11–57) in CSII group. In particular only 3 patients on MDI regressed to normoalbuminuria at the end of follow-up, whereas 14 patients on CSII regressed to normoalbuminuria ( $p < 0.001$ ). GFR decline was faster in MDI group ( $-7.9 \pm 9.9$  ml/min/yr) than in CSII group ( $-3.1 \pm 3.3$  ml/min/yr;  $p < 0.05$ ). Urinary concentrations of 8-iso-PGF2alfa were similar in the 2 groups and stable during the study. HbA1c was similar in MDI and CSII groups at entry into the study ( $8.5 \pm 1.5\%$  vs  $8.2 \pm 1.0\%$  respectively). Despite the thigh follow-up, metabolic control did not improve in both groups during the study: HbA1c remained unchanged (HbA1c at the end of the study:  $7.8 \pm 1.25\%$  in MDI group vs  $8.0 \pm 1.3\%$  in CSII group). All measures of glycaemic variability (Mean amplitude of glycaemic excursions [MAGE], Mean of daily differences [MODDs], Continuous overlapping net glycaemic action [CONGA], Low blood glucose index [LBGI]) were similar in the 2 groups throughout the study. Insulin daily dose was significantly higher in MDI than in CSII group both at entry ( $0.67 \pm 0.39$  vs  $0.50 \pm 0.11$  U/Kg/day) and at the end of the study ( $0.67 \pm 0.20$  vs  $0.54 \pm 0.12$  U/Kg/day;  $p < 0.01$ ). 24-hour blood pressure was well controlled in both groups and stable throughout the study. Mean of standard deviation of individual 24-hour blood pressure values, as a measure of blood pressure variability, were similar in both groups and stable during the follow-up period.

**Conclusion:** CSII, despite a similar blood glucose control, prevented the progression of albuminuria and the loss of GFR when compared to MDI in T1DM patients. The greater insulin requirement in patients on MDI suggests a condition of greater insulin resistance, a factor likely to contribute to the renal disease progression.

### Effect of insulin pump treatment on albuminuria and kidney function in type 1 diabetes

S. Rosenlund<sup>1,2</sup>, T.W. Hansen<sup>1</sup>, S. Andersen<sup>2</sup>, P. Rossing<sup>1,3</sup>,

<sup>1</sup>Steno Diabetes Center, Gentofte, <sup>2</sup>Hilleroed Hospital,

<sup>3</sup>University of Copenhagen, Denmark.

**Background and aims:** Treatment with continuous subcutaneous insulin infusion (CSII) may reduce urinary albumin excretion as compared to treatment with multiple daily injections (MDI). We aimed to investigate the effect of 3 years CSII treatment on albuminuria, HbA1c, and kidney function compared to MDI in a single centre clinical setting.

**Materials and methods:** Case-control study of all type 1 diabetes patients initiating CSII treatment from 2004–2010 at our outpatient clinic and followed for at least three years. We identified 193 patients and matched them (1:2) to 386 patients treated with MDI in the same period. Matching was based on diabetes duration, gender, HbA1c and normo-, micro- or macroalbuminuria at baseline. Urinary albumin creatinine ratio (UACR) was measured yearly and annual change assessed from linear regression. Unpaired t-test and adjusted ANCOVA compared treatment groups.

**Results:** At baseline, both treatment groups included 39% men with diabetes duration of (mean  $\pm$  SD)  $23 \pm 12$  years and a frequency of normo-, micro and macroalbuminuria of 84%, 12% and 4% respectively. Patients were (CSII vs. MDI)  $48 \pm 12$  vs.  $44 \pm 11$  years old, HbA1c  $68 \pm 11$  vs.  $68 \pm 10$  mmol/mol, eGFR  $100 \pm 23$  vs.  $101 \pm 25$  mL/min/1.73m<sup>2</sup>, UACR (median [IQR])  $9$  [6–19] vs.  $9$  [6–17] mg/g, and numbers on RAAS-treatment were 40 vs. 38%, ( $p > 0.58$  for all; except age;  $p < 0.001$ ). Annual change in UACR in CSII vs. MDI treated patients was (mean (CI95%))  $-11.3$  (-14.6; -8.0) vs.  $-1.1$  (-3.3; 1.1)%, ( $p < 0.001$ ). This remained significant after adjustment for diabetes duration, age, gender and baseline values of eGFR, systolic blood pressure, HbA1c and RAAS-treatment ( $p < 0.001$ ). Adjustment for average follow up values instead of baseline values did not change the significance ( $p < 0.001$ ). The yearly change in eGFR was  $-1.9 \pm 6.7$  vs.  $-1.8 \pm 4.4$  mL/min/1.73 m<sup>2</sup> ( $p = 0.73$ ) and in HbA1c  $-1.2 \pm 2.8$  vs.  $0.2 \pm 2.3$  mmol/mol ( $p < 0.001$ ). Number of patients starting RAAS-treatment during follow up was similar in CSII vs. MDI treated; 10.9 vs. 10.4 % ( $p = 0.85$ ). In multiple regression analysis, adjusted for baseline values, a larger decline in UACR was significantly associated to CSII treatment and higher UACR ( $p < 0.001$ ). After adjustment for follow up values, a larger decline in UACR was significantly associated to CSII treatment ( $p < 0.001$ ), lower average HbA1c ( $p = 0.02$ ) and stable RAAS-treatment ( $p = 0.04$ ). In adjusted analyses restricted to patients on stable RAAS-

treatment during follow up ( $n = 465$ ) only CSII treatment was significantly associated to a larger decline in UACR ( $p < 0.001$ ).

**Conclusion:** In a case control study treatment with CSII over 3 years independently reduced UACR and HbA1c compared to MDI. In these mostly normoalbuminuric patients, change in kidney function was small, and similar, in the groups. The reduced UACR was only partly explained by reduction in HbA1c and may in addition be due to less glycaemic variability. This cannot be assessed from these data. The effect of CSII treatment on albuminuria needs investigation in randomized controlled trials.

## OP 34 Novel approaches for beta cell protection

199

### Specific overexpression of the calcium-sensor sorcin in pancreatic beta cells protects against ER-stress and diet-induced type 2 diabetes

A.P. Marmugi, G.A. Rutter, I. Leclerc;  
Medicine, Imperial College London, UK.

**Background and aims:** Pancreatic beta cells use electrical signals to couple changes in blood glucose concentration to insulin release via extracellular calcium ( $\text{Ca}^{2+}$ ) influx. Sorcin (SRI) is a  $\text{Ca}^{2+}$ -binding protein whose overexpression in cardiomyocytes rescues the abnormal contractile function of the diabetic heart and plays a role in terminating  $\text{Ca}^{2+}$ -induced  $\text{Ca}^{2+}$ -release. We explored here the role of sorcin in regulating  $\text{Ca}^{2+}$  fluxes in pancreatic beta cells and its ability to protect against glucolipotoxicity *in vivo*.

**Materials and methods:** Two lines of transgenic mice were generated on a C56Bl/6 background permitting inducible overexpression of SRI cDNA with the TetOn-system specifically in beta cells. Animals bearing one (SRI-1) or ten (SRI-10) copies of the SRI transgene, and littermate controls (CTRL), were fed either a standard chow diet (SD) or a high fat diet (60% fat, HFD) and exposed to doxycycline in the drinking water (500mg/L) from 4 weeks onwards. Body weight measurements and fasting intraperitoneal glucose tolerance tests (1g/kg, IPGTT) were performed at regular intervals. Quantitative RT-PCR and real-time calcium imaging with Fura-Red (excitation light at 420 and 480nm, 40x/1.4NA objective and a cMOS camera on board an Olympus IX-71 microscope) were performed on islets isolated from either transgenic animals or from wild-type mice transduced with adenoviruses overexpressing GFP-SRI or GFP.

**Results:** Glucose tolerance during IPGTTs worsened considerably in CTRL males under HFD (120 min glycaemias (mmol/L):  $12.3 \pm 0.9$  at 8-week-old,  $22.1 \pm 1.7$  at 16-week-old,  $n=17$ ) but not in CTRL males under SD (120 min glycaemia (mmol/L):  $7.2 \pm 0.2$  at 8 weeks,  $7.3 \pm 0.5$  at 16 weeks,  $n=10$ ). Strikingly, and despite having similar body weights, male SRI-1 mice on HFD displayed improved glucose tolerance at 16 weeks of age (areas under the curve (AUC; a.u.):  $111.9 \pm 8.8$  for SRI-1,  $136.2 \pm 7.3$  for CTRL,  $n=16$ ,  $p<0.05$ ). SRI-10 males on HFD already displayed improved glucose tolerance after 8 weeks of age (AUC (a.u.):  $73.0 \pm 2.3$  for SRI-10,  $95.8 \pm 5.3$  for CTRL,  $n=22$ ,  $p<0.001$ ) and fasting glycaemia (0 min glycaemia (mmol/L):  $8.7 \pm 0.4$  for SRI-10,  $10.9 \pm 0.8$  for CTRL,  $n=22$ ,  $p<0.05$ ). mRNA levels of genes involved in endoplasmic reticulum (ER) stress, including GRP78 (fold-change normalised to beta-actin:  $0.29 \pm 0.13$ ,  $n=11$ ,  $p<0.05$ ) and CHOP ( $0.16 \pm 0.03$ ,  $n=11$ ,  $p<0.001$ ), were reduced significantly in SRI-1 versus CTRL islets. Moreover, adenovirus-mediated SRI overexpression increased basal cytosolic  $\text{Ca}^{2+}$  levels in wild-type mouse islets ( $F_{420/480}$  ratio (a.u.):  $1.0 \pm 0.02$  vs  $0.74 \pm 0.01$ ,  $n=23$  clusters/group,  $p<0.001$  vs GFP virus-infected islets) at low (3 mM) glucose and increased the peak amplitude of  $\text{Ca}^{2+}$  rises in response to high glucose (20 mM; AUC (a.u.):  $463.4 \pm 14.9$  vs  $278.2 \pm 6.0$ ,  $n=23$  clusters/group,  $p<0.001$ ) or depolarisation with KCl (20 mM; AUC (a.u.):  $157.8 \pm 5.0$  vs  $89.3 \pm 2.3$ ,  $n=23$  clusters/condition,  $p<0.001$ ).

**Conclusion:** Our *in vivo* experiments reveal that targeted SRI overexpression preserves pancreatic beta cell function and whole body glucose homeostasis during high fat feeding. These actions involve the alleviation of ER stress and increases in intracellular  $\text{Ca}^{2+}$ . Such alterations may avert apoptosis and loss of beta cell mass during type 2 diabetes.

### Chaperones ameliorate beta cell dysfunction and amyloid formation associated with human islet amyloid polypeptide overexpression

J. Montane<sup>1,2</sup>, L. Cadavez<sup>1,2</sup>, C. Castaño<sup>1,2</sup>, A. Novials<sup>1,2</sup>;

<sup>1</sup>Diabetes and Obesity Laboratory, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), <sup>2</sup>Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

**Background and aims:** In type 2 diabetes and islet transplantation beta-cell dysfunction is thought to be due to several causes, one being the formation of toxic protein aggregates called islet amyloid, formed by accumulations of misfolded human islet amyloid polypeptide (hIAPP). The process of hI-

APP misfolding and aggregation is one of the factors that may perturb the endoplasmic reticulum (ER) homeostasis, leading to beta cell dysfunction and ultimately, cell death. Molecular chaperones have been described to be important for regulation of ER response to ER stress by stabilizing protein conformation and improving ER capacity. The aim of the present work is to determine whether chaperone treatment is able to counteract hIAPP-induced beta cell dysfunction and, ultimately, diminish amyloid formation and cell death in pancreatic islets.

**Materials and methods:** hIAPP Tg islets and INS1E cells, stably expressing hIAPP (hIAPP-INS1E) were cultured with 16mM or 25 mM glucose and 400μM palmitic acid and treated with chemical chaperones taurine conjugated ursodeoxycholic (TUDCA) and phenyl butyric acid (PBA) or endogenous chaperones BiP/GRP78 (BiP) or protein disulfide isomerase (PDI). Islet function was determined by glucose-stimulated insulin secretion and gene expression and protein levels of ER stress markers (CHOP, ATF3 and spliced XBP1) were analysed by real-time RT-PCR and Western blot. Wild type and hIAPP Tg islets were cultured for 7 days at 16mM glucose and treated with TUDCA or PBA. Amyloid formation was determined by ThioS staining.

**Results:** hIAPP-INS1E cells exposed to high glucose and palmitic acid showed an increase in ER stress when compared to INS1E cells expressing rat IAPP or INS1E control cells. Treatment with chaperones BiP, PDI, TUDCA or PBA alleviated ER stress and increased insulin secretion in hIAPP-expressing cells. Treatment of wild-type and hIAPP Tg islets with BiP, PDI, TUDCA and PBA increased insulin output in basal conditions after a glucose-stimulated insulin secretion. When hIAPP Tg islets were exposed to high glucose and palmitic acid, chaperone treatment was able to revert beta cell dysfunction by restoring insulin secretion. Moreover, when hIAPP Tg islets were cultured for 7 days at 16mM glucose, amyloid plaques were formed throughout the islet engaging  $18.2 \pm 2.3\%$  of the insulin positive area. TUDCA and PBA treatment was able to diminish amyloid formation of hIAPP Tg islets to  $5.3 \pm 0.9\%$  and  $1.2 \pm 0.4\%$  respectively, indicating that chaperones may play an important role in preventing beta-cell dysfunction and amyloid formation associated to T2D.

**Conclusion:** Chaperones ameliorate induced ER stress, increase insulin secretion and ultimately, diminish amyloid formation in a context of hIAPP overexpression. These innovative approaches could reveal new therapeutic targets and aid in the development and evaluation of strategies to diminish ER stress and limit the damaging amyloid observed in islets before transplant or in type 2 diabetic patients.

### Acidic, photo-activated nanoparticles restore autophagy in beta cells exposed to high nutrient environment

K. Trudeau<sup>1</sup>, S. Sereda<sup>1</sup>, A. Colby<sup>2</sup>, M. Grinstaff<sup>2</sup>, O. Shirihai<sup>1</sup>;

<sup>1</sup>Boston University School of Medicine, <sup>2</sup>Boston University, USA.

**Background and aims:** We have previously shown that chronic (>16 hour) exposure to fatty acids (palmitate and oleate) inhibit autophagic flux in the pancreatic beta-cell, leading to accumulation of autophagosomes and decreased autophagy-dependent turnover, resulting in beta-cell dysfunction. Further investigations determined that fatty acids induced lysosomal dysfunction, characterized by loss of lysosomal acidity, lysosomal swelling, and decreased activity of lysosomal pH-dependent proteases. In this study we tested the hypothesis that fatty acid-induced impairment of lysosomal acidification plays a central role in the arrest of autophagic turnover and impaired beta-cell glucose-stimulated insulin secretion. To address this hypothesis we developed lysosome-targeted nanoparticles (NPs) that release acid upon photo-activation.

**Materials and methods:** Acidic NPs were developed that expand in size after UV-light activation, exposing carboxylic acid residues in the polymer that mediate an acidifying effect. Rhodamine-labelled NPs were tested for uptake and localization into INS1 cells (beta-cell insulinoma line) using flow cytometry and confocal imaging with LysoTracker dye. Efficacy of UV-activation and NP toxicity in INS1 cells were tested using propidium iodide staining and flow cytometry. Lysosensor Yellow/Blue dye and ratiometric imaging/analysis was performed to determine if UV-activated NPs could affect lysosome acidity and size in INS1 cells exposed to 0.4mM palmitate for 18 hours. Also, p62 and LC3-II levels in INS1 cells were assessed by Western blot to test NP-induced improvement of autophagic flux. Lastly, human islets were exposed to 2:1 oleate:palmitate for 4 days, and glucose-stimulated insulin secretion was analyzed to determine if UV-activated NPs could improve beta-cell function after fatty acid exposure.

**Results:** The NPs were equilibrated in a dose-dependent manner in INS1 and beta-cells within 1–2 hours and localized to lysosomes as assessed by co-localization with LysoTracker staining. High concentration (250 µg/mL) of NPs induced significant cell death when UV-activated but was well-tolerated when not UV-activated, indicating successful activation of NPs in intact cells and allowing determination of a non-toxic treatment dose of 25 µg/mL NPs in cells. UV-activation of NPs in INS1 cells exposed for 18 hours to palmitate showed a significant rescue of lysosomal acidity and size compared to palmitate treatment alone or palmitate co-treated with NPs that were never UV-activated. Furthermore, palmitate-induced p62 and LC3-II accumulation were decreased following UV-activation of NPs, indicating downstream improvement of autophagic flux. Finally, UV-activated NPs were able to partially restore fatty acid-induced decrease in glucose-stimulated insulin secretion in human islets, suggesting that rescuing lysosomal acidity and autophagic flux with acidic NPs can improve beta-cell function.

**Conclusion:** The capacity of acidic NPs to restore lysosomal acidity, morphology and clearance supports an upstream role for impaired lysosomal dysfunction in the development of deregulated insulin secretion. Additionally, acidic NPs may have therapeutic value in diseases where a cellular defect in lysosomal acidity inhibits autophagic flux, such as the fatty acid-induced arrest of autophagic flux in the pancreatic beta-cell.

### Reversible changes in pancreatic islet structure and function produced by elevated blood glucose

M.F. Brereton<sup>1</sup>, M. Iberl<sup>1</sup>, K. Shimomura<sup>1</sup>, Q. Zhang<sup>2</sup>, P. Proks<sup>1</sup>, A.A. Adriaenssens<sup>3</sup>, I.I. Spiliotis<sup>1</sup>, W. Dace<sup>1</sup>, K.K. Mattis<sup>1</sup>, F.M. Gribble<sup>3</sup>, F. Reimann<sup>3</sup>, A. Clark<sup>2</sup>, P. Rorsman<sup>2</sup>, F.M. Ashcroft<sup>1</sup>

<sup>1</sup>Department of Physiology, Anatomy and Genetics, University of Oxford,

<sup>2</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford,

<sup>3</sup>Cambridge Institute For Medical Research, University of Cambridge, UK.

**Background and aims:** Hyperglycaemia is common to all forms of diabetes and results from impaired insulin secretion and aberrant glucagon secretion due to changes in pancreatic islet cell function and/or mass. The extent to which hyperglycaemia *per se* underlies these alterations remains poorly understood as previous studies have been restricted to *in vitro* culture systems, or animal models where diabetes is artificially induced by β-cell ablation and other confounding factors (e.g. obesity and insulin resistance) are common. We generated a mouse model in which diabetes could be rapidly and reversibly switched on and off to study the effect of hyperglycaemia on pancreatic islet structure and function.

**Materials and methods:** An inducible human activating  $K_{ATP}$  channel mutation was expressed in β-cells of adult mice. This inhibited insulin secretion and resulted in rapid onset of diabetes. Islet morphology, ultrastructure and electrophysiological characteristics were studied.

**Results:** 4-week exposure to hyperglycaemia was associated with a significant reduction in insulin-positive cells (% of islet area composed of insulin; control: 86.5±/−0.3% vs. diabetic 27.8±/−1.7%). This reflected a significant reduction in insulin mRNA and insulin protein levels in islets ( $P<0.05$ ). Following exposure to chronic hyperglycaemia, islets became predominantly composed of glucagon-positive cells (control: 16.6±/−0.9% vs. diabetic 73.5±/−2.1%) consistent with increased glucagon mRNA and protein levels. These changes in insulin and glucagon expression did not reflect alterations in cell turnover (as assessed by Ki67 and apoptosis measurements). Instead, β-cell ultrastructure showed a striking reduction in insulin granule content. There was also a significant increase in dual insulin/glucagon-positive cells from 0.3±/−0.1% in control to 5.7±/−1.2% in diabetic islets ( $P<0.05$ ). Lineage tracing showed these cells derived from β-cells and expressed β-cell transcription factors. Furthermore, they had functional β-cell, not α-cell, voltage-gated Na<sup>+</sup> channels. Following 1 day or 4-weeks of diabetes, normoglycaemia was immediately restored (within 24h) by subcutaneous insulin or sulphonylurea therapy. Restoration of normoglycaemia with these anti-diabetic drugs prevented and fully reversed the changes in islet structure and function.

**Conclusion:** Chronic hyperglycaemia resulted in the partial loss of β-cell identity in a mouse model of β-cell dysfunction. Hyperglycaemia, rather than  $K_{ATP}$  channel activation, underlies these changes as they were all prevented, and even reversed by anti-diabetic drugs. This highlights the remarkable plasticity of β-cells, and their ability to alter their gene expression, structure and

function in response to changes in circulating glucose levels. These data suggest that rapid implementation of good glucose homeostasis in diabetes can preserve β-cell structure and function, and even reverse established changes. Supported by: Wellcome Trust, ERC, MRC

## 203

### Dual roles of a DPP-4 inhibitor on cytoprotection and proliferation of pancreatic beta cells in a mouse model of beta cell injury/regeneration

E. Mukai, A. Morita, A. Hiratsuka, T. Takatani, E.-Y. Lee, T. Miki;

Department of Medical Physiology, Chiba University, Japan.

**Background and aims:** Dipeptidyl peptidase-4 inhibitors (DPP4i) increase pancreatic β-cell mass in mouse models of diabetes mellitus. However, it remains unknown which of cytoprotection or proliferation of β-cells contributes to the increase by DPP4i. In this study, we analyzed these two events individually using a mouse model that sequentially exhibits β-cell injury and regeneration.

**Materials and methods:** We generated transgenic mice expressing diphtheria toxin (DT) receptor (DTR) and a red fluorescent protein (tomato) specifically in β-cells (*Rip-Cre;Rosa26<sup>DTR/Tomato</sup>*). To analyze cytoprotective effect of DPP-4i, the mice were pre-administered with a DPP-4i MK-0626 (3mg/kg/day, mixed in a chow) and then were treated with DT (20 µg/kg, i.p.) for β-cell ablation. Six days after β-cell ablation, pancreases were excised and subjected to morphological examination. To analyze pro-proliferative effect of MK-0626, we administered the mice with MK-0626 for 14 days starting on the day of DT injection. To assess the effect of MK-0626 on β-cells through pathways other than potentiating Glucagon-like peptide (GLP)-1 signaling, the same experiments were also performed also with a GLP-1 analog liraglutide (100 µg/kg, twice a day, s.c.). Molecular mechanism of β-cell protection was investigated using a β-cell line MIN6 cells expressing DTR.

**Results:** DT injection to *Rip-Cre;Rosa26<sup>DTR/Tomato</sup>* induced death in 96% of tomato-positive cells and a decrease in β-cell mass to ~30% at day 6 and then recovery of β-cell mass to ~50% at day 14. In *Rip-Cre;Rosa26<sup>DTR/Tomato</sup>*, blood glucose levels were not increased after β-cell ablation by DT. As regards to cytoprotective effect of MK-0626, MK-0626 administration significantly increased the number of surviving tomato-positive β-cell after DT ablation. Comparable cytoprotective effect was observed by liraglutide administration and there was no additive or synergistic effect by co-administration of MK-0626 and liraglutide. Mechanism of cytoprotection was evaluated by DT-induced cell death in MIN6 cells expressing DTR. Pretreatment of the cells with liraglutide significantly attenuated the decrease in cell viability by DT. Considering that caspase-3 activation was inhibited by liraglutide and that caspase-3 or -9 inhibitor attenuated DT-induced cell death, cytoprotective effect of GLP-1 is mediated by suppressing caspase-3 and -9 signaling. In addition, cytoprotective effect of liraglutide is significantly decreased by a PI3K inhibitor or a MEK inhibitor. As regards to β-cell proliferative effect of MK-0626, its administration significantly increased BrdU incorporation at 14 days after DT ablation.

**Conclusion:** MK-0626 increased β-cell mass by both inhibition of cell death and augmentation of proliferation in our mice. The cytoprotective effect of MK-0626 is suggested to be mediated by increased GLP-1 through PI3K and MAPK signaling.

### RNA-sequencing identifies Nova1 as a major splicing regulator in pancreatic beta cells

O. Villate<sup>1</sup>, J.-V. Turatsinze<sup>1</sup>, L.G. Mascali<sup>1</sup>, F.A. Grieco<sup>1</sup>, T.C. Nogueira<sup>1</sup>, D.A. Cunha<sup>1</sup>, M. Sammeth<sup>2</sup>, V.A. Salunkhe<sup>3</sup>, J.L.S. Esguerra<sup>3</sup>, L. Eliasson<sup>3</sup>, L. Marselli<sup>4</sup>, P. Marchetti<sup>4</sup>, D.L. Eizirik<sup>1</sup>;

<sup>1</sup>Laboratory of Experimental Medicine and ULB Center for Diabetic Research, Université Libre de Bruxelles, Belgium, <sup>2</sup>Laboratório Nacional de Computação Científica, Petropolis RJ, Brazil, <sup>3</sup>Department of Clinical Sciences Malmö, Lund University, Lund University Diabetes Centre, Malmö, Sweden, <sup>4</sup>Department of Endocrinology and Metabolism, University of Pisa, Italy.

**Background and aims:** Alternative splicing (AS) is a basic mechanism for the regulation of gene expression, affecting more than 90% of human genes. We have recently shown by exon array and RNA-sequencing that pancreatic beta cell exposure to the pro-inflammatory cytokines interleukin-1 beta (IL-1) +

interferon-gamma (IFN) modifies AS of >500 genes. Our recently published data indicate the presence of the Nova1 splicing factor in beta cells, but there is no information about its role on these cells. We have presently coupled specific knockdown (KD) of Nova1 with RNA sequencing to determine all splice variants and downstream pathways regulated by this protein in pancreatic beta cells.

**Materials and methods:** Nova1 expression was inhibited by 60% with the use of specific siRNAs. Three FACS-purified rat beta cell preparations (90–95% pure) were RNA-sequenced under control conditions or after a 48-hour KD of Nova1. Samples were sequenced on an Illumina HiSeq 2000 sequencer and the data analysed using Tophat mapper and Flux Capacitor. The Cufflinks software suite was used to identify potentially novel transcripts. Expression was considered changed if it fulfilled two criteria, namely  $p < 0.05$  by the Benjamini-Hochberg-corrected Fisher testing and modified in the same direction in all samples. Beta cell function and viability was evaluated by glucose-induced insulin secretion, glucose oxidation and by the nuclear dyes Hoechst/PI.

**Results:** RNA-sequencing and the subsequent bioinformatics analysis identified 43,460 transcripts as expressed in primary beta cells, corresponding to 18,257 genes. Nova1 KD modified expression of 18% of these genes and altered the splicing of nearly 5000 transcripts. Pathway analysis indicated that these genes are involved in exocytosis, apoptosis, calcium signalling, splicing and transcription. Nova1 KD effects on splicing of key downstream genes such as Gabrg2 and Neurexin1 were confirmed by RT-PCR ( $n=5$ ). In line with the observed pattern of gene expression, Nova1 silencing inhibited insulin secretion and voltage dependent  $Ca^{2+}$  current by respectively  $40 \pm 5\%$  ( $n=5$ ;  $P < 0.05$ ) and  $35 \pm 10\%$  ( $n=28-33$ ;  $P < 0.05$ ) but did not affect glucose oxidation suggesting a main effect of exocytosis. Importantly, Nova1 silencing induced apoptosis via the intrinsic or mitochondrial pathway in INS-1E cells, FACS-purified rat beta cells and human islet cells (increase in apoptosis of 6–20%;  $n=4-6$ ;  $P < 0.05$ ), basally and after cytokine treatment.

**Conclusion:** The present data indicate that Nova1 has a major role in beta cell function, controlling the splicing and expression of key genes involved in gene transcription, insulin release and apoptosis. These findings identify a novel layer of regulation of beta cell function, namely AS controlled by key splice regulators.

## OP 35 Hypertension in diabetes

### 205

#### Diabetes and ambulatory blood pressure monitoring: a cross-sectional analysis of 68045 hypertensive patients in Spain

O. Gonzalez Albarran<sup>1</sup>, M. Gorostidi<sup>2</sup>, J. Segura<sup>3</sup>, L. Ruilope<sup>3</sup>;

<sup>1</sup>Endocrinology, Hospital Ramón y Cajal, Madrid,

<sup>2</sup>Nephrology, Hospital Universitario de Asturias, Oviedo,

<sup>3</sup>Nephrology, Hospital Doce Octubre, Madrid, Spain.

**Background and aims:** Hypertension affects the majority of patients with diabetes and constitutes a major risk factor for vascular complications. Ambulatory blood pressure monitoring (ABPM) provides a high-quality approach in estimating the true levels of blood pressure (BP). Several population- and patient-based studies have showed the benefits of ABPM in exploring the relationship between BP and cardiovascular events. A series of reports dealing with diabetic patients have also shown a close correlation between ambulatory BP and diabetic complications. We aimed to assess such characteristics in comparison with non-diabetic hypertensives by using the Spanish Society of Hypertension ABPM Registry.

**Materials and methods:** We performed a cross-sectional analysis of a 68045 patient database from the Spanish Society of Hypertension ABPM Registry, a nation-wide network of 41200 primary-care physicians performing ABPM under standardized conditions in daily practice. We identified 12 600 (18.5%) hypertensive patients with diabetes.

**Results:** When compared with patients without diabetes, diabetic hypertensives exhibited higher systolic blood pressure (BP) levels in every ABPM period (daytime 135.4 vs. 131.8, and night-time 126.0 vs. 121.0 mmHg,  $P < 0.001$  for both) despite they were receiving more antihypertensive drugs (mean number 1.71 vs. 1.23,  $P < 0.001$ ). Consequently, diabetic patients suffered from lack of control of BP more frequently than non-diabetic subjects particularly during the night (65.5% vs. 57.4%,  $P < 0.001$ ). Prevalence of a non-dipping BP profile (64.2% vs. 51.6%,  $P < 0.001$ ) was higher in diabetic patients. In the other hand, prevalence of ‘white-coat’ hypertension in diabetic patients was 33.0%.

**Conclusion:** We conclude that there was a remarkably high prevalence of alterations in ABPM in patients with diabetes. Abnormalities in systolic BP, particularly during the night, and in circadian BP pattern could be linked with the excess of BP-related cardiovascular risk of diabetes. A wider use of ABPM in diabetic patients should be considered.

Westfalen, Bad Oeynhausen, <sup>3</sup>Novartis Pharma GmbH, Nürnberg, <sup>4</sup>Institut

für Pharmakologie und Präventive Medizin, Mahlow, <sup>5</sup>Stiftung „Institut für

Herzinfarktforschung“, Ludwigshafen, <sup>6</sup>Medizinische Klinik B, Herzzentrum

Ludwigshafen, Germany.

**Background and aims:** There has been a recent appreciation of individualized HbA1c treatment targets in patients with type-2 diabetes. Respective guidance for blood pressure Targets are inconsistent between different guidelines and decisions made should consider individual patient risk. To our knowledge there is neither clinical practice data on actually pursued blood pressure treatment targets nor on patient characteristics associated with either strategy.

**Materials and methods:** DIALOGUE is a prospective, observational, multi-center registry focusing on Treatment targets and their achievement in clinical practice. Physicians were asked at baseline on blood pressure treatment targets pursued and compared to actual blood pressure levels values achieved at 6 months.

**Results:** A total of 8,601 patients were considered for the analysis. For 3,343 of these (38.9%) a systolic blood pressure target of  $\leq 130$  mmHg (strict group), for 2,874 (33.4%) a target of  $>130$  to  $\leq 135$  mmHg (medium) and for 2,384 (27.7%) a target of  $>135$  to  $\leq 140\%$  (loose) was pursued. Patients in the strict target group were younger, had a shorter diabetes duration and less co-morbid disease (table). Overall 70.5% of those with a strict SBP target

also had a HbA1c target  $\leq 6.5\%$  and 40.7% of those with a loose SBP target also had loose HbA1c targets. At the 6 months follow-up the mean ( $\pm$ SD) SBP was  $133.4 \pm 13.5$  mmHg in the strict group (25% exceeding 140 mmHg),  $135.7 \pm 13.3$  mmHg in the medium group (25% exceeding 140 mmHg) and  $139.0 \pm 15.0$  in the loose group (25% exceeding 147 mmHg) ( $p < 0.0001$ ).

**Conclusion:** The data illustrate that systolic blood pressure targets chosen in patients with type-2 diabetes consider patient characteristics and overall comorbidity and are aligned with the corresponding HbA1c treatment targets. The lesser morbid patient are, the stricter the treatment targets.

| Baseline                                 | SBP $\leq 130$ -mmHg | $>130$ -to- $\leq 135$ mm | $>135$ -to- $\leq 140$ mm | n       |

### Considering individual variability in multiple risk markers in short-term response to angiotensin-receptor-blockade improves renal risk prediction

H.J. Lambers Heerspink<sup>1</sup>, P. Rossing<sup>2</sup>, H.-H. Parving<sup>3</sup>, D. De Zeeuw<sup>1</sup>;

<sup>1</sup>Clinical Pharmacology, University Medical Center Groningen, Netherlands,

<sup>2</sup>Steno Diabetes Centre, Gentofte,

<sup>3</sup>Medical Endocrinology, University of Copenhagen, Denmark.

**Background and aims:** The current use of Angiotensin-Receptor-Blockers (ARBs) is targeted towards blood pressure in order to ultimately decrease renal and cardiovascular (CV) risk. However, ARBs have multiple (off-target) effects that may potentiate or counteract the ultimate ARB effect on renal and CV outcomes. The extent to which the response in these off-target markers varies within an individual is unknown. We therefore investigated variability in the response to ARBs in different risk markers, the congruency in response between the markers within an individual, and the relation to hard renal outcomes.

**Materials and methods:** We used data from the RENAAL trial and assessed the change in the primary target systolic blood pressure (SBP), and the off-targets, albuminuria, potassium, haemoglobin, cholesterol and uric acid after 6 months of treatment with losartan. Response was defined as a change in expected direction whilst non-response was defined as no effect or change in opposite direction. Renal outcome was defined as end-stage renal disease (ESRD) or doubling of serum creatinine and ascertained during a median follow-up of 3 years. The improvement in predictive performance of renal outcomes for each individual after adding ARB induced changes in on-target and off-target risk markers to a renal risk score, consisting of age, gender, baseline eGFR, albuminuria, SBP, HbA1c, and haemoglobin, was assessed by C-statistic and relative integrated discrimination improvement (RIDI).

**Results:** We included 531 (71%) patients (age 60.0 years, 38% female) who had complete measurements at baseline and month 6. A response was observed in SBP (61%), albuminuria (72%), potassium (66%), haemoglobin (72%), cholesterol (61%), and uric acid (47%). The proportion of individuals with off-target responses was similar among patients with SBP reduction compared to patients with SBP rise, suggesting that off-target responses were independent of SBP response. Moreover, correlations between SBP and off-target responses within an individual were weak (all  $r < 0.2$ ). Adding the individual responses in on-target and off-target risk markers to a renal risk score significantly improved renal risk stratification (increase in c-statistic from 0.81 to 0.85,  $p < 0.001$ , and RIDI by 53.4%;  $p < 0.001$ ). Similar results were observed in two independent trials with irbesartan, the IDNT and IRMA-2 trials.

**Conclusion:** The antihypertensive ARBs show multiple effects which vary between individuals and vary between parameters within an individual. Integration of these short-term ARB induced responses of each individual in

a multiple risk marker scores significantly improves renal risk prediction. These results highlight the importance of monitoring and targeting multiple renal risk markers in response to ARB therapy to optimize renal protection.

### Distinct systolic blood pressure trajectories in type 2 diabetes patients.

#### The Diabetes Care system cohort

I. Walraven, M.R. Mast, T. Hoekstra, A.P.D. Jansen, S.P. Rauh, F. Rutters, A.A.W. van der Heijden, P.J.M. Elders, A.C. Moll, B.C.P. Polak, J.M. Dekker, G. Nijpels;

EMGO Institute for Health and Care research, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** Observational studies showed that only 40 to 60% of type 2 diabetes mellitus (T2DM) patients within primary diabetes care reach the recommended systolic blood pressure (SBP) target of  $\leq 140$  mmHg. In order to eventually improve blood pressure (BP) management, the aim of this study was to identify subgroups of T2DM patients with distinct trajectories of SBP levels. Subgroup characteristics were determined and the prevalence of microvascular complications and all-cause mortality rates over time in the different subgroups was investigated.

**Materials and methods:** 5711 T2DM patients with at least two SBP follow-up measurements were selected from a cohort of 9849 T2DM patients from the Diabetes Care system cohort in The Netherlands. The mean follow-up period was 5.7 years (range 2 - 9 years). Latent Class Growth Modelling was performed to identify subgroups of T2DM patients with distinct trajectories of SBP levels. Multinomial logistic regression analyses were conducted to determine subgroup characteristics. Associations of different subgroups with HbA1c level, retinopathy, microalbuminuria and medication use during follow-up were studied by constructing plots and by graphically comparing differences between classes.

**Results:** Four subgroups with distinct SBP trajectories were identified (Figure). The largest subgroup (85.6%) showed adequate SBP control (at or around 140 mmHg) over time. The second subgroup (5.6%) were hypertensive in first few years, responded slowly to BP management and eventually reached SBP control. The third subgroup (3.4%) showed deteriorating hypertension during the first four years, then showed insufficient response to BP management. The fourth subgroup (5.4%) showed deteriorating hypertension over time. Patients within subgroups 2-4, thus other than the adequate SBP control subgroup were significantly older, comprised more women, used more antihypertensive medication, had a higher prevalence of retinopathy and microalbuminuria and had higher all-cause mortality rates.

**Conclusion:** We identified four subgroups of T2DM patients with distinct SBP trajectories. More than 85% reached and maintained adequate SBP control. Subgroups with a more unfavourable course of SBP control also showed higher rates of retinopathy, microalbuminuria and all-cause mortality over time. This study identified important subgroups to target in order to improve BP management in T2DM patients.

### Relationships between the risk of cardiovascular events in type 2 diabetes and both visit-to-visit variability and time-to-effect in systolic blood pressure

T. Takao<sup>1</sup>, Y. Matsuyama<sup>2</sup>, H. Yanagisawa<sup>3</sup>, M. Kikuchi<sup>1</sup>, S. Kawazu<sup>1</sup>;

<sup>1</sup>Division of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, <sup>2</sup>Department of Biostatistics, School of Public Health, University of Tokyo, <sup>3</sup>Department of Public Health and Environmental Medicine, The Jikei University School of Medicine, Tokyo, Japan.

**Background and aims:** Recent studies, mostly in treated hypertensive patients, found a visit-to-visit BP variability is a risk factor for cardiovascular diseases (CVD) and organ damage independently of the mean BP. However, reports in patients with diabetes remain limited. Lack of a BP legacy effect on cardiovascular events has been reported in type 2 diabetes. However, data on the effects of early lowering of BP are still scarce. This study aimed to determine whether systolic BP (SBP) variability is able to predict, independently of the mean SBP, the incidence of CVD events in patients with type 2 diabetes, and to analyze the time-to-effect relationship between SBP and the risk of these events.

**Materials and methods:** A total of 652 (538 men, 114 women) patients with type 2 diabetes who first visited our hospital between 1995 and 1996, with at least 1 hospital visit per year and no history of CVD, and undergone 4 or more SBP determinations, were retrospectively enrolled. Patients were followed through June 2012. SD or CV was used as a measure of SBP variability. Risk of CVD events was evaluated by multivariate Cox proportional hazard models. SBP was analyzed as a mean value and a time-dependent covariate using the last observation carried forward or moving-mean during 1 year to 17 years preceding the events. For all analyses, SAS (version 9.3) was used.

**Results:** The mean values at baseline were age 55.7 years, duration of diabetes 5.6 years, BMI 23.4 kg/m<sup>2</sup>, BP 133.7/77.9 mmHg, HbA1c 8.0%, Total-cholesterol (TC) 209.3 mg/dl, and HDL-cholesterol (HDLc) 49.8 mg/dl. 275 patients were current smokers. The median follow-up period from first visit was 11.5 years, and the total number of SBP measurements was 53,949 (per-patient median: 78). By the end of follow-up, CVD events occurred in 71 patients. Hazard ratios for the incidence of CVD unadjusted, adjusted for age and sex, and for age, sex, duration of diabetes, current smoker, mean SBP, mean HbA1c, mean TC/HDLc, mean BMI, and the number of SBP measurements (ln-transformed), increased across tertiles of SD and CV of SBP (Table). The incidence of CVD was significantly associated with SBP during the preceding 2 to 8 years, with the highest significance during the preceding 3 years, and borderline significance during the preceding 1 and the preceding 9 to over 17 years.

**Conclusion:** Visit-to-visit SBP variability was able to independently predict CVD events in patients with type 2 diabetes. Increased SBP during the preceding 3 years resulted in the highest risk of CVD; therefore, to prevent CVD, SBP management should focus on stable and well-timed control.

**Table.** Cumulative incidence and hazard ratios for cardiovascular diseases (CVD) associated with tertiles of SD and CV of systolic BP (SBP)

| Outcome                            | Tertiles of SBP SD for incidence of CVD |                            |                       | p trend |
|------------------------------------|---|----------------------------|-----------------------|---------|

### Re-evaluation of patients with type 2 diabetes from the RIACE cohort using the 8<sup>th</sup> Joint National Committee cut-offs for blood pressure

A. Solini<sup>1</sup>, G. Zoppini<sup>2</sup>, C. Fondelli<sup>3</sup>, E. Orsi<sup>4</sup>, M. Arosio<sup>5</sup>, R. Trevisan<sup>6</sup>, M. Vedovato<sup>7</sup>, F. Cavalot<sup>8</sup>, O. Lamacchia<sup>9</sup>, R. Buzzetti<sup>10</sup>, G. Penno<sup>1</sup>, G. Pugliese<sup>11</sup>;

<sup>1</sup>Department of Clinical and Experimental Medicine, University of Pisa, <sup>2</sup>Division of Endocrinology and Metabolic Diseases, University of Verona, <sup>3</sup>Diabetes Unit, University of Siena, <sup>4</sup>Diabetes Unit, Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, <sup>5</sup>Endocrinology Unit, San Giuseppe Hospital, Milan, <sup>6</sup>Endocrinology and Diabetes Unit, Ospedale Riuniti, Bergamo, <sup>7</sup>Department of Clinical and Experimental Medicine, University of Padua, <sup>8</sup>Department of Clinical and Biological Sciences, University of Turin, Orbassano, <sup>9</sup>Department of Medical Sciences, University of Foggia, <sup>10</sup>Department Experimental Medicine, La Sapienza University, Rome, <sup>11</sup>Department of Clinical and Molecular Medicine, La Sapienza University, Rome, Italy.

**Background and aims:** The 8<sup>th</sup> Joint National Committee (JNC8) report has raised the recommended blood pressure (BP) threshold for drug therapy in diabetic subjects from 130/80 (JNC7) to 140/90 mmHg. This study was aimed at re-evaluating with the new BP cut-offs the prevalence of hypertension, anti-hypertensive treatment, and achievement of target BP in patients with type 2 diabetes from the Renal Insufficiency And Cardiovascular Events (RIACE) Italian Multicenter Study.

**Materials and methods:** The RIACE cohort consists of 15,773 patients, consecutively visiting 19 Diabetes Clinics throughout Italy in years 2007–2008. Exclusion criteria were dialysis or renal transplantation. BP was measured with a mercury sphygmomanometer on the right arm after at least 5 min of rest. Major acute cardiovascular disease (CVD) events were adjudicated based on hospital discharge records.

**Results:** Using the JNC7 BP targets, 6,854 patients (43.5%) had systolic BP <130 mmHg, 11,537 (73.1%) had diastolic BP <80 mmHg, and 6,276 (39.8%) met both targets. Using the JNC8 cut-offs, percentages were 66.6% for systolic BP (+23.1%), 94.2% for diastolic BP (+21.1%) and 65.7% for both (+25.9%). Change in percentage of subjects on-target rose from 21.1% to 24.3% for systolic BP and decreased from 25.0% to 16.4% for diastolic BP by age quartiles (p<0.001 for both). Based on JNC7 and JNC8 criteria, respectively, 2,228 and 3,458 patients were normotensive (NT, 14.1% and 21.9%), 13,545 and 12,315 hypertensive (HT, 85.9% and 78.1%), 11,150 and 11,150 treated HT (HT-tx, 70.7% and 70.7%, i.e. 82.3% and 90.5% of HT), and 4,048 and 6,903 on-target HT-tx (HT-tx-target 25.7% and 43.8%, i.e. 36.3% and 61.9% of HT-tx). Then, the following six groups were compared: G1, NT by JNC7 (n. 2,228, 14.1%); G2, NT only by JNC8 (n. 1,230, 7.8%); G3, untreated HT (n. 1,165, 7.4%); G1-tx, on-target by JNC7 (n. 4,048, 25.7%), G2-tx, on-target only by JNC8 (n. 2,855, 18.1%), G3-tx, not on-target (4,247, 26.9%). Prevalence values of any CVD and any coronary event were significantly higher in G1-tx (31.4% and 23.5%, respectively, p<0.001) than in G2-tx (27.6% and 19.6%) and G3-tx (26.3% and 16.1%), likely as an effect of reverse causality, i.e. a higher CVD risk prompted a stronger effort to reduce BP levels.

**Conclusion:** Achieving BP targets is easier with the JNC 8 criteria. However, it cannot be ruled out that a less aggressive approach might ultimately translate into higher BP levels mainly in subjects at high CVD risk.

## OP 36 Molecular mechanisms of insulin action in vitro

211

### The regulation of Wnt signalling pathways by insulin and NEFAs in skeletal muscle and adipose tissue of healthy humans

M. Karczewska-Kupczewska<sup>1,2</sup>, A. Nikolajuk<sup>2</sup>, M. Stefanowicz<sup>1</sup>, N. Matulewicz<sup>1</sup>, M. Straczkowski<sup>1,2</sup>;

<sup>1</sup>Department of Metabolic Diseases, Medical University of Białystok,

<sup>2</sup>Department of Prophylaxis of Metabolic Diseases, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland.

**Background and aims:** The Wnt signaling plays an important role in embryonic development, cell proliferation, cell cycle, differentiation, apoptosis and tissue homeostasis. The Wnt ligands bind to frizzled (Fzd) receptors and activate canonical ( $\beta$ -catenin dependent) and non-canonical ( $\beta$ -catenin independent) pathways. Dysregulation of Wnt signal transduction is associated with many pathophysiological states including metabolic disorders. The aim of the present study was to assess skeletal muscle and adipose tissue expression of genes associated with Wnt signaling pathways in young healthy population, their regulation by hyperinsulinemia and serum NEFAs elevation and their relationship with insulin sensitivity.

**Materials and methods:** We studied 20 healthy male subjects (mean age 25.20 $\pm$ 3.15 years, mean BMI 26.47 $\pm$ 4.64 kg/m<sup>2</sup>). The biopsies of vastus lateralis muscle and subcutaneous adipose tissue were performed at baseline and after 6 hours of euglycemic hyperinsulinemic clamp with or without Intralipid/heparin infusion. The participants were divided into subgroups of high (high-IS) and low insulin sensitivity (low-IS).

**Results:** The muscle mRNA expression of  $\beta$ -catenin, Fzd coreceptor-LDL receptor-related protein 6 (Lrp6), Dishevelled 2 (Dsh2) and adipose tissue mRNA expression of Lrp6 were higher in low-IS, whereas adipose tissue mRNA of Dsh2 and glycogen synthase kinase 3 $\beta$  (GSK3 $\beta$ ) were lower in low-IS (all  $p < 0.05$ ). Hyperinsulinemia resulted in a decrease in muscle and adipose tissue Lrp6, adipose tissue c-Myc and transcription factor 7-like 2 (TCF7L2) expression and an increase in muscle and adipose tissue Dvl1/2/3 expression (all  $p < 0.05$ ). Intralipid/heparin infusion resulted in 4-fold increase in serum NEFAs ( $p < 0.0001$ ) and decrease in insulin sensitivity by approx. 40% ( $p < 0.0001$ ). Most of the described changes in Wnt signaling pathways disappeared after NEFAs elevation and adipose tissue c-Myc expression was even up-regulated by NEFAs ( $p = 0.0005$ ).

**Conclusion:** Our data indicate that Wnt canonical signaling is increased in insulin resistant subjects and insulin could inhibit  $\beta$ -catenin dependent pathway and mediate switching between canonical and non-canonical pathways. *Supported by: Grant UDA-POIG.01.03.01-00-128/08; from the Program Innovative Economy*

**Background and aims:** Fetuin-A, a hepatokine, inhibits insulin receptor tyrosine kinase and interferes with downstream insulin signaling, and glucose uptake. Elevated levels of fetuin-A has been shown to be correlated with insulin resistance, obesity and type 2 diabetes. Fetuin-A exists in both phosphorylated and dephosphorylated forms in circulation. However, there are no reports on fetuin-A phosphorylation status in insulin resistant conditions or on its molecular characterization. The goal of this study was to characterize the role of fetuin-A phosphorylation on insulin signaling, and its association with obesity and insulin resistance.

**Materials and methods:** We generated Ser312Ala and Ser120Ala+Ser312Ala mutants to characterize effects of fetuin-A phosphorylation. Ser312-fetuin-A phosphorylation status was examined in diet-induced obese mice, ZDF rats, and obese individuals.

**Results:** While wild-type phosphorylated fetuin-A inhibited insulin signaling (IR, AKT, and MAPK, GLUT4 translocation), glucose uptake, and glycogen synthesis, the single Ser312Ala-fetuin-A mutant and the double phospho-defective mutant (Ser312Ala+Ser120Ala) were without effect, indicating that phosphorylation status of fetuin-A was critical to mediate its inhibitory effects on insulin action. We next examined phosphorylation status of fetuin-A (Ser312) in animal models of obesity and insulin resistance. Serum Ser312phosphofetuin-A levels were significantly elevated in C57BL6 diet-induced obese mice and 6 weeks-old ZDF rats, which was consistent with the observed hyperinsulinemia and increased HOMA-IR. Next, we examined total fetuin-A and Ser312-phosphorylated fetuin-A concentrations in 31 obese men and 11 age-matched normal weight individuals. While both serum fetuin-A and Ser312phosphofetuin-A levels were significantly elevated in obese individuals, only Ser312phosphofetuin-A was significantly correlated with serum insulin, HOMA, QUICKI and glucose-to-insulin ratio.

**Conclusion:** Our studies showing that that phosphorylation status of fetuin-A is critical for its inhibitory effects on insulin action, and that serum Ser312-phosphorylated fetuin-A concentrations are elevated in insulin resistant animals and humans, suggest that phosphorylated fetuin-A plays a key role in the modulation of insulin action.

### Down-regulation of miR-22 and miR-26a independently induces insulin resistance in L6 myotubes

D.K. Andersen, B. Cobb, M.E. Cleasby;

Royal Veterinary College, University of London, UK.

**Background and aims:** Insulin resistance (IR) in skeletal muscle invariably develops in advance of type 2 diabetes (T2D). MicroRNAs (miRNAs) are small non-coding RNAs that negatively regulate protein translation, via specific binding to the 3'UTRs of mRNAs. The involvement of miRNAs in normal and abnormal physiology is increasingly recognised. However, their role in the development of muscle IR is poorly characterised. We have previously shown the down-regulation of five miRNAs after 5 or 20 weeks of high-fat feeding of male Wistar rats: miR-22, miR-26a, miR-29a, miR-187 and miR-126\*. Here we interrogated miR-22 and miR-26a for roles in mediating muscle insulin sensitivity.

**Materials and methods:** L6 myoblasts were cultured and differentiated into myotubes for study. Firstly, the effects of IR induced by long-term insulin treatment (HI, 10nM), palmitic acid (PA, 0.75mM), TNF- $\alpha$  (2ng/mL) or Dexamethasone (Dex, 2nM) on miRNA expression were investigated. Subsequently, 100nM miR-22 or miR-26a miRNA inhibitor was transfected into myotubes on day 3 of differentiation and the effects on glucose uptake quantified using [<sup>3</sup>H]-2-deoxy-glucose tracer  $\pm$  100nM insulin. miRNA levels were quantified using probe-based Real-time PCR, normalising to small nucleolar RNA expression. TargetScan was used to predict targets of miR-22 that might impact upon insulin sensitivity and protein levels of these were quantified by western blotting. Data were analysed using Student's paired t-test or Two-way ANOVA with Fisher's LSD test *post-hoc*. Results are presented as percentages of the control or basal treatment condition (n=3-4 independent experiments).

**Results:** Interestingly, expression levels of both miR-22 and miR-26a in L6 myotubes were reduced by HI (to 74%,  $p = 0.047$  and 68%,  $p = 0.020$  respectively), but not by PA, TNF- $\alpha$  or Dex treatments, despite impairment in insulin-stimulated glucose disposal. Specific miRNA inhibitor treatment reduced miR-22 and miR-26a expression to 45%  $p = 0.0012$  and 41%  $p = 0.0002$ , respectively. miR-22 inhibition abolished the effect of insulin to stimulate glucose uptake in L6 myotubes, reducing it from 144% of basal in control myotubes to 98% in miR-22 silenced myotubes (Interaction  $p = 0.04$ ). miR-26a inhibition also abolished the effects of insulin stimulation on glucose uptake, although this was principally the result of a 29% increase in basal glucose disposal (Interaction  $p = 0.0029$ ). TargetScan-predicted targets of miR-22 included caveolin-3, sirtuin-1, glucose transporter-1, phosphatase and tensin homolog (PTEN) and protein tyrosine phosphatase, non-receptor type 1. Western blot analysis to date of predicted targets has identified a trend towards increased caveolin-3 (160%  $p = 0.11$ ) after miR-22 silencing, but no effect on PTEN.

**Conclusion:** These data suggest that hyperinsulinaemia is the key component of the IR syndrome that drives down-regulation of the investigated miRNAs. Both miR-22 and miR-26a are shown to contribute to muscle IR through impairment of insulin-stimulated glucose disposal. The mechanisms for the effects of miRNA inhibition are under investigation.

## 214

**GLP-1 improves the reduction of glucose uptake through SIRT-1 in skeletal muscle cells under palmitate induced-insulin resistance**T. Kim<sup>1</sup>, J. Jeon<sup>2</sup>, E. Ha<sup>2</sup>, S.-E. Choi<sup>3</sup>, S.-Y. Ahn<sup>2</sup>, S. Han<sup>2</sup>, H. Kim<sup>2</sup>, D. Kim<sup>2</sup>, Y. Kang<sup>2</sup>, K.-W. Lee<sup>2</sup>;<sup>1</sup>Internal Medicine, Kwandong University, Gangneung,<sup>2</sup>Endocrinology and Metabolism, <sup>3</sup>Institute of Medical Science, Ajou University School of Medicine, Suwon, Republic of Korea

**Background and aims:** Insulin resistance is a major pathogenesis of type 2 diabetes mellitus. Recently, the target molecules for diabetes treatment have been identified. Glucagon like peptide-1 (GLP-1) was developed as an anti-diabetic agent and is known to have a potent glucose-dependent insulinotropic action on the pancreas as well as extrapancreatic actions. SIRT1, as an NAD-dependent deacetylase, has been demonstrated in the role of protecting ageing-related diseases and beneficial effects of metabolic homeostasis. We investigated whether the actions of GLP-1 were mediated by SIRT-1 activation in skeletal muscle cells under palmitate induced-insulin resistance.

**Materials and methods:** After confirming the action of GLP-1 to palmitate-induced insulin resistance, we determined 2-[N-(7-nitrobenz-2-oxa-1,3-diazol-4-yl)amino]-2-deoxy-D-glucose (2-NDBG) uptake, GLUT4 mRNA, and the phosphorylation levels of protein related to insulin signal pathway (IRS-1, Akt) in human skeletal muscle myotubes (HSMM) exposed to palmitate (200  $\mu$ M, for 24 hours) and compared to those in HSMM exposed to palmitate and GLP-1 (200 nM) simultaneously. To elucidate whether SIRT-1 contributed to GLP-1 action in the palmitate-induced insulin resistance, we compared the levels of proliferator-activated receptor- $\gamma$ -co-activator 1 $\alpha$  (PGC1 $\alpha$ ) deacetylation in HSMM exposed to palmitate and GLP-1 (200 ng/ml) for 24 hours. Moreover, when exposed to SIRT1 inhibitor (EX527) in the same conditions, we demonstrated the changes of GLUT4 mRNA expression and insulin signaling.

**Results:** GLP-1 restored the reduction of glucose uptake, GLUT4 mRNA levels, and GLUT4 promoter activity by palmitate in human skeletal muscle myotubes. GLP-1 reduced acetylation of PGC1 $\alpha$  in HSMMs over expressed PGC1 $\alpha$ . This result suggested that GLP-1 activated a deacetylase, such as SIRT-1. SIRT1 inhibitor (EX527) suppressed GLUT4 mRNA expression by GLP-1 in HSMMs. SIRT1 inhibitor (EX527) prevented phosphorylation (IRS-1, Akt) of protein related to insulin signal pathways by GLP-1 in HSMMs. This suggested the expression of GLUT4 mRNA and the activation of insulin signaling by GLP-1 were associated with SIRT1.

**Conclusion:** Our data suggests GLP-1 improved palmitate-induced insulin resistance in HSMM by the activation of SIRT-1.

## 215

**Overexpression of the glucose transporter 1 in renal mesangial cells protects against cellular stress via Nrf2/NQO1**T. Fleming<sup>1</sup>, E. Schleicher<sup>2</sup>, H.-U. Häring<sup>2</sup>, P.P. Nawroth<sup>1</sup>;<sup>1</sup>Internal Medicine I and Clinical Chemistry, University of Heidelberg, Heidelberg, Germany,<sup>2</sup>Department of Internal Medicine, University of Tübingen, Germany.

**Background and aims:** Diabetic patients have been shown to be susceptible to the formation and accumulation of triose phosphates and the reactive metabolite methylglyoxal (MG), formed by non-enzymatic degradation on these intermediates. These findings suggest that it is not the condition of hyperglycaemia, but how glucose is handled, which underlies the development of diabetic complications. In this project, this was addressed by characterizing rat mesangial cells which stably overexpress the glucose transporter-1 protein, the rate-limiting step for the movement of glucose into the cell. In such cells, glucose uptake and utilization is increased regardless of other regulator factors.

**Materials and methods:** The phenotype of rat mesangial cells over-expressing glucose transporter-1 (GLUT1) and the respective control cells, stably expressing lac operon (LacZ) were characterized with respect to growth and energy metabolism under basal condition (11mM glucose).

**Results:** It was found that despite a significantly higher glucose uptake, rat mesangial cells over-expressing glucose transporter-1 (GLUT1) had a reduced glycolytic rate. They also had reduced levels of metabolic cofactors and intermediates. They were also found to have significantly lower number of hyper-polarized mitochondria, suggestive of altered respiratory function. This was confirmed by the decreased rate of oxygen consumption. Mitochondrial superoxide production was shown to be decreased in the GLUT1 cells;

however, generally oxidative stress within these cells was increased, suggestive of increased cellular stress as a consequence of increased glucose uptake. Preliminary screening of antioxidant defence enzymes showed that NAD(P)H dehydrogenase(quinone) 1 (NQO1), was significantly increased in terms of expression and activity as well as its regulator, Nrf2. The observed increase in antioxidant defences was confirmed by the increase in total antioxidant capacity, and increased tolerance to hydrogen peroxide and MG.

**Conclusion:** This data indicates that under conditions of high glucose uptake, antioxidant defences are increased to help protect the cell from the increased cellular stress. The observed increases in defences system whilst protective are ultimately detrimental to the cell.

## 216

**Extracellular vesicles released by hypoxic adipocytes impair insulin signalling and glucose uptake in adipocytes**S. Mora<sup>1</sup>, J. Mleczko<sup>1</sup>, J. Falcon-Perez<sup>2</sup>;<sup>1</sup>Cellular and Molecular Physiology, University of Liverpool, UK,<sup>2</sup>CIC BioGUNE, Bilbao, Spain.

**Background and aims:** Exosomes and microvesicles are extracellular vesicles (EVs) shed by many cell types that mediate cell to cell communication. EVs contain proteins and RNA species that modulate biochemical responses in target cells. Adipocytes have been shown to produce extracellular vesicles. During obesity adipocytes are subject to hypoxia. The aim of our study was to investigate whether EVs released by hypoxic adipocytes have autocrine effects in regulating insulin action and glucose uptake.

**Materials and methods:** We isolated EVs from the conditioned media of differentiated 3T3L1 adipocytes cultured under normoxia (control cells) or from cells exposed to hypoxia (1% O<sub>2</sub>) for 24hrs. EVs were purified from the culturing media using centrifugation techniques and characterized using biophysical and biochemical methods, including nanoparticle tracking analysis, cryoelectron microscopy, and immunoblotting techniques. EVs were then tested for their ability to modulate insulin action and insulin-stimulated glucose uptake in 3T3L1 adipocytes. Independent sets of differentiated 3T3L1 adipocytes were either left untreated or treated with EVs purified from control or hypoxic adipocytes for 24hr and subsequently their response to insulin stimulation was evaluated by western blotting and glucose uptake assays.

**Results:** We found that 3T3L1 adipocytes release EVs of heterogeneous sizes as determined by cryoelectron microscopy and nanoparticle tracking analysis. Hypoxia increased the release of EVs by adipocytes. Immunoblotting analysis showed that EV preparations were enriched in exosomal markers and markedly devoid of other organelle markers. Adipocytes treated with EVs obtained from hypoxic cells displayed a reduced insulin-mediated activation of glucose uptake compared to those left untreated or treated with EVs derived from control adipocytes. No differences in the expression levels of the glucose transporter GLUT4 were observed in cells treated with EVs from hypoxic adipocytes compared to those left untreated or treated with EVs from control cells. However, cells treated with EVs released from hypoxic cells exhibited reduced insulin-mediated activation of phosphatidylinositol 3-kinase as seen by a reduced phosphorylation of the downstream kinase AKT, without alterations in the total AKT levels.

**Conclusion:** Our data suggest that EVs released by hypoxic adipocytes contribute to insulin resistance, as they impair insulin signalling and glucose uptake in adipose cells.

## OP 37 Metformin: new insights into an old drug

217

**Mechanism of increase in plasma intact GLP-1 by metformin in type 2 diabetes: stimulation of GLP-1 secretion or reduction in plasma DPP-4 activity?**

T. Wu<sup>1</sup>, M.J. Bound<sup>1</sup>, C.F. Deacon<sup>2</sup>, K.L. Jones<sup>1</sup>, M. Horowitz<sup>1</sup>, C.K. Rayner<sup>1</sup>;

<sup>1</sup>Discipline of Medicine, University of Adelaide, Australia,

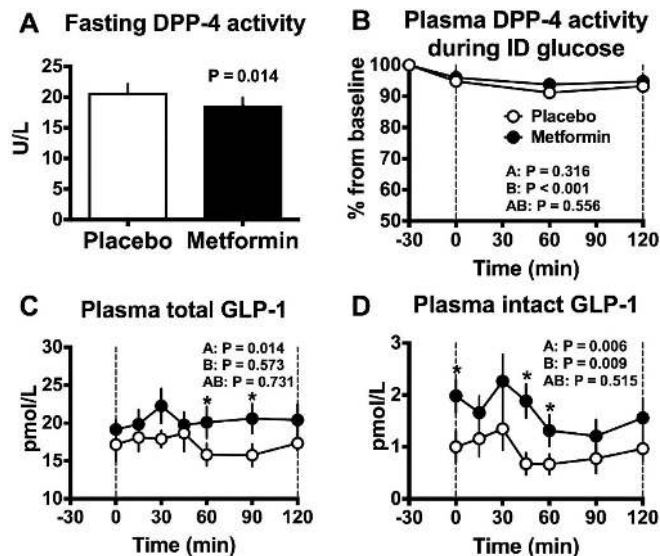

<sup>2</sup>Department of Biomedical Science, University of Copenhagen, Denmark.

**Background and aims:** Metformin increases plasma intact glucagon-like peptide-1 (GLP-1) concentrations. However, it remains uncertain whether this reflects an enhancement of GLP-1 secretion and/or a reduction in plasma dipeptidyl peptidase-4 (DPP-4) activity. We, therefore, evaluated the effects of metformin on plasma DPP-4 activity, and total and intact GLP-1 concentrations, before and during an intraduodenal (ID) glucose infusion in type 2 diabetes.

**Materials and methods:** We retrospectively assayed plasma DPP-4 activity in 12 Caucasian males with diet-controlled type 2 diabetes (HbA1c:  $6.5 \pm 0.1\%$  ( $47.6 \pm 1.4$  mmol/mol); duration of known diabetes:  $3.5 \pm 0.9$  years; age:  $63.7 \pm 1.9$  years; BMI:  $29.9 \pm 1.2$  kg/m<sup>2</sup>), treated with metformin 850 mg bd or placebo each for 7 days in a randomised crossover design, with 14 days 'washout' between. On days 5 or 8 of each treatment (6 patients each), subjects took their morning dose of metformin or placebo after an overnight fast, followed 30 min later by an ID infusion of glucose (60 g over 120 min, ie. 2 kcal/min).

**Results:** Plasma fasting DPP-4 activity was less during metformin treatment than placebo ( $18.4 \pm 1.6$  vs.  $20.5 \pm 1.7$  U/L,  $P = 0.014$ ). During ID glucose infusion ( $t = 0$ -120 min), there was a slight reduction in plasma DPP-4 activity on both days ( $P < 0.001$ ), without any difference between metformin and placebo. Both total and intact GLP-1 concentrations were greater after metformin than placebo ( $P = 0.014$  and  $0.006$ , respectively). During ID glucose infusion, the increment in intact GLP-1 (ie. difference in the areas under the curve (AUC)) after metformin versus placebo was directly related to the AUC for total GLP-1 ( $r = 0.61$ ,  $P = 0.028$ ), and tended to be inversely related to plasma DPP-4 activity ( $r = -0.48$ ,  $P = 0.098$ ).

**Conclusion:** The increase in plasma intact GLP-1 concentrations by metformin is, at least in part, attributable to stimulation of GLP-1 secretion - a reduction in soluble DPP-4 activity may also make a modest contribution.

**Intestinal glucose uptake is modulated by metformin**

J.B.L. Hoekstra, L. Bähler, K. Stroek, H. Verberne, F. Holleman;  
Academic Medical Center, Amsterdam, Netherlands.

**Background and aims:** Obesity is the result of an imbalance between energy intake and energy expenditure. Recently brown adipose tissue (BAT) has gained a lot of interest because of its capacity to convert calories into heat. BAT shows an intense 18F-Fluorodeoxyglucose-(FDG)-uptake on Positron-Emission-Tomography-(PET)-CT scans. Physiological 18F-FDG accumulation is also frequently observed in the intestine, however, the possibility of the intestine as an energy dissipating tissue has not yet been explored. Metformin is one of the few drugs in the treatment of diabetes mellitus(DM) that is associated with moderate weight loss. Interestingly, patients using metformin are known to have increased 18F-FDG-uptake in the colon. The aim of this study was to retrospectively assess determinants of 18F-FDG-uptake in the intestine in patients who underwent a primary diagnostic 18F-FDG-PET-CT scan.

**Materials and methods:** Consecutive 18F-FDG-PET-CT scans performed between January 1st and April 31st 2011 were analysed. 18F-FDG intestinal uptake was visually assessed using the 4-point scale described by Gontier et al. which uses liver uptake as a reference. (1; lower, 2; similar, 3; moderately higher than hepatic activity and 4; intense and diffuse uptake). Differences in continuous variables between the 4 grades were assessed using the Kruskal-Wallis test. Differences in categorical variables between the 4 groups were assessed using the Fisher-Freeman-Halton exact test. All variables were used as covariate in a forward logistic regression model (e.g. grade 1 & 2 vs 3&4).

**Results:** Available for analysis were 270 18F-FDG-PET-CT scans of 270 patients. The majority of patients was female (51.9%) with a median age of 61 [52-71] years, a BMI of  $25.0[22.5-28.7]$  kg/m<sup>2</sup>. Approximately 20% of the subjects smoked (smoking >1 daily). Most patients had a grade 2 (44%) or grade 3 (39%) uptake of 18F-FDG in the intestines, far less subjects had a grade 1 (9%) or grade 4 (8%) uptake of 18F-FDG. There were no significant differences between the four grading groups with regard to age, sex, BMI or smoking status. Type 1 DM was observed in 2 % of the subjects and 37% of the patients had type 2 DM. Of the DM patients, 87.2% used insulin, 87.2% used metformin and 82.1% used sulfonylurea derivatives (SU). There was a positive trend over the 4 grades for the use of insulin, SU and metformin but also for diuretic use. The use of insulin ( $p < 0.05$ ), SU ( $p < 0.001$ ), metformin ( $p < 0.001$ ) and diuretics ( $p < 0.05$ ) was significantly higher in grade 4 than grade 1. In a logistic regression analysis, use of metformin was the only significant predictor for high (e.g. grade 3 or 4 versus grade 1 or 2) 18F-FDG-uptake in all segments of the intestine, with an odds ratio(OR) of 12.4 (correlation coefficient(CC) 2.5, 95%CI 2.8-55.5). However, increased 18F-FDG-uptake in the descendens alone was associated with both metformin with an OR of 17.0 (CC 2.8, 95%CI 5.1-57.4) and anti-inflammatory drugs with an OR of 3.6 (CC 1.2, 95%CI 1.1-11.9).

**Conclusion:** Metformin use is associated with increased intestinal 18F-FDG-uptake, suggesting a potential role for increasing intestinal energy expenditure.

219

**Metformin enhances intestinal glucose uptake in patients with type 2 diabetes**

J.P. Koffert<sup>1</sup>, H. Honka<sup>1</sup>, K.A. Virtanen<sup>1</sup>, S. Kauhanen<sup>2</sup>, P. Iozzo<sup>3</sup>, R. Parkkola<sup>4</sup>, P. Nuutila<sup>1,5</sup>;

<sup>1</sup>Turku PET Centre, <sup>2</sup>Division of Digestive Surgery and Urology, Turku University Hospital, Finland, <sup>3</sup>Institute of Clinical Physiology, National Research Council, Pisa, Italy, <sup>4</sup>Department of Radiology, University of Tampere, <sup>5</sup>Department of Endocrinology, Turku University Hospital, Finland.

**Background and aims:** The intestine is emerging as a key organ in the pathogenesis of type 2 diabetes. This study's objective was to determine the effects of metformin and rosiglitazone on intestinal glucose uptake in patients with type 2 diabetes.

**Materials and methods:** Forty-one patients with newly diagnosed type 2 diabetes were randomized for treatment with metformin (1 g, b.i.d), rosiglitazone (4 mg, b.i.d), or placebo in a 26-week double-blind trial. Positron emission tomography (PET) is a key tool for the assessment of intestinal metabolism. Insulin stimulated glucose uptake in small intestine, caecum, and skeletal muscle was measured before and after treatment using [18F]-

fludeoxyglucose (FDG) PET during euglycemic hyperinsulinemic clamp. Magnetic resonance imaging (MRI) was used as an anatomical reference.

**Results:** Both active treatments improved glycemic control ( $p < 0.01$  vs. placebo). Rosiglitazone improved glucose uptake by 44% in the whole body ( $p < 0.05$ ) and by 38% in skeletal muscle ( $p < 0.01$ , in both groups), while no changes were observed in the metformin group as previously reported (Diabetes 2002). In pooled data small bowel and caecal GU were associated with fGluc ( $r = -0.52$ ,  $p = 0.001$ ;  $r = -0.43$ ,  $p = 0.01$ ) and HbA1c ( $r = -0.40$ ,  $p < 0.02$ ;  $r = -0.46$ ,  $p = 0.005$ ). Glucose uptake was increased 2-fold in the metformin group in small intestine ( $2.0 \pm 0.7$  vs.  $4.3 \pm 1.6 \mu\text{mol} [100 \text{ g}](-1) \text{ min}(-1)$ ,  $p < 0.0001$ ) and by 3.7-fold in caecum ( $1.6 \pm 0.8$  vs.  $5.0 \pm 1.9 \mu\text{mol} [100 \text{ g}](-1) \text{ min}(-1)$ ,  $p < 0.0001$ ). A significant but minor increase in the rosiglitazone group occurred in the small intestine ( $2.3 \pm 0.6$  vs.  $2.8 \pm 0.8 \mu\text{mol} [100 \text{ g}](-1) \text{ min}(-1)$ ,  $p < 0.03$ ) and this increment was associated with M-value ( $r = 0.67$ ,  $p < 0.02$ ). No changes in intestinal glucose metabolism were observed in the placebo group.

**Conclusion:** This study shows that metformin enhances glucose metabolism both in the small intestine and the large intestine in patients with newly diagnosed type 2 diabetes. This effect is not related to enhanced insulin sensitivity but associates with improved glycemic control.

## 220

### Tissue hypoxic condition, not metformin, induces lactic acidosis in patient type 2 diabetes

S. Hwang, E. Lee, Y.-H. Lee, B.-W. Lee, E. Kang, B. Cha, H. Lee; Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

**Background and aims:** Metformin is recommended as the first drug in type 2 diabetic patients and has been shown to reduce diabetic-related complications and mortality. However, the use of metformin is limited by a concern of lactic acidosis (LA), especially in patients with renal failure. Therefore, we investigated the lactic acidosis and its relationship with metformin use in patients with type 2 diabetes.

**Materials and methods:** A total of 1,954 patients with type 2 diabetes were recruited from 2007 to 2011. They were analyzed according to the estimated glomerular filtration rate (eGFR) of  $60 \text{ mL/min/1.72m}^2$ . LA was defined as serum lactate levels more than  $5 \text{ mmol/l}$  and arterial pH less than 7.35.

**Results:** According to the metformin use, there were no differences in serum lactate levels in patients with type 2 diabetes. In addition, serum lactate levels were not correlated with metformin dose ( $P = 0.350$ ). These results were comparable in patients with  $\text{eGFR} < 60 \text{ mL/min/1.72m}^2$ . Overall, the prevalence of hyperlactinemia and LA were 18.8% and 3.0%, respectively. In subgroup analysis, they showed similar results regardless of metformin use. All patients with LA had at least one condition related to hypoxia or poor tissue perfusion such as myocardial infarction, septic shock, advanced cirrhosis and bleeding. On multiple regression analysis, metformin did not affect the development of lactic acidosis. Meanwhile, the tissue hypoxic condition was an independent risk factor for the development of lactic acidosis (odds ratio: 4.437, 95% confidence interval: 1.277–15.425).

**Conclusion:** In conclusion, tissue hypoxic condition was the one of the most attributable factors for the development of lactic acidosis in patients with type 2 diabetes. The metformin use may not be the cause of lactic acidosis, but rather a coincidence in patients with type 2 diabetes.

## OP 38 Novelties in risk prediction

### 221

#### How can we best predict cardiovascular disease risk in type 1 diabetes?

##### A comparison of risk equations

R. Saunders<sup>1</sup>, K. Boye<sup>2</sup>, J. Bae<sup>2</sup>, K. Norrbacka<sup>3</sup>, L. Timlin<sup>4</sup>, R. Pollock<sup>1</sup>, W. Valentine<sup>1</sup>;

<sup>1</sup>Ossian Health Economics, Basel, Switzerland, <sup>2</sup>Eli Lilly and Company, Indianapolis, USA, <sup>3</sup>Eli Lilly and Company, Helsinki, Finland,

<sup>4</sup>Eli Lilly and Company, Windlesham, UK.

**Background and aims:** Patients with type 1 diabetes (T1D) are at increased risk of developing cardiovascular disease (CVD) compared with the general population. In this study, the generalizability of CVD prediction models for patients with T1D, as well as a model averaging approach, is evaluated.

**Materials and methods:** Literature review identified two models of CVD risk and three clinical studies in patients with T1D that could be used to derive de novo formulae for estimating CVD risk. The five models of CVD were derived from the EuroDiab study (EDS), FinnDiane Registry (FDR), Lung model (LM, based on Diabetes Control and Complications Trial [DCCT] data), Swedish National Diabetes Registry (SNDR), and Wisconsin Epidemiologic Study of Diabetic Retinopathy study (WESDR). Two additional models were developed via model averaging. The first used the mean event probability over all models to define the patient's risk of CVD. The second applied a weight, calculated as the sum of log ratios of six cohort characteristics, to each model. Prediction performance was evaluated between models and against first incident CVD in the DCCT, defined as myocardial infarction (MI), stroke or unstable angina. Two algorithms, FDR and LM, only estimated risk of MI and stroke. Goodness of fit was assessed using the Chi squared test. A successful prediction was defined as  $\geq 60\%$  likelihood ( $p \geq 0.6$ ) that the two distributions (model versus actual) were not significantly different.

**Results:** Comparing the predictive performance of the three models that estimated all three CVD endpoints, CVD events in the DCCT were successfully predicted by each model, although generally SNDR overestimated and EDS underestimated risk (Figure). WESDR ( $p = 0.99$ ) most closely matched outcomes in the DCCT. Both model averaging approaches (unweighted and weighted) made successful predictions (both  $p = 0.99$ ). Inter model comparison showed that no individual model could successfully predict outcomes in more than two of the other datasets. The unweighted model average did not aid prediction performance, however, the weighted model made successful predictions in all patient populations: SNDR ( $p = 0.99$ ), EDS ( $p = 0.6$ ), FDR ( $p = 0.6$ ), WESDR ( $p = 0.99$ ), LM ( $p = 0.99$ ) and DCCT ( $p = 0.99$ ).

**Conclusion:** A model averaging approach weighted to baseline patient characteristics was the only model to provide a successful prediction in all six test cases. By evaluating multiple risk factors, model averaging may have advantages over traditional approaches to estimating CVD risk in patients with T1D.

## 222

**Occurrence of clinical remission in adult-onset type 1 diabetes is associated with decreased risk of microvascular complications**

P. Niedzwiecki, S. Pilacinski, A. Adamska, D. Zozulinska-Ziolkiewicz;  
Clinic of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

**Background and aims:** Partial clinical remission is common in the initial course of type 1 diabetes. In this phase of disease substantial insulin secretion contributes to good metabolic control and low incidence of acute complications. The aim of the study was to determine the association between presence of partial remission and occurrence of chronic complications of type 1 diabetes.

**Materials and methods:** 240 consecutive patients (77 women, 143 men), aged 26 (IQR: 22-31) hospitalized with newly diagnosed type 1 diabetes in the Department of Internal Medicine and Diabetology in 2004-2007 were asked to participate. Of these, 220 were included in the study. 133 of patients completed prospective follow-up. Finally, data of 81 patients (24 women, 57 men), aged 33 (IQR 29-38) were included into endpoint analysis. Clinical remission was defined as time in which all of the following criteria were met: HbA1c below 6.5 %, dose of exogenous insulin below 0.3 U / kg body weight and serum C-peptide concentration above 0.5 ng / ml. Patients were divided into those who were in remission at any time during follow-up (remitters) and non-remitters. At 7 years of follow-up occurrence of chronic microvascular complications of diabetes (retinopathy, diabetic kidney disease and neuropathy) was evaluated.

**Results:** In non-remitters group higher incidence of at least one microvascular complication (46.4 vs. 7.6 %,  $p < 0.0001$ ), higher incidence of retinopathy (42.8 vs. 5.7 %,  $p < 0.0001$ ), and neuropathy (21.4 vs 1.9 %,  $p = 0.006$ ) was found. In univariate logistic regression, significant association was found between absence of remission and occurrence of at least one microvascular complication (OR: 10.6, 95% CI : 2.94-38.22,  $p = 0.002$ ). In the Cox proportional hazards regression model that included clinically significant parameters at diagnosis (presence of ketoacidosis, cigarette smoking and HbA1c value) as covariates, absence of remission was associated with occurrence of chronic complications of diabetes at 7 years [HR: 3.65 (95% CI 1.23-4.56),  $p=0.04$ ].

**Conclusion:** Occurrence of clinical remission of diabetes is associated with reduced risk of chronic microvascular complications at 7-year follow-up.

**Proinsulin in early atherosclerosis: causal factor or bystander?**

R.J. Strawbridge<sup>1</sup>, A. Silveira<sup>1</sup>, P. Gustafsson<sup>1</sup>, K. Gertow<sup>1</sup>, D. Baldassarre<sup>2,3</sup>, F. Veglia<sup>3</sup>, S. Humphries<sup>4</sup>, U. de Faire<sup>3</sup>, E. Tremoli<sup>2,3</sup>, A. Hamsten<sup>1</sup>, the IMPROVE study group;

<sup>1</sup>Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden,

<sup>2</sup>Dipartimento di Scienze Farmacologiche e Biomolecolari, Università di Milano, <sup>3</sup>IRCCS Centro Cardiologico Monzino, Milan, Italy, <sup>4</sup>Centre for Cardiovascular Genetics, University College London, UK, <sup>5</sup>Department of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Increased proinsulin levels (relative to insulin levels) have been demonstrated to predict future incidence of both Type 2 Diabetes (T2D) and cardiovascular disease (CVD), independently of classical risk factors, although the mechanisms of these relationships are poorly understood. A genome-wide association meta-analysis study conducted by the MAGIC consortium, and including this group, has identified a number of loci and genetic variants associated with increased circulating proinsulin levels. This project aims to determine whether proinsulin and/or proinsulin-associated pathways play a causal role in determining severity and rate of progression of early, subclinical atherosclerosis.

**Materials and methods:** The IMPROVE study (consisting of 3711 subjects, of whom 917 are T2D subjects) without clinical signs of CVD at enrolment, who have been carefully phenotyped and monitored with repeated state-of-the-art high-resolution carotid ultrasound examinations. Biochemical phenotyping includes measurement (by Elisa) of circulating insulin and proinsulin levels. All subjects have been genotyped on the Illumina CardioMeta200K platform, providing good coverage of 5 of the 9 loci associated with proinsulin levels. Additional genotyping to cover the remaining 4 loci has been performed. Standard statistical methods and a Mendelian randomisa-

tion approach will be used to examine the influence and causality of proinsulin on early atherosclerosis.

**Results:** Proinsulin levels demonstrated associations with progression of (but not baseline) carotid intima media thickness (cIMT). In contrast, proinsulin-associated genetic variants influenced baseline but not progression cIMT measures, independently of established CVD risk factors and proinsulin levels. Novel associations between a) novel genetic variants and proinsulin and b) proinsulin-associated SNPs and cIMT have been observed, however these require replication.

**Conclusion:** Proinsulin does not appear to be a causal factor in early sub-clinical atherosclerosis, however proinsulin-associated mechanisms are implicated.

University Hospital, <sup>3</sup>Department of Neurology, Aalborg University

Hospital, Aalborg, <sup>4</sup>Diabetes Research Division, Dept. of Medicine,

Copenhagen University Hospital Gentofte, Copenhagen,

<sup>5</sup>Department of Clinical Medicine and Endocrinology, Aalborg University Hospital, Denmark.

**Background and aims:** Diabetes Mellitus (DM) is associated with an increased risk of cardiovascular disease. We investigated the effects of antidiabetic drugs on the composite endpoint (CE) of ischemic heart disease, heart failure and stroke incidence in patients with DM.

**Materials and methods:** We conducted a nested case-control study. Cases were patients with type 1 or type 2 DM who subsequently suffered from CE; controls were DM patients with no history of CE after DM diagnosis. Using the Danish National Hospital Discharge Register, we included DM patients with information on date of DM diagnosis, date of CE, and comorbidities. From the Central Region of Jutland, Denmark, medication use and biochemical parameters (LDL, HDL, total cholesterol, triglyceride, HbA1c, and creatinine) were collected. Logistic regression analyses were conducted. The analyses were mutually adjusted for comorbidities, pharmaceutical use, and the biochemical parameters.

**Results:** The data included 14,454 patients with DM who contributed a total of 115,225 person-years. 14.8 percent (2,257) suffered from a subsequent CE. CE prior to DM diagnosis (OR= 14.83, 95%CI: 12.63-17.41), atrial fibrillation (OR= 1.99, 95%CI: 1.57-2.51), and age at diabetes diagnosis (OR= 1.01, 95%CI: 1.007-1.014) all significantly increased the risk of subsequent CE. Patients with type 2 DM had a higher risk compared to type 1 DM patients (OR= 3.05, 95%CI: 2.57-3.63). The diabetes complications retinopathy (OR= 1.70, 95%CI: 1.30-2.23), nephropathy (OR= 1.58, 95%CI: 1.28-1.95), neuropathy (OR= 1.99, 95%CI: 1.57-2.53) and peripheral artery disease (OR= 2.06, 95%CI: 1.68-2.56) increased the risk of CE so did male gender (OR= 1.12, 95%CI: 1.00-1.25), and hypertension (OR= 1.39, 95%CI: 1.20-1.62). Treatment with statins reduced the risk of CE significantly (OR= 0.65, 95%CI: 0.57-0.73) when looking at the DM group as a whole, when grouped only significant in subjects with type 2 DM (OR= 0.59, 95%CI: 0.51-0.67). Biguanides (OR= 0.54 95% CI; 0.44-0.67) and liraglutide (OR= 0.41 95% CI; 0.32-0.52) (type 2 DM) both significantly decreased the risk of CE. DPP-4 inhibitors and  $\beta$ -cell stimulating agents had a neutral effect. In the subgroup analysis, a total of 1,351 DM patients (10,229 person-years), had information on biochemical values and were included. 14.9 percent (201) suffered from a subsequent CE. When results were adjusted for biochemistry, liraglutide (OR= 0.25, 95%CI: 0.11-0.56) was the only antidiabetic drug that retained a significant reduction on the risk of CE.

**Conclusion:** We have shown an association between use of biguanides and liraglutide and a reduced risk of CE in patients with type 2 DM. The effect of liraglutide was not tied to patient biochemical values, e.g. cholesterol or glucose-control (HbA1c).

## OP 39 Inflammation in obesity and type 2 diabetes

225

### Activation of oestrogen receptor alpha in macrophages controls high-fat diet-induced inflammation of adipose tissue and prevents obesity and glucose intolerance

E. Riant<sup>1</sup>, S. Handgraaf<sup>1</sup>, A. Zakaroff<sup>1</sup>, D. Teixeira<sup>2</sup>, R. Burcelin<sup>1</sup>, J.-F. Arnal<sup>1</sup>, A. Bouloumié<sup>1</sup>, P. Gourdy<sup>1,3</sup>;

<sup>1</sup>Institut des Maladies Métaboliques et Cardiovasculaires, INSERM U1048, Toulouse, France, <sup>2</sup>Department of Biochemistry, Faculty of Medicine, Porto, Portugal, <sup>3</sup>Diabetology Department, Toulouse, France.

**Background and aims:** Estrogens have been recognized as key regulators of body composition and glucose homeostasis. However, although both clinical and experimental data clearly evidenced the crucial role of estrogen receptor alpha (ERα), the mechanisms involved in the protective actions of estrogens against obesity and diabetes remain obscure. For instance, although estrogens are known to modulate inflammatory responses through ERα dependent effects, it is still uncertain whether specific actions of these sex steroid hormones on the stroma-vascular fraction (SVF) of adipose tissue could contribute to their benefits on body composition and glucose metabolism. In the present study, we aimed to determine 1) the influence of estrogens on the adaptation of SVF cells in response to a nutritional stress; 2) the contribution of ERα-expressing myeloid cells to the prevention of obesity by estrogens.

**Materials and methods:** In a first set of experiment, 3 groups of C57Bl/6 female mice were subjected to a chow or a high-fat (HFD) diet for 12 weeks: ovariectomized (estrogen deficiency), sham-operated (endogenous estrogens) and ovariectomized treated with 17β-estradiol (E2, 80µg/kg/d, sc). Weight gain, body composition and glucose tolerance were monitored and both isolated adipocytes and SVF from visceral adipose tissue (VAT) were analyzed by flow cytometry and RT-qPCR. Then, metabolic phenotype and SVF characteristics were studied in HFD-fed mice with specific inactivation of ERα in myeloid cells (ERα-LysM-Cre+ mice).

**Results:** Both endogenous estrogens and E2 administration prevented HFD-induced obesity and glucose intolerance, as well as adipocyte hypertrophy. HFD increased the number of CD45<sup>-</sup> cells in VAT SVF, irrespective of estrogen status, but VAT infiltration by immune cells (CD45<sup>+</sup>) was strongly reduced by endogenous estrogens and E2, with a significant decrease in macrophage content (~65% CD45<sup>+</sup>/F4/80+ cells) and a predominance of M2 macrophages, as confirmed by mRNA analysis (+13-fold Ym1; -4.5-fold iNOS in E2-treated as compared to ovariectomized mice). VAT infiltration by B and TCD4<sup>+</sup> and TCD8<sup>+</sup> lymphocytes was also reduced by estrogens, but the pool of regulatory T cells was preserved. Demonstrating the role of ERα-LysM-Cre+ mice were characterized by a significant increase of HFD-induced inflammation of VAT and developed exacerbated adiposity and glucose intolerance.

**Conclusion:** These data demonstrate that estrogens limit HFD-induced inflammation of VAT and suggest that macrophages of the SVF largely contribute to their protective action against obesity and through the activation of ERα.

226

### Heme oxygenase-1 drives metaflammation and insulin resistance in mouse and man

A. Jais<sup>1</sup>, E. Einwallner<sup>1</sup>, O. Shari<sup>2</sup>, M. Bilban<sup>1</sup>, C. Duvigneau<sup>3</sup>, C. Lumeng<sup>4</sup>, W. Patsch<sup>5</sup>, O. Wagner<sup>1</sup>, J.A. Pospisilik<sup>6</sup>, H. Esterbauer<sup>1</sup>;

<sup>1</sup>Department of Laboratory Medicine, Medical University of Vienna, <sup>2</sup>Dept. of Medicine 1, Laboratory of Infection Biology, Medical University of Vienna, <sup>3</sup>Institute of Medical Biochemistry, University of Veterinary Medicine, Vienna, Austria, <sup>4</sup>University of Michigan, Ann Arbor, USA, <sup>5</sup>Paracelsus Medical University, Salzburg, Austria, <sup>6</sup>MPI for Max Planck Institute of Immunobiology and Epigenetics & Epigenetics, Freiburg, Germany.

**Background and aims:** Obesity and diabetes affect more than half a billion individuals worldwide. Interestingly, the two conditions do not always co-occur and the molecular determinants of 'healthy' versus 'unhealthy' obesity remain ill-defined. Chronic metabolic inflammation (metaflammation) is believed to be pivotal. Here, we tested a hypothesized anti-inflammatory

role for heme oxygenase-1 (HO-1) in the development of human and mouse metabolic disease. Heme oxygenases catalyze the oxidative degradation of heme, a potentially harmful pro-oxidant, into biologically active products: biliverdin IXα, carbon monoxide(CO) and ferrous iron. In addition to its role in heme catabolism, HO-1 plays important roles in various pathophysiological states associated with cellular stress.

**Materials and methods:** To address the metabolic role of HO-1 in vivo in macrophages, we have generated a myeloid-cell specific conditional HO-1 knockout mouse model ('MacHO') and examined the role of HO-1 in the development of obesity-associated adipose tissue inflammation and insulin resistance. We fed either low-fat (10% calories derived from fat) or high-fat (60% of calories derived from fat) diets to male MacHO and littermate control mice for a total of 21 weeks.

**Results:** A significant difference in body-weight between the high fat diet groups was observed after 8 weeks of HFD feeding. Both insulin sensitivity and glucose tolerance were improved in MacHO mice fed the HFD compared with littermate control mice. Similarly, obese MacHO mice showed significantly higher insulin sensitivity as measured by insulin tolerance test when compared to HFD-fed control-mice, whereas insulin sensitivity was comparable between both groups on control diet. Histological analysis of HFD WAT sections showed a higher density of smaller adipocytes and a significant reduction in macrophage cell numbers, especially of the Cd11c<sup>+</sup> pro-inflammatory macrophage subpopulation. Furthermore, we found that mice lacking myeloid Hmox1 exhibited a strong reduction in hepatic accumulation of triglycerides and cholesterol. Histological analysis showed decreased vacuole formation and a reduced number of lipid droplets, consistent with amelioration of hepatic steatosis. In line, in highly matched biopsies from 'healthy' versus insulin resistant obese subjects we find HO-1 to be amongst the strongest positive predictors of metabolic disease in humans.

**Conclusion:** Intriguingly, cellular assays show that HO-1 is defining pre-stimulation thresholds for inflammatory skewing and NF-κB amplification in macrophages. These findings identify HO-1 inhibition as a potential therapeutic strategy for metabolic disease.

### Adipose stem cells contribute to inflammation and insulin resistance through both TH-17 polarisation and increased pro-inflammatory cytokine secretion

A. Eljaafari<sup>1,2</sup>, M. Robert<sup>1,3</sup>, B. Osta<sup>4</sup>, M. Chehimi<sup>1</sup>, C. Durand<sup>1</sup>, S. Chanon<sup>1</sup>, E. Lefai<sup>1</sup>, H. Vidal<sup>1</sup>, L. Pirola<sup>1</sup>;

<sup>1</sup>Unité 1060-Carmen, INSERM, Pierre Benite, France, <sup>2</sup>Recherche Clinique, Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Pierre Bénite, <sup>3</sup>Gastro-Enterology Surgery, <sup>4</sup>Unité Immunogénomique et Inflammation, EA4130, Hopital E. Herriot, Lyon, France.

**Background and aims:** In obesity, white adipose tissue (WAT)-infiltrating immune cells induce a state of low grade inflammation. Among those cells, Th-17 cells have been identified as contributors of WAT inflammation. However, the mechanisms by which Th-17 are activated remain to be elucidated. Therefore, to gain further insight into the inflammatory processes taking place into WAT during obesity, we investigated whether adipose tissue-derived stem cells (ASC) could promote Th-17 cell activation.

**Materials and methods:** Human ASC were isolated from the stromal vascular fraction of residual WAT obtained during supra-mesocolic abdominal surgical procedures. Mononuclear cells (MNC) were prepared from blood donors, or from three surgical patients, as autologous controls. Co-cultures were performed with MNC and graded doses of ASC. Phyto-hemagglutinin A (PHA) was used for MNC stimulation. Cytokine secretion and mRNA expression were measured by ELISA and quantitative PCR, respectively. Binding of STAT3 and STAT5 on the IL-17 genomic locus was measured by chromatin immunoprecipitation (ChIP) in co-cultured cells. Finally, adipogenesis was induced in the presence or absence of conditioning medium collected from ASC-MNC co-cultures. Insulin-sensitivity and adipocyte differentiation were measured through AKT phosphorylation, and expression of mRNA markers, respectively.

**Results:** Co-cultures of ASC and PHA-activated MNC resulted in a dose-dependent increase of IL-17A secretion (p<0.0001, at the highest ASC: MNC ratio, as compared with no ASC), and in an increase of IL-1b and IL-6 secretion. In contrast, TNFα and IL-2 decreased (p=0.0003, and 0.0116, respectively), suggesting polarization towards the Th-17 lineage, and reduction of the Th-1 cell subset. ASC induced an increase of STAT3 binding on the IL-17 locus, as measured by ChIP. Physical contact between ASC and MNC

played an important role in ASC-mediated enhancement of IL-17A production, as co-cultures in transwell systems drastically decreased IL-17A production ( $p < 0.01$ ). Finally, when conditioning medium of co-cultured cells was added to fresh ASC during their differentiation into adipocytes, a reduction in insulin-mediated AKT phosphorylation was observed, together with a potent inhibition of adipogenesis, as assessed by decreased mRNA expression of FABP-4, adiponectin and PPAR $\gamma$ .

**Conclusion:** Our data demonstrate that in response to physical interaction between ASC and MNC, ASC mediate (i) polarization of T cells towards the Th-17 pathway, and (ii) enhancement of IL-1b and IL-6 secretion. Furthermore, such ASC-mediated cytokine secretion impairs ASC adipogenic capacity and adipocyte insulin sensitivity. Thus, our data suggest that ASC from WAT might contribute to the initiation of low-grade chronic inflammation in obese patients through increased secretion of IL-17A and pro-inflammatory cytokines, which may in turn inhibit adipocyte differentiation.

## 228

### Interleukin-15 signalling promotes high fat diet-induced inflammation in the liver

S. Ilangumaran, Y. Cepero-Donates, G. Lacraz, M. Mayhue, S. Ramanathan; Pediatrics, Immunology division, Université de Sherbrooke, Canada.

**Background and aims:** Interleukin-15 (IL-15) is essential for the homeostasis of lymphoid cells particularly memory CD8 T cells and NK cells. These cells are abundant in the liver, and are implicated in obesity-associated pathogenic processes. Our recent findings show that IL-15 knockout mice are resistant to high fat diet-induced obesity. IL-15 is unique among the common gamma chain receptor family of cytokines in that it needs to be trans-presented by the IL-15 receptor alpha chain (IL-15Ra). The goal of this study is to characterize obesity-associated metabolic and cellular changes in the liver of mice lacking IL-15 or IL-15Ra.

**Materials and methods:** Wildtype, IL-15 knockout (IL15-KO) and IL-15Ra KO (IL15Ra-KO) mice in C57BL/6 genetic background were maintained on high fat diet (HFD) or normal control diet. After 16 weeks, liver mass, fat accumulation in the liver, serum lipid levels and gene expression in the liver were evaluated. Primary hepatocytes were stimulated with IL-15, and signaling and gene expression were studied. Intrahepatic lymphocytes (IHL) were examined in WT, IL15-KO and IL15Ra-KO mice, as well as in hepatocyte-specific IL15Ra-KO mice by flow cytometry.

**Results:** Diet-increase in liver weight and accumulation of lipids in the liver are prevented by IL-15 or IL-15Ra deficiency. IL-15 deficiency does not affect diet-induced expression of enzymes involved in beta-oxidation of lipids in the liver. However, the liver tissues of IL15-KO and IL15Ra-KO mice showed decreased expression of TNF $\alpha$  and iNOS, chemokines CCL2, CCL5 and CXCL10, and macrophage markers CD68 and F4/80. IL-15 stimulation induced chemokine gene expression in wildtype and IL15-KO hepatocytes, but not in IL15Ra-KO hepatocytes. High fat diet enhances the number of CD4, CD8, NK and NKT cells infiltrating the liver. The NK and NKT subsets in intrahepatic lymphocytes are severely reduced in mice lacking IL-15Ra.

**Conclusion:** High fat diet-induced lipid accumulation in the liver is mediated, at least partly, by IL-15. High fat diet induces IL-15 gene expression in the liver and this is associated with increased inflammatory response. IL-15 induces chemokine gene expression in hepatocytes that may account for increased intrahepatic lymphocytes. Overall, our findings support the idea that increased availability of IL-15 in obesity may stimulate hepatocytes to promote inflammation in the liver, leading to fatty liver disease.

## OP 40 Translational immunology of type 1 diabetes

### 229

#### Functional genomics identifies *tnfaip3/A20* as a diabetes protective gene

N.W. Zammit<sup>1</sup>, E.K. Malle<sup>1</sup>, S.N. Walters<sup>1</sup>, C.C. Goodnow<sup>2</sup>, S.T. Grey<sup>1</sup>; <sup>1</sup>Garvan Institute, Darlinghurst, <sup>2</sup>John Curtin School of Medical Research, Canberra, Australia.

**Background and aims:** Single-nucleotide polymorphisms (SNPs) within *tnfaip3* (also known as A20) associate with susceptibility to type 1 diabetes and complications in type 2 diabetes. How polymorphisms within the *tnfaip3/A20* locus contribute to disease at the islet level is not understood.

**Materials and methods:** In a genome-wide *N*-ethyl-*N*-nitrosourea (ENU) mutagenesis screen of C57BL/6 mice we identified a mouse line harbouring a non-synonymous amino-acid change, at an evolutionary conserved isoleucine. The T>A mutation substituted asparagine at residue 325 in place of isoleucine (A20<sup>I325N</sup>) that lies in a highly conserved beta-hairpin loop in A20s ovarian tumour (OTU) domain, away from the C103 catalytic residue. Despite the presence of increased circulating granulocytes and CD44<sup>high</sup> T-cells, adult mice appear grossly normal and healthy; we therefore tested the effect of the mutation on islet biology.

**Results:** Here we demonstrate that pancreatic islets harbouring the A20<sup>I325N</sup> mutation to exhibit cell-intrinsic increased susceptibility to inflammatory triggers, with loss of metabolic function. When challenged with mild inflammatory stress by syngeneic transplantation of A20<sup>I325N</sup> islets into wildtype (WT) hosts, A20<sup>I325N</sup> islet grafts showed an abnormal production of inflammatory factors (e.g. CXCL10, CXCL1) with significant neutrophil infiltration. Furthermore, mutant islets exhibited severe glucose intolerance in an i.p.GTT, and an i.v.GTT revealed that beta-cell function was impaired. When directly challenged with an immunological insult in the form of allogeneic transplantation, A20<sup>I325N</sup> islets were hyper-inflammatory and more rapidly destroyed than WT allogeneic islets. Immunoblot analysis of cells harboring the A20<sup>I325N</sup> mutation show exaggerated poly-ubiquitination of RIP1 with exacerbated NF- $\kappa$ B and JNK/AP-1 signaling following TNF-stimulation. In vitro transfection studies using NF- $\kappa$ B and AP-1 luciferase reporter plasmids show WT A20 to inhibit luciferase production at the promoter level. Thus, A20 is critical for controlling NF- $\kappa$ B but also JNK activation; and loss of OTU function results in tissue hypersensitivity to inflammatory triggers and metabolic impairment. Ectopic expression of WT A20 in A20<sup>I325N</sup> islets restored control of NF- $\kappa$ B and JNK/AP1 pathways and rescued A20<sup>I325N</sup> islets from hyper-inflammation. Whole body A20<sup>I325N</sup> mutant mice show normal glucose homeostasis, however, in a diet induced obesity model (45 kcal % fat), mice homozygous for the point mutation (A20<sup>I325N/I325N</sup>) develop more severe glucose intolerance, compared to littermate controls and mice heterozygous for the point mutation (A20<sup>I325N/+</sup>). However, when A20<sup>I325N/+</sup> mice are subjected to a low-dose lipopolysaccharide (LPS; i.p.) challenge, they also developed marked glucose intolerance compared to littermate WT controls. Furthermore, glucose intolerance was coupled with islet-specific immune infiltration of the pancreas.

**Conclusion:** These data identify A20 as a diabetes protective gene. A20 negative feed-back on NF- $\kappa$ B and JNK/AP-1 pathways maintain islet inflammatory and metabolic homeostasis under vigorous inflammatory states. In contrast, functional impairment by SNPs can uncouple A20s protective effect and lead to diabetogenic outcomes.

### 230

#### Anti-CD3 / anti-CXCL10 antibody combination therapy reverts type 1 diabetes in two mouse models

S. Lasch, P. Müller, M. Bayer, J.M. Pfeilschifter, E. Hintermann, U. Christen; Goethe University Hospital, Frankfurt am Main, Germany.

**Background and aims:** Therapy of type 1 diabetes (T1D) with anti-CD3 monoclonal antibodies (a-CD3) results in a blockade of the autoimmune process in both animal models and patients with T1D patients. Treated patients show a reduced insulin need and elevated C-peptide levels. Unfortunately, this effect is only temporal and patients revert within a few years to the status they had at the beginning of the therapy. In animal models several combination therapies using a-CD3 and treatments, such as rapamycin, nasal insulin, vitamin D, FTY 720, or *Lactococcus lactis* have been successful in

blocking T1D. We used a different approach and aimed at a blockade to cellular re-entry into the islets of Langerhans after a-CD3 treatment by blocking the key chemokine CXCL10.

**Materials and methods:** We used the well-established RIP-LCMV-GP mouse model of T1D. As a target autoantigen in the  $\beta$ -cells, such mice express the glycoprotein (GP) of the lymphocytic choriomeningitis virus (LCMV) under control of the rat insulin promoter (RIP). RIP-LCMV-GP mice only develop T1D only after infection with LCMV. For the present study we used a combination therapy (CT) and treated diabetic RIP-LCMV-GP mice first with a-CD3 (3 injections in 3 days) followed by administration of a neutralizing anti-CXCL10 monoclonal antibody (a-CXCL10) (8 injections over 3 weeks). **Results:** The CT reverted T1D in RIP-LCMV-GP mice significantly (CT: 65% reversion;  $p=0,0078$  / Control: 20% reversion). Thereby, the efficacy of the monotherapies was improved (a-CD3 alone: 47% reversion;  $p=0,1168$  / a-CXCL10 alone: 36% reversion;  $p=0,3735$ ). Flow cytometry and histological experiments demonstrate a marked reduction of CD4 and CD8 T cells in the pancreas of mice treated with the CT compared to mono-therapies at day 31 after infection. Importantly, the presence of islet antigen (LCMV-GP)-specific CD8 T cells was reduced dramatically. This effect is long-lasting since CT-treated islets show almost no infiltrates up to 181 days after infection. In order to confirm our data in a different model, we conducted a pilot study with NOD mice, in which CT cured 50% of diabetic mice whereas no mice show diabetes reversion with a-CD3 or without therapy.

**Conclusion:** In summary our data suggest that a combination therapy of anti-CD3 and anti-CXCL10 antibodies results in a significant reduction of T1D in two independent mouse models. The neutralization of the key chemokine CXCL10 prevented a re-entry of aggressive T cells into the pancreas and thereby abrogated the destruction of beta-cells. Such a combination therapy might constitute a novel treatment for patients suffering from T1D.

## 231

**MiR-125a-5p is up-regulated in un-functional CD4+FOXP3+ T regulatory cells deriving from pancreatic lymph nodes of patients with type 1 diabetes and targets C-C chemokine receptor type 2**

G. Ventriglia<sup>1</sup>, G. Sebastiani<sup>1</sup>, A. Stabilini<sup>2</sup>, F. Mancarella<sup>1</sup>, L. Nigi<sup>1</sup>, T. Brusko<sup>3</sup>, M. Battaglia<sup>2</sup>, F. Dotta<sup>1</sup>;

<sup>1</sup>University of Siena and Umberto di Mario Foundation,

<sup>2</sup>Diabetes Research Institute, San Raffaele Scientific Institute, Milano, Italy,

<sup>3</sup>University of Florida, Gainesville, USA.

**Background and aims:** We previously showed that CD4+CD25brightCD127-T regulatory (Treg) cells deriving from pancreatic lymph node (PLN) of patients with type 1 diabetes (T1D) are epigenetically imprinted to be Treg, but for unknown reasons do not function as such in vitro. Importantly, this functional defect is present only in Treg cells residing in the PLN of T1D patients and not in those circulating in their peripheral blood (PB). Some microRNAs (miRNAs), an abundant class of small non-coding RNAs that regulate gene expression by affecting the degradation and translation of target mRNAs, are differentially expressed in Treg cells isolated from PLN as compared to those isolated from PB of T1D patients. Among the differentially expressed miRNAs, we found that miR-125a-5p is specifically up-regulated in Treg cells isolated from PLN of T1D patients as compared to those isolated from PB of the same donors and to those isolated from non-diabetic donors. This differential expression was not identified in T conventional cells of T1D patients, uncovering both a cell (i.e., Treg cells) and a disease-specific (i.e., T1D) miRNA expression. Thus, we aimed at further investigating the role of miR-125a-5p in Treg cells.

**Materials and methods:** CD4+CD25brightCD127- Treg cells were FACS sorted from PLN and PB of patients with T1D and from non-diabetic donors. 200 sorted cells were analyzed and miRNA expression was evaluated by RT-PCR using Taqman miRNAs single assay. Data analysis was performed using 2-ddCt method. Bioinformatic miRNAs target prediction was performed using Targetscan 6.2. Dual luciferase reporter assay was performed to experimentally validate the predicted target gene. CCR2 expression was determined by flow cytometry.

**Results:** Computational target gene analysis of miR-125a-5p was performed. Target prediction analysis retrieved some potential interesting genes involved in Treg-cell biology, including: C-C chemokine receptor type 2 (CCR2), interleukin 6 receptor (IL6R), interferon regulatory factor 4 (IRF4). Among these putative targets we focused on CCR2 to verify whether this chemokine receptor is key in the observed Treg-cell dysfunction. Firstly, this prediction was validated by renilla luciferase assay: a decreased luciferase activity following

miR-125a-5p overexpression was observed and this reduction was restored upon miRNA predicted target site mutations. Secondly, CCR2 expression on Treg cells was tested by flow cytometry and frequency of CCR2+ Treg cells was correlated with miR-125a-5p RT-PCR levels. Interestingly, lower expression of CCR2+ Treg cells correlated with higher expression of miR-125a-5p, suggesting an inverse correlation.

**Conclusion:** A disease- and tissue-specific miRNA, miR-125a-5p, has been identified in Treg cells isolated from PLN of patients with T1D. miR-125a-5p targets CCR2, thus leading to reduced CCR2 expression. Reduced expression of CCR2 may induce migration dysfunction in Treg cells residing in the PLN of T1D patients. Therefore these Treg cells could be unable to reach the target organ where they are supposed to control and possibly block the autoreactive immune response. Further in vitro and in vivo studies are ongoing to confirm this hypothesis.

**Cholecalciferol increases suppressor function in regulatory CD4+CD25+Foxp3+ T-cells from patients with new onset type 1 diabetes: a randomised controlled trial**

G. Treiber<sup>1</sup>, B. Prietl<sup>1</sup>, E. Fröhlich-Reiterer<sup>2</sup>, E. Höller<sup>1</sup>, A. Ribitsch<sup>1</sup>, M. Fritsch<sup>3</sup>, B. Rami-Merhar<sup>3</sup>, C. Steigleder-Schweiger<sup>4</sup>, M. Borkenstein<sup>2</sup>, T.R. Pieber<sup>1</sup>;

<sup>1</sup>Division of Endocrinology and Metabolism, <sup>2</sup>Department of Pediatrics and Adolescent Medicine, Medical University Graz, Austria, <sup>3</sup>Department of Pediatrics, Medical University Vienna, <sup>4</sup>Paracelsus Medical University, Salzburg, Austria.

**Background and aims:** Vitamin D has an important role in increasing the effects of innate immune processes while restraining the adaptive immune system, leading to improved outcomes in autoimmune diseases. Vitamin D deficiency is one environmental factor to influence the risk of type 1 diabetes (T1D) and in vitro data reinforce the role of vitamin D in the pathogenesis of T1D. In this study we evaluate the effects of Cholecalciferol on function of regulatory T-cells and residual b-cell function in patients with recent onset T1D.

**Materials and methods:** In this randomized, double-blinded, placebo controlled trial thirty patients (age 15 [10-16], 77% male) with new-onset T1D were assigned to receive oral therapy of cholecalciferol (70IU/kg bodyweight/day) or placebo for 12 months. Cellular frequencies were determined by FACS-analysis and functional tests were assessed with ex vivo suppression co-cultures. Mixed meal tolerance tests were performed to assess b-cell function.

**Results:** Suppressive capacity of regulatory T cells (Treg) increased with Cholecalciferol after 3, 6 and 12 month ( $p=0.0005$ ) and delta suppression capacity between Cholecalciferol (28.1 [14.9 to 43.3]%) and placebo (-20.9 [-30.1 to -11.3]%) was significant ( $p=0.002$ ). Treg frequency did not differ after 12 month between the two groups (5.75±1.48% vs 5.38±1.73%,  $p=0.187$ ). HbA1c and insulin dose were similar between the groups, fasting C-peptide appeared to decrease slower ( $p=0.078$ ) in the Cholecalciferol group (0.62±0.18 to 0.59±0.34 ng/ml) than in placebo group (0.65±0.27 to 0.40±0.25 ng/ml). Serum calcium and parathormone stayed within the normal range.

**Conclusion:** Cholecalciferol, the inactive form of vitamin D used as adjunctive immunomodulatory therapy with insulin is associated with an improvement in suppressor function of regulatory T-cells in patients with new-onset T1D. Assessment of vitamin D status and a targeted supplementation may be indicated after the diagnosis of T1D.

### Novel epigenetic markers of type 2 diabetes in the liver

S. Cauchi<sup>1,2</sup>, R. Caiazzo<sup>2,3</sup>, B. Pichard<sup>1,2</sup>, A.-S. Régent<sup>1,2</sup>, M. Canouil<sup>1,2</sup>, S. Lobbens<sup>1,2</sup>, L. Yengo<sup>1,2</sup>, A. Leloire<sup>1,2</sup>, V. Raverdy<sup>2,3</sup>, O. Poulain-Godefroy<sup>1,2</sup>, F. Pattou<sup>2,3</sup>, P. Froguel<sup>1,2</sup>;

<sup>1</sup>Genomics and Metabolic Diseases, UMR CNRS 8199, <sup>2</sup>European Genomic Institute for Diabetes (EGID), <sup>3</sup>Inserm UMR 859, Lille, France.

**Background and aims:** The liver plays an important role in the regulation of glucose homeostasis. Epigenetic markers in this organ could contribute to the pathophysiology and heritability of type 2 diabetes (T2D). Our aims were to define DNA methylation patterns associated with T2D risk in the liver, correlate these epigenetic factors with gene expression pathways and decipher intermediate metabolic traits.

**Materials and methods:** We analyzed the genome-wide methylation patterns in the liver tissue of 96 T2D cases and 96 matched normoglycemic controls using Infinium Human Methylation 450 BeadChips (Illumina). A beta-mixture quantile normalization method was applied for correcting probe design bias. Genome-wide expression profiles were also assessed in a subset of 24 T2D cases and 24 matched normoglycemic controls using HumanHT-12 v4 Expression BeadChips (Illumina).

**Results:** We identified 158 sites differentially methylated between T2D cases and controls after Bonferroni correction for multiple comparisons ( $p < 1.5 \times 10^{-7}$ ). Taken together, these sites tended to be hypomethylated in T2D cases compared to normoglycemic controls ( $p = 1 \times 10^{-7}$ ). Only two of these cytosine methylation marks were located near functionally relevant candidate genes differentially expressed between T2D cases and controls ( $p < 4.2 \times 10^{-4}$ ). Direct correlations between methylation levels and gene expressions were also observed ( $p < 1 \times 10^{-3}$ ). Finally, associations with insulin resistance ( $p < 3 \times 10^{-3}$ ) and steatosis ( $p < 3 \times 10^{-5}$ ) were detected.

**Conclusion:** We identified the first epigenetic markers associated with T2D risk in the human liver tissue. DNA methylation information can be used to identify new pathways relevant to the pathophysiology of T2D and novel targets for disease prevention and treatment.

### Identification of DNA methylation and mRNA expression changes associated with age in human pancreatic islets

K. Bacos<sup>1</sup>, P. Volkov<sup>1</sup>, T. Dayeh<sup>1</sup>, A.H. Olsson<sup>1,2</sup>, C. Ling<sup>1</sup>;

<sup>1</sup>Clinical Sciences, Lund University, Malmö, Sweden, <sup>2</sup>Endocrinology, Diabetes and Metabolism, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Increased age is associated with a reduced capacity for insulin secretion and an increased risk of type 2 diabetes. Recent studies suggest that epigenetic modifications, such as DNA methylation, play a role in the development of type 2 diabetes. DNA methylation patterns has been shown to change significantly with age in tissues such as blood and muscle, but if this is the case also in human pancreatic islets has not yet been studied.

**Materials and methods:** Microarrays were used to analyse mRNA expression and DNA methylation in human islets from 87 non-diabetic donors with an age spanning between 26–74 years. A linear regression analysis was used to determine which methylation sites and probesets associate significantly with age.

**Results:** DNA methylation data of 482,889 sites remained after quality control and the methylation level of 322 of these were significantly associated with age after correction for multiple testing. These methylation sites correspond to 214 individual genes, including loci previously associated with diabetes. Interestingly, all of the significant methylation sites showed increased DNA methylation with increasing age. Moreover, based on the annotation of the analyzed methylation sites, we found enrichment of significant sites on chromosomes 2 and 19 and in the following gene regions; TSS1500 (the region 1500 bases upstream of the transcription start site), TSS200 and the 1st exon as well as in CpG islands. Seven genes exhibited significant associations for both DNA methylation and mRNA expression with increased age. Of these, 5 showed an inverse relation, with increased methylation and reduced expression. These 5 genes encode for a ribosomal protein, a putative

zinc finger transcription factor, a histone, a mitochondrial protein and a RNA methyl transferase protein, respectively.

**Conclusion:** Together, our study demonstrates that ageing is associated with differential DNA methylation in human pancreatic islets. These epigenetic modifications may contribute to altered gene expression, impaired insulin secretion and finally affect the risk for type 2 diabetes.

### Spermatozoa from lean and obese human carry distinct epigenetic signatures

I. Donkin<sup>1</sup>, S. Verstehe<sup>1</sup>, K. Qian<sup>1</sup>, L.R. Ingerslev<sup>1</sup>, F.R. Kantor<sup>1</sup>, M. Mehta<sup>1</sup>, N. Jørgensen<sup>2</sup>, J.R. Zierath<sup>1,3</sup>, R. Barrès<sup>1</sup>;

<sup>1</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen University, Faculty of Health Sciences, <sup>2</sup>Dpt of Growth and Reproduction, Rigshospitalet, Copenhagen, Denmark, <sup>3</sup>Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Obesity is associated with metabolic dysfunction and higher prevalence of related diseases such as Type 2 Diabetes. In humans, epidemiological evidence exists showing that paternal obesity can predispose offspring to obesity, regardless of the body mass index of the mother. Moreover, recent animal studies have shown that paternal nutritional status at time of mating can affect the metabolic health of the offspring, suggesting that spermatozoa carry environmental effects to the next generation. Here, we hypothesize that spermatozoa from obese human present a specific epigenetic content that may predispose to metabolic dysfunction.

**Materials and methods:** Using deep-sequencing, we comprehensively profiled small RNA content, DNA methylation and the histone retention profile of ultra pure motile spermatozoa fractions collected from 11 obese (BMI > 30), insulin resistant, and 16 lean (BMI 20–25), normal glucose tolerant men in their reproductive age (20–40 y).

**Results:** Analysis revealed a subset of RNAs being differentially expressed in obesity, including known as well as new small RNA species. Notably, piRNA-associated genes were found to control epigenetic process and metabolic functions. We found regions differentially methylated in obesity. Interestingly, around 25% were located in putative regulatory sites, and at close proximity of genes involved in development and the regulation of metabolic processes. Positioning of histones, on the contrary, was not affected by obesity.

**Conclusion:** Here we show that obesity is associated with an altered epigenetic signature in spermatozoa. The identified differentially expressed RNA molecules and differentially methylated regions have the potential to alter gene expression in the developing embryo and participate in the predisposition of metabolic dysfunction and related comorbidities.

### Variation in phenotype and DNA methylation is detectable in an observational cohort of young adult Bangladeshis exposed to famine during in utero and postnatal life

S. Finer<sup>1,2</sup>, S. Iqbal<sup>3</sup>, W.B. Ogunkolade<sup>2</sup>, C. Mathews<sup>2</sup>, R. Lowe<sup>2</sup>, M. Smart<sup>2</sup>, V.K. Rakyant<sup>2</sup>, D.S. Alam<sup>3</sup>, G.A. Hitman<sup>2</sup>;

<sup>1</sup>Wellcome Trust-MRC Institute of Metabolic Science, University of Cambridge, <sup>2</sup>Blizard Institute, Barts & the London, Queen Mary University of London, UK, <sup>3</sup>ICDDR,B, Dhaka, Bangladesh.

**Background and aims:** Periconceptual, in utero and postnatal exposure to nutritional deficits may 'programme' cardiometabolic disease in later life. Recent human studies suggest that epigenetic variation may be associated with periconceptual nutritional deficiency, but this has not been described with postnatal exposures or replicated across studies. Aim: 1. To identify whether Bangladeshi adults exposed to famine in utero and/or in postnatal life have a programmed phenotype 2. To detect DNA methylation variation in these offspring on a genome-wide scale and at previously described targets.

**Materials and methods:** A cross-sectional cohort of adults (27–32 years) exposed to severe famine during 1974–5 in Matlab, Bangladesh was studied in three groups: 1. in utero exposed, 2. postnatal exposed, 3. Unexposed, Approach: • Clinical phenotype (n=219) • Whole blood DNA bisulphite conversion (n=159) for (i) epigenome profiling via Illumina 450k Methylation

array, (ii) targeted pyrosequencing of published methylation variants: IGF2, PAX8, ZFYVE28, EXD3, BOLA3 • Validation using an external dataset

**Results:** The in utero exposed group had an excess of underweight individuals (49%) compared to postnatal exposed (32%) or unexposed (30%); more postnatal exposed offspring (26%) were overweight compared to in utero exposed (13%) or unexposed (14%) (proportional odds model  $df=2$ , deviance ratio 3.26,  $p=0.039$ ). Of the underweight, in utero exposed had a higher mean glucose 120minutes post-glucose challenge (5.8mmol/l) compared to postnatal exposed or unexposed (both 4.8mmol/l) (ANOVA  $p<0.02$ ). The Illumina 450k array identified differential methylation between the 3 groups at 416 probes (ANOVA  $p \leq 0.001$ ) but these did not withstand correction for false discovery. Sixty-two regions showed methylation differences of  $\geq 5\%$ ; most (65%) were from the comparison of postnatal exposure to unexposed. KEGG pathway analysis suggested potential impact on pathways involved in insulin signalling, axon guidance and ABC transporters. We found a 3-fold enrichment of published epigenomic variants in human islets in type 2 diabetes in our dataset ( $p=0.01$ ). Bisulphite-pyrosequencing and/or array data showed small ( $<7\%$ ) methylation differences at PAX8 and ZFYVE28, consistent with metastable epialleles in Gambian children exposed to variable periconceptual nutrition. Small methylation differences ( $<4\%$ ) at IGF2 were consistent with the published Dutch Winter Hunger studies but are of uncertain significance.

**Conclusion:** Our data identifies phenotypic evidence of developmental programming of adult cardiometabolic disease from both in utero and postnatal famine exposure. We identify epigenetic differences in DNA methylation across multiple genomic regions, but larger studies are needed to control for false discovery. Via pathway analysis and comparison to external datasets, we suggest possible functional roles in insulin signaling and via pancreatic islet function. We replicate small quantitative differences in DNA methylation at targets previously associated with famine exposure. Future studies need larger sample sizes, longitudinal sampling and intervention to determine causality and potential reversibility.

**New biomarkers of NAFLD: results from plasma metabolomic analysis**  
M. Gaggini<sup>1</sup>, C. Saponaro<sup>1</sup>, C. Rosso<sup>2</sup>, F. Carli<sup>1</sup>, E. Buzzigoli<sup>1</sup>, D. Ciociaro<sup>1</sup>, E. Bugianesi<sup>2</sup>, A. Gastaldelli<sup>1</sup>;

<sup>1</sup>Cardiometabolic Risk Unit, Institute of Clinical Physiology, Pisa,

<sup>2</sup>Medical Sciences, University of Turin, Italy.

**Background and aims:** Non Alcoholic Fatty Liver Disease (NAFLD) is associated with both peripheral and hepatic insulin resistance and is an important risk factor for both diabetes and cardiovascular disease. Metabolomic techniques aim to identify new biomarkers related to alteration in organ metabolism. We have performed metabolomic analysis of plasma samples of subjects with NAFLD to find possible markers of metabolic dysfunction and liver disease.

**Materials and methods:** We studied 54 subjects, 45 NAFLD with liver biopsy and 9 healthy control (CT) and measured plasma concentration profile of amino acids (AA) and fatty acid (FA) by GCMS. Data were correlated with indexes of insulin resistance (IR) measured by tracers, LFTs, NAS and fibrosis score, beta-hydroxybutyrate (BOH), ox-LDL, total antioxidative status (TAS), sRAGE, and adiponectin. We calculated: a) using tracer infusion, hepatic IR as endogenous glucose production x fasting insulin (H-IR=EGPxFPI), adipose tissue insulin resistance (AT-IR) as fasting lipolysis x FPI; b) from fatty acid composition we calculated de novo lipogenesis index (DNL=16:0/18:2) and SCD1 activity as 16:1/16:0) from AA profile, the branched chain concentrations (BCAA) and the ratio of glutamate/(glycine +serine), that is as an index of glutathione biosynthesis (GSH\_I).

**Results:** Subjects with NAFLD had increased H-IR (118±10 vs. 56±7) and AT-IR (34±3 vs. 13±2), GSH-I (0.73±0.06 vs 0.33±0.09), DNL (1.17±0.05 vs 0.86±0.04) and SCD1 (0.10±0.01 vs 0.08±0.01) indices compared to controls. GSH-I, DNL and SCD1 were increased in proportion to the degree AT-IR ( $r=0.28$ ;  $r=0.41$ ;  $r=0.43$ ) and also with the increase of H-IR ( $r=0.39$ ;  $r=0.28$ ;  $r=0.32$ ). GSH\_I was increased proportionally to the severity of fibrosis ( $r=0.36$  per trend,  $p<0.0001$ ), ln(cholesterol) ( $r=0.39$ ) and negatively with ln(sRAGE) ( $r=0.30$ ) but not with TG liver content nor with NAS score, TAS, ox-LDL and adiponectin. DNL was increased proportionally to circulating ln(TG) ( $r=0.53$ ), fat in biopsy ( $r=0.45$ ) and fibrosis ( $r=0.52$ ).

**Conclusion:** Metabolomic analysis allowed the identification of indices (GSH-I, DNL and SCD1) associated with increased hepatic and adipose tissue insulin resistance and severity of fatty liver disease.

**Orphan nuclear receptor Nur77 mediates fasting-induced hepatic FGF21 expression**

K.-H. Bae<sup>1</sup>, A.-K. Min<sup>1</sup>, M.-K. Kim<sup>2</sup>, E.-H. Kim<sup>3</sup>, E.-D. Jung<sup>4</sup>, M.-J. Kim<sup>5</sup>, K.-G. Park<sup>1</sup>;

<sup>1</sup>Department of Endocrine and Metabolism of Internal medicine, Kyungpook National University School of Medicine, <sup>2</sup>Department of Endocrine and Metabolism of Internal medicine, Keimyung University Dongsan Medical Center, <sup>3</sup>Department of Endocrine and Metabolism of Internal medicine, Fatima Hospital, <sup>4</sup>Department of Endocrine and Metabolism of Internal medicine, Daegu Catholic University Medical Center, <sup>5</sup>Department of Endocrine and Metabolism of Internal medicine, Pooreen Meerae Internal Medicine Clinic, Taegu, Republic of Korea

**Background and aims:** The fasting-induced hepatic hormone, fibroblast growth factor 21 (FGF21), is an intriguing candidate for the treatment of metabolic syndromes. Although PPARalpha is known to play a major role in induction of hepatic FGF21 expression, other fasting-induced transcription factors in FGF21 expression has not be fully studied. In the present study, we investigated whether the fasting-induced activation of the transcription factors Nur77 increases hepatic FGF21.

**Materials and methods:** We examined the effects of glucagon/cAMP, a well-known hormone induced by fasting, on hepatic Nur77 and FGF21 expression in vivo and in vitro. To elucidate the association between Nur77 and FGF21 expression, we examined whether adenovirus-mediated over-expression of Nur77 (Ad-Nur77) increases FGF21 production and knockdown of Nur77 with siRNA abolished forskolin-induced FGF21 expression. To further con-

firm that Nur77 transcriptionally activates FGF21 expression, ChIP assay, EMSA and mutagenesis analysis were employed.

**Results:** We found that fasting induced hepatic Nur77 and FGF21 expression. Glucagon and forskolin increased Nur77 and FGF21 expression in vivo and in vitro, respectively. Ad-Nur77 increased FGF21 production in cultured hepatocytes. Hepatic overexpression of Nur77 via tail vein injection of Ad-Nur77 increased FGF21 mRNA and protein levels. Moreover, siRNA-Nur77 abolished the effect of forskolin on FGF21 expression. The results from ChIP assay, EMSA and mutagenesis analysis showed that Nur77 bound to putative NBRE of FGF21 promoter in cultured hepatocytes and fasting induced Nur77 binding to FGF21 promoter in vivo.

**Conclusion:** This study shows that Nur77 mediates fasting-induced hepatic FGF21 production. The present study suggests an alternative mechanism by which hepatic FGF21 transcription is mediated under fasting conditions.

### Overexpression JAZF1 protected ApoE<sup>-/-</sup> mice from atherosclerosis by inhibiting hepatic cholesterol synthesis

H. Wang<sup>1,2</sup>, L. Li<sup>1,2</sup>, P. Yan<sup>3</sup>, G. Yang<sup>3</sup>;

<sup>1</sup>the Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, Chongqing, China, <sup>2</sup>Department of Clinical Biochemistry, College of Laboratory Medicine, Chongqing Medical University,

<sup>3</sup>Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

**Background and aims:** Genome wide association studies have suggested an association of Juxtaposed with another zinc finger gene 1 (JAZF1) with type2 diabetes mellitus (T2DM). As an inhibitor of the TAK1/TR4 signaling pathway, JAZF1 has been shown to be involved in gluconeogenesis, lipid metabolism and insulin sensitivity. However, its role in insulin resistance and atherosclerosis in vivo remains unknown. The present study was designed to investigate in vivo the impact of JAZF1 on insulin resistance-associated dyslipidemia and atherosclerosis.

**Materials and methods:** We established Adenovirus-mediated JAZF1 overexpression to characterize the role of JAZF1 in the regulation of lipid metabolism and the development of atherosclerosis in normal chow- or high fat diet (HFD)-fed ApoE<sup>-/-</sup> mice. We use euglycaemic-hyperinsulinaemic clamping to examine Insulin sensitivity, Cholesterol *de novo* synthesis was measured by intraperitoneal acetate injection and atherosclerotic plaques were quantified by histological analysis. A dual-luciferase reporter assay was used to assess the ability of JAZF1 to regulate HMGCR transcriptional activity, mRNA and protein expressions were measured by qRT-PCR and Western blot, respectively.

**Results:** we showed that JAZF1 overexpression improved HFD-induced hepatic insulin resistance in C57BL/6J mice. In HFD-fed ApoE<sup>-/-</sup> mice, JAZF1 overexpression decreased serum cholesterol levels and hepatic cholesterol synthesis by inhibiting CREB dependent 3hydroxy3methylglutaryl coenzyme A reductase (HMGCR) promoter transcriptional activity and JAZF1 overexpression had significantly reduced aortic and aortic sinus en face and cross-sectional plaque areas in HFD-fed ApoE<sup>-/-</sup> mice.

**Conclusion:** we report the first evidence that JAZF1 overexpression protected against development of atherosclerosis and insulin resistance induced by a HFD in apoE<sup>-/-</sup> mice and in C57BL/6J mice. Furthermore, we provide molecular explanation by which JAZF1 can regulate hepatic cholesterol synthesis and HMGCR transcriptional activity via CREB-dependent mechanisms. Our data delineate that JAZF1 overexpression may represent a promising strategy for the treatment of insulin resistance-associated dyslipidemia and atherosclerosis.

### Defective autophagy results in reduced glycogen breakdown in the liver of IUGR newborn Wistar rats. Consequences for glucose homeostasis

E. Fernandez-Millan<sup>1</sup>, J. de Toro-Martín<sup>2</sup>, E. Lizarraga-Mollinedo<sup>1,2</sup>, F. Escriva<sup>1,2</sup>, C. Alvarez<sup>1,2</sup>;

<sup>1</sup>CIBERDEM, ISCIII, <sup>2</sup>Biochemistry and Molecular Biology II, School of Pharmacy, UCM, Madrid, Spain.

**Background and aims:** Glycogen autophagy is a highly regulated process that represents a mechanism of glucose homeostasis under conditions of demand for the production of this sugar as in the liver of newborn animals. The abrupt interruption of the maternal glucose supply with birth, leads to the development of hypoglycaemia in the newborn. This promotes glucagon secretion and triggers the normal mechanisms for the newborn to adapt to the postnatal environment. Glucagon acts through the cAMP/protein Kinase A pathways and induces glycogen autophagy. We previously showed that intrauterine growth restriction (IUGR) induced massive glycogen accumulation in the liver of fetuses and neonates. Interestingly, IUGR neonates were slightly hypoglycaemic and showed hypoglucagonaemia and glucagon resistance but insulin hypersensitivity. In this study we set out to examine the autophagic response in the liver of IUGR newborns and whether this process might be linked to the development of insulin resistance associated to IUGR. **Materials and methods:** Newborn rats naturally delivered from pregnant females fed ad libitum or 65% food-restricted from the last third of gestation, were kept separated from their mothers and used 3 or 6h after birth. Liver glycogen content was quantified by a KOH-ethanol precipitation and acid hydrolysis method. The protein levels of the enzymes involved in glucose metabolism, the markers of autophagy and ER stress were determined by western blot in hepatic homogenizes. Ultrastructural analysis of the neonatal liver was performed by electron microscopy.

**Results:** At birth (0h), liver glycogen values of control (C) and IUGR rats were  $23.8 \pm 3.2$  and  $57.4 \pm 7.3$  mg/g ( $p < 0.01$ ), respectively. In C rats, the amount of glycogen precipitously diminished at 3 and 6h of age whereas glycogen stores remained significantly elevated in restricted newborns. In agreement, glycogen synthase was found more active in IUGR group at both 3 and 6h after birth, the phosphorylated form of GSK3 increased and glycogen phosphorylase and PEPCK protein levels diminished ( $p < 0.01$ ). To address the implication of autophagy in the lack of glycogen mobilization in restricted newborns we measured autophagy markers at 3 and 6h after birth. C newborns fasted 6h, showed a marked induction of LC3B II conversion. In contrast, IUGR newborns displayed defective autophagy at this time. Electron microscopic examination showed enhanced autophagic activity and consumption of liver glycogen stores from 3 to 6h after birth in C newborns whereas in IUGR rats the formation of glycogen-containing vacuoles were rare and vast areas of cytoplasmic glycogen were observed at both 3 and 6h of age. Alpha glucosidase enzyme levels increased at 6h of postnatal life in both groups of animals. When fed a high-fat diet during 22 weeks, C rats showed enhanced autophagic activity in liver however, IUGR rats maintained lower levels of Atg7 and LC3B II and developed insulin resistance, liver steatosis and ER stress.

**Conclusion:** We suggest that defective autophagy may lead to ineffective macromolecule turnover, such as glycogen or lipids in IUGR individuals and consequently compromise hepatic metabolic function favouring insulin resistance development.

## OP 43 GLP-1 analogues: novel formulations

### 241

#### Benefits of a fixed-ratio formulation of once-daily insulin glargine/ lixisenatide (LixiLan) vs glargine in type 2 diabetes inadequately controlled on metformin

J. Rosenstock<sup>1</sup>, M. Diamant<sup>2</sup>, L. Silvestre<sup>3</sup>, E. Souhami<sup>3</sup>, T. Zhou<sup>4</sup>, V. Fonseca<sup>5</sup>;  
<sup>1</sup>Dallas Diabetes and Endocrine Center, USA, <sup>2</sup>VU University Medical  
Center, Amsterdam, Netherlands, <sup>3</sup>Sanofi, Paris, France,  
<sup>4</sup>Sanofi, Bridgewater, USA, <sup>5</sup>Tulane University Health Sciences Center,  
New Orleans, USA.

**Background and aims:** LixiLan is a fixed-ratio formulation combining insulin glargine (GLARG) with lixisenatide (Lixi) in a single pen device currently in development for the management of type 2 diabetes mellitus (T2DM). This randomized, open-label study assessed the efficacy and safety of LixiLan (GLARG 2 U / Lixi 1 µg) vs GLARG in insulin-naïve T2DM on top of metformin.

**Materials and methods:** Patients (mean baseline A<sub>1c</sub> 8.0%, BMI 32.1 kg/m<sup>2</sup>, diabetes duration 6.7 yrs) were randomized to LixiLan (n=161) or GLARG (n=162) for 24 weeks. Primary objective was non-inferiority in A<sub>1c</sub> reduction; if non-inferiority met, statistical superiority was tested.

**Results:** At 24 weeks, mean A<sub>1c</sub> was reduced to 6.3% and 6.5% with LixiLan and GLARG respectively, establishing statistical superiority of LixiLan (LS mean difference: -0.17% [-0.312% to -0.037%]; p=0.0130), and 84% and 78% achieved A<sub>1c</sub> <7%, respectively (Table). Despite substantial reductions of A<sub>1c</sub>, body weight was reduced with LixiLan (p<0.0001), with no increase in documented (≤70 mg/dL [3.9 mmol/L]) hypoglycaemic events (22% and 23%, respectively) and no severe hypoglycaemia. Composite endpoints of A<sub>1c</sub> <7% with no weight gain, or no weight gain and no hypoglycaemia were achieved significantly more often with LixiLan. Incidence of nausea and vomiting was only 7.5% and 2.5%, respectively, with LixiLan.

**Conclusion:** LixiLan achieved robust A<sub>1c</sub> reductions to 6.3% with weight loss and no increased hypoglycaemia vs GLARG, with very low gastrointestinal adverse events in T2DM inadequately controlled on metformin.

#### Efficacy and tolerability of ITCA 650 (continuous subcutaneous exenatide) in poorly controlled type 2 diabetes with baseline HbA<sub>1c</sub> >10%

R.R. Henry<sup>1</sup>, J. Rosenstock<sup>2</sup>, M.A. Baron<sup>3</sup>;

<sup>1</sup>VA San Diego Healthcare System, La Jolla, <sup>2</sup>Dallas Diabetes and Endocrine  
Center at Medical City, <sup>3</sup>Intarcia Therapeutics, Boston, USA.

**Background and aims:** ITCA 650, the injection-free GLP-1 receptor agonist that provides continuous SC exenatide for up to 12 months from a single subdermal placement, is undergoing extensive clinical evaluation in multiple Phase 3 double-blind studies. This report represents the first 6 month, open-label experience with ITCA 650 mini-pumps from an ongoing multicenter study in subjects with type 2 diabetes who did not meet enrolment criteria for the double-blind placebo controlled trial because of A1C >10%.

**Materials and methods:** Entrance criteria for this open-label trial were: A1C >10% to ≤12%, age 18-80 years, BMI 25-45 kg/m<sup>2</sup>, and on stable (≥3 months) diet and exercise and/or monotherapy or any combination of metformin, sulfonylurea, and thiazolidinedione. Treatment was initiated by placing a 3-month ITCA 650 mini-pump delivering 20 mcg/day, which was then replaced by a 6-month ITCA 650 mini-pump delivering 60 mcg/day for 26 weeks. Pre-study oral antidiabetic agents (OADs) were maintained unchanged for the 39 week of treatment. The primary endpoint was change in A1C from baseline to week 39.

**Results:** At the time of this initial interim analysis, 50, 39, and 25 of the 60 subjects enrolled had completed 13, 19, and 26 weeks of treatment; respectively. Mean baseline characteristics for the entire cohort (n=60) were A1C 10.7%, age 52.1 yrs, BMI 32.1 kg/m<sup>2</sup>, duration of diabetes 8.9 yrs, OAD use 69%. Mean reductions of A1C at Weeks 13 (n=50), 19 (n=39), and 26 (n=25) were -2.5%, -2.9%, and -3.2%, respectively. A1C reductions ≥2% were achieved by 78% of subjects who completed at least 13 weeks of treatment; 50% achieved >3% and 22% achieved ≥4% reductions. A1C targets of <7% were achieved in 22% of subjects who had completed at least 13 weeks of treatment. Adverse events were consistent with previous trials with ITCA 650.

**Conclusion:** ITCA 650 has the potential to markedly improve glycemic control in patients with severe hyperglycaemia and longstanding diabetes.

#### IDegLira, a combination of insulin degludec and liraglutide, improves both pre- and postprandial plasma glucose in patients with type 2 diabetes

A. King<sup>1</sup>, A. Philis-Tsimikas<sup>2</sup>, I.H. Langbakke<sup>3</sup>, K. Kvist<sup>3</sup>, T. Vilsbøll<sup>1</sup>;

<sup>1</sup>Diabetes Care Center, Salinas, <sup>2</sup>Scripps Whittier Diabetes Institute,

San Diego, USA, <sup>3</sup>Novo Nordisk A/S, Søborg,

<sup>4</sup>Gentofte Hospital, Hellerup, Denmark.

**Background and aims:** Pre- and postprandial glucose levels contribute importantly to overall glycaemic control and consequently clinical outcomes. This analysis explored whether a novel combination of insulin degludec (IDeg) and liraglutide (Lira), IDegLira, enabled more patients to reach recommended pre- and postprandial target ranges, compared with administration of its individual components.

**Materials and methods:** In this *post hoc* analysis of two phase 3 trials: DUAL I (IDegLira vs. IDeg and Lira in patients uncontrolled on oral antidiabetic drugs [OADs]; 52 weeks) and DUAL II (IDegLira vs. IDeg in patients uncontrolled on basal insulin + OADs; 26 weeks), we investigated at end of trial (EOT) the proportion of patients with self-measured blood glucose (BG) values within the pre-prandial target range of ≥3.9 to ≤7.2 mmol/L and postprandial target of <9 mmol/L with IDegLira compared with IDeg or Lira alone. Postprandial BG values were assessed 90 minutes after breakfast, lunch and dinner. Preprandial BG was measured before breakfast, lunch, dinner and breakfast the following day. In addition, the full 9-point profile included measurements before bedtime and at 4am. Finally, we compared the proportion of patients whose entire 9-point BG profile was between ≥3.9 and <9 mmol/L with IDegLira and IDeg or Lira alone.

**Results:** At baseline, the proportion of patients with BG values within the target ranges was similar across treatments in the two trials. At EOT, the proportion of subjects with all three postprandial BG values <9 mmol/L was significantly higher for patients treated with IDegLira (DUAL I 51%; DUAL II 37%) than those treated with IDeg (DUAL I 38%; DUAL II 25%) or Lira

(36%). The likelihood of achieving all four pre-prandial BG values within the recommended range ( $\geq 3.9$  to  $\leq 7.2$  mmol/L) was significantly greater with IDegLira (DUAL I 48%; DUAL II 44%) compared with IDeg (DUAL I 41%; DUAL II 27%) or Lira (32%). At EOT, the proportion of patients with all 9 BG values within the range  $\geq 3.9$  to  $< 9$  mmol/L was significantly higher for patients treated with IDegLira (DUAL I 39%; DUAL II 32%) than for patients treated with IDeg (DUAL I 28%; DUAL II 20%) or Lira (31%).

**Conclusion:** Treatment with IDegLira resulted in a greater likelihood of patients having both pre- and postprandial BG values within target ranges compared with either IDeg or Lira. Improved pre- and postprandial BG levels suggest that the predictability of glycaemic control within one day is increased with IDegLira.

### DURATION-NEO-1: greater HbA<sub>1c</sub> reductions with exenatide suspension once weekly by autoinjector pen vs exenatide twice daily in inadequately controlled type 2 diabetes

C.H. Wysham<sup>1</sup>, J. Rosenstock<sup>2</sup>, J. Malloy<sup>3</sup>, M. Vetter<sup>4</sup>, Y. He<sup>4</sup>, P. Öhman<sup>5</sup>, N. Iqbal<sup>4</sup>,

<sup>1</sup>Rockwood Clinic, Spokane, <sup>2</sup>Dallas Diabetes and Endocrine Center at Medical City, <sup>3</sup>Bristol-Myers Squibb, San Diego,

<sup>4</sup>Bristol-Myers Squibb, Princeton, <sup>5</sup>AstraZeneca, Gaithersburg, USA.

**Background and aims:** Once-weekly (QW) exenatide consistently improves glycaemic control and promotes weight loss in patients with type 2 diabetes mellitus (T2DM) but requires reconstitution and may be difficult to use for some patients. A QW suspension containing exenatide dispersed in microspheres suspended in a triglyceride carrier, was developed to eliminate the need for reconstitution and allow delivery via a single-use autoinjector pen. This simplified approach may enhance adherence. An open-label, 28-week study compared exenatide suspension QW (ExSQW) to exenatide twice daily (ExBID) in patients with inadequately controlled T2DM.

**Materials and methods:** Patients treated with diet/exercise or combination of oral medications (metformin, sulfonylurea or pioglitazone) were randomized (in a 3:2 ratio) to ExSQW 2 mg (n=229) or ExBID 10 mcg (n=148). The primary endpoint was change in HbA<sub>1c</sub> from baseline to Week 28 with ExSQW vs ExBID.

**Results:** Baseline characteristics were similar in both groups: mean $\pm$ SD HbA<sub>1c</sub> of 8.48 $\pm$ 1.03%, fasting plasma glucose (FPG) of 182 $\pm$ 45 mg/dL (corresponding to 10.10 $\pm$ 2.53 mmol/L), and body weight of 96.9 $\pm$ 21.0 kg. Changes in HbA<sub>1c</sub> from baseline are shown in Figure 1; at Week 28, the reduction (least-squares [LS] mean $\pm$ SE) in the ExSQW group was greater than in the ExBID group (-1.39 $\pm$ 0.09 vs -1.02 $\pm$ 0.11%; P=0.007). Achievement of HbA<sub>1c</sub>  $< 7\%$  was comparable in the ExSQW vs ExBID groups (49% vs 43%; P=0.225). Similar FPG reductions were observed in both groups as early as Week 2. By Week 28, FPG reductions reached -32.7 $\pm$ 3.9 and -22.5 $\pm$ 4.9 mg/dL (corresponding to -1.81 $\pm$ 0.22 and -1.25 $\pm$ 0.27 mmol/L) for ExSQW and ExBID, respectively (P=0.166). Body weight decreased similarly in the ExSQW (-1.49 $\pm$ 0.28 kg) and ExBID (-1.89 $\pm$ 0.36 kg) groups. Gastrointestinal (GI) adverse events (AEs) were less frequent in the ExSQW group than in the ExBID group (nausea: 9.6% vs 21.2%; diarrhea: 5.2% vs 11.6%; vomiting: 3.5% vs 6.2%, respectively), but injection-site nodules occurred more often (12.7% vs 0.7%). No major hypoglycaemia was reported; minor hypoglycaemia was infrequent, generally mild, and occurred primarily in patients with concomitant sulfonylurea use. The ExSQW and ExBID groups, respectively, had low rates of serious AEs (2.6% and 4.8%) and withdrawals due to AEs (2.2% and 4.8%). The completion rate was slightly greater with ExSQW (86.0% vs 79.7%).

**Conclusion:** ExSQW with autoinjector delivery simplified treatment with robust glycaemic control, weight loss and less GI AEs, but more injection-site nodules, than ExBID.

### Cancer occurrence in type 1 diabetes patients: a 4-country study with 8800 cancer cases in 3.7 mio person-years

B. Carstensen<sup>1</sup>, S. Friis<sup>2</sup>, J. Harding<sup>3</sup>, D.J. Magliano<sup>3</sup>, R. Sund<sup>4</sup>, I. Keskimäki<sup>5</sup>, R. Ljung<sup>6</sup>, A.-M. Svensson<sup>7</sup>, S. Wild<sup>8</sup>, S. Gudbjörnsdóttir<sup>7</sup>;

<sup>1</sup>Steno Diabetes Center, Gentofte, <sup>2</sup>Danish Cancer Society, Copenhagen, Denmark, <sup>3</sup>BakerIDI Heart and Diabetes Institute, Melbourne, Australia, <sup>4</sup>University of Helsinki, <sup>5</sup>National Institute for Health and Welfare, Helsinki, Finland, <sup>6</sup>Karolinska Institutet, Institute of Environmental Medicine, Stockholm, <sup>7</sup>University of Gothenburg, Sweden, <sup>8</sup>University of Edinburgh, UK.

**Background and aims:** Diabetes (DM) patients carry an excess risk of cancer in the order of 20-25%; this is mainly derived from follow-up of type 2 patients (T2D). The excess risk of cancer among type 1 (T1D) patients is described here as it is anticipated to be different from T2D patients.

**Materials and methods:** T1D patients from four countries with nation-wide diabetes registers: Australia (1997-2008), Denmark (1995-2009), Finland (1972-2010), and Sweden (1987-2011) were followed for cancer occurrence. T1D was defined by diagnosis of DM before age 30. Cancer incidence rates were compared to population cancer incidence rates from national cancer registries. We used Poisson-models for rates, adjusting for age and date of follow-up, and date of birth. We estimated the overall rate ratio (RR) for all T1D patients and the effect of time since DM diagnosis.

**Results:** There were a total of 8,807 cancers among T1D patients during 3.7 million person-years of follow-up with median age at cancer diagnosis 51.1 (IQR: 43.5,59.5). Overall, we found an RR of any type of cancer of 1.00 (95% CI: 0.97-1.03) among men and 1.05 (95% CI: 1.02-1.08) among women. The highest RRs were found for colorectal cancer, (RR=1.13 (M), 1.14 (F)), liver cancer (RR=2.14 (M), 1.50 (F)), pancreas cancer (RR=1.74 (M), 1.31 (F)), endometrial cancer (RR=1.4 kidney cancer (RR=1.28 (M), 1.44 (F)), and thyroid cancer (RR=1.29 (M), 1.46 (F)), all significant. We found a strong effect of diabetes duration, with an RR of 2.5 during the first year, decreasing to 1.2 (M) and 1.1 (F), after 2-5 years.

**Conclusion:** Some of the observed excess risk may be explained by risk factors for cancer being more frequent in T1D patients (obesity), however this effect is presumably smaller than in T2D patients, and hence consistent with the smaller excess risk. The long-term RR (>5 years of DM) is less than 1.2, which means that some small effect of exogenous insulin cannot be excluded, but the study is also consistent with an assumption of no such effect.

### Time-varying incidence of cancer after incident type 2 diabetes: differences by obesity-versus non-obesity-related cancers

A. Renehan<sup>1</sup>, E. Badrick<sup>2</sup>, M. Sperrin<sup>2</sup>, M. Carr<sup>2</sup>, T. Moran<sup>3</sup>, I. Buchan<sup>2</sup>;

<sup>1</sup>Institute of Cancer Sciences, University of Manchester, <sup>2</sup>Institute of Population Health, University of Manchester, <sup>3</sup>NHS, Northwest Cancer Intelligence Service, Manchester, UK.

**Background and aims:** People with Type 2 diabetes (T2D) are at increased incident risk of several cancer types, many of which are also causally linked with excess body weight. To explore these relationships further, we determined the incidence of cancer in people with incident T2D during different time windows following diabetes diagnosis, stratified as obesity- and non-obesity-related cancers.

**Materials and methods:** We used the Salford Integrated record database linked with the Northwest cancer Intelligence service (UK) for data from 1995-2010. We identified incident cohorts with (N = 10,328) and without T2D, who were matched (1:2) by age, sex and index year. Following exclusion of previous cancers, first site-specific cancers were identified prospectively in both cohorts. Obesity-related cancers were post-menopausal breast, colorectal, endometrial, kidney, gallbladder, pancreas, liver, and ovarian. Risk estimates were expressed as hazard ratios (HRs) and their 95% confidence intervals (CIs).

**Results:** Diabetic patients had a significantly higher BMI than matched controls (mean 30.9 (SD6.7) vs 27.3 (SD5.4)), and were more likely to be ever smokers (60.0% vs 52.63%). Within 6 months following diabetes onset, participants with T2D were at increased risk of obesity-related (HR 1.54, 95% CI: 0.98, 2.40) but not non-obesity-related cancers. From 6 months to 10 years,

risk associations for obesity- and non-obesity-related cancers remained close to null. After 10 years following diabetes onset, participants with T2D were at increased risk of non-obesity-related (HR 1.49, 95% CI: 1.13, 1.97) but not obesity-related cancers. These observations were robust to adjustment for smoking.

**Conclusion:** We confirmed that people with incident T2D are at increased risk of certain cancers; the risk for obesity-related cancers is particularly elevated near to the time of diabetes onset, and is likely to present detection time bias. Paradoxically, we noted elevated risk of non-obesity-related cancers among people with T2D with greater than 10 years disease duration, emphasizing the importance of assessing diabetes-cancer associations using time-varying approaches.

### Diabetes and cancer risk in a population-based study with 20 years of follow-up: the Rotterdam Study

K.M.J. De Bruijn<sup>1</sup>, R. Ruiter<sup>2</sup>, T.E. de Keyser<sup>2</sup>, A. Hofman<sup>2</sup>, B.H. Stricker<sup>2</sup>, C.H.J. van Eijck<sup>1</sup>;

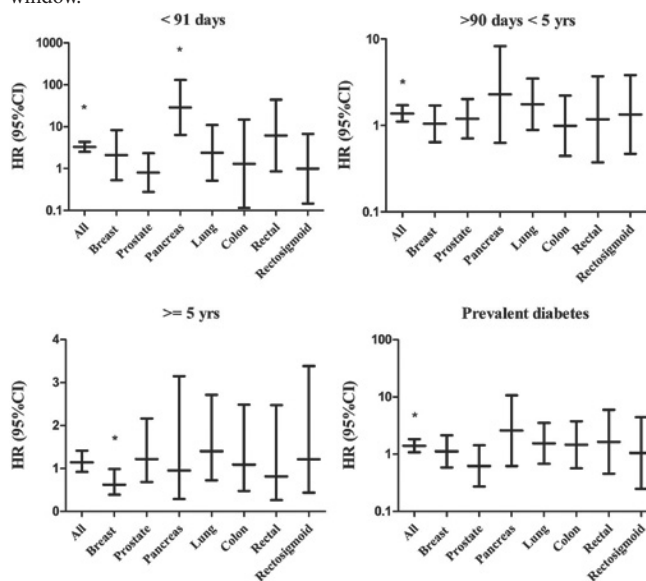

<sup>1</sup>Surgery, Erasmus University Medical Center, <sup>2</sup>Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands.

**Background and aims:** Type 2 diabetes is associated with an increased risk of cancer. Most observational studies on this topic analyze diabetes as a dichotomous risk factor without adjusting for diabetes Duration before cancer occurrence. The objective of this study was to investigate the association between diabetes duration and cancer risk in more detail.

**Materials and methods:** In this prospective cohort study, incident diabetes was diagnosed on the basis of clinical information and use of glucose-lowering medication. Details on incident cancers were obtained via general practitioners and linkage to registers for pathology. Time-dependent Cox proportional hazard models were used. Additionally, a five year latency period was taken into account.

**Results:** The study comprised 10,746 individuals. Diabetes was associated with an increased overall risk of incident cancers (HR 1.22, 95%CI 1.07-1.39). Distinguished by type of cancer, diabetes was associated with an increased risk of breast (HR 1.50, 95%CI 1.05-2.15) and pancreatic cancer (HR 2.93, 95% CI 1.75-4.89), but with a decreased risk of prostate cancer (HR 0.59, 95%CI 0.38-0.93). As a diabetes diagnosis of less than three months before a cancer diagnosis was associated with strongly increased risks for all cancers (HR 3.30, 95%CI 2.50-4.32) and pancreatic cancer (HR 28.74, 95%CI 6.32-130.58), at least a part of the association might be explained by detection bias or by protopathic bias. After adjusting for a latency period of five years, the association regarding the decreased risk of prostate cancer remained statistically significant, whereas the risk of rectal cancer increased (HR 2.26, 95%CI 1.04-4.95).

**Conclusion:** Although the magnitude of the association between diabetes and increased risk of cancer seems to be inflated by detection- or protopathic bias, an independent association remains. Future studies investigating this association should adjust for diabetes duration and a plausible etiological risk window.

**Cancer therapy alters whole body metabolism later in life: a potential role for epigenetic mechanisms**V. Nylander<sup>1</sup>, D. Simar<sup>2</sup>, M. Aznar<sup>3</sup>, L. Specht<sup>3</sup>, J.R. Zierath<sup>1</sup>, R. Barres<sup>1</sup>;<sup>1</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Denmark, <sup>2</sup>School of Medical Sciences, University of New South Wales, Sydney, Australia, <sup>3</sup>University of Copenhagen, Denmark.

**Background and aims:** Cancer survivors are at increased risk of acquiring metabolic dysfunction such as glucose intolerance and Type 2 Diabetes, years after end of cancer treatment. Epidemiological studies identified total body irradiation as the highest risk factor. Given the importance of muscle tissue in whole body glucose metabolism, we focused on skeletal muscle progenitor cells. We hypothesized that irradiation causes epigenetic changes in this cell type that could account for the delayed, deleterious effects on metabolic function. Aim: To determine if irradiation alters the DNA methylome of muscle progenitor cells, leading to altered differentiation potential and metabolic dysfunction.

**Materials and methods:** Male C57Bl/6 mice were irradiated (IRR) or not (CTL) with one dose of total body irradiation (6 Gy). Mice were allowed to recover from acute irradiation effects for 5 weeks before randomisation into groups fed CHOW or high fat diet (HFD, 60 % energy intake from fat). Metabolic characterization of mice was done by MR scan, glucose tolerance test and indirect calorimetry. Muscle progenitor cells were isolated by FACS sorting to investigate for deficiencies in intracellular pathways controlling metabolism or cell differentiation. In vitro experiments were performed using L6 rat myoblasts, which were irradiated with one dose of 1, 3 or 6 Gy. Cells were allowed to recover from irradiation for 4 weeks, before differentiation was induced and insulin signalling and DNA methylation was investigated. Statistical analysis used was one-way and two-way ANOVA for MR and body weight, and repeated measures analysis for indirect calorimetry data and glucose tolerance tests.

**Results:** After recovery from irradiation, calorie intake, oxygen consumption and energy expenditure were similar in both groups. Prolonged HFD induced impaired glucose homeostasis in IRR-HFD, but not in IRR-CHOW. This was accompanied by increased fasting insulin levels in IRR-HFD (50%,  $p=0.033$ ), whereas fasting insulin was decreased in IRR-CHOW (20%,  $p=0.022$ ), as compared to respective controls. Muscle progenitor cells collected 17 weeks post irradiation and cultured in vitro exhibited decreased growth rate (30%,  $p=0.03$ ) compared to cells collected from CTL animals. Muscle cells collected from IRR animals showed altered signalling pathways controlling cell division and differentiation. Irradiation of rat muscle cell line phenocopied the impaired activation of signalling and exhibited an altered differentiation and DNA methylation profile.

**Conclusion:** Our study confirms that irradiation induces a long-term alteration of glucose metabolism and suggests that irradiation stably alters the epigenome and the differentiation potential of muscle progenitor cells. Irradiation-induced epigenetic modification could be a mechanism by which cancer survivors develop metabolic complications later in life.

**Overexpression of cutaneous mitochondrial superoxide dismutase in recently diagnosed type 2 diabetic patients**D. Ziegler<sup>1,2</sup>, A. Strom<sup>1</sup>, S. Püttgen<sup>1</sup>, J. Brüggemann<sup>1</sup>, I. Ziegler<sup>1</sup>, B. Ringel<sup>1</sup>, M. Roden<sup>1,2</sup>, German Diabetes Study Group;<sup>1</sup>Institute for clinical Diabetology, German Diabetes Center at Heinrich Heine University, <sup>2</sup>Department of Endocrinology and Diabetology, University Hospital, Düsseldorf, Germany.

**Background and aims:** Oxidative stress resulting from enhanced free-radical formation and immune-mediated processes has been implicated in the pathogenesis of diabetic neuropathy. Since manganese superoxide dismutase 2 (SOD2) is responsible for superoxide detoxification in mitochondria, we hypothesized that cutaneous SOD2 could be overexpressed in recently diagnosed diabetes.

**Materials and methods:** We assessed skin biopsies and nerve function in 71 participants of the German Diabetes Study (GDS) with recently diagnosed type 2 diabetes (age:  $54.5\pm 0.9$  [SEM] years; male: 67.6%; BMI:  $32.2\pm 0.7$  kg/m<sup>2</sup>, diabetes duration:  $1.0\pm 0.1$  years; HbA1c:  $6.5\pm 0.1\%$ ) and 52 healthy control subjects (age:  $55.2\pm 1.2$  years; male: 53.8%,  $25.4\pm 0.5$  kg/m<sup>2</sup>). Intraepidermal nerve fibre density (IENFD) was assessed by immunohistochemistry in 3-mm punch biopsies from the distal leg. Subepidermal SOD2 area was determined by immunofluorescence using a polyclonal SOD2 antibody. CD31 immunohistochemistry was used to quantify subepidermal endothelial cell area. Peripheral nerve function was assessed by motor and sensory nerve conduction velocity (MNCV, SNCV), vibration perception thresholds (VPT), and thermal detection thresholds (TDT), while cardiac autonomic nerve function was assessed by heart rate variability (HRV) in the time and frequency domains. All comparisons were adjusted for sex, age, and BMI.

**Results:** IENFD was lower by 24% in diabetic subjects vs controls ( $6.9\pm 0.3$  vs  $9.1\pm 0.4$  fibres/mm;  $P<0.0001$ ). Subepidermal SOD2 area was increased by 60% in the diabetic group vs controls ( $0.24\pm 0.02$  vs  $0.15\pm 0.02$ ;  $P<0.0001$ ). Subepidermal endothelial cell area did not differ between the diabetes group and controls ( $2.03\pm 0.15$  vs  $1.89\pm 0.13\%$ ), but was smaller by 28% in diabetic subjects with known diabetes duration  $>1$  year compared to those who had diabetes for  $\leq 1$  year ( $1.64\pm 0.16$  vs  $2.29\pm 0.22$ ;  $P=0.047$ ). Subepidermal endothelial cell area declined ( $r=-0.33$ ;  $P=0.02$ ), whereas SOD2 area augmented with increasing diabetes duration ( $r=0.26$ ;  $P=0.032$ ). In the diabetes group, multivariate linear regression analyses revealed that subepidermal endothelial cell area was associated with IENFD ( $\beta=0.28$ ;  $P=0.048$ ), whilst SOD2 area was related to the low-frequency/high-frequency (LF/HF) ratio as an indicator of sympathovagal balance ( $\beta=0.384$ ;  $P=0.001$ ).

**Conclusion:** Patients with recently diagnosed type 2 diabetes show cutaneous SOD2 overexpression indicating enhanced local oxidative stress linked to cardiac sympathetic predominance as well as dermal microvascular alterations related to epidermal nerve fibre loss and diabetes duration. Whether cutaneous SOD2 is an early marker to predict the development of diabetic peripheral and autonomic neuropathy remains to be determined in prospective studies.

**Wound healing rate is impaired by a glucose-induced overactive Delta4-Notch1 loop**X. Zheng<sup>1</sup>, V.G. Sunkari<sup>1</sup>, I.R. Botusan<sup>1,2</sup>, J. Grünler<sup>1</sup>, A.I. Catrina<sup>3</sup>, F. Radtke<sup>4</sup>, K. Brismar<sup>1</sup>, S.-B. Catrina<sup>1</sup>;<sup>1</sup>Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, <sup>3</sup>Department of Rheumatology, Karolinska Institutet, Stockholm, Sweden, <sup>4</sup>Ecole Polytechnique Fédérale de Lausanne, Swiss Institute for Experimental Cancer Research, Switzerland.

**Background and aims:** Notch signaling is central for cell differentiation and angiogenesis. It is a cell-cell system composed of several Notch receptors (Notch1-4) and their ligands (Jagged 1-2, delta 1, 3, 4). The signaling is activated after binding of the ligands to the receptor which is followed by proteolytic cleavage of the receptor by  $\gamma$ -secretase complex with specific outcome

depending on the members of the Notch system involved. Diabetic wounds are characterized by impaired coordination of several cellular processes such as angiogenesis and cell differentiation. We have studied the potential role of Notch signaling in diabetic wound healing.

**Materials and methods:** Human dermal fibroblasts (HDF) and human dermal endothelial cells were used for *in vitro* studies and several animal models of diabetes (db/db mice and streptozotocin-induced diabetic mice) were used for *in vivo* studies. The functional consequence of the notch system modulation was studied *in vitro* by assessment of the migration of HDF and by angiogenesis assay. Notch pathway inhibition was induced either by  $\gamma$ -secretase inhibitors or by specific siRNA silencing of the Notch receptors (1–4). Using cre-lox system we have generated mice that lack Notch 1 in the skin. Wound healing rate was evaluated both in db/db mice and in skin-specific Notch1 knock-out mice in which diabetes was induced by streptozotocin.

**Results:** Notch signaling was activated in the skin of several animal models of diabetes and biopsies from patients with diabetic wounds. Hyperglycemia activated Notch pathway and had repressive effect on fibroblasts migration and angiogenesis. Mechanistically, we found that hyperglycaemia enhances delta4 expression in a Notch1-dependent manner and this positive delta4-Notch1 feedback loop contributed to the impaired wound healing in diabetes. This was confirmed *in vivo* where inhibition of Notch signaling with  $\gamma$ -secretase inhibitors improved wound healing rate just in diabetic (db/db mice) but not in control non-diabetic animals. Using loss-of-function genetic approaches we demonstrated both at the cellular level (fibroblasts, endothelial cells) as well as in an animal model that the Notch1 activation was the key player of the repressive effects of Notch on wound healing in diabetes, which was confirmed in the biopsies from patients with diabetic foot ulcers.

**Conclusion:** Glucose activates a positive feedback loop (delta4-Notch1) that contributes to the deleterious wound healing in diabetes.

### SP regulates macrophage function in diabetic wound healing

E.C. Leal<sup>1,2</sup>, A. Tellechea<sup>1,2</sup>, S. Kuchibhotla<sup>2</sup>, M.E. Auster<sup>2</sup>, F.W. LoGerfo<sup>2</sup>, L. Pradhan-Nabzdyk<sup>2</sup>, E. Carvalho<sup>1</sup>, A. Veves<sup>2</sup>;

<sup>1</sup>Center for Neurosciences and Cell Biology, Coimbra, Portugal, <sup>2</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA.

**Background and aims:** Chronic diabetic foot ulcerations develop in areas affected by diabetic neuropathy. As consequence, neuropeptides, such as substance P (SP), known to modulate inflammation, showed to be important in wound healing. However, little it is known about the effect of SP on macrophages activation. We aimed to study the effect of SP on macrophage function in diabetic wound healing progression.

**Materials and methods:** We used wild type (WT) mice and two types of genetically modified mice: one deficient of the NK1 receptor of SP (NK1RKO) and one deficient of the TAC1 gene that encodes for SP and other takinins (TAC1KO). Also, we treated the wound with SP or CJ012,255 (CJ), an inhibitor of SP receptor. Diabetes was induced by streptozotocin intraperitoneal injection, 50 mg/Kg, 5 days. The animals were kept 8 weeks diabetic prior wound healing experiment. M1 and M2 macrophages were identified by using immunohistochemistry at several phases of wound healing: baseline (Day-0), Day-3 and Day-10 post-wounding. MCP-1, IL-1 and KC was quantified by q-RT-PCR.

**Results:** The M1/M2 ratio was increased at Day-0 in WT-diabetic mice and nondiabetic and diabetic NK1R and TAC1 mice when compared to WT-nondiabetic mice. In WT-nondiabetic mice, the ratio increased at Day-3 but returned to normal levels by Day-10. In contrast, in WT-diabetic and nondiabetic and diabetic NK1R and TAC1 mice at Day-0, Day-3 and Day-10, the M1/M2 ratio remains high, suggesting a persistent inflammation. At Day-10, the M1/M2 ratio was increased in CJ- treated WT-nondiabetic and WT-diabetic mice. In contrast, SP treatment reduced the diabetes-induced increase in M1/M2 ratio. Similar results were observed in the skin gene expression of the monocyte chemoattractant 1 (MCP-1) that recruits monocytes in areas of inflammation where they are converted to macrophages. At Day-0, MCP-1 was increased in the TAC1KO mice. MCP-1 expression increased at Day-3 in all non-diabetic and diabetic mice. At day-10, all mice groups had a decreased MCP-1 expression but, nonetheless, it was increased in WT-diabetic. SP treatment increased MCP-1 expression at Day-3 in both WT-nondiabetic and diabetic wounds. At Day-10, SP treatment reduced MCP-1 expression in both WT-nondiabetic and diabetic mice while CJ-treated mice had higher expression when compared to SP-treated mice. Moreover, diabetic mice

showed an increase in IL-6 expression at baseline while SP induced a further increase in IL-6 gene expression in WT-nondiabetic mice at Day-3. NK1RKO and TAC1KO mice showed an increase in IL-6 expression at baseline. KC gene expression was also increased in WT diabetic mice at baseline and this increase persisted at Day-10. SP induced an acute increase at Day-3 that was followed by a reduction to normal levels at Day-10. NK1RKO and TAC1KO mice had also higher KC gene expression at baseline and NK1RKO mice showed a higher KC expression at Day-3.

**Conclusion:** In conclusion, the reduction in SP availability results in a pro-inflammatory activation of skin macrophages before wounding. SP also plays a major role in shifting macrophages to the M2 activation promoting wound healing. Furthermore, SP induced an increase in the acute inflammatory phase of wound healing during the early stages of wound healing but considerably reduces it in later stages, which is essential for a good skin repair.

### Living human keratinocytes as a therapeutic option to improve diabetic ulceration

D. Maucher, C. Schürmann, I. Goren, S. Frank; Pharmazentrum Frankfurt, Germany.

**Background and aims:** Diabetes-associated foot ulcerations (DFU) represent a serious clinical complication of wound healing. To date, pharmacological approaches to improve diabetic wound healing disorders still remain poor and limited. The lack of knowledge for underlying molecular and cellular mechanisms of impaired wound healing particularly adds to this unsatisfactory clinical condition. Here we used human keratinocytes (BAWD, bio-active wound dressing) as a dynamic approach to deliver a living source of multiple wound-induced mediators for treatment of highly disturbed healing conditions in severely diabetic mice.

**Materials and methods:** BAWD consists of human keratinocytes cell line (KCB1). The cells were cultured on a hyaluronic acid matrix. The KCB1 cell line represents well-characterized, safe, and highly proliferative keratinocytes, which have been initially isolated from human foreskin. For wound healing studies, six full-thickness wounds (5 mm in diameter, 3–4mm apart) were made on the back of severely diabetic C57BL/6J-db/db mice. Upon injury, mice received a coverage of skin wounds using hyaluronic acid matrix alone (vehicle) or living keratinocytes (BAWD, therapeutic). Skin biopsy specimens were obtained from the animals at day 3, 7 and 10 after injury. Protein and RNA isolation was performed and wound biopsies were fixed for histology. The transcriptome of hyaluronic acid- and BAWD-covered wound tissue was analyzed by direct mRNA sequencing. Paraffin sections (4 $\mu$ m) were stained for collagen deposition (azan trichrome) or incubated using antisera against CD31, VEGF or myosin heavy chain 7.

**Results:** BAWD strongly improved diabetes-disturbed wound healing. BAWD-covered wounds showed a very robust formation of granulation tissue in the presence of hyperglycaemia. New tissue was characterized by high expression levels of angiogenic VEGF. Induced expression of the endothelial marker Tie-2 and a high density of newly formed blood vessels defined newly formed tissue. Moreover, gene expression analyses of BAWD-improved wound tissue showed a keratinocyte-mediated induction of a large set of genes, which are known to be specifically involved in skeletal and heart muscle development, differentiation and function. Improved wound tissue upon BAWD-treatment also showed combined expression levels of the mesenchymal stem cell markers Sca-1 and CD29.

**Conclusion:** BAWD markedly improved wound healing in diabetic mice by accelerating the formation of new tissue at sites of diabetes-impaired wounds repair.

### Macro-encapsulated human embryonic stem cell-derived implants meet characteristics of clinical human islet cell grafts

E. Motté<sup>1</sup>, E. Szepessy<sup>1</sup>, K. Suenens<sup>1</sup>, G. Stangé<sup>1</sup>, M. Bomans<sup>2</sup>,  
D. Jacobs-Tulleneers-Thevissen<sup>1</sup>, Z. Ling<sup>1</sup>, E. Kroon<sup>3</sup>, D. Pipeleers<sup>1</sup>;  
<sup>1</sup>Diabetes Research Center, <sup>2</sup>Beta-Cell nv, Jette, Belgium,  
<sup>3</sup>Viacyte Inc., San Diego, USA.

**Background and aims:** Shortage of good quality human pancreases for use in organ and islet cell transplantation has led to development of large-scale laboratory sources that generate insulin-producing implants. Pancreatic endocrine cells can be formed from human embryonic stem (huES) cells following in vitro derivation to pancreatic endoderm (PE) and further differentiation in immune-incompetent mice. This study examines to which extent huES-generated implants meet characteristics of human islet cells as used in clinical transplantation.

**Materials and methods:** Free, alginate-micro- and Theracyte-macro-encapsulated huES-derived PE-grafts of similar size were implanted in mice with severe-combined-immune-deficiency. Their in vivo differentiation was compared through plasma human C-peptide levels and cellular analysis of implants at posttransplant week 20. Implants retrieved from Theracyte-macro-devices were analyzed for glucose-regulated hormone synthesis and release. Data were compared with those collected for human islet cells.

**Results:** Endocrine enrichment was higher in encapsulated than free hu-ES-implants or in clinical-grade human islet cell grafts, with enrichment in single hormone-positive alpha, beta and delta cells in macro-devices and alpha cells in microcapsules. Macro-huES-implants resulted in higher plasma human C-peptide than free human islet cell transplants with similar cell number. They exhibited equally rapid insulin- and glucagon-secretory responses to increasing and decreasing glucose concentrations during perfusion. Their insulin secretory amplitude to glucose was lower, in part attributable to a lower cellular hormone content; this was associated with lower glucose-induced insulin biosynthesis, but not with lower glucagon-induced stimulation of release.

**Conclusion:** Macro-encapsulated huES-derived implants can reach an endocrine composition and function with therapeutic potential. Their beta cells exhibit rapid glucose responsiveness with lower amplitude, compatible with an immature functional state. Comparative data with clinical-grade human islet cell grafts set references for further development and clinical translation. *Supported by: EC-FP7, JDRF encapsulation consortium, Flemish Government, FWO*

### Impaired processing of human pro-islet amyloid polypeptide (proIAPP) promotes early islet graft failure

J.A. Courtade, P.C. Orban, C.B. Verchere;  
Pathology and Laboratory Medicine, The University of British Columbia,  
Vancouver, Canada.

**Background and aims:** Islet transplantation is a promising therapy for type 1 diabetes. Long-term survival of islet grafts may be compromised not only by immune rejection but also other factors including the formation of islet amyloid from islet amyloid polypeptide (IAPP). IAPP aggregation has been linked to beta-cell dysfunction, apoptosis, and islet inflammation but the underlying mechanism of islet amyloid formation remains elusive. Elevated circulating proinsulin:insulin ratios have been detected in type 2 diabetes and in type 1 diabetic recipients of islet transplants. Processing of the IAPP precursor, proIAPP, may be similarly compromised in islet transplants and type 2 diabetes, since like proinsulin, proIAPP is processed by the beta cell prohormone convertases PC1/3 and PC2. We hypothesize that accumulation of proIAPP intermediates leads to amyloid formation and beta-cell dysfunction and assessed the impact of impaired proIAPP processing in transplanted islets.

**Materials and methods:** NOD.SCID mice (age 8-10 weeks) were made diabetic with streptozotocin and transplanted with islets from mice with beta-cell expression of human proIAPP and lacking PC2 (hIAPP<sup>Tg0</sup>; PC2<sup>-/-</sup>) or

controls (hIAPP<sup>Tg0</sup>;PC2<sup>+/-</sup>, hIAPP<sup>0/0</sup>;PC2<sup>-/-</sup>, hIAPP<sup>0/0</sup>;PC2<sup>+/-</sup>). Blood glucose was monitored weekly in recipients for 16 weeks or until graft failure (return of hyperglycaemia). Islet graft sections were stained for insulin, amyloid deposition (thioflavin S) and TUNEL positivity.

**Results:** Diabetes (blood glucose >16.9 mM) returned in almost all (90%) of recipients of hIAPP<sup>Tg0</sup>;PC2<sup>-/-</sup> islets within 16 weeks post-transplant, whereas recipients with normal human proIAPP processing (hIAPP<sup>Tg0</sup>;PC2<sup>+/-</sup>) remained normoglycemic for the entire 16 weeks. Recipients of grafts expressing native rodent IAPP, with or without PC2, similarly maintained normoglycemia. Despite early graft failure in recipients of islets with impaired human proIAPP processing, beta-cell mass remained unchanged and amyloid deposition was lower compared to human proIAPP-expressing mice with normal processing. Islet grafts had few TUNEL-positive beta cells and no difference in the number of TUNEL-positive cells among groups, suggesting that impaired human proIAPP processing compromises beta-cell function rather than promoting beta-cell apoptosis.

**Conclusion:** Impaired human proIAPP processing in islet transplants induces early graft failure without affecting beta-cell mass or increasing amyloid formation. These data suggest that impaired proIAPP processing promotes dysglycemia, possibly via the formation of early (pro)IAPP aggregates that induce beta-cell dysfunction. Our work implicates IAPP precursors as potential targets to prolong islet graft survival.

### In type 1 diabetic patients pancreas transplanted simultaneously with kidney preserves long-term kidney graft ultrastructure better than kidney transplantation alone

J.P.H. Lindahl<sup>1</sup>, F. Reinholdt<sup>2</sup>, I.A. Eide<sup>1</sup>, A. Hartmann<sup>1</sup>, O. Øyen<sup>1</sup>,  
T. Jenssen<sup>1,3</sup>;

<sup>1</sup>Department of Transplant Medicine, <sup>2</sup>Department of Pathology,  
Oslo University Hospital, Norway, <sup>3</sup>University of Tromsø, Norway.

**Background and aims:** In type 1 diabetic patients with end-stage renal disease (ESRD) we aimed to determine whether long-term normoglycaemia, as achieved by successful simultaneous pancreas and kidney (SPK) transplantation, would preserve kidney graft structure, determined by morphometry and electron microscopy (EM), and function compared with live donor kidney (LDK) transplantation alone.

**Materials and methods:** Estimated GFR (eGFR) was calculated in 25 recipients with SPK and 17 recipients with LDK in a stable phase 3 months after transplantation and annually during follow-up. Ultrasound guided kidney graft biopsies were obtained from all participants at follow-up. All biopsies were processed for light microscopy to measure glomerular volume, and EM to obtain data on glomerular basement membrane (GBM) width, mesangial fractional volume and podocyte coverage of the capillary basement membrane.

**Results:** SPK and LDK recipients were similar in age and diabetes duration at engraftment. The median duration of follow-up was 10.1 years. HbA1c was 5.6±0.4 % and 8.3±1.7 % in the SPK and LDK group, respectively (p<0.001). Compared with SPK recipients, patients who received LDK had significantly wider GBM (368.9±109.4 nm vs 281.0±56.7 nm; p=0.008) and increased mesangial fractional volume (23 (13, 59) % vs 16 (10, 41) %; p=0.006) at follow-up. Podocyte coverage of the capillary basement membrane was equal in the SPK (88 (58, 100) %) and LDK (89 (57, 100) %) group (p=0.35). Glomerular volume tended to be higher in LDK (4.5 (2.2, 8.2) × 10<sup>6</sup> μm<sup>3</sup>) compared with SPK (3.2 (1.6, 12.9) × 10<sup>6</sup> μm<sup>3</sup>) recipients (p=0.10). In the SPK group the eGFR declined from 78.3±16.7 at transplantation to 67.3±23.7 ml/min/1.73 m<sup>2</sup> at follow-up (-11.0±21.4 ml/min/1.73 m<sup>2</sup>), and the recipients of LDK declined from 68.9±13.2 to 46.2±14.2 ml/min/1.73 m<sup>2</sup> (-22.7±15.2 ml/min/1.73 m<sup>2</sup>), respectively (p=0.060).

**Conclusion:** In type 1 diabetic patients with long-term normoglycaemia after successful SPK transplantation kidney graft ultrastructure was better preserved compared with LDK.

## 256

**Coronary artery disease in type 1 diabetic patients long-term after simultaneous pancreas and kidney transplantation compared with kidney transplantation alone**T. Jenssen<sup>1,2</sup>, J.P.H. Lindahl<sup>1</sup>, A. Hartmann<sup>1</sup>, K. Endresen<sup>3</sup>, A. Günther<sup>4</sup>;<sup>1</sup>Department of Transplant Medicine, Oslo University Hospital,<sup>2</sup>University of Tromsø, <sup>3</sup>Department of Cardiology,<sup>4</sup>Department of Radiology, Oslo University Hospital, Norway.

**Background and aims:** Improved long-term glycaemic control protects against development of cardiovascular disease and death in type 1 diabetic patients. We aimed to determine whether long-term normoglycaemia, as achieved by successful pancreas and kidney transplantation (SPK), would change the development of coronary artery disease (CAD) compared with successful live donor kidney transplantation alone (LDK).

**Materials and methods:** Twenty type 1 diabetic patients who had received SPK grafts were compared with 11 recipients of LDK. All patients included underwent baseline (pre-transplant) and follow-up coronary angiography. Computed tomography (CT) examination was performed at follow-up to obtain coronary artery calcium scoring (CACS). Logistic regression was used to evaluate association between CACS and CAD.

**Results:** Recipients of SPK grafts and LDK were similar in terms of age and diabetes duration at engraftment. The median duration of follow-up was 9.2 years. HbA<sub>1c</sub> was 5.6±0.4 % and 8.4±2.0 % in the SPK and LDK group, respectively (p<0.001). In the SPK group the eGFR declined from 81.6±14.8 at transplantation to 69.9±22.0 ml/min/1.73 m<sup>2</sup> at follow-up (-11.7±22.0 ml/min/1.73 m<sup>2</sup>), and the recipients of LDK declined from 70.1±14.5 to 50.8±11.6 ml/min/1.73 m<sup>2</sup> (-19.3±11.9 ml/min/1.73 m<sup>2</sup>), respectively (p=0.22). Coronary angiography at baseline revealed that 11 out of 20 SPK recipients had CAD, defined as coronary luminal stenosis of 50 % or more in at least 1 vessel, compared with 1 out of 11 recipients in the LDK group (p=0.020). During follow-up there was no difference in patients with progression (defined as a new stenosis at or above 50 % in one or more vessels) of CAD between the SPK group (10 out of 20 recipients) and the LDK group (5 out of 11 recipients; p=0.81). Median Agatston scores of coronary arteries with CT scan at follow-up were extremely high: 1625 (9, 7368) and 1391 (4, 5897) for the SPK and LDK group, respectively (p=0.92). There was, on the other hand, no significant association between high CACS and coronary artery lumen narrowing (≥50% diameter stenosis) in the SPK group (OR 1.001, CI 1.000, 1.003; p=0.079) or in the LDK group (OR 1.000, CI 0.999, 1.001; p=0.61).

**Conclusion:** This study suggests that median 9 years of normoglycaemia, as achieved by successful SPK transplantation, is not sufficient to halt or reverse CAD in previously uraemic diabetic patients. Calcification of coronary arteries is a prominent feature in this group of patients.

**OP 47 Pharmacogenetics and disease progression**

## 257

**Modelling the rate of deterioration of diabetes in observational data: a DIRECT study**L.A. Donnelly<sup>1</sup>, K. Zhou<sup>1</sup>, C. Jennison<sup>2</sup>, E.R. Pearson<sup>1</sup>;<sup>1</sup>Division of Cardiovascular & Diabetes Medicine, University of Dundee,<sup>2</sup>Department of Mathematical Sciences, University of Bath, UK.

**Background and aims:** The rate at which diabetes progresses following diagnosis of type 2 diabetes (T2D) is highly variable between individuals. Outwith clinical trials of monotherapy such as ADOPT and UKPDS, it is challenging to model progression rates in the population of patients with diabetes due to the fact that underlying 'diabetes severity' reflects both drug treatment and HbA<sub>1c</sub>. The aim of this study was to combine these measures to derive a Diabetes Severity Score for each individual and then model the rate of progression.

**Materials and methods:** We utilised the electronic medical records from patients in the Genetics of Diabetes Audit and Research (GoDARTS) cohort, Tayside, Scotland. A Diabetes Severity Score was derived based on a patient's observed HbA<sub>1c</sub> measures from diabetes diagnosis through to study end (defined as earliest of insulin initiation, death or 31st July 2011). We expected patients to exhibit a steady progression and this would appear as a gradual increase in Diabetes Severity Score. We therefore fitted a linear model with a slope and intercept for each individual, an additional parameter for every drug combination, BMI category and an error term.

**Results:** 3533 patients were included in the analysis with a median follow up time of 7.5 years and 17 HbA<sub>1c</sub> measures. Mean age at diagnosis was 63 years and 56% were male. 12% patients progressed to insulin treatment over the follow-up period. The estimated effect on HbA<sub>1c</sub> of the diabetes drugs was in line with clinical trial data. For example Metformin lowered HbA<sub>1c</sub> in a dose dependent manner (-0.21%<500mg; -0.35% 500mg; -0.49% 850mg; -0.61% 1G; -0.8%>1G) and sulphonylureas had a dose independent effect of -0.52%. The median progression rate was an increase in 0.1% HbA<sub>1c</sub> per year. The top 25% of progressors had an increase >0.3% and the top 10% >0.6%. The lower 25% had little or no progression. When comparing the highest vs lowest quartile, predictors of rapid progression at baseline were younger age at diagnosis (mean 58.2 vs 67 years, p<0.0001); lower HDL (1.16 vs 1.24 mmol/l, p<0.0001); higher triglycerides (2.71 vs 2.39 mmol/l, p<0.0001); higher BMI (32.3 vs 31.3 kg/m<sup>2</sup>, p=0.0002) and; higher HbA<sub>1c</sub> (8.02 vs 7.75%, p=0.0015). In addition 34.1% of the highest quartile progressed to insulin vs 1.6% in the lowest.

**Conclusion:** We have developed a novel approach to model diabetes progression in observational data across multiple drug combinations. The progression rates are similar to that described for monotherapy in ADOPT (0.14% HbA<sub>1c</sub> per year in metformin group); with progression faster in those with a more obese insulin resistant phenotype. This approach can be used to investigate biological determinants of progression as well as the impact of drug effects on progression rates. Gaining insight into why some patients progress rapidly and some do not will enable a more stratified approach to the management of T2D.

**HbA<sub>1c</sub> trajectories in type 2 diabetes patients: The Diabetes Care System cohort**

G. Nijpels, I. Walraven, M.R. Mast, T. Hoekstra, A.P.D. Jansen,

A.A.W. van der Heijden, S.P. Rauh, F. Rutters, E. van 't Riet, P.J.M. Elders,

A.C. Moll, B.C.P. Polak, J.M. Dekker;

EMGO Institute for Health and Care research, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** The revised ADA/EASD guidelines for the management of type 2 diabetes mellitus (T2DM) recommend HbA<sub>1c</sub> levels of ≤ 53 mmol/mol. However, clinical characteristics of T2DM patients with glycaemic control trajectories that are distinct from achieving the recommended HbA<sub>1c</sub> target are inadequately studied. In order to eventually improve glycaemic subgroups, the primary aim of this study was to determine subgroups of T2DM patients with distinct trajectories of HbA<sub>1c</sub> levels. Furthermore, sub-

group characteristics were determined and the prevalence of microvascular complications over time was investigated.

**Materials and methods:** 5423 T2DM patients with at least two HbA1c follow-up measurements were selected out of 9849 T2DM patients from the primary Diabetes Care System cohort. The mean follow-up period was 5.7 years (range 2 to 9 years). Latent Class Growth Modelling (LCGM) was performed to identify subgroups of patients with distinct trajectories of HbA1c levels. Multinomial logistic regression analyses were conducted to determine subgroup characteristics. Associations of different subgroups with retinopathy, microalbuminuria and medication use during follow-up were studied by constructing plots and by graphically comparing differences between subgroups.

**Results:** Four subgroups with distinct trajectories of HbA1c levels were identified (Figure). The first and largest subgroup (83%) maintained good glycemic control over time (HbA1c  $\leq$  53 mmol/mol), the second subgroup (8%) initially showed severe hyperglycaemia, but reached the recommended HbA1c target within 2 years. Patients within this subgroup had significantly higher baseline HbA1c levels but were otherwise similar to the good glycemic control subgroup. The third subgroup (5%) showed hyperglycaemia and a delayed response without reaching the recommended HbA1c target. The fourth subgroup (3.0%) showed deteriorating hyperglycaemia over time. Patients within the last two subgroups were significantly younger, had higher baseline HbA1c levels and had a longer diabetes duration at baseline. These subgroups also showed a higher prevalence of retinopathy and microalbuminuria compared to the good glycemic control subgroup.

**Conclusion:** This is the first study identifying subgroups with distinct trajectories of HbA1c levels in a T2DM cohort. More than 90% of the patients reached and maintained good glycemic control. Two subgroups showed a more unfavorable course of glycemic control. These T2DM patients were younger, had higher HbA1c levels and a longer diabetes duration at baseline.

## 259

### Statistical power enhancement in diabetic drug trial by selectively sampling participants from the tails of biomarker distributions: a DIRECT study

A. Ashfaq<sup>1</sup>, N.A. Pasdar<sup>1</sup>, A. Kurbasic<sup>1</sup>, D. Shungin<sup>1</sup>, E.R. Pearson<sup>2</sup>, P.W. Franks<sup>1</sup>;

<sup>1</sup>Lund University Diabetes Research Centre, Department of Clinical Sciences, Lund University, Malmö, Sweden, <sup>2</sup>Division of Cardiovascular & Diabetes Medicine Medical Research Institute, University of Dundee, UK.

**Background and aims:** Within the IMI DIRECT Study we are seeking to identify biomarkers that modify treatment response, primarily using observational studies to generate hypotheses that will be validated in clinical trials. Here, we compared statistical power to detect gene-metformin interactions in two types of trials: approach 'A' represents interactions evaluated in an existing clinical trial that involves randomly selected participants; approach 'B' involves selecting participants on the basis of discordant levels of genetic risk score (GRS) comprised of 20 variants that modify treatment effects (genotype-based recall: GBR).

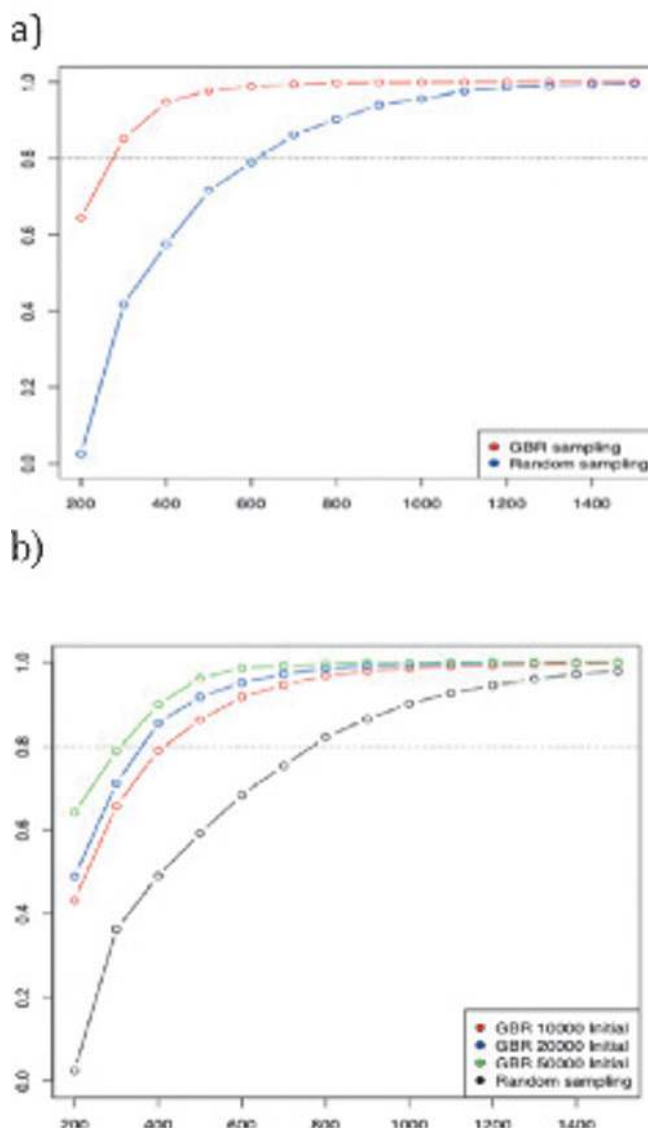

**Materials and methods:** Model assumptions were based on published data from the Diabetes Prevention Program, a randomized controlled trial of metformin treatment vs. placebo. We simulated GRS-metformin interactions, assuming the 20 GRS variants convey comparable gene-metformin interaction effects to those reported for the MATE1 locus. The effects of the metformin and placebo interventions were estimated assuming randomised treatment allocation. To simulate approach 'A', participants were randomly sampled

from a larger population-sampling frame (N=10,000-50,000), as might be the case in a conventional clinical trial. To simulate approach 'B', participants were purposefully sampled at random and from the upper tail of GRS distribution from the same sampling frames. Time to diabetes event was calculated using the proportional hazards function. Sample size calculations were performed using 1000 iterations per simulation in the R software package.

**Results:** Figure 1 shows representative results from these analyses: to obtain 80% power to detect the specified gene x metformin interaction effect, the GBR approach would require 300-400 participants, whereas the random-sampling approach would require roughly 800 participants for rare alleles (Fig. 1a). For common alleles a sample size of ~250 would suffice with the GBR approach compared with sample size of ~650 for the random sampling approach. Similarly, where interaction effects are smaller in magnitude, the difference in sample-size requirements for the random vs. the GBR sampling approach increases substantially. The size of the sampling-frame also affects power (Fig. 1b).

**Conclusion:** The GBR approach for validating observations of gene-drug interaction offers a potentially powerful alternative to conventional clinical trials, which is especially appealing when gene variants are rare and phenotyping is expensive.

**Antidepressant medication use and trajectories of fasting plasma glucose and HbA<sub>1c</sub> levels: a 9-year longitudinal study of the DESIR cohort**

M. Azevedo Da Silva, A. Dugravot, B. Balkau, A. Singh-Manoux, H. Nabi; CESP - U.1018, INSERM, Villejuif, France.

**Background and aims:** Some research has suggested that antidepressant medication use (AMU) may increase the type 2 diabetes (T2D) risk. However the causal mechanism of this association remains unclear. To study the biological plausibility of this relationship, we examined the association between AMU and changes in fasting plasma glucose (FPG) and in HbA<sub>1c</sub> levels over time.

**Materials and methods:** Participants were 4869 men (49.2%) and women, free of T2D and aged 30–65 years at baseline, followed for 9 years between 1994 and 2005 in the French D.E.S.I.R. cohort study. AMU, FPG and HbA<sub>1c</sub> were assessed concurrently at 4 medical examinations in phases 1 (1994–1996), 2 (1997–1999), 3 (2000–2002) and 4 (2003–2005). Linear mixed models were used to examine the longitudinal associations of AMU with FPG and HbA<sub>1c</sub> levels.

**Results:** FPG and HbA<sub>1c</sub> levels increased over follow-up. In model adjusted for sociodemographic characteristics, health-related behaviours, medical conditions and other medications, there was no difference in mean FPG and HbA<sub>1c</sub> levels ( $\beta = -0.001$   $p = 0.974$ ,  $\beta = 0.012$   $p = 0.662$ , respectively) among antidepressant medication users and non-users at baseline (1994–1996). The interaction term between time and AMU, suggested no increase in FPG and HbA<sub>1c</sub> levels in antidepressant users comparatively to non-used over 9-year of follow-up ( $\beta = -0.004$   $p = 0.535$ ,  $\beta = -0.002$   $p = 0.548$  respectively). Similar patterns of associations were observed when the type and the cumulative use of antidepressants over follow-up were considered.

**Conclusion:** Our results suggest that AMU is not associated with an increase in FPG and HbA<sub>1c</sub> levels over 9-year of follow-up. This suggests that the nature of the association between AMU and T2D risk, observed in previous studies, may not be causal.

**Exogenous adiponectin administration through a subcutaneous minipump reverses high-fat diet-induced impairment of adipose tissue metabolism**

P. Matafome<sup>1</sup>, T. Rodrigues<sup>1</sup>, A. Pereira<sup>1</sup>, L. Letra<sup>1</sup>, H. Azevedo<sup>2</sup>, A. Paixão<sup>1</sup>, M. Silvério<sup>1</sup>, A. Almeida<sup>2</sup>, C. Sena<sup>1</sup>, R. Seica<sup>1</sup>;

<sup>1</sup>Faculty of Medicine, University of Coimbra,

<sup>2</sup>Hitag, Biocant, Cantanhede, Portugal.

**Background and aims:** Despite adiponectin administration is thought to be a future strategy to obese or type 2 diabetic patients, it still is a myth, due to its expensive costs and absence of studies demonstrating the effectiveness of chronic exogenous adiponectin. Our aim was to develop a method to produce adiponectin for long-term adiponectin administration and test its usefulness in improving metabolic profile and adipose tissue metabolism in high-fat diet fed rats.

**Materials and methods:** Adiponectin (98  $\mu\text{g}/\text{day}$ ) was administered during 28 days through a subcutaneous minipump with continued release to normal Wistar rats fed a high-fat diet. Several systemic markers of dysmetabolism and pathways of insulin signaling and lipid storage in epididymal and subcutaneous adipose tissue were assessed.

**Results:** Exogenous adiponectin was able to decrease body weight, fasting glycaemia, HbA<sub>1c</sub> and cholesterol levels (total and non-HDL). In adipose tissue, adiponectin reverted high-fat diet-induced impairment of insulin signaling and decreased I $\kappa$ B $\alpha$  and PPAR $\gamma$  levels, which were mainly observed in epididymal adipose tissue. High-fat fed rats showed little activation of lipolysis during fasting in epididymal adipose tissue, despite no alterations were observed in the total amount of the protein. This was only partially reverted by adiponectin.

**Conclusion:** Long-term adiponectin administration through a subcutaneous minipump was able to improve pathways of insulin signaling and lipid storage in adipose tissue after the consumption of a high-fat diet. Adiponectin was also able to improve the metabolic profile, probably as a result of improved adipose tissue metabolism.

## 262

**Immuno-neutralisation of extra-cellular nicotinamide phosphoribosyltransferase as a therapeutic strategy for treatment of type 2 diabetes**

P.W. Caton<sup>1</sup>, J. Kieswich<sup>2</sup>, M. Silvestre<sup>1</sup>, M.M. Yaqoob<sup>2</sup>;

<sup>1</sup>Centre for Diabetes, Blizard Institute, Queen Mary London,

<sup>2</sup>Translational Medicine and Therapeutics, William Harvey Research Institute, Queen Mary London, UK.

**Background and aims:** The protein extra-cellular nicotinamide phosphoribosyltransferase (eNAMPT; also termed visfatin/PBEF) is elevated in serum of type 2 diabetes (T2D) patients and raised eNAMPT levels are reported to strongly correlate with declining beta-cell function. Moreover, eNAMPT reportedly exerts pro-inflammatory effects suggesting a potential pathophysiological role for eNAMPT in T2D. However, the precise functional relationship between elevated serum eNAMPT and the pathophysiology of T2D has not been determined. Interestingly, eNAMPT exists in serum as a monomer and a dimer, suggesting a potential structure/function relationship, although the precise function and specific changes in each form in T2D have not been determined.

**Materials and methods:** To investigate the role of eNAMPT in T2D, C57Bl/6 mice were fed a high-fat diet (HFD; 60% fat) for 10 weeks. In weeks 9–10, mice were administered polyclonal anti-NAMPT antibody (2.5  $\mu\text{g}/\text{ml}$ ; 2 doses/week) or saline equivalent. After week 10, mice were fasted for 16 h prior to glucose tolerance testing (2  $\text{g}/\text{kg}$  body weight glucose) or sacrificed in the fed state for tissue (islets, liver and white adipose tissue; qPCR and western blot) and serum analysis.

**Results:** Serum eNAMPT monomer levels were elevated in HFD mice, whilst dimer levels were unchanged, as assessed by Native-PAGE immunoblot. Immuno-neutralization of eNAMPT corrected HFD-mediated fasting and fed hyperglycaemia, hyperinsulinemia and impaired glucose tolerance. These

effects were mediated through improvements in beta-cell health (increased ex vivo and in vivo islet glucose-stimulated insulin secretion and increased islet size) and correction of hepatic insulin resistance (reduced gluconeogenic gene expression, increased insulin signalling). Consistent with a pro-inflammatory function of eNAMPT, improvements in glycaemia and beta-cell health following eNAMPT-immuno-neutralization were linked to lowering of HFD-mediated increases in gene expression of islet and white adipose tissue pro-inflammatory cytokines, chemokines and immune cell markers, as well as decreased mRNA levels of islet pro-apoptotic markers.

**Conclusion:** Elevated serum eNAMPT monomer levels may contribute to pathophysiology of T2D, through pro-inflammatory effects. Moreover, selective neutralization or inhibition of eNAMPT monomer represents a potential therapeutic target for treatment of T2D.

### TLR4 inhibition blocks cytokine production and restores beta cell survival in human pancreatic islets

W. He<sup>1</sup>, C. Schuster-Klein<sup>2</sup>, B. Guardiola-Lemaître<sup>2</sup>, K. Maedler<sup>1</sup>;

<sup>1</sup>Centre for Biomolecular Interactions, University of Bremen, Germany,

<sup>2</sup>ADIR-Servier Group, Suresnes, France.

**Background and aims:** Inflammatory signals are strong mediators of metabolic failure in fat, liver, brain, muscle as well as in pancreatic islets. Toll-like receptor-4 (TLR-4) signaling is one of the major pro-inflammatory pathways, whose ligands as well as downstream products, i.e. cytokines and chemokines, are increased systemically in patients with T2D as well as in at-risk individuals. TLR4 knockout mice are protected from the metabolic consequences of a high fat diet. In the present study we investigated the consequences of TLR4 activation in human islets and whether pharmacological inhibition of TLR4 restores beta-cell survival in a diabetogenic milieu.

**Materials and methods:** Isolated human islets were exposed to the TLR4 ligand Lipopolysaccharide (LPS) in the presence or absence of TLR4 receptor small molecule antagonist, TAK-242 (Resatorvid). The effect of TLR4 inhibition was compared with those achieved by the depletion of islet resident macrophages by treatment of human islets with clodronate liposomes. Expression and secretion of pro-inflammatory cytokines/chemokines were evaluated by RT-PCR and ultrasensitive ELISA. TLR4 downstream signaling activation and apoptosis were analyzed by Western Blotting.

**Results:** Treatment of isolated human islets with LPS elevated mRNA levels of pro-inflammatory cytokines/chemokines, including IL-1alpha, IL-1beta, IL-6, TNFalpha, CCL2 and IL-8. LPS induced IL-1beta secretion was confirmed by ELISA. TAK-242 completely blocked LPS-induced cytokine/chemokine expression and IL-1β secretion, while clodronate treatment only inhibited IL-1alpha/beta but not IL-6, IL-8, TNFalpha and CCL2 expression. TAK-242 could completely antagonize the effects of LPS on TLR-4 downstream signaling and apoptosis in human islets, it inhibited phosphorylation of inhibitor of nuclear factor kappa B alpha (IκBα) and c-Jun N-terminal kinase (JNK) as well as caspase-3 cleavage.

**Conclusion:** Our results show that TLR4 activation in human islets leads to islet inflammation and beta-cell apoptosis, which results in beta-cell failure, while the TLR4 inhibitor TAK-242 inhibits cytokine production and restores beta-cell survival.

### Intervention with Caspase-1 inhibitor attenuates the metabolic syndrome and prevents non alcoholic-steatohepatitis (NASH) in high fat diet-fed LDLR<sup>-/-</sup>.Leiden mice

P.Y. Wielinga, A.M. van den Hoek, K. Salic, W. Liang, T. Kooistra,

R. Kleemann;

Metabolic Health Research, Netherlands Organization for Applied Scientific Research (TNO), Leiden, Netherlands.

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a serious liver pathology which develops as a complication of the metabolic syndrome. Recently, the inflammasome was proposed to be involved in the development of NASH. Here we investigate whether a chemical inhibitor of caspase-1 in already manifest metabolic syndrome would prevent the development to NASH.

**Materials and methods:** Male LDLR<sup>-/-</sup>.Leiden mice were fed a high fat diet (HFD; group 1) or low fat diet (LFD; group 2) for 21 weeks. In a third group, intervention with caspase-1 inhibitor Ac-YVAD-CMK (40 mg/kg daily) was started after 9 weeks of HFD (manifest metabolic syndrome) and continued until 21 weeks.

**Results:** HFD treated mice developed obesity and insulin resistance after already 9 weeks of HFD feeding. Intervention with caspase-1 inhibitor attenuated a further development of insulin resistance, and reduced body weight gain as well as adipose tissue inflammation compared to HFD. Histopathological analysis of the livers clearly demonstrated prevention of NASH development with caspase-1 inhibitor: livers were less steatotic and neutrophil infiltration was diminished. Additionally, hepatic fibrosis quantified by sirius red staining and acta2 and col1a1 gene expression as observed in HFD treated mice, was completely prevented.

**Conclusion:** Intervention with a caspase-1 inhibitor in already established disease improved hallmarks of the metabolic syndrome and prevented the development of NASH. Our data further support the importance of caspase-1/inflammasome in the development of NASH and demonstrate that therapeutic intervention in the already ongoing disease process is feasible.

## PS 001 Pragmatic prediction and prevention of type 2 diabetes

### Family history of diabetes is a strong predictor of diabetes, hypertension and metabolic syndrome in Sri Lankan adults

P. Ranasinghe<sup>1</sup>, R. Jayawardena<sup>2</sup>, P. Katulanda<sup>3</sup>;<sup>1</sup>Department of Pharmacology, Faculty of Medicine, Colombo, Sri Lanka,<sup>2</sup>Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia, <sup>3</sup>Department of Clinical Medicine, Faculty of Medicine, Colombo, Sri Lanka.

**Background and aims:** Diabetes mellitus has become an important health concern in South Asia. Family history (FH) is a common non-modifiable risk factor for most of the chronic non-communicable diseases, as it is a collective reflection of the genetic susceptibility, shared environments and behaviors. Information on FH may serve as a unique and useful tool for public health and preventive medicine. The increased genetic predisposition amongst South Asians probably makes FH more important in risk assessment than in other ethnic groups. The present study aims to describe the influence of FH on diabetes prevalence and associated metabolic risk factors in a nationally-representative sample of South Asian adults from Sri Lanka.

**Materials and methods:** A cross-sectional community based national survey was conducted in 7 of the 9 provinces in Sri Lanka. Five thousand adults were recruited for the study using a multi-stage stratified cluster sampling technique. An interviewer administered questionnaire was used to collect data, which included; age, gender, area of residence, ethnicity, level of education, household monthly income, duration of diabetes, FH, height, weight, waist circumference, hip circumference and blood pressure. FH was evaluated at three levels, a) parents, b) grandparents (paternal and maternal) and c) siblings. Presence of diabetes in children was also evaluated. A binary-logistic regression analysis controlling for confounders (age, gender, body mass index and physical activity) was performed in all patients with 'presence of diabetes' as the dichotomous dependent variable and using FH in father, mother, maternal grandmother/grandfather, paternal grandmother/grandfather, siblings and children as binary independent variables. A p value <0.05 was considered significant.

**Results:** Sample size was 4485, mean age was 46.1±15.1 years and 39.5% were males. The crude prevalence of diabetes, hypertension and metabolic syndrome were 12.0%, 27.2% and 26.6% respectively. The overall prevalence of FH in the population was 25.5%. In all adults the prevalence of diabetes was significantly higher in patients with a FH (23.0%) than those without (8.2%) (p<0.001). The prevalence of diabetes also increased with the number of affected generations (one - 33.9%, two - 34.2% and three - 37.1%). Presence of a FH significantly increased the risk of diabetes (OR:3.35,95%CI:2.78-4.03), obesity (OR:2.45,95%CI:1.99-2.99), hypertension (OR:1.25,95%CI:1.08-1.45) and metabolic syndrome (OR:2.28,95%CI:1.97-2.63). In all adults presence of FH in father (OR:1.29,95%CI:1.02-1.63), mother (OR:1.23,95%CI:1.11-1.36), paternal grandfather (OR:1.27,95%CI:1.14-1.41), siblings (OR:4.18,95%CI:3.34-5.22) and children (OR:5.47,95%CI:2.93-10.19) all were associated with significantly increased risk of developing diabetes.

**Conclusion:** FH and diabetes had a graded association in the Sri Lankan population, as the prevalence increased with the increasing number of generations affected. FH of diabetes was also associated with the prevalence of obesity, metabolic syndrome and hypertension. Individuals with a FH of diabetes form an easily identifiable group who may benefit from targeted intervention to prevent the development of diabetes and related metabolic disease. Supported by: NSF Sri Lanka

### The FINDRISC scale substantially reduces its performance as a screening tool for diabetes if diagnosed by HbA1c instead of glucose

J.J. Cabre<sup>1,2</sup>, B. Costa<sup>1,2</sup>, F. Barrio<sup>1,2</sup>, J.L. Piñol<sup>1</sup>, R. Sagarra<sup>1</sup>, DE-PLAN-CAT;<sup>1</sup>Catalan Health Institute, Reus, <sup>2</sup>Diabetes and Metabolism Area, IDIAP Jordi Gol, Spain.

**Background and aims:** Recently it has been suggested that progression to diabetes can be delayed by intensive interventions when applied to real-life primary health care of high-risk subjects identified first with the simple Finn-

ish Diabetes Risk Score (FINDRISC) tool. The aim of the study was to investigate differences in the performance of the FINDRISC as a screening tool for glucose abnormalities after shifting from glucose-based diagnostic criteria to the proposed new hemoglobin (Hb)A1c-based criteria.

**Materials and methods:** A cross-sectional primary-care study was conducted as the first part of an active real-life lifestyle intervention to prevent type 2 diabetes within a high-risk Spanish Mediterranean population. Individuals without diabetes aged 45-75 years (n = 3,120) were screened using the FINDRISC. Where feasible, a subsequent 2-hour oral glucose tolerance test and HbA1c test were also carried out (n = 1,712). The performance of the risk score was calculated by applying the area under the curve (AUC) for the receiver operating characteristic, using three sets of criteria (2-hour glucose, fasting glucose, HbA1c) and three diagnostic categories (normal, prediabetes, diabetes).

**Results:** Defining diabetes by a single HbA1c measurement resulted in a significantly lower diabetes prevalence (3.6%) compared with diabetes defined by 2-hour plasma glucose (9.2%), but was not significantly lower than that obtained using fasting plasma glucose (3.1%). The FINDRISC at a cut-off of 14 had a reasonably high ability to predict diabetes using the diagnostic criteria of 2-hour or fasting glucose (AUC = 0.71) or all glucose abnormalities (AUC = 0.67 and 0.69, respectively). When HbA1c was used as the primary diagnostic criterion, the AUC for diabetes detection dropped to 0.67 (5.6% reduction in comparison with either 2-hour or fasting glucose) and fell to 0.55 for detection of all glucose abnormalities (17.9% and 20.3% reduction, respectively), with a relevant decrease in sensitivity of the risk score.

**Conclusion:** A shift from glucose-based diagnosis to HbA1c-based diagnosis substantially reduces the ability of the FINDRISC to screen for glucose abnormalities when applied in this real-life primary-care preventive strategy. As far as we know, this is the first estimate of a possible loss of performance of the FINDRISC questionnaire if there is a widespread use of these new proposed HbA1c-based diagnostic criteria, at least as a screening tool in the context of a program aimed at preventing diabetes.

267

### Value of the FINDRISK questionnaire to identify prediabetes and undetected type 2 diabetes

T.G. Dzebisashvili;

Endocrinology, Moscow Regional Research Clinical Institute named by M.F.Vladimirskiy, Moscow, Russian Federation.

**Background and aims:** The prevalence rate of Type 2 diabetes mellitus (T2D) has been increasing worldwide. The associated cardiovascular risk factors are connected with the development of micro- and macrovascular complications in the course of the disease and sometimes even before the diagnosis of diabetes. T2D is preceded by a pre-diabetic state with impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and, in many cases, the metabolic syndrome. In this state, which may last for many years, several studies have shown that diabetes can be prevented. Identification of subjects with prediabetes is therefore of great importance, so that preventive action aimed at reducing their risk of T2D and cardiovascular disease (CVD) can be offered. Due to cost-effectiveness, screening should primarily be implemented in subjects at high risk to abnormal glucose tolerance (AGT=IFG/IGT/T2D). Aim is to evaluate the FINDRISK questionnaire as a screening tool for diabetes and prediabetes in a Russian population. In addition, we analysed the association between FINDRISK and CVD risk factor levels.

**Materials and methods:** In a population-based screening for AGT, a total of 1366 adults were invited. Full data with risk score estimate and glucose tolerance status were available for 560 subjects without known diabetes. AGT was diagnosed using standard OGTT according to WHO 1999/2006 criteria. Body mass index (BMI), waist circumference (WC), hypertension, blood lipids (total cholesterol, LDL cholesterol, HDL cholesterol and triglycerides) were determined. To assess performance of the risk score with respect to T2D and AGT, the area under the receiver operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values were calculated.

**Results:** The prevalence of screen-detected T2D was 6.1%, whereas 36.1% were classified as having AGT. There was a marked increase in the prevalence of T2D and AGT with increasing value of the risk score. With risk score > 10, the positive predictive values (PPV) for T2D and AGT were 11% and 48%, respectively. Corresponding prevalence were 15% and 59% at higher level > 15. The AUC for T2D was 0.766, p < 0.001, whereas for AGT the area under the curve was 0.663, p < 0.001. Using the optimal cut-off value of 10 with the largest area under the curve to identify previously undiagnosed patients with T2D, AGT resulted in a sensitivity of 91%, 67% and specificity of

52%, 59%. To achieve this, only 50% of the total population would need to be screened. Increasing the cutoff value of the score to 15 changed the sensitivity to 38%, 25% and specificity to 86%, 90% respectively. Apart from total cholesterol and LDL cholesterol, several risk factors for cardiovascular disease: age ( $p < 0.001$ ), BMI ( $p < 0.001$ ), WC ( $p < 0.001$ ), systolic and diastolic blood pressure ( $p < 0.001$ ), fasting and 2h plasma glucose ( $p < 0.001$ ), triglycerides ( $p = 0.016$ ), HDL cholesterol ( $p = 0.003$ ) had a direct association with the FINDRISK values.

**Conclusion:** FINDRISC proved to be simple and effective test to screen subjects at high risk for T2D. With the optimal cut-off level, the FINDRISC identified 91% undetected T2D and 67% AGT with relatively high PPV 48% for AGT, but only 11% of PPV for new T2D.

## 268

### Trends in leisure time physical activity in Danish adults with diabetes

S. Molsted<sup>1</sup>, N.F. Johnsen<sup>2</sup>, O. Snorgaard<sup>3</sup>;

<sup>1</sup>Department of Cardiology, Nephrology & Endocrinology, Nordsjællands Hospital, Hillerød, <sup>2</sup>National Institute of Public Health, University of Southern Denmark, <sup>3</sup>Department of Endocrinology, Hvidovre Hospital, Copenhagen, Denmark.

**Background and aims:** During the last decades there has been an increased focus on physical activity and exercise training in treatment of diabetes. The primary aim of this study was to compare leisure time physical activity (PA) reported in 2000, 2005 and 2010 by Danish subjects with diabetes. Furthermore, we analysed the subjects' smoking, alcohol consumption, and body mass index (BMI).

**Materials and methods:** Data comprised level of leisure time PA in four categories: physical inactivity, moderate activity, medium activity, and high activity; smoking; alcohol consumption; and BMI provided by The Danish Health and Morbidity Surveys, nationwide surveys ( $n \approx 15,000$ ) from the general population. Subjects older than 45 years at the time of the surveys were included from cross-sectional analyses from 2000, 2005 and 2010.

**Results:** The diabetes prevalence was 4.5% ( $n=386$ ) in 2000, 6.0% ( $n=489$ ) in 2005, and 7.5% ( $n=622$ ) in 2010. In subjects with diabetes, percentages of inactive women decreased from 42.2% to 21.8% ( $p < 0.001$ ) and inactive men from 32.2% to 20.9% ( $p=0.01$ ), with elevated prevalence in the three ascending levels of PA (moderate, medium, or high active) from 2000 to 2010. Prevalence of daily smokers was reduced from 29.3% to 20.1% ( $p=0.002$ ). Subjects who exceeded a recommended maximum of alcohol consumption were increased from 6.5% to 14.0% ( $p=0.001$ ). The BMI increased from  $27.3 \pm 4.7$  to  $28.6 \pm 5.5$  kg.m<sup>-2</sup> in diabetes subjects ( $p=0.001$ ). In subjects without diabetes, the prevalence of physical inactivity decreased in women from 20.9% to 11.9% ( $p < 0.001$ ) and men from 17.5% to 11.4% ( $p < 0.001$ ). The PA level was reduced in subjects with diabetes compared with subjects without diabetes throughout the study.

**Conclusion:** The percentage of physically inactive Danish subjects older than 45 years with diabetes decreased from 2000 to 2010 with corresponding increases of percentages of subjects with moderate, medium, and high levels of PA. The trends of increased level of PA and decreased smoking may have impact on cardiovascular risk and positively affect the declining relative mortality among Danish patients with diabetes as shown in previous studies. On the other hand, elevated alcohol intake and increased BMI may increase the cardiovascular risk. Even though the PA level was elevated among subjects with diabetes, it remained reduced compared with the reported level of PA among subjects without diabetes.

## 269

### Effect of high intensity interval training on physical fitness, metabolic flexibility and insulin sensitivity

P. Calders, M. Bekaert, J. Ruige;  
University of Ghent, Belgium.

**Background and aims:** The purpose of this study was to evaluate the effect of high intensity interval training on anthropometric parameters, physical fitness, metabolic flexibility and insulin sensitivity in participants with overweight or obesity compared to continuous aerobic training with the same total volume.

**Materials and methods:** 16 male participants with overweight or obesity (age range: 42 - 57, body mass index: 28 - 36) were randomized in two experimental groups, high intensity interval training ( $n=8$ ) and continuous aerobic training ( $n=8$ ). Participants were excluded if they had diabetes, severe mus-

culoskeletal, cardiovascular and respiratory problems. High intensity interval training was composed of three blocks of 10 minutes at ventilatory threshold (blocks 1 and 3: 10 sprint bouts of 15 seconds, followed by 45 seconds relative rest; block 2: continuous training) twice a week for 15 weeks. Continuous aerobic training was composed of three blocks of 10 minutes continuous training. After 5 weeks, intensity was increased to 110% of ventilatory threshold. Before and after the training period, body composition, physical fitness (expressed as peakVO<sub>2</sub> and anaerobic threshold (AT)), metabolic flexibility (expressed as resting respiratory exchange ratio (rRER)) and insulin sensitivity by oral glucose tolerance test were evaluated. The OGTT-composite score was calculated as  $(10,000/\text{square root of } [\text{fasting glucose} \times \text{fasting insulin}] \times [\text{mean glucose} \times \text{mean insulin during OGTT}]$ ). Significance level was calculated based on non-parametric Kruskal-Wallis test with post hoc Mann-Whitney U-test and set at  $P < 0,05$ .

**Results:** High intensity interval training showed a significant positive evolution ( $P < 0,01$ ) compared to continuous aerobic training for peak VO<sub>2</sub> (+18%), peak Wattage (+14%), ATVO<sub>2</sub> (+14%) and ATWattage (+21%) indicating an increased aerobic capacity. After 10 weeks, there was a significant decrease ( $P < 0,05$ ) of rRER (interval: pre: 0,85; post: 0,79; continuous: pre: 0,87; post 0,86), indicating a better metabolic flexibility and a significant increase ( $P < 0,01$ ) of the OGTT composite score (interval pre: 1,67; post: 2,96; continuous pre: 2,21; post: 2,33), indicating an increased insulin sensitivity.

**Conclusion:** In this study we could observe that high intensity interval training has stronger beneficial effects on body composition, physical fitness, metabolic flexibility and insulin sensitivity compared to continuous aerobic training with the same total volume.

### A priori defined diet quality indexes and risk of type 2 diabetes mellitus: the multiethnic cohort

S. Jacobs<sup>1</sup>, C.J. Boushey<sup>2</sup>, Y. Morimoto<sup>2</sup>, L.R. Wilkens<sup>2</sup>, L. Le Marchand<sup>2</sup>, J. Kröger<sup>1</sup>, M.B. Schulze<sup>1</sup>, L.N. Kolonel<sup>2</sup>, G. Maskarinec<sup>2</sup>;

<sup>1</sup>German Institute of Human Nutrition Potsdam-Rehbrücke, Nuthetal, Germany, <sup>2</sup>University of Hawaii Cancer Center, Honolulu, USA.

**Background and aims:** Dietary patterns have been associated with diabetes incidence; however, little is known about the impact of ethnicity on this association. Our aim was to assess the association between predefined dietary indexes and risk of type 2 diabetes (T2D) among white, Japanese American, and Native Hawaiian men and women in the Hawaii component of the Multiethnic Cohort (MEC).

**Materials and methods:** After excluding participants with prevalent diabetes or missing values on covariates we used data from 41,918 men (5,791 incident cases) and 47,267 women (5,426 incident cases). Habitual dietary intake was assessed at baseline with a food frequency questionnaire designed for use in the relevant ethnic populations. Sex- and ethnic-specific hazard ratios and 95% confidence intervals were calculated using adjusted Cox models for four dietary indexes, the Healthy Eating Index-2010 (HEI-2010), the alternative HEI-2010 (AHEI-2010), the alternate Mediterranean diet score (aMed), and the Dietary Approaches to Stop Hypertension (DASH).

**Results:** We observed strong inverse associations of adherence to the DASH index and T2D risk in white men and women, as well as Japanese American women and Native Hawaiian men, with respective risk reductions of 37, 31, 19 and 21% comparing the categories of highest to lowest adherence to index (score point ranges in both sexes: 28-39 to 9-19). A higher adherence to AHEI-2010 was related with lower T2D risk in white men and women with a 26 and 22% lower risk comparing the categories of highest to lowest adherence to index (score point ranges, men: 73-101 to 25-56, women: 47-100 to 30-58), whereas higher adherence to aMed was associated with a 28% lower risk of T2D in white men only comparing the categories of highest to lowest adherence to index (score point ranges: 7-9 to 0-2). Neither the AHEI-2010 nor the aMed were related to T2D risk in other ethnic groups than whites. Adherence to HEI-2010 was not associated with T2D risk.

**Conclusion:** In this large multiethnic cohort, the DASH, the AHEI-2010, and the aMed indexes performed well in whites, whereas only the DASH index was associated with a reduction in T2D risk in Japanese American women and Native Hawaiian men. Given the possible ethnic differences, further studies are warranted that focus on dietary indexes and their performance in multiethnic and minority populations.

**Sex-specific differences in prevention of type 2 diabetes mellitus: a systematic review and meta-analysis**

J. Harreiter<sup>1</sup>, A. Glechner<sup>2</sup>, G. Gartlehner<sup>2,3</sup>, A. Kautzky<sup>1</sup>, S. Rohleder<sup>1</sup>, M. Van Noord<sup>2</sup>, A. Kaminski-Hartenthaler<sup>2</sup>, J. Tuomilehto<sup>4,5</sup>, A. Kautzky-Willer<sup>1</sup>;

<sup>1</sup>Department of Medicine III, Division of Endocrinology & Metabolism, Gender Medicine Unit, Medical University Vienna, <sup>2</sup>Department for Evidence-based Medicine and Clinical Epidemiology, Danube University, Krems, Austria, <sup>3</sup>Research Triangle Institute (RTI) International, North Carolina, USA, <sup>4</sup>Diabetes Prevention Unit, National Institute for Health and Welfare, Helsinki, Finland, <sup>5</sup>King Abdulaziz University, Jeddah, Saudi Arabia.

**Background and aims:** Type 2 diabetes mellitus (T2DM) is becoming an increasing challenge worldwide. Lifestyle interventions and several glucose lowering medications have been proved to be effective in preventing the progression to T2DM in people with prediabetes. The ADA/EASD position statement 2012 claims a patient centred approach, in which sex and gender aspects are relevant. Sex-specific differences of the efficacy and safety of diabetes prevention strategies have not been studied so far.

**Materials and methods:** A systematic search of PubMed, Cochrane, Embase, CINAHL Web of Science, and reference lists of review articles from 1980 to June 2013 was performed. Literature was dually reviewed and risk of bias was rated for each study. Only randomised controlled trials with at least 1-year follow-up that compared active lifestyle interventions with usual care and pharmacotherapy trials with glucose lowering drugs that compared active treatment with placebo were included. Random effects meta-analysis of outcomes of interest was performed.

**Results:** We identified 2548 relevant abstracts; 309 full-text articles were retrieved for further examination. Eighteen RCTs (44articles) met the eligibility criteria. Only 3 published sex-specific results; of 9 RCT's unpublished sex-specific data was supplied upon request. A similar efficacy of risk or harms of lifestyle interventions and pharmacological therapies between men and women was found. Lifestyle interventions reduced the risk to develop T2DM in prediabetic people in both sexes. After 1 year lifestyle intervention group had a lower risk than patients in control group (RR:0.60; 95% CI:0.35-1.05; 4RCTs,888patients). A 37% lower risk of progressing to T2DM for pre-diabetic people receiving an average of 3 years of lifestyle intervention compared with those under usual care (RR:0.63; 95% CI:0.51-0.79; 5RCTs,1555patients) was found. Similar preventive effects of lifestyle interventions were found in men and women after 1 and 3 years. (p=0.61, p= 0.20). Only few studies provided sex-stratified results of pharmacological therapies in T2DM prevention. Long-term evidence on potential sex differences of diabetes-associated comorbidity and mortality is missing.

**Conclusion:** The evidence indicates that intensified lifestyle intervention in structured programs is equally effective in both sexes. Therefore individually designed interventions to increase physical activity and healthy nutrition by behavioral modification for effective diabetes prevention should be offered for both sexes. More studies to reveal sex and gender-specific differences are necessary to follow a more patient centred approach.

**Beneficial effect of pitavastatin on the incidence of diabetes in women was not associated with age: sub-analysis of J-PREDICT**

T. Shiba<sup>1</sup>, K. Sakamoto<sup>1</sup>, C. Ito<sup>2</sup>, T. Yamazaki<sup>3</sup>, J. Kishimoto<sup>4</sup>, M. Noda<sup>5</sup>, Y. Terauchi<sup>6</sup>, M. Odawara<sup>7</sup>, H. Kitazato<sup>8</sup>, K. Maemura<sup>9</sup>, K. Tobe<sup>10</sup>, Y. Iwamoto<sup>11</sup>, Y. Akanuma<sup>12</sup>, T. Kadowaki<sup>13</sup>, the J-PREDICT study investigators;

<sup>1</sup>Toho University, Tokyo, <sup>2</sup>Grand Tower Medical Court, Hiroshima, <sup>3</sup>The University of Tokyo Hospital, <sup>4</sup>Kyushu University Hospital, Fukuoka, <sup>5</sup>National Center for Global Health and Medicine, Tokyo, <sup>6</sup>Yokohama City University Graduate School of Medicine, Kanagawa, <sup>7</sup>Tokyo Medical University, <sup>8</sup>Omori Red Cross Hospital, Tokyo, <sup>9</sup>Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, <sup>10</sup>University of Toyama, <sup>11</sup>Tokyo Women's Medical University, <sup>12</sup>The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, <sup>13</sup>The University of Tokyo, Japan.

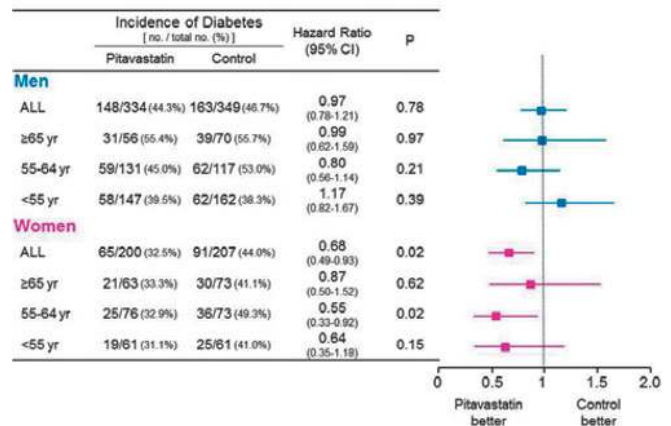

**Background and aims:** Diabetes mellitus (DM) increases the risk of coronary heart disease (CHD) far more in women than men. If statin therapy

can prevent or delay the development of diabetes, it is helpful for preventing CHD, especially in women. Thus, we conducted a sex-specific analysis in J-PREDICT comparing the effect of pitavastatin (PIT) on the incidence of diabetes in woman versus men.

**Materials and methods:** J-PREDICT study was a prospective randomized, open-label, blinded-endpoint trial evaluating the effect of PIT on the incidence of diabetes (n=1,269; 635 Control [lifestyle modification alone], 634 PIT [PIT 1-2 mg + lifestyle modification]) in Japanese subjects with impaired glucose tolerance (IGT). The primary outcome was incidence of DM defined as 2-h plasma glucose of  $\geq 200$  mg/dl or fasting plasma glucose of  $\geq 126$  mg/dl measured at least once in 75g OGTT performed every six months. This study was performed based on the full analysis set (total, n=1090; men, n=683; women, n=407).

**Results:** Women were older than men and lower in body mass index. Women and men had similar levels of glycemic and insulin-related parameters. The incidence of diabetes in women was lower by 32% (HR, 0.68; 95%CI, 0.49-0.93; p=0.02) in the PIT group compared with control group, but not significantly different between the group in men (HR, 0.97; 95%CI, 0.78-1.21; p=0.78). The analyses using stratified log-lank test and Cox proportional hazard model also brought a positive PIT effect only in women. Trends towards higher incidence of diabetes with increasing age were observed only in men. The beneficial effect of PIT was most in a group of 55 to 64 years in both genders, and only significant in women (p=0.02). Thus, incidence of diabetes in women was not associated with age (<55 years: HR, 0.64; 95%CI, 0.35-1.18; 55-64 years: HR, 0.55; 95%CI, 0.33-0.92;  $\geq 65$  years: HR, 0.87; 95%CI, 0.50-1.52). As for lipid parameters, PIT significantly reduced LDL cholesterol compared with control in men and women, but HDL cholesterol was significantly increased only in men.

**Conclusion:** PIT reduced the incidence of diabetes in women with IGT. This beneficial effect in women was not associated with age. PIT treatment may be effective even in women with moderate or low risk of CHD.

**Effect of Pitavastatin on the Incidence of Diabetes in Men and Women Stratified According to Age**

## 273

**Can delaying the onset of type 2 diabetes be cost-effective?**

A.M. Gray<sup>1</sup>, J. Leal<sup>1</sup>, O. Rivero-Arias<sup>1</sup>, S.D. Reed<sup>2</sup>, Y. Li<sup>2</sup>, K.A. Schulman<sup>3</sup>, R.M. Califf<sup>2</sup>, R.R. Holman<sup>3</sup>;

<sup>1</sup>Nuffield Department of Population Health, University of Oxford, UK, <sup>2</sup>Duke Clinical Research Institute, Duke University, Durham, USA, <sup>3</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM), University of Oxford, UK.

**Background and aims:** Type 2 diabetes is a 21st century epidemic, but lifestyle and some pharmaceutical interventions can delay its onset in at-risk subjects. We evaluated what effects a delay in diabetes onset by a hypothetical intervention could have on quality-adjusted survival and lifetime complication costs in UK and US healthcare settings, and likely cost-effectiveness at different intervention costs.

**Materials and methods:** We used data representing the characteristics of 3,058 NAVIGATOR trial subjects at the time they progressed from impaired glucose tolerance to new-onset diabetes, and simulated their remaining life-

time clinical outcomes using the UKPDS Outcomes Model. Multiple simulations examined the impact of a hypothetical intervention that delayed diabetes onset by 1, 3, 5 or 7 years on costs and (quality-adjusted) life expectancy. For simplicity, we assumed that all patients would experience the same period of delay regardless of their characteristics or previous medical history. All future costs and effects were discounted at 3.5% (UK) and 3.0% (US).

**Results:** Subjects were mean (1SD) age 66.3 (6.9) years, HbA1c 43 (7) mmol/mol, body mass index 31.5 (5.7) kg/m<sup>2</sup>, and 51% were male. The longer diabetes onset was delayed the greater was the increase in life expectancy and quality-adjusted life years (QALYs) and the decrease in the costs of diabetic complications. When diabetes onset was delayed by 7 years, undiscounted life expectancy measured from the simulation baseline increased from 13.8 to 15.4 years; discounted QALYs increased from 7.6 (US 8.0) to 8.4 (US 8.8) years, with a corresponding decrease in the discounted costs of complications from £16,741 (US \$140,967) to £16,377 (US \$140,369). Assuming an annual cost for the hypothetical intervention of £1,000 (US \$1,600), the estimated cost per QALY gained when onset was delayed by one year was £7,240 (US \$11,546), falling to £6,909 (US \$10,251) when onset was delayed by 7 years. If the annual cost for the hypothetical intervention was £3,000 (US \$4,800), the estimated cost per QALY gained when onset was delayed by one year was £22,691 (US \$34,870), falling to £21,302 (US \$32,239) when onset was delayed by 7 years.

**Conclusion:** In our analysis, interventions that can delay the onset of diabetes substantially increased remaining life expectancy and quality-adjusted survival and slightly reduced remaining lifetime complication costs. At annual costs of between £1,000 and £3,000 (US \$1,600 and \$4,800), the hypothetical intervention yielded a cost per QALY gained that remained broadly within the ranges considered cost-effective in the UK and US. Further work is required to explore heterogeneity in the patient population and parameter uncertainty in the modelling. Developing such interventions continues to be a high priority, especially given the continued growth in the global population with type 2 diabetes.

#### Blood glucose levels at baseline and incidence of type 2 diabetes: a prospective cohort study of 0.5 million adults in the China Kadoorie Biobank

H. Du<sup>1</sup>, L. Li<sup>2,3</sup>, I. Millwood<sup>1</sup>, F. Bragg<sup>1</sup>, L. Yang<sup>1</sup>, Y. Chen<sup>1</sup>, Y. Guo<sup>2</sup>, Z. Bian<sup>2</sup>, J. Chen<sup>4</sup>, R. Collins<sup>1</sup>, R. Peto<sup>1</sup>, Z. Chen<sup>1</sup>;

<sup>1</sup>CTSU, University of Oxford, UK, <sup>2</sup>Chinese Academy of Medical Sciences,

<sup>3</sup>School of Public Health, Peking University, <sup>4</sup>China National Center for Food Safety Risk Assessment, Beijing, China.

**Background and aims:** Random blood glucose (RBG) levels may be used to screen for diabetes, however the predictive value of RBG levels within the normoglycemic range on future diabetes risk has not been well studied, particularly among Chinese population.

**Materials and methods:** The study population includes 496,720 individuals enrolled into the China Kadoorie Biobank between 2004–8 from 10 diverse localities across China without prior physician diagnosed diabetes. At baseline, RBG was measured by venous blood spot test and those with RBG  $\geq$  11.1 mmol/L and those fasting blood glucose  $\geq$  7.0 mmol/L were identified as newly detected diabetes (2.8%) and excluded from the current analysis. Data on type 2 diabetes incidence was collected through electronic linkage with mortality and morbidity registries as well as with the national health insurance system. RBG was related to incidence of type 2 diabetes using Cox proportional Hazard models, with adjustment for potential confounders.

**Results:** The overall mean age of participants (n=474,423) was 51 years, mean BMI was 23.6 kg/m<sup>2</sup>, and mean RBG was 5.7 mmol/L. During the 7-year follow-up, 4194 incident cases of type 2 diabetes were identified. A dose-response relationship was observed between baseline RBG and risk of diabetes. Compared to those with RBG < 6.0 mmol/L, those with 6.0  $\leq$  RBG < 6.9 mmol/L had a diabetes hazard ratio (HR) 2.8 (95% CI: 2.7–2.9), those with 7.0  $\leq$  RBG < 7.8 mmol/L had HR 3.8 (3.5–4.1) and those with RBG  $\geq$  7.8 (i.e. pre-diabetes) had HR 6.8 (6.3–7.4). The association of RBG with diabetes risk was slightly stronger in women than in men, and in younger than in older people. Stratifying the analyses by hours since last meal (< 2 hours, 2–4 hours, 4–6 hours, or  $\geq$  6 hours) revealed a stronger association among those who had fasted for a longer period (HR of RBG  $\geq$  7.8 mmol/L 12.0 [5.3–27.2]).

**Conclusion:** In this group of adult Chinese, higher RBG levels, even those within the normoglycemic range, constitute an independent risk factor for type 2 diabetes. Such levels should probably be taken into account in identifying people at increased risk for diabetes.

#### Stressful life events and the metabolic syndrome: the Hoorn Study

F. Rutters<sup>1</sup>, S. Pilz<sup>2</sup>, A.D. Koopman<sup>1</sup>, S.P. Rauh<sup>1</sup>, S.J. Te Velde<sup>1</sup>, C.D.A. Stehouwer<sup>3</sup>, P. Elders<sup>4</sup>, G. Nijpels<sup>4</sup>, J.M. Dekker<sup>1</sup>;

<sup>1</sup>Department of Epidemiology and Biostatistics, VUmc, Amsterdam,

Netherlands, <sup>2</sup>Department of Internal Medicine, Medical University of

Graz, Austria, <sup>3</sup>Maastricht University Medical Centre, Department of

Internal Medicine, Netherlands, <sup>4</sup>Department of General Practice, VUmc,

Amsterdam, Netherlands.

**Background and aims:** The amount of psychosocial stress may play a role in the development of the Metabolic Syndrome. The aim of our current study was to evaluate whether in a population-based cohort of older men and women the number of stressful life events is associated with the Metabolic Syndrome incidence, and whether any such relationship is mediated by behavioural factors.

**Materials and methods:** The association between the number of stressful life events experienced at baseline and Metabolic Syndrome incidence after 6 years of follow up, was assessed in the Hoorn study. Subjects with the Metabolic Syndrome at baseline, defined according to the Adult Treatment Panel III (NCEP), were excluded.

**Results:** We included 1099 participants (47% male; age 60.1 $\pm$ 7 years). During 6.5 years of follow-up, 238 subjects (21.7%) developed the Metabolic Syndrome. Using logistic regression, a positive association was observed between

Metabolic Syndrome incidence at follow-up and the number of stressful life events [OR 1.11 (1-1.25)]. However, we also observed effect modification for education level (P value interaction,  $p=0.01$ ). In the low-education group, the model adjusted for age and sex showed a significant association between Metabolic Syndrome incidence and the amount of stressful life events [OR 1.20 (1.03-1.39)]. No such significant association was observed in the middle/high-education group [OR 1.05 (0.83-1.24)]. Additionally, a chi-square analysis showed a linear-by-linear association between the number of Metabolic Syndrome abnormalities and the amount of stressful life events ( $p<0.01$ ) in the low educated group. Finally, we observed that smoking, high alcohol intake and low physical activity did not mediate the association between stressful life events and Metabolic Syndrome incidence.

**Conclusion:** Experiencing more stressful life events is associated with a significantly increased risk for developing metabolic syndrome in an elderly population-based cohort, especially in persons with a low education level.

## 276

### Circulating fractalkine levels predict the development of the metabolic syndrome

Y. Xueyao, S. Zhang, D. Yu, Q. Pan, X. Dong, J. Zhou, H. Li; Department of Endocrinology, the Affiliated Sir Run Run Shaw Hospital, Hangzhou, China.

**Background and aims:** The fractalkine/CX3CR1 axis plays an important role in regulating glucose and lipid metabolism. However, the role of fractalkine in metabolic disorders remains to be fully elucidated.

**Materials and methods:** We selected 887 Chinese (40-65 years old) at baseline, with a subgroup of 459 participants examined again 2 years later. The relationship of serum fractalkine levels with the metabolic syndrome (Mets) and its components was investigated.

**Results:** At baseline, participants with MetS had a higher fractalkine concentrations than their counterparts without MetS ( $P<0.001$ ). At the 2-year follow-up, participants in the highest quartile of baseline fractalkine exhibited higher values for body mass index, waist circumference, waist-to-hip ratio, body fat percentage, blood pressure, glucose, insulin, total cholesterol, triglycerides (TG), homeostasis model assessment of insulin resistance (HOMA-IR), and lower value for high density lipoprotein- cholesterol (HDL-c) (all  $P<0.05$ ). Among 390 participants without MetS at baseline, 45 developed it at year 2. Even after multiple adjustments for visceral adipose tissue area, HOMA-IR, C-reactive protein (CRP) or TG and HDL-c, baseline fractalkine predicted the development of MetS (OR=7.18, 95%CI: 2.28-18.59).

**Conclusion:** Circulating fractalkine predicts the development of the MetS independently of central obesity, CRP, insulin resistance and dyslipidemia.

### Influence of serum osteocalcin and liver fat content on glucose metabolism in a middle-aged and elderly Chinese population

M. Xia, H.-D. Lin, H.-M. Yan, H. Bian, X.-X. Chang, X. Gao; Endocrinology, Zhongshan Hospital, Shanghai, China.

**Background and aims:** The interaction among adipose tissue, liver and bone has been disclosed. Dysregulation of this network promotes the development of metabolic diseases, including diabetes. We aimed to investigate the relationship of serum osteocalcin (OCN) secreted by osteoblasts, liver fat content (LFC) and glucose metabolism in a middle-aged and elderly Chinese community population.

**Materials and methods:** A cross-sectional study was performed on 3782 eligible participants from Shanghai Changfeng Community Study. LFC was measured via a newly-established ultrasound quantitative method. One-way ANOVA and multivariate linear regression analysis were carried out to determine the independent and joint association of OCN and LFC with glucose metabolism status.

**Results:** Decreased serum OCN was associated with higher body weight, waist circumference, diastolic blood pressure, serum triglyceride, fasting and postprandial blood glucose, fasting insulin and insulin resistance level (represented by HOMA-IR) as well as higher LFC (all  $P<0.05$ ). There was a synergistic increase seen in serum fasting blood glucose, postprandial glucose, insulin and HOMA-IR level in individuals with both increased LFC and decreased serum OCN (Figure 1). Multivariate regression analysis showed that both OCN and LFC were independently associated with FBG (std

$\beta=-0.122, P<0.001$  and std  $\beta=0.110, P<0.001$ ), PBG (std  $\beta=-0.074, P<0.001$  and std  $\beta=0.147, P<0.001$ ) and HOMA-IR (std  $\beta=-0.053, P<0.001$  and std  $\beta=0.169, P<0.001$ ).

**Conclusion:** Our results suggest that both liver and bone contribute to the development of diabetes and serum OCN and LFC may have a synergistic effect on human glucose metabolism.

## 278

### Cardio-metabolic parameters in non-diabetic patients with chronic kidney disease

M. Mota<sup>1</sup>, S. Popa<sup>1</sup>, M. Adina<sup>2</sup>, E. Mota<sup>3</sup>;

<sup>1</sup>Diabetes, Nutrition & Metabolic Diseases, University of Medicine and Pharmacy, <sup>2</sup>Diabetes, Nutrition & Metabolic Diseases, Clinical Emergency Hospital, <sup>3</sup>Nephrology, University of Medicine and Pharmacy, Craiova, Romania.

**Background and aims:** The nature of the relationship of obesity and insulin resistance (IR) with adverse clinical outcomes in chronic kidney disease (CKD) is unclear. The aim of the study was to assess association of cardio-metabolic parameters with estimated glomerular filtration rate (eGFR) in CKD and non-CKD non-diabetic subjects.

**Materials and methods:** We performed a cross-sectional analysis in a random sample of 1391 non-diabetic subjects, aged 20-79 years, derived from PREDATORR study. CKD was defined as eGFR  $<60$  ml/min/1.73m<sup>2</sup> or urinary albumin to creatinine ratio  $\geq 30$ mg/g. The analysed cardio-metabolic parameters were: waist circumference (WC), waist to height ratio (WHtR), body mass index (BMI), body adiposity index (BAI), visceral adiposity index (VAI), glycemia, insulinemia, HOMA-IR, uric acid, lipid profile, systolic and diastolic blood pressure (SBP, DBP).

**Results:** The prevalence of CKD was 7.5%, majority of CKD patients being in the age group 60-79 years. Frequent cardio-metabolic comorbidities, in subjects with CKD, were dyslipidemia (90%), abdominal obesity (89.4%), obesity (84.6%), hypertension (87.5%), prediabetes (52.9%), hyperuricemia (52.9%), IR (43.3%). Obesity, IR and dyslipidemia were prevalent in the young subjects, while abdominal obesity, prediabetes, hypertension and hyperuricemia were prevalent in elderly people. Among the cardio-metabolic comorbidities associated with presence of CKD found to be statistically significant were obesity, abdominal obesity hyperuricemia, prediabetes, hypertension ( $p<0.001$  for all), IR ( $p=0.002$ ) and dyslipidemia ( $p=0.006$ ). Young subjects with CKD had significantly higher WC ( $99.7\pm 11$  vs  $88.3\pm 17$ ;  $p<0.001$ ), WHtR ( $0.6\pm 0.08$  vs  $0.5\pm 0.08$ ;  $p=0.004$ ), BMI ( $34.2\pm 7.2$  vs  $25.3\pm 5.1$ ;  $p<0.001$ ), BAI ( $35.6\pm 10.5$  vs  $27.3\pm 5.8$ ;  $p=0.01$ ), VAI ( $2.5\pm 1.7$  vs  $1.7\pm 1.5$ ;  $p=0.02$ ), glycemia ( $81.9\pm 10$  vs  $74.6\pm 10.4$ ;  $p=0.04$ ), insulinemia ( $17\pm 9.9$  vs  $10.3\pm 8.8$ ;  $p=0.005$ ), HOMA-IR ( $3.5\pm 2.4$  vs  $1.6\pm 1.1$ ;  $p=0.003$ ) and uric acid ( $6.1\pm 1.4$  vs  $4.7\pm 1.4$ ;  $p=0.006$ ), compared to non-CKD young subjects. Elderly CKD subjects had only higher HbA1c ( $5.7\pm 0.4$  vs  $5.5\pm 0.3$ ;  $p<0.001$ ), insulinemia ( $12.8\pm 7.4$  vs  $11\pm 9.1$ ;  $p=0.001$ ), HOMA-IR ( $2.7\pm 2$  vs  $2.4\pm 2$ ;  $p=0.003$ ) and uric acid ( $6.3\pm 1.7$  vs  $5.4\pm 2.3$ ;  $p<0.001$ ) compared to non-CKD elderly subjects. In CKD subjects

eGFR was negative correlated with age ( $r=-0.3$ ;  $p<0.001$ ), uric acid ( $r=-0.3$ ;  $p=0.002$ ) and positive correlated with WC ( $r=0.2$ ;  $p=0.02$ ), WHtR ( $r=0.2$ ;  $p=0.03$ ), BMI ( $r=0.2$ ;  $p=0.01$ ). Multiple linear regression indicated that age and uric acid were negatively associated with eGFR, while WHtR was positive predictor. In non-CKD subjects a negative correlation occurred between eGFR and age and, also, all cardio-metabolic parameters (WC, WHtR, BMI, VAI, BAI, glycemia, HbA1c, HOMA-IR, triglycerides, total and LDL cholesterol, uric acid, SBP, DBP). Multiple linear regression indicated that only age, uric acid, SBP and HbA1c were negatively associated with eGFR.

**Conclusion:** This study proposed a synergistic association between cardio-metabolic syndrome components and the presence of CKD. Obesity parameters were associated with CKD in young subjects, while HOMA-IR and uric acid were associated with CKD independently of age. WHtR and uric acid may be important pathogenic factors in non-diabetic CKD patients.

## 279

### Associations of sleep duration and sleep efficiency with glucose tolerance and beta cell function in Hong Kong Chinese children and adolescents

<sup>5</sup>Paediatrics, The Chinese University of Hong Kong, Hong Kong.

**Background and aims:** Increasing evidence suggest a role of sleep duration on metabolic dysregulation and dysglycemia in adults. We aimed to examine the associations of sleep duration and sleep efficiency with glucose metabolism in Hong Kong Chinese children and adolescents.

**Materials and methods:** Children and adolescents of Chinese ethnicity aged 6-18 years were identified from a population-recruited, territory-wide survey. All subjects completed 3-day sleep diary and 3-day actigraphy for the assessments of subjective and objective sleep duration and sleep efficiency. Oral glucose tolerance test (OGTT) and insulin assays were performed. Glucose tolerance, insulin sensitivity, and pancreatic  $\beta$ -cell function were assessed by 2-hour plasma glucose level, Matsuda index ( $IS_{OGTT}$ ), and insulin secretion-sensitivity index-2 (ISSI-2), respectively. Subjects with moderate-to-severe obstructive sleep apnea (OSA) as determined by an obstructive apnea hypopnea index (OAH)  $> 5$ /hour in an overnight polysomnography were excluded from analyses. Multiple linear regression analyses were performed to explore the associations between sleep and glucose metabolism parameters. Variables with skewed distribution were log-transformed before entering into analyses.

**Results:** A total of 131 children and adolescents were studied. Among them, 13 had moderate-to-severe OSA, leaving 118 subjects eligible for the present analysis (mean age  $\pm$  SD:  $13.1 \pm 3.3$  years; male: 44.9%). After adjustment for gender, Tanner stage, BMI z-score, and OAH, sleep duration and sleep efficiency measured by actigraphy were negatively associated with log-transformed 2-hour plasma glucose levels ( $\beta \pm$  se:  $-0.042 \pm 0.022$ ,  $p = 0.054$  and  $-0.009 \pm 0.004$ ,  $p = 0.033$ , respectively) and positively associated with log-transformed ISSI-2 ( $\beta \pm$  se:  $0.102 \pm 0.049$ ,  $p = 0.038$  and  $0.023 \pm 0.009$ ,  $p = 0.014$ , respectively). There were no significant associations of log-transformed  $IS_{OGTT}$  ( $p > 0.20$ ) with sleep duration and sleep efficiency as measured by actigraphy. Moreover, no associations were found between subjective sleep duration and sleep efficiency as measured by sleep diary and all glucose metabolism parameters as mentioned above ( $p > 0.20$ ) (Table 1).

**Conclusion:** Short sleep duration and low sleep efficiency as measured by actigraphy are independent risk factors for worse glucose tolerance and  $\beta$ -cell function in children and adolescents.

**Table 1: The associations of sleep duration and sleep efficiency measured by 3-day actigraphy and 3-day sleep diary with glucose/insulin metabolic parameters**

| Outcomes                           | Predictors                      | $\beta$ | Standard error | P value $\nabla$ |

### Glycated albumin is a useful indicator for screening impending diabetes and predicting beta cell dysfunction in the pre-diabetic condition

S.M. Hong<sup>1</sup>, S.Y. Rhee<sup>1</sup>, J. Kim<sup>2</sup>, Y.C. Hwang<sup>1</sup>, C.H. Jung<sup>3</sup>, K.J. Kim<sup>4</sup>, W.S. Jeon<sup>5</sup>, S.M. Jin<sup>6</sup>, B.W. Lee<sup>4</sup>, J.T. Woo<sup>1</sup>;

<sup>1</sup>Department of Endocrinology and Metabolism, Kyung Hee University School of Medicine, <sup>2</sup>Department of Internal Medicine, Dongsuwon General Hospital, <sup>3</sup>Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, <sup>4</sup>Department of Internal Medicine, Severance Hospital, University of Yonsei College of Medicine, <sup>5</sup>Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, <sup>6</sup>Department of Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

**Background and aims:** Pre-diabetes is known as a pre-clinical stage of increased risk for overt diabetes mellitus (DM) and cardiovascular disease. Because glycated albumin (GA) has been suggested to have more potential for assessing insulin secretory dysfunction and glycemic fluctuation than HbA1c, we studied the clinical significance of GA in this stage.

**Materials and methods:** We enrolled the 1379 anti-diabetic drug naïve subjects in retrospective, multi-center, cross-sectional manner. According to the 75-g OGTT, the subjects were classified as normal glucose tolerance (NGT), isolated IFG (i-IFG), isolated IGT (i-IGT), combined glucose intolerance (CGI) and DM subgroup. We analyzed clinical characteristics of these 5 groups including GA, insulin sensitivity (HOMA2%S), and insulin secretion (HOMA2%B) index.

**Results:** Mean GA was  $11.6 \pm 1.4$ ,  $12.3 \pm 1.8$ ,  $12.3 \pm 1.9$ ,  $13.0 \pm 1.9$ ,  $18.8 \pm 7.9$  in NGT ( $n=295$ , 21.4%), i-IFG ( $n=257$ , 18.6%), i-IGT ( $n=103$ , 7.4%), CGI ( $n=257$ , 18.6%), and DM ( $n=466$ , 34%) subgroup. After adjusting covariates, adjusted mean of GA was  $12.2 \pm 0.1$ ,  $12.2 \pm 0.2$ ,  $13.1 \pm 0.1$  in i-IFG, i-IGT, and CGI subgroup ( $p < 0.001$ ), and significantly higher in CGI group by post-hoc analysis. Adjusted mean of HbA1c was also significant, but not distinguished differences among these subgroups. Moreover, correlation coefficient between HOMA2%B and GA ( $r=-0.393$ ,  $p < 0.001$ ), and HOMA2%S and GA ( $r=0.258$ ,  $p < 0.001$ ) was significantly higher than correlation with HbA1c. And these results were consistent after adjusting covariates.

**Conclusion:** We suggest that GA could be a better indicator for screening impending diabetes and assessing beta cell dysfunction in the subjects of pre-diabetic period.

**A population approach to modelling the oral glucose tolerance test in normal and impaired glucose tolerant states**

M.J. Theodorakis, G.P. Chrousos;

Endocrinology, Metabolism and Diabetes Unit, University of Athens, Greece.

**Background and aims:** The conventional approach to analyzing oral glucose tolerance testing (OGTT) data requires model identification in each individual separately (standard two stage), ignoring knowledge about the population as a whole. However, the OGTT is sparsely sampled and individual estimates are often not resolvable from the available data.

**Materials and methods:** We applied a population approach, nonlinear mixed effects modeling, to plasma glucose, insulin and C-peptide data obtained from a 120-minute OGTT undertaken by 106 subjects forming five groups with varying glucose tolerance. This method provides estimates of population means, variances and covariances of model parameters, empirical Bayes estimates of individual parameter values and measures of intra-individual (within-subject) and inter-individual (between-subject) variability. The latest version of the oral glucose minimal model was used to evaluate insulin sensitivity and a combined model approach was used to assess  $\beta$ -cell secretion. These models allowed for the reconstruction of insulin secretion and glucose absorption profiles and gave population indexes of insulin sensitivity ( $S_p=6.51\pm 1.20\times 10^{-4} \text{ min}^{-1}\cdot\mu\text{U}^{-1}\cdot\text{ml}$ ), fractional hepatic extraction of insulin ( $F=0.522\times 0.291$ ) and fractional insulin clearance ( $k_i=0.258\times 0.151 \text{ min}^{-1}$ ).

**Results:** Individuals with type 2 diabetes (T2DM) had significantly higher HOMA-IR, HbA1c and triglyceride levels compared to subjects with normal glucose tolerance (NGT). They also had increased fasting plasma insulin levels, significantly reduced insulinogenic index from 0 to 20 minutes after oral glucose, and increased fasting glucagon levels compared to NGT subjects. All had similar fasting plasma biochemical values and were without medical histories of gastroparesis, kidney disease or microvascular disease. The population model, including data from all groups of individuals, was implemented in NONMEM. When empirical post hoc Bayes estimates obtained from the population approach were used to determine individually predicted values, these points collapsed to the line of unity, showing no systematic deviations from the observed data. NGT subjects were found to have the highest median values for  $S_p$ , as well as the most variability. Mean estimates and standard errors for  $S_p$  ( $104\text{min}^{-1}\cdot\mu\text{U}^{-1}\cdot\text{ml}$ ) in the different groups were: Group 1 (normal fasting and 2-hr plasma glucose;  $17.7\pm 1.8$ ), Group 2 (normal fasting / impaired 2-hr plasma glucose;  $9.95\pm 2.0$ ), Group 3 (impaired fasting and 2-hr plasma glucose;  $5.67\pm 1.0$ ), Group 4 (normal fasting / diabetic 2-hr plasma glucose;  $3.82\pm 1.1$ ) and Group 5 (diabetic fasting and 2-hr plasma glucose;  $9.39\pm 3.8$ ). Individual insulin secretion profiles were also reconstructed from empirical Bayes estimates.

**Conclusion:** Whereas the traditional approach to parameter estimation failed to recover estimates in more than one third of the population, the population approach provided individual estimates in all subjects. Examination of the empirical Bayes estimates showed that individual parameter estimates were able to differentiate well between individuals at glucose tolerant states ranging from euglycemia to overt type 2 diabetes. Our findings suggest population analysis is a powerful tool to obtain accurate assessments of indexes of insulin sensitivity and  $\beta$ -cell function from the OGTT, especially in epidemiological studies with large numbers of sparsely sampled subjects.

**Family history is not associated with lifestyle, clinical, or anthropometric factors in newly diagnosed type 2 diabetes mellitus patients: the DD2 study**E. Svensson<sup>1</sup>, K. Berensci<sup>1</sup>, S. Sander<sup>1</sup>, A. Mor<sup>1</sup>, J. Rungby<sup>2</sup>, J.S. Nielsen<sup>3</sup>, S. Friberg<sup>4</sup>, I. Brandslund<sup>5</sup>, J.S. Christiansen<sup>6</sup>, A. Vaag<sup>7</sup>, H. Beck-Nielsen<sup>3</sup>, H.T. Sørensen<sup>1</sup>, R.W. Thomsen<sup>1</sup>;

<sup>1</sup>Department of Clinical Epidemiology, <sup>2</sup>Department of Pharmacology, Aarhus University, <sup>3</sup>Diabetes Research Centre, Department of Endocrinology, Odense University Hospital, <sup>4</sup>Department of Endocrinology, Odense University Hospital, <sup>5</sup>Department of Biochemistry, Lillebaelt Hospital, Vejle, <sup>6</sup>Department of Internal Medicine and Endocrinology, Aarhus University Hospital, <sup>7</sup>Department of Endocrinology, Rigshospitalet and University of Copenhagen, Denmark.

**Background and aims:** A positive family history of type 2 diabetes mellitus (T2D) increases the risk for developing T2D approximately two-fold, likely due to both genetic and lifestyle factors. It is unknown how having a family history of T2D is related to demographic, clinical-, lifestyle and anthropometric factors at T2D debut, thus we aimed to examine this in a cross-sectional study.

**Materials and methods:** All participants in the Danish Centre for Strategic Research in Type 2 Diabetes (DD2) cohort responded to a questionnaire, in which detailed family history of diabetes (grandparents, parents, siblings and children) was assessed. We examined the prevalence and relative risk, and corresponding 95% confidence interval (CI) of having one first-degree relative vs no first-degree relative with history of T2D according to different demographic, lifestyle, clinical and anthropometric factors at T2D debut.

**Results:** Of 2,718 T2D patients, 1,191 (44%) had one or more first-degree family relatives with diabetes, including 377 (14%) with two or more first-degree relatives. Of the patients with positive family history, 20% had affected mothers, while 17% had affected fathers. Among the newly diagnosed T2D patients, a family history of T2D was to a lesser extent seen in men compared with women (adjusted relative risk (aRR) 0.84, 95% CI 0.78-0.90). Individuals aged less than 40 years at their T2D debut were more likely to have a family history of diabetes as compared with patients aged more than or equal to 60 years at T2D debut (aRR 1.34, 95% CI 0.94-1.91). In contrast, family history of T2D was evenly distributed according to presence or absence of central obesity, large weight gain since age 20, physical activity, alcohol consumption and Charlson comorbidity score.

**Conclusion:** Almost half (44%) of newly diagnosed T2D patients have a first degree family relative with diabetes. Our results confirm that T2D heredity is stronger on the maternal side. Having a family history of diabetes is thus associated with female gender and younger age at T2D debut, whereas family history does not appear to be associated with presence of comorbidity or specific lifestyle-, clinical- and anthropometric factors at debut.

**Determinants of skin autofluorescence in the general population and in type 2 diabetes**B.H.R. Wolffenbuttel<sup>1</sup>, R. Graaff<sup>1</sup>, H.L. Lutgers<sup>1</sup>, K. Eny<sup>2</sup>, A.D. Paterson<sup>3</sup>, S.N. Slagter<sup>1</sup>, J.V. van Vliet-Ostapchouk<sup>1</sup>, M.M. van der Klauw<sup>1</sup>;

<sup>1</sup>Endocrinology, University Medical Center Groningen, Netherlands, <sup>2</sup>Program in Genetics & Genomic Biology, Hospital for Sick Children, Toronto, Canada.

**Background and aims:** Skin autofluorescence (SAF) is a non-invasive marker of advanced glycation end products and is associated with long-term diabetes complications and cardiovascular morbidity and death. SAF increases with age, and is higher among individuals with diabetes.

**Materials and methods:** We assessed the determinants of SAF in people with and without type 2 diabetes (T2DM) in the LifeLines Cohort study, a random population-based sample of inhabitants of three Northern provinces of the Netherlands. For this cross-sectional analysis, we included subjects 18-90 years of age, who had both genetic data available and SAF measurement collected between January 2008 and March 2011. We excluded subjects who were known to have type 1 diabetes and those with serum creatinine >140  $\mu\text{mol/l}$ , leaving 9025 individuals (of whom  $n=314$ , 3.5% with T2DM) for analysis. Skin autofluorescence (SAF) was measured non-invasively with the AGE Reader.

**Results:** Mean ( $\pm$ SD) age was 49 ( $\pm$ 11) yrs for the non-diabetic participants and 59 ( $\pm$ 11) yrs for the T2DM group, while mean SAF was 2.04 ( $\pm$ 0.44) arbitrary units (AU) vs 2.45 $\pm$ 0.59 AU. Linear regression showed that age, sex, body mass index, HbA1c, glomerular filtration rate (GFR), smoking, and a genetic polymorphism of N-acetyltransferase 2 (NAT2) significantly influenced SAF in the general population (all  $p < 0.001$ ) and type 2 diabetic subjects (all  $p < 0.009$ ). In addition, total cholesterol was an independent predictor of SAF in diabetes. Finally, the effect size of sex, HbA1c, smoking and NAT2 were larger in subjects with T2DM than in the general population (Table).

**Conclusion:** We conclude that SAF is influenced by several clinically significant parameters, and some of them bear a more significant influence in T2DM. These factors should be taken into account when using SAF as a predictor of cardiovascular and diabetes-related complications. The large effect of smoking in T2DM supports increasing our efforts to promote smoking cessation in those individuals.

### Environmental pollutants and the risk of type 1 diabetes

O. Vaarala<sup>1</sup>, H. Salo<sup>1</sup>, J. Koponen<sup>2</sup>, M. Knip<sup>3</sup>, H. Kiviranta<sup>2</sup>;

<sup>1</sup>Department of Vaccinations and Immune Protection, National Institute for Health and Welfare, Helsinki, <sup>2</sup>Department of Environmental Health, National Institute for Health and Welfare, Kuopio, <sup>3</sup>Children's Hospital, University of Helsinki, Finland.

**Background and aims:** Environmental pollutants have been associated with immune aberrancies, but their role as a risk factor of type 1 diabetes is not known. We explored the association of the plasma levels of environmental pollutants and later development of type 1 diabetes associated beta-cell autoantibodies in children at genetic risk of type 1 diabetes.

**Materials and methods:** We analyzed the plasma levels of 13 persistent organic pollutants (POP) and 13 perfluorinated compounds (PFC) in a series of cord blood samples and plasma samples taken at the age of 12 months from children at genetic risk of type 1 diabetes who participated in the FINDIA pilot study and were monitored for the appearance of type 1 diabetes associated autoantibodies. Plasma samples were pretreated with dispersive solid phase extraction. The PFCs and POPs were extracted with methanolic ammonium acetate and dichloromethane:hexane (1:4), respectively. The sample volume used for the analysis ranged from 25  $\mu$ L to 200  $\mu$ L. Instrumental analysis was performed with the LCMS/MS (PFAAs) and GC-MS/MS (POPs).

**Results:** The levels of 13 POPs or 13 PFCs did not differ in cord blood samples or plasma samples taken at the age of 12 months between the children who developed autoantibodies and children who remained autoantibody negative during the follow-up over the first 6 years of life. No association of environmental pollutants with the development of clinical type 1 diabetes was observed. Increased levels of both POPs and PFCs were associated with breast-feeding.

**Conclusion:** Our results do not suggest that early exposure to POPs or PFCs during pregnancy or early infancy is a risk factor for the later development of beta-cell autoimmunity and type 1 diabetes.

*Clinical Trial Registration Number:* NCT01055080

### Enteroviral infection in human type 1 diabetes: correlative evidence from multiple tissue sources in nPOD samples

S.J. Richardson<sup>1</sup>, T. Rodriguez-Calvo<sup>2</sup>, M. Oikarinen<sup>3</sup>, J.E. Laiho<sup>3</sup>,

I. Kusmartseva<sup>4</sup>, M. Campbell-Thompson<sup>4</sup>, nPOD-V Consortium, A. Baj<sup>5</sup>, A. Toniolo<sup>5</sup>, M. von Herrath<sup>2</sup>, H. Hyoty<sup>3</sup>, N.G. Morgan<sup>1</sup>;

<sup>1</sup>University of Exeter Medical School, UK, <sup>2</sup>La Jolla Institute for Allergy and Immunology, USA, <sup>3</sup>University of Tampere, Finland, <sup>4</sup>University of Florida, Gainesville, USA, <sup>5</sup>Università dell'Insubria, Varese, Italy.

**Background and aims:** Considerable evidence has accumulated to support the hypothesis that type 1 diabetes (T1D) is associated with an enteroviral infection. Much of this depends on the analysis of viral infection in blood samples but definitive proof that this is also associated with the presence of enterovirus within the organs of affected individuals is still lacking. The purpose of this study was to undertake the first fully coordinated analysis of multiple tissues available within the JDRF's network of pancreatic organ donors with diabetes (nPOD) collection. These tissues were analysed using different methods, in multiple collaborating laboratories, to assess the correlation of potential indices of enteroviral infection.

**Materials and methods:** Tissue samples (pancreas/ spleen/ PBMCs) from controls, T1D and autoantibody positive (AAb+) cases were prepared by the nPOD Pathology Core and distributed in a blinded manner to each laboratory. Samples were immunostained for enteroviral capsid protein VP1 and class I MHC [using IHC in FFPE sections and IF in frozen sections] and probed by *in situ* hybridisation for enteroviral genome. Enterovirus sequence analysis was attempted in extracts prepared from frozen spleen and PBMCs in a selection of the cases.

**Results:** Expression of enteroviral capsid protein, VP1, and hyper-expression of class I MHC were detected consistently in the islets of Langerhans of patients with T1D while VP1 was also detected in the spleens. Immunopositivity was remarkably concordant between the different laboratories, despite

the different methodologies employed. Tissues from a total of 101 cases were then examined and scored for several indices of viral infection including VP1 immunopositivity, class I MHC hyperexpression, positive *in situ* hybridisation signals and the presence of viral sequences. Among 28 controls, a total of 54 indices of viral infection were assessed independently and 7 were reported as positive (13%). In 52 type 1 diabetes cases (including those with residual insulin-containing islets and those without) 99 indices were scored and 51 were positive (51.5%). Among 21 autoantibody positive cases, 43 indices were assessed and 16 were positive (37.2%). PCR amplification and nucleic acid sequencing analysis of RNA extracted from cultured spleen cells or PBMCs revealed the presence of several enterovirus serotypes and the positivity correlated with VP1 staining in sections of tissue from the same samples.

**Conclusion:** The results support the conclusion that enteroviral infection occurs at much higher frequency in T1D pancreas than in controls. Virus can be found both in blood samples and in other tissues (e.g. pancreas, spleen). Similar evidence of persisting virus was also found in AAb+ cases, supporting the hypothesis that enteroviruses may play a role early in the development of T1D.

### Increased antibodies against other autoimmune diseases in first degree relatives of patients with type 1 diabetes

M. Szelachowska, K. Siewko, A. Zielinska, R. Maciulewski, A. Poplaska-Kita, D. Lipinska, M. Gorska; Department of Endocrinology, Diabetology and Internal Medicine, Medical University, Bialystok, Poland.

**Background and aims:** It is well known that T1D is associated with other autoimmune diseases. The aim of this study was to compare the prevalence of various auto-antibodies in first-degree relatives of patients with T1D and healthy individuals with negative family history of diabetes.

**Materials and methods:** The group studied consisted of 90 relatives and 60 healthy individuals. Serum concentrations of antibodies to anti-21-hydroxylase (21-OH-Abs), anti-gastric parietal cell antibodies (GPC-Abs), anti-thyroglobulin antibodies (TG-Abs), anti-thyroid peroxidase antibodies (TPO-Abs) and anti-TSH receptor antibodies (TSHR-Abs) were measured by commercial radioimmunoassay.

**Results:** Positive antibodies against pancreatic islet antigens were found in 34.4% of the relatives (IAA in 23.3%, GADA in 16.7% and IA-2A in 2.2%) and in none of the controls. Other antibodies (mainly TPO-Abs, TSHR-Abs and GPC-Abs) were detected in 40% of all relatives and in 93.5% of these with positive anti-islet antibodies. Median levels of 21-OH-Abs, GPC-Abs, TPO-Abs and TSHR-Abs were significantly higher in the relatives, in particular these with positive anti-islet antibodies, as compared with the group of relatives with no anti-islet antibodies and the controls. A positive correlation between IAA and TPO-Abs levels was noted in the whole group of relatives, as well as in a subgroup with anti-islet antibodies ( $r=0.549$ ,  $p<0.05$  and  $r=0.567$ ,  $p<0.05$ , respectively).

**Conclusion:** Our results demonstrated for the first time significantly higher prevalence of anti-thyroid antibodies and anti-gastric parietal cell antibodies in the first degree relatives of T1D patients, in particular in these with positive anti-islet antibodies. The finding suggest that these subjects may be at higher risk of developing not only type 1 diabetes, but also other autoimmune disorders and should be routinely screen especially for autoimmune thyroid disease and auto-immune gastritis.

## 287

### Prevalence of diabetes autoantibodies in Chinese adult patients with type 1 diabetes mellitus and its relation with beta cell function

L. Liu, H. Deng, J. Yan, H. Ai, J. Lv, S. Lin, Y. Zhang, X. Zheng, D. Yang, B. Yao, J. Weng; Department of Endocrinology, The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China.

**Background and aims:** There are limited data on the frequency of beta-cell autoantibodies in Chinese adult patients with type 1 diabetes mellitus (T1DM). Our study aimed to explore the prevalence of diabetes autoantibodies (DAs) and its relation with beta-cell function in a cohort of adult patients with T1DM in Guangdong Province, China.

**Materials and methods:** Data were derived from Guangdong T1DM Translational Medicine Study. A total of 1070 patients with T1DM (488 males and 582 females) who were  $\geq 18$  years of age and had DAs measurements available were included in this analyses. The median age was 31.7 years old and duration was 4.14 years. Autoantibodies (GADA, IA2A and ZnT8A) were measured by radioligand assay confirmed by Diabetes Antibody Standardization Program. Fasting C-peptide (FCP) and postprandial C-peptide 2 hours (PCP2h) were measured centrally by standard methods.

**Results:** 548(51.2%) subjects were positive for at least one antibody and 47(4.4%) subjects were positive for three antibodies. Among the subjects with single positive antibody, 324(89.3%), 37(10.2%) and 2(0.5%) participants were positive for GADA, IA-2A and ZnT8A, respectively. Detailed data were shown in Figure 1. DA-positive participants were younger at diagnosis (median: 25.8 vs. 27.2 years), more likely to be female, with lower BMI at diagnosis (median: 18.34 vs. 19.49 kg/m<sup>2</sup>), lower FCP levels (median: 0.12 vs. 0.17 ng/ml) and PCP2h levels (median: 0.13 vs. 0.22 ng/ml) and higher HbA<sub>1c</sub> levels (median: 8.8% vs. 8.4%), compared with those who were DA negative ( $P<0.05$  for each). A correlation was found between the number of positive antibodies and disease duration ( $r_s=0.064$ ,  $P=0.04$ ) and FCP concentration ( $r_s=-0.149$ ,  $P=0.00$ ). As the increasing of disease duration, a tendency could be also observed that the rate of decline of FCP could be faster in the DA-positive group (Figure 2).

**Conclusion:** Our data showed the prevalence of diabetes autoantibodies in Chinese adult patients with T1DM was lower than the countries with high incidence of T1DM. The characteristics of DA-positive participants could suggest a more aggressive clinical status. There might be a more progressive decline in beta-cell function on account of diabetes autoantibodies.

Figure 1: Prevalence of diabetes autoantibodies

### Relationship between glycaemic variability, functional beta cell mass and glucose disposal rate in (pre)type 1 diabetes

A. Van Dalem<sup>1</sup>, S. Demeester<sup>1</sup>, E.V. Balti<sup>1</sup>, K. Decochez<sup>1,2</sup>, I. Weets<sup>1,3</sup>, E. Vandemeulebroucke<sup>1,2</sup>, E. Coudeny<sup>1</sup>, P. Gillard<sup>1,4</sup>, C. De Block<sup>5</sup>, J. Ruige<sup>6</sup>, B. Keymeulen<sup>1,2</sup>, D.G. Pipeleers<sup>1</sup>, F.K. Gorus<sup>1,3</sup>, Belgian Diabetes Registry; <sup>1</sup>Diabetes Research Center, Brussels, <sup>2</sup>Department of Diabetology, University Hospital Brussels, <sup>3</sup>Department of Clinical Chemistry and Radio-immunology, University Hospital Brussels, <sup>4</sup>Department of Endocrinology, University Hospital Leuven, <sup>5</sup>University Hospital Antwerp, <sup>6</sup>Department of Endocrinology, University Hospital Ghent, Belgium.

**Background and aims:** Novel beta cell therapies in (pre)type 1 diabetes (T1D) aim to preserve or restore a functional beta cell mass (FBM) that avoids large glycaemic excursions. In order to define therapeutic target populations, we examine which functional reserve is needed to curb glycaemic variability (GV). As a first step we investigated cross-sectionally the correlation between GV (assessed by continuous glucose monitoring [CGM] and self-monitoring-of-blood-glucose [SMBG]) and measures of FBM and of insulin resistance.

**Materials and methods:** The study was conducted in 9 recent-onset T1D patients (13-36 years;  $n=3$  in remission defined as insulin dose  $<0.5$  U.kg<sup>-1</sup>.day<sup>-1</sup>) and in 21 persistently autoantibody-positive first-degree relatives (autoAb<sup>+</sup> FDR) with overall 50% 5-year disease risk (12-41 years;  $n=4$  with impaired glucose tolerance [IGT] at baseline). All underwent CGM (iPro2, Medtronic) for 5 days followed by hyperglycemic clamp test (10.0 mmol/l). FBM was calculated as AUC C-peptide release between min120-150, and glucose disposal rate (M) as average glucose infusion rate between min120-150 minus a space correction. We derived 90 different GV parameters from CGM measurements using the GlyVarT 1.0 program (Medtronic) and 4 GV parameters from SMBG data (Contour Link, Bayer).

**Results:** Overall, GV parameters (CGM: interquartile range<sub>day</sub>, SD<sub>day</sub> and %glycemia<sub>day</sub> >7.7 mmol/l; SMBG: SD<sub>day</sub> and range<sub>day</sub>) were inversely correlated with FBM ( $r=-0.6$  to  $-0.7$ ,  $p\leq 0.001$ ). All patients except 1 in remission and 4/21 FDR had a FBM  $\leq$ percentile 10 (P10) of healthy controls; 2 of these 4 FDR developed T1D within 9 months. Among the 17 FDR with FBM >P10, 2 exhibited elevated GV parameters. A stronger correlation was found between GV parameters and M values ( $r=-0.8$ ,  $p<0.001$ ). Most patients (except 2 in remission) had M values  $\leq$ P10 of healthy controls, vs 0/21 FDR. Of the 7/21 FDR with M  $\leq$ P33 of controls, all had ( $n=4$  including 1 with preT1D) or developed IGT ( $n=2$ ) or T1D ( $n=1$ ) within 4-10 months vs only 1/14 FDR with higher M; their GV parameters were also higher ( $p=0.007$  to  $0.053$  vs FDR with M >P33). In autoAb<sup>+</sup> FDR, M  $\leq$ P33 of controls detected presence or development of dysglycemia within 1 year with 88% sensitivity and 93% specificity. Especially when considering multiple parameters, CGM was more sensitive than SMBG in detecting individuals who later developed IGT or T1D.

**Conclusion:** In autoAb<sup>+</sup> FDR low glucose disposal rate, also reflecting insulin resistance, outperforms FBM in diagnosing or predicting dysglycemia and is closely related to elevated CGM parameters. GV could provide non-invasive outcome measures in clinical trials.

## 289

### Baseline and five year treatment characteristics of adult onset type 1 diabetes

D. Hesse, A.A. Nielsen, M. Ridderstråle;  
Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Much less is known about adult onset type 1 diabetes (AOT1D) than childhood or adolescent onset T1D. We sought to characterize the initial five years of treatment of AOT1D.

**Materials and methods:** Subjects with AOT1D between 2001 and 2012 were identified in the electronic medical records of our diabetes center. Baseline demographics and diabetes related parameters for up to five years after onset were registered. Patients with latent autoimmune diabetes of the adult (LADA) were not included. Data are shown as mean  $\pm$  standard deviation. Non-parametric tests were used throughout and a p-value <0.05 was considered statistically significant.

**Results:** 487 patients with AOT1D were identified (men/women 61/39%), age at onset  $35.2\pm 13.6$  years. 383 patients were followed for as long as possible for up to five years for this study. Patients leaving the center, some of which returned, were also accounted for. GAD antibody status was available in 335 subjects (standard onset test since 2005-08-01). 274 patients were GAD positive and 61 GAD negative (82/18%). IFCC HbA1c at onset was  $97\pm 30$  mmol/mol ( $n=487$ ). At the five year follow-up HbA1c had decreased from  $97\pm 30$  to  $69\pm 18$  mmol/mol (Kruskal Wallis [KW]  $p<0.0001$ ; Figure 1). Patients with an HbA1c <53 mmol/mol after 5 years (17%; 31 out of 178 subjects with 5 year data:  $45\pm 4$  vs.  $71\pm 16$  mmol/mol;  $p<0.0001$ ) were already showing a significantly lower HbA1c by the second quarter after diagnosis ( $45\pm 7$  vs.  $53\pm 12$  mmol/mol;  $p<0.005$ ). There was no difference in HbA1c between these groups at diagnosis ( $100\pm 20$  vs.  $97\pm 31$  mmol/mol; ns), nor concerning other diabetes related variables. Apart from HbA1c, the only other five-year outcome that was different between the groups was a lower total insulin dose in the group <53 mmol/mol ( $36\pm 22$  vs.  $52\pm 23$  IU;  $p=0.0001$ ). The likelihood of having a five year HbA1c <53 mmol/mol was four times higher in subjects who reached an HbA1c <53 mmol/mol within the first six months of treatment compared to those who did not (odds ratio 4.2 [1.4-13.0] 95%CI;  $p=0.01$ ). Over the five years, there were significant but modest increases in blood pressure, HDL-cholesterol, and BMI, and a significant decrease in triglycerides (KW  $p<0.0001$  for all), with no change in LDL-cholesterol; most changes occurring during the first two years. By contrast, there was a gradual increase in total insulin dose (KW  $p<0.0001$ ). Only 14 patients were transferred from multiple daily injections to continuous subcutaneous insulin injection during the five first years of treatment.

**Conclusion:** Tight glycaemic control in subjects with AOT1D can be maintained over time. Already within half a year from the onset/diagnosis it may be possible to predict the long term sustainability of the glycaemic treatment by looking at the HbA1c level. The lack of other predictive variables for long term prognosis, as well as the lack of indicators for the need of alternative strategies, is striking and motivates further research into this large group of patients, including comparisons with patients with childhood- and adolescent onset T1D.

## 290

### After diagnosis diabetes research support system-2 (ADDRESS-2): clinical presentation of type 1 diabetes in the beginning of the 21<sup>st</sup> century in a multi-ethnic UK cohort

V. Bravis<sup>1</sup>, A. Kaur<sup>1</sup>, H. Walkey<sup>1</sup>, I. Godsland<sup>1</sup>, C. Dayan<sup>2</sup>, M. Peakman<sup>3</sup>, P. Bingley<sup>4</sup>, N. Oliver<sup>1</sup>, D.G. Johnston<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Diabetes and Metabolism, Imperial College, London, <sup>2</sup>Cardiff University School of Medicine, <sup>3</sup>Department of Immunology, King's College, London, <sup>4</sup>Diabetes and Metabolism, University of Bristol, UK.

**Background and aims:** Type 1 diabetes (T1D) most commonly presents with the classical triad of polyuria, polydipsia and weight loss but duration and pattern of symptoms may vary. The reported frequency of diabetic ketoacidosis (DKA) at presentation of T1D is 10 to 80% that has changed little over the last decades in the developing and the developed world. The purpose of our study was to determine the frequency of DKA at presentation of T1D, in a multi-ethnic UK cohort of patients and study their clinical characteristics. **Materials and methods:** The ADDRESS-2 cohort comprises people with incident T1D, and includes clinical and demographic features and, in many, islet-specific antibodies. From 01.09.11 to 31.12.13, children over 5 and adults under 60 years with T1D were recruited to ADDRESS-2 from 134 UK recruiting sites, within 6 months of diagnosis.

**Results:** 1,440 patients were recruited (1,264 white; 65% male; 55% children; mean age 20.1y, SD 12.95; median age 15y, IQR 10-28). At presentation 96.6% described osmotic symptoms, 85.8% weight loss and 84.7% fatigue. Subjects presented with none (0.6%), one (5.6%), two (20.2%) or all three symptoms (73.8%). 43.7% presented with DKA. Symptom duration ranged from under 2 weeks to over 12 months (median 3w, IQR 2-6). There was no association between symptom type and age, gender or ethnicity. Symptom duration increased significantly with increasing age ( $p<0.01$ ), female gender ( $p<0.01$ ) and Black ethnicity ( $p=0.02$ ). There was no significant difference in age between those presenting with or without DKA (DKA: median 15.5y, IQR 11-28; non-DKA: median 15y, IQR 10-28). Gender and ethnicity were not significantly different between those presenting with DKA and those without. 92% of those presenting with DKA suffered weight loss, 90% fatigue and 97% osmotic symptoms. Weight loss and fatigue were significantly more frequent with DKA ( $p<0.01$ ) but osmotic symptoms occurred at comparable frequency ( $p=0.11$ ). Increasing number of symptoms was significantly associated with DKA presentation ( $p<0.01$ ). Mean symptom duration in those

with DKA (5.1 weeks, SD 6.2) and those without (6.5 weeks, SD 18.8) was comparable ( $p=0.42$ ). Positive autoantibody (AAb) status was not associated with symptom type, number or duration or DKA at presentation. GAD AAb titre had no effect on frequency of presentation with DKA. 8.2% of those presenting with DKA had at least one other autoimmune condition versus 4.5% of those with no DKA ( $p<0.01$ ). There was no overall significant difference in weight, height, BMI or birth weight between those with DKA or not. Family history of diabetes did not correlate with symptoms but paternal diabetes was significantly more frequent in the non-DKA population ( $p=0.01$ ).

**Conclusion:** Our study offers important insight into clinical and anthropometric characteristics of patients presenting with T1D in a modern multi-Ethnic European country. The duration of symptoms is typically short and increases with age, female gender and Black ethnicity. Weight loss, fatigue and co-existing autoimmune disease are commoner in those with DKA. The frequency of DKA at presentation of T1D remains very high, suggesting that T1D remains a public-health issue.

## 291

### Serum bilirubin is inversely related to both HbA<sub>1c</sub> and complications in people with type 1 diabetes

P. Mansell, C. Chee, T. Gazis;

Diabetes and Endocrinology, Nottingham University Hospitals, UK.

**Background and aims:** There is evidence of an inverse correlation between HbA<sub>1c</sub> and serum bilirubin in people with type 2 diabetes and in healthy populations in the Far East. We have investigated this further in a UK population with type 1 diabetes, and also whether there is any association between bilirubin and microvascular complications.

**Materials and methods:** Data were extracted from the Nottingham University Hospitals diabetes register and pathology databases and the Nottingham retinopathy screening database. Of 2067 adults registered with type 1 diabetes, we excluded those with renal failure, pregnancy or a recent diagnosis of diabetes.

**Results:** 1595 people (77% of those eligible) had HbA<sub>1c</sub> and serum bilirubin levels within a 15 month window. Mean (standard deviation) age was 45 (15) years with duration of diabetes 22 (13) years. There was an inverse relationship between HbA<sub>1c</sub> and bilirubin ( $R = -0.15$ ,  $P < 0.001$ ) which persisted in a stepwise linear regression model including also sex, age and duration of diabetes. Mean HbA<sub>1c</sub> in the group with the lowest quintile of bilirubin was 76 (19) mmol/mol compared with 66 (16) mmol/mol in the highest quintile. The results were not significantly altered by excluding those with a serum bilirubin above the reference range. The group with the lowest quintile of bilirubin concentration had a higher prevalence of microalbuminuria (27.7 vs 14.2%,  $P < 0.001$ ) and of retinopathy (29.0 vs 17.7%,  $P = 0.011$ ), compared with the remainder of the cohort.

**Conclusion:** There is a significant inverse correlation between HbA<sub>1c</sub> and bilirubin in people with type 1 diabetes in a UK population. Microvascular complications were more prevalent in those with a low bilirubin concentration, suggesting the inverse association with HbA<sub>1c</sub> is not solely a biochemical artefact.

## 292

### LDL-cholesterol is not a good marker of cardiovascular risk in type 1 diabetes: observational study in 30,778 patients: a report from the national diabetes register in Sweden

C. Hero<sup>1</sup>, A.-M. Svensson<sup>2</sup>, P. Gidlund<sup>2</sup>, B. Eliasson<sup>1</sup>, K. Eeg-Olofsson<sup>1</sup>;

<sup>1</sup>Department of Medicine, <sup>2</sup>Region Västra Götaland, Swedish National Diabetes Register, Gothenburg, Sweden.

**Background and aims:** Patients with type 1 diabetes (T1D) are at high risk of cardiovascular disease (CVD). High LDL-cholesterol (LDL) is an important risk factor in general population and in type 2 diabetes. Less is known in T1D. The aim of this study was to assess LDL and total-cholesterol to HDL-cholesterol ratio (Chol/HDL) as predictors of CVD in T1D and to evaluate the risk at different levels of LDL.

**Materials and methods:** 30,778 T1D patients, age 18–79 years, were included 2003–2006 and followed for mean 6.8 years. Mean age 46 years, diabetes duration 21 years, HbA<sub>1c</sub> 8% (NGSP), LDL 2.7 mmol/L and Chol/HDL 3.2. 10% had a history of CVD. 26.6% ( $n = 8172$ ) were treated with lipid-lowering

medication, they were older, had longer diabetes duration and 24% had previous CVD.

**Results:** There were 13.8 CVD events/1000 person years (py) in patients without and 51.7 events/1000 py in patients with lipid-lowering medication. Cox regression analyses were performed with LDL and Chol/HDL as predictors and fatal/nonfatal CVD as outcome, adjusted for other CVD risk factors. Adjusted hazard ratios (HR) per 1 mmol/L increase in LDL for CVD were 1.03 (95% CI 0.99–1.08) in all, 1.05 (1.00–1.14) in those without and 1.04 (0.98–1.1) in those with treatment. All HR were non-significant. Adjusted HR per 1 unit increase in Chol/HDL for CVD were 1.08 (1.05–1.12) in all, 1.11 (1.05–1.16) in patients without and 1.08 (1.03–1.13) in patients with lipid-lowering medication. All  $p$ -values  $< 0.01$ . We also assessed risk of CVD with octiles of LDL, octile 4 as reference (LDL 2.5–2.7). Compared to reference only patients without lipid-lowering treatment, in the highest octile (LDL  $> 3.6$  mmol/L) had significant higher risk HR 1.25 (1.02–1.52).

**Conclusion:** In our study LDL was not a significant predictor of CVD in T1D apart from in patients in the highest octile not treated with lipid-lowering medication. The ratio of Chol/HDL was a significant predictor for CVD in all groups. The ratio of chol/HDL seems to be a more reliable marker for risk.

## PS 004 Epidemiology of obesity and ectopic fat

293

**Women from South Asia, Middle East and Africa at increased risk of postpartum weight retention and type 2 diabetes:**

**a multi-ethnic population based cohort study in Oslo, Norway**

C.W. Waage<sup>1,2</sup>, R.S. Falk<sup>3</sup>, C. Sommer<sup>1,4</sup>, K. Mørkrid<sup>1,2</sup>, K.R. Richardson<sup>5,6</sup>, A. Bærug<sup>7</sup>, N. Shakeel<sup>2</sup>, K.I. Birkeland<sup>1,4</sup>, A.K. Jenum<sup>2,6</sup>;

<sup>1</sup>Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, <sup>2</sup>Institute of Health and Society, Department of General Practice, Faculty of Medicine, University of Oslo, <sup>3</sup>Department of Biostatistics, Epidemiology and Health economics, Oslo University Hospital, <sup>4</sup>Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, <sup>5</sup>Norwegian Resource Centre for Womens Health, Department for Womens and Childrens Health, Oslo University Hospital, <sup>6</sup>Faculty of Health Sciences, Oslo and Akershus University College of Applied Sciences, <sup>7</sup>Norwegian Resource Centre for Breastfeeding, Oslo University Hospital, Norway.

**Background and aims:** Pregnancy has been considered a critical period for development of overweight and its complications including type 2 diabetes, both in the mother and through diverse mechanisms including epigenetic modifications, also in her child. Immigrant women of Asian and African origin living in Europe are at higher risk for obesity, type 2 diabetes and cardiovascular diseases than the native European population. Women with gestational weight gain above recommended levels from American Institute of Medicine are at increased risk of postpartum weight retention and thereby of later obesity and related co-morbidities. The aim of the study was to explore ethnic differences in postpartum weight retention three months postpartum in a population-based, multi-ethnic study of pregnant women.

**Materials and methods:** A multi-ethnic population based cohort study from Oslo, Norway of 823 healthy pregnant women, 59 % with ethnic minority background, included from 2008-2010. A total of 642 (78% of 823) were followed till three months postpartum. A multiple linear regression analyses were performed to model the relationship between postpartum weight retention and ethnicity.

**Results:** Unadjusted mean postpartum weight retention was 2.3 kg (95% confidence interval 1.7-2.9) for women from Western Europe and ranged from 3.7-6.3 kg among ethnic minority groups. The proportion of women in the highest quintile (postpartum weight retention 8.5-24.4 kg) differed by ethnicity; 12% among Western European, 9% among East Asians, 25% among South Asians, 28% among Middle Eastern, 29% among East European and 41% among African women ( $p < 0.001$  for all versus Western Europeans, except for East Asians and Eastern Europeans). Postpartum weight retention as percentage increase of pre-pregnant body weight was 3.3% among Western Europeans, 6.5% among East Asians, 7.6% among Middle Eastern, 8.0% among Eastern Europeans, 8.4% among South Asians and 9.3% among women from Africa. After adjustments for age, gestational weight gain, parity and education, women from South Asia retained 2.8 kg (95% confidence interval 1.9-3.6), Middle East 2.0 kg (95% confidence interval 1.0-3.0) and women from Africa 4.4 kg (95% confidence interval 3.1-5.8) more than Western Europeans ( $p < 0.001$ ).

**Conclusion:** Significantly more women from South Asia, Middle East and Africa had postpartum weight retention in the highest quintile compared to Western European women.

*Clinical Trial Registration Number:* 2009/617

**The 'obesity paradox' and mortality in adults with type 2 diabetes: explained by collider biases**

E.L. Badrick<sup>1</sup>, M. Sperrin<sup>1</sup>, M. Carr<sup>1</sup>, T. Moran<sup>2</sup>, I. Buchan<sup>1</sup>, A. Renehan<sup>3</sup>;

<sup>1</sup>Institute of Population Health, University of Manchester,

<sup>2</sup>NHS, Northwest Cancer Intelligence Service,

<sup>3</sup>Institute of Cancer Sciences, University of Manchester, UK.

**Background and aims:** Among adults with type 2 diabetes (T2D), being overweight or obese near the time of diagnosis is associated with reduced risk of mortality compared with normal-weight patients - the 'obesity paradox'. We tested the hypothesis that the strengthening of the negative association

between smoking and BMI induced by the conditioning on the disease state, T2D, explains the obesity paradox.

**Materials and methods:** We developed the logic of collider bias as it pertains to the association between smoking and body mass index (BMI) in 10761 patients with T2D from the Salford Integrated Records database (Manchester, UK). We related peri-diagnosis BMI (within a year of diagnosis) and mortality using flexible parametric survival analyses with age (35 to 85 years) as the timescale, adjusting for sex and stratified by smoking, with BMI 25 to <30 kg/m<sup>2</sup> as a referent group.

**Results:** There were 1247 deaths during a mean period of 8.57 years of follow-up. A U-shaped association was observed across BMI categories (18.5 to 25.9, 25.0 to 29.9 [reference], 30.0 to 35.4, 35.0 to 39.9, and  $\geq 40.0$ ) for all-cause mortality (hazard ratio plus 95% confidence interval [CI], 1.22 (1.05-1.42); 1.00; 0.97 (0.84-1.13); 1.33 (1.09-1.62); 2.02 (1.59-2.56) respectively). The U-shaped relationship was retained in ever-smokers, but in never smokers, increased risk of mortality was only seen in Obese II-III groups (2.43 CI 1.68-3.50). The U-shaped relation was noted in younger but not older 10-year age bands. Associations remain after excluding patients who died or were censored within 2-years of diabetes diagnosis, suggesting reverse causality was not a major confounder.

**Conclusion:** We confirmed that, among adult patients with incident T2D, being normal weight or obese II/III is associated with higher mortality compared with overweight and obese I categories, but these observations were explained by collider biases due to associations of age and smoking with mortality in the diseased population. Weight loss interventions to reduce mortality in patients with T2D merits future research.

**Impact of visceral fat on skeletal muscle mass in a prospective cohort study: the Korean Sarcopenic Obesity Study (KSOS)**

H. Hong<sup>1</sup>, T. Kim<sup>2</sup>, J. Ryu<sup>1</sup>, S. Kim<sup>1</sup>, J. Yu<sup>1</sup>, N. Kim<sup>1</sup>, J. Ahn<sup>1</sup>, H. Yoo<sup>1</sup>, H. Kim<sup>1</sup>, J. Seo<sup>1</sup>, S. Kim<sup>1</sup>, N. Kim<sup>1</sup>, S. Baik<sup>1</sup>, D. Choi<sup>1</sup>, K. Choi<sup>1</sup>;

<sup>1</sup>Division of Endocrinology and Metabolism, Korea University College of Medicine, <sup>2</sup>Department of Internal Medicine, Cardiovascular and Metabolic Disease Center, College of Medicine, Inje University, Busan, Republic of Korea.

**Background and aims:** To investigate whether visceral obesity promotes a decrease in skeletal muscle mass and vice versa.

**Materials and methods:** We observed changes in anthropometric and body composition data during a follow-up period of  $27.6 \pm 2.8$  months in 379 Korean men and women (mean age  $51.9 \pm 14.6$  years) from the Korean Sarcopenic Obesity Study (KSOS), an ongoing observational prospective cohort study.

**Results:** Appendicular skeletal muscle mass (ASM) and total skeletal muscle mass were calculated using dual-energy X-ray absorptiometry, and visceral fat area (VFA) was measured using computed tomography at baseline and follow-up examination along with the various kinds of confounding or possible mediating factors. Both ASM and total skeletal muscle mass significantly decreased, whereas trunk and total fat mass increased in both men and women despite no significant change in weight and body mass index. Correlation analysis adjusting for age and gender revealed that baseline VFA was negatively correlated with changes in ASM ( $P = 0.001$ ). However, baseline ASM was not significantly associated with changes in VFA ( $P = 0.135$ ). In particular, women with visceral obesity at baseline had a greater decrease in ASM than those without visceral obesity ( $P = 0.001$ ). In multiple linear regression analysis, baseline VFA was an independent negative predictor of the changes in ASM after adjusting for confounding factors including age, gender, life style parameters, insulin resistance, high sensitivity C-reactive protein and vitamin D levels ( $P = 0.001$ ), whereas the association between baseline ASM and changes in VFA was not statistically significant ( $P = 0.142$ ).

**Conclusion:** This longitudinal study showed that visceral obesity was associated with future loss of skeletal muscle mass in Korean adults. These results may provide novel insight into sarcopenic obesity in an aging society.

## 296

**Visceral fat is associated with hyperglycaemia after renal transplantation**M. von Düring<sup>1</sup>, T. Jenssen<sup>1,2</sup>, J. Bollerslev<sup>3</sup>, K. Godang<sup>3</sup>, A. Aasberg<sup>4</sup>, A. Hartmann<sup>1</sup>;<sup>1</sup>Department of Organ Transplantation, Section of Nephrology, University of Oslo, Rikshospitalet, <sup>2</sup>Institute of Clinical Medicine, Faculty of Health Science, University of Tromsø, <sup>3</sup>Section of Specialized Endocrinology, <sup>4</sup>Department of Pharmaceutical Biosciences, School of Pharmacy, University of Oslo, Rikshospitalet, Norway.

**Background and aims:** Hyperglycaemia and new onset diabetes after transplantation (NODAT) are common complications in renal transplant recipients and are associated with impaired long-term survival. Studies in the non-transplant population suggest that visceral fat facilitates development of type 2 diabetes. The role of visceral fat for development of NODAT is not known. The aim in this study was to elucidate this relationship between visceral fat content and hyperglycaemia in renal transplant patients.

**Materials and methods:** We studied 159 renal transplant patients without a prior diagnosis of diabetes. All of them underwent oral glucose-tolerance tests (OGTTs) in a stable phase 10 weeks after transplantation. Visceral fat content was analyzed by a newly validated software (CoreScan) applied after total body composition DXA-scans using Lunar Prodigy, software version 14.10.

**Results:** The amount of visceral fat (median 1.0 kg, interquartile range = IQR 0.4 - 1.9 kg) was highest in patients with NODAT (median 2.2 kg, IQR 1.2-2.7). There was a significant difference in the amount of visceral fat between the categories of glucose tolerance; NODAT, impaired glucose tolerance (median 1.2 kg), impaired fasting glucose (median 1.0 kg) and normal glucose tolerance (median 0.8 kg) (Kruskal-Wallis ANOVA,  $p = 0.003$ ). The percentage visceral fat of the total fat mass was 97% higher in patients with NODAT (median 7.7%, IQR 6.0-8.6%) compared with NGT patients (median 3.9%, IQR 2.0-5.8%) ( $p < 0.001$ ). Percentage visceral fat of total fat mass was also a better predictor of both fasting (fPG,  $R^2 = 0.116$ ,  $p < 0.001$ ) and 2-hour plasma glucose (2hPG,  $R^2 = 0.082$ ,  $p < 0.001$ ), compared to total body fat per se or BMI in a multiple regression analysis.

**Conclusion:** Visceral fat is adversely associated with glucose metabolism in renal transplant recipients. Whether reduction of visceral fat mass may prevent development of NODAT needs further studies.

## 297

**Increased risk for diabetes development in non-diabetic Korean subjects with hypertriglyceridaemic waist phenotype**

E.-J. Rhee, M. Lee, H. Park, W. Jeon, S. Park, C.-Y. Park, W.-Y. Lee, K.-W. Oh, S.-W. Park;

Endocrinology, Department of Endocrinology and Metabolism, Kangbuk Samsung Hospital, Sungkyunkwan University, Seoul, Republic of Korea.

**Background and aims:** Hypertriglyceridemic waist (HTGW) phenotype is a simple and inexpensive screening parameter to identify people at increased risk for cardiovascular disease. We evaluated whether the HTGW phenotype predicts diabetes in Korean urban adults.

**Materials and methods:** 2,900 non-diabetic subjects (mean age 44.3 years) including 2078 male (71.7%) and 822 female (28.3%), who did annual medical check-up in a university hospital for four consecutive years were recruited. The subjects were divided into four groups according to the baseline serum triglyceride (TG) and waist circumference (WC); normal WC-normal TG (NWNT), normal WC-high TG (NWHT), high WC-normal TG (HWNT), high WC-high TG (HWHT). High serum TG was defined as  $TG \geq 150$  mg/dL and high WC was defined as  $WC \geq 90$  cm for men and  $\geq 85$  cm for women. New cases of diabetes were determined according to the self-questionnaire of the participants and fasting plasma  $\geq 126$  mg/dL. Cox proportional hazard model analysis was used to assess the cumulative incidence of diabetes according to baseline HTGW phenotypes.

**Results:** 101 (3.5%) new diabetes cases were diagnosed during four years of follow-up period. The subjects in HWHT group had the highest incidence of diabetes (8.3%) compared with the NWNT group (2.2%). The adjusted hazard ratio (aHR) for developing diabetes in the presence of HWHT phenotype at baseline was 4.11 (95% confidence interval [CI] = 2.40-7.06) after adjusting for age, and 2.44 (95% CI = 1.38-4.33) after adjusting for age, sex, total cholesterol and systolic pressure, when NWNT group was considered as the reference group.

**Conclusion:** This study demonstrated that HWHT showed the highest risk for diabetes development during four years of follow-up period. Recognizing HWHT type would be useful to identify individuals at high-risk of diabetes and, which is of great significance in reducing the incidence of diabetes among Korean urban adults.

## 298

**Metabolically healthy obesity, presence or absence of fatty liver, and risk of type 2 diabetes in Japanese individuals**Y. Heianza<sup>1,2</sup>, Y. Arase<sup>2</sup>, K. Fujihara<sup>1</sup>, S. Hsieh<sup>2</sup>, K. Saito<sup>1,2</sup>, O. Hanyu<sup>1</sup>, S. Kodama<sup>1,2</sup>, S. Hara<sup>2</sup>, H. Sone<sup>1,2</sup>;<sup>1</sup>Department of Internal Medicine, Niigata University Faculty of Medicine, <sup>2</sup>Health Management Center, Toranomon Hospital, Tokyo, Japan.

**Background and aims:** Whether a “metabolically healthy obese (MHO) phenotype” that does not include typical obesity-related metabolic abnormalities is really a benign or malignant state has not been elucidated in terms of predicting the progression to type 2 diabetes. We investigated whether the MHO phenotype was associated with an increased risk of the development of diabetes. If so, we aimed to determine what factors could explain this finding.

**Materials and methods:** Studied were 8090 Japanese individuals without diabetes (diabetes indicated by the ADA criteria). Metabolic health status was assessed by common clinical markers: blood pressure, triglycerides, HDL-cholesterol, and fasting glucose concentrations. Cut-off value for obesity (O) or normal weight (NW) was a BMI of  $25.0$  kg/m<sup>2</sup>. Participants were categorized at the baseline examination into 4 phenotypes: 1) metabolically healthy and normal weight (MHNW), 2) metabolically healthy and overweight or obese (MHO), 3) metabolically abnormal and normal weight (MANW), or 4) metabolically abnormal and overweight or obese (MAO).

**Results:** The 5-year incidence rate of diabetes was 1.2% ( $n=58/4749$ ) in MHNW individuals, 2.8% ( $n=20/719$ ) in MHO individuals, 6.0% ( $n=102/1709$ ) in MANW individuals, and 10.3% ( $n=94/913$ ) in MAO individuals. Although the MHO individuals had no or 1 metabolic factor, 47.8% had ultrasonographic fatty liver (FL). The MHO group had a significantly increased risk of diabetes compared to the MHNW group (multivariate-adjusted OR, 2.23 (95% CI 1.33, 3.75)), but this risk was attenuated after adjustment for FL. We then assessed the combined effect of obese phenotypes and FL on the development of diabetes. MHNW/non-FL group had the lowest incidence rate of diabetes (0.9%), and MHO/non-FL group also had a similarly low incidence rate of diabetes (1.1%). On the other hand, the MHO/FL group had an elevated incidence rate (4.7%). Incidence rate of diabetes was markedly high at 8.5% in the MANW/FL group and 12.6% in the MAO/FL group. Compared to the MHNW/non-FL group, the risk of diabetes in the MHO/non-FL group was not significantly elevated (OR 1.01 (0.35, 2.88)). However, the MHO/FL and MHNW/FL groups had similarly elevated risks of diabetes (OR 4.09 (95% CI 2.20, 7.60) and 3.16 (1.78, 5.62), respectively). A prediction model with age, sex, and obese phenotypes had an area under the ROC curve (AUCROC) of 0.754 for the development of diabetes. The AUCROC was slightly but significantly ( $p < 0.001$ ) improved when we added the assessment of FL into the model, with an area under the ROC curve of 0.778. The net reclassification improvement was 8.8% (95% CI 1.7% to 15.8%) by introducing the assessment of fatty liver in the prediction model.

**Conclusion:** Our results showed that individuals with MHO as defined in this study had a significantly higher risk of the development of diabetes compared to MHNW individuals without consideration of the presence of ectopic fat in the liver. However, at baseline almost half of MHO individuals had an accumulation of fat in liver as assessed by ultrasonography, and this observation partially explained the increased risk of diabetes among the MHO individuals. The presence of FL should be evaluated to assess whether an individual was actually in a metabolically benign state in predicting the development of diabetes.

## 299

**Presence and severity of obstructive sleep apnoea is independently associated with glycometabolic abnormalities in obese non-diabetic subjects**

A. Cignarelli<sup>1</sup>, S. Perrini<sup>1</sup>, A. Ciavarella<sup>1</sup>, S. Kounaki<sup>1</sup>, V. Quaranta<sup>2</sup>, M. Barbaro<sup>1</sup>, A. Di Trani<sup>1</sup>, V. Falcone<sup>2</sup>, A. Natalicchio<sup>1</sup>, L. Laviola<sup>1</sup>, O. Resta<sup>2</sup>, F. Giorgino<sup>1</sup>;

<sup>1</sup>Endocrinology & Metabolic Diseases,

<sup>2</sup>Respiratory Diseases, University of Bari, Italy.

**Background and aims:** Obstructive sleep apnea (OSA) is a common underdiagnosed condition in the obese population, and has been associated with worse glycemic control in individuals with type 2 diabetes. The relationship between OSA and glycometabolic parameters was investigated in obese non-diabetic individuals.

**Materials and methods:** Ninety-one obese subjects (57% male, mean age 45.3 ± 12 yrs, mean BMI 42.1 ± 9 kg/m<sup>2</sup>) underwent polysomnography and a 2-h oral glucose tolerance test (OGTT).

**Results:** OSA was identified in 64% of subjects (73% in male, 41% in female,  $p=0.032$   $\chi^2$ ). Obese subjects with OSA showed higher A1c (5.8% vs 5.5%,  $p=0.009$ ), plasma glucose at 120 min during OGTT (PPG120) (133 mg/dl vs 102 mg/dl,  $p=0.001$ ), triglyceride (140 mg/dl vs 117 mg/dl,  $p=0.045$ ) and uric acid (5.8 mg/dl vs 4.9 mg/dl,  $p=0.035$ ) levels than obese subjects without OSA. A1c levels and PPG120 were found to be significantly correlated with raised apnea-hypopnea index (AHI) ( $p=0.007$  and  $p=0.004$ , respectively), oxygen desaturation index ( $p=0.002$  and  $p=0.04$ , respectively), and percent of sleep time with oxyhaemoglobin saturation at <90% (ST90) ( $p=0.002$  and  $p=0.004$ , respectively). Furthermore, increasing quartiles of ST90 and AHI were associated with increasing levels of A1c and PPG120 ( $p=0.015$  and  $p=0.003$ , respectively, for ST90; and  $p=0.035$  and  $p=0.014$ , respectively, for AHI). Multiple regression analysis showed that ST90 was the strongest independent determinant of A1c, after controlling for sex, age, BMI, waist circumference, CRP, HOMA-IR ( $\beta=0.442$ ,  $p=0.007$ ). Similarly, AHI persisted as an independent determinant of A1c ( $\beta=0.414$ ,  $p=0.005$ ). Both ST90 and AHI persisted as determinants of PPG120, albeit not significantly ( $\beta=0.377$ ,  $p=0.095$ ; and  $\beta=0.358$ ,  $p=0.119$ , respectively).

**Conclusion:** OSA acts as an independent factor exacerbating the metabolic risk attributed to obesity. Recognition and treatment of OSA may decrease the progression toward type 2 diabetes in obese subjects.

## 300

**Retrospective analysis of fatty liver markers for incident diabetes: comparison between people with lower alcohol intake and higher alcohol intake**

S. Katoh<sup>1</sup>, M. Kaji<sup>1</sup>, M. Zeniya<sup>1</sup>, Y. Sakamoto<sup>1</sup>, K. Utsunomiya<sup>2</sup>;

<sup>1</sup>Harumi Triton Clinic, <sup>2</sup>Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.

**Background and aims:** Although fatty liver is a risk factor for incident diabetes, markers of fatty liver for incident diabetes have yet to be sufficiently investigated. We retrospectively analyzed fatty liver markers including serum cholinesterase (ChE) for incident diabetes and compared them between people with lower alcohol intake and higher alcohol intake in accordance with cut-off point for non-alcoholic fatty liver disease (ethanol intake 140g/week).

**Materials and methods:** Study periods I and II were defined as January 2007 to May 2009 and June 2009 to December 2011, respectively. A total of 2084 people (1389 men, 695 women; mean age: 46 years) who underwent an annual medical check-up including blood sampling after an overnight fast in Periods I and II were recruited. They were accumulated as representatives of the diurnal regional population. We excluded people positive for hepatitis B virus antigen and hepatitis C virus antibody as well as those with diabetes in Period I. Others were divided into lower alcohol intake (LAI) group (ethanol intake ≤ 140g/week,  $n=1515$ ) or higher alcohol intake group (HAI) group (ethanol intake > 140g/week,  $n=448$ ). In this study, diabetes was diagnosed by prescription of antidiabetic agents, fasting plasma glucose (FPG) ≥ 6.8mmol/l, HbA1c (NGSP) ≥ 6.5% and/or a past history of diabetes in those not yet treated with antidiabetic agents. Fatty Liver Ultrasonography scores (FLUS) were also assigned as follows: 2 points, subjects with moderate or severe fatty liver; 1 point, those with mild fatty liver; 0 points, those with normal liver. Regression coefficient (B) was calculated using logistic regression analysis.

**Results:** The mean observation period was 2.23 years, with 27 LAI subjects and 15 HAI subjects with newly developed diabetes from Periods I to II. The remaining 1488 LAI subjects and 433 HAI subjects were nondiabetic. In logistic regression analysis, alanine aminotransferase (ALT) was independently and significantly ( $B=0.025$ ,  $p=0.017$ ) associated with incident diabetes as well as age ( $B=0.065$ ,  $p=0.008$ ), BMI ( $B=0.264$ ,  $p=0.050$ ), waist circumference (WC) ( $B= - 0.120$ ,  $p=0.036$ ), fasting plasma glucose (FPG) ( $B=0.116$ ,  $p<0.001$ ) in Period I in the LAI group. Systolic and diastolic BP, Gamma-GTP, ChE, FLUS, triglyceride and HDL cholesterol were not associated. In receiver operating characteristic (ROC) analysis, the specific cut-off point in ALT in Period I for detecting incident diabetes was 24U/l (AUC 0.73,  $p<0.001$ , sensitivity 70%, specificity 70%) in the LAI group. In the HAI group, ChE was independently and significantly ( $B=0.013$ ,  $p=0.009$ ) associated with incident diabetes as well as HDL cholesterol ( $B= - 0.069$ ,  $p=0.046$ ) and FPG ( $B=0.315$ ,  $p<0.001$ ) in Period I. ALT, age, BMI, WC, systolic and diastolic BP, Gamma-GTP, FLUS and triglyceride were not associated. In ROC analysis, the specific cut-off point in ChE in Period I for incident diabetes was 372U/l (AUC 0.72,  $p<0.005$ , sensitivity 78.6%, specificity 64.8%) in the HAI group.

**Conclusion:** Although FPG was a powerful predictor for incident diabetes, ALT and ChE also independently affected incident diabetes in LAI group and HAI group, respectively. The ALT and ChE would be useful fatty liver markers for incident diabetes in non-alcoholic fatty liver disease and alcoholic fatty liver disease, respectively.

## PS 005 Descriptive epidemiology of diabetes

### 301

#### One normal range for HbA<sub>1c</sub> in every age? The effect of aging on HbA<sub>1c</sub> in the people without diabetes

J. Roth<sup>1</sup>, N. Müller<sup>1</sup>, C. Kloos<sup>1</sup>, U.A. Müller<sup>1</sup>, G. Wolf<sup>2</sup>;

<sup>1</sup>Department of Internal Medicine III, Department Endocrinology and Metabolic Disorders, <sup>2</sup>Department of Internal Medicine III, Jena, Germany.

**Background and aims:** Goals for HbA<sub>1c</sub> in National Guidelines and the cut-off value for diagnosis of diabetes are not adjusted for age yet. The Framingham Offspring Study and the National Health and Nutrition Examination Survey 2001–2004 showed a 0.6% increase of HbA<sub>1c</sub> for non diabetic people over the age of 70 compared to people below the age of 40 years. We evaluated this question in a German population.

**Materials and methods:** We analyzed the data from 10163 visits of 3861 patients without diabetes (age 44.7y; 18–93y; 72.6% women; BMI 28.0±6.5 kg/m<sup>2</sup>) which had parallel HbA<sub>1c</sub> and blood glucose measurements and information about drug treatment. The HbA<sub>1c</sub> values were divided in 3 age groups (<40y [n=3583]; ≥40 < 70y [n=5454]; >70y [n=1126]). Patients with gestational diabetes mellitus, documented use of systemic glucocorticoids or HbA<sub>1c</sub> ≥6.5% were excluded. A glucose tolerance test was not performed. Data were drawn from the electronic patients record (EMIL<sup>®</sup>) of our university outpatient department for endocrinology and metabolic disorders between 10/1992 and 01/2014. HbA<sub>1c</sub> was DCCT adjusted (mean normal range of healthy people 5.05%).

**Results:** The mean HbA<sub>1c</sub> (95. percentile) for the groups of age was: <40years 5.0±0.36% (5.6%), ≥40 < 70 years 5.3±0.38% (5.9%), ≥70 years 5.4±0.37% (6.0%). The differences between <40 years vs. 40–70 years, <40 y vs. >70 y (p<0.001) and 40–70 y vs. >70 y (p<0.001) were significant. The mean blood glucose (non fasting) was <40y 4.5±0.6; 5.2±1.1 mmol/l; ≥40 < 70y 5.0±0.74; 5.3±1.0 mmol/l and ≥70y 5.1±0.85; 5.5±1.1 mmol/l. The differences < 40 vs. 40–70y (p<0.001) and >70y (p<0.001); and 40–70y vs. >70y (p<0.001) were also significant.

**Conclusion:** HbA<sub>1c</sub> increases significantly with the age of people without diabetes. The use of different cut-off values for the diagnosis of diabetes according to age should be considered. Also HbA<sub>1c</sub> goals for old people with diabetes should consider the age dependent increase of HbA<sub>1c</sub>.

### 302

#### The association of smoking cessation with HbA<sub>1c</sub> control of diabetes mellitus: a THIN database study

L. Nichols<sup>1</sup>, R. Ryan<sup>1</sup>, A. Farley<sup>2</sup>, A. Roalfe<sup>1</sup>, M. Mohammed<sup>3</sup>, L. Szatkowski<sup>4</sup>, T. Coleman<sup>4</sup>, R. Morris<sup>5</sup>, A. Farmer<sup>6</sup>, P. Aveyard<sup>6</sup>, D. Lycett<sup>7</sup>;

<sup>1</sup>Primary Care Clinical Sciences, University of Birmingham, <sup>2</sup>Public Health, Epidemiology and Biostatistics, University of Birmingham, <sup>3</sup>University of Bradford, <sup>4</sup>University of Nottingham, <sup>5</sup>University College London, <sup>6</sup>University of Oxford, <sup>7</sup>Coventry University, UK.

**Background and aims:** Smoking increases the risk of developing type 2 diabetes mellitus. However several large observational studies have found during the first 3–5 years following smoking cessation the risk of developing diabetes is significantly greater than in continuing smokers; an association largely explained by weight gain. This increase in risk is temporary and after 10–12 years the risk is equivalent to never-smokers. There is also preliminary evidence from small cohort studies, in those who already have diabetes that control deteriorates during the first year after smoking cessation before it improves. Our objective was to examine whether an association between smoking cessation and diabetes control exists in a large representative sample of the UK population. If deterioration in diabetes control around the time of smoking cessation does occur, this may have implications for enhanced diabetic care at that time.

**Materials and methods:** A retrospective cohort study (01/01/2005 – 31/12/2010) was assembled using The Health Improvement Network (THIN) database. Inclusion criteria were: patients aged over 18, registered with their practice for at least one year on 01/01/2005, diagnosed with type 2 diabetes mellitus and whose last recorded smoking status prior to 01/01/2005 was current smoker. An adjusted multilevel regression model was developed to investigate the association between change in HbA<sub>1c</sub> and stopping smoking.

**Results:** There were 10,692 adults with type 2 diabetes who were current smokers as at 01/01/2005. Of these, 3,131 (29%) quit smoking and remained abstinent for one year or longer. After adjustment for potential confounders, patients who quit smoking had an average increase in HbA<sub>1c</sub> after quitting of 2.3mmol/l (95% CI 1.91 to 2.77, p<0.001). HbA<sub>1c</sub> did decrease as abstinence continued although the modelled trajectory showed this did not return to the levels seen in continuing smokers until 3 years after quitting. This increase in HbA<sub>1c</sub> was not mediated by weight change after quitting smoking.

**Conclusion:** Smoking cessation is associated with deterioration in glycaemic control in people with type 2 diabetes that persists for three years and appears not to be caused by weight gain. The rise in HbA<sub>1c</sub> is minor for each patient and clinician but will substantially increase microvascular complications in the whole population, which could be prevented by prompt action to improve glycaemic control on cessation. While we used an algorithm to help minimise the inaccuracies of recording smoking status within the THIN database and adjusted for missing data using imputation, our data is nonetheless limited by the accuracy of the information available within the THIN database. However, it provides the largest study so far on this phenomenon and confirms for the first time preliminary evidence of an association between quitting and worsening glycaemic control. It highlights the need for proactive review of glycaemic control and the need for prompt adjustment of medication in people with diabetes following smoking cessation.

### 303

#### How useful is HbA<sub>1c</sub> for diagnosis of diabetes in acute medical admissions?

K.T. O'Brien<sup>1</sup>, A. Liew<sup>1</sup>, F.M. Ali<sup>1</sup>, D. Quinlan<sup>1</sup>, R.A. Round<sup>2</sup>, I.M. Stratton<sup>3</sup>, P.G. Nightingale<sup>4</sup>, S.E. Manley<sup>2</sup>, G.A. Roberts<sup>1</sup>;

<sup>1</sup>Endocrinology and Diabetes Research Group, Waterford Institute of Technology, Ireland, <sup>2</sup>Clinical Biochemistry, University Hospitals Birmingham NHS Foundation Trust, Birmingham, <sup>3</sup>Gloucester Diabetic Retinopathy Research Group, Gloucestershire Hospitals NHS Foundation Trust, Cheltenham, <sup>4</sup>Wellcome Trust Clinical Research Facility, University Hospitals Birmingham NHS Foundation Trust, UK.

**Background and aims:** The detection of hyperglycaemia is important in acutely ill patients who may present with either undiagnosed diabetes, symptoms or complications of diabetes, or stress hyperglycaemia; all indicating worse outcomes.

**Materials and methods:** Over a 2 year period, 2061 (14%) patients were admitted to hospital by one consultant physician out of a total of 14432 patients. OGTT was performed in 390 (19%) patients during their admission because of suspected symptoms or complications of diabetes. IFCC-calibrated HbA<sub>1c</sub> was measured by Menarini HA8160 IE HPLC in 148 (38%) of these patients and also 22 (1%) patients diagnosed with diabetes at admission.

**Results:** The acutely ill patients diagnosed with diabetes immediately were white Caucasian, >18 years old, aged (median IQ range) 36(26 to 61) years, 55% male with admission plasma glucose (PG mmol/L) 19.3(11.8 to 27.4). Fasting PG on OGTT in those with possible symptoms or complications of diabetes, aged 70(59 to 79) years, 63% male with admission PG 6.4(5.6 to 7.4), was 5.2(4.8 to 5.7). This was similar to fasting PG on OGTT of 5.2(4.8 to 5.9) in 108 white Caucasian, primary care patients, aged 54(46 to 61) years, who were at increased diabetes risk, p=0.65. As expected, 2hPG at 9.0(7.3 to 11.4) was higher in acutely ill patients than GP patients, 5.5(4.4 to 7.5), p<0.001. HbA<sub>1c</sub> (%/mmol/mol) was highest in those diagnosed immediately on admission at 10.2(7.4 to 13.3)/88(57 to 122), p<0.001, and similar in the other groups of patients i.e. 5.7(5.3 to 6.0)/39(34 to 42) in admissions and 5.7(5.4 to 6.1)/39(36 to 43) in GP patients, p=1.00. At OGTT, 15/148 (10%) were diagnosed with diabetes on HbA<sub>1c</sub> with 14/15 (93%) confirmed on OGTT. More patients, 48/148 (32%), were diagnosed with diabetes on OGTT than HbA<sub>1c</sub>.

**Conclusion:** HbA<sub>1c</sub> could play a diagnostic role in acute medicine as outlined in the ADA 2014 Clinical Practice Recommendations which are based on expert opinion and for which more evidence is requested. Those with very high HbA<sub>1c</sub> will possibly have been diabetic for some time before admission.

304

**Achievement of individualised HbA<sub>1c</sub> treatment targets in patients with type 2 diabetes and comorbid hypertension in a real world setting: results of the DIALOGUE registry**

D. Tschöpe<sup>1</sup>, R.E. Schmieder<sup>2</sup>, C. Koch<sup>3</sup>, P. Bramlage<sup>4</sup>, T. Ouarrak<sup>5</sup>, A.K. Gitt<sup>6</sup>;

<sup>1</sup>Herz- und Diabeteszentrum Nordrhein-Westfalen, Bad Oeynhausen, <sup>2</sup>Med. Klinik <sup>4</sup>, Schwerpunkt Nephrologie / Hypertensiologie, Universitätsklinikum Erlangen, <sup>3</sup>Novartis Pharma GmbH, Nürnberg, <sup>4</sup>Institut für Pharmakologie und präventive Medizin, Mahlow, <sup>5</sup>Stiftung „Institut für Herzinfarktforschung“, Ludwigshafen, <sup>6</sup>Medizinische Klinik B, Herzzentrum Ludwigshafen, Germany.

**Background and aims:** The recent EASD consensus statement has re-focused on individualized HbA<sub>1c</sub> Treatment targets in the care of patients with type-2 diabetes mellitus. There are, however, neither clinical practice data on actually pursued treatment targets nor on patient characteristics associated with either strict or loose treatment targets.

**Materials and methods:** DIALOGUE is a prospective, observational, multi-center registry focusing on treatment targets and their achievement in clinical practice. Physicians were asked at baseline on HbA<sub>1c</sub> treatment targets pursued and compared to actual HbA<sub>1c</sub> values achieved at 6 months.

**Results:** A total of 8,636 patients were included. For 3,371 of these (39.0%) an HbA<sub>1c</sub> target of ≤6.5% (strict group), for 3,647 (42.2%) a target of >6.5 to ≤7.0% (medium) and for 1,618 (18.7%) a target of >7.0 to ≤7.5% (loose) was pursued. Patients in the strict target group were younger, had lower fasting and postprandial blood glucose values, shorter diabetes duration and less co-morbid disease at baseline than the other groups (table). At the 6 months follow-up the mean (±SD) HbA<sub>1c</sub> achieved in the strict group was 6.8±0.9% with 25% of patients exceeding 7.1%. Corresponding values for the medium and loose target group were 7.2±0.9 (25% >7.6%) and 7.7±1.2 (25% >8.3%), respectively (p<0.0001). There was a higher rate of long-acting insulin use (15.7%) in the loose target group than in the strict and medium group (8.2 vs. 14.5%) (p<0.0001).

**Conclusion:** The data illustrate a differentiated selection of HbA<sub>1c</sub> treatment targets in patients with type-2 diabetes in Germany. Patients with strict targets typically are younger, have lower blood glucose values and less comorbidity, while loose targets are sought in those with existing complications.

**Achievement of personalised HbA<sub>1c</sub> targets in patients with type 2 diabetes from the RIACE cohort**

G. Pugliese<sup>1</sup>, E. Bonora<sup>2</sup>, E. Orsi<sup>3</sup>, C. Fondelli<sup>4</sup>, R. Trevisan<sup>5</sup>, M. Vedovato<sup>6</sup>, F. Cavalot<sup>7</sup>, L. Laviola<sup>8</sup>, M.G. Baroni<sup>9</sup>, S. Morano<sup>10</sup>, A. Solini<sup>11</sup>, G. Penno<sup>11</sup>;

<sup>1</sup>Department of Clinical and Molecular Medicine, La Sapienza University, Rome, <sup>2</sup>Division of Endocrinology and Metabolic Diseases, University of Verona, <sup>3</sup>Diabetes Unit, Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, <sup>4</sup>Diabetes Unit, University of Siena, <sup>5</sup>Endocrinology and Diabetes Unit, Ospedali Riuniti, Bergamo, <sup>6</sup>Department of Clinical and Experimental Medicine, University of Padua, <sup>7</sup>Department of Clinical and Biological Sciences, University of Turin, Orbassano, <sup>8</sup>Department of Emergency and Organ Transplantation, University of Bari, <sup>9</sup>Department Experimental Medicine, La Sapienza University, Rome, <sup>10</sup>Department of Experimental Medicine, La Sapienza University, Rome, <sup>11</sup>Department of Clinical and Experimental Medicine, University of Pisa, Italy.

**Background and aims:** Though the HbA<sub>1c</sub> goal has been set at 7%, the use of personalized targets is currently recommended by several guidelines. This study was aimed at assessing the percentage of subjects with type 2 diabetes from the Renal Insufficiency And Cardiovascular Events (RIACE) Italian Multicenter Study who reach individualized HbA<sub>1c</sub> goals.

**Materials and methods:** The RIACE cohort consists of 15,773 patients, consecutively visiting 19 Diabetes Clinics throughout Italy in years 2007-2008. Exclusion criteria were dialysis or renal transplantation. HbA<sub>1c</sub> was measured by HPLC using DCCT-aligned methods. Starting from a baseline HbA<sub>1c</sub> goal of <6.5%, the target has been arbitrarily increased by 0.5% according to the presence of each of the following criteria: age >70 years; disease duration >10 years; advanced complications; and co-morbidities. As a consequence, 5 HbA<sub>1c</sub> targets were identified ranging from <6.5% to >8.5%.

**Results:** Mean HbA<sub>1c</sub> was 7.55±1.51% (median 7.30%, IQR 6.51-8.28%). The overall prevalence of subjects with HbA<sub>1c</sub> <7.0% was 40.9% (n=6,453), higher in men than in women (43.2% vs. 37.9%; p<0.0001). The 7.0% goal was reached by 71.0% of patients not taking any medication, 42.1% of those on oral hypoglycaemic agents (OHA), 17.4% of those on OHA+insulin and 24.6% of those on insulin alone (p<0.0001), with a similar trend between genders. In the RIACE cohort, 5,512 subjects (34.9%) were >70 years old, 7,931 (50.3%) had diabetes duration >10 years, 4,819 (30.6%) had ≥1 advanced complication and 2,803 (17.8%), had ≥1 severe co-morbidity. Moreover, 4,110 (G0, 26.1%), 4,914 (G1, 31.2%), 4,444 (G2, 28.2%), 1,957 (G3, 12.4%), and 348 (G4, 2.2%) met 0, 1, 2, 3, and 4 of the above criteria, respectively. The prevalence of subjects meeting personalized goals were: G0 (goal <6.5%) 34.3%; G1 (<7.0%) 41.8%; G2 (<7.5%) 50.2%; G3 (<8.0%) 59.9%; and G4 (<8.5%) 73.8% (p<0.0001); in men: G0 36.1%, G1 43.5%, G2 51.5%, G3 63.5%; and G4 77.5% (p<0.0001); in women G0 32.0%, G1 39.5%, G2 48.3%, G3 55.1%; and G4 68.7% (p<0.0001). The overall prevalence of subjects meeting personalized targets was 45.2% (47.2% in men vs. 42.8% in women, p<0.0001). After excluding subjects with HbA<sub>1c</sub> <6.5% from G2-G4, the percentage of those on-target was 37.6% (38.9% in men vs. 36.1% in women, p<0,0001).

**Conclusion:** Personalizing HbA<sub>1c</sub> goals increases the prevalence of subjects on-target, especially among those with more advanced disease. However, more than 50% of patients, and particularly 2/3 of those with short-duration, uncomplicated disease, do not meet the recommended HbA<sub>1c</sub> targets.

Clinical Trial Registration Number: NCT00715481

**Determinants of glycaemic control: a nationwide longitudinal study of 131935 newly diagnosed cases of type 2 diabetes**

A. Rawshani<sup>1</sup>, A.-M. Svensson<sup>1</sup>, B. Eliasson<sup>1</sup>, B. Zethelius<sup>2</sup>, A. Rosengren<sup>1</sup>, S. Gudbjörnsdóttir<sup>1</sup>;

<sup>1</sup>Clinical and Molecular Medicine, Inst of Medicine, Gothenburg,

<sup>2</sup>Clinical Medicine, Inst of Medicine, Uppsala, Sweden.

**Background and aims:** Studies on glycaemic (HbA<sub>1c</sub>) control have been compromised by small samples, short follow up, lack of data or unequal access to health care. We used the Swedish National Diabetes Register (2002-2011) to include 131935 newly diagnosed (within one year) cases of type 2 diabetes. We studied glycaemic control and the effect of known and suspected determinants of glycaemic control. Due to knowledge gaps, emphasis was on ethnicity, income and education.

**Materials and methods:** We assessed sex, age, BMI, duration of diabetes, education, income, ethnicity, physical activity, glucose-lowering treatment, previous cardiovascular disease, risk factors and statin treatment. We report (1) baseline characteristics; (2) progress of glycaemic control from disease onset to end of follow up (up to 10 years); (3) linear mixed models to determine the effect of the above mentioned covariates on HbA1c (mmol/mol) and time duration until HbA1c started to increase ('turn point'); (4) logistic regression was used to study the probability of achieving glycaemic control (<53 mmol/mol) the 2nd year. Sensitivity analyses were performed.

**Results:** Phenotype at diagnosis varied markedly by ethnicity; e.g age differed up to 16 years (High-income Europe versus Sub-Saharan Africa) and BMI up to 4 kg/m<sup>2</sup> (High-income Europe versus South Asia). Glycaemic control varied strikingly by ethnicity (figure 1) and socioeconomic status. Non-Western ethnicities displayed considerably higher HbA1c levels throughout follow-up. Overall, HbA1c levels started to increase after 2.9 (95% CI 2.8, 3.0) years but non-Western groups experienced the turn point up to 1 year earlier (figure 1). Target level of HbA1c was out of reach for non-Western ethnicities. Kaplan-Meier graphs revealed that this was not due to late initiation of pharmacologic treatment; paradoxically, non-Western ethnicities received pharmacologic treatment earlier. Linear models enhanced the ethnic differences in HbA1c. Interestingly, we found a strong interaction between ethnicity and type of glucose-lowering treatment (not detailed here). Sub-Saharan Africa, South & East Asia and the Middle East & North Africa displayed poorest control; generally 3–6 mmol/mol higher than high-income Europe. Higher income, but not education, was associated with lower HbA1c levels. Statin use was consistently associated with lower HbA1c (range 0.2–1.0 mmol/mol, depending on model). Logistic regression showed that income, education and, particularly, ethnicity are strongly associated with probability of not achieving glycaemic control; e.g odds ratio for South Asians was 1.7 (95% CI, 1.5, 1.9), compared to individuals from high-income Europe.

**Conclusion:** Ethnicity is a strong determinant of glycaemic control. Several non-Western populations should be targeted for interventions.

#### Trends in diabetes, obesity, hypertension over twelve years in Turkey: rate of increase in diabetes is higher than the rate of increase in obesity

**I. Satman**<sup>1</sup>, N. Dincag<sup>1</sup>, S. Kalaca<sup>2</sup>, K. Karsidag<sup>1</sup>, T. Yilmaz<sup>1</sup>, B. Omer<sup>3</sup>, Y. Tutuncu<sup>1</sup>, S. Celik<sup>1</sup>, J. Tuomilehto<sup>4,5</sup>, The TURDEP Study Group; <sup>1</sup>Endocrinology and Metabolism, Istanbul University, <sup>2</sup>Public Health, Marmara University, <sup>3</sup>Biochemistry, Istanbul University, Turkey, <sup>4</sup>South Ostrobothnia Central Hospital, Seinajoki, Finland, <sup>5</sup>Centre for Vascular Prevention, Danube University, Krems, Austria.

**Background and aims:** According to the sixth edition of Diabetes Atlas, highest prevalence of diabetes in Europe is in Turkey. We aimed to investigate the reasons of this epidemic by comparing 12-year trends in prevalence of diabetes, IGT, obesity, abdominal obesity and hypertension in two population-based surveys in Turkey.

**Materials and methods:** TURDEP-I (1998) and TURDEP-II (2010) have been conducted in the same 540 centers twelve years apart in Turkey. Both surveys covered randomized people 20 years and over; TURDEP-I (n=24,714; 55.2% women) and TURDEP-II (n=25,120; 63% women). Diabetes has been defined as previously known diabetes plus new diabetes based on OGTT 2-hPG  $\geq$ 200 mg/dL.

**Results:** Between the two surveys the mean age of the population increased by 4 years in men and women in average. The rates of increase in diabetes, IGT, obesity and abdominal obesity in men were higher in women (diabetes: 1.2 vs. 0.9 fold, IGT: 2.5 vs. 2.2 fold, obesity: 1.0 vs. 0.4 fold, abdominal obesity: 1.0 vs. 0.3 fold; p<0.001). Hypertension increased by 9% in men while decreased by 12% in women (see Figure). Absolute change in the prevalence of diabetes is correlated to the absolute change in both general (r=0.74, p<0.001) and abdominal obesity (r=0.54, p=0.004) but not to hypertension. The correlation does not change when the two populations are controlled for sex and age (general obesity: r=0.65, p=0.001, abdominal obesity: r=0.71, p<0.001).

**Conclusion:** Diabetes increased in epidemic proportion over the recent 12-year period in Turkey. Although the contributions from aging of the population and obesity are remarkable, these factors could not explain the whole problem; other lifestyle factors (such as change in nutrition and physical activity habits) should be examined in detail to find the causes of diabetes epidemic in Turkey.

**Figure:** Absolute change in diabetes, general obesity, abdominal obesity and hypertension

#### Epidemiology of hyperglycaemia in pregnancy and gestational diabetes in the World Health Organisation European region

**U. Linnenkamp**<sup>1</sup>, L. Makaroff<sup>2</sup>, L. Guariguata<sup>1</sup>, J. Beagley<sup>1</sup>, D. Whiting<sup>2</sup>, N.H. Cho<sup>3</sup>;

<sup>1</sup>International Diabetes Federation, Brussels, Belgium, <sup>2</sup>Directorate of Public Health, Medway Council, Chatham, UK, <sup>3</sup>Department in Preventive Medicine, Ajou University School of Medicine, Suwon, Republic of Korea.

**Background and aims:** Hyperglycaemia is one of the most prevalent metabolic disorders that occur during pregnancy. The International Diabetes Federation (IDF) has developed a methodology for generating estimates of the prevalence of hyperglycaemia in pregnancy (HIP), including gestational diabetes, among women of childbearing age (20–49 years). The IDF defines HIP to include both hyperglycaemia first detected in pregnancy (HFDP) as well as previously known diabetes. The IDF uses the WHO definition of people with HFDP to include people with gestational diabetes (GDM) and also those first diagnosed with diabetes in pregnancy (DIP).

**Materials and methods:** PubMed and cited literature were reviewed, to identify studies reporting prevalence of HIP. A simple scoring system was developed to characterise studies. Age-specific prevalence data from studies were entered to produce estimates for five-year age groups using logistic regression to smooth curves, with age as the independent variable. Adjustments were then made to align with recently published diagnostic criteria as defined by the WHO for hyperglycaemia first detected in pregnancy.

**Results:** We have previously presented an analysis of the global burden of HIP and we now present a more detailed analysis of the HIP burden in the WHO-EUR-Region. After scoring and exclusion requirements, 13 studies were selected representing 11 countries (Belgium, France, Hungary, Ireland, Israel, Netherlands, Norway, Poland, Spain, Turkey and United Kingdom). The majority of studies (85%) were conducted in high income countries, only two were conducted in upper middle income countries and no studies were available for lower middle and low income countries within the Region. 54% of the selected studies were conducted in a single hospital, 31% were con-

ducted in a locally representative sample leaving only a study from Hungary as being regionally representative and a study from Turkey being nationally representative. It is estimated that in 2013 of a predicted 10.7 million live births to women aged 20–49 years 15.2% were affected by HIP. Thus, within the Region, 1.7 Million live births were affected by HIP. While the highest prevalence of HIP is found in pregnant women >40 years of age, the largest numbers of cases occur in women aged 25–35. Within the countries estimated age-standardised prevalence of HIP ranged from 5.0% of all live births affected in Belgium up to 32.1% of all live births affected in Spain.

**Conclusion:** Prevalence estimates of HIP are sensitive to the data from which they are derived. Within the WHO-EUR-Region there is a lack of nationally representative studies on the prevalence of HIP, especially in lower middle income countries and low income countries. More data are needed, in particular from low income countries, to strengthen the methodology. These are the first estimates of HIP in the WHO - EUR Region and conform to the new WHO recommendations regarding diagnosis. They indicate the importance of this issue from a public health and maternal and child health perspective. *Supported by: Lilly Diabetes, Merck and Co, Novo Nordisk A/S, Pfizer, Sanofi Diabetes*

#### Prevalence of metabolic syndrome and cardiometabolic risk factors in patients with long-duration psychotic illnesses

D. Hopkins<sup>1</sup>, P. Gardner-Sood<sup>2</sup>, J. Lally<sup>2</sup>, D. Stahl<sup>3</sup>, K. Greenwood<sup>2</sup>, Z. Atakan<sup>2</sup>, S. Smith<sup>2</sup>, R. Ohlsen<sup>2</sup>, K. Ismail<sup>4</sup>, R. Murray<sup>2</sup>, F. Gaughran<sup>5</sup>; <sup>1</sup>Dept of Diabetic Medicine, King's College Hospital NHS Foundation Trust, <sup>2</sup>Institute of Psychiatry, King's College London, <sup>3</sup>Dept of Biostatistics, King's College London, <sup>4</sup>Diabetes & Psychiatry Research Group, King's College London, <sup>5</sup>National Psychosis Service, South London and Maudsley NHS Foundation Trust, London, UK.

**Background and aims:** Patients with severe mental illness have significantly reduced life expectancy with increased cardiovascular events and a high prevalence of diabetes. As a preliminary step to testing interventions to try and improve physical health outcomes in patients with established psychosis we have conducted this study to determine the prevalence of the component risk factors that comprise the metabolic syndrome in a large cohort of established patients.

**Materials and methods:** Cross-sectional study of 450 patients with established (multi-episode) psychosis recruited at five centres in the United Kingdom. Anthropometric measures (height, weight and waist circumference), and blood pressure were recorded for all subjects. In addition blood samples for HbA1c, fasting glucose and lipid profile were obtained from 296 subjects. **Results:** Mean age of the participants was 43.6 years (SD=10.1) and mean duration of psychotic illness was 15.7 years (SD=10.3). 57% of participants were male. 55% percent (n=238) were Caucasian and 33% (n=146) were of Black African or Black Caribbean ethnicity. 50% of participants were obese (body mass index, BMI>30) 44% were prescribed dibenzodiazepine antipsychotic medication (clozapine and olanzapine). There was no association between dibenzodiazepine use and BMI. Of the 296 participants with complete data 57% fulfilled the International Diabetes Federation (IDF) criteria for diagnosis of the metabolic syndrome. Prevalence of central obesity was very high with 82%, of participants exceeding IDF cut-off values for waist circumference. In addition, 54% had blood pressure above 130/85, 57% triglyceride above 1.7 mmol/l and 53% had HDL cholesterol below the IDF cut-off values of under 1.03 or 1.29 mmol/l for men and women respectively. 31% had fasting dysglycaemia (fasting glucose of 5.6 mmol/l or greater) including 26% fulfilling criteria for a diagnosis of diabetes.

**Conclusion:** These data demonstrate a high prevalence of metabolic syndrome and dysglycaemia in a relatively young population with longstanding psychosis and the presence of multiple adverse cardiometabolic risk factors that could be ameliorated to improve cardiovascular outcomes. The prevalence of central obesity is considerably greater than that of obesity diagnosed by BMI indicating a need for waist measurement to predict risk in this population.

## PS 006 Epidemiology of diabetes: comorbidities and complications

### 310

#### Prevalence of undetected thyroid disorders in subjects with diabetes in South India: a cohort analysis

G. Krishnan, A. Shankar, S. Jothydev, J. Kesavadev; Jothydev's Diabetes and Research Center, Trivandrum, India.

**Background and aims:** Thyroid function test is not a part of routine diabetes practice in India, due to the extra cost involved and the lack of time for the physician to convince the patient on the requirement of an extra expensive investigation. Many a time, symptoms of hypothyroidism in diabetes patients are mistaken for hypoglycaemia and associated metabolic syndrome and hence goes grossly undetected.

**Materials and methods:** We screened T2DM patients, presenting at our comprehensive diabetes speciality clinic for the first time, to evaluate the prevalence of thyroid disorders. Screening was done during the past 5 years, using the 'sensitive TSH test' in Cobas E411 Elecsys. Patients with undetected hypothyroidism reported mood changes, anxiety, anger, memory loss etc. which were corrected with thyroid supplementation.

**Results:** During selection of 7402 consecutive T2DM subjects aged  $\geq 21$  yrs (62.48% male), 5.83% self reported hypothyroidism; 29.67% showed abnormal TSH values, comprising of 10.42% with TSH values suggestive of sub-clinical hypothyroidism (3.04–10  $\mu$ IU/mL); 17.09% overt hypothyroidism ( $>10$   $\mu$ IU/mL) and 2.16% with low TSH values suggestive of hyperthyroidism ( $<0.05$   $\mu$ IU/mL). Abnormal TSH values showed significant association with female sex and  $>60$  yrs age group; whereas distribution of other sub-groups were not statistically significantly different. Among females, 9.09% had mildly increased TSH levels (3.04–10  $\mu$ IU/mL), 22.14% had high TSH levels ( $>10$   $\mu$ IU/mL) and 1.45% had low TSH levels ( $<0.05$   $\mu$ IU/mL). Overall, subjects with newly detected hypothyroidism showed a trend of higher BMI (1.7 kg/m<sup>2</sup>) compared to others, but this was not statistically significant ( $p>0.05$ ). The level of diabetes control was possibly confounded by treatment received and HbA1c did not significantly differ among hyperthyroid, euthyroid & sub-clinically hypothyroid patients (mean HbA1c=8.9%).

**Conclusion:** Considering the negligible extra cost of 1.26Euros for 90 tablets (presuming an average 50mcg/day dosage) of thyroid supplementation, diabetes patients will tremendously benefit from early detection of thyroid disorders. The very high prevalence of hypothyroidism in diabetes, significantly higher than in the general population, makes it imperative to include TSH test in routine diabetes evaluation in developing countries like India.

### 311

#### Prediabetes is associated with early changes in microcirculation

V.M. Shyshko<sup>1</sup>, T.V. Mokhort<sup>1</sup>, N.L. Tsapaeva<sup>2</sup>, E.E. Konstantinova<sup>3</sup>; <sup>1</sup>Endocrinology, <sup>2</sup>Inner Disease #3, Belarussian State Medical University, <sup>3</sup>Institute of Heat and Mass Exchange, National Academy of Science, Minsk, Belarus.

**Background and aims:** Microangiopathy in patients with type 2 diabetes (T2D) results from previous microcirculation abnormalities (e.g. increased permeability, disturbance of intracapillary pressure and blood flow). Hyperglycemia as well as hesitance of glucose level in patients with prediabetes (impaired glucose tolerance and impaired fasting glucose) have negative impact on microvessel status. The aim of the study was to investigate microcirculation in patients with prediabetes.

**Materials and methods:** We included 131 patients with average age 49,03  $\pm$  8,76 years. Patients were divided into 2 groups: group 1 - 37 patients with prediabetes, group 2 - 35 patients with type 2 diabetes (with duration of disease no longer as 5 years and treated with oral blood glucose lowering drug) and group 3 - 59 almost healthy person. Microcirculation was measured by computer based conjunctival biomicroscopy (Malaja et al.), results were evaluated by the set of criteria for quantitative evaluation of conjunctival microcirculation: FC (number of active capillary tubes), AVA (arteriovenous anastomosis), Mean (vascular tortuosity), SI (sludge), Mtr (microthrombosis). Severity of each criteria was scored and more severe changes had higher degree.

**Results:** Microcirculation abnormalities were revealed in patients with prediabetes: we registered statistically significant decrease of active capillary tubes (FC) (3,0[2,0;3,0]vs2,0[2,0;3,0] in control group) ( $P1-3<0,025$ ), increased

number of AVA (2,0 [2,0; 4,0] vs 2,0 [2,0; 2,0] in control group) ( $P1-3 < 0,025$ ) and Mtr (1,0 [1,0; 2,0] vs 0,0 [0,0; 1,0] in control group) ( $P1-3 < 0,001$ ). Hence in patients with prediabetes we observed hypoperfusion and microthrombosis that predispose vascular wall to atherosclerosis. We registered more significant changes in patients with T2D compared to patients with prediabetes and control group. Patients with T2D had more significant Mean (1,0 [1,0; 2,0]) compared to group 1 and 3 (1,0 [1,0; 1,0]) ( $P1-2 < 0,05$  and  $P2-3 < 0,001$  correspondingly), erythrocyte properties are also changed that is presented in sludge formation (2,0 [2,0; 4,0] vs 2,0 [2,0; 2,0] in groups 1,3) ( $P1-2 < 0,05$ ,  $P2-3 < 0,001$  correspondingly). Consequently microcirculation abnormalities in patients with prediabetes and T2D consist in changes as in vessel wall so and in intravessel homeostasis.

**Conclusion:** Analysis of microcirculation demonstrate presence of changes in microvessel system during early disturbance of glucose metabolism (that is in prediabetes). T2D is associated with more significant changes in microcirculation. Damage of microvessel is one of the factors that leads to endothelial dysfunction and atherosclerosis.

## 312

### Impact of glucose metabolism across the life course on retinal microvasculature architecture: the young Finns study

R. Tapp<sup>1</sup>, M. Hussain<sup>1</sup>, N. Hutri-Kähönen<sup>2</sup>, T. Lehtimäki<sup>2</sup>, A. Metha<sup>1</sup>, M. Kähönen<sup>2</sup>, O. Raitakari<sup>3</sup>;

<sup>1</sup>The University of Melbourne, Australia, <sup>2</sup>University of Tampere and Tampere University Hospital, <sup>3</sup>University of Turku and Turku University Hospital, Finland.

**Background and aims:** Studies in healthy adults and children indicate that retinal venular abnormalities are unrelated to arteriolar changes, and may be influenced by obesity, increased inflammation and glucose metabolism. Limited research has been conducted across the life course. We hypothesized that fasting plasma glucose (FPG) in late childhood/adolescence and change in FPG from late childhood/adolescence to mid adulthood would be associated with adverse changes in retinal microvascular architecture.

**Materials and methods:** The Cardiovascular Risk in Young Finns Study included children aged 3 to 18 years, from five Finnish University cities, with participants chosen randomly from the national population registrar from those areas. Complete data were available for 1054 participants with a gestation  $\geq 37$  weeks. Retinal microvascular measures included retinal arteriolar and venular diameters.

**Results:** The mean age of the participants was 41 years (range 34 - 49 years) at the time of retinal photography. Regression analysis showed a strong positive association between change in FPG from late childhood/adolescence to mid adulthood with venular diameter (regression coefficient ( $\beta$ ) 0.207;  $p < 0.031$ ) and no association with late childhood/adolescence or adult FPG ( $\beta$  -0.092;  $p = 0.391$  and 0.131;  $p = 0.168$  respectively), adjusted for age and sex. No association was evident between FPG and arteriolar diameter.

**Conclusion:** This is the first study to assess the impact of glucose metabolism across the life course on retinal microvascular architecture. Retinal arterioles and venules are differentially associated with FPG. Change in FPG from late childhood/adolescence to mid adulthood may adversely affect the microcirculation, with important implications for cardiovascular risk.

### Serum high-sensitivity C-reactive protein levels are associated with high risk of development of diabetic nephropathy among Japanese type 2 diabetes patients

T. Mashitani<sup>1</sup>, Y. Hayashino<sup>2</sup>, S. Tsujii<sup>2</sup>, H. Ishii<sup>1</sup>, Diabetes Distress and Care Registry at Tenri (DDCRT) Study Group;

<sup>1</sup>Nara Medical University, Kashihara, <sup>2</sup>Department of Endocrinology, Tenri Hospital, Japan.

**Background and aims:** Diabetic nephropathy is a common complication of diabetes and the leading cause of end-stage renal disease in developed countries. An understanding of the clinical characteristics and risk factors associated with diabetic nephropathy is useful for establishing effective therapeutic strategies to prevent the progression of diabetic nephropathy. Many cross-sectional studies revealed that the C-reactive protein (CRP) levels were high in patients with diabetic nephropathy. Only one previous study reported that baseline C-reactive protein (CRP) levels were associated with a subsequent

increment of urinary albumin excretion in patients with type 2 diabetes, but this study did not examine that either of progression or development of diabetic nephropathy was associated with high levels of CRP. The present study assessed the prospective association between baseline serum high-sensitivity CRP (hs-CRP) concentration and the subsequent risk of the development or progression of diabetic nephropathy among Japanese type 2 diabetes patients. **Materials and methods:** Longitudinal data were obtained from 2,256 patients with type 2 diabetes registered in a Japanese diabetes registry. To assess the independent associations between serum hs-CRP quartiles at baseline, and either the development or progression of diabetic nephropathy at 1-year follow-up, we used the Cox proportional hazards model adjusted for potential confounders.

**Results:** Mean patient ages, BMI and HbA1c levels were 66.2 years, 24.6 kg/m<sup>2</sup> and 7.5%, respectively. Firstly, we examined the association between baseline hs-CRP levels and subsequent risk of the development of diabetic nephropathy. Over the median follow-up of 0.93 years, we observed 199 cases who developed diabetic nephropathy (incidence ratio = 156.4/1000 person-years [95%CI, 137.0 to 177.6]). Baseline serum hs-CRP levels were significantly associated with the urinary albumin-creatinine ratio (UACR) at baseline ( $p < 0.001$ ). Multivariable adjusted hazards ratios for progression from normoalbuminuria to microalbuminuria were 1.25 (95% CI, 0.74 to 2.1), 1.47 (95% CI, 1.06 to 2.05;  $p = 0.022$ ) and 1.31 (95% CI, 1.03 to 1.66;  $p = 0.025$ ), respectively, for the 2nd, 3rd and 4th quartile of serum hs-CRP levels, showing a statistically significant linear trend across categories ( $p = 0.001$ ). Next, we examined the association between baseline hs-CRP levels and subsequent risk of progression of diabetic nephropathy. Over the median follow-up of 0.94 years, we observed 109 cases whose diabetic nephropathy progressed (incidence ratio = 101.0/1000 person-years [95%CI, 83.7 to 120.6], Table 2). We did not observe a significant association between hs-CRP levels and subsequent risk of diabetic nephropathy ( $p$  for trend = 0.514).

**Conclusion:** We observed a significant association between serum hs-CRP levels and baseline UACR levels. Serum hs-CRP levels were associated with the subsequent risk of developing, not progressing, diabetic nephropathy in type 2 diabetes patients independent of possible confounders. Serum hs-CRP may be useful for predicting patients' risk of developing diabetic nephropathy.

### Decrease in the incidence of renal replacement therapy for diabetes mellitus in the Netherlands

S.T. Houweling<sup>1,2</sup>, P.R. van Dijk<sup>3</sup>, A. Kramer<sup>4</sup>, S.J.J. Logtenberg<sup>3,5</sup>, A.J. Hoitsma<sup>6</sup>, N. Kleefstra<sup>3,1</sup>, K.J. Jager<sup>4</sup>, H.J.G. Bilo<sup>3</sup>;

<sup>1</sup>Medical Research Group Langerhans, <sup>2</sup>Diabetes Centre, <sup>3</sup>Diabetes centre, Zwolle, <sup>4</sup>Department of Medical Informatics, ERA-EDTA Registry, Amsterdam, <sup>5</sup>Department of Internal Medicine, University Medical Center Groningen, <sup>6</sup>RENINE Registry, Leiden, Netherlands.

**Background and aims:** Diabetes mellitus (DM) is considered the main cause of end stage renal disease (ESRD) in many countries. In general, its frequency is estimated to be about 40% of ESRD and would be expected to rise in parallel with the prevalence of DM. Aim of the present study was to investigate trends in incidence and prevalence of DM as cause of renal replacement therapy (RRT) for ESRD in the Netherlands in the period 2000-2012.

**Materials and methods:** Using the RENINE-database, a countrywide and 100% registration of subjects on RRT, the incidence and prevalence of all Dutch individuals initiating RRT having DM as primary diagnosis were obtained. The age- and gender adjusted incidence and prevalence were calculated. Trends in time were analysed with Joinpoint regression.

**Results:** The prevalence of DM in the Dutch general population (GP) increased from approximately 500.000 in 2000 to 893.000 in 2011. The number of individuals who started DM related RRT remained stable: 17.4 per million population (pmp) in 2000 and 19.1 pmp in 2012 with an annual percentage change (APC) of 0.8% (95% confidence interval (CI) -0.4;2.0). However, for RRT due to T1DM the incidence decreased from 7.3 pmp in 2000 to 3.5 pmp in 2012 with an APC of -4.8% (95%CI -6.5; -3.1). For T2DM it increased from 10.1 pmp in 2000 to 15.6 pmp in 2012 with an APC 3.1% (95%CI 1.3;4.8). The incidence of RRT due to unknown or missing causes of renal failure increased from 21.2 pmp to 28.5 pmp. The prevalence of RRT for DM increased at a lower rate after 2009: APC 1.0% (95%CI -0.4;2.5) versus 5.8% (95%CI 5.6;6.1). Compared to a non-DM reference population, patients on RRT due to T1DM and T2DM had an increased mortality, age and gender adjusted

hazard ratios: 1.8 (95%CI 1.7;2.0) and 1.4 (95%CI 1.3 - 1.4). Compared to the period of 2000-2004, patients initiating RRT in 2005-2009 had a lower mortality, age and gender adjusted hazard ratios: 0.8 (95%CI 0.7;0.8).

**Conclusion:** The incidence of RRT for DM is stable over the last decade reflecting a decrease for T1DM and an increase for T2DM. Taken together with a steady increase in prevalence of DM in the GP this may suggest that physicians may be more successful in the prevention of diabetes related ESRD

### 315

#### Cardiovascular events and all-cause mortality: associations with renal function in patients with type 2 diabetes

L.A. Garcia Rodriguez<sup>1</sup>, L. Cea Soriano<sup>1</sup>, S. Johansson<sup>2</sup>, B. Stefansson<sup>2</sup>;  
<sup>1</sup>Spanish Centre for Pharmacoepidemiologic Research (CEIFE), Madrid, Spain, <sup>2</sup>AstraZeneca R&D, Mölndal, Sweden.

**Background and aims:** Diabetes and chronic kidney disease are independent predictors of mortality and cardiovascular (CV) events. The aims of this study were to quantify the risk of death and CV events associated with estimated glomerular filtration rate (eGFR) and to identify other potential risk factors in patients with type 2 diabetes.

**Materials and methods:** In this retrospective study, data were collected from The Health Improvement Network, a UK primary care database. From a cohort of patients aged 20-90 years with type 2 diabetes, 57 946 individuals were identified who had a valid serum creatinine measurement recorded in 2000-2005. Patients were followed up from their start date (date of first ever valid recorded creatinine measurement) until they met one of the following endpoints in three separate analyses: myocardial infarction (MI), ischaemic stroke or transient ischaemic attack (IS/TIA), or death; patients were censored when they reached 90 years of age or the end of the study (31 December 2010). Individuals with a record of haemodialysis or renal transplant before their start date were excluded or censored during follow-up. Incidence rates for death, MI and IS/TIA were calculated overall and by eGFR subgroup at baseline (15-29, 30-44, 45-59 and  $\geq 60$  mL/min). Cox regression models adjusted for potential confounding factors were used to estimate hazard ratios (HRs) and their corresponding 95% confidence intervals (CIs) for death, MI and IS/TIA according to sex, age, eGFR category and duration of diabetes.

**Results:** Median follow-up times were 6.80, 6.64 and 6.56 years for death, MI, and IS/TIA, respectively. Overall incidence rates for death, MI and IS/TIA were 43.65, 9.26 and 10.39 cases per 1000 person-years, respectively. Incidence rates were highest for patients with the lowest eGFRs (15-29 mL/min): 210.01, 31.65 and 32.48 cases per 1000 person-years for death, MI and IS/TIA, respectively. For patients with an eGFR  $\geq 60$  mL/min, the corresponding incidence rates were 31.99, 7.44 and 8.65 cases per 1000 person-years. A low eGFR (15-29 mL/min) was associated with an increased risk of death (HR: 4.00; 95% CI: 3.69-4.33), MI (HR: 3.29; 95% CI: 2.68-4.04) and IS/TIA (HR: 2.47; 95% CI: 2.01-3.03) relative to eGFR  $\geq 60$  mL/min (Table). The risk of death, MI and IS/TIA significantly increased with age: HRs for patients aged 75 years or older relative to patients aged 20-49 years were 12.14 (95% CI: 10.79-13.67), 3.33 (95% CI: 1.79-3.98) and 6.64 (95% CI: 5.44-8.11), respectively. Longer duration of diabetes was associated with an increased risk of death or experiencing a CV event: HRs for patients who had had diabetes for more than 15 years relative to those who had had diabetes for less than a year were 1.74 (95% CI: 1.59-1.90) for death, 1.87 (95% CI: 1.54-2.26) for MI and 1.64 (95% CI: 1.36-1.98) for IS/TIA.

**Conclusion:** In patients with type 2 diabetes, the risks of death, MI and IS/TIA increased with age, duration of diabetes and decreasing eGFRs.

**Table** Risk of death, MI and IS/TIA according to eGFR at baseline

| eGFR (mL/min) | Death<br>IRR <sup>a</sup> (95% CI) | MI<br>IRR <sup>a</sup> (95% CI) | IS/TIA<br>IRR <sup>a</sup> (95% CI) |
|---------------|------------------------------------|---------------------------------|-------------------------------------|
| 15-29         | 4.00 (3.69-4.33)                   | 3.29 (2.68-4.04)                | 2.47 (2.01-3.03)                    |
| 30-44         | 2.24 (2.14-2.35)                   | 2.22 (1.99-2.49)                | 1.55 (1.38-1.73)                    |
| 45-59         | 1.34 (1.29-1.39)                   | 1.41 (1.30-1.54)                | 1.20 (1.11-1.30)                    |
| $\geq 60$     | 1 (-)                              | 1 (-)                           | 1 (-)                               |

#### Factors associated with cognitive impairment in patients with newly diagnosed type 2 diabetes: a cross-sectional study

C.D. Moulton<sup>1</sup>, S.A. Amiel<sup>2</sup>, R. Stewart<sup>1</sup>, K. Ismail<sup>1</sup>;  
<sup>1</sup>Institute of Psychiatry, <sup>2</sup>Department of Diabetes and Nutritional Sciences, King's College London, UK.

**Background and aims:** Type 2 diabetes (T2DM) is a major risk factor for cognitive impairment (CI) and the pandemic of T2DM is expected to increase the global dementia burden. The factors associated with CI in T2DM are poorly understood. A limitation of previous cohorts examining CI in T2DM is the variable and long duration of T2DM among participants, which increases the risk of effects being obscured by differential survival and diabetes complications. By analysing a population with newly diagnosed T2DM, we aimed to identify modifiable factors for cognitive decline at an earlier stage in the natural history of T2DM. Our primary hypothesis was that markers of glucose dysregulation would be associated with cognitive impairment and secondary hypotheses were that i) depression, ii) black or South Asian ethnicity and iii) body mass index (BMI) would be independently associated with CI in T2DM.

**Materials and methods:** We performed a cross-sectional analysis of baseline measures from the South London Diabetes (SOUL-D) cohort, a population-based multi-ethnic study of individuals diagnosed with T2DM in the last 6 months. We assessed CI using the 13-item Telephone Interview for Cognitive Status (TICS-M), which has a range of scores from 0-39. We defined CI as the lowest 10% of scores and the remainder as controls. We performed univariate and multivariate analyses of the association between CI and 1) markers of glucose dysregulation (HbA1c, fasting glucose, micro/macrovacular complications); 2) sociodemographic factors (age, gender, ethnicity); 3) vascular risk factors (BMI, hypertension, hyperlipidaemia, smoking) and 4) depression (PHQ-9 score  $>12$ ). We used Student's t-test for continuous data and  $\chi^2$  tests for categorical data and logistic regression to control for key confounding variables, including premorbid intelligence estimated by National Adult Reading Test (NART) score.

**Results:** In the preliminary analyses, of 1791 patients recruited, 1680 (93.8%) had a complete TICS-M assessment. Average diabetes duration was 4.6 (SD 2.2) months. Cognitive impairment was defined as TICS-M score  $<17$ . In univariate analyses, there were no differences in HbA1c, (p=0.22), fasting glucose (p=0.96), microvascular complications (p=0.31), macrovascular complications (p=0.41), depression (p=0.52), BMI (p=0.2), smoking (p=0.13), hyperlipidaemia (p=0.21) and hypertension (p=0.70) between patients with CI and controls. Patients with CI were older (p<0.001), more likely to be female (p<0.001), of black or South Asian/other ethnicity (p<0.05) and had lower scores on NART (p<0.0001). In multivariate analyses including age, gender, ethnicity, HbA1c, BMI and NART as covariates, the effects of age, ethnicity and NART remained significant but the effect of gender (p=0.12) was attenuated.

**Conclusion:** Although poor glycaemic control and depression are known risk factors for CI in established T2DM, this was not seen at diagnosis. Instead, older age, black or South Asian ethnicity and poorer NART scores were associated with CI at diagnosis of T2DM, though the latter two associations may partly reflect poorer literacy levels. Overall cognitive scores were lower than studies in non-diabetic populations. Our results suggest that at the time of T2DM diagnosis there may be a window of opportunity to identify patients at higher risk of CI.

#### Risk factors for atrial fibrillation in type 2 diabetes. Report from the Swedish National Diabetes Register: NDR

B. Zethelius<sup>1</sup>, S. Gudbjörnsdóttir<sup>2</sup>, B. Eliasson<sup>2</sup>, K. Eeg-Olofsson<sup>3</sup>, A.-M. Svensson<sup>2</sup>, J. Cederholm<sup>3</sup>;  
<sup>1</sup>Dept. of Public Health and Caring Sciences/Geriatrics, Uppsala University, <sup>2</sup>Dept. of Medicine, Sahlgrenska University Hospital, Gothenburg University, <sup>3</sup>Dept. of Public Health and Caring Sciences/Family Medicine and Preventive Medicine, Uppsala University, Sweden.

**Background and aims:** Atrial fibrillation (AF) is more frequent in patients with type 2 diabetes than in the general population. Further, AF has been shown to have a strong impact on risk for cardiovascular complications and mortality in patients with type 2 diabetes, who generally have elevated risks of cardiovascular complications, i.e. at least twice as common as in those with-

out diabetes. The aim was to investigate which factors that contributes to the risk of AF in type 2 diabetes using national register data from Sweden.

**Materials and methods:** Observational cohort study of 64,864 patients with type 2 diabetes, aged 30–79 years, without AF at baseline. A history of cardiovascular disease (CVD) was present in 16.9% and 3.6% had a history of congestive heart failure (CHF). Patients were, followed-up for development of AF (n=2,719) during 4.2 years from 2003 to 2009. A subgroup of 52,939 patients without history of CVD or CHF at baseline was also analysed.

**Results:** At multivariate logistic regression, odds ratios (OR) of AF were 4.49 for a baseline history of CHF and 7.98 for in-study developed CHF. Similarly for a history of CVD, the OR was 1.28 and for in-study developed myocardial infarction an OR of 1.37. Cardiovascular risk factors associated with risk for AF were hypertension (OR, 1.42), cumulative microalbuminuria (OR, 1.24), obesity (OR, 1.31) and ORs for each decade of increasing age was 1.93, and 1.43 for male gender, with all predictors  $p < 0.001$ . Among patients without history of CVD or CHF at baseline, significant predictors were similarly for in-study developed CHF (OR, 10.2), hypertension (OR, 1.52), cumulative albuminuria (OR, 1.25), obesity (OR, 1.34) and ORs for each decade of increasing age was 1.93, and 1.48 for male gender, with all predictors  $p < 0.002$ . In multivariable models, the following factors were not significantly ( $p > 0.05$ ) related to AF as the outcome: HbA1c, blood lipids and smoking status. Population Attributable Risk Percent (PARp: percent cases reduced if predictors could be eliminated) for AF was with hypertension 27%, in-study CHF 25% and previous history of CHF 8%, cumulative microalbuminuria 7% and for obesity 11%.

**Conclusion:** Except for CHF, hypertension, albuminuria and obesity account for large portions of PAR for AF in type 2 diabetes. The study underlies the contribution of CHF, hypertension and microalbuminuria to AF development, factors that are shown to be modified by pharmacological treatment including ACE-inhibition. Further, obesity also contributes to AF and life style measures aiming at weight reduction if obese may have benefits for reduction of AF incidence. Intervention studies on AF-prevention are warranted.

#### Risk of acute myocardial infarction in 121289 patients with type 2 diabetes: emphasis on socioeconomic status and ethnicity

A.-M. Svensson, A. Rawshani, A. Rosengren, S. Gudbjörnsdottir; Clinical and Molecular Medicine, Inst of Medicine, Gothenburg, Sweden.

**Background and aims:** Little is known about ethnicity and the risk of coronary heart disease (CHD) and acute myocardial infarction (AMI) in diabetes. We examined the relationship between ethnicity and CHD death or hospitalization for AMI in patients with type 2 diabetes.

**Materials and methods:** Patients included in the Swedish National Diabetes Register (2002–2006) were followed until a diagnosis of AMI or CHD death, death (other causes) or December 31 2011, through the nationwide Inpatient Registry and National Death Registry. All individuals (15.5% foreign-born) had equal access to low-cost health care. The study population included individuals from all the world's continents. Detailed data on income and education was retrieved from the Swedish National Board of Health and Welfare. Incidence rates for AMI/CHD death were estimated by Poisson regression. Relative risk was estimated by Cox regressions adjusted for ethnicity, income, education, lipids, sex, age, blood pressure, smoking, kidney function, body mass index, physical activity, chronic obstructive pulmonary disease and cardioprotective drugs. Model fitting proceeded conventionally and, where appropriate, covariates were time dependent.

**Results:** In 121289 patients with type 2 diabetes, 12861 (10.6 %) had an event (mean follow-up 6.1 years). Incidence rates (figure) varied strikingly by ethnicity. Non-Western groups, particularly Sub-Saharan Africa and Latin America displayed particularly high figures. Adjusted hazard ratios for AMI/CHD death by ethnicity was: High-income Europe, North America, 1.10 (0.97–1.25); Low-income Europe, 1.19 (1.03–1.37); Latin America & Caribbean, 1.30 (0.90–1.88); Middle East & North Africa, 1.37 (1.16–1.62); Sub-Saharan Africa, 1.15 (0.95–1.40) and South & East Asia 1.10 (0.95–1.34), compared with Nordic countries. While education had no effect on the hazard, income was strongly associated with the risk of AMI/CHD death. Belonging to the lowest income quintile was associated with a hazard ratio of 2.25 (2.15–2.39), compared to the highest quintile. Among traditional risk factors, the hazard ratios for chronic obstructive pulmonary disease and low kidney function were surprisingly high.

**Conclusion:** Ethnic disparities in risk of AMI/CHD death could be explained by modifiable risk factors.

#### INCIDENCE RATES FOR ACUTE MYOCARDIAL INFARCTION

### 319

#### Neighbourhood deprivation and inequities in mortality among patients with diabetes mellitus: a multilevel study

A. Chaikiat, X. Li, K. Sundquist; Center for Primary Health Care Research, IKVM, Malmo, Sweden.

**Background and aims:** Individuals with diabetes mellitus (DM) have higher risk of premature mortality and different mortality patterns, compared to individuals without DM. In this large-scale study, our aim was to examine if mortality (all cause and the five most common causes of death among individuals with DM in Sweden) vary by neighborhood-level deprivation after taking sociodemographic factors and comorbidities into account.

**Materials and methods:** The Swedish nationwide prescription register was used to identify 367 477 patients with DM who were followed for the outcome variable mortality in order to test whether neighborhood-level deprivation was significantly associated with mortality after adjusting for the following covariates: age, gender, marital status, family income, educational attainment, country of origin, mobility, urban/rural status and comorbidities.

**Results:** Multilevel logistic regression models were used in the statistical analyses. The odds ratio (OR) for mortality increased with increasing deprivation. The OR in high deprivation neighborhoods was 1.13 (95% CI 1.08–1.18). The five most common causes of death in the study population were coronary heart disease (CHD), stroke, psychiatric disorders, cancer and type 2 DM. For CHD and psychiatric disorders the ORs increased by increasing neighborhood deprivation and reached 1.37 (95% CI 1.26–1.48) and 1.29 (95% CI 1.04–1.61), respectively, in high deprivation neighborhoods. The corresponding OR for mortality from type 2 DM was 1.24 (95% CI 1.11–1.40).

**Conclusion:** This study shows that neighborhood-level deprivation is an important factor for mortality among patients with DM. Future research should examine possible pathways between neighborhood deprivation and mortality in order to reduce inequities in mortality among patients with DM.

#### Temporal trends in use of evidence-based treatments and risk factor control: a decade of nationwide monitoring

B. Eliasson<sup>1</sup>, A. Rawshani<sup>1</sup>, A.-M. Svensson<sup>1</sup>, N. Ekström<sup>1</sup>, B. Zethelius<sup>1</sup>, S. Gudbjörnsdóttir<sup>2</sup>;

<sup>1</sup>Clinical and Molecular Medicine, Inst of Medicine, <sup>2</sup>Clinical Medicine, Inst of Medicine, Uppsala, Sweden.

**Background and aims:** Glucose-lowering therapy with metformin is a cornerstone of diabetes treatment. Guidelines recommend instituting metformin at the time type 2 diabetes is diagnosed. Likewise, the primary preventive effects of statins in individuals with type 2 diabetes has been recognized for almost a decade. Little is known about the pace of adoption of these evidence-based medications. We examined this in a nationwide prospective study spanning over a decade.

**Materials and methods:** We used the Swedish National Diabetes Register to include 131935 newly diagnosed (within one year) cases of type 2 diabetes during 2002 to 2011. The study population was divided in ten cohorts corresponding to the year of diagnosis. To study trends in use of oral glucose-lowering drugs we included individuals who were treated with diet and lifestyle modifications at baseline. Patients were followed until initiation of oral glucose-lowering therapy or appropriate censoring. HbA1c was followed annually for each cohort. Trends in statin therapy was studied in therapy naive patients who did not experience any cardiovascular event throughout the study. Lipid markers were followed annually for each cohort. Time to event (instituting therapy) was analysed by means of Kaplan-Meier method.

**Results:** We included 58407 patients treated with diet and lifestyle modifications. We observed a striking pattern (figure I) towards earlier initiation of glucose-lowering drugs since 2002. Median time to drug in 2002 was 1730 (95% CI 1636, 1801) days compared to 471 (95% CI 420, 518) days in 2011. However, HbA1c levels displayed a different trend; HbA1c (at the same duration of diabetes) declined steadily from 2002 to 2007, whereafter levels increased. Considering statin therapy, we note the same pattern as with glucose-lowering drugs. Median time to therapy decreased from 2450 (95% CI 2360, 2530) days in 2002 to 650 (95% CI 580, 730) days in 2011. Interestingly, the curve for 2011 leveled off and crossed the curve for 2010. LDL-cholesterol displayed a pattern similar to HbA1c - an initial decline from 2002 to 2007 and thereafter a steady increase. Post hoc analysis of trends in body mass index (BMI) and physical activity sought to find an explanation for these trends; we noted that BMI at baseline and each point thereafter has increased annually since 2002.

**Conclusion:** We document a striking improvement in time to instituting oral glucose-lowering drugs. We also note that use of statins in primary prevention has accelerated in parallel. However, neither HbA1c nor lipid levels reflected these trends.

### 321

#### Prescribing patterns of antidiabetic drugs within the first year following diagnosis of type 2 diabetes: results from the DD2 study

A. Mor<sup>1</sup>, K. Berencsi<sup>1</sup>, E. Svensson<sup>1</sup>, J. Rungby<sup>2,3</sup>, J.S. Nielsen<sup>4</sup>, S. Friborg<sup>5</sup>, I. Brandslund<sup>6</sup>, J.S. Christiansen<sup>7</sup>, A. Vaag<sup>8</sup>, H. Beck-Nielsen<sup>4</sup>, H.T. Sørensen<sup>1</sup>, R.W. Thomsen<sup>1</sup>;

<sup>1</sup>Clinical Epidemiology, Aarhus University Hospital, <sup>2</sup>Pharmacology, Aarhus University Hospital, <sup>3</sup>Endocrinology, Gentofte University Hospital, Copenhagen, <sup>4</sup>Diabetes Research Centre, Endocrinology, <sup>5</sup>Endocrinology, Odense University Hospital, <sup>6</sup>Biochemistry, Lillebaelt Hospital, Vejle, <sup>7</sup>Internal Medicine and Endocrinology, Aarhus University Hospital, <sup>8</sup>Endocrinology, Rigshospital, Copenhagen, Denmark.

**Background and aims:** Real-world data are sparse on prescribing patterns of antidiabetic drugs in cases of newly diagnosed type 2 diabetes mellitus (T2DM) and on patient characteristics that may predict type of early pharmacotherapy.

**Materials and methods:** We studied 1,317 newly diagnosed T2DM patients enrolled in the Danish Centre for Strategic Research in Type 2 Diabetes (DD2) cohort from outpatient hospital clinics and general practice, with at least one year of follow-up. We described the number and type of antidiabetic drugs prescribed in the first year after T2DM diagnosis. Using Poisson regression, we calculated risk ratios (RRs) of treatment with different antidiabetic drugs associated with baseline patient characteristics.

**Results:** Of the 1,317 newly diagnosed T2DM patients, 198 (15%) did not use any antidiabetic drugs within the first year post-diagnosis, 867 (66%) used only one drug, 197 (15%) used two drugs, and 55 (4%) used three or more drugs. Figure 1 demonstrates the ranking of individual types of antidiabetic drugs used by our 1,317 T2DM patients. The likelihood of receiving combination therapy with two or more drugs in the first year post-diagnosis was substantially higher in T2DM patients aged  $\geq 3$  were at higher likelihood of receiving combination therapy (30%; RR = 1.54, 95% CI: 1.05-2.26) than T2DM patients with no comorbidity (19%). Weight gain  $> 30$  kg since 20 years of age and lack of regular physical exercise also increased the likelihood of receiving combination therapy during the first year post-diagnosis (RR = 1.42, 95% CI: 1.14-1.78 and RR = 1.42, 95% CI: 1.11-1.82, respectively). Higher likelihood of receiving combination therapy also was observed in T2DM patients with fasting blood glucose  $> 7$  mmol/L at diagnosis (RR = 3.37, 95% CI: 2.43-4.68), HbA1c  $\geq 7.5$  (RR = 3.85, 95% CI: 3.00-4.94), and C-peptide  $< 300$  pmol/L (RR = 1.78, 95% CI: 1.15-2.76).

**Conclusion:** Within the first year after T2DM diagnosis, 85% of the patients are treated with antidiabetic drugs, most commonly metformin (79%), an incretin (14%), or insulin (8%). Poor glycemic control and low C-peptide at T2DM diagnosis are predictors of combination therapy at one year. Other important predictors are young age, comorbidity, obesity, and lack of exercise.

### Factors associated with adherence to oral antihyperglycaemic monotherapy in patients with type 2 diabetes in the UK

K. Tunceli, C. Zhao, K. Iglay, K.G. Brodovicz, C.M. Alexander, L. Radican; Merck & Co., Inc., Whitehouse Station, USA.

**Background and aims:** Suboptimal medication adherence is a critical factor contributing to poor glycemic control and an increased risk of complications in patients with type 2 diabetes (T2DM). The current retrospective database analysis aims to estimate adherence to oral antihyperglycaemic monotherapy (OAM) for T2DM patients in the UK and describe factors associated with adherence in these patients.

**Materials and methods:** Patients with a physician prescription for metformin, sulfonylurea (SU), thiazolidinedione (TZD) or dipeptidyl peptidase-4 inhibitor (DPP-4i) as monotherapy between January 1, 2009 to June 30, 2012 (index period) were selected from the IMS Disease Analyser-Mediplus UK database. Patients were required to have a diagnosis of T2DM, be  $\geq 18$  years old at the time of diagnosis, and have medical records available in the database for 1 year before and after the index date. Patients were excluded if they had at least one diagnosis of type 1 diabetes mellitus, their dosing regimen (once daily or twice daily) could not be determined at the index date, they switched between once- and twice-daily dosing regimens during the 12-month post-index period, or they violated the monotherapy requirement during the 12-month post-index period. Adherence was assessed using the proportion of days covered (PDC) defined as total days medications supplied divided by days in follow-up period. Logistic regression was used to assess factors (age, gender, previous treatment status [new to or previously on OAM], dosing regimen [once- or twice-daily], and number of concomitant medications) associated with whether or not a patient is adherent (yes: PDC  $\geq 80\%$ , no: PDC  $< 80\%$ ).

**Results:** Eligible patients (N=6276; 57% men) had a mean age of 64.4 years (51.5%  $\geq 65$  years), 17.1% were on a once-daily regimen, and 58.1% were

on  $\geq 3$  concomitant medications. Overall, 60.1% of patients were adherent to OAM. The figure shows the results from the logistic regression analysis examining factors associated with being adherent to OAM. Patients younger than 45 years old and those 45 to  $< 65$  years old were 46% and 19% less likely to be adherent, respectively, compared to those 65 years and older. Compared to those taking 3 or more concomitant medications, those on no concomitant medications or 1-2 concomitant medications were 30% and 14% less likely to be adherent, respectively. Gender, dosing regimen and previous treatment status were not significantly associated with adherence in the regression model.

**Conclusion:** Medication adherence was shown to be suboptimal in this cohort of patients with T2DM in the UK. Younger age and use of fewer concomitant medications were factors associated with poor medication adherence in this study.

**Figure.** Logistic Regression Results (PDC $\geq 80\%$ )<sup>\*</sup>

### Clinical characteristics, comorbidities, and treatment patterns among patients with new-onset type 2 diabetes in a large integrated health system

K.M. Pantalone<sup>1</sup>, T.M. Hobbs<sup>2</sup>, B.J. Wells<sup>1</sup>, S.X. Kong<sup>2</sup>, M.W. Kattan<sup>1</sup>, J. Bouchard<sup>2</sup>, C. Yu<sup>1</sup>, B. Sakurada<sup>2</sup>, A. Milinovich<sup>1</sup>, W. Weng<sup>2</sup>, J. Bauman<sup>1</sup>, R.S. Zimmerman<sup>1</sup>;

<sup>1</sup>Cleveland Clinic, <sup>2</sup>Novo Nordisk, Plainsboro, USA.

**Background and aims:** The incidence of type 2 diabetes (T2D) has steadily increased over the past few decades. In the United States approximately 1.9 million people ages 20 years or older were newly diagnosed with diabetes in 2010 alone. Despite this increase, there are limited real-world data describing the clinical characteristics, comorbidities, and treatment patterns of patients with new-onset T2D. The objective of this research was to assess the profiles and treatment patterns of patients with new-onset T2D in a large integrated health system.

**Materials and methods:** An enterprise-wide electronic health record system (EHR) at a large U.S. academic health center was used to conduct a cross-sectional analysis of 26909 patients with new-onset T2D diagnosed between 2008 and 2012. Patients with T2D were identified using a validated algorithm to classify T2D subjects based on a combination of clinical diagnoses, medications, and laboratory results. Patients with new-onset diabetes were isolated by requiring at least 2 office encounters at the institution with a primary care provider and/or endocrinologist prior to the diagnosis of T2D. The population was divided into five strata based on the year in which the new-onset diagnosis of T2D occurred: 2008, 2009, 2010, 2011, and 2012. Comorbidities, glycemic control, and active prescriptions were assessed at 1 year after diagnosis.

**Results:** The population was 51.1% female and 73.5% White. A total of 4150 (15.4%), 4500 (16.7%), 5372 (20.0%), 6301 (23.4%) and 6586 (24.5%) patients were included in each of the incidence year stratum, respectively. The mean ages (years) for patients at the time of diagnosis across the incidence year strata were 62.3, 61.2, 60.8, 61.0, and 60.8, respectively. The prevalence of hypertension (HTN) within 1 year of new-onset T2D was 80%. The percentages of patients with active prescriptions for 2 or more classes of anti-diabetic agents at 1 year after diagnosis were 32.3, 32.6, 28.4, 29.5, and 31%, respectively. The selection of anti-diabetic therapy was rather consistent among the new-onset T2D patients from 2008-2012, with the only exception being a steady decline in the use of thiazolidinediones mirrored by a concordant rise

in the use of dipetidyl peptidase-4 (DPP-4) inhibitors. Interestingly, within each incidence year strata, 52.1, 47.0, 48.3, 54.2, and 55.7% of patients did not have an HbA<sub>1c</sub> measurement recorded in the lab section of the EHR within the 1<sup>st</sup> year of diagnosis. Among patients with available HbA<sub>1c</sub> values, the percentages of patients with inadequate glycemic control (HbA<sub>1c</sub>>8%) at 1 year were 25.1%, 24.4%, 22.2%, 25.9%, and 28%, respectively.

**Conclusion:** A high prevalence of HTN was observed among this population of patients with new-onset T2D. Nearly 1/3 of the new-onset T2D patients were receiving 2 or more classes of anti-diabetic agents at 1 year after diagnosis. The use of thiazolidinediones in patients with new-onset T2D has decreased, whereas the use of DPP-4 inhibitors has increased. Of note, the use of sulfonylureas has not decreased, despite the availability of several new agents. Approximately 1/2 of new-onset T2D patients did not have an HbA<sub>1c</sub> value recorded in the lab section of the EHR within the 1<sup>st</sup> year of diagnosis.

### Burden of baseline comorbidities in patients with type 2 diabetes initiating various classes of antidiabetic agents - an analysis of a large US claims database

T.M. Rehman<sup>1</sup>, S. Colilla<sup>2</sup>, T. Kou<sup>3</sup>, J. Wood<sup>3</sup>;

<sup>1</sup>Global Pharmacovigilance and Epidemiology, Bristol Myers Squibb, Wallingford, <sup>2</sup>GHEOR CORDS, Bristol Myers Squibb,

<sup>3</sup>Global Pharmacovigilance and Epidemiology, Bristol Myers Squibb, Pennington, USA.

**Background and aims:** Channeling bias is a concern when designing observational comparative studies including users of different drug classes for the management of Type 2 Diabetes Mellitus (T2DM). Characterizing the differences in patient baseline characteristics across comparator drug classes will aid in the evaluation of channeling bias. This study described patient demographic and clinical characteristics among US patients with T2DM initiating a new class of antidiabetic drug in 2012.

**Materials and methods:** US adult patients with T2DM who initiated a new class of antidiabetic drug during the first six months of 2012 (N=183,692) were identified in the Truven MarketScan Commercial Claims and Encounters database. The date of first new class of oral or injectable antidiabetic drug during the study period was defined as the index date. Patient's baseline characteristics were identified in the 12 months prior to the index date. Comorbidities were based on ICD-9-CM diagnostic codes and NDC codes used for prescriptions.

**Results:** We identified 183,692 patients with majority (40%) initiating biguanides. Similar mean age was seen in all of the drug classes except GLP-1 RA users who were younger. Contrary to other classes, GLP-1 RA users were predominantly female. Over 50% of new users had hyperlipidemia and hypertension at baseline with the prevalence being highest in DPP-4i and GLP-1 RA users. A diagnosis of obesity was most notable in GLP-1 RA users. History of heart failure was highest in insulin users. Although rare, history of acute and chronic pancreatitis was lowest in GLP-1 RA and DPP-4i users. Compared to biguanide users, more concomitant use of lipid lowering medications was observed in users of all other classes.

**Conclusion:** Differences were observed in the burden of comorbidities across different antidiabetic drug classes initiated which suggests a degree of channeling bias. Careful consideration and accounting of these factors dur-

ing analysis is needed when conducting comparative observational studies among patients treated for Type 2 diabetes.

## 325

### Hospitalisation frequency for hypoglycaemia and emergency calls in type 2 diabetes mellitus patients exposed to vildagliptin vs insulin-secretagogues in the French Health Insurance database

B. Detournay<sup>1</sup>, S. Dejager<sup>2</sup>, J. Robert<sup>1</sup>;

<sup>1</sup>Cemka-Eval, Bourg-la Reine,

<sup>2</sup>Novartis Pharma SAS, Rueil Malmaison, France.

**Background and aims:** To compare the frequency of severe hypoglycaemic episodes leading to hospitalization and of emergency calls for any cause in patients exposed to the DPP-4 inhibitor vildagliptin vs those exposed to insulin secretagogues (IS; sulphonylurea or glinide).

**Materials and methods:** Retrospective data were extracted from the EGB (Echantillon Généraliste des Bénéficiaires) database: a data resource comprising a sample of ~1% of all patients registered in the French National Health Insurance system (~600,000 patients). Type 2 diabetes mellitus patients exposed to regimens comprising either vildagliptin (excluding treatment with IS, insulin or another incretin therapy) or IS (excluding treatment with insulin and any incretin therapy) between 2009 and 2012 were selected. Hospitalizations related to hypoglycaemia during the exposure periods were identified in both cohorts. Two comparative analyses adjusting for key covariates within the model (subjects matched for age, gender, socioeconomic status, drug exposure duration), or with multivariate logistic regression, were performed.

**Results:** 1,440 patients were exposed to vildagliptin and 10,019 to IS. Patients in the IS cohort were older than in the vildagliptin cohort (mean 67.3 (SD: 12.8) years old vs. 63.5 (SD: 11.9), p<0.0001) and had a longer exposure duration over the study period (vildagliptin has been marketed since September 2009 in France). During the observation period, no patient from the vildagliptin cohort (0.0%) was hospitalized for hypoglycaemia vs 130 (1.30%) with IS (138 hospitalizations) (p<0.0005). The rough hospitalization rates for hypoglycaemia were 0 in the vildagliptin cohort vs 5.6 hospitalization/1000 patient-years [95% CI: 4.7; 6.6] in the IS cohort (p=0.02). 60 patients in the vildagliptin cohort (4.2%) vs 2,144 patients (21.4%) in the IS cohort visited the emergency department (p<0.0001), but with no significant difference between the 2 cohorts regarding the rates of all emergency calls/1000 patient-years (p=0.5). After adjustment, rates of hospitalization and of all emergency calls were significantly lower with vildagliptin vs IS (Table). Consistent results were found when considering treatment initiations only, in the IS cohort. Due to limitations in the availability of some data in the database, adjustments did not consider HbA<sub>1c</sub> levels or other potential confounding factors.

**Conclusion:** There was a significantly lower frequency of hospitalization for severe hypoglycaemia and of all emergency calls in patients exposed to vildagliptin vs IS. These real-life data should be taken into consideration in the benefit/risk evaluation of the drugs.

**Table : Adjusted comparison of the frequency of events in the 2 cohorts**

### Predicting glycaemic changes in the non-diabetic general population: a DIRECT study

A.D.M. Koopman, S.P. Rauh, the DIRECT Consortium;  
Department of Epidemiology and Biostatistics, EMGO Institute for Health and Care Research, Amsterdam, Netherlands.

**Background and aims:** Recently, glycated haemoglobin (HbA1c) levels have been introduced as a diagnostic criterion for type 2 diabetes. Our study evaluates whether in addition to baseline HbA1c levels, non-invasive measures can be used to predict changes in HbA1c levels during 6 years follow-up.

**Materials and methods:** Data from 2,887 initially non-diabetic subjects (based on ADA 2011 criteria) from 3 population-based cohorts (Hoorn Study, Inter99, KORA S4) were used to develop sex-specific linear regression models predicting change in HbA1c levels during follow-up. By using change in HbA1c levels, lab differences were avoided. To minimize overfitting of the model, we performed internal validation using bootstrapping techniques. Calibration was assessed with calibration graphs. Discriminative performance was assessed with classification tables, dichotomizing HbA1c levels ( $\geq 5.7\%$  vs  $< 5.7\%$ ).

**Results:** At baseline, mean HbA1c level was 5.6%. During a mean follow-up of 6 years (SD: 0.7 years), median change in HbA1c levels was +0.02%. HbA1c levels increased in 51% of the subjects, 2.3% of the subjects developed HbA1c levels  $\geq 6.5\%$ . After backward selection, next to baseline HbA1c levels, for men: age, waist circumference, smoking, and parental history of diabetes were retained in the prediction model (explained variance (R<sup>2</sup>): 33%); and for women: BMI and waist circumference (R<sup>2</sup>: 23%). Calibration plots showed good agreement between predicted and observed HbA1c levels at follow-up. With respect to discrimination, our model classified 75% of the subjects correctly as having high/low HbA1c levels.

**Conclusion:** In the non-diabetic population, non-invasive predictors can be used next to baseline HbA1c levels to predict change in HbA1c levels during 6 years follow-up. This model can be used in clinical practice to determine which patients are at high risk of glycaemic deterioration. High-risk patients can then be monitored more regularly than low-risk patients and targeted preventive interventions can be initiated.

### Factors associated with weight gain and hypoglycaemia and the impact upon hospitalisation in type 2 diabetes patients managed with metformin plus sulfonylurea

J. Gordon<sup>1</sup>, P. McEwan<sup>1,2</sup>, M. Evans<sup>3</sup>, J. Puelles<sup>4</sup>;

<sup>1</sup>Health Economics and Outcomes Research Ltd, Monmouth, <sup>2</sup>Swansea University Centre for Health Economics, <sup>3</sup>Cardiff and Vale University Health Board, <sup>4</sup>Takeda Global Research and Development, London, UK.

**Background and aims:** The importance of avoiding complications that decrease quality of life and consume healthcare resources in people with type 2 diabetes is well understood. However, the relationship between resource utilisation and patient phenotype is less well researched. The objective of this study was to assess factors associated with weight gain and the occurrence of hypoglycaemia in type 2 diabetes (T2DM) patients managed with metformin plus sulfonylurea (M+S), and any associated impact upon hospital resource utilisation.

**Materials and methods:** The study was a retrospective cohort study using the UK Clinical Practice Research Datalink (CPRD) and the Hospital Episode Statistics (HES) database. The cohort analysed were those with T2DM treated with M+S for at least 3 months during the period 1/1/2001 to 31/12/2011; patients with a diagnosis of malignant disease were excluded. The association between phenotypic factors at baseline (therapy escalation from metformin to M+S) and weight gain (defined as  $> 2\text{kg}$  weight change over 12 months) and primary care recorded hypoglycaemia ( $\geq 1$  episode) over 12 months following therapy escalation was assessed using logistic regression. Hospitalisation associated with increasing body mass index (BMI) and hypoglycaemia was also assessed. Analysis was undertaken using R version 2.12.2

**Results:** A total of 11,071 patients met the study inclusion/exclusion criteria with mean age at baseline of 60.7 (SD=11.4) years, 39% female, 5.4 (SD=4.0) years duration of diabetes, HbA1c 8.7% (SD=1.6), weight 92.2 kg (SD=19.6) and BMI 32.2kg/m<sup>2</sup> (SD=6.1). Weight gain (1=weight gain; 0 otherwise) was observed in 28.35% (n=3,139) and was significantly associated with baseline age (OR=0.99 for one-year increase in age, p<0.01), female gender (OR=0.87, p<0.05) and baseline weight (OR=1.003 for 1 kg increase in weight, p<0.05) and HbA1c (OR=1.06 for 1% increase in HbA1c, p=1 episode; 0 otherwise) occurred in 1.3% (n=142) of patients and was associated with duration of diabetes (OR=1.04 for one-year increase in duration, p<0.05), baseline HbA1c (OR=0.86 for 1% increase in HbA1c, p<0.05) and prior complications status (OR=1.92, p<0.05). Hospitalisation occurred in 10% of patients (n=1,125) and was significantly associated with BMI (OR=1.02 for 1 kg/m<sup>2</sup> increase in BMI, p<0.01) but not hypoglycaemia. The mean number of hospital admissions over the follow-up period was 1.7, 1.8, 1.9 and 3.1 in those with BMIs at the time of admission in the normal, overweight, obese and morbidly obese categories respectively.

**Conclusion:** This real-world observational analysis suggests there are identifiable phenotypic characteristics predictive of weight gain, and there are identifiable phenotypic characteristics predictive of hypoglycaemia. This study also shows a general relationship between increasing BMI and hospitalisation, most notably in the comparison of normal vs morbidly obese subjects, that may not be adequately captured in widely used vascular risk equations such as UKPDS in which BMI has minimal influence on risk. Consequently the value of diabetes management strategies that minimise weight gain may be underestimated.

**Analysis on incidence of new-onset diabetes mellitus after renal transplantation in different eras**

M. Yu<sup>1</sup>, C. Lv<sup>1</sup>, M. Chen<sup>1</sup>, M. Xu<sup>2</sup>, Y. Zhang<sup>1</sup>, S. He<sup>1</sup>, M. Xue<sup>1</sup>, J. Gao<sup>3</sup>, X. Gao<sup>1</sup>, T. Zhu<sup>2</sup>;

<sup>1</sup>Endocrinology, <sup>2</sup>Urology, <sup>3</sup>Evidence Base Medicine Center, Zhongshan Hospital affiliated to Fudan University, Shanghai, China

**Background and aims:** To retrospectively evaluate the long-term fluctuation of fasting plasma glucose (FPG) after renal transplantation, in order to explore the incidence of new-onset diabetes mellitus after transplantation (NODAT) in different eras.

**Materials and methods:** We retrospectively evaluated 709 patients receiving kidney transplantation at our center between 1 January, 1993 and 31 December, 2008. After excluding patients with uncompleted data, graft failure or death within 1 year after transplantation, multi-organ transplant recipients, transplant more than once or previously known diabetes, 428 patients were analyzed. The incidence of new-onset diabetes mellitus after renal transplantation was analyzed according to FPG in different eras. Immunosuppressive treatment after transplantation might be cyclosporine-A, (CSA)+ mycophenolate mofetil (MMF) (or Azathioprine (AZA)) + glucocorticoid or tacrolimus (FK506)+MMF (or AZA)+ glucocorticoid. We use AZA for anti-proliferative drug before 1997 and MMF after that. We started using FK506 in 1999 and in some patients using CD25 monoclonal antibody for immunosuppression induction since 2001. Patients were divided into three groups 1993-1996, 1997-2000, 2001-2008 according to different immunosuppressive treatment, and the incidence of NODAT was compared between different eras.

**Results:** Of the 428 Patients, 87 developed NODAT (20.3%) during a mean follow-up of 6 years. According to the different immunosuppressive treatment in the different eras, patients were divided into three groups 1993-1996, 1997-2000, 2001-2008, of which the incidence of NODAT was 18.42%, 17.46% and 21.11% respectively. There was no difference in the incidence of NODAT among three transplantation eras.

**Conclusion:** The incidence of NODAT was 20.3% in patients surviving for more than 1 year during a mean follow-up of 6 years at Zhongshan Hospital. There was no difference in the incidence of NODAT among three transplantation eras.

## 329

**Primary autoantigen specific genetic traits in the pathogenesis of type 1 diabetes**

J. Lempainen<sup>1,2</sup>, A.-P. Laine<sup>1</sup>, A. Hammam<sup>1</sup>, J. Toppari<sup>2</sup>, R. Veijola<sup>3</sup>, O. Simell<sup>2</sup>, M. Knip<sup>4,5</sup>, J. Ilonen<sup>1,6</sup>;

<sup>1</sup>Immunogenetics Laboratory, University of Turku, <sup>2</sup>Department of Pediatrics, University of Turku and Turku University Hospital, <sup>3</sup>Department of Pediatrics, University of Oulu and Oulu University Hospital, <sup>4</sup>Children's Hospital, University of Helsinki and Helsinki University Central Hospital, <sup>5</sup>Department of Pediatrics, Tampere University Hospital, <sup>6</sup>Department of Clinical Microbiology, University of Eastern Finland, Kuopio, Finland.

**Background and aims:** Natural history studies on type 1 diabetes (T1D) associated autoimmunity provide an opportunity to identify detailed mechanisms of autoantigen specific genetic traits of diseases pathogenesis. We hypothesized that if the effect of a specific T1D-risk associated genetic marker is related to the triggering autoantigen of beta-cell destruction, the effect of the single variant should be dependent on the first appearing autoantigen-specific autoantibody.

**Materials and methods:** The study subjects were participants in the prospective DIPP study and carried T1D-risk associated HLA class II genotypes. From the DIPP study cohort, we were able to identify 170 subjects with IAA as the first biochemical autoantibody and selected 325 autoantibody negative controls matched for gender, date of birth and study center. Similarly we identified 151 subjects with GADA as the first biochemical autoantibody and 285 autoantibody negative controls for them. Forty-three single nucleotide polymorphisms (SNPs) associated with T1D risk were genotyped using the Sequenom platform. Differences in effect of various SNPs on the development of autoantibodies and further progression to clinical T1D were tested among subjects with IAA or GADA as the first biochemically-defined autoantibody. Cox regression analysis was performed to test the effect of the gene markers on the T1D pathogenesis.

**Results:** The effect of INS rs689, IKZF4 rs1701704 and ERBB3 rs2292239 polymorphisms differed significantly between subjects with IAA or GADA as the first biochemical autoantibody. INS SNP strongly affected the development of clinical T1D and, in particular, the appearance of beta-cell humoral autoimmunity among the group with IAA as the first autoantibody ( $p=0.0054$  and  $0.0024$ , respectively) whereas no effect of the INS SNP on the T1D pathogenesis in the GADA group could be observed. In contrast, IKZF4 and ERBB3 SNPs were associated with the development of T1D in the GADA group ( $p=0.0022$  and  $0.0064$ , respectively) and, the two polymorphisms affected the progression rate of beta-cell destruction after the appearance of autoimmunity in the GADA group ( $p=0.0025$  and  $0.0024$ , respectively) whereas no effect of these SNPs on the appearance of T1D or the progression rate of beta-cell destruction could be observed in the IAA group.

**Conclusion:** The first appearing autoantibody specific approach revealed two genetic pathways dependent on the primary autoantigen. The effect of INS gene SNP on the pathogenesis of T1D was restricted to subjects with IAA as the first autoantibody whereas the SNPs in the IKZF4-ERBB3 locus increased the T1D risk and, more specifically, the progression rate of beta-cell destruction among subjects with GADA as the first autoantibody.

## 330

**Concentrations of soluble receptor for AGEs decline at seroconversion in children with preclinical type 1 diabetes but not in autoantibody positive non-progressors**

K.M. Salonen<sup>1</sup>, S.J. Ryhänen<sup>1</sup>, J.M. Forbes<sup>2</sup>, T. Härkönen<sup>1</sup>, J. Ilonen<sup>3</sup>, O. Simell<sup>4</sup>, R. Veijola<sup>5</sup>, P.-H. Groop<sup>6</sup>, M. Knip<sup>1,7</sup>;

<sup>1</sup>Children's Hospital, University of Helsinki, Finland, <sup>2</sup>Mater Research UQ at TRI, University of Queensland, Brisbane, Australia, <sup>3</sup>Immunogenetics Laboratory, <sup>4</sup>Department of Paediatrics, University of Turku, <sup>5</sup>Department of Paediatrics, University of Oulu, <sup>6</sup>Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, <sup>7</sup>Department of Pediatrics, Tampere University Hospital, Finland.

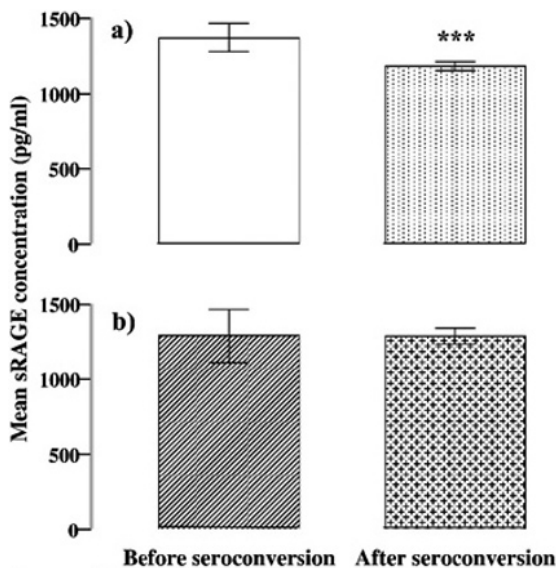

**Background and aims:** Our previous studies suggest that concentrations of soluble receptor for advanced glycation end products (sRAGE) might play a

role in the process leading to type 1 diabetes. We set out to define the changes in sRAGE in prediabetic and autoantibody positive children.

**Materials and methods:** We analyzed serum concentrations of sRAGE from samples of 168 children who progressed to type 1 diabetes and 43 children who became positive for at least 2 diabetes associated autoantibodies during prospective observation, but have not progressed to diabetes. We analyzed the sRAGE concentration before seroconversion, in the first autoantibody positive sample, and annually after that until the diagnosis of type 1 diabetes or end of follow up.

**Results:** The children who progressed to clinical type 1 diabetes were younger at seroconversion and at end of follow up than the non-progressors [2.04 ( $\pm$  1.5) years vs. 3.04 ( $\pm$  1.5) years,  $p < 0.001$ , and 5.91 ( $\pm$  3.06) years vs. 9.67 ( $\pm$  2.62) years, respectively (Mann-Whitney U-test)]. The progressors had similar or higher sRAGE than the non-progressors before seroconversion ( $p = \text{NS}$ ) but subsequently lower levels [1183 ( $\pm$  445) pg/ml vs. 1286 ( $\pm$  490) pg/ml,  $p < 0.001$  (t-test)]. The progressors had in the sample taken before seroconversion higher concentrations of sRAGE than in subsequent samples [mean sRAGE 1372 ( $\pm$  573) pg/ml vs. 1183 ( $\pm$  445) pg/ml,  $p < 0.001$  (t-test)]. The difference remained significant even after adjusting for sampling age [ $p < 0.001$  (linear regression)]. Concentrations of sRAGE were similar before and after seroconversion in the non-progressors [mean sRAGE 1290 ( $\pm$  562) pg/ml vs. 1286 ( $\pm$  490) pg/ml,  $p = \text{NS}$  (t-test)]. There was a correlation between age and sRAGE concentrations among the non-progressors [ $r$  0.13,  $p = 0.008$  (Spearman's rho)] but not in the children who eventually presented with type 1 diabetes. After seroconversion there was no significant variation in the sRAGE concentrations in the two groups.

**Conclusion:** Children who later develop type 1 diabetes have higher sRAGE concentrations before seroconversion than after the initiation of beta-cell autoimmunity. Our study suggests that non-progressors with persistent positivity to islet cell autoantibodies do not experience a similar decrease in sRAGE. As AGEs have been shown to be detrimental to beta cells, the drop in circulating sRAGE seen in temporal association with seroconversion may reflect failing protective mechanisms in the progressors.

Concentrations of sRAGE in a) children progressing to type 1 diabetes ( $n = 168$ ), and b) the non-progressors ( $n = 43$ ). \*\*\* $p < 0.001$  vs. initial sample.

#### High risk vs low risk nondiabetic first degree relatives of patients with type 1 diabetes: differences in CXCR3+, CCR4+, CD25high T memory cells and chemokine levels

T. Milicic<sup>1</sup>, A. Jotic<sup>1</sup>, I. Markovic<sup>2</sup>, K. Lalic<sup>1</sup>, L. Lukic<sup>1</sup>, N. Rajkovic<sup>1</sup>, M. Macesic<sup>1</sup>, J. Seferovic<sup>1</sup>, J. Stanaric<sup>1</sup>, N. Lalic<sup>1</sup>;

<sup>1</sup>Clinic for Endocrinology, <sup>2</sup>Institute for Biochemistry, Faculty of Medicine, University of Belgrade, Serbia.

**Background and aims:** Previously was suggested the prominent role of the chemokine receptors CXCR3 and CCR4, associated with Th1 and Th2 memory cell subsets respectively, together with impairments in T regulatory (T reg)

subset, in animal models of the initial phase of Type 1 diabetes (T1D). However, the relevance of the changes in CXCR3+ (Th1 associated), CCR4+ (Th2 associated) and CD25high subsets (T reg associated) of the T memory cells as well as in chemokine/cytokine levels, interferon- $\gamma$  inducible chemokine (IP-10) (Th1 associated), thymus-and activation-regulated chemokine (TARC) (Th2 associated) and transforming growth factor  $\beta$  (TGF $\beta$ ) (Treg associated), for risk for T1D development, has not yet been clarified. Therefore, the aim of this study was to analyze (a) the percentage of CXCR3+, CCR4+, CD25high subsets of T memory cells and (b) chemokine/cytokine levels IP-10, TARC and TGF $\beta$ , in peripheral blood of two groups, the high risk and the low risk group, of nondiabetic first-degree relatives (FDRs) of patients with T1D as well as in the group of healthy unrelated controls. The difference between the two groups of FDRs was based on presence/ absence of glutamic acid decarboxylase (GADA) and tyrosine phosphatase insulinoma antigen-2 (IA-2) antibodies. Thus, in the study we included 17 high-risk nondiabetic FDRs (GADA+, IA-2+) (group A) and 34 low-risk nondiabetic FDRs (GADA- IA-2-) (group B) and 18 healthy unrelated controls (group C).

**Materials and methods:** T1D and glucose intolerance were excluded in the study by using WHO criteria. GADA and IA-2 levels were determined by ELISA. The percentages of CXCR3+, CCR4+ and CD25high T memory cell subsets were analyzed in peripheral blood by using four-color immunofluorescence staining and flowcytometry. IP-10, TARC and TGF $\beta$  were determined by ELISA.

**Results:** When the percentage of CXCR3+ T memory cells was analyzed, it was found to be higher in group A vs groups B and C (A: 64.98 $\pm$ 5.19 vs B: 42.13 $\pm$ 11.11; C: 53.09 $\pm$ 6.29 %, A vs B:  $p < 0.001$ ; A vs C:  $p < 0.01$ ). In contrast, the percentage of CCR4+ T memory cells was significantly lower in group A vs groups B and C (A: 29.46 $\pm$ 2.83 vs B 41.90 $\pm$ 8.58; C: 40.90 $\pm$ 7.24%  $p < 0.001$ ). Simultaneously, the percentage of CD25high T memory cells was significantly lower in group A vs groups B and C (A: 0.13 $\pm$ 0.05 vs B: 0.26 $\pm$ 0.10 ; C: 0.26 $\pm$ 0.06%,  $p < 0.001$ ). On the other hand, IP-10 and TARC levels were significantly higher in group A vs B and C (A: 160.12 $\pm$ 73.40; 438.83 $\pm$ 120.62, B: 105.39 $\pm$ 71.30; 312.04 $\pm$ 151.14, C: 85.24 $\pm$ 19.82; 236.88 $\pm$ 89.19 pg/ml, respectively; A vs B  $p < 0.05$ , A vs C  $p < 0.01$ ), while there was no difference in TGF $\beta$  levels in groups A, B and C (A: 8883.17 $\pm$ 3105.96, B: 7981.04 $\pm$ 3889.51, C: 10064.44 $\pm$ 681.99 pg/ml; A vs B vs C,  $p = \text{NS}$ ).

**Conclusion:** Our results have demonstrated that high risk FDRs, showed higher levels of CXCR3+ T memory cells and IP-10, both associated with increased Th1 response, together with lower levels of CCR4+ T memory cells expressing Th2 response and CD25high T reg cells subsets, and without impairments in TGF $\beta$  level. The results imply that the risk for developing T1D might be associated with the dominant influence of Th1 autoimmune response, together with diminished Th2 autoimmune response, while Treg response in high risk FDRs was impaired but still functionally preserved.

### 332

#### Differential apoptosis in lymphocytes of patients with type 1 diabetes associated with relative expression of microRNA-146a

F. Pérez-Bravo<sup>1</sup>, G. Mancilla<sup>1</sup>, D. García-Días<sup>1</sup>, E. Codner<sup>2</sup>;

<sup>1</sup>Nutrition, University of Chile, <sup>2</sup>IDIMI, University of Chile, Santiago, Chile.

**Background and aims:** It is well established that type 1 diabetes (T1D) is an autoimmune disease. Controversial data exists regarding the differential control of the immune system in T1D patients compared to unaffected individuals. MicroRNAs (miRNAs) are involved in the control of gene expression (by negative regulation of gene expression at post-transcriptional level, by mediating translational repression or degradation of the mRNA targets). Their potential role in T cell activation and autoimmunity is controversial. We aim to elucidate relationship miR-146a in cell survival

**Materials and methods:** We investigated the expression profile of miRNAs in polymorphonuclear cells (PBMC) samples of 5 T1D patients (12-17 years old) and 5 healthy controls by means of qPCR. Cells were cultured in 96-well plates in RPMI-1640 with 10% FBS at 37 °C with 5% CO<sub>2</sub>. The activation was performed using anti-CD3 1 $\mu$ g/ml for 8 hours. RNA extraction and cDNA were performed by standard techniques. miR-146, miR-155, miR-182 and miR-155. Real-time PCR expression on time zero and after 8 h of culture was measured. Additionally we quantified baseline lymphocyte apoptosis by flow cytometry using Annexin V.

**Results:** The comparison between diabetics and controls both in basal conditions and activation showed only miR146a statistically significant differences ( $p < 0.0016$ ), miR155 ( $p = 0.14$ ) and miR182 ( $p = 0.95$ ). In relation to apoptosis, DM1 patients showed a lower rate of apoptosis (1.82%) and statistically different when compared with control subjects (7.49%),  $p = 0.0286$ . Finally,

the correlation between the percentage of apoptosis and expression of miR146a was  $r = 0.786$  ( $p < 0.0279$ )

**Conclusion:** Our results indicate that the low expression of miR-146a may be associated with a decreased rate of cell apoptosis. Thus the activation window would be higher in these patients. Previous studies have shown that molecules such as IRAK and TRAF6 are targets of miR-146a, which work in a negative feedback system for activation of NF- $\kappa$ B molecule that influences the rate of cell survival through the cell cycle progression

### 333

#### Rapid assays for detection of type 1 diabetes-associated autoantibodies in organ donors

T. Härkönen<sup>1,2</sup>, M. Kararic<sup>1,2</sup>, H. Hyöty<sup>3,4</sup>, M. Knip<sup>1,2</sup>;

<sup>1</sup>Children's Hospital, University of Helsinki and Helsinki University Central Hospital, Finland, <sup>2</sup>Diabetes and Obesity Research Program, University of Helsinki, <sup>3</sup>Department of Virology, School of Medicine, University of Tampere, <sup>4</sup>Department of Clinical Microbiology, Center for Laboratory Medicine, Tampere, Finland.

**Background and aims:** Diabetes-associated autoantibodies are essential in the prediction of type 1 diabetes and in the classification of diabetes. Autoantibodies are also used to identify autoantibody-positive organ donors in large international studies (e.g. nPOD and PEVNET) which aim at uncovering pathogenic changes in pancreas and related organs in order to understand the mechanisms of beta-cell destruction. The current study set out to develop rapid assays for autoantibodies to glutamic acid decarboxylase 65 (GADA), islet antigen-2 (IA-2A) and zinc transporter 8 (ZnT8A) by modifications of both our in-house radiobindingimmuno assay (RBA) and a commercial ELISA (RSR Limited, United Kingdom).

**Materials and methods:** We have analyzed 100 diabetic children and non-diabetic siblings for IA-2A and GADA both with conventional and rapid assays. The RBA was modified into a rapid assay by incubating the labeled antigens and serum for one hour at RT instead of overnight at 4 °C. Immune complexes were bound to Protein-A Sepharose at 4 °C for one hour. The rapid assays were further optimized by incubating serum and labeled antigen for 45 min at RT and immune complexes precipitated for 30 min at 4 °C. Further, antigen labels were made ready, standards and controls were pipetted on plates beforehand and all were kept at -80 °C. The RSR ELISAs were first performed according to the manufacturer's instructions. Then assays were modified by shortening the incubation times to 20 minutes and all incubations performed at RT. Six sera from the Finnish Pediatric Diabetes Register with varying autoantibody levels were selected and analyzed both with RIA and ELISA several times in different incubation conditions. For correlation analyses we also analyzed 17 diabetic and 20 non-diabetic siblings.

**Results:** The six sera from the Pediatric Diabetes register showed strong consistency for medium titers and negative responses, but RBA results close to cut-off values showed some discrepancies. ELISA results were more consistent. The analysis showed a strong correlation between the conventional and rapid RBA assays ( $r=0.92$  for IA-2A and  $r=0.89$  for GADA) with 1 hour incubations, ( $r=0.912$  for IA-2A,  $r=0.941$  for GADA and  $r=0.862$  for ZnT8A) with 45 min incubation and 30 min precipitation. ELISAs performed according to the manufacturer's instructions and with the rapid assays correlated well ( $r=0.96$  for IA-2A,  $r=0.98$  for GADA and  $r=0.87$  for ZnT8A).

**Conclusion:** Our results indicate, that all three (IA-2A, GADA and ZnT8A) RSR ELISA assays can be accomplished within 1 hour 45 minutes and the

results correlate well with results obtained according to the manufacturer's instructions. All three RBA assays can be performed in 2 hours 15 minutes and the results obtained correlate well with conventional in-house assays and are in good concordance with the ELISA results.

### 334

#### Combined appearance of autoantibodies against GAD, IA-2, insulin and ZnT8 in the islet autoantibody standardisation program 2013 proficiency workshop

M. Schlosser<sup>1</sup>, V. Lampasona<sup>2</sup>, A.J.K. Williams<sup>3</sup>, P.W. Mueller<sup>4</sup>, D.L. Pittman<sup>5</sup>, W.E. Winter<sup>5</sup>, B. Akolkar<sup>6</sup>, P. Achenbach<sup>7</sup>;

<sup>1</sup>Department of Medical Biochemistry and Molecular Biology, University Medical Center Greifswald, Karlsburg, Germany, <sup>2</sup>Center of Genomics, Bioinformatics and Biostatistics, Milan, Italy, <sup>3</sup>Clinical Science at North Bristol, University of Bristol, UK, <sup>4</sup>National Diabetes Laboratory, Centers for Disease Control and Prevention, Atlanta, <sup>5</sup>Department of Pathology, University of Florida, Karlsburg, <sup>6</sup>Division of Diabetes, Endocrinology and Metabolic Diseases, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, USA, <sup>7</sup>Institute of Diabetes Research, Helmholtz Center Munich, Germany.

**Background and aims:** The Islet Autoantibody Standardization Program (IASP), a continuation of the Diabetes Antibody Standardization Program (DASP) of the Immunology of Diabetes Society, set up to evaluate and improve assays for type 1 diabetes (T1D)-associated autoantibodies (AAb). The IASP 2013 workshop aimed to assess the sensitivity/specificity and concordance of assays measuring AAb to GAD (GADA), IA-2 (IA-2A), insulin (IAA), and zinc transporter 8 (ZnT8A) in laboratories throughout the world. We assessed the combined detection of these four AAb in IASP serum samples considering differences in assay performance.

**Materials and methods:** Coded sera from 50 patients with newly diagnosed T1D and 90 healthy controls were analyzed in laboratories by 33 GADA assays, 31 IA-2A assays, 18 IAA assays and 21 ZnT8A assays. Sera were categorized according to the number of laboratories calling them positive using local assay thresholds, and further stratified between patients and controls by the number of positive AAb. Category 1 (C1) included sera that were found AAb positive by at least 90% of assays. Category 2 (C2) included C1-sera plus additional sera that were found AAb positive by at least 50% of assays. Category 3 (C3) included C2-sera plus sera that were found AAb positive by at least 25% of assays.

**Results:** Of 50 patient sera, 39 (78%) were included in C1, 42 (84%) in C2 and 45 (90%) in C3. None of the 90 control sera were included in C1 (0%), while 1 (1%) and 6 (7%) control sera were included in C2 and C3 respectively. The number of multiple AAb positive patient sera increased from 27 (54%) in C1, to 37 (74%) in C2, and 39 (78%) in C3 ( $p=0.04$ ). One control serum in C2 was positive for multiple AAb. For all AAb specificities, C1-sera had significantly higher antibody titres than C2-sera ( $p<0.0001$ ). Among the 45 AAb positive patient sera in C3, 18 (39%) had all four AAb, and another 13 (26%) had three positive AAb. The most frequently AAb combination was GADA plus IA-2A plus ZnT8A and positivity for all four AAb. Among single AAb positive sera, GADA were most frequently detected in controls ( $n=3$ ).

**Conclusion:** We conclude that in the IASP 2013 proficiency workshop, laboratories with sensitive assays for GADA, IA-2A, IAA, and ZnT8A could detect AAb in almost all sera from newly diagnosed T1D patients, with multiple AAb in up to 90% of patient sera. Moreover, in these assays the number of patients with single AAb was reduced. AAb assays may infrequently detect positive signals against single but usually not multiple antigens in sera from controls. Thus the detection of different AAb is related to AAb level in both, patients and controls, and therefore dependent on assay sensitivity and threshold.

## 335

**Gadolinium chelate (Gd-DO3A-GAD), new contrast agent for non-invasive quantification of beta cell mass**K. Louchami<sup>1,2</sup>, S. Liang<sup>2</sup>, A. Rzaeva<sup>3</sup>, M. Aswendt<sup>4</sup>, A. Sener<sup>1</sup>, U. Himmelreich<sup>2</sup>;<sup>1</sup>Laboratory of Experimental Hormonology, Université Libre de Bruxelles,<sup>2</sup>Biomedical MRI Unit/MoSAIC, Dept. Imaging & Pathology, KU Leuven,<sup>3</sup>Laboratory of Hormonology, Université Libre de Bruxelles, Belgium, <sup>4</sup>Max Planck Institute for Neurological Research, Cologne, Germany.

**Background and aims:** The non-invasive imaging and quantification of pancreatic islet is considered a high-priority field of diabetes investigation. This work deals with the use of Gd-DO3A-GAD as new contrast agent in the perspective of pancreatic islets non-invasive imaging. The paramagnetic agent consists of Gd-DO3A as the Gd(III) chelate backbone. In its inactive state, long hydrocarbon side chains are anchored to one N atom of the Gd(III) chelate with glutamate moieties as head groups, which can enter the Gd(III) coordination sphere, thus limiting the water access to the paramagnetic core. Upon decarboxylation of the glutamate moieties due to the GAD (Glutamate decarboxylase) activity, there is an increase in the hydration sphere of the Gd(III) ion, leading to an increased T1 relaxivity. The present work, aims to perform the Glutamic acid decarboxylase characterization, the effect of Gd-DO3A on the insulin secretion evoked by D-glucose and the potential toxicity.

**Materials and methods:** The wistar rat pancreatic islets were obtained using the collagenase digestion method. Glutamate decarboxylase activity (14CO<sub>2</sub> production) was performed using the 14C-L-glutamic acid as substrate. The insulin secretion was measured by RIA (Radio Immuno-Assay) method. MRI experiments were performed using 9.4T Biospec small animal MRI system (Bruker, Ettlingen, Germany). Each phantom contains six tubes filled with 2% agarose in H<sub>2</sub>O. Standard Bruker T1\_map\_RAREVTR sequence is used. (TE = 12.7ms, FOV = 5cm\*5cm, Matrix size = 128\*128).

**Results:** The Glutamate decarboxylase activity (14CO<sub>2</sub> production) was measured using the 14C-L-glutamic acid as substrate in the pancreas homogenates from normal vs diabetes (Streptozotocine) wistar rats demonstrate that the enzyme activity was 4 times fold higher in the normal animals. The time related L-glutamate decarboxylase activity in rat islets and brain homogenates after 120 min incubation reached respectively 45pmol/mg wet weight and 14pmol/1000islets. The present results demonstrate that the Gd-DO3A (50mM) fails to modulate the insulin secretion evoked by D-glucose at low (2.8 mM) or high (16.7 mM) of the hexose. Last, the Pancreatic islets (500), pancreatic islet cells (10.6) and INS1E (10.6) cells were incubated during 3hours in the presence of Gd-DO3A (50mM), phantom contains six tubes filled with 2% agarose in H<sub>2</sub>O were prepared, and the MRI experiments performed using 9.4T Biospec small animal MRI system (Bruker, Ettlingen, Germany). The results show clearly that Gd-DO3A (inactive state) was activated probably due to GAD which catalyzes the conversion of glutamate into the major inhibitory neuron transmitter GABA.

**Conclusion:** L-glutamate decarboxylase enzyme, which catalyzes the conversion of glutamate seems also catalyze the Gd-DO3A. The enzyme activity is highest in the control than diabetic animals. Last, the Gd-DO3A-GAD fails to modulate the insulin secretion and didn't show any toxicity. The present results support the idea that Gd-DO3A-GAD could be used as a contrast agent for non-invasive quantification of beta cell mass.

## 336

**How to survive type 1 diabetes - the prolong study**V. Lyssenko<sup>1,2</sup>, C. Möller<sup>1</sup>, P. Storm<sup>2</sup>, W. Poon<sup>2</sup>, P. Vikman<sup>2</sup>, L. Groop<sup>2</sup>, P. Rossing<sup>1</sup>, M. Eliasson<sup>3</sup>, B. Eliasson<sup>4</sup>, K. Brismar<sup>5</sup>, P.M. Nilsson<sup>2</sup>;<sup>1</sup>Steno Diabetes Center A/S, Gentofte, Denmark,<sup>2</sup>Clinical Sciences, Lund University, Malmö, <sup>3</sup>Department of Public Health and Clinical Medicine, Umeå University, <sup>4</sup>University of Gothenburg,<sup>5</sup>Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** To successfully prevent and treat diabetes complications, identification of protective mechanisms is required for a better mechanistic understanding of how the disease develops. PROLONG (Protective Genes in Diabetic Complications and LONGevity) is a cross-sectional study of selected type 1 diabetic patients in Sweden and Denmark. The aim is to identify genetic markers, biomarkers and lifestyle factors, associated with protection from micro- or macrovascular diabetic complications in patients with long-standing type 1 diabetes.

**Materials and methods:** Patients with long diabetes duration (more than 30 years) with no major diabetic complications (i.e. nephropathy, proliferative retinopathy or laser treatment, neuropathy, myocardial infarction, stroke). As a comparator group we ascertain patients with early development of diabetic complications within 5-20 years of diabetes duration from the same geographical regions. DNA exome sequencing performed using Infinium HumanOmniExpressExome v1.1 DNA Analysis Kit. RNA sequencing performed using Illumina TruSeq Stranded mRNA Kit.

**Results:** Presently, 246 patients with type 1 diabetes are enrolled in the PROLONG study in Sweden (M/F %, 44/56, mean±SD, duration 38±12 yrs, HbA1c IFCC 64±14 mmol/mol). Based on hospital records at a diabetes centre in Denmark, we identified ~500 patients (M/F% 49/51, duration 40±9 yrs, HbA1c IFCC 54±10 mmol/mol) without major diabetic complications and 225 (M/F%, 50/50, duration 15±4 yrs, HbA1c 71.4±16.8 mmol/mol) who developed either macro-, or microvascular complications. Currently, the first DNA exome (n=96) and RNA sequencing analyses (n=96) have been completed on the Swedish PROLONG part. In line with previous observations in the Golden Years Project (UK), we observed that patients with long-standing diabetes without complications have higher HDL cholesterol (1.87±0.56 vs 1.40±0.45 mmol/l, p=1.8×10<sup>-3</sup>) and lower triglycerides (0.78±0.39 vs 1.12±0.46 mmol/l, p=2.9×10<sup>-3</sup>), and lower heart rate (74.4±10.5 vs. 83.2±14.7, p=0.001). Notably, we saw no differences in the levels of C-peptide (p=0.66), systolic (130±17 vs 130±22, p=0.86) or diastolic (89±9 vs. 92±11, p=0.18) blood pressure between individuals with or without complications. Furthermore, our preliminary analyses of the whole blood RNA expression pattern using Gorilla pathway analyses illustrated that sterol metabolism (DHCR24, SQLE, CYP51A1, HMGCS1, MSMD1 genes, etc) (cholesterol and sterol biosynthetic processes, p=9.9×10<sup>-7</sup> and p=2.2×10<sup>-6</sup>; cholesterol and sterol metabolic processes, p=2.4×10<sup>-5</sup> and p=4.6×10<sup>-5</sup>) was the top pathway associated with freedom from diabetic complications.

**Conclusion:** Our preliminary cross-sectional data suggest that patients with longstanding diabetes but free of major diabetic complications are characterised by a favourable lipid profile. Analyses are ongoing to verify, as well as dissect, the specific genomic markers that significantly differ in the sterol metabolism linked to this unique phenotype.

**Interleukin-15 and interleukin-6 concentrations in autoimmune diabetes**

K. Siewko, R. Maciulewski, A. Zielinska, A. Poplawska-Kita, D. Lipinska, M. Gorska, M. Szelachowska;

Department of Endocrinology, Diabetology and Internal Medicine, Medical University, Bialystok, Poland.

**Background and aims:** Interleukin-15 and -6 (IL-15, IL-6) play a role in an inflammation, autoimmune, infectious and cancerous processes. Their increased concentrations were observed in psoriasis, asthma, multiple sclerosis and type 2 diabetes. However, the role of IL-15 and IL-6 in autoimmune diabetes pathogenesis is still unknown. The aim of our study was to evaluate of relationship between IL-15, IL-6 and CRP concentrations in persons with newly diagnosis of autoimmune diabetes in comparison to the first degree relatives of autoimmune diabetes and healthy controls.

**Materials and methods:** The group studied consisted of 54 persons with newly diagnosis of autoimmune diabetes (28 with Latent Autoimmune Diabetes in Adults (LADA) and 26 with type 1 diabetes (DM1)) and 70 healthy first degree relatives of patients with autoimmune diabetes and 60 healthy controls. GADA, IAA, IA-2A concentrations were measured by radioimmunoassays method. IL-15, IL-6 concentrations by ELISA method and CRP concentration by immunoturbidimetric method.

**Results:** We found significantly higher concentrations of IL-15 and CRP in the whole diabetes group in comparison to the group of relatives (p<0.001, respectively) and controls (p<0.001, respectively) and between relatives group and control group (p<0.001, respectively). IL-6 concentration was significantly higher in group of diabetes in comparison to the group of relatives and controls (p<0.001, respectively). We observed significantly lower IL-6 concentrations in relatives compared to the controls (p<0.001). In group of LADA and DM1 we found significantly higher IL-15 concentration in comparison to the group of relatives and controls (p<0.001, respectively). IL-15 was significantly higher in LADA compared to DM1 (p<0.001). We also observed significantly lower IL-6 concentration in relatives group in comparison to LADA and DM1 group (p=0.002, p<0.001). 31 relatives (44.3%) had positive concentration at least of one of the antibodies (Ab) against pancreatic islet. Relatives with Ab characterized significantly lower IL-6 concentration

compared to the relatives without Ab, control group and group of patients with LADA and DM1 ( $p < 0.001$ , respectively). IL-15 and CRP were significantly higher in the group of relatives with Ab in comparison to the group of relatives without Ab and control group ( $p < 0.001$ , respectively). In DM1 and LADA groups we observed positive correlation between IL-15 and CRP ( $r = 0.22$ ,  $p < 0.01$ ;  $r = 0.25$ ,  $p < 0.03$ ).

**Conclusion:** Significantly higher IL-15, IL-6 and CRP concentrations in the whole group of diabetes and in the subgroup of LADA and DM1 in comparison to the relatives and controls can prove increase risk of cardiovascular disease in the patients of newly diagnosis of autoimmune diabetes. However lower IL-6 concentration in the group of healthy relatives, especially with positive autoantibodies relatives can be marker delaying development of diabetes. IL-15 and IL-6 can be a good markers of risk of development autoimmune diabetes and IL-15 can be especially sensitivity marker for LADA diabetes.

### 338

#### Beta cell autoantibody positivity is not useful to delineate type 1 diabetes in Southeast Asians

S. Rama Chandran, Y.M. Bee, S.Y. Goh, D.S.L. Gardner; Endocrinology, Singapore General Hospital, Singapore.

**Background and aims:** There is a high prevalence of diabetes (DM) (11.3%) in Singapore. The estimated fourfold rise in DM prevalence in youth spells a grave outlook for the future burden of DM. Young onset diabetes presents a wide spectrum of aetiologies: type 1 and 2 diabetes (T1D & T2D), less well-defined subtypes e.g. latent autoimmune diabetes of adults (LADA) and monogenic DM. Each subtype portends a unique clinical course, optimum treatment modality and risk of transmission. In Asians, delineating these subtypes is challenging; the lower prevalence of  $\beta$  cell autoantibodies (Abs), lower age and lower BMI at onset of T2D compared to Caucasians increases this difficulty. Previous studies may not have assessed Abs to more recently discovered antigens e.g. Zinc Transporter 8 (ZnT8). **Aims:** 1. To describe the prevalence of  $\beta$  cell and thyroid Abs in a cohort with young onset DM (<45 years). 2. To look at the performance of  $\beta$  cell Abs in distinguishing between DM subtypes in a group of South-East Asian (SEA) patients.

**Materials and methods:**  $n = 50$  (29F, 21M). SEA patients with young onset DM were recruited. Age at onset of DM, and BMI were recorded. Glutamic acid decarboxylase (GAD), ZnT8 and thyroid peroxidase (TPO) Abs were measured (IASP certified assays). Due to previous reports of low  $\beta$  cell Ab positivity in Asian T1D patients, this was not used as a criterion to classify DM subtype. Instead, patients were classified as having T2D if they were on oral anti-diabetic drugs (OAD) for at least 1 year before commencing insulin, were insulin independent or had no episodes of diabetes ketoacidosis (DKA), suggesting continued endogenous insulin production. The rest were classified as having T1D.

**Results:** The group was made up of 7 Malay (14%), 3 Indian (6%), and 40 Chinese (80%) patients. Based on the criteria above, 16 (32%) were classified as T1D, 34 (68%) as T2D. T2D patients had a higher BMI (mean  $27.4 \pm 5.1$  vs  $23.0 \pm 3.5$ ,  $p = 0.003$ ) and were older at DM onset (mean  $26.0 \pm 9.7$  vs  $17.3 \pm 7.3$ ,  $p = 0.003$ ). There was no significant difference in glycaemic control (T1D vs T2D: HbA1c  $72$  vs  $76$  mmol/mol). 6 of 16 (37.5%) T1D were positive for  $\beta$  cell Abs. Surprisingly, 5 of 34 (14.7%) T2D patients were positive for  $\beta$  cell Abs. 3 of these 5 were overweight/obese (BMI  $26$ – $32.1$  kg/m<sup>2</sup>) by Asian standards. 1 of the 2 remaining  $\beta$  cell Ab positive T2D patients has maintained excellent glycaemic control (HbA1c  $31$  mmol/mol) on just one OAD without insulin since diagnosis 3 years ago. TPO positivity was equivalent between T2D and T1D (20.6% vs 18.8%). In total,  $\beta$  cell Abs was positive in 11 (22% of cohort). GAD Ab positivity ( $n = 10$ , 20%) was more common;  $n = 4$  (8%) had raised ZnT8 Ab, 1 of whom was GAD Ab negative. There were no significant differences in BMI or age of DM onset between Ab positive or negative patients. 4 had a previous episode of DKA, just 1 of these had positive  $\beta$  cell Abs.

**Conclusion:** 1. In our cohort of SEA patients, a significant proportion has young onset non-insulin dependent DM. They are currently classified as having T2D, but may harbour rare variants of monogenic DM, and should be assessed further. 2.  $\beta$  cell Ab positivity was found in a significant proportion of T2D patients and its prevalence was low in T1D patients; it did not associate with insulin dependence, and did not delineate between clinically determined T1D and T2D. 3. Incorporating ZnT8 Ab to GAD Ab measurement did not offer much higher detection rates for  $\beta$  cell Ab positivity. This also further implies that autoimmunity may not be the major driving factor for  $\beta$  cell loss in Asian T1D patients.

#### Genetic variation related to tolbutamide and GLP-1 stimulated insulin secretion converges functionally in protein network space: a DIRECT study

H.K. Pedersen<sup>1</sup>, V. Gudmundsdottir<sup>1</sup>, A. Jonsson<sup>2</sup>, L.M. 't Hart<sup>3</sup>, K. Banasik<sup>4,2</sup>, D. Boomsma<sup>5</sup>, M.M.W. Eekhoff<sup>6</sup>, T. Hansen<sup>3</sup>, O.B. Pedersen<sup>2</sup>, M. McCarthy<sup>4,7</sup>, E. Pearson<sup>8</sup>, C. Workman<sup>1</sup>, R. Gupta<sup>1</sup>, S. Brunak<sup>1</sup>; <sup>1</sup>Technical University of Denmark, Kgs Lyngby, <sup>2</sup>University of Copenhagen, Denmark, <sup>3</sup>Leiden University Medical Center, Netherlands, <sup>4</sup>University of Oxford, UK, <sup>5</sup>VU University, <sup>6</sup>VU University Medical Center, Amsterdam, Netherlands, <sup>7</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, <sup>8</sup>University of Dundee, UK.

**Background and aims:** Most proteins do not perform their biological function in isolation but rather in conjunction with other proteins in cellular machines or via interactions in metabolic or signaling pathways. This notion gives rise to genetic heterogeneity; the idea that genetic variants in different genes might cause identical or similar phenotypes, possibly by converging in pathway or network space. In this study we apply a systems biology data integration approach to investigate whether genetic variation related to tolbutamide or glucagon-like peptide-1 (GLP-1) stimulated insulin secretion response (ISR) functionally converges in protein network space.

**Materials and methods:** Genetic variations related to GLP-1 and tolbutamide ISR were identified in two genome-wide association studies (GWAS) in the DIRECT consortium; one on 130 individuals who underwent a modified hyperglycemic clamp with GLP-1 infusion, and one on 700 non-diabetic individuals who underwent a tolbutamide-modified IVGTT. Both GWAS were adjusted for age, sex, familial relationships and insulin sensitivity. GWAS p-values were collapsed to gene-associated p-values using MAGENTA and subsequently converted to z-scores. As tissue-specific protein-protein interaction (PPI) networks have previously been shown to outperform global networks in disease-gene prioritisation, a  $\beta$ -cell specific PPI network was created by pruning high confidence PPIs from InWeb 3.0 using published  $\beta$ -cell specific RNAseq data. Strongly connected components in the  $\beta$ -cell specific network were identified by ClusterONE. The degree of functional convergence of drug-response implicated genetic variation was assessed by a complex-based z-score, calculated by summing gene z-scores for all proteins in the complex for both drugs. The likelihood of observing a similar degree of functional convergence by chance was estimated by calculating the combined z-score for 10,000 degree preserving sets of random proteins.

**Results:** The systems biology approach integrating GWAS-data with a  $\beta$ -cell specific PPI network identified a connected component consisting of 34 proteins, which was significantly enriched for high-scoring genes associated with GLP-1- or tolbutamide ISR at  $p \leq 1.0e-4$ . This highly connected protein complex primarily consisted of guanine nucleotide binding proteins and members of the potassium inwardly-rectifying channel, both of which have previously been linked to beta-cell function. This result cannot be explained by high overlap between genes associated with tolbutamide- or GLP-1 ISR, as only two genes were among the top 100 genes for both gene-lists (*RAB-3GAP1* and *MYH13*).

**Conclusion:** We have shown that even though the 100 top-scoring genes related to tolbutamide- and GLP-1 stimulated ISR show limited direct overlap, a subset of those converges in a protein complex with a plausible and interesting biological role in insulin secretion.

#### Intermediary diabetes mellitus (IDM): a new pathology between boundaries

C. Ionescu-Tirgoviste<sup>1</sup>, P. Gagnieu<sup>2</sup>, C. Guja<sup>1</sup>;

<sup>1</sup>Diabetes, Nutrition and Metabolic Diseases, „Carol Davila“ University of Medicine and Pharmacy,

<sup>2</sup>Institute of Genetics, University of Bucharest, Romania.

**Background and aims:** It is estimated that more than 30% of patients diagnosed with non-obesity-related type 2 diabetes may actually have what provisionally has been Latent Autoimmune Diabetes of Adults (LADA). Our study attempted to clarify the existence of this phenotype by using a new method for analyzing the promoters of genes associated with diabetes. Our

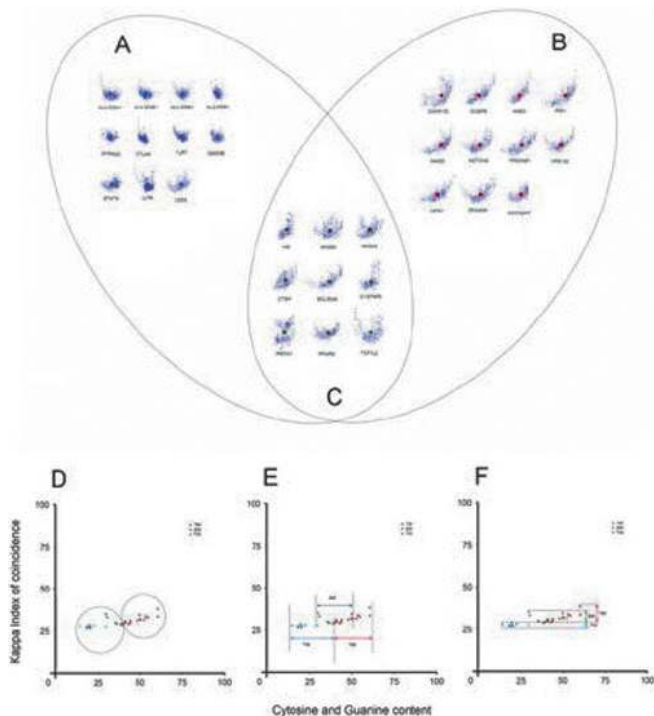

data shows that gene expression profiles could be the most important lead for detecting the primary cause of diabetes.

**Materials and methods:** In order to perform a generic analysis on gene expression profiles, we have used a total of 32 promoters of genes associated with classical T1D and T2D phenotypes. In order to measure the structural features of promoter sequences, we have used our original method of analysis based on DNA patterns (BMC Genomics 2012, 13:512). Thus, these DNA patterns can identify the transcription factors shared by genes associated with one or more phenotypes. Among the analyzed promoters of genes associated with classical T1D, we mention the HLA-DQA1, HLA-DQB1, HLA-DRB1, HLA-DPB1, PTPN22, TLR7, CTLA4, GSDMB, STAT4, IL7R, C1QTNF6, CD55, CTSH, ERBB3 and INS gene promoters and for T2D the CAMK1D, DUSP9, HHEX, IRS1, MADD, NOTCH2, TP53INP1, VPS13C, WFS1, ZFAND6, HMGA2, PPARG, CDKN2AIP, PROX1 and TCF7L2 gene promoters (Figure A-C). In order to show the general relationship between the three phenotypes, a second distribution was made by using the center of weight of the patterns (Figure D-F).

**Results:** The promoters of genes associated with the two main phenotypes of diabetes contain different DNA patterns. T1D promoters exhibit image-based patterns which show that they are a part of a special class of promoters called „AT-based“ (Figure A). The promoters of genes associated with T2D exhibit patterns that show they are a part of a special class of promoters called „CG-based“ (Figure B). This separation of classes shows that genes associated with these two phenotypes rarely share transcription factors, therefore these genes can not be coexpressed. The third type of pattern is presented by a number of genes such as CD55, C1QTNF6, INS, ERBB3, HMGA2, CTSH, SLC30A8, CDKN2AIP, PROX1, PPARG, TCF7L2 which suggest a new phenotype, an Intermediary Diabetes Mellitus (IDM), (Figure C). The shape of these patterns indicate that genes associated with IDM can use transcription factors from both phenotypes, further indicating that IDM may contain the driver genes for triggering T1D and T2D.

**Conclusion:** Our current data showed that some promoters of genes associated with the two main phenotypes of diabetes seem to be associated to a third intermediary phenotype (IDM). These new data highlights the heterogeneity of different clinical phenotypes of diabetes.

### A common variant downstream of PCSK2 is associated with reduced tolbutamide stimulated insulin release: a DIRECT study

A. Jonsson<sup>1</sup>, K. Banasik<sup>1,2</sup>, A.P. Gjesing<sup>1</sup>, A. Mahajan<sup>2</sup>, N. Robertson<sup>2,3</sup>, L.M. Hart<sup>4</sup>, E. Pearson<sup>5</sup>, M. McCarthy<sup>2,3</sup>, O. Pedersen<sup>1</sup>, T. Hansen<sup>1</sup>; <sup>1</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Denmark, <sup>2</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, <sup>3</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, <sup>4</sup>Department of Molecular Cell Biology, Leiden University Medical Center, Netherlands, <sup>5</sup>Division of Cardiovascular and Diabetes Medicine, Medical Research Institute, University of Dundee, UK.

**Background and aims:** We have previously shown that there is a high heritability of insulin secretion in response to a tolbutamide injection. The aim of this study was to perform a genome-wide association study to identify gene variants associating with tolbutamide stimulated insulin release.

**Materials and methods:** A total of 700 non-diabetic individuals, from two different cohorts, one family-based and one population-based, underwent a tolbutamide-modified frequently sampled IVGTT during which glucose was injected at 0 min and tolbutamide at 20 min. Measurements of plasma glucose, serum insulin and serum C-peptide were taken at 12 time points from fasting to 180 min and insulin secretion rate (ISR) and acute insulin response (AIR) were calculated. Genotyping was performed using the Illumina HumanCoreExome BeadChip. Association analyses adjusted for age, sex and BMI or age, sex and insulin sensitivity (Si) and separated by cohort were performed with EMMAX using the statistical package EPACTS, in order to handle relatedness in the samples. The results were then meta-analyzed using the GWAMA software.

**Results:** The strongest signal for reduced tolbutamide stimulated insulin release was seen downstream of the PCSK2 gene (AIR BMI adjusted:  $\beta = -0.216$ ,  $P = 1.6 \times 10^{-6}$ , AIR Si adjusted:  $\beta = -0.134$ ,  $P = 4.2 \times 10^{-4}$ ), which has previously been associated with reduced glucose stimulated insulin secretion in humans.

**Conclusion:** Here we show that the PCSK2 locus, not only associates with reduced glucose stimulated insulin secretion as described previously, but also shows a strong signal for reduced tolbutamide stimulated insulin release. The signal is however not genome-wide significant and further replication is needed to confirm the association.

## 342

### Exome variation affects metformin treatment response

N. van Leeuwen<sup>1</sup>, G. Nijpels<sup>2</sup>, J.M. Dekker<sup>2</sup>, L.M. Hart<sup>1</sup>; <sup>1</sup>Molecular Cell Biology, Leiden University Medical Center, <sup>2</sup>EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** Metformin is the first line treatment for type 2 diabetes. However the glycaemic response to metformin is highly variable between individuals. A recent study showed that the heritability of the absolute reduction in HbA1c was 34% and chromosome-wise heritability estimates suggested that individual genetic variants scattered across the genome account for the effect. The aim of our study was the identification of genetic factors that influence treatment response to metformin. This will help to optimize and personalize treatment in the future and it will give further insight into the working mechanism. In this study we focused on genetic variation in the exome, the part of the genome that is translated into protein because genetic variation in this region has a large a priori chance of being causal.

**Materials and methods:** Genetic variation was measured in 800 patients on metformin therapy from the Diabetes Care System ( $n > 8000$ ), a large longitudinal cohort of Dutch type 2 diabetic patients, using the Illumina Exome chip. Twenty-five percent of the patients on metformin therapy did not reach the treatment target of an HbA1c  $\leq 53$  mmol/l (7%) within one year after initiation of therapy and we assessed if this treatment failure was associated with genetic variation using logistic regression. In addition we assessed the association with the absolute change in HbA1c after one year of treatment using linear regression. In both analyses baseline HbA1c, age, BMI, eGFR, and sex, metformin dose and metformin dual/mono therapy were included as covariates.

**Results:** Several genetic variants affected the response to metformin treatment in type 2 diabetes patients. The ten most significant gene variants gave a 1.7 to 8.5 fold reduced chance of reaching the treatment goal, an HbA1c level below 53 mmol/mol and the reduction in HbA1c ranged from 2 to 8

mmol/mol per risk allele ( $p$  6.10 $\cdot$ 10 $^{-6}$  to 3.10 $\cdot$ 10 $^{-4}$ ). Most of these variants were low frequency variants and several were predicted to be damaging by SIFT/Polyphen2. However, due to the low frequency and power, replication in additional cohorts is necessary to reach genome wide significance. This replication is currently performed.

**Conclusion:** In this study we have identified a number of gene variants with relatively low frequency but a large effect on the metformin treatment response suggesting clinical usefulness in personalizing type 2 diabetes treatment. Furthermore, it identifies novel pathways modulating metformin response. However, replication in additional patients and cohorts is needed before definitive conclusions can be drawn.

### Insulin signalling genes exert a combined effect on all-cause mortality

C. Menzaghi<sup>1</sup>, A. Fontana<sup>2</sup>, M. Copetti<sup>2</sup>, S. Rizza<sup>3</sup>, B. Spoto<sup>4</sup>, G. Tripepi<sup>4</sup>, A. Marucci<sup>1</sup>, A. Testa<sup>4</sup>, F. Mallamaci<sup>4</sup>, S. De Cosmo<sup>5</sup>, S. Bacci<sup>5</sup>, M. Federici<sup>3</sup>, C. Zoccali<sup>4</sup>, V. Trischitta<sup>1</sup>;

<sup>1</sup>Research Unit of Diabetes and Endocrine Diseases, IRCCS, San Giovanni Rotondo, <sup>2</sup>Unit of Biostatistics, IRCCS, San Giovanni Rotondo, <sup>3</sup>University of Rome Tor Vergata, <sup>4</sup>Research Unit of Clinical Epidemiology and Physiopathology of Renal Disease and Hypertension, CNR-IBIM, Reggio Calabria, <sup>5</sup>Unit of Endocrinology, IRCCS, San Giovanni Rotondo, Italy.

**Background and aims:** Type 2 diabetes (T2D) and cardiovascular (CV) disease are major factors increasing all-cause mortality. Both clinical entities recognize a common soil represented by insulin resistance (IR), which by itself also predicts all-cause mortality. IR is, at least partly, genetically determined. Thus, it is conceivable that genetic factors, which modulate IR, play also a role in modulating T2D, CV disease and all-cause mortality. In fact, we have previously reported the combined effect of single nucleotide polymorphisms (SNPs) perturbing insulin signaling (*ENPP1* K121Q, rs1044498; *IRS1* G972R, rs1801278; *TRIB3* Q84R, rs2295490) on IR and, as a likely consequence, T2D and major CV events. Based on these encouraging results, we investigated whether a combined effect of these 3 SNPs affects also all-cause mortality.

**Materials and methods:** We first studied a sample comprising 742 patients (i.e. discovery sample; 238 deaths/3,520 person-years; py). Replication was assessed in a second sample of 725 diabetic patients (i.e. replication sample; 129 deaths/5,495 py).

**Results:** In the discovery sample, weighted genetic risk score (GRS), based on each SNP's effect size, was associated with all-cause mortality (HR=1.12, 95% CI=1.03-1.23). After stratification according to low or high genetic load (GL) (i.e. 0-1 or > 2 risk alleles), patients with high GL (n=123) were at increased risk of all-cause mortality (HR=1.36, 95% CI=1.00-1.86), as compared to those with low GL (n=619). In the replication sample, HR (95% CI) for all-cause mortality was 1.06 (0.94-1.19) for GRS and 1.58 (1.06-2.35) for GL. In a pooled analysis (1,467 individuals; 367 deaths) both GRS and GL were associated with all-cause mortality HRs (95% CI)=1.11 (1.01-1.22) and 1.41 (1.10-1.80), respectively.

**Conclusion:** Our finding indicates that functional non-synonymous variants affecting insulin signaling exert a joint effect on all-cause mortality and is consistent with a pathogenic role of IR on life expectancy.

## 344

### Dissecting the genetic architecture of loci with established effects on multiple cardiometabolic phenotypes and type 2 diabetes

L. Marullo<sup>1</sup>, T.O. Kilpeläinen<sup>2</sup>, B.K. Cornes<sup>3</sup>, J. Dupuis<sup>4</sup>, C. Scapoli<sup>1</sup>, R.J.F. Loos<sup>5</sup>, J.B. Meigs<sup>3</sup>, A.P. Morris<sup>6</sup>, I. Prokopenko<sup>7</sup>, on behalf of the XC-Pleiotropy Group;

<sup>1</sup>Department of Life Sciences and Biotechnology, Genetic Section, University of Ferrara, Italy, <sup>2</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Denmark, <sup>3</sup>General Medicine Division, Massachusetts General Hospital, Boston, <sup>4</sup>Department of Biostatistics, Boston University School of Public Health, <sup>5</sup>The Icahn School of Medicine at Mount Sinai, New York, USA, <sup>6</sup>Department of Biostatistics, University of Liverpool, <sup>7</sup>Department of Genomics of Common Disease, Imperial College London, UK.

**Background and aims:** Genome-wide association studies (GWAS) have identified hundreds of loci associated with Type 2 Diabetes (T2D) or other

cardiometabolic phenotypes, many of which overlap or map to the same genomic interval. Variants associated with multiple phenotypes, such as T2D, fasting insulin, triglycerides, HDL-cholesterol and body fat percentage influencing variants at *IRS1*, can provide insight into biology of correlated cardiometabolic phenotypes. However, the genetic architecture of these loci is frequently complex and needs further investigation.

**Materials and methods:** To disentangle association patterns of 630 associated SNPs (Dec 2012) from GWAS meta-analyses in Europeans for 19 quantitative phenotypes, T2D and hypertension, we defined sets of adjacent variants located less than 500kb apart and harboring 446 associated SNPs within 151 genomic regions (range=2-8 SNPs/region). We undertook approximate conditional analyses (ApCA) implemented in the GCTA tool to examine whether associations with multiple phenotypes within each region could be explained by LD.

**Results:** Across the 151 regions, we observed 14 (10%) loci in which the same SNP was associated with multiple phenotypes. Associations in 11 of these 14 loci were with epidemiologically highly correlated traits. Through ApCA, we identified 41 (27%) regions with multiple associated variants that underlie the same association signals, thus suggesting multi-phenotype effects. For 19 (13%) regions, the association with one phenotype partially explained the effect on another. Within 45 (30%) regions, multiple signals were explained by multiple non-related variants, whereas the remaining 32 (21%) regions showed complex architecture. Of the 44 regions associated with T2D, 15 contained the same association signal for other cardiometabolic phenotypes. Within 12 regions, including *ANKRD55*, *SPRY2*, *DUSP8*, *PEPD* and *HNF4A*, association with other phenotypes were not related to T2D variants. For 13 regions we observed complex architecture, while for the remaining 4 regions, the association with T2D partially explained the effect on another cardiometabolic phenotype.

**Conclusion:** Overall, a substantial number (87 or 58%) of cardiometabolic loci, of which 28 T2D loci, show potential pleiotropic effects on multiple phenotypes, which might contribute to their shared biology. Within other regions, distinct genetic effects or more complex architecture could underlie independent regulatory mechanisms.

### Genetic risk factors for diabetic complications in patients with type 2 diabetes from Ukraine

S. Alkayali<sup>1</sup>, W. Poon<sup>1</sup>, L. Cherviakova<sup>2</sup>, N. Khalimon<sup>3</sup>, P. Nilsson<sup>4</sup>, L. Groop<sup>1,5</sup>, T. Svetleisha<sup>6</sup>, T. Buldenko<sup>6</sup>, H. Vasykova<sup>6</sup>, V. Lyssenko<sup>1,7</sup>;

<sup>1</sup>Diabetes and Endocrinology, Lund University, Malmö, Sweden, <sup>2</sup>Chernihiv Regional Hospital, Ukraine, <sup>3</sup>Clinical Science, Lund University, Malmö, Sweden, <sup>4</sup>Institute for Molecular Medicine Finland FIMM, Helsinki, Finland, <sup>5</sup>Public Health Authority of Chernihiv Regional Public Administration, Ukraine, <sup>6</sup>Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Chronic hyperglycaemia is associated with increased risk of progression to macro (cardiovascular diseases) and microvascular complications (neuropathy, retinopathy and nephropathy). Recently, genome-wide association studies have identified a number of genetic loci for association with type 2 diabetes (T2D) and cardiometabolic traits. The effects of some of these genetic variants and the risk of diabetes progression to diabetes complications has been investigated in several populations, but has never been studied in Ukrainians, a population at high cardiovascular risk.

**Materials and methods:** We studied the association of a panel of 145 SNPs in loci previously reported to be associated with T2D/glycaemic traits (n=75), dyslipidemia (n=11), obesity (n=8), hypertension (n=13), cardiovascular diseases (CVD) (n=21) and microvascular complications (n=17) in approximately 3,500 subjects with T2D from the DOLCE study (M/F% 32/68, mean±SD, age-at-onset 53.5±10.6 years, BMI 31.4±5.6 kg/m<sup>2</sup>, diabetes duration 7.1±7.4 years) (Diagnostic optimization and treatment of diabetes and its complications in the Chernihiv region). Effects of genetic loci were studied using logistic regression adjusted for sex and age-at-onset for macrovascular complications, and sex and diabetes duration for microvascular complications. The analyses were performed using R software, and genotyping was performed using Mass ARRAY iPLEX (Sequenom, San Diego, CA).

**Results:** We have replicated previous associations of *GIPR* rs10423928 (OR=1.29, P=0.005), *WDR12* rs6725887 (OR=1.42, P=0.005) and *MIA3* rs17465637 (OR=1.24, P=0.04) with CVD. *VEGF* rs2010963 (OR=1.28, P=0.02) previously reported to be associated with diabetic retinopathy (DR), was in our study associated with diabetic nephropathy (DN). The risk C-allele in *TMEM26* rs1530440 (hypertension locus) was associated with increased

CVD risk (OR=1.18, P=0.04) and DN/DR (OR=1.4, P=0.01), while other two hypertension loci ATXN2 rs653178 (OR=0.87, P=0.03) and CYP17A1 rs11191548 (OR=0.75, P=0.03) with decreased CVD risk. Also, the ERBB4 rs7588550 (DN locus) was associated with increased risk for CVD (OR=1.79, P=0.01), while CVD loci PHACTR1 rs12526453 (OR=1.8, P=0.016) and PITX2 rs6843082 (OR=1.25, P=0.04) with increased risk for DR and DN.

**Conclusion:** We have replicated the previous association in GIPR, WDR12 and MIA3 for risk of CVD. Furthermore, we have demonstrated an association between risk alleles for hypertension and T2D/glycaemic traits loci and micro-/macrovascular complications. None of the studied BMI or dyslipidemia loci were significantly associated with complications in our study.

### Chemotactic cytokine receptor 5 (CCR5) gene promoter polymorphism (rs1799987) increases the risk of diabetic nephropathy in Asian type 2 diabetic patients

Z. Zhang;

Shandong Provincial Qianfoshan Hospital, Jinan, China.

**Background and aims:** To evaluate the association of CCR5/CCL5 variants with the risk of DN

**Materials and methods:** We conducted a systematic search of electronic databases (Pubmed, Embase and China National Knowledge Infrastructure) on three genetic variants (CCL5-403 G/A, CCL5-28 C/G, CCR5 59029G/A) and then 11 case-control studies involving 2512 DN cases and 2358 non DN control subjects were identified. The pooled odds ratio (OR) and 95% confidence interval (CI) were used to describe the strength of association with DN, the subgroup analysis was used to explore the heterogeneity bias among studies. Publication bias was tested by the Begg's and Egger's test.

**Results:** In the overall analysis, we found that CCR5 59029A-positive genotype (G/A or A/A) was an independent risk factor of DN (OR 1.69, 95% CI 1.13-2.55). Subgroup analysis demonstrated that the risk of CCR5 59029A-positive genotype was more significant among Asian patients with type 2 diabetic nephropathy (OR 2.08, 95% CI 1.68-2.57), but was nonsignificant in Caucasians or type 1 diabetes nephropathy (OR 1.23, 95% CI 0.52-2.92 for Caucasians; OR 0.82, 95% CI 0.56-1.20 for type 1 diabetes nephropathy). In addition, CCR5 59029A-positive genotype was associated with increased risk of albuminuria (OR 1.68, 95% CI 1.15-2.44 for microalbuminuria; OR 2.53, 95% CI 1.05-6.08 for macroalbuminuria). The CCL5 -403 G/A and CCL5-28 C/G gene polymorphism was not significantly associated with the risk of DN (OR 1.00, 95% CI 0.82-1.21 for CCL5-403 G/A; OR 1.02, 95% CI 0.79-1.33 for CCL5-28 C/G).

**Conclusion:** Our studies indicated that the CCR5 59029 A gene variant is a significant susceptibility factor for DN. Subtype of DM and ethnicity might contribute for the inconsistency present in studies. The CCL5 gene polymorphism (CCL5-403 G/A, CCL5-28 C/G) might not be a risk factor for DN.

### Indications for potential parent of origin effects within the *FTO* gene using long range phasing algorithms

X. Liu<sup>1,2</sup>, M. Scholz<sup>3,4</sup>, A. Tönjes<sup>5</sup>, M. Stumvoll<sup>1,5</sup>, P.F. Stadler<sup>2,6</sup>, Y. Böttcher<sup>1</sup>;

<sup>1</sup>IFB AdiposityDiseases, <sup>2</sup>Bioinformatics Group, Department of Computer

Science, <sup>3</sup>Institute for Medical Informatics, Statistics and Epidemiology,

<sup>4</sup>LIFE Research Centre, <sup>5</sup>Department of Medicine, University of Leipzig,

Germany, <sup>6</sup>Institute for Theoretical Chemistry, University of Vienna, Austria.

**Background and aims:** Genome-Wide Association Studies (GWAS) were successfully applied to discover associations with obesity. However, the GWAS design is based on unrelated individuals and clear inheritance information of phases is limited. Taking into account parent of origin may provide further insights into the genetic mechanisms contributing to obesity. We hypothesized there may be variants within the robustly replicated fat mass and obesity associated (*FTO*) gene that may confer different effect sizes for obesity depending on the transmission from father or mother.

**Materials and methods:** Genome-wide genotypes and pedigree information from the Sorbs population (N=525) were used. Phasing was done by applying long-range phasing and haplotype library imputation algorithm. Phased gen-

otypes among 525 individuals were generated by AlphaImpute. Subsequently, 22 SNPs within *FTO* introns 1 to 3 were selected and parent of origin specific association analyses were performed using PLINK: (i) standard association test, (ii) considering paternal and (iii) maternal alleles.

**Results:** We identified several SNPs conferring different P values depending on parental origin. Among them, rs1861868, rs1121980 and rs9939973 (all intron 1) show significantly different effect estimates beta (Student's t-Test; P<0.05). Of note, rs1121980 tags rs8050136 (r<sup>2</sup>=0.98) which was well replicated to be strongly associated with BMI.

**Conclusion:** Our results suggest that several *FTO* variants may underlie parent of origin effects modulating the risk of obesity. However, due to our limited sample size only large effects were detected. Further studies are warranted to investigate *FTO*.

### PARP-1 inhibitor, Olaparib, increases GLP-1 secretion and promotes both insulin secretion and TCF7L2 gene expression

Q. Xia<sup>1</sup>, S. Lu<sup>1</sup>, B.T. Johnston<sup>1</sup>, S. McCormack<sup>2</sup>, S.F.A. Grant<sup>1,3</sup>;<sup>1</sup>Division of Human Genetics, <sup>2</sup>Division of Endocrinology, The Children's Hospital of Philadelphia, <sup>3</sup>Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, USA.

**Background and aims:** TCF7L2 is widely considered one of the most strongly type 2 diabetes (T2D) associated loci reported to date, but the pathophysiological mechanism by which variation within this gene modulates risk is poorly understood. We previously reported the specific protein factors that bind across the presumed causal variant at this locus, rs7903146, using oligo pull-down followed by mass spectrophotometry, with the most abundant of these being poly [ADP-ribose] polymerase type 1 (PARP-1) (Xia et al., 2014). PARP-1 has a potential role in the pathophysiology of diabetes, including evidence that PARP-1 knockout mice are protected from streptozotocin-induced diabetes. Proteomic studies have suggested that PARP-1 is also a component of the TCF7L2/beta-catenin complex. One important potential regulatory target of TCF7L2 is the pro-glucagon gene, which encodes a precursor of glucagon as well as other factors important for glucose homeostasis, including glucagon-like peptide-1 (GLP-1). We investigated if an existing PARP-1 inhibitor developed for oncologic indications, Olaparib, could have a GLP-1 agonist effect and thereby suggest regulation of PARP-1 mediated GLP-1 activity as one candidate mechanism for TCF7L2-related modulation of T2D risk.

**Materials and methods:** We used the human L-cell line, NCI-H716, for GLP-1 secretion assessment. Cells were pre-treated with 10uM Olaparib and after 48 hours the cells were transferred into PBS and incubated with or without 16mM glucose for 30 minutes, after which the suspensions were collected for GLP-1 ELISA. Next, we tested the effect of Olaparib on L-cell mediated augmentation of insulin secretion. To do this, we collected the medium from the treated NCI-H716 cells and used it to culture the human beta cell line, EndoC-BH1, for 30 minutes, after which we measured insulin by ELISA. Finally, we used real-time PCR to compare relative expression of TCF7L2 in NCI-H716 L-cells in the presence and absence of Olaparib.

**Results:** Treating NCI-H716 cells with glucose increased the release of GLP-1 into the medium as expected but, interestingly, Olaparib treatment also enhanced GLP-1 secretion significantly compared with the untreated group (51.1% average increase;  $P < 0.05$ ). Furthermore, GLP-1 levels were further increased in the presence of the combination of glucose and Olaparib, compared with glucose or Olaparib alone (26.0% and 29.4% average increase, respectively;  $P < 0.05$ ). The medium collected from the NCI-H716 cells treated with 10uM Olaparib increased insulin secretion over basal levels in EndoC-BH1 cells (15.2% average increase;  $P < 0.05$ ). We also observed that TCF7L2 expression in NCI-H716 cells was highly statistically significantly increased (21.1% average increase;  $P < 0.01$ ) by Olaparib.

**Conclusion:** Our results show that inhibition of PARP-1 in NCI-H716 cells increases GLP-1 levels and augments glucose-stimulated insulin secretion in EndoC-BH1 cells. PARP-1 inhibition also increases TCF7L2 gene expression in the NCI-H716 cells. Taken together, these observations suggest that TCF7L2 modulates T2D risk through its regulation of PARP-1 related GLP-1 activity. PARP-1 inhibition may represent an avenue for therapeutic intervention for T2D.

### Defective glucose homeostasis in mice inactivated selectively for Tcf7l2 in the adult beta cell with an Ins1-controlled Cre

G. da Silva Xavier<sup>1</sup>, A. Mondragon<sup>1</sup>, R. Mitchell<sup>1</sup>, D. Hodson<sup>1</sup>, J. Ferrer<sup>2</sup>, B. Thorens<sup>3</sup>, L. Chen<sup>4</sup>, J. McGinty<sup>4</sup>, P. French<sup>4</sup>, G.A. Rutter<sup>1</sup>;<sup>1</sup>Cell Biology, <sup>2</sup>Epigenomics and Disease, Imperial College, London, UK,<sup>3</sup>Center for Integrative Genomics, University of Lausanne, Switzerland,<sup>4</sup>Physics, Imperial College, London, UK.

**Background and aims:** Single nucleotide polymorphisms in the TCF7L2 gene, including rs7903146, are associated with an elevated risk of type 2 dia-

betes in man. Previous studies of the effects of Tcf7l2 deletion in mice have provided conflicting results. In the present report we therefore inactivated Tcf7l2 specifically in pancreatic beta cells to investigate the cell-autonomous role for Tcf7l2 in these cells.

**Materials and methods:** To achieve highly selective deletion in the adult pancreatic beta cell, but not brain or other tissues, we crossed mice bearing floxed (exon 1) Tcf7l2 alleles to animals in which Cre recombinase was expressed from the Ins1 locus. Tcf7l2<sup>fl/fl</sup>::Ins1Cre<sup>+</sup>, and littermate control mice were maintained on a C57BL/6 background and on either a normal or a high fat (60%; HFD; age 8 - 20 weeks) diet (Research Diet, New Brunswick, NJ, USA). Glucose tolerance was assessed by oral and intraperitoneal administration (1 g/kg body weight) following a 16 h fast, and insulin secretion *in vivo* measured after intraperitoneal injection of glucose (3 g/kg). Insulin secretion *in vitro* was measured from groups of six islets by radioimmunoassay (Millipore). Quantitative real-time PCR was performed on islet cDNA on a Fast 7500 device (ABI) running 7500 software (ABI) and with powersYBR reagent (ABI). Changes in cytosolic calcium were assessed by Nipkow spinning disc confocal microscopy of whole islets loaded with fluo-2. Beta and alpha cell mass were assessed by optical projection tomography (19 μm resolution) of chemically-clarified pancreata double-stained for insulin and glucagon.

**Results:** Compared to littermate controls, Tcf7l2<sup>fl/fl</sup>::Ins1Cre<sup>+</sup> mice displayed impaired intraperitoneal glucose tolerance by 16 weeks (increase in AUC of 13.6 ± 2.8 %, n=6 mice per genotype,  $p < 0.05$ ), and impaired oral glucose tolerance (increase in AUC of 10.6 ± 1.3 %, n=6,  $p < 0.05$ ) from 8 weeks. Glucose intolerance was thus apparent earlier than in mice deleted for Tcf7l2 throughout the pancreas (Tcf7l2<sup>fl/fl</sup>::Pdx1.Cre<sup>+</sup> mice; observed at 20 and 12 weeks when glucose was administered by the intraperitoneal and oral route, respectively). Islets of Langerhans isolated from Tcf7l2<sup>fl/fl</sup>::Ins1Cre<sup>+</sup> mice at 20 weeks displayed impaired glucose ( $p < 0.05$ ) and GLP-1 ( $p < 0.05$ ) stimulated insulin secretion, and decreased insulin and GLP-1 receptor gene expression ( $p < 0.01$ ). Similarly, when maintained on a HFD, Tcf7l2<sup>fl/fl</sup>::Ins1Cre<sup>+</sup> mice displayed impaired glucose tolerance, and lower plasma insulin following an intraperitoneal glucose tolerance test, than littermate controls, and impaired GLP-1 stimulated insulin secretion ( $p < 0.01$ ) and cytosolic calcium increases ( $p < 0.03$ ). 20 week-old Tcf7l2<sup>fl/fl</sup>::Ins1Cre<sup>+</sup> mice that had been maintained on HFD for 12 weeks also displayed decreased (n=4, 31.7%,  $p < 0.05$ ) beta cell mass, but normal alpha cell mass, compared to littermate controls.

**Conclusion:** These findings provide further support for the view that type 2 diabetes-associated Tcf7l2 variants may exert their effects, at least in part, through cell autonomous actions on the beta cell. These include impairments in Ca<sup>2+</sup> signalling, and expansion in response to insulin resistance.

### RNA editing - an emerging role in diabetes?

J. Sun, P. Spégel, H. Mulder;

Department of Clinical Sciences, Lund University Diabetes Centre, Malmö, Sweden.

**Background and aims:** The genetic causes of T2D are still poorly understood. Previous studies have focused on discovery of genetic and epigenetic risk factors and gene-environment interactions. Less is known about post-transcriptional regulation of these risk-genes, RNA editing, in particular, which can alter genomically encoded information. Recent studies have shown that RNA editing may modulate multiple cellular functions. It was estimated that A-to-I RNA editing occurs at over a hundred million genomic sites. Hence, it is necessary to reveal the role of RNA editing events in the development of diabetes.

**Materials and methods:** To obtain putative A-to-I RNA editing events, we first built a prediction model based on the Darned database, containing a collection of editing sites from published sequencing data. Next, prediction was performed on common variants in the gene body of 104 risk genes for type-1 diabetes (T1D), type-2 diabetes (T2D), glucose traits and obesity. Finally, predicted sites of A-to-I RNA editing were checked in the DIAbetes Genetics Replication And Meta-analysis (DIAGRAM) consortium and an expression quantitative trait loci (eQTL) resource based on 5 311 human samples.

**Results:** A-to-I RNA editing events in Darned were mapped to 8 846 genes, including 46 genes related to diabetes, e.g., TCF7L2, FTO and ADCY5. GO enrichment analysis revealed that 1 540 out of these genes were enriched in metabolic processes ( $p = 1.2e^{-13}$ ). There are 141 042 common variants (dbSNP build 138) located in the gene body of 104 diabetes related genes. We decided to keep only single nucleotide variants with reference/alternative allele as A/G, G/A, T/C and C/T. This resulted in 89 367 variants, out of which 25 399 were predicted as putative A-to-I RNA editing sites, using 20 flanking nu-

cleotides DNA sequences. Notably, 14 of these variants were found in risk loci for T1D, T2D, glucose traits and obesity (WFS1, CLEC16A, ZMIZ1, FUT2, CAPN10, TAGAP, KCNJ11, SH2B3, CTSH, HNF1B, PRKD2, SLC30A8 and KCNQ1), 2/197 were overlapped with DIAGRAM. The top nine loci ( $p < 1.0 \times 10^{-30}$ ) were found located in TCF7L2, followed by six loci ( $p < 1.0 \times 10^{-13}$ ) in CDKAL1. However, most (81%) loci did not show associations with diabetes. 485 putative sites of RNA editing were cis eQTL of 137 genes and 12 putative sites of RNA editing were trans eQTL of 51 genes (false-discovery rate of 0.50).

**Conclusion:** Our results suggest that RNA-DNA mismatches should be considered as an important factor in genetic studies of diabetes. The consequences of editing in risk alleles need to be further examined.

### Global Long Interspersed Nucleotide Element 1 (LINE-1) DNA methylation in a longitudinal cohort of type 2 diabetes mellitus patients

N.S. Malipatil<sup>1</sup>, K. Siddals<sup>1</sup>, B. Fu<sup>2</sup>, M. Gibson<sup>3</sup>, R.P. Narayanan<sup>4</sup>, A.H. Heald<sup>5</sup>, R. Donn<sup>6</sup>;

<sup>1</sup>Vascular Research Group, <sup>2</sup>Centre for Biostatistics, Institute of Population Health, University of Manchester, <sup>3</sup>Vascular Research Group, Salford Royal NHS Foundation Trust, Manchester, <sup>4</sup>Department of Obesity and Endocrinology, University of Liverpool, <sup>5</sup>Department of Medicine, Leighton Hospital, Crewe, <sup>6</sup>Centre for Musculoskeletal Research, University of Manchester, UK.

**Background and aims:** Epigenetic mechanisms impact gene expression and could predispose individuals to a particular metabolic phenotype. Increased LINE-1 methylation has previously been associated with cardiovascular risk biomarkers in healthy individuals. Here we have investigated, for the first time, the relationship between global LINE-1 DNA methylation and cardio-metabolic parameters in Type 2 Diabetes Mellitus (T2DM) patients. This has been conducted using a well characterised longitudinal cohort from Salford, UK.

**Materials and methods:** Global LINE-1 DNA methylation was quantified by pyrosequencing in blood-derived DNA samples from 445 Caucasian T2DM patients using PyroMark Q96 CpG LINE-1 (Qiagen). The cohort consisted of Males 267 and Females 178; mean age 59.4yrs (males 58.7 years, females 60.4 years), with 7 years of longitudinal data. Global LINE-1 DNA methylation was analysed in relation to baseline anthropometric and biochemical measurements and their average changes per year over follow up, using multiple linear regression models adjusted for age, body mass index (BMI) and stratified by gender groups.

**Results:** Methylation at 4 CpG sites was quantified. The mean across the 4 sites was 75.1% (95% Confidence Interval (CI) 74.83% - 75.33%). There were no statistically significant methylation differences by gender (males 75.2%, females 74.90%  $p=0.270$ ) or by age ( $p=0.679$ ). Linear regression showed no significant associations with LINE-1 DNA methylation in the total cohort with; BMI [normalised beta coefficient 2.76 (95% CI -13.91 - 19.44,  $p=0.745$ )], total cholesterol [-1.59 (95% CI -4.02 - 0.83,  $p=0.198$ )], triglycerides [-2.77 (95% CI -6.76 - 1.22,  $p=0.173$ )], HDL-cholesterol [0.64 (95% CI -0.55 - 1.83),  $p=0.293$ ] or LDL-cholesterol [-8.9 (95% CI -3.09 - 1.30,  $p=0.425$ )], or with systolic Blood Pressure (BP) [-22.51 (95% CI -66.75 - 21.28,  $p=0.313$ )] or diastolic BP [-17.81 (95% CI -44.00 - 21.28,  $p=0.313$ )]. Furthermore, there was no association with glycated haemoglobin (HbA1C) [-1.35 (95% CI -5.69 - 2.98,  $p=0.540$ )] at baseline or with average change per year in HbA1C over 7 years follow up [-0.004 (95% CI -0.014 - 0.006,  $p=0.443$ ); nor with levels of high sensitivity C-reactive protein (CRP) [13.57 (95% CI -21.36 - 48.52,  $p=0.445$ )]. However, stratification by gender revealed significant association of global LINE1 DNA methylation in women with LDL levels [-4.52 (95% CI -8.23 - 0.80,  $p=0.017$ )], with HDL: LDL cholesterol ratio [2.78 (95% CI 1.02 - 4.53,  $p=0.002$ )] and a trend also towards hypomethylation with total cholesterol [-3.76 (95% CI -7.87 - 0.34,  $p=0.072$ )].

**Conclusion:** Our findings indicate a gender related difference in global LINE1 DNA methylation with specific blood metabolic parameters related to cardiovascular risk in type 2 diabetes mellitus.

### Altered DNA methylation and differential expression of genes influencing metabolism and inflammation in adipose tissue from subjects with type 2 diabetes

E. Nilsson<sup>1,2</sup>, P. Jansson<sup>3</sup>, A. Perflyev<sup>1</sup>, M. Pedersen<sup>4</sup>, M.K. Svensson<sup>5</sup>, P. Poulsen<sup>6</sup>, R. Ribbel-Madsen<sup>2</sup>, N.L. Pedersen<sup>7</sup>, P. Almgren<sup>8</sup>, J. Fadista<sup>8</sup>, T. Rönn<sup>1</sup>, B. Klarlund-Pedersen<sup>4</sup>, C. Scheele<sup>4</sup>, A. Vaag<sup>2</sup>, C. Ling<sup>1</sup>;  
<sup>1</sup>Epigenetics and Diabetes, Clinical Sciences, Malmö, Sweden, <sup>2</sup>Diabetes and Metabolism, Department of Endocrinology, Copenhagen, Denmark, <sup>3</sup>Wallenberg laboratory, Gothenburg, Sweden, <sup>4</sup>Infectious Diseases, The Centre of Inflammation and Metabolism and the Centre for Physical Activity Research, Copenhagen, Denmark, <sup>5</sup>Sahlgrenska University Hospital, Institute of Medicine, Gothenburg, Sweden, <sup>6</sup>Novo Nordisk A/S, Global Development, Bagsværd, Denmark, <sup>7</sup>Karolinska institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, <sup>8</sup>Diabetes and Endocrinology, Clinical Sciences, Malmö, Sweden.

**Background and aims:** Genetics, epigenetics and environment may together affect the susceptibility for type 2 diabetes (T2D). Our aim was to dissect molecular mechanisms underlying T2D using genome-wide expression and DNA methylation data in adipose tissue from monozygotic twin pairs discordant for T2D and independent case-control cohorts.

**Materials and methods:** Genome-wide DNA methylation and mRNA expression were analysed using the Infinium HumanMethylation450 BeadChip from Illumina and GeneChip® Human Gene 1.0 ST arrays from Affymetrix, respectively.

**Results:** In adipose tissue from discordant twin pairs, we found that decreased expression of genes involved in oxidative phosphorylation, carbohydrate-, amino acid- and lipid metabolism, and increased expression of genes involved in inflammation and glycan degradation accompany T2D. The most differentially expressed genes included *ELOVL6*, *GYS2*, *FADS1*, *SPPI* (*OPN*), *CCL18* and *IL1RN*. We replicated these results in adipose tissue from an independent case-control cohort. Several candidate genes for obesity and T2D (e.g. *IRS1* and *VEGFA*) were differentially expressed in discordant twins. We found a heritable contribution to the genome-wide DNA methylation variability in twins. Differences in DNA methylation between monozygotic twin pairs discordant for T2D were subsequently modest. However, 15,627 sites, representing 7,046 genes including candidate genes for T2D and obesity showed differential DNA methylation in adipose tissue from unrelated subjects with T2D compared with controls. 1,410 of these sites did also show differential DNA methylation in the twins discordant for T2D. For the differentially methylated sites, the heritability estimate was 0.28. We also identified copy number variants in monozygotic twin pairs discordant for T2D.

**Conclusion:** Taken together, subjects with T2D exhibit multiple transcriptional and epigenetic changes in adipose tissue relevant to the development of the disease.

## 353

### Diet-induced obesity alters methylation of HOX transcription factors in mouse visceral adipose tissue

L. Parrillo<sup>1</sup>, V. Costa<sup>2</sup>, R. Esposito<sup>2</sup>, G.A. Raciti<sup>1</sup>, G. Porciello<sup>1</sup>, C. Nigro<sup>1</sup>, P. Mirra<sup>1</sup>, A. Cozzolino<sup>1</sup>, C. Miele<sup>1</sup>, A. Ciccociocola<sup>2</sup>, F. Beguinot<sup>1</sup>;  
<sup>1</sup>DISMET & IEOS-CNR, Federico II University of Naples, <sup>2</sup>IGB-CNR, Italy.

**Background and aims:** Exposure to high-fat regimens induces epigenetic modifications which might shape the obesity phenotype. Indeed, recent work has revealed altered DNA methylation at several obesity-related genes in response to high-fat diets. However, the detailed methylome profiles determined by high-fat exposure remain to be elucidated. In the present study, we have implemented an unbiased genome-wide analysis of DNA methylation changes secondary to diet-induced obesity.

**Materials and methods:** Male C57BL/6J mice were fed either high-fat (HFD) or regular chow diets (ND) for 5 months. Methylated DNA immunoprecipitation combined with next generation sequencing (MeDIP-seq) were performed on DNA extracted from the visceral epididymal fat (VF) of the ND- and the HFD-fed mice. RT-qPCR and MeDIP-qPCR were then performed on the VF of these mice.

**Results:** Mice fed HFD gained weight (difference with the ND-fed mice significant at  $p < 0.001$ ) and developed a significant decrease in their glucose tolerance (GTT,  $p < 0.01$  vs. ND mice) and insulin sensitivity (ITT,  $p < 0.001$  vs

ND mice). MeDIP-seq analysis identified differentially methylated regions (DMRs) covering with sufficient depth almost the entire genome and showed that, in the HFD-fed mice, the number of hypermethylated DMRs was higher than that of hypomethylated DMRs. Most DMRs were located within gene bodies. Based on subsequent gene ontology analysis of the MeDIP-seq data, differentially methylated genes (DMGs) were identified in the HFD-fed mice. Interestingly, a distinct set of genes belonging to the Homeobox (HOX) gene family was found to be epigenetically modulated by chronic exposure to HFD (Hoxa1, Hoxa3, Hoxa5, Hoxb3, Hoxb6, Hoxd1, Hoxa13). Hoxa5 was selected to validate the significance of this finding by measurement of its promoter methylation status and its gene expression. Results of the MeDIP-qPCR analysis ( $p < 0.05$ ) of Hoxa5 were consistent with those generated by the MeDIP-Seq studies. In addition, the Hoxa5 mRNA expression levels were significantly decreased in the VF of the HFD- compared to those of ND-fed mice ( $p < 0.05$ ), revealing an inverse correlation with its methylation state. These changes were accompanied by increased methyltransferase Dnmt3a and methyl-CpG binding domain protein Mbd3 mRNA expression levels ( $p < 0.05$ ), suggesting that the increased methylation of several genomic regions in the HFD-fed mice is mediated, at least in part, by increased expression of Mbd3 and Dnmt3a.

**Conclusion:** Our study on a genome-wide scale indicates that, in the mouse model, diet-induced obesity is associated with DNA methylation changes in VF. DMRs are enriched in genes regulating transcription, including the HOX transcription factors. This further finding suggests that an alteration of the methylation state of some members of this gene family and their impaired transcription may represent a mechanism by which a chronic high-fat feeding impacts on VF functions.

**Background and aims:** Obesity and Type 2 Diabetes (T2D) represent major public health problems, making the need of achieving a better understanding of the pathogenesis of these disorders a priority. Similar to genetic polymorphisms, epigenetic modifications may alter transcriptional activity, impact on obesity and T2D risk and explain, in part, predisposition for these diseases. Based on MeDIPseq data, we have identified the Ankyrin repeat domain 26 (Ankrd26) gene as a target sensitive to environmental exposures. Previous work by us revealed that the Ankrd26 gene plays an important role in the control of food intake, fat mass and glucose tolerance in rodents. Indeed, mice with partial inactivation of this gene develop marked hyperphagia, severe obesity and diabetes. We aimed to investigate whether obesity in vivo or elevated free fatty acids (FFAs) in vitro may impact on Ankrd26 gene transcription by causing epigenetic modifications.

**Materials and methods:** Gene expression was evaluated by Real-time PCR analysis in the epididymal white adipose tissue (WAT), the tibialis skeletal muscle (SM) and liver (L) from diet-induced obese (DIO) C57Bl/6 mice and in 3T3-L1 adipocytes treated for 24, 48 and 96 hours with palmitate (PAL; 0.25 mM) or oleate (OLE; 0.25 mM). DNA methylation of Ankrd26 promoter (CGI: from -726 to -226 bp) was investigated by MeDIP analysis in WAT from DIO mice and in PAL treated adipocytes.

**Results:** Ankrd26 mRNA expression is decreased in WAT and SM but not in L from DIO mice (WAT: C  $0.509 \pm 0.011$  AU vs. DIO  $0.483 \pm 0.008$  AU,  $p < 0.001$ ; SM: C  $0.578 \pm 0.019$  AU vs. DIO  $0.558 \pm 0.011$  AU,  $p < 0.01$ ; L: C  $0.492 \pm 0.023$  AU vs. DIO  $0.500 \pm 0.028$  AU). In addition, PAL treatment for 96 h induces a 20% decrease of Ankrd26 mRNA levels in mature adipocytes, as well (C  $1.00 \pm 0.00$  REU, PAL24h  $0.95 \pm 0.09$  REU, PAL48h  $1.05 \pm 0.08$  REU, PAL96h  $0.82 \pm 0.04$ ,  $p < 0.001$ ). No significant effects on Ankrd26 expression are observed when cells are treated with OLE. MeDIP analysis shows a 3-fold increased immunoprecipitation of a DNA fragment covering a portion of Ankrd26 CGI both in WAT from DIO mice and in PAL-treated adipocytes. Interestingly, PAL treatment induces a 20% increase of the de novo DNA methyl transferase (DNMT) 3b mRNA expression (C  $1.00 \pm 0.00$  REU, PAL 96h  $1.19 \pm 0.03$  REU,  $p < 0.01$ ).

**Conclusion:** Hyper-methylation of Ankrd26 promoter occurs both in vivo in WAT from DIO mice and in vitro in PAL-treated adipocytes, and is inversely correlated to its mRNA expression. This suggests that environmental exposures impact Ankrd26 transcription by inducing epigenetic changes.

## 355

### DNA hyper-methylation of the zinc transport (SLC30A8) gene is associated with type 2 diabetes in a Malay population

N. Abu Seman<sup>1</sup>, W. Wan Mohamad<sup>2</sup>, C. Ostensson<sup>1,3</sup>, K. Brismar<sup>1,3</sup>, H.F. Gu<sup>1</sup>;

<sup>1</sup>Dept Of Molecular Medicine & Surgery, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Cardiovascular Diabetes & Nutrition Research Centre, Institut For Medical Research, Kuala Lumpur, Malaysia, <sup>3</sup>Department of Endocrinology, Metabolism & Diabetes, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** The solute carrier family 30 member 8 (SLC30A8) gene codes for a zinc efflux transporter related to insulin secretion in pancreatic beta-cells. Recent genetic studies have demonstrated that the common alleles of single nucleotide polymorphisms (SNPs) including rs13266634 (C/T, Arg276Trp) and rs11558471 (A/G) in the SLC30A8 gene confer the risk susceptibility to type 2 diabetes (T2D). But the question regarding whether this gene has epigenetic effects in T2D is still remained.

**Materials and methods:** To address this question, we first replicated genetic association study of the SLC30A8 gene in 992 Malay subjects with normal glucose tolerance (NGT) and T2D. Genotyping experiments were conducted with TaqMan allelic discrimination. Analyses based upon genotypes and haplotypes constructed with these two SNPs rs13266634 and rs11558471 provided compelling evidence of association with T2D in this Malay population. We then performed DNA methylation analysis of four CpG sites in the SLC30A8 gene promoter with bisulfite pyrosequencing.

**Results:** The A allele of SNP rs11558471 (A/G) and the common haplotype C-A constructed by the major alleles of this polymorphism and rs13266634 were found to be associated with T2D ( $P = 0.002$ ,  $OR = 1.334$ ,  $95\%CI = 1.110-1.602$ ;  $P = 0.008$ ,  $OR = 1.233$ ,  $95\%CI = 1.055-1.442$ ). The averaged DNA methylation levels in the SLC30A8 gene promoter in the Malay cohort were high (~78.5%). DNA methylation levels in the SLC30A8 gene were increased in T2D patients compared with NGT subjects (79.9%,  $95\% CI = 79.2-80.5\%$  vs. 77.1%,  $95\% CI = 75.4-78.6\%$ ,  $P = 0.001$ ).

**Conclusion:** The present study demonstrates for the first time that DNA hyper-methylation of the SLC30A8 gene is associated with T2D in a Malay population and suggests that this gene has epigenetic effects in T2D.

## 356

### Visceral fat tissue content and HOMA-IR better predicts type 2 diabetes risk than genetic risk score based on 70 SNPs identified by GWAS for type 2 diabetes and/or obesity

E. Adamska<sup>1</sup>, A. Kretowski<sup>1,2</sup>, J. Gosic<sup>3</sup>, N. Wawrusiewicz-Kurylonek<sup>2</sup>, M. Paczkowska<sup>1</sup>, W. Bauer<sup>1,2</sup>, A. Citko<sup>1,2</sup>, M. Ciborowski<sup>1</sup>, D. Lipinska<sup>2</sup>, M. Gorska<sup>2</sup>;

<sup>1</sup>Centre for Clinical Research, <sup>2</sup>Department of Endocrinology, Diabetology and Internal Medicine, <sup>3</sup>Centre for Experimental Medicine, Medical University of Bialystok, Poland.

**Background and aims:** The prevalence of obesity is growing rapidly effecting the large increase in type 2 diabetes (T2DM) incidence. To stop this epidemic trend it is important to find the method for early prediction of type 2 diabetes risk and motivation to begin an early lifestyle intervention. For the personal T2DM risk evaluation several factors, such as age, sex, ethnicity family history are well documented and the data concerning the role of genetic factors and gene-environment interaction has been recently accumulated. A precise interaction of these risk factors is, however, a complex process that varies both within and across populations. The aim of our study was to evaluate the role of clinical parameters and recently discovered genetic variants as a markers for type 2 diabetes for early prediction.

**Materials and methods:** Study group consisted of 945 Caucasian origin volunteers without previously known disglycaemia collected between 2009 and 2012 for the prospective 1000PLUS cohort study (463 women and 482 men, aged 18–65 years old, mean age  $40.4 \pm 0.8$  yrs). Among the study population 634 subjects were overweight/obese and 311 people had  $BMI < 25$ . In all subjects demographic data, anthropometric measurements have been recorded;

blood samples at fasting for metabolic (glucose and insulin) and genetic analyses were collected. The oral glucose tolerance test (OGTT) have been performed and type 2 diabetes was diagnosed based on WHO criteria. Body composition: percentage of total body fat, visceral (VAT) and subcutaneous adipose tissue (SAT), VAT/SAT ratio were also analyzed by bio-impedance method. Genetic risk score (GRS) for each participant was calculated using previously identified 70 loci by weighting the number of risk alleles corresponding to a particular locus by its effect size ( $\beta$ -estimate) on diabetes risk and summing these values. The studied genotypes distributions were in Hardy-Weinberg equilibrium ( $p > 0.05$ ).

**Results:** In the logistic regression analysis the risk of type 2 diabetes development was significantly associated with age [OR=1.2 (1.1–1.4),  $p=2.8 \times 10^{-6}$ ], HOMA-IR [OR=1.9 (1.4–2.6),  $p=1.9 \times 10^{-5}$ ], VAT/SAT ratio [OR=11.4 (2.0–91.7),  $p=0.01$ ] and GRS [OR=1.13 (1.05–1.2),  $p=2 \times 10^{-5}$ ] but not with BMI and gender. When particular SNPs were introduced into the regression model instead of GRS the strongest association with type 2 diabetes risk was found for rs11558471 SLC30A8 ( $p=0.03$ ), rs226000 PRRC2A ( $p=0.018$ ), rs11708067 ADCY5 ( $p=0.008$ ), rs2844479 AIF1 ( $p=0.02$ ), rs10938397 GN-PDA2 ( $p=0.001$ ), rs7647305 SFRS10 ( $p=0.01$ ), rs174550 FAD1 ( $p=0.016$ ), rs10946398 CDKAL1 ( $p < 0.04$ ), rs780094 GCKR ( $p=0.03$ ), rs340874 PROX1 ( $p=0.044$ ) assuming the additive model.

**Conclusion:** We found that visceral fat tissue content and HOMA-IR better predict type 2 diabetes risk than the genetic risk score (based on 70 SNPs identified by GWAS for type 2 diabetes and/or obesity). However both of them, the clinical and genetic factors, allow for better individual prediction of type 2 diabetes.

### Mutation in APPL1 gene may contribute to familial diabetes mellitus

S. Prudente<sup>1</sup>, J. Prapaporn<sup>2</sup>, A. Marucci<sup>3</sup>, O. Ludovico<sup>4</sup>, T. Mazza<sup>1</sup>, T. Hastings<sup>2</sup>, L. Mercuri<sup>1</sup>, D. Bailetti<sup>1</sup>, C. Mendonca<sup>2</sup>, M. Carella<sup>5</sup>, F. Barbetti<sup>6,7</sup>, V. Trischitta<sup>3</sup>, R. Di Paola<sup>3</sup>, A. Doria<sup>2,8</sup>,  
<sup>1</sup>IRCCS CSS-Mendel, Rome, Italy, <sup>2</sup>Department of Genetics and Epidemiology, Joslin Diabetes Center, Boston, USA, <sup>3</sup>Research Unit of Diabetes and Endocrine Diseases, <sup>4</sup>Clinical Unit of Endocrinology, <sup>5</sup>Medical Genetics Unit, IRCCS „Casa Sollievo della Sofferenza“, San Giovanni Rotondo, <sup>6</sup>Laboratory of Mendelian Diabetes, Bambino Gesù Childrens' Hospital, Rome, <sup>7</sup>Department of Experimental Medicine and Surgery, University of Tor Vergata, Rome, Italy, <sup>8</sup>Department of Medicine, Harvard Medical School, Boston, USA.

**Background and aims:** Familial, apparently autosomal dominant, early-onset forms of diabetes mellitus of the adulthood that are negative for mutations in known MODY genes have been repeatedly described. Except that for their age of onset, these forms of diabetes resemble classical type 2 diabetes (T2D), thereby suggesting that they are due to mutations in genes modulating insulin sensitivity and/or the fine tuning of insulin secretion rather than in genes playing a central role in insulin synthesis/secretion, as is the case for MODY. The aim of this study was to identify genetic causes of these forms of diabetes. **Materials and methods:** To accomplish this aim, whole exome sequencing was carried out in probands from 59 families from Italy and the US. New identified mutations were studied by transfection in HepG2 cells followed by evaluation of mRNA and protein expression levels along with insulin-stimulated Akt2-ser<sup>473</sup> and GSK3 $\beta$ -ser<sup>9</sup> phosphorylation.

**Results:** Two mutations in the APPL1 gene (a L552X stop-codon and a D94N missense mutation), showing segregation with diabetes, were found in two different families. Neither mutation had been previously reported in publicly available databases. APPL1 binds to Akt2 and positively modulates insulin-mediated Akt2 activation and downstream signaling, which is involved in both insulin action and secretion. Accordingly, APPL1 ablation causes insulin resistance and impaired glucose homeostasis in mice. X552 totally abolished APPL1 protein (but not mRNA) expression, consistent with its being a stop-codon mutation. N94 APPL1 was expressed at the same level as WT APPL1; however, it caused significant reduction in the enhancement of insulin-stimulated Akt2 and GSK3 $\beta$  phosphorylation observed after WT APPL1 transfection as compared to un-transfected cells, therefore behaving as a loss of function mutation. Both mutations were absent in 2970 T2D patients and in 1639 control subjects.

**Conclusion:** This is the first evidence of APPL1 mutations contributing to familial forms of diabetes mellitus of the adulthood and reaffirms the critical role of this gene in glucose homeostasis.

### Enhanced transcriptional activity of the K392R mutant form of STAT3 found in a patient with early onset diabetes is not fully dependent on phosphorylation of Tyrosine-705

M.A. Russell<sup>1</sup>, S.E. Flanagan<sup>1</sup>, S. Ellard<sup>1</sup>, T. Otonkoski<sup>2</sup>, A.T. Hattersley<sup>1</sup>, N.G. Morgan<sup>1</sup>;

<sup>1</sup>Institute of Biomedical and Clinical Science, University of Exeter Medical School, UK, <sup>2</sup>Molecular Neurology and Biomedicum Stem Cell Centre, University of Helsinki, Finland.

**Background and aims:** We have recently reported a series of 4 novel activating germline mutations in STAT3 among patients exhibiting an early onset poly autoimmune syndrome including autoimmune diabetes. In the current study we have explored the molecular basis of the enhanced activity of one of these activating mutants, K392R.

**Materials and methods:** Wildtype (WT) and mutant (K392R) STAT3 were generated and transfected transiently into HEK293 cells. In addition, stable INS-1E cells were also created expressing these constructs under the control of a tetracycline inducible promoter. Transcriptional activity was assessed using a STAT3-responsive reporter construct while total and phosphorylated STAT3 were detected by Western blotting.

**Results:** Transfection of WT and mutant (K392R) STAT3 into HEK293 cells resulted in equal levels of protein expression but differing levels of transcriptional activation. Notably, the K392R mutant dramatically increased STAT3 reporter activity relative to the WT (by  $37.1 \pm 4.7$  fold;  $p < 0.01$ ). Enhanced reporter activity was also observed in INS-1E cells expressing K392R although the absolute increase was smaller than in HEK293 cells ( $4.0 \pm 0.4$  fold;  $p < 0.01$ ). Classically, STAT3 activity is regulated mainly by phosphorylation at Tyr 705 but the extent of phosphorylation of this residue was only modestly increased in the mutant under unstimulated conditions ( $3.1 \pm 0.6$  fold vs WT;  $p < 0.05$ ) despite its markedly enhanced transcriptional activity. Addition of IL-6 (20 ng/ml) resulted in an increase in STAT3 activity in cells expressing either WT or K392R, although the increase was much greater for the mutant (a further  $7.3 \pm 1.4$  fold enhancement above that seen in WT cells stimulated with IL-6;  $p < 0.05$ ). IL-6 also further increased the extent of phosphorylation of Tyr 705 in both WT STAT3 and in the K392R mutant. The increased STAT3 activity of K392R was reduced, but not abolished, by pharmacological inhibition of the upstream kinase Jak which promotes phosphorylation of Tyr 705 (fold change from WT: K392R -  $30.7 \pm 8.4$ , K392R + Jak inhibitor -  $6.0 \pm 0.8$   $p < 0.05$ ) suggesting that the enhanced activity is not dependent fully on Tyr 705 phosphorylation. To further assess the importance of this residue, Tyr 705 was replaced by phenylalanine (Y705F) to create a double mutant (K392R/Y705F). This was less active than K392R in reporter assays but, despite the loss of Tyr 705, it still retained enhanced transcriptional activity in both the absence or presence of IL-6 ( $p < 0.01$ ).

**Conclusion:** The constitutively active K392R germline mutation of STAT3 found in a patient with poly autoimmune syndrome and early onset diabetes, induces a strong transcriptional activation which may contribute to the autoimmunity. The mechanism of activation is atypical and does not depend solely on increased phosphorylation of Tyr 705.

### The phenotypic severity of homozygous GCK mutations causing neonatal or adolescent-onset diabetes is mediated through thermostability in addition to enzyme activity

A.J. Chakera<sup>1,2</sup>, A. Raimondo<sup>3</sup>, S. Thomsen<sup>3</sup>, K. Colclough<sup>4</sup>, A. Barrett<sup>3</sup>, E. De-Franco<sup>1</sup>, A. Chatelas<sup>3</sup>, M. van de Bunt<sup>3</sup>, S.E. Flanagan<sup>1</sup>, A.T. Hattersley<sup>1,2</sup>, S. Ellard<sup>1,4</sup>, A.L. Gloy<sup>3,5</sup>;

<sup>1</sup>Institute of Biomedical and Clinical Science, University of Exeter Medical School, <sup>2</sup>Macleod Diabetes and Endocrine Centre, Royal Devon and Exeter NHS Foundation Trust, <sup>3</sup>Oxford Centre for Diabetes Endocrinology and Metabolism, <sup>4</sup>Department of Molecular Genetics, Royal Devon and Exeter NHS Foundation Trust, Exeter, <sup>5</sup>Oxford NIHR Biomedical Research Centre, UK.

**Background and aims:** Mutations in the glucokinase (GCK) gene cause a spectrum of glycaemic disorders. Homozygous loss-of-function mutations are rare and cause permanent neonatal diabetes (GCK-PNDM) requiring lifelong insulin treatment. Heterozygous loss-of-function mutations cause mild fasting hyperglycaemia irrespective of mutation severity due to compensation from the unaffected allele.

**Materials and methods:** We determined the relationship between in vitro mutation severity and clinical phenotype in a large international case series of patients with homozygous GCK mutations.

**Results:** Clinical characteristics for 30 patients with diabetes due to homozygous GCK mutations (19 unique mutations, including 16 missense) were compiled and assigned a clinical severity grade (CSG) based on birth weight and age-at-diagnosis. The majority (28/30) of subjects were diagnosed by 9 months of age, with the remaining two in adolescence. These are the first two cases of a homozygous GCK mutation diagnosed outside the neonatal period. Recombinant mutant GCK proteins were analysed for kinetic and thermostability characteristics and assigned a relative activity index (RAI) or relative stability index (RSI) value. Six of the 16 missense mutations exhibited severe kinetic defects ( $RAI \leq 0.01$ ). There was no correlation between CSG and RAI ( $r^2 = 0.02$ ,  $p = 0.65$ ), indicating that kinetics alone did not explain the phenotype. Eighty percent of the remaining mutations showed reduced thermostability, the exceptions being the two adolescent-onset mutations which exhibited increased thermostability. Comparison of CSG with RSI detected a highly significant correlation ( $r^2 = 0.63$ ,  $p = 0.006$ ).

**Conclusion:** Within the largest case series to date we demonstrate that homozygous GCK mutations can cause adolescent-onset diabetes. Protein instability is the major determinant of mutation severity.

## 360

### Cystatin C-based GFR estimate is higher than the creatinine-based GFR in HNF1A MODY and GCK MODY: results of a replication study

M. Szopa<sup>1</sup>, N. Nowak<sup>1</sup>, B. Matejko<sup>1</sup>, M. Kapusta<sup>2</sup>, J. Machlowska<sup>1</sup>, T. Klupa<sup>1</sup>, T. Koblik<sup>1</sup>, B. Zapala<sup>2</sup>, T. Staszczel<sup>2</sup>, B. Kiec-Wilk<sup>1</sup>, I. Wybranska<sup>2</sup>, M.T. Malecki<sup>1</sup>;

<sup>1</sup>Metabolic Diseases, <sup>2</sup>Clinical Biochemistry, Jagiellonian University Medical College, Krakow, Poland.

**Background and aims:** Cystatin C is a marker of glomerular filtration rate (GFR). Its level is dependent on the concentration of CRP (C-Reactive Protein), which is decreased in diabetic patients with an HNF1A-MODY. We examined previously the cystatin C as a biomarker for the HNF1A-MODY with inconsistent results and showed that the cystatin C-based GFR estimate is higher than the creatinine-based one. Currently, we aimed to perform a replication study using a new cohort of HNF1A-MODY patients and, additionally, glucokinase (GCK) MODY subjects.

**Materials and methods:** The study included 63 patients with HNF1A-MODY, 70 with GCK-MODY, 44 type 1 diabetes (T1DM), 47 type 2 diabetes (T2DM) patients and 61 subjects without diabetes. Creatinine was measured using Roche P800 analyzer (Roche Diagnostics, Burgess Hill, UK). The level of cystatin C and CRP was determined using enzyme immunoassay. GFR was calculated from the following: the creatinine with the CKD - EPI formula, and from cystatin C with the 4-variable formula. Statistical analysis to determine the difference between two (t-student) and several groups (ANOVA with post-hoc tests) was used. If necessary, non-parametric tests were utilized as equivalents. Differences in the level of cystatin C between groups (GCK-MODY, HNF1A-MODY, control, T2DM, T1DM) were adjusted for gender, age, BMI and estimated GFR (creatinine) and determined by analysis of covariance (ANCOVA). Statistical analyzes were performed using STATISTICA software 10.0.

**Results:** Cystatin C level in post-hoc analysis (Scheffe test) was significantly lower ( $p < 0.0001$ ) in the control group ( $0.73 \text{ mg/l} \pm 0.14$ ), HNF1A-MODY ( $0.74 \text{ mg/l} \pm 0.21$ ) and GCK-MODY ( $0.71 \text{ mg/l} \pm 0.15$ ) when compared to patients with T1DM ( $0.90 \text{ mg/l} \pm 0.15$ ) and T2DM ( $0.96 \text{ mg/l} \pm 0.24$ ). The differences between the groups became borderline after adjustment for the gender, BMI, age and eGFR. Comparison of GFR estimated from the creatinine level (CKD-EPI) with GFR from cystatin C (CysC eGFR) has shown no difference in T2DM and control group ( $p = 0.6938$ ). T1DM patients had significantly higher CKD-EPI than CysC eGFR ( $p = 0.0002$ ). An inverse relationship was observed in MODY patients: CysC eGFR was significantly higher compared to the CKD-EPI in both GCK ( $p = 0.031$ ) and HNF1A ( $p = 0.0143$ ) MODY patients.

**Conclusion:** We confirmed that GFR value estimated from cystatin C level in MODY patients is significantly higher compared to GFR estimated from creatinine. Interestingly, a similar finding was identified in GCK-MODY. However, Cystatin C was not a good biomarker to differentiate between various types of diabetes.

### Intima - media thickness and endothelial dysfunction in GCK and HNF1A MODY patients

G. Osmenda, M. Szopa, G. Wilk, B. Matejko, I. Solecka, T. Guzik, M.T. Malecki;

Jagiellonian University Medical College, Krakow, Poland.

**Background and aims:** Mutations in the GCK (glucokinase) gene are, along with the HNF1A gene mutations, the most frequent cause of MODY (maturity onset diabetes of the young). Heterozygous loss-of-function GCK mutations result in a moderate fasting hyperglycemia. The GCK-MODY patients are usually free from microvascular complications; however, little is known about atherosclerosis and intermediate related phenotypes. We aimed to examine intima-media thickness (IMT) and endothelial function in GCK-MODY and HNF1A-MODY compared with controls.

**Materials and methods:** 66 GCK-MODY, 50 HNF1A-MODY patients and 54 non-diabetic controls were examined. Carotid artery IMT and brachial artery FMD and NMD (nitroglycerin mediated dilatation) were assessed by ultrasonography. These parameters were compared with test for difference between two groups (t-test or U Mann Whitney test) or three groups (one way analysis of variance ANOVA or the Kruskal-Wallis test with post hoc test).

**Results:** The average maximum IMT was different among three groups -  $0.71 \pm 0.17 \text{ mm}$  in GCK-MODY,  $0.77 \pm 0.15$  in HNF1A-MODY, and  $0.71 \pm 0.15$

in the controls ( $p=0.0041$ ). In post hoc analysis maximum IMT for GCK-MODY was statistically different from HNF1a MODY ( $p=0.0371$ ) Mean IMT were as follow  $-0.62\pm 0.14$  mm in GCK-MODY,  $0.68\pm 0.13$  in HNF1a-MODY and  $0.63\pm 0.13$  in controls ( $p=0.0077$ ). Post hoc analysis showed a difference between GCK-MODY and HNF1a-MODY ( $p=0.0108$ ). The mean FMD% was  $11.0\pm 4.5\%$  in GCK-MODY,  $10.1\pm 4.9$  in HNF1a-MODY and  $13.9\pm 4.8$  in the controls ( $p=0.0001$ ). The differences between CK-MODY and HNF1a-MODY vs. controls were significant ( $p=0.0045$ ,  $p=0.0001$ , respectively). I was similar in all three groups  $-24.1\pm 4.5$ ,  $24.1\pm 3.7$  and  $24.2\pm 3.6$  in GCK-MODY, HNF1a-MODY and controls, respectively ( $p=0.7876$ ). Patients were diagnosed with diabetes at similar age (GCK-MODY:  $25.1\pm 13.5$  yrs vs. HNF1a-MODY:  $26.6\pm 11.6$ ,  $=0.4669$ ). Glycemic control was similar in diabetic groups as in the GCK-MODY group the mean  $HbA_{1c}$  was  $6.4\%\pm 0.7$ , while in HNF1a-MODY patients it reached  $6.7\pm 1.4$  ( $p=0.6936$ ).

**Conclusion:** Both examined MODY groups showed evidence of early atherosclerosis or endothelial dysfunction. Mild hyperglycemia in the GCK-MODY seems to have a fragile impact on the occurrence of intermediate atherosclerotic phenotypes.

### Clinical features of MODY-HNF1a in children and adolescents with obesity

E.A. Sechko<sup>1</sup>, L.I. Zilberman<sup>2</sup>, O.N. Ivanova<sup>2</sup>, T.L. Kuraeva<sup>2</sup>, V.A. Peterkova<sup>2</sup>, I.M. Sechenov First Moscow State Medical University, <sup>2</sup>Endocrinology Research Centre, Moscow, Russian Federation.

**Background and aims:** to study clinical features of MODY-HNF1a in children and adolescents with obesity.

**Materials and methods:** 18 patients who had heterozygous mutation in HNF1a gene were divided into 2 groups: group 1 - the patients with SDS BMI  $\geq 2$  ( $n=6$ ; 33.3%); group 2 - the patients with SDS BMI  $< 2$  ( $n=12$ ; 66.6%). We measured fasting and stimulated glucose, C-peptide, insulin levels (OGTT). The data is presented as medians (25; 75 percentile), Mann-Whitney U-test was used to compare medians.

**Results:** Age at diagnosis of diabetes: in group 1 was 10.4 years (9.5;14.4), in group 2 was 12.8 years (10.9;15.4),  $p<0,05$ . Diagnosis of diabetes in group 1: 33.3% of patient were investigated due to suspected diabetes cases because of family history, 33.3% of patient were investigated due to obesity, 33.3% of patient had the clinical features of diabetes; diagnosis of diabetes in group 2: 16.7% of patient were investigated due to suspected diabetes cases because of family history, 75% of cases were diagnosed occasionally, 8.3% of patient had the clinical features of diabetes. At the diagnosis  $HbA_{1c}$ : in group 1 was 7.3% (6.8; 7.9); in group 2 was 6.5% (6.3; 8); ( $p>0.05$ ). 100% patients in group 1 and 91,6% patients in group 2 had family history of diabetes; one of the parents had insulin dependent diabetes mellitus (66.6% and 25%, respectively group 1 and group 2), non insulin dependent diabetes mellitus (16.65% and 58.3%, respectively group 1 and group 2), gestational diabetes mellitus (16.65% and 8.3%, respectively group 1 and group 2). Disease duration was 3 years (1.1; 4.5), when diagnosis MODY-HNF1a was confirmed. We identified the novel mutations: D45fs, V119G, R229X, S249Stop. The most common Pro291fsinsC mutation was identified in 5 cases (27.7%). Clinical data is presented in Table 1. Patients in group 1 had significantly higher  $HbA_{1c}$  and fasting serum C-peptide. Two patients in group 1 were insulin resistant. Patients in groups 1 and 2 were treated with sulfonylurea (50% of all patients) and metformin (50% and 8%, respectively). 42% patients in group 2 were treated with diet only.

**Conclusion:** MODY-HNF1a may be combined with obesity and in some cases with insulin resistance in children and adolescents. Obesity is a risk factor for early manifestation and more severe diabetes. Patients in group 1 had higher C-peptide secretion. DNA testing of patient with mild diabetes, obesity and family history of diabetes could lead to diagnosis of new cases of MODY-HNF1a.

**Table 1. Clinical data of patients with MODY-HNF1a**

| Clinical data            | Group 1           | Group 2           | p        |
|--------------------------|-------------------|-------------------|----------|
| HbA1c, %                 | 7.8 (7.4; 7.9)    | 6.3 (6; 7)        | $p<0.01$ |
| C-peptide 0 min, ng/ml   | 2.2 (1.9; 2.6)    | 1.3 (1.1; 1.4)    | $p<0.01$ |
| C-peptide 60 min, ng/ml  | 4.3 (3.5; 5.2)    | 3.6 (3.3; 4.1)    | $p>0.05$ |
| C-peptide 120 min, ng/ml | 4.9 (3.9; 5.5)    | 4.4 (3.8; 5)      | $p>0.05$ |
| Insulin 0 min, U/l       | 9.4 (5.3; 12.4)   | 6.9 (5.3; 8.1)    | $p>0.05$ |
| Insulin 60 min, U/l      | 33 (22.7; 38.9)   | 25.1 (18.2; 35)   | $p>0.05$ |
| Insulin 120 min, U/l     | 21.4 (19.7; 30,8) | 22.4 (16.4; 38.2) | $p>0.05$ |

## 363

### Transcription activity testing can aid bioinformatics in ascribing pathogenicity to HNF1A variants identified by genomic sequencing in population-based cohorts

I. Aukrust<sup>1,2</sup>, L.A. Najmi<sup>1,3</sup>, J. Molnes<sup>1,4</sup>, J. Flannick<sup>4</sup>, N.P. Burt<sup>4</sup>, A. Molven<sup>1,5</sup>, L. Groop<sup>6</sup>, D. Altshuler<sup>4</sup>, S. Johansson<sup>1</sup>, L. Bjørkhaug<sup>1</sup>, P.R. Njølstad<sup>1,7</sup>;

<sup>1</sup>KG Jebsen Center for Diabetes Research, Dept of Clinical Science, University of Bergen, <sup>2</sup>Dept of Biomedicine, University of Bergen, <sup>3</sup>Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, <sup>4</sup>Program in Medical and Population Genetics, Broad Institute of Harvard and Massachusetts Institute of Technology (MIT), Cambridge, USA, <sup>5</sup>Gade Laboratory for Pathology, Dept of Clinical Medicine, University of Bergen, Norway, <sup>6</sup>Dept of Clinical Sciences, Diabetes and Endocrinology, Clinical Research Centre, Lund University, Malmö, Sweden, <sup>7</sup>Dept of Pediatrics, Haukeland University Hospital, Bergen, Norway.

**Background and aims:** In a population sample of randomly selected individuals from 3 different cohorts, as much as 2% carry rare non-synonymous variants in 1 of 7 maturity-onset diabetes of the young (MODY) genes. Interestingly, the majority of these individuals remain euglycemic through middle age. To evaluate their risk for T2D later in life, detailed analyses are required to determine the true pathogenic nature of these MODY gene variants, in addition to family pedigrees/phenotype analyses combined with bioinformatics *in silico* tools. Our aim is to test whether functional characterization of 25 rare variants (MAF<1%) in the hepatocyte nuclear factor 1 alpha (HNF1A) gene identified in randomly selected population cohorts, can aid bioinformatics to determine whether the variant is pathogenic or not.

**Materials and methods:** We classified the HNF1A variants into 5 groups: 1, not pathogenic; 2, likely not pathogenic; 3, uncertain; 4, likely pathogenic; 5, definitely pathogenic, by the mutation analysis tools PolyPhen-2, AlignGVGD og SIFT. Transactivation (TA) of HNF-1A (wild-type and mutants) was measured by luciferase assays of transient transfected HeLa cells. Protein expression levels were confirmed by immunoblotting. Investigations of their DNA binding ability (by electrophoretic mobility shift assay) and subcellular localization are pending.

**Results:** Of 25 HNF1A variants, none were in class 5, 2 were in class 4, 14 in class 3 and 9 in class 2. Three variants had transcriptional activity of 0-40%, and all were associated with diabetes (two were in class 4). Four variants had transcriptional activity of 70-100%, all were class 2 or 3. Three of these were not associated with diabetes, while one was found both in diabetic and non-diabetic individuals. Eighteen variants had transcriptional activity of 40-70%, 6 were associated with diabetes, the others not.

**Conclusion:** Functional characterization by measurement of transcriptional activity for 25 HNF1A rare variants can supplement bioinformatics in ascribing pathogenicity, and seems to be most helpful for variants in class 3.

### Endocytosis of secreted carboxyl-ester lipase protein in CEL-MODY, a syndrome of diabetes and pancreatic exocrine dysfunction

M. Dalva<sup>1,2</sup>, K. Fjeld<sup>1,2</sup>, J. Torsvik<sup>1</sup>, P.R. Njølstad<sup>1</sup>, B.B. Johannsson<sup>1,2</sup>, A. Molven<sup>3,4</sup>;

<sup>1</sup>KG Jebsen Center for Diabetes Research, Department of Clinical Science, University of Bergen, <sup>2</sup>Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, <sup>3</sup>Gade Laboratory for Pathology, Department of Clinical Medicine, University of Bergen, <sup>4</sup>Department of Pathology, Haukeland University Hospital, Bergen, Norway.

**Background and aims:** The carboxyl-ester lipase (CEL) gene, encoding the pancreatic enzyme CEL, is highly expressed in the pancreatic acinar cells. A dominant-acting frame-shift mutation (c.1686delT) in the last exon of CEL causes CEL-MODY (MODY8), a disease characterized by diabetes and pancreatic exocrine dysfunction. The resulting mutant CEL protein (CEL-MUT) has an altered, repetitive C-terminus leading to a higher tendency to aggregate and to undergo endocytosis as compared with the wild-type CEL protein (CEL-WT). We aimed to investigate the cellular reuptake of the mutant CEL protein and characterize its effect on cellular functions in acinar and  $\beta$ -cell models.

**Materials and methods:** HEK 293 cells stably expressing CEL-MUT and CEL-WT proteins were used to produce conditioned medium for use in endocytosis studies in acinar cells (rat AR42J and mouse 266-6) and  $\beta$ -cell models (rat INS-1E and mouse MIN6). We employed immunofluorescence confocal microscopy and assays of cell viability and glucose-stimulated insulin secretion.

**Results:** In stably transfected HEK293 cells, CEL-MUT was distributed in a cytoplasmic punctate pattern, whereas the CEL-WT predominantly localized typically for secreted proteins in the Golgi compartments and the endoplasmic reticulum. When untransfected acinar cells and  $\beta$ -cells were grown in conditioned medium from CEL-expressing cells, an accumulation of the CEL-MUT protein was observed in punctate structures. Long-term incubation of acinar and  $\beta$ -cells in conditioned medium showed a tendency, however not significant, of lower viability in the presence of CEL-MUT compared with CEL-WT. Glucose-stimulated insulin secretion in MIN6 cells was not reduced in the presence of the mutant protein.

**Conclusion:** Our results suggest that CEL-MUT can be endocytosed both by acinar and  $\beta$ -cells. The endocytic process might represent a mechanism of protecting cells against the exposure to CEL aggregates by cell-mediated uptake and degradation of the potentially toxic protein. Furthermore, endocytosis could be directly relevant for how the CEL-MUT causes disease affecting both the exocrine and endocrine pancreas.

### 365

#### Wolfram syndrome in the Japanese population: molecular analysis of the *WFS1* gene and characterisation of clinical features

Y. Tanizawa, K. Matsunaga, K. Tanabe, on behalf of the Japan study group of Wolfram syndrome;

Division of Endocrinology, Metabolism, Hematological Science and Therapeutics, Yamaguchi University, Graduate School of Medicine, Ube, Japan.

**Background and aims:** Wolfram syndrome (WFS) is a recessive neurologic and endocrinologic degenerative disorder, and is also known as DIDMOAD (Diabetes Insipidus, early-onset Diabetes Mellitus, progressive Optic Atrophy and Deafness) syndrome. Most affected individuals carry recessive mutations in the Wolfram syndrome 1 gene (*WFS1*). However, the phenotypic pleiomorphism, rarity and molecular complexity of this disease complicate our efforts to understand WFS. To address this limitation, we aimed to describe complications and to elucidate the contributions of the *WFS1* mutations to clinical manifestations in patients with WFS.

**Materials and methods:** The minimal ascertainment criterion for diagnosing WFS was having both early onset diabetes mellitus (DM) and bilateral optic atrophy (OA). Genetic analysis for the *WFS1* was performed by direct sequencing.

**Results:** Sixty-seven patients were identified nationally for a prevalence of one per 710,000, with 33 patients (49%) having all 4 components of DIDMOAD. In 40 subjects who agreed to participate in this investigation from 30 unrelated families, the earliest manifestation was DM at a median age of 8.7 years, followed by OA at a median age of 15.8 years. However, either OA or DI was the first diagnosed feature in 6 subjects. In 10, features other than DM predated OA. Twenty-seven patients (67.5%) had a broad spectrum of recessive mutations in the *WFS1*. Two patients had mutations in only one allele. Eleven patients (27.5%) had intact *WFS1* alleles. Ages at onset of both DM and OA in patients with recessive *WFS1* mutations were indistinguishable from those in patients without *WFS1* mutations. In the patients with predicted complete loss-of-function mutations, ages at the onsets of both DM and OA were significantly earlier than those in patients with predicted partial-loss-of function mutations.

**Conclusion:** This study emphasizes the clinical and genetic heterogeneity in patients with WFS. Genotype-phenotype correlations may exist in patients with the *WFS1* mutations, as demonstrated by the disease onset.

#### Czech prediction programme for type 1 diabetes: additional source of MODY patients?

P. Dusatkova, L. Petruzelkova, S. Pruhova, J. Vcelakova, K. Stechova, O. Cinek, Z. Sumnik, J. Lebl, S. Kolouskova;

Department of Pediatrics, 2nd Faculty of Medicine, Prague, Czech Republic.

**Background and aims:** Since 2001, we prospectively follow up first-degree relatives of patients with Type 1 Diabetes (T1D) in the Czech Prediction Programme. Monogenic forms of diabetes, in particular Maturity-Onset Diabetes of the Young (MODY), are estimated to be responsible for 1-2% of all patients with diabetes. However, the MODY occurrence could be largely underestimated because it bears several clinical features common to other types of diabetes. We aimed to search for families with MODY among participants of Prediction Programme for T1D having positive family history of diabetes.

**Materials and methods:** First-degree relatives of patients with T1D are investigated for HLA-DQ genotype and annually screened for pancreatic autoantibodies (IA-2Ab, GADAb, IAA). Among 557 families included in the Prediction Programme for T1D, a positive family history of diabetes (at least 2 affected family members) was reported in 53 families (9.5%). In these families, one proband with diabetes was chosen for mutation screening of most prevalent MODY genes (*GCK*, *HNF1A*, *HNF4A* and *INS*) by direct Sanger sequencing.

**Results:** Of the 53 families with positive family history of diabetes in the Prediction Programme for T1D, 24 (45%) were genetically diagnosed with MODY. This makes up 4% of all the families from the Prediction Programme

for T1D. The most frequent mutations in our study were detected in the *GCK* (58%), followed by *HNF1A* (38%) and *INS* (4%) genes. The family-specific mutations were subsequently observed in 25/27 (93%) participants (first-degree relatives of patients with T1D) studied in the Prediction Programme for T1D: they were asymptomatic with exception of two children with HNF1A-MODY who presented osmotic symptoms (polyuria, polydipsia) during the follow up requiring insulin treatment which could be switched to administration of suphonylurea derivatives. Comparing MODY to non-MODY families with positive family history of diabetes, mothers of subjects in the Prediction Programme had more often diabetes than fathers and siblings ( $p < 0.0001$ ), the pancreatic islet autoantibodies were absent in all subjects with MODY ( $p = 0.009$ ) and the risk DQA1 and DQB1 alleles were less frequently seen in children from MODY families followed in the Prediction Programme ( $p = 0.02$ ).

**Conclusion:** This systematic search for MODY patients in the Prediction Programme for T1D has shown that monogenic diabetes accounts for a substantial number of cases with diabetes which could be higher than estimated previously. MODY should be considered in all families with history of diabetes because they may benefit from the optimization of the therapeutic options, prediction of disease prognosis and identification of diabetes risk in family members.

### 367

#### MODY is uncommonly diagnosed in the South Asian ethnic group as a result of difficulty in differentiating young-onset type 2 diabetes from MODY

S. Misra<sup>1</sup>, B. Shields<sup>2</sup>, K. Colclough<sup>3</sup>, D.G. Johnston<sup>1</sup>, N.S. Oliver<sup>1</sup>, S. Ellard<sup>3</sup>, A.T. Hattersley<sup>2</sup>;

<sup>1</sup>Diabetes, Endocrinology & Metabolism, Imperial College London,

<sup>2</sup>NIHR Exeter Clinical Research Facility, University of Exeter,

<sup>3</sup>Molecular Genetics, Royal Devon & Exeter NHS Foundation Trust, UK.

**Background and aims:** Maturity onset diabetes of the young (MODY) has been extensively described in white-European (WE) populations, however comparatively few cases have been found in other ethnic groups. It is unclear if this reflects a genuinely lower prevalence of MODY in other ethnic groups or a disparity in testing-rates. We examined South Asian (SA) referrals for MODY testing in the UK.

**Materials and methods:** A retrospective cross-sectional analysis of UK patients referred for MODY genetic testing was undertaken (HNF1A, HNF4A and GCK). Ethnic origin, results of genetic analyses and clinical and biochemical characteristics were examined on all referrals, and sub-analysed by mutation result.

**Results:** 26 SA and 836 WE patients had mutations in one of the common MODY genes (HNF1A, HNF4A and GCK). This low SA prevalence of genetically confirmed MODY did not reflect a low referral rate, as 207 of 3491 (5.9%) referrals were SA, matching UK census data (5.3% population). However the mutation detection rate in the SA group was half that seen in the 3284 WE referrals (12.6% vs 25.5%,  $p < 0.001$ ). To analyse why the mutation detection rate was lower, we compared the clinical phenotype of SA and WE patients who a) had a genetic diagnosis of MODY and b) in whom a MODY mutation was not detected. a) Mutation phenotypes were similar between ethnic groups; SA HNF1A patients had similar age at diagnosis (18.0 vs 15 years,  $p = 0.072$ ), proportions of parental diabetes (100% vs 87.8%,  $p = 0.244$ ) and non-insulin requirement (80 vs 66.5%,  $p = 0.30$ ) to WE HNF1A patients. SA GCK patients were younger at diagnosis (12 vs. 19.5 years,  $p = 0.008$ ), with similar proportions of parental diabetes (85.6 vs. 74.5%,  $p = 0.303$ ) and non-insulin requirement (100 vs. 90.6%,  $p = 0.344$ ) to WE patients. b) Phenotypes in those tested for MODY in whom no mutation was found differed markedly between ethnic groups; SA subjects were younger at diagnosis (20 vs 25 years,  $p < 0.001$ ), with similar BMI (25.0 vs 25.2,  $p = 0.198$ ), were more likely to have an affected parent (77.3% vs 57.5%,  $p < 0.001$ ) and to be non-insulin treated (62% vs 52.1%,  $p = 0.007$ ) when compared to WE patients. The strongest predictors of MODY mutations in SA people were younger age at diagnosis (14.5 vs. 20 years,  $p = 0.001$ ) and lower BMI (20.0 vs 25.0 kg/m<sup>2</sup>,  $p < 0.001$ ) when compared to SA people without mutations.

**Conclusion:** The reduced prevalence of molecular genetically diagnosed MODY in SA people results from a lower mutation detection rate, rather than a reduced referral rate. The low detection rate in the SA group reflects the higher prevalence of early-onset, non-insulin requiring, familial diabetes that does not result from MODY mutations. Differentiating MODY from young-

onset type 2 diabetes in people of SA origin is challenging, and further work is required to develop ethnic specific targeted referral criteria.

#### Genetic testing for monogenic diabetes using targeted next-generation sequencing in the MODY registry cohort of Poland

A. Ludwig-Galezowska, M. Szopa, J. Machlowska, J. Skupien, P. Radkowski, T. Klupa, T. Koblik, B. Zapala, T. Staszal, B. Kiec-Wilk, I. Wybranska, P. Wolkow, M.T. Malecki;

Jagiellonian University Medical College, Krakow, Poland.

**Background and aims:** Specific molecular diagnosis of monogenic diabetes mellitus is important for individualized patient care. When results of standard Sanger sequencing in selected genes are negative, Next Generation Sequencing-based exome - sequencing (NGS), might provide additional diagnostic potential. NGS enables the simultaneous analysis of multiple genes in a single test. Our aim was to assess the feasibility of using NGS for a detection of mutations in a set of earlier described monogenic diabetes genes in a group of patients from the Polish Registry of MODY.

**Materials and methods:** We selected 29 genes (*GCK*, *HNF1A*, *HNF4A*, *HNF1B*, *NEUROD1*, *INS*, *CEL*, *PDX1*, *PAX4*, *BLK*, *KLF11*, *KCNJ11*, *ABCC8*, *PTFA1A*, *NEUROG3*, *RFX6*, *EIF2AK3*, *FOXP3*, *GLIS3*, *SLC19A2*, *SLC2A2*, *IER31P*, *ZFP57*, *WFS1*, *GATA6*, *GATA4*, *LMNA*, *PPARG*) in which mutations have been reported to cause MODY, neonatal diabetes, maternally inherited diabetes and deafness (MIDD) or familial partial lipodystrophy (FPLD). The Illumina MiSeq platform was used for sequencing. An exo-capture assay was designed to include coding regions and splice sites, and it was based on the assay designed by the Exeter group. A total of 41 patients were selected from our cohort of suspected MODY. Sequence data were analysed for the presence of base substitutions, small insertions or deletions (indels) and exonic deletions or duplications.

**Results:** Sequencing results were generated for all 41 patients. In two positive controls, we detected previously identified HNF1A and GCK mutation. We detected 2 known HNF1A gene mutation and 1 known GCK gene mutation (missed in Sanger sequencing) in patients previously examined with negative results towards HNF1A and GCK MODY, respectively. In the other 24 patients previously negatively tested for HNF1A or GCK MODY we found high or moderate impact mutations in GCK (4), HNF4A (2), ABCC8 (2), HNF1A (1), NEUROD1 (1), ZFP57 (1), WFS1 (1), and GATA6 (1) gene. We also included 12 patients with no prior genetic testing. In this subgroup we identified known mutations in HNF1A (3), GCK (3), ZFP57 (1) and LMNA (1) gene. Currently, we are in the process of verification the sequence differences and their segregation in families by the Sanger sequencing.

**Conclusion:** Our pilot experiments using NGS for monogenic diabetes screening in the MODY cohort confirmed that its use is feasible in routine genetic testing. The screening should include patients in whom MODY is suspected and in whom earlier Sanger-based screening for MODY generated negative results.

#### DNA testing of MIDD in patients with clinical suspicion on MODY or MIDD in Slovakia

J. Stanik<sup>1,2</sup>, M. Skopkova<sup>3</sup>, I. Masindova<sup>3</sup>, L. Valentinova<sup>2</sup>, M. Huckova<sup>2,3</sup>, L. Varga<sup>2,4</sup>, D. Danis<sup>2</sup>, M. Profant<sup>4</sup>, I. Klimes<sup>2</sup>, D. Gasperikova<sup>2,5</sup>;

<sup>1</sup>Firts Department of Pediatrics, Medical Faculty at Comenius University,

<sup>2</sup>DIABGENE & Diabetes Laboratory, Institute of Experimental

Endocrinology, SAS, <sup>3</sup>Center for Molecular Medicine, SAS, <sup>4</sup>Department

of Otorhinolaryngology - Head and Neck Surgery, Medical Faculty at

Comenius University, <sup>5</sup>Center for Molecular Medicine SAS, Bratislava,

Slovakia.

**Background and aims:** Diabetes and deafness - the leading clinical features of MIDD (Maternally Inherited Diabetes and Deafness) arise from mutations in mtDNA, most often m.3243A>G. This mutation leads to different clinical symptoms according to heteroplasmy levels in different tissues. Usually, the first presentation of MIDD is a sensorineural hearing loss emerging in adolescence; the diabetes mostly develops between 20th-40th year of life. More severe clinical presentation of the mutation is the MELAS syndrome (Mitochondrial Myopathy, Encephalopathy, Lactic Acidosis and Stroke-like epi-

sodes). The aim of our study was to search for m.3243A>G mutation among patients sent for MIDD or MODY testing, who lack mutations in the most common MODY genes (i.e. GCK, HNF1A or HNF4A).

**Materials and methods:** Unrelated probands from 257 families fulfilling at least one of the following criteria, i.e. matrilinear inheritance, diabetes plus hearing impairment, diabetes development after 20th year of life, or progressive hearing loss, were tested for m.3243A>G mutation by the RFLP and/or Real-Time PCR. The heteroplasmy was evaluated for peripheral blood and/or buccal mucosa. DNA testing was also extended to the family members of probands carrying the mutation.

**Results:** The m.3243A>G mutation was found in 18 patients from 8 families (3%). Probands' phenotypes varied from diabetes as the sole symptom to a complex picture of the MELAS syndrome (in one proband). Diabetes or impaired glucose tolerance developed all of the probands (diabetes onset ranged from 21 to 52 years), but only 3 of 10 relatives with the mutation. Five probands (62.5%), and 4 (40%) of the relatives with the mutation had hearing impairment. The heteroplasmy was higher in buccal swab samples compared to the peripheral blood (27.9±18.6% versus 12.7±17.3%). In one case, the heteroplasmy was detected in the buccal DNA only, while the blood DNA samples were repeatedly negative.

**Conclusion:** Among 257 probands with the clinical suspicion on MIDD or MODY, 8 (3%) had the m.3243A>G mutation of the mitochondrial DNA. At the time of testing, only 5 (62.5%) of the probands were diagnosed with typical combination of symptoms, i.e. diabetes and hearing loss. Therefore, DNA testing for MIDD seems to be reasonable also in diabetes patients without hearing impairment, particularly using DNA from the buccal mucosa.

### Using targeted sequencing to investigate the prevalence of monogenic diabetes in the Norwegian childhood diabetes registry

B.B. Johansson<sup>1,2</sup>, H.U. Irgens<sup>1,3</sup>, J. Molnes<sup>1,2</sup>, O. Søvik<sup>1,3</sup>, S. Levy<sup>4</sup>, D.E. Undlien<sup>5</sup>, T. Skrivarhaug<sup>6</sup>, G. Joner<sup>6,7</sup>, A. Molven<sup>1,8</sup>, S. Johansson<sup>1,2</sup>, P.R. Njølstad<sup>1,3</sup>;

<sup>1</sup>Department of Clinical Science, University of Bergen, <sup>2</sup>Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital,

<sup>3</sup>Department of Paediatrics, Haukeland University Hospital, Norway,

<sup>4</sup>Hudson Alpha Institute for Biotechnology, Huntsville, USA, <sup>5</sup>University of Oslo, <sup>6</sup>Department of Paediatrics, Oslo University Hospital, <sup>7</sup>Institute of Health and Society, University of Oslo, <sup>8</sup>Gade Institute, University of Bergen, Norway.

**Background and aims:** Type 1 diabetes is a heterogenous group of diabetes. Since about 10–15 % lack detectable levels of diabetes associated autoantibodies at diagnosis, we hypothesized that many of these may have a monogenic form of diabetes. We therefore set out to systematically screen all auto-antibody negative patients in the Norwegian Childhood Diabetes Registry for 13 genes known to cause monogenic diabetes. The aim of this study was to estimate the prevalence of common forms of monogenic diabetes in childhood diabetes and assess the usefulness of large scale gene sequencing in routine clinical care of young onset diabetes.

**Materials and methods:** The Norwegian Childhood Diabetes Registry includes 95% of all children with newly diagnosed diabetes from 2002. By 22.01.2014, the registry included 3578 children with clinical data regarding onset of diabetes, family history and treatment, as well as serum and DNA samples. In this study, we selected 478 cases that were negative for GAD and IA-2 autoantibodies, as well as and 478 GAD and IA-2 antibody-positive individuals as controls. The samples were screened by TruSeq Custom Amplicon targeted sequencing method, focusing on 13 monogenic diabetes genes (*HNF1A*, *HNF4A*, *GCK*, *NEUROD1*, *ABCC8*, *KCNJ11*, *HNF1B*, *INS*, *PDX1*, *KLF11*, *PAX4*, *BLK*, *CEL*). The amplicons targeted the protein coding regions with flanking intronic sequences, UTRs and some selected regions; *HNF4A* (c.-192), *INS* intron (c.188-31) and *GCK* (c.-71). To test the sensitivity of the assay, we tested 22 controls with known mutations in the selected target genes. We identified all these mutations. Sequencing was performed on a Miseq. All newly identified mutations were confirmed by Sanger sequencing. We used standard bioinformatics tools to assess the pathogenicity of the variants identified.

**Results:** As a first test, we screened 74 antibody negative cases that were C-peptide positive (C-peptide>200 pmol/l at diagnosis) to increase the likelihood of finding possible MODY. In the screened material we found 39 exonic and splice variants whereof twelve of the patients (16%) had a likely pathogenic mutation in *HNF1A* or *GCK*. There were no false positive variants reported by the assay. Mean exonic coverage was estimated to 505X and

94% of target exons were covered at 20X. We are currently in the process of analyzing the remaining samples.

**Conclusion:** In this preliminary study where we use targeted sequencing to investigate the prevalence of monogenic diabetes in the Norwegian Childhood Diabetes Registry we observe that 16% of the GAD- and IA-2-antibody negative patients harbor a likely pathogenic mutation. This panel-sequencing assay provides a specific and sensitive method for simultaneous analysis of 13 genes associated with monogenic diabetes.

### Clinical features of MODY2 in children and adolescents in Russian Federation

L. Zilberman<sup>1</sup>, E. Sechko<sup>1</sup>, V. Peterkova<sup>1</sup>, T. Kuraveva<sup>1</sup>, O. Ivanova<sup>2</sup>;

<sup>1</sup>Children, <sup>2</sup>Laboratory Immunology, FGBU Endocrinology Research Centre, Moscow, Russian Federation.

**Background and aims:** Maturity-onset diabetes of the young, type 2 (MODY2) is a monogenic disease caused by mutations in the glucokinase gene (*GCK*). Aim: To determine the prevalence of *GCK* gene mutations and to delineate the clinical phenotype of identified *GCK* mutation carriers in monogenic diabetes patients in Russia.

**Materials and methods:** We included 96 patients with suspected MODY. All patients were screened for *HNF1A* and *GCK* mutations by direct sequencing. **Results:** Mutations in the *GCK* were found in 46 patients (48%), and *HNF1A* mutation - in 18 patients (19%), 32 patients (33%) were negative for MODY2 and MODY3. The age at diagnosis was 10.4 yrs (7;14). 11% of patients were investigated because of clinical manifestations, 66% were diagnosed occasionally, 23% were screened because of family history. Duration of the disease was 1.3 (0.6;2.3). BMI was in normal range in 95.6% of the patients (17.0 (15.8;18.5)). BMI was increased to 28.8 (SDS BMI +3.2) in only one 8-year-old girl. HbA1c at the time of diagnosis was 6.6% (6.4;6.8). autoantibodies (ICA, GAD, IAA) were negative in all patients. GTT: Glu (mmol/L) 0<sup>-</sup> 6,6 (5,9; 7), 1-h -11,15 (9,2; 12,78), 2-h -9,15 (8,475; 10,35). Seven patients (15%) aged 11.8–13.2 yrs with normal BMI were found to be insulin-resistant (Insulin at baseline was 14.2 U/l(11.0;15.2), HOMA>3.5). Three patients requested insulin therapy (6.5%), and three other patients received sulfonylureas. 87% (40 patients) were able to maintain normal blood glucose levels with a diet and physical exercise only.

**Conclusion:** MODY3 is seemed to be less prevalent than MODY2 in Russian population. Most of the patients have asymptomatic disease and have been revealed occasionally in our study by impaired fasting glucose and slightly elevated HbA1c. Treatment for the majority of MODY2 children can be restricted by diet and physical exercise.

## 372

### The length of the deletion in the region 17q contributes to the individual variability of the phenotype of patients with renal cysts and diabetes syndrome (RCAD, HNF1B-MODY)

S. Pruhova<sup>1</sup>, P. Dusatkova<sup>1</sup>, M. Malina<sup>1</sup>, Z. Slamova<sup>2</sup>, K. Blahova<sup>1</sup>, R. Kotalova<sup>1</sup>, J. Dusek<sup>1</sup>, J. Lebl<sup>1</sup>, T. Seeman<sup>1</sup>, O. Cinek<sup>1</sup>;

<sup>1</sup>Department of Pediatrics, <sup>2</sup>Department of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Czech Republic.

**Background and aims:** The renal cysts and diabetes (RCAD) syndrome caused by defects in a gene for hepatocyte nuclear factor 1 beta (*HNF1B*) is characterized by broad spectrum of clinical features. While heterozygous point mutations detectable by Sanger sequencing are relatively rare, we focused on gross deletions of the *HNF1B* gene that are determined by MLPA (Multiplex Ligation Probe-dependent Amplification). Rather importantly, the deletions most often extend beyond the single *HNF1B* gene, thus more deleted genes may participate in the clinical picture. Objective and hypotheses. We compared the clinical phenotype of patients carrying the gross deletions whose extent was precisely determined by array comparative genomic hybridisation (aCGH), and point mutations in the *HNF1B* gene.

**Materials and methods:** In thirteen patients (6 males, median age 15.5 years) carrying the *HNF1B* gene deletion was performed aCGH on CytoChip Oligo 8x60K. The clinical data were compared with 5 patients (1 male, median age 15.5 years) having point mutations in *HNF1B*.

**Results:** The average length of heterozygous deletion was 1.69 Mb. The longest deletion reached 2.5 Mb affecting 47 genes and the shortest deletion found in three patients was 1.4 Mb long and deleted 16 genes. All patients lost also LHX1 gene encoding transcription factor important for the development of the renal and urogenital system. Compared to other deletion carriers, patients having longest deletions (2.5 and 2.1 Mb) manifested renal dysfunction at older age (10 and 30 years) with milder changes of the kidney structure (isolated cysts and functional changes only) and both presented diabetes as a first clinical feature of RCAD. Patients with shorter deletion manifested renal changes (polycystosis) prenatally and are mostly without diabetes so far. Comparing deletion and point mutation carriers, prenatal ultrasound kidney changes were found in 10/13 and 4/5 patients, respectively. Diabetes manifested at the median age of 17 years in 5/13 and 2/5 patients. Hypomagnesemia was present in 11/13 and 2/5 patients.

**Conclusion:** Regardless to the length of the deletion in the region 17q, the dominating clinical phenotype of the patients is similar compared to the patients having point mutation in the HNF1B gene. However, the length of the deletion can contribute to the individual variability in the age of manifestation and other variability of the phenotype.

## PS 013 Islet gene expression in type 2 diabetes

### 373

**Beta cell function, more than beta cell area, affects plasma glucose levels and influences the progression of type 2 diabetes in humans**

M. Suleiman, F. Olimpico, M. Bugliani, F. Syed, M. Occhipinti, F. Scatena, F. Filippini, D. Focosi, U. Boggi, P. Marchetti, L. Marselli; Department of Clinical and Experimental Medicine, Islet Cell Laboratory, University of Pisa, Italy.

**Background and aims:** Type 2 diabetes (T2D) is characterized by reduced beta cell functional mass. However, the direct relationships between beta cell amount or function with *in vivo* blood glucose levels and disease progression are unclear.

**Materials and methods:** Pancreases were obtained from 388 non-diabetic (ND) donors [age: 60±17 years, BMI: 25.2±3.8 kg/m<sup>2</sup>, mean glycemia (MG) in intensive care unit: 154±45 mg/dl] and 68 T2D subjects [(age: 71±8 years, BMI: 26.9±4.0 kg/m<sup>2</sup>, MG: 218±72 mg/dl, diabetes duration (DD): 9±7 years)]. Pancreatic insulin area (PIA) was assessed by immunocytochemistry; islets (HI) were isolated and *ex-vivo* insulin release (IR) was evaluated in response to 3.3 and 16.7 mM glucose (G).

**Results:** PIA was lower in T2D than ND subjects (0.51±0.20 vs 0.84±0.42%, p<0.001). IR (μU/islet/min) in response to 3.3 mM G (0.031±0.010 vs 0.036±0.015, p=0.004) and 16.7 mM G (0.050±0.030 vs 0.104±0.077, p<0.001) was also reduced in T2D islets, which was confirmed by calculation of stimulation index (SI, 1.6±0.7 vs 2.8±1.7, p<0.001). MG was not correlated with PIA (p=0.30), but it was inversely correlated with IR at 16.7 mM G (p=0.002) and SI (p=0.001). Anti-diabetic therapy consisted of diet alone (D) in 3 subjects, metformin (M) in 15, sulfonylurea alone or in combination with metformin in 25, insulin associated with oral agents in 6, insulin alone (I) in 9. Unsurprisingly, progression of therapeutic treatment was correlated with DD (p<0.001). There was no significant correlation between PIA and DD or pharmacological therapy. However, lower glucose stimulated IR was associated with progressively more intense diabetes therapy (p<0.001). Correlations were validated by multivariate analysis, and comparisons between therapeutic groups confirmed differences in terms of DD (from 6±3 yrs in D+M to 17±10 yrs in I), IR in response to 16.7 mM G (from 0.069±0.043 to 0.29±0.01 μU/islet/min) and SI (from 2.1±0.7 to 1.1±0.1) (p<0.01).

**Conclusion:** These results suggest that beta cell function, more than beta cell amount, affects plasma glucose levels and progression of T2D in humans; if so, improving beta cell function is a primary goal in T2D therapy.

### 374

**Uncovering conserved beta cell transcriptome of type 2 diabetes by meta-analysis of microarray data**

E.-G. Hong<sup>1</sup>, J. Ohn<sup>1</sup>, H.-S. Kwon<sup>2</sup>, B.-Y. Cha<sup>2</sup>;

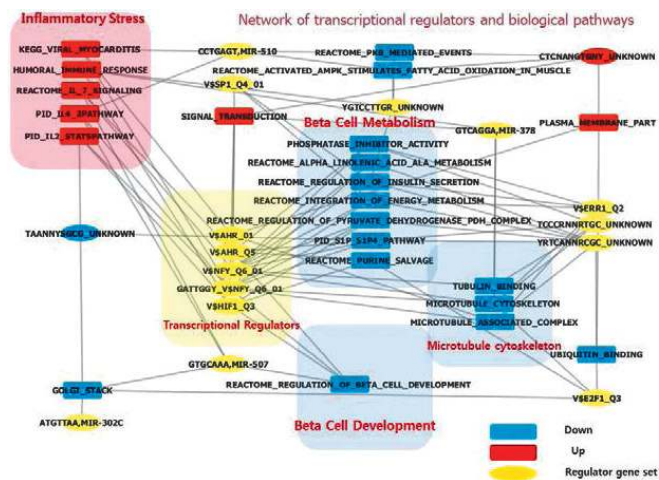

<sup>1</sup>Internal Medicine, Hallym University, Chuncheon, <sup>2</sup>Internal Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

**Background and aims:** Pancreatic beta cell dysfunction is an early manifestation during progression to diabetes. Transcriptional profiling studies of beta cells from subjects with diabetes have revealed various genes or pathways of beta cell dysfunction. We aimed to uncover conserved beta cell transcriptional signature in diabetes by meta-analyzing microarray datasets and find regulators.

**Materials and methods:** Microarray data of three independent transcriptional profiling studies of beta cells from diabetes patients (GEO IDs: GSE20966, GSE25724, and GSE38642) were obtained from the public microarray database, Gene Expression Omnibus (GEO) (<http://www.ncbi.nlm.nih.gov/geo/>). Gene Set Enrichment Analysis (GSEA) was performed for 10,294 curated mSigDB gene sets (<http://www.broadinstitute.org/gsea/msigdb>) in each microarray dataset and Enrichment Scores (ES) were calculated. As a measure of consistently altered expression, meta-Enrichment Score (Meta-ES) is defined as the sum of Enrichment Scores in three datasets. Gene sets with significantly high absolute meta-ES values (P < 0.01) are extracted. Next, we constructed the network of the significantly and consistently altered gene sets and regulators at the hub of the gene set network were assumed to be the key regulators of beta cell transcriptome of diabetes.

**Results:** 461 out of 10,294 mSigDB gene sets were significantly and consistently altered across datasets (P value of meta-ES <0.01). In gene set network, cytokine metabolism and immunologic response pathways were up-regulated, while beta cell differentiation, energy metabolism, and microtubule associated gene sets were down-regulated in all three datasets. Analysis of the network topology of transcription factor target gene sets and biological pathway/gene ontology gene sets suggests that HIF1A, aryl hydrocarbon receptor, and Nuclear Factor Y may be core regulators that account for the repressed beta cell development and metabolism of diabetes patients exposed to chronic metabolic and inflammatory stress (see attached figure).

**Conclusion:** Integrative meta-analysis of heterogeneous transcriptional profiling studies of beta cells from diabetes patients proposes that HIF1A, aryl hydrocarbon receptor, and Nuclear Factor Y may be candidate regulators of impaired beta cell development and function in patients with type 2 diabetes.

### 375

#### Serotonin receptors HTR1D and HTR2A are differentially expressed in human type 2 diabetes islet donors and regulate insulin secretion in vitro in human islets and INS (832/13) cells

H. Bennet<sup>1</sup>, A. Balhuizen<sup>1</sup>, A. Medina Benavente<sup>1</sup>, M. Dekker Nitert<sup>2</sup>, S. Essén<sup>3</sup>, P. Spégel<sup>4</sup>, P. Storm<sup>5</sup>, U. Krus<sup>6</sup>, N. Wierup<sup>7</sup>, M. Fax<sup>1</sup>;

<sup>1</sup>Diabetes and Celiac Disease, Lund University, Malmö, Sweden, <sup>2</sup>University of Queensland, Herston, Australia, <sup>3</sup>Department of Chemistry, Lund University, <sup>4</sup>Molecular Metabolism, Lund University, <sup>5</sup>Diabetes and Endocrinology, Lund University, <sup>6</sup>Islet Pathophysiology, Lund University, <sup>7</sup>Neuroendocrine Cell Biology, Lund University, Malmö, Sweden.

**Background and aims:** Regulation of overall glucose homeostasis is achieved by an intricate interplay between metabolic and nervous input to the pancreatic alpha and beta cells. Failure of adequate signals to the beta cells may result in overt type 2 diabetes (T2D). Intra islet paracrine and autocrine circuits of the monoamine 5-hydroxy tryptamine (5-HT) is stored within the islets and can potentially regulate glucose stimulated insulin release (GSIS). Discrepancies in results of the effects of 5-HT on insulin release in vitro and in vivo and lack of studies in human islets demand further investigation of the islet 5-HT systems. Moreover, diabetogenic effects of atypical antipsychotics and antidepressants that specifically targets these systems urges increased understanding of effects directly on the islets. Therefore, in this study we aimed to perform a complete transcriptional mapping of 5-HT receptors, investigate differentially expressed receptors in non diabetic and T2D human islet donors, and to study the role for these receptors in insulin secretion.

**Materials and methods:** Islet donors were obtained from the Nordic Network of Clinical transplantation in Uppsala, Sweden. RNA sequencing data of 131 islet donors (114 control donors and 17 T2D donors) were used. Validation of RNA sequencing data for receptors was performed by quantitative (Q) PCR (Applied Biosystems). One hour batch secretion experiments were performed using secretion assay buffer (2.8 mmol/l glucose, 114 mmol/l NaCl, 4.7 mmol/l KCl, 1.2 mmol/l KH<sub>2</sub>PO<sub>4</sub>, 1.16 mmol/l MgSO<sub>4</sub>, 25.5 mmol/l NaHCO<sub>3</sub>, 20 mmol/l Hepes, 2.5 mmol/l CaCl<sub>2</sub>, and 0.2% BSA), with or without addition of agonists and antagonists. Localization for receptors and amine was performed by immunohistochemistry in sections of human pancreas.

**Results:** We detected the expression of fifteen 5-HT receptors in human islets, as well as all enzymes involved in the biosynthesis of 5-HT (TPH1, TPH2 and DDC). Searching for differential receptor expression between non-diabetic and T2D islet donors, expression for HTR1D and HTR2A was found to be increased in T2D islets (p=0.0043= and p=0.0041). Batch incubations with human islets revealed that agonist for 5-HT1d (PNU142633) decrease GSIS while an agonist for 5-HT2a (TCB-2) potentiated GSIS. Conversely, an antagonist for 5-HT2a (EMV) decreased GSIS and an antagonist for 5-HT1d (LY3107609) increased GSIS. Immunohistochemistry localized 5-HT1d and 5-HT2a receptors and 5-HT to both human beta and alpha cells.

**Conclusion:** Our findings support a role for 5-HT in control of human islet hormone secretion, perhaps in a paracrine and autocrine fashion as we show that 5-HT is present in both human alpha and beta cells. Moreover, expression of HTR1D and HTR2A is changed in T2D islets, suggesting a role for these receptor in the pathophysiology of type 2 diabetes.

#### Effects of steroid treatment on beta cell mass in Japanese individuals with or without diabetes

S. Sato<sup>1</sup>, Y. Saisho<sup>1</sup>, J. Inaishi<sup>1</sup>, K. Kou<sup>1</sup>, T. Yamada<sup>2</sup>, H. Itoh<sup>1</sup>;  
<sup>1</sup>Department of Internal Medicine, <sup>2</sup>Department of Pathology, Keio University School of Medicine, Tokyo, Japan.

**Background and aims:** Steroid is widely used anti-inflammatory agent. Steroid treatment promotes hepatic and peripheral insulin resistance and, in rodent studies, increases beta cell mass (BCM). Recently we have reported that there was no increase in BCM in Japanese obese individuals compared with lean subjects. Therefore in this study, we aimed to clarify the effects of steroid treatment on BCM in Japanese individuals with or without diabetes.

**Materials and methods:** We obtained the human pancreas at autopsy from 26 non-diabetic individuals (NGT; control) and 26 steroid-treated non-diabetic individuals (SNGT) (age 63 ± 8 (mean ± S.D) vs. 60 ± 11 years, HbA1c 5.5 ± 0.6 vs. 5.3 ± 0.6%, respectively). We also obtained the pancreas from 23 steroid-treated individuals with diabetes (SDM) and 25 individuals with type 2 diabetes (DM2) (age 65 ± 8 vs. 66 ± 8 years, HbA1c 7.1 ± 1.0 vs. 7.5 ± 1.2%). To be included, cases were required to have 1) had a full autopsy within 24 h of death, 2) pancreas tissue stored with adequate size and quality. Cases were excluded if pancreas tissue showed autolysis or any abnormal change such as pancreatitis. Pancreatic sections were stained for insulin or glucagon, and fractional beta (%BCA) or alpha cell area (%ACA) was measured.

**Results:** There was no significant difference in %BCA between SNGT and NGT (1.21 ± 0.59 vs. 1.66 ± 1.05%, P = 0.29). In SNGT group, there was no significant correlation between %BCA and duration of steroid treatment (r = 0.404, P = 0.06), or total steroid dose (r = 0.354, P = 0.15). %BCA in DM2 was significantly decreased compared with NGT (0.92 ± 0.63%, P = 0.004), however there was no significant difference in %BCA between SDM and DM2 (0.99 ± 0.56%, P = 0.54). There was no correlation between %BCA and duration of steroid treatment (r = 0.065, P = 0.77) or total steroid dose (r = 0.077, P = 0.75) in SDM. When the SDM group were divided into two groups according to the presence (SDM-DM2, n = 13) or absence (SDM-NGT, n = 10) of type 2 diabetes, %BCA in SDM-NGT was significantly greater than that in SDM-DM2 (1.34 ± 0.53% vs. 0.72 ± 0.43%, P = 0.01) and comparable to that in NGT (P = 0.55). Although there was a significant negative correlation between %BCA and HbA1c in NGT plus DM2 group (r = -0.451, P = 0.004), this correlation was not observed in steroid-treated subjects (SNGT plus SDM groups) (r = -0.266, P = 0.08).

**Conclusion:** There was no increase in BCM in steroid-treated Japanese individuals with or without diabetes, suggesting that steroid treatment does not affect BCM in Japanese. No significant decrease in BCM in patients with steroid-induced diabetes suggests that the glucose intolerance in these subjects is mainly due to the presence of insulin resistance rather than the deficit of beta cell. Since we were not able to observe a significant increase in BCM in the presence of obesity or steroid use in Japanese, these findings suggest that the increase in BCM in the face of insulin resistance is extremely limited in Japanese.

## 377

**Dephosphorylation and nuclear translocation of the CREB-regulated transcription co-activator 1 (CRTC1) elevates miR-212 and miR-132 expression in insulin secreting cells**H.A. Malm<sup>1</sup>, C. Berggreen<sup>2</sup>, M. Orho-Melander<sup>1</sup>, L. Eliasson<sup>1</sup>, O. Göransson<sup>2</sup>, I.G. Mollet<sup>2</sup>;<sup>1</sup>Dept Clinical Sciences in Malmö, Lund University Diabetes Centre, Malmö, <sup>2</sup>Dept of Experimental Medical Sciences, Lund University, Lund University Diabetes Center, Sweden.

**Background and aims:** We have previously demonstrated miR-212 and miR-132 to be upregulated in diabetic GK rat islets. Others have demonstrated cAMP-responsive element binding protein (CREB) to bind CRE-sites on the miR-212/132 promoter. Here we aim to investigate mechanisms underlying cAMP-mediated transcriptional regulation of the miR-212/132 cluster in insulin secreting cells.

**Materials and methods:** INS-1 832/13 cells were cultured for 0.5, 2, 6 and 24h in various glucose concentrations and in the absence or presence of forskolin/IBMX or GLP-1 (2h). In addition, cells were transfected with siRNA against all three isoforms of CRTC or salt inducible kinases (SIKs) or with mature miR-212 and miR-132. Relative expression of miRNA and mRNA was determined by qPCR; Insulin secretion at 2.8 and 16.7 mM glucose was analyzed using RIA; protein expression and phosphorylation was evaluated with western blot analysis (WB) and CRTC1 translocation with confocal microscopy.

**Results:** Expression of both miRNAs was increased after 2h in forskolin/IBMX (3–4-fold,  $p < 0.01$ ) and increased further at 6h. CREB was phosphorylated and CRTC1 was dephosphorylated ( $p < 0.001$ ) after 30 min incubation with forskolin/IBMX. In addition, SIK2 was phosphorylated on Ser358 after forskolin/IBMX treatment ( $p < 0.001$ ). In the presence of forskolin/IBMX, expression of miR-212 and miR-132 ( $p < 0.05$ ), and insulin release at 16.7 mM glucose ( $p < 0.01$ , 50%) were decreased in CRTC1 silenced cells. Expression of CRTC1 mRNA was reduced in cells overexpressing miR-212 and miR-132 ( $p < 0.05$ ), suggesting a feedback control system. Confocal imaging revealed an accumulation of CRTC1 in INS-1 832/13 nuclei in forskolin/IBMX-incubated cells ( $p < 0.05$ ). Finally, expression of miR-132 was elevated in cells incubated with 10 ( $p < 0.05$ ) and 100 nM ( $p < 0.01$ ) GLP-1, respectively and expression of miR-212 was elevated in cells incubated with 100 nM GLP-1 ( $p < 0.05$ ).

**Conclusion:** We have demonstrated that the incretin GLP-1 is an activator of miR-212 and miR-132 expression. Furthermore, our data suggest that miR-212 and miR-132 are regulated by cAMP in INS-1 832/13 cells, and that this is in part mediated through CRTC1 presumably acting together with CREB. We are currently further addressing the potential role of SIK isoforms as upstream regulators of the CRTC1/miR-212/132 pathway.

## 378

**Pdx1 coordinately cooperates with USF transcription factors to regulate expression of Alx3 in pancreatic beta cells**

A. Fernández-Pérez, M. Vallejo;

Instituto de Investigaciones Biomédicas Alberto Sols, CSIC/UAM and CIBERDEM, Madrid, Spain.

**Background and aims:** Alx3 is emerging as an important transcription factor for the control of glucose and metabolic homeostasis. Alx3 deficiency in mice results in age-dependent pancreatic islet cell apoptosis. As a consequence, beta-cell mass and insulin content is reduced, and islet size is decreased. These mice exhibit elevated fasting blood glucose levels, impaired glucose tolerance, and insulin resistance that becomes evident as they age. These findings, together with its involvement in the regulation of the insulin gene, indicate that Alx3 is important for pancreatic islet function. For this reason, we embarked in a series of studies aimed to investigate the transcriptional mechanisms that promote Alx3 expression in pancreatic islet cells. We have previously reported that the transcription factors USF1 and USF2 bind to different E-box elements in the promoter of Alx3 to regulate basal expression in mesenchymal and pancreatic cells. In the present study, we aimed to identify additional transcription factors involved in Alx3 expression in beta cells.

**Materials and methods:** Putative regulatory elements were identified by analysis of the promoter in silico. Binding of nuclear proteins from isolated mouse islets or from MIN6 cells was investigated by chromatin immunoprecipitation and electrophoretic mobility shift assays. To assess the role of spe-

cific transcription factors on the expression of Alx3 we used siRNA. Expression of Alx3 was assessed by quantitative RT-PCR. Luciferase reporter genes were used to test for promoter activity in transfected cells.

**Results:** The functional importance of USF1 and USF2 in the regulation of the endogenous Alx3 gene was confirmed in MIN6 cells by silencing their expression using siRNA. We found that silencing USF1 and USF2 concomitantly decreased Alx3 expression by approximately 50%. In silico analysis of the Alx3 promoter led to the identification of the conserved sequence TTAATGA, a potential binding site for the pancreatic transcription factor Pdx1. Mutation of this site resulted in decreased promoter activity in transfected MIN6 cells, and diminished Pdx1-dependent transactivation in HeLa cells. ChIP assays using chromatin from isolated mouse islets, and EMSA using nuclear extracts from MIN6 cells confirmed binding of Pdx1 to the Alx3 promoter. In addition, silencing Pdx1 expression by siRNA resulted in decreased Alx3 expression in MIN6 cells. Interestingly, mutations of the USF transcription factor-binding E-boxes almost completely inhibited Pdx1-dependent transactivation of the Alx3 promoter. A similar effect was observed when Pdx1 was cotransfected with a dominant negative inhibitor of USF transcription factors. Finally, coexpression of USF1, USF2 and Pdx1 resulted in enhanced Alx3 promoter activity.

**Conclusion:** Expression of Alx3 in pancreatic islet cells is regulated by Pdx1, USF1 and USF2 transcription factors enhance Pdx1 transcriptional transactivation from binding sites located on at least three different E-boxes. These data indicate that Pdx1, USF1 and USF2 coordinately interact to maintain Alx3 gene expression in pancreatic islet beta cells.

## 379

**Islet insulin resistance promotes local apolipoprotein CIII production and beta cell failure**K. Ávall<sup>1</sup>, Y. Ali<sup>1</sup>, L. Selander<sup>1</sup>, S.K. Nilsson<sup>2</sup>, R.M. Crooke<sup>3</sup>, M.J. Graham<sup>3</sup>, P.-O. Berggren<sup>1</sup>, L. Junnti-Berggren<sup>1</sup>;<sup>1</sup>The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Stockholm, <sup>2</sup>Department of Medical Biosciences, Umeå University, Sweden, <sup>3</sup>ISIS Pharmaceuticals, Carlsbad, USA.

**Background and aims:** The progression of type-2 diabetes (T2D) occurs in phases. The initial phase is characterized by peripheral tissue insulin resistance with a beta-cell compensatory response of increasing mass and insulin secretion. With prolonged hyperinsulinemia the beta-cells start to fail, causing defects in insulin secretion and eventually increased beta-cell apoptosis. Expression of apolipoprotein CIII (apoCIII) is increased under conditions of insulin resistance and recently it has been shown that hyperglycemia induces apoCIII transcription. The aim of the present study was to test the hypothesis that islet insulin resistance leads to local production of apoCIII and consequent beta-cell failure in T2D.

**Materials and methods:** RNA was isolated and the expression of genes was measured by real-time quantitative PCR in islets from ob/ob and ob/lean mice at different ages. ApoCIII was lowered in vivo and in vitro by antisense treatment. Islets from ob/ob, C57Bl/6 and apoCIII<sup>-/-</sup> mice were transplanted into the anterior chamber of the eye (ACE) of ob/ob or C57Bl/6 mice. Changes in [Ca<sup>2+</sup>]<sub>i</sub> were measured in islets microdissected out from the ACE and the effect of five months high fat diet (HFD) was studied longitudinally by in vivo imaging.

**Results:** ApoCIII was produced locally in the islets and there was a three-fold increase in islets from 12-weeks old diabetic ob/ob mice compared to ob/lean mice. Lowering of apoCIII with antisense in vivo led to reduced body weight and improved glucose tolerance. Lowering apoCIII in vitro in isolated islets resulted in normalized Ca<sup>2+</sup>-handling and decreased caspase 3/7 activity, as a measure of apoptosis. ApoCIII<sup>-/-</sup> islets transplanted into ob/ob mice with high systemic apoCIII levels showed normal Ca<sup>2+</sup>-responses, compared to transplanted ob/ob islets with increased endogenous apoCIII levels. Transplantation of islets from C57Bl/6 mice into the ACE of one eye of HFD fed mice showed an increased size compared to apoCIII<sup>-/-</sup> islets transplanted into the other eye of the same mouse.

**Conclusion:** Insulin resistance in the pancreatic islet leads to local expression of apoCIII and compromised beta-cell function and survival that can be restored/prevented by reducing the lipoprotein in vivo. Hence, under conditions of islet insulin resistance locally produced apoCIII is an important diabetogenic factor and may constitute a novel target for the treatment of T2D.

## 380

**Intracellular cholesterol transporters, islet dysfunction and insulin secretion in type 2 diabetes mellitus**

J.B. Pinto;

Biological and Biomedical Sciences, Glasgow Caledonian University, UK.

**Background and aims:** Elevated intracellular cholesterol levels prevent glucose stimulated insulin secretion from pancreatic beta cells, by impairing  $iCa^{2+}$  elevation and its signaling, and hindering PiP2 hydrolysis, affecting actin dynamics and plasma membrane potential. Conversely, cholesterol depletion restores exocytosis of insulin granules in sterol-loaded cells. Mechanisms that improve the efficiency of intracellular cholesterol transport may therefore prove valuable therapeutically. Cholesterol-binding members of the steroidogenic acute regulatory protein domain (StarD) family of lipid trafficking proteins (STARTs) are known to modulate lipid homeostasis in a number of differing cell types, including macrophages, keratinocytes and hepatocytes; however, despite their potential therapeutic utility, little is known about the expression or function of StarD proteins, or their ligands, in beta-cells, or their relationship with insulin secretion. Our aims were to (i) investigate the expression of StarD cholesterol trafficking proteins, in BRIN-BD11 insulinoma cells, following manipulation of cellular cholesterol levels, and (ii) to explore the role of endosomal cholesterol transfer protein, StarD3, in cholesterol homeostasis and insulin secretion.

**Materials and methods:** Methodologies included radioisotopic labelling of cellular lipid pools, colorimetric assays for lipid mass, Q-PCR, immunoblotting and ELISA.

**Results:** Treatment with methyl beta-cyclodextrin (MCD; 1-10mmol l<sup>-1</sup>; 1h) efficiently removed cholesterol from BRIN-BD11 cells, dramatically increasing endogenous cholesterol biosynthesis, while cholesterol lipid complex (CLC 1:200) induced significant increases in cholesterol mass ( $p < 0.01$ ), without perturbing cholesterol biosynthesis. Secretion of insulin was modulated by cellular cholesterol content, exhibiting a biphasic response following MCD treatment, which was reflected in the expression of StarD3 protein, which increased at concentrations from 0.1 to 3mM MCD, but declined markedly at 10mM MCD. Sterol loading of cells also increased the expression of StarD3, compared with control cells, while StarD1 levels were too low in BRIN-BD11 cells for detection by immunoblotting. Levels of StarD4 protein showed a trend towards repression in cells treated with CLC, while StarD5 did not appear significantly altered under the conditions tested here.

**Conclusion:** The results suggest a possible relationship between StarD3 expression and insulin secretion, which are now being explored using the StarD3 ligand, lutein, and genetic manipulation of this protein, establishing the importance of targeting StarD proteins as tools to improve insulin secretion in beta cells.

## 381

**Low calorie sweeteners do not stimulate insulin secretion in human pancreatic beta cells**F. Bonnet<sup>1</sup>, R. Scharfmann<sup>2</sup>, E. Lepicard<sup>3</sup>, P. Czernichow<sup>4</sup>, G. Friedlander<sup>2</sup>;<sup>1</sup>Dept. of Endocrinology-Diabetology, University Hospital, Rennes,<sup>2</sup>Faculté Necker, INSERM U845, Paris, <sup>3</sup>Institute of European Expertise in Physiology (IEEP), Paris, <sup>4</sup>Pépinère d'Entreprises Institut du Cerveau et de la Moelle, Endocells, Paris, France.

**Background and aims:** High obesity and diabetes rates highlight the need for individuals to balance calories consumed with calories burned through daily activities and exercise. Low calorie sweeteners can be a helpful tool to reduce energy intake and body weight in the context of a reduced-calorie diet, by offering an alternative to caloric sweeteners. However, it has been suggested that sweeteners can stimulate insulin secretion, increase sugar intestinal absorption and increase appetite, leading to hyperglycemia and weight gain. Our aims were firstly, to determine whether low calorie sweeteners modify insulin secretion, and secondly, to determine whether or not they stimulate glucose absorption by intestinal cells.

**Materials and methods:** Insulin secretion was investigated using a unique in vitro model of human pancreatic beta cells (EndoC betaH1). Low calorie sweeteners effects were investigated in the presence of basal (low, 2.8 mM) or high (11 mM) concentrations of glucose. Various low calorie sweeteners concentrations were tested including concentrations observed in commercially available soft drinks (1 mM). Glucose transport assays were performed using

0.1 mM or 1 mM of deoxyDglucose, a non-metabolized radiolabelled glucose analogue GLUT2-specific, in CACO2 cells or beta pancreatic cells.

**Results:** Aspartame, acesulfame K (both at 0.1, 1 mM and 10mM) and blend of these two low calorie sweeteners (0.1/0.1mM, 1/1mM) did not induce insulin secretion in human pancreatic beta cells. This was observed not only in the presence of low but also of high concentrations of glucose, showing no potentiation of glucose effect upon human pancreatic beta cells. Moreover, both low calorie sweeteners did not increase human pancreatic beta cells proliferation or survival. A rise in insulin secretion was observed only in the presence of a very high dose of 50mM of acesulfame K and the 20mM aspartame/50mM acesulfame K blend. Glucose uptake in both pancreatic and intestinal cells was not modified by aspartame, acesulfame K or blends of these two low calorie sweeteners up to 10mM. At higher non physiological doses (10 mM or 20mM), only aspartame reduced GLUT2-mediated glucose uptake in pancreatic beta cells ( $p < 0.01$  for both doses of deoxy-D-glucose) and CACO2 cells (0.1 mM deoxy-D-glucose:  $p = 0.002$ ; 1 mM deoxy-D-glucose  $p = 0.0007$ ). Finally both low calorie sweeteners and the blend of low calorie sweeteners had no effect on GLUT2 expression.

**Conclusion:** At concentrations similar to those observed in commercially available soft drinks containing low-calorie sweeteners i.e. between 0.1 and 1 mM, aspartame and acesulfame K affect neither insulin secretion nor pancreatic beta cells survival and proliferation. In addition, both sweeteners alter neither glucose transport nor glucose transporters expression in both pancreatic and intestinal cells.

### The pocket protein family involved in beta cell replication during pregnancy

Y. Xu<sup>1</sup>, L. Gao<sup>1</sup>, H. Zhang<sup>1</sup>, M. Woo<sup>2</sup>, X. Wu<sup>1</sup>;<sup>1</sup>First Affiliated Hospital with Nanjing Medical University, China,<sup>2</sup>Institute of Medical Science, University of Toronto, Canada.

**Background and aims:** The pocket protein family consists of retinoblastoma protein (Rb), p107 and p130, which can repress E2F-mediated gene transcription, recruit chromatin remodeling enzymes, and undergo phosphorylation by cyclin-dependent kinases, comprising the central regulatory checkpoint that controls the mammalian G1/S-phase cell cycle transition. In spite of the sequence similarity within the DNA binding domain, they play distinct roles in the regulation of cell cycle progression. Islet beta cell replication is the main source for beta cell mass expansion during pregnancy. Activation of prolactin receptor signaling plays a key role in this process. Whether the pocket protein family is critical for beta cell replication during pregnancy is unclear. The present study is to investigate the change of Rb, p107 and p130 during pregnancy and its related mechanism in prolactin-mediated beta-cell replication.

**Materials and methods:** Pancreatic islets of C57BL/6 mice were isolated and purified by collagenase digestion at non-pregnant (NP), pregnant day 10.5 (P10.5), P14.5, P18.5 and after parturition day 4 (AP4), AP8. The gene and protein expression of Rb, p107, p130 and E2F1~5 were detected by real-time quantitative PCR and Western blotting methods. Rb and phosphor-Rb expression of islets were detected by immunofluorescence. INS-1 cells were transfected with siRNA mediated by liposome to knockdown Rb expression, and detected the change of cell cycle with prolactin stimulation by flow cytometry. INS-1 cells were cultured with inhibitors of AKT, Stat5, ERK, JNK and Pim respectively with prolactin stimulation to observe the change of Rb/E2F1 expression.

**Results:** During pregnancy, Rb, p107 and E2F1~3 gradually increased and returned back to NP level after parturition, with peak of Rb, phosphor-Rb and E2F1 at P14.5, p107 and E2F2 at AP4, E2F3 at P18.5 ( $p < 0.05$ ). p130, E2F4~5 reduced gradually during pregnancy, reached the bottom at p14.5~p18.5, then gradually returned back after parturition ( $P < 0.05$ ). Double staining of Rb and phosphor-Rb with insulin or glucagon respectively indicated that total Rb located in cytoplasm while phosphor-Rb located in nucleus. Rb and phosphor-Rb protein were expressed at NP, but strongly upregulated at P14.5 ( $P < 0.05$ ) and returned back to NP level after parturition. The mRNA and protein level of Rb, p107 and E2F1 in INS-1 cells increased significantly ( $P < 0.05$ ) while p130 decreased significantly ( $P < 0.05$ ) after prolactin stimulation. Rb knockdown in INS-1 cells by siRNA markedly increased prolactin-induced INS-1 cell proliferation with promoted G1/S-phase cell cycle transition ( $P < 0.01$ ). With the inhibitor of Stat5 and Pim respectively to block the signaling pathways, the protein expression of Rb and E2F1 were significantly decreased in prolactin-stimulated INS-1 cells ( $p < 0.05$ ). While inhibition of AKT, ERK and JNK signaling pathways did not influence Rb and E2F1 expression.

**Conclusion:** The expression of pocket protein family is dynamic changed during pregnancy. Rb is essential for G1/S-phase cell cycle transition in prolactin-induced INS-1 cell proliferation, which is the downstream of Stat5 and Pim pathway with prolactin receptor activation.

### Survivin mediated prolactin-induced INS-1 cell proliferation through both PI3K/AKT and STAT5 pathway

L. Gao<sup>1</sup>, Y. Xu<sup>1</sup>, X. Wang<sup>1</sup>, H. Zhang<sup>1</sup>, M. Woo<sup>2</sup>, X. Wu<sup>1</sup>;<sup>1</sup>Endocrinology, First Affiliated Hospital with Nanjing Medical University, China,<sup>2</sup>Institute of Medical Science, University of Toronto, Canada.

**Background and aims:** Maternal pancreatic beta-cell mass increases dramatically during pregnancy both in rodents and humans to meet the increased physiological demands. This process is mainly due to beta-cell proliferation induced by activation of prolactin receptor signaling. Our previous data showed that Survivin was dynamic expressed in the pancreatic beta cells

during pregnancy. Islet beta-cell specific Survivin deletion mice displayed glucose intolerance during pregnancy with the defection in beta-cell proliferation and beta-cell mass expansion. However, the relationship between Survivin and the multiple putative signaling pathways downstream of the prolactin receptor is unknown. This study was designed to explore the function of Survivin in prolactin-mediated beta-cell proliferation.

**Materials and methods:** INS-1 cells were cultured with prolactin stimulation. Cell proliferation was detected by cell cycle analysis by flow cytometry. The gene and protein expression of IRS2/PI3K/AKT, Jak2/Stat5 and Foxm1/Survivin were detected by real time quantitative PCR and Western blotting methods. INS-1 cells were transfected with siRNA mediated by liposome to knockdown Survivin expression, and detected the change of cell cycle with prolactin stimulation. INS-1 cells were cultured with inhibitors of AKT and Stat5 respectively with prolactin stimulation to observe the change of Foxm1/Survivin expression.

**Results:** Cell cycle analysis showed that the proliferation of INS-1 cells increased significantly with prolactin stimulation ( $P < 0.01$ ). The mRNA expression of IRS2/PI3K/AKT, Jak2/Stat5 and Foxm1/Survivin were markedly upregulated ( $P < 0.05$ ). The protein expression of pAKT, pStat5 and Survivin were elevated at the same time ( $P < 0.05$ ). However, Survivin knockdown in INS-1 cells by siRNA markedly blocked prolactin-induced INS-1 cell proliferation with delayed S phase in cell cycle ( $P < 0.01$ ). With the inhibitor of AKT and Stat5 respectively to block the signaling pathways, the protein expression of Foxm1 and Survivin were significantly decreased in prolactin-stimulated INS-1 cells ( $P < 0.05$ ).

**Conclusion:** Survivin is crucial for prolactin-induced INS-1 cell proliferation. Foxm1/Survivin is the common downstream of both PI3K/AKT and STAT5 pathway with prolactin receptor activation.

### The non-canonical Wnt ligand, Wnt4, is highly expressed in pancreatic beta cells and its expression is negatively correlated with cell growth

H.J. Welters, A. Henderson, A. Bowen;

Institute of Biomedical and Clinical Science, University of Exeter Medical School, UK.

**Background and aims:** We have previously published data showing that in beta-cells most Wnt ligands are either not present or expressed at very low levels. The exception to this is Wnt4 which is expressed at levels 10 fold higher than any other Wnt ligand. Wnt4 has been suggested to have a negative effect on beta-cell biology, with the levels in islets increased in rodent models of insulin resistance. The aim of this study is to investigate the regulation of Wnt4 expression in beta-cells and the impact of Wnt4 on beta-cell growth.

**Materials and methods:** mRNA and protein expression levels were measured by qRT-PCR and western blotting.

**Results:** We investigated Wnt4 mRNA expression in mouse organs and found that islets expressed Wnt4 at 10 fold higher levels than kidney, liver, muscle or brain (Wnt4 mRNA expression relative to housekeeping genes; kidney:  $0.01 \pm 0.004$ , liver:  $0.01 \pm 0.003$ , brain:  $0.02 \pm 0.002$ , muscle:  $0.02 \pm 0.009$  and islets:  $0.25 \pm 0.018$ , (mean  $\pm$  sem)), suggesting an important role for Wnt4 in islet cells. We used the rodent beta-cell line, INS-1 to investigate regulation of Wnt4 expression. In agreement with islet data, we found that INS-1 cells expressed high levels of Wnt4 mRNA and protein. To determine whether a diabetogenic environment altered Wnt4 expression, we treated INS-1 cells with high glucose (Wnt4 mRNA expression normalised to housekeeping genes and expressed relative to 5.5mM glucose; 5.5mM glucose:  $1 \pm 0.07$ , 16.7mM glucose:  $1.07 \pm 0.13$ , (mean  $\pm$  sem)  $n = 3$ ) or 0.25 and 0.5mM palmitate (Wnt4 mRNA expression normalised to housekeeping genes and expressed relative to control; control:  $1.0 \pm 0.06$ , 0.25mM palmitate:  $1.1 \pm 0.1$ , 0.5mM palmitate:  $0.94 \pm 0.06$ , (mean  $\pm$  sem)  $n = 3$ ) for 24hrs. However none of these treatments altered Wnt4 mRNA expression. We did though find that as cell confluence increased (with an associated decrease in cell proliferation) levels of Wnt4 mRNA increased (Fig 1). In contrast the levels of the proposed Wnt4 receptor, Fzd6, remained unchanged (Fig 1). In addition levels of Wnt4 mRNA decreased upon 6hr treatment with the growth stimulating protein, HGF (Wnt4 mRNA expression normalised to housekeeping genes and expressed relative to control; control:  $1 \pm 0.08$ , 10ng/ml HGF:  $0.47 \pm 0.07$ , (mean  $\pm$  sem)  $n = 3$ ,  $p < 0.01$ ), suggesting a negative correlation between Wnt4 expression and beta-cell proliferation. In agreement with this we find that treatment of INS-1 cells with Wnt4 is able to inhibit cell growth stimulated by the canonical Wnt ligand, Wnt3a (% change in cell growth over 72hrs compared to control;

10ng/ml Wnt3a: 114.8±1.03% (p<0.0001), 10ng/ml Wnt4: 97.1±1.04%, 10ng/ml Wnt3a+10ng/ml Wnt4: 97.3±0.97% (mean±sem, n=4).

**Conclusion:** Our data suggests that Wnt4 may act as a negative regulator of canonical Wnt signalling in beta-cells, leading to inhibition of beta-cell proliferation.

**Figure 1. Regulation of Wnt4 gene expression: A:** Cells were seeded at varying densities and mRNA extracted after 24hrs when at 25, 50 or 100% confluence. mRNA was converted to cDNA and used in qRT-PCR to measure Wnt4 and Fzd6 mRNA levels.

### 385

#### Pancreatic cell fate decisions after beta cell specific insulin gene knockout in adult mice: a new model of acute beta cell dedifferentiation

M. Szabat<sup>1</sup>, M.M. Page<sup>1</sup>, Y. Fan<sup>2</sup>, M. Trucco<sup>2</sup>, J.D. Johnson<sup>1</sup>;

<sup>1</sup>Cellular and Physiological Sciences, Diabetes Research Group, University of British Columbia, Vancouver, Canada, <sup>2</sup>Division of Immunogenetics, Children's Hospital of Pittsburgh, USA.

**Background and aims:** Pancreatic beta cell de-differentiation, including the loss of key regulatory gene networks, as well as the loss of insulin production and storage, has been associated with both type 1 and type 2 diabetes. Studies using mouse models of toxin-induced beta cell destruction have reported beta cell regeneration via beta cell proliferation or trans-differentiation of other cell types (such as alpha cells) leading to reversal of diabetes. Our aims were to define the potentially cell-autonomous role(s) insulin has in controlling beta cell fate, including differentiation/dedifferentiation, trans-differentiation, proliferation and apoptosis.

**Materials and methods:** We developed an inducible beta cell-specific insulin gene knockout model containing four engineered alleles, Pdx1-CreERT/-:mTmG+/-:Ins1-/-:Ins2<sup>f/f</sup>. Cre-positive and Cre-negative littermates injected with vehicle or tamoxifen, respectively, were used as controls. Animals (6-8 weeks) were monitored for fasting blood glucose and plasma insulin levels for a 5 week or 6 day period. Pancreatic sections were used for immunohistochemical analysis for beta cell specific markers and markers for proliferation and apoptosis. Isolated islets were also harvested for RNA sequencing and qPCR.

**Results:** Tamoxifen-induced insulin gene deletion in pancreatic beta cells led to overt diabetes, marked by severe fasting hyperglycemia within 14 ± 4 days in male mice (fasting blood glucose 29.6 ± 0.55 versus 8.7 ± 0.22mM at 5 weeks, p<0.05), with females having a delayed response (fasting blood glucose 17.6 ± 2.3 versus 8.13 ± 0.41mM at 5 weeks, p<0.05). Body weights remained stable throughout the study period in both sexes. The observed sex difference in diabetes incidence could be accounted for by differences in insulin sensitivity. As expected, plasma insulin levels were also significantly decreased to 38 ± 2.7% (p<0.05) of pre-tamoxifen levels in diabetic male mice. A significant reduction in insulin positive beta cell number/area was evident when comparing diabetic mice to non-diabetic animals. Prior to and after reaching hyperglycemia, immunohistochemical analysis of pancreatic sections did not reveal obvious signs of widespread trans-differentiation. Preliminary data also showed a 1.83 fold increase in beta cell proliferation in Cre-positive animals 6 days after tamoxifen treatment.

**Conclusion:** As expected, the loss of insulin gene expression in adult animals leads to diabetes. This study sheds light onto the fate of individual beta cells when they lose their ability to express insulin, and reveals the cell fate decisions of other pancreatic cell types when insulin secretory function in the majority of beta cells is lost, in a model that does not induce massive cell killing. These results increase our understanding of the role of insulin in the maintenance of beta cell differentiation and maturity in the adult state, as well as its possible contribution to beta cell death and dedifferentiation in diabetes.

#### Reconstruction of alpha-, beta-, and delta-cells into islet architecture upregulates Pdx1 expression through Akt/FoxO1 regulatory pathway

W. Jeon, K.-M. Lee, J.-H. Kim, S.-K. Choi;

DGIST, Daegu, Republic of Korea.

**Background and aims:** Islet transplantation has shown promise for treating insulin-dependent diabetes mellitus. However, the execution of this therapy relies largely on the availability of pancreatic tissue, and thus preparation of transplantable islets from cultured pancreatic cells is in high demand. To the best of our knowledge, *in vitro* reconstitution of pancreatic islet from native alpha-, beta-, and delta-cells has not been reported. We have previously generated a bioactive matrix named REP composed elastin-derived domains and integrin-binding Arg-Gly-Asp ligands. Using this matrix, we have very recently constructed islet-like architectures from the mixed culture of alpha-, beta-, and delta-cells from native islets and cell lines. This study aimed to investigate the signaling cascade and regulatory mechanism that promoted the islet cell survival and expression of islet-specific genes during islet reconstruction.

**Materials and methods:** Islets were isolated from 6-month aged rats and disintegrated into single cell population of alpha-, beta-, and delta-cells by trypsin treatment. Wells in a 24-well plate were treated with 200 µl of 1 µM REP matrix and incubated at 37 °C for 1 h. After protein precipitation, supernatant PBS solution was pipetted out carefully, and alpha-, beta-, and delta-cells were seeded and cultured for 7 days. On day 1, 3, 5, and 7, the reorganization of islet architecture and mRNA expression were monitored by immunofluorescence microscopy and qRT-PCR, respectively. The protein content and phosphorylation ratio were quantified by Western blot analysis.

**Results:** Our data showed that both the mRNA and protein abundances of E-cadherin and connexin-36 were much higher in the reconstructed islet than those in the conventional monolayer culture. The inhibition of E-cadherin or connexin-36 expression by siRNA severely limited islet reconstitution, suggesting the involvement of these cell adhesion molecules. Reconstructed islet exhibited higher basal insulin secretory activity, and under glucose-stimulated condition (25 mM glucose) reconstituted islet showed greater glucose-stimulated insulin secretion than the cells in the monolayer culture. Importantly, the mRNA levels of islet-specific genes such as neuroD (Beta2), slc2a2 (Glut2), ins1, ins2, and pdx1 were significantly increased during islet reorganization. In addition, expression of proliferating cell nuclear antigen (PCNA) was greatly upregulated. Furthermore, Akt phosphorylation was also significantly elevated during islet reconstruction. FoxO transcription factors play a crucial role in the regulation of differentiation, proliferation, and survival of pancreatic islet cells. To analyze Akt/FoxO1 regulatory pathway, we inhibited Akt activity during islet reconstitution. The inhibition of Akt by siRNA or MK2206 decreased both the FoxO1 phosphorylation and PCNA and Pdx1 mRNA expression. The inhibition of FoxO1 by AS1842856 caused upregulation of PCAN and Pdx1 mRNA expression and subsequent increase in their protein content. The activation of Akt accompanied by the FoxO1 phosphorylation and cytoplasmic retention of FoxO1, resulting in inactivation of transcriptional repression of Pdx1 gene expression.

**Conclusion:** We conclude that during islet reconstruction, Akt promotes islet cell survival and islet-specific gene expression through FoxO1 regulation.

**Beta cell mass expansion is impaired in aged rats exposed to 90% pancreatectomy and gastrin treatment**N. Tellez<sup>1</sup>, Y. Marti<sup>1</sup>, M. Vilaseca<sup>1</sup>, A. Pla<sup>1</sup>, E. Montanya<sup>1,2</sup>;<sup>1</sup>Diabetes, Nutrition and Endocrine diseases, CIBERDEM-IDIBELL-University of Barcelona, <sup>2</sup>Hospital Universitari de Bellvitge, Barcelona, Spain.

**Background and aims:** Aging is a non-modifiable risk factor for the development of diabetes. The contribution of impaired beta cell regeneration to this increased risk remains unknown. In young rats, 90%-pancreatectomy (Px) results in  $\beta$ -cell mass regeneration which is further enhanced with gastrin treatment. The aim of our study was to investigate the  $\beta$ -cell regeneration potential of aged rats using the 90%-Px model and gastrin treatment.

**Materials and methods:** 1 and 12 month-old Wistar rats underwent 90%-Px and were treated from the day of surgery with [15Leu] gastrin-17 (150 $\mu$ g/kg • 12h, Px+G, n=21) or with vehicle (Px+V; n=21). A group of sham-operated rats treated with vehicle was included for each age group (S+V; n=18). Pancreatic remnants were harvested on days 3 and 14 after surgery for morphometric, immunohistochemical and gene expression analysis.

**Results:** Young Px rats showed increased  $\beta$ -cell mass that was further increased with gastrin treatment. Gene expression and nuclear immunolocalization of nkx6.1 in ductal cells, and the percentage of extra-islet  $\beta$ -cells (indirect markers of  $\beta$ -cell neogenesis) were also increased in gastrin-treated young Px rats.  $\beta$ -cell apoptosis was similar among groups, and  $\beta$ -cell replication and size were similarly increased in gastrin and vehicle-treated young Px rats. In aged rats,  $\beta$ -cell mass was not increased in any of the Px groups, despite the increased  $\beta$ -cell replication and individual  $\beta$ -cell size. Gene expression and nuclear immunolocalization of nkx6.1 in ductal cells, and the percentage of extra-islet  $\beta$ -cells were not increased in aged gastrin- or vehicle-treated Px rats. The dedifferentiation-related transcription factors Neurog3 and Sox9 were significantly upregulated in islet  $\beta$ -cells from aged Px rats.

**Conclusion:** The potential for compensatory  $\beta$ -cell hyperplasia and hyper trophy is retained in aged rats. In contrast, impaired  $\beta$ -cell neogenesis along with beta cell dedifferentiation may contribute to the limited beta cell regeneration in aged rats.

**Cell surface marker expression and colony formation in islet-depleted pancreatic digests**P. Augstein<sup>1,2</sup>, E. Bandala-Sanchez<sup>2</sup>, G. Naselli<sup>2</sup>, T. Loudovaris<sup>3</sup>, L. Lee<sup>2</sup>, A. Neale<sup>2</sup>, P. Campbell<sup>3</sup>, W.J. Hawthorne<sup>4</sup>, P. Heinke<sup>1</sup>, I. Banakh<sup>2</sup>, L.C. Harrison<sup>2</sup>;<sup>1</sup>Institute of Diabetes, Karlsburg, Germany, <sup>2</sup>The Walter and Eliza Hall Institute for Medical Research, Parkville, <sup>3</sup>St. Vincent's Institute of Medical Research, Fitzroy, <sup>4</sup>Westmead Hospital, University of Sydney, Australia.

**Background and aims:** Stem cells (SCs) are characterized by self-renewal capacity and pluripotency. Hematopoietic SCs (HSC) are identified by a combination of markers and functional assays. In the adult human pancreas, the existence of SCs is debated. To identify putative stem cells, we screened islet-depleted pancreas digests, a by-product of the islet isolation procedure, for expression of surface markers and epithelial colony-forming potential (CFP).

**Materials and methods:** Islet-depleted pancreas digests from 18 cadaveric organ donors were stained with antibodies to hematopoietic, mesenchymal (MSC) and epithelial stem cell (EpSC) markers. Cells in the 'side population' (SP) were identified by Hoechst 33342 dye efflux in a BD-LSR-II-W flow cytometer. EpCam, CD133, Hpd1 and Hoechst 33342 alone or in combination were used to separate populations in a FACSAria-C sorter. CFP was evaluated in a 2D assay. Data are presented as mean  $\pm$  SEM.

**Results:** Very few cells expressed HSC markers (CD45 2.7  $\pm$  0.8 %, CD117 1.2  $\pm$  0.6 %, CD31 10.8  $\pm$  0.8 %, CD56 2.8  $\pm$  1.0 %). The MSC marker CD29 was detected on a majority of cells (97.1  $\pm$  1.0 %), whereas the other MSC markers CD44 (46.4  $\pm$  7.8 %), CD34 (34.1  $\pm$  10.8 %), CD90 (17.2  $\pm$  4.5 %), CD105 (36.1  $\pm$  11.1) and CD73 (27.6  $\pm$  5.3 %) were expressed on fewer cells. Certain EpSC markers, EpCam (75.3  $\pm$  3.9 %) and CD49f (60.9  $\pm$  7.1 %), were expressed by a majority of cells whereas others, CD133 (44.6  $\pm$  7.5 %) and CD26 (20.5  $\pm$  3.6 %), were expressed by fewer cells. The CFP of pancreas digest cells was however significantly enriched by selection for CD133<sup>high</sup>SP cells, such that CD133<sup>high</sup>SP > SP > CD133<sup>high</sup> > CD133<sup>low</sup>. The majority of CD133<sup>high</sup> (61.4  $\pm$  6.3 %) and SP (58.32  $\pm$  6.97 %) cells expressed the ductal marker

CA19-9. In the human pancreas, ductal cells express CD133 and comprise a 2-fold increased proportion (3.1 vs. 7.5 %) of the SP.

**Conclusion:** We identified two markers for the isolation of colony-forming cells. Our findings suggest that ductal cells that efflux Hoechst 33342 and express CD133<sup>high</sup> are a reservoir of stem cells in the adult human pancreas.

**Highly-efficient MSCs fusion with beta cells results in beta cell-like phenotype**Z. Azizi<sup>1,2</sup>, F. Paroni<sup>1</sup>, C. Lange<sup>2</sup>, A.R. Zander<sup>2</sup>, C. Westenfelder<sup>3</sup>, K. Maedler<sup>1</sup>;<sup>1</sup>Center for Biomolecular interactions, University of Bremen, <sup>2</sup>Center of Bone Marrow Transplantation, Universitätsklinikum Hamburg-Eppendorf, Germany, <sup>3</sup>Departments of Medicine and Physiology, University of Utah and George E. Wahlen Veterans Affairs Medical Centers, Salt Lake City, USA.

**Background and aims:** Mesenchymal stromal cells (MSC) have anti-inflammatory, anti-apoptotic and immunosuppressive effects and they are a potent source for cell therapy. Cell fusion enables rapid generation of functional new reprogrammed cells. In this study, we aimed to establish a fusion protocol of bone marrow derived human MSCs with the rat  $\beta$ -cell line (INS1-E) as well as isolated human pancreatic islets in order to generate functional insulin producing  $\beta$ -MSCs as a cell-based treatment for diabetes.

**Materials and methods:** Human MSCs were isolated from bone marrow and characterized by colony forming units in culture and flow cytometry for expression of CD73, CD105 and CD90 as well as lack of CD45, CD34 and MHCII. Multipotency was tested by differentiation into the adipogenic and osteogenic lineages. To induce cell fusion, eGFP transfected MSCs with puromycin as selection marker were cultured with either mCherry-INS1E or human dispersed isolated islets and treated with phytohemagglutinin and Polyethylene glycol (PEG).

**Results:** Of the whole cell population, 44  $\pm$  10% polykaryons were identified based on polyploidy flow cytometry at 2 days after fusion. 29  $\pm$  6% of all MSCs were identified as  $\beta$ -MSC heterokaryons based on double positivity for mCherry and eGFP. Six days after fusion and four days after puromycin selection, the  $\beta$ -cell transcription factors Nkx6.1, MafA and PDX1 and important genes for regulating  $\beta$ -cell function insulin, GLUT2 and GCK and insulin content were increased in the  $\beta$ -MSCs from fused human dispersed islets/MSCs as well as INS-1E/MSCs compared to non-fused controls after puromycin selection. Insulin positive  $\beta$ -MSCs also expressed nuclear PDX1.

**Conclusion:** Our results show an efficient established protocol for fusion of human MSCs and  $\beta$ -cells, which resulted in a  $\beta$ -cell like phenotype; this could be a novel tool for cell-based therapies of diabetes.

## 390

**A novel and reliable protocol for human embryonic stem cell differentiation into the definitive endoderm based on dispersed single cells**

U. Diekmann, S. Lenzen, O. Naujok;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** The differentiation of embryonic stem (ES) cells into organs derived from the endoderm germ layer, such as liver or pancreas require as initial step the formation of the definitive endoderm (DE). Human ES cell differentiation is usually initiated from colonies, which is the routinely used cell culture procedure. However, differences in colony size, colony number and the potentially altered sensitivity of these cells to media supplements render colonies into a suboptimal starting material. The aim of this study was the development of a reliable and highly efficient protocol for the differentiation of human ES cells into the DE lineage from dispersed single cells and their further differentiation into the pancreatic lineage.

**Materials and methods:** Three different human ES cell lines were passaged as dispersed single cells and defined cell numbers were subjected to differentiation. Different protocols for the DE induction were tested by combining various concentrations of Wnt3a, CHIR-99021 and Activin A for four days. The expression of the marker genes T, GSC, MIXL1, SOX17 and FOXA2 was analyzed by qPCR, flow cytometry, and immunofluorescent staining (IF). Furthermore, differentiation of these DE cells into the pancreatic lineage with FGF10, retinoic acid, dorsomorphine plus SB-431542 was performed. PDX1- and NGN3-positive cells were quantified by IF.

**Results:** Differentiation with CHIR-99021 and Activin A for the first 24 h and a subsequent treatment with Activin A alone resulted in the highest numbers of DE committed cells from all three tested cell lines. The expression of the marker genes SOX17 and FOXA2 were significantly increased under these conditions compared to random differentiated cells and to a classical DE differentiation protocol used as positive control. The quantification by IF and flow cytometry of DE committed cells revealed efficiencies ranging from ~70% (Hues4 and HES3) up to >80% (Hues8), a more than 2-fold increase compared to the reference protocol (~33-40%). The ES cells proliferated under this condition resulting in a more than 5-fold increased cell number after four days of differentiation. In addition, the dispersed single cells differentiated into DE were able to further differentiate into PDX1-positive progenitors (~40% after 10 days) and subsequently into NGN3-positive endocrine precursor cells (~10% after 14 days). High expression levels for the marker genes FOXA2, HNF6, MNX1 (HB9), NKX2.2, NKX6.1 and NGN3 in a manner similar to the in vivo pancreatic development were detected proofing the maturation of the pancreatic precursor cells.

**Conclusion:** This novel protocol was able to differentiate three human ES cell lines in a highly efficient manner into the DE. Therefore only low initial cell numbers and reduced concentrations of expensive growth factors were required without growth limitations. In addition, these cells were able to differentiate further into the pancreatic lineage and endocrine progenitor cells. *Supported by: REBIRTH Cluster of Excellence (DFG)*

#### Isolation and characterisation of embryo stem cell-like cells in adult human pancreas

S. Lee<sup>1,2</sup>, S. Jeong<sup>2</sup>, H. Park<sup>2</sup>, S.-C. Kim<sup>1</sup>;

<sup>1</sup>Surgery, <sup>2</sup>Asan Institute for Life Science, Asan Medical Center, Seoul, Republic of Korea.

**Background and aims:** Within recent years, stem/progenitor cells research has become a very important part of regeneration or differentiation into insulin-producing cells. However, the stem/progenitor cells are extremely rare attendance and expressing location and moment of these stem cells are not clearly demonstrated in adult human pancreatic tissue. Therefore we have identified undifferentiated embryo stem cell-like cells expression in adult human pancreas and isolated for characterization.

**Materials and methods:** Enriched human exocrine cells are obtained after COBE purification of islet isolation. For islet-depleted pancreatic exocrine cells culture, endocrine cells were sorted out with microbead conjugated PSA-NCAM antibody using magnetic-activated cell sorting (MACS) and purified CA19-9 positive pancreatic ductal cells or non-purified cells were cultured for 6 days. We observed morphology changes and RNA expression pattern of embryo stem cell markers. To identification of stem cells present location, we SSEA-4 positive cell selected from enriched exocrine cell fraction.

**Results:** Non-purified crud duct cells attached easily and epithelial-like cells extended grow up quickly from primary attached cells but purified ductal cells were showed insufficient growth. Expression of classic stem cell markers: Oct4, c-Myc, Klf4, Nanog, Sox2 and SSEA-4 mRNAs was found in crude duct and purified duct cell fraction. However, these stem cell markers was not detected or weakly expressed in PSA-NCAM negative and CA19-9 negative cell fraction. Classic stem cell mRNA markers were only expressed in SSEA-4 positive cells and SSEA-4 positive cells were detected in pancreatic duct cell by immunocytochemistry.

**Conclusion:** We characterized and isolated of SSEA-4 positive embryo stem cell-like cells in adult human pancreatic duct and hypothesize that these cells differentiate to insulin-producing cells in adult human pancreas.

#### Expression of insulin genes in foetal liver

S. Takasawa<sup>1</sup>, S. Murakami-Kawaguchi<sup>2</sup>, K. Nata<sup>3</sup>, A. Itaya-Hironaka<sup>1</sup>, S. Sakuramoto-Tsuchida<sup>1</sup>, A. Yamauchi<sup>1</sup>, H. Ota<sup>1</sup>, M. Takeda<sup>1</sup>, C. Tsuchida<sup>1</sup>, H. Tsujinaka<sup>1</sup>, T. Fujimura<sup>1</sup>, H. Okamoto<sup>4</sup>;

<sup>1</sup>Biochemistry, Nara Medical University, Kashihara, <sup>2</sup>Internal Medicine, Murakami Shinmachi Hospital, Aomori, <sup>3</sup>Medical Biochemistry, Iwate Medical University School of Pharmacy, Yahaba, <sup>4</sup>Tohoku University, Sendai, Japan.

**Background and aims:** Pancreatic beta cells are the major source of insulin in adult mammals. The cells have a limited capacity for regeneration and the destruction causes type 1 diabetes. Recently, a possible permanent cure for diabetes has been explored by using several different approaches, one of them being the transdifferentiation of nonpancreatic cells to insulin-producing cells. Hepatocytes seem to be an ideal target for the production of insulin, because both the liver and ventral pancreas appear to arise from the same cell population located within the embryonic endoderm during embryogenesis. Despite the similarity in development of these two cell types, the expression of the insulin gene in fetal liver has remained elusive because of its pancreatic beta cell-specific expression in adult animals. In the present study, we demonstrate insulin mRNA and immunoreactive cells for insulin in fetal liver and the promoter activity for insulin in fetal hepatocytes.

**Materials and methods:** Timed pregnant ICR mice were obtained from Japan SLC. On embryonic days 13.5 (E13.5), E16.5 and E18.5, livers were dissected. The livers of newborn mice were dissected at Day0. Livers from adults were dissected from 14-week-old female mice. Gene expression was analyzed by RT-PCR. Immunohistochemical analysis was carried out using antibodies against insulin, proinsulin, processed insulin, glucagon, somatostatin, and pancreatic polypeptide. Promoter activity of mouse Ins1 (-703~+14) and Ins2 (-830~+14) was measured using primary cultured fetal hepatocytes by luciferase assay. Electrophoretic mobility shift assay was carried out using whole-cell extracts of fetal liver. Human fetal (22-40 weeks) and adult liver RNAs, purchased from Clontech, were also analyzed by RT-PCR.

**Results:** The expression of insulin and transcription factors for insulin is investigated in mouse fetal liver. We detected mRNAs for Ins1 and Ins2 and proinsulin- and mature insulin-positive cells in mouse fetal liver by RT-PCR and immunohistochemistry. Glucagon, somatostatin and pancreatic polypeptide were not expressed throughout development. Mouse Ins2 and Ins1 promoters were transiently activated in mouse fetal hepatocytes of E13.5 and E16.5, respectively. Pancreatic and duodenal homeobox 1 (Pdx1) mRNA was not expressed during development of the liver. In contrast, mRNAs and proteins of neurogenic differentiation (NeuroD)/beta cell E-box transactivator 2 (Beta2) and v-maf musculoaponeurotic fibrosarcoma oncogene homolog (MafA) were almost simultaneously expressed with insulin genes in the liver. Ins2 and Ins1 promoters were activated in hepatoma cells by the transfection of the expression vector for NeuroD/Beta2 alone and by the combination of NeuroD/Beta2 and MafA, respectively. In addition, we also analyzed human fetal and adult liver RNAs and found that mRNAs for insulin, NeuroD/Beta2, and MafA were expressed in human fetal liver.

**Conclusion:** These results indicate that the expression of NeuroD/Beta2 and MafA is linked temporally with the transcription of insulin gene in fetal liver and suggest the potential usage of fetal hepatocytes to make insulin-producing cells by introducing/inducing transcription factors.

## PS 015 Metabolic coupling in insulin secretion

### 393

#### MICU2: a modulator of stimulus-secretion-coupling in INS-1 832 cells

A. Bagge<sup>1</sup>, L. Andersson<sup>1</sup>, P. Spégel<sup>1</sup>, B. Valtat<sup>1</sup>, V.K. Mootha<sup>2</sup>, H. Mulder<sup>1</sup>; <sup>1</sup>Unit of Molecular Metabolism, Lund University Diabetes Center, Malmö, Sweden, <sup>2</sup>Broad Institute, Cambridge, USA.

**Background and aims:** In  $\beta$ -cells, glucose-stimulated insulin secretion (GSIS) is tightly coupled to the metabolism of glucose, which ultimately triggers a rise in cytosolic calcium ( $\text{Ca}^{2+}$ ) levels activating the exocytotic machinery.  $\text{Ca}^{2+}$  is also involved in activation of the more sustained second-phase of insulin secretion. However, the mechanism is less clear. The regulated mitochondrial  $\text{Ca}^{2+}$ -influx during metabolic activation is critical for GSIS but the function of  $\text{Ca}_m^{2+}$  is still not fully understood. Mcu and Micu1 are subunits of the Mitochondrial Calcium Uniporter complex (MCU-complex) and have been shown to be important for ATP synthesis and GSIS. Micu2 was recently identified in mouse liver as a part of the MCU-complex functioning as a gate-keeper for  $\text{Ca}_m^{2+}$ -uptake, similar to Micu1. Our preliminary data show that an expression quantitative trait locus (eQTL) associated with the *MICU2* gene is correlated with  $\beta$ -cell function (HOMA- $\beta$ ) and fasting glucose in humans. The aim of this study was to investigate the role of Micu2 in GSIS and mitochondrial function in the clonal beta-cell line INS-1 832/13.

**Materials and methods:** *Micu2* was silenced for 72 h by siRNA in INS-1 832/13 cells, and insulin secretion was determined by radioimmunoassay, ATP content by luciferase-dependent luminescence, and lactate release as well as NADH/NAD<sup>+</sup>-ratio by colorimetric assays. Glucose utilization was measured as <sup>3</sup>H<sub>2</sub>O after stimulation with 5-<sup>3</sup>H-labeled glucose, Seahorse XF24 was used to measure respiration and metabolite profiling was done by GC/MS.

**Results:** KD of *Micu2* in INS-1 832/13 cells resulted in a 33% (N=3, p<0.001), 37% (N=3, p<0.01) and 33% (N=3, p<0.05) reduction in insulin secretion compared to control cells at 2.8 mM and 16.7 mM glucose and 10 mM glyceraldehyde, respectively. No alteration in insulin secretion was observed when cells were stimulated by pyruvate or leucine/glutamine. Respiration rate was similarly decreased in *Micu2* KD cells at 2.8 mM and 16.7 mM glucose compared to control cells, while pyruvate-stimulated respiration was unaltered. Interestingly, KD of *Micu2* abolished glucose-stimulated spare respiratory capacity by decreasing the maximal respiration rate by 44% (N=3, p<0.01); this was not observed during pyruvate-fueled respiration. KD of *Micu2* affected neither total cellular ATP content nor lactate secretion while glucose utilization was decreased. A 3.5-fold increase in the glucose-induced rise in NADH/NAD<sup>+</sup>-ratio was observed in *Micu2* KD cells compared to control cells. Metabolite profiling showed a 4-fold (N=3, p<0.05) decrease in glutamate/aspartate ratio upon *Micu2* KD.

**Conclusion:** MICU2, a subunit of the MCU complex, modulated NADH/NAD<sup>+</sup>-shuttle activity rather than dehydrogenase activities in the TCA-cycle since insulin secretion and respiration were decreased only when shuttle-dependent fuels were used. This is corroborated by decreased glucose utilization, unaltered total ATP content and lactate release as well as increased NADH/NAD<sup>+</sup>-ratio upon *Micu2* KD. The decreased glutamate/aspartate-ratio observed points to a perturbation in the malate-aspartate shuttle. Whether *Micu2* acts exclusively in  $\text{Ca}^{2+}$  activation of the malate-aspartate shuttle or physically interacts with parts of the malate-aspartate shuttle altering its activity directly remains to be resolved.

### 394

#### Trans-mitochondrial <sup>13</sup>C-flux analysis supports an important role for non-oxidative metabolism in insulin secretion from human islets

R.G. Kibbey, T.C. Alves, R.L. Pongratz, O. Yarborough, G.W. Cline, G. Mason; Internal Medicine/Endocrinology, Yale University School of Medicine, New Haven, USA.

**Background and aims:** Non-oxidative mitochondrial metabolism has previously been implicated glucose-stimulated insulin secretion (GSIS). In particular, pyruvate carboxylase (PC) and mitochondrial PEPCK (PEPCK-M) have been strongly associated with GSIS. Recent reports suggested that in

contrast to rodent islets, human islets have relatively little PC flux. The positional flux of [<sup>13</sup>C<sub>6</sub>]glucose carbons through each reaction provides important information regarding its relevance to the GSIS without perturbing normal metabolism. Current NMR-based methods are limited by sensitivity and cannot resolve the different anaplerotic fluxes.

**Materials and methods:** A novel quantitative LC/MS-based technique was developed to track <sup>13</sup>C-labeled substrates and directly measure positional step-wise metabolic fluxes in INS-1 cells and human islets. Metabolic flux analysis was performed under metabolic steady-state but isotopic non-steady-state conditions. Absolute flux was calculated with the program CWAVE using differential equations to model mass and isotope balance.

**Results:** Metabolism included oxidative (glycolysis, pyruvate dehydrogenase (PDH) and TCA cycle) and non-oxidative (PC, malic enzyme (ME) and PEPCK-M) reactions. There was significant isotope dilution between sequential steps in glycolysis and TCA consistent with very active metabolic cycling. Similar to oxygen consumption, TCA cycle flux increased incrementally with glucose (1.27±0.02, 2.31±0.06, and 5.02±0.1 fold, P<0.001, going from 2.5 to 5 to 7 to 9 mM glucose) while the contribution of PDH to the TCA cycle (~90%) remained flat. PC flux was nearly evenly divided between ME and PEPCK-M flux, though remarkably, glucose carbons flowed exclusively through PEPCK-M and not ME. PC flux increased with glucose starting at 2% to more than 50% the rate of the TCA cycle (fold increases of 3.73±0.36, 9.89±0.52, and 28.91±2.2 above background, P<0.001) and closely correlated with insulin secretion. PEPCK-M flux increased linearly with insulin secretion. Similar rates of PC relative to PDH fluxes were observed in islets from human donors.

**Conclusion:** This technique has broad applicability to the study of intracellular metabolism in normal and diabetic human islets as well as other tissues. Quantification of discrete trans-mitochondrial fluxes beta-cells supports a very significant contribution of non-oxidative metabolism to the mechanism of insulin secretion.

### 395

#### Mechanisms underlying translocation of the cAMP effector protein Epac2 to the beta cell plasma membrane

I. Alenkvist, A. Tengholm; Department of Medical Cell Biology, Uppsala, Sweden.

**Background and aims:** The second messenger cAMP promotes insulin secretion by amplifying  $\text{Ca}^{2+}$ -dependent exocytosis in pancreatic  $\beta$ -cells. Protein kinase A and Epac2, a guanine nucleotide exchange factor for the Rap family of small GTPases, mediate the effects of cAMP. Epac2 translocates to the  $\beta$ -cell plasma membrane in response to glucose and cAMP-elevating agents, but it is not known how the membrane interaction is mediated. Previous studies have shown involvement of the Ras-association domain close to the catalytic domain of the protein. The aim of the present study was to elucidate how different domains in the regulatory region contribute to membrane localization of Epac2 in  $\beta$ -cells.

**Materials and methods:** MIN6  $\beta$ -cells were co-transfected with wildtype and mutant versions of Epac2 tagged with the fluorescent proteins GFP and mCherry. Time-lapse total internal reflection fluorescence microscopy was used to monitor association of the reporter proteins with the plasma membrane in single intact or  $\alpha$ -toxin-permeabilized cells.

**Results:** Addition of cAMP to permeabilized  $\beta$ -cells evoked concentration-dependent translocation of Epac2 to the plasma membrane with half-maximal and maximal translocation at 30  $\mu\text{M}$  and >100  $\mu\text{M}$ , respectively. Whereas point mutation of the low-affinity cAMP-binding site (G114E) did not affect cAMP-induced Epac2 translocation, removal of the entire low-affinity cAMP-binding domain (CNB1) reduced the maximal translocation amplitude to 45% of control but increased the cAMP sensitivity (half-maximal translocation at 5.6  $\mu\text{M}$ ). After removal of the DEP domain, a protein module often involved in membrane anchoring, the cAMP-induced translocation was reduced by more than 90%. Epac2 translocation was also investigated in intact cells stimulated with 100  $\mu\text{M}$  of the phosphodiesterase inhibitor IBMX or by increase of the glucose concentration from 3 to 11 mM. Both stimuli triggered pronounced translocation of wildtype Epac2 to the plasma membrane. The IBMX-induced translocation after DEP removal was lower (58%) while that of the CNB1 deletion mutant was significantly higher (145%) than control. In contrast, the glucose-induced Epac2 translocation was unaffected by either of the CNB1 or DEP deletions.

**Conclusion:** cAMP-induced translocation of Epac2 to the plasma membrane involves multiple domains of the protein, including the DEP- and the

low-affinity cAMP-binding domains. The latter domain is not required for translocation, but it extends the range of effective cAMP concentrations and increases the magnitude of the translocation response. Glucose-stimulated Epac2 translocation in  $\beta$ -cells involves additional signals than cAMP elevation alone.

### 396

#### Does increased mitochondrial pool improves beta cell function? Trying to create super beta cells with PGC-1 $\alpha$ mediated mitochondrial biogenesis

A. Besseiche<sup>1</sup>, G. Guillemain<sup>1</sup>, E. Ramond<sup>1</sup>, J.-P. Riveline<sup>2</sup>, P. Ferré<sup>1</sup>, J.-F. Gautier<sup>2</sup>, B. Bréant<sup>3</sup>, B. Blondeau<sup>4</sup>;  
<sup>1</sup>Inserm-CRC, <sup>2</sup>Hopital Lariboisière, <sup>3</sup>Inserm, <sup>4</sup>UPMC-CRC, Paris, France.

**Background and aims:** Understanding diabetes and try to cure it requires defining the regulators of pancreatic beta-cell function. Because beta cells rely on their cellular metabolism, mitochondrial activity and energy production to secrete insulin properly, we tested the idea that augmenting mitochondria in beta cells might improve their insulin secretion capacity, thus generating super beta cells that would be adapted to situations of increased insulin demand. To this aim, we overexpressed in beta cells the transcriptional coregulator PGC-1 $\alpha$ , a potent inducer of mitochondrial biogenesis, and studied both in vivo and in vitro the consequences on insulin secretion.

**Materials and methods:** To carry the study, we used two models of PGC-1 $\alpha$  overexpression in beta cells: first Min6 cells overexpressing PGC-1 $\alpha$  with an adenovirus and second, transgenic mice with a specific PGC-1 $\alpha$  overexpression in mice using the Tetracycline inducible system. We measured insulin secretion in response to glucose, glucose tolerance in mice, mitochondrial function (cellular respiration, ATP turnover and reactive oxygen species - ROS - production) and assessed the beta-cell energy status by measuring the phosphorylation of the AMP-Kinase.

**Results:** In Min6 cells, PGC-1 $\alpha$  overexpression increases mitochondrial biogenesis and  $\beta$ -cell respiration but paradoxically, does not increase ATP turnover. PGC-1 $\alpha$  overexpression increases ROS production and leads to the activation of AMPK, suggesting both an oxidative and energetic stress in these cells. Instead of being improved, insulin secretion in response to glucose was blunted when PGC-1 $\alpha$  is overexpressed. Interestingly, rescuing insulin secretion was achieved using a powerful antioxidant (Tempol) to prevent ROS production or using compound C-induced, an inhibitor of AMP-kinase activation. Similar results were obtained on isolated islets from PGC-1 $\alpha$  overexpressing mice: increased ROS production, activated AMPK and blunted insulin secretion.

**Conclusion:** In beta cells, increasing mitochondria with the use of PGC-1 $\alpha$  overexpression induces both an oxidative stress and an energetic stress. Therefore, strategies to increase insulin function through increased mitochondrial function may not be efficient. Specific mechanisms underlying these defects still need to be identified. In contrast with other metabolic tissues, increased mitochondrial pool using PGC-1 $\alpha$  is not beneficial for insulin production by beta cells.

### 397

#### Mitochondrial coupling efficiency is swiftly increased by hyperoxia reciprocally to effects by hypoxia

I. Hals<sup>1</sup>, S. Bruerberg<sup>1</sup>, V. Grill<sup>1,2</sup>;  
<sup>1</sup>Inst of Cancer Research and Molecular Medicine, NTNU, Faculty of Medicine, <sup>2</sup>Department of Endocrinology, St Olav's Hospital, Trondheim University Hospital, Trondheim, Norway.

**Background and aims:** Previous exposure to hyperoxia was recently shown to negatively affect beta cell function and viability. These findings are important in the context of possible damage to beta cells during hyperoxic treatment in humans, such as in preterm babies, and therefore prompt further studies. The early time course of effects of hyperoxia has not been clarified and may provide information on mechanisms. Accordingly, here we tested for acute effects of hyperoxia on mitochondrial function

**Materials and methods:** INS-1 derived 832/13 cells were cultured in RPMI medium, usually together with 11 mM glucose. For some experiments INS-1 cells overexpressing uncoupling protein 2 (UCP-2) were used. Oxygen consumption was measured in intact cells by high-resolution respirometry (OROBOROS) before and after sequential administration of oligomycin

(which blocks the production of ATP by ATP synthase), FCCP (which induces respiration that maximises oxidative capacity), rotenone and lastly antimycin. Elevated oxygen concentration (400  $\mu$ M) was achieved in one chamber, the other containing normal levels of oxygen (200  $\mu$ M).

**Results:** The presence of hyperoxia decreased the inhibitory effect by oligomycin when the inhibitor was added 15-20 min after the introduction of hyperoxia. The ratio of oligomycin uninhibited respiration in relation to FCCP-induced respiration was increased by 59.4% (from  $0.32 \pm 0.02$  (n = 6) at normoxia to  $0.51 \pm 0.02$  (n = 20) at hyperoxia, p < 0.0003). Similar effects of hyperoxia were seen in INS-1 cells overexpressing UCP-2. The glucose concentration (5.5 or 11 mM) during respirometry did not modify the uncoupling effect of hyperoxia. Opposite effects (decreased ratio oligomycin/FCCP respiration) was seen in cells pre-exposed for 8 h to hypoxia (0.3% oxygen) ( $0.29 \pm 0.01$  vs.  $0.26 \pm 0.02$ , n = 5, p < 0.05).

**Conclusion:** 1) Beta cell mitochondria swiftly adapt to hyperoxia by increasing un-coupling 2) This effect is not mediated by UCP2, 3) The effect is reciprocal to that exerted by previous hypoxia. Altogether our findings demonstrate swift and relevant adaptability of beta cell mitochondria to differences in the oxygen environment, a feature that should, in the short term at least, promote their survival.

### 398

#### Inhibition of the malate-aspartate shuttle abolishes glucagon secretion without affecting insulin secretion from mouse pancreatic islets

L.E. Andersson<sup>1</sup>, J. Stamenkovic<sup>1</sup>, A. Bagge<sup>1</sup>, V.V. Sharoyko<sup>1</sup>, C.B. Wollheim<sup>2,3</sup>, H. Mulder<sup>1</sup>, P. Spégel<sup>1</sup>;  
<sup>1</sup>Lund University Diabetes Center, Unit of Molecular Metabolism Department of Clinical Sciences Lund University, <sup>2</sup>Department of Clinical Sciences, Lund University Diabetes Center, Lund University, Malmö, Sweden, <sup>3</sup>Department of Cell Physiology and Metabolism, University Medical Centre, Geneva, Switzerland.

**Background and aims:** Altered secretion of both insulin and glucagon has been implicated in the pathogenesis of Type 2 diabetes (T2D). The main focus of research has been on understanding the impaired insulin secretion from the pancreatic  $\beta$ -cells, leaving the mechanisms controlling glucagon secretion from the pancreatic  $\alpha$ -cells largely unresolved.

**Materials and methods:** The  $\alpha$ -cell line,  $\alpha$ TC1-6, and  $\beta$ -cell line, INS-1 832/13 were stimulated with glucose, in presence or absence of phenylsuccinate, and pyruvate after which hormone secretion, metabolite levels, glucose utilization, respiration and lactate release were assayed. Key experiments were replicated in isolated mouse islets.

**Results:** INS-1 832/13 and  $\alpha$ TC1-6 cells respectively secreted insulin and glucagon dose dependently in response to glucose. Glycolytic metabolism was similar in the two cell lines; tricarboxylic acid (TCA)-cycle metabolism, respiration and ATP-production were less glucose-responsive in  $\alpha$ TC1-6 cells. Hence, a tight coupling of glycolytic and mitochondrial metabolism was observed only in INS-1 832/13 cells. Inhibition of the malate-aspartate shuttle, using phenyl succinate, impacted glucose-provoked ATP production and glucagon secretion from  $\alpha$ TC1-6, but not INS-1 832/13 cells. Blocking the malate-aspartate shuttle increased levels of glycerol-3-phosphate only in the INS-1 832/13 cells. Accordingly, expression of components of the glycerolphosphate shuttle relative to expression of the malate-aspartate shuttle was found to be lower in  $\alpha$ TC1-6 cells. These results were confirmed in primary mouse islets, where phenyl succinate abrogated secretion of glucagon but not insulin.

**Conclusion:** Our data suggest that the glycerolphosphate shuttle augments the malate-aspartate shuttle in the  $\beta$ -cell but not so in the  $\alpha$ -cell. A suppressed activity of the glycerolphosphate shuttle in the  $\alpha$ -cell prevents the  $\alpha$ -cell from maintaining a high rate of glycolysis and glucagon secretion at high glucose levels. Importantly, pyruvate- and lactate-provoked glucagon secretion remains unaffected since they are independent of mitochondrial shuttle activity. Consequently, secretion of glucagon becomes more sensitive to fuels available during physical exercise.

**Shared and unique motifs of nutrient sensing in GLP-1 (GLUTag) and insulin (INS-1 832/13) secreting cells**P. Spégel<sup>1</sup>, L. Shcherbina<sup>2</sup>, L. Andersson<sup>1</sup>, C. Wollheim<sup>3</sup>, N. Wierup<sup>2</sup>, H. Mulder<sup>1</sup>;<sup>1</sup>Unit for Molecular Metabolism, <sup>2</sup>Unit of Neuroendocrine Cell Biology,<sup>3</sup>Lund University Diabetes Centre, Malmö, Sweden.

**Background and aims:** Glucagon-like peptide-1 (GLP-1), secreted from intestinal L-cells, promotes beta-cell proliferation and enhances glucose-stimulated insulin secretion. Despite this important role for GLP-1, much less is known about stimulus-secretion coupling in the L-cell as opposed to the beta-cell. GLP-1 secretion from L-cells has been suggested to be mainly regulated by nutrient up-take rather than metabolism of such fuels. However, it has also been shown that a, as of yet, unknown metabolic signal may potentiate secretion of the hormone. We hypothesized that levels of a potential coupling factor of GLP-1 secretion should rise in nutrient stimulated L-cells in parallel to increased hormone secretion.

**Materials and methods:** GLUTag and INS-1 832/13 cells were stimulated with a range of different secretagogues in presence and absence of various pharmacological inhibitors. Nutrient-provoked hormone secretion was assessed, in addition to profiling of alterations in metabolite levels by gas chromatography/mass spectrometry.

**Results:** Both glucose and glutamine stimulated TCA-cycle metabolism (3-9-fold,  $p < 0.05$ ) and provoked GLP-1 (1.3-fold,  $p < 0.001$ , glucose; 1.7-fold,  $p < 0.001$ , glutamine) secretion from GLUTag cells; only glucose evoked secretion of insulin (5-fold,  $p < 0.001$ ) from INS-1 832/13-cells. Both stimuli resulted in a rise in intracellular glutamate levels in GLUTag (5-fold,  $p < 0.001$ , glucose; 1.7-fold,  $p < 0.001$ , glutamine) and INS-1 832/13 (1.3-fold,  $p < 0.01$ , glucose; 30-fold,  $p < 0.001$ , glutamine). Addition of leucine, activating glutamate dehydrogenase, did not affect GLP-1 secretion from GLUTag cells while robustly releasing insulin from INS-1 832/13 cells (5.2-fold,  $p < 0.05$ ). The membrane permeable glutamate analogue dimethyl-glutamate yielded similar levels of GLP-1 secretion (1.6-fold,  $p < 0.001$ ) and intracellular glutamate levels (23-fold,  $p < 0.05$ ) as glutamine in the GLUTag cells. Addition of leucine did not affect dimethyl-glutamate stimulated GLP-1 secretion, but yielded similar levels of insulin secretion (5-fold,  $p < 0.05$ ) from INS-1 832/13 cells as the combination of glutamine and leucine. The membrane permeable pyruvate analogue methyl-pyruvate provoked neither GLP-1 secretion nor elevated glutamate levels in GLUTag cells, despite a strong effect on TCA-cycle metabolism (5-15-fold,  $p < 0.05$ ). The same compound elicited a significant increase in TCA-cycle metabolism (4-16-fold,  $p < 0.01$ ) and insulin secretion (3-fold,  $p < 0.01$ ) similar to pyruvate in the monocarboxylate transporter-1 expressing INS-1 832/13 cells; glutamate levels were unaltered. Inhibition of the oxoglutarate transporter with phenyl-succinate affected neither GLP-1 secretion nor glutamate levels in GLUTag cells, but decreased insulin secretion (-34%,  $p < 0.05$ ) and glutamate levels (-25%,  $p < 0.05$ ) in INS-1 832/13 cells.

**Conclusion:** Our findings show that metabolic coupling differs between L- and the beta-cells. Specifically, involvement and activity of glutamate dehydrogenase, mitochondrial metabolism and shuttles differed. Importantly, non-electrogenic elevation of glutamate is a signal for GLP-1 secretion, suggesting that glutamate may be a coupling factor in both glucose- and glutamine-stimulated GLP-1 secretion.

## 400

**Regulation of Glucose-Stimulated Insulin Secretion (GSIS) by miR-130a/b and miR-152 via pyruvate dehydrogenase E1 component, alpha subunit PDHA1**

J.K. Ofori, V.A. Salunkhe, A. Bagge, A. Wendt, H. Mulder, L. Eliasson, J.L.S. Esguerra;

Dept. of Clinical Sciences, Lund University Diabetes Centre, Malmö, Sweden.

**Background and aims:** MicroRNAs (miRNAs) are small RNAs that regulate genes at the post-transcription level and have been implicated in beta cell dysfunction. We have previously identified miR-130a/b and miR-152 to be up-regulated in the pancreatic islets of the non-obese type-2 diabetes (T2D) rat model Goto-Kakizaki (GK). Here we aim to investigate the contribution of these miRNAs in glucose-stimulated insulin secretion (GSIS) and to dissect their molecular functions using insulin-secreting cells.

**Materials and methods:** We cultured the “glucose-responsive”, INS-1 832/13 and “glucose-unresponsive”, INS-1 832/2 cells at low (2.8 mM) and high (16.7 mM) glucose concentrations for 1h. The expression levels of miR-130a/b and miR-152 were measured by qPCR. MiRNAs were over-expressed by transfecting mature miRNA sequences of miR-130a/b and miR-152. The effect on targets predicted by TargetScan was evaluated both on mRNA (qPCR) and protein levels (western blot). GSIS assays (at 2.8 mM and 16.7 mM glucose) were performed and the released insulin was measured using radioimmunoassay. Oxygen consumption rates were measured using extracellular flux analyzer, XF24 (Seahorse Bioscience).

**Results:** Similar to previous findings in GK islets, we found upregulation of miR-130a/b and miR-152 in the glucose-unresponsive INS-1 832/2 cells compared to INS-1 832/13 cells. At high glucose concentrations, the expression of the miR-130a, miR-130b and miR-152 decreased in INS-1 832/13 by 80 % ( $n=3$ ,  $p < 0.05$ ), 75 % ( $n=3$ ,  $p < 0.001$ ) and 60 % ( $n=3$ ,  $p < 0.05$ ) respectively but not in INS-1 832/2. Perturbing the miRNA levels in INS-1 832/13 cells by over-expression of mature miR-130a and miR-152 resulted in reduced insulin secretion by 30% at 16.7 mM glucose ( $n=3$ ;  $p < 0.01$ ) and insulin content by 70% ( $n=3$ ;  $p < 0.05$ ). We also observed decreased oxygen consumption rate after miR-130b over-expression. The putative target of the miRNAs, pyruvate dehydrogenase E1 component, alpha subunit (PDHA1) was reduced by 40% at both mRNA ( $n=3$ ,  $p < 0.05$ ) and protein level ( $n=3$ ;  $p < 0.05$ ) upon miRNA overexpression. Finally we showed that PDHA1 knock-down by siRNA reduced glucose-stimulated insulin secretion by 40% ( $n=3$ ;  $p < 0.05$ ).

**Conclusion:** We utilized clonal beta cells with disparate GSIS phenotypes to study the contribution of miRNAs in the beta cells. Perturbing the levels of miR-130a/b and miR-152 in the glucose-responsive cell line resulted in defective beta cell phenotype such as reduced insulin secretion, reduced insulin content and decreased oxygen consumption rate. Consequently, deregulation of downstream miRNA targets, such as the PDHA1, a component of pyruvate dehydrogenase complex responsible for metabolic coupling in insulin beta cells, potentially contributes in beta cell dysfunction.

## PS 016 Modulation of islet function through cell surface receptors

401

### Differential action of GLP-1 and GIP on human pancreatic islet function and viability

Y. De Marinis, P. Storm, J. Fadista, L. Groop;  
Dept of Clinical Sciences Malmö, Sweden.

**Background and aims:** Gastric inhibitory peptide (GIP) and glucagon-like peptide 1 (GLP-1) have been studied intensively in various animal models. Physiological studies of these incretins in human pancreatic islets are still lacking. Here, we have assessed the direct effects of GIP and GLP-1 on islets from non-diabetic and diabetic adult human donors.

**Materials and methods:** We investigated how the incretins affect glucose induced human islet cell activity by MTS assay. Insulin secretion from islets of 61 human donors was measured at 1 and 16.7 mM glucose. To verify various gene expression, RNA-sequencing was performed on human islets.

**Results:** When challenged by high glucose (20 mM, 72 hr), the number of metabolically active human islet cells decreased (60% decrease vs. 5.5 mM glucose,  $p < 0.001$ ), which can be partially rescued by GLP-1 analogue exendin-4 (40% decrease vs. 5.5 mM glucose,  $p < 0.001$ ), and completely reversed by GIP. In islets from diabetic donors, there was a significant decrease in numbers of metabolically active cells, and further reduced at high glucose (60% decrease,  $p < 0.001$ ). GIP completely reversed the effect of high glucose on reducing the number of metabolically active cells, while exendin-4 showed no effect. Next, we measured effect of the incretins on insulin secretion in islets from 61 donors at basal glucose (1 mM) and glucose stimulated insulin secretion (GSIS, 16.7 mM). The donors could be subdivided into two groups based on their response to glucose and incretins. In group 1 (37 donors), islets showed low basal ( $0.12 \pm 0.01$  ng/islet/hr) and GSIS ( $0.44 \pm 0.03$  ng/islet/hr) and responded well to GLP-1 (55% increase,  $p < 0.01$ ), but not to GIP. Group 2 (24 donors) showed high basal ( $0.47 \pm 0.05$  ng/islet/hr) and GSIS ( $1.59 \pm 0.14$  ng/islet/hr), had no further stimulatory effect of GLP-1 or GIP on GSIS. RNA-sequencing on islets showed that group 1 has higher mRNA expression of glucose transporter 1 gene (SLC2A1, 5.5%,  $p < 0.05$ ) and lower expression of glucose transporter 2 gene (SLC2A2, 26.7%,  $p < 0.01$ ) compared to group 2.

**Conclusion:** In conclusion, this work provides a first description of incretin effects in human pancreatic islets. We also showed that islet preparations from cadaver donors display different responses to glucose and incretins.

### Isolation of target genes of liraglutide, a GLP-1 receptor agonist, in pancreatic islets by using nano-LC-MS/MS system

E. Yoshida, J. Shirakawa, A. Kimura, H. Hirano, Y. Terauchi;  
Yokohama City University, Japan.

**Background and aims:** Activation of GLP-1 receptor potentiates insulin secretion and beta cell proliferation in endocrine pancreas. However, the precise mechanisms by which GLP-1 receptor agonist regulate signaling pathway involving insulin secretion and beta cell proliferation remain elusive. In the present work, we performed quantitative comparative proteome analysis of liraglutide-treated mouse islets by liquid chromatography-tandem mass spectrometry (LC-MS/MS) to identify novel target genes of GLP-1 receptor activation.

**Materials and methods:** Isolated islets from 8 to 10-week old C57BL/6 male mice were incubated at 5.6 mM glucose in the presence or absence of liraglutide at a concentration of 1000 nM. More than 50 islets were lysed with urea, digested with trypsin, and desalted. The extracts were subjected to nano-LC-MS/MS analysis by using LTQ Orbitrap Velos. The data were analyzed using Progenesis LC-MS software and Databases for Annotation, Visualization and Integrated Discovery (DAVID) software.

**Results:** We first confirmed that the treatment of liraglutide significantly increased proliferative BrdU-incorporated cells in isolated islets compared with vehicle control ( $p < 0.05$ ). A total of 26225 proteins were identified from 1  $\mu$ g of protein extracts in islets by LC-MS/MS. Among them, the expression levels of 1012 proteins were increased, and those of 809 proteins were decreased in the presence of liraglutide. Analysis based on Gene Ontology

(GO) categories revealed that genes up-regulated by liraglutide were linked to the biological processes of translation, vesicle-mediated transport, glycolysis, and glucose metabolic process (enrichment score  $\geq 1.3$ ). There were 19 proteins whose expressions were significantly elevated more than 2-fold by the treatment with liraglutide (anova  $p < 0.05$ ), including such as Carboxypeptidase A1, Protein disulfide-isomerase A2 (Pdia2), Glycerol-3-phosphate dehydrogenase 1-like protein, and Lithostathine-1 (Reg1). We here focused on Pdia2 and Reg1, since Pdia2 is supposed to play a role as a molecular chaperone and Reg1 is suggested to be involved in  $\beta$  cell regeneration or growth. We analyzed mRNA expression of Pdia2 and Reg1 in islets at the concentration of 5.6 mM glucose, liraglutide-treated islets showed modestly higher expression than islets of vehicle control (1.28 fold and 1.39 fold, respectively). The mRNA expression levels of these proteins were enhanced in the presence of 11.1 mM glucose (Pdia2: 7.8-fold,  $p = 0.058$  and Reg1: 9.4-fold,  $p = 0.061$ ). Whereas there were 12 proteins that were decreased less than 0.5-fold by liraglutide, Caveolin-1, a protein which is the principal structural protein of caveolae membranes, only showed significant decrease by the treatment with liraglutide (anova  $p < 0.05$ ).

**Conclusion:** These results suggested that liraglutide stimulated islet cell proliferation and altered the expression levels of proteins such as Pdia2, Reg1 and Caveolin-1 in vitro. Pdia2 and Reg1 are suggested to be involved in proliferation and regeneration of  $\beta$  cells. Caveolin-1 is reportedly related to the regulation of exocytosis and insulin receptor-mediated signaling. GO analysis showed that the target molecules of liraglutide were related to the functions involved in glucose metabolism, and the glucose signal in islets potentiated the expression of Pdia2 and Reg1 induced by liraglutide. In conclusion, Pdia2 and Reg1 are novel targets of liraglutide and may be involved in the proliferation signal in islets.

403

### Dipeptidyl peptidase 4 is expressed in pancreatic islets in a species specific manner, and its activity is increased by high glucose in isolated mouse islets

L. Liehua<sup>1</sup>, B. Omar<sup>2</sup>, B. Ahrén<sup>2</sup>;

<sup>1</sup>Endocrinology Department, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, <sup>2</sup>Department of Clinical Science, Lund University, Sweden.

**Background and aims:** Functional glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic peptide were both discovered in pancreatic  $\alpha$  cells recently, indicating a local incretin system within islets. However, whether dipeptidyl peptidase-4 (DPP-4), an indispensable part of the system, is expressed in islets and therefore may be involved in the local regulation of islet function remains uncertain. This study examined the islet distribution of DPP-4 in different species, as well as the possible regulating factors of its activity.

**Materials and methods:** Co-localization of DPP-4 and insulin or glucagon was examined with immunofluorescent staining in pancreatic sections of humans, pigs, C57BL/6 mice and Sprague Dawley rats. Isolated islets from wild type mice were cultured in different conditions for 72 hours in RPMI medium (with 0.1% bovine serum albumin, 100U/ml penicillin and 100 $\mu$ g/ml streptomycin) with the medium changed every day. DPP-4 activity of the islets was then measured using Gly-Pro-pNitroaniline as the substrate, and Nitroaniline as the standard. The examined conditions included different levels of glucose and 5.6mmol/L glucose plus 10nmol/L insulin or 100nmol/L GLP-1. DPP-4 activity was also analyzed in islets from GLP-1 receptor knockout mice (GLPR<sup>-/-</sup>) and double incretin receptor knockout mice (DIRKO).

**Results:** DPP-4 fluorescent signals were readily observed in islets of all species. A pronounced species difference was observed, however. In human and pig islets, DPP-4 was expressed exclusively in  $\alpha$  cells, with nearly no expression in  $\beta$  cells. In contrast, in mouse or rat islets, DPP-4 was expressed in a  $\beta$  cell dominant manner although low degree of expression was discovered in  $\alpha$  cells (fig.1). DPP-4 activity in isolated mouse islets was gradually increased by high glucose overtime, and the differences between 5.6 mmol/L group ( $3.6 \pm 1.2$  pmol/min/islet) and the high glucose groups was statistically significant after 72 hours of culture ( $6.3 \pm 1.1, 6.7 \pm 2.5$ , and  $7.3 \pm 1.5$  pmol/min/islet for 11.1, 16.7, and 33.3mmol/L, respectively,  $P < 0.05$  vs. 5.6mmol/L for all groups,  $n = 5$ ). There was no significant effect of 10nmol/L insulin or 100nmol/L GLP-1 on DPP-4 activity compared with control ( $5.3 \pm 1.5, 4.9 \pm 1.0$  and  $5.7 \pm 1.1$  pmol/min/islet respectively,  $P = 0.72, n = 3$ ). Lack of impact of GLP-1 on intraislet DPP-4 activity was further confirmed by the result that DPP-4 activity was similar in wild type mice, GLPR<sup>-/-</sup> mice and DIRKO mice ( $6.5 \pm 2.1, 6.9 \pm 1.6$  and  $6.5 \pm 0.7$  pmol/min/islet respectively,  $P = 0.96, n = 3$ ).

**Conclusion:** Active DPP-4 is expressed in islets in a species-specific manner. Local DPP-4 activity is directly increased by high glucose per se rather than via insulin or GLP-1 indirectly. The underlying regulatory mechanism of DPP-4 activity and its clinical implications, as well as the importance of the species difference, remain to be further investigated.

**Figure 1.** Co-localization of DPP (green) / glucagon (red) as well as DPP (green) / insulin (red) in human, pig, mouse and rat islets.

##### Defective compensatory insulin secretion causes HFD-induced glucose intolerance in mice with point mutation in free fatty acid receptor 1

G. Kaiser<sup>1,2</sup>, S. Sabrautzki<sup>3,4</sup>, F. Gerst<sup>1,2</sup>, G. Przemec<sup>4,3</sup>, H.-U. Häring<sup>1,2</sup>, M. Hrabě de Angelis<sup>3,4</sup>, S. Ullrich<sup>1,2</sup>;

<sup>1</sup>Institute for Diabetes Research and Metabolic Diseases (IDM) of the Helmholtz Center Munich, German Center for Diabetes Research (DZD e.V.), Tübingen, <sup>2</sup>Internal Medicine IV, Endocrinology, Diabetology,

Angiology, Nephrology und Clinical Chemistry, University Hospital Tübingen, <sup>3</sup>German Center for Diabetes Research (DZD e.V.), Germany,

<sup>4</sup>Institute of Experimental Genetics, Helmholtz Zentrum München, German Research Center for Environmental Health, Munich, Germany.

**Background and aims:** The fatty acid receptor 1 (FFAR1/GPR40) mediates the fatty acid-dependent augmentation of glucose-induced insulin secretion (GIIS) in pancreatic beta-cells. This feature led to the generation of specific FFAR1-agonists for the treatment of hyperglycemia. Intriguingly, *Ffar1*<sup>-/-</sup> mice were protected against liver steatosis, suggesting that antagonists of *FFAR1* could have beneficial effects on metabolism. To further understand the impact of *FFAR1* on the regulation of glucose homeostasis and insulin disposal, mice carrying point mutations in *Ffar1* were generated.

**Materials and methods:** 16,800 archived sperm samples were screened for N-ethyl-N-nitrosourea-induced point mutations in *Ffar1*. Mice were generated on C3HeB/FeJ background using three different sperm samples, each carrying one missense mutation in *Ffar1*. Heterozygous and wild-type littermates were fed chow (CD) or high fat diet (HFD) for 8 weeks. Thereafter, glucose tolerance and insulin sensitivity as well as total pancreatic insulin

content were assessed. Insulin secretion was measured in isolated islets of homozygous mice.

**Results:** Three mice strains, two with single point mutations in the extracellular (T146S and R258W) and one in the intracellular domain (L106P) of the receptor showed normal development, behavior and growth. HFD-induced insulin resistance and male mice deviated from normal glucose tolerance, although the pancreatic insulin content was almost doubled in all the mice regardless of genotype. Most interestingly, heterozygous mice carrying the T146S-mutation in *FFAR1* developed significant glucose intolerance despite the adaptive increase in insulin production. Isolated islets from T146S homozygous animals showed impaired insulin secretion in response to the *FFAR1* agonist TUG-469.

**Conclusion:** Proper activation of *FFAR1* is necessary for insulin hypersecretion in the insulin resistant state, in order to protect from HFD-induced glucose intolerance, but *FFAR1* receptor signaling may not contribute to the adaptive increase in pancreatic insulin synthesis.

##### Stimulation of free fatty acid receptor 1 reduces thioredoxin interacting protein and exhibits anti-apoptotic properties in insulin secreting cells

M. Panse<sup>1</sup>, G. Kaiser<sup>1,2</sup>, F. Gerst<sup>1,2</sup>, H.-U. Häring<sup>1,2</sup>, S. Ullrich<sup>1</sup>;

<sup>1</sup>Internal Medicine IV, University Hospital Tübingen, <sup>2</sup>Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Center Munich at the Eberhard-Karls-University of Tübingen (IDM), Germany.

**Background and aims:** Multiple observations suggest that glucose-dependent stimulation of thioredoxin interacting protein (TxNIP) expression contributes to glucotoxicity. TxNIP inhibits thioredoxin thereby increasing the mitochondrial oxidative stress. Glucose upregulates TxNIP through a ChREBP-dependent transcriptional activation. ChREBP is negatively regulated by FOXO1. Palmitic acid activates FOXO1 through PKC $\delta$  and is known to downregulate TxNIP, in spite of inducing apoptosis under glucolipotoxic conditions. Since palmitic acid also acts as a ligand for Free fatty acid receptor 1 (FFAR1), TxNIP downregulation could occur via metabolism or receptor activation. Recently we observed that *FFAR1* agonists exhibit anti-apoptotic properties under glucolipotoxic conditions. Present study investigates the underlying mechanism of the putative protective effects of *FFAR1* agonists.

**Materials and methods:** Human islets received from the European Centers of Islet Transplantation, mouse islets isolated from C57BL/6 and *Ffar1*<sup>-/-</sup> mice and INS-1E cells were treated either with palmitic acid (50-600  $\mu$ mol/l) or the *FFAR1* agonist and antagonist (TUG-469 and TUG 761 respectively, 0.1-10  $\mu$ mol/l). Changes in expression were analysed by qRT-PCR and western blot. Protein expression was downregulated by siRNA techniques.

**Results:** In human and mouse islets, as well as INS-1E cells, palmitic acid (600  $\mu$ mol/l) reduced TxNIP mRNA by more than 50% under 11 mmol/l glucose. This effect was also observed in *Ffar1*<sup>-/-</sup> mouse islets. Downregulation of PKC $\delta$  reversed the effect of palmitic acid on TxNIP, while, INS-1E cells overexpressing PKC $\delta$  and displaying high levels of nuclear FOXO1, had extremely low levels of TxNIP. In INS-1E cells, *FFAR1* agonist (3-10  $\mu$ mol/l) reduced TxNIP by more than 60% whereas the antagonist (10  $\mu$ mol/l) doubled it. In contrast to palmitic acid, the *FFAR1* agonist (10  $\mu$ mol/l) downregulated TxNIP in a *FFAR1* dependent manner. However, downregulation of either PKC $\delta$  or FOXO1 could not reverse the effects of the ligands.

**Conclusion:** The observations suggest that inhibition of TxNIP could be mediated by two distinct pathways: one pathway involves PKC $\delta$  dependent nuclear accumulation of FOXO1, stimulated by high concentrations of palmitic acid, while the other involves *FFAR1* and does not seem to involve PKC $\delta$  and FOXO1, however, it may contribute to the anti-apoptotic property of *FFAR1*.

##### Expression and function of an omega-3 fatty acid receptor GPR120 in Islets of Langerhans

M. Dogan, S.J. Persaud, P.M. Jones;

Diabetes Research Group, Division of Diabetes and Nutritional Sciences, King's College London, UK.

**Background and aims:** GPR120 and GPR40 are both activated by medium and long chain fatty acids, although they share only 10% amino acid homology. Several previous studies have demonstrated important effects on islet

function of GPR40 activation, but much less are known about the expression and function of GPR120 in islets, although it has been implicated in other metabolic processes. The current study investigated the expression of GPR120 in mouse and human islets, and measured the effects of a GPR120 agonist on islet function.

**Materials and methods:** Expression of GPR40 and GPR120 mRNAs was assessed by quantitative RT-PCR. Fluorescence immunohistochemistry was performed to localise GPR120 protein expression in mouse and human pancreas. Insulin, glucagon and somatostatin secretion were quantified by radioimmunoassay. Caspase 3/7 activities were measured to determine apoptotic responses to a mixed cytokine challenge (50 U/ml IL-1 $\beta$ , 1000 U/ml TNF- $\alpha$ , 1000 U/ml INF- $\gamma$ ).

**Results:** Both human and mouse islets expressed GPR120 mRNA, which was 6 times higher than GPR40 mRNA expression in mouse islets (data are expressed relative to  $\beta$ -actin mRNA levels; GPR120:  $0.4\pm 0.08$ ; GPR40:  $0.07\pm 0.01$ ;  $n=6$ ;  $*p<0.05$ ). In mouse islets co-localisation of GPR120 immunoreactivity was detected in both insulin-expressing  $\beta$ -cells and glucagon expressing  $\alpha$ -cells, but not with somatostatin expressing  $\delta$ -cells. In contrast, GPR120 immunoreactivity co-localized only with  $\beta$ -cells in human islets. Cytokine-induced apoptosis was significantly reduced in the presence of a selective GPR120 agonist, GAIII (luminescence: control:  $50,525\pm 2,473$  100nM GAIII:  $43,755\pm 2,054$  1 $\mu$ M:  $35,491\pm 2,828$  10 $\mu$ M:  $38,966\pm 2,519$ ;  $n=8$ ,  $P<0.01$ ). GAIII had no effect on basal (2mM glucose) insulin secretion but induced a significant potentiation of glucose-stimulated insulin secretion from mouse islets (20 mM glucose:  $2.02\pm 0.7$ ; +1 $\mu$ M GAIII:  $4.18\pm 1.22$ ng/islet/30min;  $n=8$ ,  $P<0.05$ ). In contrast, GAIII (1 $\mu$ M) had no effect on basal or stimulated glucagon and somatostatin secretion ( $p>0.2$ ). Perfusion experiments using mouse islets confirmed GAIII enhanced glucose-induced (20mM) insulin secretion and that this effect was sustainable for the duration of exposure to GAIII. The effects of GAIII to stimulate insulin secretion were reduced in the presence of a PLC inhibitor, U-73122, but not by the PKC inhibitor Go6976 (peak stimulation: 1 $\mu$ M GAIII:  $203\pm 42\%$  of 20mM glucose alone; 1 $\mu$ M GAIII+1 $\mu$ M Go6976:  $218\pm 5$  ( $p>0.2$ ); 1 $\mu$ M GAIII+1 $\mu$ M U-73122:  $109\pm 5\%$  ( $p<0.01$ ):  $n=3$ ). **Conclusion:** The medium and long chain free fatty acid receptors GPR120 and GPR40 are expressed in both mouse and human islets. GPR120 expression was identified in  $\beta$ -cells and  $\alpha$ -cells in mouse islets, but only in  $\beta$ -cells in human islets. GPR120 activation by GAIII induced a sustained potentiation of glucose-induced insulin release, but had no effect on basal insulin release, nor on basal or stimulated glucagon and somatostatin secretion. Furthermore, GAIII protected mouse islets against cytokine-induced apoptosis. These observations indicate that GPR120 is expressed by islets where it may offer a therapeutic target for regulating insulin secretion and islet cell apoptosis.

## 407

### Expression of GPR56 and collagen III in islets: a role in modulating insulin secretion

O.E. Olaniru, P.M. Jones, S.J. Persaud;  
Division of Diabetes and Nutritional Sciences, School of Medicine,  
King's College London, UK.

**Background and aims:** GPR56 is a member of the adhesion class of G-protein coupled receptors (GPCRs) and we have identified that it is one of the most highly expressed GPCRs in human islets. Collagen III is its primary agonist in the developing brain where it is found to play a significant role in formation of the cortex, and CD81, a scaffolding protein, couples GPR56 with Gq to form a stable complex in the brain. GPR56 has been associated with inhibition of apoptosis in leukaemia cells. The role of GPR56 in islets is not known, so the aim of this study was to investigate its expression and function in islets.

**Materials and methods:** GPR56, collagen III and CD81 expression were investigated in mouse and human islets by RT-PCR, Western blotting and immunohistochemistry. Insulin secretion was quantified by radioimmunoassay after acute (1 hour) or chronic (3 days) exposure to collagen III. Islet insulin content after chronic exposure was assayed by acid ethanol extraction. Apoptosis induced by exposure of mouse islets to a cytokine cocktail was quantified by the Caspase-Glo luminescence assay.

**Results:** GPR56 and CD81 mRNAs were detected by RT-PCR in MIN6  $\beta$ -cells and in mouse and human islets, while mRNA encoding collagen III was detected in islets but not in MIN6  $\beta$ -cells. Islet GPR56 expression was confirmed by detection of a 65kDa immunoreactive protein and immunohistochemistry revealed that collagen III was present in islet capillaries but

not in endocrine cells. Isolated mouse islets exposed to collagen III for 1 hour showed significant reduction in insulin secretion at 2mM glucose ( $0.41\pm 0.06$  ng/islet/h, + 100nM collagen III:  $0.11\pm 0.02$ ,  $n=6$ ,  $P<0.01$ ) and 20mM glucose-induced insulin secretion was also inhibited ( $4.05\pm 0.74$ , + 100nM collagen III:  $1.64\pm 0.32$ ,  $n=6$ ,  $P<0.01$ ). Conversely, islets incubated with 100nM collagen III for 3 days exhibited enhanced insulin secretion at both basal and stimulatory glucose concentrations (2mM glucose:  $0.26\pm 0.04$ , +100nM collagen III:  $0.83\pm 0.18$ ; 20mM glucose:  $6.33\pm 0.63$ , +100nM collagen III:  $13.30\pm 1.18$ :  $n=6-8$ ,  $P<0.01$ ). There was no effect of 3 days exposure of islets to collagen III on insulin content ( $P>0.2$ ). Measurements of caspase 3/7 activities indicated that collagen III did not provide protection against apoptosis, either basally (luminescence units:  $14,307\pm 1,830$ ; + 100nM collagen III:  $10,410\pm 1,577$ ,  $n=8$ ,  $P>0.1$ ), nor in response to exposure to a cytokine cocktail (luminescence units:  $46,746\pm 2,038$ ; +100nM collagen III:  $53,452\pm 2,671$ ,  $n=8$ ,  $P>0.2$ ). **Conclusion:** GPR56 is expressed by mouse and human islets and collagen III is localised to islet blood vessels, suggesting that GPR56 may be regulated in a paracrine manner by local interaction with its activating ligand. Exogenous collagen III does not significantly affect islet apoptosis, but prolonged treatment with collagen III enhances insulin output. Given the proximity of collagen III to islets in the pancreas it is likely that the chronic stimulatory effects are physiologically relevant and GPR56 may be a mechanism through which the islet vasculature can regulate  $\beta$ -cell function.

### The mitogenic effect of Gas6 on pancreatic beta cells is mediated via the receptor tyrosine kinase Axl

T.N. Haase<sup>1</sup>, A. Gustafsson<sup>2</sup>, A. Nalla<sup>1</sup>, L. Ringholm<sup>3</sup>, P. Damm<sup>3</sup>,  
E.R. Mathiesen<sup>3</sup>, B. Dahlbäck<sup>2</sup>, N. Billestrup<sup>1</sup>, J.H. Nielsen<sup>1</sup>;

<sup>1</sup>Department of Biomedical Sciences, University of Copenhagen, Denmark,

<sup>2</sup>Wallenberg Laboratory, Skåne University Hospital, Malmö, Sweden,

<sup>3</sup>Departments of Endocrinology and Obstetrics, University of Copenhagen, Denmark.

**Background and aims:** The pancreatic  $\beta$ -cell mass adapts through life to cope with changing metabolic requirements. Thus, the  $\beta$ -cell mass expands in situations with increased insulin requirements such as the perinatal period and during pregnancy. Growth arrest specific protein 6 (Gas6) is a ligand for the TAM family of receptor tyrosine kinases, comprising Tyro3, Axl and Mer, with the highest affinity for Axl. We have shown that Gas6 induces proliferation of  $\beta$ -cells in perinatal rats in an age-dependent manner and that  $\beta$ -cells express Axl. Whether the mitogenic effect of Gas6 on  $\beta$ -cells is mediated via Axl is unknown. Besides, Gas6 could potentially affect the  $\beta$ -cell mass in other situations in life where the  $\beta$ -cell mass expands. The aims of the current study were to 1) identify if Gas6 induce  $\beta$ -cell proliferation via Gas6-Axl signaling, 2) identify the cell signaling pathway involved, and 3) determine if plasma levels of Gas6 and sAxl (a soluble form of Axl) is regulated in the third trimester of pregnancy where an expansion of the  $\beta$ -cell mass occurs.

**Materials and methods:** The effect of BGB324 (small molecule inhibitor of Axl) on Gas6-induced  $\beta$ -cell proliferation and cell signaling, studied with a phospho-kinase array and western blotting with specific antibodies, was examined in INS1E cells and primary islets of Langerhans isolated from neonatal rats. Blood samples for measurement of Gas6, sAxl, leptin, adiponin and TNF- $\alpha$  were previously collected from healthy pregnant women ( $n=23$ ), recruited at the start of pregnancy, at median 14 (range 12-16,  $n=9$ ), 27 (25-29,  $n=9$ ) and 33 weeks (31-35,  $n=23$ ) of pregnancy. Thirteen healthy women served as a non-pregnant control group.

**Results:** Gas6 increased proliferation of INS1E cells and neonatal rat  $\beta$ -cells 25% and 60% ( $p<0.05$ ), respectively, and this effect was blunted by BGB324. After 30 min. stimulation Gas6 induced a transient increase in phosphorylation of Akt protein (pS473) in neonatal islets, but not in INS1E cells. The rise in p-Akt was blunted by BGB324. There was no difference in plasma levels of Gas6 ( $p=0.76$ ) or sAxl ( $p=0.90$ ) at 14, 27 or 33 gestational weeks or compared to non-pregnant women. In the third trimester (33 weeks) sAxl plasma levels correlated positively with plasma leptin ( $R^2=0.37$ ;  $p=0.035$ ) and plasma adiponin ( $R^2=0.39$ ;  $p=0.031$ ) and tended to correlate inversely with plasma TNF- $\alpha$  ( $R^2=0.30$ ;  $p=0.064$ ).

**Conclusion:** The mitogenic effect of Gas6 on pancreatic  $\beta$ -cells is mediated via Gas6-Axl signaling. The PI3K/Akt pathway is possibly involved in this response. The plasma levels of Gas6 and sAxl are not changed through pregnancy or compared to non-pregnant women, suggesting that circulatory Gas6/sAxl is not involved in the expansion of the  $\beta$ -cell mass in pregnancy. However, the positive correlations of sAxl with leptin and adiponin and nega-

tive correlation with TNF- $\alpha$ , associated with adipose tissue mass, insulin resistance, and inflammation, could reflect a beneficial anti-inflammatory role of sAxL. Gas6/Axl has been reported to repress TNF- $\alpha$  expression in various cell types including  $\beta$ -cells. Further studies are needed to understand the biological importance of the correlations.

**Persephin: a new player in beta cell proliferation**

A.J. Ineson<sup>1</sup>, A. Clarke<sup>1</sup>, W. Vernon<sup>2</sup>, D.M. Smith<sup>3</sup>, N.G. Morgan<sup>1</sup>, M. Sorhede-Winzell<sup>3</sup>, H.J. Welters<sup>3</sup>;

<sup>1</sup>Institute of Biomedical and Clinical Science, University of Exeter Medical School, <sup>2</sup>Astra Zeneca, Macclesfield, UK, <sup>3</sup>Astra Zeneca, Molndal, Sweden.

**Background and aims:** Defects in beta cell proliferation and survival are known to contribute to the development of Type 2 diabetes. Previously glial cell line derived neurotrophic factor (GDNF) has been shown to improve beta cell proliferation and survival. GDNF is a member of the GDNF family ligands (GFLs) which also includes artemin, neurturin and persephin. These molecules are all potent neurotrophic factors which preferentially signal via GDNF family receptor  $\alpha$  1-4 (GFR $\alpha$ 1-4) respectively. Pancreatic beta cells share a range of properties with neurons, such as expression of glutamate receptors and maintenance of membrane electrical properties which are critical for the development of action potentials involved in the release of insulin. Expression of GDNF family receptors extends these similarities. Indeed, GFLs are essential for the appropriate innervation of the developing pancreas, these nerves are associated with Schwann cells which are known to release GFLs. Currently the effects of GFLs on pancreatic beta cells are unknown and we aim to elucidate their role using the murine beta cell line, MIN6c4, as a model.

**Materials and methods:** Quantitative RT-PCR and western blotting were used to measure mRNA and protein expression respectively. Click- iT<sup>TM</sup> EdU kit was used to assess cell proliferation. Trypan blue was used to assess cell viability.

**Results:** Expression of GFR $\alpha$ 1-4 mRNA was detected in MIN6c4 cells, mouse islets and human islets (n=3, except human islets where n=2). GFR $\alpha$ 4 displayed at least 10 fold lower expression than all other receptors (Table 1). However protein expression of these receptors did not correlate with the mRNA levels. In MIN6c4 cell lysates both GFR $\alpha$ 1 and GFR $\alpha$ 4 protein was detected, but the truncated form (isoform 2) of GFR $\alpha$ 2 was more abundantly expressed than the complete receptor and GFR $\alpha$ 3 was undetected. Following 16hr serum starvation, MIN6c4 cells were incubated for 6 hrs with 100ng/ml of each GFL. Both GDNF and persephin significantly increased proliferation, whereas neurturin and artemin had no effect (fold increase compared to untreated (mean  $\pm$  sem); GDNF: 1.8  $\pm$  0.21, p<0.01, persephin: 1.6  $\pm$  0.17 p<0.05, neurturin: 1.2  $\pm$  0.16 and artemin: 1.2  $\pm$  0.14. One way ANOVA, post hoc Dunnett's test). In contrast after 1hr pretreatment with 100ng/ml of each GFL followed by 24 hr incubation with 0.5mmol/l palmitate to induce cell death, no protective effects were observed.

**Conclusion:** The lack of protein expression of GFR $\alpha$ 2 and GFR $\alpha$ 3 in MIN6c4 cells supports the lack of proliferative effects observed after treatment with their respective ligands artemin and neurturin. However the expression of GFR $\alpha$ 4 protein, despite low levels of mRNA expression, correlates with the ability of persephin to promote proliferation and suggests that, in addition to GDNF, another member of this family, is able to promote beta cell growth, thus identifying an additional potential therapeutic target.

**Overexpression of angiotensin II type 2 receptor gene induces cell apoptosis and dysfunction of insulin secretion in rat insulinoma (INS-1) cells**

M. Liu<sup>1</sup>, D.Q. Jing<sup>1</sup>, S.N. Yin<sup>1</sup>, Y. Liu<sup>2</sup>, Y. Wang<sup>3</sup>;

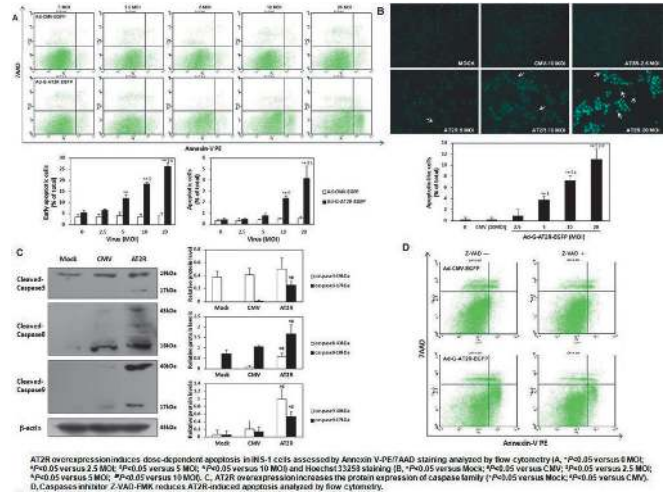

<sup>1</sup>Endocrinology, The First Affiliated Hospital of Chinese PLA General Hospital, <sup>2</sup>Geriatric Endocrinology, Chinese PLA General Hospital, <sup>3</sup>Academy of Military Medical Sciences, Beijing, China.

**Background and aims:** AngiotensinII (AngII) exerts its effects by activating its receptors, primarily type 1 (AT1R) and type 2 receptor (AT2R), however there is little known about the effects of AT2R on the function of pancreatic islet beta cells.

**Materials and methods:** To identify the precise role of AT2R in pancreatic islet beta cell, INS-1 cells were transfected with a recombinant adenoviral vector expressing AT2R (Ad-G-AT2R-EGFP). After transfection, the cell apoptosis was detected by Annexin V and Hoechst staining; cell viability was determined by MTT assay and crystal violet staining; glucose-stimulated insulin secretion (GSIS) and genes expression of components of classic GSIS pathway and the apoptotic pathway were examined.

**Results:** We found that AT2R overexpression alone induced cell apoptosis and suppressed cell viability in a dose- and time-dependent manner. These effects did not require exogenous AngII. Meanwhile, increased expression of AT2R was associated with decreased GSIS, and downregulation of insulin, pancreatic and duodenal homeobox (PDX)-1, glucose transporter (GLUT) 2 and glucokinase (GCK) mRNA expression in a dose-dependent manner. Moreover, overexpression of AT2R markedly increased cleaved caspase-3, caspase-8, and caspase-9 protein expression, but decreased Bcl-2, phospho-Akt, and phospho-ERK protein expression. AT2R-induced cell apoptosis could be blocked by the caspase inhibitor Z-VAD-FMK.

**Conclusion:** These findings suggest that AT2R overexpression trigger INS-1 cells apoptosis and dysfunction of insulin secretion, which may be mediated via cell death signaling pathway that is dependent on activation of caspase family.

### Expression of the chemokine receptors CXCR6 and CX<sub>3</sub>CR1 on CD8<sup>+</sup> T cells in diabetic RIP-LCMV mice

P. Müller<sup>1</sup>, S. Lasch<sup>1</sup>, M. Bayer<sup>1</sup>, J.M. Pfeilschifter<sup>1</sup>, A. Ludwig<sup>2</sup>, E. Hintermann<sup>1</sup>, P. Gutwein<sup>1</sup>, U. Christen<sup>1</sup>;

<sup>1</sup>Goethe University Hospital Frankfurt,

<sup>2</sup>RWTH Aachen University, Germany.

**Background and aims:** In Type 1 Diabetes (T1D) self-destructing lymphocytes are attracted to the islets of Langerhans by proinflammatory chemokines. The IFN $\gamma$  inducible transmembrane chemokines CXCL16 and CX<sub>3</sub>CL1 with their receptors CXCR6 and CX<sub>3</sub>CR1 and their sheddase ADAM 10 could be novel targets for T1D therapy. Here we investigated the expression of, and ADAM10 during the pathogenesis of T1D in a mouse model.

**Materials and methods:** We used the well-established RIP-LCMV model of T1D. As a target autoantigen in the  $\beta$ -cells, RIP-LCMV mice express the glycoprotein (GP) or the nucleoprotein (NP) of the lymphocytic choriomeningitis virus (LCMV) under control of the rat insulin promoter (RIP). RIP-LCMV-GP mice develop T1D within two to three weeks after infection with LCMV, RIP-LCMV-NP mice within one to six months after infection. In order to evaluate the influence of CXCL16/CXCR6 and CX<sub>3</sub>CL1/CX<sub>3</sub>CR1, RIP-LCMV mice were crossed to either CXCR6 or CX<sub>3</sub>CR1-deficient mice.

**Results:** Analysis of pancreas lysates from RIP-LCMV-GP mice collected at different times after infection revealed an upregulation of CXCL16 and CX<sub>3</sub>CL1 in a time dependent manner after infection with LCMV. There is a strong increase of CXCL16 and CX<sub>3</sub>CL1 production during the acute phase of infection until day 14. Thereafter in the chronic phase of the autoimmune destruction of the beta-cells the chemokine production is decreased compared to the peak at day 14, but remains elevated throughout the observation time. Histologic studies of pancreata from RIP-LCMV-GP mice collected at the same times after LCMV infection revealed an enhanced CX<sub>3</sub>CL1/CX<sub>3</sub>CR1 expression. In particular, CX<sub>3</sub>CR1 was predominantly found in infiltrates of CD4 and CD8 T cells. Stimulation of lymphocytes from different organs (spleen, pancreatic lymph nodes, and pancreas) with immunodominant LCMV-peptides followed by intracellular staining of IFN $\gamma$  to determine autoantigen-specific T-cells revealed a time dependent expression of CX<sub>3</sub>CR1 on autoantigen-specific CD8 T-cells. Importantly, CX<sub>3</sub>CR1 was expressed in a significantly higher frequency in pancreatic lymph nodes and spleen on specific CD8 T-cells, but was equally expressed in the pancreas. These data indicate a selective disappearance of specific CX<sub>3</sub>CR1<sup>+</sup> T cells after encounter of their target autoantigens in the pancreas. The peak of CX<sub>3</sub>CR1<sup>+</sup> antigen-specific T-cells from pancreatic lymph nodes to pancreas is delayed for two days indicating a migration of autoaggressive T-cells into the pancreas. Preliminary, incidence studies of RIP-LCMV-GP/NP x CXCR6<sup>GFP/GFP</sup> mice showed a significant reduction of T1D development in both models compared with RIP-LCMV.

**Conclusion:** In summary our data demonstrate that both CXCL16 and CX<sub>3</sub>CL1 are expressed after LCMV infection and remain elevated in the pancreas during the autoimmune destruction of beta-cells. However further analyses suggest that both the CX<sub>3</sub>CL1/CX<sub>3</sub>CR1 and the CXCL16/CXCR6 axis might be important for islet infiltration by antigen-specific T cells and subsequently the development of T1D.

### Commensal bacteria-LPS translocation does not promote the breakdown of T cell tolerance and autoimmune diabetes

G. Espinosa Carrasco, M. Villard, P. Plence, J. Hernandez; Inserm U844, Université de Montpellier 1, France.

**Background and aims:** Type 1 diabetes results as a failure of the mechanisms that maintain immune tolerance. Genetic and environmental factors contribute to render potentially autoreactive T cells into pathogenic effectors. Both, CD8<sup>+</sup> and CD4<sup>+</sup> T cells override tolerance and cooperate to progressively destroy the beta cells of the pancreas. Interestingly, it has recently been shown that commensal bacteria can shape and induce anti-self T cell responses. These observations suggest that bacterial products may promote the

breakdown of T cell tolerance. Here we have addressed whether the systemic translocation of LPS from commensal bacteria promotes the breakdown of peripheral T cell tolerance to pancreatic antigens.

**Materials and methods:** To address this question, we have utilized transgenic mice that express a well-characterized model antigen, influenza HA, in the beta cells of the pancreas. These mice are profoundly tolerant of the HA antigen in both the CD8<sup>+</sup> and the CD4<sup>+</sup> T cell compartments. Mild irradiation promotes the breakdown of T cell tolerance and the onset of autoimmune diabetes. One of the effects of irradiation is the systemic translocation of LPS from commensal bacteria. To assess whether bacterial LPS is responsible for the breakdown of tolerance observed we have treated mice with a cocktail of antibiotics in the drinking water in order to prevent translocation.

**Results:** Our results demonstrated that antibiotic treatment can efficiently prevent the systemic translocation of LPS induced by irradiation. Surprisingly, the absence of LPS translocation did not prevent the onset of autoimmune diabetes in transgenic mice. Beta cell-specific CD8<sup>+</sup> T cells proliferated extensively in response to self-antigen cross-presentation in the draining lymph nodes of the pancreas, differentiated into effector cells and infiltrated the islets of Langerhans inducing disease in both antibiotic treated mice and controls. Analyses of the CD11c<sup>+</sup> antigen presenting cells demonstrated that irradiation induces their activation as measured by the enhanced expression of CD80, CD86, CD70, CD40 and MHC II. However, antibiotic treatment did not completely reverse this activation in all the dendritic cell subsets analyzed.

**Conclusion:** Our results indicate that commensal bacteria LPS translocation is not sufficient to promote the breakdown of CD8<sup>+</sup> T cell peripheral tolerance and the onset of autoimmune diabetes.

### Predictive value of decision-tree analysis of blood gene expression profiles for islet infiltration in the LEW.1A1R1-*iddm* rat model of type 1 diabetes

T. Schoeppe<sup>1</sup>, H. Weiss<sup>1</sup>, R. Schmidt<sup>2</sup>, M. Tiedge<sup>1</sup>;

<sup>1</sup>IBIO, <sup>2</sup>IBIMA, University of Rostock, Germany.

**Background and aims:** The LEW.1A1R1-*iddm* rat is an animal model of spontaneous autoimmune diabetes. Islet infiltration occurs within a narrow time range between 40 and 60 days after birth resulting in progressive beta cell destruction and overt diabetes. It was the aim of this study to generate a prediction model (decision-tree) for islet infiltration that based on gene expression profiles of peripheral blood mononuclear cells (PBMC) of prediabetic normoglycaemic LEW.1A1R1-*iddm* rats.

**Materials and methods:** Normoglycaemic LEW.1A1R1-*iddm* and LEW.1A1R1 control rats were killed at the age of 40 - 60 days. Serial pancreatic sections were stained with Haematoxylin-Eosin (HE) to document the state of islet infiltration. RNA was isolated from purified PBMCs for PCR-Array analysis and RT-PCR. Gene expression data of proinflammatory cytokines, anti-inflammatory cytokines and T-cell markers were analyzed by WEKA data mining tool using C4.5 algorithm to generate a decision-tree to predict islet infiltration.

**Results:** At the stage of organ preparation all rats were normoglycaemic (blood glucose level 5 - 7.5 mmol/l) and were discriminated by the status of infiltration (uninfiltrated, infiltrated). The gene expression profile of PBMCs followed a two-peak model with high expression of chemokines at day 40, 60 and downregulation at day 50. The cytokine- and chemokine genes *Ccl2*, *Cxcl11*, *Ccl21*, *Il-18*, *TNF* (2.1-2.7fold), *Cxcl1*, *Cxcl2*, *Cxcl3* (3.6-5.4fold) and *Ccl7*, *Ccl24* (6.9-8.8fold) were upregulated at day 40 in rats with islet infiltration and facilitate recruitment of immune cells to the pancreas. A downregulation of cytokine- and chemokine genes was observed for *C4b*, *Ccl1*, *Ccl17*, *Ccl24*, *Ccr2*, *Il-1a*, *Il-1b*, *Il-6*, *Il-6r*, *Il-9*, *Tr4*, *Tr7* and *TNF* in combination with upregulated genes *Cxcl2*, *Cxcl3* and *Il-22* at day 50 in rats with progressive islet infiltration. Upregulation was also detected for *C4b*, *Ccl1*, *Ccl2*, *Ccl21*, *Ccl22*, *Il-18* (2.3-5.3fold) and was accompanied by strong expression of *Cxcl1* (33.8fold), *Cxcl3*, *Cxcl2* (10.2-11.7fold), *Ccl7* (49.7fold) and *Ccl24* (129.2fold) in infiltrated animals and highlight a significant inflammation state in the blood. Decision tree analysis showed specific combinations of genes with predictive character at different time points of islet infiltration. At the early stage of islet infiltration (d40) *Il-1 $\beta$*  proved to be the most predictive marker of islet infiltration. At d45 *Il-1 $\beta$*  and *TNF- $\alpha$*  were characteristic for islet infiltration while with progression of islet infiltration and beta cell destruction the regulatory genes *CTLA4* and *CD25* (d50), *NRP1* and *Il-1 $\beta$*  (d55) and *Il-10* (d60) gained decisive power.

**Conclusion:** The process of islet infiltration is mirrored by a two peak model of proinflammatory and antiinflammatory chemokines/cytokines expression in PBMCs. A proinflammatory gene expression profile has predictive power for the early period of islet infiltration while anti-inflammatory/regulatory genes dominate the progressive period of islet infiltration. In the late period of islet infiltration before onset of manifest hyperglycaemia proinflammatory genes showed a second peak. Thus, in risk patients the gene expression profiles in PBMCs could be an attractive strategy to monitor the state of islet autoimmunity in combination with the titer of autoantibodies.

### A LADA subform in the LEW.1AR1-iddm rat, a model for human type 1 diabetes

A. Jörns, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Hannover, Germany.

**Background and aims:** The LEW.1AR1-*iddm* rat as an animal model of human type 1 diabetes was characterized during diabetes development by an immune cell infiltrate of CD4 and CD8 T cells as well as CD68 macrophages with proinflammatory cytokine expression in pancreatic islets leading to apoptotic beta cell loss. In this rat model a late onset and slowly developing subform of diabetes could be distinguished from the early and quickly progressing one.

**Materials and methods:** Twice before and immediately after diabetes manifestation pancreatic tissue was analyzed, obtained from the rats by sequential biopsies and of the residual organ. The analyses were performed by immunohistochemistry and in situ RT-PCR for the immune cell composition and the cytokine pattern of the infiltrate including proliferation and apoptosis rate of the pancreatic beta cells in comparison with the normoglycaemic controls.

**Results:** The pancreatic islets from normoglycaemic LEW.1AR1-*iddm* rats showed no signs of immune cell infiltration and cytokine expression. Diabetes manifestation took place between day 55 and day 65 for the early developing subform. In this fulminant subform the immune cell infiltrate was equally composed of CD8 T cells and CD68 macrophages started 3 to 5 days before diabetes manifestation. Immediately after infiltrating the islets the immune cells expressed the proinflammatory cytokines, IL-1 $\beta$  and TNF- $\alpha$ . Ultrastructurally confirmed apoptotic beta cell death showed an apoptosis rate between 1.7-3.7 % in the TUNEL assay whereas the proliferation rate of beta cells ranged from 0.7-2.5 %, as identified by double immunofluorescence staining of Ki67 and insulin. Diabetes manifestation occurring after day 80 showed a prolonged infiltration process of more than 10 days before disease onset. The immune cell infiltrate composition comprised 2/3 CD68 macrophages and only 1/3 CD8 T cells. These infiltrating islets strongly expressed the chemokine Ccl2 especially attracting macrophages into the islets in contrast to islets from the fulminant subform. The proinflammatory cytokine expression pattern showed a strong expression of IL-1 $\beta$  before diabetes manifestation and later on after onset concomitant with the expression of TNF- $\alpha$ . The apoptosis rate was lower than in the fulminant subform with values between 0.8-2.0 % whereas the proliferation rate of beta cells ranged from 0.9-3.2 %.

**Conclusion:** Heterogeneities in the LEW.1AR1-*iddm* rat colony were observed during diabetes development. Animals with a later onset of diabetes showed a milder diabetes form with a high number of surviving beta cells. This subform of the LEW.1AR1-*iddm* rats starting later than day 80 with an infiltration dominated by macrophages and a slower beta cell loss resembles very well the LADA (Latent Autoimmune Diabetes in Adults) subform in human adults developing autoimmune diabetes at an age >35 years. The lower frequency of T cells and the lower expression level of TNF- $\alpha$  in the immune cell infiltrate opens the perspective to develop specific immunomodulatory treatments for the LADA type of autoimmune diabetes.

### Aberrant hypothalamic expression of the master clock gene Per1 at diabetes onset in non-obese diabetic mice

V. Burkart<sup>1</sup>, A. Reinbeck<sup>1,2</sup>, M. Ingenwerth<sup>3</sup>, A. Stahr<sup>3</sup>, H.-J. Partke<sup>1</sup>, C. von Gall<sup>3</sup>, M. Roden<sup>1,4</sup>;

<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf,

<sup>2</sup>Kidney Diseases Research, Bayer Pharma AG, Wuppertal, <sup>3</sup>Institute for

Anatomy II, Heinrich-Heine-University Düsseldorf, <sup>4</sup>Department of Endocrinology and Diabetology, University Clinics Düsseldorf, Germany.

**Background and aims:** Fundamental metabolic and immunological processes follow a circadian periodicity, which is under control of an endogenous rhythm generator in the hypothalamic suprachiasmatic nucleus (SCN). Previous studies demonstrated disturbed rhythmicity of energy metabolism and physical activity in newly diabetic non-obese diabetic (NOD) mice. We therefore hypothesized that the pathogenesis of insulin-deficient diabetes in NOD mice is associated with disturbed expression of the period circadian clock protein homolog 1 (Per1), a master regulator of circadian rhythmicity in the hypothalamus.

**Materials and methods:** Female C57BL6 mice and prediabetic (normoglycaemic) NOD mice (70-80 days old) as well as newly diabetic (< 5 d) NOD mice were kept at a 12-h light / 12-h dark cycle. The physical activity (registered as "counts") and the respiratory exchange rate (RER) of the animals were monitored in an automated modular system for comprehensive metabolic phenotyping. Immunohistochemistry of the SCN was performed to quantify the expression of the master clock gene Per1 and of the transcription factor cFos, which reflects general cerebral activity.

**Results:** C57BL6 mice as well as non-diabetic and newly diabetic NOD mice showed comparable low physical activity during light phases whereas during dark phases diabetic NOD mice showed a two-fold lower activity than C57BL6 and non-diabetic NOD mice ( $p < 0.05$ ). The altered pattern of physical activity of diabetic NOD mice was associated with a constantly decreased RER in the light ( $0.82 \pm 0.01$ ) and dark phases ( $0.83 \pm 0.01$ ) when compared to non-diabetic NOD mice (RER light phase:  $0.88 \pm 0.01$  ( $p < 0.001$ ); RER dark phase:  $0.95 \pm 0.01$  ( $p < 0.001$ )). In non-diabetic NOD mice, hypothalamic expression of Per1 was high (Per1 positive cell nuclei in SCN:  $126 \pm 19$ ) at Zeitgeber (ZT) 14 (2 h after light-on). However, at ZT02 (2 h after light-off) the Per1 expression in these animals did not show the expected reduction that is observed in C57BL6 mice ( $26 \pm 11$ ) but remained elevated ( $108 \pm 14$ ) ( $p < 0.01$ ). In NOD mice, the high levels and the lack of circadian rhythmicity of Per1 expression persisted after the onset of diabetes (ZT14:  $121 \pm 23$ , ZT02:  $97 \pm 19$ ). Higher Per1 expression in NOD mice was associated with a loss of the periodicity of their hypothalamic cFos expression after diabetes onset.

**Conclusion:** In conclusion, the finding of an aberrant hypothalamic expression of the master clock gene Per1 in prediabetic NOD mice points to a role of disturbed circadian rhythmicity during the development of insulin-deficient diabetes in this model of type 1 diabetes.

## 416

### Targeted deletion of SIRT6 in pancreatic beta cells leads to glucose intolerance

M. Song<sup>1</sup>, S. Ka<sup>1</sup>, E. Bae<sup>2</sup>, B. Park<sup>1</sup>;

<sup>1</sup>Biochemistry, Chonbuk National University, Jeonju,

<sup>2</sup>Pharmacy, Woosuk University, Wanju, Republic of Korea.

**Background and aims:** Sirtuin 6 (SIRT6) has emerged as a key regulator of glucose and fatty acid metabolism in liver and adipose tissues. However, the role of SIRT6 in pancreatic beta-cells has not reported. In this study, we examined the physiological role of SIRT6 in pancreatic beta-cell function and systemic glucose homeostasis.

**Materials and methods:** A Cre-LoxP system was used to generate beta-cell-specific SIRT6 knockout (BS6KO) mice. Metabolic and histological analyses were carried out in BS6KO mice as well as littermate controls after normal chow diet (NCD) or high fat diet (HFD) for 16 weeks. Additionally, isolated islets from BS6KO mice were used to investigate the effect of SIRT6 deletion on insulin secretion and beta-cell viability.

**Results:** While their fasting glucose and body weight were comparable with wild-type mice on NCD, BS6KO mice fed the HFD induced more weight gain and exhibited hyperglycemia in both nonfasting and 16-h fasting conditions. Oral glucose tolerance test revealed that BS6KO mice had severe glucose intolerance, which was paralleled by a reduction in insulin-immunoreactive

pancreatic beta-cell mass. Mimicking this, islets from BS6KO mice exhibited profound defects in the glucose-stimulated insulin secretion. On the contrary, normal islets transduced with SIRT6 adenovirus were resistant against cytokine- and lipo-toxicity.

**Conclusion:** In addition to being essential for maintaining glucose homeostasis, SIRT6 is involved in beta-cell function by protecting beta-cells against exogenous insults and thereby maintaining insulin secreting capacity.

## 417

### Glycogen over-accumulation in beta cells affects insulin secretion and glucose homeostasis

J. Mir<sup>1,2</sup>, R. Gasa<sup>2</sup>, J. Duran<sup>1</sup>, R. Gomis<sup>2</sup>, J.J. Guinovart<sup>1</sup>;

<sup>1</sup>Institute for Research in Biomedicine, <sup>2</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain.

**Background and aims:** The presence of detectable amounts of glycogen in  $\beta$ -cells of diabetic patients has led to the notion that excessive glycogen accumulation is involved in glucotoxicity and  $\beta$ -cell dysfunction. However, the causal contribution of  $\beta$ -cell glycogen to the pathophysiology of diabetes remains elusive. The regulatory subunit Protein targeting to glycogen (PTG) induces the dephosphorylation of glycogen synthase, resulting in a hyperactivation of this enzyme and enhanced glycogen buildup. In this study, to directly investigate the effect of increased glycogen storage in  $\beta$ -cells on glucose homeostasis and  $\beta$ -cell function, we have generated a transgenic mouse model over-expressing PTG in these cells.

**Materials and methods:** Mice over-expressing PTG in  $\beta$ -cells ( $\beta$ PTG) were generated by crossing conditional PTG transgenic mice with RIPCre mice. RIPCre littermates were used as controls (Ctrl) in all experiments. Glucose homeostasis was measured by intraperitoneal glucose tolerance test (IP-GTT) and insulin sensitivity test (ITT). Pancreatic insulin positive area was measured by morphometry. Glycogen was detected by PAS staining and by enzymatic methods after precipitation in 66% ethanol and digestion with  $\alpha$ -amylglucosidase. Insulin secretion was measured by static incubation of isolated islets and quantified by ELISA.

**Results:**  $\beta$ PTG mice were born at expected ratios and showed no differences in growth and body weight. PAS staining revealed heterogeneous glycogen accumulation in  $\beta$ -cells.  $\beta$ PTG mice exhibited a mild impairment in glucose tolerance (AUC  $\beta$ PTG vs Ctrl:  $665 \pm 65$  vs  $429 \pm 56$ ,  $p < 0.05$ ) and normal peripheral insulin sensitivity. Random plasma glucose levels were indistinguishable from controls but fasting glycaemia was significantly lower ( $\beta$ PTG vs Ctrl:  $45 \pm 1.3$  mg/dl vs  $55 \pm 2$  mg/dl,  $p < 0.05$ ). Correlating with their mild glucose intolerance, morphometric analysis revealed a 33% reduction in pancreatic insulin positive area in adult  $\beta$ PTG mice relative to controls ( $\beta$ PTG vs Ctrl:  $0.36 \pm 0.01\%$  vs  $0.54 \pm 0.04\%$ ,  $p < 0.01$ ). To address an additional effect of accumulated glycogen on insulin secretion, islets were isolated from  $\beta$ PTG and controls. Insulin content per islet was similar between  $\beta$ PTG and controls:  $500 \pm 49$  ng vs  $470 \pm 35$  ng, NS). Islets isolated from fed ad libitum  $\beta$ PTG mice contained 5-fold more glycogen than controls ( $\beta$ PTG vs Ctrl:  $5.5 \pm 0.4$  ng/islet vs  $1.1 \pm 0.3$  ng/islet,  $p < 0.001$ ) but, after an overnight fasting, glycogen was depleted to undetectable levels in both groups. Strikingly,  $\beta$ PTG islets from fed mice exhibited enhanced glucose-induced insulin secretion (percentage of release relative to insulin content at 16.7mM glucose,  $\beta$ PTG vs Ctrl:  $1.2 \pm 0.15\%$  vs  $0.68 \pm 0.11\%$ ,  $p < 0.05$ ). This improvement was lost after fasting ( $\beta$ PTG vs Ctrl:  $0.57 \pm 0.12\%$  vs  $0.58 \pm 0.11\%$ , NS), suggesting that increased glycogen levels in fed  $\beta$ PTG islets were the reason for the enhanced glucose-induced insulin secretion.

**Conclusion:** Our results support the idea that high glycogen levels may contribute to  $\beta$ -cell loss. Intriguingly, our findings also show that glycogen plays a beneficial role for glucose-induced insulin secretion. These contradictory effects of increased glycogen storage on  $\beta$ -cell physiology expose the possibility that the accumulation of glycogen has a time and/or dose dependent influence on these cells. Further investigations will be needed to define the precise mechanisms and progression of such events.

### Reduction in pancreatic beta cell mass caused by enhanced expression of Cdkn1c via interaction between C/EBP $\beta$ and epigenetic control

Y. Ihara<sup>1</sup>, S.-I. Asahara<sup>2</sup>, H. Inoue<sup>1</sup>, K. Teruyama<sup>1</sup>, T. Matsuda<sup>2</sup>, S. Seino<sup>2</sup>, Y. Kido<sup>1</sup>;

<sup>1</sup>Department of Biophysics,

<sup>2</sup>Kobe University Graduate School of Medicine, Japan.

**Background and aims:** The relationship between pancreatic  $\beta$ -cell mass and the onset and progression of type 2 diabetes mellitus has received a lot of attention in recent years. Our research focused on the Cdkn1c gene, which codes for a cell cycle inhibitor, because it is involved in the regulation of pancreatic  $\beta$ -cell mass. The Cdkn1c gene is an imprinting gene whose expression is controlled by the non-coding RNA Kcnq1ot1. We found that when the expression of Kcnq1ot1 decreased, epigenetic alterations induced an increase in the expression of Cdkn1c, which, in turn, led to a decrease in the pancreatic  $\beta$ -cell mass. We have already reported that the transcription factor C/EBP $\beta$  accumulates in the pancreatic  $\beta$ -cells of high fat-fed mice. It has been reported that a binding motif of C/EBP $\beta$  is present in the Cdkn1c promoter. On the basis of these findings, we hypothesize that the accumulation of C/EBP $\beta$  in pancreatic  $\beta$ -cells with reduced expression of Kcnq1ot1 causes further enhancement of Cdkn1c expression and promotes pancreatic  $\beta$ -cell failure.

**Materials and methods:** C/EBP $\beta$  was overexpressed in MIN6 cells treated with an inhibitor of epigenetic modification. In addition, Kcnq1ot1-truncated C/EBP $\beta$ -overexpressing mice (KT mice) were produced by cross-breeding Kcnq1ot1-truncated mice with pancreatic  $\beta$ -cell-specific C/EBP $\beta$ -overexpressing mice.

**Results:** The findings showed that the expression of Cdkn1c in MIN6 cells was not influenced by the expression level of C/EBP $\beta$ , however, it was enhanced by treatment with an inhibitor of epigenetic modification, and was further enhanced by C/EBP $\beta$  overexpression. Studies using chromatin immunoprecipitation (ChIP) assays have shown that the binding between C/EBP $\beta$  and the Cdkn1c promoter was significantly enhanced during treatment with the inhibitor than under normal conditions. In vivo studies have shown that compared to C/EBP $\beta$ -overexpressing mice and wild-type mice, KT mice show significantly higher blood glucose levels, smaller pancreatic  $\beta$ -cell mass, and enhanced expression of Cdkn1c in the pancreatic islets.

**Conclusion:** The findings suggest that the introduction of epigenetic modifications into MIN6 cells or pancreatic  $\beta$ -cells may lead to enhanced binding of C/EBP $\beta$  to the Cdkn1c promoter, then an increase in the expression levels of Cdkn1c, and a decrease in pancreatic  $\beta$ -cell mass.

## 419

### Tbc1d1 knockout increases glucose-stimulated insulin secretion from isolated mouse pancreatic islets

T. Stermann<sup>1</sup>, F. Neumann<sup>2</sup>, S. Osthold<sup>1</sup>, A. Pujol<sup>3</sup>, F. Bosch<sup>3</sup>, M. Kragl<sup>4,5</sup>, E. Lammert<sup>4,5</sup>, A. Chadt<sup>1</sup>, H. Al-Hasani<sup>1</sup>;

<sup>1</sup>Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, <sup>2</sup>German Institute for Human Nutrition, Potsdam-Rehbruecke, Nuthetal, Germany, <sup>3</sup>Center of Animal Biotechnology and Gene Therapy, Barcelona, Spain, <sup>4</sup>Institute for Beta Cell Biology, German Diabetes Center, <sup>5</sup>Institute for Metabolic Physiology, Düsseldorf, Germany.

**Background and aims:** The GTPase-activating protein TBC1D1 is known to play a crucial role in the translocation process of GLUT4 storage vesicles in skeletal muscle. Previous studies showed the expression of TBC1D1 in the pancreas, while the physiological functions and the differential expression within the pancreas are unknown. In our project we investigate the role of TBC1D1 in mouse pancreatic islets of C57BL/6J mice with  $\beta$ -cell specific overexpression of *Tbc1d1* and with a global knockout for *Tbc1d1*.

**Materials and methods:** To investigate the role of TBC1D1 in isolated mouse pancreatic islets we measured changes in glucose-stimulated insulin secretion (GSIS), palmitate uptake as well as protein and gene expression. Statistics are calculated by two-tailed, unpaired student's t-test.

**Results:** In Western blots TBC1D1 was highly enriched in the pancreatic islets. It could not be detected in *Tbc1d1*-deficient islets. Isolated islets of *Tbc1d1*-deficient mice showed a significant increase in GSIS ( $1012.06 \pm 137.65$  % vs.  $1593.36 \pm 229.47$  %,  $n=7$ ,  $p=0.03$ ). In contrast, isolated islets which overexpress *Tbc1d1* did not show any changes in insulin secretion ( $625.87 \pm 147.68$  % vs.  $597.10 \pm 164.93$  %,  $n=7$ ,  $p=0.67$ ). In addition, <sup>14</sup>C-palmitate uptake in isolated islets from *Tbc1d1*-deficient mice ( $n=6$ ) and cul-

tivated MIN6 cells after *Tbc1d1* knockdown (n=5) was significantly increased compared to respective controls ( $0,9 \pm 0,038$  fmol  $\times$  min<sup>-1</sup>  $\times$  islet<sup>-1</sup> vs.  $1,28 \pm 0,069$  fmol  $\times$  min<sup>-1</sup>  $\times$  islet<sup>-1</sup>, p<0.05 and  $0,994 \pm 0,039$  pmol  $\times$  min<sup>-1</sup>  $\times$  mg<sup>-1</sup> protein vs.  $1,251 \pm 0,057$  pmol  $\times$  min<sup>-1</sup>  $\times$  mg<sup>-1</sup> protein, p<0.01, respectively). Gene expression analysis of *Tbc1d1* knockout islets revealed the significant up-regulation of *Tbc1d4* and fatty acid receptors *Ffar3*, *Gpr119* and *Gpr120* (n=8), genes responsible for cellular lipid sensing.

**Conclusion:** We showed the enriched expression of TBC1D1 in mouse pancreatic islets compared to the exocrine tissue. The significant increase in glucose-stimulated insulin secretion of *Tbc1d1*-deficient islets demonstrates a stimulatory effect of *Tbc1d1*-deficiency. The increased <sup>14</sup>C-palmitate uptake in *Tbc1d1*-deficient islets might indicate a function for TBC1D1 in the regulation of lipid metabolism, presumably by regulating expression, transport or activity of fatty acid receptors and transporters. In a physiological context we assume that *Tbc1d1*-deficiency beneficially compensates for insulin resistance and has a protective effect on lipid overload.

### 420

#### Glucose-induced ATP generation in alpha and beta cells matches the control ranges for glucagon and insulin release

J. Li, Q. Yu, A. Tengholm, E. Gylfe;  
Medical Cell Biology, Uppsala, Sweden.

**Background and aims:** ATP is a crucial signal in glucose-stimulated insulin secretion, coupling metabolism to depolarization by blocking ATP-sensitive K<sup>+</sup> channels. ATP has been attributed various roles also in models of glucose-regulated glucagon release, but consensus about mechanisms is still lacking. The aim of the present study was to clarify whether glucose-induced ATP generation in  $\alpha$ -cells differs from that in  $\beta$ -cells in a manner consistent with a role in signal transduction of glucagon secretion. Since Ca<sup>2+</sup> is a major trigger of islet hormone secretion we also determined the relationship between Ca<sup>2+</sup> and ATP.

**Materials and methods:** Islets from transgenic GLU-RFP mice, expressing red fluorescent protein (RFP) in the  $\alpha$ -cells, or from normal C57BL/6 mice were transduced with adenovirus expressing the ATP biosensor Perceval. Total internal reflection fluorescence (TIRF) microscopy was used to monitor the sub-plasma membrane ATP concentration ([ATP]<sub>pm</sub>) in superficial islet cells. [Ca<sup>2+</sup>]<sub>pm</sub> was recorded simultaneously using the indicators Fluo-4 or Fura Red. The identity of islet cells were determined by immunostaining and/or cell-characteristic [Ca<sup>2+</sup>]<sub>pm</sub> responses.

**Results:** Elevating the glucose concentration from 3 to 20 mM induced  $\beta$ -cell-typical responses with slow [ATP]<sub>pm</sub> oscillations that were synchronized among RFP-negative cells in the islets from GLU-RFP mice. However, the RFP-positive  $\alpha$ -cells showed erratic reactions indicative of molecular interference between Perceval and RFP. We therefore analyzed [ATP]<sub>pm</sub> in normal mouse islets, identifying  $\alpha$ - and  $\beta$ -cells by cell-characteristic [Ca<sup>2+</sup>]<sub>pm</sub> responses to low and high glucose as well as to glutamate. Glucose elevation from 1 to 5 mM, which inhibits glucagon release, induced small increases in average [ATP]<sub>pm</sub> in both  $\alpha$ - ( $6 \pm 2\%$  increase of Perceval fluorescence) and  $\beta$ -cells ( $9 \pm 1\%$ ). Subsequent elevation to 20 mM glucose, which stimulates insulin secretion, resulted in a much less pronounced increase of [ATP]<sub>pm</sub> in  $\alpha$ - than in  $\beta$ -cells ( $12 \pm 3\%$  versus  $49 \pm 2\%$  above the initial baseline). However, the  $\alpha$ -cell response was left-shifted since [ATP]<sub>pm</sub> at 5 mM glucose was 45% of that at 20 mM as compared to 19% in the  $\beta$ -cells. At 3 mM glucose [ATP]<sub>pm</sub> was stable in  $\beta$ -cells but showed irregular oscillations in  $\alpha$ -cells that were antiparallel to oscillations of [Ca<sup>2+</sup>]<sub>pm</sub>. At 20 mM both  $\alpha$ - and  $\beta$ -cells showed [ATP]<sub>pm</sub> oscillations that were antiparallel to those of [Ca<sup>2+</sup>]<sub>pm</sub>.

**Conclusion:** [ATP]<sub>pm</sub> shows a left-shifted glucose dependence in  $\alpha$ -cells as compared to  $\beta$ -cells, consistent with ATP involvement in glucose-inhibited glucagon release. [Ca<sup>2+</sup>]<sub>pm</sub> oscillations in both cell types are antiparallel to those of [ATP]<sub>pm</sub> probably reflecting energy-requiring Ca<sup>2+</sup> transport.

### 421

#### Biphasic nature of glucose-induced insulin secretion is independent on energy metabolism

A.I. Tarasov, J. Galvanovskis, F. Leenders, P. Rorsman;  
OCDEM, Oxford, UK.

**Background and aims:** Insulin secretion in vivo is biphasic but the underlying mechanisms remain enigmatic. Many intracellular processes have been reported to follow an oscillatory/biphasic pattern and have thereby been implicated as regulators of insulin release kinetics. In particular, the sustained second phase of insulin secretion has been suggested to be driven by beta-cell energy metabolism. However the efforts to dissect the relationship between the oxidative metabolism and insulin secretion have been hampered by the lack of reliable technology for analysing both processes in real-time.

**Materials and methods:** We resolved the two phases of insulin secretion in intact mouse islets using high-resolution 3-D multiphoton confocal imaging with polar tracers. Cytosolic ATP/ADP ratio (using a recombinant probe Perceval) or Ca<sup>2+</sup> levels ([Ca<sup>2+</sup>]<sub>i</sub>, using trappable dyes) were recorded in parallel with secretion to correlate energy metabolism and intracellular signalling events to insulin granule exocytosis.

**Results:** Exocytosis in pancreatic beta-cells was triggered by the glucose-induced elevation of cytosolic ATP and Ca<sup>2+</sup> influx into the cytosol. Insulin secretion correlated strongly with changes in [Ca<sup>2+</sup>]<sub>i</sub> but showed little correlation with bi-phasic kinetics of ATP increases. Other substrates of oxida-

tive metabolism affecting cytosolic ATP/ADP levels, such as amino acids or methyl succinate, had no effect on the second phase of secretion. At the same time, changes in  $[Ca^{2+}]_i$  show a strong temporal correlation with exocytosis. The effects of  $[Ca^{2+}]_i$  on insulin exocytosis were potentiated by agents producing an elevation of intracellular cAMP (like GLP-1).

**Conclusion:** These findings illustrate the power of on-line high-resolution monitoring of multiple parameters in living systems. Our data suggest a hierarchy of intracellular signalling events in the control of insulin secretion. We propose that insulin release kinetics is principally determined by variations of signalling events (including  $[Ca^{2+}]_i$ ) rather than energy metabolism. The latter is likely to play the triggering role but the temporal fine-tuning is exerted via more distal events.

### Identification of Rab27a-GAP-interacting proteins and its functional analysis in pancreatic beta cells

M. Yamaoka<sup>1</sup>, T. Ando<sup>1</sup>, M. Okamoto<sup>1</sup>, T. Terabayashi<sup>1</sup>, K. Matsunaga<sup>2</sup>, R. Ishizaki<sup>2</sup>, T. Izumi<sup>2</sup>, I. Niki<sup>1</sup>, T. Ishizaki<sup>1</sup>, T. Kimura<sup>1</sup>;

<sup>1</sup>Pharmacology, Oita University, Faculty of Medicine, Yufu, <sup>2</sup>Laboratory of Molecular Endocrinology and Metabolism, Department of Molecular Medicine, Institute for Molecular and Cellular Regulation, Gunma University, Maebashi, Japan.

**Background and aims:** Membrane trafficking is crucial for the regulation of the size of the readily releasable pool of insulin granules and for the recovery of insulin secretory membranes. Rab27a, which is a member of the Rab family, have been considered to control of pre-exocytosis in pancreatic-beta cells through its GTP-dependent effectors. In contrast, the GDP-bound form has been regarded as an inactive form, because the functional binding partner of this form has not been identified. We previously identified coronin 3 as a novel GDP-dependent effector of Rab27a in pancreatic beta-cells. Moreover, we found that the insulin secretagogue glucose caused a shift from the GTP- to GDP-bound Rab27a via Rab27a-GAP, resulting in the regulation of endocytosis of insulin secretory membranes. Taken together, GTP- and GDP-bound Rab27a regulates insulin secretion at the pre-exocytotic and the endocytotic stages, respectively. In the present study, we investigated the underlying mechanisms by which Rab27a-GAP controls endocytosis of insulin secretory membranes in pancreatic beta-cells.

**Materials and methods:** Affinity column chromatography was performed to identify Rab27a-GAP interacting proteins. Extracts from the insulin-secreting beta-cell line, MIN6, were loaded onto glutathione-sepharose 4B beads coated with GST-Rab27a-GAP. The proteins bound to the columns were eluted and were analyzed by peptide mass fingerprinting. For binding assay, immunoprecipitation analysis was performed using COS7-cells expressing Rab27a-GAP. For the observation of the intracellular localization of Rab27a-GAP and Arf6-GEF, MIN6-cells were analyzed with a TIRF microscopy system or a confocal laser microscopy system.

**Results:** We identified Arf6-GEF as a Rab27a-GAP interacting protein. Arf6-GEF is a guanine nucleotide exchange factor that converts Arf6 from the GDP- to the GTP-bound form, resulting in the regulation of endocytosis through clathrin-coated vesicle formation. We found that Rab27a-GAP directly interacted with Arf6-GEF. The C-terminal region of Rab27a-GAP bound the PH domain of Arf6-GEF. Glucose stimulation induced the redistribution of both Rab27a-GAP and Arf6-GEF to the vicinity of the plasma membrane. Silencing of Arf6-GEF inhibited the glucose-induced redistribution of Rab27a-GAP. In contrast, the redistribution of Rab27a-GAP did not occur in Arf6-GEF-silencing cells.

**Conclusion:** These results indicate that Arf6-GEF is required for the glucose-induced redistribution of Rab27a-GAP. We previously reported that GDP-bound Rab27a regulates the retrograde transport of the internalized secretory membrane, the stage after the GTP-bound Arf6-dependent formation of clathrin-coated vesicles. We therefore propose a model where Rab27a-GAP is involved in both Rab27a and Arf6 signaling and plays a pivotal role in membrane trafficking for insulin secretion.

### Temperature-dependent effects of high glucose and potassium depolarisation on insulin granule mobility and exocytosis in insulin-secreting MIN6 cells

K. Schumacher<sup>1</sup>, M. Matz<sup>2</sup>, K. Baumann<sup>2</sup>, I. Rustenbeck<sup>1</sup>;

<sup>1</sup>Institute of Pharmacology and Toxicology, <sup>2</sup>Institute of Medicinal and Pharmaceutical Chemistry, University of Braunschweig, Germany.

**Background and aims:** It is widely assumed that the first phase of glucose-induced insulin secretion can be mimicked by  $K^+$  depolarization. We found, however, that the insulinotropic efficacy was differently affected by lowering the temperature. We thus compared parameters of insulin granule mobility and secretion during glucose stimulation and  $K^+$  depolarization at different temperatures.

**Materials and methods:** Insulin granules were labeled by transient transfection with insulin-EGFP and the granules present in the submembrane space were imaged by TIRF microscopy. Single MIN6 cells were continuously perfused with oxygenated HEPES-buffered Krebs-Ringer medium containing the respective stimuli at 37 °C, 32 °C, and 22 °C. The image files (1 sequence = 200 images) were evaluated by an in-house written program. The insulin secretion of MIN6 pseudo-islets was measured by perfusion with ELISA of the fractionated efflux.

**Results:** At 37 °C stimulation of the perfused MIN6 pseudo-islets with 30 mM glucose and, after a wash-out period of 10 minutes, 40 mM  $K^+$  increased insulin secretion.  $K^+$  was about twofold more effective than glucose. At 32 °C,  $K^+$  was even more effective than at 37 °C, and was markedly but only transiently effective at 22 °C. Relative to  $K^+$ , glucose lost efficacy at 32 °C and was virtually ineffective at 22 °C. When the stimuli were applied in the reversed sequence  $K^+$  was of unchanged efficacy, but glucose was almost ineffective at all temperatures. The same experimental protocol was used to measure the mobility of insulin granules in the submembrane space of perfused single MIN6 cells. Under control conditions (3 mM glucose, 37 °C), the mean number of submembrane granules was  $357 \pm 37$  per cell footprint at the beginning of image acquisition.  $33.5 \pm 1.4$  % of these remained visible throughout the sequence (long-term residents). Newly arrived granules made up  $8.9 \pm 0.6$  % per image, equivalent to about 32 granules. The number of departing granules closely mirrored that of arriving granules (mobility in the z-dimension). The short-term residents (present for  $\leq 1$  s) amounted to  $82.2 \pm 0.9$  % of the total number of granules ( $7547 \pm 928$ ) in a sequence. At all temperatures stimulation with glucose and  $K^+$  led to an increase in the number of arriving and departing granules, independent of the sequence of exposure. Consequently, the total number of granules per sequence was increased during phases of stimulation. The caging diameter (mobility in the x/y-dimension) in contrast, decreased during glucose- and  $K^+$ -stimulation at 37 °C, but not at 32 °C and 22 °C. The number of the long-term resident granules was similar for all three temperatures at basal glucose and when 40 mM  $K^+$  was applied first. However, when 30 mM glucose was applied first the number remained stable at 37 °C in contrast to a steady decline at 32 °C and 22 °C.

**Conclusion:** At all temperatures, glucose and  $K^+$  depolarization enhance the granule turnover in the submembrane space. This characteristic fits to  $K^+$ -induced secretion, whereas the temperature-dependency of the caging diameter and of the long-term resident granules reflects the secretion pattern of the glucose stimulus when it is applied first. Additionally, glucose-induced secretion is associated with limited lateral mobility and/or longer presence of the granules at the plasma membrane.

## 424

### CaMKII-mediated metabolite memory of pancreatic beta cells controls insulin secretion and is inhibited by palmitate

G.J. Santos<sup>1,2</sup>, S.M. Ferreira<sup>1</sup>, F. Ortis<sup>1</sup>, L.F. Rezende<sup>1</sup>, A.C. Dias<sup>1</sup>, E.M. Carneiro<sup>1</sup>, K.H. Kaestner<sup>2</sup>, A.C. Boscherio<sup>1</sup>, T.R. Nardeli<sup>1</sup>;

<sup>1</sup>Department of Anatomy, Cell Biology and Physiology and Biophysics, State University of Campinas, Brazil, <sup>2</sup>Department of Surgery and Institute for Diabetes, Obesity and Metabolism, University of Pennsylvania, Philadelphia, USA.

**Background and aims:**  $Ca^{2+}$ /calmodulin-dependent protein kinase II (CaMKII) functions both in regulation of insulin secretion and neurotransmitter release through common downstream mediators. Memory is the ability to acquire, to store and to evoke any kind of information. In CNS, the process behind this phenomenon in the Long-Term Potentiation (LTP) and is known

that it requires  $\text{Ca}^{2+}$  to occur. In addition, CaMKII is necessary to store information during LTP. In pancreatic  $\beta$ -cells, CaMKII plays pivotal role during GSIS process. Palmitate is a Saturated-fatty-acid-induced important for beta cell metabolism, especially during DM2 onset. It is well known that palmitate inhibits glucose-induced CaMKII phosphorylation and potentiates GSIS. Therefore, we investigate that pancreatic  $\beta$ -cells acquire and store the information as a form of "metabolic memory", just as neurons store cognitive information, and, that palmitate inhibits this process.

**Materials and methods:** To test this hypothesis, we developed a novel paradigm of pulsed exposure of mice and human  $\beta$ -cells to intervals of high glucose, followed by a 24-hour consolidation period to eliminate any acute metabolic effects. After this period, we analyzed insulin secretion (by RIA), protein expression (by Western blot), response to a glucose-ramp and the glucose-induced  $\text{Ca}^{2+}$  influx.

**Results:** Strikingly,  $\beta$ -cells exposed to this high-glucose pulse paradigm exhibited significantly stronger insulin secretion. This metabolic memory was entirely dependent on CaMKII and was inhibited by Palmitate. We also observed, in pulse group, an increase in  $\text{Ca}^{2+}$  influx induced by glucose. In addition, metabolic memory was reflected on the protein level by increased expression of proteins involved in GSIS and  $\text{Ca}^{2+}$ -dependent vesicle secretion, such as GSK, Cav1.2, SNAP25, pCaMKII and pSynapsin. Finally, we observed in human islet elevated levels of the key  $\beta$  cell transcription factor MAFA.

**Conclusion:** In summary, like neurons, human and mouse  $\beta$ -cells are able to acquire and retrieve information in a process dependent on CaMKII that is inhibited by palmitate.

## 425

### Islet microcapillary endothelial cells secrete an attenuating factor of insulin secretion

S. Sasson<sup>1</sup>, B. Daniel<sup>1</sup>, A. Livne<sup>1</sup>, K. Nurit<sup>2</sup>, G. Cohen<sup>1</sup>;

<sup>1</sup>Pharmacology, <sup>2</sup>Medicine, Hadassah-Hebrew University School of Medicine, Jerusalem, Israel.

**Background and aims:** Paracrine interactions and chemotactic signals exchanged within islet of Langerhans' endothelium and the endocrine cells have been proven critical for the development and organization of functional islet units. Moreover, autocrine and paracrine signals within the microenvironment of the islets can also modulate  $\beta$ -cell glucose-stimulated insulin secretion (GSIS). For instance, it has been shown that several extra-cellular matrix components, derived from islets' microcapillary endothelium (IME), regulate  $\beta$ -cell spreading and amplify insulin secretion. We aimed at investigating whether IME secrete other soluble factors that affect  $\beta$ -cell function and viability.

**Materials and methods:** Conventional conditioned-medium (CM) from IME (the MS-1 cell line and primary cultures of endothelial cells from rat islets) were prepared to study contact-independent IME- $\beta$ -cell interactions. Standard GSIS assay in the absence or presence of insulin secretagogues was employed. In addition, cell viability assays (cell count, MTT assay and annexin/PI flow cytometry) and size-based fractionation of the CM were performed.

**Results:** Our data show that IME-derived CM contained soluble factor(s) that markedly attenuated GSIS from both INS-1E  $\beta$ -cell line and freshly isolated rat islets. Fractionation of the CM indicated that the active factor was a high molecular weight protein. This factor reduced GSIS without changing the rate of insulin biosynthesis, cell viability and cellular ATP content. Using the insulin secretagogues IBMX, KCl, tolbutamide and L-arginine, we found that only the second phase of insulin secretion was markedly reduced by the CM. This was accompanied with a significant decrease in cellular cAMP level following glucose stimulation. Furthermore, mass spectrometric analysis of several high molecular weight proteins in the active CM fraction are currently being analysed to identify the active attenuating factors of GSIS.

**Conclusion:** These findings support the hypothesis that a paracrine interaction between IME and  $\beta$ -cells modulates glucose-dependent insulin release and may contribute to maintaining glucose homeostasis.

### Glucose-stimulated insulin secretion is reduced after treatment with rosuvastatin calcium

V.A. Salunkhe, O. Elvstam, J.L.S. Esguerra, L. Eliasson, J. Vikman, A. Wendt;

Diabetes Centre, Islet Cell Exocytosis, Clinical Research Centre, Lund University, Malmö, Sweden.

**Background and aims:** Statins are a family of drugs widely used to reduce the risk of cardiovascular disease by lowering the cholesterol levels. Rosuvastatin calcium (RS) is one of these highly prescribed statins and there are studies suggesting increased risk of diabetes for subjects on RS therapy. Whether RS influences insulin secretion from the beta-cell is yet to be established, but our group has previously shown that insulin secretion is highly sensitive to changes in plasma membrane cholesterol. Here, we aim to investigate the effects of RS on insulin secretion, exocytosis and  $\text{Ca}^{2+}$  influx through voltage-dependent  $\text{Ca}^{2+}$  channels in pancreatic beta-cells.

**Materials and methods:** The study was performed in INS-1 832/13 cells. These cells were treated with different concentrations of RS (20 nM, 200 nM, 2  $\mu\text{M}$  and 20  $\mu\text{M}$ ) for various time spans (24/48 hour (h) and 1/2 month). Insulin secretion at 2.8 and 16.7 mM glucose (G) was measured by radioimmunoassay. Exocytosis was detected as changes in membrane capacitance evoked by a train of 10 depolarizations from -70 mV to 0 mV using whole-cell patch-clamp configuration.

**Results:** First we studied influence on glucose-stimulated insulin secretion (GSIS) in INS-1 832/13 cells treated with above mentioned concentrations of RS for 48 h. In cells treated with 200 nM, 2  $\mu\text{M}$  and 20  $\mu\text{M}$  RS insulin secretion at 16.7 mM G was significantly reduced (26%, 35% and 29% reduction;  $p < 0.05$ ;  $p < 0.01$  and  $p < 0.001$  vs control, respectively;  $n = 3-4$ ). Moreover, in cells treated with 2  $\mu\text{M}$  and 20  $\mu\text{M}$  RS insulin secretion at 2.8 mM G increased significantly (67% and 165% increase;  $p < 0.05$  and  $p < 0.01$  respectively) and there was a significant reduction in total protein content (25% and 50% reduction,  $p < 0.05$  and  $p < 0.001$  respectively) compared to control. The lowest concentration of RS tested had no effect on insulin secretion at 2.8 and 16.7 mM G. We then studied exocytosis in INS-1 832/13 cells treated for 24-48 h with the RS concentrations mentioned above. There was no significant difference in exocytosis in cells treated with the lower concentrations of RS as compared to control. However, in cells treated with 20  $\mu\text{M}$  RS exocytosis and voltage-dependent  $\text{Ca}^{2+}$  current evoked by the first depolarization were significantly reduced (34% and 41% reduction,  $p < 0.05$  and  $p < 0.05$  vs control, respectively;  $n = 29-30$ ). Hence, it is tempting to speculate that RS at 20  $\mu\text{M}$  reduces exocytosis by altering properties of the voltage-dependent  $\text{Ca}^{2+}$  channels. In order to examine long term effects INS-1 832/13 cells were treated with 20 nM RS for 1 and 2 month. Subsequently, insulin secretion assay was performed but no significant change in insulin secretion was observed compared to control at this low concentration.

**Conclusion:** We conclude that RS, dose dependently reduces GSIS in INS-1 832/13 cells within 48 h. Thus, our data suggest that RS treatment might impair insulin secretion. Future experiments in *in vivo* and primary cells will further clarify if this indeed is the case.

### Improvement of glucose-stimulated insulin secretion by heparan sulfate proteoglycan syndecan-4 overexpression in mouse pancreatic beta cell line

I. Takahashi, S. Takahashi, Y. Soma, H. Kato, C. Tega, H. Kinoshita, K. Nata; Dept. of Med. Biochem., Iwate med. Univ. Sch. of Pharm., Shiwa-gun, Japan.

**Background and aims:** Heparan sulfate proteoglycans (HSPGs) are composed of a core protein to which extracellular glycosaminoglycan chains are attached. Syndecan-4 (Sdc4), one of the major heparan sulfate (HS)-containing core protein, is distributed on the cell surface, where it interacts with various proteins, including growth factors, morphogens and extracellular matrix components to regulate their signaling. We recently found that HS is localized exclusively around beta-cells in the islets of adult mice and is required for islet morphogenesis, beta-cell proliferation and insulin secretion. Furthermore, we found that the 3-O-sulfate groups of HS and Sdc4 are necessary for maintaining normal glucose-stimulated insulin secretion (GSIS), confirmed these results with RNA interference experiments. In this study, we attempted

to overexpress the core protein Sdc4 and to clarify the contribution of Sdc4 to beta-cell function.

**Materials and methods:** Subcloning of MIN6 cells, mouse pancreatic beta-cell line, was performed by the limiting dilution method. The cells were then screened and selected by an index of GSIS, KCl-induced insulin secretion, HS expression and mRNA expression of Sdc4. A stable transformant expressing the mouse Sdc4 was established by transfecting pCMV-mSDC4 and selected with hygromycin B. The stable transformant expressing the highest level of Sdc4 mRNA (by quantitative RT-PCR analysis) was used for further experimentation. GSIS activity was measured with a basal (2.8 mM) or stimulatory (11.2 or 25 mM) glucose concentrations.

**Results:** MIN6 cells were subcloned, and 30 clones were obtained. Two sublines were selected for this study, designated T3 and T16. T3 cells exhibit GSIS in a concentration-dependent manner, whereas T16 cells respond poorly to glucose. In the presence of KCl, T16 cells secreted almost the same amount of insulin as T3. Next, the expression of HS in these subclones was analyzed by western blot analysis. Immunoblot with anti-HS antibody showed a single band of 35 kDa, consistent with the reported size of the Sdc4, was detected in T3 cells. On the other hand, HS was not detected in T16 cells. In addition, the mRNA of Sdc4 was detected in T3 cells by RT-PCR analysis, while not detected in T16 cells. In Sdc4 overexpressed T16 (T16/mSdc4) cells, insulin secretory response exhibited 3.1-fold ( $p < 0.0001$ ) as glucose was increased from 2.8 to 25 mM; while, non-transfected (control) T16 cells exhibited 1.3-fold. Moreover, in Sdc4 overexpressed T3 (T3/mSdc4) cells, insulin secretory response exhibited 22.1-fold ( $p < 0.0001$ ) as glucose was increased from 2.8 to 11.2 mM; while, control T3 cells exhibited 2.7-fold ( $p < 0.005$ ).

**Conclusion:** Our data indicate that HSPG Sdc4 plays important role(s) in the glucose-stimulated insulin secretory response. However, there exists the difference in glucose responsiveness between T16/mSdc4 and T3/mSdc4 cells compared with control cells. These results indicate that it is necessary to consider the effect of HS chains covalently attached to the Sdc4 in addition to the overexpressed Sdc4.

## PS 019 Cytokine-induced beta cell death

### A combined „omics“ approach identifies NMI as a novel cytokine-induced regulator of IRE1 $\alpha$ and JNK in pancreatic beta cells

F. Brozzi<sup>1</sup>, S. Gerlo<sup>2,3</sup>, F.A. Grieco<sup>1</sup>, S. Lievens<sup>2,3</sup>, C. Gysemans<sup>4</sup>, L. Marselli<sup>5</sup>, P. Marchetti<sup>5</sup>, C. Mathieu<sup>4</sup>, J. Tavernier<sup>2,3</sup>, D.L. Eizirik<sup>1</sup>;

<sup>1</sup>Laboratory of Experimental Medicine and ULB Centre for Diabetes Research, Université Libre de Bruxelles, <sup>2</sup>Department of Medical Protein Research, VIB, Gent, <sup>3</sup>Department of Biochemistry, Ghent University, <sup>4</sup>Laboratory of Clinical and Experimental Endocrinology, KU Leuven, Belgium, <sup>5</sup>Department of Clinical and Experimental Medicine, Islet Cell Laboratory, University of Pisa, Italy.

**Background and aims:** Type 1 diabetes (T1D) is an autoimmune disease with a strong inflammatory component. The cytokines interleukin-1 $\beta$  (IL-1) and interferon- $\gamma$  (IFN) induce endoplasmic reticulum stress and the unfolded protein response (UPR) and contribute to beta cell apoptosis in T1D. IRE1 $\alpha$ , one of the UPR mediators, triggers insulin degradation and inflammation in beta cells and is critical for the transition from “physiological” to “pathological” UPR. The mechanisms regulating cytokine-induced IRE1 $\alpha$  activation in beta cells remain to be clarified. To identify novel cytokine-induced regulators of IRE1 $\alpha$  we presently combined MAPPIT (Mammalian Protein-Protein Interaction Trap)-based IRE1 $\alpha$  interactome with functional genomics analysis of beta cells exposed to IL-1 + IFN.

**Materials and methods:** By using ArrayMAPPIT, which identifies proteins that bind to the cytoplasmic domain of IRE1 $\alpha$ , we identified 31 putative IRE1 $\alpha$ -interacting proteins. These results were compared against our microarray and RNA sequencing data from INS-1E cells, FACS-purified rat beta cells and human islet cells exposed to IL-1 + IFN to identify IRE1 $\alpha$ -interacting proteins whose expression is modified by cytokines. Among the top 5 candidates, N-myc interactor (NMI) was chosen as the most promising cytokine-regulated IRE1 $\alpha$ -interacting protein. RNA interference was used to knockdown (KD) NMI in rat pancreatic beta cells and human islets and histological studies were done in pancreatic sections from non-obese diabetic (NOD) mice.

**Results:** Binary MAPPIT and immunoprecipitation confirmed NMI-IRE1 $\alpha$  interaction in rodent beta cells. NMI interacted with IRE1 $\alpha$  WT as well as with the kinase-defective K599A mutant IRE1 $\alpha$ , indicating that NMI-IRE1 $\alpha$  interaction is independent of IRE1 $\alpha$  activation. An increased expression of NMI was detected in islets from NOD mice with insulinitis, and in rodent or human beta cells exposed in vitro to IL-1 + IFN (between 3-10 fold increase;  $p < 0.05$  and  $p < 0.01$ ;  $n = 3-5$ ). NMI KD increased by 50% JNK phosphorylation ( $p < 0.001$ ;  $n = 4$ ), and increased cytokine-induced apoptosis by >10% ( $p < 0.05$ ;  $n = 4-7$ ) in rodent and human pancreatic beta cells after 24-48 h. Mechanistic studies demonstrated that NMI negatively modulates IRE1 $\alpha$ -dependent activation of JNK via the IRE1 $\alpha$ / TRAF2/ MKK7 pathway. Indeed, double KD of NMI with IRE1 $\alpha$ , TRAF2 or MKK7 significantly ( $p < 0.05$ - $p < 0.001$ ;  $n = 4$ ) reverted the effects of NMI KD on JNK activation and/or apoptosis.

**Conclusion:** By using a combined omics approach, we identified NMI induction as a novel negative feedback mechanism that decreases IRE1 $\alpha$ -dependent activation of JNK and apoptosis in cytokine-exposed beta cells.

### LATS2 controls beta cell apoptosis by regulating the MOB1-Praja2 axis

T. Yuan<sup>1</sup>, J. Kerr-Conte<sup>2</sup>, A. Ardestani<sup>1</sup>;

<sup>1</sup>Center for Biomolecular Interactions, Bremen, Germany,

<sup>2</sup>Thérapie Cellulaire du Diabète, Lille, France.

**Background and aims:** Apoptosis is the hallmark of loss of insulin-producing  $\beta$ -cells in both type of diabetes. We have recently identified Mammalian Sterile 20-like kinase 1 (MST1) as a key regulator of  $\beta$ -cell death and dysfunction in diabetes. On search for endogenous down-stream molecule(s) that mediate MST1 activation, we detected expression of the Large tumor suppressor 2 (LATS2) in  $\beta$ -cells whose activation was found under diabetic conditions. LATS2 is a serine threonine kinase and direct down-stream substrate of MST1, which plays an important role in regulating cell proliferation and apoptosis. So far, the role of LATS2 in the  $\beta$ -cell; whether LATS2 is activated

in diabetes and whether such activation triggers  $\beta$ -cell death, are not known and is investigated in this study.

**Materials and methods:** Isolated human islets and the rat  $\beta$ -cell line INS1 were exposed to a diabetic milieu (IL-1 $\beta$ /IFN $\gamma$  or increased glucose concentration (22.2 mM)). Bcl-xL, MOB1 (LATS2-associated protein), Ring-E3 lygase Praja2 (MOB1 negative regulator) and  $\beta$ -cell apoptosis (Caspase 3 & PARP cleavage) were analyzed by Western blotting. Praja2 and Bcl-xL expression were also analyzed by real-time PCR. LATS2 was overexpressed by plasmid transfection, LATS2 inactivation was performed by overexpressing dominant-negative LATS2 (dn-LATS2) or specific siRNA to LATS2. Bcl-xL turnover was performed in HEK 293 cells overexpressing Bcl-xL and LATS2.

**Results:** LATS2 was activated in human islets and INS1 cells exposed to IL-1 $\beta$ /IFN $\gamma$  or increased glucose concentrations. This correlated with MOB1 up-regulation, decreased Praja2 expression and increased  $\beta$ -cell apoptosis. Overexpression of LATS2 itself increased MOB1 levels and  $\beta$ -cell apoptosis in INS1 cells and human islets indicating that LATS2 alone is sufficient to promote  $\beta$ -cell death. MOB1 interacts with and activates LATS2 kinase activity. Interestingly, MOB1 co-precipitation with LATS2 was increased in the presence the diabetic milieu compared to untreated INS1 cells suggesting that MOB1 is essential for the higher LATS2 activity under diabetic conditions. LATS2 overexpression in INS1 cells as well as in Bcl-xL-overexpressing HEK293 cells decreased mitochondrial anti-apoptotic protein Bcl-xL without changes in Bcl-xL mRNA levels; this suggested that the decrease in Bcl-xL expression occurred at a post transcriptional level and mediated the pro-apoptotic function of LATS2. Reciprocally, inhibition of endogenous LATS2 activity by siRNA knockdown or overexpression of dominant negative LATS2 protects  $\beta$ -cells from gluco- and cytokine-induced apoptosis demonstrated by decreased caspase-3- and PARP-cleavage as well as increased Bcl-xL levels. LATS2 knockdown down-regulated MOB1 and restored Praja2 levels under diabetic conditions in INS1 cells indicating a major role of MOB1 and Praja2 in the mechanism of stress-induced  $\beta$ -cell apoptosis. Our results indicate that LATS2, MOB1 and Praja2 regulate each other and may be a component of the previously uncharacterized stress-sensitive apoptotic pathway. Under normal conditions, Praja2 promoted cell survival by degrading MOB1 and then inhibiting LATS2 action, but prolonged diabetogenic stress decreased Praja2 expression, which allowed higher MOB1 levels and pro-apoptotic LATS2 signaling.

**Conclusion:** Our results show that LATS2 plays an important role in  $\beta$ -cell apoptosis and its inhibition may provide a new strategy to restore  $\beta$ -cell survival in diabetes.

### Identification of the ubiquitin ligase SCF(FBW7) as a novel regulator of the NF- $\kappa$ B pathway in pancreatic beta cells

K. Meyerovich<sup>1</sup>, M. Fukaya<sup>1</sup>, L.F. Terra<sup>2</sup>, D.L. Eizirik<sup>1</sup>, A.K. Cardozo<sup>1</sup>;

<sup>1</sup>Université Libre de Bruxelles, Belgium,

<sup>2</sup>Universidade de São Paulo, Brazil.

**Background and aims:** Activation of the transcription factor NF- $\kappa$ B by pro-inflammatory cytokines contributes to  $\beta$ -cell demise in animal models of type 1 diabetes (T1D). Thus, understanding on how NF- $\kappa$ B is activated, is crucial to prevent  $\beta$ -cell death. SCF(FBW7) is an ubiquitin ligase with three isoforms, localised in the nucleolus, nucleus, and cytosol. It has been previously reported that FBW7 positively contributes to NF- $\kappa$ B activity in cancerous cells. The aim of this study was to evaluate whether FBW7 modulates NF- $\kappa$ B activation and survival of pancreatic  $\beta$ -cells.

**Materials and methods:** Specific siRNAs were used to downregulate FBW7 and  $\beta$ TrCP expression. Overexpression of FBW7 was carried out with plasmid encoding FBW7. Cell viability was assessed by the DNA-binding dyes Propidium Iodide and Hoechst 33342. NF- $\kappa$ B activity was measured using a luciferase reporter assay. mRNA expression of NF- $\kappa$ B-dependent genes, FBW7 and  $\beta$ TrCP was quantified by qPCR, while the proteins regulating NF- $\kappa$ B activation were analysed by Western blot.

**Results:** IL-1 $\beta$ +INF- $\gamma$  decreased FBW7 mRNA expression in primary rat  $\beta$ -cells by 45%. Knockdown of FBW7 by siRNA (FBW7) significantly increased IL-1 $\beta$ +INF- $\gamma$ -mediated NF- $\kappa$ B activation in INS-1E cells, primary beta cells as well as in human  $\beta$ -cell line as measured by a luciferase reporter promoter. This was accompanied by increased expression of the NF- $\kappa$ B target genes Rantes and CCL19. There was also a two-fold induction of nitric oxide production ( $p < 0.001$ ) in INS-1E cells. Conversely, overexpression of FBW7 significantly decreased cytokine-induced NF- $\kappa$ B activation. The effects of FBW7 on NF- $\kappa$ B activation were independent of I $\kappa$ B- $\alpha$  degradation,

as it knockdown did not modify the pattern of IL-1 $\beta$ +INF- $\gamma$ -mediated I $\kappa$ B- $\alpha$  degradation. On another hand, knockdown of FBW7 lead to accumulation of NF $\kappa$ B2 precursor p100 and increased levels of its cleaved form p52 in the nuclear fraction of INS-1E cells after 4h. Induction of NF- $\kappa$ B activity was reverted by a double knockdown approach of FBW7 and  $\beta$ TrCP, an E3 ligase, which was shown to be responsible for the proteosomal cleavage of p100 to p52. In line with these data, FBW7 knockdown potentiated the pro-apoptotic effects of IL-1 $\beta$ +INF- $\gamma$  in INS-1E cells (2-fold increase vs control siRNA,  $p < 0.001$ ), FACS purified rat  $\beta$ -cells (1.9-fold increase vs control siRNA,  $p < 0.001$ ) and human  $\beta$ -cell line.

**Conclusion:** These observations suggest that the E3 ligase FBW7 possesses an anti-apoptotic function in  $\beta$ -cells through regulation of the non-canonical NF- $\kappa$ B pathway. Moreover, it unveils the involvement of this pathway in IL-1 $\beta$ +INF- $\gamma$ -induced NF- $\kappa$ B activation.

### Fractalkine (CX3CL1), a new factor protecting beta cells against TNF- $\alpha$

K. Bouzakri, S. Rutti, C. Arous, R. Dusaulcy, P.A. Halban;

Department of Genetic Medicine and Development, CMU, Geneva, Switzerland.

**Background and aims:** We have previously shown the existence of a muscle-pancreas intercommunication axis in which fractalkine (CX3CL1), a CX3C chemokine produced by skeletal muscle cells, could be implicated. It has recently been shown that the fractalkine system modulates murine beta-cell function, and CX3CL1 expression is known to be regulated by TNF $\alpha$ , a cytokine that impacts negatively on beta cell function. However, the impact of CX3CL1 on islets and sorted beta-cells exposed to TNF $\alpha$  remains to be explored.

**Materials and methods:** Human islets and sorted beta and non-beta cells were used to measure CX3CL1 and CX3CR1 mRNA expression by RNAseq. Glucose induced insulin secretion (GIS: 1h; 16.7 mmol/l glucose) was measured using human islets following exposure to CX3CL1 (1-50 ng/ml) for 24h or rat beta cells exposed to 10 and 25ng/ml CX3CL1 for 48h alone or with 20 ng/ml TNF $\alpha$  for the last 24h. Rat beta-cell apoptosis (TUNEL) and proliferation (BrdU incorporation) were measured after 24h exposure to CX3CL1 (1 to 50 ng/ml) alone, or to CX3CL1 (20 ng/ml) for 48h with addition of cytomix (20 ng/ml TNF $\alpha$ , IL-1 $\beta$ , INF $\gamma$ ) for the last 24h. Insulin signaling was analyzed by western blot in sorted rat beta-cells exposed to CX3CL1 (25ng/ml) for 48h with TNF $\alpha$  (20ng/ml) added for the last 24h. Data are mean $\pm$ SE (5 independent experiments).

**Results:** CX3CL1 and CX3CR1 are both expressed in human islets: CX3CL1 is principally expressed by non-beta cells while its receptor is more expressed in beta-cells, as confirmed by immunofluorescence. Treatment with CX3CL1 for 24h had no significant impact on human islet and rat sorted beta cell GIS or insulin content, or on rat beta-cell proliferation and apoptosis. However, in rat sorted beta cells CX3CL1 completely blocked the adverse effect of TNF $\alpha$  on GIS (control: 2.64 $\pm$ 0.22% content/h; TNF $\alpha$ : 1.46 $\pm$ 0.11%\*; TNF $\alpha$  + 10 ng/ml CX3CL1: 3.19 $\pm$ 0.12%\*\*; TNF $\alpha$  + 25 ng/ml CX3CL1: 2.62 $\pm$ 0.31%\*\*; \* $p < 0.05$  vs. control; \*\*  $p < 0.05$  vs. TNF $\alpha$  alone) as well as partially protecting against the effects of cytomix on apoptosis (control: 0.14 $\pm$ 0.06% TUNEL-positive beta-cells; cytomix: 0.59 $\pm$ 0.22%; cytomix + 25 ng/ml CX3CL1: 0.26 $\pm$ 0.08%\*, \* $p < 0.05$  vs. control; \* $p < 0.05$  vs. cytomix alone). Furthermore, CX3CL1 (25ng/ml) treatment of sorted rat beta-cells prevented the reduction in IRS2 protein levels and in glucose-induced phosphorylation of Akt and AS160 normally evoked by TNF $\alpha$ . Such treatment with CX3CL1 also prevented TNF $\alpha$ -induced phosphorylation of mTOR and NF $\kappa$ B, without any impact on TNF $\alpha$ -induced basal ERK-1/2 phosphorylation. Finally, mTOR protein expression was reduced in cells pretreated with CX3CL1 and exposed to TNF $\alpha$ .

**Conclusion:** We demonstrate for the first time that CX3CL1 protects beta-cells from the adverse effects of TNF $\alpha$  on their function, likely by restoring phosphorylation of key proteins in the insulin signalling pathway. We further demonstrate that CX3CL1 protects rat beta-cells from cytomix-induced apoptosis. Our data suggest that CX3CL1 might be an important target to modulate the negative effects on beta-cells induced by inflammation in Diabetes

**IL-13 improves beta cell survival and protects against IL-1beta-induced beta cell death**

S. Rutti<sup>1</sup>, G. Ruozi<sup>2</sup>, L. Braga<sup>2</sup>, V. Jimenez<sup>3</sup>, A. Casellas<sup>3</sup>, C. Mallo<sup>1</sup>, E. Casana<sup>3</sup>, F. Bosch<sup>3</sup>, M. Giacca<sup>2</sup>, P. Halban<sup>1</sup>;

<sup>1</sup>Genetic Medicine and Development, University of Geneva, Switzerland,

<sup>2</sup>Molecular Medicine Laboratory, International Centre for Genetic Engineering and Biotechnology, Trieste, Italy, <sup>3</sup>School of Veterinary Medicine, Universitat autonoma de Barcelona, Spain.

**Background and aims:** IL-13 is a cytokine classically produced by anti-inflammatory T-helper-2 lymphocytes. Interestingly, IL-13 is decreased in the circulation of type 2 diabetic patients and has recently been shown to impact positively on liver and skeletal muscle. Although IL-13 can impact positively on transformed beta-cell lines, its impact and mode of action on primary human or rodent beta-cell function and survival remain to be explored.

**Materials and methods:** Human and rat dispersed islet cells and sorted beta-cells were maintained in culture for 48 h in the presence of IL-13 (1 to 50 ng/ml) alone or in combination with IL-1 $\beta$  (20 ng/ml). Insulin secretion in response to glucose (1h; 16.7 mmol/l) was measured by radioimmunoassay, proliferation by incorporation of BrdU over 48 h, cell death by TUNEL and protein expression/phosphorylation by western blot. Results are presented as mean $\pm$ SE, n=3-5 independent experiments with statistical significance of differences assessed by Student's t test or ANOVA with Bonferroni post hoc test.

**Results:** IL-13 did not affect human or rat beta-cell basal or glucose-stimulated insulin secretion, or rat beta-cell proliferation. IL-13 (10 ng/ml) decreased basal cell death in human (IL-13: 0.6 $\pm$ 0.2% TUNEL<sup>+</sup> cells vs. control: 1.1 $\pm$ 0.3%; p<0.05) and rat beta-cells (IL-13: 0.02 $\pm$ 0.01% TUNEL<sup>+</sup> cells vs. control: 0.12 $\pm$ 0.03%; p<0.05) and protected sorted rat beta-cells against IL-1 $\beta$  induced apoptosis (normalized to control: IL-1 $\beta$ : 2.6 $\pm$ 0.4, p<0.05 vs. control; IL-13 + IL-1 $\beta$ : 1.16 $\pm$ 0.3%, p<0.05 vs. IL-1 $\beta$  ). However, IL-13 was unable to protect beta-cells from IL-1 $\beta$  impaired glucose stimulated insulin secretion. IL-13 (10 ng/ml) induced phosphorylation of Akt in rat primary beta-cells after 60 min (99 $\pm$ 41% increase; p<0.05) and increased IRS2 protein expression after 48 h (68 $\pm$ 18% increase; p<0.05) without changing protein levels of Akt isoforms.

**Conclusion:** We show for the first time that IL-13 improves survival of primary beta-cells and protects against IL-1 $\beta$  induced beta-cell death, without affecting proliferation or insulin secretion. These effects may be mediated through the IRS2/Akt signalling cascade. In addition to any beneficial effects on insulin target tissues, these data suggest that IL-13 may be useful for treatment of type 2 diabetes by preserving beta-cell mass or slowing its rate of decline.

## 433

**The role of sphingosine-1-phosphate-lyase in insulin-secreting cells**

C. Hahn, M. Kaminski, S. Lenzen, E. Gurgul-Convey; Hannover Medical School, Germany.

**Background and aims:** Type 1 diabetes is an autoimmune disease with a strong inflammatory component. The sphingolipid metabolism and sphingosine-1-phosphate (S1P) play an important regulatory role in the development of several inflammatory disorders. S1P-lyase (SPL) cleaves irreversibly S1P in the last step of the sphingolipid catabolism. S1P was associated with protection against cytokine-mediated toxicity in insulin-secreting cells. However, the role of SPL in insulin-secreting cells remains unknown.

**Materials and methods:** Insulin-secreting INS1E cells were transfected with the pcDNA3.1 SPL vector or with siRNA against SPL. Cells were treated with glucose (3, 10, 30 mM) and/or cytokines (IL-1 $\beta$  600 U/ml or with a cytokine mix: IL-1 $\beta$  60 U/ml, TNF $\alpha$  185 U/ml and IFN $\gamma$  14 U/ml). After a 24 h incubation, gene expression (qRT-PCR), caspase-3 activation (Caspase-Glo 3/7 kit), ROS production (DCFDA oxidation assay), ATP (ATPlite luminescence assay) and glucose-stimulated insulin secretion (RIA) were determined.

**Results:** The measurement of SPL expression in several rat tissues and INS1E cells revealed a moderate SPL expression level in INS1E cells compared to different rat tissues. Cytokines induced caspase-3 activation in INS1E-control cells (IL-1 $\beta$  150% vs. cytokine mix 195%). This deleterious effect was significantly reduced by SPL-overexpression (IL-1 $\beta$  118% vs. cytokine mix 126%) and significantly enhanced by SPL-suppression (IL-1 $\beta$  302% vs. cytokine mix 292%). The protective effect of SPL-overexpression was associated with a reduced cytokine-induced ROS formation (INS1E-

control cells, IL-1 $\beta$  167%, cytokine mix 212%; INS1E-SPL cells, IL-1 $\beta$  132%, cytokine mix 144%). SPL-suppression increased cytokine-mediated ROS production (IL-1 $\beta$  252%, cytokine mix 290%). Interestingly, SPL-overexpression had a potentiating effect on glucose-stimulated insulin secretion (GSIS) (INS1E-control cells, 3 mM Glc 0.078, 10 mM Glc 0.206, 30 mM Glc 0.192; INS1E-SPL cells, 3 mM Glc 0.085, 10 mM Glc 0.450, 30 mM Glc 0.403 ng/ $\mu$ g DNA/h). The suppression of SPL weakened the stimulatory effect of glucose on insulin secretion (3 mM Glc 0.063, 10 mM Glc 0.071, 30 mM Glc 0.088 ng/ $\mu$ g DNA/h). Upon exposure to cytokines a significant 5-7 fold decrease in the amount of secreted insulin was observed in INS1E-control cells. The cytokine-mediated inhibition of glucose-induced insulin secretion was reduced by SPL-overexpression and potentiated by SPL-suppression. The effect of SPL on GSIS correlated with parallel changes in ATP content (INS1E-control cells, IL-1 $\beta$  85%, cytokine mix 63%; INS1E-SPL cells, IL-1 $\beta$  93%, cytokine mix 87%; INS1E-siRNA-SPL, IL-1 $\beta$  71%, cytokine mix 49%, vs. 100% of untreated cells).

**Conclusion:** This study demonstrates that SPL plays an important role in the regulation of beta cell function and the cytokine toxicity to insulin-secreting cells. It seems that the concentration of intracellular S1P, controlled by SPL, must be tightly regulated to maintain the proper beta cell function and to prevent cytokine-mediated toxicity.

## 434

**Unique effects of acute exposure to low concentrations of IL-1beta on primary beta cell function and gene expression**

C. Arous, P. Ferreira, E. Dermizakis, P. Halban;

Dept. of Genetic Medicine and Development, University Medical Center, University of Geneva, Switzerland.

**Background and aims:** The cytokine IL-1beta is thought to contribute to the low-grade systemic and islet inflammation leading to insulin secretion defects in type 2 diabetes. Indeed, longterm exposure (>24 h) of beta cells to very high concentrations (20 ng/mL) of IL-1beta results in modulation of gene expression by NF $\kappa$ B, impaired function and ultimately cell death. Interestingly, IL-1beta can also exert beneficial effects on beta cells following exposure for >24 h to low concentrations of IL-1beta, with improved insulin secretion, increased proliferation and decreased apoptosis but the mechanisms are less well understood. We have observed previously that shorter exposure (2 h) to low (0.1 ng/mL) but not high (20 ng/mL) concentrations of IL-1beta enhances glucose-stimulated insulin secretion through focal adhesion and actin remodeling. We now study the mechanism of this beneficial action of IL-1beta on beta cell function.

**Materials and methods:** Rat primary beta cells or human islets established in monolayer on extracellular matrix were incubated for 1 h at 2.8 mmol/L followed by 1 h at 16.7 mmol/L glucose in the continued presence (or not, control) of 0.1 ng/mL or 20 ng/mL rat or human IL-1beta respectively. Insulin secretion was measured by radioimmunoassay. To inhibit transcription, rat beta cells were pre-treated 1 h with actinomycin D (0.1  $\mu$ g/mL). NF $\kappa$ B (p65) was localized by immunofluorescence. RNA was extracted and sequenced by Illumina HiSeq to an average depth of 20M reads. Statistical analyses were performed in R and differential gene expression with DESeq2. Data are mean $\pm$ SE  $\geq$  3 independent observations.

**Results:** Glucose-stimulated insulin secretion (GSIS), but not basal secretion, of rat primary beta cells and human islets, was increased by 56.5  $\pm$  17.4% (p=0.032) and 74.9  $\pm$  20.5% (p=0.021) respectively by 0.1 ng/mL IL-1beta whereas 20 ng/mL was without effect. NF $\kappa$ B was translocated rapidly to the nucleus during exposure of rat beta cells to 0.1 ng/mL IL-1beta and blockade of NF $\kappa$ B activation by Bay 11-7082 (5  $\mu$ mol/L) prevented IL-1beta enhancement of GSIS. Furthermore, 0.1 ng/mL IL-1beta had no impact on GSIS in the presence of actinomycin D. Taken together these data suggested that IL-1beta enhanced GSIS through modulation of gene expression by NF $\kappa$ B. Transcriptome analysis by RNA-seq revealed 928 genes differentially expressed by the low dose and 1738 by the high dose of IL-1beta with 55 up-regulated and 88 down-regulated uniquely by 0.1 ng/mL IL-1beta (p< 0.001). Of these genes modulated uniquely by low dose IL-1beta, 6.99% were classed as vesicle and secretory granule components, 13.3% are involved in the regulation of the transcription. The expression of one gene of particular interest for beta cell function, SIRT1, was increased from 8.52  $\pm$  0.35 to 10.28  $\pm$  0.54 RPKM (p=0.016) by 2 h exposure to 0.1 ng/mL IL-1beta with no significant change with 20 ng/mL.

**Conclusion:** Acute exposure of beta cells to 0.1 ng/ml IL-1beta can act rapidly and positively on insulin secretion through the regulation of gene transcription. Results obtained with RNA sequencing analysis revealed changes

in gene expression profiles elicited uniquely by acute exposure to low but not high concentrations of IL-1beta and that could drive improved beta cell function.

#### The hepatokine fetuin-A triggers inflammation without inducing cell death but improves cAMP-dependent insulin secretion of pancreatic islets

F. Gerst<sup>1,2</sup>, G. Kaiser<sup>1,2</sup>, N. Stefan<sup>1,2</sup>, H.-U. Häring<sup>1,2</sup>, S. Ullrich<sup>1,2</sup>;

<sup>1</sup>Internal Medicine IV, University Hospital Tübingen, <sup>2</sup>Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Center Munich at the Eberhard-Karl-University of Tübingen, Germany.

**Background and aims:** Nonalcoholic fatty liver displays an altered secretion of hepatokines. Previously, we found that increased plasma levels of the hepatokine fetuin-A strongly predict the incidence of type 2 diabetes in humans. As mechanisms of action, fetuin-A directly inhibits insulin receptor signaling and augments inflammation by interacting with fatty acids to activate TLR4. In addition, we found a negative relationship of fetuin-A levels with adjusted insulin secretion only in subjects with impaired glucose tolerance. The present study aims to examine the impact of fetuin-A on fatty acid-induced effects in pancreatic beta-cells.

**Materials and methods:** Human islets received from the European Centers of Islet Transplantation (ECIT) and mouse islets were cultured in medium supplemented with human fetuin-A or serum albumin as control (0.6 mg/ml each) for 48h. Due to the low concentration of albumin palmitic acid was used at a concentration of 60 µmol/l, which does not induce metabolic stress. Changes in gene expression were analyzed by microarray and qRT-PCR. Apoptosis was estimated by TUNEL staining. Insulin secretion was evaluated after static incubation by radioimmunoassay.

**Results:** In agreement with previous observations in other cell types, fetuin-A increased 2-fold the mRNA levels of IL1β, IL33, IL24 and IL17RB in human islets. The stimulation of cytokine production depended on the activation of TLR2/4, as fetuin-A elevated the mRNA amount of IL1β and MCP-1 in WT, but not in TLR2/4 KO islets. On the contrary, palmitic acid neither stimulated nor augmented the fetuin-A-mediated cytokines production. Surprisingly, in spite of increasing the cytokine levels, fetuin-A failed to induce apoptosis and, moreover, significantly inhibited palmitic acid-induced cell death. In addition, chronic exposure to fetuin-A did not affect glucose and palmitic acid stimulated insulin secretion but it selectively and specifically improved forskolin and exendin-4 stimulation of secretion.

**Conclusion:** These results suggest that fetuin-A stimulates cytokine production in a TLR-dependent manner. However, it exerts rather beneficial effects on beta cell function, as it does not induce apoptosis and improves cAMP-amplified insulin secretion.

## PS 020 Clinical immunology of type 1 diabetes

### 436

#### The promoters of genes may be the closest link between type 1 diabetes and other autoimmune diseases

C. Guja<sup>1</sup>, P. Gagniu<sup>2</sup>, C. Ionescu-Tirgoviste<sup>1</sup>;

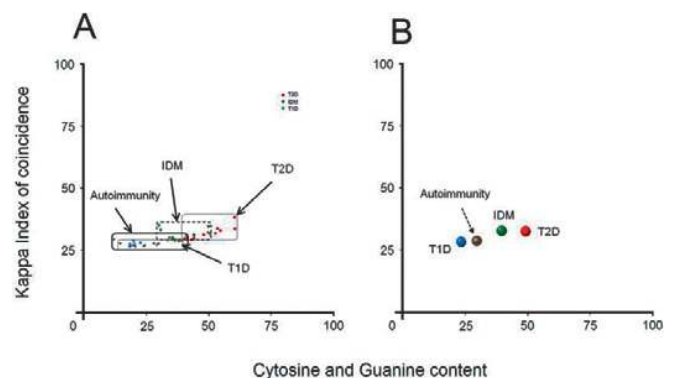

<sup>1</sup>Diabetes, Nutrition and Metabolic Diseases, „Carol Davila“ University of Medicine and Pharmacy Bucharest, <sup>2</sup>Institute of Genetics, University of Bucharest, Romania.

**Background and aims:** Type 1 diabetes (T1D) is a T-cell mediated autoimmune disease that selectively targets pancreatic beta cells. T1D is thought to arise from the progressive loss of beta cells occurring over months upto years. Despite extensive genetic studies in T1D, rarely analyzes were performed with respect to promoters of genes associated with autoimmunity and T1D.

**Materials and methods:** For our study we chose a set of representative genes for several diabetes phenotypes. We analyzed the promoters of genes associated with T1D, including HLA-DQA1, HLA-DQB1, HLA-DRB1, HLA-DPB1, PTPN22, TLR7, CTLA4, GSDMB, STAT4, IL7R, C1QTNF6, CD55, CTSH, ERBB3 and INS and with T2D, including CAMK1D, DUSP9, HHEX, IRS1, MADD, NOTCH2, TP53INP1, VPS13C, WFS1, ZFAND6, HMG2, PPARG, CDKN2AIP, PROX1 and TCF7L2. In order to detect a possible relationship between T1D and other autoimmune diseases, we analyzed the promoters of genes associated with more than one autoimmune disease, including RGS1, IL10, AFF3, IL21, INS, KIF3A, GPR183, GSDMB, ORM-DL3, PTPN2, FUT2, TLR7, PTPN22, CTLA4, CD55 and STAT4. The DNA pattern methodology that we have used, determines the coexpression relationships between genes. Thus, in the resulting distribution, the overlapping positions (or close positions) of promoters of these genes indicate that those promoters use transcription factors in common.

**Results:** Our distribution shows that there is a common denominator between promoters of genes involved in autoimmunity. Both the promoters of T1D genes and those associated with other autoimmune diseases occupy the same overlapping positions in our distribution. The figure (Figure A) below shows the general distribution of different phenotypes, namely T1D (in blue), T2D (in red), genes associated with both phenotypes (included in „Intermediary Diabetes Mellitus“ - IDM phenotype) in green and promoters of genes associated with autoimmunity (in brown). In a general distribution of the average positions of gene promoters for each phenotype (Figure B), the close functional relationship between T1D and autoimmune diseases gene promoters is becoming increasingly clear. The clustering of these genes, very close to each other, suggests that transcription factors involved in their expression may be part of the triggering mechanism of anti beta cell autoimmunity. The close distribution of the promoters of genes associated with the analyzed phenotypes represents a functional correlation, in the sense that these genes are more likely to be co-expressed.

**Conclusion:** Promoters of genes associated with T1D and with other autoimmune diseases share one common factor in causing T1D, namely the transcription factors involved in long term gene expression. The wide distribution between promoters of genes associated with T1D and T2D strongly suggests that these two phenotypes are not using transcription factors in common.

**A novel autoantibody detected in patients with fulminant type 1 diabetes**  
 F. Haseda<sup>1</sup>, A. Imagawa<sup>2</sup>, H. Nishikawa<sup>3</sup>, S. Mitsui<sup>1</sup>, C. Tsutsumi<sup>1</sup>,  
 R. Fujisawa<sup>1</sup>, H. Sano<sup>1</sup>, Y. Murase-Mishiba<sup>1</sup>, J. Terasaki<sup>1</sup>, S. Sakaguchi<sup>3</sup>,  
 T. Hanafusa<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine (I), Osaka Medical College, Takatsuki,

<sup>2</sup>Department of Metabolic Medicine, Graduate School of Medicine,

<sup>3</sup>Experimental Immunology, Immunology Frontier Research Center, Osaka University, Suita, Japan.

**Background and aims:** Fulminant type 1 diabetes (FT1D) is a subtype of type 1 diabetes characterized by complete insulin deficiency resulting from the destruction of pancreatic beta cells even at the disease onset. Massive cellular infiltration of T-cells and macrophages has been detected in islets and exocrine pancreas, suggesting that immune disorder might contribute to the development of FT1D. However, islet-related autoantibodies, such as GAD Ab or IA-2 Ab, were usually negative, indicating that we have no useful biomarker to diagnose FT1D. Therefore, we performed serological antibody analysis cyclically to discover a novel diagnostic marker of FT1D.

**Materials and methods:** First, we analyzed a total of 6 serum samples from 3 patients with FT1D (1 sample in acute and 1 in chronic phases from each patient) on over 9000 human protein arrays (Invitrogen ProtoArray<sup>®</sup> Human Protein Microarray v5.0) by fluorescence. Second, titres of the antibody were measured in sera from 20 patients with FT1D (both in acute and chronic phases), 32 patients with type 1A diabetes (T1AD), 30 patients with type 2 diabetes (T2D), 22 patients with autoimmune thyroid disease (AITD) and 30 healthy control subjects (HC) using ELISA assay. Duration of FT1D in acute and chronic phase was  $8.1 \pm 6.3$  (mean  $\pm$  SD, day) and  $24.2 \pm 9.1$ , respectively. **Results:** By serological antibody analysis of over 9000 antibodies, we detected 8 antibodies which showed high signals from all 3 patients with FT1D in acute phase (acute/chronic phase ratio > 1.4). We focused on one novel antibody that has not yet been reported in any conditions and measured its titre by ELISA assay. Titres of the antibody were  $0.1071 \pm 0.0374$  (mean  $\pm$  SD, arbitrary unit) in FT1D patients (acute phase),  $0.0823 \pm 0.0182$  in FT1D patients (chronic phase),  $0.0771 \pm 0.0171$  in T1AD patients,  $0.0710 \pm 0.0171$  in T2D patients,  $0.0701 \pm 0.0116$  in AITD patients and  $0.0641 \pm 0.0078$  in HC. Significantly high titre of the antibody was detected in sera from FT1D patients in acute phase (versus T1AD patients;  $P=0.0002$ , versus T2D patients;  $P<0.0001$ , versus AITD patients;  $P<0.0001$ , versus HC;  $P<0.0001$ ), and also in sera from FT1D patients in chronic phase (versus T1AD patients;  $P=0.0188$ , versus T2D patients;  $P=0.0093$ , versus AITD patients;  $P=0.0229$ , versus HC;  $P=0.0027$ ). Titres of the antibody were higher from FT1D patients in acute phase than those in chronic phase ( $P=0.0023$ , paired t-test). There was no significant correlation between the titres of the antibody and age, gender, HbA1c, plasma glucose and GAD or IA-2 antibody level in all diabetic patients.

**Conclusion:** We detected one novel antibody whose titre was high in sera from patients with FT1D both in acute and chronic phases. This antibody might become a diagnostic marker of FT1D.

**Inflammatory profile in patients with type 1 diabetes: exploring a hidden side of type 1 diabetes**

M.S. Ruiz de Adana<sup>1,2</sup>, E. Rubio-Martín<sup>1,2</sup>, N. Colomo<sup>1,2</sup>, M. Carreira<sup>3</sup>,  
 M.T. Anarte<sup>3</sup>, E. Maymó-Masip<sup>4,2</sup>, M. Rodríguez-Chacón<sup>4,2</sup>,  
 G. Rojo-Martínez<sup>1,2</sup>;

<sup>1</sup>Endocrinology and Nutrition, Hospital Regional Universitario de Málaga,

<sup>2</sup>CIBERDEM, Barcelona, <sup>3</sup>Departamento de Personalidad, Evaluación y

Tratamiento Psicológico, Facultad de Psicología, Universidad de Málaga,

<sup>4</sup>Research Unit, Hospital Universitari Joan XXIII, Tarragona, Spain.

**Background and aims:** The aims of this study are to compare inflammatory markers (IL-6, TNF $\alpha$ , high sensitivity C reactive protein -hsCRP-, TNF-like weak inducer of apoptosis -sTWEAK-, and scavenger receptor CD163 -sCD163-) between 158 T1DM patients and 638 healthy subjects and to evaluate if there are differences in these inflammatory markers in subjects with T1DM according to glycaemic control measured by HbA1c levels, to the type of insulin regimen (multiple daily injections [MDI] vs. continuous subcutaneous insulin infusion [CSII]), the presence of microvascular complications, the quality of life, the distress, and the symptoms of depression.

**Materials and methods:** Cross-sectional study which involved 158 patients with T1DM attending our diabetes unit. Additionally, 638 healthy subjects from the di@bet.es study (a cross sectional study comprising a representative sample of the Spanish adult population) and the Pizarra study (a population based cohort study undertaken in Pizarra, Spain) with similar age, sex distribution and BMI than the study patients were selected. Sociodemographic, clinical and biochemical data (HbA1c and lipid profile) were recorded. Quality of life was evaluated by the Diabetes Quality of Life questionnaire (DQoL), distress was assessed by the Diabetes Distress Scale (DDS), and symptoms of depression was evaluated by the Beck Depression Inventory (BDI). Inflammatory markers including IL-6, hs-CRP, TNF $\alpha$ , sTWEAK and sCD163 were measured.

**Results:** a) T1DM patients vs. healthy subjects. Patients with T1DM had lower sTWEAK levels ( $806 \pm 1312$  vs.  $1040 \pm 1212$  pg/mL,  $p=0.0001$ ) and higher IL-6 levels ( $2.6 \pm 3.0$  vs.  $1.7 \pm 2.6$  pg/mL,  $p=0.001$ ) and hsCRP levels ( $3.4 \pm 6.3$  vs.  $3.0 \pm 5.2$  mg/L,  $p=0.001$ ) than healthy subjects with similar age, sex and BMI. No significant differences were found in TNF $\alpha$  and sCD163 levels. b) T1DM patients. Patients with T1DM had significantly higher IL-6 levels if they were treated with MDI vs. CSII ( $2.9 \pm 3.3$  vs.  $1.5 \pm 1.4$  pg/mL,  $p=0.017$ ), had microvascular complications ( $3.8 \pm 3.5$  vs.  $2.2 \pm 2.8$  pg/mL,  $p=0.006$ ) and had symptoms of depression ( $3.5 \pm 3.7$  vs.  $2.2 \pm 2.6$  pg/mL,  $p=0.023$ ). If we compare patients treated with CSII with those receiving MDI, the former ones had significantly lower HbA1c levels ( $7.5 \pm 0.9$  vs.  $7.9 \pm 1.3\%$ ,  $p=0.04$ ), lower score in BDI ( $7.5 \pm 8.8$  vs.  $12.2 \pm 12.2$ ,  $p=0.008$ ), DDS ( $1.5 \pm 0.8$  vs.  $1.9 \pm 1.0$ ,  $p=0.05$ ) and DQoL ( $83.4 \pm 19.0$  vs.  $90.8 \pm 22.0$ ,  $p=0.03$ ), lower IL-6 levels and higher TNF $\alpha$  levels ( $4.6 \pm 8.5$  vs.  $1.5 \pm 0.82$  pg/mL,  $p=0.001$ ), adjusted for age, sex and BMI.

**Conclusion:** Patients with T1DM had a different inflammatory pattern than their healthy counterparts. IL-6 levels were increased in patients with T1DM receiving MDI insulin regimen, with microvascular complications, and with symptoms of depression.

## 439

**Circulating immune mediators are closely linked in the early course of adult onset type 1 diabetes**

H.F. Fleiner<sup>1</sup>, M. Radtke<sup>1</sup>, L. Ryan<sup>2</sup>, T. Moen<sup>3</sup>, V. Grill<sup>1</sup>;

<sup>1</sup>Department of Cancer Research and Molecular Medicine, <sup>2</sup>Centre of Molecular Inflammation Research, Department of Cancer Research and Molecular Medicine, <sup>3</sup>Department of Laboratory Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

**Background and aims:** Relationships between circulating immune mediators (cytokines, chemokines and growth factors) and a beta cell destructive autoimmune process are poorly elucidated in adult-onset type 1 diabetes. We measured serum levels of immune mediators in such patients with newly diagnosed disease during the course of ongoing deterioration of insulin secretion.

**Materials and methods:** Levels of 27 immune mediators were measured in 34 GADA (glutamic acid decarboxylase antibodies) positive type 1 diabetic patients, aged  $27.4 \pm 1.2$  years at a mean of 7 weeks after diagnosis (designated 0 month) and 6 months later. Endogenous insulin secretion was assessed by C-peptide glucagon stimulation tests at 0, 6 and 12 months. Supplementary data were obtained in 9 GADA positive type 1 diabetic subjects and in 43 non-diabetic age and sex matched subjects. Results were analyzed with and without adjustment for body weight (BMI).

**Results:** Mean levels of stimulated C-peptide had declined by 10% after 6 months and by 28% after 12 months. This decline was not reflected by levels of immune mediators which displayed large inter- but small intra-individual differences with only minor changes observed between measurements at 0 and at 6 months ( $p$ -values for correlations ranging from 0.000 to 0.005). Levels of the majority of immune mediators were strongly and positively correlated to each other in the diabetic subjects. However, such correlations were also found in the non-diabetic subjects and data did not suggest any network of immune mediators specific for the diabetic subjects. Body weight (BMI) was positively associated with levels of IL-1 $\alpha$ , IL-2, IL-4, IL-6, IL-17, Basic FGF, GCSE, IFN gamma and MIP-1 alpha. When adjusted for BMI, levels at 0 month for Basic FGF and MIP-1 alpha were inversely associated with the percentage decline in stimulated C-peptide from 0 to 12 months (nominally  $p<0.05$ ).

**Conclusion:** 1) There are close associations between different immune mediators 2) These associations are not specific for autoimmune diabetes 3) BMI is a major confounder 4) The associations of beta cell decline to individual immune mediators need confirmation in further studies.

### Relationship between autoantibodies combination, metabolic syndrome and its components in autoimmune diabetes in adults

T. Bulum, K. Blaslov, J. Knežević-Ćuća, L. Duvnjak, Vuk Vrhovac Clinic for Diabetes, Endocrinology and Metabolic Diseases, University Hospital Merkur, Zagreb, Croatia.

**Background and aims:** Although clinical presentation of latent autoimmune diabetes in adults (LADA) at diagnosis frequently features clinical traits of type 2 diabetes mellitus (T2DM), it is the autoimmune process that drives LADA patients through slower beta-cells destruction and insulin dependency within few years. Majority of LADA patients has pronounced positivity for glutamic acid decarboxylase enzyme antibodies (GAD-Ab) frequently accompanied by moderate levels of circulating autoantibodies to islet cell cytoplasmic antigens (ICA-Ab). Positivity for tyrosine phosphatase-like transmembrane glycoprotein (IA2-Ab) has also been reported but to a lesser extent. While simultaneous positivity for ICA-Ab, and GAD-Ab with eventual presence and of IA2-Ab indicate patients with insulin deficiency and typical type 1 LADA phenotype, GAD antibody positivity, even in higher titers, represent a marker for slower progressing LADA. The role of IA2Ab positivity in LADA phenotypisation is poorly understood and controversial. The aim of our study was to establish a possible association between autoimmune profile of patients regarding double or triple antibody positivity and LADA phenotype in the context of metabolic syndrome (MS) prevalence, individual components of metabolic syndrome and chronic diabetic complications.

**Materials and methods:** This cross-sectional study population comprised 69 islet cell antibody positive patients coming for their comprehensive annual review. Rate of positivity was calculated by determining end-point titres of samples that were converted to the units of Juvenile Diabetes Foundation (JDF-U) by comparison with a standard curve of end-point titer of standard sera. The threshold of detection was >5 JDF units. GAD and IA2-Abs were detected with an enzyme-linked immunosorbent assay (Euroimmun AG, Luebeck, Germany) and the results were expressed in arbitrary units. The cut-off limit was 10 U/ml for GAD Abs and 15 U/ml for IA2-Abs. MS was defined according to the International Diabetes Federation definition, arterial hypertension (AH) was considered as blood pressure > 130/85 mmHg or the use of antihypertensive drugs. Patients were divided into three groups: Gad Ab only positive (n=28), GAD Ab+ICA Ab positive (n=26) and GAD Ab+ICA Ab+IA2 Ab positive (n=15).

**Results:** Twenty five (36.2%) patients were male, mean age approximately 51 years with disease duration 8 years. The lowest value of waist circumference (80 vs 82 vs 89.5 cm), MS (1 vs 11 vs 15) and AH (1 vs 11 vs 16) prevalence was found in the group positive for all three antibodies compared the others two groups. In the multinomial multivariate logistic regression model higher waist circumference (OR 0.931 (0.869-0.988)), MS prevalence (OR 0.062 (0.007-0.537)) and AH prevalence (OR 0.065 (0.007-0.577)) were negatively associated with triple Ab positivity compared to single Ab positivity, and compared to double Ab positive group with ORs as follows: 0.940 (0.877-0.990), 0.097 (0.011-0.855), and 0.099 (0.011-0.879).

**Conclusion:** Our results highlight the importance of the inverse association of simultaneous Abs positivity for ICA, GAD and IA2 with the presence of MS and its components in LADA patients. This inverse relationship might implicate the presence of LADA patients' phenotype closer to type 1 diabetes.

## 441

### Autoimmune gastrointestinal markers in patients with type 1 diabetes

O. Derevyanko, T. Nikonova, N. Dalantaeva, O. Ivanova, O. Smirnova; Endocrinology Research Centre, Moscow, Russian Federation.

**Background and aims:** In patients with type 1 diabetes the prevalence of other autoimmune diseases is 3 to 5 fold higher than in non-diabetic patients. Gastrointestinal autoimmune diseases are generally asymptomatic up to an advanced stage when they become major causes of mortality if not di-

agnosed and treated on time. The presence of immunological markers may be indicative of gastrointestinal autoimmune diseases even in a clinically asymptomatic case. The aim of our study was to investigate the frequency of specific autoantibodies occurrence in patients with T1 DM, to clarify the role of polyautoimmunity in the appearance of autoantibodies and the association of autoantibody titer with clinical features of accompanying autoimmune diseases.

**Materials and methods:** 84 patients with T1DM and 21 healthy subjects (control group) were included in the study. T1DM patients were divided into two groups. The first group included 58 patients with T1DM only. The second group consisted of 26 patients with T1DM and another autoimmune disease (thyroid, celiac and Addison's disease, rheumatoid arthritis, vitiligo, myasthenia gravis). Anti-gastric parietal cells antibodies (AGPA) - markers of autoimmune gastritis, antinuclear antibodies (ANA), and anti-smooth muscle antibodies (ASMA) - markers of autoimmune hepatitis, antimitochondrial antibodies (AMA) - primary biliary cirrhosis marker were detected by using indirect immunofluorescence antibody test. All subjects were tested for ICA, GADA, IA-2A, C-peptide, HbA1c. Gastroscopy and ultrasound liver examination were performed to every patient.

**Results:** Significant difference was observed in frequency of ANA, AGPA, ASMA occurrence between the study groups and control group,  $p < 0,05$  (table 1). Significantly higher appearance of ANA was observed in patients of the 2nd group compared to the 1st group ( $p = 0,007$ ). 50% of patients with gastritis confirmed by gastroscopy had AGPA. 13% of patients with ultrasound signs of hepatic abnormalities were positive to ANA, 14% - to ASMA, 21% - to AMA compared to 28% ( $p = 0,39$ ), 38% ( $p = 0,15$ ) and 19% ( $p = 0,86$ ) of patients with normal hepatic features respectively.

**Conclusion:** Our study showed a high frequency AGPA, ANA, ASMA, AMA occurrence in patients with T1 DM. This data indicates the increased risk of gastric and hepatic autoimmune diseases in T1DM patients. Only ANA had significantly higher appearance in patients with several autoimmune diseases. This might be due to the fact that ANA is a less specific autoantibody and can cause less specific autoimmunity against several organs. Other antibodies were observed with the same frequency in both study groups ( $p < 0,05$ ) but ANA, AGPA, ASMA had significantly higher appearance in patients with diabetes compared to the control group. These findings provide a rationale for screening, early diagnosis and treatment of additional autoimmune diseases in T1DM patients.

Table 1. Autoantibody occurrence in study groups and control group

| Autoantibody | 1st group | 2nd group | Control group | $p$ 1-2 | $p$ 1-3 | $p$ 2-3 |
|--------------|-----------|-----------|---------------|---------|---------|---------|
| ANA          | 12/26=46  | 9/58=16   | 1/21=5        | 0,007   | 0,005   | 0,36    |
| AGPA         | 11/26=42  | 23/58=41  | 0/21=0        | 0,89    | 0,002   | 0,001   |
| ASMA         | 10/26=38  | 18/58=32  | 1/21=5        | 0,75    | 0,018   | 0,029   |
| AMA          | 5/26=19   | 11/58=20  | 1/21=5        | 0,79    | 0,29    | 0,21    |

### Leukocyte profiles differ between type 1 and type 2 diabetes and are associated with metabolic phenotypes. Results from the German diabetes study (GDS)

B. Menart<sup>1,2</sup>, N.C. Schloot<sup>1</sup>, R. Ruetter<sup>1,2</sup>, B. Nowotny<sup>1,2</sup>, J. Rosenbauer<sup>3,2</sup>, C. Koliaki<sup>1,2</sup>, S. Kahl<sup>1,2</sup>, M.-C. Simon<sup>1,2</sup>, J. Szendroedi<sup>1,2</sup>, M. Roden<sup>1,2,4</sup>, for the GDS group;

<sup>1</sup>Heinrich-Heine University, Institute for Clinical Diabetology,

<sup>2</sup>German Center for Diabetes Research, <sup>3</sup>Heinrich-Heine University, Institute for Biometrics and Epidemiology, <sup>4</sup>Department of Endocrinology and Diabetology, Düsseldorf, Germany.

**Background and aims:** Altered immune reactivity precedes and accompanies type 1 and type 2 diabetes. We hypothesized that the metabolic phenotype relates to the systemic cellular immune status.

**Materials and methods:** A total of 194 metabolically well controlled patients with type 1 diabetes (n=62, mean diabetes duration: 1.29 years) or type 2 diabetes (n=132, 1.98 years) and 60 normoglycemic persons underwent blood sampling for automated white blood cell counting (WBC) and flow cytometry. Whole body insulin sensitivity was measured with hyperinsulinemic-euglycemic clamp tests. Analysis of covariance was performed to compare groups and Spearman's non-parametric correlations and partial correlations adjusted for age, sex, and BMI were estimated.

**Results:** Patients with type 2 diabetes had higher WBC counts than controls ( $P < 0.001$ ) along with higher percentage of T-cells ( $P = 0.038$ ), activated T helper (Th)- ( $P < 0.001$ ) and cytotoxic T (Tc)-cells ( $P < 0.001$ ), but lower pro-

portions of natural killer (NK) cells ( $P<0.05$ ). In type 1 diabetes, percentage of activated Th- ( $P<0.001$ ) and Tc-cells ( $P=0.006$ ) were also higher compared to controls, whereas the ratio of regulatory T (Treg)-cells to activated Th-cells was lower suggesting diminished regulatory capacity. Parameters of glycaemic control (HbA1c, blood glucose) related positively to Treg-cells only in type 2 diabetes ( $P<0.05$ ). Upon age-, sex-, and body mass-adjustments, insulin sensitivity correlated positively with monocytes ( $r=0.469$ ,  $P<0.01$ ), while circulating lipids correlated positively with T-cell subsets in type 1 diabetes ( $r=0.281$ ,  $P<0.05$ ).

**Conclusion:** Immune cell phenotypes showed distinct frequencies of occurrence in both diabetes types, and associate with insulin sensitivity, glycaemia and lipidemia.

### Insulin-induced level of TNF-alpha: the early marker of type 1 diabetes mellitus

E. Repina<sup>1</sup>, E. Stepanova<sup>2</sup>, M. Shestakova<sup>1</sup>, I. Dedov<sup>1</sup>;

<sup>1</sup>Endocrinology Research Centre, <sup>2</sup>Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation.

**Background and aims:** To investigate an influence of monoclonal activator - insulin upon cytokine-producing function of peripheral blood cells in the patients with type 1 and 2 diabetes mellitus.

**Materials and methods:** 25 type 1 diabetes mellitus patients and 9 patients with type 2 diabetes mellitus were examined. As a control we examined 10 healthy persons. Mononuclear leukocytes were isolated by centrifugation in the ficoll-verographin density gradient. The cells thus obtained were resuspended in the complete nutritive medium reducing their concentration to  $2.0 \times 10^6$ /ml. Phytohemagglutinin (PHA-P, Sigma) (10 mcg/ml) and insulin (insulin human, Sigma) (10 mcg/ml) were added to the samples to stimulate mononuclear leukocytes; cell suspensions were further incubated for 36 hours. Initial, PHA-induced and insulin-induced levels of interleukin-1 (IL-1), IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, gamma interferon (IFN- $\gamma$ ) and tumor necrosis factor alpha (TNF- $\alpha$ ) in supernatants of cell cultures were measured by solid phase immunoassay at 450 nm. Results were compared with clinical characteristics of the patients. There were 8 males and 17 females in the group 1 and 2 males and 7 females in the group 2. Median age, diabetes mellitus duration, HbA1c in the group 1 and 2 were respectively 32 years, 17 years, 8,3 % and 63 years, 12 years, 9,1 %. Intensities of microvascular complication (diabetic retinopathy and diabetic nephropathy) were higher in the group 1. 8 patients (32%) from group 1 had diabetic retinopathy on the last stage and only 1 patient (11%) from the group 2 had diabetic retinopathy on the same stage. Only 1 patient (11%) from the group 2 had diabetic nephropathy on microalbuminuria stage and 7 patients from the group 1 (28%) had diabetic nephropathy on proteinuria stage and on the stage of renal failor.

**Results:** For estimation of immune response intensity we used for the first time the index of autoimmune inflammation (IAI) - correlation of insulin-induced and basal production of TNF- $\alpha$ . The T-cell response on insulin was absent in control group and in patients with type 2 diabetes mellitus. Only one patient with type 2 diabetes mellitus had IAI more than 1. It was the basis for a change the diagnosis from type 2 diabetes to type 1 diabetes mellitus. Our patients with type 1 diabetes mellitus had IAI from 3,09 till 19,23. It correlated with the stage and intensities of microvascular complications (diabetic retinopathy and diabetic nephropathy) of these patients.

**Conclusion:** The TNF- $\alpha$  production ratio of insulin-stimulated versus resting cells may be used as a reliable early marker of autoimmune versions of diabetes mellitus, marker of autoimmune process activity in pancreatic tissue and disease severity in type 1 diabetic patients.

## 444

### Regulatory T cell dysfunction in type 1 diabetes

A. Zóka<sup>1</sup>, A. Somogyi<sup>1</sup>, G. Barna<sup>2</sup>, Á. Oláh<sup>1</sup>, Z. Al-Aissa<sup>1</sup>, O. Hadarits<sup>3</sup>, G. Firneisz<sup>1</sup>;

<sup>1</sup>2nd Department of Internal Medicine, <sup>2</sup>1st Department of Pathology and Experimental Cancer Research, <sup>3</sup>1st Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary.

**Background and aims:** Type 1 diabetes mellitus (T1DM) develops as a result of the autoimmune damage of pancreatic  $\beta$ -cells. Regulatory T-cells (Treg) have a crucial role in limiting the naturally occurring autoreactivity. Foxp3 is a master regulator transcription factor of Treg differentiation. Active Treg cells express high levels of IL-2 receptor  $\alpha$ -chain (CD25) and CTLA4 (Cytotoxic T-Lymphocyte Antigen 4). The aim of our study was to clarify certain details of the immunological dysregulation and Treg dysfunction.

**Materials and methods:** Forty patients with T1DM (M/F= 19/21;  $33.7 \pm 10.04$  years) and forty age-matched non-diabetic control subjects (M/F=16/24;  $32.97 \pm 11.63$  years;) were involved. The mean disease duration was  $15.76 (\pm 7.23)$  years. Fasting, EDTA-anticoagulated blood samples were collected. CD3, CD4, CD8, and CD25 surface proteins, intracellular CTLA4 and intranuclear Foxp3 were stained with specific fluorescent antibodies. A Beckman Coulter Navios flow cytometer and Kaluza software were used for quantitative analysis. Fluorescence intensity was described as median fluorescence intensity (MFI). Shapiro-Wilks normality test, Mann-Whitney-U-test, T-test and the Statsoft Statistica software were used.

**Results:** The proportion of Foxp3+ cells among CD4+ lymphocytes was not different in T1DM patients and control subjects. The proportion of CD25+ cells among CD4+Foxp3+ lymphocytes was lower in T1DM patients ( $72.89 \pm 7.74\%$  vs.  $63.23 \pm 12\%$ ,  $p<0.0001$ ). CD25 and CTLA4 expression (MFI) of T-lymphocytes was significantly lower in T1DM patients (CD25:  $0.2 \pm 0.21$  vs.  $0.38 \pm 0.33$ ,  $p<0.01$ ; CTLA4:  $1.02 \pm 0.45$  vs.  $1.3 \pm 0.48$ ,  $p<0.05$ ). Positive correlation was observed between the CD25 and the CTLA4 expression of T-lymphocytes ( $p<0.0001$ ;  $r=0.57$ ).

**Conclusion:** Although the CD4+Foxp3+ Treg cell population was not quantitatively different, the higher proportion of CD4+Foxp3+CD25- cells and lower CTLA4 expression in T-lymphocytes may reflect an increased proportion of the inactive Treg cell subpopulation. This might contribute to the impaired immune regulation. To overcome the impaired Treg cell activation in T1DM might be an attractive therapeutic approach in the future.

## PS 021 Measuring and preserving insulin secretion in type 1 diabetes

445

### <sup>111</sup>In-exendin uptake in the pancreas correlates with the beta cell mass but not with the alpha cell mass

M. Brom, C. Frielink, L. Joosten, M. Gotthardt;  
Department of Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, Netherlands.

**Background and aims:** A method to non-invasively determine the beta cell mass *in vivo* would enable us to study the pathophysiology of diabetes and is still a major unmet need. Targeting of the GLP-1R with <sup>111</sup>In-labeled exendin is an attractive approach for determination of the beta cell mass and preclinical studies as well as a proof-of-concept study in type 1 diabetic patients and healthy subjects showed a direct correlation of beta cell mass and radiotracer uptake. Despite these highly promising initial results, the influence of alpha cells on the uptake of the radiotracer remains a matter of debate. In this study we examined the specificity of <sup>111</sup>In-exendin in a rat model for beta cell loss by comparing the uptake of the tracer with the beta and alpha cell mass.

**Materials and methods:** Brown Norway rats were treated with 45 or 60 mg/kg alloxan (n=4 per group) in order to destroy the beta cells and 4 rats were injected with vehicle as a control. One week after injection of alloxan, 15 MBq <sup>111</sup>In-exendin (corresponding to 0.1 µg exendin) was injected and the pancreas was dissected 1 h after injection of <sup>111</sup>In-exendin. The radioactivity concentration was measured in a gamma counter and the beta cell and alpha cell mass were determined by morphometric analysis after immunohistochemical staining for insulin and glucagon, respectively.

**Results:** The uptake of <sup>111</sup>In-exendin (percentage of the injected dose) showed a strong positive linear correlation with the beta cell mass (Pearson r = 0.90). The absolute alpha cell mass was similar in healthy rats (2.2 ± 0.4 mg) and rats treated with 45 or 60 mg/kg alloxan (2.3 ± 0.3 mg and 1.8 ± 0.3 mg, respectively) and there was no significant correlation between the alpha cell mass and the uptake of <sup>111</sup>In-exendin (Pearson r = 0.31). The total mass of the endocrine pancreas was reduced in the alloxan treated rats (8.5 ± 1.9 mg, 5.5 ± 1.7 mg, and 2.8 ± 0.8 mg for healthy, 45 and 60 mg/kg alloxan, respectively) and percentage of glucagon positive cells of the total endocrine mass was increased after alloxan treatment (26% ± 4%, 43% ± 8%, and 69% ± 21% alpha cells of the total endocrine mass for healthy, 45 and 60 mg/kg alloxan, respectively). The uptake of <sup>111</sup>In-exendin showed a negative linear correlation with the alpha cell fraction (calculated by dividing the alpha cell mass by the total endocrine mass, Pearson r = -0.81).

**Conclusion:** The uptake of <sup>111</sup>In-exendin correlated with the beta cell mass, but not with the alpha cell mass. Together with the increased relative alpha cell mass and the negative linear correlation between the <sup>111</sup>In-exendin uptake and alpha cell fraction, these data clearly indicate towards specificity of <sup>111</sup>In-exendin to beta cells and that the influence of the alpha cells on <sup>111</sup>In-exendin uptake is negligible.

### Towards clinical PET imaging of pancreatic beta cells with [<sup>18</sup>F]exendin-4

K. Mikkola<sup>1</sup>, C.-B. Yim<sup>1</sup>, P. Lehtiniemi<sup>1</sup>, V.-V. Elomaa<sup>1</sup>, T. Ishizu<sup>1</sup>, J. Rajander<sup>2</sup>, O. Solin<sup>1,2</sup>, P. Nuutila<sup>1</sup>;

<sup>1</sup>Turku PET Centre, University of Turku and Turku University Central Hospital, <sup>2</sup>Accelerator Laboratory, Åbo Akademi University, Turku, Finland.

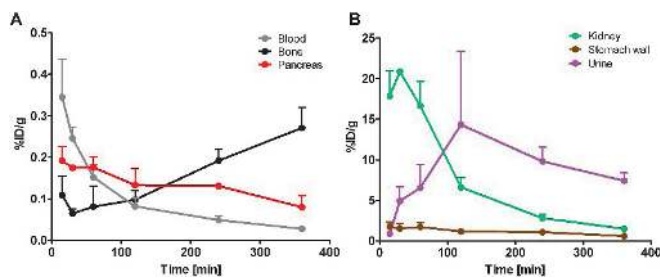

**Background and aims:** [<sup>18</sup>F]exendin-4 is a radioligand specific for the glucagon-like peptide-1 receptor (GLP-1R) abundantly expressed in beta cells. Quantitative non-invasive PET (positron emission tomography) imaging of pancreatic beta cells would serve as a valuable diagnostic tool and provide means to monitor therapeutic interventions. Several exendin based tracers have been intensively explored for beta cell imaging. The obstacle with these has been high uptake in the kidneys. The aim of this study is to develop a novel [<sup>18</sup>F]exendin-4 tracer for clinical imaging of beta cells with PET.

**Materials and methods:** Biodistribution and kinetics of [<sup>18</sup>F]exendin-4 was evaluated in Sprague-Dawley rats (N=3-9 per time point) weighing 250–300 g. After intravenous injection of [<sup>18</sup>F]exendin-4 (19 ± 3 MBq/kg, mass 0.3 ± 0.2 nmol/kg) rats were sacrificed at 15 min, 30 min, 1 h, 2 h, 4 h or 6 h. The

organ-specific radioactivity was reported as a percentage of the injected dose per gram of tissue (%ID/g). The GLP-1R specificity was assessed using cold exendin-3 (N=1). Intrapancreatic distribution of radioactivity was assessed using autoradiography. Islet labelling was verified by immunohistochemistry and islet-to-exocrine tissue ratios were analysed. Radioactive metabolites were determined by HPLC. For PET scans, rats were imaged up to six hours (dynamic 0-1 h, static 3.5-4 h and static 5.30-6 h) using Inveon Multimodality PET/CT.

**Results:** Radioactivity was nearly constant in the pancreas over the course of the study (0.18 ± 0.03 %ID/g at 1 h and 0.08 ± 0.03 %ID/g at 6 h p.i., Fig. 1A). Blocking studies indicated GLP-1R specific uptake in the islets. Autoradiography analysis of pancreatic sections showed that the islet-to-exocrine tissue ratio was 78 ± 29 at 1 h p.i. The amount of unchanged tracer in plasma was 28.3 ± 3.5 % at 1 h p.i. In line with other exendin based tracers, [<sup>18</sup>F]exendin-4 uptake by kidneys was high at 1 hour time point (16.7 ± 3.0 %ID/g), but thereafter its clearance was fast and retention decreased (1.5 ± 0.4 %ID/g, at 6 h p.i., Fig. 1B). After 6 h PET imaging, the highest tracer uptake was found in kidney, lung and stomach wall. Radioactivity in bone was low, indicating low defluorination of the tracer.

**Conclusion:** In conclusion, we found a specific and sustained uptake of [<sup>18</sup>F]exendin-4 in the pancreatic islets and high renal clearance of the tracer. These indications are promising for the development of novel [<sup>18</sup>F]exendin-4 towards clinical imaging of beta cells. Currently we are investigating [<sup>18</sup>F]exendin-4 biodistribution and pancreatic uptake in larger animals. Figure 1. Biodistribution of [<sup>18</sup>F]exendin-4 radioactivity in rat at various time points after tracer injection.

### <sup>111</sup>In-exendin imaging in patients with type 1 diabetes and healthy controls

W. Woliner - van der Weg<sup>1</sup>, M. Brom<sup>1</sup>, M. Béhe<sup>2</sup>, C.J.J. Tack<sup>3</sup>, O.C. Boerman<sup>1</sup>, M.J.R. Janssen<sup>1</sup>, M. Gotthardt<sup>1</sup>;

<sup>1</sup>Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, Netherlands, <sup>2</sup>Paul Scherrer Institute, Center for Radiopharmaceutical Sciences, Villigen-PSI, Switzerland, <sup>3</sup>Internal Medicine, Radboud University Medical Center, Nijmegen, Netherlands.

**Background and aims:** Currently the beta cell mass (BCM) can, in contrast to beta cell function, not be measured non-invasively. A non-invasive test would help to increase our knowledge about changes in beta cell mass during the development and treatment of diabetes. Preclinical studies showed that the pancreatic uptake of <sup>111</sup>In-labeled exendin, which targets to the glucagon-like peptide-1 (GLP-1) receptor, directly correlates with BCM. As a first step into clinical use of <sup>111</sup>In-exendin imaging for beta cell quantification, we acquired and analyzed single photon emission computed tomography (SPECT) images after <sup>111</sup>In-exendin administration in T1D patients and healthy subjects.

**Materials and methods:** Patients with long standing T1D (BMI below 27, age 21-60 yr, minimal 5 year duration of T1D) and healthy controls (normal glucose tolerance measured by OGTT, matched for age, gender and BMI) were eligible for the study. Four, 24 and 48 hours after i.v. injection of 150 MBq <sup>111</sup>In-Exendin-4, SPECT images were acquired for quantitative assessment of the uptake into the pancreatic beta cells. The pancreas volume was measured by CT. Uptake calculation was based on the counts within two spherical volumes of interest (VOIs) placed in the head and corpus region, multiplied by the pancreas volume. Counts were corrected for administered activity and time after injection, leading to the pancreatic uptake in counts per MBq (c/MBq).

**Results:** To date, 10 T1D patients and 8 healthy volunteers were included. The T1D patients showed an average uptake of 451 c/MBq in the whole pancreas

(SD 426 c/MBq). The average uptake of the healthy controls was more than two and a half times higher; 1258 c/MBq per pancreas (SD 645 c/MBq). Both groups showed large interindividual differences: the uptake in T1D patients ranges from 81 to 1445 c/MBq per pancreas and in the healthy subjects from 264 to 1998 c/MBq per pancreas. (See figure 1) Also the concentration of  $^{111}\text{In}$ -Exendin in the pancreas (not corrected for pancreas size) is more than two times lower in the group with T1D. The images and subsequent quantitative analysis show that the  $^{111}\text{In}$  retention in the pancreas remains stable for at least 4 to 48 hours after injection in the pancreas.

**Conclusion:** This clinical study indicates that  $^{111}\text{In}$ -Exendin imaging with SPECT could indeed be the first technology to enable non-invasive beta cell quantification. In line with literature, it visualizes considerable interindividual differences in both groups and shows a, in general, much lower uptake of  $^{111}\text{In}$ -Exendin in T1D patients than in healthy volunteers. Therefore it could be a valuable tool for further elucidating the complex pathophysiology in diabetes.

### Glucagon and mixed-meal tests to estimate beta cell and incretin functions in normals: relevance for studies in type 1 diabetes

C. Guglielmi<sup>1</sup>, L. Valente<sup>1</sup>, S. Falluca<sup>1</sup>, S. Angeletti<sup>1</sup>, S. Briganti<sup>1</sup>, M. De Pascalis<sup>1</sup>, J.M. Lachin<sup>2</sup>, P. Pozzilli<sup>1</sup>;

<sup>1</sup>University Campus Bio Medico, Roma, Italy,

<sup>2</sup>The George Washington University, Rockville, USA.

**Background and aims:** Measurement of C-peptide after the administration of different stimuli is the only instrument able to directly measure in vivo beta cell function and it is used as primary endpoint in several immunointervention trials. The two tests currently used are Glucagon Stimulation Test (GST) and Mixed Meal Tolerance Test (MMTT).

**Materials and methods:** We carried out a study in 10 healthy subjects (25-40 yrs) to evaluate beta cell function, Gastric Inhibitory Peptide (GIP) and Glucagon Like Peptide 1 (GLP1) which may affect C-peptide response to the two tests. GST and MMTT were carried out one week apart according to standard tests.

**Results:** At the end of GST (20 min) stimulated C-peptide showed a mean increase from baseline of 147.1% while at the end of MMTT (120 min), the mean increase of C-peptide was equal to 99.8% ( $\Delta$ increase= 47.2%) while Max C-peptide reached during MMTT was greater than that gained during GST (C-pept maxMMTT=2.3nmol/L vs C-pep maxGST=1.9nmol/L). A positive and linear correlation was found between the incremental AUC (iAUC) C-peptide in GST and iAUC C-peptide in MMTT ( $r=0.61$ ,  $p=0.05$ ). These data show that the two tests can be considered equivalent in assessing beta cell function although there are differences: in MMTT, but not in GST, the incretin response affects C-peptide levels. A positive and linear correlation between GIP and C-peptide levels was found during MMTT ( $r=0.92$ ,

$p=0.008$ ) and a positive and exponential correlation was found between GIP and insulin during MMTT ( $R^2=0.82$ ). This was not the case with GST. No correlation was found between GLP-1 and C-peptide levels during MMTT and between GIP or GLP1 levels and C-peptide during GST.

**Conclusion:** Although the two stimulation tests may produce a similar response in C-peptide, they diverge in that the beta cell response to GST test is independent of the incretin axis whereas this is not the case with MMTT. This result indicates the two tests differ in their mechanisms of action of stimulating C-peptide secretion.

### Functioning beta cells in type 1 diabetes may not be as low as it is presumed

G. Tamer<sup>1</sup>, B. Dogan<sup>2</sup>, I. Ocakoglu<sup>3</sup>, O. Kostek<sup>4</sup>, I. Kartal<sup>1</sup>, G. Sagun<sup>4</sup>, M. Adas<sup>5</sup>, I. Tamer<sup>6</sup>, H.H. Mutlu<sup>2</sup>, A. Orhun<sup>3</sup>;

<sup>1</sup>Division of Endocrinology and Metabolism, Department of Internal Medicine, <sup>2</sup>Department of Family Medicine, <sup>3</sup>Department of Biochemistry, <sup>4</sup>Department of Internal Medicine, Medeniyet University, Goztepe Training and Research Hospital, <sup>5</sup>Division of Endocrinology and Metabolism, Department of Internal Medicine, Okmeydanı Training and Research Hospital, <sup>6</sup>Department of Family Medicine, Dr Lutfi Kirdar Kartal Training and Research Hospital, Istanbul, Turkey.

**Background and aims:** Enhancing endogenous insulin production in type 1 diabetic patients (T1DP) can improve glycemic control and decrease complications and rates of mortality. However, it can be successful even if sufficient  $\beta$ -cell function is present. We aimed to evaluate the extent of  $\beta$ -cell function by determining fasting levels of C-peptide and those after meal stimulus.

**Materials and methods:** Sixtythree T1DP were enrolled. Ethics committee of our hospital approved the study protocol, which was in accordance with the Helsinki Declaration. Fasting C-peptide levels of all participants and stimulated (at 90<sup>th</sup> minute post mixed meal) C-peptide levels of 54 were measured by using an electrochemiluminescence assay. Two categorizations were done using fasting (the first categorization) and at 90<sup>th</sup> minute post mixed meal test (the second categorization) of C-peptide levels. For the first categorization; the groups were classified as follows: patients with undetectable  $\leq 0.1$  ng/mL (group 1); with minimal 0.1-0.8 ng/ml (group 2); and with sustained  $\geq 0.8$  ng/mL (group 3) C-peptide levels. For the second categorization, groups were as follows: patients with undetectable  $\leq 0.1$  ng/mL (group 1); with minimal 0.1-0.8 ng/ml (group 2); and with sustained  $\geq 0.8$  ng/mL (group 3) C-peptide levels which increased at the 90<sup>th</sup> minute after the meal  $\geq 150\%$  of fasting C-peptide level.

**Results:** For the first category; 25.4%, 49.2%, 25.4% of T1DP were in group 1, group 2 and group 3, respectively. For the second category; 22.2% of T1DP were in group 1, 24.1% of them in group 2 and 53.7% of them in group 3. For the first categorization 74% and for the second categorization 77.8% of T1DP had detectable C-peptide levels. More than 50% of T1DP had a response to meal stimulus with C-peptide levels  $\geq 0.8$  ng/mL which increased up to  $\geq 150\%$  of fasting C-peptide levels like non-diabetics.

**Conclusion:** The finding that presence of insulin secretion which increases after meals, suggests the possibility of undergoing  $\beta$ -cell regeneration within many T1DP.

## 450

### Residual beta cell function in long-standing childhood onset type 1 diabetes

P.J. Bingley<sup>1</sup>, R.J. Aitken<sup>1</sup>, I.V. Wilson<sup>1</sup>, A.E. Long<sup>1</sup>, A.J.K. Williams<sup>1</sup>, T. McDonald<sup>2</sup>, S. Wong<sup>3</sup>, A.T. Hattersley<sup>2</sup>, K.M. Gillespie<sup>1</sup>;

<sup>1</sup>School of Clinical Sciences, University of Bristol, <sup>2</sup>University of Exeter Medical School, <sup>3</sup>Institute of Molecular and Experimental Medicine,

Cardiff University School of Medicine, UK.

**Background and aims:** Some people with type 1 diabetes have functioning beta cells years after diagnosis, but the reason is unclear. We aimed to determine the frequency of residual C-peptide secretion in people with long-standing type 1 diabetes recruited to the Bart's-Oxford study at diagnosis and relate this to current and baseline islet autoantibodies.

**Materials and methods:** We measured two-hour post-meal urine C-peptide:creatinine ratio (UCPCR) and autoantibodies to glutamate decarboxylase (GADA) and islet antigen-2 (IA2A) in samples collected from 140 patients (median age at diagnosis 11.9 years, 50% male) a median of 22 years

(range 12.2–28 years) after diagnosis. Baseline status for GADA, IA2A and zinc transporter 8 autoantibodies was determined in samples collected within 24 months of diagnosis (median 33 days). UCPCR thresholds equivalent to mixed meal-stimulated serum C-peptide  $\geq 0.2$  nmol/L and  $\geq 0.03$  nmol/L were used to define 'preserved' and 'minimal' endogenous insulin secretion. HLA class II genotype was established by PCR-SSP. Associations were examined by chi-squared and non-parametric testing.

**Results:** Of the 140 patients, 23 (16.4%) still had detectable endogenous insulin secretion; seven (5.0%) 'preserved' and 16 (11.4%) 'minimal'. 62% of participants had at least one antibody in current samples; 29% were GADA+ and 50% IA2A+. Persistent C-peptide secretion was inversely related to age at diagnosis ( $p=0.0009$ ), and no one diagnosed before age 10 had 'preserved' secretion. UCPCR was independent of diabetes duration and baseline or current autoantibody status. Of 7 individuals with 'preserved' endogenous insulin secretion, 6 had GADA at diagnosis with at least one diabetes risk-associated HLA class II haplotype.

**Conclusion:** A subset of patients with proven autoimmune-mediated type 1 diabetes has endogenous insulin secretion many years after diagnosis, but this is rarely found in individuals diagnosed in early childhood. Ongoing islet autoimmunity is also common. We hypothesise that, while aggressive early onset autoimmunity results in complete beta cell destruction, the less aggressive autoimmune process associated with later onset type 1 diabetes allows residual beta cells to provide a focus for persistent function as a result of regulated autoimmunity and/or beta cell renewal.

### High GADA titer significantly increases the risk of insulin requirement in LADA: a 7-year follow-up (NIRAD Study 7)

S. Zampetti<sup>1</sup>, G. Campagna<sup>1</sup>, C. Tiberti<sup>1</sup>, M. Songini<sup>3</sup>, M. Arpi<sup>4</sup>, G. De Simone<sup>5</sup>, E. Cossu<sup>6</sup>, L. Cocco<sup>7</sup>, G. Leto<sup>2</sup>, E. Bosi<sup>8</sup>, F. Giorgino<sup>9</sup>, M. Spoletini<sup>2</sup>, R. Buzzetti<sup>2</sup>, NIRAD Study Group;

<sup>1</sup>Sapienza University, Rome, <sup>2</sup>San Michele Hospital, Cagliari, <sup>3</sup>Catania University, <sup>4</sup>ASL Napoli, <sup>5</sup>University of Cagliari, <sup>6</sup>Cardarelli Hospital, Campobasso, <sup>8</sup>San Raffaele Institute, Milan, <sup>9</sup>University of Bari, Italy.

**Background and aims:** The aim of the study was to determine whether glutamic acid decarboxylase antibody (GADA) titer and other clinical parameters could define the risk of progression to insulin therapy in LADA patients during a 7-years follow-up.

**Materials and methods:** N= 222 LADA and n=430 type 2 diabetes subjects were followed for 7-years from the time of GADA screening to evaluate their progression towards insulin therapy. Kaplan-Meier curves and multivariate logistic regression analysis were performed to identify markers able to influence this progression.

**Results:** During the follow-up, drop out was 4% in both groups. N=119 (56.1%) out of n=212 LADA and n=86 (20.9%) out of n=412 type 2 diabetes required insulin. Kaplan-Meier plots showed that 74/104 (71.1%) of high GADA titer required insulin compared to 45/108 (41.6%) of low GADA titer and to 86/412 (20.9%) of type 2 diabetes ( $p<0.0001$  for both). BMI  $\leq 25$  kg/m<sup>2</sup> and positivity to IA-2IC and ZnT8 were also markers of faster progression ( $p<0.0001$  for both). The proportion of LADA requiring insulin was significantly higher in the group of subjects treated also with sulfonylurea in the first year from diagnosis than in those treated with diet and/or insulin sensitizers ( $p<0.001$ ). Multivariate analysis confirmed that presence of high GADA titer was a significant predictor of insulin ( $p<0.0001$ , OR=6.95).

**Conclusion:** High GADA titer, BMI  $\leq 25$ , ZnT8 and IA2IC positivity and sulfonylurea, in the first year from diagnosis, significantly increase the progression towards insulin requirement in LADA.

## 452

### Pre-existing insulin autoantibodies predict efficacy of otelixizumab in preserving residual beta cell function in recent-onset type 1 diabetes

S. Demeester<sup>1</sup>, B. Keymeulen<sup>1</sup>, L. Kaufman<sup>1</sup>, A. Van Dalem<sup>1</sup>, E.V. Balti<sup>1</sup>, U. Van de Velde<sup>1</sup>, P. Goubert<sup>1</sup>, K. Verhaeghen<sup>1</sup>, H.W. Davidson<sup>2</sup>, J.M. Wenzlau<sup>2</sup>, I. Weets<sup>1</sup>, D.G. Pipeleers<sup>1</sup>, F.K. Gorus<sup>1</sup>;

<sup>1</sup>Diabetes Research Center, Brussel, Belgium,

<sup>2</sup>Barbara Davis Center for Childhood Diabetes, Aurora, USA.

**Background and aims:** Immune interventions have shown partial and transient efficacy in preserving beta cell function in recent-onset type 1 diabetes. Future trials would benefit from biomarkers that predict therapeutic response, particularly when targeting subclinical disease. (Auto)antibodies against insulin (I(A)A), GAD (GADA), IA-2 (IA-2A) and ZnT8 (ZnT8A) were measured from this perspective during a randomized placebo-controlled anti-CD3-study (otelixizumab, GSK).

**Materials and methods:** Eighty recent-onset type 1 diabetic patients (n=40 otelixizumab, n=40 placebo) were included and levels of autoantibodies and stimulated C peptide release were measured at baseline (median duration of insulin treatment: 7 days) and every 6 months until 18 months after randomisation. I(A)A, GADA, IA-2A and ZnT8A levels were determined by liquid-phase radio binding assays, C-peptide release was measured during hyperglycaemic glucose-clamp.

**Results:** At baseline and during follow-up, levels of GADA, IA-2A and ZnT8A were not significantly different between treatment arms. Compared to placebo treated patients, anti-CD3-treated participants experienced a less pronounced insulin-induced rise in I(A)A, but only in initially IAA+ participants with relatively preserved beta cell function at baseline and concomitantly lower insulin needs. Univariate analysis identified IAA level at screening as well as C-peptide release at entry as predictors of anti-CD3 efficacy in terms of the preservation of beta cell function, but in multivariate analysis only IAA was retained ( $p=0.026$ ).

**Conclusion:** Pre-existing insulin autoantibodies represent an independent marker for the therapeutic response of recent-onset type 1 patients to anti-CD3 treatment. Future immune intervention trials in (pre)type 1 diabetes should consider both presence of IAA and relatively preserved functional beta cell mass as inclusion criteria.

### Evaluation of DiaPep277 treatment in type 1 diabetes by integrated analysis

D. Elias<sup>1</sup>, A. Avron<sup>1</sup>, M. Tamir<sup>1</sup>, R. Eren<sup>1</sup>, D. Peled<sup>1</sup>, S. Dagan<sup>1</sup>, I. Raz<sup>2</sup>, P. Pozzilli<sup>3</sup>, T. Linn<sup>4</sup>, F. Bonnici<sup>5</sup>, DIA-AID<sup>1</sup> Study Group;

<sup>1</sup>Andromeda Biotech Ltd., Yavne, Israel, <sup>2</sup>Diabetes Unit, Hadassah University Hospital, Jerusalem, Israel, <sup>3</sup>Endocrinology & Metabolic Diseases, University Campus Bio-Medico, Rome, Italy,

<sup>4</sup>University Hospital Giessen, Germany, <sup>5</sup>UCT Private Academic Hospital, Cape Town, South Africa.

RETRACTED

On behalf of the authors identified below, Itamar Raz, the corresponding author, has formally requested to retract Abstract 453, cited above, which was published in Diabetologia Supplement 1, September 2014—the Abstract Volume of 2014 EASD Annual meeting.

The abstract reports on the DIA-AID 1 trial, which examined the safety and efficacy of DiaPep277 to treat type 1 diabetes. The DIA-AID 1 trial was funded by Andromeda Biotech, Ltd.

On 8 September 2014, Hyperion Therapeutics, Inc., which acquired Andromeda Biotech in June 2014, announced that it had chosen to terminate the DiaPep277 programme. As stated in the press release issued by Hyperion Therapeutics, ‘The company has uncovered evidence that certain employees of Andromeda Biotech, Ltd ... engaged in serious misconduct, including collusion with a third-party biostatistics firm in Israel to improperly receive un-blinded DIA-AID 1 trial data and to use such data in order to manipulate the analyses to obtain a favorable result’ [1].

The corresponding author writes:

‘In view of the public statements by Hyperion Therapeutics [1] regarding alleged scientific misconduct, we, the authors of this statement, are retracting the above-cited abstract. We wish to emphasize that we were not involved in the assembly of the raw data or the alleged misconduct.

‘The following authors support the decision to retract the article: Itamar Raz, Paolo Pozzilli, Thomas Linn and Francois Bonnici.’

Diabetologia was only able to contact four of the six coauthors who are/were Andromeda Biotech employees—Dana Elias, Merana Tamir, Rachel Eren and Shlomo Dagan. None of these co-authors responded to emails and therefore none of the Andromeda Biotech employees were part of this retraction process.

## PS 022 Beta cell ER stress and apoptosis

454

### Cross-interaction between C/EBPβ and AMPK determines the pancreatic beta cell mass

Y. Mieda<sup>1</sup>, T. Matsuda<sup>2</sup>, T. Kawamoto<sup>1</sup>, E. Suzuki<sup>2</sup>, S.-I. Asahara<sup>2</sup>, A. Kanno<sup>2</sup>, M. Koyanagi<sup>2</sup>, Y. Kido<sup>1</sup>;

<sup>1</sup>Division of Medical Chemistry, Department of Biophysics, Kobe University Graduate School of Health Sciences, <sup>2</sup>Division of Diabetes and Endocrinology, Department of Internal Medicine, Kobe University Graduate School of Medicine, Japan.

**Background and aims:** Accumulation of C/EBPβ plays an important role in pancreatic β-cell failure caused by endoplasmic reticulum (ER) stress. Pancreatic β cell mass increases when gene modification or DPP-4 inhibitors are used to reduce expression of C/EBPβ accumulated in type 2 diabetes model mice or pancreatic β-cell specific C/EBPβ transgenic mice. We, therefore, aimed to elucidate the control mechanism of C/EBPβ expression.

**Materials and methods:** MIN6 cells were loaded with AICAR, metformin, and Extensin-4 to assess the relationship between AMPK activity and C/EBPβ expression levels. The effect of C/EBPβ phosphorylation on expression levels was also investigated. Further, vildagliptin and metformin were administered to pancreatic β cell specific C/EBPβ transgenic (TG) mice to investigate the relationship between C/EBPβ expression levels and AMPK activity in the pancreatic islets.

**Results:** In the pancreatic β-cells, ER stress causes enhanced expression and accumulation of C/EBPβ. The accumulated C/EBPβ was shown to inhibit AMPK activity by lowering the AMP/ATP ratio. C/EBPβ expression levels were, however, inhibited when AMPK was activated, and enhanced when AMPK was inactivated. In other words, AMPK activity and C/EBPβ expression levels were negatively correlated. Some of these effects are thought to involve T188 phosphorylation of C/EBPβ. In other words, the decreased AMPK was thought to increase C/EBPβ expression by raising the stability of C/EBPβ as a protein via enhanced T188 phosphorylation of C/EBPβ. In the pancreatic islets of the TG mice, increased C/EBPβ expression was accompanied by decreased AMPK activity. When the DPP-4 inhibitor vildagliptin was administered to the TG mice, the pancreatic islets exhibited improved AMPK activity accompanied by inhibited C/EBPβ expression. Moreover, with concomitant administration of vildagliptin and metformin, the pancreatic islets exhibited even greater activation of AMPK accompanied by even greater inhibition of C/EBPβ expression compared to vildagliptin alone. As a result, glucose tolerance was even further improved.

**Conclusion:** When pancreatic β cells are loaded with ER stress, enhanced C/EBPβ expression and decreased AMPK activity are thought to act synergistically to bring about pancreatic β cell failure. T188 phosphorylation of C/EBPβ also played an important role in control of C/EBPβ expression by AMPK or ER stress. An increase in the pancreatic β cell mass and inhibition of C/EBPβ expression by vildagliptin was accompanied by activation of AMPK. Combining vildagliptin and metformin exhibited even greater AMPK activation accompanied by an increase in pancreatic β cell mass and inhibition of C/EBPβ expression, compared to vildagliptin alone. This suggests that decreased AMPK activity and enhanced C/EBPβ expression form a vicious cycle to bring about pancreatic β cell failure.

### Enhancing peroxiredoxin 4 expression improves insulin biosynthesis and glucose-induced insulin secretion in insulin-producing INS-1E cells

I. Mehmeti, S. Lortz, M. Elsner, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** Oxidative protein folding is crucial for the structural stability and proper function of most secretory proteins and polypeptide hormones such as insulin. This process takes place in the endoplasmic reticulum (ER) and is accomplished by protein disulfide isomerase (PDI) and ER oxidoreductin 1β (ERO-1β), generating stoichiometric amounts of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) as byproduct. During insulin resistance in the pre-diabetic state, increased insulin biosynthesis can overwhelm the ER antioxidative and folding capacity, causing an imbalance in the ER redox homeostasis and

oxidative stress. Peroxiredoxin 4 (Prdx4), an ER-specific antioxidative peroxidase can utilize luminal H<sub>2</sub>O<sub>2</sub> as driving force for reoxidizing PDI family members, thus efficiently contributing to disulfide bond formation. Therefore the aim of this study was to examine the functional significance of Prdx4 on  $\beta$ -cell function with emphasis on insulin content and secretion during stimulation with nutrient secretagogues.

**Materials and methods:** The ER-specific Prdx4 was specifically overexpressed in insulin-producing INS-1E cells. The Prdx4 overexpression was verified by Western blot, while its antioxidative effect was assessed by DCF in the presence of 5 mM dithiothreitol (DTT). Insulin content and secretion were determined by RIA and proinsulin transcription by qRT-PCR after stimulation with glucose (3, 10, 30 mM) and a combination of leucine (10 mM) plus glutamine (2 mM).

**Results:** Immunoblotting revealed that INS-1E cells stably transduced with a lentiviral construct carrying Prdx4 exhibited a significant increase in the Prdx4 expression compared to control cells. Exposure of control cells to DTT resulted in a significant generation of reactive oxygen species (ROS), whereas Prdx4 overexpression completely prevented the DTT-mediated ROS generation. Overexpression of Prdx4 led to an improved insulin secretion after stimulation with 10 and 30 mM glucose compared to control cells, while the basal insulin secretion at 3 mM glucose was not affected. An augmented insulin secretion could also be observed in Prdx4 overexpressing cells incubated with leucine plus glutamine. In addition, Prdx4 overexpressing cells exhibited an enhanced proinsulin mRNA transcription and insulin content when compared to control cells.

**Conclusion:** These data strongly suggest that enhancing ER-specific peroxiredoxin 4 expression in glucose-responsive insulin-secreting INS-1E cells significantly metabolized the DTT-mediated H<sub>2</sub>O<sub>2</sub> generation within the ER and improved the glucose-induced insulin-secretion, which was accompanied by the enhancing proinsulin gene transcription and insulin content. This beta cell beneficial effect was also observed upon stimulation with leucine, another nutrient insulin secretagogue, indicating that the effect is not restricted to glucose. Thus, Prdx4 improves the ER folding capacity and could contribute to the preservation of beta cell function under conditions of high insulin requirement.

### Targeted overexpression of glycosylation-negative catalase mutations in the endoplasmic reticulum of insulin-producing cells

S. Lortz, I. Mehmeti, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** In reaction to peripheral insulin resistance in type 2 diabetes mellitus,  $\beta$ -cells show initially an increased insulin secretion. Escalated insulin biosynthesis and secretion require an enhanced capacity for protein folding and disulfide bond formation, resulting in an increased production of H<sub>2</sub>O<sub>2</sub> in the endoplasmic reticulum (ER). A direct quantification is not possible due to the oxidative environment in the ER and catalase overexpression for compensating an elevated H<sub>2</sub>O<sub>2</sub> production failed due to N-glycosylation of the catalase protein. Therefore, a glycosylation-negative ER-targeted catalase variant, designed by mutagenesis, should be overexpressed to reduce the H<sub>2</sub>O<sub>2</sub> concentration in the ER of insulin-secreting cells and to proof its potential impact on insulin secretion and ER stress.

**Materials and methods:** The two potential N-glycosylation sites of the human catalase protein were eliminated by PCR-mediated mutagenesis. The generated catalase variants were peroxisomally overexpressed to confirm that catalase enzyme activity was unaffected by the mutations, before the ER-specific expression was carried out in RINm5F and INS-1E cells. Catalase functionality in the ER and prevention of N-glycosylation was examined by enzyme activity measurement, incubation with H<sub>2</sub>O<sub>2</sub> and Western blot analysis. Glucose-induced insulin secretion was quantified by RIA and typical ER stress markers were quantified by qRT-PCR analysis.

**Results:** Despite of the mutation of the N-glycosylation motives at asparagine-244 and -439, catalase activity was not affected by both single mutants (N244: 938±114, N439: 972±101, untransfected: 16±4 U/ $\mu$ g protein). After overexpression of both variants in the ER only the ER-catalase-N244 showed enzyme activity and lack of glycosylation, whereas ER-catalase-N439 was still glycosylated and only a slightly elevated catalase activity could be detected (N244: 935±51, N439: 74±10 U/ $\mu$ g protein). Quantification of catalase enzyme activity of the double mutant N244/439 after peroxisomal and ER-targeted overexpression revealed lower catalase activity in both compartments compared with N244 (peroxisome: 278 ± 17, ER: 168 ± 12 U/ $\mu$ g protein). Measurement of glucose-induced insulin secretion and of ER stress-induced

genes showed no significant changes compared with untransfected control cells.

**Conclusion:** With the overexpression of ER-catalase-N244 a highly effective H<sub>2</sub>O<sub>2</sub> inactivation within the ER could be achieved for the first time. Double mutation of both N-glycosylation motives N-244 and -439 was associated with partial loss of function, possibly due to the destruction of the three-dimensional enzyme structure. Since catalase has a high H<sub>2</sub>O<sub>2</sub> inactivation capacity and is not involved in the protein folding process, the enzyme is an ideal tool for the investigation of insulin biosynthesis-associated oxidative ER stress, postulated for type 2 diabetes, or oxidative stress induced by misfolded protein aggregation in the ER. However, increased H<sub>2</sub>O<sub>2</sub> inactivation through overexpression of ER-Catalase-N244 had no influence on insulin biosynthesis and the ER-stress response.

## 457

### ATF6 $\beta$ regulates the *Wfs1* gene and has a cell survival role in the ER stress response in pancreatic beta cells

A. Volchuk, T. Odisho, L. Zhang;

Cellular & Molecular Biology, Toronto General Research Institute, Canada.

**Background and aims:** Endoplasmic reticulum (ER) stress has been implicated in the development of pancreatic  $\beta$ -cell dysfunction and death resulting in type 2 diabetes. The Unfolded Protein Response (UPR) is the cellular system that responds to ER stress and consists of three main ER stress sensors, PERK, IRE1 and ATF6. Activating transcription factor 6 (ATF6) is an essential component of the UPR in cells undergoing ER stress that consists of two distinct genes, ATF6 $\alpha$  and ATF6 $\beta$ . The ATF6 $\beta$  isoform has been less studied and its role in the UPR in  $\beta$ -cells is unclear.

**Materials and methods:** Rodent islets and insulinoma cell lines were used to examine ATF6 $\beta$  function. Microarray and qPCR validation was employed to identify ATF6 $\beta$  target genes and siRNA knock-down and adenoviral overexpression was used to assess the role of ATF6 $\beta$  in ER stress-induced apoptosis.

**Results:** ATF6 $\beta$  mRNA and protein were detected in pancreatic  $\beta$ -cell lines and rodent and human islets and the protein was proteolyzed to the nuclear active form (ATF6 $\beta$ p60) in response to pharmacological ER stress. Knock-down of ATF6 $\beta$  using siRNA in INS-1 832/13 insulinoma cells did not affect mRNA induction of several major ER stress response genes in response to tunicamycin-induced ER stress, suggesting ATF6 $\beta$  is not essential for the basic UPR. Expressing active ATF6 $\beta$ p60 and ATF6 $\alpha$ p50 followed by microarray analysis revealed that ATF6 $\beta$  and ATF6 $\alpha$  regulate similar UPR genes, including chaperones and ERAD components, although some genes such as *Wfs1* are ATF6 $\beta$ -specific. Interestingly, knockdown of ATF6 $\beta$  increased the susceptibility of INS-1 832/13  $\beta$ -cells to apoptosis under both control and ER stress conditions, while overexpression of active ATF6 $\beta$ p60 reduced apoptosis.

**Conclusion:** ATF6 $\beta$  is not essential for induction of major ER stress response genes, but is required to maintain cell survival in  $\beta$ -cells undergoing chronic ER stress. The ATF6 $\beta$  pro-survival role may relate to induction of genes that promote cell survival such as *Wfs1*.

### The novel translation initiation factor, eIF2A, is up-regulated by endoplasmic reticulum stress and protects beta cells from apoptosis

E. Panzhinskiy<sup>1</sup>, F. Taghizadeh<sup>1</sup>, K.-Y. Chu<sup>1</sup>, Y. Yang<sup>1</sup>, E. Jan<sup>2</sup>, J.D. Johnson<sup>1</sup>;

<sup>1</sup>Cellular and Physiological Sciences,

<sup>2</sup>Biochemistry, University of British Columbia, Vancouver, Canada.

**Background and aims:** Endoplasmic reticulum (ER) stress is an important mediator of pancreatic beta cell loss in diabetes. Recent reports have associated inhibition of protein synthesis by the ER stress-induced unfolded protein response (UPR) with apoptosis. ER-stress associated translation reprogramming increase translation of stress-response mRNAs, but the signaling pathways that modulate this process in beta cells are not well studied. Recently, the novel translation initiation factors eIF2A and eIF2D have been implicated in the translation of specific mRNAs under stress conditions in other systems. We investigated the role of eIF2A and eIF2D in the regulation of UPR gene expression and ER-stress-induced apoptosis in beta cells.

**Materials and methods:** Thapsigargin (Tg, 1  $\mu$ mol/l), palmitate (PA, 0.5 mmol/l in BSA) were used to induce ER stress in primary mouse islets and mouse insulinoma cells (MIN6). Real-time RT-PCR, Western Blot and im-

munocytochemistry were used to assess gene expression. Apoptosis was assessed by flow cytometry of propidium iodide (PI) stained cells. Differences between means were considered statistically significant when  $p < 0.05$ .

**Results:** We found that eIF2A and eIF2D were expressed in mouse islets at both mRNA and protein levels. We compared eIF2A protein expression levels between different mouse tissues (heart, brain, liver, muscle, spleen, pancreatic islets) and found that they were highest in the pancreatic islets. eIF2D protein levels did not significantly differ between islets and other tissues. Fluorescent microscopy revealed that eIF2A and eIF2D were mainly localized in the cytoplasm of primary beta cells. Using MIN6 cells, we found gradual induction of eIF2A protein expression over the time course of Tg-induced ER stress, with the maximal fold increase of  $1.78 \pm 0.18$  ( $n = 4$ ) after 24 h, which coincided with activation of pro-apoptotic markers C/EBP homologous protein (CHOP,  $137 \pm 24$  fold,  $n = 4$ ) and cleaved caspase-3 ( $234 \pm 11$  fold,  $n = 4$ ). We also observed a  $1.66 \pm 0.17$  fold increase ( $n = 4$ ) in eIF2D protein levels after 6 h of Tg-treatment that coincided with maximum Activating Transcription Factor-4 protein levels ( $8.7 \pm 1.3$  fold increase,  $n = 4$ ). However, the effect was transient and after 24 h of Tg treatment, eIF2D protein levels were not different from the basal level. Treatment of MIN6 cells with PA for 24 h also significantly increased protein levels of eIF2A ( $2.1 \pm 0.5$  fold,  $n = 3$ ) with no significant differences in eIF2D levels observed. Isolated mouse islets treated with either Tg or PA for 24 h showed elevated levels of eIF2A protein (by  $1.35 \pm 0.5$  and  $1.43 \pm 0.2$  fold respectively,  $n = 3$ ) when compared to basal conditions, but not eIF2D. Importantly, we demonstrated that overexpression of recombinant eIF2A (10-fold) in MIN6 cells reduced thapsigargin-induced apoptosis by  $51 \pm 15\%$  ( $n = 3$ ). We found that decreased death of beta cells overexpressing eIF2A after 24 h of thapsigargin treatment was accompanied by decreased expression of UPR pro-apoptotic marker CHOP by  $45 \pm 13\%$  ( $n = 3$ ).

**Conclusion:** We conclude that eIF2A and eIF2D are expressed and differentially regulated over the course of UPR in beta cells. Also we identified a novel protective role for eIF2A in the context of ER-stressed beta cells via the inhibition of CHOP. Thus, eIF2A may potentially serve as a new therapeutic target in diabetes.

### The balance between adaptive and apoptotic unfolded protein responses regulates beta cell death through JNK, XBP1 and CHOP

J.Y. Chan, J. Luzuriaga, D.R. Laybutt;

Garvan Institute of Medical Research, Sydney, Australia.

**Background and aims:** The loss of  $\beta$ -cell mass due to increased apoptosis is critical in both type 1 and type 2 diabetes. Pro-inflammatory cytokines and saturated fatty acids are potential mediators of  $\beta$ -cell apoptosis, although the mechanisms are poorly understood. Endoplasmic reticulum (ER) stress is present in  $\beta$ -cells in both type 1 and type 2 diabetes. ER stress is resolved through adaptive actions of the unfolded protein response (UPR). However,  $\beta$ -cells are prone to failure of the adaptive UPR with consequent activation of pro-apoptotic UPR, but the mechanisms are unclear. Here, we investigated the role of key ER stress-responsive transcription factors, XBP1 and CHOP, in the UPR induced by cytokines (IL-1 $\beta$ , TNF- $\alpha$  and IFN- $\gamma$ ) or the saturated fatty acid, palmitate. We also examined the influence of Jun N-terminal kinase (JNK) activity in the UPR and the significance of these responses in  $\beta$ -cell survival.

**Materials and methods:** MIN6  $\beta$ -cells and mouse islets were exposed for 24–48 h to the combination of pro-inflammatory cytokines, IL-1 $\beta$  (100 U/ml), TNF- $\alpha$  (100 U/ml), IFN- $\gamma$  (250 U/ml) or the saturated fatty acid, palmitate (0.4 mM coupled to 0.92% BSA). siRNA was used to silence XBP1 and CHOP in MIN6 cells. IRE1/XBP1 inhibitor (4 $\mu$ 8c - 30  $\mu$ M) was used in mouse islets. SP600125 (20  $\mu$ M) was used to inhibit JNK activity.  $\beta$ -cell death was measured using a cell death detection ELISA. Gene and protein expression changes were assessed by real-time PCR and Western blot.

**Results:** In MIN6 cells, exposure to cytokines or palmitate resulted in increased cell death and ER stress, which featured marked increases in pro-apoptotic UPR markers, CHOP, *Atf3* and *Trib3*. siRNA-mediated inhibition of XBP1 reduced the expression of adaptive UPR markers, including ER chaperones and foldases (*BiP*, *Grp94*, *Fkbp11*, *Erp72*, *Edem1*) and potentiated cytokine- and palmitate-induced apoptosis ( $p < 0.001$ ). The enhancement of apoptosis was prevented by concomitant siRNA-mediated reduction of CHOP ( $p < 0.001$ ). IRE1/XBP1 inhibition by 4 $\mu$ 8c also increased cytokine- and palmitate-induced apoptosis in mouse islets. These findings suggest that XBP1-mediated maintenance of the adaptive UPR inhibits CHOP-dependent

apoptosis following chronic cytokine and palmitate exposure in  $\beta$ -cells. Cytokine exposure also increased levels of phosphorylated JNK. JNK inhibition by SP600125 prevented the inhibitory effects of cytokines on XBP1 and adaptive UPR gene expression, lowered pro-apoptotic UPR gene expression, and protected  $\beta$ -cells from cytokine-induced cell death ( $p < 0.001$ ).

**Conclusion:** These data suggest that JNK activity regulates the balance of the UPR in  $\beta$ -cells under conditions of ER stress; JNK activation inhibits XBP1-mediated UPR adaptation and promotes apoptotic UPR in  $\beta$ -cells. The differential regulation of adaptive and apoptotic UPR by JNK activation may provide a mechanism for the propensity of  $\beta$ -cells to apoptosis rather than ER stress adaptation in type 1 and type 2 diabetes.

### Chronic ethanol consumption inhibits Glucokinase transcriptional activity through ATF3/PDX-1/HDAC1 axis and triggers metabolic syndrome in vivo

W.-H. Kim, J.-Y. Kim, K.-J. Park, D.-Y. Lee, G.-H. Kim, Y.-J. Lee;

Korea National Institute of Health, Cheongwon-gun, Chungbuk, Republic of Korea.

**Background and aims:** Chronic ethanol consumption induces pancreatic  $\beta$ -cell dysfunction through glucokinase (GCK) nitration and downregulation, leading to impaired glucose tolerance and insulin resistance; but the underlying mechanism remain largely unknown.

**Materials and methods:** To this, the 6-week male C57BL/6J mice were fed with 5% ethanol-containing liquid diet for 8 weeks and examined the effects of in vivo ATF3 silencing on GCK downregulation and metabolic alterations in ethanol-fed mice.

**Results:** Here, we demonstrate that GCK gene expression and promoter activity in pancreatic  $\beta$ -cells were suppressed by chronic ethanol exposure *in vivo* and *in vitro*; whereas expression of activating transcription factor 3 (ATF3) and its binding to the putative ATF/CREB site on GCK promoter were upregulated. Furthermore, *in vitro* ethanol-induced ATF3 inhibited the positive effect of PDX-1 on GCK transcriptional regulation, enhanced recruitment of HDAC1/2 and histone H3 deacetylation, and subsequently augmented the interaction of HDAC1/PDX-1 on the GCK promoter, which were diminished by ATF3 siRNA. Corroboratory, *in vivo* ATF3-silencing reversed ethanol-mediated GCK downregulation and  $\beta$ -cell dysfunction, followed by the amelioration of impaired glucose tolerance and insulin resistance. ATF3 association with T2D with alcohol consumption was supported by the identification of a novel non-coding variant, rs6670133, in the ATF3 gene after adjusting for age, sex, and alcohol consumption in Korean T2D population ( $P = 0.041$ ).

**Conclusion:** We identified ethanol-induced ATF3 fosters  $\beta$ -cell dysfunction via GCK downregulation and that its loss ameliorates metabolic syndromes and could be a potential therapeutic target in treating T2D.

### Antiapoptotic HSPB1 mediates prolactin-induced cytoprotective effects on beta cells

R.A.M. Wailemann<sup>1,2</sup>, L.F. Terra<sup>1</sup>, T.C. Oliveira<sup>1</sup>, A.F. Santos<sup>1</sup>,

M.C. Sogayar<sup>1,3</sup>, L. Labriola<sup>1</sup>;

<sup>1</sup>Biochemistry, Chemistry Institute, <sup>2</sup>School of Arts, Science and Humanities (EACH), <sup>3</sup>Cell and Molecular Therapy Center (NUCEL/NETCEM), University of São Paulo, Brazil.

**Background and aims:** Transplantation of isolated pancreatic islets is an alternative for treatment of type 1 Diabetes; which is limited by the shortage of organ donors. Ex-vivo expansion of islet cell cultures appears as an attractive strategy; however, the islet fate in culture is determined, at least in part, by the balance between pro- and anti-apoptotic mediators. We have shown that recombinant human prolactin (rhPRL) inhibits beta-cell apoptosis. Moreover, we have recently reported PRL-induced up-regulation of the anti-apoptotic HSPB1 in human islets. Since the function of HSPB1 in beta-cells has not been directly studied, we set out to explore the role of HSPB1 in prolactin-induced beta-cell cytoprotection.

**Materials and methods:** We used primary cultures of human pancreatic islets and parental and HSPB1 knocked-down Min6 cells. Apoptosis was evaluated by DNA fragmentation and quantified by flow cytometry. Protein levels

of the Bcl-2 gene family members, caspase-9, HSTF1, P38, pP38, STAT-1 and pSTAT-1 were assessed by Western blotting. Caspase 3 and 8 activities were studied by fluorimetric assays.

**Results:** Our data showed that upon cytokines and rhPRL treatment, the proportion of fragmented nuclei was increased in HSPB1 silenced cells ( $p < 0.05$ ) when compared to control cells. In addition, the inhibition of cytokine-induced caspase-3 and caspase-8 activities as well as Bcl-2/Bax ratio and caspase-9 protein levels mediated by rhPRL in wild type cells was significantly reverted in knocked-down cells ( $p < 0.05$ ). Moreover, the kinetics of HSPB1 and HSTF1 expression levels were studied in primary cultures of human pancreatic islets which were serum starved and treated with rhPRL for short periods of time (from 10 min to 2h). The results showed that while HSTF1 presented a significant increase ( $p < 0.01$ ) in protein expression level after 10 min of rhPRL treatment, HSPB1 reached its maximum expression level upon 2h of hormonal treatment. Additionally, a significant ( $p < 0.05$ ) increase in STAT1 phosphorylation levels was detected after 10 min of rhPRL treatment reaching the highest peak upon 30 min ( $p < 0.001$ ) of hormonal treatment.

**Conclusion:** Therefore, we demonstrated a key role for HSPB1 in rhPRL-induced cytoprotective effects, since the lack of this protein completely abolished the beneficial effects induced by PRL on beta-cell death. Moreover, we provided for the first time, evidence for the co-regulation of HSPB1 and HSTF1 induced by rhPRL in human pancreatic cells which could be mediated by activated STAT1. Collectively, our results point to a promising target which could lead to the mitigation of beta-cell death through the up-regulation of an endogenous protective pathway which is not dependent on the modulation of the immune system.

### Modulation of glutamate signalling in human islets of Langerhans under hyperglycaemia

C. Perego<sup>1</sup>, S. Moretti<sup>1</sup>, E.S. Di Cairano<sup>1</sup>, F. Daniele<sup>1</sup>, F. Bertuzzi<sup>2</sup>, A. Davalli<sup>3</sup>, F. Folli<sup>4</sup>;

<sup>1</sup>DiSFB Dept of Pharmacological and Biomolecular Sciences, University of Milano, <sup>2</sup>Niguarda Cà Granda Hospital, <sup>3</sup>Dept. of Internal Medicine, Diabetes & Endocrinology Unit, Ospedale San Raffaele, Milano, Italy, <sup>4</sup>Dept. of Medicine Diabetes Division, University of Texas Health Science Center, San Antonio, USA.

**Background and aims:** Increasing evidence suggests that the excitatory neurotransmitter L-glutamate functions as a paracrine/autocrine signal in human islet of Langerhans. L-glutamate is released by  $\alpha$ -cells together with glucagon and modulates hormone secretion by acting on specific glutamate receptors. When present at elevated concentrations, it may induce beta-cell death through oxidative stress. Its interstitial concentration is regulated by glutamate transporters of the SLC1A family which are expressed on the plasma membrane of endocrine cells. Their functional activity is essential for islet function as shown by the fact that their pharmacological inhibition increases glutamate concentration in the islets and causes beta-cell death. Aim of this study was to verify whether chronic hyperglycaemia may modulate the glutamate signalling system in human islets of Langerhans.

**Materials and methods:** Human islets were incubated under chronic (3 days) hyperglycaemia (16.7 mmol/l glucose) or normoglycemia (5.5 mmol/l glucose), and the expression and function of plasma membrane glutamate transporters and intracellular signalling proteins were studied by quantitative PCR analysis, western blotting, immunofluorescence, [<sup>3</sup>H]-Glutamate uptake and Ca<sup>2+</sup>-imaging experiments.

**Results:** Quantitative PCR analysis revealed a 40±3% reduction in the total ASCT2/SLC1A5 expression after incubation in chronic hyperglycaemia. No changes in the total GLT1/SLC1A2 mRNA and protein expression in human islets were detected. Immunofluorescence experiments performed on human islets exposed to hyperglycaemia revealed GLT1 relocalization into intracellular vesicular compartments of beta-cells. Because of this relocalization, the GLT1-mediated surface activity measured by [<sup>3</sup>H]D-glutamate uptake was inhibited by 31±5% relative to normoglycemic conditions ( $p < 0.05$ ; n=4 in triplicate). Chronic hyperglycaemia induced a downregulation of the PI3K/Akt pathway in human beta-cells, suggesting a possible involvement of this pathway in the modulation of GLT-1 trafficking (35±3% downregulation of P-Akt expression, n=5 islet preparations). In line with this possibility, PI3K inhibition with 100  $\mu$ M LY293 caused the GLT1 relocalization in intracellular compartments, and a 75±8% downregulation of its activity, relative to control conditions ( $p < 0.001$ ; n=2 different islet isolations, in quadruplicate).

Chronic treatment with 10  $\mu$ M ceftriaxone, a drug capable to upregulate GLT1 expression, significantly prevented hyperglycaemia-induced apoptosis in human islets (65±12% reduction of apoptosis.  $P < 0.001$ ; n=2 preparations, in quadruplicate).

**Conclusion:** Our data indicate that glutamate signalling in human islet is altered in hyperglycaemia and this may further contribute to beta-cell death. Targeting glutamate signalling system components may be a promising approach to prevent beta-cell death and to control glucose homeostasis in diabetes.

## PS 023 Mechanisms of lipotoxicity

463

### Inhibition of *de novo* lipogenesis by lysosomal acid lipase in beta cells helps counter-regulate insulin secretion

G.L. Pearson<sup>1</sup>, P.J. Meikle<sup>2</sup>, N. Mellett<sup>3</sup>, H. Du<sup>3</sup>, T.J. Biden<sup>1</sup>;<sup>1</sup>Garvan Institute of Medical Research, Darlinghurst, <sup>2</sup>Baker IDI, Melbourne, Australia, <sup>3</sup>School of Medicine, Indiana University, Indianapolis, USA.

**Background and aims:** Endogenous lipolysis is hypothesised to contribute to the amplification phase of glucose-stimulated insulin secretion (GSIS) in pancreatic  $\beta$ -cells, mediated acutely by neutral lipases. Recent work shows that lysosomal acid lipase (LAL), an acidic lipase responsible for the breakdown of lipid delivered to the lysosome, is a negative regulator of GSIS. However, the exact mechanism of action of LAL and its role in whole body glucose homeostasis are unclear. Our current aims were to: (1) investigate glucose homeostasis in global LAL knock-out (KO) mice and (2) further characterise its mechanism of action.

**Materials and methods:** Wild-type (WT) and LAL KO mice were subjected to intraperitoneal glucose-tolerance tests (i.p. GTT). GSIS was measured by insulin RIA in islets isolated from WT and LAL KO mice. After 24 h LAL inhibition with Lalistat (5  $\mu$ mol/l) in MIN6 cells, gene expression was analysed by RT-PCR and lipid mass was assessed using mass spectrometry.

**Results:** LAL KO mice had significantly lower glucose excursions during an i.p.GTT compared to WT mice (AUC mean $\pm$ SEM: WT 1514.3 $\pm$ 104.8 n=10; LAL KO 1087.0 $\pm$ 95.2 n=7; P<0.05 two-way ANOVA). This was most notable 30 min after the glucose bolus, and coincided with significantly higher insulin levels throughout the i.p.GTT (insulin AUC mean $\pm$ SEM: WT 18.6 $\pm$ 0.9 n=10; LAL KO 44.3 $\pm$ 4.3 n=7; P<0.001 two-way ANOVA). To delineate a  $\beta$ -cell specific effect of LAL deletion, islets were assessed for GSIS *ex vivo*. Islets from LAL KO mice had increased GSIS at 20mmol/l glucose compared to WT islets (pg insulin/islet/h $\pm$ SEM, n=5: WT 516.3 $\pm$ 69.1; LAL KO 872.5 $\pm$ 108.8; P<0.05 paired t-test). Together these data confirm that LAL has a physiological role in  $\beta$ -cell function and acts to inhibit insulin secretion *in vivo*. In mechanistic studies we determined that LAL inhibition in MIN6 cells enhanced expression of genes associated with *de novo* lipogenesis (Dgat1, Gpam), as well as the lipase Lipe. The cholesterol transporter Abca1 was significantly downregulated. These data indicate that inhibition of LAL upregulates *de novo* lipogenesis, which acts to increase lipid signals that enhance GSIS. Consistent with this, mass spectrometry revealed that disaturated diacylglycerol mass was increased 3-fold after acute 20mmol/l glucose stimulation (n=4, p<0.05 unpaired t-test), and with LAL inhibition this was further potentiated 1.5-fold (n=4, p<0.01 paired t-test).

**Conclusion:** Our data further elaborate the importance of neutral lipid turnover in  $\beta$ -cell function, highlighting the key role of LAL in whole body glucose homeostasis and insulin secretion. In addition to its known role in regulating lipophagy, our data suggests that LAL mediated lipid breakdown also inhibits insulin secretion by downregulating *de novo* lipogenesis. It is likely that LAL plays a key role in limiting insulin secretion during starvation. *Supported by: NHMRC PhD scholarship and NHMRC project grants*

### Involvement of actin cytoskeleton in free fatty acid-induced beta cell death

A. Natalicchio, R. Labarbuta, F. Tortosa, G. Biondi, N. Marrano, A. Leonardini, A. Cignarelli, S. Perrini, L. Laviola, F. Giorgino; Endocrinology &amp; Metabolic Diseases, University of Bari, Italy.

**Background and aims:** The role of actin cytoskeleton in regulation of pancreatic beta-cell survival has not been investigated. In this study, actin cytoskeleton remodeling was examined in the context of beta-cell apoptosis induced by free fatty acids (FFA).

**Materials and methods:** Studies were carried out in human pancreatic insulin-releasing 1.1B4 cells treated with 0.2 mM palmitate up to 24 h with or without pretreatment with 0.01  $\mu$ M cytochalasin D (CD) for 2 h or 25 nM jasplakinolide for 2 h. Actin cytoskeleton was visualized by immunofluorescence techniques. Expression and activation levels of the proteins under investigation were evaluated by immunoblotting techniques. Cell apoptosis was detected by measurements of cytosolic release of oligosomes (ELISA assay).

**Results:** Exposure of human 1.1B4 pancreatic beta-cells to 0.2 mM palmitate resulted in a 10- to-14-fold increase in cell apoptosis (p<0.05). The organiza-

tion of actin filaments was then examined in 1.1B4 beta-cells following exposure to palmitate. Palmitate induced a typical peripheral distribution of actin filaments consistent with their mechanical supporting function for shrinking of apoptotic cells. Treatment of beta-cells with cytochalasin D (CD) (0.01  $\mu$ M, 2 h) led to collapse of the filamentous actin structures and a more rounded cell shape, and inhibited the effect of palmitate on apoptosis (p<0.05). To further investigate the role of actin cytoskeleton in palmitate-induced apoptosis, 1.1B4 beta-cells were treated with jasplakinolide, a potent inducer of actin polymerization. Jasplakinolide (25 nM, 2 h) led to the formation of relatively fine stress fibers and large aggregations of actin filaments, and enhanced palmitate-induced apoptosis (p<0.05). In addition, palmitate-induced phosphorylation of the pro-apoptotic stress kinases JNK and p38 MAPK was reduced (by 45% and 90%) or increased (by 47% and 35%) after treatment with CD or jasplakinolide, respectively (p<0.05). Finally, palmitate induced a decrease in Akt phosphorylation, and this was prevented by CD (p<0.05); preincubation of beta-cells with the PI 3-kinase inhibitor LY294002 abrogated the ability of CD to restore Akt phosphorylation and to inhibit palmitate-induced apoptosis (p<0.05).

**Conclusion:** In conclusion, disruption and stabilization of actin cytoskeleton inhibit and enhance, respectively, FFA-induced beta-cell death. The essential role of actin cytoskeleton in FFA-induced apoptosis is coupled with activation of the pro-apoptotic JNK and p38 MAPK and inhibition of the anti-apoptotic Akt kinase.

### Glucolipotoxicity inhibits ceramide transport between endoplasmic reticulum and Golgi apparatus in pancreatic beta cells

J. Veret<sup>1</sup>, E. Gjoni<sup>2</sup>, A. Cinque<sup>2</sup>, N. Coant<sup>1</sup>, N. Islam<sup>3</sup>, C. Ng<sup>3</sup>, C. Magnan<sup>1</sup>, L. Riboni<sup>2</sup>, P. Viani<sup>2</sup>, P. Giussani<sup>2</sup>, H. Le Stunff<sup>2</sup>;<sup>1</sup>UMR CNRS 8251, Unité Biologie Fonctionnelle et Adaptative, Paris, France, <sup>2</sup>Department of Medical Biotechnology and Translational Medicine, Milano, Italy, <sup>3</sup>School of Biology and Environmental Science, Dublin, Ireland.

**Background and aims:** In type 2 diabetes (TD2) the chronic adverse effects of fatty acids (FA) on beta cell function and viability have been correlated to hyperglycaemia. Gluco-lipotoxicity refers to the combined, deleterious effects of elevated glucose and fatty acid levels on pancreatic beta-cell function and survival. Gluco-lipotoxicity caused beta-cell apoptosis and may thus contribute to progressive beta-cell loss in TD2. The molecular pathways and regulators involved in the detrimental effects of chronic exposure to FA, in particular palmitate, include the *de novo* synthesis of ceramide (Cer) in the endoplasmic reticulum (ER). However, increasing Cer levels in ER can also be due to a reduction of Cer utilization for complex sphingolipids synthesis. Therefore, we studied the effect of glucolipotoxicity on Cer metabolism in beta cells and its impact on beta-cell apoptosis.

**Materials and methods:** INS-1 cells were cultured with 0.4 mM palmitate and 5 or 30 mM of glucose. INS-1 cell apoptosis was determined by caspase 3/7 activity assay. Sphingolipid metabolites were analyzed by liquid chromatography-mass spectrometry. Metabolism of Cer was measured in INS-1 beta cells with [3H]sphingosine, a precursor of sphingolipid biosynthesis. Transport of C5-Bodipy-ceramides between ER and Golgi apparatus was analysed by fluorescence confocal microscopy. Down-regulation of Cer transporter CERT was made by specific siRNA.

**Results:** Both nutrients taken separately did not induce INS-1 cell death, whereas the combined treatment with palmitate and glucose resulted in an extensive beta cell apoptosis and this was associated to a significant increase of Cer levels. The presence of fumonisin-B1, an inhibitor of Cer biosynthesis, partially reversed the apoptosis induced by the combined treatment with palmitate and glucose. Metabolic studies using [3H]sphingosine as precursor of sphingolipid biosynthesis show that treatment with palmitate results in a small but significant increase of [3H]Cer associated to a decrease of [3H] sphingomyelin (SM) at 5 mM glucose. Inhibition of Cer utilization for SM biosynthesis was significantly potentiated by the presence of 30 mM glucose. Lipidomic analysis showed that glucolipotoxicity inhibited biosynthesis of complex sphingolipids. Fluorescence microscopy studies using C5-Bodipy-Cer show that at high glucolipotoxicity reduces the fluorescence accumulation in the perinuclear region representative of the Golgi apparatus. Interestingly, this was associated with an inhibition of the Cer transporter CERT function. Inhibition of CERT was mediated by a decrease of its expression and an increase of its phosphorylation status. Finally, selective silencing of CERT expression increased INS-1 cell apoptosis induced by palmitate.

**Conclusion:** Altogether these data suggest that glucolipotoxicity increased Cer accumulation in the ER through also through a decreased utilization of

newly synthesized Cer for SM biosynthesis. Moreover, these results support a role of Cer transport between ER and Golgi apparatus in the regulation of beta cell death induced by gluco-lipototoxicity.

## 466

### Palmitate and glucose induce autophagy in INS(832/13) cells

A.S. Medina, H. Bennet, M. Fex;

Diabetes and Celiac Disease, Lund University, Malmö, Sweden.

**Background and aims:** Autophagy is an important biological process by which proteins and organelles are sequestered in autophagosomal membrane vesicles and delivered to the lysosome for degradation. Eukaryotic cells can degrade long-lived proteins and intracellular organelles through macroautophagy, for instance during periods of an increased energy demand. In addition, autophagy may function as a first line cellular defense to protect cells against various stressors and pathogens. The ATG genes, are crucial in regulating the formation of autophagy membranes, and dysfunctional regulation/expression of these may be involved in disease processes. The role of autophagy and/or regulation of ATG genes in type 2 diabetes are incompletely understood, although some evidence points to the involvement of autophagy in this disease. Therefore, the aim of this study was to investigate the exact cellular stressors that induce autophagy and ATG gene expression in beta cells in-vitro.

**Materials and methods:** The INS(832/13) beta cell line was cultured in combination with 30mM glucose, 0.5mM palmitate, or a combination of both, cytokines, LPS and tamoxifen (as a positive control) and untreated cells as a negative control. Incubations were performed for 6, 12, 24, and 48 hours to investigate the degree of autophagy visualized by fluorescent LC3B staining and confocal microscopy. Quantitative (Q)-PCR for ATG genes was performed in cells treated under each condition and insulin secretion analysis were performed following standard protocols.

**Results:** LC3B expression was used as the classical readout for autophagy. A preliminary time-course experiment evaluating INS(832/13) cells after 6, 12, 24, and 48 hours exposure to 30mM glucose and 0.5mM palmitate and a combination of both (glucolipototoxicity) indicated that autophagy response was maximal between 12 and 24 hours, and more prominent in cells treated with palmitate alone as compared to glucose treatment alone. The combination of both glucose and palmitate did not induce more autophagy than palmitate treatment, which was evaluated by counting the LC3B positive dots in each sample. The LC3B dot-like structures appear in the cytoplasm and perinuclear region and were more evident in all treated groups when compared to non-treated cells. An increase in expression was observed for ATG5, and ATG12 after 24 h incubation with palmitate. Insulin secretion was measured in cells treated in these conditions and preliminary data suggest a decreased in response to treatment with both palmitate and glucose. This indicates that the autophagic response induced by glucolipototoxicity inhibits insulin release, perhaps by mechanism relating to changes in autophagic response.

**Conclusion:** Our findings in vitro in INS(832/13) beta cells indicate that increased palmitate levels represent a powerful activator for the autophagy process which is coupled to an increase of specific ATG genes, necessary for the formation of the autophagosome. These changes are accompanied by a reduction in glucose stimulated insulin release.

## 467

### L-type voltage-gated calcium channels mediate sensitivity to glucolipototoxicity in beta cells via activation of nuclear receptors Nr4a and inhibition of autophagy

P.J. Buda<sup>1</sup>, E. Zhang<sup>1</sup>, J. Esguerra<sup>2</sup>, E. Renstrom<sup>1</sup>;

<sup>1</sup>Islets pathophysiology,

<sup>2</sup>Islet cells exocytosis, Lund University, Malmö, Sweden.

**Background and aims:** Glucolipototoxicity is considered a major factor driving the gradual demise of pancreatic beta-cells mass in type 2-diabetes. Countering this, autophagy allows cells to survive under adverse conditions. Recent reports underscore the protective role of autophagy in animal models exposed to free-fatty acids and high concentrations of glucose. However, little is known about the involvement of autophagy in diabetes progression and its regulation in pancreatic B-cells is poorly understood. Under high glucose and palmitate conditions voltage-gated calcium channels (VGCC) become activated and in turn stimulate extracellular calcium-dependent gene expres-

sion. In this study we investigated which VGCC-activated genes are essential for autophagy regulation and whether deliberate tuning of expression of these genes under glucolipototoxic conditions could improve beta-cell viability through the activation of autophagy.

**Materials and methods:** Genes activated by VGCC were revealed by use of affymetrix microarray performed on INS-1 cells after stimulation with 70mM potassium chloride. Amongst them autophagy related genes were identified based on the literature studies. Expression of these genes was measured by quantitative PCR and western blot. Their relation to the type of VGCC was obtained owing to specific VGCC inhibitors. Autophagy was assessed by use of western blot where the ratio of LC3B II over I form was calculated, and as well as by use of confocal microscopy on INS-1 cells wherein the number of LC3B-GFP puncta was counted. Apoptosis was measured by use of both flow cytometry (the number of AnnexinV and ViaProbe positive cells) and ELISA assay measuring enrichment of nucleosomes in cytosol.

**Results:** Affymetrix microarray revealed that activation of VGCC with 70mM potassium chloride upregulated autophagy related nuclear receptors Nr4a: NUR77 and NOR-1. Quantitative PCR showed 10-times increase of NUR77 and NOR-1 genes under high potassium conditions. At the same time activation of VGCC inhibited autophagy, which was indicated by 20% decrease in LC3B II/I ratio and 50% decrease in the number of LC3B-GFP puncta in beta-cells. This coincided with 50% reduction of AMPK phosphorylation - the main autophagy activator. Inhibition of VGCC-activated NUR77 and NOR-1 expression by isradipine or downregulation of both genes with siRNA restored AMPK activity and ablated inhibitory effect of high potassium on autophagy. 25 mM glucose with 0,5 mM palmitate inhibited autophagy which was indicated by 70% decrease in LC3B-GFP puncta and increased 10 times the number of AnnexinV and ViaProbe positive cells as compared to low glucose conditions. Isradipine or autophagy inducing rapamycin reduced apoptosis by 20% under glucolipototoxic conditions. Finally, cells depleted of both NUR77 and NOR-1 gained 25% improvement in cell viability at the presence of high glucose and palmitate.

**Conclusion:** Our study shows that inhibition of autophagy by L-type VGCC makes beta-cells more vulnerable to apoptosis under glucolipototoxic conditions. Beneficial for cell viability activation of autophagy can be obtained by inhibition of L-type calcium currents as it prevents induction of anti-autophagic - NUR77 and NOR-1.

## 468

### Lipototoxicity alters the genome-wide epigenetic pattern in human pancreatic islets

C.A. Ling<sup>1</sup>, E. Hall<sup>1</sup>, P. Volkov<sup>1</sup>, T. Dayeh<sup>1</sup>, K. Bacos<sup>1</sup>, T. Rönn<sup>1</sup>, M. Dekker Nitert<sup>2</sup>;

<sup>1</sup>Clinical Sciences, Lund University, Malmö, Sweden,

<sup>2</sup>The University of Queensland, Brisbane, Australia.

**Background and aims:** Circulating levels of free fatty acids are often increased in subjects with type 2 diabetes (T2D). Long-term exposure to lipids has harmful effects on islet function and insulin secretion. Epigenetic modifications such as DNA methylation may contribute to T2D. However, there is limited information on whether fatty acids alter the epigenetic pattern in human pancreatic islets. Our aim was therefore to analyse the genome-wide DNA methylation pattern in human pancreatic islets exposed to palmitate for 48 hours and relate methylation to gene expression and insulin secretion in the islets.

**Materials and methods:** mRNA expression and DNA methylation were analysed genome-wide in human islets using microarrays.

**Results:** Palmitate treatment for 48 hours decreased glucose-stimulated insulin secretion but did not affect apoptosis in the human islets. We found 1860 genes with differential expression in palmitate-treated human islets. These include candidate genes for T2D such as GLIS3, HNF1B and SLC30A8. Additionally, palmitate altered the expression of genes in glycolysis/gluconeogenesis, pyruvate metabolism, fatty acid metabolism, glutathione metabolism in human islets. The global DNA methylation level and DNA methylation levels of CpG island shelves and shores, 5'UTR, 3'UTR and gene body regions were altered in human islets exposed to palmitate. Moreover, 290 genes with differential expression had a corresponding change in DNA methylation e.g. several candidate genes for T2D. Importantly, 67 of these genes were also associated with BMI and 37 were differentially expressed in islets from T2D patients.

**Conclusion:** We demonstrate that lipotoxicity gives rise to epigenetic modifications as well as transcriptional changes in human pancreatic islets. These changes may contribute to impaired insulin secretion and T2D.

### EPA and DHA protect pancreatic islets against palmitate toxicity

C.F. Lucena, L.P. Roma, K. Veras, M. Graciano, A.R. Carpinelli;  
Physiology and Biophysics, University of São Paulo, Brazil.

**Background and aims:** In previous studies, we have shown that fish oil supplementation improve the antioxidant defense in pancreatic islets from healthy rats. To test whether these effects were due to  $\omega$ -3 fatty acids present in high concentrations in the supplemented diet, we decided to test whether EPA and DHA have the same effects in vitro and protect pancreatic beta cells from palmitate toxicity.

**Materials and methods:** Pancreatic islets were obtained by collagenase digestion and cultured with RPMI 1640 medium containing 10mM glucose, 10% FBS, penicillin and streptomycin. After overnight culture, islets were divided in four groups: control (vehicle ethanol),  $\omega$ -3 fatty acids (50 $\mu$ M EPA + 50 $\mu$ M DHA), 100  $\mu$ M Palmitate (P), P $\omega$ 3 (50  $\mu$ M EPA + 50  $\mu$ M DHA + 100 $\mu$ M palmitate). Islet cell death, glucose stimulated insulin secretion (GSIS) and superoxide (ROS) content (cytosolic and mitochondrial) were analyzed after 48 h culture. Some of the experiments were performed using dispersed cells. Briefly, after 48 h culture, islets were dispersed into small cell clusters using trypsin and gentle pipetting in a Ca<sup>2+</sup>-free medium. Cells were then analyzed by flow cytometry.

**Results:** 48h culture in the presence of P increased beta cell ROS production and apoptosis and impaired GSIS. Under these conditions, EPA+DHA triggered a parallel ~60-65 % reduction in ROS production and beta-cell apoptosis induced by P, and induced significant protection against the impairment in GSIS (~1,28ng insulin in P vs ~1,60ng insulin in P $\omega$ 3, per islets/hour). The reduction in insulin secretion was not due to decreased insulin content. When dispersed cells were analyzed by flow cytometry, there was no difference in mitochondrial ROS production (mitosox probe). On the other hand, ROS production was increased with P and reduced to control levels when P cells were cultured in the presence of EPA and DHA, confirming the results obtained with whole islets using confocal microscopy. Apoptosis was also increased in P vs control and the addition of  $\omega$ -3 is not significantly different from control.

**Conclusion:** Our results show that EPA+DHA protect pancreatic islets from alterations induced by palmitate, i.e. increased superoxide production, decreased viability and beta cell function. The effects may result from decreased cytosolic superoxide production, which in turn can lead to increased viability and beta cell function. As we previously reported, in vivo  $\omega$ -3 supplementation decrease protein levels of NAD(P)H oxidase subunits and consequently superoxide production in pancreatic islets. Considering that in vitro effects do not involve mitochondrial superoxide production, we can speculate that this protection might involve downregulation of NAD(P)H oxidase. However, further experiments are needed to elucidate the mechanisms involved in the protection of  $\omega$ 3 fatty acids against palmitate toxicity.

### Different regulation of beta cell proliferation induced by short-term and long-term high-fat diet loading

A. Nakamura<sup>1</sup>, N. Kitao<sup>1</sup>, H. Nomoto<sup>1</sup>, H. Miyoshi<sup>1</sup>, Y. Terauchi<sup>2</sup>, T. Atsumi<sup>1</sup>;

<sup>1</sup>Division of Immunology and Metabolism, Hokkaido University, Sapporo,

<sup>2</sup>Yokohama City University, Japan.

**Background and aims:** Evidence has mounted that insufficient adaptation of beta cell mass is symptomatic of type 2 diabetes. Because the adaptation mechanism of beta cell mass in response to insulin resistance is not fully understood, elucidating this mechanism is absolutely required for developing strategies of diabetes treatment. Previously, we demonstrated that insulin receptor substrate-2 (Irs2) is critically required for beta cell proliferation to occur in response to high-fat (HF) diet-induced insulin resistance. Recently, it was reported that beta cell proliferation began within the first 7 days of HF diet loading. However, it is unclear whether Irs2 is required for beta cell

proliferation induced by short-term HF diet loading. Here, we investigated the effect of short-term HF diet loading on the regulation of beta cell proliferation.

**Materials and methods:** Eight-week-old C57bl/6J mice were given free access to either standard chow (SC) or a HF diet. After 7 days on the above diets, we investigated body weight, blood glucose, visceral fat weight, liver weight and pancreatic weight in these mice. Also, insulin tolerance test and immunohistochemical analysis to assess beta cell proliferation and mass were performed. Furthermore, we evaluated the changes in expression levels of genes involved in beta cell proliferation and function in islets isolated from these mice.

**Results:** Body weight and fed blood glucose levels were significantly higher in the mice on the HF diet than those in the mice fed SC. Although visceral fat weight were significantly higher in the mice on the HF diet than those in the mice fed SC, there were no differences in liver weight or pancreatic weight between the two groups. The glucose-lowering effect of insulin in the mice on the HF diet was equivalent to that in the mice fed SC on day 6. Immunohistochemical analysis revealed that there was a significant increase in stimulated the BrdU incorporation rate in the mice on the HF diet in comparison with the mice fed SC on day 7, although there was no difference in the area of the beta cells relative to that of the whole pancreatic tissues between the two groups. Real-time quantitative PCR showed that Ki67 and Cyclin A2 mRNA were significantly increased in the mice on the HF diet in comparison with the mice fed SC. However, no increase in the expression levels of Irs2 or genes involved in beta cell function, such as pancreatic and duodenal homeobox-1, glucokinase, insulin-1, or insulin-2 were noted in the mice on the HF diet as compared with that in the mice fed SC.

**Conclusion:** Beta cell proliferation was induced by HF diet loading only for 7 days without up-regulation of Irs2. Our results suggest different regulation of beta cell proliferation induced by short-term and long-term high-fat diet loading.

## 471

### Metabolic and pancreatic effects of transplantation of mesenchymal stem cells in a model of insulin resistance and type 2 diabetes

A.M.O. Leal<sup>1</sup>, P.G. Bueno<sup>2</sup>, G.D. Pisani<sup>2</sup>, J.U. Yaochite<sup>3</sup>, K.F. Malmegrin<sup>3</sup>, L. Avó<sup>1</sup>;

<sup>1</sup>Medicine, <sup>2</sup>Physiology, Federal University of São Carlos,

<sup>3</sup>University of São Paulo, Ribeirão Preto, Brazil.

**Background and aims:** Type 2 Diabetes Mellitus (DM2) is associated with insulin resistance and dysfunction of pancreatic  $\beta$  cells. The regenerative cellular therapy, in particular with multi/pluripotent cells has been investigated as a potential therapeutic strategy for DM2. Among them, mesenchymal stem cells (MSCs) due to its immuno regulatory role are important therapeutic candidates. The purpose of this study was to investigate the effects of multiple infusions of MSCs on glucose homeostasis and morphometry of the pancreatic islets in high fat diet-induced diabetes in *Swiss* mice.

**Materials and methods:** *Swiss* mice were fed a standard diet or a high fat diet for eight weeks. The animals were then divided into 3 groups: non-diabetic group (fed a standard diet), untreated diabetic group and MSCs transplanted group. The transplanted mice received 4 intraperitoneal infusions of MSCs cells (5-8 x 10<sup>6</sup> MSCs resuspended in buffer). Diabetic untreated animals received only buffer injection and non-diabetic group did not receive injections. Fasting plasma glucose (FPG) was determined weekly and glucose (GTT) and insulin (ITT) tolerance tests were performed at 1, 2, 3, and 4 months after the infusions of MSCs. Four months after infusion of the MSCs, the animals were decapitated and pancreas and serum were collected for analysis.

**Results:** The MSCs transplanted animals were classified as responder (FPG < 180mg/dL) or non-responder (FPG > 180mg/dL). According to this criterion, 72.2 % and 27.8 % of MSCs transplanted animals were classified as responders and non-responders, respectively. Fasting glycemia decreased significantly (p<0.05) in responders mice seven weeks after the infusion of MSCs compared to the untreated diabetic group. Four months after MSCs, GTT and ITT areas under the curve (AUC) decreased significantly (p<0.05) in responders mice compared to untreated diabetic mice. Serum insulin concentration was significantly higher in untreated diabetic animals than in non-diabetic animals (p<0.05) and was not different in responders and non-responders transplanted mice. Total islet area and volume of  $\beta$  cells were not different among the groups. However, the volume of  $\alpha$  cells was significantly (p<0.05) lower in untreated diabetic animals and responders mice compared to non-diabetic and non-responders mice, respectively. Apoptosis of islet cells was significantly (p<0.05) bigger in untreated diabetic animals

than in non-diabetic mice, and significantly lower in responders mice than in untreated diabetic and non-responders animals. Islet cell proliferation was significantly ( $p < 0.05$ ) lower in untreated diabetic animals than in non-diabetic mice. However, islet cell proliferation was not different in transplanted animals compared to non-diabetic and untreated diabetic animals. There was a positive correlation between apoptosis of islet cells and fasting glycemia ( $r = 0.56$ ;  $p = 0.002$ ) and AUC of GTT ( $r = 0.59$ ;  $p = 0.001$ ) and ITT ( $r = 0.42$ ;  $p = 0.03$ ), and a negative correlation of proliferation of islet cells and fasting glycemia ( $r = 0.39$ ;  $p = 0.03$ ).

**Conclusion:** The results indicate that multiple infusions of MSCs decrease glucose intolerance and apoptosis in pancreatic islets and increase insulin sensitivity in high fat diet-induced diabetic mice.

### 472

#### Absence of CXCL10 prolongs islet graft survival in an autoimmune transplantation setting

C. Bender, S. Christen, J. Pfeilschifter, E. Hintermann, U. Christen; Pharmazentrum Frankfurt, Goethe University Hospital, Germany.

**Background and aims:** Type 1 diabetes (T1D) results from the autoimmune destruction of insulin-producing beta-cells in the pancreas. The chemokine CXCL10 seems to play an important role in the recruitment of autoaggressive lymphocytes to the islets of Langerhans. Since transplantation of isolated islets is a promising therapy of T1D, but has been hampered by the fact that islet grafts get rejected even in presence of an immunosuppressive regimen, we intended to investigate a possible influence of CXCL10 on the islet rejection process.

**Materials and methods:** We used three different transplantation settings, including syngeneic, allogeneic and autoimmune transplantations. For the syngeneic and allogeneic transplantation we used streptozotocin-treated diabetic recipients (C57Bl/6 or FVB background). In order to investigate the autoimmune rejection we used diabetic RIP-LCMV-GP mice as recipients. The RIP-LCMV-GP mice express the glycoprotein (GP) of the lymphocytic choriomeningitis virus (LCMV) under control of the rat insulin promoter (RIP) specifically in the beta-cell of the pancreatic islets of Langerhans. One of the advantages of the RIP-LCMV-GP model is the uses of a well-defined target autoantigen which allows a precise observation and quantification of the destructive immune response resulting in the islet graft rejection. Pancreatic islets were isolated from either C57Bl/6 and CXCL10-deficient mice (syngeneic and allogeneic settings) or RIP-LCMV-GP and RIP-LCMV-GP x CXCL10-deficient mice (autoimmune setting) and were transplanted under the left kidney capsule of diabetic recipient mice.

**Results:** CXCL10 was expressed by islet grafts early after transplantation. However, no significant differences in the survival of wildtype or CXCL10-deficient islets have been observed in the syngeneic (C57Bl/6 islets into C57Bl/6 recipients) and allogeneic (C57Bl/6 islets into FVB recipients) settings. In contrast, autoimmune (RIP-LCMV-GP islets into RIP-LCMV-GP mice) transplantations demonstrated a marked prolongation of islet graft survival in the absence of CXCL10 in the transplanted islets. Insulin production was intact for more than 100 days post-transplantation in non-rejected islet graft.

**Conclusion:** Consequently, CXCL10 might play a role in islet graft rejection in an autoimmune transplantation setting, and might be a potential therapeutic target to prolong islet graft survival.

#### Improved revascularization of islet graft by angiogenic monocyte subpopulation derived from spheroid culture of bone marrow mononuclear cells

S.-M. Jin, B. Oh, S.-H. Oh, S. Oh, K. Hur, M.-S. Lee, M.-K. Lee, J. Kim; Samsung Medical Center, Seoul, Republic of Korea.

**Background and aims:** Spheroid culture method is an effective strategy for the ex vivo expansion of autologous therapeutic cell population. We investigated if co-transplantation of spheroids (BM-spheroid) formed by 3D culture of bone marrow-derived mononuclear cells (BM-MNCs) could improve the revascularization and organization of islet grafts.

**Materials and methods:** Angiogenic capacity of the spheres formed by spheroid culture of BM-MNCs (BM-spheres) for 3 to 5 days was assessed by in vitro and in vivo models. A syngeneic marginal mass renal subcapsular islet transplantation model was used to determine the post-transplant outcome of co-transplanted BM-spheres and islets. Using green fluorescent protein transgenic (GFP-Tg) mice, the role of BM-spheroid and donor/recipient endothelial cells in revascularization was assessed by immunohistochemistry.

**Results:** The main cellular component of BM-spheres were CXCR4<sup>+</sup>CD14<sup>+</sup> myeloid cells. BM-sphere showed a superior angiogenic capacity over the fresh BM-MNCs and remnant non-spheroid BM-MNCs after spheroid culture. Co-transplantation with BM-spheres improved the outcome of syngeneic islet transplantation in terms of glucose tolerance, diabetes reversal

rate, plasma insulin levels, and fraction of endocrine cells and proliferating  $\beta$ -cells in graft immunohistochemistry. Co-transplantation with BM-spheres increased the vessel density derived from the donors and recipients.

**Conclusion:** Co-transplantation of islets and angiogenic myeloid cells derived from the BM-spheroid improved the outcome of marginal mass islet transplantation by facilitation of revascularization.

### First evaluation of a closed, continuous media renewal system for human islets of Langerhans

M. Ståhle<sup>1</sup>, A. Friberg<sup>1</sup>, S. Ingvast<sup>1</sup>, O. Korsgren<sup>1</sup>, A. Lams<sup>2</sup>, B. Delorme<sup>2</sup>;

<sup>1</sup>Clinical Immunology, Immunology, Genetics and Pathology, Uppsala, Sweden, <sup>2</sup>Macopharma, Lille, France.

**Background and aims:** Many clinical islet centres have adopted a short storage period for islets prior to transplantation. A storage period provides time for quality assessment of islets, recipient matching, transport of islets and patients to transplant centre and initiation of immunosuppressive protocols. There are, however, risks for loss of islet tissue and contamination during the storage period. To reduce contamination risks and improve handling and storage conditions, the present study presents the first evaluation data from a new closed PReservation ISlet system (called PRISM) specifically developed for islet storage with regulated continuous media renewal.

**Materials and methods:** At the end of the isolation process, purified islets were split and stored either in single transfer packs for platelets (Fenwal, Sweden) as control or in the new V1.4 PRISM automate (Macopharma, France) for 4–5 days. Islets were both kept in CMRL-1066 supplemented with 10 mM HEPES, 10 mM nicotinamid, 2 mM L-glutamine, 50  $\mu$ g/mL gentamicin, 5 mM sodium pyruvate, 20  $\mu$ g/mL ciprofloxacin and 10% blood group-compatible human serum. After a first over night storage at 37°C, the temperature was lowered to 25°C for the rest of the study period. Culture media exchanges were either performed manually for islets in the platelet bags or automatically using the PRISM automate. Islet quality assessments were performed at day 1 and last day (4 or 5) and included glucose-stimulated insulin release, intracellular insulin content, ADP/ATP ratio, cytokine expression and recovery.

**Results:** No differences were found between islets kept in the PRISM automate compared to islets kept in single transfer packs for platelets regarding stimulated insulin release, intracellular insulin content, ADP/ATP ratio or expression of MCP-1, tissue factor, IL-6 or IL-8.

**Conclusion:** The closed, automatic media renewal PRISM technology seems to preserve functional integrity of clinical grade human islets kept in storage as well as standard clinical practice. It presents an attractive method for standardization and automation of islet storage.

## 475

### Feasibility of islet magnetic resonance imaging using ferumoxytol in intraportal islet transplantation

J. Kim, S.-M. Jin, M.-K. Lee, M.-S. Lee, K. Hur, J. Jun; Samsung Medical Center, Seoul, Republic of Korea.

**Background and aims:** There is a clinical need for an alternative labeling agent for magnetic resonance imaging (MRI) in cell therapy including islet transplantation, because superparamagnetic iron oxide (SPIO) has been withdrawn from the market. We aimed to evaluate the feasibility of islet magnetic resonance imaging using ferumoxytol, which is a clinically available ultrasmall superparamagnetic iron oxide (uSPIO) as an iron supplement drug.

**Materials and methods:** We compared islet function and viability of control islets and islets labeled with ferumoxytol. In vitro efficacy of ferumoxytol labeling was assessed with prussian blue stain, electron microscopy and ex vivo MRI of labeled islets. In vivo efficacy of labeling was assessed in both renal subcapsular and intraportal islet transplantation models.

**Results:** Labeling with ferumoxytol up to 800 $\mu$ g/mL did not compromise the viability and glucose-stimulated insulin secretion of labeled islets. Prussian blue stain of labeled islets showed internalized ferumoxytol particles. Ex vivo magnetic resonance imaging of islets labeled with ferumoxytol (up to 800 $\mu$ g/mL) for 48hr revealed visible hypointense spots representing labeled islets. In syngeneic renal subcapsular islet transplantation model, islet MRI at 14 days-post-transplantation (DPTs) showed visible hypointense spots representing islet graft. In islet MRI at 7 and 14 days after syngeneic intraportal

islet transplantation, there was a difference in the total area of hypointense spots between recipients with normoglycemia and hyperglycemia at 28 DPTs. **Conclusion:** Islet MRI using ferumoxytol was feasible in terms of in vitro and in vivo efficacy and safety. Labeling islet with ferumoxytol could be a useful option for estimation of islet mass in clinical islet transplantation.

## 476

### Outcomes for adults with type 1 diabetes referred with severe hypoglycaemia and/or referred for islet transplantation to a specialist hypoglycaemia service

M.L. Byrne<sup>1</sup>, P. Srinivasan<sup>2</sup>, N.D. Heaton<sup>2</sup>, D. Hopkins<sup>3</sup>, S.A. Amiel<sup>1</sup>, P. Choudhary<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, <sup>2</sup>Institute of Liver Studies,

<sup>3</sup>Department of Diabetes, King's College Hospital, London, UK.

**Background and aims:** Severe hypoglycaemia (SH) and fear of hypoglycaemia remain major barriers to achieving good diabetes control. In adults with type 1 diabetes (T1D), structured education in flexible insulin therapy (e.g. DAFNE, Dose Adjustment For Normal Eating) reduces SH by 65%, and technology (insulin pump therapy and sensors) 4-fold. For persistent SH, despite optimised medical therapy, islet cell transplantation is indicated, reducing SH from 20.0 [7.0–50.0] to 0.3 [0.0–1.6] episodes per patient/year. We examined outcomes for patients referred to a diabetes centre with an islet transplant unit for islet transplantation and/or problematic hypoglycaemia.

**Materials and methods:** Retrospective case note audit of all people with T1D referred to islet transplant unit for islet transplantation and/or with problematic hypoglycaemia between 2009 and 2012 [n=82]. 45 met criteria for islet cell transplantation having >1 SH in previous year. Optimal outcome was defined as  $\leq$ 1 severe hypoglycaemic episode over the past 12 months as documented at most recent visit.

**Results:** The cohort was 55.6% male, mean ( $\pm$ SD) age 44.8 ( $\pm$ 11.7) years, BMI 25.2 ( $\pm$ 3.6) kg/m<sup>2</sup> and duration of diabetes 28.1 ( $\pm$ 13.4) years. HbA1c at index visit was 8.5% ( $\pm$ 1.8), median [IQR] frequency of severe hypoglycaemia was 6.0 [2.0–21.5] per patient/year and 84.4% had impaired awareness of hypoglycaemia. 84.4% were referred from secondary diabetes services, 13.3% had completed DAFNE and 31.1% were using insulin pumps. Nine patients (20.0%) had initial assessment only (3 died, 2 did not attend follow up and 4 were referred back to local team with a new management plan). Follow up of the remaining 36 had a median duration of 28.5 [17.8–42.5] months, during which SH fell from 6.0 [2.0–24.0] to 0.0 [0.0–3.0] events per patient/year;  $p$ <0.0001, without deterioration in HbA1c [8.3% to 8.1% [67.2mmol/mol vs. 65.0mmol/mol];  $p$ =0.239]. 26 out of 36 remained on medical therapy (11 had dose adjustment alone; 11 completed DAFNE; 10 converted to pump; 3 used sensors). 17 out of 26 achieved optimisation (13=0 SH and 4=1 SH) with a SH reduction from 2.0 [1.5–9.0] to 0.0 [0.0–0.5] episodes per patient/year;  $p$ <0.0001, again without detrimental effect on HbA1c [8.1% to 7.7% [65mmol/mol vs. 60.7mmol/mol];  $p$ =0.072]. 9 out of 26 were not resolved but SH fell from 7.0 [4.8–40.5] to 4.0 [2.5–6.3] episodes per patient/year;  $p$ =0.058. The remaining 10 patients were listed for transplantation. 80% had completed DAFNE, 100% converted to insulin pump therapy and 70% used sensors. There was a trend to higher baseline SH rate in the group needing transplantation [2.0 [1.5–9.0] (optimised) vs. 7.0 [4.8–40.5] (improved) vs. 8.0 [5.3–106.0] (transplantation);  $p$ =0.060]. Overall, 47.2% of patients were resolved; 25.0% improved and 27.8% required transplantation.

**Conclusion:** The majority of patients presenting with problematic severe hypoglycaemia can be improved with appropriately supported non-transplant therapeutic options, around half achieving complete resolution. Despite optimised therapy, a third will require transplantation. Provision of expertise in hypoglycaemia management is essential to give people with T1D and SH appropriate options and focus limited transplant resources on the most needy.

## Meal tests to assess beta cell function and mass in islet-transplanted patients

J.-F.R. Brun<sup>1</sup>, L. Bories<sup>2</sup>, T. Berney<sup>3</sup>, J. Mercier<sup>1</sup>, P.-Y. Benhamou<sup>4</sup>, A. Wojtusciszyn<sup>2</sup>;

<sup>1</sup>INSERM U1046, Equipe d'Explorations Métaboliques, <sup>2</sup>INSERM U1001, Department of Endocrinology, Diabetes, and Nutrition, Montpellier, France, <sup>3</sup>Department of Surgery, Cell Isolation and Transplant Center, Geneva, Switzerland, <sup>4</sup>Inserm, U1055, Grenoble, France.

**Background and aims:** Current model-derived calculations of insulin secretion based on C-peptide kinetics during a meal test allow to measure the two phases of insulin secretion. The second phase expressed as a  $\beta$ -cell glucose sensitivity (BCS) has been shown to be a strong predictor of diabetes progression, and recent studies also suggest that it is closely related to the size of pancreatic beta-cell mass. Since beta-cell mass is a critical factor for the outcome of pancreatic islet transplantation, we measured these parameters in transplanted patients in order to see whether they were related to glucose tolerance.

**Materials and methods:** We performed 13 standardized breakfast tests (76 g of carbohydrates) in 7 patients treated with islet transplantation (5 F/2 M, age 32–60 yr; weight: 51.3–72.8 kg, time after transplantation 3–44 months) and compared them to 103 non-diabetic controls (C). Calculation of insulin sensitivity (Caumo's oral minimal model) and insulin secretion rate (ISR) (Van Cauter's model), with calculation of beta-cell sensitivity to glucose (BCS) and insulin secretion parameters given by the classical models of Breda and of Mari were done with the results of the tests.

**Results:** According to fasting glycemia and glycemia at 2 hours, breakfast tests showed 6 normoglycemic profiles (NP) and 7 diabetic profiles (DP). NP patients had significant lower HbA<sub>1c</sub> (5.9% VS 7.1%;  $p < 0.001$ ) and were insulin-independent compared to DP who all resumed insulin. No differences were observed between groups regarding time after transplantation. Comparison of NP and DP with C showed that total ISR was higher in C than in the two groups of transplanted patients:  $110,98 \pm 4,11$  pMol/m<sup>2</sup> in C vs  $61,17 \pm 9,75$  ( $p < 0,005$ ) in NP and  $26,88 \pm 7,78$  in DP ( $p < 0.02$  compared to NP). Maximal insulin secretion exhibited the same trend: C:  $777,27 \pm 31,51$  pMol/min/m<sup>2</sup> > NP  $421,24 \pm 72,76$  > DP  $181,80 \pm 52,25$  (C vs NP  $p < 0.01$ ; NP vs DP  $p < 0.02$ ). The most significant difference was found with beta-cell sensitivity C:  $126,90 \pm 5,94$  pMol/min/mmol/m<sup>2</sup> > NP  $61,53 \pm 11,73$  > DP  $12,89 \pm 3,72$  (C vs NP  $p < 0.005$ ; NP vs DP  $p < 0.01$ ). First phase index calculated according to Breda's model was also lower in DP vs NP ( $p < 0,001$ ). Insulin sensitivity did not differ among the 3 groups.

**Conclusion:** These results show that insulin secretion remains lower than normal in islet-transplanted patients if they have normal glucose tolerance, and is even lowered if they are still diabetic. BCS values are extremely low when islet-transplanted patients are diabetic and remain lower than normal (in the range observed in type-2 diabetics) when they have a normal glucose tolerance. This quantitative evaluation of insulin secretion is thus likely to be useful for the follow up of islet transplantation, even if its prognostic relevance remains to be studied.

## 478

## Actual 10 year pancreas transplant alone (PTA) results in a single centre experience

M. Occhipinti, F. Vistoli, M. Barsotti, W. Baronti, L. Rondinini, G. Amorese, U. Boggi, P. Marchetti; Department of Clinical and Experimental Medicine, University of Pisa, Italy.

**Background and aims:** PTA for the treatment of selected type 1 diabetic patients is receiving increasing attention. However, information on PTA long-term outcome is still limited. Aim of this study was to investigate the results of PTA performed in our center after 10 yrs of follow-up.

**Materials and methods:** From December 2000 to December 2003, 34 type 1 diabetic patients (age:  $37 \pm 9$  yrs; 17 males/17 females; BMI:  $23.5 \pm 3.3$  kg/m<sup>2</sup>, duration of diabetes:  $23.6 \pm 10.1$  yrs, insulin requirement:  $47 \pm 10$  UI/day) underwent PTA with the portal-enteric drainage approach. Immunosuppression consisted of basiliximab and high dose steroids as induction, and mycophenolate mophetil, tacrolimus and low dose steroid as maintenance treatment. Actual patient and pancreas (insulin-independence) survival, biochemical parameters and indexes of cardiovascular status were analyzed at 10 yrs after transplantation.

**Results:** Ten-year patient survival was 97% (33/34 patients; 1 death with functioning graft occurred at 5 yr post-transplant due to stroke), and death censored pancreas survival was 63.6%. Failures were due to acute rejection (2 cases) and chronic rejection (10 cases). Patients with functioning grafts were normoglycemic in the absence of exogenous insulin therapy (fasting plasma glucose:  $96 \pm 19$  vs  $230 \pm 108$  mg/dl, HbA<sub>1c</sub>:  $5.8 \pm 0.6$  vs  $8.3 \pm 1.8\%$ , both  $p < 0.001$  vs pre-transplantation values), with sustained endogenous insulin secretion (C-peptide levels:  $2.8 \pm 1.5$  vs  $0.1 \pm 0.1$  ng/ml,  $p < 0.001$ ). Total cholesterol ( $157 \pm 40$  vs  $193 \pm 31$  mg/dl,  $p < 0.001$ ) and LDL cholesterol ( $95 \pm 36$  vs  $128 \pm 36$  mg/dl,  $p < 0.001$ ) were lower after PTA, with no significant changes in statin therapy. Blood pressure values resulted similar before as after transplantation (systolic:  $126 \pm 12$  vs  $125 \pm 17$  mmHg; diastolic:  $74 \pm 10$  vs  $78 \pm 10$  mmHg), with unchanged anti-hypertensive therapy. Estimated glomerular filtration rate (EPI-MDRD) decreased at a rate of  $1.7 \pm 2.1$  ml/min/yr, and albumin excretion rate was lower after PTA ( $0.17 \pm 0.24$  vs  $1.6 \pm 2.9$  g/24h,  $p < 0.05$ ). Left ventricular ejection fraction increased after transplantation from  $54.1 \pm 4.3$  to  $58.9 \pm 2.7\%$  ( $p < 0.01$ ).

**Conclusion:** In this single centre experience, PTA successfully and safely allowed long-term (10-yr) actual patient survival and insulin-independence, and associated with improvement of several biochemical and clinical parameters.

## 479

## Diabetic neuropathy in pancreas and kidney transplant recipients: follow-up after 8 years of normoglycaemia

P. Boucek<sup>1</sup>, T. Havrdova<sup>1</sup>, L. Voska<sup>1</sup>, A. Lodererova<sup>1</sup>, H. Vondrova<sup>2</sup>, R. Krejci<sup>2</sup>, F. Saudek<sup>1</sup>, K. Lipar<sup>1</sup>, C. Sommer<sup>3</sup>;

<sup>1</sup>Institute for Clinical and Experimental Medicine, <sup>2</sup>Thomayer Hospital, Prague, Czech Republic, <sup>3</sup>University of Würzburg, Germany.

**Background and aims:** Very advanced forms of diabetic peripheral neuropathy are generally present in pancreas/kidney transplant candidates. We present long-term follow-up data on the effect of normoglycemia after a simultaneous pancreas/kidney transplantation (SPK) on epidermal nerve fibre (ENF) density and neurological function in type 1 diabetic (DM) recipients.

**Materials and methods:** Lower thigh 3-mm skin biopsies with ENF counts (indirect immunofluorescence method), autonomic function (AFT) and quantitative sensory testing (QST) and electrophysiological examinations were performed at time of and at 8 years post-SPK in 12 Type 1 DM patients (mean  $\pm$  SD age  $44 \pm 10$ ; pre-transplant DM duration  $28 \pm 9$  years). Cardiovascular autonomic reflex tests included heart rate variation with deep breathing (I-E), Valsalva ratio (VR) and heart rate (30:15) and systolic blood pressure ( $\Delta$  sBP) responses to standing. Vibration perception thresholds (VPT; biothesiometer) were used for quantitative sensory testing. Electrophysiology data analyzed were sensory (median and sural) and motor (median, tibial and peroneal) nerve conduction velocities (NCV) and peak action potential amplitudes. ENF counts, AFT and QST were also performed in 14 sex- and age-matched healthy controls (C). The Mann-Whitney U test and Wilcoxon test were used for statistical analysis.

**Results:** At follow-up, SPK recipients were insulin-independent with excellent glycemic control (HbA<sub>1c</sub>  $37 \pm 3$  mmol/mol) and kidney graft function (S-creatinine  $102 \pm 2$   $\mu$ mol/L; eGFR  $61 \pm 17$  ml/min). However, the severe ENF

depletion present at baseline (SPK vs. C:  $0.8 \pm 1.3$  vs.  $11.4 \pm 4.2$  ENF/mm skin surface;  $p < 0.001$ ) was not improved at follow-up ( $1.4 \pm 4.7$  ENF/mm;  $p > 0.05$  vs. baseline) with total ENF absence in 11 biopsies. Similarly, all AFT and QST results were clearly abnormal in SPK recipients in comparison with C and no amelioration occurred after long-term normoglycemia. Although some improvement was seen at follow-up in several electrophysiological parameters, statistical significance for the SPK group as a whole was achieved in median motor NCV only (median; interquartile range, pre- vs. post-SPK: 47.5; 43.0 to 50.0 vs. 51.4; 50.9 to 55.3 m/s;  $p = 0.004$ ).

**Conclusion:** Lower limb epidermal nerve fibre depletion and neurological function tests - except for median motor nerve conduction velocity - were not significantly improved following establishment of long-term normoglycemia in pancreas/kidney transplant recipients. These results confirm the poor reversibility of advanced structural and functional changes in diabetic peripheral neuropathy.

### Effect of simultaneous kidney-pancreas transplantation in patients with type 1 diabetes to stabilise / progression of complications

M. Shamkhalova<sup>1</sup>, A. Glazunova<sup>1</sup>, M. Biragova<sup>1</sup>, S. Gracheva<sup>1</sup>, M. Shestakova<sup>1</sup>, Y. Moysyuk<sup>2</sup>, A. Pinchuk<sup>3</sup>, I. Dmitriev<sup>3</sup>, S. Arzumanov<sup>4</sup>;

<sup>1</sup>Diabetic Nephropathy, National Research Centre for Endocrinology,

<sup>2</sup>Transplantation of liver and kidney, Academician V.I. Shumakov Federal Research Center of Transplantology and artificial organs, <sup>3</sup>Transplantation of the pancreas and kidney, Scientific-Research Institute of Emergency Care. N.a. N.V. Sklifosofskiy, <sup>4</sup>Kidney transplantation and vascular surgery in urology and hemodialysis, Federal Research Centre of Urology, the Ministry of Health of Russia, Moscow, Russian Federation.

**Background and aims:** To evaluate the effect of successfully simultaneous kidney- pancreas transplantation (SPK) in patients with type 1 diabetes mellitus (T1DM) to stabilize/progression of complications.

**Materials and methods:** The study included 8 patients on standard immunosuppressive triple therapy. The average duration of T1DM 25 years [20,5;25], the duration of diabetic nephropathy (DN) - 7,96 лет[6,8;9,0]. All patients (3 men and 5 women) remained in the study for at least months [12;25,5] after the transplantation.

**Results:** The mean level of HbA1c in the group before the study was 8,65 % [8,4;9,1], then decreased to individualising glycemic targets - 5,75% [5,55;6,0] after SPK. According to a continuous glucose monitoring system using «iPRO2» marked euglycemia during the day (glycemia 3,9-8,9 mmol/l - 89 %, to lower than 3,9 mmol / l - 11% , higher than 8,9 mmol/l - 0 % of the time of day). The examination determined normoalbuminuria, GFR 80,125 [71;90,5]. All patients had normal levels of hemoglobin 120,125 [112,5;130,0], parathormone 64,94[61,37;67,5], phosphorus 1,2 [1,05;1,4], blood pressure 110[110,0;111,5]. The progression of initial proliferative diabetic retinopathy (DR) in the post-transplantation period was observed in 37,5 % of patients, followed by performing a vitrectomy and additional sessions laser panretinal photocoagulation. At 87,5% (7 people) identified nonstenotic atherosclerosis of the lower extremities, 1 patient - significant stenosis of the popliteal, posterior tibial artery to the right, requiring holding endovascular balloon angioplasty and stenting. In 75 % (6 people) developed ulcerative defects in the lower limbs and 4 people observed the progression of the chronic stage of osteoarthropathy.

**Conclusion:** In addition to the recovery of renal function and euglycemia in patients with T1DM undergoing SPK, noted the progression of DR and diabetic foot syndrome, which bear witness to the genesis of multivariate diabetic complications requiring verification and timely therapy.

## PS 025 Hypoglycaemia rates and their economic burden

Ramachandran's Diabetes Hospitals, Chennai, India.

**Background and aims:** Hypoglycaemia is an important concern for patients with diabetes and physicians when setting glycaemic targets. The Hypoglycaemia Assessment Tool (HAT) study, the largest and most comprehensive of its kind, assessed self-reported hypoglycaemia and associated predictive factors in a global population of patients with insulin-treated diabetes.

**Materials and methods:** HAT was a non-interventional, multicentre, 6-month retrospective and 1-month prospective study of hypoglycaemic events in 24 countries using self-assessment questionnaires and patient diaries (for 28 days) in people aged  $\geq 18$  years with type 1 (T1D) or type 2 (T2D) diabetes using insulin for  $\geq 12$  months attending routine clinics. Associations between predictive factors and hypoglycaemia were examined using negative binomial regression models adjusted for period and country.

**Results:** 27,585 patients completed the study (Table 1). 83.4% of patients with T1D and 50.8% of patients with T2D experienced  $\geq 1$  hypoglycaemic event in the 4 weeks before baseline (51.5 and 16.5 events per patient year). Higher ( $p < 0.001$ ) incidence rates were reported in the 4 weeks after baseline (73.3 [T1D] and 19.3 [T2D] events per patient year). A greater percentage of patients with T1D vs T2D reported any (83.0 vs 46.5%), nocturnal (40.6 vs 15.9%) or severe (14.4 vs 8.9) hypoglycaemia in the prospective period. A weak correlation was seen (irrespective of diabetes type) between incidence of any hypoglycaemia and duration of diabetes (incidence rate ratio 1.01, 95% CI 1.01; 1.02) or duration of insulin therapy (1.04, 95% CI 1.03; 1.04).

**Conclusion:** In this large, multinational population of patients with T1D or insulin-treated T2D, rates of overall, nocturnal and severe hypoglycaemia were higher than previously reported. An increased incidence of overall hypoglycaemia in the prospective study indicated significant under-reporting of hypoglycaemia.

### Hypoglycaemia study questionnaire in patients with diabetes R. Tahhan;

Endocrinology, Al-Zahra Hospital, Dubai, United Arab Emirates.

**Background and aims:** To identify the frequency of self-reporting Moderate and severe hypoglycemia hypo and its relation to demographic, clinical variables, fear of hypoglycemia FoH and mood among adults with diabetes in outpatients clinics in United Arab Emirates.

**Materials and methods:** The study adapted hypoglycemia patient questionnaire by ADA/Endocrine society 2013 workshop on hypo. After obtaining approval of hospital ethical committee, patient verbal consent, adults' patients with diabetes attending the clinics were encouraged to participate. FoH was assessed by Hypoglycemia fear survey HFS-II. WHO-5 survey is conducted for mood assessment when total HFS-II score  $\geq 9$ . Hypoglycemia incidence was grouped according to its impact on patient's function into two groups; mild / no hypo and moderate/severe hypo group. Analysis was done using SPSS 21 for windows. Comparison between quantitative variables used student T-test or ANOVA when applicable and Chi-square test for qualitative variables.

**Results:** Total study sample is 104 patients with diabetes, mainly DM2 92.3% 96/104.59.6 % ( 42) females and 40.2% (62) males. Mean age, BMI, diabetes duration and HbA1c; 45.88 $\pm$ 9.6, 30.88 $\pm$ 6.04, 7.68 $\pm$ 5.89, and 7.60 $\pm$ 1.33 respectively. 56.7% reported mild/no hypo 59/104 versus 43.3 % (45) mod/severe hypo. Diabetes duration increased the incidence of moderate/severe hypo; 6.41 $\pm$ 5.71 (59) vs 9.36 $\pm$ 5.75 (45) for no/mild hypo and mod/severe hypo respectively p= 0.002 but not for the other variables; age, HbA1c, BMI, RBG. Total HFS-II and its sub-scale worry and behavior scores were significantly higher among those subjects reporting mod/severe hypo; 26.47 $\pm$ 22.7, 16.86 $\pm$ 15.1, 9.35 $\pm$ 9.44 respectively vs 9.83 $\pm$ 11.57, 6.19 $\pm$ 7.66, 3.64 $\pm$ 6.77 for with mild/no hypo group P<0.001. Median score for total HFS-II in the sample is 10. An analysis using the cutoff more than 10 versus  $\leq 10$  was statistically significant in differentiating mod/severe hypo group from no/mild hypo 34.9% vs 72.2% p= 0.001. In the subgroups of female gender versus male, the mean and median for the HFS worry subscale score was higher in the female

subgroup compared to the male group; 16.25 $\pm$ 14.40, 13 and 8.61 $\pm$ 11.54, 4.5 p=0.005 respectively. The latter reflects a higher fear of hypo among females in the sample. A higher score but not significant in WHO-5 survey reflects a better mood among mild/no hypo 99.94 $\pm$ 5.11 compared to mod/severe hypo group 59.87 $\pm$ 16.8 (p= 0.092). Driving and diabetes; 31.7% and 6.1% of questionnaire respondents are checking their B.G sometimes and always before driving while they are on anti-hyperglycemic medications. 50% of insulin users are not doing so at all and 44.4% and 5.65% reported performing blood glucose checking sometimes and always before their journey. 15.1% 13/104 reported hypo while driving in the last one year.

**Conclusion:** The ADA/Endocrine society hypoglycemia questionnaire is a useful tool for self-reporting hypoglycemia. FoH is significant among patients with moderate/severe hypo and can be effectively highlighted by HFS-II. More educational efforts are needed to ensure safe driving in patients with diabetes in UAE.

**Background and aims:** Some studies suggest differences in gender should be considered when individualizing treatment for people with type 2 diabetes mellitus.

**Materials and methods:** We studied the effects of gender on the risk for hypoglycemia and its perception in the SAVOR-TIMI 53 trial, a randomized controlled trial in which 16,492 patients with type 2 diabetes mellitus were randomized to saxagliptin or placebo and were followed for a median of 2.1 years. Patients were requested to record hypoglycemic episodes which were defined based on symptoms suggestive of hypoglycemia that recovered by carbohydrate ingestion and/or documentation of low blood glucose < 54 mg/dl (minor) or the need for assistance from another person (major).

**Results:** A total of 11,037 (66.9%) males and 5,455 (33.1%) females were included in the trial. Hypoglycemic events were reported by 16.2% of men and 16.1% of women; however, the event rate was higher in men (4.1 vs. 3.6 events/subject throughout follow up, p=0.002). Women were more likely than men to report clinical symptoms associated with hypoglycemia (83% vs. 76% of events, p<0.01), to require intervention (64% vs. 55%, p<0.001) which was generally oral glucose, or to need assistance from another person (3.3% vs. 2.6%, p=0.05). Missing a meal was the most frequently identified trigger for hypoglycemia and was more common in women than in men (24% vs. 16%, p<0.001). Finger stick glucose levels were reported in 83.0% and 81.5% of episodes by men and women respectively (p=0.6). Women reported hypoglycemic events at higher glucose levels than men. Glucose levels  $>=63$ mg%

were documented in 15% of hypoglycemic events reported by women and in 11% of episodes reported by men ( $p<0.001$ ). Low ( $<63\text{mg/dl}$ ) blood glucose levels were reported in 72% of the hypoglycemic episodes in men and 67% in women ( $p=0.02$ ).

**Conclusion:** These findings indicate significant gender differences in the perception of hypoglycemia. The mechanisms and impact of these findings on diabetes management need further study.

### Risk and protective factors for severe hypoglycaemia in patients with type 1 diabetes

T. Wohland<sup>1</sup>, T. Tiemann<sup>2</sup>, O.-M. Patzer<sup>3</sup>, J. Holstein<sup>4</sup>, P. Kovacs<sup>1</sup>, A. Holstein<sup>3</sup>;

<sup>1</sup>IFB AdiposityDiseases Leipzig, University of Leipzig, Genetics of Obesity and Diabetes, <sup>2</sup>Outpatient Diabetes Center, Rinteln, <sup>3</sup>Lippe-Deilmold Hospital, 1st Department of Medicine, <sup>4</sup>Charité, University Medicine Berlin, Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Germany.

**Background and aims:** Severe hypoglycaemia (SH) is associated with a critical prognosis. In addition to its acute life-threatening potential, SH may increase cardiovascular and all-cause mortality irrespective of diabetes type. Therefore, preventing from SH is a crucial challenge which requires better understanding of the predisposing risk factors. Our aim was to characterize the clinical circumstances of SH in patients with type 1 diabetes (T1DM) in a German population under the conditions of real life and to evaluate corresponding risk factors.

**Materials and methods:** Prospective population-based, observational trial and case control study. All SH occurring between 2007 and 2013 in a large tertiary care hospital in the Lippe-Deilmold area (200.000 inhabitants) were captured. The clinical characteristics of patients with T1DM and SH were compared with an unselected regional control group of 165 patients with T1DM who did not experience SH in the seven-year period. SH was defined as a symptomatic event requiring treatment with intravenous glucose or administration of glucagon and being confirmed by a blood glucose measurement of  $<50\text{ mg/dl}$ . Predictive factors for SH were analysed by a multivariate regression model.

**Results:** A total of 959 episodes of SH in 679 patients were registered: 37.1% of cases (356/959) were related to T1DM, 51.9% (498/959) to T2DM, 3% (29/959) to pancreoprivic diabetes and 7.9% (76/959) occurred in non-diabetic individuals. The 356 cases of SH in T1DM (initial blood glucose  $31.6\pm 10.7\text{ mg/dl}$ ) comprised 189 subjects. 50.6% (180/356) of these hypoglycaemic episodes were related to only 29 patients who experienced  $\geq 3$  SH. Hypoglycaemic individuals with T1DM and the 165 subjects without SH had a similar mean age ( $48.0\pm 19.0$  vs.  $47.5\pm 17.4$  years; n.s.), diabetes duration ( $24.7\pm 15.5$  vs.  $23.8\pm 15.2$  years; n.s.) and comparable HbA1c values ( $7.5\pm 1.3\%$  vs.  $7.7\pm 1.4\%$ ; n.s.). Under regression analyses dementia (Odds Ratio and 95% confidence interval; OR 12.93 [1.60;104.86]), living in care homes or care by home nursing services (OR 4.84 [1.33;17.63]), use of NPH as basal insulin supply (OR 3.05 [1.31;7.07]), treatment with  $\beta$ -blockers (OR 2.19 [1.20;4.00]), impaired awareness of hypoglycaemia (OR 2.16 [1.14;4.10]), hyperlipoproteinemia (OR 1.95 [1.09;3.48]) and extensive comorbidities (OR 1.48 [1.25;1.75]) were significant risk factors for SH (all  $p<0.05$ ). In contrast, use of short acting insulin analogues (OR 0.29 [0.17;0.49]), higher frequency of blood glucose self measurement (OR 0.43 [0.23;0.79]) and female sex (OR 0.61 [0.39;0.96]) appeared to be protective against SH (all  $p<0.05$ ).

**Conclusion:** Individuals with T1DM and SH clearly distinguish from those without SH as they are characterized by a cluster of risk factors and personal circumstances. At least, some of these predictive factors can be influenced by individualized therapies. In particular, the use of insulin analogues could be beneficial to prevent SH. The high proportion of patients with recurrent SH remains a therapeutic challenge.

### The influence of new European Union driver's licence legislation on reporting of severe hypoglycaemia by patients with type 1 diabetes

R.M. Agesen<sup>1</sup>, L.A.H. Færch<sup>1</sup>, M.-L. Allingbjerg<sup>1</sup>, B. Thorsteinsson<sup>1,2</sup>, U. Pedersen-Bjergaard<sup>1,2</sup>;

<sup>1</sup>Department of Cardiology, Nephrology, and Endocrinology, Nordsjællands University Hospital, Hillerød, <sup>2</sup>Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark.

**Background and aims:** The risk of losing privileges such as driver's licence may hamper reporting of severe hypoglycaemia by patients with type 1 diabetes and result in concealed severe hypoglycaemia. We tested the hypotheses that the implementation in Denmark of new stricter European Union (EU) legislation on driver's licencing with the purpose to improve traffic safety in January 2012 has reduced the self-reported rate of severe hypoglycaemia in a routine clinical setting and that anonymous reporting results in higher event rates.

**Materials and methods:** A cohort of 309 patients with type 1 diabetes were recruited from our outpatient clinic. Numbers of severe hypoglycaemic events defined by need for treatment assistance from another person were retrieved from medical records in the years 2010 to 2012 and retrospectively reported in an anonymous questionnaire. Data from medical records in 2012 were compared with those from 2010 and 2011 and with data from questionnaire.

**Results:** Reported rates of severe hypoglycaemia in the medical records were reduced by 55% in 2012 compared to the prior years ( $p=0.034$ ). The fraction of subjects reporting recurrent episodes was grossly reduced from 5.6% to 1.5% ( $p=0.014$ ). Compared to reporting in the questionnaire the rate of severe hypoglycaemia in 2012 was 70% lower ( $p<0.001$ ).

**Conclusion:** Reporting of severe hypoglycaemia by patients with type 1 diabetes is significantly reduced following implementation of EU driver's licensing legislation, primarily due to a marked reduction in the fraction of subjects reporting recurrent episodes that according to the new regulations implies withdrawal of driver's licensing. The growing burden of concealed severe hypoglycaemia may impair the safety of affected patients and unintendedly paradoxically reduce the general traffic safety.

## 486

### Risk factors and economic burden of hypoglycaemia in patients with type 2 diabetes mellitus initiating basal insulin in a U.S. managed care system

C. Gerrits<sup>1</sup>, E. Chou<sup>1</sup>, H.-W. Chung<sup>2</sup>, H. Wang<sup>1</sup>, Q. Zhang<sup>1</sup>;

<sup>1</sup>R&D, Sanofi, Bridgewater, <sup>2</sup>TechData, King of Prussia, USA.

**Background and aims:** A retrospective study assessing risk factors of hypoglycemia and associated economic burden, in terms of healthcare utilisation and expenditures perspective, in adult patients with Type 2 Diabetes Mellitus initiating basal insulin on oral antidiabetic drug during 2006 to 2012 from a U.S. national claims database (Innovus LabRx).

**Materials and methods:** All patients had 24 months of continuous healthcare coverage with 12 months before (Baseline) and 12 months after (Follow-up) the initiation of basal insulin. Logistic regression was adapted to identify risk factors of hypoglycemia occurred at 1-year Follow-up, adjusting Baseline patient characteristics including age, gender, comorbidities, prescriptions, hypoglycemia status and healthcare utilisation. The economic burden of hypoglycemia was evaluated accounting for Baseline patient characteristics with a generalised liner model assuming gamma distribution with long link for healthcare costs. The subpopulation of patients without sulfonylurea or beta-blocker was also evaluated.

**Results:** While 6.8% (719/10,607) of the basal insulin initiator cohort (mean age 54 years, 44% females) had at least one medical claim for hypoglycemia, 5.9% had hypoglycemia in patients who did not use sulfonylurea or beta-blocker, and 9.8% in patients who were 65 years or older. Hypoglycemia was strongly associated with baseline hypoglycemia (Odds Ratio (OR)=5.78, 95% CI: 4.68-7.14) as well as baseline comorbidity (Charlson Comorbidity Index: 3.4 for patients with hypoglycemia vs. 2.4 for patients without hypoglycemia), microvascular disorder (OR=1.36, 95% CI:1.12-1.66), macrovascular disorder (OR=1.33, 95% CI:1.09-1.62), pancreatitis (OR=1.62, 95% CI:1.06-2.47), foot exam (OR=2.93, 95% CI:2.28-3.76), and hospitalisation (OR=1.30, 95% CI:1.07-1.58). During Follow-up, patients with hypoglycemia vs. those who

did not, incurred a total healthcare cost of \$36,680 (95% CI: \$34,245–\$39,288) vs. \$16,850 (95% CI: \$16,549–\$17,156), diabetes medical costs (\$10,350 vs. \$2,403;  $p < 0.01$ ), and total number of inpatient days (19.8 vs. 3.4;  $p < 0.01$ ). An average hypoglycemia related hospitalisation cost was \$20,838. For every hypoglycemia episode avoided, an average Medical cost of \$733 can be saved. A 10% risk reduction in hypoglycemia was associated with an annual Medical saving of \$496.

**Conclusion:** Medically attended hypoglycemia was associated with and could be predicted by pre-existing comorbidity and result in increased healthcare utilisation and expenditures. An alternative basal insulin treatment with reduced risk of hypoglycemia can lessen economic burden.

### Severe hypoglycaemia often results in hospital visits and ambulance calls regardless of insulin regimen

S.R. Heller<sup>1</sup>, B.M. Frier<sup>2</sup>, M.L. Herslov<sup>3</sup>, J. Gundgaard<sup>4</sup>, S. Gough<sup>5</sup>;

<sup>1</sup>Academic Unit of Diabetes, Endocrinology and Metabolism, University of Sheffield, <sup>2</sup>The Queen's Medical Research Institute, University of Edinburgh, UK, <sup>3</sup>Medical & Science, Novo Nordisk A/S, <sup>4</sup>Health Economics & HTA, Novo Nordisk A/S, Søborg, Denmark, <sup>5</sup>NIHR Oxford Biomedical Research Centre, University of Oxford, UK.

**Background and aims:** Severe hypoglycaemia is a serious complication associated with glucose-lowering treatment, in particular insulin and sulphonylureas, resulting in significant morbidity, and incurring considerable financial cost. Resource utilisation associated with severe hypoglycaemia was assessed across three insulin regimens: patients with type 2 diabetes (T2D) treated with basal insulin plus oral therapy (T2BOT), patients with T2D treated with multiple daily injections (T2MDI) and patients with type 1 diabetes (T1D) treated with basal-bolus insulin (T1BB) in a large clinical development programme.

**Materials and methods:** Data relating to severe hypoglycaemic events (defined as episode in which the patient required external assistance for recovery) from the insulin degludec (IDeg) and insulin degludec/insulin aspart (IDegAsp) phase 3 programme (14 trials), which included the comparators insulin glargine (IGlar), biphasic insulin aspart (BIAsp), insulin detemir (IDet) and sitagliptin, were analysed using descriptive statistics. Mealtime insulin aspart (IAsp) was used in some regimens. This analysis used the clinical trial serious adverse events records, which documented whether an ambulance/emergency response team, a hospital/emergency room visit for  $\leq 24$  hours, or a hospital visit of  $> 24$  hours were required.

**Results:** In total, 536 severe hypoglycaemic events were analysed, of which 157 (29.3%) required an ambulance/emergency team, 64 (11.9%) led to hospital/emergency room attendance of  $\leq 24$  h and 36 (6.7%) required hospital admission ( $> 24$  h) (Table). Although the number of events were lower in patients with T2D compared with T1D, the proportion resulting in hospital treatment for  $\leq 24$  h were similar across treatment regimens, whereas a higher proportion (47.6%) in the T2BOT group required hospital treatment for  $> 24$  h vs T1BB (5.0%) and T2MDI (5.3%). This resource utilisation and associated financial burden are significant: the UK tariffs for "Admitted Patient Care & Outpatient Procedures - Diabetes with Hypoglycaemic Disorders" are £1,269 for  $\leq 69$  years and £2,187 for  $\geq 70$  years, in addition to £235 for an ambulance transfer. This yields an average cost per event across treatment regimens of £305 ((11.9%+6.7%)\*£1269+29.3%\*£235) for patients  $\leq 69$  and £476 ((11.9%+6.7%)\*£2187+29.3%\*£235) for patients  $\geq 70$  years

**Conclusion:** This analysis suggests that severe hypoglycaemic events often result in emergency/ ambulance calls and treatment in hospital, and was observed with all insulin regimens, incurring a substantial economic burden. Thus, preventative measures to reduce severe hypoglycaemia are likely to reduce this burden.

### Derivation and validation of a risk prediction tool for hypoglycaemia in hospitalised medical patients

B.R. Shah<sup>1,2</sup>, S. Walji<sup>3</sup>, A. Kiss<sup>2</sup>, J.E. James<sup>1</sup>, J.M. Lowe<sup>1,2</sup>;

<sup>1</sup>Department of Medicine, University of Toronto,

<sup>2</sup>Sunnybrook Research Institute, <sup>3</sup>Department of Family and Community Medicine, University of Toronto, Canada.

**Background and aims:** There is no objective way of identifying, on admission to hospital, those patients with diabetes who are at risk for hypoglycaemia. At present, most admitted patients with diabetes have their blood glucose monitored frequently but many never have glucose readings below an acceptable range. A method of identifying those at greatest risk of hypoglycaemia would lead to efficiencies in care delivery and improvements in quality of care and patient safety. The aim of this study was to develop and validate a tool using data available at the time of admission to predict the risk of hypoglycaemia during hospitalisation.

**Materials and methods:** A derivation cohort was identified of 300 randomly selected patients with diabetes admitted to a medical inpatient unit at a tertiary care teaching hospital in Toronto, Canada between November 2009 and October 2010. All point-of-care glucose tests were collected, and hypoglycaemia was defined as any result during the hospitalisation  $\leq 3.9$  mmol/L. Pre-specified candidate variables were abstracted from hospital records for each patient. Multivariable logistic regression was used to identify the independent predictors of hypoglycaemia using a backwards stepwise elimination method. The regression coefficients from the model were converted into an integer points score, and receiver operative characteristic curves were used to determine the threshold score that maximized sensitivity and specificity. The model was tested in a validation cohort of 300 randomly selected patients with the same inclusion criteria from a different Toronto tertiary care teaching hospital. Discrimination of the model was assessed using the c-statistic, and calibration was assessed using the Hosmer-Lemeshow goodness-of-fit test.

**Results:** In the derivation cohort, 105 (35%) patients had hypoglycaemia during their hospitalisation. The predictor variables remaining after backwards elimination were sulphonylurea use, insulin use, beta-blocker use, alpha-blocker use, an emergency department visit for any reason in the prior 6 months, fever and serum creatinine. The integer points scores derived from the model are shown in the Table. A summary score of  $\geq 15$  had a sensitivity of 79% and a specificity of 55% for predicting hypoglycaemia. In the validation cohort, this model had a c-statistic of 0.703 and the Hosmer-Lemeshow test had a p value of 0.50.

**Conclusion:** We have derived and validated an easy-to-use index that could be applied at the time of admission, which is moderately discriminative for predicting hypoglycaemia in hospitalised medical patients with diabetes.

| Variable   | Points |
|--|--------|
| On a sulfonylurea                                  | 12     |
| On insulin   | 5      |
| On a beta-blocker                                  | 4      |
| On an alpha-blocker                                | 4      |
| Emergency department visit (in prior 6 months)     | 17     |
| Temperature on admission $\geq 38^{\circ}\text{C}$ | 21     |
| Serum creatinine ( $\mu\text{mol/L}$ )             |        |
| $\leq 99$  | 0      |
| 100 to 139   | 1      |
| 140 to 199   | 2      |
| $\geq 200$   | 3      |

### The Local Impact of Hypoglycaemia Tool (LIHT)<sup>1</sup> for estimating the economic impact of hypoglycaemic episodes in national, local and user-defined populations

W.A. Parekh<sup>1</sup>, D. Ashley<sup>1</sup>, B. Chubb<sup>1</sup>, M. Evans<sup>2</sup>, H. Gillies<sup>3</sup>,  
<sup>1</sup>Health Economics & Outcomes Research, EU Market Access, Novo Nordisk Ltd, Crawley, <sup>2</sup>Consultant Diabetologist, University Hospital, Llandough, Cardiff, <sup>3</sup>Abacus International, Bicester, UK.

**Background and aims:** Insulin is the most efficacious glucose lowering therapy for patients with diabetes, however, a common short-term adverse effect of insulin therapy is hypoglycaemia. Hypoglycaemia has a major impact on patients' lives affecting employment, driving, relationships, travel, and leisure activities. Severe and non-severe hypoglycaemic episodes also represent a substantial and often under-estimated cost burden to the National Health Service (NHS) and society through increased treatment costs and reduced productivity. The purpose of the Local Impact of Hypoglycaemia Tool (LIHT) is to help clinicians and budget holders estimate the cost of hypoglycaemia in the UK and specifically in their locality at the Primary Care Organisation (PCO), General Practice (GP) or user defined population level.

**Materials and methods:** The LIHT is a versatile model which allows the incorporation of real-life local data. The user selects a region/population of interest and based on the epidemiology of diabetes in the UK the model estimates the number of insulin-treated adults with type 1 and type 2 diabetes in that region. Using hypoglycaemia rates from the UK Hypoglycaemia Study Group (UKHSG) observational study, and the cost of a hypoglycaemic episode, the annual cost of severe and non-severe hypoglycaemic episodes in that population is estimated. The cost of a hypoglycaemic episode is dependent on the utilisation and unit costs of healthcare resources (blood glucose testing, glucose preparations, health care professional consultations, ambulance and hospital costs, derived from MIMS, Personal Social Services Research Unit (Health & Social Care) and NHS Tariff information), and is estimated to range from £1.67 to £2,195. In addition to the direct costs incurred by the NHS, indirect costs associated with lost productivity are estimated.

**Results:** The model highlights the cost burden of hypoglycaemia in the UK for insulin-treated adults with diabetes. On a national level, with a UK population of almost 67 million people, the total cost of managing hypoglycaemic episodes in insulin-treated adults with diabetes is an estimated £363.6m per year (£235.6m for severe and £128m for non-severe episodes, respectively). In addition, hypoglycaemic episodes are associated with indirect and hidden costs, such as lost productivity and higher rates of falls and fractures. On a local health economy level the model can provide estimations for each particular PCO within the UK. Using a hypothetical population of 100,000, the total cost of managing hypoglycaemic episodes is estimated to be £543,493 per year (£352,163 for severe and £191,330 for non-severe episodes, respectively). **Conclusion:** This model highlights the substantial cost burden to the NHS of hypoglycaemia in insulin-treated adults and may aid clinicians and NHS budget holders with choices regarding insulin treatments. The model offers an opportunity to explore how reducing hypoglycaemia can improve the quality of diabetes care for patients and result in potential budget savings.

## PS 026 Insulin secretion in animal models

### 490

#### Influence of fasting duration on glucose metabolism in C57BL/6J mice during intravenous glucose tolerance test

A.-H. Thorén Fischer, M. Abels, N. Wierup;  
 Clinical Sciences in Malmö, Lund University, Neuroendocrine Cell Biology, Malmö, Sweden.

**Background and aims:** The intravenous glucose tolerance test (IvGTT) is commonly used to study insulin release and beta cell function in both humans and animal models. IvGTT is often preceded by a period of fasting and different laboratories use different protocols for this. Because the IvGTT is frequently used and a lot of conclusions are drawn from it, it is important to standardize the performance and use conditions that best reflect the situation aimed to study, e.g. fasting or starvation. In this study we wanted to investigate how different fasting time affects insulin secretion and glucose elimination during IvGTT in mice. The time durations were chosen based upon commonly used fasting times to find a fasting duration that gave the strongest insulin response and glucose elimination.

**Materials and methods:** 20g C57BL/6J BomTac female mice (n=5 in each group) were fasted for different times (12 hour, 4 hour and 1 hour). The mice were anaesthetized with Hypnorm/Dormicum 30 minutes prior to the experiment. A basal blood sample was taken from all the mice. Thereafter, glucose (1 g/kg) was injected in a tail vein, and six following blood samples were taken at 1, 5, 10, 20, 50 and 75 minutes. All blood samples were taken from the retro orbital plexus. Glucose (colorimetric assay) and insulin (ELISA) were analyzed in plasma.

**Results:** The mice fasted for 12 hours had higher basal glucose levels, compared with mice fasted for 1 and 4 hours ( $p < 0.05$ ). This group also had a decreased insulin response (acute insulin response (AIR), 2.5 vs. 6.6 and 6.7,  $p < 0.001$ ) after glucose administration, which resulted in a trend towards decreased glucose elimination (Kg, 1.9 vs. 2.8 and 2.7,  $p = 0.06$ ). When comparing the groups fasted for 1 or 4 hours there was no difference in either glucose elimination or insulin response.

**Conclusion:** When planning in vivo experiment with mice it is important to know how they respond to different treatments such as fasting duration. In this study we show that the fasting time chosen for an IvGTT in normal C57BL/6J mice strongly effect the results, both concerning insulin release and glucose elimination we aimed to optimize the IvGTT protocol with a fasting time that gave maximal insulin release and glucose elimination. Our data suggest that 1h fasting is optimal for this. However, 12h fasting should be avoided, since it affects insulin release and glucose elimination negatively, probably as a stress response to starvation.

#### Impact of glucose dosing regimens on evaluating glucose tolerance and beta cell function by intravenous glucose test in diet induced obese mice

G. Pacini<sup>1</sup>, B. Omar<sup>2</sup>, B. Ahrén<sup>2</sup>,  
<sup>1</sup>Metabolic Unit, ISIB-CNR, Padova, Italy,  
<sup>2</sup>Department of Medicine, Lund University, Sweden.

**Background and aims:** Metabolic studies require accurate measurements of islet function, in particular insulin secretion. An important aspect is the adaptation of beta cell function to insulin resistance, which is best described by the *disposition index*, derived from analyzing insulin and glucose data from an intravenous glucose tolerance test (IVGTT). One caveat when calculating this index is that basing the glucose dose on the individual's total body weight can result in large differences in the amount of glucose given to lean and obese individuals. In this study, we therefore evaluated alternative glucose dosing regimens for the determination of the impact of glucose dosing on measures of beta cell function in normal and diet induced obese (DIO) mice. **Materials and methods:** The glucose dosing regimens used for the IVGTT were either 0.35 mg per kg total body weight (BW) or per kg lean BW or a fixed glucose dose based on the average BW for all experimental mice. A total of 84 IVGTT were performed in 28 six-week old female C57BL6/JBomTac mice, 14 fed with 10% fat (CD) and 14 with a high fat diet (60% fat, HFD) for eight weeks before glucose tolerance testing. Lean body mass was determined

by dual emission x-ray absorptiometry using a PIXImus imager. IVGTTs were performed on 5 hour fasted mice. After injecting glucose in a tail vein, samples were taken from a retrobulbar intraorbital capillary plexus at 1, 5, 10, 20, 30 and 50 minutes for determination of insulin and glucose concentration. Glucose was dosed per total body mass (0.35g/kg), per lean body mass (0.35 g/lean kg) or equal for all animals (10 mg).

**Results:** Each regimen detected a similar decrease in insulin sensitivity in DIO mice. The different glucose dosing regimens gave, however, diverging results in regards to glucose elimination and the acute insulin response. Thus, the fixed dose regimen was the only that revealed impairment of glucose elimination in HFD (glucose elimination rate  $1.4 \pm 0.2$  vs.  $2.4 \pm 0.2$  %/min,  $P < 0.01$ ), whereas dosing according to total BW was the only regimen which showed significant increases in acute insulin response in HFD mice (peak insulin concentration  $1246 \pm 230$  vs.  $480 \pm 160$  pmol/l,  $P < 0.01$ ). The fixed dose glucose dosing regimen was the only one that revealed a significant decline in the disposition index value in HFD mice ( $0.7 \pm 0.1$  vs.  $1.1 \pm 0.1$ ,  $P < 0.05$ ), which is characteristic of type 2 diabetes in humans.

**Conclusion:** Our results therefore show that using different glucose dosing regimens during IVGTT in DIO mice, it is possible to model different aspects of physiology which are similar to prediabetes and type 2 diabetes in humans, with the fixed dose regimen producing a phenotype that most closely resembles human type 2 diabetes.

## 492

### Beta cell-specific over-expression of CART improves beta cell function in vivo

M. Abels, M. Riva, A.-H. Thorén Fischer, N. Wierup;  
Clinical Sciences in Malmö, Lund University, Neuroendocrine Cell Biology, Malmö, Sweden.

**Background and aims:** Cocaine- and amphetamine-regulated transcript (CART) is a regulator of islet hormone secretion, enhancing insulin secretion and lowering glucagon secretion, thereby fine-tuning blood glucose levels. CART also protects beta cells against glucotoxicity-induced apoptosis in vitro. Furthermore, beta cell CART expression is regulated by glucose and CART is up-regulated in beta cells of type 2 diabetes (T2D) patients and rodent models of T2D. The aim of this study was to examine the impact of up-regulated beta cell CART on in vivo beta cell function and survival, both crucial components for retaining normal glucose homeostasis.

**Materials and methods:** We generated transgenic mice that express CART under the control of the PDX1 promotor, resulting in overexpression of CART specifically in the beta cells (CARTtg). Mice (4 month, 6 months, and 10 months) were subjected to intravenous glucose tolerance test (IVGTT) to study insulin secretion in vivo. To study in vivo beta cell survival, mice were subjected to a multiple low dose streptozotocin (STZ)-treatment to induce diabetes, followed by weekly glucose monitoring and IVGTT 3 weeks after treatment.

**Results:** 4-6 months old CARTtg mice displayed normal in vivo insulin secretion compared to wild type (WT) littermates. However, at the age of 10 months CARTtg mice displayed increased insulin secretory capacity (acute insulin release, AIR) during an IVGTT compared to WT mice (WT: 3.3 vs. CARTtg: 6.3,  $p = 0.02$ ). This was paralleled by improved glucose elimination (Kg) (WT: 1.8 vs. CARTtg: 2.5,  $p = 0.03$ ). In STZ-treated mice blood glucose levels were elevated, compared to control mice already after 1 week (12.5mM vs. 7.9mM,  $p < 0.001$ ). From 3 weeks after STZ-treatment CARTtg mice displayed lower glucose levels compared to WT mice (WT: 17.1mM vs. CARTtg: 21.7mM,  $p < 0.001$ ) suggesting improved remaining insulin secretory capacity. This was confirmed by IVGTT showing that CARTtg mice secreted more insulin throughout the glucose tolerance test (Insulin AUC WT: 48 vs. CARTtg: 69.4,  $p = 0.02$ ), which resulted in lower glucose levels (AUC glucose 1-20 min, WT: 642 vs. CARTtg: 557,  $p < 0.05$ ).

**Conclusion:** Here we show that overexpression of CART in beta cells provokes improved insulin secretory capacity in vivo. Furthermore, we also show that increased beta cell CART restores insulin secretion and glucose homeostasis after diabetes induction, probably as a result of enhanced beta cell survival. In view of that CART is up-regulated in islets of T2D patients; our data suggest that CART is up-regulated in T2D as a homeostatic response trying to overcome hyperglycemia

### LKB1-dependent regulation of incretin actions in pancreatic beta cells by metformin and adiponectin

K. Shinmura<sup>1</sup>, T. Negoro<sup>2</sup>, Y. Nakano<sup>2</sup>, T. Hirano<sup>1</sup>;  
<sup>1</sup>Department of Medicine, Division of Diabetes, Metabolism and endocrinology, Showa University School of Medicine, <sup>2</sup>Department of Pharmacogenomics, Showa University School of Pharmacy, Tokyo, Japan.

**Background and aims:** Metformin is widely used to treat DM and improves blood glucose concentration through activation of LKB1-AMPK pathway. On the other hand, incretins, GLP-1 and GIP, raise intracellular  $Ca^{2+}$  and cAMP concentration in pancreatic  $\beta$ -cells, resulting in insulin secretion. Incretin and metformin are concurrently used for the treatment of type 2 diabetes and so we examined the effect of metformin on insulin secretion by incretin. We also examined the effect of adiponectin, which physiologically activates LKB1-AMPK pathway. Furthermore, we analyzed whether LKB1 plays a key role for the regulation of  $Ca^{2+}$  and cAMP by metformin and adiponectin.

**Materials and methods:** Insulin secretion, cAMP production, and intracellular  $Ca^{2+}$  concentration were analyzed using MIN6 cells by stimulating with GLP-1 or GIP. Amount of insulin secretion was measured with the Mouse Insulin ELISA KIT (TMB) (AKRIN-011T, Shibayagi, Gunma, Japan). For cAMP assay, MIN6 cells were transfected with pGloSensor<sup>TM</sup>20F cAMP Plasmid by Neon<sup>TM</sup> Transfection System and cAMP production was measured by luminescence spectroscopy using GloSensor<sup>TM</sup> cAMP assay (Promega, USA) reagent. Intracellular  $Ca^{2+}$  concentration was measured by the Fura-2 fluorescence-imaging analytic method using Meta Fulora video image analyzer. For the knock down analysis of LKB1, the gene-specific siRNA was transfected by Neon System.

**Results:** Under physiological glucose concentration (5.5mM) but not under high glucose concentration (16.7 mM),  $Ca^{2+}$  influx by GLP-1 or GIP stimulation was inhibited by metformin and adiponectin resulting in decreased insulin secretion. Furthermore, metformin and adiponectin regulated cAMP response by incretins. Knock down of LKB1 by siRNAs abrogated the effects of metformin on the action of incretins under physiological glucose concentration.

**Conclusion:** Metformin and adiponectin regulated both  $Ca^{2+}$  and cAMP responses raised by GIP and GLP-1 under physiological glucose concentration but not under high glucose condition. According to the knock down experiments, LKB1 is involved in cAMP production and  $Ca^{2+}$  response promoted by metformin. Now we are investigating whether knock down of LKB1 can abrogate the same effect of adiponectin.

## 494

### Kinome-wide RNAi screen identifies regulators of insulin like peptide production in drosophila melanogaster

K. Hasygar<sup>1,2</sup>, V. Hietakangas<sup>1,2</sup>;  
<sup>1</sup>Department of Biosciences/Genetics, University of Helsinki,  
<sup>2</sup>Institute of Biotechnology, Helsinki, Finland.

**Background and aims:** Insulin/IGF pathway plays a critical role in adjusting the growth, metabolism and lifespan of animals in response to nutrition. Aberrations in the pathway are causal for human metabolic diseases, most notably diabetes. Insulin/IGF like signaling (IIS) is highly conserved in multicellular animals, making simple genetic model systems, like *Drosophila*, useful in dissecting the genes involved in IIS. Aim of our project is to identify signaling pathways regulating production of insulin like peptides in *Drosophila melanogaster*. *Drosophila melanogaster* has eight insulin like peptides, four of which are secreted from fourteen median neurosecretory cells called insulin producing cells (IPCs). IPCs are considered to be *Drosophila* counterparts of pancreatic beta cells. They regulate metabolic homeostasis and growth of the organism. In this study, we have performed a focused tissue-specific in vivo RNAi screen to identify signaling pathways regulating insulin production in IPCs.

**Materials and methods:** dILP2-Gal4; UAS-GFP driver line was used for IPC specific knockdown of kinases. RNAi lines against kinases were obtained from VDRC, Austria and Bloomington Stock Center, USA. qRT-PCR assays were used to measure mRNA levels of insulin like peptides and immunostainings using anti-dILP2 antibody were used to assess secretion of insulin like peptides.

**Results:** 231 protein kinases were screened of which twelve genes showed severe undergrowth phenotype upon knockdown. These hits were confirmed using at least two independent RNAi lines. These genes were analyzed for

their roles in IPC viability, insulin-like peptide (dILP) mRNA expression and dILP2 secretion. None of the kinases had an effect on the viability of IPCs. One of the kinases, Tousled-like kinase, showed significantly reduced dILP3 expression. Further, knockdown of several identified genes like ADCK, PKC98E, Rio2, aPKC, CDK12 and Rio1 showed accumulation of dILP2 in IPCs, implying disturbed dILP2 secretion. One of the genes, aPKC, has previously been linked to insulin secretion in mammals, suggesting conserved function. The mechanisms of action of other genes which are not previously studied with respect to insulin signaling are being investigated.

**Conclusion:** In conclusion, we have identified twelve protein kinases, which regulate insulin production in *Drosophila melanogaster*. One of the genes, Tlk, regulates dILP3 transcription in IPCs. Further, ADCK, PKC98E, Rio2, aPKC, CDK12 and Rio1 play a role in secretion of insulin like peptide 2 from IPCs.

### Antidiabetic effects of tigerinin-1R in mice chronically maintained on high fat diet

Y.H.A. Abdel-Wahab, O.O. Ojo, D.K. Srinivasan, B.O. Owolabi, P.R. Flatt; School of Biomedical Sciences, University of Ulster, Coleraine, UK.

**Background and aims:** We previously reported *in vitro* and acute *in vivo* insulinotropic effects of tigerinin-1R (RVCSAIPICH.NH<sub>2</sub>), an amphibian host defence peptide, isolated from the skin secretion of *Hoplobatrachus rugulosus*. The present study investigated plasma degradation and chronic metabolic effects of tigerinin-1R in Swiss NIH mice fed a high fat diet to induce obesity-diabetes.

**Materials and methods:** Proteolytic degradation of synthetic tigerinin-1R was investigated by reversed-phase HPLC and MALDI-TOF mass spectrometry using GLP-1(7-36) as positive control. Changes in glycaemic responses and metabolic parameters were measured in mice with high fat diet-induced obesity-diabetes treated with twice-daily intraperitoneal injection of tigerinin-1R (75nmol/kgbw) for 15 days. Glucose concentrations were measured by glucose oxidase method using an Analox GM9 glucose analyser and insulin concentrations were measured by radioimmunoassay. Indirect calorimetry and body composition were measured by CLAMS and DEXA whole body scanning. Insulin secretory responses of islets isolated from treated and untreated mice were examined.

**Results:** Unlike GLP-1(7-36), tigerinin-1R was resistant to *in vitro* degradation by plasma enzymes. Twice-daily injection of tigerinin-1R (75nmol/kg bw) for 15 days had no significant effect on food intake or body weight. Non-fasting glucose levels were significantly lowered (16%,  $P < 0.05$ ) and insulin levels were elevated (20%,  $P < 0.05$ ) compared to saline treated controls at the end of the treatment period. Glycaemic responses to oral and intraperitoneal glucose administration (180mmol/kg body weight) were improved by 26% ( $P < 0.05$ ) and 22% ( $P < 0.05$ ) respectively in mice treated with tigerinin-1R. Plasma insulin responses to glucose administration were also significantly enhanced by 40% ( $P < 0.001$ , oral) and 41% ( $P < 0.001$ , intraperitoneal). Treatment with the peptide had no effect on insulin sensitivity but compared to saline treated controls significantly improved beta cell responses of isolated islets in response to GLP-1 (10<sup>-6</sup>M, 1.9-fold,  $P < 0.001$ ), GIP (10<sup>-6</sup>M, 1.6-fold,  $P < 0.05$ , alanine (10mM, 1.4-fold,  $P < 0.001$ ), L-arginine (10mM, 1.6-fold,  $P < 0.05$ ) and KCl (30mM, 2.0-fold). Oxygen consumption, CO<sub>2</sub> production, respiratory exchange ratio, energy expenditure and body composition were not significantly altered by treatment with tigerinin-1R.

**Conclusion:** These observations provide the first evidence for the therapeutic potential of tigerinin-1R as a novel anti-diabetic agent.

## 496

### Gamma-oryzanol, a unique component of brown rice, improves pancreatic islet function via inhibition of exaggerated dopamine receptor signalling

C. Kozuka<sup>1</sup>, S. Sunagawa<sup>1</sup>, R. Ueda<sup>1</sup>, M. Higa<sup>2</sup>, H. Tanaka<sup>3</sup>, C. Takayama<sup>4</sup>, M. Matsushita<sup>5</sup>, S. Oyadomari<sup>6</sup>, M. Shimabukuro<sup>7</sup>, H. Masuzaki<sup>1</sup>; <sup>1</sup>Division of Endocrinology, Diabetes and Metabolism, Hematology, Rheumatology, University of the Ryukyus, <sup>2</sup>the Diabetes and Life-style Related Disease Center, Tomishiro Central Hospital, <sup>3</sup>Tanaka Clinic, <sup>4</sup>Department of Molecular Anatomy, University of the Ryukyus, <sup>5</sup>Department of Molecular and Cellular Physiology, University of the Ryukyus, Okinawa, <sup>6</sup>Institute for Genome Research, <sup>7</sup>Graduate School of Health Biosciences, University of Tokushima, Japan.

**Background and aims:** We recently demonstrated that  $\gamma$ -oryzanol, a major bioactive component of brown rice, prevents obesity and type 2 diabetes. Gamma-oryzanol attenuated the preference for dietary fat through reduction of exaggerated endoplasmic reticulum (ER) stress in high fat diet (HFD)-induced obese mice. We also found that  $\gamma$ -oryzanol improved HFD-induced glucose intolerance, but the underlying mechanism still remains unclear. On the other hand, previous studies showed that local dopamine D2 receptor (D2R) signaling prevents insulin secretion in islets. In this context, we tested the potential involvement of D2R signaling in  $\gamma$ -oryzanol-mediated glucose homeostasis in pancreatic islets.

**Materials and methods:** Gamma-oryzanol was delivered into the stomach of male C57BL/6J mice by a gavage needle and its effects on islets function were determined. Response of a series of drugs influencing D2R signaling and  $\gamma$ -oryzanol, and insulin secretion in pancreatic  $\beta$ -cell line, MIN6 cells and isolated islets was assessed.

**Results:** In islets from HFD-fed obese mice, D2R signaling was exaggerated in islets from mice fed HFD (e.g. D2R mRNA level; 2.0-fold increase vs. chow-fed mice,  $p < 0.05$ ), where augmented ER stress coexisted (e.g. Chop mRNA level; 2.1-fold increase vs. chow-fed mice,  $p < 0.01$ ). In pancreatic  $\beta$ -cell line, MIN6 cells and isolated islets,  $\gamma$ -oryzanol activated the cAMP/cAMP-dependent protein kinase (PKA) pathway via inhibition of D2R signaling, thereby enhancement of glucose-stimulated insulin secretion (GSIS) (insulin secretion, 25mM glucose; MIN6 cells, 1.3-fold,  $p < 0.05$ , islets, 2.2-fold increase vs. vehicle-treated cells,  $p < 0.01$ ). In contrast, exaggerated secretion of insulin-counteracting hormone, glucagon was remarkably suppressed by  $\gamma$ -oryzanol both *in vivo* and *in vitro*. ER stress is linked to the regulation of pancreatic  $\beta$ -cell functions and the pathophysiology of type 2 diabetes. ER stress in  $\beta$ -cells leads to apoptosis and suppression of insulin biosynthesis. We also found that  $\gamma$ -oryzanol reduces ER stress in islets from HFD-fed mice (e.g. Chop mRNA level; 37 % reduction,  $p < 0.05$ ). Moreover, in MIN6 cells treated with tunicamycin, an ER stress inducer,  $\gamma$ -oryzanol improved insulin secretion and prevented ER stress-induced apoptosis.

**Conclusion:** These data indicate that  $\gamma$ -oryzanol directly improves the survival and function of murine pancreatic islets. A series of the effects of  $\gamma$ -oryzanol on pancreatic islets may shed light on a novel, natural food-based medicine for type 2 diabetes in humans.

## 497

### Activation of GPR120 by fatty acid agonists augments insulin release from pancreatic islets and improves glucose tolerance in mice

A.M. McKillop, B.M. Moran, Y.H.A. Abdel-Wahab, P.R. Flatt; School of Biomedical Sciences, University of Ulster, Coleraine, UK.

**Background and aims:** GPR120 is a rhodopsin-like GPCR that has a high affinity for long chain saturated fatty acids 14-18 carbons and unsaturated fatty acids 16-22 carbons. This aim of this study was to assess the potency and selectivity of various GPR120 agonists and determine the cellular localisation of GPR120 in clonal beta cells and pancreatic islets.

**Materials and methods:** Insulin secretion and alterations in intracellular Ca<sup>2+</sup> and cAMP response to glucose and GPR120 agonists including endogenous agonists (ALA, EPA, DHA) and a synthetic analogue (GW-9508) were examined using clonal pancreatic BRIN-BD11 cells, mouse pancreatic islets and *in-vivo* studies using NIH Swiss mice. Cytotoxicity was assessed by LDH release. Cellular localisation of GPR120 was explored by double staining immunohistochemistry.

**Results:** The most potent and selective GPR120 agonist tested was ALA (EC<sub>50</sub> 1.2x10<sup>-8</sup> mol/l) at 10<sup>-8</sup>-10<sup>-4</sup> mol/l with a 1.5- to 2.1-fold increase in insulin

release at 5.6mM glucose ( $p < 0.001$ ), with maximum stimulation of insulin secretion by 53% at  $10^{-4}$  mol/l ( $p < 0.001$ ) in BRIN-BD11 cells. Stimulation of insulin secretion was observed with GW-9508 ( $6.4 \times 10^{-8}$  mol/l; 47%), EPA ( $7.9 \times 10^{-8}$  mol/l; 36%) and DHA ( $1.0 \times 10^{-7}$  mol/l; 50%) at 5.6mM glucose. At stimulatory glucose concentrations, ALA was the most potent agonist tested ( $EC_{50}$  of  $8.5 \times 10^{-8}$  mol/l) at  $10^{-8}$ – $10^{-4}$  mol/l with a 1.2- to 1.6-fold increase in insulin release at 16.7mM glucose ( $p < 0.05$ – $p < 0.001$ ). DHA enhanced insulin release at  $10^{-7}$ – $10^{-4}$  mol/l by 1.3- to 1.7-fold ( $p < 0.01$ – $p < 0.001$ ) ( $EC_{50}$  of  $1.2 \times 10^{-7}$  mol/l) while EPA augmented insulin secretion at  $10^{-9}$ – $10^{-4}$  mol/l by 1.2- to 1.6-fold ( $p < 0.05$ – $p < 0.001$ ) ( $EC_{50}$  of  $1.7 \times 10^{-5}$  mol/l). Synthetic agonist GW-9508 enhanced insulin secretion at  $10^{-8}$ – $10^{-4}$  mol/l by 1.2- to 1.7-fold ( $p < 0.05$ – $p < 0.001$ ) ( $EC_{50}$  of  $7.0 \times 10^{-7}$  mol/l). Results were corroborated by islet studies, with no evidence of cytotoxic effects. Dose-dependent insulin secretion by GPR120 agonists was glucose-sensitive and accompanied by elevations of intracellular  $Ca^{2+}$  ( $p < 0.05$ – $p < 0.001$ ) and cAMP ( $p < 0.05$ – $p < 0.01$ ). Immunocytochemistry demonstrated GPR120 expression on BRIN-BD11 cells and was confined to islet beta cells with no distribution on alpha cells. Administration of GPR120 agonists (0.1  $\mu$ mol/kg body weight) in glucose tolerance studies was tested in mice. Using AUC data, ALA ( $p < 0.05$ ), EPA ( $p < 0.05$ ) and GW-9508 ( $p < 0.01$ ) decreased the glycaemic excursion. Similarly both EPA ( $p < 0.05$ ) and GW-9508 ( $p < 0.01$ ) enhanced insulin release by 35–40% after 15 min while both small molecules stimulated insulin secretion by 33–41 after 30 min ( $p < 0.01$ ). All agonists tested with exception of DHA augmented glucose-induced insulin release ( $p < 0.05$ – $p < 0.01$ ) when compared to glucose alone.

**Conclusion:** GPR120 is expressed on pancreatic beta cells, and agonists at this receptor are potent insulin secretagogues, with therapeutic potential for type 2 diabetes.

## 498

### Chronic glucocorticoid treatment induced insulin resistance but improved glucose tolerance due to increased insulin secretion and beta cell neogenesis

H.T.T. Do<sup>1,2</sup>, A. Besseiche<sup>2,3</sup>, G. Dorothée<sup>1</sup>, B. Fève<sup>1,4</sup>, B. Blondeau<sup>3,2</sup>, M. Buysse<sup>1,4</sup>,

<sup>3</sup>INSERM UMR\_S1138, <sup>4</sup>APHP Hôpital Saint-Antoine, Paris, France.

**Background and aims:** Cortisol and corticosterone, the physiological glucocorticoids (GCs) in humans and rodents, respectively, have pleiotropic functions to modulate blood pressure, immune responses, and energy homeostasis. GCs and synthetic GCs are commonly used for the treatment of inflammatory diseases but their adverse effects can overcome their benefit, restricting their long-term use. More specifically, GCs exert deleterious effects on glucose metabolism, leading to a wide range of alterations from insulin resistance to complicated diabetes, but also induce weight gain associated with lipodystrophy.

**Materials and methods:** In this study, we investigated the effects of a long-term GC exposure in C57/Bl6 male mice. Corticosterone (CORT) was given in drinking water (100  $\mu$ g/mL) for 8 weeks. Glucose tolerance, insulin sensitivity, gene expression in adipocytes and pancreatic islets and pancreatic morphometry were studied.

**Results:** Mice treated with GC had a significant weight gain ( $\Delta = 7.1$  g vs 3.0 g,  $p < 0.001$ ) with an accumulation of both brown (x3,  $p < 0.001$ ) and white (x2,  $p < 0.01$ ) adipose tissues, characterized by a visceral adipocyte hyperplasia and subcutaneous adipocyte hypertrophy. Surprisingly, GC treatment promoted macrophage infiltration (F4/80, CD68) (x5,  $p < 0.05$ ) within all adipose tissues. Of note, a M1/inflammatory macrophage phenotype (MCP1, IL6, TNF $\alpha$ ) was restricted to visceral adipose tissue compared to subcutaneous fat depot, suggesting a substantial damaging effect on insulin sensitivity. Accordingly, CORT treatment induced an insulin-resistance, as demonstrated by insulin tolerance test and HOMA-IR (x10,  $p < 0.001$ ) as well as an decreased glucose uptake into adipose tissue (-50%,  $p < 0.01$ ). CORT mice exhibited also postprandial hyperglycaemia (following *ad libitum* nocturnal feeding) (259 mg/dL vs 140 mg/dL,  $p < 0.001$ ) but this effect was lost in fasted condition due to a reduced hepatic gluconeogenesis measured by pyruvate tolerance test. Strikingly, following a 6-h-fasting, GC treatment resulted in an improved glucose tolerance (OGTT/IPGTT), due to increased plasma insulin levels (x8,  $p < 0.001$ ). Pancreatic analysis revealed a dramatic increase of  $\beta$ -cell fraction (4.3% vs 0.6%,  $p < 0.05$ ) and  $\beta$ -cell mass (x7,  $p < 0.05$ ) associated with improvement in insulin secretion capacity from isolated islets. Increased islets size was observed (x2,  $p < 0.05$ ), due to  $\beta$ -cell proliferation. More surprisingly, a dramatic increased islet density was found (x4,  $p < 0.05$ ),

revealing  $\beta$ -cell neogenesis, a result confirmed by increased *Ngn3* expression. Several other  $\beta$ -cell genes (*Pdx1*, *Rfx6*, *Nkx 2.2*, *NeuroD*, *Ins*) were up-regulated, pointing to a new insight into GC-induced  $\beta$ -cell adaptation.

**Conclusion:** In this study we demonstrated that GC could differentially act on various fat depots to promote metabolic alteration and evidenced a new function of GCs on  $\beta$ -cell neogenesis.

### Effects of caloric restriction and *Ins1* gene dosage on glucose homeostasis in female mice

D.A. Dionne, N.M. Templeman, J.D. Johnson;

Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

**Background and aims:** Therapeutic benefits of caloric restriction (CR) on clinical outcomes in treatment of neurodegenerative disease, cancer, cardiovascular disease, and diabetes have been proposed. Studies indicate the positive health outcomes produced by CR may involve cellular nutrient-sensing pathways including insulin/insulin-like growth factor 1 signalling. CR has been reported to have significant effects on glucose metabolism and body composition, lowering fasting blood glucose and insulin, as well as improving glucose tolerance and insulin sensitivity. However, it is not clear which, if any, of the effects of CR are due to the lowering of circulating insulin. To determine whether CR-improved glucose homeostasis is a function of circulating insulin-dependent mechanisms we performed a gene-dosage study with mice either wildtype or heterozygous at the insulin 1 gene locus, while lacking the insulin 2 gene entirely. We have previously shown that male *Ins1*<sup>+/-</sup>:*Ins2*<sup>-/-</sup> mice are protected from diet-induced obesity compared to *Ins1*<sup>+/+</sup>:*Ins2*<sup>-/-</sup> littermate controls. In the present study, using female mice of the same genotypes, we compared how changes to caloric intake and insulin gene dosage affect circulating hormone levels, glucose homeostasis, energy expenditure, markers of healthy aging, and longevity.

**Materials and methods:** Female *Ins1*<sup>+/-</sup>:*Ins2*<sup>-/-</sup> mice and *Ins1*<sup>+/+</sup>:*Ins2*<sup>-/-</sup> littermate controls were fed a chow diet *ad libitum* (AL) until 13 weeks of age, then half of the mice continued AL feeding, while the others were placed on a CR diet where they were fed 60% of what their genotype-matched littermate controls ate daily. All mice were singly housed and CR mice were fed at night. Body mass, insulin secretion, and blood glucose response to intraperitoneal injections of glucose or insulin were assessed over a 1-year period.

**Results:** With the onset of CR, body mass in both genotypes fell and reached a new equilibrium by 20 weeks of age. Until ~38 weeks of age, food intake of AL-fed and hence CR fed *Ins1*<sup>+/-</sup>:*Ins2*<sup>-/-</sup> mice was modestly higher than that of *Ins1*<sup>+/+</sup>:*Ins2*<sup>-/-</sup>, leading to a small difference in mean body weight of CR mice that disappeared as food intake of the two genotypes converged. As expected, mice on CR had lower fasting and fed plasma glucose when compared to genotype controls ( $p < 0.05$ ). CR improved glucose tolerance in mice at 25 and 51 weeks of age, irrespective of *Ins1* gene dosage. All groups had comparable glucose-stimulated insulin levels at 27 and 53 weeks of age. However, we observed paradoxical effects of CR on insulin sensitivity. While the first 30 minutes post-injection were similar across groups, CR mice of both genotypes exhibited a rapid recovery to baseline glucose. Fasting insulin levels at 53 weeks were also paradoxical, with *Ins1* gene dosage having no effect in CR mice. In fact, CR *Ins1*<sup>+/-</sup>:*Ins2*<sup>-/-</sup> mice had significantly increased circulating insulin ( $p < 0.05$ ) when compared to AL control. CR *Ins1*<sup>+/+</sup>:*Ins2*<sup>-/-</sup> mice exhibited the expected reduction in circulating insulin compared to AL control ( $0.21 \pm 0.08$  versus  $0.31 \pm 0.07$  ng/ml;  $p = 0.0575$ ).

**Conclusion:** Our results suggest one *Ins1* allele is able to produce equal amounts of insulin as two alleles, although if a stressor is applied, such as ageing, this may be abrogated. CR appears able to prevent this loss and cause a rapid blood glucose recovery after exogenous insulin in a manner not observed in other studies.

### Across glucose tolerance spectrum, men display greater decreases in insulin secretion than women

S.S. Shankar<sup>1</sup>, R.H. Raymond<sup>2</sup>, D. Chen<sup>3</sup>, C. Cobelli<sup>4</sup>, C. Dalla Man<sup>4</sup>, D.S. Lee<sup>5</sup>, R.P. Robertson<sup>3</sup>, D. Stefanovski<sup>6</sup>, M.T. Vassileva<sup>7</sup>, D.A. Fryburg<sup>8</sup>, for the Beta Cell Team of FNIH Biomarkers Consortium;

<sup>1</sup>Eli Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, <sup>2</sup>RSquared Solutions, Skillman, <sup>3</sup>Pfizer Pharmatherapeutics R & D, Cambridge, USA, <sup>4</sup>University of Padova, Italy, <sup>5</sup>Pacific Northwest Diabetes Research Institute, Seattle, <sup>6</sup>Cedars-Sinai Medical Center, Los Angeles, <sup>7</sup>Foundation for the NIH Biomarkers Consortium, Bethesda, <sup>8</sup>ROI BioPharma Consulting, East Lyme, USA.

**Background and aims:** Little is known about gender differences in insulin secretion (IS). As part of a project examining the utility of beta cell function tests, we studied effect of gender on IS response to the arginine (ARG) stimulation test (AST) and the mixed meal tolerance test (MMTT) in overnight fasted, obese men (M) and women (W) with normal glucose tolerance (NGT), prediabetes (PDM) and type 2 diabetes (T2DM).

**Materials and methods:** For AST, acute IS (AIRarg) was measured over 5 min at baseline glucose after an i.v. ARG bolus (5 gm over 30 sec). Immediately following these samples, a 60 min infusion (900 mg/min) of glucose was initiated; ARG was administered again after 50 min of the glucose infusion; IS samples were then repeated (AIRmax). All arg results are baseline-adjusted. For MMTT, IS (Φtot and DItot) were measured in response to a standardized 450 kCal meal and estimated using minimal model.

**Results:** The table below summarizes the results. Within each gender significant declines in insulin secretion were detected for all 4 parameters (NGT and PDM were largely similar v. T2DM). To compare the changes in insulin secretion of women to men across the glucose tolerance groups, an ANCOVA model was developed. Of covariates tested (BMI and age), only age was included in the model as a significant covariate. ANCOVA showed that from NGT to T2DM, as seen in both the AST and MMTT, the decline in insulin secretion is greater in men than in women.

**Conclusion:** We conclude that 1) in a cross-sectional analysis of men and women with NGT, PDM, and T2DM, insulin secretion declines in both genders; 2) From NGT to T2DM, men show a greater decline than women in 2 different tests of insulin secretion. These results may have implications for gender balance in study designs measuring insulin secretion.

### Circulating non-esterified fatty acids (NEFA) do not associate with beta cell dysfunction: evidence from the RISC study

E. Rebelos<sup>1</sup>, A. Natali<sup>1</sup>, A. Mari<sup>1</sup>, B. Balkau<sup>2</sup>, A. Golay<sup>3</sup>, P. Piatti<sup>4</sup>, N. Lalic<sup>5</sup>, M. Laakso<sup>6</sup>, E. Ferrannini<sup>1</sup>;

<sup>1</sup>Department of Clinical and Experimental Medicine, University of Pisa, Italy, <sup>2</sup>INSERM U 258, Villejuif, France, <sup>3</sup>Department of Clinical and Experimental Medicine, University Hospitals of Geneva and University of Geneva, Switzerland, <sup>4</sup>Internal Medicine Department, Cardio-Diabetes Trials Unit, Scientific Institute San Raffaele, Milan, Italy, <sup>5</sup>Faculty of Medicine, Clinic for Endocrinology, Diabetes and Metabolic Disease, University of Belgrade, Serbia, <sup>6</sup>Department of Medicine, University of Eastern Finland, Kuopio University Hospital, Finland.

**Background and aims:** It is commonly held that chronically elevated NEFA levels adversely affects insulin secretion and insulin action (lipotoxicity). Although the association between NEFA and insulin resistance is well established, the effect of raised NEFA on β-cell function has only been explored in small experimental protocols using acute elevations in NEFA. Our aim was to analyse the relationship between endogenous NEFA levels and insulin secretion and β-cell function both cross-sectionally and longitudinally.

**Materials and methods:** In 701 women and 566 men from the Relationship Between Insulin Sensitivity and Cardiovascular Disease (RISC) cohort (mean age 44 years, BMI range 17-44 kg/m<sup>2</sup>, 14% with impaired fasting glycaemia (IFG) and 9% with impaired glucose tolerance (IGT)) followed up for 3 years, we measured insulin sensitivity (by a euglycaemic insulin clamp) and β-cell function (by modelling of the C-peptide response to oral glucose and as the acute insulin response (AIR) to intravenous glucose).

**Results:** At baseline, both fasting and insulin-suppressed NEFA were significantly (p<0.0001) higher across glucose tolerance groups, while insulin sensitivity was lower (p<0.0001), insulin output was higher (p<0.0001) and β-cell glucose sensitivity and AIR were lower (both p<0.0001). By multiple logistic analyses adjusting for center, sex, age, BMI, WHR, and glucose tolerance, both fasting and insulin-suppressed NEFA were inversely related to insulin sensitivity (both p<0.0001). Furthermore, after also adjusting for insulin sensitivity, insulin-suppressed NEFA were positively associated with total insulin output (p=0.0042). In contrast, in the same multivariate models neither fasting nor insulin-suppressed NEFA were related to β-cell glucose sensitivity or AIR. This result was confirmed when also accounting for insulin sensitivity or family history of diabetes. At follow up, glucose tolerance status worsened in 127 subjects. By multiple logistic regression, this change was predicted by male gender, higher age and higher waist-to-hip ratio, worse baseline glucose tolerance, lower insulin sensitivity and β-cell glucose sensitivity (area under ROC curve = 0.79). In this model, neither baseline fasting nor baseline insulin-suppressed NEFA were significant predictors of progression.

**Conclusion:** In the non-diabetic and prediabetic state, circulating endogenous NEFA are independently associated with impaired insulin sensitivity and enhanced insulin release but not with measures of β-cell function, and do not predict deterioration of glucose tolerance. Thus, in the RISC cohort there is no evidence for β-cell lipotoxicity of endogenous total NEFA concentrations.

### Increment of serum C-peptide by glucagon test closely correlates with human beta cell mass

Y. Fujita<sup>1</sup>, J. Kozawa<sup>1</sup>, H. Iwahashi<sup>1</sup>, S. Yoneda<sup>1</sup>, S. Uno<sup>1</sup>, A. Yoshikawa<sup>1</sup>, H. Eguchi<sup>2</sup>, H. Nagano<sup>2</sup>, A. Imagawa<sup>1</sup>, I. Shimomura<sup>1</sup>;

<sup>1</sup>Department of Metabolic Medicine,

<sup>2</sup>Department of Gastroenterological Surgery, Osaka University, Suita, Japan.

**Background and aims:** Evaluation of beta-cell mass is important in clinical practice of diabetes. Our objective was to evaluate the relationships between human beta-cell mass and various clinical parameters, including insulin secretory capacities.

**Materials and methods:** We conducted a study of pancreatic tissues obtained from 32 (19 males and 13 females) patients undergoing a pancreatotomy between 2008 and 2012 in the Department of Gastroenterological Surgery of our hospital, and who had not been treated with oral hypoglycaemic agents or insulin. They were classified into normal glucose tolerance (NGT, n=13), impaired glucose tolerance (IGT, n=9), and diabetes mellitus (DM, n=10). Their insulin secretory capacity was evaluated by homeostasis model assessment

of beta-cell function [HOMA-beta, fasting immunoreactive insulin ( $\mu\text{IU/ml}$ )  $\times 20$  / (fasting plasma glucose (mmol/l) - 3.5)], C-peptide index [fasting C-peptide (nmol/l) / fasting plasma glucose (mmol/l)], insulinogenic index [ $\Delta$  serum insulin 0-30 min (pmol/l) /  $\Delta$  plasma glucose 0-30 min (mmol/l) in 75 g-OGTT] and  $\Delta$ C-peptide by glucagon test [ $\Delta$ C-peptide, increment of serum C-peptide (nmol/l) at 6 min after intravenous injection of 1-mg glucagon]. Pancreatic samples were fixed in formaldehyde, embedded in paraffin for subsequent analysis and cut from these paraffin blocks into 5- $\mu\text{m}$  thick sections. We used immunohistochemistry to determine pancreatic beta-cell area. The relative beta-cell area represented the proportion of insulin-positive cell area to whole pancreatic section (%).

**Results:** The mean of relative beta-cell area was  $1.072 \pm 0.424$ ,  $0.998 \pm 0.419$  and  $0.762 \pm 0.441\%$ , in NGT, IGT and DM, respectively.  $\Delta$ C-peptide ( $r=0.64$ ,  $p=0.002$ ), HOMA-beta ( $r=0.50$ ,  $p=0.003$ ) and C-peptide index ( $r=0.36$ ,  $p=0.042$ ) correlated significantly and positively with the relative beta-cell area. Insulinogenic index tended to correlate positively but not significantly with the relative beta-cell area ( $r=0.33$ ,  $p=0.078$ ). Among them,  $\Delta$ C-peptide showed the closest association with the relative beta-cell area. Age tended to correlate negatively but not significantly with the relative beta-cell area ( $r=-0.33$ ,  $p=0.066$ ). Neither BMI nor HbA1c showed a significant correlation with the relative beta-cell area ( $r=0.26$ ,  $p=0.147$ ;  $r=-0.16$ ,  $p=0.378$ , respectively). Glucose levels at 0, 30, 60, 120 min in 75 g-oral glucose tolerance test (OGTT) tended to correlate negatively with the relative beta-cell area ( $r=-0.26$ ,  $p=0.145$ ,  $r=-0.30$ ,  $p=0.105$ ,  $r=-0.31$ ,  $p=0.087$ ,  $r=-0.34$ ,  $p=0.064$ , respectively), while the area under the curve of plasma glucose level from 0 to 120 min in 75 g-OGTT correlated significantly and negatively with the relative beta-cell area ( $r=-0.36$ ,  $p=0.045$ ).

**Conclusion:**  $\Delta$ C-peptide by glucagon test, HOMA-beta, and CPI correlated closely with beta-cell area, and  $\Delta$ C-peptide was the most valuable index for the prediction of beta-cell mass.

## 503

### Normal meal tolerance test is more valuable than glucagon stimulation test in type 2 diabetes

Y. Fujioka, T. Ohkura, K. Shoji, K. Sumi, H. Shiochi, N. Yamamoto, K. Matsuzawa, A. Murawaki, S. Izawa, H. Ohkura, M. Kato, S. Taniguchi, K. Yamamoto;  
Tottori University Faculty of Medicine, Yonago, Japan.

**Background and aims:** The glucagon stimulation test (GST) is a standard method of evaluating endogenous insulin secretion. However, the GST has adverse effects and takes effort. In contrast, the meal tolerance test (MTT) has no adverse effect and cheaper than GST. Moreover, to perform the MTT by normal meal is important to evaluate insulin secretion in real life. However, the MTT is affected by the glucotoxicity than GST in the hyperglycemic state. The aim of this study is to evaluate the properties of the glucagon stimulation test and normal meal tolerance test in type 2 diabetes patients.

**Materials and methods:** We enrolled 142 patients of type 2 diabetes (mean: age 61.0, M/F: 80/62, BMI 24.7, HbA1c 9.4) and performed the GST and the MTT. We performed the MTT by using a normal diabetes food of 30kcal/ day per ideal body weight, which contains 60% of carbohydrates, protein 20%, lipid 20%. In the MTT, patients continued oral hypoglycemic agents and insulin treatment as usual. In the MTT, we measured plasma glucose (PG) and serum C-peptide immunoreactivity (CPR), and plasma insulin level before and 120minutes after meal load. We calculated increment of CPR ( $\Delta$ CPR) by subtracting fasting CPR (FCPR) from 6 minutes after glucagon injection and 120 minutes after meal load.

**Results:** The mean fasting PG (FPG) was 154 mg/dl, the mean FCPR was 2.2 ng/ml, the mean  $\Delta$ CPR was 2.0 ng/ml, and the mean  $\Delta$ MTT $\Delta$ CPR was 3.1 ng/ml. 104 patients represent higher  $\Delta$ CPR in the MTT than the GST, and the mean  $\Delta$ MTT $\Delta$ CPR was significantly higher than the mean  $\Delta$ GST $\Delta$ CPR ( $P<0.01$ ). To exclude influence of antidiabetic drugs, we examined 42 subjects that did not use antidiabetic agents. The mean  $\Delta$ GST $\Delta$ CPR was 2.4 ng/ml, and the mean  $\Delta$ MTT $\Delta$ CPR was 4.3 ng/ml and the mean  $\Delta$ MTT $\Delta$ CPR was significantly higher than the mean  $\Delta$ GST $\Delta$ CPR ( $P<0.01$ ). To consider influence of glucotoxicity to both test, we performed ROC analysis by FPG. The optimal cut point of the FPG was under 147 mg/dl to define the MTT superior to the GST (sensitivity 0.64, specificity 0.76, AUC 0.73).

**Conclusion:** The MTT could examine insulin secretion including incretin effect by the meal load, and it may be one of the reasons why the  $\Delta$ MTT $\Delta$ CPR is higher than the  $\Delta$ GST $\Delta$ CPR. Therefore, the MTT could evaluate the endogenous insulin secretion ability more than the GST. However, the MTT is affected by the glucotoxicity than the GST. We had better consider to perform

the GST in the hyperglycemic state, especially FPG is 147mg/dl or more. We need to use the GST and the MTT properly by a level of the FPG. In conclusion, the MTT is more valuable as an insulin secretion test in type 2 diabetes patients than the GST.

## 504

### Adaptation of beta cell response to carbohydrate loading: influence of insulin resistance

R. Bizzotto<sup>1</sup>, B.E. Hurwitz<sup>2,3</sup>, N. Schneiderman<sup>2,3</sup>, J.B. Marks<sup>4</sup>, A.J. Mendez<sup>2,4</sup>, A. Gonzalez<sup>2</sup>, N. Gonzalez<sup>2</sup>, M.M. Llabre<sup>2,3</sup>, E. Santini<sup>5</sup>, J.S. Skyler<sup>4</sup>, A. Mari<sup>1</sup>, E. Ferrannini<sup>5</sup>;

<sup>1</sup>Institute of Biomedical Engineering, CNR, Padova, Italy, <sup>2</sup>Behavioral Medicine Research Center, University of Miami, Miami, <sup>3</sup>Department of Psychology, University of Miami, Coral Gables, <sup>4</sup>Division of Endocrinology, Diabetes and Metabolism, Miller School of Medicine, University of Miami, Miami, USA, <sup>5</sup>Department of Clinical & Experimental Medicine, University of Pisa, Italy.

**Background and aims:** To maintain euglycemia, the  $\beta$ -cell must cope with variable carbohydrate intake (ChI) and with insulin resistance. Aim of this study was to quantify how insulin secretion adapts to variable ChI in insulin sensitive (IS) and insulin resistant (IR) individuals.

**Materials and methods:** 143 nondiabetic subjects, aged 18-55 years were classified as IS (n=64) or IR (n=79) using the euglycemic clamp. On sequential days, subjects were given a meal every 3½ hours over a 14-hour period (4 meals/day), with standard (300 kcal) or double (600 kcal) ChI in random order. Serial measurements of glucose, insulin and C peptide were obtained. Model-based total insulin secretion,  $\beta$ -cell glucose sensitivity (slope of the glucose concentration-insulin secretion relationship), and potentiation (fold enhancement of glucose sensitivity from baseline) were calculated.

**Results:** Total insulin secretion increased from 300-kcal to 600-kcal ChI in both groups, and was higher in IR compared to IS (Table).  $\beta$ -cell glucose sensitivity followed a similar pattern. Potentiation was also increased with the ChI load, but in IR the increase was blunted. In IR, mean glucose levels and their increase from 300-kcal to 600-kcal ChI were higher than in IS. In multivariate regression, mean glucose was significantly positively related to ChI and negatively to insulin sensitivity,  $\beta$ -cell glucose sensitivity and potentiation ( $r^2 = 0.37$ ,  $p<0.0001$ ). In IR, the percentage of plasma glucose values  $\geq 11.1$  mmol/L rose from 2.3% to 6% on doubling ChI, whereas it declined from 0.6% to 0.2% in the IS group.

**Conclusion:** Higher carbohydrate meal content elicited an insulin secretion response that was higher both in absolute terms and in relation to the glucose levels; this response was enhanced in IR. However, the enhancement of potentiation from 300-kcal to 600-kcal ChI was impaired in IR subjects, in whom the up-regulation of  $\beta$ -cell glucose sensitivity compensation was insufficient to preserve glucose tolerance to the same extent as in IS subjects. Therefore, even in nondiabetic subjects insulin resistance is associated with a relative incompetence of  $\beta$ -cell function despite insulin hypersecretion.

| Parameter  | IS              |                 | IR              |                 |
|--|-----------------|-----------------|-----------------|-----------------|
|  | 300 kcal        | 600 kcal        | 300 kcal        | 600 kcal        |
| Total insulin secretion (nmol m <sup>-2</sup> )                                | 206 [75]        | 283 [90]        | 312 [113]       | 448 [165]       |
| Glucose sensitivity (pmol min <sup>-1</sup> m <sup>-2</sup> mM <sup>-1</sup> ) | 90 [44]         | 113 [55]        | 108 [50]        | 122 [67]        |
| Potentiation (fold)  | 1.47 [0.71]     | 2.23 [1.05]     | 1.42 [0.54]     | 1.79 [1.08]     |
| glucose AUC (mol.h)  | 0.66 $\pm$ 0.07 | 0.69 $\pm$ 0.12 | 1.02 $\pm$ 0.06 | 1.59 $\pm$ 0.10 |

Data are mean $\pm$ SE or median [interquartile range]. IS vs IR and 300 vs 600 kcal intake differences are significant by two-way ANOVA.

**Decrease in plasma mannose level after glucose load is associated with glucose tolerance: plasma mannose level as a putative indicator of glycogenolysis**S. Hirano<sup>1</sup>, K. Yoshimura<sup>1</sup>, H. Takata<sup>1</sup>, S. Ohmi<sup>1</sup>, T. Taguchi<sup>2</sup>, S. Yamada<sup>2</sup>, I. Miwa<sup>2</sup>, Y. Terada<sup>1</sup>, S. Fujimoto<sup>1</sup>;<sup>1</sup>Department of Endocrinology, Metabolism and Nephrology, Kochi University, Nankoku,<sup>2</sup>Department of Pathobiochemistry, Meijo University, Nagoya, Japan.

**Background and aims:** Mannose is a monosaccharide constituent of glycoproteins and glycolipids. Experiments in rats showed previously that the plasma mannose level decreases after glucose load which causes insulin secretion in normal rats, but does not decrease in diabetic rats and that hepatic glycogenolysis is a source of this plasma mannose, but these results are not fully elucidated in human. Subjects with glucose intolerance have impaired secretion and sensitivity of insulin, which are the most important factors in suppression of glycogenolysis. To explore the possibility of the plasma mannose level as an indicator of glycogenolysis in human, the decrease in plasma mannose levels after glucose load in subjects with various degrees of glucose intolerance was examined and was analyzed to clarify association with clinical factors.

**Materials and methods:** 75g OGTT was performed on Japanese subjects without diabetic medication from whom informed consent was obtained. Based on OGTT data, subjects were classified as normal (NGT), impaired glucose tolerance (IGT), and diabetes (DM) according to WHO criteria. In each group, 25 subjects were consecutively recruited [total 75 subjects, age: 65±11 (mean±SD); male/female: 34/41; BMI: 24.9±3.8 (mean±SD)]. Insulinogenic index (IGI) as an index of insulin secretion and QUICKI and Matsuda index as indices of insulin sensitivity were calculated. Mannose was assayed using established method. Briefly, after labeling with 4-aminobenzoyl ethyl ester, the concentration of mannose was determined using HPLC. Glucose contained in samples was confirmed not to affect the assay. The study protocol was approved by the ethics committee of the institute.

**Results:** Plasma mean levels of glucose during 120 min (Gm) were significantly different among groups [NGT: 138±20, n=25; IGT: 178±27, n=25; DM: 226±24 mg/dl, n=25, (means±SD)], while mean IRI during 120 min (Im) did not significantly differ. Basal levels of mannose were similar among groups (NGT: 40.8±10.0; IGT: 43.7±11.2; DM: 45.0±12.0 μM). After glucose load, the plasma mannose level was decreased gradually and reached plateau at 90 min in NGT, but was not decreased significantly in DM. Plasma changes of mannose during 120 min from base line ( $M_{120}-M_0$ ) were significantly different among groups (NGT: -16.7±8.2; IGT: -9.0±9.8; DM: -1.4±9.3 μM,  $P<0.001$  ANOVA). Simple regression analysis revealed that  $M_{120}-M_0$  was not significantly associated with Im, but was significantly associated with IGI ( $R=-0.282$ ,  $P=0.014$ ), QUICKI ( $R=-0.237$ ,  $P=0.041$ ), Matsuda index ( $R=0.254$ ,  $P=0.027$ ), and Gm ( $R=0.544$ ,  $P<0.001$ ).

**Conclusion:** The plasma mannose level was decreased after glucose load in normal glucose tolerance, but was not decreased in diabetes. The decrease in plasma mannose level after glucose load was associated with glucose tolerance, represented by the mean glucose level after glucose load. Moreover, it was associated with indices of insulin secretion and insulin sensitivity. These results support the possibility of the plasma mannose level as an indicator of glycogenolysis in human.

## 506

**Analysis of pancreatic response after oral glucose tolerance test in adults with cystic fibrosis**I. Sánchez-López<sup>1</sup>, M.A. Sampedro-Núñez<sup>1</sup>, S. Campos<sup>1</sup>, A. Vicuña<sup>1</sup>, M. Zelada<sup>1</sup>, M.Á. Maíllo<sup>1</sup>, A. Mossé<sup>1</sup>, A.M. Ramos-Leví<sup>1</sup>, R.M. Girón<sup>2</sup>, M. Marazuela<sup>1</sup>, A. Arranz<sup>1</sup>;<sup>1</sup>Endocrinology,<sup>2</sup>Pulmonary Medicine, Hospital Universitario de La Princesa, Madrid, Spain.

**Background and aims:** Abnormalities in carbohydrate metabolism are particularly relevant in adults with cystic fibrosis (CF) because of their high prevalence (about 75 percent), and impact on morbidity and mortality in these patients. Oral glucose tolerance test (OGTT) provides important information about pancreatic secretion in these subjects. The aim of this study is to analyze baseline and pancreatic response along OGTT in adults with CF.

**Materials and methods:** Retrospective study based on the performance of OGTT in 37 adult patients with CF followed in our hospital. Glucose, C-

Peptide and insulin were measured at fasting and at 30, 60, 90 and 120 minutes after a 75 grams glucose load. According to the results, patients were classified into: normal glucose tolerance (NGT), impaired glucose tolerance (IGT), indeterminate glycemia (INDET) and cystic fibrosis-related diabetes (CFRD). The following insulin secretion indexes were determined: HOMA-β, insulinogenic index (II) and first phase-OGTT (FIOGTT). Areas under the curve (AUC) were calculated for each group, and variance for the different variables was analyzed. Statistical analysis was performed using SPSS for Windows, version 15.0.

**Results:** 37 patients. OGTT **Results:** 35.1% NGT; 32.4% IGT; 13.5% INDET; 18.9% CFRD. Significant differences ( $p<0.05$ ) between groups were obtained at all times of the glucose curve except at fasting, and at 120 minutes for the ratio glucose/insulin. A greater glucose AUC in CFRD patients and a greater overall insulin and C-Peptide secretion in NGT and INDET groups were observed. In early stages of the OGTT, lower values of insulin and HOMA-β, II and FIOGTT indexes were observed in INDET group ( $p<0.05$ ). However, from time 60 min onwards, an increased insulin response in INDET group was observed compared to the rest.

**Conclusion:** OGTT shows a progressive deterioration of insulin secretion in prediabetic states. INDET and IGT subjects have a failure of the early response and a delayed pancreatic secretion as a preliminary step to the development of CFRD.

## 507

**Relationship of whole-body fuel oxidative partitioning with insulin secretion and beta cell function in non-diabetic humans**J.E. Galgani<sup>1</sup>, M.L. Mizgier<sup>1</sup>, A. Mari<sup>2</sup>, E. Ravussin<sup>3</sup>;<sup>1</sup>Pontificia Universidad Católica de Chile, Santiago, Chile,<sup>2</sup>Istituto di Ingegneria Biomedica, Padova, Italy,<sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, USA.

**Background and aims:** It is commonly reported that whole-body insulin sensitivity is inversely related with glucose-stimulated insulin secretion. This finding suggests a putative crosstalk between peripheral organs and pancreas. Such organ crosstalk could be mediated by changes in glucose flux (i.e. uptake, oxidation or storage) in insulin-sensitive tissues, which may lead to the release of a circulating factor driving insulin secretion. To gain insight on such a metabolic feedback loop, we related fasting, postprandial and 24-hour whole-body non-protein respiratory quotient (npRQ), an index of fuel oxidative partitioning (i.e. carbohydrate relative to fat oxidation), with insulin secretion and beta cell function in non-diabetic individuals.

**Materials and methods:** Thirty non-diabetic participants (15/15 males/females; 35±12 [SD] years old; 27±4 kg/m<sup>2</sup>) were studied over three days. On day 1, npRQ was determined under fasting and postprandial (75-gram oral glucose tolerance test, OGTT) conditions. On day 2, participants spent 24 hours in a respiratory chamber while fed with a standard, isoenergetic mixed diet. On day 3, insulin sensitivity was assessed by a 2-hour euglycemic-hyperinsulinemic clamp. Insulin secretion was estimated by deconvolution of serum C-peptide concentration (fasting and postprandial) or 24-hour urinary C-peptide excretion (corrected for energy intake). In addition, beta cell function parameters including rate sensitivity (indicative of first-phase glucose-induced insulin response) and glucose sensitivity (slope of the glucose concentration vs. insulin secretion relationship) were calculated by mathematical modelling.

**Results:** Insulin secretion estimated over 24 hours from urinary C-peptide excretion was directly related with fasting ( $r=0.64$ ;  $p<0.001$ ) and glucose-stimulated ( $r=0.66$ ;  $p<0.001$ ) insulin secretion. The classical inverse association between insulin sensitivity (by clamp) and insulin secretion was also confirmed over 24 hours ( $r=-0.62$ ;  $p<0.01$ ), in response to an OGTT ( $r=-0.50$ ;  $p<0.01$ ) and overnight fasting ( $r=-0.40$ ;  $p<0.05$ ). Interestingly, insulin secretion (from urinary C-peptide excretion) was inversely correlated with 24-hour npRQ ( $r=-0.61$ ;  $p=0.001$ ), even after controlling for insulin sensitivity and energy balance ( $r=-0.52$ ;  $p=0.01$ ). However, fasting or glucose-stimulated npRQ did not correlate with insulin secretion rate (from serum C-peptide). Fasting npRQ correlated directly with rate sensitivity ( $r=0.40$ ;  $p<0.05$ ), while the association with glucose sensitivity was borderline ( $r=0.34$ ;  $p=0.08$ ).

**Conclusion:** Fuel oxidative partitioning determined over a day appears to influence 24-hour insulin secretion, although such association did not hold when a shorter period was considered. In addition, the first-phase glucose-induced insulin response (i.e. rate sensitivity) may be sensitive to the level of fasting fuel oxidative partitioning. These findings lend support to the hypothesis that a crosstalk between peripheral tissues and pancreas plays a role on insulin secretion. Intervention studies targeting peripheral (e.g. skeletal

muscle) carbohydrate oxidation and its effect on insulin secretion deserve further research.

## 508

### Role of parasympathetic activity in insulin secretion in metabolically healthy obese patients

C. Cussac-Pillegand, S. Chiheb, Y. Jaber, C. Cyrille, R. Duteil, E. Cosson, P. Valensi;

AP-HP, Jean Verdier Hospital, Bondy, France.

**Background and aims:** Cardiac parasympathetic activity is often altered in obese non-diabetic patients, even in the metabolic healthy obese individuals. We here hypothesized that the persistence of a good parasympathetic activity could contribute to a better insulin secretion in the presence of insulin resistance.

**Materials and methods:** We recruited 47 obese patients (BMI  $42.3 \pm 6.5$  kg/m<sup>2</sup>,  $35.5 \pm 12.7$  years). Among them 31 with only one criterion of the metabolic syndrome (fasting hyperglycemia in only one patient) in addition to a large waist circumference was considered as metabolically healthy. Cardiac parasympathetic activity (HF-HR) and vascular sympathetic activity (LF-SBP) were evaluated by spectral analysis of heart rate (HR) and systolic blood pressure (SBP) variations (Finapres<sup>®</sup>), respectively. An oral glucose tolerance test was performed. Two indexes of insulin resistance (Matsuda and HOMA-IR), and composite indexes of insulin secretion (insulinogenic index = IGI =  $\Delta$ insulinemia(T0-T30)/ $\Delta$ glycemia(T0-T30); and oral disposition index = ODI = IGI/insulinemia) were calculated.

**Results:** Patients with a lower parasympathetic activity (HF-HR < median value: 2.61) had a lower Matsuda index ( $p=0.012$ ), and ODI ( $p<0.03$ ), higher plasma glucose levels at 90 and 120 min after glucose challenge ( $p$  median value) while age and BMI were similar. In metabolically healthy patients, but not in patients with more metabolic criteria, the same results were found, noticeably with plasma glucose during OGTT (at 60, 90, 120, 150, 180 min;  $p=0.007$  to 0.058) and LF-SBP ( $p=0.006$ ) higher in those with HF-HR < median, and a significant correlation of ODI with HF-HR ( $r=0.464$ ,  $p=0.008$ ).

**Conclusion:** These results strongly suggest that vagal activity contributes to enhance insulin secretion in insulin resistant obese individuals. In metabolically healthy obese patients, low vagal activity together with a predominant sympathetic activity is associated with a more marked insulin resistance and reduced compensatory insulin secretion, leading to glucose disorders.

## 509

### Impact of serum triglyceride and HDL-cholesterol levels on early-phase insulin secretion in prediabetic subjects

M. Shimodaira, T. Niwa, K. Nakajima, M. Kobayashi, N. Hanyu; Department of Internal Medicine, Iida Municipal Hospital, Japan.

**Background and aims:**  $\beta$  cell dysfunction plays a fundamental role in the onset and progression of type 2 diabetes (T2DM), and the loss of early-phase insulin secretion is thought to be an early marker of T2DM. Recent studies have shown that increased triglycerides (TG) and decreased HDL-cholesterol (HDL-C) levels are risks for the onset of T2DM. However, in subjects with prediabetes (impaired fasting glucose, impaired glucose tolerance and the two combined), the association between lipid profiles and insulin secretion has not been well studied. The aim of this study was to investigate the relationship between serum TG and HDL-C levels and early-phase insulin secretion following a 75-g oral glucose tolerance test (OGTT) in prediabetic subjects.

**Materials and methods:** We evaluated 663 prediabetic subjects (322 males and 341 females; age,  $52 \pm 8$  years; BMI,  $23.8 \pm 3.1$ ) who were not taking lipid-lowering agents. Prediabetes was defined as fasting plasma glucose of 5.6–6.9 mmol/L or 2h post-challenge plasma glucose of 7.8–11.0 mmol/L. Insulin secretion was estimated by the insulinogenic index (IGI) [ $\Delta$ insulin/ $\Delta$ glucose (30 min–0 min)] and disposition index (DI; IGI/HOMA-IR), which is an adjusted measure of  $\beta$  cell function that accounts for variations in insulin sensitivity. The relationship between continuous variables was examined by Pearson's linear regression analysis. A stepwise multiple linear regression analyses was performed to assess independent relationships between DI and the clinical variables including age, sex, BMI, blood pressure, uric acid, total cholesterol (TC), TG, HDL, LDL-cholesterol (LDL-C), HbA1c, eGFR and

smoking status. Because of collinearity between TG and HDL-C, two regression models were performed, which took into account each of these variables. **Results:** Pearson's linear regression analysis revealed that IGI and DI were positively correlated with HDL-C levels ( $r = 0.264$ ,  $P = 0.004$  and  $r = 0.278$ ,  $P = 0.002$ , respectively). Moreover, the indices were negatively correlated with the log-transformed TG ( $r = -0.190$ ,  $P = 0.006$  and  $r = -0.133$ ,  $P = 0.004$ , respectively). However, TC and LDL-C were not associated with indices of insulin secretion. Multivariate linear regression analyses revealed that DI was independently and positively correlated with HDL-C ( $\beta = 0.149$ ,  $P = 0.004$ ) and negatively with log-transformed TG ( $\beta = -0.249$ ,  $P = 0.004$ ).

**Conclusion:** Our results provide evidence that, in prediabetic subjects, lower HDL-C and higher TG levels are associated with dysfunctional early-phase insulin secretion. Thus, more attention should be placed on serum HDL-C and TG levels in prediabetic subjects because of their potential progression to T2DM.

## PS 028 Insulin secretion in diabetes

510

### Most people with long duration of type 1 diabetes are insulin microsecretors and produce their own endogenous insulin

T.J. McDonald<sup>1</sup>, R. Oram<sup>1</sup>, B. Shields<sup>1</sup>, E. Pearson<sup>2</sup>, A. Hattersley<sup>1</sup>;

<sup>1</sup>University of Exeter Medical School,

<sup>2</sup>University of Dundee, Medical Research Institute, UK.

**Background and aims:** Ultrasensitive assays that can detect C-peptide under 5 pmol/L allow detection of very low levels of c-peptide. We aimed to use urine c-peptide creatinine ratio (UCPCR) to assess endogenous insulin in a large cross-sectional population-based study of patients with Type 1 diabetes (T1D).

**Materials and methods:** We recruited 944 patients from primary and secondary care in 2 UK centres. All diagnosed under 30 years, duration >5 years, clinical diagnosis of T1D. Median (IQR) age of diagnosis 11 (6–17)y, duration 18 (11–26)y, HbA1c 8.7 (7.9–9.8)%, insulin dose 0.78 (0.60–0.97) u/kg/24hr, and BMI 25.6 (23.3–28.6) Kg/m<sup>2</sup>. All provided a home post-meal UCPCR.

**Results:** 81% (790/944) had detectable endogenous production (median (IQR) UCPCR 0.012 (0.004–0.038) nmol/mmol). Most had very low, historically undetectable, levels (492/944, 53%, UCPCR >0.001–0.03 nmol/mmol). 8% had C-peptide levels above the DCCT cut off of significant endogenous insulin. Absolute UCPCR levels fell with duration but the proportion with detectable UCPCR never fell below 73% (maximum duration 47 years). Age of diagnosis and duration independent predictors of C-peptide in multivariate modelling.

**Conclusion:** The majority of patients with long duration T1D are insulin microsecretors and have detectable urine c-peptide. Some rare individuals with T1D maintain higher levels of endogenous insulin for many years after diagnosis of diabetes. The fact that some beta cells remain in most with long-standing T1D may reflect escape from immune attack, or beta cell regeneration. Understanding this may lead to a better understanding of pathogenesis in T1D and open new possibilities for treatment.

### Presence and titer of GAD antibodies are determinants of beta cell function in patients with newly diagnosed type 2 diabetes mellitus: further insights in the metabolic phenotype of LADA patients

M. Trombetta<sup>1</sup>, L. Boselli<sup>1</sup>, C. Brangani<sup>1</sup>, F. Zardi<sup>2</sup>, C. Negri<sup>3</sup>, V. Stoico<sup>3</sup>, E. Bonora<sup>1</sup>, R. Bonadonna<sup>4</sup>;

<sup>1</sup>Medicine, University of Verona, <sup>2</sup>Hospital of Bolzano, <sup>3</sup>AOUI of Verona,

<sup>4</sup>Medicine, University of Parma and AOUI of Parma, Italy.

**Background and aims:** Latent Autoimmune Diabetes in Adults (LADA) is a metabolic disorder at the crossroad between type 1 (T1DM) and type 2 diabetes (T2DM). Aim of our study was to carefully assess beta cell function and insulin sensitivity in patients with LADA, in comparison to patients with either type 2 diabetes clinically undistinguishable from LADA or typical type 2 diabetes.

**Materials and methods:** In 35 (M/F=19/16) patients (mean±SEM: age 57.4±1.6 years, BMI 27.5±0.9 kg/m<sup>2</sup>) with newly diagnosed LADA were compared to 35 patients with newly diagnosed T2DM matched for age, gender, BMI and HbA1c (LADA-like). The latter group was extracted from the database of the Verona Newly Diagnosed Type 2 diabetes (VNDS; N=589 GADA-negative patients) The rest of VNDS patients herein represent typical T2DM. LADA patients were further divided in two groups according to GADA levels (median 4 kU/L): low GAD-LADA (GADA below 4kU/L) and high GAD-LADA (GADA above 4kU/L). In all patients we performed on separate days: 1. prolonged (5-hours) frequently sampled OGTT to assess derivative control (DC) and proportional control (PC) of beta cell function by state of art mathematical modeling of glucose and C-peptide curves; 2. standard euglycemic insulin clamp to assess insulin sensitivity (SI).

**Results:** SI was not statistically different (p<0.12) in LADA-like and in LADA patients, but in the latter was higher (+28%) than in VNDS (812±66 vs 635±16 μmol.min<sup>-1</sup>.m<sup>-2</sup> BSA, respectively; p=0.01). The DC of beta cell function was impaired in LADA compared to LADA-like (p<0.01) and to VNDS (p<0.05). The PC in LADA was similar to LADA-like (p=0.42), but it was reduced when compared to VNDS (p<0.03). High GAD- and low GAD-LADA had similar SI, but the former had worse PC of beta cell function than the latter (p<0.01).

**Conclusion:** Patients with newly diagnosed LADA display more severe defects in beta cell function even when compared to LADA-like patients with newly diagnosed T2DM; furthermore, the higher the GADA titer, the worse is beta cell dysfunction. These data may be of help in optimizing metabolic therapy and in refining metabolic prognosis of these patients.

### Influence of the human herpes virus 8 infection on beta cell function and insulin sensitivity in ketosis prone diabetes

J.-L. Nguewa<sup>1</sup>, F. Agbalika<sup>2</sup>, B. Baz<sup>1</sup>, S. Chon<sup>1</sup>, P. Boudou<sup>3</sup>, J.-P. Riveline<sup>1</sup>, S.P. Choukem<sup>4</sup>, E. Sobngwi<sup>5</sup>, J.-F. Gautier<sup>1</sup>;

<sup>1</sup>University Center for Diabetes and its Complications, Endocrinology and Diabetology Department, Lariboisiere Hospital, <sup>2</sup>Department of Microbiology, <sup>3</sup>Department of Hormonology and Biochemistry, St. Louis Hospital, Paris, France, <sup>4</sup>Endocrinology and Diabetology Department, University of Buea, <sup>5</sup>Endocrinology and Diabetology Department, National Obesity Center, Yaounde, Cameroon.

**Background and aims:** Ketosis Prone diabetes (KPD), an atypical diabetes with ketosis at onset and absence of β-cell autoantibodies is characterized after the ketotic episode by long-term non-insulin dependence (remission) for a majority of patients. Human herpes virus 8 (HHV-8) infection has been associated with KPD in patients of sub-Saharan African origin. Our objective was to investigate whether HHV-8 infection impacts on insulin secretion and/or insulin sensitivity in KPD at different stages of the disease.

**Materials and methods:** We compared patients with (KPD+) and without (KPD-) HHV-8 infection in 3 different groups. In group 1, 11 KPD+ and 7 KPD- in remission (HbA1c level <7.0% at least 3 months apart after withdrawal of exogenous insulin treatment) underwent an OGTT, a glucose ramping + arginine test and a hyperinsulinemic euglycaemic clamp. Group 2 consisted of 17 KPD+ and 11 KPD- explored one week after ketosis resolution by C-peptide measurement in response to IV glucagon (delta C-peptide) and by the short insulin tolerance test (ITT). In group 3, we enrolled 40 KPD+ and 59 KPD- hospitalized for treatment adjustment because of elevated A1c. All KPD underwent delta C-peptide at 2 different occasions (V1 and V2). V1 was made 3.1±2.5 [mean±SD] years after the diagnosis of diabetes and V2 conducted 3.6±5.4 years after V1. Detection of HHV-8 antibodies was performed using 3 techniques, one for detection of antibodies against lytic antigens, a second against latent nuclear antigens and the last detecting the HHV-8 capsid protein.

**Results:** In each group, KPD- and KPD+ were comparable in terms of age, age at diabetes diagnosis, duration of diabetes, duration of remission (group 1), BMI and HbA1c (group 1, group 2). In group 1, the insulinogenic index and insulin secretion rates were higher in KPD+ compared to KPD-, whereas insulin secretion in response to arginine and insulin sensitivity were similar. In group 2, delta C-peptide was up to 3-fold higher in KPD+ compared to KPD- while the glucose disappearance rate K<sub>ITT</sub> were similar between the 2 groups. In group 3, A1c levels in KPD+ were lower than KPD- and delta C-peptide was higher in KPD+ compared to KPD- at V1 and V2.

**Conclusion:** In conclusion, either in remission, shortly after ketosis resolution or during long term follow-up, latent HHV-8 infection is associated with better insulin secretion in response to glucose in patients of sub-Saharan African origin with KPD. Mechanisms by which latent HHV-8 infection impact on  $\beta$ -cell functions need to be unraveled.

|                                   |   | KPD+               | KPD-                | *p      |

## 513

### Correlation between the indices for glycaemic variability and 24-hour urinary C-peptide values in patients with type 1 diabetes mellitus as assessed by CGM

C. Seo, R. Nishimura, Y. Onda, D. Tsujino, K. Andou, K. Ustunomiya; Division of Diabetes, Metabolism and Endocrinology Department, The Jikei University School of Medicine, Tokyo, Japan.

**Background and aims:** Loss of pancreatic cell function, abnormal secretion of the counter-regulatory hormones, inappropriate treatment, insulin resistance, malingering/manipulation, concomitant diseases such as infection and some other endocrine disease, and mental/somatic stress are reported to be among the factors that tend to make glycemic control difficult in patients with type 1 diabetes. First and foremost of these are, however, loss of pancreatic  $\beta$  cell function and abnormal secretion of the counter-regulatory hormones. Therefore, stable glycemic control becomes progressively lost with the loss of pancreatic  $\beta$  cell function. While, generally, it often proves extremely difficult to achieve glycemic control in type 1 diabetes, not all patients with type 1 diabetes exhibit unstable diabetes and a subset of patients exhibit stable glycemic control. In the latter patients, pancreatic  $\beta$  cell function is shown to be preserved to a certain extent, thus contributing to their stable glycemic control. However, to date, there are very few studies in which residual pancreatic  $\beta$  cell function was examined for correlation with glycemic variation evaluated by using Continuous Glucose Monitoring (CGM) that allows glucose levels to be measured on a continuous basis.

**Materials and methods:** Of all patients being treated with intensive insulin therapy (excluding Continuous Subcutaneous Insulin Infusion) and monitored by CGM, a total of 59 patients with type 1 diabetes (males/females, 20/39) with detectable urinary C-peptide immunoreactivity (U-CPR) from 24-hour samples were included in the study. Values measured for continuous 24 hours and free from measurement errors were used for current analysis. U-CPR values were used as an index for insulin-secretory capacity and the SD of 24-hour-glucose concentration was used as an index for stability of glycemic control. The subjects' U-CPR values were examined for correlation with their duration of disease, BMI, and HbA1c values, as well as the SD of their glucose concentration. Statistical analyses were performed by using SPSS 17.0. Spearman's rank sum correlation coefficients were used to test for correlation between the variables examined.

**Results:** All data are shown as median and interquartile range. The subjects' median U-CPR value was 1.4 (0.9-6.9)  $\mu$ g/day, their median age 39 (32-58) years, duration of disease 11 (6-22) years, BMI 21.2 (19.4-23.2) kg/m<sup>2</sup>, HbA1c value 8.0 (7.1-9.4)%, their total insulin dose 36 (28-48) units, and their basal

insulin ratio(basal insulin dose/total insulin dose) 44.4 (37.5-54.3)%. A significant negative correlation was noted between their U-CPR values and the SD of their glucose concentration ( $r = -0.305$ ;  $P = 0.019$ ), as well as between their U-CPR values and their duration of disease ( $r = -0.353$ ;  $P = 0.006$ ), and between their U-CPR values and their basal insulin ratio ( $r = -0.268$ ;  $P = 0.040$ ). However, there was no significant correlation between their U-CPR values and their age, BMI, HbA1c values or total insulin units.

**Conclusion:** Our study demonstrated that the lower the U-CPR values in patients with type 1 diabetes, the greater their glycemic variability and that the longer their duration of disease, the lower the U-CPR values, suggesting that U-CPR assessment may have a key role in predicting glycemic variations in patients with type 1 diabetes.

## 514

### Factors affecting glycaemic variability in patients with type 2 diabetes

S.-Y. Yoo<sup>1</sup>, S.-A. Lee<sup>1</sup>, H.-J. Chin<sup>2</sup>, D.-H. Lee<sup>3</sup>, G. Koh<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Jeju National University Hospital,

<sup>2</sup>Department of Internal Medicine, Hankook General Hospital, Jeju,

<sup>3</sup>Department of Internal Medicine, Wonkwang University Hospital, Jeollabuk-do, Republic of Korea.

**Background and aims:** It is not widely known about factors determining glucose fluctuations in diabetic patients. Also, the role of glycemic variability in the development of cardiovascular diseases remains controversial. We investigated the relationship between indices of glycemic variability, cardiovascular (CV) risk factors, and clinical and laboratory variables in type 2 diabetic patients.

**Materials and methods:** We enrolled 236 type 2 diabetic patients which performed a 7-point SMBG more than once during each month for 3 consecutive months. From their SMBG data, glycemic variability indices (standard deviation (SD) and M-value) were calculated monthly. HbA1c was measured on the last day of the third month. BMI, waist circumference (WC), blood pressures (BP), duration of diabetes, hsCRP, fibrinogen, ALT, GGT, creatinine, uric acid, total cholesterol, triglyceride (TG), HDL-C, LDL-C, urine albumin:creatinine ratio (UACR) and ankle-brachial pressure index (ABI) were assessed. Treatment stage of diabetes was defined based on the number of oral hypoglycemic agents and the administration of insulin. The 10-year risk for CVD was calculated using 2013 ACC/AHA Prevention Guidelines Atherosclerotic Cardiovascular Disease (ASCVD) Risk Estimator.

**Results:** The SD was significantly correlated with duration of diabetes ( $r=0.291$ ;  $p<0.001$ ) and UACR ( $r=0.144$ ;  $p=0.028$ ), but not with BMI, WC, BP, hsCRP, fibrinogen, ALT, GGT, creatinine, uric acid, lipid profile and ABI. The M-value was correlated with duration of diabetes ( $r=0.301$ ;  $p<0.001$ ), UACR ( $r=0.210$ ;  $p=0.001$ ), BMI ( $r=0.129$ ;  $p=0.049$ ), WC ( $r=0.163$ ;  $p=0.013$ ) and TG ( $r=0.181$ ;  $p=0.005$ ), but not with other parameters. Using hierarchical regression analysis to adjust for HbA1c and other covariates, only diabetes duration remained independent correlate of the SD ( $\beta=0.200$ ,  $p<0.01$ ) and M-value ( $\beta=0.154$ ;  $p<0.01$ ). CV risk factors failed to maintain its independent association. The patients were divided into three groups according to diabetes treatment stage and 10-year ASCVD risk, respectively. SD and M-value showed significant differences according to increasing treatment stage ( $pANOVA<0.001$ ;  $pTREND<0.001$  and  $pANOVA<0.001$ ;  $pTREND<0.001$ , respectively), but not increasing 10-year ASCVD risk ( $pANOVA=0.707$ ;  $pTREND=0.518$  and  $pANOVA=0.472$ ;  $pTREND=0.780$ , respectively).

**Conclusion:** In this study, duration of diabetes rather than CV risk factors was an independent variable of indices of glycemic variability. And the indices were positively correlated to treatment stage of diabetes more than 10-year ASCVD risk. These findings suggest that glycemic variability is largely determined by  $\beta$ -cell function which deteriorates with increasing duration of diabetes, but not cardiovascular complication.

Figure 1. Plots of glycemic variability indices according to stage of diabetic treatment (A) and 10 year atherosclerotic cardiovascular disease (ASCVD) risk (B).

**Loss of glucose sensitivity and islet neogenesis predict the occurrence of diabetes after acute beta cell reduction**

A.V. Sun<sup>1</sup>, T. Mezza<sup>1</sup>, G. Sorice<sup>1</sup>, C. Conte<sup>1</sup>, C. Cefalo<sup>1</sup>, R.N. Kulkarni<sup>2</sup>, A. Mari<sup>3</sup>, A. Giaccari<sup>1</sup>;  
<sup>1</sup>Catholic University, Rome, Italy, <sup>2</sup>Joslin Diabetes Center, Boston, USA, <sup>3</sup>CNR, Padova, Italy.

**Background and aims:** Progressive deterioration in  $\beta$  cell function and decrease in  $\beta$  cell mass represent the main mechanisms involved in type 2 diabetes. To investigate if the deterioration of the  $\beta$  cell function corresponds to a loss of  $\beta$  cell mass, we performed oral glucose tolerance tests (OGTT), hyperglycemic clamps (HC) and followed by arginine stimulation in 16 patients undergoing pancreatoduodenectomy (PD), pre- and post-surgery. To further explore whether Islet features could be justified by in vivo beta cell function, we explored neogenesis from duct cells, islet size and trans-differentiation of a cells to  $\beta$  cells.

**Materials and methods:** Based on post-surgery OGTT, subjects were divided into 3 groups of glucose tolerance: normal (NGT, n=5), impaired (IGT, n=4) or diabetes (DM, n=7) (8 F/8 M, 51±15 yrs.). To evaluate  $\beta$  cell function,  $\beta$  cell glucose sensitivity (GS) during HC was calculated as the ratio of insulin secretion and glucose increments. During surgery, pancreas samples were collected for IHC for glucagon, insulin and somatostatin+ cells to assess islet morphology. Ductal cells were stained by CK19.

**Results:** Before surgery, Arginine-stimulated Insulin Secretion (AIS) was similar across groups, whereas GS was lower in IGT and DM as compared with NGT subjects (62.9±23.1 and 45.5±11.2 vs 90.6±18.7 pmol•min<sup>-1</sup>•m<sup>-2</sup>, respectively). Following 50% PD, GS decreased in all patients (p<0.01 for all groups), but the reduction was greater in DM compared to IGT and NGT patients ( $\Delta$ GS: NGT -0.20±0.19 vs. IGT -0.27±0.11 vs. DM 0.37±0.08; p<0.003). A similarly scaled reduction was observed in  $\Delta$ AIS (NGT -0.38±0.13 vs. IGT -0.76±0.06 vs. DM -0.90±0.04; p<0.01) and in 2nd phase insulin secretion. IHC demonstrated an increase in islet size, insulin+ CK19+ cells (p<0.05) and scattered islets (<8 cells) (p=0.01) in DM patients, as compared with NGT and IGT.

**Conclusion:** In this study, loss of GS was the most reliable parameter for predicting the appearance of diabetes after 50% PD. Increased islet size and neogenesis could be compensatory mechanisms to cope with reduced function (GS) and to preserve  $\beta$  cell mass, at least as estimated by AIS. However, increased islet size does not seem to be able to compensate for the loss of glucose sensitivity.

**Serum bilirubin concentrations are positively associated with serum C-peptide levels in patients with type 2 diabetes**

J.-O. Chung, D.-H. Cho, D.-J. Chung, M.-Y. Chung;  
 Chonnam National University Medical School, Gwangju, Republic of Korea.

**Background and aims:** Bilirubin, the natural end product of heme metabolism, has been recognized as a potent endogenous antioxidant. Several clinical studies have demonstrated the inverse correlation between serum bilirubin levels and the risk of diabetes. However, the relationship between serum bilirubin levels and serum C-peptide levels in patients with type 2 diabetes has not been fully understood. The aim of the study was to investigate the relationship between physiological serum total bilirubin concentrations and serum C-peptide levels in Korean patients with type 2 diabetes.

**Materials and methods:** A total of 588 patients with type 2 diabetes (M: 337, F: 251, mean age 56.4 ± 13.6 years) were investigated in this cross-sectional study. All patients were allowed to eat a standardized meal. Fasting C-peptide level, 2-hour postprandial C-peptide level, and  $\Delta$ C-peptide (postprandial C-peptide minus fasting C-peptide) level were measured in all patients.

**Results:** Fasting C-peptide level, postprandial C-peptide level, and  $\Delta$ C-peptide level tended to be higher in patients with increased bilirubin concentrations. Partial correlation analysis showed that serum bilirubin levels were significantly correlated with fasting C-peptide level (r=0.159, P < 0.001), postprandial C-peptide level (r=0.209, P < 0.001), and  $\Delta$ C-peptide level (r=0.186, P < 0.001) after adjustment for other covariates. In the multivariate model, the association between serum bilirubin concentrations and serum C-peptide levels remained significant, after adjustment for confounding factors including age, gender, familial diabetes, hypertension, hyperlipidemia, body mass index, glycated hemoglobin, duration of diabetes, and associated liver function tests (fasting C-peptide level:  $\beta$ =0.083, P=0.041; postprandial C-peptide level:  $\beta$ =0.106, P=0.005;  $\Delta$ C-peptide level:  $\beta$ =0.096, P=0.015, respectively).

**Conclusion:** Serum bilirubin concentrations within the physiologic range were positively associated with serum C-peptide levels in patients with type 2 diabetes.

## 517

### Improved beta cell and disposition function leads to reduction in daily insulin dosage over time in patients with type 2 diabetes treated by long-term CSII therapy

S. Choi<sup>1</sup>, E. Hong<sup>1</sup>, K.-J. Kim<sup>1</sup>, H. An<sup>1</sup>, Y. Noh<sup>2</sup>;

<sup>1</sup>Endocrinology and Metabolism, <sup>2</sup>Biochemistry, School of Medicine, Konkuk University, Seoul, Republic of Korea.

**Background and aims:** We observed the daily insulin dosage required to maintain normoglycemia decreased over time during long-term continuous insulin infusion (CSII) therapy in patients with type 2 diabetes. To see if the decreased daily insulin dosage is related to changes in beta cell function and insulin resistance during CSII therapy, we examined changes in C-peptidogenic Index (CI), Matzda Index (MI), and disposition Index (DI; product of CI and MI) for 1 year.

**Materials and methods:** Two hundred seventeen patients with type 2 diabetes (age,  $59.1 \pm 11.1$  years; male, 113; female, 104; duration,  $12.6 \pm 10.2$  years; body mass index,  $23.7 \pm 3.7$  kg/m<sup>2</sup>; HbA1c  $8.9 \pm 2.1$  %) were treated by CSII. Blood samplings were performed at baseline and 6 months and 1 year after CSII therapy (after overnight fasting and 2 hours after ingestion of 500 kcal-mixed meal).

**Results:** After 1 year of CSII therapy, HbA1c decreased from  $8.9 \pm 2.1$  to  $7.3 \pm 1.7$  % ( $p < 0.001$ ), serum C-peptide level increased from  $4.8 \pm 2.8$  to  $6.0 \pm 2.9$  ng/ml ( $p < 0.001$ ), and CI increased from  $0.021 \pm 0.018$  to  $0.029 \pm 0.017$  ( $p < 0.001$ ) at 2 hours after meal ingestion. DI increased from  $0.060 \pm 0.059$  to  $0.069 \pm 0.045$  ( $p < 0.003$ ). Daily insulin dosage decreased from  $71.7 \pm 34.4$  to  $46.3 \pm 31.1$  IU/day ( $p < 0.001$ ). This decreased daily insulin dosage was associated with the increased value of CI, DI and MI significantly by multiple regression analysis ( $p < 0.05$ ).

**Conclusion:** The resolution of glucotoxicity through long-term CSII therapy may contribute to restoration of beta cell function and disposition capability in type 2 diabetic patients. It is suggested that the daily insulin requirement decreased due to improved beta cell function and disposition capability during long-term CSII therapy in type 2 diabetic patients.

Figure 1. Change of daily insulin dosage, C-peptidogenic index and disposition index during one year of CSII therapy. All data points are different significantly from baseline ( $p < 0.001$ ).

## 518

### Synergistic beta cell effect of macronutrients in a mixed meal is preserved in drug-naïve subjects with type 2 diabetes

W. Alsalam<sup>1</sup>, L. Ohlsson<sup>1</sup>, B. Omar<sup>1</sup>, G. Pacini<sup>2</sup>, B. Ahrén<sup>1</sup>;

<sup>1</sup>Dept of Clinical Sciences, Lund, Sweden,

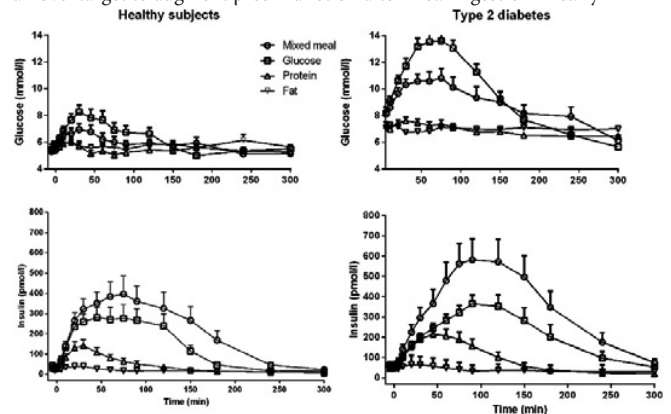

<sup>2</sup>Metabolic Unit ISIB, Padova, Italy.

**Background and aims:** The macronutrient composition of a meal is fundamental for glycemic control through their synergistic stimulation of insulin secretion in healthy subjects. Since the relevance of this synergistic effect for development of type 2 diabetes (T2D) is unknown, we have explored it in drug-naïve well-controlled subjects with T2D compared to age- and BMI-matched healthy subjects.

**Materials and methods:** After an overnight fast, eighteen (13M,5F) well-controlled drug-naïve T2D subjects (mean age 64 yrs, BMI 27.2 kg/m<sup>2</sup>, HbA1c 44 mmol/mol=6.0%) and eighteen (11M,7F) healthy subjects (mean age 63 yrs, BMI 25.3 kg/m<sup>2</sup>) underwent four tests in random order ingesting either a liquid mixed meal (550kcal; 60% carbohydrate, 20% protein and 20% fat) or each of the individual macronutrients: glucose (83g=330kcal) protein (whey protein, 30g=110kcal) or fat (sunflower and rapeseed oil, 12g=110kcal); all tests 350ml; samples were taken for analysis of glucose, insulin and intact GLP-1 (iGLP-1); their Suprabasal (sb) and total (t) 120 min areas under the curve (AUC) were calculated.  $\beta$ -cell function estimated as insulinogenic index [IGI=sb AUCinsulin/sb AUCglucose] and oral glucose insulin sensitivity (OGIS) were calculated from the glucose and insulin concentration.

**Results:** In healthy subjects, mixed meal (which included all three macronutrients) augmented insulin levels and  $\beta$ -cell function compared to glucose alone which resulted in lower postchallenge glycemia (IGI  $49 \pm 7.2$  vs.  $33.8 \pm 5.5$  pmol/mmol,  $p=0.0009$ ): tAUCglucose:  $776 \pm 36$  vs  $890 \pm 52$  pmol/l min,  $p=0.009$  with no significant difference in iGLP-1 levels (tAUCGLP-1  $802 \pm 118$  vs  $926 \pm 123$  pmol/l min,  $p=0.5$ ). T2D subjects showed exactly the same augmenting effects on  $\beta$ -cell function of mixed meal vs. glucose alone (IGI:  $42.6 \pm 7$  vs.  $22.5 \pm 5.5$  pmol/mmol  $p=0.007$ ) and tAUCglucose:  $1231 \pm 63$  vs  $1484 \pm 18.2$  mmol/l min,  $p < 0.0001$  with, again, no significant difference in iGLP-1 levels (tAUCGLP-1  $933.6 \pm 156$  vs  $939 \pm 134$  pmol/l min,  $p=0.9$ ). In fact, the relative increase of IGI by mixed meal compared to glucose alone was well preserved in T2D ( $19.9 \pm 5.4$  vs  $15.8 \pm 3.4$  pmol/mmol,  $p=0.5$ ). OGIS was higher in healthy subjects than in T2D after both mixed meal ( $398 \pm 15,304 \pm 15$  ml/min/m<sup>2</sup>,  $p=0.0005$ ) and glucose ( $407 \pm 14,324 \pm 12$  ml/min/m<sup>2</sup>,  $p=0.003$ ).

**Conclusion:** Adding protein and fat to glucose in a mixed meal results in increased insulin levels due to augmented  $\beta$ -cell function which prevents hyperglycemia when compared to ingestion of glucose alone. This synergistic effect of protein and fat on  $\beta$ -cell function, being not associated with augmented iGLP-1 levels, is well preserved in early stages of T2D pinpointing that a synergistic macronutrient effect may attempt to rescue the failing  $\beta$ -cell response to glucose. The detailed mechanism of this synergy may offer a novel target to augment  $\beta$ -cell function after meal ingestion in early T2D

### Impact of Roux-en-Y gastric bypass on distribution of enteroendocrine cells and their gene expression in obese patients with type 2 diabetes and non-diabetic controls

N.A. Rhee<sup>1</sup>, C.D. Wahlgren<sup>1</sup>, J. Pedersen<sup>2</sup>, E. Langholz<sup>3</sup>, E.P. Wandall<sup>3</sup>, S.U. Friis<sup>3</sup>, P. Vilmann<sup>4</sup>, S.J. Paulsen<sup>5</sup>, V.B. Kristiansen<sup>6</sup>, J. Jelsing<sup>5</sup>, S.S. Poulsen<sup>2</sup>, J.J. Holst<sup>2</sup>, T. Vilsbøll<sup>1</sup>, F.K. Knop<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Gentofte Hospital, Diabetes Research Division, Hellerup, <sup>2</sup>Department of Biomedical Sciences, University of Copenhagen, <sup>3</sup>Department of Medicine, Unit of Enteroscopy, University of Copenhagen, Hellerup, <sup>4</sup>Gastro Unit, Copenhagen University Hospital Herlev, <sup>5</sup>Gubra Aps, Hørsholm, Denmark, <sup>6</sup>Gastro Unit, Copenhagen University Hospital Hvidovre, Denmark.

**Background and aims:** RYGB is a weight-reducing surgical procedure, which changes macroscopic gut anatomy and the route of ingested nutrients and secretory products through the gastrointestinal tract, resulting in weight loss and improved glucose homeostasis in the majority of subjects. The aim of this study was to describe the impact of Roux-en-Y gastric bypass (RYGB) on the distribution of small intestinal enteroendocrine cells and the expression of their hormonal products in obese patients with type 2 diabetes and non-diabetic controls.

**Materials and methods:** Twelve obese subjects with type 2 diabetes and 11 age and BMI matched controls underwent RYGB and enteroscopy at least 4 months later. Mucosa biopsies from both procedures were immunohistochemically stained for cholecystokinin (CCK), glucose-dependent insulinotropic polypeptide (GIP), glucagon-like peptide-1 (GLP-1) and peptide YY (PYY) and gene expression analyses were performed looking at ghrelin (GHRL), CCK, secretin, GIP, GLP-1, PYY, neurotensin and farnesoid X receptor (FXR).

**Results:** Mean time ( $\pm$ SEM) of enteroscopy after RYGB was 10.4 $\pm$ 0.8 months. Immunohistochemically there was an increase in the density of cells staining positive for CCK, GIP, GLP-1 and PYY (controls only) after vs. before RYGB. The gene expression of GHRL, secretin and GIP mRNA was down-regulated after RYGB. CCK, PYY, neurotensin and FXR mRNA gene expression was unaltered after RYGB whereas GLP-1 mRNA was up-regulated in both groups.

**Conclusion:** Numerous alterations in the distribution of enteroendocrine cells and their expression of hormonal products is seen after RYGB. These changes may play an important role in the metabolic improvements seen after RYGB.

### Insulin-like peptide 5 is an orexigenic gastro-intestinal hormone secreted from colonic L-cells

F. Reimann<sup>1</sup>, H. Heffron<sup>2</sup>, P. Richards<sup>1</sup>, J. Powell<sup>2</sup>, M. Binda<sup>3</sup>, J. Doran<sup>2</sup>, Y. Toyoda<sup>2</sup>, J.D. Wade<sup>4</sup>, S. Aparicio<sup>5</sup>, M. Carlton<sup>2</sup>, A.P. Coll<sup>1</sup>, S. O'Rahilly<sup>1</sup>, F.M. Gribble<sup>1</sup>, J. Grosse<sup>2</sup>;

<sup>1</sup>University of Cambridge, <sup>2</sup>Takeda, Cambridge, UK,

<sup>3</sup>Frimorfo Ltd, Fribourg, Switzerland, <sup>4</sup>University of Melbourne, Australia,

<sup>5</sup>BCCAB, Vancouver, Canada.

**Background and aims:** Intestinal hormones secreted from enteroendocrine L-cells orchestrate the fate of ingested nutrients. Glucagon-like peptide-1 (GLP-1) acts as an incretin, thus boosting postprandial insulin secretion, and both GLP-1 and peptide YY (PYY) inhibit further food intake. Using a transgenic mouse model fluorescently labelling proglucagon expressing cells, we identified insulin-like peptide-5 (Insl5) as another hormone expressed in colonic L-cells, and characterised its role in murine physiology.

**Materials and methods:** Expression of Insl5 was investigated by RT-PCR and immunohisto-chemistry. Plasma levels of Insl5 after fasting and re-feeding were assessed by ELISA (Kamiya). Wild-type and newly generated Insl5-receptor (relaxin/insulin-like family peptide receptor-4) knock-out (Rxfp4<sup>-/-</sup>) mice, accustomed to fasting and/or i.p. injections, were injected with Insl5 (either from Phoenix or chemically synthesised in Melbourne) or polyclonal Insl5 antibodies (Phoenix) and assessed for food intake. All animal studies were in accordance with the UK Home Office legislation and approved by the appropriate ethical committee.

**Results:** RT-PCR detected specific Insl5 expression in colonic, but not duodenal/jejunal L-cells and immunofluorescence microscopy confirmed co-expression with proglucagon in an overlapping set of vesicles. In spite of a previous report of reduced insulin responses in Insl5<sup>-/-</sup> mice, we failed to detect significant effects of Insl5 on insulin secretion from isolated islets, and Rxfp4<sup>-/-</sup> mice did not exhibit impaired glucose tolerance. However, we observed that over-night fasted mice had elevated plasma Insl5 levels (4.2  $\pm$  0.5 pg/ml) which fell after 10 hrs of re-feeding (2.7  $\pm$  0.2 pg/ml, n = 10). This effect was pronounced in mice restricted to 60% caloric intake for 2 weeks (32.7  $\pm$  6.4 pg/ml fasting; 2.5  $\pm$  0.2 pg/ml 10 h refed, n=10) but blunted in mice receiving a 45% high-fat diet, consistent with the finding that colonic Insl5 mRNA expression was elevated in the calorie restricted group. Over-night fasted mice injected with Insl5 (0, 8, 40, 200 or 1000 ng/25g body weight) showed a dose dependent increase in food intake (225  $\pm$  25 mg chow/20 min at the highest dose compared to 13  $\pm$  12.5 mg chow/20 min in the placebo group). This effect was absent in Rxfp4<sup>-/-</sup> mice. Tail vein injection with polyclonal Insl5 antibodies blunted re-feeding responses in fasted mice (5.8  $\pm$  0.2 g cumulative food intake/24 h at 100  $\mu$ g Insl5-IgG/mouse compared to 7.1  $\pm$  0.1 g after injection of an unspecific control IgG, n = 5 respectively) and this effect was also absent in Rxfp4<sup>-/-</sup> mice.

**Conclusion:** These results are consistent with Insl5 acting as an orexigenic peptide secreted from the distal intestine, joining the only other established orexigenic gut-peptide, ghrelin, which is secreted from the stomach. Co-expression in a subset of anorexigenic peptide (GLP-1 and PYY) secreting L-cells is surprising and requires further investigations.

### Mechanism and physiological roles of glucose sensing in enteroendocrine cells

E. Lee, T. Miki;

Department of Medical Physiology, Chiba University, Graduate School of Medicine, Japan.

**Background and aims:** Glucagon-like peptide 1 (GLP-1) is secreted from enteroendocrine L-cells in response to oral glucose ingestion and plays an important role in dampening the rise in postprandial blood glucose levels. However, the mechanism of glucose sensing in the L-cells and its physiological consequence is not fully understood. In this study, the mechanism of glucose sensing in the L-cells and the physiological importance of luminal glucose sensing in the maintenance of glucose homeostasis was examined in mice in vivo.

**Materials and methods:** C57BL/6 mice were administrated with carbohydrates (glucose or maltose) together with or without an antagonist of SGLT1 (phloridzin) or GLUT2 (phloretin) and the portal blood was collected and subjected to GLP-1 assay. The activation of enteroendocrine cells and neurons in the brainstem was detected by immunostaining of phospho-CaMK2. In addition, glucose-induced suppression of gluconeogenesis was evaluated by both oral (p.o.) and intraperitoneal (i.p.) administration.

**Results:** Significant GLP-1 secretion was induced by intraduodenal glucose administration at 5 min after infusion. The secretion was significantly blocked by co-administration of phloridzin but not by phloretin. I.p. glucose administration failed to trigger GLP-1 secretion. While plasma GLP-1 concentration was not increased at 30 min after oral glucose administration, it was significantly increased by oral maltose. Interestingly, GLP-1 secretion at 30 min after maltose administration was not suppressed by phloridzin, suggesting that glucose-sensing mechanism in L-cells differs between early and late phases after stimulation. Immunostaining of duodenum revealed that enteroendocrine cells and small numbers of nonepithelial cells in the villi were detected positive for phospho-CaMK2 at 5 min after intraduodenal glucose administration. Similarly, several cells in the medulla oblongata were shown to be activated by intraduodenal glucose administration. We also examined the gluconeogenesis and STAT3 phosphorylation in the liver in response to either p.o. or i.p. glucose administration. Interestingly, the suppression of gluconeogenesis and induction of STAT3 phosphorylation by p.o. administration was significantly potent than that by i.p. administration.

**Conclusion:** Glucose sensing in L-cells is dependent on SGLT1-mediated signaling in the early phase but becomes independent in the late phase after luminal glucose stimulation. Our data suggested that glucose in the gut lumen first activates enteroendocrine cells and then the information is transferred to several nuclei in the brain stem, influencing the glucose metabolism in the liver.

**Free fatty acid receptor GPR120 is highly expressed in enteroendocrine K cells of upper small intestine and has a critical role in GIP secretion after fat ingestion**

K. Iwasaki<sup>1</sup>, N. Harada<sup>1</sup>, K. Sasaki<sup>1</sup>, S. Yamane<sup>1</sup>, K. Iida<sup>2</sup>, K. Suzuki<sup>1</sup>, A. Hamasaki<sup>1</sup>, E. Joo<sup>1</sup>, D. Nasteska<sup>1</sup>, K. Shibue<sup>1</sup>, T. Harada<sup>1</sup>, A. Hirasawa<sup>2</sup>, N. Inagaki<sup>1</sup>;

<sup>1</sup>Department of Diabetes, Endocrinology and Nutrition, Graduate School of Medicine, <sup>2</sup>Department of Genomic Drug Discovery Science, Graduate School of Pharmaceutical Sciences, Kyoto University, Japan.

**Background and aims:** Gastric inhibitory polypeptide (GIP) is an incretin secreted from enteroendocrine K-cells in response to fat and glucose ingestion. Recently, free fatty acid receptor (FFAR) GPR120 was identified as a “lipid sensor” and was involved in GLP-1 secretion. However, GPR120 expression and role in K-cells remain unclear. In this study, we elucidated GPR120 gene expression in K-cells using GIP-GFP knock-in (GIP-GFP) mice in which K-cells can be visualized by GFP fluorescence. Furthermore, we clarified the effects of GPR120 on GIP secretion using GPR120-deficient mice (GPR120<sup>-/-</sup>) and GPR120 antagonist.

**Materials and methods:** The number of GFP-positive cells was measured by flow cytometry analysis and immunohistochemistry. GFP-positive cells and GFP-negative cells were collected as K-cells and non-K-cells, respectively, from GI tract of GIP-GFP mice by flow cytometer. GIP content in GFP-positive and GFP-negative cells were measured by ELISA. GIP mRNA and FFAR mRNA expressions (GPR40, GPR41, GPR43, GPR119, and GPR120) in GFP-positive and GFP-negative cells were assessed by sq RT-PCR. Oral glucose tolerance tests (OGTTs) and lard tolerance tests (OLTTS) were performed using GPR120<sup>-/-</sup> mice and wild-type (WT) mice to evaluate total GIP secretion. After oral or intravenous administration of GPR120 antagonist in C57/BL6 mice, total GIP levels during OLTTS were measured.

**Results:** GFP-positive cells were observed in small intestine, but not in stomach and colon. K-cell number and GIP content and mRNA expression in K-cells were significantly higher in upper small intestine than those in lower small intestine. GPR120 mRNA was highly expressed in K-cells (but not in GFP-negative cells) of upper small intestine, while GPR40 mRNA and GPR41 mRNA were highly expressed in K-cells (but not in GFP-negative cells) of lower small intestine. GPR120<sup>-/-</sup> mice had lower GIP secretion (75% reduction) during OLTTS compared to WT mice, but not during OGTT. Oral administration of GPR120 antagonist significantly attenuated lard oil-induced GIP secretion. On the other hand, intravenous administration of GPR120 antagonist did not reduce GIP levels after lard oil ingestion.

**Conclusion:** We confirmed that GPR120 is substantially expressed in K cells of the upper small intestine. Our results using GPR120<sup>-/-</sup> mice and a GPR120 antagonist demonstrate that GPR120 plays a critical role in lipid-induced GIP secretion from K-cells population located mainly in upper small intestine.

**CART is a regulator of GIP and GLP-1 expression and secretion in vitro**

L. Shcherbina, N. Wierup;

Lund University Diabetes Centre, Lund University, Malmö, Sweden.

**Background and aims:** Cocaine- and amphetamine-regulated transcript (CART) is a regulatory peptide that controls islet hormone secretion and beta-cell survival. We have recently shown that CART is expressed in human enteroendocrine cells, including L- and K-cells in the human duodenum and jejunum. Furthermore, we have shown that CART plasma levels increase after a meal in humans. In the present study we aimed to examine whether endogenous L- and K-cell CART regulates incretin hormone secretion and expression.

**Materials and methods:** CART gene expression was silenced using siRNA in GLUTag and STC-1 cells, used as L- and K-cell models respectively. Gene expression was assessed with qPCR, protein content and secretion with ELISA, and cell survival using WST-1 assay.

**Results:** CART silencing resulted in a 84.6±5.9% reduction in CART mRNA levels in GLUTag cells (p<0.001) and in a 58.5±8.1% reduction of CART mRNA in STC-1 cells (p<0.001). This was paralleled by increased incretin gene expression in both GLUTag and STC-1 cells. In GLUTag cells GLP-1 mRNA expression was increased by 133.7±12.5% after CART silencing (p<0.001). This corresponded to 2.3±0.8 fold increase in GLP-1 (active) content (p<0.05). In STC-1 cells silencing of CART increased mRNA levels of both GLP-1 and GIP by 147±7.1% and 125±8% respectively (p<0.001). In

addition, silencing of CART provoked increased GLP-1 (active) secretion in GLUTag cells stimulated with 2.8 mM glucose, 16.7 mM glucose and IBMX and 16.7 mM glucose (3.79±0.15, 3.78±0.32 and 4.45±0.32-fold respectively, p<0.001). Moreover, CART silencing provoked 1.71±0.39-fold (P<0.05) increased cell survival in GLUTag cells.

**Conclusion:** We conclude that CART expressed in L-cells and K-cells acts as a regulator of incretin synthesis and secretion.

**In vivo beta cell glucose sensitivity regulates ex vivo islet size, transdifferentiation and GLP1 immunoreactivity in the alpha cells in humans**

T. Mezza<sup>1</sup>, A.V. Sun<sup>1</sup>, C. Conte<sup>1</sup>, G. Sorice<sup>1</sup>, S. Moffa<sup>1</sup>, C. Cefalo<sup>1</sup>, R.N. Kulkarni<sup>2</sup>, A. Mari<sup>3</sup>, A. Giaccari<sup>1</sup>;

<sup>1</sup>Catholic University, Rome, Italy, <sup>2</sup>Joslin Diabetes Center, Boston, USA, <sup>3</sup>CNR, Padova, Italy.

**Background and aims:** Neogenesis from duct cells, increased islet size and trans-differentiation of a cells to β cells likely represent compensatory mechanisms to cope with the increased insulin demand in insulin resistance states. Following pancreateoduodenectomy healthy patients displays an increase in GLP-1 secretion, the mechanism contributing to greater GLP-1 secretion is not fully understood and suggests either hypersecretion by existing intestinal L-cells and/or other potential sources of the incretin hormone. Among those, α cells are a potential source of the incretin hormone.

**Materials and methods:** To investigate the relation between in-vivo insulin secretion (IS), sensitivity and incretin effect with ex-vivo islet characteristics, 18 non-diabetic patients (10 F/8 M, 51±15 yrs., BMI 27.9±5.3 kg/m<sup>2</sup>) scheduled for pancreateoduodenectomy underwent a 2-h hyperglycemic clamp, a mixed meal test and an hyperinsulinemic euglycemic clamp. β cell glucose sensitivity (GS) was calculated as the ratio of insulin secretion and glucose increments, both during the hyperglycemic clamp and mixed meal test. The incretin effect was estimated as the ratio of glucose sensitivity during the HC and MMT. Pancreas samples were collected during surgery for IHC for glucagon, insulin and GLP1+ cells to assess islet morphology. Neogenesis was evaluated by the quantification of scattered islets and ductal cells by CK19 immunostaining and trans-differentiation of α to β cell was quantified by counting the % of insulin and glucagon double positive cells.

**Results:** When subjects were classified as insulin sensitive or resistant (using the median glucose uptake during the euglycemic clamp [4.9 mg•kg<sup>-1</sup>•min<sup>-2</sup>] as a cut-off), insulin resistant subjects displayed a significantly higher basal IS (IR 127±23.7 vs. IS 91.7±6.78 pmol•min<sup>-1</sup>•m<sup>-2</sup>, p=0.04), whereas GS during HC (IR 47.7±10.5 vs. IS 91.5±17.4 pmol•min<sup>-1</sup>•m<sup>-2</sup>•mM<sup>-1</sup>, p=0.03) was significantly lower. Analysis of the entire group revealed an inverse correlation between islet size and GS (r= -0.49; p<0.05) and GU, and between GS and % of double+ cells (r=-0.72; p=0.03). No correlation was found between neogenesis markers and GS. Following the pancreateoduodenectomy, the incretin effect was significantly decreased in the insulin sensitive patients (Incretin effect before surgery 3.21±0.88 vs. after surgery 1.48±0.31, p=0.05), whereas no changes were observed in the insulinresistant subjects (Incretin effect before surgery 2.03±0.41 vs. after surgery 2.16±0.96, p=NS).

**Conclusion:** Our data suggest that insulin resistance determines alterations in islet morphology and β cell function, with a strict correlation between function and morphology. Impaired β cell GS might represent a major stimulus for the induction of trans-differentiation of α to β cells and increased islet size. Further, relative compensation of incretin effect following PD may be driven by the increased α mass and the GLP1 immunoreactivity in the α cells observed in insulinresistance.

## 525

**Effect of acute GIP- and GLP-1- infusion on circulating levels of pro-atrial natriuretic peptide in subjects with different stages of glucose tolerance**

N.N. Rudovich<sup>1</sup>, A. Sparwasser<sup>2</sup>, W. Doehner<sup>3</sup>, O. Pivovarova<sup>1</sup>, A. Arafat<sup>4</sup>, A. Bergmann<sup>5</sup>, M. Nauck<sup>6</sup>, A.F.H. Pfeiffer<sup>1</sup>;

<sup>1</sup>Clinical Nutrition, DIFE Potsdam, Nuthetal, <sup>2</sup>Thermo Fisher Scientific, B.R.A.H.M.S GmbH, Biotechnology Centre Hennigsdorf, <sup>3</sup>Interdisciplinary stroke research, <sup>4</sup>Campus Mitte, Charité University Medicine, <sup>5</sup>Sphingotec GmbH, Biotechnology Centre Hennigsdorf, Berlin, <sup>6</sup>Diabeteszentrum Bad Lauterberg, Germany.

**Background and aims:** Glucagon-like peptide-1 (GLP-1) receptor agonist acts antihypertensive via release of atrial natriuretic peptide in mice. Moreover, reduction of glycemic load by alpha-glucosidase inhibitors increase circulating levels of pro-atrial natriuretic peptide (proANP) suggesting an evidence of gut-heart axis also in humans. Whether GLP-1 and glucose-dependent insulinotropic peptide (GIP) interact with NP system in humans is unknown.

**Materials and methods:** Twelve patients with type 2 diabetes (T2DM) (nine men and three women; 61 ± 10 years; BMI 30.0 ± 3.7 kg/m<sup>2</sup>; HbA(1c) 7.3 ± 1.5%) were studied. In randomized order, intravenous infusions of GLP-1(7-36)-amide (1.2 pmol • kg<sup>-1</sup> • min<sup>-1</sup>), GIP (4 pmol • kg<sup>-1</sup> • min<sup>-1</sup>), GLP-1 plus GIP, and placebo were administered over 360 min after an overnight fast (≥ 1 day wash-out period between experiments). Additionally, effect of 240 min GIP-infusion (2 pmol • kg<sup>-1</sup> • min<sup>-1</sup>) on proANP was studied in glucose-tolerant male subjects (n=8). Plasma proANP concentrations were measured by an automated mid-region-directed proANP immunoassay.

**Results:** GLP-1 decreased proANP levels (mean ± sem, 44.1 ± 3.1 vs. 34.2 ± 3.0 pmol/l; p < 0.05). During placebo, GIP and GIP + GLP-1 infusion no significant changes of circulating proANP were observed in T2DM subjects. In glucose tolerant subjects, proANP levels are decreased at the end of the experiments with placebo and GIP (51.9 ± 6.5 vs. 40.0 ± 5.4 pmol/l in placebo, p < 0.05; 49.5 ± 6.3 vs. 40.8 ± 6.5 pmol/l in GIP-tests, p = 0.051).

**Conclusion:** As proANP concentration reflects ANP secretion, our data could not confirm interactions between two major incretins and ANP in humans.

*Clinical Trial Registration Number: NCT00774488*

## 526

**Novel GIP receptor-mediated bioassay more accurately reflects changes of GIP activity than traditional assays**

T. Yanagimachi, Y. Fujita, Y. Takeda, J. Honjo, H. Kitsunai, H. Sakagami, Y. Takiyama, A. Abiko, Y. Makino, M. Haneda;  
Division of Metabolism and Biosystemic Science, Department of Internal Medicine, Asahikawa Medical University, Japan.

**Background and aims:** GIP and GLP-1 are incretins released from the gut rapidly inactivated by dipeptidyl peptidase-4 (DPP-4) after secretion into truncated forms that are no longer insulinotropic forms of incretins. Although recently developed ELISA kits may be able to measure active incretins levels, it is unclear if the available assays detect totally biological active forms. Moreover, recent reports suggest GIP has a short-form isoform GIP (1-30) secreted from gut and pancreas, which may not be detectable by the available methods. Therefore, we determined active GIP and GLP-1 levels from human blood samples using novel cell-based, receptor-mediated bioassays.

**Materials and methods:** We utilized the cell lines stably co-transfected with human-form GIP or GLP-1 receptors and a cAMP-inducible luciferase expression construct for bioassays. We performed a 75 g OGTT in six non-diabetic subjects and measured plasma total GIP (Millipore), total GLP-1 (Millipore), insulin, C-peptide and glucagon levels by ELISA, active GIP and active GLP-1 levels by bioassays. Next, we performed another OGTT in identical subjects after administration of DPP-4 inhibitor (sitagliptin: 100 mg/day) for three days. We measured plasma total/active GIP and GLP-1 levels as above. Additionally, we compared the efficacy of our GIP bioassay with that of a commercial active GIP ELISA kit (IBL, Japan) by measuring samples from identical subjects before and after sitagliptin administration.

**Results:** To evaluate the specificity of the bioassays, we confirmed their responsiveness with several synthetic incretin receptor agonists. In the GIP bioassay, GIP (1-42) and short-form GIP (1-30) almost equivalently increased luciferase activity in a concentration dependent manner. In the GLP-1 bioassay, exendin-4 produced almost comparable luciferase activity to GLP-1

(7-36 amide) but liraglutide did less than GLP-1 (7-36 amide). In samples collected during on OGTT, total GIP levels rapidly increased from 0 min to 15 min and gradually increased up to 120 min (68.8 ± 11.4 pmol/l). In contrast, active GIP levels peaked at 30 min (42.3 ± 4.3 pmol/l) and dropped at 60 min. Notably, active GIP had a positive correlation with the insulin levels. Total GLP-1 levels increased to 30 min and remained at similar levels up to 120 min (25.4 ± 2.7 pmol/l). In contrast, active GLP-1 levels reached a peak at 30 min and then dropped. Administration of a DPP-4 inhibitor to identical subjects induced 1.4-fold increase of active GLP-1 levels at 15 minutes after oral glucose load. Interestingly, active GIP measured by bioassay levels increased approximately by 20-fold after DPP-4 treatment. But total and active GIP levels by ELISA were increased just 1.7 and 2.1-fold, respectively. Other DPP-4 inhibitors (linagliptin: 5 mg/day and vildagliptin: 100 mg/day) showed similar effect to sitagliptin. Then we investigated the discrepancy in measured active GIP levels between bioassay and ELISA. We first confirmed that Sitagliptin per se did not increase luciferase activity. The bioassay could detect short-form GIP (1-30), but total or active ELISA kits could not at all.

**Conclusion:** We propose that the bioassays more accurately reflect the contribution of the incretins in the entero-insular axis and short-form GIP (1-30) may be more important than GIP (1-42) in DPP-4 inhibitor treatment.

### Effects of a non-glucose food preload on oral glucose tolerance in subjects with impaired glucose tolerance and type 2 diabetes

D. Trico<sup>1,2</sup>, A. Tulipani<sup>1</sup>, S. Baldi<sup>1</sup>, C. Morgantini<sup>2</sup>, M.P. Macedo<sup>3</sup>, A. Mari<sup>4</sup>, E. Ferrannini<sup>1</sup>, A. Natali<sup>1</sup>;

<sup>1</sup>Department of Clinical and Experimental Medicine, University of Pisa,

<sup>2</sup>Scuola Superiore Sant'Anna, Pisa,

<sup>3</sup>Centro de Estudos de Doenças Crónicas, Universidade Nova de Lisboa,

<sup>4</sup>Institute of Biomedical Engineering, National Research Council, Padova, Italy.

**Background and aims:** Protein and fat ingestion delays gastric emptying and stimulates gut hormones release. Recent studies have suggested that these effects could be exploited to improve the plasma glucose excursions induced by carbohydrates in type 2 diabetic patients (T2D). The present study was designed to measure the impact of a small non-glucose food preload on the major components of glucose homeostasis in subjects with impaired glucose tolerance (IGT) and T2D and to test whether gut hormones participate in this response.

**Materials and methods:** Ten diet-controlled T2D patients (8 males, age 55±7 years, BMI 28.7±4.7 kg/m<sup>2</sup>, HbA1c 48±2 mmol/l) and thirteen IGT subjects (7 males, age 47±5 years, BMI 26.3±1.6 kg/m<sup>2</sup>, HbA1c 38±1 mmol/l) were enrolled. On two separate days, after an overnight fast, they were randomised to a preload of either 500 ml of water (control) or Parmesan cheese (50 g) plus a boiled egg with 300 ml of water; 30 minutes later they underwent a standard 75 gr oral glucose tolerance test (OGTT). Arterialised timed blood samples were collected to measure plasma glucose, insulin, C-peptide, GLP-1 and GIP. Two stable glucose tracers were administered ([6,6-<sup>2</sup>H<sub>2</sub>]glucose and [U-<sup>13</sup>C]glucose, *i.v.* and *per os* respectively) to measure the rate of appearance of ingested (RaO) and endogenous glucose and the glucose clearance. Three major components of β-cell function, namely glucose sensitivity (βGS), rate sensitivity (βRS) and potentiation (POT) were evaluated by modeling insulin secretion (estimated from C-peptide deconvolution) and plasma glucose. Insulin sensitivity was estimated using the OGIS method.

**Results:** In T2D patients, the plasma glucose rise during the OGTT was significantly lower after the food preload than after water ingestion (iAUC -49.4±5.9%, p<0.0002). The food preload produced a delay in glucose absorption (RaO iAUC -27±12%, p<0.05), an enhancement of βGS (+102±31%, p<0.006), and an increase in GLP-1 (iAUC +176±49%, p<0.004) and GIP response (iAUC +74±31%, p<0.03), while insulin sensitivity, glucose clearance, endogenous glucose production, βRS and POT were not affected. In IGT subjects, the effect of the food preload on glucose tolerance was less pronounced (iAUC -39±7%, p<0.0002) and explained by a significant improvement in POT (+43±17%, p<0.04) and a minor delay in glucose absorption (RaO iAUC -16±8%, p<0.01). While the GLP-1 response was similarly enhanced (iAUC +149±58%, p<0.002), GIP secretion in IGTs was stimulated to a greater extent (iAUC +179±49%, p<0.001). In the whole dataset, glucose tolerance improved in proportion to its baseline derangement and was not correlated to the changes in either GLP-1 or GIP.

**Conclusion:** A small non-glucose food preload significantly improves glucose tolerance in diet-controlled T2D and IGT. This results from different combinations of delayed glucose absorption and improved β-cell function in the two study groups. Simple diet recommendations have the potential to control postprandial hyperglycaemia in T2D patients by engaging mechanisms, other than gut hormones, that appear to be preserved in the early stages of the disease.

### Relationship between meal induced glucagon-like peptide-1 response and metabolic syndrome prevalence in type 1 diabetic patients

L. Duvnjak, K. Blaslov, T. Bulum, J. Knežević-Čučić; University hospital Merkur, Zagreb, Croatia.

**Background and aims:** Metabolic syndrome (MS) can be found in about 30–40 % of type 1 diabetic (T1DM). While there is a growing body of evidence suggesting that meal induced glucagon-like peptide-1 (GLP-1) response in type 2 diabetic (T2DM) patients is diminished, GLP-1 secretion in T1DM and population with MS was not extensively studied. We aimed to analyse the

relationship between fasting total GLP-1 level, meal induced GLP-1 response and MS prevalence in T1DM patients.

**Materials and methods:** A total of 77 T1DM patients (61% male, mean age 46 years, median BMI 25 kg/m<sup>2</sup>, median diabetes duration of 21 years) were included. MS was diagnosed in 26 (33.76%) of them according to IDF (International Diabetes Federation) definition (2009 year) including at least two of the following criteria: waist circumference >80 cm in female (94 in male), triglycerides above 1.7 mmol/L or specific treatment, HDL cholesterol <1.03 mmol/L in males and 130 or diastolic >85 mm Hg, or specific treatment, fasting plasma glucose (FPG): > 5.6 mmol/L, or previously diagnosed T2DM. The control group included 10 normal glucose tolerance (NGT) subjects adjusted for age, gender and BMI. Circulating GLP-1 level was measured before and 30 min after a test meal. The test meal (324 (324–528) kcal) comprised about 20% fat, 60% carbohydrate, and 20% protein. Total GLP-1 level was measured by ELISA using ALPCO Diagnostics kit. The change between 30 minutes postprandial and fasting GLP-1 concentration was calculated: ΔGLP-1=postprandial GLP-1-fasting GLP-1 concentration.

**Results:** T1DM patients showed significantly lower total fasting, postprandial and meal induced GLP-1 level compared to NGT group. Between T1DM patients significantly higher rise in circulating GLP-1 level was noticed in group without compared to those with MS (1.89±2.25 pmol/L vs 0.77±1.74 pmol/L, p=0.017). Between the T1DM without MS and NGT group a significant difference in total fasting GLP-1 (1.34±1.39, 2.99±1.34, p=0.003), postprandial GLP-1 level (3.24±2.43, 5.18±2.85, p=0.017) and ΔGLP-1 (1.89±2.25, 2.17±1.66, p=0.032) was found. The difference in meal induced change between these two groups was not significant (p=0.487). In the multivariate logistic regression analysis, ΔGLP-1 concentration was significantly inversely associated with the presence of MS after adjustment for age, sex, duration of diabetes and calorie intake (0.704 (0.528–0.956)).

**Conclusion:** In T1DM patients higher meal induced GLP-1 response is inversely related to the presence of MS. The possible role of GLP-1 in the pathogenesis of MS in T1DM needs to be further investigated.

### Intravenous arginine stimulates GLP-1 release across spectrum of glucose tolerance

H. Ruetten<sup>1</sup>, R.H. Raymond<sup>2</sup>, R.A. Calle<sup>3</sup>, C. Cao<sup>4</sup>, D.S. Lee<sup>3</sup>, R.P. Robertson<sup>5</sup>, S.S. Shankar<sup>6</sup>, M. Staten<sup>7</sup>, D. Stefanovski<sup>8</sup>, M.T. Vassileva<sup>9</sup>, A. Vella<sup>10</sup>, G.C. Weir<sup>11</sup>, D.A. Fryburg<sup>12</sup>, for the Beta Cell Team of FNIH Biomarkers Consortium;

<sup>1</sup>Sanofi, Inc., Frankfurt am Main, Germany, <sup>2</sup>RSquared Solutions, Skillman,

<sup>3</sup>Pfizer Pharmatherapeutics R & D, Cambridge, <sup>4</sup>Takeda, Inc., Chicago,

<sup>5</sup>Pacific Northwest Diabetes Research Institute, Seattle, <sup>6</sup>Eli Lilly, Inc,

Indianapolis, <sup>7</sup>NIDDK, National Institutes of Health, Bethesda, <sup>8</sup>Cedars-

Sinai Medical Center, Los Angeles, <sup>9</sup>Foundation for the NIH Biomarkers

Consortium, Bethesda, <sup>10</sup>Mayo Clinic, Rochester, <sup>11</sup>Joslin Diabetes Center,

Boston, <sup>12</sup>ROI BioPharma Consulting, East Lyme, USA.

**Background and aims:** Meal-induced secretion of GLP-1 has been well-described, yet limited data exist on *i.v.* secretagogues of GLP-1. As part of a series of experiments to characterize beta cell response to *i.v.* arginine (arg), we previously showed that insulin secretion (AIRarg) responses to arg differed

across glucose tolerance (GT) groups. In the same subjects we report total GLP-1 responses to i.v. arg in 53 obese subjects with normal glucose tolerance (NGT), prediabetes (PDM), and type 2 diabetes (T2DM).

**Materials and methods:** Following an overnight fast, samples were acquire for total GLP-1 pre- and for 10 min post an i.v. arg bolus (5 gm over 30 sec) at basal glucose. Pre- and post-arg GLP-1 samples were also acquired during the last 10 min of a 60 min glucose infusion (900 mg/min).

**Results:** The table summarizes results during basal glucose period; previously reported and baseline adjusted AIRarg insulin responses are also included. Pre-arg fasting GLP-1 differed across GT spectrum, highest in T2DM. ARG elicited GLP-1 secretion in all 3 GTs, with greater changes in PDM and T2DM than NGT (Delta GLP-1). Pre-arg GLP-1 did not correlate with AIRarg, whereas change in GLP-1 correlated with AIRarg for NGT and T2DM but not PDM in basal glucose state (NGT/T2DM:  $r = 0.52/0.49$   $P < 0.02$ ; PDM  $r = 0.16$  NS). Similar responses observed during high glucose infusion (not shown).

**Conclusion:** We conclude that 1) i.v. arginine acutely stimulates GLP-1 secretion irrespective of glucose tolerance status; 2) Pre-arginine GLP-1 was not associated with insulin secretory response, but GLP-1 secretion after arginine is positively associated with insulin secretion in NGT and T2DM.

### Effects of region of small intestine exposed to glucose on incretin hormones, insulinaemia and glycaemia in healthy older subjects

R.S. Rigda<sup>1</sup>, T.J. Little<sup>1,2</sup>, L.G. Trahair<sup>1</sup>, K. Lange<sup>2</sup>, C. Feinle-Bisset<sup>1,2</sup>, C.K. Rayner<sup>1,2</sup>, M. Horowitz<sup>1,2</sup>, K.L. Jones<sup>1,2</sup>;

<sup>1</sup>Medicine, University of Adelaide, <sup>2</sup>NHMRC Centre of Research Excellence in Translating Nutritional Science to Good Health, Adelaide, Australia.

**Background and aims:** The release of incretin hormones is pivotal to post-prandial glucose homeostasis. We have reported that the stimulation of glucagon-like peptide-1 (GLP-1), but not glucose-dependent insulinotropic peptide (GIP), is dependent on the length of small intestine exposed to glucose, but the impact of the region of small intestine remains uncertain. The aims of this study were to determine the incretin, insulinaemic and glycaemic responses to intraduodenal (ID) glucose when the proximal small intestinal region (~60cm from the pylorus) is bypassed.

**Materials and methods:** Ten healthy older subjects (9M,1F; age 65-79yr) were studied on 2 separate occasions after an overnight fast, in random order. On each occasion they were intubated with a custom-designed catheter incorporating an intraduodenal (ID) balloon to isolate proximal (<60cm from pylorus) small intestinal regions. Each subject then received ID glucose (3kcal/min) into either a) both the proximal and distal regions "GPD", or b) the distal region only "GD" for 60min. On the GPD study day, glucose was infused into the proximal region and aspirated every 10min, so that the amount of residual glucose to be infused into the distal region could be calculated. On the GD study day, 0.9% saline was infused concurrently into the proximal region. Blood glucose and plasma insulin, total GIP and GLP-1 were measured between  $t = 0-60$ min, and the insulin/glucose ratio at 60min calculated. Data were analysed using Student's paired t-tests and expressed as mean ± SEM.

**Results:** There were rises in blood glucose and plasma insulin, GIP and GLP-1 on both days ( $P < 0.01$ ). When the responses to GD and GPD were compared there was no significant difference in blood glucose, or plasma in-

ulin, although mean values for blood glucose were less, and plasma insulin greater, with GD and the insulin/glucose ratio at 60min was greater with GD ( $11.8 \pm 2.3$  vs  $7.8 \pm 1.2$ ,  $P < 0.05$ ). The stimulation of GIP was less ( $P < 0.01$ ), and that of GLP-1 greater ( $P < 0.05$ ), with GD.

**Conclusion:** We conclude that the effects of enteral glucose on GIP and GLP-1 are dependent on the region of small intestine exposed with a consequent impact on insulinaemia.

**Table: Blood glucose and plasma insulin, GIP and GLP-1**

### Encapsulated glutamine significantly increases circulating concentrations of glucagon-like peptide-1 and insulin and increases meal size in healthy volunteers

C.L. Meek<sup>1</sup>, F. Reimann<sup>1</sup>, A.J. Park<sup>2</sup>, F.M. Gribble<sup>1</sup>;

<sup>1</sup>University of Cambridge, <sup>2</sup>Addenbrooke's Hospital, Cambridge, UK.

**Background and aims:** Type 2 diabetes (T2D) is now a major cause of death and disability worldwide. At present, bariatric surgery is the only treatment capable of inducing diabetes remission, possibly due to enhanced nutrient delivery to the distal gut, a phenomenon which is associated with marked increases in the secretion of gut hormones, such as glucagon-like peptide 1 (GLP-1). However, the use of bariatric surgery is limited by expense and invasiveness and there is an urgent need to identify safe and affordable non-surgical treatments which can promote similar effects. Previous work in vitro has identified that glutamine is a potent secretagogue of GLP-1. The aim of the current study was to identify if encapsulated glutamine can increase endogenous secretion of GLP-1 in human volunteers using a delivery system which targets glutamine release to the ileum. A secondary aim was to assess the effect of the encapsulated glutamine on glucose tolerance and meal size.

**Materials and methods:** A randomized, double blind, placebo-controlled cross-over study was performed to assess the effects of a single dose of encapsulated glutamine (6g, 3.6g or placebo) on venous concentrations of total GLP-1 in fasting healthy volunteers. Glutamine was encapsulated by a company specialising in drug delivery. Each capsule was coated with Acryl-Eze to promote capsule release around the mid ileum. Capsules were made using GMP-grade materials and were tested for stability to determine the shelf life. The effects of capsule ingestion upon glucose tolerance and meal size were studied using a standard 75g oral glucose tolerance test and ad libitum meal respectively. The study received ethical approval from the local research ethics committee and all participants gave written informed consent. Statistical analysis was performed using the paired t test.

**Results:** 29 participants were recruited in total (14 male, 15 female; age 22-58 years, body mass index 18.5 - 31.8 kg/m<sup>2</sup>). Ingestion of 6g glutamine was associated with increased concentrations of GLP-1 after 90 minutes ( $n = 10$ ; 3.6 pmol/l vs 2.2 pmol/l for placebo;  $p = 0.006$ ), increased concentrations of insulin after 90 minutes ( $n = 10$ ; 62.0 pmol/l vs 50.9 pmol/l;  $p = 0.047$ ) and increased meal size at 120 minutes ( $n = 10$ ; 542g vs 481g eaten;  $p = 0.008$ ). No safety concerns were identified following the ingestion of encapsulated glutamine.

**Conclusion:** A single oral dose of encapsulated glutamine is able to promote increased secretion of GLP-1 and is associated with increased insulin release. However, this promoted increased meal size, an undesirable effect, perhaps because the orexigenic effects of insulin release predominated over the anorexic effects of GLP-1 release following administration of glutamine. In conclusion, GLP-1 release was promoted in vivo using a single dose of encapsulated glutamine but the effect size was small and was not associated with beneficial metabolic effects.

**Gallbladder emptying and single-dose metformin elicit robust and additive glucagon-like peptide-1 responses**

U. Rohde<sup>1</sup>, D.P. Sonne<sup>1</sup>, M. Hansen<sup>1</sup>, A. Brønden<sup>1</sup>, M. Christensen<sup>1</sup>, J.F. Rehfeld<sup>2</sup>, J.J. Holst<sup>3</sup>, T. Vilsbøll<sup>1</sup>, F.K. Knop<sup>1</sup>;

<sup>1</sup>Diabetes Research Division, Gentofte Hospital, Hellerup,

<sup>2</sup>Department of Clinical Biochemistry, Rigshospitalet,

<sup>3</sup>Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark.

**Background and aims:** Preclinical studies suggest that gallbladder emptying and subsequent activation of the bile acid receptor TGR5 on enteroendocrine L cells leads to glucagon-like peptide-1 (GLP-1) secretion. Drugs affecting bile acid binding (colesevelam (COL)) or reabsorption (metformin (MET)) seem to increase postprandial GLP-1 secretion in humans. We hypothesised that gallbladder emptying stimulates human GLP-1 secretion and that COL and MET, respectively, would potentiate any GLP-1 secretion induced by gallbladder emptying.

**Materials and methods:** Ten subjects (age (mean±SD): 23.4±3.8 years; BMI: 21.9±1.8 kg/m<sup>2</sup>; HbA1c: 5.1±0.3%) were studied on 6 randomised days. In a double-blind fashion the subjects received 1) COL (3.75 g); 2) MET (1.5 g); or 3) placebo (PLA) in 50 ml water admixed 1.5 g paracetamol (for evaluation of gastric emptying) administered via nasogastric tube, with a concomitant 60-minute iv infusion of saline and cholecystokinin-8 (CCK), respectively. Blood was sampled for 4 hours for measurements of plasma GLP-1, glucose, insulin, C-peptide and glucagon. Gallbladder emptying was measured by ultrasound. Food intake was assessed at the end of each day.

**Results:** CCK infusion during PLA induced complete gallbladder emptying and a significant GLP-1 response (incremental AUC) compared to saline infusion (392±173 (mean±SEM) vs. -277±94 pM×min, p=0.02). MET without CCK elicited a significant GLP-1 response (215±87 vs. -277±94 pM×min (saline+PLA), p=0.002), which was potentiated by CCK-induced gallbladder emptying (963±202 pM×min (CCK+MET), p=0.03). COL did not elicit significant GLP-1 responses. Plasma glucose was not affected by the interventions, nor was insulin, C-peptide, glucagon or food intake.

**Conclusion:** CCK-induced gallbladder emptying and single dose metformin, respectively, elicit robust and additive GLP-1 responses in humans. We, therefore, speculate that metformins mode of action includes stimulation of GLP-1 secretion by both bile acid-dependent and independent mechanisms.

## 533

**Effect of the bile acid chenodeoxycholic acid and the bile acid sequestrant colesevelam on glucose metabolism in patients with type 2 diabetes and in healthy control subjects**

M. Hansen<sup>1,2</sup>, M. Scheltema<sup>1,3</sup>, D.P. Sonne<sup>1,2</sup>, J.F. Rehfeld<sup>4</sup>, J.J. Holst<sup>2,5</sup>, T. Vilsbøll<sup>1</sup>, F.K. Knop<sup>1,2</sup>;

<sup>1</sup>Department of Internal Medicine, Gentofte Hospital, Diabetes Research Division, Hellerup, <sup>2</sup>University of Copenhagen, Department of Biomedical Sciences, Denmark, <sup>3</sup>University of Amsterdam, Department of Endocrinology and Metabolism, Netherlands, <sup>4</sup>Rigshospitalet, Department of Clinical Biochemistry, Copenhagen, <sup>5</sup>University of Copenhagen, Novo Nordisk Foundation Center for Metabolic Research, Denmark.

**Background and aims:** In patients with type 2 diabetes, rectal administration of bile acids, and oral bile acid sequestrants lower plasma glucose (PG). We evaluated the effects of chenodeoxycholic acid (CDCA) and the bile acid sequestrant colesevelam (COL), delivered by intragastric tube, on glucagon-like peptide-1 (GLP-1) (primary endpoint), PG, insulin, C-peptide, glucagon, cholecystokinin (CCK), gastric emptying, gallbladder volume, appetite and food intake, in a placebo-controlled, double-blinded study.

**Materials and methods:** On 4 separate days 10 patients with type 2 diabetes (age (mean±SD): 62±7 years, BMI: 28.9±2.3 kg/m<sup>2</sup>; HbA1c: 53±12 mmol/mol) and 10 matched healthy control subjects (age: 61±10 years, BMI: 28.2±3.2 kg/m<sup>2</sup>; HbA1c: 37±4 mmol/mol) received 1) CDCA (1.25 g); 2) COL (3.75 g), 3) CDCA+COL, or 4) placebo; suspended in 100 ml of water with 1.5 g paracetamol (for evaluation of gastric emptying). During 180 min blood was drawn, gallbladder volume was evaluated by ultrasound, and appetite perception was evaluated by visual analogue scale. At the end of each day ad libitum food intake was evaluated.

**Results:** In both the patients with type 2 diabetes and the healthy subjects, CDCA elicited a significant increase in GLP-1 vs. COL, CDCA+COL and placebo (p<0.05). While none of the interventions changed PG, CDCA elicited

a small but significant increase in C-peptide/PG ratio vs. COL, CDCA+COL and placebo in both groups. CDCA increased glucagon in both groups vs. COL, CDCA+COL and placebo. In the healthy control subjects, COL increased CCK significantly vs. CDCA, CDCA+COL and placebo, but not in patients with type 2 diabetes. CDCA slowed gastric emptying in both groups. COL tended to decrease gallbladder volume, whereas CDCA increased gallbladder volume. The interventions did not affect appetite perception or food intake.

**Conclusion:** Intragastric administration of CDCA increased GLP-1, insulin (measured as C-peptide/PG ratio) and glucagon secretion, and slowed gastric emptying. We speculate that the GLP-1 and subsequent insulin secretion is mediated by bile acid-induced TGR5 activation on L cells. Bile acid sequestration does not appear to have an acute effect on GLP-1 secretion in humans. *Clinical Trial Registration Number:* NCT01666223

**Early improvements in glucose metabolism after Roux-en-Y gastric bypass surgery are not explained by increased total bile acids or fibroblast growth factor 19**

N.B. Jørgensen<sup>1</sup>, C. Dirksen<sup>1</sup>, K.N. Bojsen-Møller<sup>1</sup>, V.B. Kristiansen<sup>2</sup>, B.S. Wulff<sup>3</sup>, J.J. Holst<sup>4</sup>, S. Madsbad<sup>1</sup>, T.R. Clausen<sup>3</sup>;

<sup>1</sup>Dept. of Endocrinology, Hvidovre Hospital, <sup>2</sup>Dept. of Surgery, Hvidovre Hospital, Køge, <sup>3</sup>Diabetes and Obesity Biology, Novo Nordisk A/S, Måløv,

<sup>4</sup>Dept. of Biomedical Sciences, University of Copenhagen, Denmark.

**Background and aims:** Bile acids and fibroblast growth factor 19 (FGF19) have been suggested as key mediators of the dramatic improvements in glucose metabolism after Roux-en-Y gastric bypass (RYGB). The aim of this study is to describe fasting and postprandial total bile acid (TBA) and FGF19 concentrations before and after RYGB and relate them to parameters of glucose metabolism.

**Materials and methods:** In this prospective study, we enrolled 13 patients with type 2 diabetes (T2D) (BMI: 42.8 [95% c.i.: 40.1-45.7] kg/m<sup>2</sup>) and 12 subjects with normal glucose tolerance (NGT) (BMI: 41.3 [38.8-44.0] kg/m<sup>2</sup>). They were subjected to a 4-hour liquid meal test before, 1 week, 3 months and 1 year after RYGB. Blood was sampled for TBA and FGF19 as well as markers of glucose metabolism. Effects of time after surgery and group were analyzed by analysis of variance (ANOVA) in a linear mixed effects model using time from surgery and group (T2D or NGT) as fixed effects and subjects as random effect.

**Results:** Fasting TBA concentrations decreased 1 week after RYGB in NGT subjects but increased gradually thereafter in both groups with time from surgery (T2D: pre: 1.3 μmol/L [0.7-2.4], 1 week: 1.3 [0.7-2.3], 3 months: 1.5 [0.8-2.6], 1 year: 3.3 [2.3-4.7]; NGT: 1.6 [1.1-2.4], 0.8 [0.4-1.5], 2.3 [1.6-3.4], 2.6 [1.8-3.7], ANOVA ptime<0.001). Fasting FGF19 concentrations were unchanged after RYGB (ptime=0.6). Postprandial TBA concentrations were unchanged in T2D patients and decreased in NGT subjects 1 week after RYGB but increased afterwards with time from surgery (AUC TBA: T2D: 627 mmol x min/L [410-958], 481 [250-926], 1091 [829-1438], 1818 [1395-2368], NGT: 639 [521-784], 402 [320-505], 1338 [1051-1703], 1497 [1218-2368], ptime<0.001). Changes in AUC FGF19 followed the same pattern as AUC TBA (ptime<0.001). No significant group differences of fasting or postprandial TBA and FGF19 concentrations were found. HOMA-IR decreased, beta-cell function improved, and GLP-1 secretion greatly increased shortly (1 week) after RYGB.

**Conclusion:** The lack of change or even decline in TBA and FGF19 shortly after RYGB suggests that altered bile acid metabolism does not contribute to the acute improvements in glucose metabolism early after RYGB. Later changes may play a role on the longer term.

### Inhibition of GIP receptor signalling in adipose tissue reduces insulin resistance in high fat diet-induced obesity

E. Joo, N. Harada, T. Fukushima, A. Hamasaki, S. Yamane, K. Iwasaki, D. Nasteska, K. Shibue, T. Harada, K. Suzuki, N. Inagaki; Department of Diabetes, Endocrinology and Nutrition, Graduate School of Medicine, Kyoto University, Japan.

**Background and aims:** Gastric inhibitory polypeptide (GIP) is an incretin that potentiates insulin secretion. GIP receptor (GIPR) is expressed not only in  $\beta$ -cells, but in adipose tissue as well, and previous *in vitro* studies show that GIP directly induces energy accumulation into the adipose tissue. Therefore, GIP has a direct and indirect effect (via insulin) on induction of adiposity. However, the effect of direct GIP action on adiposity *in vivo* remains unclear. In this study, we generated adipose tissue-specific GIPR-deficient mice (GIPRfat<sup>-/-</sup>) and clarified the direct GIP action in adipose tissue *in vivo*.

**Materials and methods:** GIPRfat<sup>-/-</sup> were generated from floxed GIPR mice (Lox) and adipocyte protein 2 (aP2)-Cre transgenic mice (aP2). GIPRfat<sup>-/-</sup>, Lox, and aP2 were fed normal fat diet (NFD: 10% fat) or high fat diet (HFD: 60% fat) and their body weight gain was measured. After 15 weeks of NFD or HFD feeding, oral glucose tolerance test (OGTT), insulin tolerance test (ITT), and histological analyses (liver and adipose tissue) were performed. Fat volume (CT scan), energy expenditure, activity count, and triglyceride (TG) content in liver were measured.

**Results:** In GIPRfat<sup>-/-</sup>, expression levels of GIPR mRNA were substantially lower in visceral and subcutaneous adipose tissue (90% reduction). Body weight gain, blood glucose levels, and insulin levels during OGTT did not differ among three types of mice under NFD condition. Under HFD condition, body weight gain was slightly lower in GIPRfat<sup>-/-</sup> compared to that of control mice (Lox and aP2). Fat volume and adipocyte size did not differ between HFD-fed GIPRfat<sup>-/-</sup> and control mice. OGTT data showed that insulin and glucose levels were significantly lower in HFD-fed GIPRfat<sup>-/-</sup> compared to control mice. HOMA-IR and ITT data showed that insulin resistance was reduced in HFD-fed GIPRfat<sup>-/-</sup>. Furthermore, fat content in liver was significantly lower in HFD-fed GIPRfat<sup>-/-</sup> compared to control mice. Histological analysis showed that hepatic steatosis was reduced in HFD-fed GIPRfat<sup>-/-</sup>. There was no significant difference in energy expenditure and mouse activity among three types of mice under HFD feeding.

**Conclusion:** GIP receptor signaling in the adipose tissue plays an important role in HFD-induced insulin resistance without increase in fat mass *in vivo*.

### The long-acting analogue of short-form GIP does not induce obesity in normal mice but ameliorates chronic hyperglycaemia in low-dose streptozotocin-induced diabetic mice

A. Fujita, T. Yanagimachi, K.K. Atageldiyeva, J. Honjo, Y. Takiyama, Y. Abiko, Y. Makino, M. Haneda; Department of Internal Medicine, Asahikawa Medical University, Japan.

**Background and aims:** It is still ambiguous whether GIP can be beneficial as potential therapeutics in the diabetic state. However, we reported that a short-isoform GIP, GIP (1-30), which is released chiefly from pancreatic alpha cells, may function not only as glucose-dependent insulin release in a paracrine manner, but also as the fetal islet development. Again, it is previously reported that GIP (1-30) less potentiates fat accumulation in contrast to GIP (1-42) secreted from the gut. To investigate the possibility of short-form GIP, we tested the efficacy of a long-acting GIP (1-30) analogue *in vivo* and investigated whether the analogue can suppress the progression to hyperglycaemia and improve glycaemia in low-dose streptozotocin (LD-STZ) mice.

**Materials and methods:** We synthesized dipeptidyl peptidase-4 (DPP-4) resistant GIP (1-30) analogue via modification of the second position alanine and then attaching 40kDa polyethylene glycol (PEG) to the C-terminus. First, we administered PEGylated (350–7000 pmol/body) or non-PEGylated GIP to the non-diabetic control mice by the subcutaneous single injection, and evaluated pharmacokinetics of the peptides from 60 min until day 7. To measure plasma GIP activity, we employed the novel receptor-mediated bioassay reflecting cAMP production *in vitro*. Then, we used non-diabetic and LD-STZ-induced diabetic mice, with or without administration of the PEGylated GIP analogue. We designated mice to four groups, non-STZ,

STZ, non-STZ+GIP, STZ+GIP, respectively. We injected the PEGylated GIP analogue or vehicle subcutaneously every 3 days (initial dose 100 pmol/body and maintenance dose 70 pmol/body) and monitored body weight and non-fasted blood glucose until day 30. We measured HbA1c levels and conducted intraperitoneal glucose tolerance tests (IPGTT) at the end. Finally, we evaluated the islet morphology via double immunofluorescent staining with insulin and glucagon.

**Results:** The single subcutaneous injection of PEGylated GIP analogue gradually increased GIP activity in plasma but maintained much longer (the approximate half-life was 48 hours), whilst the injection of non-PEGylated analogue rapidly increased the activity but vanished within 2 hours. The maximum-dose injection of PEGylated GIP still augmented to detect biological GIP activity until day 7. Persistent PEGylated GIP treatment neither induced obesity nor affected glycemic levels in non-STZ groups. In contrast, PEGylated GIP treatment significantly decreased non-fasted blood glucose levels, reduced HbA1c levels (STZ+GIP: 4.9±0.2% vs STZ: 5.7±0.4%,  $p<0.05$ ) and improved glucose excursion after IPGTT (STZ+GIP: 2465±114 vs STZ: 2961±166 min x mmol/l, AUC glucose,  $p<0.01$ ) in LD-STZ mice. GIP treatment did not significantly increase insulin levels after IPGTT. However, GIP treatment ameliorated alpha cell expansion in the islets concomitant with suppressing elevated plasma glucagon levels observed in non-treated LD-STZ mice (STZ).

**Conclusion:** Our results indicate that the PEGylated short-form GIP analogue is possibly durable enough to suppress the progression to overt hyperglycaemia with improving the islet function in LD-STZ-induced diabetic mice. *Supported by: JSPS JDF*

### Neural mechanisms contribute to islet effects of both GLP-1 and GIP

L. Ahlqvist, B. Åhrén; Medicine, Clinical Sciences, Lund, Sweden.

**Background and aims:** After meal intake, the incretin hormones glucagon-like peptide 1 (GLP-1) and glucose-dependent insulinotropic peptide (GIP) mediate 50–70% of  $\beta$ -cell insulin secretion. The rapid inactivation of the incretin hormones makes them very short-lived in the circulation which has questioned their role as circulatory hormones. Previous studies showing expression of GLP-1 receptors in vagal nerve cells and induction of electrical impulses in both afferent and efferent vagal nerve fibers by GLP-1 have instead indicated that the incretin hormones work through vagal nerve fibers. Therefore, the aim of this project was to examine whether blocking muscarinic receptors, i.e. the effector system of the cholinergic islet system, disrupts the insulinotropic effects of GLP-1 and GIP.

**Materials and methods:** Fasted anesthetized C57BL/6J female mice were given either saline or atropine methyl bromide (5 mg/kg) intraperitoneally 12 minutes before intravenous glucose administration (0.35 g/kg), co-injected with GLP-1 or GIP (both at 3 nmol/kg) via the tail vein. Blood was collected from the retrobulbar, intraorbital capillary plexus before and at 1, 5, 10, 20, 30 and 50 minutes after intravenous challenge for analysis of plasma glucose (glucose oxidase) and insulin (ELISA). Pancreatic islets were isolated by collagenase digestion and incubated (1h) in 2.8 and 11.1 mM glucose, with or without the presence of atropine (100  $\mu$ M), GLP-1 (100 nM), GIP (100 nM), atropine (100  $\mu$ M)/GLP-1 (100 nM) or atropine (100  $\mu$ M)/GIP (100 nM). The supernatant was analyzed for insulin.

**Results:** Atropine significantly reduced the insulin response to glucose + GLP-1 compared to saline (5 min: 1.2±0.2 vs. 2.5±0.4 nM,  $P<0.01$ ). Similarly, atropine also reduced the insulin response to glucose + GIP (5 min: 1.6±0.3 vs. 2.7±0.5 nM,  $P<0.05$  and 10 min: 0.6±0.1 vs. 1.4±0.3 nM,  $P<0.05$ ). Atropine did not affect the insulin response to glucose alone. In contrast, during islet incubations atropine did not affect the insulin secretory responses to GLP-1 or GIP.

**Conclusion:** We show here that blocking of muscarinic signaling by atropine markedly suppresses the insulinotropic effect of both GLP-1 and GIP *in vivo* but not in isolated islets. Based on these results, together with the finding of incretin hormone receptors on vagal nerve fibers, we therefore suggest that neural mechanisms contribute to the islet effects of both GLP-1 and GIP. Since only low levels of circulating intact incretin hormones reach the islets, parasympathetic vagal regulation of insulin secretion may therefore be an important component of the incretin effect.

### Effects of exogenous glucagon-like peptide-1 on the blood pressure, heart rate, mesenteric blood flow and glycaemic responses to intraduodenal glucose in older subjects

L.G. Trahair<sup>1,2</sup>, M. Horowitz<sup>1,2</sup>, T. Hausken<sup>3</sup>, C. Feinle-Bisset<sup>1,2</sup>, C.K. Rayner<sup>1,2</sup>, K.L. Jones<sup>1,2</sup>;

<sup>1</sup>Discipline of Medicine, The University of Adelaide, <sup>2</sup>NHMRC Centre of Research Excellence in Translating Nutritional Science to Good Health, The University of Adelaide, Australia, <sup>3</sup>Section for Gastroenterology, Department of Clinical Medicine, University of Bergen, Norway.

**Background and aims:** A postprandial fall in blood pressure (BP) occurs frequently in healthy older subjects and type 2 patients, the magnitude of which is related to the rate of gastric emptying (GE) and rise in splanchnic blood flow. Postprandial hypotension (PPH) is now recognised as an important clinical problem in these groups. In humans, exogenous glucagon-like peptide-1 (GLP-1) has been reported to increase BP in two studies, but not another, while clinical trials of GLP-1 agonists in type 2 diabetes and obesity have reported a modest reduction in BP and a rise in heart rate (HR). Studies relating to the cardiovascular effects of GLP-1 and its agonists have not, however, discriminated between fasting, as opposed to postprandial, BP and HR. The aims of this study were to determine whether exogenous GLP-1 modulates the effects of an intraduodenal (ID) glucose infusion on BP, HR and splanchnic blood flow in healthy older subjects.

**Materials and methods:** On two separate days, 10 healthy 'older' subjects (9M,1F; age 73 ± 2 yr) received an infusion of GLP-1 (0.9 pmol/kg/min IV), or saline for 90 min (t = -30 - 60 min) in random order. Between t = 0 - 60 min, ID glucose was infused at 3 kcal/min. BP and HR were assessed with an automated device (Dinamap, GE Medical Systems), superior mesenteric artery (SMA) flow by Doppler ultrasonography and blood glucose and serum insulin were also measured. Results are shown (mean ± SEM).

**Results:** During the 'fasting' period (t = -30 - 0 min), GLP-1 had no effect on BP (P = 0.40) or HR (P = 0.59). In response to ID glucose (t = 0 - 60 min), systolic BP decreased (P < 0.001; Figure 1A), and both HR (P < 0.001; Figure 1B) and SMA flow (P < 0.05; Figure 1C) increased, on both days. GLP-1 attenuated the maximum fall in systolic BP (saline: -14 ± 3 vs. GLP-1: -9 ± 2 mmHg; P < 0.05), tended to increase the maximum rise in HR (saline: 13 ± 3 vs. GLP-1: 15 ± 3 BPM; P = 0.09) and increased the maximum rise in SMA flow (saline: 500 ± 52 vs. GLP-1: 837 ± 102 ml/min; P < 0.01). GLP-1 diminished the peak glycaemic response to ID glucose (saline: 10.3 ± 0.5 vs. GLP-1: 9.3 ± 0.3 mmol/L; P < 0.05) and increased the AUC 0 - 60 min insulin/glucose ratio (saline: 3.5 ± 0.7 vs. GLP-1: 4.9 ± 0.9; P < 0.05).

**Conclusion:** In healthy older subjects, acute administration of GLP-1 attenuates the hypotensive response to ID glucose, apparently independent of changes in HR, and potentiates the increase in SMA flow. Given that GLP-1 also slows GE, a role in the management of PPH warrants evaluation.

### Impaired incretin effect and gastrointestinal-mediated glucose disposal in non-diabetic patients with cirrhosis

F.K. Knop<sup>1</sup>, L. Gluud<sup>2</sup>, A.E. Junker<sup>1</sup>, J.J. Holst<sup>3</sup>, T. Vilsbøll<sup>1</sup>;

<sup>1</sup>Diabetes Research Division, Gentofte, <sup>2</sup>Department of Gastroenterology, Hvidovre, <sup>3</sup>Department of Biomedical Science, Copenhagen, Denmark.

**Background and aims:** Cirrhosis is often complicated by glucose intolerance, but the pathogenesis not yet completely understood. We evaluated the incretin effect and gastrointestinal-mediated glucose disposal (GIGD) in non-diabetic patients with biopsy-verified liver cirrhosis.

**Materials and methods:** Patients with compensated cirrhosis (Child Pugh A or B) and matched healthy controls underwent a 4h 50g-oral glucose tolerance test (OGTT) and an isoglycaemic intravenous glucose infusion (IIGI) on two separate days. We calculated the incretin effect [ $100\% \times (\text{AUCC-peptide, OGTT} - \text{AUCC-peptide, IIGI} / \text{AUCC-peptide, OGTT})$ ], the GIGD

[ $100\% \times (\text{glucoseOGTT} - \text{glucoseIIGI} / \text{glucoseOGTT})$ ] and insulin resistance (according to the homeostatic model assessment (HOMAIR)). Characteristics of participants are summarised as median±interquartile range and compared using non-parametric analyses.

**Results:** Ten patients (5 women) with cirrhosis (age: 54±15 years; BMI: 26±6 kg/m<sup>2</sup>; fasting plasma glucose (FPG): 5.8±0.7 mM; HbA1c: 38±6 mmol/mol (5.6±0.4%)) and 10 matched healthy controls (age: 58±17 years; BMI: 29±1 kg/m<sup>2</sup>; FPG: 5.2±0.4 mM; HbA1c: 34±6 mmol/mol (5.5±0.2%)) were included. Patients with cirrhosis were more glucose intolerant (AUCOGTT: 609±458 (cirrhosis) vs. 180±109 mM×min (controls), P<0.01) and insulin resistant (HOMAIR: 3.7±4.9 (cirrhosis) vs. 2.6±1.4 (controls), P<0.05) than controls. Isoglycaemia was achieved using 35±12 g of glucose in patients with cirrhosis and 24±10 g in healthy controls (P<0.01). Patients with cirrhosis had impaired incretin effect (35±44 (cirrhosis) vs. 55±30% (controls), P<0.01) and GIGD (30±23 (cirrhosis) vs. 52±20% (controls), P<0.01).

**Conclusion:** Non-diabetic patients with cirrhosis exhibit impaired incretin effect and GIGD, which may contribute to the glucose intolerance associated with cirrhosis.

### Gastrointestinal-mediated glucose disposal in total pancreatectomised patients

A. Lund<sup>1,2</sup>, J.I. Bagger<sup>1,2</sup>, M. Christensen<sup>1,2</sup>, M. Grøndahl<sup>1,2</sup>, E.R. Mathiesen<sup>3</sup>, C.P. Hansen<sup>4</sup>, J. Storkholm<sup>4</sup>, S. Larsen<sup>1</sup>, J.J. Holst<sup>2</sup>, T. Vilsbøll<sup>1</sup>, F.K. Knop<sup>1,2</sup>;

<sup>1</sup>Diabetes Research Center, Gentofte Hospital, <sup>2</sup>Department of Biomedical Sciences, University of Copenhagen, <sup>3</sup>Center for Pregnant Women with Diabetes, Department of Endocrinology, <sup>4</sup>Department of Gastrointestinal Surgery, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Gastrointestinal-mediated glucose-disposal (GIGD) after OGTT reflects the percentage of glucose disposal caused by the oral route of glucose administration. It accounts for as much as 70% in healthy subjects. Mediators of GIGD may include the incretin hormones, gut microbiota, first-pass hepatic uptake of glucose, and at present unknown factors. It is likely that incretin-mediated potentiation of pancreatic insulin secretion constitutes a major contributor to GIGD, but so far, it has not been possible to discriminate between pancreatic and extrapancreatic mechanisms underlying GIGD. We aimed to evaluate the impact of extrapancreatic effects on GIGD.

**Materials and methods:** Data from 7 total pancreatectomised patients (age: 61±4 years; BMI: 22.3±1.4 kg/m<sup>2</sup>; HbA1c: 63±4 mmol/mol (mean±SEM)) and 8 healthy control subjects (age: 58±3 years; BMI 23.2±0.9 kg/m<sup>2</sup>; HbA1c: 32±2 mmol/mol) were included in the present analysis. Participants were examined over two experimental days: a 75g-OGTT and a corresponding isoglycaemic i.v. glucose infusion (IIGI). Difference between administered glucose during OGTT and IIGI within the group of pancreatectomised patients were used to evaluate the impact of extrapancreatic mechanisms on GIGD.

**Results:** In healthy control subjects, 27±2 g of glucose was infused intravenously to copy the plasma glucose profile from the 75g-OGTT, resulting in a GIGD of 65±2%. In total pancreatectomised patients we used 76±3 g of glucose to copy the plasma glucose profile from the 75g-OGTT, resulting in a GIGD of -2±5% (i.e. that the pancreatectomised subjects disposed of i.v. and oral glucose similarly).

**Conclusion:** The low GIGD in pancreatectomised patients suggests that extrapancreatic factors do not play a major role in GIGD. The need for a larger glucose load on the IIGI day could however point to the existence of gut-derived factors (e.g. gut-derived glucagon) contributing to a worsening of oral glucose tolerance in pancreatectomised patients.

## 541

**Preserved incretin effect despite significant hyperinsulinaemia following glucose loading in South Asians, in comparison to Caucasians**R. Ahluwalia<sup>1</sup>, T.L. Vilsboll<sup>2</sup>, L. Ranganath<sup>1</sup>, J.J. Meier<sup>3</sup>, J. Vora<sup>1</sup>, F.K. Knop<sup>2</sup>;<sup>1</sup>The Royal Liverpool & Broadgreen University Hospitals NHS Trust, Liverpool, UK, <sup>2</sup>Diabetes Research Division, Copenhagen University Hospital Gentofte, Denmark, <sup>3</sup>Department of Medicine, St. Josef-Hospital, Ruhr-University, Bochum, Germany.

**Background and aims:** Circulating hyperinsulinaemia in normal glucose tolerant South Asians is reflective of underlying insulin resistance. Role of incretin hormones in this adaptive islet response in South Asians, remains to be explored. Our study aims to investigate the incretin effect in matched groups of South Asians and Caucasians.

**Materials and methods:** Ten South Asian subjects (age: 34±4 years (mean±SEM); BMI 24.5±1 kg/m<sup>2</sup>; fasting plasma glucose (FPG): 4.8±0.2 mmol/l) and twelve age and BMI-matched Caucasian subjects (age: 31±3 years; BMI 24.6±1 kg/m<sup>2</sup>; FPG: 4.6±0.1 mmol/l) with normal glucose tolerance were recruited. On two different days, subjects underwent a 4h 50g-OGTT and an isoglycaemic i.v. glucose (20%) infusion (IGII), respectively, involving sampling of insulin, C-peptide, glucagon and incretin hormones. The incretin effect was measured using the following formula based on beta cell secretory responses (AUCs):  $100 \times (\text{AUC}_{\text{OGTT}} - \text{AUC}_{\text{IGII}}) / \text{AUC}_{\text{OGTT}}$

**Results:** Fasting insulin levels were higher in South Asians vs. Caucasians (12.0±1.6 vs. 8.0±0.8 mU/l, p=0.02). The oral glucose curves were replicated successfully during the IGII studies. The integrated insulin responses after OGTT and IIGI, respectively, were significantly higher in South Asians vs. Caucasians (OGTT: 10239±1683 vs. 5377±616 mU/l x min, p=0.008; IGII: 5610±1347 vs. 2703±321 mU/l x min, p=0.03). Incretin effects were similar in the two groups (48±6 vs. 49±2%, p=0.8).

**Conclusion:** Our findings show preserved incretin effect despite insulin resistance and hyperinsulinaemia in normal glucose tolerant South Asians.

## 542

**Difference in insulin responsiveness between meal- and glucagon-loading test in Japanese type 2 diabetes**T. Kitamoto<sup>1,2</sup>, E. Nara<sup>2</sup>, Y. Matsuzawa<sup>2</sup>, J. Saito<sup>2</sup>, M. Omura<sup>2</sup>, T. Nishikawa<sup>2</sup>;<sup>1</sup>Clinical Cell Biology and Medicine, Chiba University,<sup>2</sup>Endocrinology and Diabetes Center, Yokohama Rosai Hospital, Japan.

**Background and aims:** Responsiveness of c-peptide (CPR) to mixed meal tolerance test (MT) is a useful marker to evaluate the insulin secretion ability such as postprandial responsiveness of insulin production in type 2 diabetes. On the other hand, the total capacity of endogenous insulin secretion can be examined by the response of CPR after glucagon loading test (GT). Basal ability of insulin production was reported to be relatively impaired in Japanese type 2 diabetes, rather than Western patients, suggesting that incretin-related agents can be much more effective for glycemic control in Japanese than Western patients. Then, we tried to compare the responsiveness of CPR to MT and GT in Japanese type 2 diabetes for clarifying effectiveness of incretin-based therapy, such as DPP4 inhibitor (DPP4i) or GLP-1 analog (GLP-1A).

**Materials and methods:** We enrolled 95 Japanese type 2 diabetes patients prescribed DPP4i or GLP-1A from 2011 to 2012. CPR response ( $\Delta$ CPR) to MT and GT was analyzed. Then, we divided the patients into 2 groups; controlled patients who reached glycemic target (HbA1c<7.0%) and uncontrolled patients whose HbA1c was over 8.0% at 6 months after each treatment. We compared the clinical characteristics and responsiveness of CPR to MT with those to GT.

**Results:** DPP4i and GLP-1A were individually used in 47 and 48 patients, respectively. CPR response to MT was significantly higher in 29 cases than 7 uncontrolled patients among 47 patients treated with DPP4i (3.5±2.0 vs. 1.9±1.3 (ng/ml); p=0.022). CPR response to GT was significantly higher in 16 cases than 22 uncontrolled patients among 48 patients treated with GLP-1A (2.1±0.8 vs. 1.3±0.8 (ng/ml); p=0.003). The ROC analysis in each group showed optimal cut off point of  $\Delta$ CPR by MT was under 2.0 ng/ml in cases showing HbA1c>8.0% in DPP4i-treated group, while in GLP-1A-treated group, that of  $\Delta$ CPR by GT was over 1.39 and under 1.26 ng/ml in cases showing HbA1c<7.0% and HbA1c>8.0%, respectively. Moreover, 86% of uncontrolled patients by DPP4i-treatment showed more than 1.39 in  $\Delta$ CPR in GT, suggesting that they can be successfully treated with GLP-1A.

**Conclusion:** The present study clearly demonstrated that the gut-mediated insulin secretion estimated by MT can predict the efficacy of DPP4i, while total capacity of cAMP-mediated insulin secretion examined by GT may predict usefulness of GLP-1A. We can, therefore, simply decide whether DPP4i or GLP-1A might be effective for controlling hyperglycemia in Japanese type 2 diabetes by performing MT and GT.

## PS 032 Novel approaches for identifying and targeting determinants of glucose tolerance

543

**Glypican-4 is increased in human subjects with impaired glucose tolerance and decreased in patients with newly diagnosed type 2 diabetes**

H. Wang<sup>1,2</sup>, L. Li<sup>1,2</sup>, K. Li<sup>3</sup>, G. Yang<sup>3</sup>,

<sup>1</sup>College of Laboratory Medicine, <sup>2</sup>Key Laboratory of Diagnostic Medicine (Ministry of Education), <sup>3</sup>Department of Endocrinology and Department of Surgery, Chongqing Medical University, China.

**Background and aims:** Glypican-4 (GPC-4), a membrane-bound hormone owing to a glycosyl-phosphatidylinositol (GPI) anchor, is synthesized and secreted by adipose tissues. GPC-4 differentially expressed in visceral and subcutaneous adipose tissue, and the expression in human white adipose tissue (WAT) was highly correlated with BMI and the WHR. However, no report has demonstrated the relationship of circulating levels of GPC-4 with impaired glucose tolerance (IGT) or T2DM in humans. The aim of the current study is to investigate whether GPC-4 correlates with obesity and insulin resistance by cross-sectional and interventional studies on anthropometric, metabolic, and hormonal predictors of circulating GPC-4.

**Materials and methods:** Circulating GPC-4 was measured with ELISA in subjects with NGT, IGT, and nT2DM who are involved in the study from June 1, 2013 to November 10, 2013. EHC were performed in healthy and T2DM subjects. Plasma glucose was measured by the glucose oxidase method. HbA1c was measured by HPLC. Plasma insulin was measured by radioimmunoassay. Plasma FFA was measured with a commercial kit. Total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, and triglycerides were analyzed enzymatically using an autoanalyzer. Real-time RT-PCR and Western blotting were used to assess mRNA and protein expression of GPC-4.

**Results:** Circulating GPC-4 levels were significantly higher in IGT subjects and lower in nT2DM subjects compared to controls. Circulating GPC-4 was positively correlated with BMI, WHR, HOMA-IS and FAT%, while it was inversely correlated with FBG and HbA1c. Excluding diabetic subjects, increasing GPC-4 levels were associated with HOMA-IR and M values ( $r = 0.247$  and  $r = -0.491$ ; both  $P < 0.05$ ). In T2DM patients, GPC-4 mRNA expression were significantly reduced by 35 % in muscle and 28 % in fat compared to normal controls (both  $P < 0.05$ ). GPC-4 protein levels were significantly reduced by about 51 % in both muscle and fat relative to normal subjects (both  $P < 0.05$ ). GPC-4 levels were significantly increased upon an oral glucose intake. The secretion of GPC-4 exhibited a characteristic diurnal rhythm in humans, with a major rise occurring between afternoon and midnight.

**Conclusion:** The present study revealed a difference in GPC-4 levels in normal, IGT and nT2DM subjects as well as a significant association between circulating GPC-4 levels and IGT or nT2DM and various anthropometric and metabolic parameters. Our results demonstrated for the first time that circulating GPC-4 concentrations were increased in IGT subjects and reduced in nT2DM subjects. We have also demonstrated that GPC-4 was associated with some metabolic or obesity related parameters, and that GPC-4 was affected by an oral glucose challenge. We also found evidence to suggest that the down-regulation of GPC-4 expression in muscle and adipose tissues may be responsible for the reduced circulating GPC-4 levels in T2DM patients. Thus, our data suggest that GPC-4 is likely to play a major role in the development of obesity, insulin resistance, and T2DM in humans.

**Bombesin receptor subtype-3 (BRS-3) and its synthetic agonist: therapeutic tandem for obese/type 2 diabetic patients**

N. González<sup>1</sup>, A. Martín-Duce<sup>2</sup>, F. Martínez-Arrieta<sup>3</sup>, I. Ramos-Álvarez<sup>4</sup>, Z. Moreno-Villegas<sup>4</sup>, S. Portal-Núñez<sup>5</sup>, R. Sanz<sup>5</sup>, J. Egido<sup>4</sup>;

<sup>1</sup>IIS-Fundación Jiménez Díaz-CIBERDEM-UAM, <sup>2</sup>Universidad de Alcalá,

<sup>3</sup>Hospital Universitario Puerta de Hierro, <sup>4</sup>IIS-Fundación Jiménez Díaz-

CIBERDEM, <sup>5</sup>IIS-Fundación Jiménez Díaz, Madrid, Spain.

**Background and aims:** BRS-3 gene/protein expressions are lower than normal (N) in skeletal muscle from obese (OB) or type 2 diabetic (T2D) patients; moreover in myocytes from all three groups, insulin-mimetic effects of [D-Tyr6,β-Ala11,Phe13,Nle14]bombesin6-14—synthetic BRS-3 agonist—, have been reported (v.g.: kinase phosphorylation increases, glucose metabolism improving). Also, our previous data related to BRS-3, in patients simultaneously diagnosed with obesity and type 2 diabetes (OB/T2D), pointed out its potential therapeutic interest, leading the current study in: A) pieces of skeletal muscle from OB/T2D—BRS-3 expression—; B) primary cultured myocytes from OB/T2D patients, —BRS-3 signalling pathways, by using [D-Tyr6,β-Ala11,Phe13,Nle14]bombesin6-14, and confirmed its effect on glucose transport (GT) and glycogen synthase activity (GSA)—.

**Materials and methods:** 10 OB/T2D patients (3F/7M; age:49±3 yrs; glucose:112±6 mg/dl; cholesterol:184±9 mg/dl; triglycerides:143±18 mg/dl; Dianben treatment) and 23 N subjects (19F/4M; age:50±3; glucose:96±2; cholesterol:185±8; triglycerides:98±9) undergoing surgery, previous informed consent given, were included. BRS-3 gene expression -RT-PCR-, BRS-3 protein, PKB, p70s6K, p42/44MAPKs and p90RSK1 phosphorylation -Western Blot-, GT and GSA -glucose precursors-; insulin acted as positive control. ANOVA (Levene/Bonferroni test; using SPSS 21.000) was performed;  $p < 0.05$  significant value.

**Results:** In OB/T2D muscle pieces, BRS-3 mRNA level (23.6±1.3 times down-regulated,  $p < 0.0001$ ;  $n = 5$ ) and protein values (49±7% of N,  $p < 0.05$ ;  $n = 3$ ) were lower compared to N. In primary cultured myocytes from 5 OB/T2D, the phosphorylation basal values of all kinases were reduced ( $p < 0.05$ ), compared to normal state. BRS-3's agonist at 10-11 up 10-8M, slightly increased PKB phosphorylation (overallmean:126±2% control,  $p < 0.02$ ), being reduced compared to that exerted by insulin (10-9M:143±4%). At 10-10M ligand, p70s6K activation (136±10% control,  $p = 0.035$ ), and 10-9M insulin (132±8%,  $p = 0.037$ ) were equal; no increments compared to basal were detected at higher agonist concentrations (10-9 up 10-8M; overallmean: 109±4%). The ligand at 10-11M, induced maximal phosphorylation of MAPKs (p42:159±15% control; p44:166±11%;  $p < 0.0001$ ), and p90RSK1 increase was showed at 10-11M compound (148±2%,  $p < 0.0001$ ), being at 10-10 up 10-8M (overallmean:133±3%), identical to that detected at 10-9M insulin (133±4%). In OB/T2D myocytes, BRS-3-agonist stimulated GT, already detected at 10-12M (133±9% control), maximal at 10-11M (160±9%,  $p < 0.0001$ ) and maintained up to 10-8M (overallmean: 153±7%,  $p < 0.007$ ); this action was lower to that detected at 10-8M insulin (202±9%,  $p = 0.009$ ). The effect of the agonist on GSA, achieved the maximum at 10-11M (165±16% control;  $p < 0.0001$ ), which was not different, from that obtained at higher concentrations 10-10 up 10-8M (overallmean: 145±5%;  $p < 0.008$ ).

**Conclusion:** Taken together these results from samples, which combine two major metabolic diseases -obesity and type 2 diabetes-, confirm that BRS-3 receptor and its agonist could be useful as a therapeutic tandem also for OB/T2D patients.

**Insight into the molecular mechanism of action of BTI320, a non-systemic novel drug to control serum glucose levels in individuals with diabetes**

K. Mayo<sup>1</sup>, M.C. Miller<sup>2</sup>, Y. Bobruff<sup>3</sup>, P. Sheehan<sup>4</sup>, D. Platt<sup>4</sup>, C.G. Parkin<sup>5</sup>;

<sup>1</sup>University of Minnesota Health Sciences Center, Minneapolis,

<sup>2</sup>Department of Biochemistry, University of Minnesota Health Sciences

Center, Minneapolis, <sup>3</sup>Research, Boston Therapeutics, Manchester, <sup>4</sup>Boston

Therapeutics, Manchester, <sup>5</sup>CGParkin Communications, Inc., Boulder City,

USA.

**Background and aims:** Starch is an  $\alpha(1 \Rightarrow 4)$ -linked polymer of glucose, which is enzymatically digested or hydrolyzed down to smaller polysaccharides (e.g. dextrin) and then onto smaller sugars like maltotriose and maltose, and eventually to glucose. The key enzymes responsible for the breakdown of starch

are generally called  $\alpha$ -glycosidases, with  $\alpha$ -amylase being primary among them. BTI320 is a novel, non-systemic therapy that safely reduces postprandial glucose excursions with reduced side effects compared with acarbose. Acarbose is a natural microbial pseudo-tetrasaccharide that binds reversibly and competitively to the oligosaccharide binding site of  $\alpha$ -glycosidases. BTI320 is composed of non-glucose-containing polysaccharides. It is essentially a composite of two modified galactomannans: GM- $\alpha$  (1 $\Rightarrow$ 1) linked polymer; and GM- $\beta$  (1 $\Rightarrow$ 4) linked polymer. We believe that BTI320 functions by targeting several polysaccharide hydrolyzing enzymes and that the active ingredient is GM- $\alpha$ .

**Materials and methods:** The present study was focused on assessing the molecular mechanism of action of BTI320 in relationship to  $\alpha$ -amylase. We used  $^1\text{H}$  and  $^{13}\text{C}$  nuclear magnetic resonance (NMR) spectroscopy to investigate interactions between BTI320 components, GM- $\alpha$  and GM- $\beta$ , and the enzyme  $\alpha$ -amylase, as well as the effects that GM- $\alpha$  and GM- $\beta$  have on the rates of amylase-mediated starch hydrolysis towards glucose. The amylose iodine assay was also used to assess starch hydrolysis. Results are compared with those on acarbose.

**Results:** Chemical shift changes in NMR spectra of  $\alpha$ -amylase demonstrate that GM- $\alpha$  interacts with the enzyme, possibly at or near its active site; GM- $\beta$  appears to have no effect on  $\alpha$ -amylase. GM- $\alpha$  and GM- $\beta$  both interact with starch and apparently change the amylose structure, thus affecting how amylase hydrolyses the starch. Under certain conditions, the rate constants for starch (1 mg/ml) hydrolysis with  $\alpha$ -amylase goes from 22.5 s $^{-1}$  in the absence of GM- $\alpha$  to 2.7 s $^{-1}$  in the presence of 4 mg/ml GM- $\alpha$  ( $p < 0.005$ ). The effect on the rate of starch hydrolysis with acarbose is similar, but at acarbose concentrations of about 100-fold less. In addition, comparison of NMR data on  $\alpha$ -amylase with GM- $\alpha$  and acarbose suggest that GM- $\alpha$  binds at or near the same site on the enzyme as acarbose.

**Conclusion:** GM- $\alpha$  acts as an inhibitor, possibly competitive, of  $\alpha$ -amylase function, and appears to be the active ingredient in BTI320. Our findings provide insight into how BTI320 may function in vivo and support the potential viability of BTI320 as an alternative to acarbose therapy for glycemic control.

### Different clinical responses to exenitide, insulin and pioglitazone are associated with TNF-857C/T polymorphism in newly diagnosed type 2 diabetic patients

H. Xu<sup>1</sup>, W. Xu<sup>1</sup>, W. Ren<sup>1</sup>, Z. Chen<sup>1</sup>, F. Xu<sup>1</sup>, K. Zeng<sup>1</sup>, J. Weng<sup>1</sup>, X. Ma<sup>2</sup>;

<sup>1</sup>The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China,

<sup>2</sup>Weill Cornell Medical College, New York, USA.

**Background and aims:** TNF- $\alpha$  is one of the pivotal proinflammatory cytokines contributing to insulin resistance. Yet the association of TNF-1031T/C-863C/A-857C/T genotype with clinical efficacy of exenitide, insulin or pioglitazone in type 2 diabetes has not been explored.

**Materials and methods:** Newly diagnosed and drug-naïve type 2 diabetic patients with HbA<sub>1c</sub> between 7% and 10% were enrolled nationwide. All patients were randomly assigned to exenitide, insulin or pioglitazone group. TNF-1031T/C-863C/A-857C/T polymorphisms were obtained by genomic DNA sequencing. Clinical efficacy were evaluated by examining changes of HbA<sub>1c</sub>, both fasting and 2 hour postprandial plasma glucose, insulin levels, HOMA-B, HOMA-IR, lipid profiles after one year treatment with anti-hyperglycemic agents mentioned as above and were analyzed according to different genotype groups. Molecular mechanisms of TNF polymorphisms on transcriptional regulation were investigated by constructing luciferase reporters carrying the corresponding single nuclear polymorphism followed by transient transfection in RAW264.7 cells and electrophoretic mobility shift assay.

**Results:** Ten different TNF-1031T/C-863C/A-857C/T genotypes were found in 382 enrolled patients. All baseline parameters were comparable among different TNF genotype groups. One year treatment of each agent effectively decreased HbA<sub>1c</sub>, fasting and 2 hour postprandial plasma glucose levels ( $P < 0.05$ ). Weight gain was observed by the end of insulin therapy in all genotype groups, which resulting an increase of HOMA-IR accordingly ( $P < 0.05$ ). However, exenitide and pioglitazone reduced HOMA-IR significantly in patients with TNF-1031TT-863CC-857CC genotype (TCC) (before vs after: 1.58 $\pm$ 0.62 vs 1.22 $\pm$ 1.10, 1.68 $\pm$ 0.63 vs 0.97 $\pm$ 1.02, respectively,  $P < 0.05$ ). On the contrary, no statistically changes of HOMA-IR was induced in TNF-1031TT-863CC-857CT genotype carriers (TCT) by the same medications (1.77 $\pm$ 0.50 vs 1.42 $\pm$ 1.01, 1.49 $\pm$ 0.78 vs 1.24 $\pm$ 0.83). Exenitide induced a comparably dramatic weight loss as to 4.7% in TCC patients and 4.5% in TCT ones (both

$P < 0.05$ ), waist and hip circumferences decreased in the former (before vs after, 89.95 $\pm$ 8.25 vs 87.35 $\pm$ 9.00, 98.08 $\pm$ 5.35 vs 95.35 $\pm$ 6.68 cm, respectively,  $P < 0.05$ ) while not in the latter (before vs after, 87.72 $\pm$ 16.14 vs 86.81 $\pm$ 10.45, 95.92 $\pm$ 16.30 vs 96.00 $\pm$ 7.06 cm, respectively). In vitro studies demonstrated that human TNF-857T-allele containing luciferase reporter exhibited over 2 fold greater transcriptional activity than that of the -857C allele across all experimental conditions: unstimulated or stimulated with LPS, IFN- $\gamma$ , or both. EMSA analyses with biotin-labeled -857C- or T-allele probes revealed differential nuclear DNA-binding activities that were stronger with the C allele than the T allele, which transcriptional factor OCT1 could bind. And overexpression of OCT1 totally diminished differences of luciferase activity between -857T-allele and -857C-allele.

**Conclusion:** TNF-857T showed an OCT1 mediated, constitutively up-regulated transcriptional activities of TNF gene, which may restrain the effect of insulin resistance improvement of exenitide and pioglitazone in Chinese type 2 diabetic patients.

### The effect of atorvastatin vs pravastatin on glucose homeostasis in the Otsuka Long-Evans Tokushima Fatty (OLETF) rats

S. Moon<sup>1,2</sup>, E.-S. Kim<sup>1,3</sup>, J.-H. Lee<sup>1</sup>, S. Kim<sup>1</sup>, E.-Y. Mo<sup>1</sup>, J.-H. Han<sup>1</sup>, Y.-B. Ahn<sup>2</sup>, H.-S. Son<sup>3</sup>;

<sup>1</sup>Division of Endocrinology and Metabolism, The Catholic University of Korea, Incheon, <sup>2</sup>The Catholic University of Korea, Suwon,

<sup>3</sup>The Catholic University of Korea, Uijeongbu, Republic of Korea.

**Background and aims:** New-onset diabetes has been observed in clinical trials and meta-analyses involving statin therapy. Controversy exists regarding the effects of statin treatment on progressive insulin resistance. To investigate the effect of atorvastatin (AS) vs pravastatin (PS) on glucose homeostasis in the Otsuka Long-Evans Tokushima Fatty (OLETF) rats.

**Materials and methods:** Thirty OLETF rats of 10 weeks of age were randomly divided into 3 groups: untreated (n=10); AS-treated (n=10); PS-treated (n=10) rats. As normal control rats (n=10), Long-Evans Tokushima Otsuka (LETO) were used. OLETF rats were either untreated or treated with AS (100 mg/kg per day) or PS (25 mg/kg per day) from 12 weeks of age for 24 weeks. We measured daily food intake, weekly body weight and casual blood glucose levels. At 20 and 36 weeks of age, an oral glucose tolerance test (OGTT) was performed from the tail vein after overnight fasting.

**Results:** Food intake and casual blood glucose levels did not show significant differences among OLETF rats during the periods of studies. However, compared with untreated OLETF rats, body weight was decreased significantly at 31 to 35 weeks of age in PS-treated rats. Long-term treatment with statins, either from 12 or 36 weeks of age, mean fasting blood glucose, insulin, GIP and glucagon levels were not statistically different among OLETF rats. However, fasting GLP-1 level at 20 weeks and stimulated 30 min GLP-1 level at 36 weeks were significantly low in statin treated OLETF rats compared with untreated OLETF rats ( $p < 0.002$ ), in addition, fasting C-peptide level at 36 weeks was significantly decreased in PS-treated OLETF rats compared with untreated OLETF rats,  $p < 0.023$ ). Kitt, HOMA-IR and  $\beta$ -cell mass at 20 or 36 weeks of age were not significantly different between three treated OLETF rats compared with untreated OLETF rats.

**Conclusion:** The results suggest that long-term treatment with statin did not increased blood glucose levels, however, statin therapy might be associated with a decrease of GLP-1 levels over 20 weeks of age in statin treatment rat model of spontaneously developing type 2 DM. Taken together with previous reports, present study imply a role for affecting incretin physiology by statin.

## 548

**The identification of novel metabolites that track with improvements in glycaemia following a 12-week lifestyle intervention in high risk individuals**

A. Kennedy<sup>1</sup>, J. Cobb<sup>2</sup>, G. O'Donoghue<sup>3</sup>, G. Anderson<sup>3</sup>, N. McCaffrey<sup>1</sup>, S. Cleary<sup>1</sup>, E. Durkan<sup>1</sup>, H. Kenny<sup>1</sup>, J. Monedero<sup>1</sup>, K.-P. Adam<sup>3</sup>, M. Sinnott<sup>4</sup>, B. Carr<sup>4</sup>, T. Thybo<sup>3</sup>, J. Nolan<sup>3</sup>, D. O'Gorman<sup>1</sup>;

<sup>1</sup>Centre of Preventive Medicine and School of Health & Human Performance, Dublin City University, Ireland, <sup>2</sup>Metabolon Inc, Durham, USA, <sup>3</sup>Steno Diabetes Centre, Copenhagen, Denmark, <sup>4</sup>Vhi Healthcare, Dublin, Ireland.

**Background and aims:** A number of studies have identified fasting metabolites associated with insulin resistance, dysglycemia and type 2 diabetes. It is not known if metabolites respond to lifestyle modifications that reduce the risk of type 2 diabetes. The purpose of this study was to identify metabolite biomarkers, linked to dysglycaemia, that track with improvements in plasma glucose following a lifestyle intervention in high risk individuals.

**Materials and methods:** As part of the DEXLIFE programme, individuals with a FINDRISC score >12 or impaired fasting/2-hr glucose volunteered to participate in a 12-week diet and exercise intervention (n=104). An oral glucose tolerance test, body composition assessment(DEXA) and maximal aerobic capacity were determined before and after the intervention. Using the stable isotope dilution technique, quantitative assays were developed for a set of 23 candidate biomarker metabolites previously linked to dysglycemia. This set included:  $\alpha$ -hydroxybutyric acid (AHB), linoleoylglycerophosphocholine (LGPC), oleic acid,  $\alpha$ -ketoglutaric acid, 2-amino adipic acid, glycine, aromatic amino acids, and the 3 branched-chain amino acids and several of their catabolites.

**Results:** After the 12-week intervention fasting levels of 12 of the 23 metabolites were significantly different (p10% (n=16) there was a significant decrease in plasma tyrosine,  $\alpha$ -ketoglutarate and phenylalanine (p<0.05) as well as increased glycine and serine (p10% decrease in 2-hr glucose (n=35) was associated with significant decreases in branched-chain amino acid catabolites 3-methyl-2-oxopentanoic acid, 3-methyl-2-oxo-butyric acid, 4-methyl-2-oxopentanoic acid (p<0.05) in addition to insulin,  $\alpha$ -ketoglutarate, tyrosine (p<0.05) and increased glycine (p<0.05). The fold change in body weight was positively associated with the fold change in phenylalanine, tyrosine, leucine, isoleucine, 3-methyl-2-oxopentanoic acid and insulin (p<0.05) and negatively associated with glycine (p<0.05).

**Conclusion:** A subset of metabolites linked to dysglycaemia track with improvements in fasting and 2-hr glucose following a 12-week lifestyle intervention in high risk individuals. These metabolites are sensitive to small changes in metabolic function and may be useful for monitoring diabetes prevention programmes.

*Supported by: DEXLIFE project (EU FP7 programme, Grant agreement no: 279228)*

## 549

**Fasting and postprandial hyperglycaemia: their relative contributions to the overall hyperglycaemia and their determinants in Korean patients with type 2 diabetes**

J. Kim<sup>1</sup>, S.-Y. Yoo<sup>1</sup>, S.-A. Lee<sup>1</sup>, D.-H. Lee<sup>2</sup>, H.-J. Chin<sup>3</sup>, G. Koh<sup>1</sup>;

<sup>1</sup>Internal Medicine, Jeju National University Hospital,

<sup>2</sup>Internal Medicine, Wonkwang University Hospital, Iksan,

<sup>3</sup>Hankook General Hospital, Jeju, Republic of Korea.

**Background and aims:** Monnier et al. showed greater contributions of postprandial (PHG) and fasting (FHG) hyperglycaemia to overall hyperglycaemia at lower and higher HbA1c, respectively. However, it has never been studied in Korean diabetic patients. In addition, there have been few studies about determinant factors in postprandial and fasting glucose levels. Therefore, we assessed the relative contributions of PHG and FHG to the overall hyperglycaemia and the influencing factors on PHG and FHG in Korean patients with type 2 diabetes.

**Materials and methods:** We enrolled 195 Korean type 2 diabetic patients which did not take insulin or  $\alpha$ -glucosidase inhibitor. They performed a seven-point self-monitoring of blood glucose (7-point SMBG) more than once during each month for 3 consecutive months. Glucose area under the curve (AUC) above 100 mg/dL (5.5 mmol/L) was defined as AUC(total) to represent the overall hyperglycemia. The area under the curve above fasting glucose level was considered the postprandial hyperglycemia (AUC(PHG)).

The fasting hyperglycemia (AUC(FHG)) was calculated as [(AUC(total) - AUC(PHG)]. The relative contributions of PHG and FHG to overall hyperglycaemia were respectively defined as the proportions of AUC(PHG) and AUC(FHG) to AUC(TOTAL).

**Results:** The relative contribution of PHG showed a significant difference and gradual decrement according to increasing quartiles of HbA1c (66.9±6.0, 36.1±6.0, 40.3±3.2, 32.3±3.8%; P(ANOVA)<0.001, P(TREND)<0.001). And the contribution of FHG was increased progressively with increasing quartiles of HbA1c (33.0±9.5, 63.8±6.0, 59.6±3.2, 67.6±3.8%; P(ANOVA)<0.001, P(TREND)<0.001). AUC(PHG) was positively correlated to age (r=0.191; p<0.01), systolic blood pressure (r=0.185; p<0.01), duration of diabetes age (r=0.185; p<0.01), C-peptide (r=0.198; p<0.01), HbA1c (r=0.282; p<0.01), and hsCRP (r=0.145; p<0.05). AUC(FHG) was positively correlated to body weight (r=0.190; p<0.01), waist circumference (r=0.185; p<0.01), C-peptide (r=0.217; p<0.01), HbA1c (r=0.658; p<0.01), alanine aminotransferase (r=0.228; p<0.01), and triglyceride (r=0.278; p<0.01) but negatively correlated to age (r=-0.146; p<0.05). Using multiple linear regression to adjust for age, sex and other covariates, only age ( $\beta$ =0.181; p<0.05) and triglyceride ( $\beta$ =0.150; p<0.01) remained significant variables of the AUC(PHG) and AUC(FHG), respectively.

**Conclusion:** In Korean type 2 diabetic patients, postprandial hyperglycemia predominantly contribute to overall hyperglycemia at lower HbA1c level, whereas fasting hyperglycemia is a predominant contributor to it at higher HbA1c level. And age and plasma triglyceride are independent predictors of postprandial and fasting hyperglycaemia, respectively.

## 550

**A putative role of P4 and E2 in the maternal late-onset glucose intolerance induced by gestational glucocorticoid excess**

P.R.L. Gomes, S. Bordin;

University of Sao Paulo, Brazil.

**Background and aims:** In order to guarantee a proper maternal glycaemic control, at the end of pregnancy the pancreatic islets undergo a transient morpho-functional remodelling. We have shown that pancreatic beta cell resetting involves the modulation of several intracellular pathways, most of them in a glucocorticoid (GC)-dependent manner. On the other hand, we have recently described that the excess of GC at the end of pregnancy results in a late-onset of glucose intolerance due to an impairment of GSIS. This phenomenon is correlated with an early up-regulation of miR-29 expression, a validated target of progesterone (P4). Of note, P4 was reported as a beta cell pro-apoptotic hormone, whereas estrogen (E2) abolishes the cytokine-induced beta-cell death. Thus, we hypothesized that the functional resetting of the maternal pancreatic islets could depend on the proper E2 and P4 signalling. The aim of this work was to investigate the mechanisms involved in the late-onset maternal glucose intolerance induced by gestational GC excess, focusing on E2 and P4 signalling in pancreatic islets.

**Materials and methods:** Pregnant Wistar rats were treated with dexamethasone, 0.2 mg/kg daily in drinking water during the 14th to 19th day of pregnancy (P-DEX). Age-matched untreated pregnant rats (P) were used as controls. At the 19th day of pregnancy, DEX-treated and untreated rats were euthanized and pancreatic islets were isolated and used for western blot, qPCR analysis and GSIS; serum was used for P4 and E2 measurement. The Ethics Committee approved the study, and complies with the Brazilian Society of Laboratory Animal Science.

**Results:** P4 levels were significantly reduced in P-DEX compared to P rats (respectively 155.7±45.1 and 295.5±44.8 ng/ml; p<0.05), as well as the expression of progesterone receptor (PR) (0.2±0.1 times of P group; p<0.05). Neither E2 levels (55.6±22.6 and 41.4±20.8 pg/ml, respectively for P and P-DEX rats) nor ER $\beta$  expression was altered by the treatment, but ER $\beta$  was increased (9.4±2.6 times higher than P islets; p<0.05). SGK1, a GC target that negatively regulates insulin secretion, was upregulated in islets from P-DEX rats (1.9±1.5 times of control values; p<0.05). In parallel, maximum insulin response to glucose was lower than untreated P rats (0.6±0.2 times of P; p<0.05), but still responsive to glucose. In the presence of 2.8 mM glucose, insulin secretion values were 0.53±0.06 ng/ml (0.48±0.04 ng/ml in virgin rats), and with 16.7 mM glucose the values reached 1.17±0.19 ng/ml (1.34±0.10 ng/ml in virgin rats). The expression of inflammatory markers was also assessed. Compared to P islets, phospho-IKK/IKK ratio and NF- $\kappa$ B expression were reduced in P-DEX (respectively 0.7±0.1 and 0.3±0.1 times of P islets; p<0.05).

**Conclusion:** The lower levels of P4 and PR in P-DEX islets is likely to be a factor involved in the previously described up-regulation of miR-29. The up-regulation of ER $\beta$  induced by DEX treatment could be preserving the secretory responsiveness to glucose. Finally, the down-regulation of inflammatory markers could disrupt beta cell resetting after parturition, thus reflecting in an inappropriate maternal glucose homeostasis.

## PS 033 Determinants of insulin sensitivity and glycaemic control

551

### Determinants of insulin sensitivity in Middle Eastern immigrants and native Swedes

L. Bennet<sup>1</sup>, L. Groop<sup>2</sup>, P.W. Franks<sup>3</sup>;

<sup>1</sup>Department of Clinical Sciences, Family Medicine, Lund University,

<sup>2</sup>Department of Clinical Sciences, Lund University Diabetes Center,

<sup>3</sup>Department of Clinical Sciences, Genetic and Molecular Epidemiology, Lund University, Malmö, Sweden.

**Background and aims:** Little is known about the metabolic, lifestyle and heritable risk factors that underlie the observation that type 2 diabetes (T2D) is highly prevalent amongst Middle Eastern immigrants to Northern Europe. Hence, in the current report from the MEDIM study (the impact of Migration and Ethnicity on Diabetes in Malmö), we aimed to (1) investigate insulin sensitivity and secretion (2) study risk factors associated with T2D and (3) investigate the contribution of metabolic-, demographic- and lifestyle-related risk factors for impaired insulin sensitivity index (ISI) in immigrants from Iraq, with comparisons to native Swedes.

**Materials and methods:** Population-based, cross-sectional study conducted 2010-2012 including residents 30 to 75 years of age born in Iraq or Sweden, in whom 10-h fasting blood samples and oral glucose tolerance tests were performed. Further, sociodemography, lifestyle behaviors and comorbidity were assessed by questionnaires. Insulin sensitivity and secretion were assessed by Matsuda indices. Outcomes were T2D and ISI. Associations were assessed by logistic- and linear regression analysis.

**Results:** In Iraqi ( $n=1398$ ) compared to Swedish ( $n=757$ ) participants, T2D was twice as prevalent (11.6 vs. 5.8%,  $p<0.001$ ) and T2D onset occurred more than six years earlier. The prevalence of family history of T2D was twice as frequent in Iraqis compared with Swedes. ISI was generally lower in Iraqis as compared to Swedes (ISI 76.9 vs. 102.3,  $p<0.001$  (mmol/L\*mIE/L)<sup>-1</sup>). Although insulin secretion (CIR) was generally higher in Iraqis, insulin response relative to the degree of insulin resistance (DIo) was lower in Iraqis than in Swedes (12712.9 vs. 14659.2 mmol/L<sup>-1</sup>\* mmol/L<sup>-1</sup> mmol/L<sup>-1</sup>,  $p<0.001$ ). Lower ISI and DIo in Iraqis than in Swedes were also observed in participants without T2D as well as in participants with normal waist circumference and/or normal weight (BMI<25kg/m<sup>2</sup>). Further, Iraqis without T2D presented a less advantageous glucose and lipid profile, larger waist circumference and higher BMI compared to Swedes (Table 1). Irrespective of other traditional risk factors for T2D, ISI conveyed higher standardized odds of T2D in Iraqis than in Swedes; the difference between the magnitude of these relationships was confirmed by a statistically significant interaction between country of birth and ISI ( $P_{\text{intersensitivity}}=0.044$ ). There was no interaction between country of birth and CIR. The crude difference in ISI according to ethnicity remained significant even when adjusting for metabolic-, anthropometric-, and lifestyle factors.

**Conclusion:** The key findings of this study are that there are ethnic differences in the relationship of insulin sensitivity with T2D; our study suggests that ethnic background modifies the effect of insulin sensitivity on the risk of T2D diabetes and further that the impaired insulin sensitivity in this Arabic population is only partly explained by excess waist circumference or other known risk factors for insulin sensitivity. We conclude that Middle Eastern immigrant populations are likely to benefit greatly from interventions focused on improving insulin sensitivity.

### Effect of lowering plasma glucose and FFA concentrations on insulin sensitivity and beta cell function in T2DM individuals

M. Abdul-Ghani, A. Merovci, C. Solis, J. Xiong, G. Daniele,

A. Chavez-Valazquez, D. Tripathy, R.A. DeFronzo;

Medicine\Diabetes, University of Texas Health Science Center at San Antonio, USA.

**Background and aims:** Chronic elevation in plasma FFA (lipotoxicity) and plasma glucose (gluco-toxicity) concentrations have been shown to have detrimental effect on both core defects (insulin resistance and beta cell dys-

function) in T2DM. We have shown that lowering plasma FFA and plasma glucose concentrations separately in T2DM individuals improves beta cell function and ameliorate insulin resistance. In the present study, we examined the effect of lowering both the plasma FFA and glucose concentrations on beta cell function and insulin sensitivity in T2DM individuals.

**Materials and methods:** 12 T2DM subjects (age=49 ±3, BMI=31.1± 1.8, HbA1c = 8.5 ± 0.3, diabetes duration = 8.5 ± 0.3 years) received treatment with dapagliflozin (10 mg/day) for 3 weeks and during the third week they also received acipimox (250 mg four times daily). 75 gram OGTT and euglycemic insulin clamp were performed at baseline and at weeks 2 and 3.

**Results:** Compared to baseline, dapagliflozin lowered the fasting plasma glucose concentration at 2 weeks (181±9 to 146±9, p<0.01); the decrease in (FPG) was accompanied by significant increase in insulin-stimulated total glucose disposal (TGD) (4.16 ±0.71 to 5.15±0.73, p<0.05), and beta cell function.  $\Delta C\text{-pep}/\Delta G_{[0-120]}\div IR$  increased by 105% (p=0.003). At week 3, plasma FFA concentration was decreased by 28% compared to week 2 and this decrease was accompanied by a small, non-significant increase (by 9%) in insulin-mediated TGD, beta cell function ( $\Delta C\text{-pep}/\Delta G_{[0-120]}\div IR$ ) increased further by 53% (0.15±0.03 to 0.23 ±0.04, p=0.02).

**Conclusion:** Simultaneously lowering the plasma glucose and FFA concentrations has an additive effect to improve beta cell function, but not to improve insulin sensitivity.

### Effects of a lifestyle intervention in a pre-diabetic mouse model: glucose homeostasis and pancreatic beta cell function and mass

A. Gonzalez-Franquesa<sup>1</sup>, L. Navarro-Martinez<sup>1</sup>, R. Fernández-Ruiz<sup>2</sup>, P.M. García-Rovés<sup>1,2</sup>,

<sup>1</sup>Diabetes and Obesity Laboratory, IDIBAPS, <sup>2</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** Pancreatic beta-cells play a major role in obesity-related type 2 diabetes (T2DM) aetiology. Thus, pancreatic beta-cell plasticity is defined as the ability of the cells to adapt their function and mass to the variations in insulin demand. It is already known that during pregnancy mouse pancreatic beta-cell mass increases but it is then rapidly reversed towards the end of the pregnancy. Although pancreatic beta-cell mass has been extensively studied, many considerations of its plasticity in different physiological and pathological situations remain still unknown. This study assesses the adaptations that occur in pancreatic beta-cells before and after following a lifestyle intervention programme aimed to recover glucose homeostasis in an animal model of diet-induced obesity and pre-diabetes.

**Materials and methods:** C57BL/6J male mice were divided in three groups: a control group (Ctrl) (fed with chow standard diet), a pathological group (HFD) (fed for 16 weeks with 45% HFD, D12451 Open Source Diets™) and an intervention group (Int) in which mice followed a lifestyle intervention after they have reached the pathological state. This lifestyle intervention consisted on calorie restriction, modification of the 45% HFD with mono- and poly-unsaturated fatty acids and the replacement of sucrose by corn starch, and an exercise training programme for 5 weeks. Insulin tolerance test (ITT), glucose tolerance test (IGTT), body weight evolution, fat volume, tissue weights, inflammatory profile, and fasting insulin and leptin levels were assessed for the three groups. Pancreases were excised for immunohistochemistry studies. Pancreatic islets were isolated for in vitro glucose-stimulated insulin secretion (GSIS).

**Results:** The mice in the HFD group were glucose intolerant and showed insulin resistance when compared to their littermates, Ctrl group. Moreover, those mice on the HFD group were significantly overweight, hyperglycemic, hyperinsulinemic, and hyperleptinemic after an overnight fasting. Morphological analyses of the pancreases showed that the HFD group mice had an increase in beta-cell mass with more and bigger pancreatic islets than the Ctrl littermate mice. Isolated islets from HFD mice showed an increase in in vitro GSIS when incubated in 16.7mM of glucose. The mice on the Int group were leaner, returning to the Ctrl group body, liver and pancreas weight values and reducing the increase in fat volume of the mice in the HFD group. Those mice showed a general improvement in glucose homeostasis. However, the mice on the Int group were still moderately hyperglycemic and hyperinsulinemic after overnight fasting. Morphometric analysis of the pancreas showed that insulin positive area remained unchanged with respect to the HFD group although a significant increment in the number of small islets was observed.

**Conclusion:** Our lifestyle intervention improved most of the deleterious effects that led to a diet-induced pre-diabetic state in the absence of significant effects on pancreatic beta cells.

## 554

### Plasma 26RFa is increased in diabetic patients: evidence for an involvement in glucose homeostasis

G. Prevost<sup>1,2</sup>, L. Jeandel<sup>2</sup>, A. Arabo<sup>2</sup>, H. Berrahmoune<sup>1</sup>, M. Mehio<sup>2</sup>, D. Alexandre<sup>2</sup>, Y. Anouar<sup>2</sup>, H. Lefebvre<sup>1,2</sup>, N. Chartrel<sup>2</sup>;

<sup>1</sup>Endocrinology, Diabetes and Metabolic Diseases, CHU ROUEN, Rouen, <sup>2</sup>Institut National de la Santé et de la Recherche Médicale (INSERM), Unité (U)<sup>982</sup>, Neuronal and Neuroendocrine Differentiation and Communication Laboratory, Institute of Research and Innovation in Biomedicine, Normandie University, University of Rouen, Mont saint Aignan, France.

**Background and aims:** 26RFa is an orexigenic neuropeptide identified as the endogenous ligand of the human orphan receptor GPR103. Moreover, animal studies suggest that 26RFa is involved in the pathophysiology of obesity. The aim of this study was to investigate plasma 26RFa level in obese and diabetic patients, and to explore a possible link between 26RFa and glucose homeostasis.

**Materials and methods:** Fasting plasma 26RFa was determined by using a specific radioimmunoassay in 161 subjects divided into 4 groups: controls, obese patients, obese type 2 diabetic patients and type 1 diabetic patients. Plasma 26RFa was also evaluated during a 180 min oral glucose tolerant test (OGTT) in 10 healthy controls. Immunohistochemical studies with anti-26RFa and anti-GPR103 antibodies were performed on human pancreatic slices. Finally, 26RFa was injected in C57Bl mice during an intraperitoneal glucose tolerance test (IPGTT).

**Results:** Fasting plasma 26RFa was significantly increased in obese patients as compared to controls (352±47 vs 224±32 pg/ml; p<0.05), but even more in type 1 and type 2 diabetic patients (605±115 pg/ml and 677±99 pg/ml vs controls; p<0.001). Plasma 26RFa was positively correlated with age and blood glucose, but not with the BMI. In multivariate linear analysis, the correlation between fasting 26RFa level and blood glucose was independent from age. During the OGTT in controls, plasma 26RFa significantly increased at 120 min after the oral glucose load (+57,3% ; p<0.05). Immunohistochemical studies revealed that 26RFa and its receptor were present in the beta pancreatic cells. Finally, intraperitoneal 26RFa injection during IPGTT was associated with a reduced glucose-induced hyperglycemia, and an increase of insulin secretion.

**Conclusion:** This study reports for the first time that plasma 26RFa is increased in diabetic patients and is correlated to blood glucose. Moreover, animal studies suggest that the neuropeptide exerts its anti-hyperglycemic effect, at least in part, via an increase of insulin secretion.

## 555

### An unusual metabolic interplay: type 1 diabetes and glutaric aciduria type 1

A. Galderisi<sup>1</sup>, V. Moret<sup>1</sup>, L. Giordano<sup>2</sup>, A.B. Burlina<sup>2</sup>, C. Monciotti<sup>1</sup>;

<sup>1</sup>Pediatric Diabetology Unit, <sup>2</sup>Metabolic Unit, Department of Woman's and Child's Health, University of Padua, Italy.

**Background and aims:** Type 1 diabetes (T1D) metabolic balance is affected by several variables (foods, insulin dose and daily-life activities of our patients). The management becomes more difficult if an extra factor affects the glucose homeostasis such as in the case we report: the concomitant occurrence of Glutaric aciduria type 1 (GA1, a rare organic aciduria) and Type 1 diabetes in a young boy. Even if their coexistence may appear a pure coincidental association, their interplay shows an unexpected phenotype.

**Materials and methods:** A 21 months boy, treated for T1D since the age of 15 months (anti-GAD>2000kU/L at onset), was referred to our attention from another center for the onset of GA1. Due to the severe neurological impairment, consequent on GA1 related basal ganglia damage, he required enteral nutrition via nasogastric tube, receiving an age adapted lysine free diet, arginine (100 mg/kg/die) and carnitine (160 mg/kg/die). Insulin therapy was adapted to this regimen. CGMS (Medtronic®Guardian RT) highlighted a marked tendency to hypoglycemic events (30% of daily values below the range (mean AUC<3.9mmol/L: 0,8) in the early morning hours (4-6am), poor controlled by our insulin adjustments. (fig.1;human insulin, blue arrows; glargine, red arrow).

**Results:** After 15 days from the beginning of diet and therapy for GA1 we observed a drop of anti GAD to 233KUI/L and a marked reduction of hypoglycemia (mean AUC<3.9mmol/L: 0), with an increased insulin requirement. **Conclusion:** Animal models of GA1 showed an impairment of gluconeogenesis, involving Krebs disfunction in liver and GAD enzyme in brain. To date it has never been confirmed in humans with GA1. This is the first CGMS data from a GA1 patient: the hypoglycemia during nocturnal starvation reflects this gluconeogenetic impairment. The reduction of hypoglycemic events, the drop of anti-GAD, with the beginning of GA1 therapy, supports the observation on animal models. We can suppose that the contemporary presence of anti-GAD and the deficit of Krebs in T1D, may exacerbate the hypoglycemic events of GA1 making them clinically relevant.

### Higher mean glucose levels and glucose variability in non-diabetes sepsis/septic shock patients than in healthy subjects

A. Sriwittkamol, N. Suwansaksri, L. Preechasuk, C. Permpikul, S. Vannasaeng;

Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

**Background and aims:** Hyperglycemia is one of the factors linked to increase mortality in sepsis or septic shock patients. Retrospective study had shown that the glucose variability (GV) associated with increased mortality in these patients. Until now, data on GV in sepsis/septic shock patients are sparse. Moreover, there is no prospective study to demonstrate whether glucose variability in sepsis patients is different from healthy subjects. Therefore, the aims of this study were to compare glucose profiles including mean glucose levels and glucose variability between sepsis patients and healthy subjects, and to study the correlation of glucose variability calculated from glucose level obtained from continuous glucose monitoring (CGM) and capillary plasma glucose (CPG).

**Materials and methods:** Sepsis patients (SEPSIS) who had no history of diabetes and hemoglobin A1c (A1C) < 6.5% were recruited. All subjects had 72-hour continuous glucose monitor or CGM, using iPro 2 (Medtronic, US) within 12 hours after admission. 72-hour CGM was also applied to healthy subjects without diabetes to serve as a control group (CON). Capillary plasma glucose (CPG) was obtained from both groups for 4 to 6 times per day during the study period 3. Glucose levels (GL) obtained from CGM and CPG during the 24-hour and 72-hour were used to calculate mean glucose level (MGL24h and MGL72h), and glucose variability including standard deviation (SD24h and SD72h), coefficient of variation (CV24h and CV72h) and mean amplitude of glycemic excursion (MAGE24h and MAGE72h).

**Results:** This was a prospective study. Fourteen subjects with sepsis and ten healthy subjects were recruited. SEPSIS was older than CON whereas there was no difference in sex, BMI and A1C. Glucose profiles obtained from CGM and CPG demonstrated the similar results as shown in table. The MGL24h and MGL72h were significant higher in SEPSIS than CON. The GV during 72-hour as demonstrated by SD72h, MAGE72h were also higher in SEPSIS than CON. The glucose profiles obtained from CGM and CPG in SEPSIS had a strong correlation.

**Conclusion:** Patients without diabetes who sepsis had elevated mean glucose levels at 24-hour and 72-hour and glucose variability at 72-hour as compared to healthy subjects. Therefore, the strategy aimed to target both mean glucose level and glucose variability might have benefit in non-diabetic patients with sepsis/septic shock. We also demonstrated that the use of 4 to 6 time points of capillary glucose levels to calculate the glucose profiles provided accurate data similar to those obtained from CGM in sepsis patients.

**Table 1: Glucose profiles from CGM and CPG in SEPSIS and CON during 24 and 72 hours**

|                             | Continuous glucose monitoring (CGM) |                   |         | Capillary plasma glucose (CPG) |                   |         |

**Effects of chronic variable stress and dietary fat on insulin sensitivity**

S. Müller-Lüthloff<sup>1</sup>, T. Jelenik<sup>2</sup>, S. Hartwig<sup>1</sup>, S. Lehr<sup>1</sup>, P. Nowotny<sup>2</sup>, M. Roden<sup>2,3</sup>, H. Al-Hasani<sup>1</sup>, T.R. Castañeda<sup>1</sup>;

<sup>1</sup>Institute for Clinical Biochemistry and Pathobiochemistry, <sup>2</sup>Institute for Clinical Diabetology, German Diabetes Center, Leibniz Center for Diabetes Research, <sup>3</sup>Department of Endocrinology and Diabetology, University Clinics Düsseldorf, Heinrich Heine University, Düsseldorf, Germany.

**Background and aims:** Stress is a state of threat to homeostasis that may contribute to metabolic disorders such as visceral obesity and type 2 diabetes. However, there is a lack of studies analyzing the long-term consequences of chronic stress on insulin sensitivity and its relation to fat consumption. Our aim was to characterize how chronic variable stress (CVS) in relation to dietary fat affects insulin sensitivity in mice.

**Materials and methods:** Three-months old, body weight (BW)-matched male C57BL/6 mice were exposed to a random series of stressors for 15 days (CVS), the unstressed control mice were housed separately (Ctrl). Body composition was analyzed with NMR. After CVS, blood was collected (08:00–12:00 am) for corticosterone and insulin analysis. Subsequently, mice were consuming a low- (Chow) or a high-fat diet (HFD) for three months and insulin sensitivity was measured *in vivo* with hyperinsulinemic-euglycemic clamps. Statistical differences were considered significant at  $p < 0.05$  (two-tailed unpaired t-test).

**Results:** CVS mice ( $n=24$ ) had lower BW ( $25.49 \pm 0.33$  g,  $p < 0.001$ ) and lean mass ( $23.08 \pm 0.37$  g,  $p < 0.001$ ) with no changes in fat mass ( $2.23 \pm 0.08$  g) compared to the Ctrl group ( $n=24$ ), ( $28.32 \pm 0.36$  g,  $25.37 \pm 0.39$  g,  $2.25 \pm 0.09$  g, respectively). Plasma levels of corticosterone were higher in the CVS group ( $n=22-24$ ) ( $109.90 \pm 13.71$  vs  $60.37 \pm 7.55$  ng/ml,  $p < 0.01$ ) as well as insulin levels ( $0.65 \pm 0.06$  vs  $0.47 \pm 0.03$  ng/ml,  $p < 0.01$ ) compared to the Ctrl group ( $n=19-24$ ). When fed Chow, the CVS group ( $n=10$ ) showed a trend to lower basal endogenous glucose production (EGP) ( $20.01 \pm 1.12$  vs  $23.86 \pm 1.48$  mg/kg/min,  $p=0.055$ ), while insulin-stimulated glucose disposal (Rd) in peripheral tissues was increased in CVS compared to Ctrl ( $363 \pm 29$  vs  $275 \pm 17$  % of basal,  $p < 0.05$ ). On HFD, basal EGP was unchanged, while Rd ( $135 \pm 12$  vs  $192 \pm 14$  % of basal,  $p < 0.01$ ) was decreased with CVS. Suppression of EGP by insulin was unaffected by CVS. CVS-Chow mice showed lower plasma adiponectin ( $5.87 \pm 0.43$  vs  $11.29 \pm 1.39$   $\mu$ g/ml,  $p < 0.01$ ) and a trend towards lower resistin ( $0.13 \pm 0.005$  vs  $0.14 \pm 0.005$   $\mu$ g/ml,  $p=0.06$ ) compared to Ctrl. CVS-HFD mice showed lower plasma adiponectin ( $7.99 \pm 0.89$  vs  $15.74 \pm 3.28$   $\mu$ g/ml,  $p < 0.05$ ) and a trend towards higher resistin ( $0.17 \pm 0.02$  vs  $0.11 \pm 0.02$   $\mu$ g/ml,  $p=0.06$ ) compared to Ctrl.

**Conclusion:** When fat consumption is low, chronic stress improves insulin sensitivity through higher peripheral glucose disposal. On the contrary, HFD consumption exacerbates insulin resistance under these conditions. Changes in adipokine profiles could be a possible mechanism underlying the effects of CVS and dietary fat on peripheral insulin sensitivity.

**Oxygen restriction as challenge test reveals early diet-induced health effects**

E.M. van Schothorst<sup>1</sup>, L. Duivenvoorde<sup>1</sup>, D. Derous<sup>1</sup>, I. van der Stelt<sup>1</sup>, J. Masania<sup>2</sup>, N. Rabbani<sup>2</sup>, P.J. Thornalley<sup>2</sup>, J. Keijer<sup>1</sup>;

<sup>1</sup>Human and Animal Physiology, Wageningen University, Netherlands,

<sup>2</sup>Clinical Sciences Research Laboratories, Warwick Medical School, Coventry, UK.

**Background and aims:** Challenge tests stress homeostasis and may reveal deviations in health that remain masked under unchallenged conditions. Ideally, challenge tests are non-invasive and applicable in an early phase of a study. The response to oxygen restriction (OxR; mild normobaric 12% O<sub>2</sub>) measures the flexibility to adapt metabolism. Metabolic inflexibility is one of the hallmarks of the metabolic syndrome and underlying insulin resistance.

**Materials and methods:** Male C57BL/6J OlaHsd adult mice were fed a low-fat (LF) or high-fat (HF) diet for only five days. Indirect calorimetry was used to assess the response to OxR. Serum markers, including protein glycation/oxidation, and gene expression in liver and white adipose tissue (WAT) were analyzed.

**Results:** Although HF-fed mice had a significant higher body weight (BW) after five days of feeding, HF-fed and LF-fed mice did not differ in calorimetric values under normal conditions nor in fasting state. Moreover, the

subgroups of mice that were fasted and exposed to OxR during the last 6h showed no differences in BW (gain), nor in blood glucose levels. Exposure to OxR, however, revealed significant differences in substrate use with the HF-fed mice showing higher fatty acid oxidation levels and oxygen consumption, while their activity was similar to LF-fed mice. Furthermore, hepatic and WAT transcript levels differed significantly between both groups indicating differences in their adaptation to OxR. Only HF-fed mice showed increased hepatic lactate/glucose metabolism upon OxR, while LF-fed mice showed an increased oxidative stress response in WAT (see Figure). The adaptation in HF-fed mice appeared to be dampened, associated with increased serum markers of protein glycation/oxidation, whereas these changes were absent in LF-fed mice.

**Conclusion:** An oxygen restriction challenge test is a promising new method to test food products on potential beneficial effects for metabolic health. Differential metabolic adaptations upon OxR in hepatic lactate metabolism and stress response. Transcripts appeared up-regulated by OxR both in LF and HF (blue), only in HF (red), only in LF (green), or non-regulated (black). Lactate/Glucose metabolism (A) was analysed in liver, stress response mainly in WAT (B). Underlined transcripts denote up-regulation by HF vs LF under normoxia. Mod1 appeared down regulated by HF vs LF under normoxia. \*: not determined.

**A syndrome of hyperinsulinaemic reactive hypoglycaemia associated with mutations in the human insulin receptor gene: two cases report**

Y. Kuroda<sup>1,2</sup>, H. Iwashashi<sup>1</sup>, I. Mineo<sup>3</sup>, K. Fukui<sup>1</sup>, A. Fukuhara<sup>1</sup>, R. Iwamoto<sup>1</sup>, A. Imagawa<sup>1</sup>, I. Shimomura<sup>1</sup>;

<sup>1</sup>Department of Metabolic Medicine, Graduate School of Medicine,

<sup>2</sup>Department of Endocrinology and Metabolism, Sumitomo Hospital,

<sup>3</sup>Diabetes Center, Toyonaka Municipal Hospital, Osaka, Japan.

**Background and aims:** Hyperinsulinemic hypoglycaemia in adults is the most frequently caused insulinoma but some cases, especially reactive hypoglycaemia, remain unexplained. We have experienced two independent cases of hyperinsulinemic reactive hypoglycaemia with adolescence or adult onset and analysed their pathophysiology and insulin receptor (IR) genes including those of their relatives.

**Materials and methods:** Genomic DNA was extracted from the patient's leukocytes and the direct sequencing for all exons of IR gene was performed. In overexpression experiments, we used pCMV expression vector and HEK293 cells, and the mutant IR described below was generated by PCR-based mutagenesis.

**Results:** Case 1 was a 42-year-old man. He had experienced recurrent episodes of finger tremor and cold sweat that dispelled by drinking juice since he was about 30 years old. His body mass index was 20.7. Laboratory tests showed fasting plasma glucose (FPG) was 76 mg/dl, fasting immunoreactive insulin (F-IRI) was 19.0  $\mu$ U/ml, fasting C-peptide (F-CPR) was 1.37 ng/ml, and HbA1c was 5.0%. A 75g OGTT exhibited normal glucose tolerance pattern and reactive hypoglycaemia at 3h. Case 2 was a 34-year-old man. Since he was fifteen years old, he had experienced recurrent episodes of finger tremor and cold sweat that dispelled by drinking juice. Laboratory tests showed FPG was 104mg/dl, F-IRI was 71.7  $\mu$ U/ml, F-CPR was 3.1ng/ml, and HbA1c was 6.7%. A 75g OGTT exhibited diabetic pattern and reactive hypoglycaemia at 4h. In both cases, neither anti-insulin nor anti-IR antibody was observed. We found that the former case had a novel missense mutation (Arg229Cys) in both alleles of IR gene, and both his parents had the same mutation only in one allele but not hyperinsulinaemic reactive hypoglycaemia. Furthermore, we also found that the latter case had a novel nonsense mutation (Trp1273X) followed by a mutation (Gln1274Lys) in a single allele of IR gene and his nine-year old son had the same mutation in one allele and also hyperinsulinaemic reactive hypoglycaemia. Overexpression experiments of the mutant gene (Arg229Cys) in HEK293 cells revealed increase of preproreceptor-mature

receptor ratio of IR protein and reduced Akt phosphorylation by insulin stimulation (at concentration of 0.1 or 1.0nM) compared to wild type.

**Conclusion:** In two cases of hyperinsulinaemic reactive hypoglycaemia, we found novel mutations in the IR gene considered to be linked to their hypoglycemia. We propose a disease entity of a syndrome of hyperinsulinaemic reactive hypoglycaemia associated with mutations in the human IR gene.

### APPL1 affects on glucose uptake induced by uniaxial stretch in C2C12 myotubes

T. Saito, Y. Shimoda, Y. Tagaya, E. Yamada, S. Okada, M. Yamada; Medicine and Molecular Science, Gunma University, Maebashi, Japan.

**Background and aims:** Adaptor protein, phosphotyrosine interaction, PH domain and leucine zipper containing 1 (APPL1) was identified as protein kinase B or Akt (PKB/Akt) binding protein. It has been reported that APPL1 highly expresses in adipose and muscle tissues and has an important role in GLUT4 translocation in response to insulin and adiponectin via Akt or 5' adenosine monophosphate-activated protein kinase (AMPK) dependent pathway. We found that Akt and AMPK were activated in mouse derived muscle cell line, C2C12 cell, in response to uniaxial stretch stimulation. Therefore, this study aimed to investigate the function of APPL1 in C2C12 myotubes on GLUT4 translocation mechanism stimulated by mechanical stretch.

**Materials and methods:** C2C12 myoblasts were grown on an elastic silicone chamber and promoted differentiation. Differentiated C2C12 myotubes were stimulated by cyclic uniaxial stretch (10% of initial length, 10 cycle/min) for 5 hours. Plasmid DNA was transfected into C2C12 myoblasts by electroporation. Glucose uptake was measured by enzymatic assay and the localization of APPL1 was examined by immunofluorescence. Compound C, an AMPK inhibitor, or protein kinase C (PKC) zeta pseudosubstrate, a PKC inhibitor, was administered to block the activity of AMPK or PKC zeta pathway during stretch.

**Results:** Stretch increased glucose uptake, Akt, AMPK, and PKC zeta phosphorylation without affecting protein expression of these proteins and GLUT4. APPL1 localized at perinuclear in basal condition and moved to plasma membrane after stretch stimulation. Stretch-induced glucose uptake, AMPK, and PKC zeta phosphorylation were statistically increased by 26%, 28%, and 30%, respectively, in APPL1 transfected cells compared to non-transfected. On the other hand, stretch-induced Akt activation was suppressed by 30% in APPL1-overexpressed cells. Although compound C didn't affect on glucose uptake, PKC zeta pseudosubstrate suppressed glucose uptake induced by APPL1 by 67% in stimulated condition.

**Conclusion:** These results suggest that APPL1 is regulated by stretch stimulation and promote stretch induced glucose uptake in C2C12 myotubes mainly through PKC zeta dependent signaling pathway, but not AMPK dependent pathway.

### Acetic acid enhances glucose uptake and blood flow rates in the skeletal muscle in humans with impaired glucose tolerance

E. Petsiou<sup>1</sup>, P. Mitrou<sup>2</sup>, E. Papakonstantinou<sup>1</sup>, E. Maratou<sup>2</sup>, V. Lambadiari<sup>1</sup>, F. Spanoudi<sup>1</sup>, S.A. Raptis<sup>1,2</sup>, G. Dimitriadis<sup>1</sup>;

<sup>1</sup>2nd Department of Internal Medicine and Research Institute, Athens University Medical School, Attikon University Hospital,

<sup>2</sup>Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications (H.N.D.C), Athens, Greece.

**Background and aims:** Previous studies support the antiglycaemic effect of vinegar. However, the effect of vinegar on endothelial function and muscle glucose metabolism has not been studied in humans. This cross-over study aims to investigate the effects of vinegar on plasma glucose, insulin and lipid levels, as well as blood flow and muscle glucose uptake in subjects with impaired glucose tolerance (IGT), using the arteriovenous difference technique.

**Materials and methods:** Eight subjects with IGT (age 46+4years, BMI 29+2), without any medication therapy, were randomised to consume vinegar (30ml vinegar containing 6% acetic acid, 20ml water) or placebo (50ml water) before a mixed meal (566kcal; 75g carbohydrates, 26g protein, 6g fat). Plasma samples were taken at 15-60min intervals for 300min from the radial artery and from a forearm vein for measurements of glucose, insulin, triglycerides, non-esterified fatty acids (NEFA) and glycerol. Muscle blood flow was measured with strain-gauge plethysmography. Glucose flux was calculated as the

arteriovenous difference of glucose multiplied by the blood flow rates. The cross-over study was conducted 1 week later.

**Results:** Vinegar compared to placebo: 1) decreased arterial plasma insulin (8101+1410 vs 12008+1645mU/L\*min,  $p=0.043$ ) 2) increased forearm blood flow (404+97 vs 134+71 ml/min/100ml tissue\*min,  $p=0.048$ ) 3) increased muscle glucose uptake (933+74 vs 603+108 $\mu$ mol/100ml tissue,  $p=0.02$ ) 4) decreased arterial plasma triglycerides (45+11 vs 86+10 nmol/L\*min,  $p=0.036$ ), without changing NEFA and glycerol.

**Conclusion:** In individuals with impaired glucose tolerance, vinegar addition to a mixed meal results in an enhancement of muscle blood flow rates, an improvement of glucose uptake by the forearm muscle and a reduction of postprandial hyperinsulinaemia and hypertriglyceridaemia. From this point of view vinegar may be considered beneficial for improving insulin resistance and metabolic abnormalities in the atherogenic prediabetic state.

## 562

### Disclosing acute caffeine action on insulin sensitivity: effects on skeletal muscle

M.J. Ribeiro<sup>1</sup>, J.F. Sacramento<sup>1</sup>, S. Yubero<sup>2</sup>, B.F. Melo<sup>1</sup>, A. Obeso<sup>2</sup>, C. Gonzalez<sup>2</sup>, M.P. Guarino<sup>1,3</sup>, S.V. Conde<sup>4</sup>;

<sup>1</sup>CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Portugal, <sup>2</sup>Departamento de Bioquímica y Biología Molecular y Fisiología, Universidad de Valladolid, Facultad de Medicina. IBGM, CSIC. Ciber de Enfermedades Respiratorias, CIBERES, Instituto de Salud Carlos III, Valladolid, Spain, <sup>3</sup>UIS- Unidade de Investigação em Saúde- Escola Superior de Saúde de Leiria- Instituto Politécnico de Leiria, Portugal.

**Background and aims:** Caffeine, a non-selective adenosine antagonist, is the behaviorally active substance most widely consumed in the world. When consumed regularly, this xanthine presents beneficial effects on type 2 diabetes and metabolic syndrome. However, the sensitizing effect of chronic caffeine intake contrasts with acute caffeine administration that has been associated with an increase in insulin resistance (IR). The aim of this work was to investigate the effect of acute caffeine administration on insulin sensitivity and the involvement of adenosine receptors. Additionally, the mechanism behind caffeine-mediated effects in skeletal muscle was assessed.

**Materials and methods:** In vivo experiments were performed in Wistar rats of both sexes, aged 3 months (200–350g) anaesthetized with pentobarbitone (60mg/Kg). The effect of the acute administration of caffeine (0.001–5 $\mu$ M), DPCPX (A1 antagonist, 0.0005–5 $\mu$ M), SCH58261 (A2A antagonist, 0.0005–5 $\mu$ M) and MRS1754 (A2B antagonist, 0.001–5 $\mu$ M) on insulin sensitivity was evaluated by means of an insulin tolerance test. Skeletal muscle Glut4 and AMPK $\alpha$ 1 expression were quantified by Western-blot. The effect of A1 and A2B adenosine agonists on glucose uptake was evaluated. Sodium nitroprussiate (SNP, 10nM), a nitric oxide (NO) donor was used to evaluate the effect of NO on adenosine antagonism induced-IR.

**Results:** Acute caffeine decreased insulin sensitivity in a concentration dependent manner ( $E_{max}=55.54 \pm 5.37\%$ ,  $IC_{50}=11.61nM$ ), an effect that is mediated by A1 and A2B adenosine receptors. Additionally, in skeletal muscle, acute caffeine administration did not modify AMPK expression, however it significantly decreased Glut4 by 23.23% and 31.81% (0.05 and 0.5 $\mu$ M of caffeine, respectively). We found that A1, but not A2B agonists significantly increased glucose uptake to  $2.11 \pm 0.04$  nmol.mg<sup>-1</sup> tissue in skeletal muscle when compared to control ( $1.69 \pm 0.04$  nmol.mg<sup>-1</sup> tissue). SNP partially reversed DPCPX and MRS1754 induced-IR by 77.4 and 51.1%, respectively, when compared with the application of adenosine antagonists alone (KITT DPCPX= $2.12 \pm 0.44\%$  glucose.min<sup>-1</sup>; KITT MRS1754= $2.16 \pm 0.08\%$  glucose.min<sup>-1</sup>).

**Conclusion:** Acute caffeine administration decreases insulin sensitivity in a concentration dependent manner being this effect mediated by A1 and A2B adenosine receptors. In skeletal muscle, the effect of caffeine on insulin sensitivity involves a decrease in Glut4 expression and in insulin-dependent glucose uptake that is mediated mainly by A1 adenosine receptors. Additionally, adenosine-mediated insulin sensitivity seems to involve NO production and its sensitizing actions.

### Glucose uptake independent of insulin action: role of S-nitrosilated insulin chains

J.M. Gaspar<sup>1,2</sup>, I.S. Lima<sup>1,2</sup>, J. Caldeira<sup>3</sup>, Y.-B. Kim<sup>2</sup>, M.P. Macedo<sup>1,4</sup>;

<sup>1</sup>Chronic Disease Center (CEDOC), New Medical School, Lisbon, Portugal, <sup>2</sup>Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Boston, USA, <sup>3</sup>REQUIMTE, Faculty of Sciences and Technology, <sup>4</sup>Portuguese Association of Diabetes and Education Research Center (APDP-ERC), Lisbon, Portugal.

**Background and aims:** Portal insulin is removed (50–70%) during first pass transit in the liver by a process called insulin clearance. Protein disulfide isomerase (PDI) mediates insulin clearance by reduction of insulin disulfide bonds, breaking it into A and B chains by a mechanism that requires glutathione (GSH). Previously, we reported that A/B chains of insulin could be S-nitrosated (A-SNO and B-SNO) in vitro, forming nitrosothiols. After a meal, the increase of GSH levels together with the activation of parasympathetic nervous system which leads to nitric oxide (NO) release results in an increase in peripheral insulin sensitivity. A concurrent increase in hepatic PDI activity cleaves and nitrosilates A and B chain of insulin (A-SNO e B-SNO). Our hypothesis is that S-nitrosilated modified derivatives of insulin, A-SNO and B-SNO, produced during the insulin clearance process stimulates glucose uptake in skeletal muscle by a mechanism independent of the insulin signalling pathway.

**Materials and methods:** The presence of BSNO in the liver of Wistar rats was analyzed by immunoprecipitation of S-nitrosilation proteins following by western blot for B-chain. Physiological effects of S-nitrosilated modified derivatives of insulin were evaluated in differentiated skeletal muscle cells (L6-mycGLUT4 cells) and adipocytes (3T3-L1 cells). The cells were stimulated with 100nM insulin, A-chain, B-chain, A-SNO and B-SNO to evaluate glucose uptake using 3H-Glucose method. To analyse detailed signalling pathways activated by these insulin derivatives we performed cellular extracts and by western blotting technique we investigate the enrolled proteins.

**Results:** We detected the existence of BSNO in liver homogenates of rats and that BSNO levels were decreased (23% comparing with sham rats) in animals that were subjected to an hepatic denervation of parasympathetic nerves - NO pathway. We observed that A-SNO and B-SNO significantly stimulates glucose uptake in L6 muscle cells ( $159.8 \pm 19.2\%$  and  $204.8 \pm 30.2\%$  to control, respectively), similar to insulin stimulus ( $203.1 \pm 15.0$ ). The stimulation of glucose uptake was mediated by the activation of AMPK pathway, detected by the increase in phosphorylation of Thr172 AMPK. We also observed that these insulin derivatives did not activate the canonical insulin pathway. In adipocytes we observed that A-chain and B-chain insulin derivatives increase glucose uptake ( $309.2 \pm 83.2\%$  and  $319.0 \pm 23.6\%$  to control, respectively). In a lesser extent B-SNO also stimulates glucose uptake ( $193.6 \pm 13.8\%$  to control). In adipocytes these derivatives does not activate either the canonical insulin pathway or AMPK signaling pathway.

**Conclusion:** As a conclusion insulin clearance process can lead to the formation of A/B chain and/or the respective S-nitrosilated derivatives. In adipocytes, mainly A-chain and B-chain stimulates glucose uptake. On the other hand when insulin derivatives are S-nitrosilated (A-SNO and B-SNO) they act on skeletal muscle promoting glucose uptake, through activation of AMPK signaling pathway.

### Treatment with small, subthyrototoxic doses of thyroxine can improve peripheral cellular glucose transport and insulin sensitivity in patients with type 2 diabetes

E. Maratou<sup>1</sup>, V. Lambadiari<sup>2</sup>, F. Spanoudi<sup>2</sup>, E. Vassilatou<sup>2</sup>, G. Matsagouras<sup>2</sup>, E. Hatzigelaki<sup>2</sup>, P. Mitrou<sup>1</sup>, S.A. Raptis<sup>1,2</sup>, G. Dimitriadis<sup>2</sup>;

<sup>1</sup>Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications (HNDC), <sup>2</sup>2nd Department of Internal Medicine, Research Institute and Diabetes Center, Athens University, "Attikon" University Hospital, Athens, Greece.

**Background and aims:** Variation of plasma thyroid hormones' levels influences insulin sensitivity and peripheral glucose disposal. Administration of high doses of thyroxine to healthy humans induces insulin resistance, whereas moderate doses increase peripheral glucose disposal. We investigated the effect of the administration of small doses of thyroxine to healthy humans

and patients with type 2 diabetes on the insulin sensitivity indices, in vitro glucose uptake and GLUT4 recruitment in the plasma membrane of peripheral monocytes.

**Materials and methods:** Eleven healthy, euthyroid subjects (CON) with a micronodular texture of the thyroid gland, aged  $40.8 \pm 2.7$  yrs, BMI  $26.6 \pm 0.83$  kg/m<sup>2</sup>, T3  $118.1 \pm 5$  ng/dl ( $1.818 \pm 0.077$  nmol/l), T4  $7.1 \pm 0.3$  µg/dl ( $91.377 \pm 3.861$  nmol/l), TSH  $1.235 \pm 0.109$  µU/ml, and eleven treatment-naive subjects with type 2 diabetes (DM) [aged  $42.9 \pm 3.8$  yrs, BMI  $27.48 \pm 1.39$  kg/m<sup>2</sup>, T3  $119 \pm 5.7$  ng/dl ( $1.832 \pm 0.087$  nmol/l), T4  $8.13 \pm 0.46$  µg/dl ( $104.8 \pm 5.93$  nmol/l), TSH  $1.51 \pm 0.14$  µU/ml], were studied before and after administration of 50 µg of thyroxine once daily for 2 months. The study was approved by the hospital ethics committee, and subjects gave informed consent. A meal was given to the participants. Blood was drawn before the meal for the study of glucose uptake and GLUT4 abundance in peripheral monocytes and several blood samples were drawn for 300min from a forearm deep vein and the radial artery for measurements of glucose, insulin and HOMA-IR and Matsuda indices. The insulin's effect on GLUT4 translocation from cytoplasmic depots to plasma membrane was studied by stimulating monocytes with various concentrations of the hormone (0, 25, 50, 100 and 200uU/ml). The increment of enrichment of plasma membrane to GLUT4 is represented as %increment from baseline (0mU/l) to maximal concentration (200mU/l). Plasma membrane GLUT4 abundance and glucose uptake (fluorescent analogue 6-NBDG) were studied in isolated monocytes by flow cytometry.

**Results:** The area under the curve of the 6-NBDG uptake was significantly higher in both CON (pre treatment  $7392.7 \pm 577.4$  vs. post treatment  $9383.8 \pm 460$ ,  $P < 0.05$ ) and DM (pre treatment  $5597 \pm 245$  vs. post treatment  $8916 \pm 1009$ ,  $P < 0.05$ ) after the administration of thyroxine. The abundance of plasma membrane GLUT4 increased after the treatment in both CON (pre treatment  $29.6\% \pm 3.76$  vs. post treatment  $41.93\% \pm 3.72$ ,  $P < 0.05$ ) and DM group (pre treatment  $10.96\% \pm 2.25$  vs. post treatment  $34.44\% \pm 5.08$ ,  $P < 0.005$ ). Glucose uptake and GLUT4 abundance in plasma membrane of monocytes improved, TSH levels reduced significantly post-treatment ( $P < 0.0001$ ). Glucose, insulin levels and HbA1c reduced significantly in DM group. HOMA-IR and Matsuda indices improved post-treatment.

**Conclusion:** Administration of small, subthyrotoxic doses of thyroxine to euthyroid diabetic patients and healthy individuals, can improve peripheral cellular glucose uptake and insulin sensitivity. This could be of therapeutic importance in insulin-resistant subjects.

## 565

### Administration of small doses of thyroxine to euthyroid type-2 diabetic patients increased insulin-stimulated peripheral glucose uptake and improved glucose tolerance

F. Spanoudi<sup>1</sup>, E. Maratou<sup>2</sup>, E. Vassilatou<sup>1</sup>, G. Matsagouras<sup>1</sup>, E. Hatzigelaki<sup>1</sup>, S.A. Raptis<sup>2,1</sup>, G. Dimitriadis<sup>1</sup>, V. Lambadiari<sup>1</sup>;

<sup>1</sup>2nd Department of Internal Medicine, Research Institute and Diabetes Center, Athens University, "Attikon" University Hospital,

<sup>2</sup>Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications (HNDC), Athens, Greece.

**Background and aims:** Variation of plasma thyroid hormones' levels influences insulin sensitivity and peripheral glucose disposal. Administration of high doses of thyroxine to healthy humans induces insulin resistance, whereas moderate doses increase peripheral glucose disposal. We investigated the effect of the administration of small doses of thyroxine to healthy humans and patients with type 2 diabetes on postprandial forearm muscle glucose uptake, and insulin sensitivity indices.

**Materials and methods:** A meal was given to eleven healthy euthyroid subjects (aged  $40.8 \pm 2.7$  yrs, BMI  $26.6 \pm 0.83$  kg/m<sup>2</sup>, T3  $118.1 \pm 5$  ng/dl ( $1.818 \pm 0.077$  nmol/l), T4  $7.1 \pm 0.3$  µg/dl ( $91.377 \pm 3.861$  nmol/l), TSH  $1.235 \pm 0.109$  µU/ml) and eleven treatment-naive patients with type 2 diabetes (aged  $42.9 \pm 3.8$  yrs, BMI  $27.48 \pm 1.39$  kg/m<sup>2</sup>, T3  $119 \pm 5.7$  ng/dl ( $1.832 \pm 0.087$  nmol/l), T4  $8.13 \pm 0.46$  µg/dl ( $104.8 \pm 5.93$  nmol/l), TSH  $1.51 \pm 0.14$  µU/ml). Blood was drawn for 300min from a forearm deep vein and the radial artery for measurements of glucose, insulin, and glucose uptake. Forearm blood flow (BF) was measured with strain-gauge-plethysmography. Forearm Glucose-uptake, HOMA-IR, hepatic-insulin-sensitivity-index and ISI-Index (0-120) were calculated. After the first meal-tolerance-test, treatment with 50µg of thyroxine once daily was initiated for a 2-month period. Then a second identical test was repeated.

**Results:** TSH levels reduced significantly post-treatment (DM:  $1.51 \pm 0.11$  vs.  $0.79 \pm 0.11$  µU/ml,  $p < 0.0001$ ). Glucose, insulin levels and HbA1c reduced significantly in the diabetic group, ( $2867 \pm 117$  vs.  $2315 \pm 108$  mMmin,  $p < 0.0001$ ), ( $30426 \pm 5041$  vs.  $18230 \pm 3495$  mUmin,  $p < 0.0001$ ), ( $8.35 \pm 0.18\%$

vs.  $7.31 \pm 0.256\%$ ,  $p < 0.0001$ ), respectively. Peak-baseline BF and Glucose-uptake (AUC0-300min) increased significantly ( $1.952 \pm 0.3$  vs.  $3.54 \pm 0.26$  ml/min per 100cc tissue,  $p = 0.0009$ ) and ( $556 \pm 71$  vs.  $973 \pm 81$  µmol per 100cc tissue,  $p = 0.0026$ ), respectively. All insulin-sensitivity indices improved post-treatment (ISI-HOMA:  $0.207 \pm 0.024$  vs.  $0.44 \pm 0.027$ ,  $p < 0.0001$ ), (Gutt-Index:  $34.3 \pm 2.43$  vs.  $54.7 \pm 5.3$  mg.L2/mmol/mU/min). The patients' weight was stable within the treatment period.

**Conclusion:** Administration of small, subthyrotoxic doses of thyroxine to euthyroid diabetic patients and healthy individuals, can improve peripheral glucose disposal and overall insulin sensitivity. The insulin sensitizing effect of thyroid hormone "boosting" within normal levels, improved glycaemia and insulin sensitivity indices. This could be of therapeutic importance in insulin-resistant subjects.

## 566

### Testosterone improves glucose homeostasis by increasing glucose uptake and glycolysis in human liver cells

D.M. Kelly<sup>1</sup>, P.L. Harrison<sup>2</sup>, S. Akhtar<sup>1</sup>, H.T. Jones<sup>3</sup>;

<sup>1</sup>Human Metabolism, University of Sheffield, ,

<sup>2</sup>Biomedical Research Centre, Sheffield Hallam University,

<sup>3</sup>Barnsley Hospital NHS Foundation Trust, Barnsley, UK.

**Background and aims:** Men with low testosterone levels are at an increased risk of developing type-2 diabetes (T2D). Restoring testosterone to within the normal range through replacement therapy (TRT) improves insulin resistance and glycaemic control in hypogonadal men with T2D. The cellular mechanisms underlying these actions remain unknown but may be due, in part, to an effect on the liver as a major metabolic organ involved in glucose regulation. We have previously shown in testicular feminised mice, which have low testosterone levels and a non-functional androgen receptor (AR), that hepatic expression of glucose regulatory targets were significantly reduced and that TRT had a beneficial effect. Here we investigate the effect of testosterone on glucose homeostasis in human liver cells as a mechanism to improve glucose control and T2D.

**Materials and methods:** Glucose uptake was assessed using 2-NBDG, a fluorescent glucose analogue, in HepG2 cells treated with either testosterone (1-100nM) or vehicle control for 24h. Metformin was used as a positive control (5mM, 10mM). Flutamide was used to block AR actions. XF metabolic assays (Seahorse Bioscience) were performed to further assess cellular bioenergetics and mitochondrial function. Cells were analysed for mRNA and protein expression of targets of glucose regulation (Hexokinase 4, HK4; Phosphofructokinase, PFK; Mitogen-activated protein kinase kinase, MAP2K), by qPCR and western blotting.

**Results:** Glucose uptake was increased in testosterone treated cells at 10nM ( $117 \pm 3.8\%$  of control,  $P \leq 0.05$ ) and 100nM ( $117 \pm 4.3\%$ ,  $P \leq 0.05$ ) concentrations compared to control. This increase was similar to that of Metformin 5mM ( $113 \pm 3.5\%$ ,  $P \geq 0.9$ ) and 10mM ( $122 \pm 4.8$ ,  $P \geq 0.9$ ). Flutamide had no effect on testosterone action on glucose uptake. Extracellular acidification rate as an indicator of changes in the rate of glycolysis were marginally increased in testosterone treated cells. Similarly, oxygen consumption rate as a function of mitochondrial respiration was slightly but not significantly increased in testosterone treated cells. HK4 protein expression was increased in 10nM testosterone treated cells versus vehicle control ( $0.56 \pm 0.04$  vs  $0.24 \pm 0.11$  arbitrary densitometry units [ADU],  $P = 0.08$ ), and significantly at 100nM concentrations ( $0.68 \pm 0.25$  vs  $0.24 \pm 0.11$  ADU,  $P \leq 0.05$ ). No difference was observed between treated and untreated cells for PFK and LXR protein expression and for mRNA expression of all targets.

**Conclusion:** Testosterone increases glucose uptake in HepG2 cells as a mechanism to potentially improve hepatic glucose control. This action may be via increased hepatic glycolysis involving the upregulation of HK4 expression (a key regulatory enzyme in glycolysis) or increased mitochondrial respiration. This effect may also be, in part, AR-independent. Testosterone may improve T2D in men via actions on hepatic glucose regulation.

## 567

## Impaired hepatic insulin extraction in type 2 diabetes

F. Piccinini<sup>1</sup>, C. Dalla Man<sup>1</sup>, A. Vella<sup>2</sup>, C. Cobelli<sup>1</sup>;<sup>1</sup>Department of Information Engineering, University of Padova, Italy,<sup>2</sup>Mayo Clinic, Rochester, USA.

**Background and aims:** The evaluation of hepatic insulin extraction (HE) during a meal is fundamental for understanding the regulation of carbohydrate metabolism in healthy (H), prediabetic (PD), and type 2 diabetic (T2DM) subjects. In this study we use a new physiologically-based mathematical model for estimating HE across the spectrum of glucose tolerance.

**Materials and methods:** To this purpose we studied 18 H (age=49.6±8.2 yr, BMI=27.7±3.1 kg/m<sup>2</sup>), 35 PD (both impaired glucose tolerant and impaired fasting glucose; age=53.2±7.7 yr, BMI=30.1±5.0 kg/m<sup>2</sup>) and 22 T2DM subjects (age=53.9±6.9 yr, BMI=32.7±4.9 kg/m<sup>2</sup>). Each subject underwent a standard mixed meal (75 g glucose, 43% carbohydrate, 17% protein, 40% fat). Frequent plasma sampling was undertaken in all the subjects in order to measure plasma glucose, insulin and C-peptide concentrations. The model assumes that C-peptide kinetics is described by a two-compartment model, insulin kinetics by a three-compartment model, and insulin secretion is a sum of two components, i.e. one proportional to glucose rate of change and one proportional, with a constant delay, to glucose concentration. HE suppression is assumed to be linearly dependent on plasma glucose concentrations. Basal (HE<sub>b</sub>) and total (HE<sub>tot</sub>) HE indices can be derived from the model parameters, as well as a new index quantifying HE sensitivity to glucose (S<sub>G</sub><sup>HE</sup>).

**Results:** The model well fitted C-peptide and insulin data in all the subjects, also providing precise parameter estimates. Rank sum test showed that HE<sub>b</sub> and HE<sub>tot</sub> are significantly lower in T2DM than H subjects (HE<sub>b</sub>=49% vs. 64%, p=0.01; HE<sub>tot</sub>=43% vs. 59%, p=0.04). Moreover, S<sub>G</sub><sup>HE</sup> is significantly lower in T2DM than PD (S<sub>G</sub><sup>HE</sup>=0.10 vs. 0.14 l/mmol, p=0.006) and H subjects (S<sub>G</sub><sup>HE</sup>=0.10 vs. 0.13 l/mmol, p=0.02). Figure 1 shows the average HE profiles reconstructed by the model in the three groups: evidently the basal state is impaired in T2DM, as it is confirmed by the statistical test, moreover, in T2DM, the profile has a longer low phase, and recovers slower than H and PD subjects.

**Conclusion:** The new physiological model for the quantification of HE, initially developed in H subjects, has been successfully used both in PD and T2DM. This model allows the estimation of a new index measuring HE sensitivity to glucose. This was significantly lower in T2DM compared to H and PD, likely due to an inability of plasma glucose to suppress HE.

## The effect of glycaemic variability on expression of genes involved in the development of hyperglycaemia induced tissue damage

K. Kuricová<sup>1</sup>, L. Pácal<sup>1</sup>, V. Dvořáková<sup>1</sup>, J. Šoupa<sup>2</sup>, M. Prázný<sup>2</sup>, K. Kaňková<sup>1</sup>;<sup>1</sup>Department of Pathological Physiology, Masaryk University, Brno,<sup>2</sup>23rd Department of Internal Medicine, Charles University, Prague, Czech Republic.

**Background and aims:** Large prospective studies provided evidence of relationship between long-term diabetes compensation expressed as HbA1c and the risk of diabetic complications. However, HbA1c and diabetes duration explain only small portion of complications risk. It is well known that patients with the same HbA1c differ in amplitudes and duration of glycaemic excursions. Therefore, short-term (i.e. during the day) glycaemic excursions, so called glycaemic variability (GV), are debated currently. Animal experiments and *in vitro* studies showed that oscillating glucose may have more deleterious effect on cells due to higher production of superoxide than hyperglycaemia itself. Therefore, aim of our study was to evaluate the effect of GV on the expression of genes whose products are involved in the development of tissue damage in diabetes. We compared the effect of low and high GV of diabetics, GV of healthy subjects and chronic normo- and hyperglycaemia. Specifically, we detected gene expression of glyoxalase 1 (GLO1), heme oxygenase (HMOX), receptor for advanced glycation end-products (RAGE), p53, superoxide dismutase (SOD2), DJ-1 (an enzyme with glyoxalase activity), transketolase (TKT) and thiamine pyrophosphokinase (TPK1).

**Materials and methods:** Primary human umbilical vein endothelial cells (HUVEC) were cultured 24 hours in the following settings mimicking situation in humans (both diabetics and healthy) and in commonly used *in vitro* hyperglycaemia model: (A) high GV (standard deviation [SD] > 5), (B) low GV (SD < 3), (C) non-diabetics (SD = 1), (D) continuous normoglycaemia (5 mmol/l) and (E) continuous hyperglycaemia (25 mmol/l). Based on real 24 hours glycaemic curves from type 1 diabetics (3 patients with low GV and 3 with high GV) and healthy subjects (2 curves) we created 24 hours profiles with medium change after 2 hours. After 24 hours cells were harvested and RNA isolated and reverse transcribed using commercial kits (Roche). Gene expression was determined using quantitative PCR with predesigned probes (TaqMan™ Assay) with β-actin as a reference gene.

**Results:** HMOX expression was significantly lower in both low and high GV compared to GV of healthy subjects (P = 0.04, Mann-Whitney test). Similar pattern was also found in four of the selected genes (p53, SOD2, GLO1, DJ-1) although statistically not significant (all P > 0.05, Mann-Whitney test). Expression of all genes with exception of DJ-1 was significantly higher in continuous normoglycaemia when compared to low and high GV (all P < 0.04, Mann-Whitney). Finally, no significant difference was found between continuous hyperglycemia and low and high GV (all P > 0.05).

**Conclusion:** Results of our pilot study indicate that the effect of either low or high GV on expression of selected genes involved in diabetes induced tissue damage does not significantly differ from the effect of continuous hyperglycaemia.

### Beneficial roll of TAZ modulator, TM-25659, in obese and diabetic conditions

J.-G. Jeong<sup>1</sup>, J. Jeon<sup>1</sup>, E. Ha<sup>1</sup>, S.-E. Choi<sup>2</sup>, S.-A. Lee<sup>1</sup>, Y. Kang<sup>2</sup>, M. Bae<sup>3</sup>, J. Ahn<sup>3</sup>, H. Jeong<sup>4</sup>, E. Hwang<sup>4</sup>, S. Han<sup>1</sup>, D. Kim<sup>1</sup>, K.-W. Lee<sup>1</sup>;

<sup>1</sup>Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, <sup>2</sup>Institute of Medical Science, Ajou University School of Medicine, Suwon, <sup>3</sup>Korea Research Institute of Chemical Technology, University of Science & Technology, <sup>4</sup>College of Pharmacy, Graduate School of Pharmaceutical Sciences, and Global Top<sup>2</sup> Research Program, Ewha Womans University, Seoul, Republic of Korea.

**Background and aims:** The transcriptional co-activator with PDZ-binding motif (TAZ) inhibits adipocyte development by intervention with peroxisome proliferator-activated receptor (PPAR)-gamma. Recently, PPAR-gamma has been implicated in muscle lipid accumulation. Therefore, we investigated the effects of TAZ modulator on skeletal muscle function in C2 myotubes and in C57BL/6J mice. In a previous study, Jang et al identified 2-butyl-5-methyl-6-(pyridine-3-yl)-3-[2'-(1H-tetrazole-5-yl)-biphenyl-4-ylmethyl]-3H-imidazo[4,5-b]pyridine (TM-25659) as a TAZ modulator and was shown to decrease weight gain in a high fat diet-induced obese model.

**Materials and methods:** We measured insulin signaling and glucose uptake using immunoblotting and 2-NBDG uptake. To elucidate the preventing mechanism of TM-25659 on palmitate-induced C2 myotubes insulin signaling, we performed real-time PCR with pro-inflammatory cytokines (TNF-alpha, IL-1-beta, IL-6 and MCP-1) mRNA. Male C57BL/6J mice that were fed a HFD for 8 weeks were randomly assigned for an additional 6 weeks to 3 groups: normal diet (ND), HFD, HFD+TM-25659. After treatment, oral glucose tolerance test (OGTT) and intraperitoneal insulin tolerance test (IP-ITT) were performed to evaluate anti-diabetic effects. After sacrifice, tissue extracts of the soleus muscle were obtained for quantification of insulin signaling through Akt phosphorylation proteins by immunoblotting.

**Results:** In our present study, we confirmed TM-25659 considerably inhibits palmitate-induced insulin resistance on C2 myotubes. Moreover, we showed that TM-25659 significantly suppresses high fat diet (HFD) induced insulin resistance in C57BL/6J mice skeletal muscle. Consequently, the TM-25659-treated group showed improved HFD-reduced glucose tolerance, increased insulin sensitivity, and increased AKT phosphorylation protein. Also, TM-25659 down-regulated expression of genes involved in pro-inflammation.

**Conclusion:** These results suggest TAZ modulator, TM-25659, play a beneficial role in controlling insulin resistance in obese and diabetic conditions.

### Human skeletal muscle clock: implications in myokine secretion in physiology and pathophysiology

S. Skarupelova<sup>1</sup>, L. Perrin<sup>1</sup>, E. Lefai<sup>2</sup>, H. Vidal<sup>2</sup>, J. Philippe<sup>1</sup>, C. Dibner<sup>1</sup>;

**Background and aims:** Circadian rhythms are present in many organisms of different complexity, representing an adaptation mechanism allowing adjustment of organism's internal processes to the external world. In mammals circadian system is organized in a hierarchical structure with a central pacemaker residing in hypothalamic suprachiasmatic nuclei that in its turn controls peripheral secondary clocks in organs including skeletal muscle. The aim of our study was to characterize molecular clock and its function in human primary skeletal muscle of healthy, overweight and obese subjects.

**Materials and methods:** Human primary myoblasts were derived from muscle biopsies of *Musculus gluteus maximus*. Bioluminescent reporters *Bmal1-luciferase* and *Per2-luciferase* were introduced by lentiviral transduction, and allowed visualization of the oscillatory profiles of *Bmal1* and *Per2* continuously in living cells. For clock ablation myotubes were transfected with siRNA-targeting *Clock*. Secretory profiles of myokine IL6 (ELISA measurements), assessed in parallel with bioluminescence profile recording, were compared in myotubes with functional and ablated clock.

**Results:** Our experiments revealed that fully differentiated *in vitro* synchronized myotubes exhibited circadian rhythm with a period length of about 24.6 hours. Oscillation period tended to be longer in case of overweight and obese subjects. Endogenous core clock transcripts as well as bioluminescent profiles showed sustained circadian expression pattern with pronounced amplitude. Around 90% of *Clock* knockdown significantly flattened oscillatory profile of *Bmal1-luciferase* reporter and amplitude of endogenous core clock transcripts. Our results revealed that the primary myotubes with intact clock secret IL6 in the circadian manner. Moreover, remarkable down regulation of IL6 secretion was observed upon clock ablation, meaning that the clock machinery might regulate IL6 secretion in human skeletal muscle.

**Conclusion:** Our data demonstrate that the human skeletal muscle exhibits pronounced circadian oscillations that impacts on the muscle IL6 secretory function. Moreover, changes in rhythmicity of circadian machinery in human skeletal muscle might be associated with metabolic disorders such as obesity.

### Role of the RNA binding protein Sam68 in leptin and insulin signalling in granulosa cells

V. Sanchez-Margalet<sup>1</sup>, T. Vilarino-García<sup>1</sup>, A. Perez-Perez<sup>1</sup>, F. Sanchez-Jimenez<sup>1</sup>, V. Blasco<sup>2</sup>, N. Prados-Nodd<sup>2</sup>, M. Fernandez-Sanchez<sup>2</sup>;

<sup>1</sup>Medical Biochemistry and Molecular Biology and Immunology, Virgen Macarena University Hospital, <sup>2</sup>Instituto Valenciano de Infertilidad, Seville, Spain.

**Background and aims:** Obesity is a medical problem not only because it is associated with type 2 diabetes and cardiovascular risk, but also because in reproductive-age women obesity is associated with polycystic ovary syndrome (PCOS), insulin resistance and decreased fertility. The RNA-binding protein Sam68 is expressed in granulosa cells and the knockout female mice are subfertile, with ovulation problems. Since we have previously found that Sam68 may be recruited to insulin and leptin receptors, we planned to study the participation of Sam68 in signaling and action of insulin and leptin receptors in granulosa cells. In addition, we aimed to study the expression of Sam68 in granulosa cells in response to leptin and insulin *in vitro*.

**Materials and methods:** Signaling was studied by immunoprecipitation and immunoblot of the phosphorylated proteins. The expression of Sam68 is inhibited by antisense strategy. The expression level of Sam68, and leptin and insulin receptors are quantified by qPCR and immunoblot.

**Results:** We have found that Sam68 is tyrosine phosphorylated by insulin or leptin stimulation in granulosa cells, recruiting Sam68 to signaling complexes and decreasing its RNA binding capacity. In addition, both insulin and leptin increase the expression of Sam68 in granulosa cells. Finally, full expression of Sam68 is required for the activation of PI3K and MAPK signaling pathways by insulin or leptin in granulosa cells.

**Conclusion:** Sam68 is recruited to leptin and insulin receptor signaling, its expression is induced by both hormones, and Sam68 is necessary for the full activation of insulin and leptin receptor signal transduction in granulosa cells. Sam68 may be a new important element in the ovarian insulin resistance and the decreased fertility found in obese women.

### Insulin regulates glycogen synthesis in endometrial epithelial cells through an increase in glycogen synthase

G. Choe, C.A. Flannery, F. Saleh, H.S. Taylor; Obstetrics, Gynecology, & Reproductive Sciences, Yale School of Medicine, New Haven, USA.

**Background and aims:** Endometrial gland secretion of glucose, lipids, and protein supports blastocyst nutrition prior to establishment of placental circulation. The endometrial glands fill with glycogen during the secretory phase in preparation for implantation, and regulation of glycogen synthesis has been attributed to progesterone. However, we hypothesized that insulin regulates glycogen synthesis in endometrial epithelial cells as it does in traditional insulin targets such as liver and muscle.

**Materials and methods:** We isolated endometrial epithelial and stromal cells from eight healthy women, and treated the cells separately with insulin, medroxyprogesterone (MPA), or vehicle. After 48hours, the cells were lysed,

and glycogen was isolated and quantified. Total and phosphorylated glycogen synthase (GS) and glycogen synthase kinase 3 $\alpha/\beta$  (GSK3 $\alpha/\beta$ ) were evaluated by western blot after a 30min or 48hr hormone stimulation. Endometrial tissue from 45 women distributed across the menstrual cycle was assessed for insulin receptor  $\beta$  (IR $\beta$ ) by PCR and IHC.

**Results:** We found that IR $\beta$  had higher expression during the secretory phase of the menstrual cycle, with an increase in expression in both epithelial and stromal cells between day 16 and 24 of the menstrual cycle. In vitro MPA increases IR $\beta$  expression over 25-fold in primary stromal cells ( $p < 0.0001$ ) and to a lesser extent in epithelial cells. Insulin induces a 4.5-fold increase in glycogen content in primary epithelial cells ( $p < 0.01$ ), whereas MPA did not directly alter glycogen content relative to vehicle. In stromal cells, neither insulin nor MPA altered glycogen content. Insulin induced phosphorylation of GSK3 $\alpha/\beta$  acutely, and a 3.6-fold increase in GS protein by 48 hours ( $p = 0.005$ ). **Conclusion:** We demonstrate that progesterone regulates IR $\beta$  expression during the secretory phase, facilitating insulin action. Insulin, not progesterone, directly regulates glycogen synthesis through an increase in GS as well as acute phosphorylation events. This mechanism is novel and distinct from insulin regulation of glycogen synthesis in the liver and muscle that is accomplished predominantly through acute phosphorylation events of GSK3 $\alpha/\beta$  and GS. A lasting increase in GS in response to insulin enables endometrial epithelial cells to synthesize glycogen continuously, independent of short term nutrient flux. This distinct regulation of glycogen synthesis is a unique adaptation to allow glycogen accumulation in endometrium. These findings suggest that successful implantation requires insulin, and may explain why women with insulin resistance have lower implantation rates.

### ECSCR negatively regulates insulin sensitivity via PTEN stabilisation in endothelial cells

M. Ohta<sup>1,2</sup>, T. Sugano<sup>2</sup>, N. Inoue<sup>1,2</sup>, M. Whelan<sup>1</sup>, J. Matsumoto<sup>1,2</sup>, K. Inoue<sup>2</sup>, K. Mizuno<sup>1,2</sup>, M. Aikawa<sup>1</sup>;

<sup>1</sup>Center for Interdisciplinary Cardiovascular Sciences, Brigham and

Women's Hospital, Harvard Medical School, Boston, USA,

<sup>2</sup>Kowa company, Ltd, Tokyo, Japan.

**Background and aims:** Endothelial insulin resistance impairs insulin delivery into skeletal muscle, and insulin-dependent glucose disposal is reduced in obesity patients with type 2 diabetes mellitus (T2DM). Endothelial cell surface expressed chemotaxis and apoptosis regulator (ECSCR) is a cell-surface protein selectively expressed on endothelial cells. Recent study revealed ECSCR is potentially therapeutic target for T2DM to enhance Akt/eNOS phosphorylation and improve insulin sensitivity in Ecsr-deficient mice. However, the underlying mechanism is still unknown. We investigated the mechanism how ECSCR negatively regulate insulin signaling using human umbilical vein endothelial cells (HUVECs) and mouse pancreatic endothelial cell line (MS1).

**Materials and methods:** HUVECs and MS1 were transfected with vector expressing FLAG-MYC-tagged ECSCR and the pCMV6 control vector for overexpression study. HUVECs were transfected with siRNA for ECSCR and scramble control sequence for knockdown study. Protein degradation activities of PTEN and PTP1B were evaluated on HUVECs with 10  $\mu\text{g}/\text{mL}$  of cycloheximide. mRNA and Proteins from cells were collected for RT-PCR and western blot analysis. All results are representative of at least three independent experiments.

**Results:** ECSCR overexpression on HUVECs and MS1 suppressed basal phosphorylation of Akt at Ser473. ECSCR knockdown on HUVECs increased phosphorylation of Akt at Ser473. ECSCR knockdown also significantly increased genes expression of PTEN and PTP1B, which are negatively modulating insulin signal on HUVECs. However, only PTEN protein amount in HUVECs was decreased. To identify the mechanism how ECSCR modulates insulin signaling, we evaluated the protein degradation activity of PTEN and PTP1B on HUVECs. ECSCR knockdown strongly enhanced the degradation of PTEN, but not PTP1B. Insulin stimulation accelerated PTEN degradation in HUVECs with ECSCR knockdown.

**Conclusion:** Taken together, our data proposed new mechanism that ECSCR selectively stabilize PTEN protein to prevent from protein degradation in HUVECs. ECSCR inhibition will be potentially new class of therapeutic target to improve endothelial insulin sensitivity in T2DM.

Fig 1. ARIA knock-down induces PTEN and PTP1B gene expression on HUVEC cells. Black bar represents Scramble group and white bar is ARIA knock-down group. Result represents mean  $\pm$  S.D. of relative gene expression ( $n = 3$ ). \* $p < 0.05$  (vs cells transfected with the scramble sequence, Student t-test).

### Insulin resistance of pancreatic alpha cells with age under high fat diet in mice

S. Schinner, B. Funk;

Endocrinology and Diabetes, University Hospital Düsseldorf, Germany.

**Background and aims:** Insulin and GLP-1 are strong inhibitors of glucagon release from pancreatic alpha-cells. Obesity causes insulin resistance of liver and skeletal muscle. However, it is not known if obesity causes insulin resistance in alpha-cells. In addition, the effectiveness of GLP-1 in ameliorating glucose tolerance and suppressing glucagon in aged organisms is not well understood. Therefore, we investigated insulin responsiveness of alpha-cells in a mouse model of obesity and GLP-1 (exendin-4) responsiveness in wildtype mice of different age

**Materials and methods:** Young (6 weeks) and old (8 months) C57BL6 wild-type mice ( $n = 27$ ) were fed with a high-fat-diet (HFD) (60% kcal of fat) over a period of 8 weeks to induce obesity and hyperinsulinaemia. Intraperitoneal glucose-tolerance-tests (ipGTT) were performed and levels of glucose, insulin and glucagon were assessed. Lean mice fed a standard diet served as controls ( $n = 27$ ). In addition, young (6 weeks) and old (8 months) C57BL6 wild-type mice were treated with exendin-4 (10nM/kg bodyweight; ip) over a period of 3 weeks followed by an ipGTT assessing glucose tolerance and glucagon secretion.

**Results:** Young as well as old mice gained approx. 40% of body weight after HFD compared to controls. In controls the blood glucose levels were  $335 \pm 66 \text{ mg}/\text{dl}$  in young and  $275 \pm 72 \text{ mg}/\text{dl}$  in old mice 30 min after glucose load with corresponding levels of insulin ( $360 \pm 60$  vs.  $470 \pm 120 \text{ ng}/\text{ml}$ ) and glucagon ( $26 \pm 5$  vs.  $39 \pm 11 \text{ pg}/\text{ml}$ ). In young mice on HFD the blood glucose levels were comparable with  $335 \pm 68 \text{ mg}/\text{dl}$  after 30 min. In contrast, old mice after HFD showed significantly increased glucose levels of  $503 \pm 100 \text{ mg}/\text{dl}$  at 30 min. Insulin levels increased 1,7fold ( $810 \pm 286$ ) after 30 min. and 6fold ( $2.170 \pm 280 \text{ ng}/\text{ml}$ ) after 120 minutes. Of note, glucagon levels were not suppressed ( $62 \pm 2 \text{ pg}/\text{ml}$  after 30min and  $45 \pm 4 \text{ pg}/\text{ml}$  after 120min) despite the peaks in insulin release. In vitro experiments revealed that isolated islets from old animals after HFD showed no inhibition of glucagon release in response to insulin. Exendin-4 treatment improved glucose-tolerance in young and old mice at comparable levels (young: control 0 min blood glucose =  $77 \pm 31$ , 30 min =  $328 \pm 41$ ; exdn-4: 0 min =  $100 \pm 26$ , 30 min =  $163 \pm 14 \text{ mg}/\text{dl}$ ; old mice: control 0 min =  $82 \pm 28$ , 30 min =  $314 \pm 57$ ; exdn-4 0 min =  $95 \pm 21$ , 30 min =  $160 \pm 30 \text{ mg}/\text{dl}$ ). Interestingly, basal glucagon levels were higher in older mice than in young mice ( $56 \pm 8$  vs.  $44 \pm 6 \text{ pg}/\text{ml}$ ). The response in glucagon levels was comparable between controls and exendin-4 treated animals (young: control 0 min =  $44 \pm 6$ , 30 min =  $29 \pm 9$ ; exdn-4 0 min =  $42 \pm 12$ , 30 min =  $38 \pm 14 \text{ pg}/\text{ml}$ ; old: control 0 min =  $56 \pm 8$ , 30 min =  $36 \pm 9$ ; exdn-4 0 min =  $57 \pm 10$ , 30 min =  $34 \pm 5 \text{ pg}/\text{ml}$ ).

**Conclusion:** Higher age predisposes to impaired glucose tolerance after high-fat-diet in this animal model. Furthermore, high levels of endogenous

insulin in old mice on HFD fail to suppress glucagon release, indicating insulin resistance of glucagon producing alpha-cells. This was paralleled by *in vitro* findings with islets from old mice under HFD.
