Abstract

Wavelengths, transition rates, and line strengths are calculated for the 76 possible multipole (E1, M1, E2, M2, E3, M3) transitions between the excited $3s^23p^63d^94l$, $3s^23p^53d^{10}4l$, and $3s3p^63d^{10}4l$ and the ground $3s^23p^63d^{10}$ states in Ni-like ions with the nuclear charges ranging from $Z = 30$ to 100. Relativistic many-body perturbation theory (RMBPT), including the Breit interaction, is used to evaluate energies and transition rates for multipole transitions in hole-particle systems. This method is based on relativistic many-body perturbation theory, agrees with MCDF calculations in lowest-order, includes all second-order correlation corrections and includes corrections from negative energy states. The calculations start from a $1s^22s^22p^63s^23p^63d^{10}$ Dirac-Fock potential. First-order perturbation theory is used to obtain intermediate-coupling coefficients, and second-order RMBPT is used to determine the matrix elements. The contributions from negative-energy states are included in the second-order E1,

M1, E2, M2, E3, and M3 matrix elements. The resulting transition energies and transition rates are compared with experimental values and with results from other recent calculations. As a result, we present wavelengths and transition rates data for the selected transitions that includes the 76 possible multipole (E1, M1, E2, M2, E3, M3) transitions between the excited $3s^23p^63d^94l$, $3s^23p^53d^{10}4l$, and $3s3p^63d^{10}4l$ states and the ground $3s^23p^63d^{10}$ state in Ni-like ions. Trends of the line strengths for the 76 multipole transitions and oscillator strengths for the 13 E1 transitions as function of Z are illustrated graphically. The Z dependence of the energy splitting for all triplet terms of the $3s^23p^63d^94l$, $3s^23p^53d^{10}4l$, and $3s3p^63d^{10}4l$ configurations are shown in the range of $Z = 30$ – 100 .

INTRODUCTION

Relativistic many-body perturbation theory (RMBPT) was used recently to study atomic characteristics of particle-hole excitations of closed-shell ions [1, 2, 3, 4, 5, 6, 7]. In the first of these studies, energies [1, 2, 3] and oscillator strengths [4] in Ne-like ions were considered by Avgoustoglou *et al.* Reduced matrix elements, oscillator strengths, and transition rates into the ground state for all allowed and forbidden electric- and magnetic-dipole and electric- and magnetic-quadrupole transitions (E1, M1, E2, M2) in Ne-like ions were presented by Safronova *et al* in Ref. [5]. The second-order RMBPT calculations for Ni-like ions was used in Ref. [6, 7] to determine excitation energies and E1, M1, E2, M2 transition rates.

The Ni-isoelectronic sequence has been studied extensively in connection with x-ray lasers [8, 9, 10, 11, 12, 13]. A detailed analysis of 3-4 transitions in the x-ray spectra of Ni-like Gd ($Z=64$) produced in a tokamak was presented by van Goeler *et al.* [14] and in the x-ray spectrum from laser produced plasmas of Ni-like Ba ($Z=56$), La ($Z=57$), and Pr ($Z=59$) was reported by Doron *et al.* [15] and Zigler *et al.* [16]. In particular, ab-initio calculations were performed in Ref. [15] using the relativistic parametric potential computer code (RELAC) [17] to identify $3d - nf$ ($n=4$ to 8), $3p - 4s$, and $3p - 4d$ transitions of Ni-like Ba. Atomic structure calculations for highly ionized tungsten (Rb-like W^{37+} to Co-like W^{47+}) were done by Fournier [18] with using the graphical angular momentum coupling code ANGULAR and RELAC code. The RELAC code was used by Busquet *et al.* [19] to identify x-ray spectral lines emitted by a target of Au ($Z=79$). Zhang *et al.* [20], using the Dirac-Fock-Slater (DFS) code evaluated excitation energies and oscillator strengths for the 33 Ni-like ions with $60 \leq Z \leq 92$. Energy levels and radiative rates for allowed transitions among the 107 fine-structure levels for the $n = 4$ excited configurations of Ni-like ions with $Z = 60, 62, 63, 73, 74$ were calculated using the fully relativistic GRASP code [21].

The $n=3-4$ transitions observed in x-ray spectra of Ni-like ions (Ag^{19+} - Pb^{54+}) were investigated

theoretically by Quinet and Biémont [22], where the MCDF approach (Grant's code) was used to calculate wavelengths and oscillator strengths for the $3d - 4p$, $3d - 4f$, $3p - 4s$, and $3p - 4d$ electric-dipole transitions. The relative magnitudes of the electric-multipole (E1, E2, E3) and magnetic-multipole (M1, M2, M3) radiative decay rates calculated by the MCDF approach, were presented by Biémont [23] for the 17 lowest levels of highly ionized nickel-like ions. Observations of electric-quadrupole and magnetic-octupole decay in the x-ray spectrum of highly charged Ni-like ions (Th^{62+} and U^{64+}) were reported by Beiersdorfer *et al.* in Ref. [24]. There are fewer papers concerned with the analysis of the $4s - 4p$ and $4p - 4d$ transitions in Ni-like ions in Ref. [25, 26].

In the present paper, relativistic many-body perturbation theory (RMBPT) is used to determine the energies of $3s^2 3p^6 3d^9 4l(J)$, $3s^2 3p^5 3d^{10} 4l(J)$, and $3s 3p^6 3d^{10} 4l(J)$ states of Ni-like ions with nuclear charges $Z=30-100$. The calculations are carried out to second order in perturbation theory. We consider all possible $3l$ holes and $4l$ particles leading to the 56 odd-parity $3d^{-1} 4p(J)$, $3d^{-1} 4f(J)$, $3p^{-1} 4s(J)$, $3p^{-1} 4d(J)$, $3s^{-1} 4p(J)$, and $3s^{-1} 4f(J)$ excited states and the 50 even-parity $3d^{-1} 4s(J)$, $3d^{-1} 4d(J)$, $3p^{-1} 4p(J)$, $3p^{-1} 4f(J)$, $3s^{-1} 4s(J)$, and $3s^{-1} 4d(J)$ excited states in Ni-like ions with $Z=30$ to 100.

Relativistic MBPT is used to determine line strengths, oscillator strengths, and transition rates for all allowed and forbidden electric-multipole and magnetic-multipole (E1, E2, E3, M1, M2, M3) transitions from $3s^2 3p^6 3d^9 4l(J)$, $3s^2 3p^5 3d^{10} 4l(J)$, and $3s 3p^6 3d^{10} 4l(J)$ excited states into the ground state in Ni-like ions. Retarded E1, E2, and E3 matrix elements are evaluated in both length and velocity forms.

METHOD

Details of the RMBPT method were presented in Refs. [1, 6] for the calculation of energies of hole-particle states, in Ref. [27] for the calculation of energies of particle-particle states, in Ref. [28] for the

calculation of radiative electric-dipole rates in two-particle states, and in Ref. [5, 7] for calculation of radiative electric-dipole, electric-quadrupole, magnetic-dipole, and magnetic-quadrupole rates in Ne- and Ni-like systems. We will present here only the model space for Ni-like ions without repeating the detailed discussions given in the above mentioned references. The calculations are carried out using basis sets of Dirac-Hartree-Fock (DHF) orbitals. The orbitals used in the present calculation are obtained as linear combinations of B-splines. These B-spline basis orbitals are determined using the method described in Ref. [29]. We use 50 B-splines of order 10 for each single-particle angular momentum state and include all orbitals with orbital angular momentum $l \leq 9$ in our basis set.

For atoms with one hole in closed shells and one valence electron, the model space is formed from hole-particle states of the type $a_v^+ a_a |0\rangle$, where $|0\rangle$ is the closed-shell $1s_{1/2}^2 2s_{1/2}^2 2p_{1/2}^2 2p_{3/2}^4 3s_{1/2}^2 3p_{1/2}^2 3p_{3/2}^4 3d_{3/2}^4 3d_{5/2}^6$ ground state. The single-particle indices v range over states in the valence shell and the single-hole indices a range over the closed core. For our study of low-lying $3l^{-1}4l'$ states of Ni-like ions, values of a are $3s_{1/2}$, $3p_{1/2}$, $3p_{3/2}$, $3d_{3/2}$, and $3d_{5/2}$, while values of v are $4s_{1/2}$, $4p_{1/2}$, $4p_{3/2}$, $4d_{3/2}$, $4d_{5/2}$, $4f_{5/2}$, and $4f_{7/2}$. To obtain an orthonormal model of states, we consider the coupled states $\Phi_{JM}(av)$ defined by

$$\Phi_{JM}(av) = \sqrt{(2J+1)} \sum_{m_a m_v} (-1)^{j_v - m_v} \begin{pmatrix} j_v & J & j_a \\ -m_v & M & m_a \end{pmatrix} a_{vm_v}^\dagger a_{am_a} |0\rangle. \quad (1)$$

Combining the $n = 3$ hole orbitals and the $n = 4$ particle orbitals in nickel, we obtain 56 odd-parity states consisting of 5 $J = 0$ states, 13 $J = 1$ states, 15 $J = 2$ states, 12 $J = 3$ states, 7 $J = 4$ states, 3 $J = 5$ states, and one $J = 6$ state. Additionally, there are 50 even-parity states consisting of 5 $J = 0$ states, 12 $J = 1$ states, 14 $J = 2$ states, 11 $J = 3$ states, 6 $J = 4$ states, and two $J = 5$ states. The distribution of the 106 states in the model space is summarized in Table I. In this table, we give both jj and LS designations for hole-particle states. Instead of using the $3l_j^{-1}4l'_j$,

or $3l^{-1}4l'$ designations, we use simpler designations $3l_j4l'_j$ or $3l4l'$ in this and following tables and throughout the text.

Physical hole-particle states are linear combinations of uncoupled hole-particle states (av) in the model space that have fixed values of angular momentum and parity. The first-order expansion coefficient $C_1^N(av)$ is the N -th eigenvector of the first-order effective Hamiltonian, and E_1^N is the corresponding eigenvalue. In the present calculation, both Coulomb and Breit interactions are included in the first-order effective Hamiltonian. The resulting eigenvectors are used to determine the second-order Coulomb and Breit corrections and coupled multipole matrix elements [6, 7].

Usually, either LS or jj designations are used to label the resulting eigenvectors rather than simply enumerating with an index N . The LS designations for the resulting eigenvectors and eigenvalues and jj designations for the uncoupled states are used for simplicity in all following figures and tables and the text below.

Z -dependence of eigenvectors and eigenvalues in Ni-like ions

In Figs. 1–6, we illustrate the Z -dependence of the eigenvectors of the $3l_j 4l'_j$ [J] hole-particle states. Strong mixing between states within the odd-parity complex with $J=1$ was discussed in many papers (see, for example, [6]). We refer to a set of states of the same parity and the same J as a complex of states. Additionally, we found strong mixing within the odd-parity complex with $J=2$ and even-parity complex with $J=1$ and 2. There is much smaller mixing within the odd- and even-parity complex with $J=3$.

In Figs. 1–3, we show the dependence of the eigenvectors for the examples of odd-parity states with $J=1, 2$, and 3, respectively. The dependence of the eigenvectors for the even-parity states with $J=1-3$ are shown in Figs. 4–6. The $J=1$ even-parity complex includes 12 states which are listed in Table I. Using the first-order expansion coefficients $C^Q(av[J])$ defined previously, we can

present the resulting eigenvectors as

$$\begin{aligned}
\Phi(Q) = & C^Q(3d_{3/2}4s_{1/2}[1])\Phi(3d_{3/2}4s_{1/2}[1]) + \\
& C^Q(3d_{5/2}4d_{3/2}[1])\Phi(3d_{5/2}4d_{3/2}[1]) + C^Q(3d_{5/2}4d_{5/2}[1])\Phi(3d_{5/2}4d_{5/2}[1]) + \\
& C^Q(3d_{3/2}4d_{3/2}[1])\Phi(3d_{3/2}4d_{3/2}[1]) + C^Q(3d_{3/2}4d_{5/2}[1])\Phi(3d_{3/2}4d_{5/2}[1]) + \\
& C^Q(3p_{3/2}4p_{1/2}[1])\Phi(3p_{3/2}4p_{1/2}[1]) + C^Q(3p_{3/2}4p_{3/2}[1])\Phi(3p_{3/2}4p_{3/2}[1]) + \\
& C^Q(3p_{1/2}4p_{1/2}[1])\Phi(3p_{1/2}4p_{1/2}[1]) + C^Q(3p_{1/2}4p_{3/2}[1])\Phi(3p_{1/2}4p_{3/2}[1]) + \\
& C^Q(3p_{3/2}4f_{5/2}[1])\Phi(3p_{3/2}4f_{5/2}[1]) + \\
& C^Q(3s_{1/2}4s_{1/2}[1])\Phi(3s_{1/2}4s_{1/2}[1]) + C^Q(3s_{1/2}4d_{3/2}[1])\Phi(3s_{1/2}4d_{3/2}[1]). \quad (2)
\end{aligned}$$

As a result, the 144 $C^Q(av[J])$ coefficients are needed to describe the 12 eigenvalues. These coefficients are often called mixing coefficients. For simplicity, we plot only two or three curves chosen from the 12 mixing coefficients $C^Q(3l_j4l'_{j'}[1])$ for the $Q = 3d4d \ ^3D_1$, $Q = 3d4d \ ^3P_1$, $Q = 3p4p \ ^3D_1$, $Q = 3p4p \ ^1P_1$, $Q = 3p4p \ ^3P_1$, and $Q = 3s4s \ ^3S_1$ presented in Fig. 4. These coefficients are chosen to illustrate the mixing of the states; the remaining mixing coefficients give very small contributions to those states. We observe strong mixing even between states with different configurations: $3d_j4d_{j'}[1] + 3p_j4p_{j'}[1]$, $3p_j4p_{j'}[1] + 3p_j4f_{j'}[1]$, and $3p_j4p_{j'}[1] + 3s_j4s_{j'}[1]$. Strong mixing of states occurs for high- Z ions in the region for $Z= 80 - 85$. A similar behavior is seen in Figs. 1, 2, and 5 where the Z -dependence of eigenvectors for odd-parity complexes with $J=1, 2$, and for even-parity complexes with $J=2$ is shown. It should be noted that the mixing for odd- and even-parity states with $J = 3$ occurs only inside one configuration but with different j ($3d_{5/2}4p_{3/2}[3] + 3d_{3/2}4p_{3/2}[3]$, for example, shown in Fig. 3, and $3p_{3/2}4f_{5/2}[3] + 3p_{3/2}4f_{7/2}[3]$, for example, shown in Fig. 6).

Energies, relative to the ground state, of even- and odd-parity states divided by $(Z - 21)^2$, are shown in Figs. 7 and 8. It should be noted that Z was decreased by 21 to provide better presentation of the energy diagrams. We plot a subset of energy levels to illustrate the Z dependence, choosing

all singlet terms and one representative example among the triplet terms. As a result, we show 24 levels instead of 50 in Fig. 7, and 28 levels instead of 56 in Fig. 8. As can be seen from Figs. 7 and 8, the Z dependence of energy levels is very different for the $3d4l\ ^{1,3}L_J$ (Figs. 7a, 7b, 8a, 8b, and 8c), the $3p4l\ LSJ$ (Figs. 7c, 7d, 8d, and 8e), and the $3s4l\ ^{1,3}L_J$ (Figs. 7e, 7f, and 8f) states. For example, the curves describing the energy ($E/(Z - 21)^2$) of $3dnl\ ^{1,3}L_J$ states increase for small Z ($Z = 30 - 40$) and become almost constant for high Z . The curves describing the energy ($E/(Z - 21)^2$) of $3pnl\ ^{1,3}L_J$ and $3snl\ ^{1,3}L_J$ states, by contrast, decrease with increasing Z for small Z ($Z = 30 - 50$) and become almost constant for high Z . The values of $E/(Z - 21)^2$ for the $3pnl\ LSJ$ states change less than for the $3s4l\ ^{1,3}L_J$ states (6000 - 9000 cm^{-1} instead of 7000 - 14000 cm^{-1}). The values of $E/(Z - 21)^2$ for the $3d4l\ ^{1,3}L_J$ states vary between 1000 cm^{-1} and 6000 cm^{-1} .

It should be noted that the LS designations were chosen based upon small values of the multiplet splitting for low- Z ions. To confirm those LS designations we obtained the fine structure splitting for the $3d4s\ ^3D$, $3d4p[{}^3P, {}^3D, {}^3F]$, $3d4d[{}^3P, {}^3D, {}^3F, {}^3G]$, $3d4f[{}^3P, {}^3D, {}^3F, {}^3G, {}^3H]$, $3p4s[{}^3P]$, $3p4p[{}^3P, {}^3D]$, $3p4d[{}^3P, {}^3D, {}^3F]$, $3p4f[{}^3D, {}^3F, {}^3G]$, $3s4p\ ^3P$, and $3s4f\ ^3F$ triplets.

Energy differences between levels of odd- and even-parity triplet terms, divided by $(Z - 21)^2$, are shown in Figs. 9–10 and Fig. 11, respectively. The energy intervals for the $3d4p({}^3P_2 - {}^3P_1)$, $3d4p({}^3D_3 - {}^3D_2)$, $3d4p({}^3F_3 - {}^3F_2)$, $3d4f({}^3P_2 - {}^3P_1)$, $3d4f({}^3G_4 - {}^3G_3)$, $3d4f({}^3G_5 - {}^3G_4)$, $3d4f({}^3H_5 - {}^3H_4)$, and $3p4s({}^3P_1 - {}^3P_0)$ states are very small and almost do not change with Z as can be seen from Fig. 9. There is a very sharp variation of the splitting with Z for the $3d4f\ ^3D$ term but the energies $\Delta E/(Z - 21)^2$ change by small values, from -40 cm^{-1} to 20 cm^{-1} . The energy intervals vary strongly with the nuclear charge for the $3d4p({}^3P_1 - {}^3P_0)$, $3d4p({}^3D_2 - {}^3D_1)$, $3d4p({}^3F_4 - {}^3F_3)$, $3d4f({}^3P_1 - {}^3P_0)$, and $3d4f({}^3H_6 - {}^3H_5)$ states. A similar behavior of the splitting can be observed in Figs. 10 and 11. Our calculations show that the fine structure of almost all

levels shown in Figs. 9-11 do not follow the Landé rules even for small Z . The unusual splittings are principally due to changes from LS to jj coupling, with mixing from other triplet and singlet states. The different J states are mixed differently. Further experimental confirmation would be very helpful in verifying the correctness of these sometimes sensitive mixing parameters.

COMPARISON AND DISCUSSION

In Table II, we compare our results for the excitation energies of the 106 levels in Ni-like tungsten with theoretical results obtained by different codes: the DFS code by Zhang *et al.* [20], the GRASP code by Aggarwal *et al.* [21], the COWAN code [30], and the RELAC code by Fournier [18]. Labelling of levels with headings 'DFS' are taken from Table IV of Ref. [20], with headings 'GRASP' are taken from Table III of Ref. [21], and with headings 'RELAC' are taken from Tables III and IV of Ref. [18]. The LSJ labelling is used in data obtained by the RMBPT and the COWAN codes. It should be noted that those two labellings are different for some levels. In the COWAN code, a label for every level was chosen by the maximum value among the eigenvectors. This is sometimes not convenient when two levels have the same label. In present paper, we use the RMBPT code to evaluate energies for the whole isoelectronic sequence. It is known that the crossing of energy levels inside one complex with a fixed J is forbidden by the Wigner and Neumann theorem (see, for example, in Ref. [31]). As a result, we can use only the numbering of the levels by the ordering of the energies. As was already mentioned, either LS or jj designations are used to label the resulting eigenvectors and eigenvalues rather than simply enumerating them with an index N . We choose the LS designations here since the jj designations are used for uncoupled matrix elements. The LSJ labels are chosen based upon small values of the multiplet splitting for low- Z ions.

We did not repeat the comparison of RMBPT results with experimental data given in our previous paper [6] where excellent agreement was found for high Z ions ($Z \geq 47$). In the present

paper a new computer code was developed that allowed us to consider not only high- Z ions ($Z \geq 47$), as was done previously [6], but also low- Z ions ($30 \leq Z \leq 46$). We found only very small differences (0.003 - 0.01 % even for $Z=50$) in the wavelengths between our present results and the results in [6]. As can be seen from Table II, the difference between the results from RMBPT and DFS calculations is much larger, 0.06–0.2%. There are no large differences between the results obtained from DFS and GRASP calculations.

In Table III, wavelengths (λ in \AA) and oscillator strengths (f) for odd-parity states with $J=1$ are given. We have limited the table to those transitions given in Ref. [20]. A comparison of f obtained by the RMBPT and DFS codes is given. We use LSJ labelling for the RMBPT data and use the “M1” – “M15” designations employed in Table I and Table III of Ref. [20] for the DFS data. As can be seen from Table III, the disagreement between our RMBPT oscillator strengths and the DFS results is about 3–10% except in cases with very small values of oscillator strengths. It should be noted that for the $3p4d\ ^3D_1$ and $3s4p\ ^3P_1$ states it was difficult to follow the permutation of the labels with Z , and we are not sure that we found the correct values for comparison with our RMBPT f values.

RESULTS

In Table IV, we present our results for wavelengths (λ in \AA) and multipole (E1, E2, E3, M1, M2, and M3) transition rates (A in s^{-1}) for the Ni-like ions with nuclear charge $Z = 36 - 92$. Level designations are given in three columns for odd-parity states with $J=1$ (E1 transitions), $J=2$ (M2 transitions), and $J=3$ (E3 transitions) and in three columns for even-parity states with $J=1$ (M1 transitions), $J=2$ (E2 transitions), and $J=3$ (M3 transitions). We already mentioned previously that we use LSJ designations. For each of the 76 multipole transitions we present wavelengths and transition rates.

The general trends of the Z -dependence of the line strengths for the E1, M2, E3, M1, E2, and M3 transitions are presented in Figs. 12, 13, 14, 15, 16, 17, respectively. The Z -dependence of the oscillator strengths for E1 transitions are presented in Figs. 18 for Ni-like ions with nuclear charge $Z = 30 - 100$.

The E1, E2, E3, M1, M2, and M3 transition probabilities A (s^{-1}) for the transitions between the excited $3l4l'$ LSJ states and the ground state are obtained in terms of line strengths S (a.u.) and wavelength $\lambda(\text{\AA})$ as

$$\begin{aligned}
A(E1) &= \frac{2.02613 \times 10^{18}}{(2J+1)\lambda^3} S(E1), & A(M1) &= \frac{2.69735 \times 10^{13}}{(2J+1)\lambda^3} S(M1) \\
A(E2) &= \frac{1.11995 \times 10^{18}}{(2J+1)\lambda^5} S(E2), & A(M2) &= \frac{1.49097 \times 10^{13}}{(2J+1)\lambda^5} S(M2) \\
A(E3) &= \frac{3.14441 \times 10^{17}}{(2J+1)\lambda^7} S(E3), & A(M3) &= \frac{4.18610 \times 10^{12}}{(2J+1)\lambda^7} S(M3)
\end{aligned} \tag{3}$$

Line strengths (S) and oscillator strengths (f) for the 13 E1 lines from $3d4p$ [3P_1 , 3D_1 , 1P_1], $3d4f$ [3P_1 , 3D_1 , 1P_1], $3p4s$ [1P_1 , 3P_1], $3p4d$ [3P_1 , 3D_1 , 1P_1], and $3s4p$ [3P_1 , 1P_1] levels to the ground state are plotted in Figs. 12 and 18. The sharp features in the curves shown in these figures can be explained in many cases by strong mixing of states within the odd-parity complex with $J=1$. The deep minimum in the curve with the $3d4p$ 3P label in the $Z=43-44$ range can be explained by the mixing of the $3d_{3/2}4p_{1/2}$ [1] and $3d_{5/2}4p_{3/2}$ [1] states. The double cusp in the curve with the $3d4f$ 3P label in the interval $Z=57-59$ is due to mixing of the $3d_{5/2}4f_{5/2}$ [1] and $3d_{5/2}4f_{7/2}$ [1] states. The mixing of the $3d_{5/2}4f_{7/2}$ [1] and $3d_{3/2}4f_{5/2}$ [1] states in the $Z=55-56$ range gives a singularity in the curve with the $3d4f$ 3D_1 label. The mixing of the $3d_{3/2}4f_{5/2}$ [1] and $3p_{3/2}4s_{1/2}$ [1] states in the $Z=49-50$ range gives a singularity in the curves with the $3d4f$ 1P_1 and $3p4s$ 1P_1 labels.

Line strengths, S , for the 15 M2 lines from odd-parity states with $J=2$, and for the 12 E3 lines from odd-parity states with $J=3$ levels to the ground state are plotted in Figs. 13 and 14, respectively. The sharp features in the curves shown in Fig. 13 can be explained in many cases

by strong mixing of the $3d_j4p_{j'}$ [2] and $3d_j4f_{j'}$ [2] states within the odd-parity complex with $J=2$. The curves describing the $3d4p$ [3F_3 , 1F_3 , 3D_3], $3d4f$ [3D_3 , 3F_3], and $3p4d$ [3F_3 , 1F_3 , 3D_3] line strengths in Fig. 14 decrease smoothly with Z without any sharp features.

Line strengths, S , for the 12 M1 lines from even parity states with $J=1$ to the ground state are plotted in Fig. 15. The deep minima in the curve describing the $3d4d$ 1P line strength for small Z can be explained by strong mixing between the $3d_{5/2}4d_{3/2}$ [1] and $3d_{5/2}4d_{5/2}$ [1] states. As can be seen from graphs in Fig. 15, the number of singularities depends on the hole state; the curves describing S of the $3d4s$ 3D_1 and $3d4d$ LSJ states are more smooth than the curves describing S of $3p4p$ LSJ , and $3p4f$ LSJ . The largest number of singularities can be observed for the curve describing S of the $3s4s$ 3S_1 . These singularities are caused by the contribution of second-order uncoupled matrix elements; the sign of the denominator changes with Z and the denominator becomes very small (see Refs [6, 7] for detail). In this case, the contribution of the term with these small denominators becomes much larger than any other contribution, leading to new singularities in the Z -dependence of the line strengths. We can remove some of these singularities by increasing our model space to include the $3d_jnp_{j'}$ and $3d_jnf_{j'}$ states with $n=5$ and 6.

Line strengths, S , for the 14 E2 lines from even-parity states with $J=2$, and for the 10 M3 lines from even-parity states with $J=3$ to the ground state are plotted in Figs. 16 and 17. The curves describing the $3d4s$ [3D_2 , 1D_2] line strengths decrease smoothly with Z without any sharp features. It should be noted that the difference in values of S for the $3d4s$ 3D_2 and $3d4s$ 1D_2 lines is not large, they even cross each other for $Z=47-48$. There is also only a small difference in the values of S for the $3d4d$ 3D_2 , $3d4d$ 3F_2 , and $3d4d$ 1D_2 states shown in Fig. 16.

CONCLUSION

We have presented a systematic second-order relativistic MBPT study of line strengths, oscillator strengths, and transition rates for the $3l-4l'$ multipole (E1, E2, E3, M1, M2, M3) transitions in Ni-like ions with nuclear charges Z ranging from 30 to 100. Our retarded multipole matrix elements included correlation corrections from Coulomb and Breit interactions; contributions from negative energy states were also included to insure gauge independence. Both length and velocity forms of the matrix elements were evaluated and small differences, caused by the non locality of the starting HF potential, were found between the two forms. Second-order RMBPT transition energies were used in our evaluation of oscillator strengths and transition rates. These calculations were compared with other calculations. For $Z \geq 36$, we believe that the present theoretical data are more accurate than other theoretical data for transitions between $n = 4$ states and the ground state in Ni-like ions. We hope that these results will be useful in analyzing older experiments and in planning new ones involving Ni-like ions. Additionally, these calculations provide basic theoretical input amplitudes for calculations of multipole matrix elements, oscillator strengths, and transition rates in core-excited states of Cu-like system.

EXPLANATION OF GRAPHS

GRAPHS 1–6. Mixing coefficients for odd- and even-parity states with $J=1-3$ as functions of Z .

The calculated mixing coefficients $C^Q(3l_j4l'_j, [J])$ for given states are plotted as a function of the nuclear charge Z . Configurations in jj and LS coupling scheme $3l_j4l'_j$ and $3l4l'$ and whole momenta J and LSJ , respectively, are used as a label for each figure.

GRAPHS 7–8. Energies ($E/(Z-21)^2$) in cm^{-1} for even- and odd-parity states as functions of Z .

The calculated energies E divided by $(Z-21)^2$ for given states as included in each figure, are plotted as a function of the nuclear charge Z . Configurations $3l4l'$ and whole LSJ are used as a label for each figure.

Energies divided by $(Z-21)^2$, $E/(Z-21)^2$, are plotted in cm^{-1} unit.

GRAPHS 9–11. Energy splitting ($\Delta E/(Z-21)^2$) in cm^{-1} for terms of even- and odd-parity states as functions of Z .

The calculated energies between two levels, ΔE divided by $(Z-21)^2$ for given levels as included in figure, are plotted as a function of the nuclear charge Z . Configurations $3l4l'$ and whole LSJ are used as a label for each figure.

Energy differences divided by $(Z-21)^2$, $\Delta E/(Z-21)^2$, are plotted in cm^{-1} unit.

GRAPHS 12–17. E1, M2, E3, M1, E2, and M3 line strengths between odd- and even-parity states with $J = 1-3$ and the ground state as function of Z .

The calculated line strengths S for given transition is plotted as a function of nuclear charge Z . Configurations $3l4l'$ and whole LSJ are used as a label for each figure.

Line strengths, S are plotted in atomic unit.

GRAPH 18. Oscillator strengths between odd-parity states with $J = 1$ and the ground state as

function of Z .

The calculated oscillator strengths f for a given transition is plotted as a function of the nuclear charge Z . Configurations $3l4l'$ and whole LSJ are used as a label for each figure.

Oscillator strengths f are plotted in arbitrary unit.

EXPLANATION OF TABLES

TABLE I. Comparison of the jj - and LS -coupling schemes for hole-particle states in the $3l_j4l'_{j'}$ and $3l4l'$ LSJ complexes.

Configurations in jj and LS coupling scheme $3l_j4l'_{j'}$ and $3l4l'$ with whole momenta J and LSJ , respectively, are given in columns.

TABLE II. Energies (1000 cm^{-1}) of Ni-like tungsten relative to the ground state. Comparison of RMBPT data with theoretical results from the DFS code by Zhang *et al.*, from GRASP by Aggarwal *et al.*, from the COWAN code, and from RELAC by Fournier.

In the columns 1 and 7, we give the configuration and the whole momenta LSJ for excited states, in the columns 3, 5, and 9, we give the labels of levels used in above mentioned papers .

The rows contain energies in 1000 cm^{-1} unit.

TABLE III. Wavelengths (λ in \AA) and oscillator strengths f of Ni-like ions for odd-parity states with $J=1$. Comparison of RMBPT data with theoretical results from the DFS code by Zhang *et al.*.

Configurations $3l4l'$ and whole momenta LSJ are given as column headings.

The rows contain the nuclear charge Z , wavelengths (λ in \AA), and oscillator strengths f in arbitrary units.

TABLE IV. Wavelengths (λ in \AA) and multipole (E1, E2, E3, M1, M2, and M3) transition rates (A in s^{-1}) for Ni-like ions with the nuclear charge $Z=36-92$.

The following notation is used: $a[-b]=a^{-b}$, $a[b]=a^{+b}$, and $a[00]=a$ to represent powers of ten.

In the first, fourth, and seventh column, we give the configuration and the whole momenta LSJ for the excited state.

The rows contain the wavelengths in Å and transition rates in s^{-1} , beginning from $Z=36$ up to $Z=92$ for the last page of table.

Table IV: Wavelengths (λ in Å) and multipole (E1, E2, E3, M1, M2, and M3) transition rates (A in s^{-1}) for Ni-like ions with nuclear charge $Z=36-92$. Numbers in brackets represent powers of 10.

level	λ	A^{E1}	level	λ	A^{M2}	level	λ	A^{E3}

FIG. 1: Mixing coefficients for odd-parity states with $J=1$ as functions of Z

FIG. 2: Mixing coefficients for odd-parity states with $J=2$ as functions of Z

FIG. 3: Mixing coefficients for odd-parity states with $J=3$ as functions of Z

FIG. 4: Mixing coefficients for even-parity states with $J=1$ as functions of Z

FIG. 5: Mixing coefficients for even-parity states with $J=2$ as functions of Z

FIG. 6: Mixing coefficients for even-parity states with $J=3$ as functions of Z

FIG. 7: Energies $(E/(Z - 21)^2)$ in cm⁻¹ for even-parity states as function of Z

FIG. 8: Energies ($E/(Z-21)^2$) in cm^{-1} for odd-parity states as function of Z

FIG. 9: Energy splitting ($\Delta E/(Z - 21)^2$) in cm^{-1} for terms of odd-parity states as function of Z

FIG. 10: Energy splitting ($\Delta E/(Z - 21)^2$) in cm $^{-1}$ for terms of odd- and even-parity states as function of Z

FIG. 11: Energy splitting ($\Delta E/(Z - 21)^2$) in cm⁻¹ for terms of even-parity states as function of Z

FIG. 12: E1 line strengths between odd-parity states with $J = 1$ and the ground state as function of Z

FIG. 13: M2 line strengths between odd-parity states with $J = 2$ and the ground state as function of Z

FIG. 14: E3 line strengths between odd-parity states with $J = 3$ and the ground state as function of Z

FIG. 15: M1 line strengths between even-parity states with $J = 1$ and the ground state as function of Z

FIG. 16: E2 line strengths between even-parity states with $J = 2$ and the ground state as function of Z

FIG. 17: M3 line strengths between even-parity states with $J = 3$ and the ground state as function of Z

FIG. 18: Oscillator strengths between odd-parity states with $J = 1$ and the ground state as function of Z
