**Potential competing interests:** No potential competing interests to declare.

The article summarises how block chain technology is used in the industry's payment systems for electric vehicles. The author clarifies their technique for gathering, categorising, and rating relevant papers, which is a valuable example of the methodology utilised. A total of 21 papers have been reviewed. The core and sub-themes that best characterise the body of work are selected, and implications and applications are examined based on a final sample of twenty-one articles.

Here is a summary of the comments:

- Although the applied approach is sound, it would be advisable to provide a particular context for the identified core and sub-themes.
- Even though the title refers to Block chain EV Payment Systems, there is little emphasis on payment systems, or the writers' actual notion needs to be successfully conveyed.
- It would be best if the authors gave a statistical analysis of the various nations that permit the usage of crypto-assets as a payment method at EV charging stations.
- The study discusses three research topics, with the main emphasis being on the research gaps and consequences based on what others have said, but further input from the authors on their viewpoints and own conclusions is required. The discussion section requires this.
- Additionally, it would be beneficial to demonstrate the direct responses to each of the three research questions. The authors should identify several problems or constraints you have learned about in the literature and offer some solutions in the section on directions for future study.
- The authors omitted any studies released in 2023.
- The work is excellent overall, and the paper might have academic significance.
