## 49. CROSS-SECTION FORMULAE FOR SPECIFIC PROCESSES

Revised October 2009 by H. Baer (University of Oklahoma) and R.N. Cahn (LBNL).

### PART I: STANDARD MODEL PROCESSES

Setting aside leptonproduction (for which, see Sec. 16 of this *Review*), the cross sections of primary interest are those with light incident particles,  $e^+e^-$ ,  $\gamma\gamma$ ,  $q\bar{q}$ ,  $gq$ ,  $gg$ , etc., where  $g$  and  $q$  represent gluons and light quarks. The produced particles include both light particles and heavy ones -  $t$ ,  $W$ ,  $Z$ , and the Higgs boson  $H$ . We provide the production cross sections calculated within the Standard Model for several such processes.

#### 49.1. Resonance Formation

Resonant cross sections are generally described by the Breit-Wigner formula (Sec. 19 of this *Review*).

$$\sigma(E) = \frac{2J+1}{(2S_1+1)(2S_2+1)} \frac{4\pi}{k^2} \left[ \frac{\Gamma^2/4}{(E-E_0)^2 + \Gamma^2/4} \right] B_{in} B_{out}, \quad (49.1)$$

where  $E$  is the c.m. energy,  $J$  is the spin of the resonance, and the number of polarization states of the two incident particles are  $2S_1+1$  and  $2S_2+1$ . The c.m. momentum in the initial state is  $k$ ,  $E_0$  is the c.m. energy at the resonance, and  $\Gamma$  is the full width at half maximum height of the resonance. The branching fraction for the resonance into the initial-state channel is  $B_{in}$  and into the final-state channel is  $B_{out}$ . For a narrow resonance, the factor in square brackets may be replaced by  $\pi\Gamma\delta(E-E_0)/2$ .

#### 49.2. Production of light particles

The production of point-like, spin-1/2 fermions in  $e^+e^-$  annihilation through a virtual photon,  $e^+e^- \rightarrow \gamma^* \rightarrow f\bar{f}$ , at c.m. energy squared  $s$  is given by

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \beta [1 + \cos^2\theta + (1-\beta^2)\sin^2\theta] Q_f^2, \quad (49.2)$$

where  $\beta$  is  $v/c$  for the produced fermions in the c.m.,  $\theta$  is the c.m. scattering angle, and  $Q_f$  is the charge of the fermion. The factor  $N_c$  is 1 for charged leptons and 3 for quarks. In the ultrarelativistic limit,  $\beta \rightarrow 1$ ,

$$\sigma = N_c Q_f^2 \frac{4\pi\alpha^2}{3s} = N_c Q_f^2 \frac{86.8 \text{ nb}}{s (\text{GeV}^2)}. \quad (49.3)$$

The cross section for the annihilation of a  $q\bar{q}$  pair into a distinct pair  $q'\bar{q}'$  through a gluon is completely analogous up to color factors, with the replacement  $\alpha \rightarrow \alpha_s$ . Treating all quarks as massless, averaging over the colors of the initial quarks and defining  $t = -s \sin^2(\theta/2)$ ,  $u = -s \cos^2(\theta/2)$ , one finds [1]

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow q'\bar{q}') = \frac{\alpha_s^2}{9s} \frac{t^2 + u^2}{s^2}. \quad (49.4)$$

Crossing symmetry gives

$$\frac{d\sigma}{d\Omega}(qq' \rightarrow qq') = \frac{\alpha_s^2}{9s} \frac{s^2 + u^2}{t^2}. \quad (49.5)$$

If the quarks  $q$  and  $q'$  are identical, we have

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow q\bar{q}) = \frac{\alpha_s^2}{9s} \left[ \frac{t^2 + u^2}{s^2} + \frac{s^2 + u^2}{t^2} - \frac{2u^2}{3st} \right], \quad (49.6)$$

and by crossing

$$\frac{d\sigma}{d\Omega}(qq \rightarrow qq) = \frac{\alpha_s^2}{9s} \left[ \frac{t^2 + s^2}{u^2} + \frac{s^2 + u^2}{t^2} - \frac{2s^2}{3ut} \right]. \quad (49.7)$$

Annihilation of  $e^+e^-$  into  $\gamma\gamma$  has the cross section

$$\frac{d\sigma}{d\Omega}(e^+e^- \rightarrow \gamma\gamma) = \frac{\alpha^2}{2s} \frac{u^2 + t^2}{tu}. \quad (49.8)$$

The related QCD process also has a triple-gluon coupling. The cross section is

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow gg) = \frac{8\alpha_s^2}{27s} (t^2 + u^2) \left( \frac{1}{tu} - \frac{9}{4s^2} \right). \quad (49.9)$$

The crossed reactions are

$$\frac{d\sigma}{d\Omega}(qg \rightarrow qg) = \frac{\alpha_s^2}{9s} (s^2 + u^2) \left( -\frac{1}{su} + \frac{9}{4t^2} \right) \quad (49.10)$$

and

$$\frac{d\sigma}{d\Omega}(gg \rightarrow q\bar{q}) = \frac{\alpha_s^2}{24s} (t^2 + u^2) \left( \frac{1}{tu} - \frac{9}{4s^2} \right). \quad (49.11)$$

Finally,

$$\frac{d\sigma}{d\Omega}(gg \rightarrow gg) = \frac{9\alpha_s^2}{8s} \left( 3 - \frac{ut}{s^2} - \frac{su}{t^2} - \frac{st}{u^2} \right). \quad (49.12)$$

Lepton-quark scattering is analogous (neglecting  $Z$  exchange)

$$\frac{d\sigma}{d\Omega}(eq \rightarrow eq) = \frac{\alpha^2}{2s} e_q^2 \frac{s^2 + u^2}{t^2}. \quad (49.13)$$

where  $e_q$  is the charge of the quark. For neutrino scattering with the four-Fermi interaction

$$\frac{d\sigma}{d\Omega}(\nu d \rightarrow \ell^- u) = \frac{G_F^2 s}{4\pi^2}, \quad (49.14)$$

where the Cabibbo angle suppression is ignored. Similarly

$$\frac{d\sigma}{d\Omega}(\nu \bar{u} \rightarrow \ell^- \bar{d}) = \frac{G_F^2 s}{4\pi^2} \frac{(1 + \cos\theta)^2}{4}. \quad (49.15)$$

To obtain the formulae for deep inelastic scattering (presented in more detail in Section 16) we consider quarks of type  $i$  carrying a fraction  $x = Q^2/(2M\nu)$  of the nucleon's energy, where  $\nu = E - E'$  is the energy lost by the lepton in the nucleon rest frame. With  $y = \nu/E$  we have the correspondences

$$1 + \cos\theta \rightarrow 2(1-y),$$

$$d\Omega_{cm} \rightarrow 4\pi f_i(x) dx dy, \quad (49.16)$$

where the latter incorporates the quark distribution,  $f_i(x)$ . In this way we find

$$\begin{aligned} \frac{d\sigma}{dx dy}(eN \rightarrow eX) &= \frac{4\pi\alpha^2 xs}{Q^4} \frac{1}{2} [1 + (1-y)^2] \\ &\times \left[ \frac{4}{9}(u(x) + \bar{u}(x) + \dots) + \frac{1}{9}(d(x) + \bar{d}(x) + \dots) \right] \end{aligned} \quad (49.17)$$

where now  $s = 2ME$  is the cm energy squared for the electron-nucleon collision and we have suppressed contributions from higher mass quarks.

Similarly,

$$\frac{d\sigma}{dx dy}(\nu N \rightarrow \ell^- X) = \frac{G_F^2 xs}{\pi} [(d(x) + \dots) + (1-y)^2(\bar{u}(x) + \dots)] \quad (49.18)$$

and

$$\frac{d\sigma}{dx dy}(\bar{\nu} N \rightarrow \ell^+ X) = \frac{G_F^2 xs}{\pi} [(\bar{d}(x) + \dots) + (1-y)^2(u(x) + \dots)]. \quad (49.19)$$

Quasi-elastic neutrino scattering ( $\nu_\mu n \rightarrow \mu^- p$ ,  $\bar{\nu}_\mu p \rightarrow \mu^+ n$ ) is directly related to the crossed reaction, neutron decay. The formula for the differential cross section is presented, for example, in N.J. Baker *et al.*, Phys. Rev. **D23**, 2499 (1981).

### 49.3. Hadroproduction of heavy quarks

For hadroproduction of heavy quarks  $Q = c, b, t$ , it is important to include mass effects in the formulae. For  $q\bar{q} \rightarrow Q\bar{Q}$ , one has

$$\frac{d\sigma}{d\Omega}(q\bar{q} \rightarrow Q\bar{Q}) = \frac{\alpha_s^2}{9s^3} \sqrt{1 - \frac{4m_Q^2}{s}} \left[ (m_Q^2 - t)^2 + (m_Q^2 - u)^2 + 2m_Q^2 s \right], \quad (49.20)$$

while for  $gg \rightarrow Q\bar{Q}$  one has

$$\begin{aligned} \frac{d\sigma}{d\Omega}(gg \rightarrow Q\bar{Q}) = & \frac{\alpha_s^2}{32s} \sqrt{1 - \frac{4m_Q^2}{s}} \left[ \frac{6}{s^2} (m_Q^2 - t)(m_Q^2 - u) \right. \\ & - \frac{m_Q^2(s - 4m_Q^2)}{3(m_Q^2 - t)(m_Q^2 - u)} \\ & + \frac{4}{3} \frac{(m_Q^2 - t)(m_Q^2 - u) - 2m_Q^2(m_Q^2 + t)}{(m_Q^2 - t)^2} \\ & + \frac{4}{3} \frac{(m_Q^2 - t)(m_Q^2 - u) - 2m_Q^2(m_Q^2 + u)}{(m_Q^2 - u)^2} \\ & - 3 \frac{(m_Q^2 - t)(m_Q^2 - u) + m_Q^2(u - t)}{s(m_Q^2 - t)} \\ & \left. - 3 \frac{(m_Q^2 - t)(m_Q^2 - u) + m_Q^2(t - u)}{s(m_Q^2 - u)} \right]. \quad (49.21) \end{aligned}$$

### 49.4. Production of Weak Gauge Bosons

#### 49.4.1. $W$ and $Z$ resonant production :

Resonant production of a single  $W$  or  $Z$  is governed by the partial widths

$$\Gamma(W \rightarrow \ell_i \bar{\nu}_i) = \frac{\sqrt{2}G_F m_W^3}{12\pi} \quad (49.22)$$

$$\Gamma(W \rightarrow q_i \bar{q}_j) = 3 \frac{\sqrt{2}G_F |V_{ij}|^2 m_W^3}{12\pi} \quad (49.23)$$

$$\begin{aligned} \Gamma(Z \rightarrow f\bar{f}) = & N_c \frac{\sqrt{2}G_F m_Z^3}{6\pi} \\ & \times \left[ (T_3 - Q_f \sin^2 \theta_W)^2 + (Q_f \sin^2 \theta_W)^2 \right] \quad (49.24) \end{aligned}$$

The weak mixing angle is  $\theta_W$ . The CKM matrix elements are indicated by  $V_{ij}$  and  $N_c$  is 3 for  $q\bar{q}$  final states and 1 for leptonic final states.

The full differential cross section for  $f_i \bar{f}_j \rightarrow (W, Z) \rightarrow f'_i \bar{f}'_{j'}$  is given by

$$\begin{aligned} \frac{d\sigma}{d\Omega} = & \frac{N_c^f}{N_c^{i'}} \cdot \frac{1}{256\pi^2 s} \cdot \frac{s^2}{(s - M^2)^2 + s\Gamma^2} \\ & \times \left[ (L^2 + R^2)(L'^2 + R'^2)(1 + \cos^2 \theta) \right. \\ & \left. + (L^2 - R^2)(L'^2 - R'^2)2 \cos \theta \right] \quad (49.25) \end{aligned}$$

where  $M$  is the mass of the  $W$  or  $Z$ . The couplings for the  $W$  are  $L = (8G_F m_W^2 / \sqrt{2})^{1/2} V_{ij} / \sqrt{2}$ ;  $R = 0$  where  $V_{ij}$  is the corresponding CKM matrix element, with an analogous expression for  $L'$  and  $R'$ . For  $Z$ , the couplings are  $L = (8G_F m_Z^2 / \sqrt{2})^{1/2} (T_3 - \sin^2 \theta_W Q)$ ;  $R = -(8G_F m_Z^2 / \sqrt{2})^{1/2} \sin^2 \theta_W Q$ , where  $T_3$  is the weak isospin of the initial left-handed fermion and  $Q$  is the initial fermion's electric charge. The expressions for  $L'$  and  $R'$  are analogous. The color factors  $N_c^{i,f}$  are 3 for initial or final quarks and 1 for initial or final leptons.

#### 49.4.2. Production of pairs of weak gauge bosons :

The cross section for  $f\bar{f} \rightarrow W^+ W^-$  is given in term of the couplings of the left-handed and right-handed fermion  $f$ ,  $\ell = 2(T_3 - Qx_W)$ ,  $r = -2Qx_W$ , where  $T_3$  is the third component of weak isospin for the left-handed  $f$ ,  $Q$  is its electric charge (in units of the proton charge), and  $x_W = \sin^2 \theta_W$ :

$$\begin{aligned} \frac{d\sigma}{dt} = & \frac{2\pi\alpha^2}{N_c s^2} \left\{ \left[ \left( Q + \frac{\ell + r}{4x_W} \frac{s}{s - m_Z^2} \right)^2 + \left( \frac{\ell - r}{4x_W} \frac{s}{s - m_Z^2} \right)^2 \right] A(s, t, u) \right. \\ & + \frac{1}{2x_W} \left( Q + \frac{\ell}{2x_W} \frac{s}{s - m_Z^2} \right) (\Theta(-Q)I(s, t, u) - \Theta(Q)I(s, u, t)) \\ & \left. + \frac{1}{8x_W^2} (\Theta(-Q)E(s, t, u) + \Theta(Q)E(s, u, t)) \right\}, \quad (49.26) \end{aligned}$$

where  $\Theta(x)$  is 1 for  $x > 0$  and 0 for  $x < 0$ , and where

$$\begin{aligned} A(s, t, u) = & \left( \frac{tu}{m_W^4} - 1 \right) \left( \frac{1}{4} - \frac{m_W^2}{s} + 3 \frac{m_W^4}{s^2} \right) + \frac{s}{m_W^2} - 4, \\ I(s, t, u) = & \left( \frac{tu}{m_W^4} - 1 \right) \left( \frac{1}{4} - \frac{m_W^2}{2s} - \frac{m_W^4}{st} \right) + \frac{s}{m_W^2} - 2 + 2 \frac{m_W^2}{t}, \\ E(s, t, u) = & \left( \frac{tu}{m_W^4} - 1 \right) \left( \frac{1}{4} + \frac{m_W^4}{t^2} \right) + \frac{s}{m_W^2}, \quad (49.27) \end{aligned}$$

and  $s, t, u$  are the usual Mandelstam variables with  $s = (p_f + p_{\bar{f}})^2$ ,  $t = (p_f - p_{W^-})^2$ ,  $u = (p_f - p_{W^+})^2$ . The factor  $N_c$  is 3 for quarks and 1 for leptons.

The analogous cross-section for  $q_i \bar{q}_j \rightarrow W^\pm Z^0$  is

$$\begin{aligned} \frac{d\sigma}{dt} = & \frac{\pi\alpha^2 |V_{ij}|^2}{6s^2 x_W^2} \left\{ \left( \frac{1}{s - m_W^2} \right)^2 \left[ \left( \frac{9 - 8x_W}{4} \right) (ut - m_W^2 m_Z^2) \right. \right. \\ & + (8x_W - 6)s(m_W^2 + m_Z^2) \left. \right] \\ & + \left[ \frac{ut - m_W^2 m_Z^2 - s(m_W^2 + m_Z^2)}{s - m_W^2} \right] \left[ \frac{\ell_j}{t} - \frac{\ell_i}{u} \right] \\ & \left. + \frac{ut - m_W^2 m_Z^2}{4(1 - x_W)} \left[ \frac{\ell_j^2}{t^2} + \frac{\ell_i^2}{u^2} \right] + \frac{s(m_W^2 + m_Z^2)}{2(1 - x_W)} \frac{\ell_i \ell_j}{tu} \right\}, \quad (49.28) \end{aligned}$$

where  $\ell_i$  and  $\ell_j$  are the couplings of the left-handed  $q_i$  and  $q_j$  as defined above. The CKM matrix element between  $q_i$  and  $q_j$  is  $V_{ij}$ .

The cross section for  $q_i \bar{q}_i \rightarrow Z^0 Z^0$  is

$$\frac{d\sigma}{dt} = \frac{\pi\alpha^2}{96} \frac{\ell_i^4 + r_i^4}{x_W^2 (1 - x_W^2)^2 s^2} \left[ \frac{t}{u} + \frac{u}{t} + \frac{4m_Z^2 s}{tu} - m_Z^4 \left( \frac{1}{t^2} + \frac{1}{u^2} \right) \right]. \quad (49.29)$$

### 49.5. Production of Higgs Bosons

#### 49.5.1. Resonant Production :

The Higgs boson of the Standard Model can be produced resonantly in the collisions of quarks, leptons,  $W$  or  $Z$  bosons, gluons, or photons. The production cross section is thus controlled by the partial width of the Higgs boson into the entrance channel and its total width. The branching fractions for the Standard Model Higgs boson are shown in Fig. 1 of the "Searches for Higgs bosons" review in the Particle Listings section, as a function of the Higgs boson mass. The partial widths are given by the relations

$$\Gamma(H \rightarrow f\bar{f}) = \frac{G_F m_f^2 m_H N_c}{4\pi\sqrt{2}} \left(1 - 4m_f^2/m_H^2\right)^{3/2}, \quad (49.30)$$

$$\Gamma(H \rightarrow W^+W^-) = \frac{G_F m_H^3 \beta_W}{32\pi\sqrt{2}} \left(4 - 4a_W + 3a_W^2\right), \quad (49.31)$$

$$\Gamma(H \rightarrow ZZ) = \frac{G_F m_H^3 \beta_Z}{64\pi\sqrt{2}} \left(4 - 4a_Z + 3a_Z^2\right), \quad (49.32)$$

where  $N_c$  is 3 for quarks and 1 for leptons and where  $a_W = 1 - \beta_W^2 = 4m_W^2/m_H^2$  and  $a_Z = 1 - \beta_Z^2 = 4m_Z^2/m_H^2$ . The decay to two gluons proceeds through quark loops, with the  $t$  quark dominating [2]. Explicitly,

$$\Gamma(H \rightarrow gg) = \frac{\alpha_s^2 G_F m_H^3}{36\pi^3 \sqrt{2}} \left| \sum_q I(m_q^2/m_H^2) \right|^2, \quad (49.33)$$

where  $I(z)$  is complex for  $z < 1/4$ . For  $z < 2 \times 10^{-3}$ ,  $|I(z)|$  is small so the light quarks contribute negligibly. For  $m_H < 2m_t$ ,  $z > 1/4$  and

$$I(z) = 3 \left[ 2z + 2z(1-4z) \left( \sin^{-1} \frac{1}{2\sqrt{z}} \right)^2 \right], \quad (49.34)$$

which has the limit  $I(z) \rightarrow 1$  as  $z \rightarrow \infty$ .

#### 49.5.2. Higgs Boson Production in $W^*$ and $Z^*$ decay :

The Standard Model Higgs boson can be produced in the decay of a virtual  $W$  or  $Z$  ("Higgsstrahlung") [3,4]: In particular, if  $k$  is the c.m. momentum of the Higgs boson,

$$\sigma(q_i \bar{q}_j \rightarrow WH) = \frac{\pi \alpha^2 |V_{ij}|^2}{36 \sin^4 \theta_W} \frac{2k}{\sqrt{s}} \frac{k^2 + 3m_W^2}{(s - m_W^2)^2} \quad (49.35)$$

$$\sigma(f\bar{f} \rightarrow ZH) = \frac{2\pi \alpha^2 (\ell_f^2 + r_f^2)}{48 N_c \sin^4 \theta_W \cos^4 \theta_W} \frac{2k}{\sqrt{s}} \frac{k^2 + 3m_Z^2}{(s - m_Z^2)^2}, \quad (49.36)$$

where  $\ell$  and  $r$  are defined as above.

#### 49.5.3. $W$ and $Z$ Fusion :

Just as high-energy electrons can be regarded as sources of virtual photon beams, at very high energies they are sources of virtual  $W$  and  $Z$  beams. For Higgs boson production, it is the longitudinal components of the  $W$ s and  $Z$ s that are important [5]. The distribution of longitudinal  $W$ s carrying a fraction  $y$  of the electron's energy is [6]

$$f(y) = \frac{g^2}{16\pi^2} \frac{1-y}{y}, \quad (49.37)$$

where  $g = e/\sin \theta_W$ . In the limit  $s \gg m_H \gg m_W$ , the partial decay rate is  $\Gamma(H \rightarrow W_L W_L) = (g^2/64\pi)(m_H^3/m_W^2)$  and in the equivalent  $W$  approximation [7]

$$\sigma(e^+e^- \rightarrow \bar{\nu}_e \nu_e H) = \frac{1}{16m_W^2} \left( \frac{\alpha}{\sin^2 \theta_W} \right)^3 \times \left[ \left( 1 + \frac{m_H^2}{s} \right) \log \frac{s}{m_H^2} - 2 + 2 \frac{m_H^2}{s} \right]. \quad (49.38)$$

There are significant corrections to this relation when  $m_H$  is not large compared to  $m_W$  [8]. For  $m_H = 150$  GeV, the estimate is too high by 51% for  $\sqrt{s} = 1000$  GeV, 32% too high at  $\sqrt{s} = 2000$  GeV, and 22% too high at  $\sqrt{s} = 4000$  GeV. Fusion of  $ZZ$  to make a Higgs boson can be treated similarly. Identical formulae apply for Higgs production in the collisions of quarks whose charges permit the emission of a  $W^+$  and a  $W^-$ , except that QCD corrections and CKM matrix elements are required. Even in the absence of QCD corrections, the fine-structure constant ought to be evaluated at the scale of the collision, say  $m_W$ . All quarks contribute to the  $ZZ$  fusion process.

### 49.6. Inclusive hadronic reactions

One-particle inclusive cross sections  $E d^3\sigma/d^3p$  for the production of a particle of momentum  $p$  are conveniently expressed in terms of rapidity  $y$  (see above) and the momentum  $p_T$  transverse to the beam direction (in the c.m.):

$$E \frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi dy p_T dp_T^2}. \quad (49.39)$$

In appropriate circumstances, the cross section may be decomposed as a partonic cross section multiplied by the probabilities of finding partons of the prescribed momenta:

$$\sigma_{\text{hadronic}} = \sum_{ij} \int dx_1 dx_2 f_i(x_1) f_j(x_2) d\hat{\sigma}_{\text{partonic}}, \quad (49.40)$$

The probability that a parton of type  $i$  carries a fraction of the incident particle's that lies between  $x_1$  and  $x_1 + dx_1$  is  $f_i(x_1)dx_1$  and similarly for partons in the other incident particle. The partonic collision is specified by its c.m. energy squared  $\hat{s} = x_1 x_2 s$  and the momentum transfer squared  $\hat{t}$ . The final hadronic state is more conveniently specified by the rapidities  $y_1, y_2$  of the two jets resulting from the collision and the transverse momentum  $p_T$ . The connection between the differentials is

$$dx_1 dx_2 d\hat{t} = dy_1 dy_2 \frac{\hat{s}}{s} dp_T^2, \quad (49.41)$$

so that

$$\frac{d^3\sigma}{dy_1 dy_2 dp_T^2} = \frac{\hat{s}}{s} \left[ f_i(x_1) f_j(x_2) \frac{d\hat{\sigma}}{d\hat{t}}(\hat{s}, \hat{t}, \hat{u}) + f_i(x_2) f_j(x_1) \frac{d\hat{\sigma}}{d\hat{t}}(\hat{s}, \hat{u}, \hat{t}) \right], \quad (49.42)$$

where we have taken into account the possibility that the incident parton types might arise from either incident particle. The second term should be dropped if the types are identical:  $i = j$ .

### 49.7. Two-photon processes

In the Weizsäcker-Williams picture, a high-energy electron beam is accompanied by a spectrum of virtual photons of energies  $\omega$  and invariant-mass squared  $q^2 = -Q^2$ , for which the photon number density is

$$dn = \frac{\alpha}{\pi} \left[ 1 - \frac{\omega}{E} + \frac{\omega^2}{E^2} - \frac{m_e^2 \omega^2}{Q^2 E^2} \right] \frac{d\omega}{\omega} \frac{dQ^2}{Q^2}, \quad (49.43)$$

where  $E$  is the energy of the electron beam. The cross section for  $e^+e^- \rightarrow e^+e^-X$  is then [9]

$$d\sigma_{e^+e^- \rightarrow e^+e^-X}(s) = dn_1 dn_2 d\sigma_{\gamma\gamma \rightarrow X}(W^2), \quad (49.44)$$

where  $W^2 = m_X^2$ . Integrating from the lower limit  $Q^2 = m_e^2 \frac{\omega_i^2}{E_i(E_i - \omega_i)}$  to a maximum  $Q^2$  gives

$$\sigma_{e^+e^- \rightarrow e^+e^-X}(s) = \frac{\alpha^2}{\pi^2} \int_{z_{th}}^1 \frac{dz}{z} \times \left[ \left( \ln \frac{Q_{max}^2}{zm_e^2} - 1 \right)^2 f(z) + \frac{1}{3} (\ln z)^3 \right] \sigma_{\gamma\gamma \rightarrow X}(zs), \quad (49.45)$$

where

$$f(z) = \left(1 + \frac{1}{2}z\right)^2 \ln(1/z) - \frac{1}{2}(1-z)(3+z). \quad (49.46)$$

The appropriate value of  $Q_{max}^2$  depends on the properties of the produced system  $X$ . For production of hadronic systems,  $Q_{max}^2 \approx m_p^2$ ,

while for lepton-pair production,  $Q^2 \approx W^2$ . For production of a resonance with spin  $J \neq 1$ , we have

$$\sigma_{e^+e^- \rightarrow e^+e^- R}(s) = (2J+1) \frac{8\alpha^2 \Gamma_{R \rightarrow \gamma\gamma}}{m_R^3} \times \left[ f(m_R^2/s) \left( \ln \frac{m_V^2 s}{m_e^2 m_R^2} - 1 \right)^2 - \frac{1}{3} \left( \ln \frac{s}{M_R^2} \right)^3 \right], \quad (49.47)$$

where  $m_V$  is the mass that enters into the form factor for the  $\gamma\gamma \rightarrow R$  transition, typically  $m_\rho$ .

## PART II: PROCESSES BEYOND THE STANDARD MODEL

### 49.8. Production of supersymmetric particles

In supersymmetric (SUSY) theories (see Supersymmetric Particle Searches in this *Review*), every boson has a fermionic superpartner, and every fermion has a bosonic superpartner. The minimal supersymmetric Standard Model (MSSM) is a direct supersymmetrization of the Standard Model (SM), although a second Higgs doublet is needed to avoid triangle anomalies [10]. Under *soft* SUSY breaking, superpartner masses are lifted above the SM particle masses. In weak scale SUSY, the superpartners are invoked to stabilize the weak scale under radiative corrections, so the superpartners are expected to have masses of order the TeV scale.

#### 49.8.1. Gluino and squark production :

The superpartners of gluons are the color octet, spin- $\frac{1}{2}$  gluinos ( $\tilde{g}$ ), while each helicity component of quark flavor has a spin-0 *squark* partner, *e.g.*  $\tilde{q}_L$  and  $\tilde{q}_R$ . Third generation left- and right- squarks are expected to have large mixing, resulting in mass eigenstates  $\tilde{q}_1$  and  $\tilde{q}_2$ , with  $m_{\tilde{q}_1} < m_{\tilde{q}_2}$  (here,  $q$  denotes any of the SM flavors of quarks and  $\tilde{q}_i$  the corresponding flavor and type ( $i = L, R$  or  $1, 2$ ) of squark). Gluino pair production ( $\tilde{g}\tilde{g}$ ) takes place via either glue-glue or quark-antiquark annihilation [11].

The subprocess cross sections are usually presented as differential distributions in the Mandelstam variables  $s$ ,  $t$  and  $u$ . Note that for a  $2 \rightarrow 2$  scattering subprocess  $ab \rightarrow cd$ , the Mandelstam variable  $s = (p_a + p_b)^2 = (p_c + p_d)^2$ , where  $p_a$  is the 4-momentum of particle  $a$ , and so forth. The variable  $t = (p_c - p_a)^2$ , where  $c$  and  $a$  are taken conventionally to be the most similar particles in the subprocess. The variable  $u$  would then be equal to  $(p_d - p_a)^2$ . Note that since  $s$ ,  $t$  and  $u$  are squares of 4-vectors, they are invariants in any inertial reference frame.

Gluino pair production at hadron colliders is described by:

$$\begin{aligned} \frac{d\sigma}{dt}(gg \rightarrow \tilde{g}\tilde{g}) &= \frac{9\pi\alpha_s^2}{4s^2} \left\{ \frac{2(m_g^2 - t)(m_g^2 - u)}{s^2} \right. \\ &+ \frac{(m_g^2 - t)(m_g^2 - u) - 2m_g^2(m_g^2 + t)}{(m_g^2 - t)^2} \\ &+ \frac{(m_g^2 - t)(m_g^2 - u) - 2m_g^2(m_g^2 + u)}{(m_g^2 - u)^2} + \frac{m_g^2(s - 4m_g^2)}{(m_g^2 - t)(m_g^2 - u)} \\ &\left. - \frac{(m_g^2 - t)(m_g^2 - u) + m_g^2(u - t)}{s(m_g^2 - t)} - \frac{(m_g^2 - t)(m_g^2 - u) + m_g^2(t - u)}{s(m_g^2 - u)} \right\}, \quad (49.48) \end{aligned}$$

where  $\alpha_s$  is the strong fine structure constant. Also,

$$\begin{aligned} \frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{g}\tilde{g}) &= \frac{8\pi\alpha_s^2}{9s^2} \left\{ \frac{4}{3} \left( \frac{m_g^2 - t}{m_q^2 - t} \right)^2 + \frac{4}{3} \left( \frac{m_g^2 - u}{m_q^2 - u} \right)^2 \right. \\ &+ \frac{3}{s^2} [(m_g^2 - t)^2 + (m_g^2 - u)^2 + 2m_g^2 s] - 3 \frac{(m_g^2 - t)^2 + m_g^2 s}{s(m_q^2 - t)} \\ &\left. - 3 \frac{(m_g^2 - u)^2 + m_g^2 s}{s(m_q^2 - u)} + \frac{1}{3} \frac{m_g^2 s}{(m_q^2 - t)(m_q^2 - u)} \right\}. \quad (49.49) \end{aligned}$$

Gluinos can also be produced in association with squarks:  $\tilde{g}\tilde{q}_i$  production, where  $\tilde{q}_i$  represents any of the various types (left-, right- or mixed) and flavors of squarks. The subprocess cross section is independent of whether the squark is the right-, left- or mixed type:

$$\begin{aligned} \frac{d\sigma}{dt}(gq \rightarrow \tilde{g}\tilde{q}_i) &= \frac{\pi\alpha_s^2}{24s^2} \left[ \frac{16}{3}(s^2 + (m_{\tilde{q}_i}^2 - u)^2) + \frac{4}{3}s(m_{\tilde{q}_i}^2 - u) \right] \\ &\times \left( (m_g^2 - u)^2 + (m_{\tilde{q}_i}^2 - m_g^2)^2 + \frac{2sm_g^2(m_{\tilde{q}_i}^2 - m_g^2)}{(m_g^2 - t)} \right). \quad (49.50) \end{aligned}$$

There are many different subprocesses for production of squark pairs. Since left- and right- squarks generally have different masses and different decay patterns, we present the differential cross section for each subprocess of  $\tilde{q}_i$  ( $i = L, R$  or  $1, 2$ ) separately. (In early literature, the following formulae were often combined into a single equation which didn't differentiate the various squark types.) The result for  $gg \rightarrow \tilde{q}_i\tilde{q}_i$  is:

$$\begin{aligned} \frac{d\sigma}{dt}(gg \rightarrow \tilde{q}_i\tilde{q}_i) &= \frac{\pi\alpha_s^2}{4s^2} \left\{ \frac{1}{3} \left( \frac{m_q^2 + t}{m_q^2 - t} \right)^2 + \frac{1}{3} \left( \frac{m_q^2 + u}{m_q^2 - u} \right)^2 \right. \\ &+ \frac{3}{32s^2} (8s(4m_q^2 - s) + 4(u - t)^2) + \frac{7}{12} \\ &- \frac{1}{48} \frac{(4m_q^2 - s)^2}{(m_q^2 - t)(m_q^2 - u)} \\ &+ \frac{3}{32} \frac{[(t - u)(4m_q^2 + 4t - s) - 2(m_q^2 - u)(6m_q^2 + 2t - s)]}{s(m_q^2 - t)} \\ &+ \frac{3}{32} \frac{[(u - t)(4m_q^2 + 4u - s) - 2(m_q^2 - t)(6m_q^2 + 2u - s)]}{s(m_q^2 - u)} \\ &\left. + \frac{7}{96} \frac{[4m_q^2 + 4t - s]}{m_q^2 - t} + \frac{7}{96} \frac{[4m_q^2 + 4u - s]}{m_q^2 - u} \right\}, \quad (49.51) \end{aligned}$$

which has an obvious  $u \leftrightarrow t$  symmetry.

For  $q\bar{q} \rightarrow \tilde{q}_i\tilde{q}_i$  with the same initial and final state flavors, we have

$$\begin{aligned} \frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{q}_i\tilde{q}_i) &= \frac{2\pi\alpha_s^2}{9s^2} \left\{ \frac{1}{(t - m_q^2)^2} + \frac{2}{s^2} - \frac{2/3}{s(t - m_q^2)} \right\} \\ &\times [-st - (t - m_{\tilde{q}_i}^2)^2], \quad (49.52) \end{aligned}$$

while if initial and final state flavors are different ( $q\bar{q} \rightarrow \tilde{q}_i'\tilde{q}_i'$ ) we instead have

$$\frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{q}_i'\tilde{q}_i') = \frac{4\pi\alpha_s^2}{9s^4} [-st - (t - m_{\tilde{q}_i'}^2)^2]. \quad (49.53)$$

If the two initial state quarks are of different flavors, then we have

$$\frac{d\sigma}{dt}(q\bar{q}' \rightarrow \tilde{q}_i\tilde{q}_i') = \frac{2\pi\alpha_s^2}{9s^2} \frac{-st - (t - m_{\tilde{q}_i}^2)^2}{(t - m_{\tilde{q}_i'}^2)^2}. \quad (49.54)$$

If the initial quarks are of different flavor and final state squarks are of different type ( $i \neq j$ ) then

$$\frac{d\sigma}{dt}(q\bar{q}' \rightarrow \tilde{q}_i\tilde{q}_j') = \frac{2\pi\alpha_s^2}{9s^2} \frac{m_g^2 s}{(t - m_{\tilde{q}_j'}^2)^2}. \quad (49.55)$$

For same-flavor initial state quarks, but final state unlike-type squarks, we also have

$$\frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{q}_i\tilde{q}_j) = \frac{2\pi\alpha_s^2}{9s^2} \frac{m_g^2 s}{(t - m_{\tilde{q}_j}^2)^2}. \quad (49.56)$$

There also exist cross sections for quark-quark annihilation to squark pairs. For same flavor quark-quark annihilation to same flavor/same type final state squarks,

$$\begin{aligned} \frac{d\sigma}{dt}(qq \rightarrow \tilde{q}_i \tilde{q}_i) &= \\ &= \frac{\pi \alpha_s^2 m_g^2}{9s^2} \left\{ \frac{1}{(t - m_g^2)^2} + \frac{1}{(u - m_g^2)^2} - \frac{2/3}{(t - m_g^2)(u - m_g^2)} \right\}, \end{aligned} \quad (49.57)$$

while if the final type squarks are different ( $i \neq j$ ), we have

$$\begin{aligned} \frac{d\sigma}{dt}(qq \rightarrow \tilde{q}_i \tilde{q}_j) &= \\ &= \frac{2\pi \alpha_s^2}{9s^2} \left\{ \frac{[-st - (t - m_{\tilde{q}_i}^2)(t - m_{\tilde{q}_j}^2)]}{(t - m_g^2)} + \frac{[-su - (u - m_{\tilde{q}_i}^2)(u - m_{\tilde{q}_j}^2)]}{(u - m_g^2)} \right\}. \end{aligned} \quad (49.58)$$

If initial/final state flavors are different, but final state squark types are the same, then

$$\frac{d\sigma}{dt}(qq' \rightarrow \tilde{q}_i \tilde{q}_i') = \frac{2\pi \alpha_s^2}{9s^2} \frac{m_g^2 s}{(t - m_g^2)^2}. \quad (49.59)$$

If initial quark flavors are different and final squark types are different, then

$$\frac{d\sigma}{dt}(qq' \rightarrow \tilde{q}_i \tilde{q}_j') = \frac{2\pi \alpha_s^2}{9s^2} \frac{-st - (t - m_{\tilde{q}_i}^2)(t - m_{\tilde{q}_j}^2)}{(t - m_g^2)^2}. \quad (49.60)$$

#### 49.8.2. Gluino and squark associated production :

In the MSSM, the charged spin- $\frac{1}{2}$  winos and higgsinos mix to make chargino states  $\chi_1^\pm$  and  $\chi_2^\pm$ , with  $m_{\chi_1^\pm} < m_{\chi_2^\pm}$ . The spin- $\frac{1}{2}$  neutral bino, wino and higgsino fields mix to give four neutralino mass eigenstates  $\chi_{1,2,3,4}^0$  ordered according to mass. We sometimes denote the charginos and neutralinos collectively as -inos for notational simplicity

For gluino and squark production in association with charginos and neutralinos [12], the quark-squark-neutralino couplings\* are defined by the interaction Lagrangian terms  $\mathcal{L}_{f\tilde{f}\tilde{\chi}_i^0} = \left[ iA_{\tilde{\chi}_i^0}^f \tilde{f}_L^\dagger \tilde{\chi}_i^0 P_L f + iB_{\tilde{\chi}_i^0}^f \tilde{f}_R^\dagger \tilde{\chi}_i^0 P_R f + \text{h.c.} \right]$ , where  $A_{\tilde{\chi}_i^0}^f$  and  $B_{\tilde{\chi}_i^0}^f$  are coupling constants involving gauge couplings, neutralino mixing elements and in the case of third generation fermions, Yukawa couplings. Their form depends on the conventions used for setting up the MSSM Lagrangian, and can be found in various reviews [13] and textbooks [14,15].  $P_L$  and  $P_R$  are the usual left- and right-spinor projection operators and  $f$  denotes any of the SM fermions  $u, d, e, \nu_e, \dots$ . The fermion-sfermion- chargino couplings have the form  $\mathcal{L} = \left[ iA_{\tilde{\chi}_i^\pm}^d \tilde{u}_L^\dagger \tilde{\chi}_i^\pm P_L d + iA_{\tilde{\chi}_i^\pm}^u \tilde{d}_L^\dagger \tilde{\chi}_i^\pm P_L u + \text{h.c.} \right]$  for  $u$  and  $d$  quarks, where the  $A_{\tilde{\chi}_i^\pm}^d$  and  $A_{\tilde{\chi}_i^\pm}^u$  couplings are again convention-dependent, and can be found in textbooks. The superscript  $c$  denotes “charge conjugate spinor”, defined by  $\psi^c \equiv C\bar{\psi}^T$ .

The subprocess cross sections for chargino-squark associated production occur via squark exchange and are given by

$$\frac{d\sigma}{dt}(\bar{u}g \rightarrow \tilde{\chi}_i^- \tilde{d}_L) = \frac{\alpha_s}{24s^2} |A_{\tilde{\chi}_i^-}^u|^2 \psi(m_{\tilde{d}_L}, m_{\tilde{\chi}_i^-}, t), \quad (49.61)$$

$$\frac{d\sigma}{dt}(dg \rightarrow \tilde{\chi}_i^- \tilde{u}_L) = \frac{\alpha_s}{24s^2} |A_{\tilde{\chi}_i^-}^d|^2 \psi(m_{\tilde{u}_L}, m_{\tilde{\chi}_i^-}, t), \quad (49.62)$$

\* The couplings  $A_{\tilde{\chi}_i^0}^f$  and  $B_{\tilde{\chi}_i^0}^f$  are given explicitly in Ref. 15 in Eq. (8.87). Also, the couplings  $A_{\tilde{\chi}_i^\pm}^d$  and  $A_{\tilde{\chi}_i^\pm}^u$  are given in Eq. (8.93). The couplings  $X_i^j$  and  $Y_i^j$  are given by Eq. (8.103), while the  $x_i$  and  $y_i$  couplings are given in Eq. (8.100). Finally, the couplings  $W_{ij}$  are given in Eq. (8.101).

while neutralino-squark production is given by

$$\frac{d\sigma}{dt}(qg \rightarrow \tilde{\chi}_i^0 \tilde{q}) = \frac{\alpha_s}{24s^2} \left( |A_{\tilde{\chi}_i^0}^q|^2 + |B_{\tilde{\chi}_i^0}^q|^2 \right) \psi(m_{\tilde{q}}, m_{\tilde{\chi}_i^0}, t), \quad (49.63)$$

where

$$\begin{aligned} \psi(m_1, m_2, t) &= \frac{s + t - m_1^2}{2s} - \frac{m_1^2(m_2^2 - t)}{(m_1^2 - t)^2} \\ &+ \frac{t(m_2^2 - m_1^2) + m_2^2(s - m_2^2 + m_1^2)}{s(m_1^2 - t)}. \end{aligned} \quad (49.64)$$

Here, the variable  $t$  is given by the square of “squark-minus-quark” four-momentum. The neutralino-gluino associated production cross section also occurs via squark exchange and is given by

$$\begin{aligned} \frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{\chi}_i^0 \tilde{g}) &= \frac{\alpha_s}{18s^2} \left( |A_{\tilde{\chi}_i^0}^q|^2 + |B_{\tilde{\chi}_i^0}^q|^2 \right) \left[ \frac{(m_{\tilde{\chi}_i^0}^2 - t)(m_g^2 - t)}{(m_g^2 - t)^2} \right. \\ &+ \left. \frac{(m_{\tilde{\chi}_i^0}^2 - u)(m_g^2 - u)}{(m_g^2 - u)^2} - \frac{2\eta_i \eta_{\tilde{g}} m_{\tilde{g}} m_{\tilde{\chi}_i^0} s}{(m_g^2 - t)(m_g^2 - u)} \right], \end{aligned} \quad (49.65)$$

where  $\eta_i$  is the sign of the neutralino mass eigenvalue and  $\eta_{\tilde{g}}$  is the sign of the gluino mass eigenvalue. We also have chargino-gluino associated production:

$$\begin{aligned} \frac{d\sigma}{dt}(\bar{u}d \rightarrow \tilde{\chi}_i^- \tilde{g}) &= \frac{\alpha_s}{18s^2} \left[ |A_{\tilde{\chi}_i^-}^u|^2 \frac{(m_{\tilde{\chi}_i^-}^2 - t)(m_g^2 - t)}{(m_{\tilde{d}_L}^2 - t)^2} \right. \\ &+ |A_{\tilde{\chi}_i^-}^d|^2 \frac{(m_{\tilde{\chi}_i^-}^2 - u)(m_g^2 - u)}{(m_{\tilde{u}_L}^2 - u)^2} + \left. \frac{2\eta_{\tilde{g}} \text{Re}(A_{\tilde{\chi}_i^-}^u A_{\tilde{\chi}_i^-}^d) m_{\tilde{g}} m_{\tilde{\chi}_i^-} s}{(m_{\tilde{d}_L}^2 - t)(m_{\tilde{u}_L}^2 - u)} \right], \end{aligned} \quad (49.66)$$

where  $\hat{t} = (\tilde{g} - d)^2$  and in the third term one must take the real part of the in general complex coupling constant product.

#### 49.8.3. Slepton and sneutrino production :

The subprocess cross section for  $\tilde{\ell}_L \tilde{\nu}_{\ell_L}$  production ( $\ell = e$  or  $\mu$ ) occurs via  $s$ -channel  $W$  exchange and is given by

$$\frac{d\sigma}{dt}(d\bar{u} \rightarrow \tilde{\ell}_L \tilde{\nu}_{\ell_L}) = \frac{g^4 |D_W(s)|^2}{192\pi s^2} \left( tu - m_{\tilde{\ell}_L}^2 m_{\tilde{\nu}_{\ell_L}}^2 \right), \quad (49.67)$$

where  $D_W(s) = 1/(s - M_W^2 + iM_W\Gamma_W)$  is the  $W$ -boson propagator denominator. The production of  $\tilde{\tau}_1 \tilde{\nu}_\tau$  is given as above, but replacing  $m_{\tilde{\ell}_L} \rightarrow m_{\tilde{\tau}_1}$ ,  $m_{\tilde{\nu}_{\ell_L}} \rightarrow m_{\tilde{\nu}_\tau}$  and multiplying by an overall factor of  $\cos^2 \theta_\tau$  (where  $\theta_\tau$  is the tau-slepton mixing angle). Similar substitutions hold for  $\tilde{\tau}_2 \tilde{\nu}_\tau$  production, except the overall factor is  $\sin^2 \theta_\tau$ .

**Table 49.1:** The constants  $\alpha_f$  and  $\beta_f$  that appear in in the SM neutral current Lagrangian. Here  $t \equiv \tan \theta_W$  and  $c \equiv \cot \theta_W$ .

$f$	$q_f$	$\alpha_f$	$\beta_f$
$\ell$	-1	$\frac{1}{4}(3t - c)$	$\frac{1}{4}(t + c)$
$\nu_\ell$	0	$\frac{1}{4}(t + c)$	$-\frac{1}{4}(t + c)$
$u$	$\frac{2}{3}$	$-\frac{5}{12}t + \frac{1}{4}c$	$-\frac{1}{4}(t + c)$
$d$	$-\frac{1}{3}$	$\frac{1}{12}t - \frac{1}{4}c$	$\frac{1}{4}(t + c)$

The subprocess cross section for  $\tilde{\ell}_L \bar{\ell}_L$  production occurs via  $s$ -channel  $\gamma$  and  $Z$  exchange, and depends on the neutral current interaction, with fermion couplings to  $\gamma$  and  $Z^0$  given by  $\mathcal{L}_{\text{neutral}} = -e q_f \bar{f} \gamma^\mu f A_\mu + e \bar{f} \gamma^\mu (\alpha_f + \beta_f \gamma_5) f Z_\mu$  (with values of  $q_f$ ,  $\alpha_f$ , and  $\beta_f$  given in Table 49.1).

The subprocess cross section is given by

$$\frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{\ell}_L \bar{\ell}_L) = \frac{e^4}{24\pi s^2} (tu - m_{\tilde{\ell}_L}^4) \times \left\{ \frac{q_\ell^2 q_q^2}{s^2} + (\alpha_\ell - \beta_\ell)^2 (\alpha_q^2 + \beta_q^2) |D_Z(s)|^2 + \frac{2q_\ell q_q \alpha_q (\alpha_\ell - \beta_\ell) (s - M_Z^2)}{s} |D_Z(s)|^2 \right\}, \quad (49.68)$$

where  $D_Z(s) = 1/(s - M_Z^2 + iM_Z\Gamma_Z)$ . The cross section for sneutrino production is given by the same formula, but with  $\alpha_\ell$ ,  $\beta_\ell$ ,  $q_\ell$  and  $m_{\tilde{\ell}_L}$  replaced by  $\alpha_\nu$ ,  $\beta_\nu$ , 0 and  $m_{\tilde{\nu}_L}$ , respectively. The cross section for  $\tilde{\tau}_1 \bar{\tau}_1$  production is obtained by replacing  $m_{\tilde{\ell}_L} \rightarrow m_{\tilde{\tau}_1}$  and  $\beta_\ell \rightarrow \beta_\ell \cos 2\theta_\tau$ .

The cross section for  $\tilde{\ell}_R \bar{\ell}_R$  production is given by substituting  $\alpha_\ell - \beta_\ell \rightarrow \alpha_\ell + \beta_\ell$  and  $m_{\tilde{\ell}_L} \rightarrow m_{\tilde{\ell}_R}$  in the equation above. The cross section for  $\tilde{\tau}_2 \bar{\tau}_2$  production is obtained from the formula for  $\tilde{\ell}_R \bar{\ell}_R$  production by replacing  $m_{\tilde{\ell}_R} \rightarrow m_{\tilde{\tau}_2}$  and  $\beta_\ell \rightarrow \beta_\ell \cos 2\theta_\tau$ .

Finally, the cross section for  $\tilde{\tau}_1 \bar{\tau}_2$  production occurs only via  $Z$  exchange, and is given by

$$\frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{\tau}_1 \bar{\tau}_2) = \frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{\tau}_1 \bar{\tau}_1) = \frac{e^4}{24\pi s^2} (\alpha_q^2 + \beta_q^2) \beta_\ell^2 \sin^2 2\theta_\tau |D_Z(s)|^2 (ut - m_{\tilde{\tau}_1}^2 m_{\tilde{\tau}_2}^2). \quad (49.69)$$

#### 49.8.4. Chargino and neutralino pair production :

##### 49.8.4.1. $\tilde{\chi}_i^- \tilde{\chi}_j^0$ production:

The subprocess cross section for  $d\bar{u} \rightarrow \tilde{\chi}_i^- \tilde{\chi}_j^0$  depends on Lagrangian couplings  $\mathcal{L}_{W\bar{u}d} = -\frac{g}{\sqrt{2}} \bar{u} \gamma_\mu P_L d W^{+\mu} + \text{h.c.}$ ,  $\mathcal{L}_{W\tilde{\chi}_i^- \tilde{\chi}_j^0} = -g(-i)^{\theta_j} \bar{\tilde{\chi}}_i^- [X_i^j + Y_i^j \gamma_5] \gamma_\mu \tilde{\chi}_j^0 W^{-\mu} + \text{h.c.}$ ,  $\mathcal{L}_{q\bar{q}\tilde{\chi}_i^-} = iA_{\tilde{\chi}_i^-}^d \bar{u}_L \tilde{\chi}_i^- P_L d + iA_{\tilde{\chi}_i^-}^u \bar{d}_L \tilde{\chi}_i^- P_L u + \text{h.c.}$  and  $\mathcal{L}_{q\bar{q}\tilde{\chi}_j^0} = iA_{\tilde{\chi}_j^0}^q \bar{q}_L \tilde{\chi}_j^0 P_L q + \text{h.c.}$ . Contributing diagrams include  $W$  exchange and also  $\tilde{d}_L$  and  $\tilde{u}_L$  squark exchange. The  $X_i^j$  and  $Y_i^j$  couplings are new, and again convention-dependent: the cross section formulae works if the interaction Lagrangian is written in the above form, so that the couplings can be suitably extracted. The term  $\theta_j = 0$  (1) if  $m_{\tilde{\chi}_j^0} > 0$  ( $< 0$ ); it comes about because the neutralino field must be re-defined by a  $-i\gamma_5$  transformation if its mass eigenvalue is negative [15]. The subprocess cross section is given in terms of dot products of four momenta, where particle labels are used to denote their four-momenta; note that all mass terms in the cross section formulae are positive definite, so that the signs of mass eigenstates have been absorbed into the Lagrangian couplings, as for instance in Ref. [15]. We then have

$$\frac{d\sigma}{dt}(d\bar{u} \rightarrow \tilde{\chi}_i^- \tilde{\chi}_j^0) = \frac{1}{192\pi s^2} \left[ T_W + T_{\tilde{d}_L} + T_{\tilde{u}_L} + T_{W\tilde{d}_L} + T_{W\tilde{u}_L} + T_{\tilde{d}_L \tilde{u}_L} \right] \quad (49.70)$$

where

$$T_W = 8g^4 |D_W(s)|^2 \left\{ [X_i^{j2} + Y_i^{j2}] (\tilde{\chi}_j^0 \cdot d \tilde{\chi}_i^- \cdot \bar{u} + \tilde{\chi}_j^0 \cdot \bar{u} \tilde{\chi}_i^- \cdot d) + 2(X_i^j Y_i^j) (\tilde{\chi}_j^0 \cdot d \tilde{\chi}_i^- \cdot \bar{u} - \tilde{\chi}_j^0 \cdot \bar{u} \tilde{\chi}_i^- \cdot d) + [X_i^{j2} - Y_i^{j2}] m_{\tilde{\chi}_i^-} m_{\tilde{\chi}_j^0} d \cdot \bar{u} \right\}, \quad (49.71)$$

$$T_{\tilde{d}_L} = \frac{4|A_{\tilde{\chi}_i^-}^d|^2 |A_{\tilde{\chi}_j^0}^d|^2}{[(\tilde{\chi}_i^- - \bar{u})^2 - m_{\tilde{d}_L}^2]^2} d \cdot \tilde{\chi}_j^0 \tilde{\chi}_i^- \cdot \bar{u}, \quad (49.72)$$

$$T_{\tilde{u}_L} = \frac{4|A_{\tilde{\chi}_i^-}^d|^2 |A_{\tilde{\chi}_j^0}^u|^2}{[(\tilde{\chi}_j^0 - \bar{u})^2 - m_{\tilde{u}_L}^2]^2} \bar{u} \cdot \tilde{\chi}_j^0 \tilde{\chi}_i^- \cdot d \quad (49.73)$$

$$T_{W\tilde{d}_L} = \frac{-\sqrt{2}g^2 \text{Re}[A_{\tilde{\chi}_j^0}^{d*} A_{\tilde{\chi}_i^-}^u (-i)^{\theta_j}] (s - M_W^2) |D_W(s)|^2}{(\tilde{\chi}_i^- - \bar{u})^2 - m_{\tilde{d}_L}^2} \times \left\{ 8(X_i^j + Y_i^j) \tilde{\chi}_j^0 \cdot d \bar{u} \cdot \tilde{\chi}_i^- + 4(X_i^j - Y_i^j) m_{\tilde{\chi}_i^-} m_{\tilde{\chi}_j^0} d \cdot \bar{u} \right\} \quad (49.74)$$

$$T_{W\tilde{u}_L} = \frac{\sqrt{2}g^2 \text{Re}[A_{\tilde{\chi}_j^0}^{d*} A_{\tilde{\chi}_i^-}^u (-i)^{\theta_j}] (s - M_W^2) |D_W(s)|^2}{(\tilde{\chi}_j^0 - \bar{u})^2 - m_{\tilde{u}_L}^2} \times \left\{ 8(X_i^j - Y_i^j) \tilde{\chi}_j^0 \cdot d \bar{u} \cdot \tilde{\chi}_i^- + 4(X_i^j + Y_i^j) m_{\tilde{\chi}_i^-} m_{\tilde{\chi}_j^0} d \cdot \bar{u} \right\} \quad (49.75)$$

and

$$T_{\tilde{d}_L \tilde{u}_L} = -\frac{4 \text{Re}[A_{\tilde{\chi}_j^0}^d A_{\tilde{\chi}_i^-}^{u*} A_{\tilde{\chi}_i^-}^{d*} A_{\tilde{\chi}_j^0}^u] m_{\tilde{\chi}_i^-} m_{\tilde{\chi}_j^0} d \cdot \bar{u}}{[(\tilde{\chi}_i^- - \bar{u})^2 - m_{\tilde{d}_L}^2][(\tilde{\chi}_j^0 - \bar{u})^2 - m_{\tilde{u}_L}^2]}. \quad (49.76)$$

##### 49.8.4.2. Chargino pair production:

The subprocess cross section for  $d\bar{d} \rightarrow \tilde{\chi}_i^- \tilde{\chi}_i^+$  ( $i = 1, 2$ ) depends on Lagrangian couplings  $\mathcal{L} = e \tilde{\chi}_i^- \gamma_\mu \tilde{\chi}_i^+ A^\mu - e \cot \theta_W \tilde{\chi}_i^- \gamma_\mu (x_i - y_i \gamma_5) \tilde{\chi}_i^+ Z^\mu$  and also  $\mathcal{L} \ni iA_{\tilde{\chi}_i^-}^d \bar{u}_L \tilde{\chi}_i^- P_L d + iA_{\tilde{\chi}_i^-}^u \bar{d}_L \tilde{\chi}_i^- P_L u + \text{h.c.}$ . Contributing diagrams include  $s$ -channel  $\gamma$ ,  $Z^0$  exchange and  $t$ -channel  $\tilde{u}_L$  exchange [16,17]. The couplings  $x_i$  and  $y_i$  are again new and as usual convention-dependent.

The subprocess cross section is given by

$$\frac{d\sigma}{dt}(d\bar{d} \rightarrow \tilde{\chi}_i^- \tilde{\chi}_i^+) = \frac{1}{192\pi s^2} [T_\gamma + T_Z + T_{\tilde{u}_L} + T_{\gamma Z} + T_{\gamma \tilde{u}_L} + T_{Z \tilde{u}_L}] \quad (49.77)$$

where

$$T_\gamma = \frac{32e^4 q_d^2}{s^2} \left[ d \cdot \tilde{\chi}_i^+ \bar{d} \cdot \tilde{\chi}_i^- + d \cdot \tilde{\chi}_i^- \bar{d} \cdot \tilde{\chi}_i^+ + m_{\tilde{\chi}_i^-}^2 d \cdot \bar{d} \right] \quad (49.78)$$

$$T_Z = 32e^4 \cot^2 \theta_W |D_Z(s)|^2$$

$$\left\{ (\alpha_d^2 + \beta_d^2) (x_i^2 + y_i^2) \left[ d \cdot \tilde{\chi}_i^+ \bar{d} \cdot \tilde{\chi}_i^- + d \cdot \tilde{\chi}_i^- \bar{d} \cdot \tilde{\chi}_i^+ + m_{\tilde{\chi}_i^-}^2 d \cdot \bar{d} \right] \mp 4\alpha_d \beta_d x_i y_i [d \cdot \tilde{\chi}_i^+ \bar{d} \cdot \tilde{\chi}_i^- - d \cdot \tilde{\chi}_i^- \bar{d} \cdot \tilde{\chi}_i^+] - 2y_i^2 (\alpha_d^2 + \beta_d^2) m_{\tilde{\chi}_i^-}^2 d \cdot \bar{d} \right\}, \quad (49.79)$$

$$T_{\tilde{u}_L} = \frac{4|A_{\tilde{\chi}_i^-}^d|^4}{[(d - \tilde{\chi}_i^-)^2 - m_{\tilde{u}_L}^2]^2} d \cdot \tilde{\chi}_i^- \bar{d} \cdot \tilde{\chi}_i^+ \quad (49.80)$$

$$T_{\gamma Z} = \frac{64e^4 \cot \theta_W q_d (s - M_Z^2) |D_Z(s)|^2}{s} \times$$

$$\left\{ \alpha_d x_i \left( d \cdot \tilde{\chi}_i^+ \bar{d} \cdot \tilde{\chi}_i^- + d \cdot \tilde{\chi}_i^- \bar{d} \cdot \tilde{\chi}_i^+ + m_{\tilde{\chi}_i^-}^2 d \cdot \bar{d} \right) \pm \beta_d y_i (d \cdot \tilde{\chi}_i^- \bar{d} \cdot \tilde{\chi}_i^+ - d \cdot \tilde{\chi}_i^+ \bar{d} \cdot \tilde{\chi}_i^-) \right\} \quad (49.81)$$

$$T_{\gamma \tilde{u}_L} = \mp \frac{8e^2 q_d}{s} \frac{|A_{\tilde{\chi}_i^-}^d|^2}{[(d - \tilde{\chi}_i^-)^2 - m_{\tilde{u}_L}^2]} \left\{ 2\bar{d} \cdot \tilde{\chi}_i^+ d \cdot \tilde{\chi}_i^- + m_{\tilde{\chi}_i^-}^2 d \cdot \bar{d} \right\} \quad (49.82)$$

and

$$T_{Z\tilde{u}_L} = \mp 8e^2 \cot \theta_W |D_Z(s)|^2 \frac{|A_{\tilde{\chi}_i^-}^d|^2 (s - M_Z^2)}{[(d - \tilde{\chi}_i^-)^2 - m_{\tilde{u}_L}^2]} (\alpha_d - \beta_d) \\ \times \left\{ 2(x_i \mp y_i) d \cdot \tilde{\chi}_i^- \tilde{d} \cdot \tilde{\chi}_i^+ + m_{\tilde{\chi}_i^-}^2 (x_i \pm y_i) d \cdot \tilde{d} \right\} \quad (49.83)$$

using the upper of the sign choices.

The cross section for  $u\bar{u} \rightarrow \tilde{\chi}_i^+ \tilde{\chi}_i^-$  can be obtained from the above by replacing  $\alpha_d \rightarrow \alpha_u$ ,  $\beta_d \rightarrow \beta_u$ ,  $q_d \rightarrow q_u$ ,  $\tilde{u}_L \rightarrow \tilde{d}_L$ ,  $A_{\tilde{\chi}_i^-}^d \rightarrow A_{\tilde{\chi}_i^-}^u$ ,  $d \rightarrow \bar{u}$ ,  $\bar{d} \rightarrow u$  and adopting the lower of the sign choices everywhere.

The cross section for  $q\bar{q} \rightarrow \tilde{\chi}_1^- \tilde{\chi}_2^+$ ,  $\tilde{\chi}_1^+ \tilde{\chi}_2^-$  can occur via  $Z$  and  $\tilde{q}_L$  exchange. It is usually much smaller than  $\tilde{\chi}_{1,2}^- \tilde{\chi}_{1,2}^+$  production, so the cross section will not be presented here. It can be found in Appendix A of Ref. 15.

#### 49.8.4.3. Neutralino pair production:

Neutralino pair production via  $q\bar{q}$  fusion takes place via  $s$ -channel  $Z$  exchange plus  $t$ - and  $u$ -channel left- and right- squark exchange (5 diagrams) [17,18]. The Lagrangian couplings (see previous footnote\*) needed include terms given above plus terms of the form  $\mathcal{L} = W_{ij} \tilde{\chi}_i^0 \gamma_\mu (\gamma_5)^{\theta_i + \theta_j + 1} \tilde{\chi}_j^0 Z^\mu$ . The couplings  $W_{ij}$  depend only on the *higgsino* components of the neutralinos  $i$  and  $j$ . The subprocess cross section is given by:

$$\frac{d\sigma}{dt}(q\bar{q} \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0) = \frac{1}{192\pi s^2} [T_Z + T_{\tilde{q}_L} + T_{\tilde{q}_R} + T_{Z\tilde{q}_L} + T_{Z\tilde{q}_R}] \quad (49.84)$$

where

$$T_Z = 128e^2 |W_{ij}|^2 (\alpha_q^2 + \beta_q^2) |D_Z(s)|^2 \\ \left[ q \cdot \tilde{\chi}_i^0 \tilde{q} \cdot \tilde{\chi}_j^0 + q \cdot \tilde{\chi}_j^0 \tilde{q} \cdot \tilde{\chi}_i^0 - \eta_i \eta_j m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q} \right], \quad (49.85)$$

$$T_{\tilde{q}_L} = 4|A_{\tilde{\chi}_i^0}^q|^2 |A_{\tilde{\chi}_j^0}^q|^2 \left\{ \frac{q \cdot \tilde{\chi}_i^0 \tilde{q} \cdot \tilde{\chi}_j^0}{[(\tilde{\chi}_i^0 - q)^2 - m_{\tilde{q}_L}^2]^2} + \frac{q \cdot \tilde{\chi}_j^0 \tilde{q} \cdot \tilde{\chi}_i^0}{[(\tilde{\chi}_j^0 - q)^2 - m_{\tilde{q}_L}^2]^2} \right. \\ \left. - \eta_i \eta_j \frac{m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q}}{[(\tilde{\chi}_i^0 - q)^2 - m_{\tilde{q}_L}^2][(\tilde{\chi}_j^0 - q)^2 - m_{\tilde{q}_L}^2]} \right\} \quad (49.86)$$

$$T_{\tilde{q}_R} = 4|B_{\tilde{\chi}_i^0}^q|^2 |B_{\tilde{\chi}_j^0}^q|^2 \left\{ \frac{q \cdot \tilde{\chi}_i^0 \tilde{q} \cdot \tilde{\chi}_j^0}{[(\tilde{\chi}_i^0 - q)^2 - m_{\tilde{q}_R}^2]^2} + \frac{q \cdot \tilde{\chi}_j^0 \tilde{q} \cdot \tilde{\chi}_i^0}{[(\tilde{\chi}_j^0 - q)^2 - m_{\tilde{q}_R}^2]^2} \right. \\ \left. - \eta_i \eta_j \frac{m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q}}{[(\tilde{\chi}_i^0 - q)^2 - m_{\tilde{q}_R}^2][(\tilde{\chi}_j^0 - q)^2 - m_{\tilde{q}_R}^2]} \right\} \quad (49.87)$$

$$T_{Z\tilde{q}_L} = 16e(\alpha_q - \beta_q)(s - M_Z^2) |D_Z(s)|^2 \\ \left\{ \frac{\text{Re}(W_{ij} A_{\tilde{\chi}_i^0}^{q*} A_{\tilde{\chi}_j^0}^q)}{[(\tilde{\chi}_i^0 - q)^2 - m_{\tilde{q}_L}^2]} \left[ 2q \cdot \tilde{\chi}_i^0 \tilde{q} \cdot \tilde{\chi}_j^0 - \eta_i \eta_j m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q} \right] \right. \\ \left. + \eta_i \eta_j \frac{\text{Re}(W_{ij} A_{\tilde{\chi}_i^0}^q A_{\tilde{\chi}_j^0}^{q*})}{[(\tilde{\chi}_j^0 - q)^2 - m_{\tilde{q}_L}^2]} \left[ 2q \cdot \tilde{\chi}_j^0 \tilde{q} \cdot \tilde{\chi}_i^0 - \eta_i \eta_j m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q} \right] \right\} \quad (49.88)$$

$$T_{Z\tilde{q}_R} = 16e(\alpha_q + \beta_q)(s - M_Z^2) |D_Z(s)|^2 \\ \left\{ \frac{\text{Re}(W_{ij} B_{\tilde{\chi}_i^0}^{q*} B_{\tilde{\chi}_j^0}^q)}{[(\tilde{\chi}_i^0 - q)^2 - m_{\tilde{q}_R}^2]} \left[ 2q \cdot \tilde{\chi}_i^0 \tilde{q} \cdot \tilde{\chi}_j^0 - \eta_i \eta_j m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q} \right] \right. \\ \left. - \eta_i \eta_j \frac{\text{Re}(W_{ij} B_{\tilde{\chi}_i^0}^q B_{\tilde{\chi}_j^0}^{q*})}{[(\tilde{\chi}_j^0 - q)^2 - m_{\tilde{q}_R}^2]} \left[ 2q \cdot \tilde{\chi}_j^0 \tilde{q} \cdot \tilde{\chi}_i^0 - \eta_i \eta_j m_{\tilde{\chi}_i^0} m_{\tilde{\chi}_j^0} q \cdot \tilde{q} \right] \right\}. \quad (49.89)$$

As before,  $\eta_i = \pm 1$  corresponding to whether the neutralino mass eigenvalue is positive or negative. When  $i = j$  in the above formula, one must remember to integrate over just  $2\pi$  steradians of solid angle to avoid double counting in the total cross section.

## 49.9. Universal extra dimensions

In the Universal Extra Dimension (UED) model of Ref. [19] (see Ref. [20] for a review of models with extra spacetime dimensions), the Standard Model is embedded in a five dimensional theory, where the fifth dimension is compactified on an  $S_1/Z_2$  orbifold. Each SM chirality state is then the zero mode of an infinite tower of Kaluza-Klein excitations labelled by  $n = 0 - \infty$ . A KK parity is usually assumed to hold, where each state is assigned KK-parity  $P = (-1)^n$ . If the compactification scale is around a TeV, then the  $n = 1$  (or even higher) KK modes may be accessible to collider searches.

Of interest for hadron colliders are the production of massive  $n \geq 1$  quark or gluon pairs. These production cross sections have been calculated in Ref. [21,22]. We list here results for the  $n = 1$  case only with  $M_1 = 1/R$  ( $R$  is the compactification radius) and  $s$ ,  $t$  and  $u$  are the usual Mandelstam variables; more general formulae can be found in Ref. [22]. The superscript  $*$  stands for any KK excited state, while  $\bullet$  stands for left chirality states and  $\circ$  stands for right chirality states.

$$\frac{d\sigma}{dt} = \frac{1}{16\pi s^2} T \quad (49.90)$$

where

$$T(q\bar{q} \rightarrow g^* g^*) = \frac{2g_s^4}{27} \left[ M_1^2 \left( -\frac{4s^3}{t'^2 u'^2} + \frac{57s}{t' u'} - \frac{108}{s} \right) \right. \\ \left. + \frac{20s^2}{t' u'} - 93 + \frac{108t' u'}{s^2} \right] \quad (49.91)$$

and

$$T(gg \rightarrow g^* g^*) = \frac{9g_s^4}{27} \left[ 3M_1^4 \frac{s^2 + t'^2 + u'^2}{t'^2 u'^2} - 3M_1^2 \frac{s^2 + t'^2 + u'^2}{st' u'} + 1 \right. \\ \left. + \frac{(s^2 + t'^2 + u'^2)^3}{4s^2 t'^2 u'^2} - \frac{t' u'}{s^2} \right] \quad (49.92)$$

where  $t' = t - M_1^2$  and  $u' = u - M_1^2$ .

Also,

$$T(q\bar{q} \rightarrow q_1^* \bar{q}_1^*) = \frac{4g_s^4}{9} \left[ \frac{2M_1^2}{s} + \frac{t'^2 + u'^2}{s^2} \right],$$

$$T(q\bar{q} \rightarrow q_1^* \bar{q}_1^*) = \frac{g_s^4}{9} \left[ 2M_1^2 \left( \frac{4}{s} + \frac{s}{t'^2} - \frac{1}{t'} \right) \right. \\ \left. + \frac{23}{6} + \frac{2s^2}{t'^2} + \frac{8s}{3t'} + \frac{6t'}{s} + \frac{8t'^2}{s^2} \right],$$

$$T(qq \rightarrow q_1^* \bar{q}_1^*) = \frac{g_s^4}{27} \left[ M_1^2 \left( 6 \frac{t'}{u'^2} + 6 \frac{u'}{t'^2} - \frac{s}{t' u'} \right) \right. \\ \left. + 2 \left( 3 \frac{t'^2}{u'^2} + 3 \frac{u'^2}{t'^2} + 4 \frac{s^2}{t' u'} - 5 \right) \right],$$

$$T(gg \rightarrow q_1^* \bar{q}_1^*) = g_s^4 \left[ M_1^4 \frac{-4}{t' u'} \left( \frac{s^2}{6t' u'} - \frac{3}{8} \right) \right. \\ \left. + M_1^2 \frac{4}{s} \left( \frac{s^2}{6t' u'} - \frac{3}{8} \right) + \frac{s^2}{6t' u'} - \frac{17}{24} + \frac{3t' u'}{4s^2} \right],$$

$$T(gq \rightarrow g^* q_1^*) = \frac{-g_s^4}{3} \left[ \frac{5s^2}{12t'^2} + \frac{s^3}{t'^2 u'} + \frac{11su'}{6t'^2} + \frac{5u'^2}{12t'^2} + \frac{u'^3}{st'^2} \right],$$

$$T(q\bar{q}' \rightarrow q_1^* \bar{q}_1^*) = \frac{g_s^4}{18} \left[ 4M_1^4 \frac{s}{t'^2} + 5 + 4 \frac{s^2}{t'^2} + 8 \frac{s}{t'} \right],$$

$$T(qq' \rightarrow q_1^* \bar{q}_1^*) = \frac{2g_s^4}{9} \left[ -M_1^2 \frac{s}{t'^2} + \frac{1}{4} + \frac{s^2}{t'^2} \right],$$

$$T(qq \rightarrow q_1^\bullet q_1^\circ) = \frac{g_s^4}{9} \left[ M_1^2 \left( \frac{2s^3}{t'^2 u'^2} - \frac{4s}{t' u'} \right) + 2 \frac{s^4}{t'^2 u'^2} - 8 \frac{s^2}{t' u'} + 5 \right],$$

$$T(q\bar{q}' \rightarrow q_1^\bullet \bar{q}_1^\circ) = \frac{g_s^4}{9} \left[ 2M_1^2 \left( \frac{1}{t'} + \frac{u'}{t'^2} \right) + \frac{5}{2} + \frac{4u'}{t'} + \frac{2u'^2}{t'^2} \right],$$

and

$$T(qq' \rightarrow q_1^\bullet q_1^\circ) = \frac{g_s^4}{9} \left[ -2M_1^2 \left( \frac{1}{t'} + \frac{u'}{t'^2} \right) + \frac{1}{2} + \frac{2u'^2}{t'^2} \right].$$

#### 49.10. Large extra dimensions

In the ADD theory [23] with large extra dimensions (LED), the SM particles are confined to a 3-brane, while gravity propagates in the bulk. It is assumed that the  $n$  extra dimensions are compactified on an  $n$ -dimensional torus of volume  $(2\pi r)^n$ , so that the fundamental  $4+n$  dimensional Planck scale  $M_*$  is related to the usual 4-dimensional Planck scale  $M_{Pl}$  by  $M_{Pl}^2 = M_*^{n+2} (2\pi r)^n$ . If  $M_* \sim 1$  TeV, then the  $M_W - M_{Pl}$  hierarchy problem is just due to gravity propagating in the large extra dimensions.

In these theories, the KK-excited graviton states  $G_{\mu\nu}^n$  for  $n = 1 - \infty$  can be produced at collider experiments. The graviton couplings to matter are suppressed by  $1/M_{Pl}$ , so that graviton emission cross sections  $d\sigma/dt \sim 1/M_{Pl}^2$ . However, the mass splittings between the excited graviton states can be tiny, so the graviton eigenstates are usually approximated by a continuum distribution. A summation (integration) over all allowed graviton emissions ends up cancelling the  $1/M_{Pl}^2$  factor, so that observable cross section rates can be attained. Some of the fundamental production formulae for a KK graviton (denoted  $G$ ) of mass  $m$  at hadron colliders include the subprocesses

$$\frac{d\sigma_m}{dt}(f\bar{f} \rightarrow \gamma G) = \frac{\alpha Q_f^2}{16N_f s M_{Pl}^2} F_1\left(\frac{t}{s}, \frac{m^2}{s}\right), \quad (49.93)$$

where  $Q_f$  is the charge of fermion  $f$  and  $N_f$  is the number of QCD colors of  $f$ . Also,

$$\frac{d\sigma_m}{dt}(q\bar{q} \rightarrow gG) = \frac{\alpha_s}{36 s M_{Pl}^2} F_1\left(\frac{t}{s}, \frac{m^2}{s}\right), \quad (49.94)$$

$$\frac{d\sigma_m}{dt}(qg \rightarrow qG) = \frac{\alpha_s}{96 s M_{Pl}^2} F_2\left(\frac{t}{s}, \frac{m^2}{s}\right), \quad (49.95)$$

$$\frac{d\sigma_m}{dt}(gg \rightarrow gG) = \frac{3\alpha_s}{16 s M_{Pl}^2} F_3\left(\frac{t}{s}, \frac{m^2}{s}\right), \quad (49.96)$$

where

$$F_1(x, y) = \frac{1}{x(y-1-x)} \left[ -4x(1+x)(1+2x+2x^2) + y(1+6x+18x^2+16x^3) - 6y^2x(1+2x) + y^3(1+4x) \right] \quad (49.97)$$

$$F_2(x, y) = -(y-1-x)F_1\left(\frac{x}{y-1-x}, \frac{y}{y-1-x}\right) \quad (49.98)$$

and

$$F_3(x, y) = \frac{1}{x(y-1-x)} \left[ 1+2x+3x^2+2x^3+x^4 - 2y(1+x^3) + 3y^2(1+x^2) - 2y^3(1+x) + y^4 \right]. \quad (49.99)$$

These formulae must then be multiplied by the graviton density of states formula  $dN = S_{n-1} \frac{M_{Pl}^2}{M_*^{n+2}} m^{n-1} dm$  to gain the cross section

$$\frac{d^2\sigma}{dtdm} = S_{n-1} \frac{M_{Pl}^2}{M_*^{n+2}} m^{n-1} \frac{d\sigma_m}{dt} \quad (49.100)$$

where  $S_n = \frac{(2\pi)^{n/2}}{\Gamma(n/2)}$  is the surface area of an  $n$ -dimensional sphere of unit radius.

Virtual graviton processes can also be searched for at colliders. For instance, in Ref. [24] the cross section for Drell-Yan production of lepton pairs via gluon fusion was calculated, where it is found that, in the center-of-mass system

$$\frac{d\sigma}{dz}(gg \rightarrow \ell^+ \ell^-) = \frac{\lambda^2 s^3}{64\pi M_*^8} (1-z^2)(1+z^2) \quad (49.101)$$

where  $z = \cos\theta$  and  $\lambda$  is a model-dependent coupling constant  $\sim 1$ . Formulae for Drell-Yan production via  $q\bar{q}$  fusion can also be found in Refs. [24,25].

#### 49.11. Warped extra dimensions

In the Randall-Sundrum model [26] of warped extra dimensions, the arena for physics is a 5-d anti-deSitter ( $AdS_5$ ) spacetime, for which a non-factorizable metric exists with a metric warp factor  $e^{-2\sigma(\phi)}$ . It is assumed that two opposite tension 3-branes exist within  $AdS_5$  at the two ends of an  $S_1/Z_2$  orbifold parametrized by co-ordinate  $\phi$  which runs from  $0 - \pi$ . The 4-D solution of the Einstein equations yields  $\sigma(\phi) = kr_c|\phi|$ , where  $r_c$  is the compactification radius of the extra dimension and  $k \sim M_{Pl}$ . The 4-D effective action allows one to identify  $\bar{M}_{Pl}^2 = \frac{M^3}{k}(1 - e^{-2kr_c\pi})$ , where  $M$  is the 5-D Planck scale. Physical particles on the TeV scale (SM) brane have mass  $m = e^{-kr_c\pi} m_0$ , where  $m_0$  is a fundamental mass of order the Planck scale. Thus, the weak scale-Planck scale hierarchy occurs due to the existence of the exponential warp factor if  $kr_c \sim 12$ .

In the simplest versions of the RS model, the TeV-scale brane contains only SM particles plus a tower of KK gravitons. The RS gravitons have mass  $m_n = kx_n e^{-kr_c\pi}$ , where the  $x_i$  are roots of Bessel functions  $J_1(x_n) = 0$ , with  $x_1 \simeq 3.83$ ,  $x_2 \simeq 7.02$  etc. While the RS zero-mode graviton couplings suppressed by  $1/\bar{M}_{Pl}$  and are thus inconsequential for collider searches, the  $n=1$  and higher modes have couplings suppressed instead by  $\Lambda_\pi = e^{-kr_c\pi} \bar{M}_{Pl} \sim TeV$ . The  $n=1$  RS graviton should have width  $\Gamma_1 = \rho m_1 x_1^2 (k/\bar{M}_{Pl})^2$ , where  $\rho$  is a constant depending on how many decay modes are open. The formulae for dilepton production via virtual RS graviton exchange can be gained from the above formulae for the ADD scenario via the replacement [27]

$$\frac{\lambda}{M_*^4} \rightarrow \frac{i^2}{8\Lambda_\pi^2} \sum_{n=1}^{\infty} \frac{1}{s - m_n^2 + im_n\Gamma_n}. \quad (49.102)$$

## 50. Neutrino Cross Section Measurements

Revised August 2015 by G.P. Zeller (Fermilab)

Neutrino cross sections are an essential ingredient in all neutrino experiments. Interest in neutrino scattering has recently increased due to the need for such information in the interpretation of neutrino oscillation data. Historically, neutrino scattering results on both charged current (CC) and neutral current (NC) channels have been collected over many decades using a variety of targets, analysis techniques, and detector technologies. With the advent of intense neutrino sources constructed for neutrino oscillation investigations, experiments are now remeasuring these cross sections with a renewed appreciation for nuclear effects<sup>†</sup> and the importance of improved neutrino flux estimations. This work summarizes accelerator-based neutrino cross section measurements performed in the  $\sim 0.1 - 300$  GeV range with an emphasis on inclusive, quasi-elastic, and pion production processes, areas where we have the most experimental input at present (Table 50.1 and Table 50.2). For a more comprehensive discussion of neutrino cross sections, including neutrino-electron elastic scattering and lower energy neutrino measurements, the reader is directed to a recent review of this subject [1]. Here, we survey existing experimental data on neutrino interactions and do not attempt to provide a census of the associated theoretical calculations, which are both important and plentiful.

### 50.1. Inclusive Scattering

Over the years, many experiments have measured the total inclusive cross section for neutrino ( $\nu_\mu N \rightarrow \mu^- X$ ) and antineutrino ( $\bar{\nu}_\mu N \rightarrow \mu^+ X$ ) scattering off nucleons covering a broad range of neutrino energies. As can be seen in Fig. 50.1, the inclusive cross section approaches a linear dependence on neutrino energy. Such behavior is expected for point-like scattering of neutrinos from quarks, an assumption which breaks down at lower energies. To provide a more complete picture, differential cross sections for such inclusive scattering processes have been reported – these include measurements on iron from NuTeV [42] and, more recently, at lower neutrino energies on argon from ArgoNeuT [2,3] and on carbon from T2K [37]. MINERvA has also provided new measurements of the ratios of the muon neutrino CC inclusive scattering cross section on a variety of nuclear targets such as lead, iron, and carbon [11]. At high energy, the inclusive cross section is dominated by deep inelastic scattering (DIS). Several high energy neutrino experiments have measured the DIS cross sections for specific final states, for example opposite-sign dimuon production. The most recent dimuon cross section measurements include those from CHORUS [43], NOMAD [44], and NuTeV [45]. At lower neutrino energies, the inclusive cross section is an additionally complex combination of quasi-elastic scattering and pion production processes, two areas we discuss next.

**Fig. 50.1:** Measurements of  $\nu_\mu$  and  $\bar{\nu}_\mu$  CC inclusive scattering cross sections (per nucleon) divided by neutrino energy as a function of neutrino energy. Note the transition between logarithmic and linear scales occurring at 100 GeV. Neutrino cross sections are typically twice as large as their corresponding antineutrino counterparts, although this difference can be larger at lower energies. NC cross sections (not shown) are generally smaller but non-negligible compared to the CC scattering case.

<sup>†</sup> Nuclear effects refer to kinematic and final state effects which impact neutrino scattering off nuclei. Such effects can be significant and are particularly relevant given that modern neutrino experiments make use of nuclear targets to increase their event yields.

**Table 50.1:** List of beam properties, nuclear targets, and durations for modern accelerator-based neutrino experiments studying neutrino scattering.

Experiment	beam	$\langle E_\nu \rangle, \langle E_{\bar{\nu}} \rangle$ GeV	neutrino target(s)	run period
ArgoNeuT	$\nu, \bar{\nu}$	4.3, 3.6	Ar	2009 – 2010
ICARUS	$\nu$	20.0	Ar	2010 – 2012
K2K	$\nu$	1.3	CH, H <sub>2</sub> O	2003 – 2004
MicroBooNE	$\nu$	0.8	Ar	2015 –
MINERvA	$\nu, \bar{\nu}$	3.5 (LE), 5.5 (ME)	He, CH, H <sub>2</sub> O, Fe, Pb	2009 –
MiniBooNE	$\nu, \bar{\nu}$	0.8, 0.7	CH <sub>2</sub>	2002 – 2012
MINOS	$\nu, \bar{\nu}$	3.5, 6.1	Fe	2004 –
NOMAD	$\nu, \bar{\nu}$	23.4, 19.7	C	1995 – 1998
NOvA	$\nu, \bar{\nu}$	2.0, 2.0	CH <sub>2</sub>	2010 –
SciBooNE	$\nu, \bar{\nu}$	0.8, 0.7	CH	2007 – 2008
T2K	$\nu, \bar{\nu}$	0.6, 0.6	CH, H <sub>2</sub> O	2010 –

**Table 50.2:** Summary of published neutrino cross section measurements from modern accelerator-based experiments. All measurements are  $\nu_\mu$  or  $\bar{\nu}_\mu$  scattering with the exception of the last column which is a  $\nu_e$  measurement.

Experiment	inclusive	$0\pi$	$\pi^\pm$	$\pi^0$	$\nu_e$
ArgoNeuT	CC [2,3]	2p [4]	CC [5]	–	–
K2K	–	CC [6]	CC [7,8]	CC [9], NC [10]	–
MINERvA	CC [11]	CC [12,13], 1p [14]	CC [15]	CC [16]	–
MiniBooNE	–	CC [17,18], $M_A$ [19], NC [20,21,22]	CC [23,24]	CC [25], NC [26,27]	–
MINOS	CC [28]	$M_A$ [29]	–	–	–
NOMAD	CC [30]	CC [31]	–	NC [32]	–
SciBooNE	CC [33]	–	CC [34]	NC [35,36]	–
T2K	CC [37,38]	CC [39], NC [40]	–	–	CC [41]

## 50.2. Quasi-elastic scattering

Quasi-elastic (QE) scattering is the dominant neutrino interaction for neutrino energies less than  $\sim 1$  GeV and represents a large fraction of the signal samples in many neutrino oscillation experiments. Historically, neutrino (antineutrino) quasi-elastic scattering refers to the process,  $\nu_\mu n \rightarrow \mu^- p$  ( $\bar{\nu}_\mu p \rightarrow \mu^+ n$ ), where a charged lepton and single nucleon are ejected in the elastic interaction of a neutrino (or antineutrino) with a nucleon in the target material. This is the final state one would strictly observe, for example, in scattering off of a free nucleon target. Fig. 50.2 displays the current status of existing measurements of  $\nu_\mu$  and  $\bar{\nu}_\mu$  QE scattering cross sections as a function of neutrino energy. In this plot, and all others in this review, the prediction from a representative neutrino event generator (NUANCE) [46] provides a theoretical comparator. Other generators and more sophisticated calculations exist which can yield significantly different predictions [47]. Note that modern experiments have recently opted to report QE cross sections as a function of final state muon or proton kinematics [17,18,48]. Such distributions are more difficult to compare between experiments but are much less model-dependent and provide more stringent tests of the theory than cross sections as a function of neutrino energy ( $E_\nu$ ) or 4-momentum transfer ( $Q^2$ ).

In many of these initial measurements of the neutrino QE cross section, bubble chamber experiments employed light targets ( $H_2$  or  $D_2$ ) and required both the detection of the final state muon and single nucleon<sup>‡</sup>; thus the final state was clear and elastic kinematic conditions could be verified. The situation is more complicated, of course, for heavier nuclear targets. In this case, nuclear effects can impact the size and shape of the cross section as well as the final state kinematics and topology. Due to intranuclear hadron rescattering and the possible effects of correlations between target nucleons, additional nucleons may be ejected in the final state; hence, a QE interaction on a nuclear target does not always imply the ejection of a *single* nucleon. One therefore needs to take some care in defining what one means by neutrino QE scattering when scattering off targets heavier than  $H_2$  or  $D_2$ . Adding to the complexity, recent MiniBooNE measurements of the  $\nu_\mu$  and  $\bar{\nu}_\mu$  QE scattering cross sections on carbon near 1 GeV have revealed a significantly larger cross section than originally anticipated [17,18]. Such an enhancement was observed many years prior in electron-nucleus scattering [57] and is believed to be due to the presence of correlations between target nucleons in the nucleus. As a result, the impact of such nuclear effects on neutrino QE scattering has recently

<sup>‡</sup> In the case of  $D_2$ , many experiments additionally observed the spectator proton.

**Figure 50.2:** Measurements of  $\nu_\mu$  (black) and  $\bar{\nu}_\mu$  (red) QE scattering cross sections (per nucleon) as a function of neutrino energy. Data on a variety of nuclear targets are shown, including measurements from ANL [49], BEBC [50], BNL [51], FNAL [52], LSND [53], T2K [39], MINERvA [12], MiniBooNE [17,18], GGM [54], NOMAD [31], Serpukhov [55], and SKAT [56]. Shown is the QE free nucleon scattering prediction from NUANCE [46] assuming  $M_A = 1.0$  GeV. This prediction is significantly altered by nuclear effects in the case of neutrino-nucleus scattering. Although plotted together, care should be taken in interpreting measurements performed on targets heavier than  $D_2$  due to possible differences in QE identification and kinematics.

been the subject of intense experimental and theoretical scrutiny with potential implications on event rates, nucleon emission, neutrino energy reconstruction, and neutrino/antineutrino ratios. The reader is referred to a recent review of the situation in [58,59]. Additional measurements are clearly needed before a complete understanding is achieved. To help drive further progress, neutrino-nucleus QE cross sections have been reported for the first time in the form of double-differential distributions in muon kinematics,  $d^2\sigma/dT_\mu d\cos\theta_\mu$ , by MiniBooNE [17,18] thus reducing the model-dependence of the reported data and allowing a more rigorous two-dimensional test of the underlying nuclear theory. Experiments such as ArgoNeuT have begun to provide the first measurements of proton multiplicities in neutrino-argon QE scattering [4,48], a critical ingredient in understanding the hadronic side of these interactions and final state effects. MINOS, NOvA, and T2K have started to study QE interactions in their near detectors with sizable statistics [29,39,60]. Most recently, MINERvA has measured the differential cross section,  $d\sigma/dQ_{QE}^2$ ,  $\nu_e$  QE scattering [61], single proton emission [14], and vertex energy in both  $\nu_\mu$  and  $\bar{\nu}_\mu$  QE interactions in hydrocarbon [12,13]. With the MiniBooNE results having revealed additional complexities in the QE channel, measurements from other neutrino experiments are crucial for getting a better handle on the underlying nuclear physics impacting neutrino-nucleus interactions. What we once thought was “simple” QE scattering is in fact not so simple.

In addition to such charged current investigations, measurements of the neutral current counterpart of this channel have also been performed. The most recent NC elastic scattering cross section measurements include those from BNL E734 [62], MiniBooNE [20,21,22], and T2K [40]. A number of measurements of the Cabibbo-suppressed antineutrino QE hyperon production cross section have additionally been reported [56,63], although not in recent years.

### 50.3. Pion Production

In addition to such elastic processes, neutrinos can also inelastically scatter producing a nucleon excited state ( $\Delta$ ,  $N^*$ ). Such baryonic resonances quickly decay, most often to a nucleon and single-pion final state. Historically, experiments have measured various exclusive final states associated with these reactions, the majority of which have been on hydrogen and deuterium targets [1].

In addition to such resonance production processes, neutrinos can also coherently scatter off of the entire nucleus and produce a distinctly forward-scattered single pion final state. Both CC ( $\nu_\mu A \rightarrow \mu^- A\pi^+$ ,  $\bar{\nu}_\mu A \rightarrow \mu^+ A\pi^-$ ) and NC ( $\nu_\mu A \rightarrow \nu_\mu A\pi^0$ ,  $\bar{\nu}_\mu A \rightarrow \bar{\nu}_\mu A\pi^0$ ) processes are possible in this case. Even though the level of coherent pion production is small compared to resonant processes, observations exist across a broad energy range and on multiple nuclear targets [64]. More recently, several modern neutrino experiments have measured coherent pion production cross sections including ArgoNeuT [5], K2K [8], MINERvA [15], MiniBooNE [27], MINOS [65], NOMAD [32], and SciBooNE [34,36].

As with QE scattering, a new appreciation for the significance of nuclear effects has surfaced in pion production channels, again due to the use of heavy nuclear targets in modern neutrino experiments. Many experiments have been careful to report cross sections for various detected final states, thereby not correcting for large and uncertain nuclear effects (e.g., pion rescattering, charge exchange, and absorption) which can introduce unwanted sources of uncertainty and model dependence. Recent measurements of single-pion cross sections, as published by K2K [9,10], MiniBooNE [24], and SciBooNE [35], take the form of ratios with respect to QE or CC inclusive scattering samples. Providing the most comprehensive survey of neutrino single-pion production to date, MiniBooNE has recently published a total of 16 single- and double-differential cross sections for both the final state muon (in the case of CC scattering) and pion in these interactions; thus, providing the first measurements of these distributions (Fig. 50.3) [23–26]. MINERvA has recently produced similar kinematic measurements at higher neutrino energies (Fig. 50.4) [16,66]. Regardless of the interaction channel, such differential cross section measurements (in terms of observed final state particle kinematics) are now preferred for their reduced model dependence and for the additional kinematic information they provide. Such a new direction has been the focus of modern measurements as opposed to the reporting of more model-dependent, historical cross sections as a function of  $E_\nu$  or  $Q^2$ . Together with similar results for other interaction channels, a better understanding and modeling of nuclear effects will be possible moving forward.

**Figure 50.3:** Differential cross sections for CC and NC pion production from MiniBooNE at a mean neutrino energy of 0.8 GeV. Shown here are the measurements as a function of the momentum of the outgoing pion in the interaction, a kinematic that is particularly sensitive to final state interactions. Other distributions are also available in the publications listed in the legend.

It should be noted that baryonic resonances can also decay to multi-pion, other mesonic ( $K$ ,  $\eta$ ,  $\rho$ , etc.), and even photon final states. Experimental results for these channels are typically sparse or non-existent [1]; however, photon production processes can be an important background for  $\nu_\mu \rightarrow \nu_e$  appearance searches and thus have become the focus of some recent experimental investigations; for example, in NOMAD [67].

**Figure 50.4:** Differential cross sections for neutrino and antineutrino pion production from MINERvA at a mean neutrino energy of 3.3 GeV. Shown here are the measurements as a function of the momentum of the outgoing pion in the interaction, a kinematic that is particularly sensitive to final state interactions. Other distributions are also available in the publications listed in the legend. Note that while the MINERvA  $\nu_\mu$  measurement includes both  $\pi^+$  and  $\pi^-$  production, the sample is almost entirely ( $> 99\%$ )  $\pi^+$  final states.

#### 50.4. Outlook

Currently operating experiments will continue to produce additional neutrino cross section measurements as they accumulate additional statistics, while a few new experiments will soon be coming online. In the coming years, analysis of a broad energy range of data on a variety of targets in the MINERvA experiment will provide the most detailed analysis yet of nuclear effects in neutrino interactions. Data from ArgoNeuT, ICARUS, MicroBooNE, and SBND will probe deeper into complex neutrino final states using the superior capabilities of liquid argon time projection chambers, while the T2K and NOvA near detectors will collect high statistics samples in intense neutrino beams. Together, these investigations should significantly advance our understanding of neutrino-nucleus scattering in the next decade.

#### 50.5. Acknowledgments

The author thanks Anne Schukraft (Fermilab) for help in updating the plots contained in this review.

## 51. PLOTS OF CROSS SECTIONS AND RELATED QUANTITIES

(For neutrino plots, see review article "Neutrino Cross Section Measurements" by G.P. Zeller in this edition of RPP)

**Figure 51.1:** Inclusive differential jet cross sections, in the central rapidity region, plotted as a function of the jet transverse momentum. Results earlier than from the Tevatron Run 2 used transverse energy rather than transverse momentum and pseudo-rapidity  $\eta$  rather than rapidity  $y$ , but  $p_T$  and  $y$  are used for all results shown here for simplicity. The error bars plotted are in most cases the experimental stat. and syst. errors added in quadrature. The CDF and D0 measurements use jet sizes of 0.7 (JetClu for CDF Run 1, and Midpoint and  $k_T$  for CDF Run 2, a cone algorithm for D0 in Run 1 and the Midpoint algorithm in Run 2). The ATLAS results are plotted for the antikt algorithm for  $R=0.4$ , while the CMS results also use antikt, but with  $R=0.5$ . NLO QCD predictions in general provide a good description of the Tevatron and LHC data; the Tevatron jet data in fact are crucial components of global PDF fits, and the LHC data are starting to be used as well. Comparisons with the older cross sections are more difficult due to the nature of the jet algorithms used. **ATLAS:** Phys. Rev. **D86**, 014022 (2012), Eur. Phys. J **C73**, 2509 (2013); **CMS:** Phys. Rev. **D84**, 052011 (2011); **CDF:** Phys. Rev. **D75**, 092006 (2007), Phys. Rev. **D64**, 032001 (2001), Phys. Rev. Lett. **70**, 1376 (1993); **D0:** Phys. Rev. **D64**, 032003 (2001); **UA2:** Phys. Lett. **B257**, 232 (1991); **UA1:** Phys. Lett. **172**, 461 (1986); **R807:** Phys. Lett. **B123**, 133 (1983). (Courtesy of J. Huston, Michigan State University, 2013.)

**Figure 51.2:** Isolated photon cross sections plotted as a function of the photon transverse momentum. The errors are either statistical only, or statistical and systematic added in quadrature. **ATLAS:** Phys. Lett. **B706**, 150 (2011); **CMS:** Phys. Rev. **D84**, 052011 (2011); **D0:** Phys. Lett. **B639**, 151 (2006), Phys. Rev. Lett. **87**, 251805 (2001); **CDF:** Phys. Rev. **D65**, 112003 (2002); **UA6:** Phys. Lett. **B206**, 163 (1988); **UA1:** Phys. Lett. **B209**, 385 (1988); **UA2:** Phys. Lett. **B288**, 386 (1992). (Courtesy of J. Huston, Michigan State University, 2013.)

Differential Cross Section for  $W$  and  $Z$  Boson Production

**Figure 51.3:** Differential cross sections for  $W$  and  $Z$  production shown as a function of the boson transverse momentum. The errors plotted are either statistical only or statistical and systematic added in quadrature. The results are in good agreement with theoretical predictions that include both the effects of NLO corrections and of  $q_T$  resummation. **ATLAS:** Phys. Rev. **D85**, 012005 (2012), Phys. Lett. **B705**, 415 (2011); **CMS:** Phys. Rev. **D85**, 032002 (2012); **D0:** Phys. Lett. **B513**, 292 (2001), Phys. Rev. Lett. **84**, 2792 (2000); **CDF:** Phys. Rev. Lett. **84**, 845 (2000). (Courtesy of J. Huston, Michigan State University, 2013.)

Pseudorapidity Distributions in  $pp$  and  $p\bar{p}$  Interactions

**Figure 51.4:** Charged particle pseudorapidity distributions in  $pp$  collisions for  $53 \text{ GeV} \leq \sqrt{s} \leq 1800 \text{ GeV}$ . UA5 data from the  $S\bar{p}p$ S are taken from G.J. Alner *et al.*, Z. Phys. **C33**, 1 (1986), and from the ISR from K. Alpgöard *et al.*, Phys. Lett. **112B** 193 (1982). The UA5 data are shown for both the full inelastic cross-section and with singly diffractive events excluded. Additional non single-diffractive measurements are available from CDF at the Tevatron, F. Abe *et al.*, Phys. Rev. **D41**, 2330 (1990) and from P238 at the  $S\bar{p}p$ S, R. Harr *et al.*, Phys. Lett. **B401**, 176 (1997). These may be compared with both inclusive and non single-diffractive measurements in  $pp$  collisions at the LHC from ALICE, K. Aamodt *et al.*, Eur. Phys. J. **C68**, 89 (2010) and for non single-diffractive interactions from CMS, V. Khachatryan *et al.*, JHEP 1002:041 (2010), Phys. Rev. Lett. **105**, 022002 (2010). (Courtesy of D.R. Ward, Cambridge Univ., 2013)

### Average Hadron Multiplicities in Hadronic $e^+e^-$ Annihilation Events

**Table 51.1:** Average hadron multiplicities per hadronic  $e^+e^-$  annihilation event at  $\sqrt{s} \approx 10, 29\text{--}35, 91$ , and  $130\text{--}200$  GeV. The rates given include decay products from resonances with  $c\tau < 10$  cm, and include the corresponding anti-particle state. Correlations of the systematic uncertainties were considered for the calculation of the averages. Quoted errors are not increased by scale factor  $S$ . (Updated August 2015 by O. Biebel, LMU, Munich)

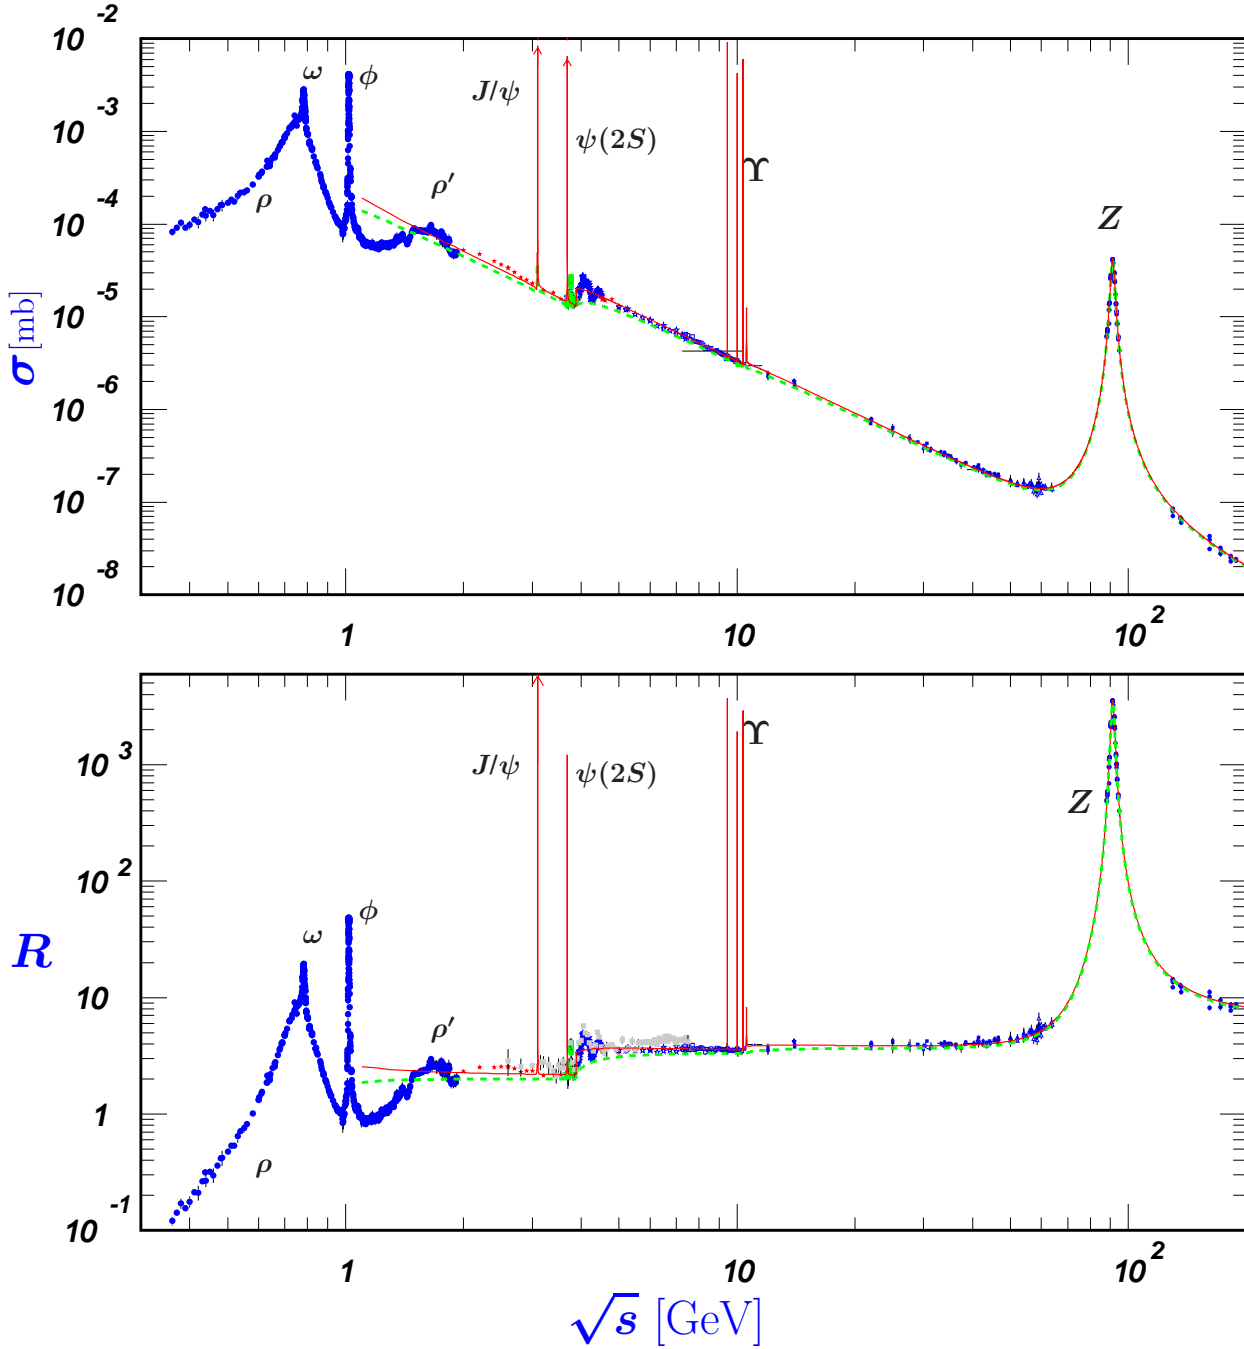

Particle	$\sqrt{s} \approx 10$ GeV	$\sqrt{s} = 29\text{--}35$ GeV	$\sqrt{s} = 91$ GeV	$\sqrt{s} = 130\text{--}200$ GeV

## Notes for Table 51.1:

- (a)  $\sigma_{\text{had}} = 3.33 \pm 0.05 \pm 0.21$  nb (CLEO: Phys. Rev. **D29**, 1254 (1984)) has been used in converting the measured cross sections to average hadron multiplicities.
- (b)  $B(D_s \rightarrow \eta\pi, \eta'\pi)$  was used (RPP 1994).
- (c) Comprises both charged and neutral  $B$  meson states.
- (d) The Standard Model  $B(Z \rightarrow b\bar{b}) = 0.217$  was used.
- (e)  $x_p = p/p_{\text{beam}} > 0.1$  only.
- (f) Both charge states.
- (g)  $B(D^*(2010)^+ \rightarrow D^0\pi^+) \times B(D^0 \rightarrow K^-\pi^+)$  has been used (RPP 2000).
- (h)  $B(D_s^* \rightarrow D_s^+\gamma)$ ,  $B(D_s^+ \rightarrow \phi\pi^+)$ ,  $B(\phi \rightarrow K^+K^-)$  have been used (RPP 1998).
- (i) Any charge state (*i.e.*,  $B_d^*$ ,  $B_u^*$ , or  $B_s^*$ ).
- (j)  $B(Z \rightarrow \text{hadrons}) = 0.699$  was used (RPP 1994).
- (k) Any charge state (*i.e.*,  $B_d^{**}$ ,  $B_u^{**}$ , or  $B_s^{**}$ ).
- (l) Assumes  $B(D_{s1}^+ \rightarrow D^{*+}K^0 + D^{*0}K^+) = 100\%$  and  $B(D_{s2}^+ \rightarrow D^0K^+) = 45\%$ .
- (m) The value was derived from the cross section of  $\Lambda_c^+ \rightarrow p\pi K$  using (a) and assuming the branching fraction to be  $(5.0 \pm 1.3)\%$  (RPP 2004).

$\sigma$  and  $R$  in  $e^+e^-$  Collisions

**Figure 51.5:** World data on the total cross section of  $e^+e^- \rightarrow \text{hadrons}$  and the ratio  $R(s) = \sigma(e^+e^- \rightarrow \text{hadrons}, s) / \sigma(e^+e^- \rightarrow \mu^+\mu^-, s)$ .  $\sigma(e^+e^- \rightarrow \text{hadrons}, s)$  is the experimental cross section corrected for initial state radiation and electron-positron vertex loops,  $\sigma(e^+e^- \rightarrow \mu^+\mu^-, s) = 4\pi\alpha^2(s)/3s$ . Data errors are total below 2 GeV and statistical above 2 GeV. The curves are an educative guide: the broken one (green) is a naive quark-parton model prediction, and the solid one (red) is 3-loop pQCD prediction (see “Quantum Chromodynamics” section of this Review, Eq. (9.7) or, for more details, K. G. Chetyrkin *et al.*, Nucl. Phys. **B586**, 56 (2000) (Erratum *ibid.* **B634**, 413 (2002))). Breit-Wigner parameterizations of  $J/\psi$ ,  $\psi(2S)$ , and  $\Upsilon(nS)$ ,  $n = 1, 2, 3, 4$  are also shown. The full list of references to the original data and the details of the  $R$  ratio extraction from them can be found in [arXiv:hep-ph/0312114]. Corresponding computer-readable data files are available at <http://pdg.lbl.gov/current/xsect/>. (Courtesy of the COMPAS (Protvino) and HEPDATA (Durham) Groups, August 2015. Corrections by P. Janot (CERN) and M. Schmitt (Northwestern U.)

### $R$ in Light-Flavor, Charm, and Beauty Threshold Regions

**Figure 51.6:**  $R$  in the light-flavor, charm, and beauty threshold regions. Data errors are total below 2 GeV and statistical above 2 GeV. The curves are the same as in Fig. 51.5. **Note:** CLEO data above  $\Upsilon(4S)$  were not fully corrected for radiative effects, and we retain them on the plot only for illustrative purposes with a normalization factor of 0.8. The full list of references to the original data and the details of the  $R$  ratio extraction from them can be found in [arXiv:hep-ph/0312114]. The computer-readable data are available at <http://pdg.lbl.gov/current/xsect/>. (Courtesy of the COMPAS (Protvino) and HEPDATA (Durham) Groups, August 2015.)

Annihilation Cross Section Near  $M_Z$ 

**Figure 51.7:** Combined data from the ALEPH, DELPHI, L3, and OPAL Collaborations for the cross section in  $e^+e^-$  annihilation into hadronic final states as a function of the center-of-mass energy near the Z pole. The curves show the predictions of the Standard Model with two, three, and four species of light neutrinos. The asymmetry of the curve is produced by initial-state radiation. Note that the error bars have been increased by a factor ten for display purposes. References:

## Total Hadronic Cross Sections

(Updated June 2016, COMPAS group, IHEP, Protvino)

This updated version of the total hadronic cross sections review is based on the first half of 2015 update of the database for total cross section and the ratio of the real-to-imaginary parts of the forward elastic scattering hadronic amplitudes. New data on total  $pp$  collisions cross sections from CERN-LHC-TOTEM [1–4] and CERN-LHC-ATLAS [5] were added.

We use a procedure for ranking models as described in [6] to identify the safest parameterizations for extrapolations. Incidentally, the models giving the best fit of accelerator data also reproduce the experimental cosmic ray nucleon–nucleon data extracted from nucleon–air data with no need of any extra phenomenological corrections to the data.

The statement in [6] that the models with universal (across of collision initial states)  $B \log^2(s/s_0)$  asymptotic term work much better than the models with  $B \log(s/s_0)$  or  $B(s/s_0)^\Delta$  terms was confirmed in [7–11] based on matching traditional asymptotic parameterizations with low energy data in different ways. However in these references the scale parameter  $s_0$  was still claimed to be dependent on the colliding particles as it should be for the asymptotic form of parameterizations constructed by the Regge-Gribov phenomenology prescriptions.

The possibility of the universal  $\log^2(s/s_0)$  rise of the hadronic total cross sections for different colliding particles was first pointed out by W. Heisenberg [12–13] and discussed many times (see for example [14] and more recent [15–17], and references therein). In [16] the universality of the asymptotic total collision cross sections has been advocated for hadron-nucleus collisions. In [17] additional indications to the universal asymptotic high-energy behavior for hadronic total collision cross sections in form  $B \log^2(s/s_0)$  were obtained from lattice QCD.

In this review we use HPR<sub>1</sub>R<sub>2</sub> model of highest COMPETE-rank modified (as in 2012 version) to save the universality of the rising part in new form that explicitly includes dependence of the  $s_0$  and  $B$  on the initial state mass parameters and the new scale parameter  $M$ .

$$\sigma^{a\bar{b}} = H \log^2 \left( \frac{s}{s_M^{ab}} \right) + P^{ab} + R_1^{ab} \left( \frac{s}{s_M^{ab}} \right)^{-\eta_1} \pm R_2^{ab} \left( \frac{s}{s_M^{ab}} \right)^{-\eta_2};$$

$$\rho^{a\bar{b}} = \frac{1}{\sigma^{a\bar{b}}} \left[ \pi H \log \left( \frac{s}{s_M^{ab}} \right) - R_1^{ab} \left( \frac{s}{s_M^{ab}} \right)^{-\eta_1} \tan \left( \frac{\eta_1 \pi}{2} \right) \pm R_2^{ab} \left( \frac{s}{s_M^{ab}} \right)^{-\eta_2} \cot \left( \frac{\eta_2 \pi}{2} \right) \right],$$

where upper signs in formulas are for particles and lower signs for antiparticles. The adjustable parameters are as follows:

$H = \pi \frac{(hc)^2}{M^2}$  in mb, where notation  $H^\S$  is after Heisenberg(1952,1975);

$P^{ab}$  in mb, are Pomeranchuk's(1958) constant terms;

$R_i^{ab}$  in mb are the intensities of the effective secondary Regge pole contributions named after Regge-Gribov(1961);

$s, s_M^{ab} = (m_a + m_b + M)^2$  are in  $\text{GeV}^2$ ;

$m_a, m_b, (m_{\gamma^*} = m_{\rho(770)})$  are the masses of initial state particles, and  $M$  – the mass parameter defining the rate of universal rise of the cross sections are all in  $\text{GeV}$ . Parameters  $M, \eta_1$  and  $\eta_2$  are universal for all collisions considered.

Exact factorization hypothesis was used for both  $H \log^2(\frac{s}{s_M^{ab}})$  and  $P^{ab}$  to extend the universal rise of the total hadronic cross sections to the  $\gamma(p, d) \rightarrow \text{hadrons}$  and  $\gamma\gamma \rightarrow \text{hadrons}$  collisions. This results in one additional adjustable parameter  $\delta$  with substitutions:

$$\pi H \log^2 \left( \frac{s}{s_M^{\gamma(p,d)}} \right) + P^{\gamma(p,d)} \Rightarrow \delta \left[ \pi(1, \lambda) H \log^2 \left( \frac{s}{s_M^{\gamma(p,d)}} \right) + P^{p(p,d)} \right];$$

$$\pi H \log^2 \left( \frac{s}{s_M^{\gamma\gamma}} \right) + P^{\gamma\gamma} \Rightarrow \delta^2 \left[ \pi H \log^2 \left( \frac{s}{s_M^{\gamma\gamma}} \right) + P^{pp} \right].$$

These parameterizations were used for simultaneous fit with **35** adjustable parameters to the data on collisions:

$$(\bar{p}, p) (p, n, d); \quad \Sigma^- p; \quad \pi^\mp (p, n, d); \quad K^\mp (p, n, d); \quad \gamma p; \quad \gamma \gamma; \quad \gamma d.$$

The results of the fits are presented in the following table and figures. In the table, two values of the fit quality indicator  $\text{FQ} = \chi^2/(\text{Npt} - 35)$  are reported in the last element of the first row, where **Npt** is the number of data points in corresponding sample.  $\text{FQ}_{\text{INT}}$  calculated with “internal” parameter values of machine precision (16 digits) and  $\text{FQ}_{\text{EXT}}$  calculated with rounded parameter values as displayed in the table in accordance with PDG rules (Section 5.3 of J. Beringer *et al.*, (Particle Data Group), Phys. Rev. **D86**, 010001 (2012)), recent metrology recommendations [18] and rules for safe uniform rounding of correlated data [19]. The uniformity of the quality of data description across different collisions is shown in the last two columns of the table; **npt** is the number of data points in a subsample and  $\chi^2/\text{npt}$  is the contribution of the subsample to the global  $\chi^2$  reduced to **npt**.

<sup>\S</sup>For collisions with deuteron target  $H_d = \lambda H$  where dimensionless parameter  $\lambda$  is introduced to test the universality of the Heisenberg rise for particle–nuclear and nuclear–nuclear collisions.

To construct the parameter scatter region we follow Section 39.4.2.2 of J. Beringer *et al.* (Particle Data Group), Phys. Rev. **D86**, 010001 (2012) and recent metrology JCGM 101:2008 recommendations and produce the direct Monte Carlo propagation of uncertainties from experimental data to the uncertainties of the best fit parameters. To do this we interpret the whole input data sample as statistically independent sample with total experimental uncertainty at each experimental data point being a Gaussian standard deviation. This technical assumption allows us to generate MC sampling of experimental data and to obtain at each MC trial new “biased” best fit parameters belonging to scatter region of the initial best fit parameters values. These biased best fit parameters constitute the MC-samples of cardinalities  $|MC_{cut}|$  at each  $\sqrt{s}$  cutoff and are the basis for construction of three 35-dimensional empirical parameter distributions.

In paper [19] the asymptotic bounds (Froissart, Martin) on the possible rise of the total collision cross sections in the form  $\log^2(s/s_0)$  was questioned in favour of possible faster rising forms. It was supported by the fits presented in [18] where the form  $\log^c(s/s_0)$  with adjustable  $c$  was tested on  $(\bar{p})pp$  data only and it was claimed that values of  $c$  obtained in number of different fits are statistically compatible with  $c \in [2.2, 2.4]$ .

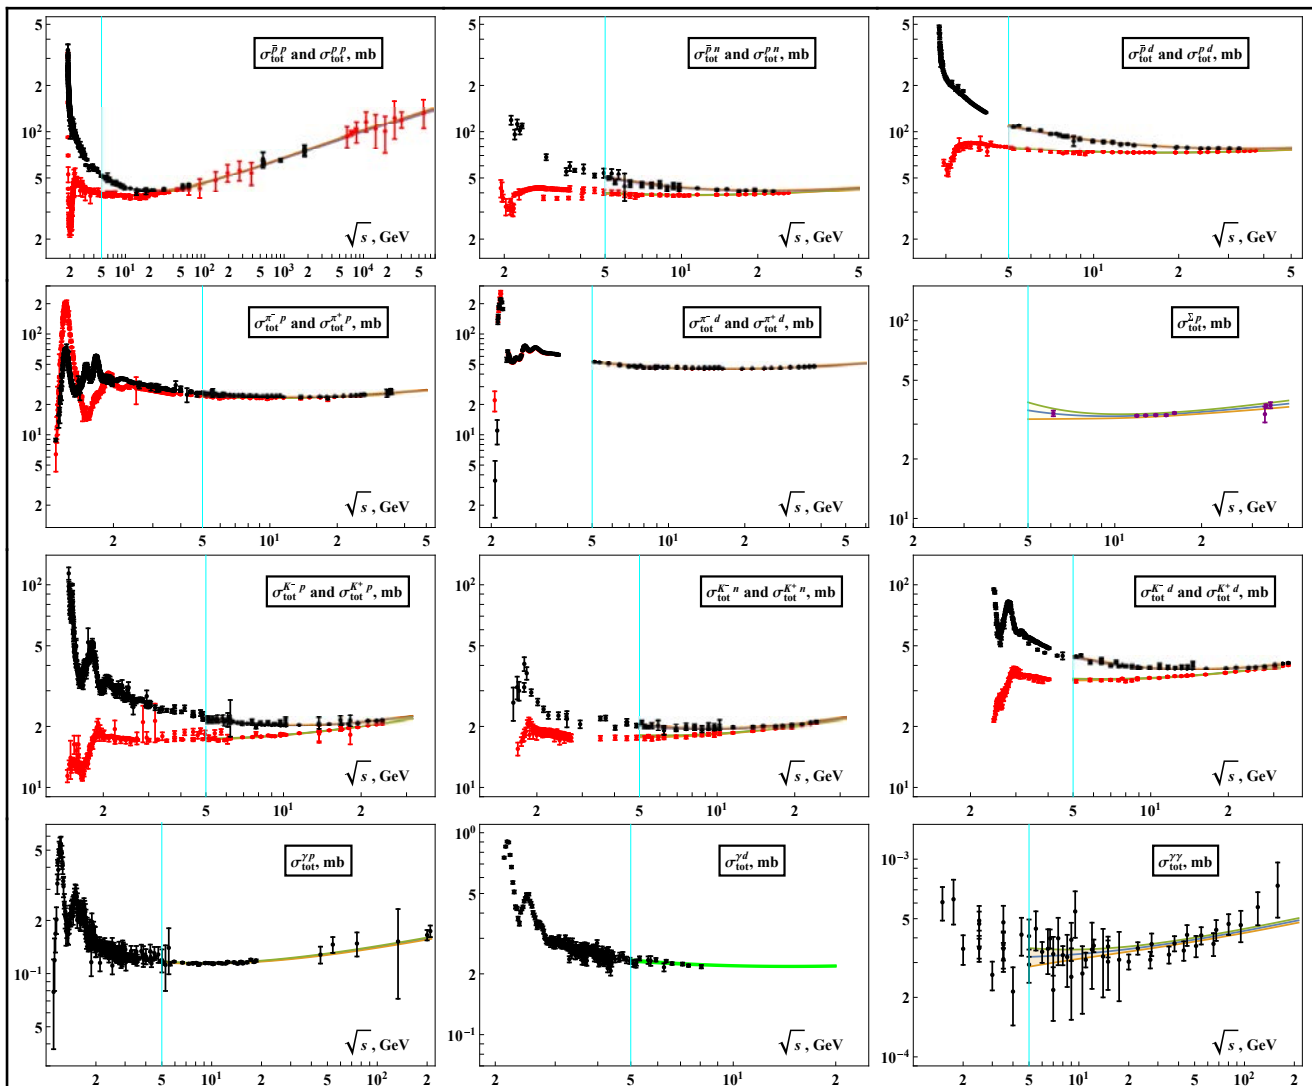

We have performed our global fit with adjustable  $c$  to the total cross sections and available  $p$ -parameters (as of August 2015) including TOTEM data point at 8 TeV [20]. For this fit we have 36 adjustable parameters. Fit was done with all data at  $\sqrt{s} \geq 5$  GeV with  $FQ = 0.87$ . We have obtained value  $c = 1.98 \pm 0.01$  (Hessian error) which is in two standard deviation lower than  $c = 2$  (exact) and possibly could be tentatively interpreted as an indication to the slower universal rising total cross sections as it was proposed 45 years ago by Cheng and Wu in the form  $\log^2\left(\frac{(s/s_0)^a}{\log^2(s/s_0)}\right)$  in their seminal paper [21]. However, to notice this difference much experimental, theoretical, and modelling work has to be done.

In conclusion, the Heisenberg prediction of the universal  $\log^2(s/s_M)$  form of asymptotic rise of the hadronic collision total cross sections is still actual and should be tested in all aspects at available colliders operating with  $(\bar{p}, p, nuclei)$  beams and in experiments with cosmic rays.

**Figure 51.8:** Summary of  $h^\mp p \rightarrow \text{anything}$ ,  $\gamma p \rightarrow \text{hadrons}$ ,  $\gamma \gamma \rightarrow \text{hadrons}$  total cross sections  $\sigma^{ab}$  in mb and  $\rho^{h^\mp p}$  the ratio of real to imaginary parts of the forward hadronic amplitudes. Also for qualitative comparison of the uniformity of data description by HPR<sub>1</sub>R<sub>2</sub>-model across the different collisions and observables. The uncertainties for the experimental data points include both the statistical and systematic errors. Curves, corresponding to fit above 5 GeV cut, are plotted with error bands calculated with parameter covariance matrix constructed on MC-propagated vectors from 95% quantile of the empirical distribution.

**Figure 51.9:** Summary of all total collision cross sections jointly fitted with available hadronic  $\rho$  parameter data. Corresponding computer-readable data files may be found at <http://pdg.lbl.gov/xsect/contents.html>

## High Energy Elastic $\bar{p}p$ and $pp$ Differential Cross Sections

(Updated June 2016, COMPAS group, IHEP, Protvino)

Using new results from FNAL-COLLIDER-D0 experiment in  $\bar{p}p$  elastic collisions at  $\sqrt{s} = 1.96$  TeV [1], CERN-LHC-TOTEM, CERN-LHC-ATLAS experiments in  $pp$  elastic collisions at  $\sqrt{s} = 7, 8$  TeV [2–3] and PAO experiment in proton-air collisions at 57 TeV [4] the amplitudes of the elastic  $\bar{p}p$  and  $pp$  collisions are investigated in a most broad region in  $\sqrt{s}$  and  $t$  via three observables  $d\sigma/dt(s, t)$ ,  $\sigma^{tot}(s)$ , and  $\rho(s)$ . The summary of the database for  $d\sigma/dt(s, t)$  is presented in Figure 51.10, where projection of the  $d\sigma/dt(\sqrt{s}, t)$  to the  $(d\sigma/dt, -t)$  plane orthogonal to the  $\sqrt{s}$  axis is displayed.

**Figure 51.10:** Cumulative plots of data on  $d\sigma/dt$  for  $\bar{p}p$  (blue) and  $pp$  (red) elastic collisions at  $\sqrt{s} \geq 2.99$  GeV. Number of data points  $N_{pt} = 6629$

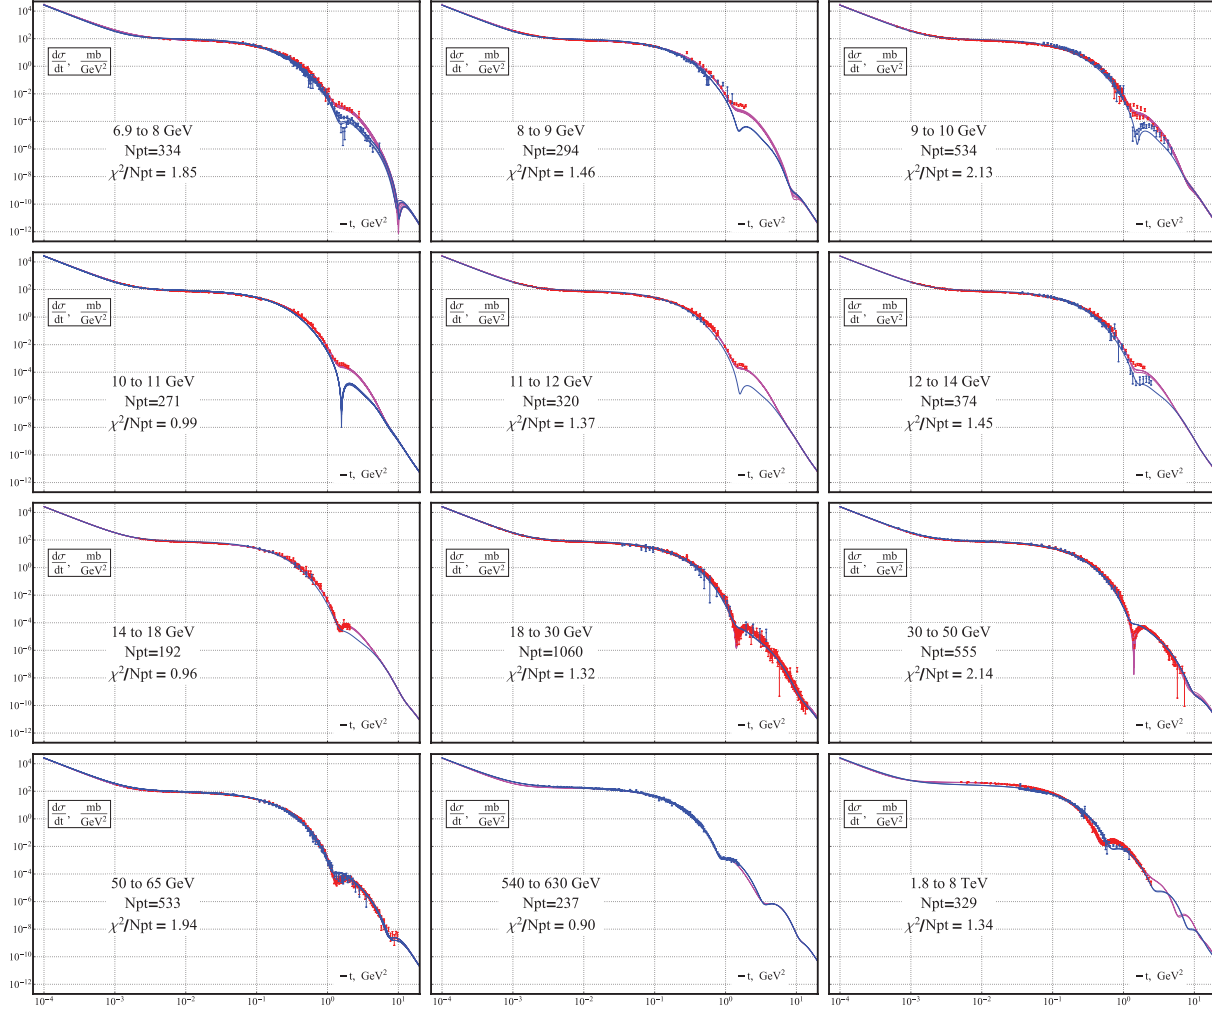

**Figure 51.11:** Cumulative plots of data on  $d\sigma/dt$  and model description for  $\bar{p}p$  (blue,blue) and  $pp$  (red,magenta) elastic collisions at  $\sqrt{s} \geq 6.9$  GeV.

All characteristic features of the  $d\sigma/dt(\sqrt{s}, t)$  behavior in  $-t$  and  $\sqrt{s}$  are clearly seen:

- The energy-dependent Coulomb-Nuclear Interference (CNI) effects at small  $-t$ ;
- Diffractive peaks with crossover effect at  $-t \approx 0.16$  GeV<sup>2</sup> for particle-antiparticle data at same energies;
- The first dip/shoulder moving to the left with growing  $\sqrt{s}$ . New data on  $d\sigma/dt$  in  $\bar{p}p$  and  $pp$  elastic collisions at highest accelerator energies have challenged all previous model predictions that gave “not so bad qualitative agreement” with previously available data on  $d\sigma/dt$ . There is a need to reveal a quantitative and statistically complete picture of the data description by at least one model with most ambitious claim on the “best known description”. There are several conceptually related papers with such a claims [5–7] but with different areas of applicability and without treatment of the CNI region. Description of  $d\sigma/dt$  by our model (a variation of AGNM [7] parameterization) at  $\sqrt{s} \geq 6.9$  GeV is displayed on Figure 51.11.

Historically the most complete compilations on  $d\sigma/dt$  data expressed in Mandelstam variables  $\sqrt{s}$  and  $t$  were published in Landolt-Börnstein volumes (now available in digital form) up to 1981 [8]. Updated (in high energy part) analogous CLM-compilation [9] (available in computer readable form) was compiled with help of HEPDATA and COMPAS databases and released in 2006. In our fits we use the CLM-compilation with minor corrections, filled detected gaps, and updated with new data published up to August 2015. We performed simultaneous fits to the sample of data on  $d\sigma/dt(s, t)$ ,  $\sigma^{tot}(s)$ , and  $\rho(s)$  in  $\bar{p}p$  and  $pp$  collisions at  $6.9 \text{ GeV} \leq \sqrt{s} \leq 8 \text{ TeV}$  and all available  $t$ . Overall fit quality  $FQ = \chi^2(N_{pt})/(5266 - 37) = 1.60$ , which is unreliable for our number of degrees of freedom. Removing contributions to  $\chi^2(d\sigma/dt)$  from  $N_{out} = 277$  points with  $\chi^2(point) > (2.4)^2$  (of  $2.4 \times \text{standard deviation (std)}$ ) – randomly scattered outliers) we have  $\chi^2(N_{rest})/(N_{rest}) = 1.02$ , where  $N_{rest} = N_{pt}(d\sigma/dt) - N_{out}$ . The uniformity level of the fit quality in different intervals of  $\sqrt{s}$  is shown on Figure 51.12.

**Figure 51.12:** All 12 energy intervals are non-overlapping and cover all data points. All panels have axis labelled as in Figure 51.11. All data sets corresponding to the same energy have model curve drawn. Some panels have no red or blue data points. In such a cases we add the curve as prediction of the model.

To reveal a more complete picture of phenomenological description of the elastic scattering data we originally selected the most flexible model (43 parameters) from [7] with most broad claimed area of applicability. It turns out that without partial removal of some data (made in [7]) the claimed solution cannot be used even as starting point for adjustments, most probably, because of over-rounded published parameter values, or misprints in parameter tables, or strong parameter correlations. Moreover, numerous fits with different starting points failed to find any locally stable solution with physically reasonable adjustable parameter values. We obtain a stable solution only with addition of data in CNI region and with slightly modified parameterization to reduce the number of adjustable parameters from 43 to 37. Our expressions for observables  $\sigma_{\pm}^{tot}(s)$ ,  $\rho_{\pm}(s)$ , and  $d\sigma_{\pm}/dt(s, t)$  with sign “+” for  $pp$  and sign “-” for  $\bar{p}p$  collisions are constructed (in notations of [7]) using corresponding scattering amplitudes: nuclear  $T_{\pm}(s, t)$  and Coulomb  $T_{\pm}^c(s, t)$  both in  $\text{mb} \cdot \text{GeV}^2$  as follows:

$$\sigma_{\pm}^{tot}(s) = \frac{\text{Im } T_{\pm}(s, 0)}{\sqrt{s(s - 4m_p^2)}}, \quad \rho_{\pm}(s) = \frac{\text{Re } T_{\pm}(s, 0)}{\text{Im } T_{\pm}(s, 0)}, \quad \frac{d\sigma_{\pm}}{dt}(s, t) = \frac{|T_{\pm}(s, t) + T_{\pm}^c(s, t)|^2}{16\pi(\hbar c)^2 s(s - 4m_p^2)},$$

where constants:  $m_p$  stands for proton mass, and  $(\hbar c)^2$  for  $\text{mb-to-GeV}^2$  conversion factor. Nuclear amplitudes  $T_{\pm}(s, t)$  are linearly combined crossing even  $F_+(\hat{s}, t)$  and crossing odd  $F_-(\hat{s}, t)$  functions.

$$T_{\pm}(s, t) = [F_+(\hat{s}, t) \pm F_-(\hat{s}, t)],$$

$$F_+(\hat{s}, t) = F_+^H(\hat{s}, t) + F_+^P(\hat{s}, t) + F_+^{PP}(\hat{s}, t) + F_+^R(\hat{s}, t) + F_+^{RP}(\hat{s}, t) + N_+(s, t),$$

$$F_-(\hat{s}, t) = F_-^{MO}(\hat{s}, t) + F_-^O(\hat{s}, t) + F_-^{OP}(\hat{s}, t) + F_-^R(\hat{s}, t) + F_-^{RP}(\hat{s}, t) + N_-(s, t),$$

$$F_+^H(\hat{s}, t) = i\hat{s} \left\{ \begin{array}{l} H_1 \frac{2J_1(K+\tilde{\tau})}{K+\tilde{\tau}} \cdot e^{b+1t} \ln^2 \tilde{s} + \\ H_2 J_0(K+\tilde{\tau}) \cdot e^{b+2t} \ln \tilde{s} + \\ H_3 [J_0(K+\tilde{\tau}) - K+\tilde{\tau} J_1(K+\tilde{\tau})] \cdot e^{b+3t} \end{array} \right\}, \quad F_-^{MO}(\hat{s}, t) = \hat{s} \left\{ \begin{array}{l} O_1 \frac{\sin(K-\tilde{\tau})}{K-\tilde{\tau}} e^{b-1t} \cdot \ln^2 \tilde{s} + \\ O_2 \cos(K-\tilde{\tau}) e^{b-2t} \cdot \ln \tilde{s} + \\ O_3 e^{b-3t} \end{array} \right\},$$

$$\begin{aligned}
F_+^P(\hat{s}, t) &= -C_P e^{b_P t} e^{-i\frac{\pi}{2}\alpha_P(t)} (\hat{s})^{\alpha_P(t)}, & F_-^O(\hat{s}, t) &= iC_O e^{b_O t} e^{-i\frac{\pi}{2}\alpha_O(t)} (\hat{s})^{\alpha_O(t)} (1 + A_O t), \\

\hat{s}(s, t) &\equiv \hat{s} = (-t + 2s - 4m_p^2)/(2s_0), & s_0 &= 1 \text{ GeV}^2; & \ln(\hat{s}) &= \ln(\hat{s}) - i\frac{\pi}{2}; & \tilde{\tau} &= \sqrt{-t/t_0} \ln \hat{s}, & t_0 &= 1 \text{ GeV}^2.
\end{aligned}$$

Coulomb amplitudes are taken with dipole electric nucleon form factor

$$T_{\pm}^C(s, t) = \mp e^{[\pm i\alpha\Phi_{\pm}^{NC}(s, t)]} \cdot 8\pi(\hbar c)^2 \alpha \cdot \frac{s}{t} \cdot \left(1 - \frac{t}{\Lambda^2}\right)^{-4},$$

where:  $\Phi_{\pm}^{CN}(s, t) = \ln \left[ -\frac{t}{2} \left( B_{\pm}(s) + \frac{8}{\Lambda^2} \right) \right] + \gamma - \frac{4t}{\Lambda^2} \ln \left( -\frac{4t}{\Lambda^2} \right) - \frac{2t}{\Lambda^2}$  is the CNI phase in the R. Cahn form [10];  $\Lambda = \sqrt{0.71} \text{ GeV}$ ;  $\alpha$  – fine structure constant;  $\gamma$  – Euler constant. Instead of the traditional definition of the  $d\sigma_{\pm}/dt(s, t)$  slope function  $B_{\pm}(s) = \left[ \frac{d}{dt} \ln \left( \frac{d\sigma_{\pm}}{dt}(s, t) \right) \right]_{t=0}$ , we set  $B_{\pm}(s) = \frac{\sigma_{\pm}(s)}{4\pi(\hbar c)^2}$  to simplify calculations and to get faster minimization procedures. The odderon contribution at  $t = 0$  can be switched off by replacing all exponents  $e^{b_i t}$  by  $e^{b_i t}(1 - e^{-t/t_{min}})$  in the above expressions for all odderon related terms, where  $t_{min}$  is the minimal  $|t|$ -value for which the data exist in the  $d\sigma/dt$  database. The resulting non-intersecting  $\sigma_{\mp}(\sqrt{s})$  and  $\rho_{mp}(\sqrt{s})$  curves can be obtained without significant degradation to the fit quality [11]. The effect of switching odderon contribution on and off at  $t = 0$  is shown in Figure 51.13.

**Figure 51.13:** Comparisons of  $d\sigma/dt$  at  $\sqrt{s} = 7 \text{ TeV}$ ,  $d\sigma^{tot}$ , and  $\rho(\sqrt{s})$  data with our two variants of AGNM [7] models. Right-hand panels have odderons switched off at  $t = 0$ . Curves for integrated elastic cross sections and inelastic cross sections were obtained from integration of the elastic differential cross sections. Data from experiments are not used in the fits.

The best fit parameter values and their standard deviations for both models are listed in the tables below. The table on the left (right) is with (without) oderon contribution. Estimates of the std were obtained by the MC-propagation of the assumed Gaussian distribution for each individual data point. Despite of poor MC statistics, the obtained “propagated” covariance matrix is in good conditions and gives reasonable std estimates. The quality of the fit to the  $\sigma_{\mp}^{tot}(s)$  and  $\rho_{\mp}(s)$  data is presented in Figure 51.13. Error bands were calculated by propagation of the parameter scatter region to the scatter region of these observables.

<b>FQ<sub>INT</sub> = 1.598; FQ<sub>EXT</sub> = 1.604; with oderon</b>				$A_{OP}$	GeV <sup>-2</sup>	<b>0.0</b>	(fix)	<b>FQ<sub>INT</sub> = 1.648; FQ<sub>EXT</sub> = 1.694; without oderon (at <math>t=0</math>)</b>				$A_{OP}$	GeV <sup>-2</sup>	<b>0.0</b>	(fix)
				$A_O$	GeV <sup>-2</sup>	-34.72	2.01					$A_O$	GeV <sup>-2</sup>	-34.72	0.52

FQ<sub>INT</sub> calculated with “internal” parameter values of machine precision (16 digits) and FQ<sub>EXT</sub> calculated with rounded parameter values as displayed in the table in accordance with PDG rules.

In summary, the solution obtained gives satisfactory picture of the used parametric description of the current database on observables related to elastic (anti)proton–proton scattering amplitudes, and reveals problems with lack of good data at the pre-asymptotic energies. Indeed:

1. Noisy data in dip/shoulder regions does not allow to tune parameters to give credible description of the depth of dips;
2. All frames in Figure 51.12 with  $\sqrt{s} \leq 12$  GeV apparently show that there is an urgent need in  $\bar{p}p$  data at CNI as well as at the first dip/shoulder “ $-t$ ” intervals;
3. Frame marked as “9 to 10 GeV” shows some contradictory data samples in  $pp$  collisions (48 “2.4-std outliers” out of 565 data points). There are no model independent resolution of these contradictions other than remeasurements with much higher statistics and more precise measuring systems. New accurate experimental data are highly desirable;
4. There is a sharp difference in descriptions of  $\rho$  parameter data from our global fits with HPR<sub>1</sub>R<sub>2</sub> model without oderon contribution (non-intersecting  $\rho_{\mp}$  curves) and our variant of AGNM model [7] with oderons (intersecting  $\rho_{\mp}$  curves). Further modelling is needed to remove this difference. Another issue to note is that the  $\rho_-(\sqrt{s})$  curve is consistently above the  $\rho_+(\sqrt{s})$  curve with a constant offset (see Figure 19 in [12]);
5. The 277 ( $> 2.4\sigma$ ) outliers contribute to about one third of the total  $\chi^2$  for the 5009 experimental data points. This issue is not fully understood but may indicate that the procedure of removing some “uncomfortable data” [11,13-15] should be examined more carefully.

## INTRODUCTION TO THE PARTICLE LISTINGS

Illustrative key . . . . .	601
Abbreviations . . . . .	602

# Illustrative Key to the Particle Listings

Name of particle. "Old" name used before 1986 renaming scheme also given if different. See the section "Naming Scheme for Hadrons" for details.

$a_0(1200)$

$I^G(J^{PC}) = 1^-(0^{++})$

Particle quantum numbers (where known).

OMITTED FROM SUMMARY TABLE  
Evidence not compelling, may be a kinematic effect.

Indicates particle omitted from Particle Physics Summary Table, implying particle's existence is not confirmed.

Quantity tabulated below.

## $a_0(1200)$ MASS

Top line gives our best value (and error) of quantity tabulated here, based on weighted average of measurements used. Could also be from fit, best limit, estimate, or other evaluation. See next page for details.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	CHG	COMMENT
<b>1206 ± 7 OUR AVERAGE</b>					
1210 ± 8 ± 9	3000	FENNER 87	MMS	-	3.5 $\pi^- p$
1198 ± 10		PIERCE 83	ASPK	+	2.1 $K^- p$
1216 ± 11 ± 9	1500	MERRILL 81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
1192 ± 16	200	LYNCH 81	HBC	±	2.7 $\pi^- p$

General comments on particle.

"Document id" for this result; full reference given below.

Measurement technique. (See abbreviations on next page.)

Footnote number linking measurement to text of footnote.

<sup>1</sup>Systematic error was added quadratically by us in our 1986 edition.

## $a_0(1200)$ WIDTH

Number of events above background.

Measured value used in averages, fits, limits, etc.

Error in measured value (often statistical only; followed by systematic if separately known; the two are combined in quadrature for averaging and fitting.)

Measured value *not used* in averages, fits, limits, etc. See the Introductory Text for explanations.

Arrow points to weighted average.

Shaded pattern extends  $\pm 1\sigma$  (scaled by "scale factor" S) from weighted average.

Value and error for each experiment.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	CHG	COMMENT
<b>41 ± 11 OUR AVERAGE</b>					Error includes scale factor of 1.8. See the ideogram below.
50 ± 8		PIERCE 83	ASPK	+	2.1 $K^- p$
70 + 30 - 20	200	LYNCH 81	HBC	±	2.7 $\pi^- p$
25 ± 5 ± 7		MERRILL 81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<60		FENNER 87	MMS	-	3.5 $\pi^- p$

Scale factor > 1 indicates possibly inconsistent data.

Reaction producing particle, or general comments.

"Change bar" indicates result added or changed since previous edition.

Charge(s) of particle(s) detected.

Ideogram to display possibly inconsistent data. Curve is sum of Gaussians, one for each experiment (area of Gaussian = 1/error; width of Gaussian =  $\pm$ error). See Introductory Text for discussion.

Contribution of experiment to  $\chi^2$  (if no entry present, experiment not used in calculating  $\chi^2$  or scale factor because of very large error).

## $a_0(1200)$ DECAY MODES

Partial decay mode (labeled by  $\Gamma_i$ ).

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
$\Gamma_1$ $3\pi$	(65.2 ± 1.3) %	S=1.7
$\Gamma_2$ $K\bar{K}$	(34.8 ± 1.3) %	S=1.7
$\Gamma_3$ $\eta\pi^\pm$	< 4.9 × 10 <sup>-4</sup>	CL=95%

Our best value for branching fraction as determined from data averaging, fitting, evaluating, limit selection, etc. This list is basically a compact summary of results in the Branching Ratio section below.

## $a_0(1200)$ BRANCHING RATIOS

Branching ratio.

Our best value (and error) of quantity tabulated, as determined from constrained fit (using *all significant* measured branching ratios for this particle).

Weighted average of measurements of this ratio only.

Footnote (referring to LYNCH 81).

## Indicator of Procedure Used to Obtain Our Result

OUR AVERAGE	From a weighted average of selected data.
OUR FIT	From a constrained or overdetermined multiparameter fit of selected data.
OUR EVALUATION	Not from a direct measurement, but evaluated from measurements of other quantities.
OUR ESTIMATE	Based on the observed range of the data. Not from a formal statistical procedure.
OUR LIMIT	For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

BES2	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES3	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BIS2	BIS-2 spectrometer at Serpukhov
BKEI	BENKEI spectrometer system at KEK Proton Synchrotron
BOLO	Bolometer, a cryogenic thermal detector
BONA	Bonanza nonmagnetic detector at DORIS
BORX	BOREXINO
BPWA	Barrelet-zero partial-wave analysis
CALO	Calorimeter
CAST	CAST experiment at CERN
CBAL	Crystal Ball detector at SLAC-SPEAR or DORIS
CBAR	Crystal Barrel detector at CERN-LEAR
CBOX	Crystal Box at LAMPF
CBTP	CBELSA/TAPS Collaboration
CC	Cloud chamber
CCFR	Columbia-Chicago-Fermilab-Rochester detector
CDEX	China Dark Matter Experiment
CDF	Collider detector at Fermilab
CDF2	CDF-II Collab.
CDHS	CDHS neutrino detector at CERN
CDM2	CDMS II, Cryogenic Dark Matter Search at Soudan Underground Lab.
CDMS	CDMS Collaboration
CELL	CELLO detector at DESY
CGNT	CoGeNT dark matter search experiment
CHER	Cherenkov detector
CHM2	CHARM-II neutrino detector (glass) at CERN
CHOZ	Nuclear Power Station near Chooz, France
CHRM	CHARM neutrino detector (marble) at CERN

CHRS	CHORUS Collaboration – CERN SPS
CIB	Cosmic Infrared Background
CIBS	CERN-IHEP boson spectrometer
CLAS	Jefferson CLAS Collab.
CLE2	CLEO II detector at CESR
CLE3	CLEO III detector at CESR
CLEC	CLEO-c detector at CESR
CLEO	Cornell magnetic detector at CESR
CMB	Cosmic Microwave Background
CMD	Cryogenic magnetic detector at VEPP-2M, Novosibirsk
CMD2	Cryogenic magnetic detector 2 at VEPP-2M, Novosibirsk
CMD3	Cryogenic magnetic detector 3 at VEPP-2000, Novosibirsk
CMS	CMS detector at CERN LHC
CNTR	Counters
COMB	Combined analysis of data from independent experiments.
COMP	COMPASS experiment at the CERN SPS
COSM	Cosmology and astrophysics
COSY	COSY-TOF Collaboration
COUP	COUPP (the Chicagoland Observatory for Underground Particle Physics) Collab.
CPLR	CPLEAR Collaboration
CRBT	Crystal Ball and TAPS detector at MAMI
CRES	CRESST cryogenic detector
CRYB	Crystal Ball at BNL
CRYM	Crystal Ball detector at Mainz Microtron MAMI
CSB2	Columbia U. - Stony Brook BGO calorimeter inserted in NaI array
CSME	COSME Collaboration
CUOR	CUORICINO experiment at Gran Sasso Laboratory.
CUSB	Columbia U. - Stony Brook segmented NaI detector at CESR
D0	D0 detector at Fermilab Tevatron Collider
DAMA	DAMA, dark matter detector at Gran Sasso National Lab.
DASP	DESY double-arm spectrometer
DAYA	Daya Bay Collaboration
DBC	Deuterium bubble chamber
DCHZ	Double Chooz Collaboration
DLCO	DELCO detector at SLAC-SPEAR or SLAC-PEP
DLPH	DELPHI detector at LEP
DM1	Magnetic detector no. 1 at Orsay DCI collider
DM2	Magnetic detector no. 2 at Orsay DCI collider
DMIC	DAMIC Dark Matter in CCD experiment at Fermilab
DMTP	Dark Matter Time Projection Chamber (DMTPC) directional detection experiment
DONU	DONUT Collab.
DPWA	Energy-dependent partial-wave analysis
DRFT	Directional dark matter detector at Boulby Underground Science Facility
DS50	DarkSide-50 Liquid Argon TPC at Gran Sasso National Laboratory
E621	Fermilab E621 detector
E653	Fermilab E653 detector
E665	Fermilab E665 detector
E687	Fermilab E687 detector
E691	Fermilab E691 detector
E705	Fermilab E705 Spectrometer-Calorimeter
E731	Fermilab E731 Spectrometer-Calorimeter
E756	Fermilab E756 detector
E760	Fermilab E760 detector
E761	Fermilab E761 detector
E771	Fermilab E771 detector
E773	Fermilab E773 Spectrometer-Calorimeter
E789	Fermilab E789 detector
E791	Fermilab E791 detector
E799	Fermilab E799 Spectrometer-Calorimeter
E835	Fermilab E835 detector
EDE2	EDELWEISS II dark matter search Collaboration
EDEL	EDELWEISS dark matter search Collaboration
EHS	Four-pi detector at CERN
ELEC	Electronic combination
EMC	European muon collaboration detector at CERN
EMUL	Emulsions
FAST	Fiber Active Scintillator Target detector at PSI
FBC	Freon bubble chamber
FENI	FENICE (at the ADONE collider of Frascati)
FIT	Fit to previously existing data
FLAT	Large Area Telescope onboard the Fermi Gamma-Ray Space Telescope (Fermi-LAT)
FMPS	Fermilab Multiparticle Spectrometer
FOCS	FNAL E831 FOCUS Collab.
FRAB	ADONE $B\bar{B}$ group detector

# Abbreviations Used in the Particle Listings

FRAG	ADONE $\gamma\gamma$ group detector	MAC	MAC detector at PEP/SLAC
FRAM	ADONE MEA group detector	MBOO	Fermilab MiniBooNE neutrino experiment
FREJ	FREJUS Collaboration – modular flash chamber detector (calorimeter)	MBR	Molecular beam resonance technique
GA24	Hodoscope Cherenkov $\gamma$ calorimeter (IHEP GAMS-2000) (CERN GAMS-4000)	MCRO	MACRO detector in Gran Sasso
GALX	GALLEX solar neutrino detector in the Gran Sasso Underground Lab.	MD1	Magnetic detector at VEPP-4, Novosibirsk
GAM2	IHEP hodoscope Cherenkov $\gamma$ calorimeter GAMS-2000	MDRP	Millikan drop measurement
GAM4	CERN hodoscope Cherenkov $\gamma$ calorimeter GAMS-4000	MEG	Muon to electron conversion detector at PSI
GAMS	IHEP hodoscope Cherenkov $\gamma$ calorimeter GAMS-4 $\pi$	MGIC	MAGIC Telescopes gamma-ray observatory.
GNO	Gallium Neutrino Observatory in the Gran Sasso Underground Lab.	MICA	Underground mica deposits
GOLI	CERN Goliath spectrometer	MINS	Fermilab MINOS experiment
GRAL	GRAAL Collaboration	MIRA	MIRABELLE Liquid-hydrogen bubble chamber
H1	H1 detector at DESY/HERA	MLEV	Magnetic levitation
HBC	Hydrogen bubble chamber	MLS	Modified Laurent Series
HDBC	Hydrogen and deuterium bubble chambers	MMS	Missing mass spectrometer
HDES	HADES Collaboration at GSI in Darmstadt	MPS	Multiparticle spectrometer at BNL
HDMO	Heidelberg-Moscow Experiment	MPS2	Multiparticle spectrometer upgrade at BNL
HDMS	Heidelberg Dark Matter Search Experiment	MPSF	Multiparticle spectrometer at Fermilab
HEBC	Helium bubble chamber	MPWA	Model-dependent partial-wave analysis
HEPT	Helium proportional tubes	MRK1	SLAC Mark-I detector
HERB	HERA-B detector at DESY/HERA	MRK2	SLAC Mark-II detector
HERM	HERMES detector at DESY/HERA	MRK3	SLAC Mark-III detector
HESS	High Energy Stereoscopic System gamma-ray instrument	MRKJ	Mark-J detector at DESY
HFS	Hyperfine structure	MRS	Magnetic resonance spectrometer
HLBC	Heavy-liquid bubble chamber	MUG2	MUON(g-2)
HOME	Homestake underground scintillation detector	MWPC	Multi-Wire Proportional Chamber
HPGE	High-purity Germanium detector	NA14	CERN NA14
HPW	Harvard-Pennsylvania-Wisconsin detector	NA31	CERN NA31 Spectrometer-Calorimeter
HRS	SLAC high-resolution spectrometer	NA32	CERN NA32 Spectrometer
HYBR	Hybrid: bubble chamber + electronics	NA48	CERN NA48 Collaboration
HYCP	HyperCP Collab. (FNAL E-871)	NA49	CERN NA49 Collaboration
IACT	Imaging Air Cherenkov Telescope	NA60	CERN NA60 Collaboration
ICAR	ICARUS experiment at Gran Sasso Laboratory.	NA62	CERN NA62 Experiment
ICCB	IceCube neutrino detector at South Pole	NAGE	NEWAGE, New generation WIMP-search experiment with advanced gaseous tracking
IGEX	IGEX Collab.	NAIA	NAIAD (NaI Advanced Detector) dark matter search experiment
IMB	Irvine-Michigan-Brookhaven underground Cherenkov detector	ND	NaI detector at VEPP-2M, Novosibirsk
IMB3	Irvine-Michigan-Brookhaven underground Cherenkov detector	NICE	Serpukhov nonmagnetic precision spectrometer
INDU	Magnetic induction	NMR	Nuclear magnetic resonance
IPWA	Energy-independent partial-wave analysis	NOMD	NOMAD Collaboration, CERN SPS
ISTR	IHEP ISTRA+ spectrometer-calorimeter	NTEV	NuTeV Collab. at Fermilab
JADE	JADE detector at DESY	nTRV	neutron Time-Reversal Violation
K246	KEK E246 detector with polarimeter	NUSX	Mont Blanc NUSEX underground detector
K2K	KEK to Super-Kamiokande	OBLX	OBELIX detector at LEAR
K391	KEK E391a detector	OLYA	Detector at VEPP-2M and VEPP-4, Novosibirsk
K470	KEK-E470 Stopping K detector	OMEG	CERN OMEGA spectrometer
KAM2	KAMIOKANDE-II underground Cherenkov detector	OPAL	OPAL detector at LEP
KAMI	KAMIOKANDE underground Cherenkov detector	OPER	OPERA experiment with emulsion tracking at Gran Sasso
KAR2	KARMEN2 calorimeter at the ISIS neutron spallation source at Rutherford	OSPK	Optical spark chamber
KARM	KARMEN calorimeter at the ISIS neutron spallation source at Rutherford	PANX	PandaX dual-phase liquid xenon dark matter experiment at Jin-Ping
KEDR	detector operating at VEPP-4M collider (Novosibirsk)	PIBE	The PIBETA detector at the Paul Scherrer Institute (PSI), Switzerland.
KIMS	Korea Invisible Mass Search experiment at YangYang, Korea	PICA	PICASSO dark matter search experiment
KLND	KamLand Collab. (Japan)	PICO	PICO bubble chamber experiment in SNOLAB underground laboratory
KLOE	KLOE detector at DAFNE (the Frascati e <sup>+</sup> e <sup>-</sup> collider Italy)	PIE3	$\pi$ E3 beam-line of Paul Scherrer Institute
KOLR	Kolar Gold Field underground detector	PLAS	Plastic detector
KTEV	KTeV Collaboration	PLUT	DESY PLUTO detector
L3	L3 detector at LEP	PMLA	PAMELA space spectrometer on Resurs-DK1 satellite
LASR	Laser	PRMX	The PRIMEX detector in Hall B at TJNAF
LASS	Large-angle superconducting solenoid spectrometer at SLAC	PWA	Partial-wave analysis
LATT	Lattice calculations	REDE	Resonance depolarization
LEBC	Little European bubble chamber at CERN	RENO	RENO Collaboration
LEGS	BNL LEGS Collab.	RICE	Radio Ice Cherenkov Experiment
LENA	Nonmagnetic lead-glass NaI detector at DORIS	RVUE	Review of previous data
LEP	From combination of all 4 LEP experiments: ALEPH, DELPHI, L3, OPAL	SAGE	US - Russian Gallium Experiment
LEPS	Low-Energy Pion Spectrometer at the Paul Scherrer Institute	SCDM	SuperCDMS experiment at Soudan Underground Lab.
LGW	Lead Glass Wall collaboration at SPEAR/SLAC	SELX	FNAL SELEX Collab.
LHC	Combined analysis of LHC experiments	SFM	CERN split-field magnet
LHCB	LHCb detector at CERN LHC	SHF	SLAC Hybrid Facility Photon Collaboration
LSD	Mont Blanc liquid scintillator detector	SIGM	Serpukhov CERN-IHEP magnetic spectrometer (SIGMA)
LSND	Liquid Scintillator Neutrino Detector	SILI	Silicon detector
LSW	Light Shining through a Wall	SIMP	SIMPLE, dark matter detector at Laboratori Nazionali del Sud
LUX	Large Underground Xenon experiment at SURF	SKAM	Super-Kamiokande Collab.
		SLAX	Solar Axion Experiment in Canfranc Underground Laboratory
		SLD	SLC Large Detector for e <sup>+</sup> e <sup>-</sup> colliding beams at SLAC
		SMPL	SIMPLE, Superheated Instrument for Massive Particle Experiments

## Abbreviations Used in the Particle Listings

SND	Novosibirisk Spherical neutral detector at VEPP-2M	BAPS	Bulletin of the American Physical Society
SNDR	SINDRUM spectrometer at PSI	BASUP	Bulletin of the Academy of Science, USSR (Physics)
SNO	SNO Collaboration (Sudbury Neutrino Observatory)	CJNP	Chinese Journal of Nuclear Physics
SOU2	Soudan 2 underground detector	CJP	Canadian Journal of Physics
SOUT	Soudan underground detector	CNPP	Comments on Nuclear and Particle Physics
SPEC	Spectrometer	CP	Chinese Physics
SPED	From maximum of speed plot or resonant amplitude	CPC	Chinese Physics C
SPHR	Bonn SAPHIR Collab.	CTP	Communications in Theoretical Physics
SPNX	SPHINX spectrometer at IHEP accelerator	CZJP	Czechoslovak Journal of Physics
SPRK	Spark chamber	DANS	Doklady Akademii nauk SSSR
SQID	SQUID device	EPJ	The European Physical Journal
STRC	Streamer chamber	EPL	Europhysics Letters
SVD2	SVD-2 experiment at IHEP, Protvino	FECAF	Fizika Elementarnykh Chastits i Atomnogo Yadra
T2K	T2K Collaboration	HADJ	Hadronic Journal
TASS	DESY TASSO detector	IJMP	International Journal of Modern Physics
TEVA	Combined analysis of CDF and DØ experiments	JAP	Journal of Applied Physics
TEXO	TEXONO Collab., ultra low energy Ge detector at Kuo-Sheng Laboratory	JCAP	Journal of Cosmology and Astroparticle Physics
THEO	Theoretical or heavily model-dependent result	JETP	English Translation of Soviet Physics ZETF
TNF	TNF-IHEP facility at 70 GeV IHEP accelerator	JETPL	English Translation of Soviet Physics ZETF Letters
TOF	Time-of-flight	JHEP	Journal of High Energy Physics
TOPZ	TOPAZ detector at KEK-TRISTAN	JINR	Joint Inst. for Nuclear Research
TPC	TPC detector at PEP/SLAC	JINRRC	JINR Rapid Communications
TPS	Tagged photon spectrometer at Fermilab	JP	Journal of Physics
TRAP	Penning trap	JPA	Journal of Physics, A
TWST	TWIST spectrometer at TRIUMF	JPB	Journal of Physics, B
UA1	UA1 detector at CERN	JPCRD	Journal of Physical and Chemical Reference Data
UA2	UA2 detector at CERN	JPCS	Journal of Physics: Conference Series
UA5	UA5 detector at CERN	JPG	Journal of Physics, G
UCNA	UCNA collaboration using polarized ultracold neutrons at LANSCE	JPSJ	Journal of the Physical Society of Japan
UKDM	UK Dark Matter Collab.	LNC	Lettère Nuovo Cimento
VES	Vertex Spectrometer Facility at 70 GeV IHEP accelerator	MNRAS	Monthly Notices of the Royal Astronomical Society
VLBI	Very Long Baseline Interferometer	MPL	Modern Physics Letters
VNS	VENUS detector at KEK-TRISTAN	NAST	New Astronomy
VRTS	Very Energetic Radiation Imaging Telescope Array System (VERITAS)	NAT	Nature
WA75	CERN WA75 experiment	NATP	Nature Physics
WA82	CERN WA82 experiment	NC	Nuovo Cimento
WA89	CERN WA89 experiment	NIM	Nuclear Instruments and Methods
WARP	Liquid argon detector for CDM searches at Gran Sasso	NJP	New Journal of Physics
WASA	WASA detector at CELSIUS, Uppsala and at COSY, Juelich	NP	Nuclear Physics
WIRE	Wire chamber	NPBPS	Nuclear Physics B Proceedings Supplement
X100	XENON100 dark matter search experiment at Gran Sasso National Laboratory	PAN	Physics of Atomic Nuclei (formerly SJNP)
XE10	XENON10 experiment at Gran Sasso National Laboratory	PD	Physics Doklady (Magazine)
XEBC	Xenon bubble chamber	PDAT	Physik Daten
XMAS	XMASS, liquid xenon scintillation detector at Kamioka Observatory	PL	Physics Letters
ZEP2	ZEPLIN-II dark matter detector	PN	Particles and Nuclei
ZEP3	ZEPLIN-III dark matter detector at Palmer Underground Lab.	PPCF	Plasma Physics and Controlled Fusion
ZEPL	ZEPLIN-I galactic dark matter detector	PPN	Physics of Particles and Nuclei (formerly SJNP)
ZEUS	ZEUS detector at DESY/HERA	PPNL	Physics of Particles and Nuclei Letters
		PPNP	Progress in Particles and Nuclear Physics
		PPSL	Proc. of the Physical Society of London
		PR	Physical Review
		PRAM	Pramana
		PRL	Physical Review Letters
		PRPL	Physics Reports (Physics Letters C)
		PRSE	Proc. of the Royal Society of Edinburgh
		PRSL	Proc. of the Royal Society of London, Section A
		PS	Physica Scripta
		PTEP	Progress of Theoretical and Experimental Physics
		PTP	Progress of Theoretical Physics
		PTPS	Progress of Theoretical Physics Supplement
		PTRSL	Phil. Trans. Royal Society of London
		RA	Radiochimica Acta
		RMP	Reviews of Modern Physics
		RNC	La Rivista del Nuovo Cimento
		RPP	Reports on Progress in Physics
		RRP	Revue Roumaine de Physique
		SCI	Science
		SJNP	Soviet Journal of Nuclear Physics
		SJPN	Soviet Journal of Particles and Nuclei
		SPD	Soviet Physics Doklady (Magazine)
		SPU	Soviet Physics - Uspekhi
		UFN	Usp. Fiz. Nauk – Russian version of SPU
		YAF	Yadernaya Fizika
		ZETF	Zhurnal Eksperimental'noi i Teoreticheskoi Fiziki
		ZETFP	Zhurnal Eksperimental'noi i Teoreticheskoi Fiziki, Pis'ma v Redakts

### Conferences

Conferences are generally referred to by the location at which they were held (e.g., HAMBURG, TORONTO, CORNELL, BRIGHTON, etc.).

### Journals

AA	Astronomy and Astrophysics
ADVP	Advances in Physics
AFIS	Anales de Fisica
AJP	American Journal of Physics
AL	Astronomy Letters
ANP	Annals of Physics
ANPL	Annals of Physics (Leipzig)
ANYAS	Annals of the New York Academy of Sciences
AP	Atomic Physics
APAH	Acta Physica Academiae Scientiarum Hungaricae
APJ	Astrophysical Journal
APJS	Astrophysical Journal Suppl.
APP	Acta Physica Polonica
APS	Acta Physica Slovaca
ARNPS	Annual Review of Nuclear and Particle Science
ARNS	Annual Review of Nuclear Science
ASP	Astroparticle Physics
AST	American Statistician

## GAUGE AND HIGGS BOSONS

 $\gamma$  (photon)

$$I(J^{PC}) = 0.1(1^{--})$$

 $\gamma$  MASS

Results prior to 2008 are critiqued in GOLDHABER 10. All experimental results published prior to 2005 are summarized in detail by TU 05.

The following conversions are useful:  $1 \text{ eV} = 1.783 \times 10^{-33} \text{ g} = 1.957 \times 10^{-6} m_e$ ;  $\lambda_C = (1.973 \times 10^{-7} \text{ m}) \times (1 \text{ eV}/m_\gamma)$ .

- 1 RYUTOV 07 extends the method of RYUTOV 97 to the radius of Pluto's orbit.
- 2 EGOROV 14 studies chromatic dispersion of lensed quasar positions ("gravitational rainbows") that could be produced by any of several mechanisms, among them via photon mass. Limit not competitive but obtained on cosmological distance scales.
- 3 ACCIOLY 10 limits come from possible alterations of anomalous magnetic moment of electron and gravitational deflection of electromagnetic radiation. Reported limits are not "claimed" by the authors and in any case are not competitive.
- 4 When trying to measure  $m$  one must distinguish between measurements performed on large and small scales. If the photon acquires mass by the Higgs mechanism, the large-scale behavior of the photon might be effectively Maxwellian. If, on the other hand, one postulates the Proca regime for all scales, the very existence of the galactic field implies  $m < 10^{-26} \text{ eV}$ , as correctly calculated by YAMAGUCHI 59 and CHIBISOV 76.
- 5 TU 06 continues the work of LUO 03, with extended LAKES 98 method, reporting the improved limit  $\mu^2 A = (0.7 \pm 1.7) \times 10^{-13} \text{ T/m}$  if  $A = 0.2 \mu\text{G}$  out to  $4 \times 10^{22} \text{ m}$ . Reported result  $\mu = (0.9 \pm 1.5) \times 10^{-52} \text{ g}$  reduces to the frequentist mass limit  $1.2 \times 10^{-19} \text{ eV}$  (FELDMAN 98).
- 6 FULLEKRUG 04 adopted KROLL 71A method with newer and better Schumann resonance data. Result questionable because assumed frequency shift with photon mass is assumed to be linear. It is quadratic according to theorem by GOLDHABER 71B, KROLL 71, and PARK 71.
- 7 LUO 03 extends LAKES 98 technique to set a limit on  $\mu^2 A$ , where  $\mu^{-1}$  is the Compton wavelength  $\lambda_C$  of the massive photon and  $A$  is the ambient vector potential. The important departure is that the apparatus rotates, removing sensitivity to the direction of  $A$ . They take  $A = 10^{12} \text{ Tm}$ , due to "cluster level fields." But see comment of GOLDHABER 03 and reply by LUO 03b.
- 8 LAKES 98 reports limits on torque on a toroid Cavendish balance, obtaining a limit on  $\mu^2 A < 2 \times 10^{-9} \text{ Tm}^2/\text{m}^2$  via the Maxwell-Proca equations, where  $\mu^{-1}$  is the characteristic length associated with the photon mass and  $A$  is the ambient vector potential in the Lorentz gauge. Assuming  $A \approx 1 \times 10^{12} \text{ Tm}$  due to cluster fields he obtains  $\mu^{-1} > 2 \times 10^{10} \text{ m}$ , corresponding to  $\mu < 1 \times 10^{-17} \text{ eV}$ . A more conservative limit, using  $A \approx (1 \mu\text{G}) \times (600 \text{ pc})$  based on the galactic field, is  $\mu^{-1} > 1 \times 10^9 \text{ m}$  or  $\mu < 2 \times 10^{-16} \text{ eV}$ .
- 9 RYUTOV 97 uses a magnetohydrodynamics argument concerning survival of the Sun's field to the radius of the Earth's orbit. "To reconcile observations to theory, one has to reduce [the photon mass] by approximately an order of magnitude compared with" per DAVIS 75. "Secure limit, best by this method" (per GOLDHABER 10).
- 10 FISCHBACH 94 analysis is based on terrestrial magnetic fields; approach analogous to DAVIS 75. Similar result based on a much smaller planet probably follows from more precise  $B$  field mapping. "Secure limit, best by this method" (per GOLDHABER 10).
- 11 CHERNIKOV 92, motivated by possibility that photon exhibits mass only below some unknown critical temperature, searches for departure from Ampere's Law at  $1.24 \text{ K}$ . See also RYAN 85.
- 12 RYAN 85, motivated by possibility that photon exhibits mass only below some unknown critical temperature, sets mass limit at  $< (1.5 \pm 1.4) \times 10^{-42} \text{ g}$  based on Coulomb's Law departure limit at  $1.36 \text{ K}$ . We report the result as frequentist 90% CL (FELDMAN 98).
- 13 CHIBISOV 76 depends in critical way on assumptions such as applicability of virial theorem. Some of the arguments given only in unpublished references.

- 14 DAVIS 75 analysis of Pioneer-10 data on Jupiter's magnetic field. "Secure limit, best by this method" (per GOLDHABER 10).
- 15 FRANKEN 71 method is of dubious validity (KROLL 71A, JACKSON 99, GOLDHABER 10, and references therein).
- 16 KROLL 71A used low frequency Schumann resonances in cavity between the conducting earth and resistive ionosphere, overcoming objections to resonant-cavity methods (JACKSON 99, GOLDHABER 10, and references therein). "Secure limit, best by this method" (per GOLDHABER 10).
- 17 WILLIAMS 71 is landmark test of Coulomb's law. "Secure limit, best by this method" (per GOLDHABER 10).

 $\gamma$  CHARGE

OKUN 06 has argued that schemes in which all photons are charged are inconsistent. He says that if a neutral photon is also admitted to avoid this problem, then other problems emerge, such as those connected with the emission and absorption of charged photons by charged particles. He concludes that in the absence of a self-consistent phenomenological basis, interpretation of experimental data is at best difficult.

- 1 ALTSCHUL 07b looks for Aharonov-Bohm phase shift in addition to geometric phase shift in radio interference fringes (VSOP mission).
- 2 CAPRINI 05 uses isotropy of the cosmic microwave background to place stringent limits on possible charge asymmetry of the Universe. Charge limits are set on the photon, neutrino, and dark matter particles. Valid if charge asymmetries produced by different particles are not anticorrelated.
- 3 KOBYCHEV 05 considers a variety of observable effects of photon charge for extragalactic compact radio sources. Best limits if source observed through a foreground cluster of galaxies.
- 4 SEMERTZIDIS 03 reports the first laboratory limit on the photon charge in the last 30 years. Straightforward improvements in the apparatus could attain a sensitivity of  $10^{-20} \text{ e}$ .
- 5 SIVARAM 95 requires that CMB photon charge density not overwhelm gravity. Result scales as  $\Omega_M h^2$ .
- 6 RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to dispersion by free electrons in the interstellar medium has the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.
- 7 See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAFFELT 94 note.

### graviton MASS

In 1970 van Dam amd Veltman (VANDAM 70) showed that "... there is a discrete difference between the theory with zero-mass and a theory with finite mass, no matter how small as compared to all external momenta. ... We may conclude that the graviton has rigorously zero mass." However, see GOLDHABER 10 and references therein. It has been of interest to set experimental limits, whether or not a finite mass can exist. In most (but not all) cases limits have been set on the distance without evidence for a Yukawa cutoff. *h*<sub>0</sub> is the Hubble constant in units of 100 km s<sup>-1</sup> Mpc<sup>-1</sup>.

The following conversions are useful: 1 eV = 1.783 × 10<sup>-33</sup> g = 1.957 × 10<sup>-6</sup> *m<sub>e</sub>*;  $\lambda_C = (1.973 \times 10^{-7} \text{ m}) \times (1 \text{ eV} / m_g)$ .

- 1 CHOUDHURY 04 concludes from a study of weak-lensing data that masses heavier than about the inverse of 100 Mpc seem to be ruled out if the gravitation field has the Yukawa form.
- 2 ABBOTT 16 assumes modified dispersion relation for gravitational waves.
- 3 BRITO 13 explore massive graviton (spin-2) fluctuations around rotating black holes.
- 4 BASKARAN 08 consider fluctuations in pulsar timing due to photon interactions ("surfing") with background gravitational waves.
- 5 GRUZINOV 05 uses the DGP model (DVALI 00) showing that non-perturbative effects restore continuity with Einstein's equations as the graviton mass approaches 0, then bases his limit on Solar System observations.
- 6 GERSHTEIN 04 use non-Einstein field relativistic theory of gravity (RTG), with a massive graviton, to obtain the 95% CL mass limit implied by the value of  $\Omega_{tot} = 1.02 \pm 0.02$  current at the time of publication.
- 7 DVALI 03 suggest scale of horizon distance via DGP model (DVALI 00). For a horizon distance of  $3 \times 10^{26}$  m (about age of Universe/*c*; GOLDHABER 10) this graviton mass limit is implied.
- 8 FINN 02 analyze the orbital decay rates of PSR B1913+16 and PSR B1534+12 with a possible graviton mass as a parameter. The combined frequentist mass limit is at 90%CL.
- 9 As of 2014, limits on d*P*/d*t* are now about 0.1% (see T. Damour, "Experimental tests of gravitational theory," in this Review).
- 10 DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity *c* (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor [spin 2]-biscalar theories.

## THE MASS AND WIDTH OF THE W BOSON

Revised September 2013 by M.W. Gr newald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

Precision determination of the W-mass is of great importance in testing the internal consistency of the Standard Model. From the time of its discovery in 1983, the W-boson has been studied and its mass determined in p  and e<sup>+</sup>e<sup>-</sup> interactions; it is currently studied in pp interactions at the LHC. The W mass and width definition used here corresponds to a Breit-Wigner with mass-dependent width.

Production of on-shell W bosons at hadron colliders is tagged by the high *p<sub>T</sub>* charged lepton from its decay. Owing to the unknown parton-parton effective energy and missing energy in the longitudinal direction, the collider experiments reconstruct the transverse mass of the W, and derive the W mass from comparing the transverse mass distribution with Monte Carlo predictions as a function of *M<sub>W</sub>*. These analyses use the electron and muon decay modes of the W boson.

Figure 1: Measurements of the W-boson mass by the LEP and Tevatron experiments.

In the  $e^+e^-$  collider (LEP) a precise knowledge of the beam energy enables one to determine the  $e^+e^- \rightarrow W^+W^-$  cross section as a function of center of mass energy, as well as to reconstruct the W mass precisely from its decay products, even if one of them decays leptonically. Close to the  $W^+W^-$  threshold (161 GeV), the dependence of the W-pair production cross section on  $M_W$  is large, and this was used to determine  $M_W$ . At higher energies (172 to 209 GeV) this dependence is much weaker and W-bosons were directly reconstructed and the mass determined as the invariant mass of its decay products, improving the resolution with a kinematic fit.

**Figure 2:** Measurements of the W-boson width by the LEP and Tevatron experiments.

In order to compute the LEP average W mass, each experiment provided its measured W mass for the  $q\bar{q}q\bar{q}$  and  $q\bar{q}\ell\bar{\nu}_\ell$ ,  $\ell = e, \mu, \tau$  channels at each center-of-mass energy, along with a detailed break-up of errors: statistical, uncorrelated, partially correlated and fully correlated systematics [1]. These have been combined to obtain a LEP W mass of  $M_W = 80.376 \pm 0.033$  GeV. Errors due to uncertainties in LEP energy (9 MeV), and possible effect of color reconnection (CR) and Bose-Einstein correlations (BEC) between quarks from different W's (8 MeV) are included. The mass difference between  $q\bar{q}q\bar{q}$  and  $q\bar{q}\ell\bar{\nu}_\ell$  final states (due to possible CR and BEC effects) is  $-12 \pm 45$  MeV. In a similar manner, the width results obtained at LEP have been combined, resulting in  $\Gamma_W = 2.195 \pm 0.083$  GeV [1].

The two Tevatron experiments have also identified common systematic errors. Between the two experiments, uncertainties due to the parton distribution functions, radiative corrections, and choice of mass (width) in the width (mass) measurements are treated as correlated. An average W width

of  $\Gamma_W = 2.046 \pm 0.049$  GeV [2] is obtained. Errors of 20 MeV and 7 MeV accounting for PDF and radiative correction uncertainties in this width combination dominate the correlated uncertainties. At the 2012 winter conferences, the CDF and D0 experiments have presented new results for the mass of the W boson based on  $2-4 \text{ fb}^{-1}$  of Run-II data,  $80.387 \pm 0.019$  GeV [3] and  $80.375 \pm 0.023$  GeV [4], respectively. The W-mass determination from the Tevatron experiments has thus become very precise. Combining all Tevatron results from Run-I and Run-II using an improved treatment of correlations, a new average of  $80.387 \pm 0.016$  GeV is obtained [5], with common uncertainties of 10 MeV (PDF) and 4 MeV (radiative corrections).

The LEP and Tevatron results on mass and width, which are based on all results available, are compared in Fig. 1 and Fig. 2. Good agreement between the results is observed. Combining these results, assuming no common systematic uncertainties between the LEP and the Tevatron measurements, yields an average W mass of  $M_W = 80.385 \pm 0.015$  GeV and a W width of  $\Gamma_W = 2.085 \pm 0.042$  GeV.

The Standard Model prediction from the electroweak fit, using Z-pole data plus  $m_{\text{top}}$  measurement, gives a W-boson mass of  $M_W = 80.363 \pm 0.020$  GeV and a W-boson width of  $\Gamma_W = 2.091 \pm 0.002$  GeV [1].

## W MASS

The W-mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average W mass based on published results is  $80.376 \pm 0.033$  GeV [SCHAE13a]. The combined Tevatron data yields an average W mass of  $80.387 \pm 0.016$  GeV [AALTONEN13a].

OUR FIT uses these average LEP and Tevatron mass values and combines them assuming no correlations.

<sup>1</sup> ABAZOV 14N is a combination of ABAZOV 09AB and ABAZOV 12F, also giving more details on the analysis.

<sup>2</sup> AALTONEN 12E select 470k  $W \rightarrow e\nu$  decays and 625k  $W \rightarrow \mu\nu$  decays in 2.2 fb<sup>-1</sup> of Run-II data. The mass is determined using the transverse mass, transverse lepton momentum and transverse missing energy distributions, accounting for correlations. This result supersedes AALTONEN 07F. AALTONEN 14D gives more details on the procedures followed by the authors.

<sup>3</sup> ABDALLAH 08A use direct reconstruction of the kinematics of  $W^+ W^- \rightarrow q\bar{q}\ell\nu$  and  $W^+ W^- \rightarrow q\bar{q}q\bar{q}$  events for energies 172 GeV and above. The  $W$  mass was also extracted from the dependence of the  $WW$  cross section close to the production threshold and combined appropriately to obtain the final result. The systematic error includes  $\pm 0.025 \text{ GeV}$  due to final state interactions and  $\pm 0.009 \text{ GeV}$  due to LEP energy uncertainty.

<sup>4</sup> ABBIENDI 06 use direct reconstruction of the kinematics of  $W^+ W^- \rightarrow q\bar{q}\ell\nu_\ell$  and  $W^+ W^- \rightarrow q\bar{q}q\bar{q}$  events. The result quoted here is obtained combining this mass value with the results using  $W^+ W^- \rightarrow \ell\nu_\ell\ell'\nu_{\ell'}$  events in the energy range 183–207 GeV (ABBIENDI 03c) and the dependence of the  $WW$  production cross-section on  $m_{WW}$  at threshold. The systematic error includes  $\pm 0.009 \text{ GeV}$  due to the uncertainty on the LEP beam energy.

<sup>5</sup> ACHARD 06 use direct reconstruction of the kinematics of  $W^+ W^- \rightarrow q\bar{q}\ell\nu_\ell$  and  $W^+ W^- \rightarrow q\bar{q}q\bar{q}$  events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this mass value with the results obtained from a direct  $W$  mass reconstruction at 172 and 183 GeV and with those from the dependence of the  $WW$  production cross-section on  $m_{WW}$  at 161 and 172 GeV (ACCIARRI 99).

<sup>6</sup> SCHAEEL 06 use direct reconstruction of the kinematics of  $W^+ W^- \rightarrow q\bar{q}\ell\nu_\ell$  and  $W^+ W^- \rightarrow q\bar{q}q\bar{q}$  events in the C.M. energy range 183–209 GeV. The result quoted here is obtained combining this mass value with those obtained from the dependence of the  $W$  pair production cross-section on  $m_{WW}$  at 161 and 172 GeV (BARATE 97 and BARATE 97s respectively). The systematic error includes  $\pm 0.009 \text{ GeV}$  due to possible effects of final state interactions in the  $q\bar{q}q\bar{q}$  channel and  $\pm 0.009 \text{ GeV}$  due to the uncertainty on the LEP beam energy.

<sup>7</sup> ABAZOV 02D improve the measurement of the  $W$ -boson mass including  $W \rightarrow e\nu_e$  events in which the electron is close to a boundary of a central electromagnetic calorimeter module. Properly combining the results obtained by fitting  $m_T(W)$ ,  $p_T(e)$ , and  $p_T(\nu)$ , this sample provides a mass value of 80.574 ± 0.405 GeV. The value reported here is a combination of this measurement with all previous D0  $W$ -boson mass measurements.

<sup>8</sup> AFFOLDER 01E fit the transverse mass spectrum of 30115  $W \rightarrow e\nu_e$  events ( $M_{WW} = 80.473 \pm 0.065 \pm 0.092 \text{ GeV}$ ) and of 14740  $W \rightarrow \mu\nu_\mu$  events ( $M_{WW} = 80.465 \pm 0.100 \pm 0.103 \text{ GeV}$ ) obtained in the run IB (1994–95). Combining the electron and muon results, accounting for correlated uncertainties, yields  $M_{WW} = 80.470 \pm 0.089 \text{ GeV}$ . They combine this value with their measurement of ABE 95P reported in run IA (1992–93) to obtain the quoted value.

<sup>9</sup> ABAZOV 12F select 1677k  $W \rightarrow e\nu$  decays in 4.3 fb<sup>-1</sup> of Run-II data. The mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations.

<sup>10</sup> ABAZOV 09AB study the transverse mass, transverse electron momentum, and transverse missing energy in a sample of 0.5 million  $W \rightarrow e\nu$  decays selected in Run-II data. The quoted result combines all three methods, accounting for correlations.

<sup>11</sup> AALTONEN 07F obtain high purity  $W \rightarrow e\nu_e$  and  $W \rightarrow \mu\nu_\mu$  candidate samples totaling 63,964 and 51,128 events respectively. The  $W$  mass value quoted above is derived by simultaneously fitting the transverse mass and the lepton, and neutrino  $p_T$  distributions.

<sup>12</sup> AKTAS 06 fit the  $Q^2$  dependence ( $300 < Q^2 < 30,000 \text{ GeV}^2$ ) of the charged-current differential cross section with a propagator mass. The first error is experimental and the second corresponds to uncertainties due to input parameters and model assumptions.

<sup>13</sup> CHEKANOV 02c fit the  $Q^2$  dependence ( $200 < Q^2 < 60,000 \text{ GeV}^2$ ) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

<sup>14</sup> BREITWEG 00D fit the  $Q^2$  dependence ( $200 < Q^2 < 22500 \text{ GeV}^2$ ) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

<sup>15</sup> ALITTI 92B result has two contributions to the systematic error ( $\pm 0.83$ ); one ( $\pm 0.81$ ) cancels in  $m_{WW}/m_Z$  and one ( $\pm 0.17$ ) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP  $m_Z$  value, because we perform our own combined fit.

<sup>16</sup> There are two contributions to the systematic error ( $\pm 0.84$ ): one ( $\pm 0.81$ ) which cancels in  $m_{WW}/m_Z$  and one ( $\pm 0.21$ ) which is non-cancelling. These were added in quadrature.

<sup>17</sup> ABE 89i systematic error dominated by the uncertainty in the absolute energy scale.

<sup>18</sup> ALBAJAR 89 result is from a total sample of 299  $W \rightarrow e\nu$  events.

<sup>19</sup> ALBAJAR 89 result is from a total sample of 67  $W \rightarrow \mu\nu$  events.

<sup>20</sup> ALBAJAR 89 result is from  $W \rightarrow \tau\nu$  events.

## W WIDTH

The  $W$  width listed here corresponds to the width parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average  $W$  width based on published results is  $2.195 \pm 0.083 \text{ GeV}$  [SCHAEEL 13A]. The combined Tevatron data yields an average  $W$  width of  $2.046 \pm 0.049 \text{ GeV}$  [FERMILAB-TM-2460-E].

OUR FIT uses these average LEP and Tevatron width values and combines them assuming no correlations.

- <sup>7</sup> ABZOV 02e obtain this result fitting the high-end tail (90–200 GeV) of the transverse-mass spectrum in semileptonic  $W \rightarrow e\nu_e$  decays.
- <sup>8</sup> AFFOLDER 00m fit the high transverse mass (100–200 GeV)  $W \rightarrow e\nu_e$  and  $W \rightarrow \mu\nu_\mu$  events to obtain  $\Gamma(W) = 2.04 \pm 0.11(\text{stat}) \pm 0.09(\text{syst})$  GeV. This is combined with the earlier CDF measurement (ABE 95c) to obtain the quoted result.
- <sup>9</sup> ABBOTT 00b measure  $R = 10.43 \pm 0.27$  for the  $W \rightarrow e\nu_e$  decay channel. They use the SM theoretical predictions for  $\sigma(W)/\sigma(Z)$  and  $\Gamma(W \rightarrow e\nu_e)$  and the world average for  $B(Z \rightarrow ee)$ . The value quoted here is obtained combining this result ( $2.169 \pm 0.070$  GeV) with that of ABBOTT 99h.
- <sup>10</sup> ABE 95w measured  $R = 10.90 \pm 0.32 \pm 0.29$ . They use  $m_W = 80.23 \pm 0.18$  GeV,  $\sigma(W)/\sigma(Z) = 3.35 \pm 0.03$ ,  $\Gamma(W \rightarrow e\nu) = 225.9 \pm 0.9$  MeV,  $\Gamma(Z \rightarrow e^+e^-) = 83.98 \pm 0.18$  MeV, and  $\Gamma(Z) = 2.4969 \pm 0.0038$  GeV.
- <sup>11</sup> ALITTI 92 measured  $R = 10.4 \pm 0.7 \pm 0.3$ . The values of  $\sigma(Z)$  and  $\sigma(W)$  come from  $O(\alpha_s^2)$  calculations using  $m_W = 80.14 \pm 0.27$  GeV, and  $m_Z = 91.175 \pm 0.021$  GeV along with the corresponding value of  $\sin^2\theta_W = 0.2274$ . They use  $\sigma(W)/\sigma(Z) = 3.26 \pm 0.07 \pm 0.05$  and  $\Gamma(Z) = 2.487 \pm 0.010$  GeV.
- <sup>12</sup> ALBAJAR 91 measured  $R = 9.5 \pm 1.1$  (stat. + syst.).  $\sigma(W)/\sigma(Z)$  is calculated in QCD at the parton level using  $m_W = 80.18 \pm 0.28$  GeV and  $m_Z = 91.172 \pm 0.031$  GeV along with  $\sin^2\theta_W = 0.2322 \pm 0.0014$ . They use  $\sigma(W)/\sigma(Z) = 3.23 \pm 0.05$  and  $\Gamma(Z) = 2.498 \pm 0.020$  GeV. This measurement is obtained combining both the electron and muon channels.

### W<sup>+</sup> DECAY MODES

$W^-$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $\ell^+ \nu$	[a] $(10.86 \pm 0.09) \%$	
$\Gamma_2$ $e^+ \nu$	$(10.71 \pm 0.16) \%$	
$\Gamma_3$ $\mu^+ \nu$	$(10.63 \pm 0.15) \%$	
$\Gamma_4$ $\tau^+ \nu$	$(11.38 \pm 0.21) \%$	
$\Gamma_5$ hadrons	$(67.41 \pm 0.27) \%$	
$\Gamma_6$ $\pi^+ \gamma$	$< 7$	$\times 10^{-6}$ 95%
$\Gamma_7$ $D_s^+ \gamma$	$< 1.3$	$\times 10^{-3}$ 95%
$\Gamma_8$ $cX$	$(33.3 \pm 2.6) \%$	
$\Gamma_9$ $c\bar{s}$	$(31 \pm 13 \pm 11) \%$	
$\Gamma_{10}$ invisible	[b] $(1.4 \pm 2.9) \%$	

[a]  $\ell$  indicates each type of lepton ( $e$ ,  $\mu$ , and  $\tau$ ), not sum over them.

[b] This represents the width for the decay of the  $W$  boson into a charged particle with momentum below detectability,  $p < 200$  MeV.

### W PARTIAL WIDTHS

$\Gamma(\text{invisible})$	$\Gamma_{10}$
This represents the width for the decay of the $W$ boson into a charged particle with momentum below detectability, $p < 200$ MeV.	
VALUE (MeV)	DOCUMENT ID TECN COMMENT
$30^{+52}_{-48} \pm 33$	<sup>1</sup> BARATE 99i ALEP $E_{cm}^{ee} = 161+172+183$ GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •	
	<sup>2</sup> BARATE 99l ALEP $E_{cm}^{ee} = 161+172+183$ GeV

- <sup>1</sup> BARATE 99i measure this quantity using the dependence of the total cross section  $\sigma_{WW}$  upon a change in the total width. The fit is performed to the  $WW$  measured cross sections at 161, 172, and 183 GeV. This partial width is  $< 139$  MeV at 95%CL.
- <sup>2</sup> BARATE 99l use  $W$ -pair production to search for effectively invisible  $W$  decays, tagging with the decay of the other  $W$  boson to Standard Model particles. The partial width for effectively invisible decay is  $< 27$  MeV at 95%CL.

### W BRANCHING RATIOS

Overall fits are performed to determine the branching ratios of the  $W$  boson. Averages on  $W \rightarrow e\nu$ ,  $W \rightarrow \mu\nu$ , and  $W \rightarrow \tau\nu$ , and their correlations are obtained by combining results from the four LEP experiments properly taking into account the common systematic uncertainties and their correlations [SCHAE 13a]. A first fit determines the three individual leptonic branching ratios  $B(W \rightarrow e\nu)$ ,  $B(W \rightarrow \mu\nu)$ , and  $B(W \rightarrow \tau\nu)$ . This fit has a  $\chi^2 = 6.3$  for 9 degrees of freedom. The correlation coefficients between the branching fractions are 0.14 ( $e-\mu$ ),  $-0.20$  ( $e-\tau$ ),  $-0.12$  ( $\mu-\tau$ ). A second fit assumes lepton universality and determines the leptonic branching ratio  $\text{br } W \rightarrow \ell\nu$  and the hadronic branching ratio is derived as  $B(W \rightarrow \text{hadrons}) = 1-3 \text{ br } W \rightarrow \ell$ . This fit has a  $\chi^2 = 15.4$  for 11 degrees of freedom.

## W

<sup>1</sup> ABBOTT 00D measure  $\sigma_{W \times B}(W \rightarrow \tau \nu_\tau) = 2.22 \pm 0.09 \pm 0.10 \pm 0.10$  nb. Using the ABBOTT 00B result  $\sigma_{W \times B}(W \rightarrow e \nu_e) = 2.31 \pm 0.01 \pm 0.05 \pm 0.10$  nb, they quote the ratio of the couplings from which we derive this measurement.

<sup>2</sup> ABE 92E use two procedures for selecting  $W \rightarrow \tau \nu_\tau$  events. The missing  $E_T$  trigger leads to  $132 \pm 14 \pm 8$  events and the  $\tau$  trigger to  $47 \pm 9 \pm 4$  events. Proper statistical and systematic correlations are taken into account to arrive at  $\sigma_B(W \rightarrow \tau \nu) = 2.05 \pm 0.27$  nb. Combined with ABE 91C result on  $\sigma_B(W \rightarrow e \nu)$ , ABE 92E quote a ratio of the couplings from which we derive this measurement.

<sup>3</sup> This measurement is derived by us from the ratio of the couplings of ALITTI 92F.

<sup>2</sup> ABREU,P 00F measure  $\langle N_{\text{charged}} \rangle = 39.12 \pm 0.33 \pm 0.36$  and  $38.11 \pm 0.57 \pm 0.44$  in the fully hadronic final states at 189 and 183 GeV respectively, and  $\langle N_{\text{charged}} \rangle = 19.49 \pm 0.31 \pm 0.27$  and  $19.78 \pm 0.49 \pm 0.43$  in the semileptonic final states. The value quoted is a weighted average without assuming any correlations.

<sup>3</sup> ABBIENDI 99N use the final states  $W^+ W^- \rightarrow q\bar{q} \ell \bar{\nu}_\ell$  to derive this value.

<sup>4</sup> ABREU 98C combine results from both the fully hadronic as well semileptonic  $WW$  final states after demonstrating that the  $W$  decay charged multiplicity is independent of the topology within errors.

### TRIPLE GAUGE COUPLINGS (TGC'S) EXTRACTION OF TRIPLE GAUGE COUPLINGS (TGCS)

Revised August 2015 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Fourteen independent couplings, seven each for  $ZWW$  and  $\gamma WW$ , completely describe the  $VWW$  vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and U(1) gauge invariance. Of each of the seven TGCs, three conserve  $C$  and  $P$  individually, three violate  $CP$ , and one violates  $C$  and  $P$  individually while conserving  $CP$ . Assumption of  $C$  and  $P$  conservation and electromagnetic gauge invariance reduces the number of independent  $VWW$  couplings to five: one common set [1,2] is  $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$ , where  $\kappa_\gamma = \kappa_Z = g_1^Z = 1$  and  $\lambda_\gamma = \lambda_Z = 0$  in the Standard Model at tree level. The parameters  $\kappa_Z$  and  $\lambda_Z$  are related to the other three due to constraints of gauge invariance as follows:  $\kappa_Z = g_1^Z - (\kappa_\gamma - 1) \tan^2 \theta_W$  and  $\lambda_Z = \lambda_\gamma$ , where  $\theta_W$  is the weak mixing angle. The  $W$  magnetic dipole moment,  $\mu_W$ , and the  $W$  electric quadrupole moment,  $q_W$ , are expressed as  $\mu_W = e(1 + \kappa_\gamma + \lambda_\gamma)/2M_W$  and  $q_W = -e(\kappa_\gamma - \lambda_\gamma)/M_W^2$ .

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. At LEP2, the  $VWW$  coupling arises in  $W$ -pair production via  $s$ -channel exchange, or in single  $W$  production via the radiation of a virtual photon off the incident  $e^+$  or  $e^-$ . At the Tevatron and the LHC, hard-photon bremsstrahlung off a produced  $W$  or  $Z$  signals the presence of a triple-gauge vertex. In order to extract the value of one TGC, the others are generally kept fixed to their SM values. While most analyses use the above gauge constraints in the extraction of TGCs, one analysis of  $W$ -pair events also determines the real and imaginary parts of all 14 couplings using unconstrained single-parameter fits [3]. The results are consistent. Some experiments have determined limits on the couplings under various non-LEP scenarios and assuming different values of the form factor  $\Lambda$ , where the coupling parameters are scaled by  $1/(1 + s/\Lambda^2)^2$ . For practical reasons it is not possible to quote all such determinations in the listings. For that the individual papers may be consulted.

<sup>1</sup> ABDALLAH 10 use data on the final states  $e^+e^- \rightarrow jj\ell\nu, jjjj, jjX, \ell X$ , at center-of-mass energies between 189–209 GeV at LEP2, where  $j = \text{jet}$ ,  $\ell = \text{lepton}$ , and  $X$  represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

<sup>2</sup> SCHAE1 05A study single-photon, single- $W$ , and  $WW$ -pair production from 183 to 209 GeV. The result quoted here is derived from the  $WW$ -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>3</sup> ABBIENDI 04D combine results from  $W^+W^-$  in all decay channels. Only  $CP$ -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is  $0.923 < g_1^Z < 1.054$ .

<sup>4</sup> ACHARD 04D study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained from the  $WW$ -pair production sample including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>5</sup> AAD 14Y determine the electroweak  $Z$ -dijet cross section in 8 TeV  $pp$  collisions.  $Z \rightarrow ee$  and  $Z \rightarrow \mu\mu$  decays are selected with the di-lepton  $p_T > 20$  GeV and mass in the 81–101 GeV range. Minimum two jets are required with  $p_T > 55$  and 45 GeV and no additional jets with  $p_T > 25$  GeV in the rapidity interval between them. The normalized  $p_T$  balance between the  $Z$  and the two jets is required to be  $< 0.15$ . This leads to a selection of 900 events with dijet mass  $> 1$  TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit  $0.5 < g_1^Z < 1.26$  for a form factor value  $\Lambda = \infty$ .

<sup>6</sup> AAD 13AL study  $WW$  production in  $pp$  collisions and select 1325  $WW$  candidates in decay modes with electrons or muons with an expected background of  $369 \pm 61$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda = \text{infinity}$ , a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $0.961 < g_1^Z < 1.052$ . Supersedes AAD 12AC.

<sup>7</sup> CHATRCHYAN 13BF determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of  $247 \pm 34$ . The  $p_T$  distribution of the leading lepton is fitted to obtain 95% C.L. limits of  $0.905 \leq g_1^Z \leq 1.095$ .

<sup>8</sup> AAD 12CD study  $WZ$  production in  $pp$  collisions and select 317  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $68.0 \pm 10.0$  events. The resulting 95% C.L. range is:  $0.943 < g_1^Z < 1.093$ . Supersedes AAD 12V.

<sup>9</sup> AALTONEN 12AC study  $WZ$  production in  $p\bar{p}$  collisions and select 63  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $7.9 \pm 1.0$  events. Based on the cross section and shape of the  $Z$  transverse momentum spectrum, the following 95% C.L. range is reported:  $0.92 < g_1^Z < 1.20$  for a form factor of  $\Lambda = 2$  TeV.

<sup>10</sup> ABAZOV 12AG combine new results with already published results on  $W\gamma, WW$  and  $WZ$  production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of  $\Lambda = 2$  TeV is  $g_1^Z = 1.022^{+0.032}_{-0.030}$ .

<sup>11</sup> ABAZOV 11 study the  $p\bar{p} \rightarrow 3\nu$  process arising in  $WZ$  production. They observe 34  $WZ$  candidates with an estimated background of 6 events. An analysis of the  $p_T$  spectrum of the  $Z$  boson leads to a 95% C.L. limit of  $0.944 < g_1^Z < 1.154$ , for a form factor  $\Lambda = 2$  TeV.

<sup>12</sup> AALTONEN 10K study  $p\bar{p} \rightarrow W^+W^-$  with  $W \rightarrow e/\mu\nu$ . The  $p_T$  of the leading (second) lepton is required to be  $> 20$  (10) GeV. The final number of events selected is 654 of which  $320 \pm 47$  are estimated to be background. The 95% C.L. interval is  $0.76 < g_1^Z < 1.34$  for  $\Lambda = 1.5$  TeV and  $0.78 < g_1^Z < 1.30$  for  $\Lambda = 2$  TeV.

<sup>13</sup> ABAZOV 09AD study the  $p\bar{p} \rightarrow \ell\nu 2\text{jet}$  process arising in  $WW$  and  $WZ$  production. They select 12,473 (14,392) events in the electron (muon) channel with an expected

di-boson signal of  $436$  (527) events. The results on the anomalous couplings are derived from an analysis of the  $p_T$  spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is  $0.88 < g_1^Z < 1.20$ .

<sup>14</sup> ABAZOV 09AJ study the  $p\bar{p} \rightarrow 2\ell 2\nu$  process arising in  $WW$  production. They select 100 events with an expected  $WW$  signal of 65 events. An analysis of the  $p_T$  spectrum of the two charged leptons leads to 95% C.L. limits of  $0.86 < g_1^Z < 1.3$ , for a form factor  $\Lambda = 2$  TeV.

<sup>15</sup> ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in  $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$ , where  $\ell = e$  or  $\mu$ . Values of all other couplings are fixed to their standard model values.

<sup>16</sup> ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and  $p_T(Z)$  distribution in  $WZ$  production with both the  $W$  and the  $Z$  decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $0.86 < g_1^Z < 1.35$ .

<sup>17</sup> ABAZOV 05S study  $p\bar{p} \rightarrow WZ$  production with a subsequent trilepton decay to  $\ell\nu\ell'\bar{\ell}'$  ( $\ell$  and  $\ell' = e$  or  $\mu$ ). Three events (estimated background  $0.71 \pm 0.08$  events) with  $WZ$  decay characteristics are observed from which they derive limits on the anomalous  $WWZ$  couplings. The 95% CL limit for a form factor scale  $\Lambda = 1.5$  TeV is  $0.51 < g_1^Z < 1.66$ , fixing  $\lambda_Z$  and  $\kappa_Z$  to their Standard Model values.

<sup>18</sup> ABREU 01I combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$  and  $W\nu_e$  final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is  $0.84 < g_1^Z < 1.13$ .

<sup>19</sup> ABBOTT 99I perform a simultaneous fit to the  $W\gamma, WW \rightarrow \text{dilepton}, WW/WZ \rightarrow e\nu jj, WW/WZ \rightarrow \mu\nu jj$ , and  $WZ \rightarrow \text{trilepton}$  data samples. For  $\Lambda = 2.0$  TeV, the 95%CL limits are  $0.63 < g_1^Z < 1.57$ , fixing  $\lambda_Z$  and  $\kappa_Z$  to their Standard Model values, and assuming Standard Model values for the  $WW\gamma$  couplings.

**$\kappa_\gamma$**

<sup>1</sup> ABDALLAH 10 use data on the final states  $e^+e^- \rightarrow jj\ell\nu, jjjj, jjX, \ell X$ , at center-of-mass energies between 189–209 GeV at LEP2, where  $j = \text{jet}$ ,  $\ell = \text{lepton}$ , and  $X$  represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

<sup>2</sup> SCHAE1 05A study single-photon, single- $W$ , and  $WW$ -pair production from 183 to 209 GeV. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>3</sup> ABBIENDI 04D combine results from  $W^+W^-$  in all decay channels. Only  $CP$ -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is  $0.73 < \kappa_\gamma < 1.07$ .

<sup>4</sup> ACHARD 04D study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>5</sup> CHATRCHYAN 14AB measure  $W\gamma$  production cross section for  $p_T^\gamma > 15$  GeV and  $R(\ell\gamma) > 0.7$ , which is the separation between the  $\gamma$  and the final state charged lepton ( $e$  or  $\mu$ ) in the azimuthal angle-pseudorapidity ( $\phi - \eta$ ) plane. After background subtraction the number of  $e\nu\gamma$  and  $\mu\nu\gamma$  events is determined to be  $3200 \pm 325$  and  $4970 \pm 543$  respectively, compatible with expectations from the SM. This leads to a 95% CL limit of  $0.62 < \kappa_\gamma < 1.29$ , assuming other parameters have SM values.

# Gauge & Higgs Boson Particle Listings

## W

- <sup>6</sup> AAD 13AN study  $W\gamma$  production in  $pp$  collisions. In events with no additional jet, 4449 (6578)  $W$  decays to electron (muon) are selected, with an expected background of  $1662 \pm 262$  (2538  $\pm$  362) events. Analysing the photon  $p_T$  spectrum above 100 GeV yields a 95% C.L. limit of  $0.59 < \kappa_\gamma < 1.46$ . Supersedes AAD 12Bx.
- <sup>7</sup> CHATRCHYAN 13BF determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247  $\pm$  34. The  $p_T$  distribution of the leading lepton is fitted to obtain 95% C.L. limits of  $0.79 \leq \kappa_\gamma \leq 1.22$ .
- <sup>8</sup> ABAZOV 12AG combine new results with already published results on  $W\gamma$ ,  $WW$  and  $WZ$  production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of  $\Lambda = 2$  TeV is  $\kappa_\gamma = 1.048^{+0.106}_{-0.105}$ .
- <sup>9</sup> ABAZOV 11AC study  $W\gamma$  production in  $p\bar{p}$  collisions at 1.96 TeV, with the  $W$  decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon  $E_T$  spectrum above 15 GeV yields at 95% C.L. the result:  $0.6 < \kappa_\gamma < 1.4$  for a formfactor  $\Lambda = 2$  TeV.
- <sup>10</sup> CHATRCHYAN 11M study  $W\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using 36 pb<sup>-1</sup>  $pp$  data with the  $W$  decaying to electron and muon. The total cross section is measured for photon transverse energy  $E_T^\gamma > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell, \gamma) > 0.7$ . The number of candidate (background) events is 452 (228  $\pm$  21) for the electron channel and 520 (277  $\pm$  25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of  $-0.11 < \kappa_\gamma < 0.204$ .
- <sup>11</sup> AALTONEN 10K study  $p\bar{p} \rightarrow W^+W^-$  with  $W \rightarrow e/\mu\nu$ . The  $p_T$  of the leading (second) lepton is required to be  $> 20$  (10) GeV. The final number of events selected is 654 of which 320  $\pm$  47 are estimated to be background. The 95% C.L. interval is  $0.37 < \kappa_\gamma < 1.72$  for  $\Lambda = 1.5$  TeV and  $0.43 < \kappa_\gamma < 1.65$  for  $\Lambda = 2$  TeV.
- <sup>12</sup> AARON 09B study single- $W$  production in  $ep$  collisions at 0.3 TeV C.M. energy. They select 53  $W \rightarrow e/\mu$  events with a standard model expectation of  $54.1 \pm 7.4$  events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of  $-3.7 < \kappa_\gamma < -1.5$  or  $0.3 < \kappa_\gamma < 1.5$ , where the ambiguity is due to the quadratic dependence of the cross section to the coupling parameter.
- <sup>13</sup> ABAZOV 09AD study the  $p\bar{p} \rightarrow \ell\nu 2\text{jet}$  process arising in  $WW$  and  $WZ$  production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the  $p_T$  spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is  $0.56 < \kappa_\gamma < 1.55$ .
- <sup>14</sup> ABAZOV 09AJ study the  $p\bar{p} \rightarrow 2\ell 2\nu$  process arising in  $WW$  production. They select 100 events with an expected  $WW$  signal of 65 events. An analysis of the  $p_T$  spectrum of the two charged leptons leads to 95% C.L. limits of  $0.46 < \kappa_\gamma < 1.83$ , for a form factor  $\Lambda = 2$  TeV.
- <sup>15</sup> ABAZOV 08R use  $0.7 \text{ fb}^{-1}$   $p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV to select 263  $W\gamma + X$  events, of which 187 constitute signal, with the  $W$  decaying into an electron or a muon, which is required to be well separated from a photon with  $E_T > 9$  GeV. A likelihood fit to the photon  $E_T$  spectrum yields a 95% CL limit  $0.49 < \kappa_\gamma < 1.51$  with other couplings fixed to their Standard Model values.
- <sup>16</sup> ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in  $e^+e^- \rightarrow W^+W^- \rightarrow (q\bar{q})(\ell\nu)$ , where  $\ell = e$  or  $\mu$ . Values of all other couplings are fixed to their standard model values.
- <sup>17</sup> AALTONEN 07L set limits on anomalous TGCs using the  $p_T(W)$  distribution in  $WW$  and  $WZ$  production with the  $W$  decaying to an electron or muon and the  $Z$  to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are  $0.54 < \kappa_\gamma < 1.39$  for a form factor scale  $\Lambda = 1.5$  TeV.
- <sup>18</sup> ABAZOV 06H study  $p\bar{p} \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+\nu_e e^-\bar{\nu}_e$ ,  $WW \rightarrow e^+\nu_e \mu^+\bar{\nu}_\mu$  or  $WW \rightarrow \mu^+\nu_\mu \mu^-\bar{\nu}_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 1$  TeV is  $-0.05 < \kappa_\gamma < 2.29$ , fixing  $\lambda_\gamma = 0$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $0.68 < \kappa < 1.45$ .
- <sup>19</sup> ABAZOV 05J perform a likelihood fit to the photon  $E_T$  spectrum of  $W\gamma + X$  events, where the  $W$  decays to an electron or muon which is required to be well separated from the photon. For  $\Lambda = 2.0$  TeV the 95% CL limits are  $0.12 < \kappa_\gamma < 1.96$ . In the fit  $\lambda_\gamma$  is kept fixed to its Standard Model value.
- <sup>20</sup> ABREU 01I combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$ ,  $W\nu_e$ , and  $\nu\bar{\nu}\gamma$  final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is  $0.87 < \kappa_\gamma < 1.68$ .
- <sup>21</sup> BREITWEG 00 search for  $W$  production in events with large hadronic  $p_T$ . For  $p_T > 20$  GeV, the upper limit on the cross section gives the 95%CL limit  $-3.7 < \kappa_\gamma < 2.5$  (for  $\lambda_\gamma = 0$ ).
- <sup>22</sup> ABBOTT 99I perform a simultaneous fit to the  $W\gamma$ ,  $WW \rightarrow$  dilepton,  $WW/WZ \rightarrow e\nu jj$ ,  $WW/WZ \rightarrow \mu\nu jj$ , and  $WZ \rightarrow$  trilepton data samples. For  $\Lambda = 2.0$  TeV, the 95%CL limits are  $0.75 < \kappa_\gamma < 1.39$ .

$\lambda_\gamma$

OUR FIT below is taken from [SCHAE 13A].

- <sup>20</sup> ABBOTT 99I D0  $E_{\text{cm}}^{p\bar{p}} = 1.8$  TeV
- <sup>1</sup> ABDALLAH 10 use data on the final states  $e^+e^- \rightarrow jj\ell\nu, jjjj, jjX, \ell X$ , at center-of-mass energies between 189–209 GeV at LEP2, where  $j = \text{jet}$ ,  $\ell = \text{lepton}$ , and  $X$  represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.
- <sup>2</sup> SCHAE 05A study single-photon, single- $W$ , and  $WW$ -pair production from 183 to 209 GeV. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- <sup>3</sup> ABBIENDI 04D combine results from  $W^+W^-$  in all decay channels. Only  $CP$ -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is  $-0.13 < \kappa_\gamma < 0.01$ .
- <sup>4</sup> ACHARD 04D study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- <sup>5</sup> CHATRCHYAN 14AB measure  $W\gamma$  production cross section for  $p_T^\gamma > 15$  GeV and  $R(\ell\gamma) > 0.7$ , which is the separation between the  $\gamma$  and the final state charged lepton ( $e$  or  $\mu$ ) in the azimuthal angle-pseudorapidity ( $\phi - \eta$ ) plane. After background subtraction the number of  $e\nu\gamma$  and  $\mu\nu\gamma$  events is determined to be  $3200 \pm 325$  and  $4970 \pm 543$  respectively, compatible with expectations from the SM. This leads to a 95% CL limit of  $-0.050 < \kappa_\gamma < 0.037$ , assuming all other parameters have SM values.
- <sup>6</sup> AAD 13AN study  $W\gamma$  production in  $pp$  collisions. In events with no additional jet, 4449 (6578)  $W$  decays to electron (muon) are selected, with an expected background of  $1662 \pm 262$  (2538  $\pm$  362) events. Analysing the photon  $p_T$  spectrum above 100 GeV yields a 95% C.L. limit of  $-0.065 < \kappa_\gamma < 0.061$ . Supersedes AAD 12Bx.
- <sup>7</sup> ABAZOV 12AG combine new results with already published results on  $W\gamma$ ,  $WW$  and  $WZ$  production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of  $\Lambda = 2$  TeV is  $\lambda_\gamma = 0.007^{+0.021}_{-0.022}$ .
- <sup>8</sup> ABAZOV 11AC study  $W\gamma$  production in  $p\bar{p}$  collisions at 1.96 TeV, with the  $W$  decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon  $E_T$  spectrum above 15 GeV yields at 95% C.L. the result:  $-0.08 < \lambda_\gamma < 0.07$  for a formfactor  $\Lambda = 2$  TeV.
- <sup>9</sup> CHATRCHYAN 11M study  $W\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using 36 pb<sup>-1</sup>  $pp$  data with the  $W$  decaying to electron and muon. The total cross section is measured for photon transverse energy  $E_T^\gamma > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell, \gamma) > 0.7$ . The number of candidate (background) events is 452 (228  $\pm$  21) for the electron channel and 520 (277  $\pm$  25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of  $-0.18 < \lambda_\gamma < 0.17$ .
- <sup>10</sup> AARON 09B study single- $W$  production in  $ep$  collisions at 0.3 TeV C.M. energy. They select 53  $W \rightarrow e/\mu$  events with a standard model expectation of  $54.1 \pm 7.4$  events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of  $-2.5 < \lambda_\gamma < 2.5$ .
- <sup>11</sup> ABAZOV 09AD study the  $p\bar{p} \rightarrow \ell\nu 2\text{jet}$  process arising in  $WW$  and  $WZ$  production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the  $p_T$  spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is  $-0.10 < \lambda_\gamma < 0.11$ .
- <sup>12</sup> ABAZOV 09AJ study the  $p\bar{p} \rightarrow 2\ell 2\nu$  process arising in  $WW$  production. They select 100 events with an expected  $WW$  signal of 65 events. An analysis of the  $p_T$  spectrum of the two charged leptons leads to 95% C.L. limits of  $-0.14 < \lambda_\gamma < 0.18$ , for a form factor  $\Lambda = 2$  TeV.
- <sup>13</sup> ABAZOV 08R use  $0.7 \text{ fb}^{-1}$   $p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV to select 263  $W\gamma + X$  events, of which 187 constitute signal, with the  $W$  decaying into an electron or a muon, which is required to be well separated from a photon with  $E_T > 9$  GeV. A likelihood fit to the photon  $E_T$  spectrum yields a 95% CL limit  $-0.12 < \lambda_\gamma < 0.13$  with other couplings fixed to their Standard Model values.
- <sup>14</sup> ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in  $e^+e^- \rightarrow W^+W^- \rightarrow (q\bar{q})(\ell\nu)$ , where  $\ell = e$  or  $\mu$ . Values of all other couplings are fixed to their standard model values.
- <sup>15</sup> AALTONEN 07L set limits on anomalous TGCs using the  $p_T(W)$  distribution in  $WW$  and  $WZ$  production with the  $W$  decaying to an electron or muon and the  $Z$  to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are  $-0.18 < \lambda_\gamma < 0.17$  for a form factor scale  $\Lambda = 1.5$  TeV.

- <sup>16</sup>ABAZOV 06H study  $\bar{p}p \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+ \nu_e e^- \bar{\nu}_e$ ,  $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$  or  $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 1$  TeV is  $-0.97 < \lambda_\gamma < 1.04$ , fixing  $\kappa_\gamma=1$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $-0.29 < \lambda < 0.30$ .
- <sup>17</sup>ABAZOV 05J perform a likelihood fit to the photon  $E_T$  spectrum of  $W\gamma + X$  events, where the  $W$  decays to an electron or muon which is required to be well separated from the photon. For  $\Lambda = 2.0$  TeV the 95% CL limits are  $-0.20 < \lambda_\gamma < 0.20$ . In the fit  $\kappa_\gamma$  is kept fixed to its Standard Model value.
- <sup>18</sup>ABREU 01i combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$ ,  $W\nu_e$ , and  $\nu\bar{\nu}\gamma$  final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is  $-0.11 < \lambda_\gamma < 0.23$ .
- <sup>19</sup>BREITWEG 00 search for  $W$  production in events with large hadronic  $p_T$ . For  $p_T > 20$  GeV, the upper limit on the cross section gives the 95%CL limit  $-3.2 < \lambda_\gamma < 3.2$  for  $\kappa_\gamma$  fixed to its Standard Model value.
- <sup>20</sup>ABBOTT 99i perform a simultaneous fit to the  $W\gamma$ ,  $WW \rightarrow$  dilepton,  $WW/WZ \rightarrow e\nu jj$ ,  $WW/WZ \rightarrow \mu\nu jj$ , and  $WZ \rightarrow$  trilepton data samples. For  $\Lambda = 2.0$  TeV, the 95%CL limits are  $-0.18 < \lambda_\gamma < 0.19$ .

 **$\kappa_Z$** 

This coupling is  $CP$ -conserving ( $C$ - and  $P$ - separately conserving).

- <sup>1</sup>ACHARD 04D study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the  $WW$ -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- <sup>2</sup>AAD 13AL study  $WW$  production in  $pp$  collisions and select 1325  $WW$  candidates in decay modes with electrons or muons with an expected background of  $369 \pm 61$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda =$  infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $0.957 < \kappa_Z < 1.043$ . Supersedes AAD 12AC.
- <sup>3</sup>AAD 12CD study  $WZ$  production in  $pp$  collisions and select 317  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $68.0 \pm 10.0$  events. The resulting 95% C.L. range is:  $0.63 < \kappa_Z < 1.57$ . Supersedes AAD 12V.
- <sup>4</sup>AALTONEN 12AC study  $WZ$  production in  $p\bar{p}$  collisions and select 63  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $7.9 \pm 1.0$  events. Based on the cross section and shape of the  $Z$  transverse momentum spectrum, the following 95% C.L. range is reported:  $0.61 < \kappa_Z < 1.90$  for a form factor of  $\Lambda = 2$  TeV.
- <sup>5</sup>ABAZOV 11 study the  $p\bar{p} \rightarrow 3\ell\nu$  process arising in  $WZ$  production. They observe 34  $WZ$  candidates with an estimated background of 6 events. An analysis of the  $p_T$  spectrum of the  $Z$  boson leads to a 95% C.L. limit of  $0.600 < \kappa_Z < 1.675$ , for a form factor  $\Lambda = 2$  TeV.
- <sup>6</sup>ABAZOV 06H study  $\bar{p}p \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+ \nu_e e^- \bar{\nu}_e$ ,  $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$  or  $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $0.55 < \kappa_Z < 1.55$ , fixing  $\lambda_Z=0$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $0.68 < \kappa < 1.45$ .
- <sup>7</sup>ABAZOV 05s study  $\bar{p}p \rightarrow WZ$  production with a subsequent trilepton decay to  $\ell\nu\ell'\bar{\ell}'$  ( $\ell$  and  $\ell' = e$  or  $\mu$ ). Three events (estimated background  $0.71 \pm 0.08$  events) with  $WZ$  decay characteristics are observed from which they derive limits on the anomalous  $WWZ$  couplings. The 95% CL limit for a form factor scale  $\Lambda = 1$  TeV is  $-1.0 < \kappa_Z < 3.4$ , fixing  $\lambda_Z$  and  $g_1^Z$  to their Standard Model values.

 **$\lambda_Z$**

- <sup>1</sup>ACHARD 04D study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the  $WW$ -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- <sup>2</sup>AAD 14Y determine the electroweak  $Z$ -dijet cross section in 8 TeV  $pp$  collisions.  $Z \rightarrow ee$  and  $Z \rightarrow \mu\mu$  decays are selected with the di-lepton  $p_T > 20$  GeV and mass in the 81-101 GeV range. Minimum two jets are required with  $p_T > 55$  and 45 GeV and no additional jets with  $p_T > 25$  GeV in the rapidity interval between them. The normalized  $p_T$  balance between the  $Z$  and the two jets is required to be  $< 0.15$ . This leads to a selection of 900 events with dijet mass  $> 1$  TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit  $-0.15 < \lambda_Z < 0.13$  for a form factor value  $\Lambda = \infty$ .
- <sup>3</sup>AAD 13AL study  $WW$  production in  $pp$  collisions and select 1325  $WW$  candidates in decay modes with electrons or muons with an expected background of  $369 \pm 61$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda =$  infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $-0.062 < \lambda_Z < 0.059$ . Supersedes AAD 12AC.
- <sup>4</sup>CHATRCHYAN 13BF determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of  $247 \pm 34$ . The  $p_T$  distribution of the leading lepton is fitted to obtain 95% C.L. limits of  $-0.048 \leq \lambda_Z \leq 0.048$ .
- <sup>5</sup>AAD 12CD study  $WZ$  production in  $pp$  collisions and select 317  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $68.0 \pm 10.0$  events. The resulting 95% C.L. range is:  $-0.046 < \lambda_Z < 0.047$ . Supersedes AAD 12V.
- <sup>6</sup>AALTONEN 12AC study  $WZ$  production in  $p\bar{p}$  collisions and select 63  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $7.9 \pm 1.0$  events. Based on the cross section and shape of the  $Z$  transverse momentum spectrum, the following 95% C.L. range is reported:  $-0.08 < \lambda_Z < 0.10$  for a form factor of  $\Lambda = 2$  TeV.
- <sup>7</sup>ABAZOV 11 study the  $p\bar{p} \rightarrow 3\ell\nu$  process arising in  $WZ$  production. They observe 34  $WZ$  candidates with an estimated background of 6 events. An analysis of the  $p_T$  spectrum of the  $Z$  boson leads to a 95% C.L. limit of  $-0.077 < \lambda_Z < 0.093$ , for a form factor  $\Lambda = 2$  TeV.
- <sup>8</sup>AALTONEN 10K study  $p\bar{p} \rightarrow W^+W^-$  with  $W \rightarrow e/\mu\nu$ . The  $p_T$  of the leading (second) lepton is required to be  $> 20$  (10) GeV. The final number of events selected is 654 of which  $320 \pm 47$  are estimated to be background. The 95% C.L. interval is  $-0.16 < \lambda_Z < 0.16$  for  $\Lambda = 1.5$  TeV and  $-0.14 < \lambda_Z < 0.15$  for  $\Lambda = 2$  TeV.
- <sup>9</sup>ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and  $p_T(Z)$  distribution in  $WZ$  production with both the  $W$  and the  $Z$  decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $-0.17 < \lambda_Z < 0.21$ .
- <sup>10</sup>ABAZOV 06H study  $\bar{p}p \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+ \nu_e e^- \bar{\nu}_e$ ,  $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$  or  $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $-0.39 < \lambda_Z < 0.39$ , fixing  $\kappa_Z=1$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $-0.29 < \lambda < 0.30$ .
- <sup>11</sup>ABAZOV 05s study  $\bar{p}p \rightarrow WZ$  production with a subsequent trilepton decay to  $\ell\nu\ell'\bar{\ell}'$  ( $\ell$  and  $\ell' = e$  or  $\mu$ ). Three events (estimated background  $0.71 \pm 0.08$  events) with  $WZ$  decay characteristics are observed from which they derive limits on the anomalous  $WWZ$  couplings. The 95% CL limit for a form factor scale  $\Lambda = 1.5$  TeV is  $-0.48 < \lambda_Z < 0.48$ , fixing  $g_1^Z$  and  $\kappa_Z$  to their Standard Model values.

 **$g_5^Z$** 

This coupling is  $CP$ -conserving but  $C$ - and  $P$ -violating.

## W ANOMALOUS MAGNETIC MOMENT

The full magnetic moment is given by  $\mu_W = e(1 + \kappa + \lambda)/2m_W$ . In the Standard Model, at tree level,  $\kappa = 1$  and  $\lambda = 0$ . Some papers have defined  $\Delta\kappa = 1 - \kappa$  and assume that  $\lambda = 0$ . Note that the electric quadrupole moment is given by  $-e(\kappa - \lambda)/m_W^2$ . A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter  $\Lambda$  appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the  $W$  boson becomes manifest.

<sup>1</sup> ABREU 01i combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$ ,  $W\nu_e$ , and  $\nu\bar{\nu}\gamma$  final states with results from ABREU 99L at 183 GeV to determine  $\Delta g_Z^2$ ,  $\Delta\kappa_\gamma$ , and  $\lambda_\gamma$ .  $\Delta\kappa_\gamma$  and  $\lambda_\gamma$  are simultaneously floated in the fit to determine  $\mu_W$ .

<sup>2</sup> ABE 95g report  $-1.3 < \kappa < 3.2$  for  $\lambda = 0$  and  $-0.7 < \lambda < 0.7$  for  $\kappa = 1$  in  $p\bar{p} \rightarrow e\nu_e\gamma X$  and  $\mu\nu_\mu\gamma X$  at  $\sqrt{s} = 1.8$  TeV.

<sup>3</sup> ALITTI 92c measure  $\kappa = 1 \pm 2.6$  and  $\lambda = 0 \pm 1.7$  in  $p\bar{p} \rightarrow e\nu\gamma + X$  at  $\sqrt{s} = 630$  GeV. At 95%CL they report  $-3.5 < \kappa < 5.9$  and  $-3.6 < \lambda < 3.5$ .

<sup>4</sup> SAMUEL 92 use preliminary CDF and UA2 data and find  $-2.4 < \kappa < 3.7$  at 96%CL and  $-3.1 < \kappa < 4.2$  at 95%CL respectively. They use data for  $W\gamma$  production and radiative  $W$  decay.

<sup>5</sup> SAMUEL 91 use preliminary CDF data for  $p\bar{p} \rightarrow W\gamma X$  to obtain  $-11.3 \leq \Delta\kappa \leq 10.9$ . Note that their  $\kappa = 1 - \Delta\kappa$ .

<sup>6</sup> GRIFOLS 88 uses deviation from  $\rho$  parameter to set limit  $\Delta\kappa \lesssim 65 (M_W^2/\Lambda^2)$ .

<sup>7</sup> GROTH 87 finds the limit  $-37 < \Delta\kappa < 73.5$  (90% CL) from the experimental limits on  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$  assuming three neutrino generations and  $-19.5 < \Delta\kappa < 56$  for four generations. Note their  $\Delta\kappa$  has the opposite sign as our definition.

<sup>8</sup> VANDERBIJ 87 uses existing limits to the photon structure to obtain  $|\Delta\kappa| < 33 (m_W/\Lambda)$ . In addition VANDERBIJ 87 discusses problems with using the  $\rho$  parameter of the Standard Model to determine  $\Delta\kappa$ .

<sup>9</sup> GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole ( $\lambda$ ) moments  $1.05 > \Delta\kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$ . In the Standard Model  $\lambda = 0$ .

<sup>10</sup> SUZUKI 85 uses partial-wave unitarity at high energies to obtain  $|\Delta\kappa| \lesssim 190 (m_W/\Lambda)^2$ . From the anomalous magnetic moment of the muon, SUZUKI 85 obtains  $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$ . Finally SUZUKI 85 uses deviations from the  $\rho$  parameter and obtains a very qualitative, order-of-magnitude limit  $|\Delta\kappa| \lesssim 150 (m_W/\Lambda)^4$  if  $|\Delta\kappa| \ll 1$ .

<sup>11</sup> HERZOG 84 consider the contribution of  $W$ -boson to muon magnetic moment including anomalous coupling of  $WW\gamma$ . Obtain a limit  $-1 < \Delta\kappa < 3$  for  $\Lambda \gtrsim 1$  TeV.

## ANOMALOUS W/Z QUARTIC COUPLINGS

### ANOMALOUS W/Z QUARTIC COUPLINGS (QGCS)

Revised November 2015 by M.W. Gr newald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings,  $WWZZ$ ,  $WWZ\gamma$ ,  $WW\gamma\gamma$ , and  $ZZ\gamma\gamma$ , were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowers dimensional representation of operators (dimension 6) which presumes the  $SU(2) \times U(1)$  gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings,  $a_0, a_c, a_n$ , are expressed in terms of the following dimension-6 operators [1,2];

$$\begin{aligned} L_6^0 &= -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ L_6^c &= -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha \\ L_6^n &= -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_{\nu}^{(j)} W^{(k)\alpha} F^{\mu\nu} \\ \tilde{L}_6^0 &= -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ \tilde{L}_6^n &= -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} \tilde{W}_{\mu\alpha}^{(i)} W_{\nu}^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu} \end{aligned}$$

where  $F, W$  are photon and  $W$  fields,  $L_6^0$  and  $L_6^c$  conserve  $C$ ,  $P$  separately ( $\tilde{L}_6^0$  conserves only  $C$ ) and generate anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings,  $L_6^n$  violates  $CP$  ( $\tilde{L}_6^n$  violates both  $C$  and  $P$ ) and generates an anomalous  $W^+W^-Z\gamma$  coupling, and  $\Lambda$  is an energy scale for new physics. For the  $ZZ\gamma\gamma$  coupling the  $CP$ -violating term represented by  $L_6^n$  does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the  $WW\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings separately, leading to two sets parametrized as  $a_0^V/\Lambda^2$  and  $a_c^V/\Lambda^2$ , where  $V = W$  or  $Z$ .

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used

this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = & -\frac{e^2 a_0^W}{8 \Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+a} W_a^- \\ & -\frac{e^2 a_c^W}{16 \Lambda^2} F_{\mu\nu} F^{\mu a} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ & -e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+a} W_a^- \\ & -\frac{e^2 g^2 \kappa_c^W}{2 \Lambda^2} F_{\mu\nu} Z^{\mu a} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ & + \frac{f_{T,0}}{\Lambda^4} \text{Tr}[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times \text{Tr}[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is  $\Lambda$ , and  $g = e/\sin(\theta_W)$ ,  $e$  being the unit electric charge and  $\theta_W$  the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators  $a_0^W/\Lambda^2$  and  $a_c^W/\Lambda^2$  are associated with the  $WW\gamma\gamma$  vertex. Among dimension 8 operators,  $\kappa_0^W/\Lambda^2$  and  $\kappa_c^W/\Lambda^2$  are associated with the  $WWZ\gamma$  vertex, whereas the parameter  $f_{T,0}/\Lambda^4$  contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters  $f_{M,i}/\Lambda^4$  as follows [3]:

$$\begin{aligned}\frac{a_0^W}{\Lambda^2} &= -\frac{4M_W^2}{g^2} \frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,2}}{\Lambda^4} \\ \frac{a_c^W}{\Lambda^2} &= -\frac{4M_W^2}{g^2} \frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,3}}{\Lambda^4}\end{aligned}$$

where  $g' = e/\cos(\theta_W)$  and  $M_W$  is the invariant mass of the  $W$  boson. This relation provides a translation between limits on dimension 6 operators  $a_{0,c}^W$  and  $f_{M,j}/\Lambda^4$ . It is further required [4] that  $f_{M,0} = 2f_{M,2}$  and  $f_{M,1} = 2f_{M,3}$  which suppresses contributions to the  $WWZ\gamma$  vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total –  $f_{S,i}$ ,  $i = 1, 2$ ,  $f_{M,i}$ ,  $i = 0, \dots, 8$  and  $f_{T,i}$ ,  $i = 0, \dots, 9$  – each scaled by  $1/\Lambda^4$ .

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters  $\alpha_4$  and  $\alpha_5$ , which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

Anomalous  $W$  quartic couplings are measured by the experiments at LEP, the Tevatron, and the LHC. Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below). As discussed in the review on the “Anomalous  $W/Z$  quartic couplings (QGCS),” the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for the use in the future publications by the experiments.

<sup>1</sup>AAD 15N study  $W\gamma\gamma$  events in 8 TeV  $pp$  interactions, where the  $W$  decays into an electron or a muon. The events are characterized by an isolated lepton, a missing transverse energy due to the decay neutrino, and two isolated photons, with the  $p_T$  of the lepton and the photons being  $> 20$  GeV. The number of candidate events observed in the electron channel for  $N(\text{jet}) \geq 0$  and  $N(\text{jet}) = 0$  is 47 and 15, the corresponding numbers for the muon channel being 110 and 53. The backgrounds expected are  $30.2 \pm 7.4$ ,  $8.7 \pm 3.0$ ,  $52.1 \pm 12.2$ , and  $24.4 \pm 8.3$  respectively. The 95% C.L. limits on the values of the parameters  $f_{T,0}/\Lambda^4$ ,  $f_{M,2}/\Lambda^4$  and  $f_{M,3}/\Lambda^4$  are  $-0.9$ – $0.9 \times 10^2$ ,  $-0.8$ – $0.8 \times 10^4$ , and  $-1.5$ – $1.4 \times 10^4$  respectively, without application of a form factor  $\Lambda_{FF}$ .

<sup>2</sup>KHACHATRYAN 15D study vector-boson-scattering tagged by two jets, requiring two same-sign charged leptons arising from  $W^\pm W^\pm$  production and decay. The two jets must have a transverse momentum larger than 30 GeV, while the leptons, electrons or muons, must have a transverse momentum  $> 20$  GeV. The dijet mass is required to be  $> 500$  GeV, the dilepton mass  $> 50$  GeV, with additional requirement of differing from the  $Z$  mass by  $> 15$  GeV. In the two categories  $W^+ W^+$  and  $W^- W^-$ , 10 and 2 data events are observed in a data sample corresponding to an integrated luminosity of  $19.4 \text{ fb}^{-1}$ , with an expected background of  $3.1 \pm 0.6$  and  $2.6 \pm 0.5$  events. Analysing the distribution of the dilepton invariant mass, the following limits at 95% C.L. are obtained, in units of  $\text{TeV}^{-4}$ :  $-38 < f_{S,0}/\Lambda^4 < 40$ ,  $-118 < f_{S,1}/\Lambda^4 < 120$ ,  $-33 < f_{M,0}/\Lambda^4 < 32$ ,  $-44 < f_{M,1}/\Lambda^4 < 47$ ,  $-65 < f_{M,6}/\Lambda^4 < 63$ ,  $-70 < f_{M,7}/\Lambda^4 < 66$ ,  $-4.2 < f_{T,0}/\Lambda^4 < 4.6$ ,  $-1.9 < f_{T,1}/\Lambda^4 < 2.2$ ,  $-6.2 < f_{T,2}/\Lambda^4 < 6.4$ .

<sup>3</sup>AAD 14AM analyze electroweak production of  $WW$  jet same-charge diboson plus two jets production, with the  $W$  bosons decaying to electron or muon, to study the quartic  $WWWW$  coupling. In a kinematic region enhancing the electroweak production over the strong production, 34 events are observed in the data while  $29.8 \pm 2.4$  events are expected with a background of  $15.9 \pm 1.9$  events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the quartic gauge couplings:  $-0.14 < \alpha_4 < 0.16$  and  $-0.23 < \alpha_5 < 0.24$ .

<sup>4</sup>CHATRCHYAN 14Q study  $WV\gamma$  production in 8 TeV  $pp$  collisions, in the single lepton final state, with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \text{dijet}$  or  $W \rightarrow \ell\nu$ ,  $W \rightarrow \text{dijet}$ , the dijet mass resolution precluding differentiation between the  $W$  and  $Z$ .  $p_T$  and pseudo-rapidity cuts are put on the lepton, the photon and the two jets to minimize backgrounds. The dijet mass is required to be between 7–100 GeV and  $|\Delta\eta_{jj}| < 1.4$ . The selected number of muon (electron) events are 183 (139), with SM expectation being  $194.2 \pm 11.5$  ( $147.9 \pm 10.7$ ) including signal and background. The photon  $E_T$  distribution is used to set limits on the anomalous quartic couplings. The following 95% CL limits are deduced (all in units of  $\text{TeV}^{-2}$  or  $\text{TeV}^{-4}$ ):  $-21 < a_0^W/\Lambda^2 < 20$ ,  $-34 < a_c^W/\Lambda^2 < 32$ ,  $-12 < \kappa_0^W/\Lambda^2 < 10$  and  $-18 < \kappa_c^W/\Lambda^2 < 17$ ; and  $-25 < f_{T,0}/\Lambda^4 < 24 \text{ TeV}^{-4}$ .

<sup>5</sup>ABAZOV 13D searches for anomalous  $WW\gamma\gamma$  quartic gauge couplings in the two-photon-mediated process  $pp \rightarrow ppWW$ , assuming the  $WW\gamma$  triple gauge boson couplings to be at their Standard Model values. 946 events containing an  $e^+e^-$  pair with missing energy are selected in a total luminosity of  $9.7 \text{ fb}^{-1}$ , with an expectation of  $983 \pm 108$  events from Standard-Model processes. The following 1-parameter limits at 95% CL are obtained:  $|a_0^W/\Lambda^2| < 4.3 \times 10^{-4} \text{ GeV}^{-2}$  ( $a_c^W = 0$ ),  $|a_c^W/\Lambda^2| < 1.5 \times 10^{-3} \text{ GeV}^{-2}$  ( $a_0^W = 0$ ).

<sup>6</sup>CHATRCHYAN 13AA searches for anomalous  $WW\gamma\gamma$  quartic gauge couplings in the two-photon-mediated process  $pp \rightarrow ppWW$ , assuming the  $WW\gamma$  triple gauge boson couplings to be at their Standard Model values. 2 events containing an  $e^\pm\mu^\mp$  pair with  $p_T(e, \mu) > 30$  GeV are selected in a total luminosity of  $5.05 \text{ fb}^{-1}$ , with an expected  $ppWW$  signal of  $2.2 \pm 0.4$  events and an expected background of  $0.84 \pm 0.15$  events. The following 1-parameter limits at 95% CL are obtained from the  $p_T(e, \mu)$  spectrum:

## W, Z

$|a_0^W/\Lambda^2| < 4.0 \times 10^{-6} \text{ GeV}^{-2}$  ( $a_c^W = 0$ ),  $|a_c^W/\Lambda^2| < 1.5 \times 10^{-5} \text{ GeV}^{-2}$  ( $a_0^W = 0$ ).

<sup>7</sup> ABBIENDI 04B select  $187 e^+e^- \rightarrow W^+W^-\gamma$  events in the C.M. energy range 180–209 GeV, where  $E_\gamma > 2.5 \text{ GeV}$ , the photon has a polar angle  $|\cos\theta_\gamma| < 0.975$  and is well isolated from the nearest jet and charged lepton, and the effective masses of both fermion-antifermion systems agree with the  $W$  mass within  $3\Gamma_W$ . The measured differential cross section as a function of the photon energy and photon polar angle is used to extract the 95% CL limits:  $-0.020 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.053 \text{ GeV}^{-2} < a_c/\Lambda^2 < 0.037 \text{ GeV}^{-2}$  and  $-0.16 \text{ GeV}^{-2} < a_n/\Lambda^2 < 0.15 \text{ GeV}^{-2}$ .

<sup>8</sup> ABBIENDI 04L select  $20 e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  acoplanar events in the energy range 180–209 GeV and  $176 e^+e^- \rightarrow q\bar{q}\gamma\gamma$  events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  quartic couplings. Further combining with the  $W^+W^-\gamma$  sample of ABBIENDI 04B the following one-parameter 95% CL limits are obtained:  $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$ ,  $-0.029 < a_c^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$ ,  $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.052 < a_c^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$ .

<sup>9</sup> In the CM energy range 183 to 209 GeV HEISTER 04A select  $30 e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be  $> 5^\circ$ ,  $E_\gamma/\sqrt{s} > 0.025$  (the more energetic photon having energy  $> 0.2\sqrt{s}$ ),  $p_{T_\gamma}/E_{\text{beam}} > 0.05$  and  $|\cos\theta_\gamma| < 0.94$ . A likelihood fit to the photon energy and recoil missing mass yields the following one-parameter 95% CL limits:  $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$ ,  $-0.041 < a_c^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$ ,  $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$ ,  $-0.099 < a_c^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$ .

<sup>10</sup> ABDALLAH 03i select  $122 e^+e^- \rightarrow W^+W^-\gamma$  events in the C.M. energy range 189–209 GeV, where  $E_\gamma > 5 \text{ GeV}$ , the photon has a polar angle  $|\cos\theta_\gamma| < 0.95$  and is well isolated from the nearest charged fermion. A fit to the photon energy spectrum yields  $a_c/\Lambda^2 = 0.000 \pm 0.019 \text{ GeV}^{-2}$ ,  $a_0/\Lambda^2 = -0.004 \pm 0.018 \text{ GeV}^{-2}$ ,  $\bar{a}_0/\Lambda^2 = -0.007 \pm 0.019 \text{ GeV}^{-2}$ ,  $a_n/\Lambda^2 = -0.09 \pm 0.16 \text{ GeV}^{-2}$ , and  $\bar{a}_n/\Lambda^2 = +0.05 \pm 0.07 \text{ GeV}^{-2}$ , keeping the other parameters fixed to their Standard Model values(0). The 95% CL limits are:  $-0.063 \text{ GeV}^{-2} < a_c/\Lambda^2 < +0.032 \text{ GeV}^{-2}$ ,  $-0.020 \text{ GeV}^{-2} < a_0/\Lambda^2 < +0.020 \text{ GeV}^{-2}$ ,  $-0.020 \text{ GeV}^{-2} < \bar{a}_0/\Lambda^2 < +0.020 \text{ GeV}^{-2}$ ,  $-0.18 \text{ GeV}^{-2} < a_n/\Lambda^2 < +0.14 \text{ GeV}^{-2}$ ,  $-0.16 \text{ GeV}^{-2} < \bar{a}_n/\Lambda^2 < +0.17 \text{ GeV}^{-2}$ .

<sup>11</sup> ACHARD 02F select  $86 e^+e^- \rightarrow W^+W^-\gamma$  events at 192–207 GeV, where  $E_\gamma > 5 \text{ GeV}$  and the photon is well isolated. They also select 43 acoplanar  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  events in this energy range, where the photon energies are  $> 5 \text{ GeV}$  and  $> 1 \text{ GeV}$  and the photon polar angles are between  $14^\circ$  and  $166^\circ$ . All these 43 events are in the recoil mass region corresponding to the Z (75–110 GeV). Using the shape and normalization of the photon spectra in the  $W^+W^-\gamma$  events, and combining with the 42 event sample from 189 GeV data (ACCIARRI 00T), they obtain:  $a_0/\Lambda^2 = 0.000 \pm 0.010 \text{ GeV}^{-2}$ ,  $a_c/\Lambda^2 = -0.013 \pm 0.023 \text{ GeV}^{-2}$ , and  $a_n/\Lambda^2 = -0.002 \pm 0.076 \text{ GeV}^{-2}$ . Further combining the analyses of  $W^+W^-\gamma$  events with the low recoil mass region of  $\nu\bar{\nu}\gamma\gamma$  events (including samples collected at 183 + 189 GeV), they obtain the following one-parameter 95% CL limits:  $-0.015 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.015 \text{ GeV}^{-2}$ ,  $-0.048 \text{ GeV}^{-2} < a_c/\Lambda^2 < 0.026 \text{ GeV}^{-2}$ , and  $-0.14 \text{ GeV}^{-2} < a_n/\Lambda^2 < 0.13 \text{ GeV}^{-2}$ .

### THE Z BOSON

Revised September 2013 by M.W. Grunewald (U. College Dublin and U. Ghent), and A. Gurtu (Formerly Tata Inst.).

Precision measurements at the Z-boson resonance using electron-positron colliding beams began in 1989 at the SLC and at LEP. During 1989–95, the four LEP experiments (ALEPH, DELPHI, L3, OPAL) made high-statistics studies of the production and decay properties of the Z. Although the SLD experiment at the SLC collected much lower statistics, it was able to match the precision of LEP experiments in determining

the effective electroweak mixing angle  $\sin^2\bar{\theta}_W$  and the rates of  $Z$  decay to  $b$ - and  $c$ -quarks, owing to availability of polarized electron beams, small beam size, and stable beam spot.

The  $Z$ -boson properties reported in this section may broadly be categorized as:

- The standard ‘lineshape’ parameters of the  $Z$  consisting of its mass,  $M_Z$ , its total width,  $\Gamma_Z$ , and its partial decay widths,  $\Gamma(\text{hadrons})$ , and  $\Gamma(\ell\bar{\ell})$  where  $\ell = e, \mu, \tau, \nu$ ;
- $Z$  asymmetries in leptonic decays and extraction of  $Z$  couplings to charged and neutral leptons;
- The  $b$ - and  $c$ -quark-related partial widths and charge asymmetries which require special techniques;
- Determination of  $Z$  decay modes and the search for modes that violate known conservation laws;
- Average particle multiplicities in hadronic  $Z$  decay;
- $Z$  anomalous couplings.

The effective vector and axial-vector coupling constants describing the  $Z$ -to-fermion coupling are also measured in  $p\bar{p}$  and  $ep$  collisions at the Tevatron and at HERA. The corresponding cross-section formulae are given in Section 39 (Cross-section formulae for specific processes) and Section 16 (Structure Functions) in this *Review*. In this minireview, we concentrate on the measurements in  $e^+e^-$  collisions at LEP and SLC.

The standard ‘lineshape’ parameters of the  $Z$  are determined from an analysis of the production cross sections of these final states in  $e^+e^-$  collisions. The  $Z \rightarrow \nu\bar{\nu}(\gamma)$  state is identified directly by detecting single photon production and indirectly by subtracting the visible partial widths from the total width. Inclusion in this analysis of the forward-backward asymmetry of charged leptons,  $A_{FB}^{(0,\ell)}$ , of the  $\tau$  polarization,  $P(\tau)$ , and its forward-backward asymmetry,  $P(\tau)^{fb}$ , enables the separate determination of the effective vector ( $\bar{g}_V$ ) and axial vector ( $\bar{g}_A$ ) couplings of the  $Z$  to these leptons and the ratio ( $\bar{g}_V/\bar{g}_A$ ), which is related to the effective electroweak mixing angle  $\sin^2\bar{\theta}_W$  (see the “Electroweak Model and Constraints on New Physics” review).

Determination of the  $b$ - and  $c$ -quark-related partial widths and charge asymmetries involves tagging the  $b$  and  $c$  quarks for which various methods are employed: requiring the presence of a high momentum prompt lepton in the event with high transverse momentum with respect to the accompanying jet; impact parameter and lifetime tagging using precision vertex measurement with high-resolution detectors; application of neural-network techniques to classify events as  $b$  or non- $b$  on a statistical basis using event-shape variables; and using the presence of a charmed meson ( $D/D^*$ ) or a kaon as a tag.

### ***Z*-parameter determination**

LEP was run at energy points on and around the  $Z$  mass (88–94 GeV) constituting an energy ‘scan.’ The shape of the cross-section variation around the  $Z$  peak can be described by a Breit-Wigner *ansatz* with an energy-dependent

total width [1–3]. The **three** main properties of this distribution, viz., the **position** of the peak, the **width** of the distribution, and the **height** of the peak, determine respectively the values of  $M_Z$ ,  $\Gamma_Z$ , and  $\Gamma(e^+e^-) \times \Gamma(f\bar{f})$ , where  $\Gamma(e^+e^-)$  and  $\Gamma(f\bar{f})$  are the electron and fermion partial widths of the  $Z$ . The quantitative determination of these parameters is done by writing analytic expressions for these cross sections in terms of the parameters, and fitting the calculated cross sections to the measured ones by varying these parameters, taking properly into account all the errors. Single-photon exchange ( $\sigma_\gamma^0$ ) and  $\gamma$ - $Z$  interference ( $\sigma_{\gamma Z}^0$ ) are included, and the large ( $\sim 25\%$ ) initial-state radiation (ISR) effects are taken into account by convoluting the analytic expressions over a ‘Radiator Function’ [1–5]  $H(s, s')$ . Thus for the process  $e^+e^- \rightarrow f\bar{f}$ :

$$\sigma_f(s) = \int H(s, s') \sigma_f^0(s') ds' \quad (1)$$

$$\sigma_f^0(s) = \sigma_Z^0 + \sigma_\gamma^0 + \sigma_{\gamma Z}^0 \quad (2)$$

$$\sigma_Z^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(f\bar{f})}{\Gamma_Z^2} \frac{s \Gamma_Z^2}{(s - M_Z^2)^2 + s^2 \Gamma_Z^2 / M_Z^2} \quad (3)$$

$$\sigma_\gamma^0 = \frac{4\pi\alpha^2(s)}{3s} Q_f^2 N_c^f \quad (4)$$

$$\begin{aligned} \sigma_{\gamma Z}^0 = & - \frac{2\sqrt{2}\alpha(s)}{3} (Q_f G_F N_c^f \mathcal{G}_V^e \mathcal{G}_V^f) \\ & \times \frac{(s - M_Z^2) M_Z^2}{(s - M_Z^2)^2 + s^2 \Gamma_Z^2 / M_Z^2} \end{aligned} \quad (5)$$

where  $Q_f$  is the charge of the fermion,  $N_c^f = 3$  for quarks and 1 for leptons, and  $\mathcal{G}_V^f$  is the vector coupling of the  $Z$  to the fermion-antifermion pair  $f\bar{f}$ .

Since  $\sigma_{\gamma Z}^0$  is expected to be much less than  $\sigma_Z^0$ , the LEP Collaborations have generally calculated the interference term in the framework of the Standard Model. This fixing of  $\sigma_{\gamma Z}^0$  leads to a tighter constraint on  $M_Z$ , and consequently a smaller error on its fitted value. It is possible to relax this constraint and carry out the fit within the S-matrix framework, which is briefly described in the next section.

In the above framework, the QED radiative corrections have been explicitly taken into account by convoluting over the ISR and allowing the electromagnetic coupling constant to run [6]:  $\alpha(s) = \alpha/(1 - \Delta\alpha)$ . On the other hand, weak radiative corrections that depend upon the assumptions of the electroweak theory and on the values of  $M_{\text{top}}$  and  $M_{\text{Higgs}}$  are accounted for by **absorbing them into the couplings**, which are then called the *effective* couplings  $\mathcal{G}_V$  and  $\mathcal{G}_A$  (or alternatively the effective parameters of the  $\star$  scheme of Kennedy and Lynn [7].)

$\mathcal{G}_V^f$  and  $\mathcal{G}_A^f$  are complex numbers with small imaginary parts. As experimental data does not allow simultaneous extraction of both real and imaginary parts of the effective couplings, the convention  $g_A^f = \text{Re}(\mathcal{G}_A^f)$  and  $g_V^f = \text{Re}(\mathcal{G}_V^f)$  is used and the imaginary parts are added in the fitting code [4].

Defining

$$A_f = 2 \frac{g_V^f \cdot g_A^f}{(g_V^f)^2 + (g_A^f)^2} \quad (6)$$

# Gauge & Higgs Boson Particle Listings

## Z

the lowest-order expressions for the various lepton-related asymmetries on the  $Z$  pole are [8–10]  $A_{FB}^{(0,\ell)} = (3/4)A_e A_f$ ,  $P(\tau) = -A_\tau$ ,  $P(\tau)^{fb} = -(3/4)A_e$ ,  $A_{LR} = A_e$ . The full analysis takes into account the energy-dependence of the asymmetries. Experimentally  $A_{LR}$  is defined as  $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$ , where  $\sigma_{L(R)}$  are the  $e^+e^- \rightarrow Z$  production cross sections with left- (right)-handed electrons.

The definition of the partial decay width of the  $Z$  to  $f\bar{f}$  includes the effects of QED and QCD final-state corrections, as well as the contribution due to the imaginary parts of the couplings:

$$\Gamma(f\bar{f}) = \frac{G_F M_Z^3}{6\sqrt{2}\pi} N_c^f \left( |g_A^f|^2 R_A^f + |g_V^f|^2 R_V^f \right) + \Delta_{ew/QCD} \quad (7)$$

where  $R_V^f$  and  $R_A^f$  are radiator factors to account for final state QED and QCD corrections, as well as effects due to nonzero fermion masses, and  $\Delta_{ew/QCD}$  represents the non-factorizable electroweak/QCD corrections.

### S-matrix approach to the Z

While most experimental analyses of LEP/SLC data have followed the ‘Breit-Wigner’ approach, an alternative S-matrix-based analysis is also possible. The  $Z$ , like all unstable particles, is associated with a complex pole in the S matrix. The pole position is process-independent and gauge-invariant. The mass,  $\bar{M}_Z$ , and width,  $\bar{\Gamma}_Z$ , can be defined in terms of the pole in the energy plane via [11–14]

$$\bar{s} = \bar{M}_Z^2 - i\bar{M}_Z\bar{\Gamma}_Z \quad (8)$$

leading to the relations

$$\begin{aligned} \bar{M}_Z &= M_Z / \sqrt{1 + \Gamma_Z^2/M_Z^2} \\ &\approx M_Z - 34.1 \text{ MeV} \end{aligned} \quad (9)$$

$$\begin{aligned} \bar{\Gamma}_Z &= \Gamma_Z / \sqrt{1 + \Gamma_Z^2/M_Z^2} \\ &\approx \Gamma_Z - 0.9 \text{ MeV} . \end{aligned} \quad (10)$$

The LEP collaborations [15] have analyzed their data using the S-matrix approach as defined in Eq. (8), in addition to the conventional one. They observe a downward shift in the  $Z$  mass as expected.

### Handling the large-angle $e^+e^-$ final state

Unlike other  $f\bar{f}$  decay final states of the  $Z$ , the  $e^+e^-$  final state has a contribution not only from the  $s$ -channel but also from the  $t$ -channel and  $s$ - $t$  interference. The full amplitude is not amenable to fast calculation, which is essential if one has to carry out minimization fits within reasonable computer time. The usual procedure is to calculate the non- $s$  channel part of the cross section separately using the Standard Model programs ALIBABA [16] or TOPAZ0 [17], with the measured value of  $M_{\text{top}}$ , and  $M_{\text{Higgs}} = 150 \text{ GeV}$ , and add it to the  $s$ -channel cross section calculated as for other channels. This leads to two additional sources of error in the analysis: firstly, the theoretical calculation in ALIBABA itself is known to be

accurate to  $\sim 0.5\%$ , and secondly, there is uncertainty due to the error on  $M_{\text{top}}$  and the unknown value of  $M_{\text{Higgs}}$  (100–1000 GeV). These errors are propagated into the analysis by including them in the systematic error on the  $e^+e^-$  final state. As these errors are common to the four LEP experiments, this is taken into account when performing the LEP average.

### Errors due to uncertainty in LEP energy determination [18–23]

The systematic errors related to the LEP energy measurement can be classified as:

- The absolute energy scale error;
- Energy-point-to-energy-point errors due to the non-linear response of the magnets to the exciting currents;
- Energy-point-to-energy-point errors due to possible higher-order effects in the relationship between the dipole field and beam energy;
- Energy reproducibility errors due to various unknown uncertainties in temperatures, tidal effects, corrector settings, RF status, *etc.*

Precise energy calibration was done outside normal data-taking using the resonant depolarization technique. Run-time energies were determined every 10 minutes by measuring the relevant machine parameters and using a model which takes into account all the known effects, including leakage currents produced by trains in the Geneva area and the tidal effects due to gravitational forces of the Sun and the Moon. The LEP Energy Working Group has provided a covariance matrix from the determination of LEP energies for the different running periods during 1993–1995 [18].

### Choice of fit parameters

The LEP Collaborations have chosen the following primary set of parameters for fitting:  $M_Z$ ,  $\Gamma_Z$ ,  $\sigma_{\text{hadron}}^0$ ,  $R(\text{lepton})$ ,  $A_{FB}^{(0,\ell)}$ , where  $R(\text{lepton}) = \Gamma(\text{hadrons})/\Gamma(\text{lepton})$ ,  $\sigma_{\text{hadron}}^0 = 12\pi\Gamma(e^+e^-)\Gamma(\text{hadrons})/M_Z^2\Gamma_Z^2$ . With a knowledge of these fitted parameters and their covariance matrix, any other parameter can be derived. The main advantage of these parameters is that they form a physics motivated set of parameters with much reduced correlations.

Thus, the most general fit carried out to cross section and asymmetry data determines the **nine parameters**:  $M_Z$ ,  $\Gamma_Z$ ,  $\sigma_{\text{hadron}}^0$ ,  $R(e)$ ,  $R(\mu)$ ,  $R(\tau)$ ,  $A_{FB}^{(0,e)}$ ,  $A_{FB}^{(0,\mu)}$ ,  $A_{FB}^{(0,\tau)}$ . Assumption of lepton universality leads to a **five-parameter fit** determining  $M_Z$ ,  $\Gamma_Z$ ,  $\sigma_{\text{hadron}}^0$ ,  $R(\text{lepton})$ ,  $A_{FB}^{(0,\ell)}$ .

### Combining results from LEP and SLC experiments

With a steady increase in statistics over the years and improved understanding of the common systematic errors between LEP experiments, the procedures for combining results have evolved continuously [24]. The Line Shape Sub-group of the LEP Electroweak Working Group investigated the effects of these common errors, and devised a combination procedure for the precise determination of the  $Z$  parameters from LEP experiments. Using these procedures, this note also gives the

results after combining the final parameter sets from the four experiments, and these are the results quoted as the fit results in the  $Z$  listings below. Transformation of variables leads to values of derived parameters like partial decay widths and branching ratios to hadrons and leptons. Finally, transforming the LEP combined nine parameter set to  $(M_Z, \Gamma_Z, \sigma_{\text{hadron}}^0, g_A^f, g_V^f, f = e, \mu, \tau)$  using the average values of lepton asymmetry parameters  $(A_e, A_\mu, A_\tau)$  as constraints, leads to the best fitted values of the vector and axial-vector couplings  $(g_V, g_A)$  of the charged leptons to the  $Z$ .

Brief remarks on the handling of common errors and their magnitudes are given below. The identified common errors are those coming from

- (a) LEP energy-calibration uncertainties, and
- (b) the theoretical uncertainties in (i) the luminosity determination using small angle Bhabha scattering, (ii) estimating the non- $s$  channel contribution to large angle Bhabha scattering, (iii) the calculation of QED radiative effects, and (iv) the parametrization of the cross section in terms of the parameter set used.

#### Common LEP energy errors

All the collaborations incorporate in their fit the full LEP energy error matrix as provided by the LEP energy group for their intersection region [18]. The effect of these errors is separated out from that of other errors by carrying out fits with energy errors scaled up and down by  $\sim 10\%$  and redoing the fits. From the observed changes in the overall error matrix, the covariance matrix of the common energy errors is determined. Common LEP energy errors lead to uncertainties on  $M_Z$ ,  $\Gamma_Z$ , and  $\sigma_{\text{hadron}}^0$  of 1.7, 1.2 MeV, and 0.011 nb, respectively.

#### Common luminosity errors

BHLUMI 4.04 [25] is used by all LEP collaborations for small-angle Bhabha scattering leading to a common uncertainty in their measured cross sections of 0.061% [26]. BHLUMI does not include a correction for production of light fermion pairs. OPAL explicitly corrects for this effect and reduces their luminosity uncertainty to 0.054%, which is taken fully correlated with the other experiments. The other three experiments among themselves have a common uncertainty of 0.061%.

#### Common non- $s$ channel uncertainties

The same standard model programs ALIBABA [16] and TOPAZ0 [17] are used to calculate the non- $s$  channel contribution to the large angle Bhabha scattering [27]. As this contribution is a function of the  $Z$  mass, which itself is a variable in the fit, it is parametrized as a function of  $M_Z$  by each collaboration to properly track this contribution as  $M_Z$  varies in the fit. The common errors on  $R_e$  and  $A_{FB}^{(0,e)}$  are 0.024 and 0.0014 respectively, and are correlated between them.

#### Common theoretical uncertainties: QED

There are large initial-state photon and fermion pair radiation effects near the  $Z$  resonance, for which the best currently available evaluations include contributions up to  $\mathcal{O}(\alpha^3)$ . To

estimate the remaining uncertainties, different schemes are incorporated in the standard model programs ZFITTER [5], TOPAZ0 [17], and MIZA [28]. Comparing the different options leads to error estimates of 0.3 and 0.2 MeV on  $M_Z$  and  $\Gamma_Z$  respectively, and of 0.02% on  $\sigma_{\text{hadron}}^0$ .

#### Common theoretical uncertainties: parametrization of lineshape and asymmetries

To estimate uncertainties arising from ambiguities in the model-independent parametrization of the differential cross-section near the  $Z$  resonance, results from TOPAZ0 and ZFITTER were compared by using ZFITTER to fit the cross sections and asymmetries calculated using TOPAZ0. The resulting uncertainties on  $M_Z$ ,  $\Gamma_Z$ ,  $\sigma_{\text{hadron}}^0$ ,  $R(\text{lepton})$ , and  $A_{FB}^{(0,\ell)}$  are 0.1 MeV, 0.1 MeV, 0.001 nb, 0.004, and 0.0001 respectively.

Thus, the overall theoretical errors on  $M_Z$ ,  $\Gamma_Z$ ,  $\sigma_{\text{hadron}}^0$  are 0.3 MeV, 0.2 MeV, and 0.008 nb respectively; on each  $R(\text{lepton})$  is 0.004 and on each  $A_{FB}^{(0,\ell)}$  is 0.0001. Within the set of three  $R(\text{lepton})$ 's and the set of three  $A_{FB}^{(0,\ell)}$ 's, the respective errors are fully correlated.

All the theory-related errors mentioned above utilize Standard Model programs which need the Higgs mass and running electromagnetic coupling constant as inputs; uncertainties on these inputs will also lead to common errors. All LEP collaborations used the same set of inputs for Standard Model calculations:  $M_Z = 91.187$  GeV, the Fermi constant  $G_F = (1.16637 \pm 0.00001) \times 10^{-5} \text{ GeV}^{-2}$  [29],  $\alpha^{(5)}(M_Z) = 1/128.877 \pm 0.090$  [30],  $\alpha_s(M_Z) = 0.119$  [31],  $M_{\text{top}} = 174.3 \pm 5.1$  GeV [31] and  $M_{\text{Higgs}} = 150$  GeV. The only observable effect, on  $M_Z$ , is due to the variation of  $M_{\text{Higgs}}$  between 100–1000 GeV (due to the variation of the  $\gamma/Z$  interference term which is taken from the Standard Model):  $M_Z$  changes by +0.23 MeV per unit change in  $\log_{10} M_{\text{Higgs}}/\text{GeV}$ , which is not an error but a correction to be applied once  $M_{\text{Higgs}}$  is determined. The effect is much smaller than the error on  $M_Z$  ( $\pm 2.1$  MeV).

#### Methodology of combining the LEP experimental results

The LEP experimental results actually used for combination are slightly modified from those published by the experiments (which are given in the Listings below). This has been done in order to facilitate the procedure by making the inputs more consistent. These modified results are given explicitly in [24]. The main differences compared to the published results are (a) consistent use of ZFITTER 6.23 and TOPAZ0 (the published ALEPH results used ZFITTER 6.10); (b) use of the combined energy-error matrix, which makes a difference of 0.1 MeV on the  $M_Z$  and  $\Gamma_Z$  for L3 only as at that intersection the RF modeling uncertainties are the largest.

Thus, nine-parameter sets from all four experiments with their covariance matrices are used together with all the common errors correlations. A grand covariance matrix,  $V$ , is constructed and a combined nine-parameter set is obtained by minimizing  $\chi^2 = \Delta^T V^{-1} \Delta$ , where  $\Delta$  is the vector of residuals of the combined parameter set to the results of individual

# Gauge & Higgs Boson Particle Listings

## Z

experiments. Imposing lepton universality in the combination results in the combined five parameter set.

### Study of $Z \rightarrow b\bar{b}$ and $Z \rightarrow c\bar{c}$

In the sector of  $c$ - and  $b$ -physics, the LEP experiments have measured the ratios of partial widths  $R_b = \Gamma(Z \rightarrow b\bar{b})/\Gamma(Z \rightarrow \text{hadrons})$ , and  $R_c = \Gamma(Z \rightarrow c\bar{c})/\Gamma(Z \rightarrow \text{hadrons})$ , and the forward-backward (charge) asymmetries  $A_{FB}^{b\bar{b}}$  and  $A_{FB}^{c\bar{c}}$ . The SLD experiment at SLC has measured the ratios  $R_c$  and  $R_b$  and, utilizing the polarization of the electron beam, was able to obtain the final state coupling parameters  $A_b$  and  $A_c$  from a measurement of the left-right forward-backward asymmetry of  $b$ - and  $c$ -quarks. The high precision measurement of  $R_c$  at SLD was made possible owing to the small beam size and very stable beam spot at SLC, coupled with a highly precise CCD pixel detector. Several of the analyses have also determined other quantities, in particular the semileptonic branching ratios,  $B(b \rightarrow \ell^-)$ ,  $B(b \rightarrow c \rightarrow \ell^+)$ , and  $B(c \rightarrow \ell^+)$ , the average time-integrated  $B^0\bar{B}^0$  mixing parameter  $\bar{\chi}$  and the probabilities for a  $c$ -quark to fragment into a  $D^+$ , a  $D_s$ , a  $D^{*+}$ , or a charmed baryon. The latter measurements do not concern properties of the  $Z$  boson, and hence they do not appear in the Listing below. However, for completeness, we will report at the end of this minireview their values as obtained fitting the data contained in the  $Z$  section. All these quantities are correlated with the electroweak parameters, and since the mixture of  $b$  hadrons is different from the one at the  $\Upsilon(4S)$ , their values might differ from those measured at the  $\Upsilon(4S)$ .

All the above quantities are correlated to each other since:

- Several analyses (for example the lepton fits) determine more than one parameter simultaneously;
- Some of the electroweak parameters depend explicitly on the values of other parameters (for example  $R_b$  depends on  $R_c$ );
- Common tagging and analysis techniques produce common systematic uncertainties.

The LEP Electroweak Heavy Flavour Working Group has developed [32] a procedure for combining the measurements taking into account known sources of correlation. The combining procedure determines fourteen parameters: the six parameters of interest in the electroweak sector,  $R_b$ ,  $R_c$ ,  $A_{FB}^{b\bar{b}}$ ,  $A_{FB}^{c\bar{c}}$ ,  $A_b$  and  $A_c$  and, in addition,  $B(b \rightarrow \ell^-)$ ,  $B(b \rightarrow c \rightarrow \ell^+)$ ,  $B(c \rightarrow \ell^+)$ ,  $\bar{\chi}$ ,  $f(D^+)$ ,  $f(D_s)$ ,  $f(c_{\text{baryon}})$  and  $P(c \rightarrow D^{*+}) \times B(D^{*+} \rightarrow \pi^+ D^0)$ , to take into account their correlations with the electroweak parameters. Before the fit both the peak and off-peak asymmetries are translated to the common energy  $\sqrt{s} = 91.26$  GeV using the predicted energy-dependence from ZFITTER [5].

### Summary of the measurements and of the various kinds of analysis

The measurements of  $R_b$  and  $R_c$  fall into two classes. In the first, named single-tag measurement, a method for selecting  $b$  and  $c$  events is applied and the number of tagged events is counted. A second technique, named double-tag measurement,

has the advantage that the tagging efficiency is directly derived from the data thereby reducing the systematic error on the measurement.

The measurements in the  $b$ - and  $c$ -sector can be essentially grouped in the following categories:

- Lifetime (and lepton) double-tagging measurements of  $R_b$ . These are the most precise measurements of  $R_b$  and obviously dominate the combined result. The main sources of systematics come from the charm contamination and from estimating the hemisphere  $b$ -tagging efficiency correlation;
- Analyses with  $D/D^{*\pm}$  to measure  $R_c$ . These measurements make use of several different tagging techniques (inclusive/exclusive double tag, exclusive double tag, reconstruction of all weakly decaying charmed states) and no assumptions are made on the energy-dependence of charm fragmentation;
- A measurement of  $R_c$  using single leptons and assuming  $B(b \rightarrow c \rightarrow \ell^+)$ ;
- Lepton fits which use hadronic events with one or more leptons in the final state to measure the asymmetries  $A_{FB}^{b\bar{b}}$  and  $A_{FB}^{c\bar{c}}$ . Each analysis usually gives several other electroweak parameters. The dominant sources of systematics are due to lepton identification, to other semileptonic branching ratios and to the modeling of the semileptonic decay;
- Measurements of  $A_{FB}^{b\bar{b}}$  using lifetime tagged events with a hemisphere charge measurement. These measurements dominate the combined result;
- Analyses with  $D/D^{*\pm}$  to measure  $A_{FB}^{c\bar{c}}$  or simultaneously  $A_{FB}^{b\bar{b}}$  and  $A_{FB}^{c\bar{c}}$ ;
- Measurements of  $A_b$  and  $A_c$  from SLD, using several tagging methods (lepton, kaon,  $D/D^*$ , and vertex mass). These quantities are directly extracted from a measurement of the left-right forward-backward asymmetry in  $c\bar{c}$  and  $b\bar{b}$  production using a polarized electron beam.

### Averaging procedure

All the measurements are provided by the LEP and SLD Collaborations in the form of tables with a detailed breakdown of the systematic errors of each measurement and its dependence on other electroweak parameters.

The averaging proceeds via the following steps:

- Define and propagate a consistent set of external inputs such as branching ratios, hadron lifetimes, fragmentation models *etc.* All the measurements are checked to ensure that all use a common set of assumptions (for instance, since the QCD corrections for the forward-backward asymmetries are strongly dependent on the experimental conditions, the data are corrected before combining);

- Form the full (statistical and systematic) covariance matrix of the measurements. The systematic correlations between different analyses are calculated from the detailed error breakdown in the measurement tables. The correlations relating several measurements made by the same analysis are also used;
- Take into account any explicit dependence of a measurement on the other electroweak parameters. As an example of this dependence, we illustrate the case of the double-tag measurement of  $R_b$ , where  $c$ -quarks constitute the main background. The normalization of the charm contribution is not usually fixed by the data and the measurement of  $R_b$  depends on the assumed value of  $R_c$ , which can be written as:

$$R_b = R_b^{\text{meas}} + a(R_c) \frac{(R_c - R_c^{\text{used}})}{R_c}, \quad (11)$$

where  $R_b^{\text{meas}}$  is the result of the analysis which assumed a value of  $R_c = R_c^{\text{used}}$  and  $a(R_c)$  is the constant which gives the dependence on  $R_c$ ;

- Perform a  $\chi^2$  minimization with respect to the combined electroweak parameters.

After the fit the average peak asymmetries  $A_{FB}^{c\bar{c}}$  and  $A_{FB}^{b\bar{b}}$  are corrected for the energy shift from 91.26 GeV to  $M_Z$  and for QED (initial state radiation),  $\gamma$  exchange, and  $\gamma Z$  interference effects, to obtain the corresponding pole asymmetries  $A_{FB}^{0,c}$  and  $A_{FB}^{0,b}$ .

This averaging procedure, using the fourteen parameters described above, and applied to the data contained in the Z particle listing below, gives the following results (where the last 8 parameters do not depend directly on the Z):

$$R_b^0 = 0.21629 \pm 0.00066$$

$$R_c^0 = 0.1721 \pm 0.0030$$

$$A_{FB}^{0,b} = 0.0992 \pm 0.0016$$

$$A_{FB}^{0,c} = 0.0707 \pm 0.0035$$

$$A_b = 0.923 \pm 0.020$$

$$A_c = 0.670 \pm 0.027$$

$$B(b \rightarrow \ell^-) = 0.1071 \pm 0.0022$$

$$B(b \rightarrow c \rightarrow \ell^+) = 0.0801 \pm 0.0018$$

$$B(c \rightarrow \ell^+) = 0.0969 \pm 0.0031$$

$$\bar{\chi} = 0.1250 \pm 0.0039$$

$$f(D^+) = 0.235 \pm 0.016$$

$$f(D_s) = 0.126 \pm 0.026$$

$$f(c_{\text{baryon}}) = 0.093 \pm 0.022$$

$$P(c \rightarrow D^{*+}) \times B(D^{*+} \rightarrow \pi^+ D^0) = 0.1622 \pm 0.0048$$

Among the non-electroweak observables, the B semileptonic branching fraction  $B(b \rightarrow \ell^-)$  is of special interest, since the dominant error source on this quantity is the dependence on the semileptonic decay model for  $b \rightarrow \ell^-$ , with  $\Delta B(b \rightarrow \ell^-)_{b \rightarrow \ell^- \text{ model}} = 0.0012$ . Extensive studies have been made to understand the size of this error. Among the electroweak quantities, the quark asymmetries with leptons depend also on the semileptonic decay model, while the asymmetries using other methods usually do not. The fit implicitly requires that the different methods give consistent results and this effectively constrains the decay model, and thus reduces in principle the error from this source in the fit result.

To obtain a conservative estimate of the modelling error, the above fit has been repeated removing all asymmetry measurements. The results of the fit on B-decay related observables are [24]:  $B(b \rightarrow \ell^-) = 0.1069 \pm 0.0022$ , with  $\Delta B(b \rightarrow \ell^-)_{b \rightarrow \ell^- \text{ model}} = 0.0013$ ,  $B(b \rightarrow c \rightarrow \ell^+) = 0.0802 \pm 0.0019$  and  $\bar{\chi} = 0.1259 \pm 0.0042$ .

### Z MASS

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The Z-boson mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass dependent width. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the  $\gamma - Z$  interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 00q and ABBIENDI 04g for a detailed investigation of both these issues.

VALUE (GeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>91.1876 ± 0.0021 OUR FIT</b>

• • • We do not use the following data for averages, fits, limits, etc. • • •

91.1872 ± 0.0033		<sup>5</sup> ABBIENDI	04G OPAL	$E_{\text{cm}}^{\text{ee}} = \text{LEP1} +$ $130-209$ GeV
91.272 ± 0.032 ± 0.033		<sup>6</sup> ACHARD	04c L3	$E_{\text{cm}}^{\text{ee}} = 183-209$ GeV
91.1875 ± 0.0039	3.97M	<sup>7</sup> ACCIARRI	00Q L3	$E_{\text{cm}}^{\text{ee}} = \text{LEP1} +$ $130-189$ GeV
91.151 ± 0.008		<sup>8</sup> MIYABAYASHI	95 TOPZ	$E_{\text{cm}}^{\text{ee}} = 57.8$ GeV
91.74 ± 0.28 ± 0.93	156	<sup>9</sup> ALITTI	92B UA2	$E_{\text{cm}}^{\text{e}\bar{\text{e}}} = 630$ GeV
90.9 ± 0.3 ± 0.2	188	<sup>10</sup> ABE	89c CDF	$E_{\text{cm}}^{\text{e}\bar{\text{e}}} = 1.8$ TeV
91.14 ± 0.12	480	<sup>11</sup> ABRAMS	89B MRK2	$E_{\text{cm}}^{\text{e}\bar{\text{e}}} = 89-93$ GeV
93.1 ± 1.0 ± 3.0	24	<sup>12</sup> ALBAJAR	89 UA1	$E_{\text{cm}}^{\text{e}\bar{\text{e}}} = 546,630$ GeV

- <sup>1</sup> ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty.
- <sup>2</sup> The error includes 1.6 MeV due to LEP energy uncertainty.
- <sup>3</sup> The error includes 1.8 MeV due to LEP energy uncertainty.
- <sup>4</sup> BARATE 00c error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty.
- <sup>5</sup> ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit-Wigner fits.
- <sup>6</sup> ACHARD 04c select  $e^+e^- \rightarrow Z\gamma$  events with hard initial-state radiation. Z decays to  $q\bar{q}$  and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.
- <sup>7</sup> ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00c) as constraints. The 130–189 GeV data constrains the  $\gamma/Z$  interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of  $\pm 2.3$  MeV due to the uncertainty on the  $\gamma Z$  interference.
- <sup>8</sup> MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.
- <sup>9</sup> Enters fit through  $W/Z$  mass ratio given in the W Particle Listings. The ALITTI 92B systematic error ( $\pm 0.93$ ) has two contributions: one ( $\pm 0.92$ ) cancels in  $m_W/m_Z$  and one ( $\pm 0.12$ ) is noncancelling. These were added in quadrature.
- <sup>10</sup> First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
- <sup>11</sup> ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
- <sup>12</sup> ALBAJAR 89 result is from a total sample of  $33 Z \rightarrow e^+e^-$  events.

### Z WIDTH

# Gauge & Higgs Boson Particle Listings

## Z

<sup>10</sup> Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either  $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$ , CL = 90% or  $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$ . Assuming Standard-Model value  $\Gamma(W) = 2.65$  GeV then gives  $\Gamma(Z) < 2.89 \pm 0.19$  or  $= 2.17^{+0.50}_{-0.37} \pm 0.16$ .

[a]  $\ell$  indicates each type of lepton ( $e$ ,  $\mu$ , and  $\tau$ ), not sum over them.

[b] Here  $\ell$  indicates  $e$  or  $\mu$ .

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] This value is updated using the product of (i) the  $Z \rightarrow b\bar{b}$  fraction from this listing and (ii) the  $b$ -hadron fraction in an unbiased sample of weakly decaying  $b$ -hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFAG, [http://www.slac.stanford.edu/xorg/hfag/osc/PDG\\_2009/#FRACZ](http://www.slac.stanford.edu/xorg/hfag/osc/PDG_2009/#FRACZ)).

[e] See the Particle Listings below for the  $\gamma$  energy range used in this measurement.

[f] For  $m_{\gamma\gamma} = (60 \pm 5)$  GeV.

### Z PARTIAL WIDTHS

#### $\Gamma(e^+ e^-)$

$\Gamma_1$

For the LEP experiments, this parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>83.91 <math>\pm</math> 0.12 OUR FIT</b>

• • • We do not use the following data for averages, fits, limits, etc. • • •			
0.1623 ± 0.0085 ± 0.0209	<sup>6</sup> ABREU	95D	DLPH $E_{\text{cm}}^{\text{ee}} = 88\text{--}94$ GeV

<sup>1</sup> ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of  $c\bar{c}$  events using a double tag method. The single  $c$ -tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and  $R_C$  is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of  $\pm 0.0006$  due to the uncertainty on  $R_b$ .

<sup>2</sup> ABREU 00 obtain this result properly combining the measurement from the  $D^{*+}$  production rate ( $R_C = 0.1610 \pm 0.0104 \pm 0.0077 \pm 0.0043$  (BR)) with that from the overall charm counting ( $R_C = 0.1692 \pm 0.0047 \pm 0.0063 \pm 0.0074$  (BR)) in  $c\bar{c}$  events. The systematic error includes an uncertainty of  $\pm 0.0054$  due to the uncertainty on the charmed hadron branching fractions.

<sup>3</sup> BARATE 00B use exclusive decay modes to independently determine the quantities  $R_C \times f(c \rightarrow X)$ ,  $X = D^0$ ,  $D^+$ ,  $D_s^+$ , and  $\Lambda_c$ . Estimating  $R_C \times f(c \rightarrow \Xi_c^-/\Omega_c^-) = 0.0034$ , they simply sum over all the charm decays to obtain  $R_C = 0.1738 \pm 0.0047 \pm 0.0088 \pm 0.0075$  (BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G,  $R_C = 0.1681 \pm 0.0054 \pm 0.0062$ ) to obtain the quoted value.

<sup>4</sup> ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet  $D^{*\pm}$  mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive  $D^{*\pm}$ ) tag is used. The  $b$  content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed  $D^{*\pm}$  meson in the opposite jet. The systematic error includes an uncertainty of  $\pm 0.006$  due to the external branching ratios.

<sup>5</sup> ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from  $D^0$ ,  $D^+$ ,  $D_s^+$ , and  $\Lambda_c^+$ , and assuming that strange-charmed baryons account for the 15% of the  $\Lambda_c^+$  production. An uncertainty of  $\pm 0.005$  due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

<sup>6</sup> ABREU 95D perform a maximum likelihood fit to the combined  $p$  and  $p_T$  distributions of single and dilepton samples. The second error includes an uncertainty of  $\pm 0.0124$  due to models and branching ratios.

 $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$  $\Gamma_{11}/\Gamma_7$ 

OUR FIT is obtained by a simultaneous fit to several  $c$ - and  $b$ -quark measurements as explained in the note “The Z boson” and ref. LEP-SLC 06.

The Standard Model predicts  $R_b = 0.21581$  for  $m_t = 174.3$  GeV and  $M_H = 150$  GeV.

<sup>1</sup> ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of  $b\bar{b}$  events using a double tag method. The single  $b$ -tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the  $D$ -meson mass). ABE 05F obtain  $R_b = 0.21604 \pm 0.00098 \pm 0.00074$  where the systematic error includes an uncertainty of  $\pm 0.00012$  due to the uncertainty on  $R_C$ . The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of  $\pm 0.00012$  due to the uncertainty on  $R_C$ .

<sup>2</sup> ACCIARRI 00 obtain this result using a double-tagging technique, with a high  $p_T$  lepton tag and an impact parameter tag in opposite hemispheres.

<sup>3</sup> ABBIENDI 99B tag  $Z \rightarrow b\bar{b}$  decays using leptons and/or separated decay vertices. The  $b$ -tagging efficiency is measured directly from the data using a double-tagging technique.

<sup>4</sup> ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For  $R_C$  different from its Standard Model value of 0.172,  $R_b$  varies as  $-0.024 \times (R_C - 0.172)$ .

<sup>5</sup> BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify  $Z \rightarrow b\bar{b}$  candidates. They further use  $c$ - and  $u$  $d$ -selection tags to identify the background. For  $R_C$  different from its Standard Model value of 0.172,  $R_b$  varies as  $-0.019 \times (R_C - 0.172)$ .

<sup>6</sup> ABREU 95D perform a maximum likelihood fit to the combined  $p$  and  $p_T$  distributions of single and dilepton samples. The second error includes an uncertainty of  $\pm 0.0023$  due to models and branching ratios.

<sup>7</sup> BUSKULIC 94G perform a simultaneous fit to the  $p$  and  $p_T$  spectra of both single and dilepton events.

<sup>8</sup> JACOBSEN 91 tagged  $b\bar{b}$  events by requiring coincidence of  $\geq 3$  tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties ( $\pm 0.014$ ).

 $\Gamma(b\bar{b}b\bar{b})/\Gamma(\text{hadrons})$  $\Gamma_{12}/\Gamma_7$

seen	<sup>1</sup> ABDALLAH 05C	DLPH	$E_{\text{cm}}^{\text{ee}} = 88\text{--}94$ GeV

<sup>1</sup> ABDALLAH 05C searched for the charmed strange baryon  $\Xi_c^0$  in the decay channel  $\Xi_c^0 \rightarrow \Xi^- \pi^+$  ( $\Xi^- \rightarrow \Lambda \pi^-$ ). The production rate is measured to be  $f_{\Xi_c^0} \times B(\Xi_c^0 \rightarrow \Xi^- \pi^+) = (4.7 \pm 1.4 \pm 1.1) \times 10^{-4}$  per hadronic  $Z$  decay.

 $\Gamma(\Xi_b X)/\Gamma(\text{hadrons})$  $\Gamma_{45}/\Gamma_7$ 

Here  $\Xi_b$  is used as a notation for the strange  $b$ -baryon states  $\Xi_b^-$  and  $\Xi_b^0$ .

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
seen	<sup>1</sup> ABDALLAH 05C	DLPH	$E_{\text{cm}}^{\text{ee}} = 88\text{--}94$ GeV
seen	<sup>2</sup> BUSKULIC 96T	ALEP	$E_{\text{cm}}^{\text{ee}} = 88\text{--}94$ GeV
seen	<sup>3</sup> ABREU 95V	DLPH	$E_{\text{cm}}^{\text{ee}} = 88\text{--}94$ GeV

<sup>1</sup> ABDALLAH 05C searched for the beauty strange baryon  $\Xi_b$  in the inclusive semileptonic decay channel  $\Xi_b \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X$ . Evidence for the  $\Xi_b$  production is seen from the observation of  $\Xi^\mp$  production accompanied by a lepton of the same sign. From the excess of “right-sign” pairs  $\Xi^\mp \ell^\mp$  compared to “wrong-sign” pairs  $\Xi^\mp \ell^\pm$  the production rate is measured to be  $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X) = (3.0 \pm 1.0 \pm 0.3) \times 10^{-4}$  per lepton species, averaged over electrons and muons.

<sup>2</sup> BUSKULIC 96T investigate  $\Xi$ -lepton correlations and find a significant excess of “right-sign” pairs  $\Xi^\mp \ell^\mp$  compared to “wrong-sign” pairs  $\Xi^\mp \ell^\pm$ . This excess is interpreted as evidence for  $\Xi_b$  semileptonic decay. The measured product branching ratio is  $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow X_c X \ell^- \bar{\nu}_\ell) \times B(X_c \rightarrow \Xi^- X') = (5.4 \pm 1.1 \pm 0.8) \times 10^{-4}$  per lepton species, averaged over electrons and muons, with  $X_c$  a charmed baryon.

<sup>3</sup> ABREU 95V observe an excess of “right-sign” pairs  $\Xi^\mp \ell^\mp$  compared to “wrong-sign” pairs  $\Xi^\mp \ell^\pm$  in jets; this excess is interpreted as evidence for the beauty strange baryon  $\Xi_b$  production, with  $\Xi_b \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X$ . They find that the probability for this signal to come from non  $b$ -baryon decays is less than  $5 \times 10^{-4}$  and that  $\Lambda_b$  decays can account for less than 10% of these events. The  $\Xi_b$  production rate is then measured to be  $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X) = (5.9 \pm 2.1 \pm 1.0) \times 10^{-4}$  per lepton species, averaged over electrons and muons.

 $\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons})$  $\Gamma_{46}/\Gamma_7$ 

“OUR EVALUATION” is obtained using our current values for  $f(b \rightarrow b\text{-baryon})$  and  $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$ . We calculate  $\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons}) = R_b \times f(b \rightarrow b\text{-baryon})$ . The decay fraction  $f(b \rightarrow b\text{-baryon})$  was provided by the Heavy Flavor Averaging Group (HFAG, [http://www.slac.stanford.edu/xorg/hfag/osc/PDG\\_2009](http://www.slac.stanford.edu/xorg/hfag/osc/PDG_2009)).

## Z HADRONIC POLE CROSS SECTION

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

## Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters,  $A_e$ ,  $A_\mu$ , and  $A_\tau$ . By convention the sign of  $g_A^e$  is fixed to be negative (and opposite to that of  $g_V^e$  obtained using  $\nu_e$  scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and  $A_e$ ,  $A_\mu$ , and  $A_\tau$  measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where  $p\bar{p}$  and  $e p$  data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.528 ± 0.085</b>	<sup>1</sup> VILAIN	94	CHM2 From $\nu_\mu e$ and $\nu_e e$ scattering

<sup>1</sup> VILAIN 94 derive this value from their value of  $g^{\nu \mu}$  and their ratio  $g^{\nu e}/g^{\nu \mu} = 1.05^{+0.15}_{-0.18}$ .

#### $g^{\nu \mu}$

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.502 ± 0.017</b>	<sup>1</sup> VILAIN	94	CHM2 From $\nu_\mu e$ scattering

<sup>1</sup> VILAIN 94 derive this value from their measurement of the couplings  $g_A^{\nu \mu} = -0.503 \pm 0.017$  and  $g_V^{\nu \mu} = -0.035 \pm 0.017$  obtained from  $\nu_\mu e$  scattering. We have re-evaluated this value using the current PDG values for  $g_A^e$  and  $g_V^e$ .

### Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where  $g_V^f$  and  $g_A^f$  are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The Z boson" and ref. LEP-SLC 06.

#### $A_e$

Using polarized beams, this quantity can also be measured as  $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$ , where  $\sigma_L$  and  $\sigma_R$  are the  $e^+e^-$  production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of  $c\bar{c}$  events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying c-quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (9970 events)  $A_c = 0.6747 \pm 0.0290 \pm 0.0233$ . Taking into account all correlations with earlier results reported in ABE 02G and ABE 01c, they obtain the quoted overall SLD result.

<sup>2</sup> ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously  $A_b$  and  $A_c$ .

<sup>3</sup> ABE 01c tag  $Z \rightarrow c\bar{c}$  events using two techniques: exclusive reconstruction of  $D^{*+}$ ,  $D^+$  and  $D^0$  mesons and the soft pion tag for  $D^{*+} \rightarrow D^0\pi^+$ . The large background from D mesons produced in  $b\bar{b}$  events is separated efficiently from the signal using precision vertex information. When combining the  $A_c$  values from these two samples, care is taken to avoid double counting of events common to the two samples, and common systematic errors are properly taken into account.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.907 ± 0.020 ± 0.024	48028	<sup>2</sup> ABE 03f	SLD	$E_{\text{cm}}^{\text{ee}} = 91.24$ GeV
0.919 ± 0.030 ± 0.024		<sup>3</sup> ABE 02g	SLD	$E_{\text{cm}}^{\text{ee}} = 91.24$ GeV
0.855 ± 0.088 ± 0.102	7473	<sup>4</sup> ABE 99L	SLD	$E_{\text{cm}}^{\text{ee}} = 91.27$ GeV

<sup>1</sup> ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of  $b\bar{b}$  events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying  $b$ -quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events)  $A_b = 0.9173 \pm 0.0184 \pm 0.0173$ . Taking into account all correlations with earlier results reported in ABE 03f, ABE 02g and ABE 99L, they obtain the quoted overall SLD result.

<sup>2</sup> ABE 03f obtain an enriched sample of  $b\bar{b}$  events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying  $b$  quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure  $A_b = 0.906 \pm 0.022 \pm 0.023$ . The value quoted here is obtained combining the above with the result of ABE 98i (1993–1995 data sample).

<sup>3</sup> ABE 02g tag  $b$  and  $c$  quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously  $A_b$  and  $A_c$ .

<sup>4</sup> ABE 99L obtain an enriched sample of  $b\bar{b}$  events tagging with an inclusive vertex mass cut. For distinguishing  $b$  and  $\bar{b}$  quarks they use the charge of identified  $K^\pm$ .

### TRANSVERSE SPIN CORRELATIONS IN $Z \rightarrow \tau^+ \tau^-$

The correlations between the transverse spin components of  $\tau^+ \tau^-$  produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

$$C_{TN} = -2 \frac{|g_A^\tau| |g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2} \sin(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

$C_{TT}$  refers to the transverse-transverse (within the collision plane) spin correlation and  $C_{TN}$  refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal  $\tau$  polarization  $P_\tau$  ( $= -A_\tau$ ) is given by:

$$P_\tau = -2 \frac{|g_A^\tau| |g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2} \cos(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

Here  $\Phi$  is the phase and the phase difference  $\Phi_{g_V^\tau} - \Phi_{g_A^\tau}$  can be obtained using both the measurements of  $C_{TN}$  and  $P_\tau$ .

### $C_{TT}$

### FORWARD-BACKWARD $e^+ e^- \rightarrow f \bar{f}$ CHARGE ASYMMETRIES

These asymmetries are experimentally determined by tagging the respective lepton or quark flavor in  $e^+ e^-$  interactions. Details of heavy flavor ( $c$ - or  $b$ -quark) tagging at LEP are described in the note on "The Z boson" and ref. LEP-SLC 06. The Standard Model predictions for LEP data have been (re)computed using the ZFITTER package (version 6.36) with input parameters  $M_Z = 91.187$  GeV,  $M_{\text{top}} = 174.3$  GeV,  $M_{\text{Higgs}} = 150$  GeV,  $\alpha_s = 0.119$ ,  $\alpha^{(5)}$  ( $M_Z$ ) =  $1/128.877$  and the Fermi constant  $G_F = 1.16637 \times 10^{-5} \text{ GeV}^{-2}$  (see the note on "The Z boson" for references). For non-LEP data the Standard Model predictions are as given by the authors of the respective publications.

### $A_{\text{FB}}^{(0,e)}$ CHARGE ASYMMETRY IN $e^+ e^- \rightarrow e^+ e^-$

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). For the Z peak, we report the pole asymmetry defined by  $(3/4)A_e^2$  as determined by the nine-parameter fit to cross-section and lepton forward-backward asymmetry data.

<sup>1</sup> ABBIENDI 01a error includes approximately 0.26 due to statistics and 0.14 due to event selection systematics.

<sup>2</sup> BARATE 00c error includes approximately 0.26 due to statistics and 0.11 due to experimental systematics.

<sup>3</sup> ABE 90i measurements in the range  $50 \leq \sqrt{s} \leq 60.8$  GeV.

<sup>4</sup> BACALA 89 systematic error is about 5%.

### $A_{FB}^{(0,\ell)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow \ell^+\ell^-$

For the Z peak, we report the pole asymmetry defined by  $(3/4)A_{FB}^2$  as determined by the five-parameter fit to cross-section and lepton forward-backward asymmetry data assuming lepton universality. For details see the note "The Z boson" and ref. LEP-SLC 06.

<b><math>4.0 \pm 6.7 \pm 2.8</math></b>	<b>7.2</b>	<b>91.2</b>	<sup>1</sup> ACKERSTAFF 97t	OPAL

<sup>1</sup> ACKERSTAFF 97t measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types.

### $A_{FB}^{(0,s)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow s\bar{s}$

The  $s$ -quark asymmetry is derived from measurements of the forward-backward asymmetry of fast hadrons containing an  $s$  quark.

ASYMMETRY (%)	STD. MODEL	$\sqrt{s}$ (GeV)	DOCUMENT ID	TECN
<b><math>9.8 \pm 1.1</math> OUR AVERAGE</b>				
$10.08 \pm 1.13 \pm 0.40$	10.1	91.2	<sup>1</sup> ABREU 00b	DLPH
$6.8 \pm 3.5 \pm 1.1$	10.1	91.2	<sup>2</sup> ACKERSTAFF 97t	OPAL

<sup>1</sup> ABREU 00b tag the presence of an  $s$  quark requiring a high-momentum-identified charged kaon. The  $s$ -quark pole asymmetry is extracted from the charged-kaon asymmetry taking the expected  $d$ - and  $u$ -quark asymmetries from the Standard Model and using the measured values for the  $c$ - and  $b$ -quark asymmetries.

<sup>2</sup> ACKERSTAFF 97t measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types. The value reported here corresponds then to the forward-backward asymmetry for "down-type" quarks.

### $A_{FB}^{(0,c)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow c\bar{c}$

OUR FIT, which is obtained by a simultaneous fit to several  $c$ - and  $b$ -quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06, refers to the **Z pole** asymmetry. The experimental values, on the other hand, correspond to the measurements carried out at the respective energies.

<sup>1</sup> ABDALLAH 05 obtain an enriched samples of  $b\bar{b}$  events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.

<sup>2</sup> ABDALLAH 04F tag  $b$ - and  $c$ -quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of  $c\bar{c}$  and  $b\bar{b}$  events are obtained using lifetime information.

<sup>3</sup> ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the  $b$  and  $c$  quark forward-backward asymmetries as well as the average  $B^0\text{-}\bar{B}^0$  mixing.

<sup>4</sup> ABBIENDI 02i tag  $Z^0 \rightarrow b\bar{b}$  decays using a combination of secondary vertex and lepton tags. The sign of the  $b$ -quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.

<sup>5</sup> HEISTER 02H measure simultaneously  $b$  and  $c$  quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

<sup>6</sup> HEISTER 01D tag  $Z \rightarrow b\bar{b}$  events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The  $b$ -quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of  $A_{FB}^e$  and  $R_b$  is given as  $+0.103 (A_{FB}^e - 0.0651) - 0.440 (R_b - 0.21585)$ .

<sup>7</sup> ABREU 99Y tag  $Z \rightarrow b\bar{b}$  and  $Z \rightarrow c\bar{c}$  events by an exclusive reconstruction of several  $D$  meson decay modes ( $D^{*+}$ ,  $D^0$ , and  $D^+$  with their charge-conjugate states).

<sup>8</sup> ACCIARRI 99D tag  $Z \rightarrow b\bar{b}$  events using high  $p$  and  $p_T$  leptons. The analysis determines simultaneously a mixing parameter  $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$  which is used to correct the observed asymmetry.

<sup>9</sup> ACCIARRI 98U tag  $Z \rightarrow b\bar{b}$  events using lifetime and measure the jet charge using the hemisphere charge.

<sup>10</sup> ALEXANDER 97C identify the  $b$  and  $c$  events using a  $D/D^*$  tag.

### CHARGE ASYMMETRY IN $e^+e^- \rightarrow q\bar{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on  $B^0\text{-}\bar{B}^0$  mixing and on other electroweak parameters.

### ANOMALOUS $ZZ\gamma$ , $Z\gamma\gamma$ , AND $ZZV$ COUPLINGS

### ANOMALOUS $ZZ\gamma$ , $Z\gamma\gamma$ , AND $ZZV$ COUPLINGS

Revised September 2013 by M.W. Grünewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell  $Z\gamma$  production, deviations from the Standard Model for the  $Z\gamma\gamma^*$  and  $Z\gamma Z^*$  couplings may be described in terms of eight parameters,  $h_i^V$  ( $i = 1, 4$ ;  $V = \gamma, Z$ ) [1]. The

parameters  $h_i^\gamma$  describe the  $Z\gamma\gamma^*$  couplings and the parameters  $h_i^Z$  the  $Z\gamma Z^*$  couplings. In this formalism  $h_1^V$  and  $h_2^V$  lead to  $CP$ -violating and  $h_3^V$  and  $h_4^V$  to  $CP$ -conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation,  $h_i^V(s) = h_{i0}^V/(1 + s/\Lambda^2)^n$ , where  $\Lambda$  is the energy scale for the manifestation of a new phenomenon and  $n$  is a sufficiently large power. By convention one uses  $n = 3$  for  $h_{1,3}^V$  and  $n = 4$  for  $h_{2,4}^V$ . Usually limits on  $h_i^V$ 's are put assuming some value of  $\Lambda$ , sometimes  $\infty$ .

In on-shell  $ZZ$  production, deviations from the Standard Model for the  $ZZ\gamma^*$  and  $ZZZ^*$  couplings may be described by means of four anomalous couplings  $f_i^V$  ( $i = 4, 5$ ;  $V = \gamma, Z$ ) [2]. As above, the parameters  $f_i^\gamma$  describe the  $ZZ\gamma^*$  couplings and the parameters  $f_i^Z$  the  $ZZZ^*$  couplings. The anomalous couplings  $f_5^V$  lead to violation of  $C$  and  $P$  symmetries while  $f_4^V$  introduces  $CP$  violation. Also here, formfactors depending on a scale  $\Lambda$  are used.

All these couplings  $h_i^V$  and  $f_i^V$  are zero at tree level in the Standard Model; they are measured in  $e^+e^-$ ,  $p\bar{p}$  and  $pp$  collisions at LEP, Tevatron and LHC.

### $h_i^V$

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$\begin{aligned} -0.12 < h_1^Z < +0.11, & \quad -0.07 < h_2^Z < +0.07, \\ -0.19 < h_3^Z < +0.06, & \quad -0.04 < h_4^Z < +0.13, \\ -0.05 < h_1^\gamma < +0.05, & \quad -0.04 < h_2^\gamma < +0.02, \\ -0.05 < h_3^\gamma < +0.00, & \quad +0.01 < h_4^\gamma < +0.05. \end{aligned}$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

<sup>1</sup> KHACHATRYAN 15AC study  $Z\gamma$  events in 8 TeV  $pp$  interactions, where the  $Z$  decays into 2 same-flavor, opposite sign leptons ( $e$  or  $\mu$ ) and a photon with  $p_T > 15$  GeV. The  $p_T$  of a lepton is required to be  $> 20$  GeV/ $c$ , their effective mass  $> 50$  GeV, and the photon should have a separation  $\Delta R > 0.7$  with each lepton. The observed  $p_T$  distribution of the photons is used to extract the 95% C.L. limits:  $-3.8 \times 10^{-3} < h_3^Z < 3.7 \times 10^{-3}$ ,  $-3.1 \times 10^{-5} < h_4^Z < 3.0 \times 10^{-5}$ ,  $-4.6 \times 10^{-3} < h_3^\gamma < 4.6 \times 10^{-3}$ ,  $-3.6 \times 10^{-5} < h_4^\gamma < 3.5 \times 10^{-5}$ .

- <sup>2</sup> CHATRCHYAN 14AB measure  $Z\gamma$  production cross section for  $p_T^{\gamma} > 15$  GeV and  $R(\ell\gamma) > 0.7$ , which is the separation between the  $\gamma$  and the final state charged lepton ( $e$  or  $\mu$ ) in the azimuthal angle-pseudorapidity ( $\phi - \eta$ ) plane. The di-lepton mass is required to be  $> 50$  GeV. After background subtraction the number of  $e\bar{e}\gamma$  and  $\mu\bar{\mu}\gamma$  events is determined to be  $3160 \pm 120$  and  $5030 \pm 233$  respectively, compatible with expectations from the SM. This leads to a 95% CL limits of  $-1 \times 10^{-2} < h_3^Z < 1 \times 10^{-2}$ ,  $-9 \times 10^{-5} < h_4^Z < 9 \times 10^{-5}$ ,  $-9 \times 10^{-3} < h_5^Z < 9 \times 10^{-3}$ ,  $-8 \times 10^{-5} < h_4^Z < 8 \times 10^{-5}$ , assuming  $h_1^V$  and  $h_2^V$  have SM values,  $V = \gamma$  or  $Z$ .
- <sup>3</sup> AAD 13AN study  $Z\gamma$  production in  $pp$  collisions. In events with no additional jet, 1417 (2031)  $Z$  decays to electron (muon) pairs are selected, with an expected background of  $156 \pm 54$  ( $244 \pm 64$ ) events, as well as 662  $Z$  decays to neutrino pairs with an expected background of  $302 \pm 42$  events. Analysing the photon  $p_T$  spectrum above 100 GeV yields the 95% C.L. limits:  $-0.013 < h_3^Z < 0.014$ ,  $-8.7 \times 10^{-5} < h_4^Z < 8.7 \times 10^{-5}$ ,  $-0.015 < h_3^Z < 0.016$ ,  $-9.4 \times 10^{-5} < h_4^Z < 9.2 \times 10^{-5}$ . Supersedes AAD 12BX.
- <sup>4</sup> CHATRCHYAN 13BI determine the  $Z\gamma \rightarrow \nu\bar{\nu}\gamma$  cross section by selecting events with a photon of  $E_T > 145$  GeV and a  $p_T > 130$  GeV. 73 candidate events are observed with an expected SM background of  $30.2 \pm 6.5$ . The  $E_T$  spectrum of the photon is used to set 95% C.L. limits as follows:  $|h_3^Z| < 2.7 \times 10^{-3}$ ,  $|h_4^Z| < 1.3 \times 10^{-5}$ ,  $|h_3^Z| < 2.9 \times 10^{-3}$ ,  $|h_4^Z| < 1.5 \times 10^{-5}$ .
- <sup>5</sup> ABAZOV 12S study  $Z\gamma$  production in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV using  $6.2 \text{ fb}^{-1}$  of data where the  $Z$  decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of  $255 \pm 16$  ( $285 \pm 24$ ) events. Based on the photon  $p_T$  spectrum, and including also earlier data and the  $Z \rightarrow \nu\bar{\nu}$  decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported:  $|h_{03}^Z| < 0.026$ ,  $|h_{04}^Z| < 0.0013$ ,  $|h_{03}^Z| < 0.027$ ,  $|h_{04}^Z| < 0.0014$  for a form factor scale of  $\Lambda = 1.5$  TeV.
- <sup>6</sup> AALTONEN 11S study  $Z\gamma$  events in  $p\bar{p}$  interactions at  $\sqrt{s} = 1.96$  TeV with integrated luminosity  $5.1 \text{ fb}^{-1}$  for  $Z \rightarrow e^+e^-/\mu^+\mu^-$  and  $4.9 \text{ fb}^{-1}$  for  $Z \rightarrow \nu\bar{\nu}$ . For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one  $> 20$  GeV and the other  $> 10$  GeV. The isolated photon must have  $E_T > 50$  GeV. They observe 91 events with  $87.2 \pm 7.8$  events expected from standard model processes. For the  $\nu\bar{\nu}$  case they require solitary photons with  $E_T > 25$  GeV and missing  $E_T > 25$  GeV and observe 85 events with standard model expectation of  $85.9 \pm 5.6$  events. Taking the form factor  $\Lambda = 1.5$  TeV they derive 95% C.L. limits as  $|h_3^Z| < 0.022$  and  $|h_4^Z| < 0.0009$ .
- <sup>7</sup> CHATRCHYAN 11M study  $Z\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using 36  $\text{pb}^{-1}$   $pp$  data, where the  $Z$  decays to  $e^+e^-$  or  $\mu^+\mu^-$ . The total cross sections are measured for photon transverse energy  $E_T^{\gamma} > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell, \gamma) > 0.7$  with the dilepton invariant mass requirement of  $M_{\ell\ell} > 50$  GeV. The number of  $e^+e^-\gamma$  and  $\mu^+\mu^-\gamma$  candidates is 81 and 90 with estimated backgrounds of  $20.5 \pm 2.5$  and  $27.3 \pm 3.2$  events respectively. The 95% CL limits for  $ZZ\gamma$  couplings are  $-0.05 < h_3^Z < 0.06$  and  $-0.0005 < h_4^Z < 0.0005$ , and for  $Z\gamma\gamma$  couplings are  $-0.07 < h_3^Z < 0.07$  and  $-0.0005 < h_4^Z < 0.0006$ .
- <sup>8</sup> ABAZOV 09L study  $Z\gamma, Z \rightarrow \nu\bar{\nu}$  production in  $p\bar{p}$  collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy  $E_T$  larger than 90 GeV, with an expected background of 17 events. Based on the photon  $E_T$  spectrum and including also  $Z$  decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported:  $|h_{30}^Z| < 0.033$ ,  $|h_{40}^Z| < 0.0017$ ,  $|h_{30}^Z| < 0.033$ ,  $|h_{40}^Z| < 0.0017$ .
- <sup>9</sup> ABAZOV 07M use 968  $p\bar{p} \rightarrow e^+e^-/\mu^+\mu^-\gamma X$  candidates, at 1.96 TeV center of mass energy, to tag  $p\bar{p} \rightarrow Z\gamma$  events by requiring  $E_T(\gamma) > 7$  GeV, lepton-gamma separation  $\Delta R_{\ell\gamma} > 0.7$ , and dilepton invariant mass  $> 30$  GeV. The cross section is in agreement with the SM prediction. Using these  $Z\gamma$  events they obtain 95% C.L. limits on each  $h_i^V$ , keeping all others fixed at their SM values. They report:  $-0.083 < h_{30}^Z < 0.082$ ,  $-0.0053 < h_{40}^Z < 0.0054$ ,  $-0.085 < h_{30}^Z < 0.084$ ,  $-0.0053 < h_{40}^Z < 0.0054$ , for the form factor scale  $\Lambda = 1.2$  TeV.
- <sup>10</sup> Using data collected at  $\sqrt{s} = 183\text{--}208$  GeV, ABDALLAH 07c select 1,877  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or  $\nu\bar{\nu}$ , 171  $e^+e^- \rightarrow ZZ$  events with  $Z \rightarrow q\bar{q}$  or lepton pair (except an explicit  $\tau$  pair), and 74  $e^+e^- \rightarrow Z\gamma^*$  events with a  $q\bar{q}\mu^+\mu^-$  or  $q\bar{q}e^+e^-$  signature, to derive 95% CL limits on  $h_i^V$ . Each limit is derived with other parameters set to zero. They report:  $-0.23 < h_1^Z < 0.23$ ,  $-0.30 < h_2^Z < 0.16$ ,  $-0.14 < h_1^Z < 0.14$ ,  $-0.049 < h_3^Z < 0.044$ .
- <sup>11</sup> ACHARD 04H select 3515  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or  $\nu\bar{\nu}$  at  $\sqrt{s} = 189\text{--}209$  GeV to derive 95% CL limits on  $h_i^V$ . For deriving each limit the other parameters are fixed at zero. They report:  $-0.153 < h_1^Z < 0.141$ ,  $-0.087 < h_2^Z < 0.079$ ,  $-0.220 < h_3^Z < 0.112$ ,  $-0.068 < h_4^Z < 0.148$ ,  $-0.057 < h_1^Z < 0.057$ ,  $-0.050 < h_2^Z < 0.023$ ,  $-0.059 < h_3^Z < 0.004$ ,  $-0.004 < h_4^Z < 0.042$ .
- <sup>12</sup> ABBIENDI, G 00C study  $e^+e^- \rightarrow Z\gamma$  events (with  $Z \rightarrow q\bar{q}$  and  $Z \rightarrow \nu\bar{\nu}$ ) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings:  $h_1^Z = 0.000 \pm 0.100$  ( $-0.190, 0.190$ ),  $h_2^Z = 0.000 \pm 0.068$  ( $-0.128, 0.128$ ),  $h_3^Z = -0.074 \pm 0.102$  ( $-0.269, 0.119$ ),  $h_4^Z = 0.046 \pm 0.068$  ( $-0.084, 0.175$ ),  $h_1^Z = 0.000 \pm 0.061$  ( $-0.115, 0.115$ ),  $h_2^Z = 0.000 \pm 0.041$  ( $-0.077, 0.077$ ),  $h_3^Z = -0.080 \pm 0.039$  ( $-0.164, -0.006$ ),  $h_4^Z = 0.064 \pm 0.033$  ( $-0.030, +0.134$ ). The results are derived assuming that only one coupling at a time is different from zero.
- <sup>13</sup> ABBOTT 98M study  $p\bar{p} \rightarrow Z\gamma + X$ , with  $Z \rightarrow e^+e^-, \mu^+\mu^-, \nu\bar{\nu}$  at 1.8 TeV, to obtain 95% CL limits at  $\Lambda = 750$  GeV:  $|h_{30}^Z| < 0.36$ ,  $|h_{40}^Z| < 0.05$  (keeping  $h_1^Z = 0$ ), and  $|h_{30}^Z| < 0.37$ ,  $|h_{40}^Z| < 0.05$  (keeping  $h_2^Z = 0$ ). Limits on the  $CP$ -violating couplings are  $|h_{10}^Z| < 0.36$ ,  $|h_{20}^Z| < 0.05$  (keeping  $h_1^Z = 0$ ), and  $|h_{10}^Z| < 0.37$ ,  $|h_{20}^Z| < 0.05$  (keeping  $h_2^Z = 0$ ).
- <sup>14</sup> ABREU 98K determine a 95% CL upper limit on  $\sigma(e^+e^- \rightarrow \gamma + \text{invisible particles}) < 2.5 \text{ pb}$  using 161 and 172 GeV data. This is used to set 95% CL limits on  $|h_{30}^Z| < 0.8$  and  $|h_{30}^Z| < 1.3$ , derived at a scale  $\Lambda = 1$  TeV and with  $n = 3$  in the form factor representation.
- $f_i^V$**   
Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAE 13A]:
- $$\begin{aligned} -0.28 < f_4^Z < +0.32, & \quad -0.34 < f_5^Z < +0.35, \\ -0.17 < f_4^Z < +0.19, & \quad -0.35 < f_5^Z < +0.32. \end{aligned}$$
- Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

- <sup>1</sup> KHACHATRYAN 15B study  $ZZ$  production in 8 TeV  $pp$  collisions. In the decay modes  $ZZ \rightarrow 4e, 4\mu, 2e2\mu, 54, 75, 148$  events are observed, with an expected background of  $2.2 \pm 0.9, 1.2 \pm 0.6$ , and  $2.4 \pm 1.0$  events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained:  $|f_4^Z| < 0.004$ ,  $|f_5^Z| < 0.004$ ,  $|f_4^Z| < 0.005$ ,  $|f_5^Z| < 0.005$ .
- <sup>2</sup> KHACHATRYAN 15BC use the cross section measurement of the final state  $pp \rightarrow Z \rightarrow 2\ell 2\nu$  ( $\ell$  being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton  $p_T > 45$  GeV. The reduced missing  $E_T$  is required to be  $> 65$  GeV, which takes into account the fake missing  $E_T$  due to detector effects. The numbers of  $e^+e^-$  and  $\mu^+\mu^-$  events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set:  $-0.0028 < f_4^Z < 0.0032$ ,  $-0.0037 < f_4^Z < 0.0033$ ,  $-0.0029 < f_5^Z < 0.0031$ ,  $-0.0033 < f_5^Z < 0.0037$ . Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states  $pp \rightarrow ZZ \rightarrow 2\ell 2\ell'$  where  $\ell$  and  $\ell'$  are an electron or a muon, the best limits are  $-0.0022 < f_4^Z < 0.0026$ ,  $-0.0029 < f_4^Z < 0.0026$ ,  $-0.0023 < f_5^Z < 0.0023$ ,  $-0.0026 < f_5^Z < 0.0027$ .
- <sup>3</sup> AAD 13Z study  $ZZ$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. In the  $ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$  final state they observe a total of 66 events with an expected background of  $0.9 \pm 1.3$ . In the  $ZZ \rightarrow \ell^+\ell^-\nu\bar{\nu}$  final state they observe a total of 87 events with an expected background of  $46.9 \pm 5.2$ . The limits on anomalous TGCs are determined using the observed and expected numbers of these  $ZZ$  events binned in  $p_T^Z$ . The 95% C.L. are as follows: for form factor scale  $\Lambda = \infty$ ,  $-0.015 < f_4^Z < 0.015$ ,  $-0.013 < f_4^Z < 0.013$ ,  $-0.016 < f_5^Z < 0.015$ ,  $-0.013 < f_5^Z < 0.013$ ; for form factor scale  $\Lambda = 3$  TeV,  $-0.022 < f_4^Z < 0.023$ ,  $-0.019 < f_4^Z < 0.019$ ,  $-0.023 < f_5^Z < 0.023$ ,  $-0.020 < f_5^Z < 0.019$ .
- <sup>4</sup> CHATRCHYAN 13B study  $ZZ$  production in  $pp$  collisions and select 54  $ZZ$  candidates in the  $Z$  decay channel with electrons or muons with an expected background of  $1.4 \pm 0.5$  events. The resulting 95% C.L. ranges are:  $-0.013 < f_4^Z < 0.015$ ,  $-0.011 < f_4^Z < 0.012$ ,  $-0.014 < f_5^Z < 0.014$ ,  $-0.012 < f_5^Z < 0.012$ .
- <sup>5</sup> Using data collected in the center of mass energy range 192–209 GeV, SCHAE 09 select 318  $e^+e^- \rightarrow ZZ$  events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits:  $-0.321 < f_4^Z < 0.318$ ,  $-0.534 < f_4^Z < 0.534$ ,  $-0.724 < f_5^Z < 0.733$ ,  $-1.194 < f_5^Z < 1.190$ .
- <sup>6</sup> ABAZOV 08K search for  $ZZ$  and  $Z\gamma^*$  events with  $1 \text{ fb}^{-1}$   $p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV in  $(e)(e), (\mu\mu)(\mu\mu), (e)(\mu\mu)$  final states requiring the lepton pair masses to be  $> 30$  GeV. They observe 1 event, which is consistent with an expected signal of  $1.71 \pm 0.15$  events and a background of  $0.13 \pm 0.03$  events. From this they derive the following limits, for a form factor ( $\Lambda$ ) value of 1.2 TeV:  $-0.28 < f_{40}^Z < 0.28$ ,  $-0.31 < f_{50}^Z < 0.29$ ,  $-0.26 < f_{40}^Z < 0.26$ ,  $-0.30 < f_{50}^Z < 0.28$ .
- <sup>7</sup> Using data collected at  $\sqrt{s} = 183\text{--}208$  GeV, ABDALLAH 07c select 171  $e^+e^- \rightarrow ZZ$  events with  $Z \rightarrow q\bar{q}$  or lepton pair (except an explicit  $\tau$  pair), and 74  $e^+e^- \rightarrow Z\gamma^*$  events with a  $q\bar{q}\mu^+\mu^-$  or  $q\bar{q}e^+e^-$  signature, to derive 95% CL limits on  $f_i^V$ . Each limit is derived with other parameters set to zero. They report:  $-0.40 < f_4^Z < 0.42$ ,  $-0.38 < f_5^Z < 0.62$ ,  $-0.23 < f_4^Z < 0.25$ ,  $-0.52 < f_5^Z < 0.48$ .
- <sup>8</sup> ABBIENDI 04C study  $ZZ$  production in  $e^+e^-$  collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00W data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits:  $-0.45 < f_4^Z < 0.58$ ,  $-0.94 < f_5^Z < 0.25$ ,  $-0.32 < f_4^Z < 0.33$ , and  $-0.71 < f_5^Z < 0.59$ .
- <sup>9</sup> ACHARD 03D study  $Z$ -boson pair production in  $e^+e^-$  collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively, 286

# Gauge & Higgs Boson Particle Listings

## Z

events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 011 results (656 events, expected background of 512 events), they report the following 95% CL limits:  $-0.48 \leq f_4^Z \leq 0.46$ ,  $-0.36 \leq f_5^Z \leq 1.03$ ,  $-0.28 \leq f_4^\gamma \leq 0.28$ , and  $-0.40 \leq f_5^\gamma \leq 0.47$ .

### ANOMALOUS W/Z QUARTIC COUPLINGS

#### ANOMALOUS W/Z QUARTIC COUPLINGS (QGCS)

Revised November 2015 by M.W. Gr  nwald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings,  $WWZZ$ ,  $WWZ\gamma$ ,  $WW\gamma\gamma$ , and  $ZZ\gamma\gamma$ , were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowers dimensional representation of operators (dimension 6) which presumes the  $SU(2) \times U(1)$  gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings,  $a_0, a_c, a_n$ , are expressed in terms of the following dimension-6 operators [1,2];

$$\begin{aligned} L_6^0 &= -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ L_6^c &= -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha \\ L_6^n &= -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} F^{\mu\nu} \\ \tilde{L}_6^0 &= -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ \tilde{L}_6^n &= -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu} \end{aligned}$$

where  $F, W$  are photon and  $W$  fields,  $L_6^0$  and  $L_6^c$  conserve  $C, P$  separately ( $\tilde{L}_6^0$  conserves only  $C$ ) and generate anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings,  $L_6^n$  violates  $CP$  ( $\tilde{L}_6^n$  violates both  $C$  and  $P$ ) and generates an anomalous  $W^+W^-Z\gamma$  coupling, and  $\Lambda$  is an energy scale for new physics. For the  $ZZ\gamma\gamma$  coupling the  $CP$ -violating term represented by  $L_6^n$  does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the  $WW\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings separately, leading to two sets parametrized as  $a_0^V/\Lambda^2$  and  $a_c^V/\Lambda^2$ , where  $V = W$  or  $Z$ .

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned} \mathcal{L}_{AQGC} &= -\frac{e^2}{8} \frac{a_0^W}{\Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+a} W_a^- \\ &\quad -\frac{e^2}{16} \frac{a_c^W}{\Lambda^2} F_{\mu\nu} F^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad -e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+a} W_a^- \end{aligned}$$

$$\begin{aligned} &\quad -\frac{e^2 g^2}{2} \frac{\kappa_c^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad + \frac{f_{T,0}}{\Lambda^4} Tr[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}] \end{aligned}$$

The energy scale of possible new physics is  $\Lambda$ , and  $g = e/\sin(\theta_W)$ ,  $e$  being the unit electric charge and  $\theta_W$  the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators  $a_0^W/\Lambda^2$  and  $a_c^W/\Lambda^2$  are associated with the  $WW\gamma\gamma$  vertex. Among dimension 8 operators,  $\kappa_0^W/\Lambda^2$  and  $\kappa_c^W/\Lambda^2$  are associated with the  $WWZ\gamma$  vertex, whereas the parameter  $f_{T,0}/\Lambda^4$  contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters  $f_{M,i}/\Lambda^4$  as follows [3]:

$$\begin{aligned} \frac{a_0^W}{\Lambda^2} &= -\frac{4M_W^2}{g^2} \frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,2}}{\Lambda^4} \\ \frac{a_c^W}{\Lambda^2} &= -\frac{4M_W^2}{g^2} \frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,3}}{\Lambda^4} \end{aligned}$$

where  $g' = e/\cos(\theta_W)$  and  $M_W$  is the invariant mass of the  $W$  boson. This relation provides a translation between limits on dimension 6 operators  $a_{0,c}^W$  and  $f_{M,j}/\Lambda^4$ . It is further required [4] that  $f_{M,0} = 2f_{M,2}$  and  $f_{M,1} = 2f_{M,3}$  which suppresses contributions to the  $WWZ\gamma$  vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total –  $f_{S,i}$ ,  $i = 1, 2$ ,  $f_{M,i}$ ,  $i = 0, \dots, 8$  and  $f_{T,i}$ ,  $i = 0, \dots, 9$  – each scaled by  $1/\Lambda^4$ .

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters  $\alpha_4$  and  $\alpha_5$ , which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

### $a_0/\Lambda^2$ , $a_c/\Lambda^2$

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the  $ZZ\gamma\gamma$  vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$

$$-0.029 < a_c^Z/\Lambda^2 < +0.039$$

Anomalous Z quartic couplings can also be measured by the experiments at the Tevatron and the LHC. As discussed in the review on “Anomalous  $W/Z$  quartic couplings (QGCs),” the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for use in future publications by the experiments.

<sup>1</sup> ABBIENDI 04L OPAL

<sup>2</sup> HEISTER 04A ALEP

<sup>3</sup> ACHARD 02G L3

- ABBIENDI 04L select  $20 e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  acoplanar events in the energy range 180–209 GeV and  $176 e^+e^- \rightarrow q\bar{q}\gamma\gamma$  events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  quartic couplings. Further combining with the  $W^+W^-\gamma$  sample of ABBIENDI 04b the following one-parameter 95% CL limits are obtained:  $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$ ,  $-0.029 < a_c^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$ ,  $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.052 < a_c^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$ .
- In the CM energy range 183 to 209 GeV HEISTER 04A select  $30 e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be  $> 5^\circ$ ,  $E_\gamma/\sqrt{s} > 0.025$  (the more energetic photon having energy  $> 0.2\sqrt{s}$ ),  $p_{T\gamma}/E_{\text{beam}} > 0.05$  and  $|\cos\theta_\gamma| < 0.94$ . A likelihood fit to the photon energy and recoil missing mass yields the following one-parameter 95% CL limits:  $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$ ,  $-0.041 < a_c^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$ ,  $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$ ,  $-0.099 < a_c^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$ .
- ACHARD 02G study  $e^+e^- \rightarrow Z\gamma\gamma \rightarrow q\bar{q}\gamma\gamma$  events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy  $> 5 \text{ GeV}$  and  $|\cos\theta| < 0.97$ , and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ( $\beta < 0.73$ ) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the  $q\bar{q}\gamma\gamma$  state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values  $a_0/\Lambda^2 = 0.00 \pm 0.02 \text{ GeV}^{-2}$  and  $a_c/\Lambda^2 = 0.03 \pm 0.02 \text{ GeV}^{-2}$ , where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits  $-0.02 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.03 \text{ GeV}^{-2}$  and  $-0.07 \text{ GeV}^{-2} < a_c/\Lambda^2 < 0.05 \text{ GeV}^{-2}$ .

## H<sup>0</sup>

$J = 0$

In the following  $H^0$  refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of  $H^0$  and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections “Searches for Neutral Higgs Bosons” and “Searches for Charged Higgs Bosons ( $H^\pm$  and  $H^{\pm\pm}$ )”, respectively.

- 1 Combined value from  $\gamma\gamma$  and  $ZZ^* \rightarrow 4\ell$  final states.
- 2 ATLAS and CMS data are fitted simultaneously.
- 3 KHACHATRYAN 15AM use up to 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 4 AAD 14W use 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at 8 TeV.
- 5 CHATRCHYAN 14AA use 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 6 CHATRCHYAN 14K use 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 7 KHACHATRYAN 14P use 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 8 AAD 13AK use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. Superseded by AAD 14W.
- 9 CHATRCHYAN 13J use 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 12.2 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 10 AAD 12AI obtain results based on 4.6–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.8–5.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. An excess of events over background with a local significance of 5.9  $\sigma$  is observed at  $m_{H^0} = 126$  GeV. See also AAD 12DA.
- 11 CHATRCHYAN 12N obtain results based on 4.9–5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.1–5.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. An excess of events over background with a local significance of 5.0  $\sigma$  is observed at about  $m_{H^0} = 125$  GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

### H<sup>0</sup> SPIN AND CP PROPERTIES

The observation of the signal in the  $\gamma\gamma$  final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the  $CP$  properties is in general much more difficult since in principle the observed state could consist of any admixture of  $CP$ -even and  $CP$ -odd components. As a first step, the compatibility of the data with distinct hypotheses of pure  $CP$ -even and pure  $CP$ -odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different  $CP$  states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a  $CP$ -even and a  $CP$ -odd state, as the cross section ratios depend in addition also on the coupling strengths of the  $CP$ -even and  $CP$ -odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of  $CP$  mixing.

11 AAD	13AJ ATLS	$H^0 \rightarrow \gamma\gamma, ZZ^* \rightarrow 4\ell, WW^* \rightarrow \ell\nu\ell\nu$	
12 CHATRCHYAN13J	CMS	$H^0 \rightarrow ZZ^* \rightarrow 4\ell$	

- 1 AAD 16 study  $H^0 \rightarrow \gamma\gamma$  with an effective Lagrangian including  $CP$  even and odd terms in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.
- 2 AAD 15AX compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV, using the process  $H^0 \rightarrow WW^* \rightarrow e\nu\mu\nu$ .  $2^+$  hypotheses are excluded at 84.5–99.4%CL,  $0^-$  at 96.5%CL,  $0^+$  (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible  $CP$  mixture parameters.

- <sup>3</sup> AAD 15c compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ , using the processes  $H^0 \rightarrow ZZ^* \rightarrow 4\ell$ ,  $H^0 \rightarrow \gamma\gamma$  and combine with AAD 15Ax data.  $0^+$  (field strength coupling),  $0^-$  and several  $2^+$  hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible  $CP$  mixture parameters.
- <sup>4</sup> AALTONEN 15 combine AALTONEN 15b and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a  $0^-$  and a  $2^+$  state. Assuming the SM event rate, the  $J^{CP} = 0^-$  ( $2^+$ ) hypothesis is excluded at the  $5.0\sigma$  ( $4.9\sigma$ ) level.
- <sup>5</sup> AALTONEN 15B compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in  $9.45 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ , using the processes  $ZH^0 \rightarrow \ell\ell b\bar{b}$ ,  $WH^0 \rightarrow \ell\nu b\bar{b}$ , and  $ZH^0 \rightarrow \nu\nu b\bar{b}$ . Bounds on the production rates of  $0^-$  and  $2^+$  (graviton-like) states are set, see their tables II and III.
- <sup>6</sup> KHACHATRYAN 15V compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in up to  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ , using the processes  $H^0 \rightarrow 4\ell$ ,  $H^0 \rightarrow WW^*$ , and  $H^0 \rightarrow \gamma\gamma$ .  $0^-$  is excluded at 99.98% CL, and several  $2^+$  hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.99% CL in  $ZZ^*$  and  $WW^*$  modes. Limits on anomalous couplings and several cross section fractions, treating the case of  $CP$ -mixed states, are also given.
- <sup>7</sup> ABAZOV 14F compare the  $J^{CP} = 0^+$  Standard Model assignment with  $J^{CP} = 0^-$  and  $2^+$  (graviton-like coupling) hypotheses in up to  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states  $ZH \rightarrow \ell\ell b\bar{b}$ ,  $WH \rightarrow \ell\nu b\bar{b}$ , and  $ZH \rightarrow \nu\nu b\bar{b}$ . The  $0^-$  ( $2^+$ ) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a  $0^+$  state with another  $J^{CP}$  state, the cross section fractions  $f_X = \sigma_X/(\sigma_0 + \sigma_X)$  are considered, where  $X = 0^-, 2^+$ . Values for  $f_0 - (f_2 +)$  above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.
- <sup>8</sup> CHATRCHYAN 14AA compare the  $J^{CP} = 0^+$  Standard Model assignment with various  $J^{CP}$  hypotheses in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ .  $J^{CP} = 0^-$  and  $1^\pm$  hypotheses are excluded at 99% CL, and several  $J = 2$  hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a  $0^+$  state with another  $J^{CP}$  state, the cross section fraction  $f_{a3} = |a_3|^2 \sigma_3 / (|a_1|^2 \sigma_1 + |a_2|^2 \sigma_2 + |a_3|^2 \sigma_3)$  is considered, where the case  $a_3 = 1$ ,  $a_1 = a_2 = 0$  corresponds to a pure  $CP$ -odd state. Assuming  $a_2 = 0$ , a value for  $f_{a3}$  above 0.51 is excluded at 95% CL.
- <sup>9</sup> CHATRCHYAN 14G compare the  $J^{CP} = 0^+$  Standard Model assignment with  $J^{CP} = 0^-$  and  $2^+$  (graviton-like coupling) hypotheses in  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.4 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . Varying the fraction of the production of the  $2^+$  state via  $gg$  and  $q\bar{q}$ ,  $2^+$  hypotheses are disfavored at CL between 83.7 and 99.8%. The  $0^-$  hypothesis is disfavored against  $0^+$  at the 65.3% CL.
- <sup>10</sup> KHACHATRYAN 14P compare the  $J^{CP} = 0^+$  Standard Model assignment with a  $2^+$  (graviton-like coupling) hypothesis in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . Varying the fraction of the production of the  $2^+$  state via  $gg$  and  $q\bar{q}$ ,  $2^+$  hypotheses are disfavored at CL between 71 and 94%.
- <sup>11</sup> AAD 13AJ compare the spin 0,  $CP$ -even hypothesis with specific alternative hypotheses of spin 0,  $CP$ -odd, spin 1,  $CP$ -even and  $CP$ -odd, and spin 2,  $CP$ -even modes using the Higgs boson decays  $H \rightarrow \gamma\gamma$ ,  $H \rightarrow ZZ^* \rightarrow 4\ell$  and  $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  and combinations thereof. The data are compatible with the spin 0,  $CP$ -even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.
- <sup>12</sup> CHATRCHYAN 13J study angular distributions of the lepton pairs in the  $ZZ^*$  channel where both  $Z$  bosons decay to  $e$  or  $\mu$  pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure  $CP$ -even hypothesis, while the pure  $CP$ -odd hypothesis is disfavored.

## $H^0$ DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to  $ZZ^*$  and interference effects between signal and background in Higgs decays to  $\gamma\gamma$  can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to  $ZZ^*$  rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

- <sup>1</sup> KHACHATRYAN 15AM combine  $\gamma\gamma$  and  $ZZ^* \rightarrow 4\ell$  results. The expected limit is 2.3 GeV.
- <sup>2</sup> KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance  $\tau < 1.9 \times 10^{-13} \text{ s}$ .  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at 8 TeV are used.
- <sup>3</sup> AAD 14W use  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at 8 TeV. The expected limit is 6.2 GeV.
- <sup>4</sup> AAD 15BE derive constraints on the total width from comparing  $ZZ^*$  and  $WW^*$  production via on-shell and off-shell  $H^0$  using  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . The K factor for the background processes is assumed to be equal to that for the signal.
- <sup>5</sup> KHACHATRYAN 15BA derive constraints on the total width from comparing  $ZZ^*$  production via on-shell and off-shell  $H^0$  with an unconstrained anomalous coupling.  $4\ell$  final states in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$  are used.
- <sup>6</sup> CHATRCHYAN 14AA use  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The expected limit is 2.8 GeV.
- <sup>7</sup> KHACHATRYAN 14D derive constraints on the total width from comparing  $ZZ^*$  production via on-shell and off-shell  $H^0$ .  $4\ell$  and  $\ell\ell\nu\nu$  final states in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$  are used.
- <sup>8</sup> KHACHATRYAN 14P use  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The expected limit is 3.1 GeV.

<0.65	95	5 CHATRCHYAN14B	CMS	$pp \rightarrow qqH^0 X$ , 8 TeV

- 1 AAD 140 search for  $pp \rightarrow H^0 Z X$ ,  $Z \rightarrow \ell\ell$ , with  $H^0$  decaying to invisible final states in 4.5 fb<sup>-1</sup> at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_{H^0} = 125.5$  GeV and assumes the Standard Model rate for  $H^0 Z$  production.
- 2 CHATRCHYAN 14B search for  $pp \rightarrow H^0 Z X$ ,  $Z \rightarrow \ell\ell$  and  $Z \rightarrow b\bar{b}$ , and also  $pp \rightarrow qqH^0 X$  with  $H^0$  decaying to invisible final states using data at  $E_{\text{cm}} = 7$  and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from  $H^0 Z$  and  $qqH^0$ . It is given for  $m_{H^0} = 125$  GeV and assumes the Standard Model rates for the two production processes.
- 3 AAD 15BD search for  $pp \rightarrow H^0 WX$  and  $pp \rightarrow H^0 ZX$  with  $W$  or  $Z$  decaying hadronically and  $H^0$  decaying to invisible final states using data at  $E_{\text{cm}} = 8$  TeV. The quoted limit is given for  $m_{H^0} = 125$  GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from  $H^0 W$ ,  $H^0 Z$  and the gluon-fusion process.
- 4 CHATRCHYAN 14B search for  $pp \rightarrow H^0 ZX$  with  $H^0$  decaying to invisible final states and  $Z \rightarrow \ell\ell$  in 4.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV, and also with  $Z \rightarrow b\bar{b}$  in 18.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_{H^0} = 125$  GeV and assumes the Standard Model rate for  $H^0 Z$  production.
- 5 CHATRCHYAN 14B search for  $pp \rightarrow qqH^0 X$  (vector boson fusion) with  $H^0$  decaying to invisible final states in 19.5 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_{H^0} = 125$  GeV and assumes the Standard Model rate for  $qqH^0$  production.

## $H^0$ SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The  $H^0$  signal strength in a particular final state  $xx$  is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value,  $\sigma \cdot \text{B}(H^0 \rightarrow xx) / (\sigma \cdot \text{B}(H^0 \rightarrow xx))_{\text{SM}}$ , for the specified mass value of  $H^0$ . For the SM predictions, see DITTMAYER 11, DITTMAYER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

- 1 AAD 16J perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and 8 TeV. The signal strengths for individual production processes are  $1.03^{+0.16}_{-0.14}$  for gluon fusion,  $1.18^{+0.25}_{-0.23}$  for vector boson fusion,  $0.89^{+0.40}_{-0.38}$  for  $WH^0$  production,  $0.79^{+0.38}_{-0.36}$  for  $ZH^0$  production, and  $2.3^{+0.7}_{-0.6}$  for  $t\bar{t}H^0$  production.
- 2 The uncertainties represent statistics, experimental systematics, theory systematics on the background, and theory systematics on the signal. The quoted signal strengths are given for  $m_{H^0} = 125.09$  GeV. In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.
- 3 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb<sup>-1</sup> and 9.7 fb<sup>-1</sup>, respectively, of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.

- 4 AAD 16K use up to 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are  $1.23^{+0.14}_{-0.08} \pm 0.09^{+0.16}_{-0.12}$  for gluon fusion,  $1.23^{+0.28}_{-0.27} \pm 0.13^{+0.11}_{-0.09}$  for vector boson fusion,  $0.80^{+0.31}_{-0.30} \pm 0.17^{+0.10}_{-0.05}$  for  $W/ZH^0$  production, and  $1.81^{+0.52}_{-0.50} \pm 0.58^{+0.31}_{-0.55} \pm 0.12$  for  $t\bar{t}H^0$  production. The quoted signal strengths are given for  $m_{H^0} = 125.36$  GeV.
- 5 AAD 15P measure total and differential cross sections of the process  $pp \rightarrow H^0 X$  at  $E_{\text{cm}} = 8$  TeV with 20.3 fb<sup>-1</sup>.  $\gamma\gamma$  and  $4\ell$  final states are used.  $\sigma(pp \rightarrow H^0 X) = 33.0 \pm 5.3 \pm 1.6$  pb is given. See their Figs. 2 and 3 for data on differential cross sections.
- 6 KHACHATRYAN 15AM use up to 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of  $0.85^{+0.19}_{-0.16}$  for gluon fusion,  $1.16^{+0.37}_{-0.34}$  for vector boson fusion,  $0.92^{+0.38}_{-0.36}$  for  $WH^0$ ,  $ZH^0$  production, and  $2.90^{+1.08}_{-0.94}$  for  $t\bar{t}H^0$  production.
- 7 AAD 13AK use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The combined signal strength is based on the  $\gamma\gamma$ ,  $ZZ^* \rightarrow 4\ell$ , and  $WW^* \rightarrow \ell\nu\ell\nu$  channels. The quoted signal strength is given for  $m_{H^0} = 125.5$  GeV. Reported statistical error value modified following private communication with the experiment.
- 8 AALTONEN 13L combine all CDF results with 9.45–10.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- 9 ABAZOV 13L combine all D0 results with up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- 10 AAD 12AI obtain results based on 4.6–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.8–5.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. An excess of events over background with a local significance of 5.9  $\sigma$  is observed at  $m_{H^0} = 126$  GeV. The quoted signal strengths are given for  $m_{H^0} = 126$  GeV. See also AAD 12DA.
- 11 CHATRCHYAN 12N obtain results based on 4.9–5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.1–5.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. An excess of events over background with a local significance of 5.0  $\sigma$  is observed at about  $m_{H^0} = 125$  GeV. The combined signal strength is based on the  $\gamma\gamma$ ,  $ZZ^*$ ,  $WW^*$ ,  $\tau^+\tau^-$ , and  $b\bar{b}$  channels. The quoted signal strength is given for  $m_{H^0} = 125.5$  GeV. See also CHATRCHYAN 13Y.

- 1 AAD 16J perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and 8 TeV. The signal strengths for individual production processes are  $0.84^{+0.17}_{-0.17}$  for gluon fusion,  $1.2^{+0.4}_{-0.4}$  for vector boson fusion,  $1.6^{+1.2}_{-1.0}$  for  $WH^0$  production,  $5.9^{+2.6}_{-2.2}$  for  $ZH^0$  production, and  $5.0^{+1.8}_{-1.7}$  for  $t\bar{t}H^0$  production.
- 2 In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_{H^0} = 125.09$  GeV.
- 3 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb<sup>-1</sup> and 9.7 fb<sup>-1</sup>, respectively, of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- 4 AAD 16K use up to 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV.
- 5 AAD 15AA use 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The signal strength for the gluon fusion and vector boson fusion mode is  $1.02^{+0.19}_{-0.18} \pm 0.22$  and  $1.27^{+0.44}_{-0.40} \pm 0.30$ , respectively. The quoted signal strengths are given for  $m_{H^0} = 125.36$  GeV.
- 6 AAD 15AQ use 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV.

See key on page 601

## Gauge &amp; Higgs Boson Particle Listings

 $H^0$ 

- <sup>7</sup> AAD 15AQ combine their result on  $W/ZH^0$  production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV.
- <sup>8</sup> CHATRCHYAN 14G use  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and  $19.4 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for  $m_{H^0} = 125.6$  GeV.
- <sup>9</sup> AAD 13AK use  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and  $20.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.5$  GeV. Superseded by AAD 15AA.
- <sup>10</sup> AALTONEN 13L combine all CDF results with  $9.45\text{--}10.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>11</sup> ABAZOV 13L combine all D0 results with up to  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>12</sup> AAD 12AI obtain results based on  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and  $5.8 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The quoted signal strengths are given for  $m_{H^0} = 126$  GeV. See also AAD 12DA.
- <sup>13</sup> CHATRCHYAN 12N obtain results based on  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and  $5.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.5$  GeV. See also CHATRCHYAN 13Y.

- <sup>1</sup> AAD 16J perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ . The signal strengths for individual production processes are  $1.13^{+0.23}_{-0.31}$  for gluon fusion and  $0.1^{+1.1}_{-0.6}$  for vector boson fusion.
- <sup>2</sup> In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_{H^0} = 125.09$  GeV.
- <sup>3</sup> AAD 16K use up to  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV.
- <sup>4</sup> AAD 15F use  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV. The signal strength for the gluon fusion production mode is  $1.66^{+0.45+0.25}_{-0.41-0.15}$ , while the signal strength for the vector boson fusion production mode is  $0.26^{+1.60+0.36}_{-0.91-0.23}$ .
- <sup>5</sup> AAD 14AR measure the cross section for  $pp \rightarrow H^0 X, H^0 \rightarrow ZZ^*$  using  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . They give  $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08 \text{ fb}$  in their fiducial region, where  $1.30 \pm 0.13 \text{ fb}$  is expected in the Standard Model for  $m_{H^0} = 125.4$  GeV. Various differential cross sections are also given, which are in agreement with the Standard Model expectations.
- <sup>6</sup> CHATRCHYAN 14AA use  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_{H^0} = 125.6$  GeV. The signal strength for the gluon fusion and  $t\bar{t}H$  production mode is  $0.80^{+0.46}_{-0.36}$ , while the signal strength for the vector boson fusion and  $WH^0, ZH^0$  production mode is  $1.7^{+2.2}_{-2.1}$ .
- <sup>7</sup> AAD 13AK use  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_{H^0} = 125.5$  GeV.
- <sup>8</sup> CHATRCHYAN 13J obtain results based on  $ZZ \rightarrow 4\ell$  final states in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $12.2 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_{H^0} = 125.8$  GeV. Superseded by CHATRCHYAN 14AA.
- <sup>9</sup> AAD 12AI obtain results based on  $4.7\text{--}4.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.8 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strengths are given for  $m_{H^0} = 126$  GeV. See also AAD 12DA.
- <sup>10</sup> CHATRCHYAN 12N obtain results based on  $4.9\text{--}5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.1\text{--}5.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . An excess of events over background with a local significance of  $5.0 \sigma$  is observed at about  $m_{H^0} = 125$  GeV. The quoted signal strengths are given for  $m_{H^0} = 125.5$  GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

## $H^0$

- <sup>1</sup> AAD 16j perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and 8 TeV. The signal strengths for individual production processes are  $1.0^{+0.5}_{-0.5}$  for  $WH^0$  production,  $0.4^{+0.4}_{-0.4}$  for  $ZH^0$  production, and  $1.1^{+1.0}_{-1.0}$  for  $t\bar{t}H^0$  production.
- <sup>2</sup> In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_{H^0} = 125.09$  GeV.
- <sup>3</sup> AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb<sup>-1</sup> and 9.7 fb<sup>-1</sup>, respectively, of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>4</sup> AAD 16k use up to 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV.
- <sup>5</sup> AAD 15g use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.36$  GeV.
- <sup>6</sup> KHACHATRYAN 15z search for vector-boson fusion production of  $H^0$  decaying to  $b\bar{b}$  in up to 19.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>7</sup> KHACHATRYAN 15z combined vector boson fusion,  $WH^0$ ,  $ZH^0$  production, and  $t\bar{t}H^0$  production results. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>8</sup> CHATRCHYAN 14Ai use up to 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 18.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV. See also CHATRCHYAN 14Aj.
- <sup>9</sup> AALTONEN 13L combine all CDF results with 9.45–10.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>10</sup> ABAZOV 13L combine all D0 results with up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The quoted signal strength is given for  $m_{H^0} = 125$  GeV.
- <sup>11</sup> AAD 12Ai obtain results based on 4.6–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. The quoted signal strengths are given in their Fig. 10 for  $m_{H^0} = 126$  GeV. See also Fig. 13 of AAD 12Da.
- <sup>12</sup> AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region  $m_{H^0} = 120$ –135 GeV, with a local significance of up to 3.3  $\sigma$ . The local significance at  $m_{H^0} = 125$  GeV is 2.8  $\sigma$ , which corresponds to  $(\sigma(H^0 W) + \sigma(H^0 Z)) \cdot \text{B}(H^0 \rightarrow b\bar{b}) = (0.23^{+0.09}_{-0.08})$  pb, compared to the Standard Model expectation at  $m_{H^0} = 125$  GeV of  $0.12 \pm 0.01$  pb. Superseded by AALTONEN 13M.
- <sup>13</sup> CHATRCHYAN 12N obtain results based on 5.0 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.1 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted signal strength is given for  $m_{H^0} = 125.5$  GeV. See also CHATRCHYAN 13Y.

### MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [ $H_1^0$  and  $H_2^0$ ], where we define  $m_{H_1^0} < m_{H_2^0}$ , a pseudoscalar ( $A^0$ ), and a charged Higgs pair ( $H^\pm$ ).  $H_1^0$  and  $H_2^0$  are also called  $h$  and  $H$  in the literature. There are two free parameters in the Higgs sector which can be chosen to be  $m_{A^0}$  and  $\tan\beta = v_2/v_1$ , the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be  $m_{H_1^0} \leq m_Z$ ,  $m_{H_2^0} \geq m_Z$ ,  $m_{A^0} \geq m_{H_1^0}$ , and  $m_{H^\pm} \geq m_W$ .

However, as described in the review on “Status of Higgs Boson Physics” in this Volume these relations are violated by radiative corrections.

Unless otherwise noted, the experiments in  $e^+e^-$  collisions search for the processes  $e^+e^- \rightarrow H_1^0 Z^0$  in the channels used for the Standard Model Higgs searches and  $e^+e^- \rightarrow H_1^0 A^0$  in the final states  $b\bar{b}b\bar{b}$  and  $b\bar{b}\tau^+\tau^-$ . In  $p\bar{p}$  and  $pp$  collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the  $A^0$  mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between  $m_{A^0}$  and  $m_{H_1^0}$ . As discussed

in the review on “Status of Higgs Boson Physics” in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the  $t$  quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger  $t$  and  $\tilde{t}$  masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections, and the results are given for the  $m_h^{\text{max}}$  benchmark scenario, which gives rise to the most conservative upper bound on the mass of  $H_1^0$  for given values of  $m_{A^0}$  and  $\tan\beta$ , see CARENA 99b, CARENA 03, and CARENA 13.

Limits in the low-mass region of  $H_1^0$ , as well as other by now obsolete limits from different techniques, have been removed from this compilation, and can be found in earlier editions of this Review. Unless otherwise stated, the following results assume no invisible  $H_1^0$  or  $A^0$  decays.

The observed signal at about 125 GeV, see section “ $H^0$ ”, can be interpreted as one of the neutral Higgs bosons of supersymmetric models.

## Neutral Higgs Bosons, Searches for

- <sup>3</sup> Search for  $e^+e^- \rightarrow H_1^0 A^0$  in the final states  $b\bar{b}b\bar{b}$  and  $b\bar{b}\tau^+\tau^-$ , and  $e^+e^- \rightarrow H_1^0 Z$ . Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and  $\mu = -200$  GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for  $m_t = 175$  GeV, and for the  $m_h^{\max}$  scenario.
- <sup>4</sup> ABBIENDI 04M exclude  $0.7 < \tan\beta < 1.9$ , assuming  $m_t = 174.3$  GeV. Limits for other MSSM benchmark scenarios, as well as for CP violating cases, are also given.
- <sup>5</sup> ACHARD 02H also search for the final state  $H_1^0 Z \rightarrow 2A^0 q\bar{q}, A^0 \rightarrow q\bar{q}$ . In addition, the MSSM parameter set in the “large- $\mu$ ” and “no-mixing” scenarios are examined.
- <sup>6</sup> KHACHATRYAN 16A search for production of a Higgs boson in gluon fusion and in association with a  $b\bar{b}$  pair followed by the decay  $H_{1,2}^0/A^0 \rightarrow \mu^+\mu^-$  in 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the  $m_h^{\text{mod+}}$  benchmark scenario and Fig. 9 for limits on cross section times branching ratio.
- <sup>7</sup> AAD 15CE search for production of  $H_2^0$  decaying to  $H^0 H^0$  in the final states  $b\bar{b}\tau^+\tau^-$  and  $\gamma\gamma WW^*$  in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV and combine with data from AAD 15H ( $\gamma\gamma b\bar{b}$ ) and AAD 15BK ( $b\bar{b}b\bar{b}$ ). See their Fig. 7 for excluded regions in the parameter space in several scenarios.
- <sup>8</sup> KHACHATRYAN 15AY search for production of a Higgs boson in association with a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for  $m_{A^0} = 100\text{--}900$  GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.
- <sup>9</sup> AAD 14AW search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in 19.5–20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 140$  GeV, the region  $\tan\beta > 5.4$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>10</sup> KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a  $b$  quark followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 140$  GeV, the region  $\tan\beta > 3.8$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>11</sup> AAD 13o search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  and  $\mu^+\mu^-$  with 4.7–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For  $m_{A^0} = 110\text{--}170$  GeV,  $\tan\beta \gtrsim 10$  is excluded, and for  $\tan\beta = 50$ ,  $m_{A^0}$  below 470 GeV is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>12</sup> AAIJ 13T search for production of a Higgs boson in the forward region in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in 1.0 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.
- <sup>13</sup> CHATRCHYAN 13AG search for production of a Higgs boson in association with a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$  in 2.7–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For  $m_{A^0} = 90\text{--}350$  GeV, upper bounds on  $\tan\beta$  of 18–42 at 95% CL are obtained in the  $m_h^{\max}$  scenario with  $\mu = +200$  GeV.
- <sup>14</sup> AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.
- <sup>15</sup> AALTONEN 12X search for associated production of a Higgs boson and a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , with 2.6 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.
- <sup>16</sup> ABAZOV 12C search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with 7.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 90\text{--}180$  GeV,  $\tan\beta \gtrsim 30$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>17</sup> CHATRCHYAN 12K search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with 4.6 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 160$  GeV, the region  $\tan\beta > 7.1$  is excluded at 95% CL in the  $m_h^{\max}$  scenario. Superseded by KHACHATRYAN 14M.
- <sup>18</sup> ABAZOV 11K search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , in 5.2 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for  $\mu = -200$  GeV.
- <sup>19</sup> ABAZOV 11W search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau\tau$ , in 7.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.
- <sup>20</sup> AALTONEN 09AR search for Higgs bosons decaying to  $\tau^+\tau^-$  in two doublet models in 1.8 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Fig. 2 for the limit on  $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- <sup>21</sup> ABBIENDI 03C search for  $e^+e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, gg$ , or  $\tau^+\tau^-$ . In the no-mixing scenario, the region  $m_{H_1^0} = 45\text{--}85$  GeV and  $m_{A^0} = 2\text{--}9.5$  GeV is excluded at 95% CL.
- <sup>22</sup> HEISTER 02 excludes the range  $0.7 < \tan\beta < 2.3$ . A wider range is excluded with different stop mixing assumptions. Updates BARATE 01c.

## Neutral Higgs Bosons, Searches for

- <sup>10</sup> KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a  $b$  quark followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 140$  GeV, the region  $\tan\beta > 3.8$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>11</sup> AAD 13o search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  and  $\mu^+\mu^-$  with 4.7–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For  $m_{A^0} = 110$ –170 GeV,  $\tan\beta \gtrsim 10$  is excluded, and for  $\tan\beta = 50$ ,  $m_{A^0}$  below 470 GeV is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>12</sup> AAIJ 13T search for production of a Higgs boson in the forward region in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in 1.0 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.
- <sup>13</sup> CHATRCHYAN 13AG search for production of a Higgs boson in association with a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$  in 2.7–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For  $m_{A^0} = 90$ –350 GeV, upper bounds on  $\tan\beta$  of 18–42 at 95% CL are obtained in the  $m_h^{\max}$  scenario with  $\mu = +200$  GeV.
- <sup>14</sup> AALTONEN 12AQ combine AALTONEN 12x and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.
- <sup>15</sup> AALTONEN 12x search for associated production of a Higgs boson and a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , with 2.6 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.
- <sup>16</sup> ABAZOV 12c search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with 7.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV and combine with ABAZOV 11w and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 90$ –180 GeV,  $\tan\beta \gtrsim 30$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.
- <sup>17</sup> CHATRCHYAN 12K search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with 4.6 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 160$  GeV, the region  $\tan\beta > 7.1$  is excluded at 95% CL in the  $m_h^{\max}$  scenario. Superseded by KHACHATRYAN 14M.
- <sup>18</sup> ABAZOV 11K search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , in 5.2 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 5/ Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for  $\mu = -200$  GeV.
- <sup>19</sup> ABAZOV 11w search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau\tau$ , in 7.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.
- <sup>20</sup> AALTONEN 09AR search for Higgs bosons decaying to  $\tau^+\tau^-$  in two doublet models in 1.8 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 2 for the limit on  $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- <sup>21</sup> ACOSTA 05g search for  $H_{1,2}^0/A^0$  production in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV with  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ . At  $m_{A^0} = 100$  GeV, the obtained cross section upper limit is above theoretical expectation.
- <sup>22</sup> ABBIENDI 03c search for  $e^+e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0$ ,  $A^0 \rightarrow c\bar{c}$ ,  $g g$ , or  $\tau^+\tau^-$ . In the no-mixing scenario, the region  $m_{H_1^0} = 45$ –85 GeV and  $m_{A^0} = 2$ –9.5 GeV is excluded at 95% CL.
- <sup>23</sup> AKEROYD 02 examine the possibility of a light  $A^0$  with  $\tan\beta < 1$ . Electroweak measurements are found to be inconsistent with such a scenario.

## MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on “Status of Higgs Boson Physics”). Concerning the mass limits for  $H^0$  and  $A^0$  listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about 125 GeV, see section “ $H^0$ ”, can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

1	AAD 15BK	search for production of a heavy $H_2^0$ decaying to $H^0 H^0$ in the final state $b\bar{b}b\bar{b}$ in 19.5 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 15–18 for excluded regions in the parameter space.		
2	AAD 15s	search for production of $A^0$ decaying to $Z H^0 \rightarrow \ell^+ \ell^- b\bar{b}, \nu\bar{\nu}b\bar{b}$ and $\ell^+ \ell^- \tau^+ \tau^-$ in 20.3 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.		
3	KHACHATRYAN 15BB	search for $H_2^0, A^0 \rightarrow \gamma\gamma$ in 19.7 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.		
4	KHACHATRYAN 15N	search for production of $A^0$ decaying to $Z H^0 \rightarrow \ell^+ \ell^- b\bar{b}$ in 19.7 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta - \alpha)$ plane for $m_{A^0} = 300$ GeV.		
5	AAD 14M	search for the decay cascade $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$ decaying to $b\bar{b}$ in 20.3 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H_2^0} = 325$ –1025 GeV and $m_{H^\pm} = 225$ –825 GeV.		
6	KHACHATRYAN 14Q	search for $H_2^0 \rightarrow H^0 H^0$ and $A^0 \rightarrow Z H^0$ in 19.5 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for $m_{H_2^0} = 260$ –360 GeV and their Figs. 7–9 for limits in two-Higgs-doublet models.		
7	AALTONEN 09AR	search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb <sup>-1</sup> of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.		
8	ABBIENDI 05A	search for $e^+e^- \rightarrow H_1^0 A^0$ in general Type-II two-doublet models, with decays $H_1^0, A^0 \rightarrow q\bar{q}, g g, \tau^+\tau^-$ , and $H_1^0 \rightarrow A^0 A^0$ .		
9	ABDALLAH 05D	search for $e^+e^- \rightarrow H^0 Z$ and $H^0 A^0$ with $H^0, A^0$ decaying to two jets of any flavor including $g g$ . The limit is for SM $H^0 Z$ production cross section with $B(H^0 \rightarrow jj) = 1$ .		
10	ABDALLAH 04o	search for $Z \rightarrow b\bar{b} H^0, b\bar{b} A^0, \tau^+\tau^- H^0$ and $\tau^+\tau^- A^0$ in the final states $4b, b\bar{b}\tau^+\tau^-$ , and $4\tau$ . See paper for limits on Yukawa couplings.		
11	ABDALLAH 04o	search for $e^+e^- \rightarrow H^0 Z$ and $H^0 A^0$ , with $H^0, A^0$ decaying to $b\bar{b}, \tau^+\tau^-$ , or $H^0 \rightarrow A^0 A^0$ at $E_{cm} = 189$ –208 GeV. See paper for limits on couplings.		
12	ABBIENDI 02D	search for $Z \rightarrow b\bar{b} H^0$ and $b\bar{b} A^0$ with $H_1^0/A^0 \rightarrow \tau^+\tau^-$ , in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.		
13	ABBIENDI 01E	search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq 189$ GeV. In addition to usual final states, the decays $H_1^0, A^0 \rightarrow q\bar{q}, g g$ are searched for. See their Figs. 15, 16 for excluded regions.		
14	ABBIENDI 99E	search for $e^+e^- \rightarrow H^0 A^0$ and $H^0 Z$ at $E_{cm} = 183$ GeV. The limit is with $m_H = m_A$ in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the $m_H$ – $m_A$ plane. Updates the results of ACKERSTAFF 98s.		
15	See Fig. 4 of ABREU 95H	for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta > 1$ , the region $m_{H^0} + m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL.		
16	PICH 92	analyse $H^0$ with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm, \eta$ rare decays are shown in Figs. 3, 4. The considered mass region is not totally excluded.		

### Mass Limits for $H^0$ with Vanishing Yukawa Couplings

These limits assume that  $H^0$  couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as “fermiophobic”).

- 1 AALTONEN 13K search for  $H^0 \rightarrow WW^{(*)}$  in 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (1.3–6.6) times the expected cross section is given in the range  $m_{H^0} = 110$ –200 GeV at 95% CL.
- 2 AALTONEN 13L combine all CDF searches with 9.45–10.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV.
- 3 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV.
- 4 ABAZOV 13G search for  $H^0 \rightarrow WW^{(*)}$  in 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (2–9) times the expected cross section is given for  $m_{H^0} = 100$ –200 GeV at 95% CL.
- 5 ABAZOV 13H search for  $H^0 \rightarrow \gamma\gamma$  in 9.6 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV.
- 6 ABAZOV 13I search for  $H^0$  production in the final state with one lepton and two or more jets plus missing  $E_T$  in 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The search is sensitive to  $WH^0, ZH^0$  and vector-boson fusion Higgs production with  $H^0 \rightarrow WW^{(*)}$ . A limit on cross section times branching ratio which corresponds to (8–30) times the expected cross section is given in the range  $m_{H^0} = 100$ –200 GeV at 95% CL.
- 7 ABAZOV 13J search for  $H^0$  production in the final states  $e\mu\mu, e\mu\mu, \mu\tau\tau$ , and  $e^\pm\mu^\pm$  in 8.6–9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The search is sensitive to  $WH^0, ZH^0$  production with  $H^0 \rightarrow WW^{(*)}, ZZ^{(*)}$ , decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4–13.0) times the expected cross section is given in the range  $m_{H^0} = 100$ –200 GeV at 95% CL.
- 8 ABAZOV 13L combine all D0 results with up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV.
- 9 CHATRCHYAN 13AL search for  $H^0 \rightarrow \gamma\gamma$  in 5.1 fb<sup>-1</sup> and 5.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  and 8 TeV.
- 10 AAD 12N search for  $H^0 \rightarrow \gamma\gamma$  with 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110$ –150 GeV.
- 11 AALTONEN 12AN search for  $H^0 \rightarrow \gamma\gamma$  with 10 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV in the mass range  $m_{H^0} = 100$ –150 GeV.
- 12 CHATRCHYAN 12A0 use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, and CHATRCHYAN 12C.
- 13 AALTONEN 09AB search for  $H^0 \rightarrow \gamma\gamma$  in 3.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV in the mass range  $m_{H^0} = 70$ –150 GeV. Associated  $H^0 W, H^0 Z$  production and  $WW, ZZ$  fusion are considered.
- 14 ABAZOV 08U search for  $H^0 \rightarrow \gamma\gamma$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV in the mass range  $m_{H^0} = 70$ –150 GeV. Associated  $H^0 W, H^0 Z$  production and  $WW, ZZ$  fusion are considered. See their Tab. 1 for the limit on  $\sigma \cdot B(H^0 \rightarrow \gamma\gamma)$ , and see their Fig. 3 for the excluded region in the  $m_{H^0} - B(H^0 \rightarrow \gamma\gamma)$  plane.
- 15 SCHAEEL 07 search for Higgs bosons in association with a fermion pair and decaying to  $WW^{*}$ . The limit is from this search and HEISTER 02L for a  $H^0$  with SM production cross section.
- 16 Search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+\ell^-$ , or  $\nu\bar{\nu}$ , at  $E_{\text{cm}} \leq 209$  GeV. The limit is for a  $H^0$  with SM production cross section.
- 17 Updates ABREU 01F.
- 18 ACHARD 03C search for  $e^+e^- \rightarrow ZH^0$  followed by  $H^0 \rightarrow WW^{*}$  or  $ZZ^{*}$  at  $E_{\text{cm}} = 200$ –209 GeV and combine with the ACHARD 02C result. The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow WW^{*}) + B(H^0 \rightarrow ZZ^{*}) = 1$ ,  $m_{H^0} > 108.1$  GeV is obtained. See fig. 6 for the limits under different BR assumptions.
- 19 For  $B(H^0 \rightarrow \gamma\gamma) = 1$ ,  $m_{H^0} > 117$  GeV is obtained.
- 20 ACHARD 02C search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+\ell^-$ , or  $\nu\bar{\nu}$ , at  $E_{\text{cm}} \leq 209$  GeV. The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow \gamma\gamma) = 1$ ,  $m_{H^0} > 114$  GeV is obtained.
- 21 AFFOLDER 01H search for associated production of a  $\gamma\gamma$  resonance and a  $W$  or  $Z$  (tagged by two jets, an isolated lepton, or missing  $E_T$ ). The limit assumes Standard Model values for the production cross section and for the couplings of the  $H^0$  to  $W$  and  $Z$  bosons. See their Fig. 11 for limits with  $B(H^0 \rightarrow \gamma\gamma) < 1$ .
- 22 ACCIARRI 00S search for associated production of a  $\gamma\gamma$  resonance with a  $q\bar{q}, \nu\bar{\nu}$ , or  $\ell^+\ell^-$  pair in  $e^+e^-$  collisions at  $E_{\text{cm}} = 189$  GeV. The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow \gamma\gamma) = 1$ ,  $m_{H^0} > 98$  GeV is obtained. See their Fig. 5 for limits on  $B(H \rightarrow \gamma\gamma) \cdot \sigma(e^+e^- \rightarrow Hf\bar{f}) / \sigma(e^+e^- \rightarrow Hf\bar{f})$  (SM).
- 23 BARATE 00L search for associated production of a  $\gamma\gamma$  resonance with a  $q\bar{q}, \nu\bar{\nu}$ , or  $\ell^+\ell^-$  pair in  $e^+e^-$  collisions at  $E_{\text{cm}} = 88$ –202 GeV. The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow \gamma\gamma) = 1$ ,  $m_{H^0} > 109$  GeV is obtained. See their Fig. 3 for limits on  $B(H \rightarrow \gamma\gamma) \cdot \sigma(e^+e^- \rightarrow Hf\bar{f}) / \sigma(e^+e^- \rightarrow Hf\bar{f})$  (SM).
- 24 ABBIENDI 99O search for associated production of a  $\gamma\gamma$  resonance with a  $q\bar{q}, \nu\bar{\nu}$ , or  $\ell^+\ell^-$  pair in  $e^+e^-$  collisions at 189 GeV. The limit is for a  $H^0$  with SM production cross

section. See their Fig. 4 for limits on  $\sigma(e^+e^- \rightarrow H^0 Z^0) \times B(H^0 \rightarrow \gamma\gamma) \times B(X^0 \rightarrow f\bar{f})$  for various masses. Updates the results of ACKERSTAFF 98Y.

- 25 ABBOTT 99B search for associated production of a  $\gamma\gamma$  resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the  $H^0$  to  $W$  and  $Z$  bosons. Limits in the range of  $\sigma(H^0 + Z/W) \cdot B(H^0 \rightarrow \gamma\gamma) = 0.80$ –0.34 pb are obtained in the mass range  $m_{H^0} = 65$ –150 GeV.

- 26 ABREU 99P search for  $e^+e^- \rightarrow H^0 \gamma$  with  $H^0 \rightarrow b\bar{b}$  or  $\gamma\gamma$ , and  $e^+e^- \rightarrow H^0 q\bar{q}$  with  $H^0 \rightarrow \gamma\gamma$ . See their Fig. 4 for limits on  $\sigma \times B$ . Explicit limits within an effective interaction framework are also given.

## Mass Limits for $H^0$ Decaying to Invisible Final States

These limits are for a neutral scalar  $H^0$  which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of  $H^0$  to ordinary particles unless otherwise stated.

See their Fig. 6 for a limit on the cross section times branching ratio for  $m_{H^0} = 115$ –300 GeV.
- 2 AAD 15BH search for events with a jet and missing  $E_T$  in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. Limits on  $\sigma(H^0) B(H^0 \rightarrow \text{invisible}) < (44\text{--}10)$  pb (95%CL) is given for  $m_{H^0} = 115$ –300 GeV.
- 3 AAD 14BA search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle which decays to collimated pairs of  $e^+e^-, \mu^+\mu^-,$  or  $\pi^+\pi^-$  plus invisible particles, in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Figs. 15 and 16 for limits on cross section times branching ratio.
- 4 AAD 14O search for  $p\bar{p} \rightarrow H^0 ZX, Z \rightarrow \ell\ell$  with  $H^0$  decaying to invisible final states in 4.5 fb<sup>-1</sup> at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. See their Fig. 3 for a limit on the cross section times branching ratio for  $m_{H^0} = 110$ –400 GeV.
- 5 CHATRCHYAN 14B search for  $p\bar{p} \rightarrow H^0 ZX, Z \rightarrow \ell\ell$  and  $Z \rightarrow b\bar{b}$ , and also  $p\bar{p} \rightarrow qqH^0 X$  with  $H^0$  decaying to invisible final states using data at  $E_{\text{cm}} = 7$  and 8 TeV. See their Figs. 10, 11 for limits on the cross section times branching ratio for  $m_{H^0} = 100$ –400 GeV.
- 6 AAD 13AG search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle which decays to  $\mu^+\mu^- X^0$ , in 1.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 7 for limits on cross section times branching ratio.
- 7 AAD 13AT search for  $H^0$  production in the decay  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  eventually decays to clusters of collimated  $e^+e^-$  pairs, in 2.04 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 3 for limits on cross section times branching ratio.
- 8 CHATRCHYAN 13BJ search for  $H^0$  production in the decay chain  $H^0 \rightarrow X^0 X^0, X^0 \rightarrow \mu^+\mu^- X^0$  in 5.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 2 for limits on cross section times branching ratio.
- 9 AAD 12AQ search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle which decays mainly to  $b\bar{b}$  in the muon detector, in 1.94 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 3 for limits on cross section times branching ratio for  $m_{H^0} = 120, 140$  GeV,  $m_{X^0} = 20, 40$  GeV in the  $c\tau$  range of 0.5–35 m.
- 10 AALTONEN 12AB search for  $H^0$  production in the decay  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  eventually decays to clusters of collimated  $\ell^+\ell^-$  pairs, in 5.1 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.
- 11 AALTONEN 12U search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle with  $c\tau \approx 1$  cm which decays mainly to  $b\bar{b}$ , in 3.2 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Figs. 9 and 10 for limits on cross section times branching ratio for  $m_{H^0} = (130\text{--}170)$  GeV,  $m_{X^0} = 20, 40$  GeV.
- 12 ABBIENDI 10 search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying invisibly. The limit assumes SM production cross section and  $B(H^0 \rightarrow \text{invisible}) = 1$ .
- 13 ABBIENDI 07 search for  $e^+e^- \rightarrow H^0 Z$  with  $Z \rightarrow q\bar{q}$  and  $H^0$  decaying to invisible final states. The  $H^0$  width is varied between 1 GeV and 3 TeV. A limit  $\sigma \cdot B(H^0 \rightarrow \text{invisible}) < (0.07\text{--}0.57)$  pb (95%CL) is obtained at  $E_{\text{cm}} = 206$  GeV for  $m_{H^0} = 60$ –114 GeV.
- 14 Search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying invisibly. The limit assumes SM production cross section and  $B(H^0 \rightarrow \text{invisible}) = 1$ .
- 15 ACCIARRI 00M search for  $e^+e^- \rightarrow ZH^0$  with  $H^0$  decaying invisibly at  $E_{\text{cm}} = 183$ –189 GeV. The limit assumes SM production cross section and  $B(H^0 \rightarrow \text{invisible}) = 1$ . See their Fig. 6 for limits for smaller branching ratios.

- 1 KHACHATRYAN 16F search for the decay  $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$  in 19.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Fig. 8 for cross section limits for  $m_{A^0} = 4-8$  GeV.
- 2 LEES 15H search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $c\bar{c}$  and give limits on  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow c\bar{c})$  in the range  $7.4 \times 10^{-5} - 2.4 \times 10^{-3}$  (90% CL) for  $4.00 \leq m_{A^0} \leq 8.95$  and  $9.10 \leq m_{A^0} \leq 9.25$  GeV. See their Fig. 6.
- 3 LEES 13C search for the process  $\Upsilon(2S, 3S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $\mu^+ \mu^-$  and give limits on  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(0.3-9.7) \times 10^{-6}$  (90% CL) for  $0.212 \leq m_{A^0} \leq 9.20$  GeV. See their Fig. 5(e) for limits on the  $b-A^0$  Yukawa coupling derived by combining this result with AUBERT 09Z.
- 4 LEES 13L search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $g\bar{g}$  or  $s\bar{s}$  and give limits on  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow g\bar{g})$  between  $1 \times 10^{-6}$  and  $2 \times 10^{-2}$  (90% CL) for  $0.5 \leq m_{A^0} \leq 9.0$  GeV, and  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow s\bar{s})$  between  $4 \times 10^{-6}$  and  $1 \times 10^{-3}$  (90% CL) for  $1.5 \leq m_{A^0} \leq 9.0$  GeV. See their Fig. 4.
- 5 LEES 13R search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $\tau^+ \tau^-$  and give limits on  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \tau^+ \tau^-)$  in the range  $0.9-13 \times 10^{-5}$  (90% CL) for  $3.6 \leq m_{A^0} \leq 9.2$  GeV. See their Fig. 4 for limits on the  $b-A^0$  Yukawa coupling derived by combining this result with AUBERT 09P.
- 6 CHATRCHYAN 12V search for  $A^0$  production in the decay  $A^0 \rightarrow \mu^+ \mu^-$  with 1.3 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on  $\sigma(A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(1.5-7.5)$  pb is given for  $m_{A^0} = (5.5-8.7)$  and  $(11.5-14)$  GeV at 95% CL.
- 7 AALTONEN 11P search in 2.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV for the decay chain  $t \rightarrow b H^+, H^+ \rightarrow W^+ A^0, A^0 \rightarrow \tau^+ \tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow b H^+)$  for  $90 < m_{H^+} < 160$  GeV.
- 8 ABOUZAID 11A search for the decay chain  $K_L \rightarrow \pi^0 \pi^0 A^0, A^0 \rightarrow \mu^+ \mu^-$  and give a limit  $B(K_L \rightarrow \pi^0 \pi^0 A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-) < 1.0 \times 10^{-10}$  at 90% CL for  $m_{A^0} = 214.3$  MeV. The search was motivated by PARK 05.
- 9 DEL-AMO-SANCHEZ 11J search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to invisible final states. They give limits on  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \text{invisible})$  in the range  $(1.9-4.5) \times 10^{-6}$  (90% CL) for  $0 \leq m_{A^0} \leq 8.0$  GeV, and  $(2.7-37) \times 10^{-6}$  for  $8.0 \leq m_{A^0} \leq 9.2$  GeV.
- 11 LEES 11H search for the process  $\Upsilon(2S, 3S) \rightarrow A^0 \gamma$  with  $A^0$  decaying hadronically and give limits on  $B(\Upsilon(2S, 3S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \text{hadrons})$  in the range  $1 \times 10^{-6} - 8 \times 10^{-5}$  (90% CL) for  $0.3 < m_{A^0} < 7$  GeV. The decay rates for  $\Upsilon(2S)$  and  $\Upsilon(3S)$  are assumed to be equal up to the phase space factor. See their Fig. 5.
- 12 ANDREAS 10 analyze constraints from rare decays and other processes on a light  $A^0$  with  $m_{A^0} < 2m_\mu$  and give limits on its coupling to fermions at the level of  $10^{-4}$  times the Standard Model value.
- 13 HYUN 10 search for the decay chain  $B^0 \rightarrow K^{*0} A^0, A^0 \rightarrow \mu^+ \mu^-$  and give a limit on  $B(B^0 \rightarrow K^{*0} A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(2.26-5.53) \times 10^{-8}$  at 90% CL for  $m_{A^0} = 212-300$  MeV. The limit for  $m_{A^0} = 214.3$  MeV is  $2.26 \times 10^{-8}$ .
- 14 HYUN 10 search for the decay chain  $B^0 \rightarrow \rho^0 A^0, A^0 \rightarrow \mu^+ \mu^-$  and give a limit on  $B(B^0 \rightarrow \rho^0 A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(1.73-4.51) \times 10^{-8}$  at 90% CL for  $m_{A^0} = 212-300$  MeV. The limit for  $m_{A^0} = 214.3$  MeV is  $1.73 \times 10^{-8}$ .
- 15 AUBERT 09P search for the process  $\Upsilon(3S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \tau^+ \tau^-$  for  $4.03 < m_{A^0} < 9.52$  and  $9.61 < m_{A^0} < 10.10$  GeV, and give limits on  $B(\Upsilon(3S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \tau^+ \tau^-)$  in the range  $(1.5-16) \times 10^{-5}$  (90% CL).
- 16 AUBERT 09Z search for the process  $\Upsilon(2S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \mu^+ \mu^-$  for  $0.212 < m_{A^0} < 9.3$  GeV and give limits on  $B(\Upsilon(2S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(0.3-8) \times 10^{-6}$  (90% CL).
- 17 AUBERT 09Z search for the process  $\Upsilon(3S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \mu^+ \mu^-$  for  $0.212 < m_{A^0} < 9.3$  GeV and give limits on  $B(\Upsilon(3S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(0.3-5) \times 10^{-6}$  (90% CL).

- 18 TUNG 09 search for the decay chain  $K_L \rightarrow \pi^0 \pi^0 A^0, A^0 \rightarrow \gamma \gamma$  and give a limit on  $B(K_L \rightarrow \pi^0 \pi^0 A^0) \cdot B(A^0 \rightarrow \gamma \gamma)$  in the range  $(2.4-10.7) \times 10^{-7}$  at 90% CL for  $m_{A^0} = 194.3-219.3$  MeV. The limit for  $m_{A^0} = 214.3$  MeV is  $2.4 \times 10^{-7}$ .
- 19 LOVE 08 search for the process  $\Upsilon(1S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \mu^+ \mu^-$  (for  $m_{A^0} < 2m_\tau$ ) and  $A^0 \rightarrow \tau^+ \tau^-$ . Limits on  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \ell^+ \ell^-)$  in the range  $10^{-6}-10^{-4}$  (90% CL) are given.
- 20 BESSION 07 give a limit  $B(\Upsilon(1S) \rightarrow \eta_b \gamma) \cdot B(\eta_b \rightarrow \tau^+ \tau^-) < 0.27\%$  (95% CL), which constrains a possible  $A^0$  exchange contribution to the  $\eta_b$  decay.
- 21 PARK 05 found three candidate events for  $\Sigma^+ \rightarrow p \mu^+ \mu^-$  in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with  $m_{A^0} = 214.3 \pm 0.5$  MeV and the branching fraction  $B(\Sigma^+ \rightarrow p A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-) = (3.1^{+2.4}_{-1.9} \pm 1.5) \times 10^{-8}$ .
- 22 BALEST 95 give limits  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot 1.5 \times 10^{-5}$  at 90% CL for  $m_{A^0} < 5$  GeV. The limit becomes  $< 10^{-4}$  for  $m_{A^0} < 7.7$  GeV.
- 23 ANTREASIAN 90c give limits  $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot 5.6 \times 10^{-5}$  at 90% CL for  $m_{A^0} < 7.2$  GeV.  $A^0$  is assumed not to decay in the detector.

- 1 AAD 16C search for production of a heavy  $H^0$  state decaying to  $W^+ W^-$  in the final states  $\ell\nu\ell\nu$  and  $\ell\nu q\bar{q}$  in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Figs. 12, 13, and 16 for upper limits on  $\sigma(H^0) \cdot B(H^0 \rightarrow W^+ W^-)$  for  $m_{H^0}$  ranging from 300 GeV to 1000 or 1500 GeV with various assumptions on the total width of  $H^0$ .
- 2 KHACHATRYAN 16F search for the decay  $H^0_2 \rightarrow H^0_1 H^0_1 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$  with  $m_{H^0_2} = 125$  GeV in 19.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Fig. 8 for cross section limits for  $m_{H^0_1} = 4-8$  GeV.
- 3 AAD 15BK search for production of a heavy  $H^0_2$  decaying to  $H^0 H^0$  in the final state  $b\bar{b}b\bar{b}$  in 19.5 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Fig. 14(c) for  $\sigma(H^0_2) \cdot B(H^0_2 \rightarrow H^0 H^0)$  for  $m_{H^0_2} = 500-1500$  GeV with  $\Gamma_{H^0_2} = 1$  GeV.
- 4 AAD 15BZ search for the decay  $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \tau^+ \tau^-$  ( $m_{H^0} = 125$  GeV) in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Fig. 6 for limits on cross section times branching ratio for  $m_{A^0} = 3.7-5.0$  GeV.
- 5 AAD 15BZ search for a state  $H^0_2$  via the decay  $H^0_2 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \tau^+ \tau^-$  in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Fig. 6 for limits on cross section times branching ratio for  $m_{H^0_2} = 100-500$  GeV and  $m_{A^0} = 5$  GeV.

## Neutral Higgs Bosons, Searches for

- <sup>6</sup> AAD 15CE search for production of a heavy  $H_2^0$  decaying to  $H^0 H^0$  in the final states  $b\bar{b}\tau^+\tau^-$  and  $\gamma\gamma WW^*$  in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV and combine with data from AAD 15H and AAD 15BK. A limit  $\sigma(H_2^0) B(H_2^0 \rightarrow H^0 H^0) < 2.1\text{--}0.011$  pb (95% CL) is given for  $m_{H_2^0} = 260\text{--}1000$  GeV. See their Fig. 6.
- <sup>7</sup> AAD 15H search for production of a heavy  $H_2^0$  decaying to  $H^0 H^0$  in the final state  $\gamma\gamma b\bar{b}$  in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. A limit of  $\sigma(H_2^0) B(H_2^0 \rightarrow H^0 H^0) < 3.5\text{--}0.7$  pb is given for  $m_{H_2^0} = 260\text{--}500$  GeV at 95% CL. See their Fig. 3.
- <sup>8</sup> AAD 15s search for production of  $A^0$  decaying to  $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}, \nu\bar{\nu}b\bar{b}$  and  $\ell^+\ell^-\tau^+\tau^-$  in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 3 for cross section limits for  $m_{A^0} = 200\text{--}1000$  GeV.
- <sup>9</sup> KHACHATRYAN 15AW search for production of a heavy state  $H_2^0$  of an electroweak singlet extension of the Standard Model via the decays of  $H_2^0$  to  $W^+W^-$  and  $ZZ$  in up to 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and up to 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV in the range  $m_{H_2^0} = 145\text{--}1000$  GeV. See their Figs. 8 and 9 for limits in the parameter space of the model.
- <sup>10</sup> KHACHATRYAN 15BB search for production of a resonance  $H^0$  decaying to  $\gamma\gamma$  in 19.7 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 7 for limits on cross section times branching ratio for  $m_{H^0} = 150\text{--}850$  GeV.
- <sup>11</sup> KHACHATRYAN 15N search for production of  $A^0$  decaying to  $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}$  in 19.7 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 3 for limits on cross section times branching ratios for  $m_{A^0} = 225\text{--}600$  GeV.
- <sup>12</sup> KHACHATRYAN 15o search for production of a high-mass narrow resonance  $A^0$  decaying to  $ZH^0 \rightarrow q\bar{q}\tau^+\tau^-$  in 19.7 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 6 for limits on cross section times branching ratios for  $m_{A^0} = 800\text{--}2500$  GeV.
- <sup>13</sup> AAD 14AP search for a second  $H^0$  state decaying to  $\gamma\gamma$  in addition to the state at about 125 GeV in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 4 for limits on cross section times branching ratio for  $m_{H^0} = 65\text{--}600$  GeV.
- <sup>14</sup> AAD 14M search for the decay cascade  $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$  decaying to  $b\bar{b}$  in 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Table III for limits on cross section times branching ratio for  $m_{H_2^0} = 325\text{--}1025$  GeV and  $m_{H^\pm} = 225\text{--}925$  GeV.
- <sup>15</sup> CHATRCHYAN 14G search for a second  $H^0$  state decaying to  $WW^{(*)}$  in addition to the observed signal at about 125 GeV using 4.9 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.4 fb $^{-1}$  at  $E_{cm} = 8$  TeV. See their Fig. 21 (right) for cross section limits in the mass range 110–600 GeV.
- <sup>16</sup> KHACHATRYAN 14P search for a second  $H^0$  state decaying to  $\gamma\gamma$  in addition to the observed signal at about 125 GeV using 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV. See their Figs. 27 and 28 for cross section limits in the mass range 110–150 GeV.
- <sup>17</sup> AALTONEN 13P search for production of a heavy Higgs boson  $H^0$  that decays into a charged Higgs boson  $H^\pm$  and a lighter Higgs boson  $H^0$  via the decay chain  $H^0 \rightarrow H^\pm W^\mp, H^\pm \rightarrow W^\pm H^0, H^0 \rightarrow b\bar{b}$  in the final state  $\ell\nu$  plus 4 jets in 8.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 4 for limits on cross section times branching ratio in the  $m_{H^\pm}\text{--}m_{H^0}$  plane for  $m_{H^0} = 126$  GeV.
- <sup>18</sup> CHATRCHYAN 13B search for  $H^0$  production in the decay chain  $H^0 \rightarrow A^0 A^0, A^0 \rightarrow \mu^+\mu^-$  in 5.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 2 for limits on cross section times branching ratio.
- <sup>19</sup> AALTONEN 11P search in 2.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+A^0, A^0 \rightarrow \tau^+\tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160$  GeV.
- <sup>20</sup> ABBIENDI 10 search for  $e^+e^- \rightarrow ZH^0$  with the decay chain  $H^0 \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0, \tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + (\gamma \text{ or } Z^*)$ , when  $\tilde{\chi}_1^0$  and  $\tilde{\chi}_2^0$  are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on  $m_{H^0}$  of 108.4 (107.0) GeV (95% CL) is obtained for SM  $ZH^0$  cross section and  $B(H^0 \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0) = 1$ .
- <sup>21</sup> SCHAEEL 10 search for the process  $e^+e^- \rightarrow H^0 Z$  followed by the decay chain  $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+\tau^-\tau^+\tau^-$  with  $Z \rightarrow \ell^+\ell^-, \nu\bar{\nu}$  at  $E_{cm} = 183\text{--}209$  GeV. For a  $H^0 Z Z$  coupling equal to the SM value,  $B(H^0 \rightarrow A^0 A^0) = B(A^0 \rightarrow \tau^+\tau^-) = 1$ , and  $m_{A^0} = 4\text{--}10$  GeV,  $m_{H^0}$  up to 107 GeV is excluded at 95% CL.
- <sup>22</sup> ABAZOV 09V search for  $H^0$  production followed by the decay chain  $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\mu^+\mu^-$  or  $\mu^+\mu^-\tau^+\tau^-$  in 4.2 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 3 for limits on  $\sigma(H^0) \cdot B(H^0 \rightarrow A^0 A^0)$  for  $m_{A^0} = 3.6\text{--}19$  GeV.
- <sup>23</sup> ABBIENDI 05A search for  $e^+e^- \rightarrow H_1^0 A^0$  in general Type-II two-doublet models, with decays  $H_1^0, A^0 \rightarrow q\bar{q}, gg, \tau^+\tau^-$ , and  $H_1^0 \rightarrow A^0 A^0$ .
- <sup>24</sup> ABBIENDI 04K search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying to two jets of any flavor including  $gg$ . The limit is for SM production cross section with  $B(H^0 \rightarrow jj) = 1$ .
- <sup>25</sup> ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to  $W$  or  $Z$  bosons, assuming SM decays of the Higgs. Results in Fig. 26.
- <sup>26</sup> ACHARD 04B search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying to  $b\bar{b}, c\bar{c}$ , or  $gg$ . The limit is for SM production cross section with  $B(H^0 \rightarrow jj) = 1$ .
- <sup>27</sup> ACHARD 04F search for  $H^0$  with anomalous coupling to gauge boson pairs in the processes  $e^+e^- \rightarrow H^0 \gamma, e^+e^- H^0, H^0 Z$  with decays  $H^0 \rightarrow f\bar{f}, \gamma\gamma, Z\gamma$ , and  $W^*W$  at  $E_{cm} = 189\text{--}209$  GeV. See paper for limits.
- <sup>28</sup> ABBIENDI 03F search for  $H^0 \rightarrow$  anything in  $e^+e^- \rightarrow H^0 Z$ , using the recoil mass spectrum of  $Z \rightarrow e^+e^-$  or  $\mu^+\mu^-$ . In addition, it searched for  $Z \rightarrow \nu\bar{\nu}$  and  $H^0 \rightarrow e^+e^-$  or photons. Scenarios with large width or continuum  $H^0$  mass distribution are considered. See their Figs. 11–14 for the results.
- <sup>29</sup> ABBIENDI 03G search for  $e^+e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, gg$ , or  $\tau^+\tau^-$  in the region  $m_{H_1^0} = 45\text{--}86$  GeV and  $m_{A^0} = 2\text{--}11$  GeV. See their Fig. 7 for the limits.

- <sup>30</sup> Search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+\ell^-,$  or  $\nu\bar{\nu}$ , at  $E_{cm} \leq 209$  GeV. The limit is for a  $H^0$  with SM production cross section and  $B(H^0 \rightarrow f\bar{f})=0$  for all fermions  $f$ .
- <sup>31</sup> For  $B(H^0 \rightarrow \gamma\gamma)=1$ ,  $m_{H^0} > 113.1$  GeV is obtained.
- <sup>32</sup> HEISTER 02M search for  $e^+e^- \rightarrow H^0 Z$ , assuming that  $H^0$  decays to  $q\bar{q}, gg$ , or  $\tau^+\tau^-$  only. The limit assumes SM production cross section.
- <sup>33</sup> ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at  $E_{cm} \leq 189$  GeV. In addition to usual final states, the decays  $H_1^0, A^0 \rightarrow q\bar{q}, gg$  are searched for. See their Figs. 15,16 for excluded regions.
- <sup>34</sup> ACCIARRI 00R search for  $e^+e^- \rightarrow H^0 \gamma$  with  $H^0 \rightarrow b\bar{b}, Z\gamma$ , or  $\gamma\gamma$ . See their Fig. 3 for limits on  $\sigma \cdot B$ . Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.
- <sup>35</sup> ACCIARRI 00R search for the two-photon type processes  $e^+e^- \rightarrow e^+e^- H^0$  with  $H^0 \rightarrow b\bar{b}$  or  $\gamma\gamma$ . See their Fig. 4 for limits on  $\Gamma(H^0 \rightarrow \gamma\gamma) \cdot B(H^0 \rightarrow \gamma\gamma \text{ or } b\bar{b})$  for  $m_{H^0}=70\text{--}170$  GeV.
- <sup>36</sup> GONZALEZ-GARCIA 98B use  $D\bar{D}$  limit for  $\gamma\gamma$  events with missing  $E_T$  in  $p\bar{p}$  collisions (ABBOTT 98) to constrain possible  $ZH$  or  $WH$  production followed by unconventional  $H \rightarrow \gamma\gamma$  decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.
- <sup>37</sup> KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no  $H_1^0 Z Z$  coupling and obtain  $m_{H_1^0} \gtrsim 5$  GeV or  $m_{A^0} \gtrsim 5$  GeV for  $\tan\beta > 50$ . Other Higgs bosons are assumed to be much heavier.
- <sup>38</sup> ALEXANDER 96H give  $B(Z \rightarrow H^0 \gamma) \times B(H^0 \rightarrow q\bar{q}) < 1\text{--}4 \times 10^{-5}$  (95%CL) and  $B(Z \rightarrow H^0 \gamma) \times B(H^0 \rightarrow b\bar{b}) < 0.7\text{--}2 \times 10^{-5}$  (95%CL) in the range  $20 < m_{H^0} < 80$  GeV.

## SEARCHES FOR A HIGGS BOSON WITH STANDARD MODEL COUPLINGS

These listings are based on experimental searches for a scalar boson whose couplings to  $W, Z$  and fermions are precisely those of the Higgs boson predicted by the three-generation Standard Model with the minimal Higgs sector.

For a review and a bibliography, see the review on “Status of Higgs Boson Physics.”

### Direct Mass Limits for $H^0$

The mass limits shown below apply to a Higgs boson  $H^0$  with Standard Model couplings whose mass is a priori unknown. These mass limits are compatible with and independent of the observed signal at about 125 GeV. In particular, the symbol  $H^0$  employed below does not in general refer to the observed signal at about 125 GeV.

The cross section times branching ratio limits quoted in the footnotes below are typically given relative to those of a Standard Model Higgs boson of the relevant mass. These limits can be reinterpreted in terms of more general models (e.g. extended Higgs sectors) in which the Higgs couplings to  $W, Z$  and fermions are re-scaled from their Standard Model values.

All data that have been superseded by newer results are marked as “not used” or have been removed from this compilation, and are documented in previous editions of this Review of Particle Physics.

<sup>1</sup> KHACHATRYAN 15AW search for  $H^0$  production in the decays  $H^0 \rightarrow W^{+}W^{-} \rightarrow \ell\nu\ell\nu, \ell\nu q\bar{q}$ , and  $H^0 \rightarrow ZZ \rightarrow 4\ell, \ell\ell\tau\tau, \ell\ell\nu\nu$ , and  $\ell\ell q\bar{q}$  in up to  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$  in the range  $m_{H^0} = 145\text{--}1000 \text{ GeV}$ . See their Fig. 7 for limits on cross section times branching ratio.

<sup>2</sup> AALTONEN 13L combine all CDF searches with  $9.45\text{--}10.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.45\text{--}4.8)$  times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}200 \text{ GeV}$  at 95% CL. An excess of events over background is observed with a local significance of  $2.0 \sigma$  at  $m_{H^0} = 125 \text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 124 and 203 GeV are excluded at 95% CL.

<sup>3</sup> AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations. A limit on cross section times branching ratio which corresponds to  $(0.37\text{--}3.1)$  times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}200 \text{ GeV}$  at 95% CL. An excess of events over background is observed with a local significance of  $3.0\sigma$  at  $m_{H^0} = 125 \text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 121 and 225 GeV are excluded at 95% CL.

<sup>4</sup> ABAZOV 13L combine all D0 results with up to  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.66\text{--}3.1)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 90\text{--}200 \text{ GeV}$  at 95% CL. An excess of events over background is observed with a local significance of  $1.7\sigma$  at  $m_{H^0} = 125 \text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 125 and 218 GeV are excluded at 95% CL.

<sup>5</sup> CHATRCHYAN 12N search for  $H^0$  production in the decays  $H \rightarrow \gamma\gamma, ZZ^{*} \rightarrow 4\ell, WW^{*} \rightarrow \ell\nu\ell\nu, \tau\tau$ , and  $b\bar{b}$  in  $4.9\text{--}5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.1\text{--}5.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The expected exclusion region for no signal is  $110\text{--}145 \text{ GeV}$  at 99.9% CL. See also CHATRCHYAN 13Y.

<sup>6</sup> Search for  $e^{+}e^{-} \rightarrow H^0 Z$  at  $E_{\text{cm}} \leq 209 \text{ GeV}$  in the final states  $H^0 \rightarrow b\bar{b}$  with  $Z \rightarrow \ell\ell, \nu\bar{\nu}, q\bar{q}, \tau^{+}\tau^{-}$  and  $H^0 \rightarrow \tau^{+}\tau^{-}$  with  $Z \rightarrow q\bar{q}$ .

<sup>7</sup> Combination of the results of all LEP experiments.

<sup>8</sup> A  $3\sigma$  excess of candidate events compatible with  $m_{H^0}$  near  $114 \text{ GeV}$  is observed in the combined channels  $q\bar{q}q\bar{q}, q\bar{q}\ell\bar{\ell}, q\bar{q}\tau^{+}\tau^{-}$ .

<sup>9</sup> AAD 15AA search for  $H^0 \rightarrow WW^{(*)}$  in  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.2\text{--}6)$  times the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}200 \text{ GeV}$  at 95% CL.

<sup>10</sup> AAD 15G search for  $WH^0$  and  $ZH^0$  production followed by  $H^0 \rightarrow b\bar{b}$  in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . A limit on the cross section times branching ratio which corresponds to  $(0.8\text{--}2.6)$  times the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}140 \text{ GeV}$  at 95% CL.

<sup>11</sup> AAD 14AS search for  $H^0 \rightarrow \mu^{+}\mu^{-}$  in  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . A limit on the cross section times branching ratio which corresponds to  $(6.5\text{--}16.8)$  times the expected Standard Model cross section is given for  $m_{H^0} = 120\text{--}150 \text{ GeV}$  at 95% CL.

<sup>12</sup> AAD 14J search for  $H^0 \rightarrow Z\gamma \rightarrow \ell\ell\gamma$  in  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(4\text{--}18)$  times the expected Standard Model cross section is given for  $m_{H^0} = 120\text{--}150 \text{ GeV}$  at 95% CL.

<sup>13</sup> CHATRCHYAN 14AA search for  $H^0$  production in the decay mode  $H^0 \rightarrow ZZ^{(*)} \rightarrow 4\ell$  in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The expected exclusion region for no signal is  $115\text{--}740 \text{ GeV}$  at the 95% CL. See their Fig. 18 for cross section limits for  $m_{H^0} = 110\text{--}1000 \text{ GeV}$ .

<sup>14</sup> CHATRCHYAN 14AI search for  $WH^0$  and  $ZH^0$  production followed by  $H^0 \rightarrow b\bar{b}$  in up to  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $18.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . A limit on the cross section times branching ratio which corresponds to  $(1\text{--}3)$  times the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}135 \text{ GeV}$  at 95% CL.

<sup>15</sup> CHATRCHYAN 14G search for  $H^0$  production in the decay mode  $H^0 \rightarrow WW^{(*)} \rightarrow \ell\nu\ell\nu$  in  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.4 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The expected exclusion region for no signal is  $115\text{--}600 \text{ GeV}$  at the 95% CL. See their Fig. 21 (left) for cross section limits for  $m_{H^0} = 110\text{--}600 \text{ GeV}$ .

<sup>16</sup> AALTONEN 13B search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}, Z \rightarrow \nu\bar{\nu}$ , and  $H^0 W$  production in  $H^0 \rightarrow b\bar{b}, W \rightarrow \ell\nu$  ( $\ell$  not identified) with an improved  $b$  identification algorithm in  $9.45 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.72\text{--}11.8)$  times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 3.06, where 3.33 is expected for no signal.

<sup>17</sup> AALTONEN 13C search for associated  $H^0 W$  and  $H^0 Z$  as well as vector-boson fusion  $H^0 q\bar{q}$  production in the final state  $H^0 \rightarrow b\bar{b}, W/Z \rightarrow q\bar{q}$  with  $9.45 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is  $(7.0\text{--}64.6)$  times larger than the expected Standard Model cross section is given in the range  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 9.0, where 11.0 is expected for no signal.

<sup>18</sup> AALTONEN 13K search for  $H^0$  production (with a possible additional  $W$  or  $Z$ ) in the final state  $H^0 \rightarrow WW^{(*)} \rightarrow \ell\nu\ell\nu$  in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.49\text{--}14.1)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 110\text{--}200 \text{ GeV}$  at 95% CL. The limit at  $m_{H^0} = 125 \text{ GeV}$  is 3.26, where 3.25 is expected for no signal. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 124 and 200 GeV are excluded at 95% CL.

<sup>19</sup> ABAZOV 13E search for  $H^0$  production in four-lepton final states from  $H^0 \rightarrow ZZ^{(*)}$  and  $H^0 Z$  in  $9.6\text{--}9.8 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(8.6\text{--}78.9)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 115\text{--}200 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 42.3, where 42.8 is expected for no signal.

<sup>20</sup> ABAZOV 13F search for  $H^0$  production in final states  $e\tau jj$  and  $\mu\tau jj$  in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The search is sensitive to  $H \rightarrow \tau\tau$  and  $H \rightarrow WW^{(*)}$ . A limit on cross section times branching ratio which corresponds to  $(9.4\text{--}17.9)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 105\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 11.3, where 9.0 is expected for no signal.

<sup>21</sup> ABAZOV 13G search for  $H^0$  production in final states  $H^0 \rightarrow WW^{(*)} \rightarrow \ell^{+}\nu\ell^{-}\nu$  in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  and give a limit on cross section times branching ratio for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 4.1, where 3.4 is expected for no signal. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 125 and 218 GeV are excluded at 95% CL.

<sup>22</sup> ABAZOV 13H search for  $H^0$  production with the decay  $H^0 \rightarrow \gamma\gamma$  in  $9.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(8.3\text{--}25.4)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 12.8, where 8.7 is expected for no signal.

<sup>23</sup> ABAZOV 13I search for  $H^0$  production in the final state with one lepton and two or more jets plus missing  $E_T$  with  $b$  identification in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The search is mainly sensitive to  $H^0 W \rightarrow b\bar{b}\ell\nu, H^0 \rightarrow WW^{(*)} \rightarrow \ell\nu q\bar{q}$ , and  $H^0 V \rightarrow V W W^{(*)} \rightarrow \ell\nu q\bar{q} q\bar{q}$  ( $V = W, Z$ ). A limit on cross section times branching ratio which corresponds to  $(1.3\text{--}11.4)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 90\text{--}200 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 5.8, where 4.7 is expected for no signal. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 150 and 188 GeV are excluded at 95% CL.

<sup>24</sup> ABAZOV 13J search for  $H^0$  production in the final states  $e\mu\mu, e\mu\mu, \mu\tau\tau$ , and  $e^{\pm}\mu^{\pm}$  in  $8.6\text{--}9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The search is sensitive to  $WH^0, ZH^0$  and gluon fusion production with  $H^0 \rightarrow WW^{(*)}, ZZ^{(*)}$ , decaying to leptonic final states, and to  $WH^0, ZH^0$  production with  $H^0 \rightarrow \tau^{+}\tau^{-}$ . A limit on cross section times branching ratio which corresponds to  $(4.4\text{--}12.7)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 100\text{--}200 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 8.4, where 6.3 is expected for no signal.

<sup>25</sup> ABAZOV 13K search for associated  $H^0 Z$  production in the final states  $\ell\ell b\bar{b}$  with  $b$  identification in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(1.8\text{--}5.3)$  times the expected Standard Model

## Neutral Higgs Bosons, Searches for

- cross section is given for  $m_{H^0} = 90\text{--}150$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 7.1, where 5.1 is expected for no signal.
- 26 CHATRCHYAN 13AL search for  $H^0 \rightarrow \tau^+\tau^-, WW^*$ , and  $ZZ^*$  in 5.1 fb $^{-1}$  and 5.3 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  and 8 TeV. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 110 and 600 GeV are excluded at 99% CL.
- 27 CHATRCHYAN 13BK search for  $H^0 \rightarrow Z\gamma \rightarrow \ell\ell\gamma$  in 5.0 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.6 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range  $m_{H^0} = 120\text{--}160$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 9.5, where 10 is expected for no signal.
- 28 CHATRCHYAN 13Q search for  $H^0$  production in the decays  $H^0 \rightarrow W^+W^- \rightarrow \ell\nu\ell\nu$ ,  $\ell\nu q\bar{q}$  and  $H^0 \rightarrow ZZ \rightarrow 4\ell$ ,  $\ell\ell\tau\tau$ ,  $\ell\ell\nu\nu$ , and  $\ell\ell q\bar{q}$  in up to 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV in the range  $m_{H^0} = 145\text{--}1000$  GeV. Superseded by KHACHATRYAN 15AW.
- 29 CHATRCHYAN 13X search for  $H^0 t\bar{t}$  production followed by  $H^0 \rightarrow b\bar{b}$ , one top decaying to  $\ell\nu$  and the other to either  $\ell\nu$  or  $q\bar{q}$  in 5.0 fb $^{-1}$  and 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  and 8 TeV. A limit on cross section times branching ratio which corresponds to (4.0–8.6) times the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}140$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 5.8, where 5.2 is expected for no signal.
- 30 CHATRCHYAN 13Y search for  $H^0$  production in the decay  $H \rightarrow \gamma\gamma$  in 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The expected exclusion region for no signal is 110–144 GeV at 95% CL.
- 31 CHATRCHYAN 13Y search for  $H^0$  production in the decay  $H \rightarrow ZZ^* \rightarrow 4\ell$  in 5.0 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The expected exclusion region for no signal is 120–180 GeV at 95% CL.
- 32 CHATRCHYAN 13Y search for  $H^0$  production in the decay  $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  in 4.9 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The expected exclusion region for no signal is 122–160 GeV at 95% CL.
- 33 AAD 12AI search for  $H^0$  production in  $pp$  collisions for the final states  $H^0 \rightarrow ZZ^*$ ,  $\gamma\gamma$ ,  $WW^*$ ,  $b\bar{b}$ ,  $\tau\tau$  with 4.6–4.8 fb $^{-1}$  at  $E_{\text{cm}} = 7$  TeV, and  $H^0 \rightarrow ZZ^* \rightarrow 4\ell$ ,  $\gamma\gamma$ ,  $WW^*$   $\rightarrow e\nu\mu\nu$  with 5.8–5.9 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The 99% CL excluded range is 113–114, 117–121, and 132–527 GeV. An excess of events over background with a local significance of 5.9  $\sigma$  is observed at  $m_{H^0} = 126$  GeV.
- 34 AAD 12AJ search for  $H^0$  production in the decay  $H^0 \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  with 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (0.2–10) times the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}600$  GeV at 95% CL.
- 35 AAD 12BU search for  $H^0$  production in the decay  $H \rightarrow \tau^+\tau^-$  with 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (2.9–11.7) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150$  GeV at 95% CL.
- 36 AAD 12BZ search for  $H^0$  production in the decay  $H \rightarrow ZZ \rightarrow \ell^+\ell^-\nu\bar{\nu}$  with 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (0.2–4) times the expected Standard Model cross section is given for  $m_{H^0} = 200\text{--}600$  GeV at 95% CL.
- 37 AAD 12CA search for  $H^0$  production in the decay  $H \rightarrow ZZ \rightarrow \ell^+\ell^-q\bar{q}$  with 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (0.7–9) times the expected Standard Model cross section is given for  $m_{H^0} = 200\text{--}600$  GeV at 95% CL.
- 38 AAD 12CN search for associated  $H^0 W$  and  $H^0 Z$  production in the channels  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell^+\ell^-$ ,  $\nu\bar{\nu}$ , and  $H^0 \rightarrow b\bar{b}$ , with 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (2.5–5.5) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}130$  GeV at 95% CL.
- 39 AAD 12CO search for  $H^0$  production in the decay  $H \rightarrow WW \rightarrow \ell\nu q\bar{q}$  with 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (1.9–10) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 300\text{--}600$  GeV at 95% CL.
- 40 AAD 12D search for  $H^0$  production with  $H \rightarrow ZZ^* \rightarrow 4\ell$  in 4.8 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110\text{--}600$  GeV. An excess of events over background with a local significance of 2.1  $\sigma$  is observed at 125 GeV.
- 41 AAD 12G search for  $H^0$  production with  $H \rightarrow \gamma\gamma$  in 4.9 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110\text{--}150$  GeV. An excess of events over background with a local significance of 2.8  $\sigma$  is observed at 126.5 GeV.
- 42 AALTONEN 12AK search for associated  $H^0 t\bar{t}$  production in the decay chain  $t\bar{t} \rightarrow W W b\bar{b} \rightarrow \ell\nu q\bar{q} b\bar{b}$  with 9.45 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (10–40) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 20.5, where 12.6 is expected.
- 43 AALTONEN 12AM search for  $H^0$  production in inclusive four-lepton final states coming from  $H^0 \rightarrow ZZ, H^0 Z \rightarrow WW^* \ell\ell$ , or  $H^0 Z \rightarrow \tau\tau\ell\ell$ , with 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (7.2–42.4) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 120\text{--}300$  GeV at 95% CL. The best limit is for  $m_{H^0} = 200$  GeV.
- 44 AALTONEN 12AN search for  $H^0$  production in the decay  $H^0 \rightarrow \gamma\gamma$  with 10 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (7.7–21.3) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 17.0, where 9.9 is expected.
- 45 AALTONEN 12J search for  $H^0$  production in the decay  $H^0 \rightarrow \tau^+\tau^-$  (one leptonic, the other hadronic) with 6.0 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (14.6–70.2) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150$  GeV at 95% CL. The best limit is for  $m_{H^0} = 120$  GeV.
- 46 AALTONEN 12Q search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \ell^+\ell^-$  with 9.45 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (1.0–37.5) times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}150$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 7.1, where 3.9 is expected. A broad excess of events for  $m_{H^0} > 110$  GeV is observed, with a local significance of 2.4  $\sigma$  at  $m_{H^0} = 135$  GeV.
- 47 AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12O, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region  $m_{H^0} = 120\text{--}135$  GeV, with a local significance of up to 3.3  $\sigma$ . The local significance at  $m_{H^0} = 125$  GeV is 2.8  $\sigma$ , which corresponds to  $(\sigma(H^0 W) + \sigma(H^0 Z)) B(H^0 \rightarrow b\bar{b}) = (0.23^{+0.09}_{-0.06})$  pb, compared to the Standard Model expectation at  $m_{H^0} = 125$  GeV of  $0.12 \pm 0.01$  pb.
- 48 ABAZOV 12K search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \nu\bar{\nu}$ , and  $H^0 W$  production with  $W \rightarrow \ell\nu$  ( $\ell$  not identified) with 9.5 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (1.9–16.8) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 4.3, where 3.9 is expected.
- 49 CHATRCHYAN 12AY search for associated  $H^0 W$  and  $H^0 Z$  production in the channels  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell^+\ell^-$ , and  $H^0 \rightarrow \tau\tau$ ,  $WW^*$ , with 5 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (3.1–9.1) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}200$  GeV at 95% CL.
- 50 CHATRCHYAN 12AY combine CHATRCHYAN 12F and CHATRCHYAN 12AO in addition and give a limit on cross section times branching ratio which is (2.1–3.7) times larger than the expected Standard Model cross section for  $m_{H^0} = 110\text{--}170$  GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 3.3.
- 51 CHATRCHYAN 12C search for  $H^0$  production with  $H \rightarrow ZZ \rightarrow \ell^+\ell^-\tau^+\tau^-$  in 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (4–12) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 190\text{--}600$  GeV at 95% CL. The best limit is at  $m_{H^0} = 200$  GeV.
- 52 CHATRCHYAN 12D search for  $H^0$  production with  $H \rightarrow ZZ^* \rightarrow \ell^+\ell^-q\bar{q}$  in 4.6 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (1–22) times the expected Standard Model cross section is given for  $m_{H^0} = 130\text{--}164$  GeV, 200–600 GeV at 95% CL. The best limit is at  $m_{H^0} = 230$  GeV. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values in the ranges  $m_{H^0} = 154\text{--}161$  GeV and 200–470 GeV are excluded at 95% CL.
- 53 CHATRCHYAN 12E search for  $H^0$  production with  $H \rightarrow WW^* \rightarrow \ell^+\nu\ell^-\bar{\nu}$  in 4.6 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110\text{--}600$  GeV.
- 54 CHATRCHYAN 12F search for associated  $H^0 W$  and  $H^0 Z$  production followed by  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell^+\ell^-$ ,  $\nu\bar{\nu}$ , and  $H^0 \rightarrow b\bar{b}$ , in 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (3.1–9.0) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}135$  GeV at 95% CL. The best limit is at  $m_{H^0} = 110$  GeV.
- 55 CHATRCHYAN 12G search for  $H^0$  production with  $H \rightarrow \gamma\gamma$  in 4.8 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110\text{--}150$  GeV. An excess of events over background with a local significance of 3.1  $\sigma$  is observed at 124 GeV.
- 56 CHATRCHYAN 12H search for  $H^0$  production with  $H \rightarrow ZZ^* \rightarrow 4\ell$  in 4.7 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110\text{--}600$  GeV. Excesses of events over background are observed around 119, 126 and 320 GeV. The region  $m_{H^0} = 114.4\text{--}134$  GeV remains consistent with the expectation for the production of a SM-like Higgs boson.
- 57 CHATRCHYAN 12I search for  $H^0$  production with  $H \rightarrow ZZ \rightarrow \ell^+\ell^-\nu\bar{\nu}$  in 4.6 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 250\text{--}600$  GeV.
- 58 CHATRCHYAN 12K search for  $H^0$  production in the decay  $H \rightarrow \tau^+\tau^-$  with 4.6 fb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (3.2–7.0) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}145$  GeV at 95% CL.
- 59 ABAZOV 11G search for  $H^0$  production in 5.4 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV in the decay mode  $H^0 \rightarrow WW^* \rightarrow \ell\nu q\bar{q}$  (and processes with similar final states). A limit on cross section times branching ratio which is (3.9–37) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 115\text{--}200$  GeV at 95% CL. The best limit is at  $m_{H^0} = 160$  GeV.
- 60 CHATRCHYAN 11J search for  $H^0$  production with  $H \rightarrow W^+W^- \rightarrow \ell\ell\nu\nu$  in 36 pb $^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 6 for a limit on cross section times branching ratio for  $m_{H^0} = 120\text{--}600$  GeV at 95% CL. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 144 and 207 GeV are excluded at 95% CL.
- 61 AALTONEN 10F combine searches for  $H^0$  decaying to  $W^+W^-$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with 4.8 fb $^{-1}$  (CDF) and 5.4 fb $^{-1}$  (DØ).
- 62 AALTONEN 10M combine searches for  $H^0$  decaying to  $W^+W^-$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with 4.8 fb $^{-1}$  (CDF) and 5.4 fb $^{-1}$  (DØ) and derive limits  $\sigma(p\bar{p} \rightarrow H^0) \cdot B(H^0 \rightarrow W^+W^-) < (1.75\text{--}0.38)$  pb for  $m_H = 120\text{--}165$  GeV, where  $H^0$  is produced in  $g g$  fusion. In the Standard Model with an additional generation of heavy quarks,  $m_{H^0}$  between 131 and 204 GeV is excluded at 95% CL.
- 63 AALTONEN 09A search for  $H^0$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV in the decay mode  $H^0 \rightarrow WW^* \rightarrow \ell^+\ell^-\nu\bar{\nu}$ . A limit on  $\sigma(H^0) \cdot B(H^0 \rightarrow WW^*)$  between 0.7 and 2.5 pb (95% CL) is given for  $m_{H^0} = 110\text{--}200$  GeV, which is 1.7–4.5 times larger than the expected Standard Model cross section. The best limit is obtained for  $m_{H^0} = 160$  GeV.
- 64 ABAZOV 09U search for  $H^0 \rightarrow \tau^+\tau^-$  with  $\tau \rightarrow$  hadrons in 1 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The production mechanisms include associated  $W/Z+H^0$  production, weak boson fusion, and gluon fusion. A limit (95% CL) is given for  $m_{H^0} = 105\text{--}145$  GeV, which is 20–82 times larger than the expected Standard Model cross section. The limit for  $m_{H^0} = 115$  GeV is 29 times larger than the expected Standard Model cross section.
- 65 ABAZOV 06 search for Higgs boson production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with the decay chain  $H^0 \rightarrow WW^* \rightarrow \ell^\pm\nu\ell^\mp\bar{\nu}$ . A limit  $\sigma(H^0) \cdot B(H^0 \rightarrow WW^*) <$

## Neutral Higgs Bosons, Searches for

(5.6–3.2) pb (95 %CL) is given for  $m_{H^0} = 120\text{--}200$  GeV, which far exceeds the expected Standard Model cross section.  
 66 ABABOV 060 search for associated  $H^0 W$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with the decay  $H^0 \rightarrow WW^*$ , in the final states  $\ell^\pm \ell'^\mp \nu \nu' X$  where  $\ell = e, \mu$ .  
 A limit  $\sigma(H^0 W) \cdot \text{B}(H^0 \rightarrow WW^*) < (3.2\text{--}2.8)$  pb (95 %CL) is given for  $m_{H^0} = 115\text{--}175$  GeV, which far exceeds the expected Standard Model cross section.

### Indirect Mass Limits for $H^0$ from Electroweak Analysis

The mass limits shown below apply to a Higgs boson  $H^0$  with Standard Model couplings whose mass is a priori unknown.

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

VALUE (GeV)	DOCUMENT ID	TECN

• • • We do not use the following data for averages, fits, limits, etc. • • •

- <sup>1</sup> BAAK 12A make Standard Model fits to Z and neutral current parameters,  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.
- <sup>2</sup> BAAK 12 make Standard Model fits to Z and neutral current parameters,  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is  $120^{+12}_{-5}$  GeV.
- <sup>3</sup> ERLER 10A makes Standard Model fits to Z and neutral current parameters,  $m_t$ ,  $m_W$  measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.
- <sup>4</sup> LEP-SLC 06 make Standard Model fits to Z parameters from LEP/SLC and  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2005 with  $\Delta\alpha_{\text{had}}^{(5)}(m_Z) = 0.02758 \pm 0.00035$ . The 95% CL limit is 285 GeV.

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

### CONTENTS:

$H^\pm$  (Charged Higgs) Mass Limits

Mass limits for  $H^{\pm\pm}$  (doubly-charged Higgs boson)

– Limits for  $H^{\pm\pm}$  with  $T_3 = \pm 1$

– Limits for  $H^{\pm\pm}$  with  $T_3 = 0$

### $H^\pm$ (Charged Higgs) MASS LIMITS

Unless otherwise stated, the limits below assume  $B(H^\pm \rightarrow \tau^+ \nu) + B(H^\pm \rightarrow c\bar{s}) = 1$ , and hold for all values of  $B(H^\pm \rightarrow \tau^+ \nu_\tau)$ , and assume  $H^\pm$  weak isospin of  $T_3 = \pm 1/2$ . In the following,  $\tan\beta$  is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in  $e^+e^-$  collisions at and above the  $Z$  pole have conclusively ruled out the existence of a charged Higgs in the region  $m_{H^\pm} \lesssim 45$  GeV, and are meanwhile superseded by the searches in higher energy  $e^+e^-$  collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the  $e^+e^- \rightarrow H^\pm H^\mp$  process. Limits from  $b \rightarrow s\gamma$  decays are usually stronger in generic 2HDM models than in Supersymmetric models.

<sup>1</sup> LEP 13 give a limit that refers to the Type II scenario. The limit for  $B(H^\pm \rightarrow \tau\nu) = 1$  is 94 GeV (95% CL), and for  $B(H^\pm \rightarrow c\bar{s}) = 1$  the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode  $H^\pm \rightarrow A^0 W^*$  with  $A^0 \rightarrow b\bar{b}$ , which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if  $m_{A^0} > 12$  GeV.

<sup>2</sup> ABBIENDI 12 also search for the decay mode  $H^\pm \rightarrow A^0 W^*$  with  $A^0 \rightarrow b\bar{b}$ .

<sup>3</sup> AAD 15AF search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow \tau^\pm \nu$  in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Upper limits on  $B(t \rightarrow bH^\pm) B(H^\pm \rightarrow \tau\nu)$  between  $2.3 \times 10^{-3}$  and  $1.3 \times 10^{-2}$  (95% CL) are given for  $m_{H^\pm} = 80$ –160 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region  $m_{H^\pm} < 140$  GeV is excluded for  $\tan\beta > 1$  in the considered scenarios.

<sup>4</sup> AAD 15AF search for  $tH^\pm$  associated production followed by  $H^\pm \rightarrow \tau^\pm \nu$  in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Upper limits on  $\sigma(tH^\pm) B(H^\pm \rightarrow \tau\nu)$  between 760 and 4.5 fb (95% CL) are given for  $m_{H^\pm} = 180$ –1000 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.

<sup>5</sup> AAD 15M search for vector boson fusion production of  $H^\pm$  decaying to  $W^\pm Z \rightarrow q\bar{q}l^+l^-$  in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 2 for limits on cross section times branching ratio for  $m_{H^\pm} = 200$ –1000 GeV, and Fig. 3 for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

<sup>6</sup> KHACHATRYAN 15AX search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow \tau^\pm \nu$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Upper limits on  $B(t \rightarrow bH^\pm) B(H^\pm \rightarrow \tau\nu)$  between  $1.2 \times 10^{-2}$  and  $1.5 \times 10^{-3}$  (95% CL) are given for  $m_{H^\pm} = 80$ –160 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region  $m_{H^\pm} < 155$  GeV is excluded for  $\tan\beta > 1$  in the considered scenarios.

<sup>7</sup> KHACHATRYAN 15AX search for  $tH^\pm$  associated production followed by  $H^\pm \rightarrow t\bar{b}$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Upper limits on  $\sigma(tH^\pm) B(H^\pm \rightarrow t\bar{b})$  between 2.0 and 0.13 pb (95% CL) are given for  $m_{H^\pm} = 180$ –600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

<sup>8</sup> KHACHATRYAN 15AX search for  $tH^\pm$  associated production followed by  $H^\pm \rightarrow \tau^\pm \nu$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Upper limits on  $\sigma(tH^\pm) B(H^\pm \rightarrow \tau\nu)$  between 380 and 25 fb (95% CL) are given for  $m_{H^\pm} = 180$ –600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

<sup>9</sup> KHACHATRYAN 15BF search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow c\bar{s}$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Upper limits on  $B(t \rightarrow bH^\pm) B(H^\pm \rightarrow c\bar{s})$  between  $1.2 \times 10^{-2}$  and  $6.5 \times 10^{-2}$  (95% CL) are given for  $m_{H^\pm} = 90$ –160 GeV.

<sup>10</sup> AAD 14M search for the decay cascade  $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$  decaying to  $b\bar{b}$  in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Table III for limits on cross section times branching ratio for  $m_{H_2^0} = 325$ –1025 GeV and  $m_{H^\pm} = 225$ –925 GeV.

<sup>11</sup> AALTONEN 14A measure  $B(t \rightarrow b\tau\nu) = 0.096 \pm 0.028$  using 9 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. For  $m_{H^\pm} = 80$ –140 GeV, this measured value is translated to a limit  $B(t \rightarrow bH^\pm) < 0.059$  at 95% CL assuming  $B(H^\pm \rightarrow \tau^\pm \nu) = 1$ .

<sup>12</sup> AAD 13AC search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow c\bar{s}$  (flavor unidentified) in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. Upper limits on  $B(t \rightarrow bH^\pm)$  between 0.05 and 0.01 (95%CL) are given for  $m_{H^\pm} = 90$ –150 GeV and  $B(H^\pm \rightarrow c\bar{s}) = 1$ .

<sup>13</sup> AAD 13V search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow \tau^\pm \nu$  through violation of lepton universality with 4.6 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. Upper limits on  $B(t \rightarrow bH^\pm)$  between 0.032 and 0.044 (95% CL) are given for  $m_{H^\pm} = 90$ –140 GeV and  $B(H^\pm \rightarrow \tau^\pm \nu) = 1$ . By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for  $m_{H^\pm} = 90$ –160 GeV. See their Fig. 7 for the excluded region in the  $m_h^{\max}$  scenario of the MSSM.

<sup>14</sup> AAD 12BH search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow \tau^\pm \nu$  with 4.6 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. Upper limits on  $B(t \rightarrow bH^\pm)$  between 0.01 and 0.05 (95% CL) are given for  $m_{H^\pm} = 90$ –160 GeV and  $B(H^\pm \rightarrow \tau^\pm \nu) = 1$ . See their Fig. 8 for the excluded region in the  $m_h^{\max}$  scenario of the MSSM.

<sup>15</sup> CHATRCHYAN 12AA search for  $t\bar{t}$  production followed by  $t \rightarrow bH^\pm, H^\pm \rightarrow \tau^\pm \nu$  with 2 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. Upper limits on  $B(t \rightarrow bH^\pm)$  between 0.019 and 0.041 (95% CL) are given for  $m_{H^\pm} = 80$ –160 GeV and  $B(H^\pm \rightarrow \tau^\pm \nu) = 1$ .

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

- <sup>16</sup> AALTONEN 11P search in  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+A^0, A^0 \rightarrow \tau^+\tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160 \text{ GeV}$ .
- <sup>17</sup> DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays,  $b \rightarrow s\gamma, B, B_s$  mixings, and  $Z \rightarrow b\bar{b}$ . The limit holds irrespective of  $\tan\beta$ .
- <sup>18</sup> AALTONEN 09AJ search for  $t \rightarrow bH^+, H^+ \rightarrow c\bar{s}$  in  $t\bar{t}$  events in  $2.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.08 and 0.32 (95% CL) are given for  $m_{H^+} = 60\text{--}150 \text{ GeV}$  and  $B(H^+ \rightarrow c\bar{s}) = 1$ .
- <sup>19</sup> ABAZOV 09AC search for  $t \rightarrow bH^+, H^+ \rightarrow \tau^+\nu$  in  $t\bar{t}$  events in  $0.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.19 and 0.25 (95% CL) are given for  $m_{H^+} = 80\text{--}155 \text{ GeV}$  and  $B(H^+ \rightarrow \tau^+\nu) = 1$ . See their Fig. 4 for an excluded region in a MSSM scenario.
- <sup>20</sup> ABAZOV 09AG measure  $t\bar{t}$  cross sections in final states with  $\ell$  + jets ( $\ell = e, \mu$ ),  $\ell\bar{\ell}$ , and  $\tau\ell$  in  $1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ , which constrains possible  $t \rightarrow bH^+$  branching fractions. Upper limits (95% CL) on  $B(t \rightarrow bH^+)$  between 0.15 and 0.40 (0.48 and 0.57) are given for  $B(H^+ \rightarrow \tau^+\nu) = 1$  ( $B(H^+ \rightarrow c\bar{s}) = 1$ ) for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ .
- <sup>21</sup> ABAZOV 09AI search for  $t \rightarrow bH^+$  in  $t\bar{t}$  events in  $1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Final states with  $\ell$  + jets ( $\ell = e, \mu$ ),  $\ell\bar{\ell}$ , and  $\tau\ell$  are examined. Upper limits on  $B(t \rightarrow bH^+)$  (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for  $B(H^+ \rightarrow \tau^+\nu) = 1$  ( $B(H^+ \rightarrow c\bar{s}) = 1$ ) for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ . For  $B(H^+ \rightarrow \tau^+\nu) = 1$  also a simultaneous extraction of  $B(t \rightarrow bH^+)$  and the  $t\bar{t}$  cross section is performed, yielding a limit on  $B(t \rightarrow bH^+)$  between 0.12 and 0.26 for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ . See their Figs. 5–8 for excluded regions in several MSSM scenarios.
- <sup>22</sup> ABAZOV 09P search for  $H^\pm$  production by  $q\bar{q}$  annihilation followed by  $H^\pm \rightarrow t\bar{b}$  decay in  $0.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Cross section limits in several two-doublet models are given for  $m_{H^\pm} = 180\text{--}300 \text{ GeV}$ . A region with  $20 \lesssim \tan\beta \lesssim 70$  is excluded (95% CL) for  $180 \text{ GeV} \lesssim m_{H^\pm} \lesssim 184 \text{ GeV}$  in type-I models.
- <sup>23</sup> ABULECNA 06E search for associated  $H^0 W$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A fit is made for  $t\bar{t}$  production processes in dilepton, lepton + jets, and lepton +  $\tau$  final states, with the decays  $t \rightarrow W^+b$  and  $t \rightarrow H^+b$  followed by  $H^\pm \rightarrow \tau^+\nu, c\bar{s}, t^*\bar{b}$ , or  $W^+H^0$ . Within the MSSM the search is sensitive to the region  $\tan\beta < 1$  or  $> 30$  in the mass range  $m_{H^\pm} = 80\text{--}160 \text{ GeV}$ . See Fig. 2 for the excluded region in a certain MSSM scenario.
- <sup>24</sup> ABDALLAH 04I search for  $e^+e^- \rightarrow H^+H^-$  with  $H^\pm$  decaying to  $\tau\nu, c\bar{s}$ , or  $W^*A^0$  in Type-I two-Higgs-doublet models.
- <sup>25</sup> ABBIENDI 03 give a limit  $m_{H^\pm} > 1.28\tan\beta \text{ GeV}$  (95%CL) in Type II two-doublet models.
- <sup>26</sup> ABAZOV 02B search for a charged Higgs boson in top decays with  $H^\pm \rightarrow \tau^+\nu$  at  $E_{\text{cm}} = 1.8 \text{ TeV}$ . For  $m_{H^\pm} = 75 \text{ GeV}$ , the region  $\tan\beta > 32.0$  is excluded at 95% CL. The excluded mass region extends to over 140 GeV for  $\tan\beta$  values above 100.
- <sup>27</sup> BORZUMATI 02 point out that the decay modes such as  $b\bar{b}W, A^0 W$ , and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.
- <sup>28</sup> ABBIENDI 03Q give a limit  $\tan\beta/m_{H^\pm} < 0.53 \text{ GeV}^{-1}$  (95%CL) in Type II two-doublet models.
- <sup>29</sup> BARATE 01E give a limit  $\tan\beta/m_{H^\pm} < 0.40 \text{ GeV}^{-1}$  (90% CL) in Type II two-doublet models. An independent measurement of  $B \rightarrow \tau\nu_\tau X$  gives  $\tan\beta/m_{H^\pm} < 0.49 \text{ GeV}^{-1}$  (90% CL).
- <sup>30</sup> GAMBINO 01 use the world average data in the summer of 2001  $B(b \rightarrow s\gamma) = (3.23 \pm 0.42) \times 10^{-4}$ . The limit applies for Type-II two-doublet models.
- <sup>31</sup> AFFOLDER 00I search for a charged Higgs boson in top decays with  $H^\pm \rightarrow \tau^+\nu$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$ . The excluded mass region extends to over 120 GeV for  $\tan\beta$  values above 100 and  $B(\tau\nu) = 1$ . If  $B(t \rightarrow bH^+) \gtrsim 0.6$ ,  $m_{H^\pm}$  up to 160 GeV is excluded. Updates ABE 97L.
- <sup>32</sup> ABBOTT 99C search for a charged Higgs boson in top decays in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$ , by comparing the observed  $t\bar{t}$  cross section (extracted from the data assuming the dominant decay  $t \rightarrow bW^+$ ) with theoretical expectation. The search is sensitive to regions of the domains  $\tan\beta \lesssim 1, 50 < m_{H^\pm}(\text{GeV}) \lesssim 120$  and  $\tan\beta \gtrsim 40, 50 < m_{H^\pm}(\text{GeV}) \lesssim 160$ . See Fig. 3 for the details of the excluded region.
- <sup>33</sup> ACKERSTAFF 99D measure the Michel parameters  $\rho, \xi, \eta$ , and  $\xi\delta$  in leptonic  $\tau$  decays from  $Z \rightarrow \tau\tau$ . Assuming  $e\text{--}\mu$  universality, the limit  $m_{H^\pm} > 0.97 \tan\beta \text{ GeV}$  (95% CL) is obtained for two-doublet models in which only one doublet couples to leptons.
- <sup>34</sup> ACCIARRI 97F give a limit  $m_{H^\pm} > 2.6 \tan\beta \text{ GeV}$  (90% CL) from their limit on the exclusive  $B \rightarrow \tau\nu_\tau$  branching ratio.
- <sup>35</sup> AMMAR 97B measure the Michel parameter  $\rho$  from  $\tau \rightarrow e\nu\nu$  decays and assumes  $e/\mu$  universality to extract the Michel  $\eta$  parameter from  $\tau \rightarrow \mu\nu\nu$  decays. The measurement is translated to a lower limit on  $m_{H^\pm}$  in a two-doublet model  $m_{H^\pm} > 0.97 \tan\beta \text{ GeV}$  (90% CL).
- <sup>36</sup> COARASA 97 reanalyzed the constraint on the  $(m_{H^\pm}, \tan\beta)$  plane derived from the inclusive  $B \rightarrow \tau\nu_\tau X$  branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.
- <sup>37</sup> GUCHAIT 97 studies the constraints on  $m_{H^\pm}$  set by Tevatron data on  $\ell\tau$  final states in  $t\bar{t} \rightarrow (Wb)(Hb), W \rightarrow \ell\nu, H \rightarrow \tau\nu_\tau$ . See Fig. 2 for the excluded region.
- <sup>38</sup> MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large  $B_c \rightarrow \tau\nu_\tau$  background to  $B_u \rightarrow \tau\nu_\tau$  decays. Stronger limits are obtained.
- <sup>39</sup> STAHL 97 fit  $\tau$  lifetime, leptonic branching ratios, and the Michel parameters and derive limit  $m_{H^\pm} > 1.5 \tan\beta \text{ GeV}$  (90% CL) for a two-doublet model. See also STAHL 94.
- <sup>40</sup> ALAM 95 measure the inclusive  $b \rightarrow s\gamma$  branching ratio at  $T(45)$  and give  $B(b \rightarrow s\gamma) < 4.2 \times 10^{-4}$  (95% CL), which translates to the limit  $m_{H^\pm} > [244 + 63/(\tan\beta)^{1.3}] \text{ GeV}$  in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.
- <sup>41</sup> BUSKULIC 95 give a limit  $m_{H^\pm} > 1.9 \tan\beta \text{ GeV}$  (90% CL) for Type-II models from  $b \rightarrow \tau\nu_\tau X$  branching ratio, as proposed in GROSSMAN 94.

### MASS LIMITS for $H^{\pm\pm}$ (doubly-charged Higgs boson)

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin  $T_3$  is thus restricted to two possibilities depending on lepton chiralities:  $T_3(H^{\pm\pm}) = \pm 1$ , with the coupling  $g_{\ell\ell}$  to  $\ell_L^-\ell_L^-$  and  $\ell_R^+\ell_R^+$  ("left-handed") and  $T_3(H^{\pm\pm}) = 0$ , with the coupling to  $\ell_R^-\ell_R^-$  and  $\ell_L^+\ell_L^+$  ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group  $SU(2)_L \times SU(2)_R \times U(1)$ , the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

- <sup>1</sup> AAD 15AG search for  $H^{++}H^{--}$  production in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.
- <sup>2</sup> AAD 15AP search for  $H^{++}H^{--}$  production in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>3</sup> CHATRCHYAN 12AU search for  $H^{++}H^{--}$  production with  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated  $H^{++}H^{--}$  production or assuming different scenarios.
- <sup>4</sup> ABDALLAH 03 search for  $H^{++}H^{--}$  pair production either followed by  $H^{++} \rightarrow \tau^+\tau^+$ , or decaying outside the detector.
- <sup>5</sup> ABBIENDI 02c searches for pair production of  $H^{++}H^{--}$ , with  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  ( $\ell, \ell' = e, \mu, \tau$ ). The limit holds for  $\ell=\ell'=\tau$ , and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for  $g(H\ell\ell) \gtrsim 10^{-7}$ .
- <sup>6</sup> KANEMURA 15 examine the case where  $H^{++}$  decays preferentially to  $W^{(*)}W^{(*)}$  and estimate that a lower mass limit of  $\sim 84 \text{ GeV}$  can be derived from the same-sign dilepton data of AAD 15AG if  $H^{++}$  decays with 100% branching ratio to  $W^{(*)}W^{(*)}$ .
- <sup>7</sup> KHACHATRYAN 15D search for  $H^{\pm\pm}$  production by vector boson fusion followed by the decay  $H^{\pm\pm} \rightarrow W^\pm W^\pm$  in  $19.4 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratio for  $m_{H^{++}}$  between 160 and 800 GeV.
- <sup>8</sup> KANEMURA 14 examine the case where  $H^{++}$  decays preferentially to  $W^{(*)}W^{(*)}$  and estimate that a lower mass limit of  $\sim 60 \text{ GeV}$  can be derived from the same-sign dilepton data of AAD 12CY.
- <sup>9</sup> AAD 13Y search for  $H^{++}H^{--}$  production in a generic search of events with three charged leptons in  $4.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>10</sup> AAD 12AY search for  $H^{++}H^{--}$  production with  $1.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>11</sup> AAD 12CQ search for  $H^{++}H^{--}$  production with  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

# Gauge & Higgs Boson Particle Listings

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

- <sup>12</sup> ABAZOV 12A search for  $H^{++}H^{--}$  production in  $7.0\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ .
- <sup>13</sup> AALTONEN 11AF search for  $H^{++}H^{--}$  production in  $6.1\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ .
- <sup>14</sup> AALTONEN 08AA search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>15</sup> ABAZOV 08v search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . The limit is for  $B(H \rightarrow \mu\mu) = 1$ . The limit is updated in ABAZOV 12A.
- <sup>16</sup> AKTAS 06A search for single  $H^{\pm\pm}$  production in  $ep$  collisions at HERA. Assuming that  $H^{++}$  only couples to  $e^+\mu^+$  with  $g_{e\mu} = 0.3$  (electromagnetic strength), a limit  $m_{H^{++}} > 141\text{ GeV}$  (95% CL) is derived. For the case where  $H^{++}$  couples to  $e\tau$  only the limit is 112 GeV.
- <sup>17</sup> ACOSTA 05L search for  $H^{++}H^{--}$  pair production in  $p\bar{p}$  collisions. The limit is valid for  $g_{\ell\ell'} < 10^{-8}$  so that the Higgs decays outside the detector.
- <sup>18</sup> ABAZOV 04E search for  $H^{++}H^{--}$  pair production in  $H^{\pm\pm} \rightarrow \mu^\pm\mu^\pm$ . The limit is valid for  $g_{\mu\mu} \gtrsim 10^{-7}$ .
- <sup>19</sup> ABBIENDI 03Q searches for single  $H^{\pm\pm}$  via direct production in  $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$ , and via  $t$ -channel exchange in  $e^+e^- \rightarrow e^+e^-$ . In the direct case, and assuming  $B(H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm) = 1$ , a 95% CL limit on  $h_{ee} < 0.071$  is set for  $m_{H^{\pm\pm}} < 160\text{ GeV}$  (see Fig. 6). In the second case, indirect limits on  $h_{ee}$  are set for  $m_{H^{\pm\pm}} < 2\text{ TeV}$  (see Fig. 8).
- <sup>20</sup> GORDEEV 97 search for muonium-antimuonium conversion and find  $G_{M\bar{M}}/G_F < 0.14$  (90% CL), where  $G_{M\bar{M}}$  is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to  $m_{H^{++}} > 210\text{ GeV}$  if the Yukawa couplings of  $H^{++}$  to  $ee$  and  $\mu\mu$  are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- <sup>21</sup> ASAKA 95 point out that  $H^{++}$  decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.
- <sup>22</sup> ACTON 92M limit assumes  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  or  $H^{\pm\pm}$  does not decay in the detector. Thus the region  $g_{\ell\ell} \approx 10^{-7}$  is not excluded.
- <sup>23</sup> ACTON 92M from  $\Delta\Gamma_Z < 40\text{ MeV}$ .
- <sup>24</sup> SWARTZ 90 assume  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  (any flavor). The limits are valid for the Higgs-lepton coupling  $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$ . The limits improve somewhat for  $ee$  and  $\mu\mu$  decay modes.

- <sup>2</sup> AAD 15AP search for  $H^{++}H^{--}$  production in  $20.3\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 8\text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>3</sup> ABDALLAH 03 search for  $H^{++}H^{--}$  pair production either followed by  $H^{++} \rightarrow \tau^+\tau^+$ , or decaying outside the detector.
- <sup>4</sup> ACHARD 03F search for  $e^+e^- \rightarrow H^{++}H^{--}$  with  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$ . The limit holds for  $\ell = \ell' = \tau$ , and slightly different limits apply for other flavor combinations. The limit is valid for  $g_{\ell\ell'} \gtrsim 10^{-7}$ .
- <sup>5</sup> ABBIENDI 02c searches for pair production of  $H^{++}H^{--}$ , with  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  ( $\ell, \ell' = e, \mu, \tau$ ). the limit holds for  $\ell = \ell' = \tau$ , and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for  $g(H\ell\ell) \gtrsim 10^{-7}$ .
- <sup>6</sup> AAD 12AY search for  $H^{++}H^{--}$  production with  $1.6\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>7</sup> AAD 12CQ search for  $H^{++}H^{--}$  production with  $4.7\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.
- <sup>8</sup> ABAZOV 12A search for  $H^{++}H^{--}$  production in  $7.0\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ .

- <sup>9</sup> AALTONEN 11AF search for  $H^{++}H^{--}$  production in  $6.1\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ .
- <sup>10</sup> ABAZOV 08v search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . The limit is for  $B(H \rightarrow \mu\mu) = 1$ . The limit is updated in ABAZOV 12A.
- <sup>11</sup> AKTAS 06A search for single  $H^{\pm\pm}$  production in  $ep$  collisions at HERA. Assuming that  $H^{++}$  only couples to  $e^+\mu^+$  with  $g_{e\mu} = 0.3$  (electromagnetic strength), a limit  $m_{H^{++}} > 141\text{ GeV}$  (95% CL) is derived. For the case where  $H^{++}$  couples to  $e\tau$  only the limit is 112 GeV.
- <sup>12</sup> ACOSTA 05L search for  $H^{++}H^{--}$  pair production in  $p\bar{p}$  collisions. The limit is valid for  $g_{\ell\ell'} < 10^{-8}$  so that the Higgs decays outside the detector.
- <sup>13</sup> ABAZOV 04E search for  $H^{++}H^{--}$  pair production in  $H^{\pm\pm} \rightarrow \mu^\pm\mu^\pm$ . The limit is valid for  $g_{\mu\mu} \gtrsim 10^{-7}$ .
- <sup>14</sup> ABBIENDI 03Q searches for single  $H^{\pm\pm}$  via direct production in  $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$ , and via  $t$ -channel exchange in  $e^+e^- \rightarrow e^+e^-$ . In the direct case, and assuming  $B(H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm) = 1$ , a 95% CL limit on  $h_{ee} < 0.071$  is set for  $m_{H^{\pm\pm}} < 160\text{ GeV}$  (see Fig. 6). In the second case, indirect limits on  $h_{ee}$  are set for  $m_{H^{\pm\pm}} < 2\text{ TeV}$  (see Fig. 8).
- <sup>15</sup> GORDEEV 97 search for muonium-antimuonium conversion and find  $G_{M\bar{M}}/G_F < 0.14$  (90% CL), where  $G_{M\bar{M}}$  is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to  $m_{H^{++}} > 210\text{ GeV}$  if the Yukawa couplings of  $H^{++}$  to  $ee$  and  $\mu\mu$  are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- <sup>16</sup> ACTON 92M limit assumes  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  or  $H^{\pm\pm}$  does not decay in the detector. Thus the region  $g_{\ell\ell} \approx 10^{-7}$  is not excluded.
- <sup>17</sup> ACTON 92M from  $\Delta\Gamma_Z < 40\text{ MeV}$ .
- <sup>18</sup> SWARTZ 90 assume  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  (any flavor). The limits are valid for the Higgs-lepton coupling  $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$ . The limits improve somewhat for  $ee$  and  $\mu\mu$  decay modes.

## New Heavy Bosons ( $W'$ , $Z'$ , leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than  $W$ 's and  $Z$ 's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons. The latest unpublished results are described in “ $W'$  Searches” and “ $Z'$  Searches” reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

### $W'$ -BOSON SEARCHES

Revised March 2016 by M.-C. Chen (UC Irvine), B.A. Dobrescu (Fermilab) and S. Willocq (U Massachusetts).

The  $W'$  boson is a massive hypothetical particle of spin 1 and electric charge  $\pm 1$ , which is a color singlet and is predicted in various extensions of the Standard Model (SM).

**$W'$  couplings to quarks and leptons.** The Lagrangian terms describing couplings of a  $W'^+$  boson to fermions are given by

$$\frac{W'^+_\mu}{\sqrt{2}} \left[ \bar{u}_i (C_{qij}^R P_R + C_{qij}^L P_L) \gamma^\mu d_j + \bar{\nu}_i (C_{\ell ij}^R P_R + C_{\ell ij}^L P_L) \gamma^\mu e_j \right]. \quad (1)$$

Here  $u, d, \nu$  and  $e$  are the SM fermions in the mass eigenstate basis,  $i, j = 1, 2, 3$  label the fermion generation, and  $P_{R,L} = (1 \pm \gamma_5)/2$ . The coefficients  $C_{qij}^R$ ,  $C_{qij}^L$ ,  $C_{\ell ij}^R$ , and  $C_{\ell ij}^L$  are complex dimensionless parameters. If  $C_{\ell ij}^R \neq 0$ , then the  $i$ th generation includes a right-handed neutrino. Using this notation, the SM  $W$  couplings are  $C_q^L = g_{VCKM}$ ,  $C_\ell^L = g \approx 0.63$  and  $C_q^R = C_\ell^R = 0$ .

Unitarity considerations imply that the  $W'$  boson is associated with a spontaneously-broken gauge symmetry. This is true even when it is a composite particle (*e.g.*,  $\rho^\pm$ -like bound states [1]) if its mass is much smaller than the compositeness scale, or a Kaluza-Klein mode in theories where the  $W$  boson propagates in extra dimensions [2]. The simplest extension of the electroweak gauge group that includes a  $W'$  boson is  $SU(2)_1 \times SU(2)_2 \times U(1)$ , but larger groups are encountered in some theories. A generic property of these gauge theories is

that they also include a  $Z'$  boson [3]; whether the  $W'$  boson can be discovered first depends on theoretical and experimental details.

A tree-level mass mixing may be induced between the electrically-charged gauge bosons. Upon diagonalization of their mass matrix, the  $W - Z$  mass ratio and the couplings of the observed  $W$  boson are shifted from the SM values. Their measurements imply that the mixing angle between the gauge eigenstates,  $\theta_+$ , must be smaller than about  $10^{-2}$ . In certain theories the mixing is negligible (*e.g.* due to a new parity [4]), even when the  $W'$  mass is near the electroweak scale.

The  $W'$  coupling to  $WZ$  is fixed by Lorentz and gauge invariances, and to leading order in  $\theta_+$  is given by [5]

$$\frac{g \theta_+ i}{\cos \theta_W} [W'^+_\mu (W^-_\nu Z^{\nu\mu} + Z_\nu W^{-\mu\nu}) + Z^\nu W^{-\mu} W'^+_{\nu\mu}] + \text{H.c.}, \quad (2)$$

where  $W^{\mu\nu} \equiv \partial^\mu W^\nu - \partial^\nu W^\mu$ , etc. The  $\theta_W$  dependence shown here corrects the one given in [6], which has been referred to as the Extended Gauge Model by the experimental collaborations. The  $W'$  coupling to  $Wh^0$ , where  $h^0$  is the SM Higgs boson, is

$$-\xi_h g_{W'} M_W W'^+_\mu W^{\mu-} h^0 + \text{H.c.}, \quad (3)$$

where  $g_{W'}$  is the gauge coupling of the  $W'$  boson, and the coefficient  $\xi_h$  satisfies  $\xi_h \leq 1$  in simple Higgs sectors [5].

In models based on the “left-right symmetric” gauge group [7],  $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ , the SM fermions that couple to the  $W$  boson transform as doublets under  $SU(2)_L$  while the other fermions transform as doublets under  $SU(2)_R$ . Consequently, the  $W'$  boson couples primarily to right-handed fermions; its coupling to left-handed fermions arises due to the  $\theta_+$  mixing, so that  $C_q^L$  is proportional to the CKM matrix and its elements are much smaller than the diagonal elements of  $C_q^R$ . Generically,  $C_q^R$  does not need to be proportional to  $V_{CKM}$ .

There are many other models based on the  $SU(2)_1 \times SU(2)_2 \times U(1)$  gauge symmetry. In the “alternate left-right” model [8], all the couplings shown in Eq. (1) vanish, but there are some new fermions such that the  $W'$  boson couples to pairs involving a SM fermion and a new fermion. In the “unified SM” [9], the left-handed quarks are doublets under one  $SU(2)$ , and the left-handed leptons are doublets under a different  $SU(2)$ , leading to a mostly leptophobic  $W'$  boson:  $C_{\ell ij}^L \ll C_{qij}^L$  and  $C_{\ell ij}^R = C_{qij}^R = 0$ . Fermions of different generations may also transform as doublets under different  $SU(2)$  gauge groups [10]. In particular, the couplings to third generation quarks may be enhanced [11].

It is also possible that the  $W'$  couplings to SM fermions are highly suppressed. For example, if the quarks and leptons are singlets under one  $SU(2)$  [12], then the couplings are proportional to the tiny mixing angle  $\theta_+$ . Similar suppressions may arise if some vectorlike fermions mix with the SM fermions [13].

Gauge groups that embed the electroweak symmetry, such as  $SU(3)_W \times U(1)$  or  $SU(4)_W \times U(1)$ , also include one or more  $W'$  bosons [14].

## Gauge & Higgs Boson Particle Listings

### New Heavy Bosons

**Collider searches.** At LEP-II,  $W'$  bosons could have been produced in pairs via their photon and  $Z$  couplings. The production cross section is large enough to rule out  $M_{W'} < \sqrt{s}/2 \approx 105$  GeV for most patterns of decay modes.

At hadron colliders,  $W'$  bosons can be detected through resonant pair production of fermions or electroweak bosons. Assuming that the  $W'$  width is much smaller than its mass, the contribution of the  $s$ -channel  $W'$  boson exchange to the total rate for  $pp \rightarrow f\bar{f}'X$ , where  $f$  and  $f'$  are fermions with an  $f\bar{f}'$  electric charge of  $\pm 1$ , and  $X$  is any final state, may be approximated by the branching fraction  $B(W' \rightarrow f\bar{f}')$  times the production cross section

$$\sigma(pp \rightarrow W'X) \simeq \frac{\pi}{48s} \sum_{i,j} \left[ (C_{qij}^L)^2 + (C_{qij}^R)^2 \right] w_{ij}(M_{W'}^2/s, M_{W'}) . \quad (4)$$

The functions  $w_{ij}$  include the information about proton structure, and are given to leading order in  $\alpha_s$  by

$$w_{ij}(z, \mu) = \int_z^1 \frac{dx}{x} \left[ u_i(x, \mu) \bar{d}_j\left(\frac{z}{x}, \mu\right) + \bar{u}_i(x, \mu) d_j\left(\frac{z}{x}, \mu\right) \right], \quad (5)$$

where  $u_i(x, \mu)$  and  $d_i(x, \mu)$  are the parton distributions inside the proton, at the factorization scale  $\mu$  and parton momentum fraction  $x$ , for the up- and down-type quark of the  $i$ th generation, respectively. QCD corrections to  $W'$  production are sizable (they also include quark-gluon initial states), but preserve the above factorization of couplings at next-to-leading order [15].

The most commonly studied  $W'$  signal consists of a high-momentum electron or muon and large missing transverse momentum, with the transverse mass distribution forming a Jacobian peak with its endpoint at  $M_{W'}$  (see Fig. 1e of [16]). Given that the branching fractions for  $W' \rightarrow e\nu$  and  $W' \rightarrow \mu\nu$  could be very different, these channels should be analyzed separately. Searches in these channels often implicitly assume that the left-handed couplings vanish (no interference between  $W$  and  $W'$ ), and that the right-handed neutrino is light compared to the  $W'$  boson and escapes the detector. These assumptions correspond to the following choice of parameters:  $C_q^R = gV_{\text{CKM}}$ ,  $C_q^L = g$ ,  $C_\ell^L = C_\ell^R = 0$ , which define a model that is essentially equivalent to the Sequential SM used in many searches. However, if a  $W'$  boson were discovered and the final state fermions have left-handed helicity, then the effects of  $W - W'$  interference could be observed [17], providing useful information about the  $W'$  couplings.

In the  $e\nu$  channel, the ATLAS and CMS Collaborations set limits on the  $W'$  production cross section times branching fraction (and thus indirectly on the  $W'$  couplings) when  $M_{W'}$  is in the 0.2 – 6 TeV range, based on 20 fb $^{-1}$  of LHC data at  $\sqrt{s} = 8$  TeV [16,18] and 2–3 fb $^{-1}$  at  $\sqrt{s} = 13$  TeV [19,20], as shown in Fig. 1. ATLAS sets the strongest mass lower limit  $M_{W'} > 4.0$  TeV in the Sequential SM (all limits in this mini-review are at the 95% CL). The coupling limits are much weaker for  $M_{W'} < 200$  GeV, a range last explored with the Tevatron at  $\sqrt{s} = 1.8$  TeV [21].

**Figure 1:** Upper limit on  $\sigma(pp \rightarrow W'X) B(W' \rightarrow e\nu)$  from ATLAS [20], at 95% CL. The red line shows the theoretical prediction in the Sequential SM.

In the  $\mu\nu$  channel, ATLAS and CMS set rate limits for  $M_{W'}$  in the 0.2 – 6 TeV range from the same analyses as mentioned above, with the strongest lower mass limit of 4.0 TeV set by CMS [19] using the  $\sqrt{s} = 13$  TeV data. When combined with the  $e\nu$  channel, the upper limit on the  $\sqrt{s} = 13$  TeV cross section times branching fraction to  $\ell\nu$  varies between 1 and 2 fb for  $M_{W'}$  between 1 and 5 TeV [19]. Only weak limits on  $W' \rightarrow \mu\nu$  exist for  $M_{W'} < 200$  GeV [22]. Note that masses of the order of the electroweak scale are interesting from a theory point of view, while lepton universality does not necessarily apply to a  $W'$  boson.

A dedicated search for  $W' \rightarrow \tau\nu$  has been performed by the CMS Collaboration at 8 TeV [23]. Limits are set on  $\sigma \cdot B$  for  $M_{W'}$  between 0.3 and 4.0 TeV. A lower mass limit of 2.7 TeV is set in the Sequential SM.

The  $W'$  decay into a lepton and a right-handed neutrino,  $\nu_R$ , may also be followed by the  $\nu_R$  decay through a virtual  $W'$  boson into a lepton and two quark jets. The ATLAS [24] and CMS [25] searches in the  $eejj$  and  $\mu\mu jj$  channels have set limits on the cross section times branching fraction as a function of the  $\nu_R$  mass or of  $M_{W'}$ . These searches are typically performed with same-charge lepton pairs that provide strong background reduction and are motivated by models with a left-right symmetry. However, it is also interesting to search in final states with opposite-charge lepton pairs, as done in the CMS analysis.

The  $t\bar{b}$  channel is particularly important because a  $W'$  boson that couples only to right-handed fermions cannot decay to leptons when the right-handed neutrinos are heavier than the  $W'$  boson (additional motivations are provided by a  $W'$  boson with enhanced couplings to the third generation [11], and by a leptophobic  $W'$  boson). The usual signature consists of a leptonically-decaying  $W$  boson and two  $b$ -jets. Recent studies have also incorporated the fully hadronic decay channel for  $M_{W'} \gg m_t$  with the use of jet substructure techniques to tag

**Figure 2:** Upper limits on  $W'$  couplings (at 95% CL) using the  $t\bar{b}$  and  $\bar{t}b$  final states, assuming that the diagonal couplings are generation independent. Left panel: ATLAS [26] limit on  $C_{q11}^R/g$ . Right panel: CMS [27] limit on  $M_{W'}$  as contours in the  $C_{q11}^R/g - C_{q11}^L/g$  plane.

highly boosted top-jets. Upper limits on the  $W'$  couplings to right- and left-handed quarks normalized to the SM  $W$  couplings have been set by ATLAS [26] and CMS [27] at  $\sqrt{s} = 8$  TeV, as shown in Fig. 2. Using about 2 fb<sup>-1</sup> of data at  $\sqrt{s} = 13$  TeV in the  $\ell + \text{jets}$  channel, CMS [28] sets an upper limit on the  $W'$  production cross section times branching fraction to the  $\ell\nu b\bar{b}$  final state decreasing from 1.6 pb at  $M_{W'} = 1$  TeV to 35 fb at  $M_{W'} = 3$  TeV. The limit  $M_{W'} > 2.38$  TeV obtained in the Sequential SM with a light  $\nu_R$  increases with the  $\nu_R$  mass. The best limits on the couplings to right-handed quarks for  $M_{W'}$  in the 300–600 GeV range have been set by CDF with 9.5 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV [29]. Finally, if  $W'$  couplings to left-handed quarks are large, then interference effects modify the SM  $s$ -channel single-top production [30].

Searches for dijet resonances may be used to set limits on  $W' \rightarrow q\bar{q}'$ . The best limits on  $W'$  couplings to quarks have been set by UA2 [31] in the 140 – 250 GeV mass range, by CDF [32] in the 250 – 500 GeV range and by CMS [33] in the 500 – 750 GeV range. ATLAS and CMS provide similar coverage in the  $\sim 0.75 - 7$  TeV range with data collected at  $\sqrt{s} = 8$  and 13 TeV [34] with the most stringent lower  $W'$  mass limit in the Sequential SM set to 2.6 TeV using 13 TeV data.

In some theories [4], the  $W'$  couplings to SM fermions are suppressed by discrete symmetries.  $W'$  production then occurs in pairs, through a photon or  $Z$  boson. The decay modes are model-dependent and often involve other new particles. The ensuing collider signals arise from cascade decays and typically include missing transverse momentum.

Searches for  $WZ$  resonances at the LHC have focused on the process  $pp \rightarrow W' \rightarrow WZ$  with the production mainly from  $u\bar{d} \rightarrow W'$  assuming SM-like couplings to quarks. ATLAS and CMS have set the strongest upper limits on the  $W'WZ$  coupling for  $M_{W'}$  in the 0.2 – 4 TeV range with a combination of fully leptonic, semi-leptonic and fully hadronic channels at both 8 and 13 TeV [35,36,37,38]. ATLAS has also combined the results from all channels at 8 TeV and obtains  $M_{W'} > 1.81$  TeV in the Sequential SM [39].

A fermiophobic  $W'$  boson that couples to  $WZ$  may be produced at hadron colliders in association with a  $Z$  boson, or

via  $WZ$  fusion. This would give rise to  $(WZ)Z$  and  $(WZ)jj$  final states, where the parentheses represent a resonance [40].

$W'$  bosons have also been searched for recently in final states with a  $W$  boson and a SM Higgs boson in the channels  $W \rightarrow \ell\nu$  and  $h^0 \rightarrow b\bar{b}$  or  $h^0 \rightarrow WW$  by ATLAS [41,42] and CMS [43] at  $\sqrt{s} = 8$  and 13 TeV. Cross section limits are set for  $W'$  masses in the range between 0.4 and 3.0 TeV. The strongest lower limit on the mass is set by the ATLAS 13 TeV analysis:  $M_{W'} > 1.49$  TeV in the context of the Heavy Vector Triplet weakly-coupled scenario A [44].

**Low-energy constraints.** The properties of  $W'$  bosons are also constrained by measurements of processes at energies much below  $M_{W'}$ . The bounds on  $W - W'$  mixing [45] are mostly due to the change in  $W$  properties compared to the SM. Limits on deviations in the  $ZWW$  couplings provide a leading constraint for fermiophobic  $W'$  bosons [13].

Constraints arising from low-energy effects of  $W'$  exchange are strongly model-dependent. If the  $W'$  couplings to quarks are not suppressed, then box diagrams involving a  $W$  and a  $W'$  boson contribute to neutral meson-mixing. In the case of  $W'$  couplings to right-handed quarks as in the left-right symmetric model, the limit from  $K_L - K_S$  mixing is severe:  $M_{W'} > 2.9$  TeV for  $C_q^L = C_q^R$  [46]. However, if no correlation between the  $W'$  and  $W$  couplings is assumed, then the limit on  $M_{W'}$  may be significantly relaxed [47].

$W'$  exchange also contributes at tree level to various low-energy processes. In particular, it would impact the measurement of the Fermi constant  $G_F$  in muon decay, which in turn would change the predictions of many other electroweak processes. A recent test of parity violation in polarized muon decay [48] has set limits of about 600 GeV on  $M_{W'}$ , assuming  $W'$  couplings to right-handed leptons as in left-right symmetric models and a light  $\nu_R$ . There are also  $W'$  contributions to the neutron electric dipole moment,  $\beta$  decays, and other processes [45].

If right-handed neutrinos have Majorana masses, then there are tree-level contributions to neutrinoless double-beta decay, and a limit on  $M_{W'}$  versus the  $\nu_R$  mass may be derived [49]. For  $\nu_R$  masses below a few GeV, the  $W'$  boson contributes to leptonic and semileptonic  $B$  meson decays, so that limits may be placed on various combinations of  $W'$  parameters [47]. For  $\nu_R$  masses below  $\sim 30$  MeV, the most stringent constraints on  $M_{W'}$  are due to the limits on  $\nu_R$  emission from supernovae.

### MASS LIMITS for $W'$ (Heavy Charged Vector Boson Other Than $W$ ) in Hadron Collider Experiments

Couplings of  $W'$  to quarks and leptons are taken to be identical with those of  $W$ . The following limits are obtained from  $p\bar{p}$  or  $pp \rightarrow W'X$  with  $W'$  decaying to the mode indicated in the comments. New decay channels (*e.g.*,  $W' \rightarrow WZ$ ) are assumed to be suppressed. The most recent preliminary results can be found in the “ $W'$ -boson searches” review above.

## New Heavy Bosons

- <sup>1</sup> AAD 15Au search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow q\bar{q}'$ ,  $Z \rightarrow \ell^+\ell^-$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>2</sup> AAD 15Av limit is for a SM like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- <sup>3</sup> AAD 15Az search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow q\bar{q}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>4</sup> AAD 15CP search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow q\bar{q}$ ,  $Z \rightarrow q\bar{q}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>5</sup> AAD 15R limit is for a SM like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- <sup>6</sup> AAD 15v search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- <sup>7</sup> KHACHATRYAN 15c search for  $W'$  decaying via  $WZ$  to fully leptonic final states using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = M_W/M_{W'}$ .
- <sup>8</sup> KHACHATRYAN 15T limit is for  $W'$  with SM-like coupling which interferes the SM  $W$  boson constructively using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. For  $W'$  without interference, the limit becomes  $> 3280$  GeV.
- <sup>9</sup> KHACHATRYAN 15v search new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- <sup>10</sup> AAD 14s search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell\ell$  using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>11</sup> KHACHATRYAN 14 search for  $W'$  decaying into  $WZ$  final state with  $W \rightarrow q\bar{q}$ ,  $Z \rightarrow q\bar{q}$  using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>12</sup> KHACHATRYAN 14o search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell jj$ . The quoted limit is for  $M_{\nu_{eR}} = M_{\nu_{\mu R}} = M_{W_R}/2$ . See their Fig. 3 and Fig. 5 for excluded regions in the  $M_{W_R} - M_{\nu}$  plane.
- <sup>13</sup> CHATRCHYAN 13E limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson using  $pp$  collisions at  $\sqrt{s}=7$  TeV. For  $W'$  with right-handed coupling, the bound becomes  $>1850$  GeV ( $>1910$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes  $>1640$  GeV.
- <sup>14</sup> AAD 15BB search for  $W'$  decaying into  $Wh$  with  $W \rightarrow \ell\nu$ ,  $h \rightarrow b\bar{b}$ . See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.
- <sup>15</sup> AALTONEN 15C limit is for a SM-like right-handed  $W'$  assuming  $W' \rightarrow \ell\nu$  decays are forbidden, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV. See their Fig. 3 for limit on  $g_{W'WZ}$ .
- <sup>16</sup> AAD 14AT search for a narrow charged vector boson decaying to  $W\gamma$ . See their Fig. 3a for the exclusion limit in  $M_{W'} - \sigma_B$  plane.
- <sup>17</sup> KHACHATRYAN 14A search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow q\bar{q}$ , or  $W \rightarrow q\bar{q}$ ,  $Z \rightarrow \ell\ell$ .  $pp$  collisions data at  $\sqrt{s}=8$  TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass-width plane.
- <sup>18</sup> AAD 13Ao search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow 2j$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>19</sup> CHATRCHYAN 13AJ search for resonances decaying to  $WZ$  pair, using the hadronic decay modes of  $W$  and  $Z$ , in  $pp$  collisions at  $\sqrt{s}=7$  TeV. See their Fig. 7 for the limit on the cross section.
- <sup>20</sup> CHATRCHYAN 13AQ limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson using  $pp$  collisions at  $\sqrt{s}=7$  TeV.
- <sup>21</sup> CHATRCHYAN 13U search for  $W'$  decaying to the  $WZ$  final state, with  $W$  decaying into jets, in  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>22</sup> The AAD 12Av quoted limit is for a SM-like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV.  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- <sup>23</sup> AAD 12BB use  $pp$  collisions data at  $\sqrt{s}=7$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- <sup>24</sup> AAD 12CK search for  $pp \rightarrow tW'$ ,  $W' \rightarrow \tau q$  events in  $pp$  collisions. See their Fig. 5 for the limit on  $\sigma \cdot B$ .
- <sup>25</sup> AAD 12CR use  $pp$  collisions at  $\sqrt{s}=7$  TeV.
- <sup>26</sup> AAD 12M search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell jj$ . See their Fig. 4 for the limit in the  $m_N - m_{W'}$  plane.
- <sup>27</sup> AALTONEN 12N search for  $p\bar{p} \rightarrow tW'$ ,  $W' \rightarrow \tau d$  events in  $p\bar{p}$  collisions. See their Fig. 3 for the limit on  $\sigma \cdot B$ .
- <sup>28</sup> CHATRCHYAN 12AR search for  $pp \rightarrow tW'$ ,  $W' \rightarrow \tau d$  events in  $pp$  collisions. See their Fig. 2 for the limit on  $\sigma \cdot B$ .
- <sup>29</sup> CHATRCHYAN 12BG search for right-handed  $W_R$  in  $pp$  collisions  $\sqrt{s} = 7$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell jj$ . See their Fig. 3 for the limit in the  $m_N - m_{W'}$  plane.
- <sup>30</sup> ABZOV 11H use data from  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV. The quoted limit is obtained assuming  $W'WZ$  coupling strength is the same as the ordinary  $WWZ$  coupling strength in the Standard Model.
- <sup>31</sup> ABZOV 11L limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV. For  $W'$  with right-handed coupling, the bound becomes  $>885$  GeV ( $>890$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes  $>916$  GeV.
- <sup>32</sup> AALTONEN 10N use  $p\bar{p}$  collision data at  $\sqrt{s}=1.96$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ . See their Fig. 4 for limits in mass-coupling plane.

- <sup>33</sup> AALTONEN 09AC search for new particle decaying to dijets using  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV.
- <sup>34</sup> The ACOSTA 03B quoted limit is for  $M_{W'} \gg M_{\nu_R}$ , using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV. For  $M_{W'} < M_{\nu_R}$ ,  $M_{W'}$  between 225 and 566 GeV is excluded.
- <sup>35</sup> The quoted limit is obtained assuming  $W'WZ$  coupling strength is the same as the ordinary  $WWZ$  coupling strength in the Standard Model, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV. See their Fig. 2 for the limits on the production cross sections as a function of the  $W'$  width.
- <sup>36</sup> AFFOLDER 01i combine a new bound on  $W' \rightarrow e\nu$  of 754 GeV, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV, with the bound of ABE 00 on  $W' \rightarrow \mu\nu$  to obtain quoted bound.
- <sup>37</sup> ABE 97c search for new particle decaying to dijets using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV.
- <sup>38</sup> For bounds on  $W_R$  with nonzero right-handed mass, see Fig. 5 from ABACHI 96c.
- <sup>39</sup> ABACHI 95E assume that the decay  $W' \rightarrow WZ$  is suppressed and that the neutrino from  $W'$  decay is stable and has a mass significantly less  $m_{W'}$ .
- <sup>40</sup> RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed  $K$  factor.

### $W_R$ (Right-Handed $W$ Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89b, and COLANGELO 91.  $g_R = g_L$  assumed. [Limits in the section MASS LIMITS for  $W'$  below are also valid for  $W_R$  if  $m_{\nu_R} \ll m_{W_R}$ .] Some limits assume manifest left-right symmetry, i.e., the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89b. Limits on the  $W_L - W_R$  mixing angle  $\zeta$  are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

## New Heavy Bosons

- <sup>12</sup> The quoted limit is from  $\mu$  decay parameters. BARENBOIM 97 also evaluate limit from  $K_L - K_S$  mass difference.
- <sup>13</sup> STAHL 97 limit is from fit to  $\tau$ -decay parameters.
- <sup>14</sup> ALLET 96 measured polarization-asymmetry correlation in  $^{12}\text{N} \beta^+$  decay. The listed limit assumes zero  $L$ - $R$  mixing.
- <sup>15</sup> KUZNETSOV 95 limit is from measurements of the asymmetry  $\langle \bar{p}_\nu \cdot \sigma_n \rangle$  in the  $\beta$  decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94b.
- <sup>16</sup> KUZNETSOV 94b limit is from measurements of the asymmetry  $\langle \bar{p}_\nu \cdot \sigma_n \rangle$  in the  $\beta$  decay of polarized neutrons. Zero mixing assumed.
- <sup>17</sup> BHATTACHARYYA 93 uses  $Z$ - $Z'$  mixing limit from LEP '90 data, assuming a specific Higgs sector of  $\text{SU}(2)_L \times \text{SU}(2)_R \times \text{U}(1)$  gauge model. The limit is for  $m_t = 200$  GeV and slightly improves for smaller  $m_t$ .
- <sup>18</sup> SEVERIJNS 93 measured polarization-asymmetry correlation in  $^{107}\text{In} \beta^+$  decay. The listed limit assumes zero  $L$ - $R$  mixing. Value quoted here is from SEVERIJNS 94 erratum.
- <sup>19</sup> IMAZATO 92 measure positron asymmetry in  $K^+ \rightarrow \mu^+ \nu_\mu$  decay and obtain  $\xi P_\mu > 0.990$  (90% CL). If  $W_R$  couples to  $u\bar{s}$  with full weak strength ( $V_{us}^R = 1$ ), the result corresponds to  $m_{W_R} > 653$  GeV. See their Fig. 4 for  $m_{W_R}$  limits for general  $|V_{us}^R|^2 = 1 - |V_{ud}^R|^2$ .
- <sup>20</sup> POLAK 92b limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming  $\zeta = 0$ . Supersedes POLAK 91.
- <sup>21</sup> AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.
- <sup>22</sup> COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.
- <sup>23</sup> POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming  $\zeta = 0$ . Superseded by POLAK 92b.
- <sup>24</sup> BARBIERI 89b limit holds for  $m_{\nu_R} \leq 10$  MeV.
- <sup>25</sup> LANGACKER 89b limit is for any  $\nu_R$  mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.
- <sup>26</sup> BALKE 88 limit is for  $m_{\nu_R} = 0$  and  $m_{\nu_{\mu R}} \leq 50$  MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.
- <sup>27</sup> JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point  $e^+$  spectrum in the decay of the highly polarized  $\mu^+$ .
- <sup>28</sup> STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay  $e^+$  spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
- <sup>29</sup> BERGSMAN 83 set limit  $m_{W_2}/m_{W_1} > 1.9$  at CL = 90%.
- <sup>30</sup> CARR 83 is TRIUMF experiment with a highly polarized  $\mu^+$  beam. Looked for deviation from  $V-A$  at the high momentum end of the decay  $e^+$  energy spectrum. Limit from previous world-average muon polarization parameter is  $m_{W_R} > 240$  GeV. Assumes a light right-handed neutrino.
- <sup>31</sup> BEALL 82 limit is obtained assuming that  $W_R$  contribution to  $K_L^0 - K_S^0$  mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

### Limit on $W_L$ - $W_R$ Mixing Angle $\zeta$

Lighter mass eigenstate  $W_1 = W_L \cos \zeta - W_R \sin \zeta$ . Light  $\nu_R$  assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

- <sup>1</sup> ACKERSTAFF 99b limit is from  $\tau$  decay parameters.
- <sup>2</sup> CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
- <sup>3</sup> The quoted limit is from  $\mu$  decay parameters. BARENBOIM 97 also evaluate limit from  $K_L - K_S$  mass difference.
- <sup>4</sup> MISHRA 92 limit is from the absence of extra large- $x$ , large- $y$   $\bar{\nu}_\mu N \rightarrow \bar{\nu}_\mu X$  events at Tevatron, assuming left-handed  $\nu$  and right-handed  $\bar{\nu}$  in the neutrino mass. The result gives  $\zeta^2(1 - 2m_{W_1}^2/m_{W_2}^2) < 0.0015$ . The limit is independent of  $\nu_R$  mass.
- <sup>5</sup> AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
- <sup>6</sup> BARBIERI 89b limit holds for  $m_{\nu_R} \leq 10$  MeV.
- <sup>7</sup> First JODIDIO 86 result assumes  $m_{W_R} = \infty$ , second is for unconstrained  $m_{W_R}$ .

### Z'-BOSON SEARCHES

Revised Jan. 2016 by M.-C. Chen (UC Irvine), B.A. Dobrescu (Fermilab) and S. Willocq (Univ. of Massachusetts).

The  $Z'$  boson is a massive, electrically-neutral and color-singlet hypothetical particle of spin 1. This particle is predicted

in many extensions of the Standard Model (SM) and has been the object of extensive phenomenological studies [1].

**$Z'$  boson couplings to quarks and leptons.** The couplings of a  $Z'$  boson to the first-generation fermions are given by

$$Z'_\mu (g_u^L \bar{u}_L \gamma^\mu u_L + g_d^L \bar{d}_L \gamma^\mu d_L + g_u^R \bar{u}_R \gamma^\mu u_R + g_d^R \bar{d}_R \gamma^\mu d_R + g_\nu^L \bar{\nu}_L \gamma^\mu \nu_L + g_e^L \bar{e}_L \gamma^\mu e_L + g_e^R \bar{e}_R \gamma^\mu e_R), \quad (1)$$

where  $u, d, \nu$  and  $e$  are the quark and lepton fields in the mass eigenstate basis, and the coefficients  $g_u^L, g_d^L, g_u^R, g_d^R, g_\nu^L, g_e^L, g_e^R$  are real dimensionless parameters. If the  $Z'$  couplings to quarks and leptons are generation-independent, then these seven parameters describe the couplings of the  $Z'$  boson to all SM fermions. More generally, however, the  $Z'$  couplings to fermions are generation-dependent, in which case Eq. (1) may be written with generation indices  $i, j = 1, 2, 3$  labeling the quark and lepton fields, and with the seven coefficients promoted to  $3 \times 3$  Hermitian matrices (e.g.,  $g_{eij}^L \bar{e}_L^i \gamma^\mu e_L^j$ , where  $e_L^j$  is the left-handed muon, etc.).

These parameters describing the  $Z'$  boson interactions with quarks and leptons are subject to some theoretical constraints. Quantum field theories that include a heavy spin-1 particle are well behaved at high energies only if that particle is a gauge boson associated with a spontaneously broken gauge symmetry. Quantum effects preserve the gauge symmetry only if the couplings of the gauge boson to fermions satisfy anomaly cancellation conditions. Furthermore, the fermion charges under the new gauge symmetry are constrained by the requirement that the quarks and leptons get masses from gauge-invariant interactions with Higgs fields.

The relation between the couplings displayed in Eq. (1) and the gauge charges  $z_{fi}^L$  and  $z_{fi}^R$  of the fermions  $f = u, d, \nu, e$  involves the unitary  $3 \times 3$  matrices  $V_f^L$  and  $V_f^R$  that transform the gauge eigenstate fermions  $f_L^i$  and  $f_R^i$ , respectively, into the mass eigenstates. The  $Z'$  couplings are also modified if the new gauge boson in the gauge eigenstate basis ( $\tilde{Z}'_\mu$ ) has a kinetic mixing  $(-\chi/2)B^{\mu\nu}\tilde{Z}'_{\mu\nu}$  with the hypercharge gauge boson  $B^\mu$  ( $\chi$  is a dimensionless parameter), or a mass mixing  $\delta M^2 \tilde{Z}^\mu \tilde{Z}'_\mu$  with the linear combination ( $\tilde{Z}_\mu$ ) of neutral bosons that couples as the SM  $Z$  boson [2]. Since both the kinetic and mass mixings shift the mass and couplings of the  $Z$  boson, electroweak measurements impose upper limits on  $\chi$  and  $\delta M^2/(M_{Z'}^2 - M_Z^2)$  of the order of  $10^{-3}$  [3]. Keeping only linear terms in these two small quantities, the couplings of the mass-eigenstate  $Z'$  boson are given by

$$g_{fij}^L = g_z V_{fii'}^L z_{f'i'}^L (V_f^L)_{ij}^\dagger + \frac{e}{c_W} \left( \frac{s_W \chi M_{Z'}^2 + \delta M^2}{2s_W (M_{Z'}^2 - M_Z^2)} \sigma_f^3 - \epsilon Q_f \right),$$

$$g_{fij}^R = g_z V_{fii'}^R z_{f'i'}^R (V_f^R)_{ij}^\dagger - \frac{e}{c_W} \epsilon Q_f, \quad (2)$$

where  $g_z$  is the new gauge coupling,  $Q_f$  is the electric charge of  $f$ ,  $e$  is the electromagnetic gauge coupling,  $s_W$  and  $c_W$  are the

**Table 1:** Examples of generation-independent  $U(1)'$  charges for quarks and leptons. The parameter  $x$  is an arbitrary rational number. Anomaly cancellation requires certain new fermions [5].

fermion	$U(1)_{B-xL}$	$U(1)_{10+5}$	$U(1)_{d-xu}$	$U(1)_{q+xu}$
$(u_L, d_L)$	1/3	1/3	0	1/3
$u_R$	1/3	-1/3	$-x/3$	$x/3$
$d_R$	1/3	$-x/3$	1/3	$(2-x)/3$
$(\nu_L, e_L)$	$-x$	$x/3$	$(-1+x)/3$	-1
$e_R$	$-x$	-1/3	$x/3$	$-(2+x)/3$

sine and cosine of the weak mixing angle,  $\sigma_f^3 = +1$  for  $f = u, \nu$  and  $\sigma_f^3 = -1$  for  $f = d, e$ , and

$$\epsilon = \frac{\chi (M_{Z'}^2 - c_W^2 M_Z^2) + s_W \delta M^2}{M_{Z'}^2 - M_Z^2}. \quad (3)$$

The interaction of the  $Z'$  boson with a pair of  $W$  bosons has the form

$$\left( i(W_\mu^- Z'_\nu - W_\nu^- Z'_\mu) \partial^\mu W^{+\nu} + \text{H.c.} \right) + i(W_\mu^+ W_\nu^- - W_\nu^+ W_\mu^-) \partial^\mu Z'^{\nu} \quad (4)$$

with a coefficient of order  $M_W^2/M_{Z'}^2$  [4]. The  $Z'$  also couples to one SM Higgs boson and one  $Z$  boson,  $Z'_\mu Z^\mu h^0$ , with a coefficient of order  $M_Z$ .

**$U(1)$  gauge groups.** A simple origin of a  $Z'$  boson is a new  $U(1)'$  gauge symmetry. In that case, the matricial equalities  $z_u^L = z_d^L$  and  $z_\nu^L = z_e^L$  are required by the SM  $SU(2)_W$  gauge symmetry. Given that the  $U(1)'$  interaction is not asymptotically free, the theory may be well-behaved at high energies (*e.g.*, by embedding  $U(1)'$  in a non-Abelian gauge group) only if the charges are commensurate numbers, *i.e.* any ratio of charges is a rational number. Satisfying the anomaly cancellation conditions (which include an equation cubic in charges) with rational numbers is highly nontrivial and in general new fermions charged under  $U(1)'$  are necessary.

Consider first generation-independent couplings (the  $V_f$  matrices then disappear from Eq. (2)) and neglect the  $\tilde{Z} - \tilde{Z}'$  mixing, so that there are five commensurate couplings:  $g_q^L, g_u^R, g_d^R, g_l^L, g_e^R$ . Four sets of charges are displayed in Table 1, each of them spanned by a free parameter  $x$  [5]. The first set, labelled  $B - xL$ , has charges proportional to the baryon number minus  $x$  times the lepton number. These charges allow all SM Yukawa couplings to a Higgs doublet which is neutral under  $U(1)_{B-xL}$ , so that there is no tree-level  $\tilde{Z} - \tilde{Z}'$  mixing. For  $x = 1$  one recovers the  $U(1)_{B-L}$  group, which is non-anomalous in the presence of one “right-handed neutrino” (a chiral fermion that is a singlet under the SM gauge group) per generation. For  $x \neq 1$ , it is necessary to include some fermions that are vector-like (*i.e.* their mass terms are gauge invariant) with respect to the electroweak gauge group and chiral with respect to  $U(1)_{B-xL}$ . In the particular cases  $x = 0$  or  $x \gg 1$ , the  $Z'$  is leptophobic or quark-phobic, respectively.

The second set,  $U(1)_{10+5}$ , has charges that commute with the representations of the  $SU(5)$  grand unified group. Here  $x$  is related to the mixing angle between the two  $U(1)$  bosons encountered in the  $E_6 \rightarrow SU(5) \times U(1) \times U(1)$  symmetry breaking patterns of grand unified theories [1,6]. This set leads to  $\tilde{Z} - \tilde{Z}'$  mass mixing at tree level, such that for a  $Z'$  mass close to the electroweak scale, the measurements at the  $Z$ -pole require some fine tuning between the charges and VEVs of the two Higgs doublets. Vector-like fermions charged under the electroweak gauge group and also carrying color are required (except for  $x = -3$ ) to make this set anomaly free. The particular cases  $x = -3, 1, -1/2$  are usually labelled  $U(1)_\chi$ ,  $U(1)_\psi$ , and  $U(1)_\eta$ , respectively. Under the third set,  $U(1)_{d-xu}$ , the weak-doublet quarks are neutral, and the ratio of  $u_R$  and  $d_R$  charges is  $-x$ . For  $x = 1$  this is the “right-handed” group  $U(1)_R$ . For  $x = 0$ , the charges are those of the  $E_6$ -inspired  $U(1)_I$  group, which requires new quarks and leptons. Other generation-independent sets of  $U(1)'$  charges are given in [7].

In the absence of new fermions charged under the SM group, the most general generation-independent charge assignment is  $U(1)_{q+xu}$ , which is a linear combination of hypercharge and  $B - L$ . Many other anomaly-free solutions exist if generation-dependent charges are allowed. An example is  $B - xL_e - yL_\mu + (y - 3)L_\tau$ , with  $x, y$  free parameters. This allows all fermion masses to be generated by Yukawa couplings to a single Higgs doublet, without inducing tree-level flavor-changing neutral current (FCNC) processes. There are also lepton-flavor dependent charges that allow neutrino masses to arise only from operators of high dimensionality [8].

If the  $SU(2)_W$ -doublet quarks have generation-dependent  $U(1)'$  charges, then the mass eigenstate quarks have flavor off-diagonal couplings to the  $Z'$  boson (see Eq. (1), and note that  $V_u^L (V_d^L)^\dagger$  is the CKM matrix). These are severely constrained by measurements of FCNC processes, which in this case are mediated at tree-level by  $Z'$  boson exchange [9]. The constraints are relaxed if the first and second generation charges are the same, although they are increasingly tightened by the measurements of  $B$  meson properties [10]. If only the  $SU(2)_W$ -singlet quarks have generation-dependent  $U(1)'$  charges, there is more freedom in adjusting the flavor off-diagonal couplings because the  $V_{u,d}^R$  matrices are not observable in the SM.

The anomaly cancellation conditions for  $U(1)'$  could be relaxed only if there is an axion with certain dimension-5 couplings to the gauge bosons. However, such a scenario violates unitarity unless the quantum field theory description breaks down at a scale near  $M_{Z'}$  [11].

**Other models.**  $Z'$  bosons may also arise from larger gauge groups. These may extend the electroweak group, as in  $SU(2) \times SU(2) \times U(1)$ , or may embed the electroweak group, as in  $SU(3)_W \times U(1)$  [12]. If the larger group is spontaneously broken down to  $SU(2)_W \times U(1)_Y \times U(1)'$  at a scale  $v_\star \gg M_{Z'}/g_z$ , then the above discussion applies up to corrections of order  $M_{Z'}^2/(g_z v_\star)^2$ . For  $v_\star \sim M_{Z'}/g_z$ , additional gauge bosons have

## Gauge & Higgs Boson Particle Listings

### New Heavy Bosons

masses comparable to  $M_{Z'}$ , including at least a  $W'$  boson [12]. If the larger gauge group breaks together with the electroweak symmetry directly to the electromagnetic  $U(1)_{\text{em}}$ , then the left-handed fermion charges are no longer correlated ( $z_u^L \neq z_d^L$ ,  $z_\nu^L \neq z_e^L$ ) and a  $Z'W^+W^-$  coupling is induced.

If the electroweak gauge bosons propagate in extra dimensions, then their Kaluza-Klein (KK) excitations include a series of  $Z'$  boson pairs. Each of these pairs can be associated with a different  $SU(2) \times U(1)$  gauge group in four dimensions. The properties of the KK particles depend strongly on the extra-dimensional theory [13]. For example, in universal extra dimensions there is a parity that forces all couplings of Eq. (1) to vanish in the case of the lightest KK bosons, while allowing couplings to pairs of fermions involving a SM and a heavy vector-like fermion. There are also 4-dimensional gauge theories (*e.g.* little Higgs with  $T$  parity) with  $Z'$  bosons exhibiting similar properties. By contrast, in a warped extra dimension, the couplings of Eq. (1) may be sizable even when SM fields propagate along the extra dimension.

$Z'$  bosons may also be composite particles. For example, in confining gauge theories [14], the  $\rho$ -like bound state is a spin-1 boson that may be interpreted as arising from a spontaneously broken gauge symmetry [15].

**Resonances versus cascade decays.** In the presence of the couplings shown in Eq. (1), the  $Z'$  boson may be produced in the  $s$ -channel at colliders, and would decay to pairs of fermions. The decay width into a pair of electrons is given by

$$\Gamma(Z' \rightarrow e^+e^-) \simeq \left[ (g_e^L)^2 + (g_e^R)^2 \right] \frac{M_{Z'}}{24\pi}, \quad (5)$$

where small corrections from electroweak loops are not included. The decay width into  $q\bar{q}$  is similar, except for an additional color factor of 3, QCD radiative corrections, and fermion mass corrections. Thus, one may compute the  $Z'$  branching fractions in terms of the couplings of Eq. (1). However, other decay channels, such as  $WW$  or a pair of new particles, could have large widths and need to be added to the total decay width.

As mentioned above, there are theories in which the  $Z'$  couplings are controlled by a discrete symmetry that forbids decays into a pair of SM particles. Typically, such theories involve several new particles, which may be produced only in pairs and undergo cascade decays through  $Z'$  bosons, leading to signals involving some missing (transverse) momentum. Given that the cascade decays depend on the properties of new particles other than the  $Z'$  boson, this case is not discussed further here.

**LEP-II limits.** The  $Z'$  contribution to the cross sections for  $e^+e^- \rightarrow f\bar{f}$  proceeds through an  $s$ -channel  $Z'$  exchange (when  $f = e$ , there are also  $t$ - and  $u$ -channel exchanges). For  $M_{Z'} < \sqrt{s}$ , the  $Z'$  appears as an  $f\bar{f}$  resonance in the radiative return process where photon emission tunes the effective center-of-mass energy to  $M_{Z'}$ . The agreement between the LEP-II measurements and the SM predictions implies that either the  $Z'$  couplings are smaller than or of order  $10^{-2}$ , or else  $M_{Z'}$  is

**Figure 1:** Upper limit on  $\sigma(pp \rightarrow Z'X \rightarrow \ell^+\ell^-X)$  with  $\ell = e$  or  $\mu$  as a function of  $M_{Z'}$  [23], assuming equal couplings for electrons and muons. The lines labelled by  $Z'_\psi$  and  $Z'_\chi$  are theoretical predictions for the  $U(1)_{10+x5}$  models in Table 1 with  $x = -3$  and  $x = +1$ , respectively, for  $g_z$  fixed by an  $E_6$  unification condition. The  $Z'_{\text{SSM}}$  line corresponds to  $Z'$  couplings equal to those of the  $Z$  boson.

above 209 GeV, the maximum energy of LEP-II. In the latter case, the  $Z'$  effects may be approximated up to corrections of order  $s/M_{Z'}^2$  by the contact interactions

$$\frac{g_z^2}{M_{Z'}^2 - s} [\bar{e}\gamma_\mu (z_e^L P_L + z_e^R P_R) e] [\bar{f}\gamma^\mu (z_f^L P_L + z_f^R P_R) f], \quad (6)$$

where  $P_{L,R}$  are chirality projection operators, and the relation between  $Z'$  couplings and charges (see Eq. (2) in the limit where the mass and kinetic mixings are neglected) is used, assuming generation-independent charges. The four LEP collaborations have set limits on the coefficients of such operators for all possible chiral structures and for various combinations of fermions [16]. Thus, one may derive bounds on  $(M_{Z'}/g_z)|z_e^L z_f^L|^{-1/2}$  and the analogous combinations of  $LR$ ,  $RL$  and  $RR$  charges, which are typically on the order of a few TeV. LEP-II limits were derived [5] on the four sets of charges shown in Table 1.

Somewhat stronger bounds can be set on  $M_{Z'}/g_z$  for specific sets of  $Z'$  couplings if the effects of several operators from Eq. (6) are combined. Dedicated analyses by the LEP collaborations have set limits on  $Z'$  bosons for particular values of the gauge coupling (see section 3.5 of [16]).

**Searches at hadron colliders.**  $Z'$  bosons with couplings to quarks (see Eq. (1)) may be produced at hadron colliders in the  $s$ -channel and would show up as resonances in the invariant mass distribution of the decay products. The cross section for

See key on page 601

## Gauge & Higgs Boson Particle Listings

### New Heavy Bosons

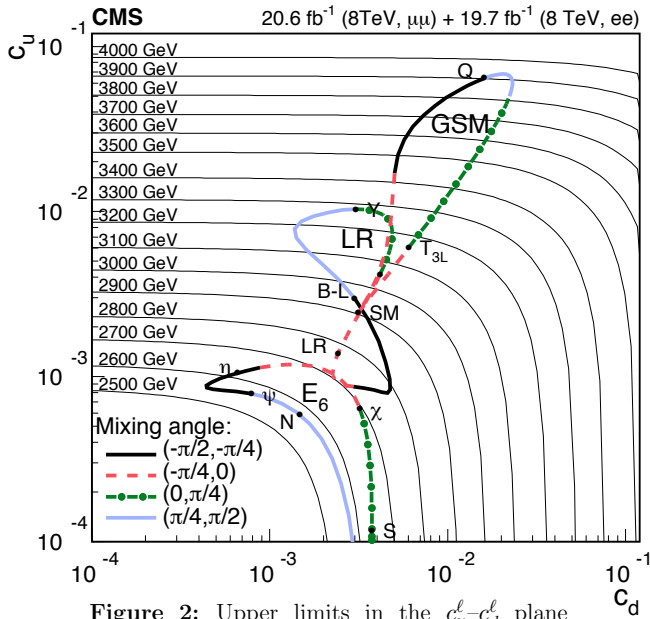

producing a  $Z'$  boson at the LHC, which then decays to some  $f\bar{f}$  final state, takes the form

$$\sigma(pp \rightarrow Z'X \rightarrow f\bar{f}X) \simeq \frac{\pi}{48s} \sum_q c_q^f w_q(s, M_{Z'}^2) \quad (7)$$

for flavor-diagonal couplings to quarks. Here, we have neglected the interference with the SM contribution to  $f\bar{f}$  production, which is a good approximation for a narrow  $Z'$  resonance (deviations from the narrow width approximation are discussed in [17]). The coefficients

$$c_q^f = \left[ (g_q^f)^2 + (g_q^f)^2 \right] B(Z' \rightarrow f\bar{f}) \quad (8)$$

contain all the dependence on the  $Z'$  couplings, while the functions  $w_q$  include all the information about parton distributions and QCD corrections [5,7]. This factorization holds exactly to NLO and the deviations from it induced at NNLO are very small. Note that the  $w_u$  and  $w_d$  functions are substantially larger than the  $w_q$  functions for the other quarks. Eq. (7) also applies to the Tevatron, except for changing the  $pp$  initial state to  $p\bar{p}$ , which implies that the  $w_q(s, M_{Z'}^2)$  functions are replaced by some other functions  $\bar{w}_q((1.96 \text{ TeV})^2, M_{Z'}^2)$ .

**Figure 2:** Upper limits in the  $c_u^\ell - c_d^\ell$  plane ( $\ell = e$  or  $\mu$ ), set by CMS [25], are shown as thin lines for certain  $M_{Z'}$  values. For specific sets of charges (labelled by  $E_6$ , GSM and LR, and described in [7]) parametrized by a mixing angle, the lower mass limit is given by the intersection of thick and thin lines. The black dots with smaller labels represent particular models.

It is common to present results of  $Z'$  searches as limits on the cross section versus  $M_{Z'}$  (see for example Fig. 1). An alternative is to plot exclusion curves for fixed  $M_{Z'}$  values in the  $c_u^\ell - c_d^\ell$  planes, allowing a simple derivation of the mass limit within any  $Z'$  model. The CMS upper limits in the  $c_u^\ell - c_d^\ell$  plane ( $\ell = e$  or  $\mu$ ) for different  $M_{Z'}$  are shown in Fig. 2 (for Tevatron limits, see [18,7]).

The discovery of a dilepton resonance at the LHC would determine the  $Z'$  mass and width. A measurement of the total cross section would define a band in the  $c_u^\ell - c_d^\ell$  plane. Angular distributions can be used to measure several combinations of  $Z'$  parameters (an example of how angular distributions improve the Tevatron sensitivity is given in [19]). Even though the original quark direction in a  $pp$  collider is unknown, the leptonic forward-backward asymmetry  $A_{FB}^\ell$  can be extracted from the kinematics of the dilepton system, and is sensitive to parity-violating couplings. A fit to the  $Z'$  rapidity distribution can distinguish between the couplings to up and down quarks. These measurements, combined with off-peak observables, have the potential to differentiate among various  $Z'$  models [20]. With  $100 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 14 \text{ TeV}$ , the spin of the  $Z'$  boson may be determined for  $M_{Z'} \leq 3 \text{ TeV}$  [21], and the expected sensitivity extends to  $M_{Z'} \sim 4 - 5 \text{ TeV}$  for many models [22].

Searches for  $Z'$  decays to  $e^+e^-$  and  $\mu^+\mu^-$  by the ATLAS and CMS collaborations set 95% C.L. lower limits on the  $Z'$  mass in the range between 2.8 and 3.4 TeV, depending on the specific model [23,24]. Lower mass limits for the flavor-violating leptonic final states have also been reported by ATLAS and CMS [26]; the limits obtained at 13 TeV in the  $e^\pm\mu^\mp$  channel are similar to those in the lepton-conserving channels above. In the case of final states with taus, lower limits obtained at 8 TeV are  $\approx 2.0 \text{ TeV}$  for the  $\tau^+\tau^-$  [27] decay and  $\approx 2.2 \text{ TeV}$  for the flavor-violating decays  $e^\pm\tau^\mp$  and  $\mu^\pm\tau^\mp$ .

Final states with higher background,  $t\bar{t}$ ,  $b\bar{b}$  and  $jj$ , are also important as they probe various combinations of  $Z'$  couplings to quarks. In the  $t\bar{t}$  channel, the 8 TeV data [28] sets lower mass limits in the 2–2.5 TeV range in a model where  $Z'$  couples only to the quarks of the first and third generations [29]. In the  $jj$  channel, the 13 TeV data [30] has been used to set limits on the production cross section of  $Z'$  bosons of masses larger than 1.5 TeV, where the trigger efficiency has reached its asymptotic value. For a comparison of earlier dijet resonance searches, see [31]. In the  $b\bar{b}$  channel [32], the  $b$  tagging leads to a reduction in both the background and the signal, so it may prove useful only if the  $Z' \rightarrow b\bar{b}$  branching fraction is large.

$Z'$  decays to  $Zh^0$  with  $Z \rightarrow \ell^+\ell^-$  or  $\nu\bar{\nu}$  and  $h^0 \rightarrow b\bar{b}$  have been studied by ATLAS [33] using 13 TeV data. The lower mass limit obtained in the context of the Heavy Vector Triplet model weakly-coupled scenario A [34] is 1.48 TeV. The  $Zh^0$  channel with the  $Z$  decaying hadronically and the Higgs boson decaying either hadronically or into  $\tau^+\tau^-$  has been studied by CMS [35] using 8 TeV data.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

The  $pp \rightarrow Z'X \rightarrow W^+W^-X$  process has also been searched for at the LHC. The channel where the  $Z'$  boson is produced through its couplings to quarks, and the  $W$  bosons decay hadronically, has been explored using boosted techniques to analyze the 13 TeV data [36]. The  $Z'$  boson may also be produced through its couplings to  $W$  bosons [37].

At the Tevatron, the CDF and DØ collaborations have searched for  $Z'$  bosons in the  $e^+e^-$  [38],  $\mu^+\mu^-$  [39],  $e^\pm\mu^\mp$  [40],  $\tau^+\tau^-$  [41],  $t\bar{t}$  [42],  $jj$  [43] and  $W^+W^-$  [44] final states. Although these limits have been often superseded by the LHC results, the Tevatron limits on certain  $Z'$  couplings (most notably, those arising from  $jj$  resonance searches [31]) remain competitive for  $M_{Z'}$  below about 0.5 TeV.

**Table 2:** Lower mass limits (in GeV) at 95% C.L. on various  $Z'$  bosons. The electroweak results [3] from low energy and  $W$  and  $Z$  boson data are for Higgs sectors consisting of doublets and singlets only ( $\rho_0 = 1$ ). The gauge coupling is fixed by an  $SO(10)$  unification condition for  $U(1)_\chi$ ,  $U(1)_\psi$  and  $U(1)_\eta$ . The secluded  $Z_S$  emerges in a supersymmetric model [46], and  $Z_{SSM}$  is the sequential  $Z'$  (same coupling as the SM  $Z$  boson). The last three columns show the limits from dilepton resonance searches at the LHC [23,24] and the Tevatron [39,38], and from  $e^+e^- \rightarrow f\bar{f}$  measurements at LEP-II [16].

$Z'$	electroweak	ATLAS/CMS	CDF/DØ	LEP-II
$Z_\chi$	1141	3080	930	785
$Z_\psi$	147	2790	917	500
$Z_\eta$	427	2850	938	500
$Z_S$	1257	3030	858	—
$Z_{SSM}$	1403	3400	1071	1760

**Low-energy constraints.**  $Z'$  boson properties are also constrained by a variety of low-energy experiments [45]. Polarized electron-nucleon scattering and atomic parity violation are sensitive to electron-quark contact interactions, which get contributions from  $Z'$  exchange that can be expressed in terms of the couplings introduced in Eq. (1) and  $M_{Z'}$ . Further corrections to the electron-quark contact interactions are induced in the presence of  $\tilde{Z} - Z'$  mixing because of the shifts in the  $Z$  couplings to quarks and leptons [2]. Deep-inelastic neutrino-nucleon scattering is similarly affected by  $Z'$  bosons. Other low-energy observables are discussed in [3]. In some models, the lower limits on  $M_{Z'}$  set by low energy data are above 1 TeV, as shown in Table 2 (for more general models, see [1,5,47]). The mass bounds from direct searches at the LHC [23,24] exceed the electroweak constraints by a factor of two or more for the models considered there. While the electroweak constraints can be slightly improved by fixing the Higgs mass to the value

measured at the LHC, and the collider bounds are moderately weakened if there are open exotic decay channels [48], this conclusion will not change.

Although the LHC data are most constraining for many  $Z'$  models, one should be careful in assessing the relative reach of various experiments given the freedom in  $Z'$  couplings. For example, a  $Z'$  coupled to  $B - yL_\mu + (y - 3)L_\tau$  has implications for the muon  $g - 2$ , neutrino oscillations or  $\tau$  decays, and would be hard to see in processes involving first-generation fermions. Moreover, the combination of LHC searches and low-energy measurements could allow a precise determination of the  $Z'$  parameters [49].

### MASS LIMITS for $Z'$ (Heavy Neutral Vector Boson Other Than $Z$ )

#### Limits for $Z'_{SM}$

$Z'_{SM}$  is assumed to have couplings with quarks and leptons which are identical to those of  $Z$ , and decays only to known fermions. The most recent preliminary results can be found in the "Z'-boson searches" review above.

- 1 AAD 15AM search for resonances decaying to  $\tau^+ \tau^-$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 2 KHACHATRYAN 15AE search for resonances decaying to  $e^+ e^-, \mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 3 KHACHATRYAN 15V search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 4 AAD 14v search for resonances decaying to  $e^+ e^-, \mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 5 CHATRCHYAN 13A use  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 6 CHATRCHYAN 120 search for resonances decaying to  $\tau^+ \tau^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 7 CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
- 8 AAD 13s search for resonances decaying to  $\tau^+ \tau^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 9 CHATRCHYAN 13AF search for resonances decaying to  $e^+ e^-, \mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV and 8 TeV.
- 10 AAD 12cc search for resonances decaying to  $e^+ e^-, \mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 11 AALTONEN 11i search for resonances decaying to  $\mu^+ \mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 12 ABZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+ e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 13 The quoted limit assumes  $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$ . See their Fig. 4 for limits in mass-coupling plane.
- 14 AALTONEN 09AC search for new particle decaying to dijets.
- 15 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0026 < \theta < 0.0006$ .
- 16 ABDALLAH 06C use data  $\sqrt{s} = 130$ –207 GeV.
- 17 ACOSTA 05R search for resonances decaying to tau lepton pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 18 ABBIENDI 04G give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00422 < \theta < 0.00091$ .  $\sqrt{s} = 91$  to 207 GeV.
- 19 ABZOV 01B search for resonances in  $p\bar{p} \rightarrow e^+ e^-$  at  $\sqrt{s} = 1.8$  TeV. They find  $\sigma \cdot B(Z' \rightarrow e\bar{e}) < 0.06$  pb for  $M_{Z'} > 500$  GeV.
- 20 ABREU 00S uses LEP data at  $\sqrt{s} = 90$  to 189 GeV.
- 21 BARATE 00i search for deviations in cross section and asymmetries in  $e^+ e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 22 ERLER 99 give 90%CL limit on the  $Z$ - $Z'$  mixing  $-0.0041 < \theta < 0.0003$ .  $\rho_0 = 1$  is assumed.
- 23 ABE 97S find  $\sigma(Z') \times B(e^+ e^-, \mu^+ \mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 24 VILAIN 94B assume  $m_t = 150$  GeV.
- 25 ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes  $B(Z' \rightarrow q\bar{q}) = 0.7$ . See their Fig. 5 for limits in the  $m_{Z'} - B(q\bar{q})$  plane.
- 26 RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 27 ABE 90F use data for  $R, R_{\ell\ell}$ , and  $A_{\ell\ell}$ . They fix  $m_W = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_Z = 91.13 \pm 0.03$  GeV.

#### Limits for $Z_{LR}$

$Z_{LR}$  is the extra neutral boson in left-right symmetric models.  $g_L = g_R$  is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the  $W'$ ). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

<sup>1</sup> DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0012 < \theta < 0.0004$ .

<sup>2</sup> ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40 \text{ fb}$  for  $m_{Z'} > 600 \text{ GeV}$  at  $\sqrt{s} = 1.8 \text{ TeV}$ .

<sup>3</sup> ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0013 < \theta < 0.0006$ .

<sup>4</sup> ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0028$ . See their Fig. 14 for limit contours in the mass-mixing plane.

<sup>5</sup> ABBIENDI 04c give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00098 < \theta < 0.00190$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.

<sup>6</sup> CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

<sup>7</sup> ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0018$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.

<sup>8</sup> BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.

<sup>9</sup> CHAY 00 also find  $-0.0003 < \theta < 0.0019$ . For  $g_R$  free,  $m_{Z'} > 430 \text{ GeV}$ .

<sup>10</sup> ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_{LR}$  and  $Z_\chi$ .

<sup>11</sup> CASALBUONI 99 discuss the discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$ . It is shown that the data are better described in a class of models including the  $Z_{LR}$  model.

<sup>12</sup> CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds  $|\theta| < 0.0042$ .

<sup>13</sup> ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0009 < \theta < 0.0017$ .

<sup>14</sup> ERLER 99 assumes 2 Higgs doublets, transforming as 10 of  $\text{SO}(10)$ , embedded in  $E_6$ .

<sup>15</sup> BARENBOIM 98 also gives 68% CL limits on the  $Z$ - $Z'$  mixing  $-0.0005 < \theta < 0.0033$ . Assumes Higgs sector of minimal left-right model.

<sup>16</sup> CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.

<sup>17</sup> VILAIN 94B assume  $m_t = 150 \text{ GeV}$  and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.

<sup>18</sup> RIZZO 93 analyses CDF limit on possible two-jet resonances.

<sup>19</sup> GRIFOLS 90 limit holds for  $m_{\nu_R} \lesssim 1 \text{ MeV}$ . A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.

<sup>20</sup> BARBIERI 89B limit holds for  $m_{\nu_R} \lesssim 10 \text{ MeV}$ . Bounds depend on assumed supernova core temperature.

### Limits for $Z_\chi$

$Z_\chi$  is the extra neutral boson in  $\text{SO}(10) \rightarrow \text{SU}(5) \times \text{U}(1)_\chi$ .  $g_\chi = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

<sup>1</sup> AAD 14v search for resonances decaying to  $e^+e^-, \mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$ .

<sup>2</sup> ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0016 < \theta < 0.0006$ .

<sup>3</sup> AAD 12cc search for resonances decaying to  $e^+e^-, \mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$ .

<sup>4</sup> AALTONEN 11i search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .

<sup>5</sup> ABAZOV 11A, AALTONEN 09t, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .

<sup>6</sup> DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0011 < \theta < 0.0007$ .

<sup>7</sup> AALTONEN 09v search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .

<sup>8</sup> ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0031$ . See their Fig. 14 for limit contours in the mass-mixing plane.

<sup>9</sup> ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .

<sup>10</sup> ABBIENDI 04c give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00099 < \theta < 0.00194$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.

<sup>11</sup> BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino  $\delta N_\nu < 1$ . The quark-hadron transition temperature  $T_C = 150 \text{ MeV}$  is assumed. The limit with  $T_C = 400 \text{ MeV}$  is  $> 4300 \text{ GeV}$ .

<sup>12</sup> CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

<sup>13</sup> ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0017$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.

<sup>14</sup> BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.

<sup>15</sup> CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H = 100 \text{ GeV}$ . See Fig. 3 for limits in the mass-mixing plane.

<sup>16</sup> ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_{LR}$  and  $Z_\chi$ .

<sup>17</sup> ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_\chi$ .

<sup>18</sup> ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0020 < \theta < 0.0015$ .

<sup>19</sup> ERLER 99 assumes 2 Higgs doublets, transforming as 10 of  $\text{SO}(10)$ , embedded in  $E_6$ .

<sup>20</sup> CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.

<sup>21</sup> ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40 \text{ fb}$  for  $m_{Z'} > 600 \text{ GeV}$  at  $\sqrt{s} = 1.8 \text{ TeV}$ .

<sup>22</sup>  $Z$ - $Z'$  mixing is assumed to be zero.  $\sqrt{s} = 57.77 \text{ GeV}$ .

<sup>23</sup> VILAIN 94B assume  $m_t = 150 \text{ GeV}$  and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.

<sup>24</sup> FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos  $\Delta N_\nu < 0.5$  and is valid for  $m_{\nu_R} < 1 \text{ MeV}$ .

<sup>25</sup> ABE 90f use data for  $R, R_{\ell\ell}$ , and  $A_{\ell\ell}$ . ABE 90f fix  $m_W = 80.49 \pm 0.43 \pm 0.24 \text{ GeV}$  and  $m_Z = 91.13 \pm 0.03 \text{ GeV}$ .

<sup>26</sup> Assumes the nucleosynthesis bound on the effective number of light neutrinos ( $\delta N_\nu < 1$ ) and that  $\nu_R$  is light ( $\lesssim 1 \text{ MeV}$ ).

<sup>27</sup> GRIFOLS 90 limit holds for  $m_{\nu_R} \lesssim 1 \text{ MeV}$ . See also GRIFOLS 90D, RIZZO 91.

### Limits for $Z_\psi$

$Z_\psi$  is the extra neutral boson in  $E_6 \rightarrow \text{SO}(10) \times \text{U}(1)_\psi$ .  $g_\psi = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 1 KHACHATRYAN 15AE search for resonances decaying to  $e^+e^-$ ,  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 2 AAD 14V search for resonances decaying to  $e^+e^-$ ,  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 3 CHATRCHYAN 12o search for resonances decaying to  $\tau^+\tau^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 4 DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0019 < \theta < 0.0007$ .
- 5 CHATRCHYAN 13AF search for resonances decaying to  $e^+e^-$ ,  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV and 8 TeV.
- 6 AAD 12CC search for resonances decaying to  $e^+e^-$ ,  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 7 CHATRCHYAN 12M search for resonances decaying to  $e^+e^-$  or  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 8 AALTONEN 11I search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 9 ABZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 10 AALTONEN 09V search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 11 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0018 < \theta < 0.0009$ .
- 12 ABDALLAH 06C give 95% CL limit  $|\theta| < 0.0027$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 13 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 14 ABBIENDI 04G give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00129 < \theta < 0.00258$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 15 BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino  $\delta N_\nu < 1$ . The quark-hadron transition temperature  $T_C = 150$  MeV is assumed. The limit with  $T_C = 400$  MeV is  $> 1100$  GeV.
- 16 ABREU 00S give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0018$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.
- 17 BARATE 00I search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 18 CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H = 100$  GeV. See Fig. 3 for limits in the mass-mixing plane.
- 19 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0013 < \theta < 0.0024$ .
- 20 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 21 ABE 97S find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 22 VILAIN 94B assume  $m_t = 150$  GeV and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.
- 23 ABE 90F use data for  $R$ ,  $R_{\ell\ell}$ , and  $A_{\ell\ell}$ . ABE 90F fix  $m_W = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_Z = 91.13 \pm 0.03$  GeV.
- 24 Assumes the nucleosynthesis bound on the effective number of light neutrinos ( $\delta N_\nu < 1$ ) and that  $\nu_R$  is light ( $\lesssim 1$  MeV).
- 25 GRIFOLS 90D limit holds for  $m_{\nu_R} \lesssim 1$  MeV. See also RIZZO 91.

### Limits for $Z_\eta$

$Z_\eta$  is the extra neutral boson in  $E_6$  models, corresponding to  $Q_\eta = \sqrt{3/8} Q_\chi - \sqrt{5/8} Q_\psi$ .  $g_\eta = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

<sup>1</sup> KHACHATRYAN 16E search for a leptophobic top-color  $Z'$  decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes that  $\Gamma_{Z'}/m_{Z'} = 0.012$ . Also  $m_{Z'} < 2.9$  TeV is excluded for wider topcolor  $Z'$  with  $\Gamma_{Z'}/m_{Z'} = 0.1$ .

<sup>2</sup> AAD 15A0 search for narrow resonance decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See Fig. 11 for limit on  $\sigma_B$ .

<sup>3</sup> AAD 15AT search for monoprot production plus large missing  $E_T$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV and give constraints on a  $Z'$  model having  $Z'u\bar{t}$  coupling.  $Z'$  is assumed to decay invisibly. See their Fig. 6 for limits on  $\sigma \cdot B$ .

<sup>4</sup> AAD 15CD search for decays of Higgs bosons to 4  $\ell$  states via  $Z'$  bosons,  $h \rightarrow Z'Z' \rightarrow 4\ell$  or  $h \rightarrow Z'Z' \rightarrow 4\ell$ . See Fig. 5 for the limit on the signal strength of the  $h \rightarrow Z'Z' \rightarrow 4\ell$  process and Fig. 16 for the limit on  $h \rightarrow Z'Z' \rightarrow 4\ell$ .

<sup>5</sup> AAD 15o search for new particle with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See their Fig. 2 for limits on  $\sigma_B$ .

<sup>6</sup> KHACHATRYAN 15F search for monoprot production plus large missing  $E_T$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV and give constraints on a  $Z'$  model having  $Z'u\bar{t}$  coupling.  $Z'$  is assumed to decay invisibly. See Fig. 3 for limits on  $\sigma_B$ .

<sup>7</sup> KHACHATRYAN 15O search for narrow  $Z'$  resonance decaying to  $Zh$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See their Fig. 6 for limit on  $\sigma_B$ .

<sup>8</sup> AAD 14AT search for a narrow neutral vector boson decaying to  $Z\gamma$ . See their Fig. 3b for the exclusion limit in  $m_{Z'} - \sigma_B$  plane.

<sup>9</sup> KHACHATRYAN 14A search for new resonance in the  $WW$  ( $\ell\nu q\bar{q}$ ) and the  $ZZ$  ( $\ell\ell q\bar{q}$ ) channels using  $pp$  collisions at  $\sqrt{s}=8$  TeV. See their Fig.13 for the exclusion limit on the number of events in the mass-width plane.

<sup>10</sup> MARTINEZ 14 use various electroweak data to constrain the  $Z'$  boson in the 3-3-1 models.

<sup>11</sup> AAD 13A1 search for new particle with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. See their Fig. 2 for limits on  $\sigma \cdot B$ .

<sup>12</sup> AAD 13A0 search for a leptophobic top-color  $Z'$  decaying to  $t\bar{t}$ . The quoted limit assumes that  $\Gamma_{Z'}/m_{Z'} = 0.012$ .

<sup>13</sup> CHATRCHYAN 13BM search for top-color  $Z'$  decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .

<sup>14</sup> CHATRCHYAN 13AP search for top-color leptophobic  $Z'$  decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .

<sup>15</sup> AAD 12BV search for narrow resonance decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. See their Fig. 7 for limit on  $\sigma \cdot B$ .

<sup>16</sup> AAD 12K search for narrow resonance decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. See their Fig. 5 for limit on  $\sigma \cdot B$ .

<sup>17</sup> AALTONEN 12AR search for chromophilic  $Z'$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. See their Fig. 5 for limit on  $\sigma \cdot B$ .

<sup>18</sup> AALTONEN 12N search for  $p\bar{p} \rightarrow tZ', Z' \rightarrow \bar{t}u$  events in  $p\bar{p}$  collisions. See their Fig. 3 for the limit on  $\sigma \cdot B$ .

<sup>19</sup> ABAZOV 12R search for top-color  $Z'$  boson decaying exclusively to  $t\bar{t}$ . The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .

<sup>20</sup> CHATRCHYAN 12AI search for  $pp \rightarrow t\bar{t}$  events and give constraints on a  $Z'$  model having  $Z'\bar{t}t$  coupling. See their Fig. 4 for the limit in mass-coupling plane.

<sup>21</sup> Search for resonance decaying to  $t\bar{t}$ . See their Fig. 6 for limit on  $\sigma \cdot B$ .

<sup>22</sup> AAD 11H search for new particle with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. See their Fig. 3 for exclusion plot on the production cross section.

<sup>23</sup> AAD 11Z search for new particle with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. See their Fig. 3 for limit on  $\sigma \cdot B$ .

<sup>24</sup> Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 4 for limit on  $\sigma \cdot B$ .

<sup>25</sup> Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 3 for limit on  $\sigma \cdot B$ .

<sup>26</sup> CHATRCHYAN 11o search for same-sign top production in  $pp$  collisions induced by a hypothetical FCNC  $Z'$  at  $\sqrt{s} = 7$  TeV. See their Fig. 3 for limit in mass-coupling plane.

<sup>27</sup> Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 3 for limit on  $\sigma \cdot B$ .

<sup>28</sup> ABULENCIA 06M search for new particle with lepton flavor violating decay at  $\sqrt{s} = 1.96$  TeV. See their Fig.4 for an exclusion plot on a mass-coupling plane.

<sup>29</sup> Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 2 for limit on  $\sigma \cdot B$ .

<sup>30</sup> BARGER 03b use the nucleosynthesis bound on the effective number of light neutrino  $\delta N_\nu$ . See their Figs. 4-5 for limits in general  $E_6$  motivated models.

<sup>31</sup> CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H=100$  GeV. See Fig. 2 for limits in general  $E_6$ -motivated models.

<sup>32</sup> CHO 98 study constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, assuming no  $Z$ - $Z'$  mixing.

<sup>33</sup> Search for  $Z'$  decaying to dijets at  $\sqrt{s}=1.8$  TeV. For  $Z'$  with electromagnetic strength coupling, no bound is obtained.

### Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the  $Z$  boson or photon in  $d=1$  extra dimension. These bounds can also be interpreted as a lower bound on  $1/R$ , the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the 4+ $d$ -dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this Review.

VALUE (TeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • •				We do not use the following data for averages, fits, limits, etc. • • •

> 4.7		1	MUECK	02	RVUE	Electroweak
> 3.3	95	2	CORNET	00	RVUE	$e\nu qq'$
>5000		3	DELGADO	00	RVUE	$\epsilon_K$
> 2.6	95	4	DELGADO	00	RVUE	Electroweak
> 3.3	95	5	RIZZO	00	RVUE	Electroweak
> 2.9	95	6	MARCIAÑO	99	RVUE	Electroweak
> 2.5	95	7	MASIP	99	RVUE	Electroweak
> 1.6	90	8	NATH	99	RVUE	Electroweak
> 3.4	95	9	STRUMIA	99	RVUE	Electroweak

- <sup>1</sup> MUECK 02 limit is  $2\sigma$  and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)<sub>L</sub>, bulk-U(1)<sub>Y</sub>, and of bulk-SU(2)<sub>L</sub>, brane-U(1)<sub>Y</sub>, the corresponding limits are  $> 4.6$  TeV,  $> 4.3$  TeV and  $> 3.0$  TeV, respectively.
- <sup>2</sup> Bound is derived from limits on  $e\nu qq'$  contact interaction, using data from HERA and the Tevatron.
- <sup>3</sup> Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from  $\Delta m_K$ .
- <sup>4</sup> See Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary conditions can be found which permit KK states down to 950 GeV and that agree with the measurement of  $Q_W(\text{Cs})$ . Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV.
- <sup>5</sup> Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV.
- <sup>6</sup> Bound is derived from global electroweak analysis but considering only presence of the KK  $W$  bosons.
- <sup>7</sup> Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk.
- <sup>8</sup> Bounds from effect of KK states on  $G_F$ ,  $\alpha$ ,  $M_W$ , and  $M_Z$ . Hard cutoff at string scale determined using gauge coupling unification. Limits for  $d=2,3,4$  rise to 3.5, 5.7, and 7.8 TeV.
- <sup>9</sup> Bound obtained for Higgs confined to the matter brane with  $m_H=500$  GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

## LEPTOQUARKS

Updated September 2015 by S. Rolli (US Department of Energy) and M. Tanabashi (Nagoya U.)

Leptoquarks are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary SM fermions are dimensionless and invariant under the standard model (SM) gauge group. Table 1 shows the list of all possible quantum numbers with this assumption [1]. The columns of  $SU(3)_C$ ,  $SU(2)_W$ , and  $U(1)_Y$  in Table 1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

**Table 1:** Possible leptoquarks and their quantum numbers.

Spin	$3B+L$	$SU(3)_c$	$SU(2)_W$	$U(1)_Y$	Allowed coupling
0	-2	$\bar{3}$	1	1/3	$\bar{q}_L^c \ell_L$ or $\bar{u}_R^c e_R$
0	-2	$\bar{3}$	1	4/3	$\bar{d}_R^c e_R$
0	-2	$\bar{3}$	3	1/3	$\bar{q}_L^c \ell_L$
1	-2	$\bar{3}$	2	5/6	$\bar{q}_L^c \gamma^\mu e_R$ or $\bar{d}_R^c \gamma^\mu \ell_L$
1	-2	$\bar{3}$	2	-1/6	$\bar{u}_R^c \gamma^\mu \ell_L$
0	0	3	2	7/6	$\bar{q}_L e_R$ or $\bar{u}_R \ell_L$
0	0	3	2	1/6	$\bar{d}_R \ell_L$
1	0	3	1	2/3	$\bar{q}_L \gamma^\mu \ell_L$ or $\bar{d}_R \gamma^\mu e_R$
1	0	3	1	5/3	$\bar{u}_R \gamma^\mu e_R$
1	0	3	3	2/3	$\bar{q}_L \gamma^\mu \ell_L$

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible [2,3].

Leptoquark states are expected to exist in various extensions of SM. The Pati-Salam model [4] is an example predicting the existence of a leptoquark state. Vector leptoquark states also exist in grand unification theories based on  $SU(5)$  [5],  $SO(10)$  [6], which includes Pati-Salam color  $SU(4)$ , and larger gauge groups. Scalar quarks in supersymmetric models with R-parity violation may also have leptoquark-type Yukawa couplings. The bounds on the leptoquark states can therefore be applied to constrain R-parity-violating supersymmetric models. Scalar leptoquarks are expected to exist at TeV scale in extended technicolor models [7,8] where leptoquark states appear as the bound states of techni-fermions. Compositeness of quarks and leptons also provides examples of models which may have light leptoquark states [9].

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from the bounds on the leptoquark-induced four-fermion interactions, which are obtained from low-energy experiments, or from collider experiments below threshold.

If a leptoquark couples to fermions belonging to more than a single generation in the mass eigenbasis of the SM fermions, it can induce four-fermion interactions causing flavor-changing neutral currents and lepton-family-number violations. The quantum number assignment of Table 1 allows several leptoquark states to couple to both left- and right-handed quarks simultaneously. Such leptoquark states are called non-chiral and may cause four-fermion interactions affecting the  $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$  ratio [10]. Non-chiral scalar leptoquarks also contribute to the muon anomalous magnetic moment [11,12]. Since indirect limits provide more stringent constraints on these types of leptoquarks, it is often assumed that a leptoquark state couples only to a single generation in a chiral interaction, for which indirect limits become much weaker. Additionally, this assumption gives strong constraints on concrete models of leptoquarks.

Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first- (second-, third-) generation leptoquarks. Refs. [13,14] give extensive lists of the bounds on the leptoquark-induced four-fermion interactions. For the isoscalar and vector leptoquarks  $S_0$  and  $V_0$ , for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds of Ref. 13 read  $\lambda^2 < 0.03 \times (M_{LQ}/300 \text{ GeV})^2$  for  $S_0$ , and  $\lambda^2 < 0.02 \times (M_{LQ}/300 \text{ GeV})^2$  for  $V_0$  ( $\lambda^2 < 5 \times (M_{LQ}/300 \text{ GeV})^2$  for  $S_0$ , and  $\lambda^2 < 3 \times (M_{LQ}/300 \text{ GeV})^2$  for  $V_0$ ) with  $\lambda$  being the leptoquark coupling strength. The  $e^+e^-$  experiments are sensitive to the indirect effects coming from  $t$ - and  $u$ -channel exchanges of leptoquarks in the  $e^+e^- \rightarrow q\bar{q}$  process.

The HERA experiments give bounds on the leptoquark-induced four-fermion interaction. For detailed bounds obtained in this way, see the Boson Particle Listings for “Indirect Limits for Leptoquarks” and its references.

Collider experiments provide direct limits on the leptoquark states through limits on the pair- and single-production cross sections. The leading-order cross sections of the parton processes

$$\begin{aligned} q + \bar{q} &\rightarrow LQ + \overline{LQ} \\ g + g &\rightarrow LQ + \overline{LQ} \\ e + q &\rightarrow LQ \end{aligned} \quad (1)$$

may be written as [15]

$$\begin{aligned} \hat{\sigma}_{LO}[q\bar{q} \rightarrow LQ + \overline{LQ}] &= \frac{2\alpha_s^2\pi}{27\hat{s}}\beta^3, \\ \hat{\sigma}_{LO}[gg \rightarrow LQ + \overline{LQ}] &= \frac{\alpha_s^2\pi}{96\hat{s}} \\ &\times \left[ \beta(41 - 31\beta^2) + (18\beta^2 - \beta^4 - 17) \log \frac{1+\beta}{1-\beta} \right], \\ \hat{\sigma}_{LO}[eq \rightarrow LQ] &= \frac{\pi\lambda^2}{4}\delta(\hat{s} - M_{LQ}^2) \end{aligned} \quad (2)$$

for a scalar leptoquark. Here  $\sqrt{\hat{s}}$  is the invariant energy of the parton subprocess, and  $\beta \equiv \sqrt{1 - 4M_{LQ}^2/\hat{s}}$ . The leptoquark Yukawa coupling is given by  $\lambda$ . Leptoquarks are also produced singly at hadron colliders through  $g + q \rightarrow LQ + \ell$  [16], which allows extending to higher masses the collider reach in the leptoquark search [17], depending on the leptoquark Yukawa coupling.

The LHC, Tevatron and LEP experiments search for pair production of the leptoquark states, which arises from the leptoquark gauge interaction. The searches are carried on in signatures including high  $P_T$  leptons,  $E_T$  jets and large missing transverse energy, due to the typical decay of the leptoquark. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 1. Since all of the leptoquark states belong to color-triplet representation, the scalar leptoquark pair-production cross section at the Tevatron and LHC can be determined solely as a function of the leptoquark mass without making further assumptions. This is in contrast to the indirect or single-production limits, which give constraints in the leptoquark mass-coupling plane. For the first- and second-generation scalar leptoquark states with decaying branching fraction  $\beta = B(eq) = 1$  and  $\beta = B(\mu q) = 1$ , the CDF and DØ experiments obtain the lower bounds on the leptoquark mass  $> 236 \text{ GeV}$  (first generation, CDF) [18],  $> 299 \text{ GeV}$  (first generation, DØ) [19],  $> 226 \text{ GeV}$  (second generation, CDF) [20], and  $> 316 \text{ GeV}$  (second generation, DØ) [21] at 95% CL. Third generation leptoquark mass bounds come from the DØ experiment [22] which sets a limit at  $247 \text{ GeV}$  for a charge  $-1/3$  third generation scalar leptoquark, at 95% C.L.

## New Heavy Bosons

Recent results from the LHC proton-proton collider, running at a center of mass energy of 7 and 8 TeV, extend previous Tevatron mass limits for scalar leptoquarks to  $> 830$  GeV (first generation, CMS,  $\beta = 1$ ,  $\sqrt{s} = 7$  TeV) and  $> 640$  GeV (first generation, CMS,  $\beta = 0.5$ ,  $\sqrt{s} = 7$  TeV) [23];  $> 1050$  GeV (first generation, ATLAS,  $\beta = 1$ ,  $\sqrt{s} = 8$  TeV) and  $> 900$  GeV (first generation, ATLAS,  $\beta = 0.5$ ,  $\sqrt{s} = 8$  TeV) [24];  $> 1070$  GeV (second generation, CMS,  $\beta = 1$ ,  $\sqrt{s} = 7$  TeV) [25] and  $> 785$  GeV (second generation, CMS,  $\beta = 0.5$ ,  $\sqrt{s} = 7$  TeV) [25]; and  $> 1000$  GeV (second generation, ATLAS,  $\beta = 1$ ,  $\sqrt{s} = 8$  TeV) and  $> 850$  GeV (second generation, ATLAS,  $\beta = 0.5$ ,  $\sqrt{s} = 8$  TeV) [24]. All limits at 95% C.L.

As for third generation leptoquarks, CMS results are the following: 1) assuming that all leptoquarks decay to a top quark and a  $\tau$  lepton, the existence of pair produced, third-generation leptoquarks up to a mass of 685 GeV ( $\beta = 1$ ) is excluded at 95% confidence level [26]; 2) assuming that all leptoquarks decay to a bottom quark and a  $\tau$  lepton, the existence of pair produced, third-generation leptoquarks up to a mass of 740 GeV ( $\beta = 1$ ) is excluded at 95% confidence level [27]; 3) assuming that all leptoquarks decay to a bottom quark and a  $\tau$  neutrino, the existence of pair produced, third-generation leptoquarks up to a mass of 450 GeV ( $\beta = 0.5$ ) is excluded at 95% confidence level [28].

The ATLAS collaboration has a limit on third generation scalar leptoquark for the case of  $\beta = 1$  of 525 GeV [29] and 625 GeV for third-generation leptoquarks in the bottom  $\tau$  neutrino channel, and 640 GeV in the top  $\tau$  neutrino channel [24].

The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are not determined even if we fix its gauge quantum numbers as listed in the Table [30]. The production of vector leptoquarks depends in general on additional assumptions that the leptoquark couplings and their pair-production cross sections are enhanced relative to the scalar leptoquark contributions. At the Tevatron for instance, since the acceptance for vector and scalar leptoquark detection is similar, limits on the vector leptoquark mass will be more stringent (see for example [36,19]). The leptoquark pair-production cross sections in  $e^+e^-$  collisions depend on the leptoquark  $SU(2) \times U(1)$  quantum numbers and Yukawa coupling with electron [31]. The OPAL experiment sets mass bounds on various leptoquark states from the pair-production cross sections [32]. For a second-generation weak-isosinglet weak-hypercharge  $-4/3$  scalar-leptoquark state, for example, the OPAL pair-production bound is  $M_{LQ} > 100$  GeV/ $c^2$  at 95% C.L. The LEP experiments also searched for the single production of the leptoquark states from the process  $e\gamma \rightarrow LQ + q$ .

The most stringent searches for the leptoquark single production are performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the leptoquark mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling  $\lambda = 0.1$ , the ZEUS bounds on the first-generation

leptoquarks range from 248 to 290 GeV, depending on the leptoquark species [33]. Recently the H1 Collaboration released a comprehensive summary of searches for first generation leptoquarks using the full data sample collected in  $ep$  collisions at HERA (446 pb $^{-1}$ ). No evidence of production of leptoquarks is observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength  $\lambda = 0.3$ , first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [35]

The search for LQ will be continued with more LHC data. Early feasibility studies by the LHC experiments ATLAS [37] and CMS [38] indicate that clear signals can be established for masses up to about  $M(LQ)$  1.3 to 1.4 TeV for first- and second-generation scalar LQ, with a likely final reach 1.5 TeV, for collisions at 14 TeV in the center of mass.

5 KHACHATRYAN 15AJ search for scalar leptoquarks using  $\tau\tau tt$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\tau\tau) = 1$ .

6 KHACHATRYAN 14T search for scalar leptoquarks decaying to  $\tau b$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\tau b) = 1$ . See their Fig. 5 for exclusion limit as function of  $B(\tau b)$ .

7 AAD 13AE search for scalar leptoquarks using  $\tau\tau bb$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\tau b) = 1$ .

8 CHATRCHYAN 12AG search for scalar leptoquarks using  $eejj$  and  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$ , the limit becomes 640 GeV.

9 CHATRCHYAN 12AG search for scalar leptoquarks using  $\mu\mu jj$  and  $\mu\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 650 GeV.

10 CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to  $\tau b$  in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above is for scalar leptoquarks with  $B(\tau b) = 1$ .

11 AAD 12H search for scalar leptoquarks using  $eejj$  and  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$ , the limit becomes 607 GeV.

12 AAD 12O search for scalar leptoquarks using  $\mu\mu jj$  and  $\mu\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 594 GeV.

13 CHATRCHYAN 12BO search for scalar leptoquarks decaying to  $\nu b$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. The limit above assumes  $B(\nu b) = 1$ .

14 AAD 11D search for scalar leptoquarks using  $eejj$  and  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$ , the limit becomes 319 GeV.

15 AAD 11D search for scalar leptoquarks using  $\mu\mu jj$  and  $\mu\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 362 GeV.

16 ABAZOV 11V search for scalar leptoquarks using  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 0.5$ .

17 CHATRCHYAN 11N search for scalar leptoquarks using  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 0.5$ .

18 KHACHATRYAN 11D search for scalar leptoquarks using  $eejj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ .

19 KHACHATRYAN 11E search for scalar leptoquarks using  $\mu\mu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ .

20 ABAZOV 10L search for pair productions of scalar leptoquark state decaying to  $\nu b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu b) = 1$ .

21 ABAZOV 09 search for scalar leptoquarks using  $\mu\mu jj$  and  $\mu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 270 GeV.

22 ABAZOV 09AF search for scalar leptoquarks using  $eejj$  and  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  the bound becomes 284 GeV.

23 AALTONEN 08P search for vector leptoquarks using  $\tau^+ b \bar{b}$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is  $>317$  GeV (251 GeV) at 95% CL for  $B(\tau b) = 1$ .

24 Search for pair production of scalar leptoquark state decaying to  $\tau b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\tau b) = 1$ .

25 Search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu q) = 1$ .

26 ABAZOV 07J search for pair productions of scalar leptoquark state decaying to  $\nu b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu b) = 1$ .

27 ABAZOV 06A search for scalar leptoquarks using  $\mu\mu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and 1.96 TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 204 GeV.

28 ABAZOV 06L search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and at 1.96 TeV. The limit above assumes  $B(\nu q) = 1$ .

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

- <sup>29</sup> ABULENCIA 06T search for scalar leptoquarks using  $\mu\mu jj$ ,  $\nu\nu jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted limit assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$  or  $0.1$ , the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of  $B(\mu q)$ .
- <sup>30</sup> ABAZOV 05H search for scalar leptoquarks using  $eejj$  and  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and 1.96 TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  the bound becomes 234 GeV.
- <sup>31</sup> ACOSTA 05P search for scalar leptoquarks using  $eejj$ ,  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and  $0.1$ , the bound becomes 205 GeV and 145 GeV, respectively.
- <sup>32</sup> ABBIENDI 03R search for scalar/vector leptoquarks in  $e^+e^-$  collisions at  $\sqrt{s} = 189$ –209 GeV. The quoted limits are for charge  $-4/3$  isospin 0 scalar-leptoquark with  $B(\ell q) = 1$ . See their table 12 for other cases.
- <sup>33</sup> ABAZOV 02 search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.
- <sup>34</sup> ABAZOV 01D search for scalar leptoquarks using  $e\nu jj$ ,  $eejj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and  $0$ , the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.
- <sup>35</sup> ABBIENDI 00M search for scalar/vector leptoquarks in  $e^+e^-$  collisions at  $\sqrt{s} = 183$  GeV. The quoted limits are for charge  $-4/3$  isospin 0 scalar-leptoquarks with  $B(\ell q) = 1$ . See their Table 8 and Figs. 6–9 for other cases.
- <sup>36</sup> ABBOTT 00C search for scalar leptoquarks using  $\mu\mu jj$ ,  $\nu\nu jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$  and  $0$ , the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.
- <sup>37</sup> AFFOLDER 00K search for scalar leptoquark using  $\nu\nu cc$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit assumes  $B(\nu c) = 1$ . Bounds for vector leptoquarks are also given.
- <sup>38</sup> AFFOLDER 00K search for scalar leptoquark using  $\nu\nu bb$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit assumes  $B(\nu b) = 1$ . Bounds for vector leptoquarks are also given.
- <sup>39</sup> ABBOTT 99J search for leptoquarks using  $\mu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for a scalar leptoquark with  $B(\mu q) = B(\nu q) = 0.5$ . Limits on vector leptoquarks range from 240 to 290 GeV.
- <sup>40</sup> ABBOTT 98E search for scalar leptoquarks using  $e\nu jj$ ,  $eejj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and  $0$ , the bound becomes 204 and 79 GeV, respectively.
- <sup>41</sup> ABBOTT 98J search for charge  $-1/3$  third generation scalar and vector leptoquarks in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for scalar leptoquark with  $B(\nu b) = 1$ .
- <sup>42</sup> ABE 98S search for scalar leptoquarks using  $\mu\mu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit is for  $B(\mu q) = 1$ . For  $B(\mu q) = B(\nu q) = 0.5$ , the limit is  $> 160$  GeV.
- <sup>43</sup> GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97X and ABBOTT 98E.
- <sup>44</sup> ABE 97F search for third generation scalar and vector leptoquarks in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for scalar leptoquark with  $B(\tau b) = 1$ .
- <sup>45</sup> ABE 97X search for scalar leptoquarks using  $eejj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit is for  $B(eq) = 1$ .
- <sup>46</sup> Limit is for charge  $-1/3$  isospin-0 leptoquark with  $B(\ell q) = 2/3$ .
- <sup>47</sup> First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.
- <sup>48</sup> Limits are for charge  $-1/3$ , isospin-0 scalar leptoquarks decaying to  $\ell^- q$  or  $\nu q$  with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.
- <sup>49</sup> KIM 90 assume pair production of charge  $2/3$  scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of  $d e^+$  and  $u \bar{\nu}$  ( $s \mu^+$  and  $c \tau$ ). See paper for limits for specific branching ratios.
- <sup>50</sup> BARTEL 87B limit is valid when a pair of charge  $2/3$  spinless leptoquarks  $X$  is produced with point coupling, and when they decay under the constraint  $B(X \rightarrow c \bar{\nu}_\mu) + B(X \rightarrow s \mu^+) = 1$ .
- <sup>51</sup> BEHREND 86B assumed that a charge  $2/3$  spinless leptoquark,  $\chi$ , decays either into  $s \mu^+$  or  $c \tau$ .  $B(X \rightarrow s \mu^+) + B(X \rightarrow c \tau) = 1$ .

### MASS LIMITS for Leptoquarks from Single Production

These limits depend on the  $q$ - $\ell$ -leptoquark coupling  $g_{LQ}$ . It is often assumed that  $g_{LQ}^2/4\pi = 1/137$ . Limits shown are for a scalar, weak isoscalar, charge  $-1/3$  leptoquark.

- <sup>1</sup> ABRAWOWICZ 12A limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e\bar{\nu}$ . See their Figs. 12–17 and Table 4 for states with different quantum numbers.
- <sup>2</sup> Limit from single production in  $Z$  decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes  $B(\ell q) = 2/3$ . The limit is 77 GeV if first and second leptoquarks are degenerate.
- <sup>3</sup> AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2–3 and Tables 1–4 for detailed limits.
- <sup>4</sup> The quoted limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e\bar{\nu}$ . See their Figs. 3–5 for limits on states with different quantum numbers.
- <sup>5</sup> ABAZOV 07E search for leptoquark single production through  $q\bar{q}$  fusion process in  $p\bar{p}$  collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.
- <sup>6</sup> AKTAS 05B limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e\bar{\nu}$ . See their Fig. 3 for limits on states with different quantum numbers.
- <sup>7</sup> CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–10 and Tables 1–8 for detailed limits.
- <sup>8</sup> CHEKANOV 03B limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e\bar{\nu}$ . See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.
- <sup>9</sup> For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.
- <sup>10</sup> CHEKANOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits.
- <sup>11</sup> For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.
- <sup>12</sup> See their Fig. 14 for limits in the mass-coupling plane.
- <sup>13</sup> BREITWEG 00E search for  $F=0$  leptoquarks in  $e^+p$  collisions. For limits in mass-coupling plane, see their Fig. 11.
- <sup>14</sup> ABREU 99G limit obtained from process  $e\gamma \rightarrow LQ + q$ . For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.
- <sup>15</sup> For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.
- <sup>16</sup> DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.
- <sup>17</sup> DERRICK 93 search for single leptoquark production in  $e p$  collisions with the decay  $e q$  and  $\nu q$ . The limit is for leptoquark coupling of electromagnetic strength and assumes  $B(e q) = B(\nu q) = 1/2$ . The limit for  $B(e q) = 1$  is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

## New Heavy Bosons

- 4 KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from  $b \rightarrow s \ell^+ \ell^-$  decays.
- 5 AARON 11c limit is for weak isotriplet spin-0 leptoquark at strong coupling  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of  $e q$  contact interactions.
- 6 DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from  $K, B, \tau$  decays, meson mixings,  $LFV$ ,  $g-2$  and  $Z \rightarrow b\bar{b}$ .
- 7 AKTAS 07a search for lepton-flavor violation in  $ep$  collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.
- 8 SCHAE 07a limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.
- 9 SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from  $K \rightarrow e\mu, B \rightarrow e\tau$  decays.
- 10 CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.
- 11 ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on  $e^\pm q$  contact interactions.
- 12 The bound is derived from  $B(B^0 \rightarrow e^\pm \mu^\mp) < 1.7 \times 10^{-7}$ .
- 13 CHEKANOV 02 search for lepton-flavor violation in  $ep$  collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.
- 14 CHEUNG 01b quoted limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.
- 15 ACCIARRI 00p limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.
- 16 ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling,  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 2.
- 17 ADLOFF 00 limits are from the  $Q^2$  spectrum measurement of  $e^+p \rightarrow e^+X$ .
- 18 BARATE 00i search for deviations in cross section and jet-charge asymmetry in  $e^+e^- \rightarrow q\bar{q}$  due to  $t$ -channel exchange of a leptoquark at  $\sqrt{s}=130$  to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.
- 19 BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.
- 20 GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.
- 21 ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.
- 22 ABBENDI 99 limits are from  $e^+e^- \rightarrow q\bar{q}$  cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.
- 23 ABE 98v quoted limit is from  $B(B_s \rightarrow e^\pm \mu^\mp) < 8.2 \times 10^{-6}$ . ABE 98v also obtain a similar limit on  $M_{LQ} > 20.4$  TeV from  $B(B_d \rightarrow e^\pm \mu^\mp) < 4.5 \times 10^{-6}$ . Both bounds assume the non-canonical association of the  $b$  quark with electrons or muons under SU(4).
- 24 ACCIARRI 98j limit is from  $e^+e^- \rightarrow q\bar{q}$  cross section at  $\sqrt{s}=130$ –172 GeV which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.
- 25 ACKERSTAFF 98v limits are from  $e^+e^- \rightarrow q\bar{q}$  and  $e^+e^- \rightarrow b\bar{b}$  cross sections at  $\sqrt{s}=130$ –172 GeV, which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.
- 26 DEANDREA 97 limit is for  $R_2$  leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.
- 27 DERRICK 97 search for lepton-flavor violation in  $ep$  collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.
- 28 GROSSMAN 97 estimate the upper bounds on the branching fraction  $B \rightarrow \tau^+ \tau^- (X)$  from the absence of the  $B$  decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.
- 29 JADACH 97 limit is from  $e^+e^- \rightarrow q\bar{q}$  cross section at  $\sqrt{s}=172.3$  GeV which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.
- 30 KUZNETSOV 95b use  $\pi, K, B, \tau$  decays and  $\mu e$  conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from  $K_L \rightarrow \mu e$  decay assuming zero mixing.
- 31 MIZUKOSHI 95 calculate the one-loop radiative correction to the Z-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.
- 32 BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the  $Z$ .  $m_H=250$  GeV,  $\alpha_s(m_Z)=0.12$ ,  $m_t=180$  GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to  $\bar{e}_L t_R, \bar{\nu}_L \tau_R$ , and  $\bar{\tau}_L$ , see Fig. 2 in BHATTACHARYYA 94b erratum and Fig. 3.
- 33 DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from  $\pi, K, D, B, \mu, \tau$  decays and meson mixings, etc. See Table 15 of DAVIDSON 94 for detail.
- 34 KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on  $\pi^0 \rightarrow \nu\nu$ .
- 35 LEURER 94, LEURER 94b limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in  $\pi_{e2}$  decay provides a much more stringent bound.
- 36 MAHANTA 94 gives bounds of  $P$ - and  $T$ -violating scalar-leptoquark couplings from atomic and molecular experiments.
- 37 From  $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$  ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling  $4g^2/M^2 (\bar{\nu}_L e_L u_R) (\bar{d}_L e_R)$  with  $g=0.004$  for spin-0 leptoquark and  $g^2/M^2 (\bar{\nu}_L \gamma_\mu u_L) (\bar{d}_R \gamma^\mu e_R)$  with  $g \approx 0.6$  for spin-1 leptoquark.

- <sup>1</sup> KHACHATRYAN 15v search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- <sup>2</sup> KHACHATRYAN 16e search for KK gluon decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- <sup>3</sup> KHACHATRYAN 15av search for pair productions of neutral color-octet weak-triplet scalar particles ( $\theta^0$ ), decaying to  $b\bar{b}, Z g$  or  $\gamma g$ , in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The  $\theta^0$  particle is often predicted in coloron ( $G'$ , color-octet gauge boson) models and appear in the  $pp$  collisions through  $G' \rightarrow \theta^0 \theta^0$  decays. Assuming  $B(\theta^0 \rightarrow b\bar{b}) = 0.5$ , they give limits  $m_{\theta^0} > 623$  GeV (426 GeV) for  $m_{G'} = 2.3 m_{\theta^0}$  ( $m_{G'} = 5 m_{\theta^0}$ ).
- <sup>4</sup> AALTONEN 13r search for new resonance decaying to  $\sigma\sigma$ , with hypothetical strongly interacting  $\sigma$  particle subsequently decaying to 2 jets, in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV, using data corresponding to an integrated luminosity of  $6.6 \text{ fb}^{-1}$ . For  $50 \text{ GeV} < m_\sigma < m_{g_A}/2$ , axigluons in mass range 150–400 GeV are excluded.
- <sup>5</sup> CHATRCHYAN 13A search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- <sup>6</sup> CHATRCHYAN 13As search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- <sup>7</sup> CHATRCHYAN 13Au search for the pair produced color-octet vector bosons decaying to  $q\bar{q}$  pairs in  $pp$  collisions. The quoted limit is for  $B(g_A \rightarrow q\bar{q}) = 1$ .
- <sup>8</sup> ABZOV 12r search for massive color octet vector particle decaying to  $t\bar{t}$ . The quoted limit assumes  $g_A$  couplings with light quarks are suppressed by 0.2.
- <sup>9</sup> CHATRCHYAN 11v search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- <sup>10</sup> AALTONEN 10L search for massive color octet non-chiral vector particle decaying into  $t\bar{t}$  pair with mass in the range  $400 \text{ GeV} < M < 800 \text{ GeV}$ . See their Fig. 6 for limit in the mass-coupling plane.
- <sup>11</sup> KHACHATRYAN 10 search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- <sup>12</sup> AALTONEN 09ac search for new narrow resonance decaying to dijets.
- <sup>13</sup> CHOUDHURY 07 limit is from the  $t\bar{t}$  production cross section measured at CDF.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

<sup>14</sup> DONCHESKI 98 compare  $\alpha_s$  derived from low-energy data and that from  $\Gamma(Z \rightarrow \text{hadrons})/\Gamma(Z \rightarrow \text{leptons})$ .  
<sup>15</sup> ABE 97G search for new particle decaying to dijets.  
<sup>16</sup> ABE 95N assume axiguons decaying to quarks in the Standard Model only.  
<sup>17</sup> ABE 93G assume  $\Gamma(g_A) = N\alpha_s m_{g_A}/6$  with  $N = 10$ .  
<sup>18</sup> CUYPERS 91 compare  $\alpha_s$  measured in  $\Upsilon$  decay and that from  $R$  at PEP/PETRA energies.  
<sup>19</sup> ABE 90H assumes  $\Gamma(g_A) = N\alpha_s m_{g_A}/6$  with  $N = 5$  ( $\Gamma(g_A) = 0.09 m_{g_A}$ ). For  $N = 10$ , the excluded region is reduced to 120–150 GeV.  
<sup>20</sup> ROBINETT 89 result demands partial-wave unitarity of  $J = 0$   $t\bar{t} \rightarrow t\bar{t}$  scattering amplitude and derives a limit  $m_{g_A} > 0.5 m_t$ . Assumes  $m_t > 56$  GeV.  
<sup>21</sup> ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution.  $\Gamma(g_A) < 0.4 m_{g_A}$  assumed. See also BAGGER 88.  
<sup>22</sup> CUYPERS 88 requires  $\Gamma(\Upsilon \rightarrow g g_A) < \Gamma(\Upsilon \rightarrow g g g)$ . A similar result is obtained by DONCHESKI 88.  
<sup>23</sup> DONCHESKI 88B requires  $\Gamma(\Upsilon \rightarrow g q \bar{q})/\Gamma(\Upsilon \rightarrow g g g) < 0.25$ , where the former decay proceeds via axiguon exchange. A more conservative estimate of  $< 0.5$  leads to  $m_{g_A} > 21$  GeV.

### MASS LIMITS for Color-Octet Scalar Bosons

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 150–287	95	<sup>1</sup> KHACHATRYAN...15AV CMS <sup>2</sup> AAD 13K ATLS	$pp \rightarrow \Theta^0 \Theta^0 \rightarrow b\bar{b} Z g$ $pp \rightarrow S_8 S_8 X, S_8 \rightarrow 2$ jets	
<sup>1</sup> KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles ( $\Theta^0$ ), decaying to $b\bar{b}$ , $Z g$ or $\gamma g$ , in $pp$ collisions at $\sqrt{s} = 8$ TeV. The $\Theta^0$ particle is often predicted in coloron ( $G'$ , color-octet gauge boson) models and appear in the $pp$ collisions through $G' \rightarrow \Theta^0 \Theta^0$ decays. Assuming $B(\Theta^0 \rightarrow b\bar{b}) = 0.5$ , they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3 m_{\Theta^0}$ ( $m_{G'} = 5 m_{\Theta^0}$ ). <sup>2</sup> AAD 13K search for pair production of color-octet scalar particles in $pp$ collisions at $\sqrt{s} = 7$ TeV. Cross section limits are interpreted as mass limits on scalar partners of a Dirac gluino.				

### X<sup>0</sup> (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state  $X^0$  decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

<sup>1</sup> BARATE 98U obtain limits on  $B(Z \rightarrow \gamma X^0)B(X^0 \rightarrow \ell\bar{\ell}, q\bar{q}, g g, \gamma\gamma, \nu\bar{\nu})$ . See their Fig. 17.  
<sup>2</sup> See Fig. 4 of ACCIARRI 97Q for the upper limit on  $B(Z \rightarrow \gamma X^0; E_{\gamma} > E_{\min})$  as a function of  $E_{\min}$ .  
<sup>3</sup> ACTON 93E give  $\sigma(e^+ e^- \rightarrow X^0 \gamma) \cdot B(X^0 \rightarrow \gamma\gamma) < 0.4$  pb (95%CL) for  $m_{X^0} = 60 \pm 2.5$  GeV. If the process occurs via s-channel  $\gamma$  exchange, the limit translates to  $\Gamma(X^0) \cdot B(X^0 \rightarrow \gamma\gamma)^2 < 20$  MeV for  $m_{X^0} = 60 \pm 1$  GeV.  
<sup>4</sup> ABREU 92D give  $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (3\text{--}10)$  pb for  $m_{X^0} = 10\text{--}78$  GeV. A very similar limit is obtained for spin-1  $X^0$ .  
<sup>5</sup> ADRIANI 92F search for isolated  $\gamma$  in hadronic Z decays. The limit  $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (2\text{--}10)$  pb (95%CL) is given for  $m_{X^0} = 25\text{--}85$  GeV.  
<sup>6</sup> ACTON 91 searches for  $Z \rightarrow Z^* X^0$ ,  $Z^* \rightarrow e^+ e^-, \mu^+ \mu^-, \text{ or } \nu\bar{\nu}$ . Excludes any new scalar  $X^0$  with  $m_{X^0} < 9.5$  GeV/c if it has the same coupling to  $ZZ^*$  as the MSM Higgs boson.  
<sup>7</sup> ACTON 91B limits are for  $m_{X^0} = 60\text{--}85$  GeV.  
<sup>8</sup> ADEVA 91D limits are for  $m_{X^0} = 30\text{--}89$  GeV.  
<sup>9</sup> ADEVA 91D limits are for  $m_{X^0} = 30\text{--}86$  GeV.  
<sup>10</sup> AKRAWY 90J give  $\Gamma(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < 1.9$  MeV (95%CL) for  $m_{X^0} = 32\text{--}80$  GeV. We divide by  $\Gamma(Z) = 2.5$  GeV to get product of branching ratios. For nonresonant transitions, the limit is  $B(Z \rightarrow \gamma q \bar{q}) < 8.2$  MeV assuming three-body phase space distribution.

### MASS LIMITS for a Heavy Neutral Boson Coupling to $e^+ e^-$

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				

none 55–61		<sup>1</sup> ODAKA 89	VNS	$\Gamma(X^0 \rightarrow e^+ e^-) \cdot B(X^0 \rightarrow \text{had.}) \gtrsim 0.2$ MeV
$>45$	95	<sup>2</sup> DERRICK 86	HRS	$\Gamma(X^0 \rightarrow e^+ e^-) = 6$ MeV
$>46.6$	95	<sup>3</sup> ADEVA 85	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 10$ keV
$>48$	95	<sup>3</sup> ADEVA 85	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 4$ MeV
		<sup>4</sup> BERGER 85B	PLUT	
none 39.8–45.5		<sup>5</sup> ADEVA 84	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 10$ keV
$>47.8$	95	<sup>5</sup> ADEVA 84	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 4$ MeV
none 39.8–45.2		<sup>5</sup> BEHREND 84C	CELL	
$>47$	95	<sup>5</sup> BEHREND 84C	CELL	$\Gamma(X^0 \rightarrow e^+ e^-) = 4$ MeV

<sup>1</sup> ODAKA 89 looked for a narrow or wide scalar resonance in  $e^+ e^- \rightarrow \text{hadrons}$  at  $E_{\text{cm}} = 55.0\text{--}60.8$  GeV.  
<sup>2</sup> DERRICK 86 found no deviation from the Standard Model Bhabha scattering at  $E_{\text{cm}} = 29$  GeV and set limits on the possible scalar boson  $e^+ e^-$  coupling. See their figure 4 for excluded region in the  $\Gamma(X^0 \rightarrow e^+ e^-) - m_{X^0}$  plane. Electronic chiral invariance requires a parity doublet of  $X^0$ , in which case the limit applies for  $\Gamma(X^0 \rightarrow e^+ e^-) = 3$  MeV.  
<sup>3</sup> ADEVA 85 first limit is from  $2\gamma, \mu^+ \mu^-, \text{ hadrons}$  assuming  $X^0$  is a scalar. Second limit is from  $e^+ e^-$  channel.  $E_{\text{cm}} = 40\text{--}47$  GeV. Supersedes ADEVA 84.  
<sup>4</sup> BERGER 85B looked for effect of spin-0 boson exchange in  $e^+ e^- \rightarrow e^+ e^-$  and  $\mu^+ \mu^-$  at  $E_{\text{cm}} = 34.7$  GeV. See Fig. 5 for excluded region in the  $m_{X^0} - \Gamma(X^0)$  plane.  
<sup>5</sup> ADEVA 84 and BEHREND 84C have  $E_{\text{cm}} = 39.8\text{--}45.5$  GeV. MARK-J searched  $X^0$  in  $e^+ e^- \rightarrow \text{hadrons}$ ,  $2\gamma, \mu^+ \mu^-, e^+ e^-$  and CELLO in the same channels plus  $\tau$  pair. No narrow or broad  $X^0$  is found in the energy range. They also searched for the effect of  $X^0$  with  $m_X > E_{\text{cm}}$ . The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for  $\Gamma(X^0 \rightarrow e^+ e^-) = 2$  MeV if  $X^0$  is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

### Search for X<sup>0</sup> Resonance in $e^+ e^-$ Collisions

The limit is for  $\Gamma(X^0 \rightarrow e^+ e^-) \cdot B(X^0 \rightarrow f)$ , where  $f$  is the specified final state. Spin 0 is assumed for  $X^0$ .

VALUE (keV)	CL%	DOCUMENT ID	TECN	COMMENT

• • • We do not use the following data for averages, fits, limits, etc. • • •			
	<sup>1</sup> ABBIENDI 03D	OPAL	$X^0 \rightarrow \gamma\gamma$
	<sup>2</sup> ABREU 00Z	DLPH	$X^0$ decaying invisibly
	<sup>3</sup> ADAM 96C	DLPH	$X^0$ decaying invisibly

<sup>1</sup> ABBIENDI 03D measure the  $e^+ e^- \rightarrow \gamma\gamma\gamma$  cross section at  $\sqrt{s} = 181\text{--}209$  GeV. The upper bound on the production cross section,  $\sigma(e^+ e^- \rightarrow X^0 \gamma)$  times the branching ratio for  $X^0 \rightarrow \gamma\gamma$ , is less than 0.03 pb at 95%CL for  $X^0$  masses between 20 and 180 GeV. See their Fig. 9b for the limits in the mass-cross section plane.  
<sup>2</sup> ABREU 00Z is from the single photon cross section at  $\sqrt{s} = 183, 189$  GeV. The production cross section upper limit is less than 0.3 pb for  $X^0$  mass between 40 and 160 GeV. See their Fig. 4 for the limit in mass-cross section plane.  
<sup>3</sup> ADAM 96C is from the single photon production cross at  $\sqrt{s} = 130, 136$  GeV. The upper bound is less than 3 pb for  $X^0$  masses between 60 and 130 GeV. See their Fig. 5 for the exact bound on the cross section  $\sigma(e^+ e^- \rightarrow \gamma X^0)$ .

### Search for X<sup>0</sup> Resonance in $Z \rightarrow f \bar{f} X^0$

The limit is for  $B(Z \rightarrow f \bar{f} X^0) \cdot B(X^0 \rightarrow F)$  where  $f$  is a fermion and  $F$  is the specified final state. Spin 0 is assumed for  $X^0$ .

## Axions ( $A^0$ ) and Other Very Light Bosons, Searches for

### AXIONS AND OTHER SIMILAR PARTICLES

Revised January 2016 by A. Ringwald (DESY), L.J. Rosenberg and G. Rybka (U. of Washington).

#### Introduction

In this section, we list coupling-strength and mass limits for light neutral scalar or pseudoscalar bosons that couple weakly to normal matter and radiation. Such bosons may arise from a global spontaneously broken  $U(1)$  symmetry, resulting in a massless Nambu-Goldstone (NG) boson. If there is a small explicit symmetry breaking, either already in the Lagrangian or due to quantum effects such as anomalies, the boson acquires a mass and is called a pseudo-NG boson. Typical examples are axions ( $A^0$ ) [1,2], familons [3] and Majorons [4], associated, respectively, with a spontaneously broken Peccei-Quinn, family and lepton-number symmetry.

A common characteristic among these light bosons  $\phi$  is that their coupling to Standard-Model particles is suppressed by the energy scale that characterizes the symmetry breaking, *i.e.*, the decay constant  $f$ . The interaction Lagrangian is

$$\mathcal{L} = f^{-1} J^\mu \partial_\mu \phi, \quad (1)$$

where  $J^\mu$  is the Noether current of the spontaneously broken global symmetry. If  $f$  is very large, these new particles interact very weakly. Detecting them would provide a window to physics far beyond what can be probed at accelerators.

Axions are of particular interest because the Peccei-Quinn (PQ) mechanism remains perhaps the most credible scheme to preserve CP in QCD. Moreover, the cold dark matter of the universe may well consist of axions and they are searched for in dedicated experiments with a realistic chance of discovery.

Originally it was assumed that the PQ scale  $f_A$  was related to the electroweak symmetry-breaking scale  $v_{\text{weak}} =$

See key on page 601

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

$(\sqrt{2}G_F)^{-1/2} = 247$  GeV. However, the associated “standard” and “variant” axions were quickly excluded—we refer to the Listings for detailed limits. Here we focus on “invisible axions” with  $f_A \gg v_{\text{weak}}$  as the main possibility.

Axions have a characteristic two-photon vertex, inherited from their mixing with  $\pi^0$  and  $\eta$ . This coupling allows for the main search strategy based on axion-photon conversion in external magnetic fields [5], an effect that also can be of astrophysical interest. While for axions the product “ $A\gamma\gamma$  interaction strength  $\times$  mass” is essentially fixed by the corresponding  $\pi^0$  properties, one may consider a more general class of axion-like particles (ALPs) where the two parameters (coupling and mass) are independent. A number of experiments explore this more general parameter space. ALPs populating the latter are predicted to arise generically, in addition to the axion, in low-energy effective field theories emerging from string theory [6]. The latter often contain also very light Abelian vector bosons under which the Standard-Model particles are not charged: so-called hidden-sector photons, dark photons or paraphotons. They share a number of phenomenological features with the axion and ALPs, notably the possibility of hidden photon to photon conversion. Their physics cases and the current constraints are compiled in Ref. [7].

### I. THEORY

#### I.1 Peccei-Quinn mechanism and axions

The QCD Lagrangian includes a CP-violating term  $\mathcal{L}_\Theta = -\bar{\Theta}(\alpha_s/8\pi)G^{\mu\nu a}\tilde{G}_{\mu\nu}^a$ , where  $-\pi \leq \bar{\Theta} \leq +\pi$  is the effective  $\bar{\Theta}$  parameter after diagonalizing quark masses,  $G_{\mu\nu}^a$  is the color field strength tensor, and  $\tilde{G}^{a,\mu\nu} \equiv \epsilon^{\mu\nu\lambda\rho}G_{\lambda\rho}^a/2$ , with  $\epsilon^{0123} = 1$ , its dual. Limits on the neutron electric dipole moment [8] imply  $|\bar{\Theta}| \lesssim 10^{-10}$  even though  $\bar{\Theta} = \mathcal{O}(1)$  is otherwise completely satisfactory. The spontaneously broken global Peccei-Quinn symmetry  $U(1)_{\text{PQ}}$  was introduced to solve this “strong CP problem” [1], the axion being the pseudo-NG boson of  $U(1)_{\text{PQ}}$  [2]. This symmetry is broken due to the axion’s anomalous triangle coupling to gluons,

$$\mathcal{L} = \left( \frac{\phi_A}{f_A} - \bar{\Theta} \right) \frac{\alpha_s}{8\pi} G^{\mu\nu a} \tilde{G}_{\mu\nu}^a, \quad (2)$$

where  $\phi_A$  is the axion field and  $f_A$  the axion decay constant. Color anomaly factors have been absorbed in the normalization of  $f_A$  which is defined by this Lagrangian. Thus normalized,  $f_A$  is the quantity that enters all low-energy phenomena [9]. Non-perturbative topological fluctuations of the gluon fields in QCD induce a potential for  $\phi_A$  whose minimum is at  $\phi_A = \bar{\Theta} f_A$ , thereby canceling the  $\bar{\Theta}$  term in the QCD Lagrangian and thus restoring CP symmetry.

The resulting axion mass, in units of the PQ scale  $f_A$ , is identical to the square root of the topological susceptibility in QCD,  $m_A f_A = \sqrt{\chi}$ . The latter can be evaluated further [10], exploiting the chiral limit (masses of up and down quarks much smaller than the scale of QCD), yielding  $m_A f_A = \sqrt{\chi} \approx f_\pi m_\pi$ ,

where  $m_\pi = 135$  MeV and  $f_\pi \approx 92$  MeV. In more detail one finds, to leading order in chiral perturbation theory,

$$m_A = \frac{z^{1/2}}{1+z} \frac{f_\pi m_\pi}{f_A} = \frac{0.60 \text{ MeV}}{f_A/10^{10} \text{ GeV}}, \quad (3)$$

where  $z = m_u/m_d$ . We have used the canonical value  $z = 0.56$  [11], although the range  $z = 0.38\text{--}0.58$  is plausible [12]. The next-to-leading order correction to the axion mass has been evaluated recently in Ref. [13].

Originally one assumed  $f_A \sim v_{\text{weak}}$  [1,2]. Tree-level flavor conservation fixes the axion properties in terms of a single parameter: the ratio of the vacuum expectation values of two Higgs fields that appear as a minimal ingredient. This “standard axion” was excluded after extensive searches [14]. A narrow peak structure observed in positron spectra from heavy ion collisions [15] suggested an axion-like particle of mass 1.8 MeV that decays into  $e^+e^-$ , but extensive follow-up searches were negative. “Variant axion models” were proposed which keep  $f_A \sim v_{\text{weak}}$  while relaxing the constraint of tree-level flavor conservation [16], but these models are also excluded [17].

However, axions with  $f_A \gg v_{\text{weak}}$  evade all current experimental limits. One generic class of models invokes “hadronic axions” where new heavy quarks carry  $U(1)_{\text{PQ}}$  charges, leaving ordinary quarks and leptons without tree-level axion couplings. The archetype is the KSVZ model [18], where in addition the heavy quarks are electrically neutral. Another generic class requires at least two Higgs doublets and ordinary quarks and leptons carry PQ charges, the archetype being the DFSZ model [19]. All of these models contain at least one electroweak singlet scalar that acquires a vacuum expectation value and thereby breaks the PQ symmetry. The KSVZ and DFSZ models are frequently used as benchmark examples, but other models exist where both heavy quarks and Higgs doublets carry PQ charges. In supersymmetric models, the axion is part of a supermultiplet and thus inevitably accompanied by a spin-0 saxion and a spin-1 axino, which both also have couplings suppressed by  $f_A$ , and are expected to have large masses due to supersymmetry breaking [20].

#### I.2 Model-dependent axion couplings

Although the generic axion interactions scale approximately with  $f_\pi/f_A$  from the corresponding  $\pi^0$  couplings, there are non-negligible model-dependent factors and uncertainties. The axion’s two-photon interaction plays a key role for many searches,

$$\mathcal{L}_{A\gamma\gamma} = -\frac{G_{A\gamma\gamma}}{4} F_{\mu\nu} \tilde{F}^{\mu\nu} \phi_A = G_{A\gamma\gamma} \mathbf{E} \cdot \mathbf{B} \phi_A, \quad (4)$$

where  $F$  is the electromagnetic field-strength tensor and  $\tilde{F}^{\mu\nu} \equiv \epsilon^{\mu\nu\lambda\rho}F_{\lambda\rho}/2$ , with  $\epsilon^{0123} = 1$ , its dual. The coupling constant is

$$\begin{aligned} G_{A\gamma\gamma} &= \frac{\alpha}{2\pi f_A} \left( \frac{E}{N} - \frac{2}{3} \frac{4+z}{1+z} \right) \\ &= \frac{\alpha}{2\pi} \left( \frac{E}{N} - \frac{2}{3} \frac{4+z}{1+z} \right) \frac{1+z}{z^{1/2}} \frac{m_A}{m_\pi f_\pi}, \end{aligned} \quad (5)$$

where  $E$  and  $N$  are the electromagnetic and color anomalies of the axial current associated with the axion. In grand unified

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

models, and notably for DFSZ [19],  $E/N = 8/3$ , whereas for KSVZ [18]  $E/N = 0$  if the electric charge of the new heavy quark is taken to vanish. In general, a broad range of  $E/N$  values is possible [21], as indicated by the yellow band in Figure 1. The two-photon decay width is

$$\Gamma_{A \rightarrow \gamma\gamma} = \frac{G_{A\gamma\gamma}^2 m_A^3}{64\pi} = 1.1 \times 10^{-24} \text{ s}^{-1} \left( \frac{m_A}{\text{eV}} \right)^5. \quad (6)$$

The second expression uses Eq. (5) with  $z = 0.56$  and  $E/N = 0$ . Axions decay faster than the age of the universe if  $m_A \gtrsim 20 \text{ eV}$ .

**Figure 1:** Exclusion plot for axion-like particles as described in the text.

The interaction with fermions  $f$  has derivative form and is invariant under a shift  $\phi_A \rightarrow \phi_A + \phi_0$  as behooves a NG boson,

$$\mathcal{L}_{Aff} = \frac{C_f}{2f_A} \bar{\Psi}_f \gamma^\mu \gamma_5 \Psi_f \partial_\mu \phi_A. \quad (7)$$

Here,  $\Psi_f$  is the fermion field,  $m_f$  its mass, and  $C_f$  a model-dependent coefficient. The dimensionless combination  $g_{Aff} \equiv C_f m_f / f_A$  plays the role of a Yukawa coupling and  $\alpha_{Aff} \equiv g_{Aff}^2 / 4\pi$  of a “fine-structure constant.” The often-used pseudoscalar form  $\mathcal{L}_{Aff} = -i(C_f m_f / f_A) \bar{\Psi}_f \gamma_5 \Psi_f \phi_A$  need not be equivalent to the appropriate derivative structure, for example when two NG bosons are attached to one fermion line as in axion emission by nucleon bremsstrahlung [22].

In the DFSZ model [19], the tree-level coupling coefficient to electrons is [23]

$$C_e = \frac{\cos^2 \beta'}{3}, \quad (8)$$

where  $\tan \beta' = v_d / v_u$  is the ratio of the vacuum expectation value  $v_d$  of the Higgs field  $H_d$  giving masses to the down-type quarks and the vacuum expectation value  $v_u$  of the Higgs field  $H_u$  giving masses to the up-type quarks. (The prime at the angle indicates that the convention in the axion literature differs from the one in the Higgs literature, which uses  $\tan \beta = v_u / v_d = \cot \beta'$  [24].)

For nucleons,  $C_{n,p}$  are related to axial-vector current matrix elements by generalized Goldberger-Treiman relations,

$$\begin{aligned} C_p &= (C_u - \eta) \Delta u + (C_d - \eta z) \Delta d + (C_s - \eta w) \Delta s, \\ C_n &= (C_u - \eta) \Delta d + (C_d - \eta z) \Delta u + (C_s - \eta w) \Delta s. \end{aligned} \quad (9)$$

Here,  $\eta = (1 + z + w)^{-1}$  with  $z = m_u / m_d$  and  $w = m_u / m_s \ll z$  and the  $\Delta q$  are given by the axial vector current matrix element  $\Delta q S_\mu = \langle p | \bar{q} \gamma_\mu \gamma_5 q | p \rangle$  with  $S_\mu$  the proton spin.

Neutron beta decay and strong isospin symmetry considerations imply  $\Delta u - \Delta d = F + D = 1.269 \pm 0.003$ , whereas hyperon decays and flavor SU(3) symmetry imply  $\Delta u + \Delta d - 2\Delta s = 3F - D = 0.586 \pm 0.031$  [25]. The strange-quark contribution is  $\Delta s = -0.08 \pm 0.01_{\text{stat}} \pm 0.05_{\text{sys}}$  from the COMPASS experiment [26], and  $\Delta s = -0.085 \pm 0.008_{\text{exp}} \pm 0.013_{\text{theor}} \pm 0.009_{\text{evol}}$  from HERMES [25], in agreement with each other and with an early estimate of  $\Delta s = -0.11 \pm 0.03$  [27]. We thus adopt  $\Delta u = 0.84 \pm 0.02$ ,  $\Delta d = -0.43 \pm 0.02$  and  $\Delta s = -0.09 \pm 0.02$ , very similar to what was used in the axion literature.

The uncertainty of the axion-nucleon couplings is dominated by the uncertainty  $z = m_u / m_d = 0.38 - 0.58$  that we mentioned earlier. For hadronic axions  $C_{u,d,s} = 0$ , so that  $-0.51 < C_p < -0.36$  and  $0.10 > C_n > -0.05$ . Therefore it is well possible that  $C_n = 0$  whereas  $C_p$  does not vanish within the plausible  $z$  range. In the DFSZ model,  $C_u = \frac{1}{3} \sin^2 \beta'$  and  $C_d = \frac{1}{3} \cos^2 \beta'$  and  $C_n$  and  $C_p$  as functions of  $\beta'$  and  $z$  do not vanish simultaneously.

The axion-pion interaction is given by the Lagrangian [28]

$$\mathcal{L}_{A\pi} = \frac{C_{A\pi}}{f_\pi f_A} (\pi^0 \pi^+ \partial_\mu \pi^- + \pi^0 \pi^- \partial_\mu \pi^+ - 2\pi^+ \pi^- \partial_\mu \pi^0) \partial_\mu \phi_A, \quad (10)$$

where  $C_{A\pi} = (1 - z) / [3(1 + z)]$  in hadronic models. The chiral symmetry-breaking Lagrangian provides an additional term  $\mathcal{L}'_{A\pi} \propto (m_\pi^2 / f_\pi f_A) (\pi^0 \pi^0 + 2\pi^- \pi^+) \pi^0 \phi_A$ . For hadronic axions it vanishes identically, in contrast to the DFSZ model (Roberto Peccei, private communication).

## II. LABORATORY SEARCHES

### II.1 Light shining through walls

Searching for “invisible axions” is extremely challenging due to its extraordinarily feeble coupling to normal matter and radiation. Currently, the most promising approaches rely on the axion-two-photon vertex, allowing for axion-photon conversion in external electric or magnetic fields [5]. For the Coulomb field of a charged particle, the conversion is best viewed as a scattering process,  $\gamma + Ze \leftrightarrow Ze + A$ , called Primakoff effect [29]. In the other extreme of a macroscopic field, usually a large-scale  $B$ -field, the momentum transfer is small, the interaction coherent over a large distance, and the conversion is best viewed as an axion-photon oscillation phenomenon in analogy to neutrino flavor oscillations [30].

Photons propagating through a transverse magnetic field, with incident  $\mathbf{E}_\gamma$  and magnet  $\mathbf{B}$  parallel, may convert into axions. For  $m_A^2 L / 2\omega \ll 2\pi$ , where  $L$  is the length of the  $B$  field region and  $\omega$  the photon energy, the resultant axion beam is coherent with the incident photon beam and the

See key on page 601

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

conversion probability is  $\Pi \sim (1/4)(G_{A\gamma\gamma}BL)^2$ . A practical realization uses a laser beam propagating down the bore of a superconducting dipole magnet (like the bending magnets in high-energy accelerators). If another magnet is in line with the first, but shielded by an optical barrier, then photons may be regenerated from the pure axion beam [31]. The overall probability is  $P(\gamma \rightarrow A \rightarrow \gamma) = \Pi^2$ .

The first such experiment utilized two magnets of length  $L = 4.4$  m and  $B = 3.7$  T and found  $|G_{A\gamma\gamma}| < 6.7 \times 10^{-7} \text{ GeV}^{-1}$  at 95% CL for  $m_A < 1$  meV [32]. More recently, several such experiments were performed (see Listings) [33,34]. The current best limit,  $|G_{A\gamma\gamma}| < 3.5 \times 10^{-8} \text{ GeV}^{-1}$  at 95% CL for  $m_A \lesssim 0.3$  meV (see Figure 1), has been achieved by the OSQAR (Optical Search for QED Vacuum Birefringence, Axions, and Photon Regeneration) experiment, which exploited two 9 T LHC dipole magnets and an 18.5 W continuous wave laser emitting at the wavelength of 532 nm [34]. Some of these experiments have also reported limits for scalar bosons where the photon  $\mathbf{E}_\gamma$  must be chosen perpendicular to the magnet  $\mathbf{B}$ .

The concept of resonantly enhanced photon regeneration may open unexplored regions of coupling strength [35]. In this scheme, both the production and detection magnets are within Fabry-Perot optical cavities and actively locked in frequency. The  $\gamma \rightarrow A \rightarrow \gamma$  rate is enhanced by a factor  $2\mathcal{F}\mathcal{F}'/\pi^2$  relative to a single-pass experiment, where  $\mathcal{F}$  and  $\mathcal{F}'$  are the finesses of the two cavities. The resonant enhancement could be of order  $10^{(10-12)}$ , improving the  $G_{A\gamma\gamma}$  sensitivity by  $10^{(2.5-3)}$ . The experiment ALPS II (Any Light Particle Search II) is based on this concept and aims at an improvement of the current laboratory bound on  $G_{A\gamma\gamma}$  by a factor  $\sim 3 \times 10^3$  in the year 2018 [36].

Resonantly enhanced photon regeneration has already been exploited in experiments searching for "radiowaves shining through a shielding" [37,38]. For  $m_A \lesssim 10^{-5}$  eV, the upper bound on  $G_{A\gamma\gamma}$  established by the CROWS (CERN Resonant Weakly Interacting sub-eV Particle Search) experiment [39] is slightly less stringent than the one set by OSQAR.

### II.2 Photon polarization

An alternative to regenerating the lost photons is to use the beam itself to detect conversion: the polarization of light propagating through a transverse  $B$  field suffers dichroism and birefringence [40]. Dichroism: The  $E_\parallel$  component, but not  $E_\perp$ , is depleted by axion production, causing a small rotation of linearly polarized light. For  $m_A^2 L/2\omega \ll 2\pi$ , the effect is independent of  $m_A$ . For heavier axions, it oscillates and diminishes as  $m_A$  increases, and it vanishes for  $m_A > \omega$ . Birefringence: This rotation occurs because there is mixing of virtual axions in the  $E_\parallel$  state, but not for  $E_\perp$ . Hence, linearly polarized light will develop elliptical polarization. Higher-order QED also induces vacuum magnetic birefringence (VMB). A search for these effects was performed in the same dipole magnets in the early experiment above [41]. The dichroic rotation gave a stronger limit than the ellipticity rotation:

$|G_{A\gamma\gamma}| < 3.6 \times 10^{-7} \text{ GeV}^{-1}$  at 95% CL for  $m_A < 5 \times 10^{-4}$  eV. The ellipticity limits are better at higher masses, as they fall off smoothly and do not terminate at  $m_A$ .

In 2006 the PVLAS collaboration reported a signature of magnetically induced vacuum dichroism that could be interpreted as the effect of a pseudoscalar with  $m_A = 1\text{--}1.5$  meV and  $|G_{A\gamma\gamma}| = (1.6\text{--}5) \times 10^{-6} \text{ GeV}^{-1}$  [42]. Since then, these findings are attributed to instrumental artifacts [43]. This particle interpretation is also excluded by the above photon regeneration searches that were inspired by the original PVLAS result. Recently, the fourth generation setup of the PVLAS experiment has published new results on searches for VMB (see Figure 1) and dichroism [44]. The bounds from the non-observation of the latter on  $G_{A\gamma\gamma}$  are slightly weaker than the ones from OSQAR.

### II.3 Long-range forces

New bosons would mediate long-range forces, which are severely constrained by "fifth force" experiments [45]. Those looking for new mass-spin couplings provide significant constraints on pseudoscalar bosons [46]. Presently, the most restrictive limits are obtained from combining long-range force measurements with stellar cooling arguments [47]. For the moment, any of these limits are far from realistic values expected for axions. Still, these efforts provide constraints on more general low-mass bosons.

Recently, a method was proposed that can extend the search for axion-mediated spin-dependent forces by several orders of magnitude [48]. By combining techniques used in nuclear magnetic resonance and short-distance tests of gravity, this method appears to be sensitive to axions in the  $\mu\text{eV} - \text{meV}$  mass range, independent of the cosmic axion abundance.

## III. AXIONS FROM ASTROPHYSICAL SOURCES

### III.1 Stellar energy-loss limits:

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, *etc.*) are produced in hot astrophysical plasmas, and can thus transport energy out of stars. The coupling strength of these particles with normal matter and radiation is bounded by the constraint that stellar lifetimes or energy-loss rates not conflict with observation [49–51].

We begin this discussion with our Sun and concentrate on hadronic axions. They are produced predominantly by the Primakoff process  $\gamma + Ze \rightarrow Ze + A$ . Integrating over a standard solar model yields the axion luminosity [52]

$$L_A = G_{10}^2 1.85 \times 10^{-3} L_\odot, \quad (11)$$

where  $G_{10} = |G_{A\gamma\gamma}| \times 10^{10} \text{ GeV}$ . The maximum of the spectrum is at 3.0 keV, the average at 4.2 keV, and the number flux at Earth is  $G_{10}^2 3.75 \times 10^{11} \text{ cm}^{-2} \text{ s}^{-1}$ . The solar photon luminosity is fixed, so axion losses require enhanced nuclear energy production and thus enhanced neutrino fluxes. The all-flavor measurements by SNO together with a standard solar

## Gauge & Higgs Boson Particle Listings

### Axions ( $A^0$ ) and Other Very Light Bosons

model imply  $L_A \lesssim 0.10 L_\odot$ , corresponding to  $G_{10} \lesssim 7$  [53], mildly superseding a similar limit from helioseismology [54]. Recently, the limit was improved to  $G_{10} < 4.1$  (at  $3\sigma$ ), exploiting a new statistical analysis that combined helioseismology (sound speed, surface helium and convective radius) and solar neutrino observations, including theoretical and observational errors, and accounting for tensions between input parameters of solar models, in particular the solar element abundances [55].

A more restrictive limit derives from globular-cluster (GC) stars that allow for detailed tests of stellar-evolution theory. The stars on the horizontal branch (HB) in the color-magnitude diagram have reached helium burning with a core-averaged energy release of about  $80 \text{ erg g}^{-1} \text{ s}^{-1}$ , compared to Primakoff axion losses of  $G_{10}^2 30 \text{ erg g}^{-1} \text{ s}^{-1}$ . The accelerated consumption of helium reduces the HB lifetime by about  $80/(80+30 G_{10}^2)$ . Number counts of HB stars in a large sample of 39 Galactic GCs compared with the number of red giants (that are not much affected by Primakoff losses) give a weak indication of non-standard losses which may be accounted by Primakoff-like axion emission, if the photon coupling is in the range  $|G_{A\gamma\gamma}| = 4.5^{+1.2}_{-1.6} \times 10^{-11} \text{ GeV}^{-1}$  [56]. Still, the upper bound found in this analysis,

$$|G_{A\gamma\gamma}| < 6.6 \times 10^{-11} \text{ GeV}^{-1} \text{ (95\% CL)}, \quad (12)$$

represents the strongest limit on  $G_{A\gamma\gamma}$  for a wide mass range, see Figure 1.

**Figure 2:** Exclusion ranges as described in the text. The intervals in the bottom row are the approximate ADMX, CASPER, CAST, and IAXO search ranges, with green regions indicating the projected reach. Limits on coupling strengths are translated into limits on  $m_A$  and  $f_A$  using  $z = 0.56$  and the KSVZ values for the coupling strengths, if not indicated otherwise. The “Beam Dump” bar is a rough representation of the exclusion range for standard or variant axions. The limits for the axion-electron coupling are determined for the DFSZ model with an axion-electron coupling corresponding to  $\cos^2 \beta' = 1/2$ .

We translate the conservative constraint, Equation 12, on  $G_{A\gamma\gamma}$  to  $f_A > 3.4 \times 10^7 \text{ GeV}$  ( $m_A < 0.2 \text{ eV}$ ), using  $z = 0.56$  and  $E/N = 0$  as in the KSVZ model, and show the excluded range in Figure 2. For the DFSZ model with  $E/N = 8/3$ , the corresponding limits are slightly less restrictive,  $f_A > 1.3 \times 10^7 \text{ GeV}$  ( $m_A < 0.5 \text{ eV}$ ). The weak indication of an extra energy loss points to a range  $76 \text{ meV} \lesssim m_A \lesssim 150 \text{ meV}$  ( $0.21 \text{ eV} \lesssim m_A \lesssim 0.41 \text{ eV}$ ) for the KSVZ (DFSZ) model. The exact high-mass end of the exclusion range has not been determined. The relevant temperature is around  $10 \text{ keV}$  and the average photon energy is therefore around  $30 \text{ keV}$ . The excluded  $m_A$  range thus certainly extends beyond the shown  $100 \text{ keV}$ .

If axions couple directly to electrons, the dominant emission processes are atomic axio-recombination and axio-deexcitation, axio-bremsstrahlung in electron-ion or electron-electron collisions, and Compton scattering [57]. Stars in the red giant (RG) branch of the color-magnitude diagram of GCs are particularly sensitive to these processes. In fact, they would lead to an extension of the latter to larger brightness. A recent analysis provided high-precision photometry for the Galactic globular cluster M5 (NGC 5904), allowing for a detailed comparison between the observed tip of the RG branch with predictions based on state-of-the-art stellar evolution theory [58]. It was found that, within the uncertainties, the observed and predicted tip of the RG branch brightness agree reasonably well within uncertainties, leading to the bound

$$\alpha_{Aee} < 1.5 \times 10^{-26} \text{ (95\% CL)}, \quad (13)$$

implying an upper bound on the axion mass in the DFSZ model,

$$m_A \cos^2 \beta' < 15 \text{ meV (95\% CL)}, \quad (14)$$

see Figure 2. Intriguingly, the agreement would improve with a small amount of extra cooling that slightly postpones helium ignition, preferring an electron coupling around  $\alpha_{Aee} \sim 2.8 \times 10^{-27}$ , corresponding to  $m_A \cos^2 \beta' \sim 7 \text{ meV}$ . Recently, it has been pointed out that the best fit simultaneously explaining the extra energy losses of HB stars reported above and the ones of RGs prefers a photon coupling around  $G_{A\gamma\gamma} \sim \text{few} \times 10^{-12} \text{ GeV}^{-1}$  and an electron coupling of order  $\alpha_{Aee} \sim 10^{-27}$  [59].

Bremsstrahlung is also efficient in white dwarfs (WDs), where the Primakoff and Compton processes are suppressed by the large plasma frequency. A comparison of the predicted and observed luminosity function of WDs can be used to put limits on  $\alpha_{Aee}$  [60]. A recent analysis, based on detailed WD cooling treatment and new data on the WD luminosity function (WDLF) of the Galactic Disk, found that electron couplings above  $\alpha_{Aee} \gtrsim 6 \times 10^{-27}$ , corresponding to a DFSZ axion mass  $m_A \cos^2 \beta' \gtrsim 10 \text{ meV}$ , are disfavoured [61], see Figure 2. Lower couplings can not be discarded from the current knowledge of the WDLF of the Galactic Disk. On the contrary, features in some WDLFs can be interpreted as suggestions for electron couplings in the range  $4.1 \times 10^{-28} \lesssim$

See key on page 601

## Gauge & Higgs Boson Particle Listings

### Axions ( $A^0$ ) and Other Very Light Bosons

$\alpha_{Aee} \lesssim 3.7 \times 10^{-27}$ , corresponding to  $2.5 \text{ MeV} \lesssim m_A \cos^2 \beta' \lesssim 7.5 \text{ MeV}$  [61,62], see Figure 2. For pulsationally unstable WDs (ZZ Ceti stars), the period decrease  $\dot{P}/P$  is a measure of the cooling speed. The corresponding observations of the pulsating WDs G117-B15A and R548 imply additional cooling that can be interpreted also in terms of similar axion losses [63].

Similar constraints derive from the measured duration of the neutrino signal of the supernova SN 1987A. Numerical simulations for a variety of cases, including axions and Kaluza-Klein gravitons, reveal that the energy-loss rate of a nuclear medium at the density  $3 \times 10^{14} \text{ g cm}^{-3}$  and temperature 30 MeV should not exceed about  $1 \times 10^{19} \text{ erg g}^{-1} \text{ s}^{-1}$  [50]. The energy-loss rate from nucleon bremsstrahlung,  $N + N \rightarrow N + N + A$ , is  $(C_N/2f_A)^2 (T^4/\pi^2 m_N) F$ . Here  $F$  is a numerical factor that represents an integral over the dynamical spin-density structure function because axions couple to the nucleon spin. For realistic conditions, even after considerable effort, one is limited to a heuristic estimate leading to  $F \approx 1$  [51].

The SN 1987A limits are of particular interest for hadronic axions where the bounds on  $\alpha_{Aee}$  are moot. Within uncertainties of  $z = m_u/m_d$  a reasonable choice for the coupling constants is then  $C_p = -0.4$  and  $C_n = 0$ . Using a proton fraction of 0.3,  $F = 1$ , and  $T = 30 \text{ MeV}$  one finds [51]

$$f_A \gtrsim 4 \times 10^8 \text{ GeV} \quad \text{and} \quad m_A \lesssim 16 \text{ MeV}, \quad (15)$$

see Figure 2. If axions interact sufficiently strongly they are trapped. Only about three orders of magnitude in  $g_{ANN}$  or  $m_A$  are excluded, a range shown somewhat schematically in Figure 2. For even larger couplings, the axion flux would have been negligible, yet it would have triggered additional events in the detectors, excluding a further range [64]. A possible gap between these two SN 1987A arguments was discussed as the “hadronic axion window” under the assumption that  $G_{A\gamma\gamma}$  was anomalously small [65]. This range is now excluded by hot dark matter bounds (see below).

Intriguingly, there is another hint for excessive stellar energy losses from the neutron star (NS) in the supernova remnant Cassiopeia A (Cas A): its surface temperature measured over 10 years reveals an unusually fast cooling rate. This may be interpreted as a hint for extra cooling by axion neutron bremsstrahlung, requiring a coupling to the neutron of size [66]

$$g_{Ann} = (3.8 \pm 3) \times 10^{-10} \quad (16)$$

corresponding to an axion mass

$$m_A = (2.4 \pm 2) \text{ MeV}/C_n, \quad (17)$$

see Figure 2. The hint is compatible with the state-of-the-art upper limit on this coupling,

$$g_{Ann} < 8 \times 10^{-10}, \quad (18)$$

from NS cooling [67]. In fact, as recently pointed out, the more rapid cooling of the superfluid core in the neutron star

may also arise from a phase transition of the neutron condensate into a multicomponent state [68].

Finally, let us note that if the interpretation of the various hints for additional cooling of stars reported in this section in terms of emission of axions with  $m_A \sim \text{MeV}$  were correct, SNe would lose a large fraction of their energy as axions. This would lead to a diffuse SN axion background in the universe with an energy density comparable to the extra-galactic background light [69]. However, there is no apparent way of detecting it or the axion burst from the next nearby SN.

### III.2 Searches for solar axions and ALPs

Instead of using stellar energy losses to derive axion limits, one can also search directly for these fluxes, notably from the Sun. The main focus has been on axion-like particles with a two-photon vertex. They are produced by the Primakoff process with a flux given by Equation 11 and an average energy of 4.2 keV, and can be detected at Earth with the reverse process in a macroscopic  $B$ -field (“axion helioscope”) [5]. In order to extend the sensitivity in mass towards larger values, one can endow the photon with an effective mass in a gas,  $m_\gamma = \omega_{\text{plas}}$ , thus matching the axion and photon dispersion relations [70].

An early implementation of these ideas used a conventional dipole magnet, with a conversion volume of variable-pressure gas with a xenon proportional chamber as x-ray detector [71]. The conversion magnet was fixed in orientation and collected data for about 1000 s/day. Axions were excluded for  $|G_{A\gamma\gamma}| < 3.6 \times 10^{-9} \text{ GeV}^{-1}$  for  $m_A < 0.03 \text{ eV}$ , and  $|G_{A\gamma\gamma}| < 7.7 \times 10^{-9} \text{ GeV}^{-1}$  for  $0.03 < m_A < 0.11 \text{ eV}$  at 95% CL.

Later, the Tokyo axion helioscope used a superconducting magnet on a tracking mount, viewing the Sun continuously. They reported  $|G_{A\gamma\gamma}| < 6 \times 10^{-10} \text{ GeV}^{-1}$  for  $m_A < 0.3 \text{ eV}$  [72]. This experiment was recommissioned and a similar limit for masses around 1 eV was reported [73].

The most recent helioscope CAST (CERN Axion Solar Telescope) uses a decommissioned LHC dipole magnet on a tracking mount. The hardware includes grazing-incidence x-ray optics with solid-state x-ray detectors, as well as a novel x-ray Micromegas position-sensitive gaseous detector. CAST has established a 95% CL limit  $|G_{A\gamma\gamma}| < 8.8 \times 10^{-11} \text{ GeV}^{-1}$  for  $m_A < 0.02 \text{ eV}$  [52]. To cover larger masses, the magnet bores are filled with a gas at varying pressure. The runs with  $^4\text{He}$  cover masses up to about 0.4 eV [74], providing the  $^4\text{He}$  limits shown in Figure 1. To cover yet larger masses,  $^3\text{He}$  was used to achieve a larger pressure at cryogenic temperatures. Limits up to 1.17 eV allowed CAST to “cross the axion line” for the KSVZ model [75], see Figure 1.

Recently, the XENON100 experiment has presented first results of searches for solar axions and ALPs [76]. The axion-electron coupling constant,  $g_{Aee}$ , has been probed by exploiting the axio-electric effect in liquid xenon, resulting in an upper bound

$$g_{Aee} < 7.7 \times 10^{-12} \quad (90\% \text{ CL}), \quad (19)$$

## Gauge & Higgs Boson Particle Listings

### Axions ( $A^0$ ) and Other Very Light Bosons

excluding DFSZ models with  $m_A \cos^2 \beta' > 0.27 \text{ eV}$ , cf. see Figure 2.

Going to yet larger masses in a helioscope search is not well motivated because of the cosmic hot dark matter bound of  $m_A \lesssim 1 \text{ eV}$  (see below). Sensitivity to significantly smaller values of  $G_{A\gamma\gamma}$  can be achieved with a next-generation axion helioscope with a much larger magnetic-field cross section. Realistic design options for this “International Axion Observatory” (IAXO) have been studied in some detail [77]. Such a next-generation axion helioscope may also push the sensitivity in the product of couplings to photons and to electrons,  $G_{A\gamma\gamma} g_{Aee}$ , into a range beyond stellar energy-loss limits and test the hypothesis that WD cooling is dominated by axion emission [78].

Other Primakoff searches for solar axions and ALPs have been carried out using crystal detectors, exploiting the coherent conversion of axions into photons when the axion angle of incidence satisfies a Bragg condition with a crystal plane [79]. However, none of these limits is more restrictive than the one derived from the constraint on the solar axion luminosity ( $L_A \lesssim 0.10 L_\odot$ ) discussed earlier.

Another idea is to look at the Sun with an x-ray satellite when the Earth is in between. Solar axions and ALPs would convert in the Earth magnetic field on the far side and could be detected [80]. The sensitivity to  $G_{A\gamma\gamma}$  could be comparable to CAST, but only for much smaller  $m_A$ . Deep solar x-ray measurements with existing satellites, using the solar magnetosphere as conversion region, have reported preliminary limits on  $G_{A\gamma\gamma}$  [81].

#### III.3 Conversion of astrophysical photon fluxes

Large-scale  $B$  fields exist in astrophysics that can induce axion-photon oscillations. In practical cases,  $B$  is much smaller than in the laboratory, whereas the conversion region  $L$  is much larger. Therefore, while the product  $BL$  can be large, realistic sensitivities are usually restricted to very low-mass particles, far away from the “axion band” in a plot like Figure 1.

One example is SN 1987A, which would have emitted a burst of axion-like particles (ALPs) due to the Primakoff production in its core. They would have partially converted into  $\gamma$ -rays in the galactic  $B$ -field. The lack of a gamma-ray signal in the GRS instrument of the SMM satellite in coincidence with the observation of the neutrinos emitted from SN1987A therefore provides a strong bound on their coupling to photons [82]. Recently, this bound has been revisited and the underlying physics has been brought to the current state-of-the-art, as far as modelling of the supernova and the Milky-Way magnetic field are concerned, resulting in the limit [83]

$$|G_{A\gamma\gamma}| < 5.3 \times 10^{-12} \text{ GeV}^{-1}, \text{ for } m_A \lesssim 4.4 \times 10^{-10} \text{ eV}.$$

Magnetically induced oscillations between photons and axion-like particles (ALPs) can modify the photon fluxes from distant sources in various ways, featuring (i) frequency-dependent dimming, (ii) modified polarization, and (iii) avoid- ing absorption by propagation in the form of axions.

For example, dimming of SNe Ia could influence the interpretation in terms of cosmic acceleration [84], although it has become clear that photon-ALP conversion could only be a sub-dominant effect [85]. Searches for linearly polarised emission from magnetised white dwarfs [86] and changes of the linear polarisation from radio galaxies (see, e.g., Ref. [87]) provide limits close to  $G_{A\gamma\gamma} \sim 10^{-11} \text{ GeV}^{-1}$ , for masses  $m_A \lesssim 10^{-7} \text{ eV}$  and  $m_A \lesssim 10^{-15} \text{ eV}$ , respectively, albeit with uncertainties related to the underlying assumptions. Even stronger limits,  $G_{A\gamma\gamma} \lesssim 2 \times 10^{-13} \text{ GeV}^{-1}$ , for  $m_A \lesssim 10^{-14} \text{ eV}$ , have been obtained by exploiting high-precision measurements of quasar polarisations [88].

Remarkably, it appears that the universe could be too transparent to TeV  $\gamma$ -rays that should be absorbed by pair production on the extra-galactic background light [89]. The situation is not conclusive at present [90], but the possible role of photon-ALP oscillations in TeV  $\gamma$ -ray astronomy is tantalizing [91]. Fortunately, the region in ALP parameter space,  $G_{A\gamma\gamma} \sim 10^{-12} - 10^{-10} \text{ GeV}^{-1}$  for  $m_A \lesssim 10^{-7} \text{ eV}$  [92], required to explain the anomalous TeV transparency of the universe, could be conceivably probed by the next generation of laboratory experiments (ALPS II) and helioscopes (IAXO) mentioned above. This parameter region can also be probed by searching for an irregular behavior of the gamma ray spectrum of distant active galactic nuclei (AGN), expected to arise from photon-ALP mixing in a limited energy range. The H.E.S.S. collaboration has set a limit of  $|G_{A\gamma\gamma}| \lesssim 2.1 \times 10^{-11} \text{ GeV}^{-1}$ , for  $1.5 \times 10^{-8} \text{ eV} \lesssim m_A \lesssim 6.0 \times 10^{-8} \text{ eV}$ , from the non-observation of an irregular behavior of the spectrum of the AGN PKS 2155 [93], see Figure 1.

Last but not least, it was found that observed soft X-ray excesses in many galaxy clusters may be explained by the conversion of a hypothetical cosmic ALP background (CAB) radiation, corresponding to an effective number  $\Delta N_{\text{eff}}$  of extra neutrinos, into photons in the cluster magnetic fields [94]. This explanation requires that the CAB spectrum is peaked in the soft X-ray region and that the ALP coupling and mass satisfy  $|G_{A\gamma\gamma}| \gtrsim (1 - 2) \times 10^{-13} \text{ GeV}^{-1} \sqrt{0.5/\Delta N_{\text{eff}}}$ , for  $m_A \lesssim 10^{-12} \text{ eV}$ .

#### III.4 Superradiance of black holes

Ultralight bosonic fields such as axions or ALPs can affect the dynamics and gravitational wave emission of rapidly rotating astrophysical black holes through the Penrose superradiance mechanism. When their Compton wavelength is of order of the black hole size, they form bound states around the black hole nucleus. Their occupation number grows exponentially by extracting rotational energy and angular momentum from the ergosphere, thus forming a rotating Bose-Einstein condensate emitting gravitational waves. For black holes lighter than  $10^7$  solar masses, accretion cannot replenish the spin of the black hole. The existence of destabilizing ultralight bosonic fields thus leads to gaps in the mass vs. spin plot of rapidly rotating black holes. Stellar black hole spin measurements – exploiting

## Gauge & Higgs Boson Particle Listings

### Axions ( $A^0$ ) and Other Very Light Bosons

well-studied binaries and two independent techniques – exclude a mass range  $6 \times 10^{-13} \text{ eV} < m_A < 2 \times 10^{-11} \text{ eV}$  at  $2\sigma$ , which for the axion excludes  $3 \times 10^{17} \text{ GeV} < f_A < 1 \times 10^{19} \text{ GeV}$  [95]. Long lasting, monochromatic gravitational wave signals, which can be distinguished from ordinary astrophysical sources, are expected to be produced by axions transitioning between the levels of the gravitational atom and axions annihilating to gravitons. Accordingly, the gravitational wave detector Advanced LIGO should be sensitive to the axion in the  $m_A \sim 10^{-10} \text{ eV}$  region.

#### IV. COSMIC AXIONS

##### IV.1 Cosmic axion populations

In the early universe, axions are produced by processes involving quarks and gluons [96]. After color confinement, the dominant thermalization process is  $\pi + \pi \leftrightarrow \pi + A$  [28]. The resulting axion population would contribute a hot dark matter component in analogy to massive neutrinos. Cosmological precision data provide restrictive constraints on a possible hot dark-matter fraction that translate into  $m_A \lesssim 1 \text{ eV}$  [97], but in detail depend on the used data set and assumed cosmological model. In the future, data from a EUCLID-like survey combined with Planck CMB data can detect hot dark matter axions mass  $m_A \gtrsim 0.15 \text{ eV}$  at very high significance [98].

For  $m_A \gtrsim 20 \text{ eV}$ , axions decay fast on a cosmic time scale, removing the axion population while injecting photons. This excess radiation provides additional limits up to very large axion masses [99]. An anomalously small  $G_{A\gamma\gamma}$  provides no loophole because suppressing decays leads to thermal axions overwhelming the mass density of the universe.

The main cosmological interest in axions derives from their possible role as cold dark matter (CDM). In addition to thermal processes, axions are abundantly produced by the “re-alignment mechanism” [100]. After the breakdown of the PQ symmetry, the axion field relaxes somewhere in the “bottom of the wine bottle” potential. Near the QCD epoch, topological fluctuations of the gluon fields such as instantons explicitly break the PQ symmetry, the very effect that causes dynamical PQ symmetry restoration. This “tilting of the wine bottle” drives the axion field toward the CP-conserving minimum, thereby exciting coherent oscillations of the axion field that ultimately represent a condensate of CDM. The fractional cosmic mass density in this homogeneous field mode is [101,102],

$$\begin{aligned} \Omega_A^{\text{real}} h^2 &\approx 0.11 \left( \frac{f_A}{5 \times 10^{11} \text{ GeV}} \right)^{1.19} F \bar{\Theta}_i^2 \\ &= 0.11 \left( \frac{12 \text{ } \mu\text{eV}}{m_A} \right)^{1.19} F \bar{\Theta}_i^2, \end{aligned} \quad (20)$$

where  $h$  is the present-day Hubble expansion parameter in units of  $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$ , and  $-\pi \leq \bar{\Theta}_i \leq \pi$  is the initial “misalignment angle” relative to the CP-conserving position attained in the causally connected region which evolved into today’s observable universe.  $F = F(\bar{\Theta}_i, f_A)$  is a factor accounting for anharmonicities in the axion potential.

For  $F \bar{\Theta}_i^2 = \mathcal{O}(1)$ ,  $m_A$  should be above  $\sim 10 \text{ } \mu\text{eV}$  in order that the cosmic axion density does not exceed the observed CDM density,  $\Omega_{\text{CDM}} h^2 = 0.11$ . However, much smaller axion masses (much higher PQ scales) would still be possible if the PQ symmetry is broken during inflation and not restored afterwards. In this case, the initial value  $\bar{\Theta}_i$  may just happen to be small enough in today’s observable universe (“anthropic axion window” [103]). However, since the axion field is then present during inflation and thus subject to quantum fluctuations, the non-observation of the associated isocurvature fluctuations in the CMB puts severe constraints in the  $(f_A, r)$  plane, where  $r$  is the ratio of the power in tensor to the one in scalar fluctuations [104]. In fact, isocurvature constraints, combined with a future measurement of a sizeable  $r$ , would strongly disfavor axions with [105]

$$f_A \gtrsim 1.3 \times 10^{13} \text{ GeV} \left( \frac{r}{0.1} \right)^{1/2}, \quad m_A \lesssim 0.4 \text{ } \mu\text{eV} \left( \frac{r}{0.1} \right)^{-1/2}.$$

If the PQ symmetry breakdown takes place after inflation,  $\bar{\Theta}_i$  will take on different values in different patches of the universe. The average contribution is [101]

$$\Omega_A^{\text{real}} h^2 \approx 0.11 \left( \frac{41 \text{ } \mu\text{eV}}{m_A} \right)^{1.19}. \quad (21)$$

However, the additional contribution from the decay of topological defects suffers from significant uncertainties. According to Sikivie and collaborators, these populations are comparable to the re-alignment contribution [106]. Other groups find a significantly enhanced axion density [102,107] or rather, a larger  $m_A$  value for axions providing CDM, namely

$$m_A \approx (0.8 - 1.3) \times 10^{-4} \text{ eV}, \quad (22)$$

for models with short-lived (requiring unit color anomaly  $N = 1$ ) domain walls, such as the KSVZ model, and

$$m_A \approx (6 \times 10^{-4} - 4 \times 10^{-3}) \text{ eV}, \quad (23)$$

for models with long-lived ( $N > 1$ ) domain walls, such as an accidental DFSZ model [108], where the PQ symmetry is broken by higher dimensional Planck suppressed operators, see Figure 2. Moreover, the spatial axion density variations are large at the QCD transition and they are not erased by free streaming. When matter begins to dominate the universe, gravitationally bound “axion mini clusters” form promptly [109]. A significant fraction of CDM axions can reside in these bound objects.

In the above predictions of the fractional cosmic mass density in axions, the exponent, 1.19, arises from the non-trivial temperature dependence of the axion mass  $m_A(T) = \sqrt{\chi(T)}/f_A$ , which has been obtained from the dilute instanton gas/liquid approximation (DIGA). Lattice QCD provides a first principle technique to determine the topological susceptibility  $\chi(T)$  in the relevant temperature range around the QCD phase transition. A full result needs two ingredients: physical quark masses and a controlled continuum extrapolation from

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

non-vanishing to zero lattice spacings. The latter has been done recently in the quenched framework (neglecting the effects of light quarks) and compared with the prediction of the DIGA [110,111]. Nice agreement was found for the temperature dependence, whereas the overall normalization of the DIGA result turned out to differ from the non-perturbative continuum extrapolated lattice results by a factor of order ten [111]. If this finding can be extrapolated to full QCD, the prediction of the axion mass relevant for dark matter will decrease by about 20% compared to the DIGA prediction. Lattice simulations with physical quark masses are about two-to-three orders of magnitude more CPU intensive than quenched ones. In addition one expects much smaller topological susceptibilities and larger cutoff effects. Correspondingly, available pioneering studies in full QCD [112] do not extend to the relevant temperature range and may still suffer from strong cutoff effects. But lattice campaigns dedicated to axion cosmology are ongoing.

In R-parity conserving supersymmetric models, more possibilities arise: cold dark matter might be a mixture of axions along with the lightest SUSY particle (LSP) [20]. Candidates for the LSP include the lightest neutralino, the gravitino, the axino, or a sneutrino. In the case of a neutralino LSP, saxion and axino production in the early universe have a strong impact on the neutralino and axion abundance. The former almost always gets increased beyond its thermal-production-only value, favoring then models with higgsino-like or wino-like neutralinos [113]. For large values of  $f_A$ , saxions from the vacuum re-alignment mechanism may produce large relic dilution via entropy dumping, thus allowing for much larger values of  $f_A$ , sometimes as high as approaching the GUT scale,  $\sim 10^{16}$  GeV, for natural values of the initial re-alignment angle. Then the dark matter may be either neutralino- or axion-dominated, or a comparable mixture. In such scenarios, one might expect eventual direct detection of both relic neutralinos and relic axions.

Finally, it is worth mentioning that the non-thermal production mechanisms attributed to axions are indeed generic to bosonic weakly interacting ultra-light particles such as ALPs: a wide range in  $G_{A\gamma\gamma} - m_A$  parameter space outside the axion band can generically contain models with adequate CDM density [114].

### IV.2 Telescope searches

The two-photon decay is extremely slow for axions with masses in the CDM regime, but could be detectable for eV masses. The signature would be a quasi-monochromatic emission line from galaxies and galaxy clusters. The expected optical line intensity for DFSZ axions is similar to the continuum night emission. An early search in three rich Abell clusters [115], and a recent search in two rich Abell clusters [116], exclude the “Telescope” range in Figure 1 and Figure 2 unless the axion-photon coupling is strongly suppressed. Of course, axions in this mass range would anyway provide an excessive hot DM contribution.

Very low-mass axions in halos produce a weak quasi-monochromatic radio line. Virial velocities in undisrupted dwarf galaxies are very low, and the axion decay line would therefore be extremely narrow. A search with the Haystack radio telescope on three nearby dwarf galaxies provided a limit  $|G_{A\gamma\gamma}| < 1.0 \times 10^{-9} \text{ GeV}^{-1}$  at 96% CL for  $298 < m_A < 363 \mu\text{eV}$  [117]. However, this combination of  $m_A$  and  $G_{A\gamma\gamma}$  does not exclude plausible axion models.

### IV.3 Microwave cavity experiments

The limits of Figure 2 suggest that axions, if they exist, provide a significant fraction or even perhaps all of the cosmic CDM. In a broad range of the plausible  $m_A$  range for CDM, galactic halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q electromagnetic cavity permeated by a strong static  $B$  field [5,118]. The cavity frequency is tunable, and the signal is maximized when the frequency is the total axion energy, rest mass plus kinetic energy, of  $\nu = (m_A/2\pi) [1 + \mathcal{O}(10^{-6})]$ , the width above the rest mass representing the virial distribution in the galaxy. The frequency spectrum may also contain finer structure from axions more recently fallen into the galactic potential and not yet completely virialized [119].

**Figure 3:** Exclusion region reported from the microwave cavity experiments RBF and UF [120] and ADMX [121]. A local dark-matter density of  $450 \text{ MeV cm}^{-3}$  is assumed.

The feasibility of this technique was established in early experiments of relatively small sensitive volume,  $\mathcal{O}(1 \text{ liter})$ , with HFET-based amplifiers, setting limits in the range  $4.5 < m_A < 16.3 \mu\text{eV}$  [120], but lacking by 2–3 orders of magnitude the sensitivity required to detect realistic axions. Later, ADMX ( $B \sim 8 \text{ T}$ ,  $V \sim 200 \text{ liters}$ ) has achieved sensitivity to KSVZ axions, assuming they saturate the local dark matter density and are well virialized, over the mass range  $1.9\text{--}3.3 \mu\text{eV}$  [121]. Should halo axions have a significant component not yet virialized, ADMX is sensitive to DFSZ

See key on page 601

## Gauge & Higgs Boson Particle Listings

### Axions ( $A^0$ ) and Other Very Light Bosons

axions [122]. The corresponding 90% CL exclusion regions shown in Figure 3 are normalized to an assumed local CDM density of  $7.5 \times 10^{-25} \text{ g cm}^{-3}$  ( $450 \text{ MeV cm}^{-3}$ ). More recently the ADMX experiment commissioned an upgrade [123] that replaces the microwave HFET amplifiers by near quantum-limited low-noise dc SQUID microwave amplifiers [124], allowing for a significantly improved sensitivity [125]. This apparatus is also sensitive to other hypothetical light bosons, such as hidden photons or chameleons, over a limited parameter space [114,126]. Alternatively, a Rydberg atom single-photon detector [127] can in principle evade the standard quantum limit for coherent photon detection.

Other new concepts for searching for axion dark matter are also being investigated. For instance, photons from dark matter axions or ALPs could be focused in a manner similar to a dish antenna instead of a resonant cavity [128], enabling broadband searches at higher masses than the RF technique. Searches for hidden photon dark matter exploiting this technique are already underway [129]. Another alternative to the microwave cavity technique is based on a novel detector architecture consisting of an open, Fabry-Perot resonator and a series of current-carrying wire planes [130]. The Orpheus detector has demonstrated this new technique, excluding dark matter ALPs with masses between  $68.2$  and  $76.5 \mu\text{eV}$  and axion-photon couplings greater than  $4 \times 10^{-7} \text{ GeV}^{-1}$ . This technique may be able to probe dark matter axions in the mass range from  $40$  to  $700 \mu\text{eV}$ . Another proposed axion dark matter search method sensitive in the  $100 \mu\text{eV}$  mass range is to cool a kilogram-sized sample to millikelvin temperatures and count axion induced atomic transitions using laser techniques [131].

#### IV.4 Magnetic resonance searches

The oscillating galactic dark matter axion field induces oscillating nuclear electric dipole moments (EDMs). These EDMs cause the precession of nuclear spins in a nucleon spin polarized sample in the presence of an electric field. The resulting transverse magnetization can be searched for by exploiting magnetic-resonance (MR) techniques, which are most sensitive in the range of low oscillation frequencies corresponding to sub-neV axion masses. The aim of the corresponding Cosmic Axion Spin Precession Experiment (CASPER) [132] is to probe axion dark matter in the anthropic window,  $f_A \gtrsim 10^{15} \text{ GeV}$ , corresponding to  $m_A \lesssim \text{neV}$ , complementary to the classic axion window probed by the RF cavity technique.

In the intermediate mass region,  $\text{neV} \lesssim m_A \lesssim 0.1 \mu\text{eV}$ , one may exploit a cooled LC circuit and precision magnetometry to search for the oscillating electric current induced by dark matter axions in a strong magnetic field [133].

An eventually non-zero axion electron coupling  $g_{Aee}$  will lead to a spin precession about the axion dark matter wind [134]. The QUAX (QUaerere AXions) experiment aims at exploiting MR inside a magnetized material [135]. Because of the higher Larmor frequency of the electron, it is sensitive in the classic window.

#### Conclusions

There is a strengthening physics case for very weakly coupled ultralight particles beyond the Standard Model. The elegant solution of the strong CP problem proposed by Peccei and Quinn yields a particularly strong motivation for the axion. In many theoretically appealing ultraviolet completions of the Standard Model axions and axion-like particles occur automatically. Moreover, they are natural cold dark matter candidates. Perhaps the first hints of their existence have already been seen in the anomalous excessive cooling of stars and the anomalous transparency of the Universe for VHE gamma rays. Interestingly, a significant portion of previously unexplored, but phenomenologically very interesting and theoretically very well motivated axion and ALP parameter space can be tackled in the foreseeable future by a number of terrestrial experiments searching for axion/ALP dark matter, for solar axions/ALPs, and for light apparently shining through a wall.

### $A^0$ (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

VALUE (MeV)	DOCUMENT ID	TECN.	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
>0.2	BARROSO	82	ASTR Standard Axion
>0.25	1 RAFFELT	82	ASTR Standard Axion
>0.2	2 DICUS	78c	ASTR Standard Axion
	MIKAELIAN	78	ASTR Stellar emission
>0.3	2 SATO	78	ASTR Standard Axion
>0.2	VYSOTSKII	78	ASTR Standard Axion

<sup>1</sup> Lower bound from 5.5 MeV  $\gamma$ -ray line from the sun.

<sup>2</sup> Lower bound from requiring the red giants' stellar evolution not be disrupted by axion emission.

### $A^0$ (Axion) and Other Light Boson ( $X^0$ ) Searches in Hadron Decays

Limits are for branching ratios.

<sup>1</sup> The limit is for  $\tau_{X^0} = 10$  ps and  $m_{X^0} = 214-4350$  MeV. See their Fig. 4 for mass- and lifetime-dependent limits.

<sup>2</sup> Limits between  $2.0 \times 10^{-5}$  and  $1.5 \times 10^{-6}$  are obtained for  $m_{X^0} = 20-100$  MeV (see their Fig. 8). Angular momentum conservation requires that  $X^0$  has spin  $\geq 1$ .

<sup>3</sup> The limit is for  $B(\phi \rightarrow \eta X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies to  $m_{X^0} = 410$  MeV. It is derived by analyzing  $\eta \rightarrow \pi^0 \pi^0 \pi^0$  and  $\pi^- \pi^+ \pi^0$ . Limits between  $1 \times 10^{-6}$  and  $2 \times 10^{-8}$  are obtained for  $m_{X^0} \leq 450$  MeV (see their Fig. 6).

<sup>4</sup> ARCHILLI 12 analyzed  $\eta \rightarrow \pi^+ \pi^- \pi^0$  decays. Derived limits on  $\alpha'/\alpha < 2 \times 10^{-5}$  for  $m_{X^0} = 50-420$  MeV at 90% CL. See their Fig. 8 for mass-dependent limits.

<sup>5</sup> This limit is for  $B(\pi^0 \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies for  $m_{X^0} = 90$  MeV and  $\tau_{X^0} \simeq 1 \times 10^{-8}$  sec. Limits between  $10^{-8}$  and  $2 \times 10^{-15}$  are obtained for  $m_{X^0} = 3-120$  MeV and  $\tau_{X^0} = 1 \times 10^{-11}-1$  sec. See their Fig. 3 for limits at different masses and lifetimes.

<sup>6</sup> This limit is for  $B(\eta \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies for  $m_{X^0} = 100$  MeV and  $\tau_{X^0} \simeq 6 \times 10^{-9}$  sec. Limits between  $10^{-5}$  and  $3 \times 10^{-14}$  are obtained for  $m_{X^0} \lesssim 550$  MeV and  $\tau_{X^0} = 10^{-10}-10$  sec. See their Fig. 5 for limits at different mass and lifetime and for  $\eta'$  decays.

<sup>7</sup> This limit applies for a mass near 180 MeV. For other masses in the range  $m_{X^0} = 150-250$  MeV the limit is less restrictive, but still improves ADLER 02c and ATIYA 93B.

<sup>8</sup> ANISIMOVSKY 04 bound is for  $m_{X^0} = 0$ .

<sup>9</sup> ADLER 02c bound is for  $m_{X^0} < 60$  MeV. See Fig. 2 for limits at higher masses.

<sup>10</sup> The quoted limit is for  $m_{X^0} = 0-80$  MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.

<sup>11</sup> ALTEGOER 98 looked for  $X^0$  from  $\pi^0$  decay which penetrate the shielding and convert to  $\pi^0$  in the external Coulomb field of a nucleus.

See key on page 601

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>12</sup> KITCHING 97 limit is for  $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$  and applies for  $m_{X^0} \simeq 50$  MeV,  $\tau_{X^0} < 10^{-10}$  s. Limits are provided for  $0 < m_{X^0} < 100$  MeV,  $\tau_{X^0} < 10^{-8}$  s.
- <sup>13</sup> ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable  $X^0$  particles and extends to  $m_{X^0}=80$  MeV at the same level. See paper for dependence on finite lifetime.
- <sup>14</sup> AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution.
- <sup>15</sup> The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of  $X^0$  decay modes. It applies to  $\tau(X^0) > 10^{-23}$  sec.
- <sup>16</sup> ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable  $X^0$  of  $m_{X^0}=150$ –250 MeV, and the limit becomes stronger ( $10^{-8}$ ) for  $m_{X^0}=180$ –240 MeV.
- <sup>17</sup> NG 93 studied the production of  $X^0$  via  $\gamma\gamma \rightarrow \pi^0 \rightarrow \gamma X^0$  in the early universe at  $T \simeq 1$  MeV. The bound on extra neutrinos from nucleosynthesis  $\Delta N_\nu < 0.3$  (WALKER 91) is employed. It applies to  $m_{X^0} \ll 1$  MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier  $X^0$ .
- <sup>18</sup> ALLIEGRO 92 limit applies for  $m_{X^0}=150$ –340 MeV and is the branching ratio times the decay probability. Limit is  $< 1.5 \times 10^{-8}$  at 99%CL.
- <sup>19</sup> ATIYA 92 looked for a peak in missing mass distribution. The limit applies to  $m_{X^0}=0$ –130 MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires  $X^0$  to be a vector particle.
- <sup>20</sup> BARABASH 92 is a beam dump experiment that searched for a light Higgs. Limits between  $1 \times 10^{-12}$  and  $1 \times 10^{-7}$  are obtained for  $3 < m_{X^0} < 40$  MeV.
- <sup>21</sup> Limits between  $1 \times 10^{-12}$  and 1 are obtained for  $4 < m_{X^0} < 69$  MeV.
- <sup>22</sup> Limits between  $1 \times 10^{-11}$  and  $5 \times 10^{-3}$  are obtained for  $4 < m_{X^0} < 63$  MeV.
- <sup>23</sup> Limits between  $1 \times 10^{-14}$  and 1 are obtained for  $3 < m_{X^0} < 82$  MeV.
- <sup>24</sup> MEIJERDREES 92 limit applies for  $\tau_{X^0} = 10^{-23}$ – $10^{-11}$  sec. Limits between  $2 \times 10^{-4}$  and  $4 \times 10^{-6}$  are obtained for  $m_{X^0} = 25$ –120 MeV. Angular momentum conservation requires that  $X^0$  has spin  $\geq 1$ .
- <sup>25</sup> ATIYA 90B limit is for  $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$  and applies for  $m_{X^0} = 50$  MeV,  $\tau_{X^0} < 10^{-10}$  s. Limits are also provided for  $0 < m_{X^0} < 100$  MeV,  $\tau_{X^0} < 10^{-8}$  s.
- <sup>26</sup> KORENCHENKO 87 limit assumes  $m_{A^0} = 1.7$  MeV,  $\tau_{A^0} \lesssim 10^{-12}$  s, and  $B(A^0 \rightarrow e^+ e^-) = 1$ .
- <sup>27</sup> EICHLER 86 looked for  $\pi^+ \rightarrow e^+ \nu A^0$  followed by  $A^0 \rightarrow e^+ e^-$ . Limits on the branching fraction depend on the mass and and lifetime of  $A^0$ . The quoted limits are valid when  $\tau(A^0) \gtrsim 3 \cdot 10^{-10}$  s if the decays are kinematically allowed.
- <sup>28</sup> YAMAZAKI 84 looked for a discrete line in  $K^+ \rightarrow \pi^+ X$ . Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.
- <sup>29</sup> ASANO 82 at KEK set limits for  $B(K^+ \rightarrow \pi^+ X^0)$  for  $m_{X^0} < 100$  MeV as  $BR < 4 \cdot 10^{-8}$  for  $\tau(X^0 \rightarrow n\gamma\text{'s}) > 1 \cdot 10^{-9}$  s,  $BR < 1.4 \times 10^{-6}$  for  $\tau < 1 \cdot 10^{-9}$  s.
- <sup>30</sup> ASANO 81B is KEK experiment. Set  $B(K^+ \rightarrow \pi^+ X^0) < 3.8 \times 10^{-8}$  at CL = 90%.
- <sup>31</sup> ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 ( $3 < m < 40$  MeV) contradicts experimental muon anomalous magnetic moments.

### $A^0$ (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

		<sup>7</sup> AMALDI 85	CNTR	Ortho-positronium
		<sup>8</sup> CARBONI 83	CNTR	Ortho-positronium

- <sup>1</sup> BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.
- <sup>2</sup> The ASAI 94 limit is based on inclusive photon spectrum and is independent of  $A^0$  decay modes.
- <sup>3</sup> The AKOPYAN 91 limit applies for a short-lived  $A^0$  with  $\tau_{A^0} < 10^{-13}$   $m_{A^0}$  [keV] s.
- <sup>4</sup> ASAI 91 limit translates to  $g_{A^0 e^+ e^-}^2 / 4\pi < 1.1 \times 10^{-11}$  (90% CL) for  $m_{A^0} < 800$  keV.
- <sup>5</sup> The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of  $A^0$  decay modes.
- <sup>6</sup> ORITO 89 limit translates to  $g_{A^0 e^+ e^-}^2 / 4\pi < 6.2 \times 10^{-10}$ . Somewhat more sensitive limits are obtained for larger  $m_{A^0}$ :  $B < 7.6 \times 10^{-6}$  at 100 keV.
- <sup>7</sup> AMALDI 85 set limits  $B(A^0 \gamma) / B(\gamma\gamma\gamma) < (1\text{--}5) \times 10^{-6}$  for  $m_{A^0} = 900\text{--}100 \text{ keV}$  which are about 1/10 of the CARBONI 83 limits.
- <sup>8</sup> CARBONI 83 looked for orthopositronium  $\rightarrow A^0 \gamma$ . Set limit for  $A^0$  electron coupling squared,  $g(e e A^0)^2 / (4\pi) < 6 \cdot 10^{-10}$ – $7 \cdot 10^{-9}$  for  $m_{A^0}$  from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from  $g\text{--}2$  experiments.

### $A^0$ (Axion) Search in Photoproduction

VALUE	DOCUMENT ID	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •		
<sup>1</sup> BASSOMPIERRE... 95	$m_{A^0} = 1.8 \pm 0.2 \text{ MeV}$	
<sup>1</sup> BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of $e^+ e^-$ pairs in the region $m_{e^+ e^-} = 1.8 \pm 0.2 \text{ MeV}$ . They obtained bounds on the production rate $A^0$ for $\tau(A^0) = 10^{-18}$ – $10^{-9}$ sec. They also found an excess of events in the range $m_{e^+ e^-} = 2.1\text{--}3.5 \text{ MeV}$ .		

### $A^0$ (Axion) Production in Hadron Collisions

Limits are for  $\sigma(A^0) / \sigma(\pi^0)$ .

- <sup>1</sup> JAIN 07 claims evidence for  $A^0 \rightarrow e^+ e^-$  produced in  $^{207}\text{Pb}$  collision on nuclear emulsion (Ag/Br) for  $m(A^0) = 7 \pm 1$  or  $19 \pm 1 \text{ MeV}$  and  $\tau(A^0) \leq 10^{-13} \text{ s}$ .
- <sup>2</sup> AHMAD 97 reports a result of APEX Collaboration which studied positron production in  $^{238}\text{U} + ^{232}\text{Ta}$  and  $^{238}\text{U} + ^{181}\text{Ta}$  collisions, without requiring a coincident electron. No narrow lines were found for  $250 < E_{e^+} < 750 \text{ keV}$ .

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>3</sup> LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy  $e^+e^-$  line at  $\sim 635$  keV in  $^{238}\text{U}+^{181}\text{Ta}$  collision. Limits on the production probability for a narrow sum-energy  $e^+e^-$  line are set. See their Table 2.
- <sup>4</sup> GANZ 96 (EPOS II Collaboration) has placed upper bounds on the production cross section of  $e^+e^-$  pairs from  $^{238}\text{U}+^{181}\text{Ta}$  and  $^{238}\text{U}+^{232}\text{Th}$  collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of  $e^+e^-$  pairs. These limits rule out the existence of peaks in the  $e^+e^-$  sum-energy distribution, reported by an earlier version of this experiment.
- <sup>5</sup> KAMEL 96 looked for  $e^+e^-$  pairs from the collision of  $^{32}\text{S}$  (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity  $m_{ee} > 2$  MeV.
- <sup>6</sup> BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of  $e^+e^-$  or  $\mu^+\mu^-$  from the produce  $A^0$ . See Fig. 5 for the excluded region in  $m_{A^0}$ - $x$  plane. For the standard axion,  $0.3 < x < 25$  is excluded at 95% CL. If combined with BLUEMLEIN 91,  $0.008 < x < 32$  is excluded.
- <sup>7</sup> MEIJERDREES 92 give  $\Gamma(\pi^-\rho \rightarrow nA^0)\cdot\text{B}(A^0 \rightarrow e^+e^-)/\Gamma(\pi^-\rho \rightarrow \text{all}) < 10^{-5}$  (90% CL) for  $m_{A^0} = 100$  MeV,  $\tau_{A^0} = 10^{-11}-10^{-23}$  sec. Limits ranging from  $2.5 \times 10^{-3}$  to  $10^{-7}$  are given for  $m_{A^0} = 25-136$  MeV.
- <sup>8</sup> BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for  $A^0 \rightarrow e^+e^-$ ,  $2\gamma$  are found. Fig. 6 gives the excluded region in  $m_{A^0}$ - $x$  plane ( $x = \tan\beta = v_2/v_1$ ). Standard axion is excluded for  $0.2 < m_{A^0} < 3.2$  MeV for most  $x > 1$ ,  $0.2-11$  MeV for most  $x < 1$ .
- <sup>9</sup> FAISSNER 89 searched for  $A^0 \rightarrow e^+e^-$  in a proton beam dump experiment at SIN. No evidence of events was observed over the background. A standard axion with mass  $2m_e-20$  MeV is excluded. Lower limit on  $f_{A^0}$  of  $\simeq 10^4$  GeV is given for  $m_{A^0} = 2m_e-20$  MeV.
- <sup>10</sup> DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass  $\sim 1.1$ ,  $\sim 2.1$ , and  $\sim 9$  MeV, lifetimes  $10^{-16}-10^{-15}$  s decaying to  $e^+e^-$  and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with  $\pi^0$  Dalitz decay. DEBOER 89b is a reply which contests the criticism.
- <sup>11</sup> EL-NADI 88 claim the existence of a neutral particle decaying into  $e^+e^-$  with mass  $1.60 \pm 0.59$  MeV, lifetime  $(0.15 \pm 0.01) \times 10^{-14}$  s, which is produced in heavy ion interactions with emulsion nuclei at  $\sim 4$  GeV/c/nucleon.
- <sup>12</sup> FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for  $A^0 \rightarrow \gamma\gamma$ . A standard axion decaying to  $2\gamma$  is excluded except for a region  $x \simeq 1$ . Lower limit on  $f_{A^0}$  of  $10^2-10^3$  GeV is given for  $m_{A^0} = 0.1-1$  MeV.
- <sup>13</sup> BADIER 86 did not find long-lived  $A^0$  in 300 GeV  $\pi^-$  Beam Dump Experiment that decays into  $e^+e^-$  in the mass range  $m_{A^0} = (20-200)$  MeV, which excludes the  $A^0$  decay constant  $f(A^0)$  in the interval (60-600) GeV. See their figure 6 for excluded region on  $f(A^0)$ - $m_{A^0}$  plane.
- <sup>14</sup> BERGSMAN 85 look for  $A^0 \rightarrow 2\gamma$ ,  $e^+e^-$ ,  $\mu^+\mu^-$ . First limit above is for  $m_{A^0} = 1$  MeV; second is for 200 MeV. See their figure 4 for excluded region on  $f_{A^0}$ - $m_{A^0}$  plane, where  $f_{A^0}$  is  $A^0$  decay constant. For Peccei-Quinn PECEI 77  $A^0$ ,  $m_{A^0} < 180$  keV and  $\tau > 0.037$  s. (CL = 90%). For the axion of FAISSNER 81b at 250 keV, BERGSMAN 85 expect 15 events but observe zero.
- <sup>15</sup> FAISSNER 83 observed 19  $1\gamma$  and 12  $2\gamma$  events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.
- <sup>16</sup> FAISSNER 83b extrapolate SIN  $\gamma$  signal to LAMPF  $\nu$  experimental condition. Resulting 370  $\gamma$ 's are not at variance with LAMPF upper limit of 450  $\gamma$ 's. Derived from LAMPF limit that  $[d\sigma(A^0)/d\omega \text{ at } 90^\circ] m_{A^0}/\tau_{A^0} < 14 \times 10^{-35} \text{ cm}^2 \text{ sr}^{-1} \text{ MeV ms}^{-1}$ . See comment on FRANK 83b.
- <sup>17</sup> FRANK 83b stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN- $A^0$  are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450  $\gamma$ 's. See comment on FAISSNER 83b.
- <sup>18</sup> HOFFMAN 83 set CL = 90% limit  $d\sigma/dt \text{ B}(e^+e^-) < 3.5 \times 10^{-32} \text{ cm}^2/\text{GeV}^2$  for  $140 < m_{A^0} < 160$  MeV. Limit assumes  $\tau(A^0) < 10^{-9}$  s.
- <sup>19</sup> FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since  $2\gamma$  peak rate remarkably decreases if iron wall is set in front of the decay region.
- <sup>20</sup> FAISSNER 81 see excess  $\mu e$  events. Suggest axion interactions.
- <sup>21</sup> FAISSNER 81b is SIN 590 MeV proton beam dump. Observed  $14.5 \pm 5.0$  events of  $2\gamma$  decay of long-lived neutral penetrating particle with  $m_{2\gamma} \lesssim 1$  MeV. Axion interpretation with  $\eta$ - $A^0$  mixing gives  $m_{A^0} = 250 \pm 25$  keV,  $\tau_{(2\gamma)} = (7.3 \pm 3.7) \times 10^{-3}$  s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83b, FRANK 83b, and BERGSMAN 85. Also see in the next subsection ALEKSEEV 82b, CAVAGNAC 83, and ANANEV 85.
- <sup>22</sup> KIM 81 analyzed 8 candidates for  $A^0 \rightarrow 2\gamma$  obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is  $(0.86 \sim 5.6) \times 10^{-3}$  s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.
- <sup>23</sup> FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for  $A^0 \rightarrow e^+e^-$  decay. Assuming  $A^0/\pi^0 = 5.5 \times 10^{-7}$ , obtained decay rate limit  $20/(A^0 \text{ mass})$  MeV/s (CL = 90%), which is about  $10^{-7}$  below theory and interpreted as upper limit to  $m_{A^0} < 2m_e$ .
- <sup>24</sup> JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events  $[\sigma(\text{production})\sigma(\text{interaction}) < 7 \times 10^{-68} \text{ cm}^4]$ , CL = 90%. Second limit is from nonobservation of axion decays into  $2\gamma$ 's or  $e^+e^-$ , and for axion mass a few MeV.
- <sup>25</sup> SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.
- <sup>26</sup> BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either  $2\gamma$  or  $e^+e^-$ . No signal found. CL = 90% limits for model parameter(s) are given.
- <sup>27</sup> COTEUS 79 is a beam dump experiment at BNL.

- <sup>28</sup> DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.
- <sup>29</sup> BELLOTTI 78 first value comes from search for  $A^0 \rightarrow e^+e^-$ . Second value comes from search for  $A^0 \rightarrow 2\gamma$ , assuming mass  $< 2m_e$ . For any mass satisfying this, limit is above value  $\times (\text{mass}^{-4})$ . Third value uses data of PL 60B 401 and quotes  $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67} \text{ cm}^4$ .
- <sup>30</sup> BOSETTI 78B quotes  $\sigma(\text{production})\sigma(\text{interaction}) < 2 \times 10^{-67} \text{ cm}^4$ .
- <sup>31</sup> DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.
- <sup>32</sup> MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).
- <sup>33</sup> VYSOTSKI 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

### $A^0$ (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1	CHANG 07		Primakoff or Compton
2	ALTMANN 95	CNTR	Reactor; $A^0 \rightarrow e^+e^-$
3	KETOV 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
4	KOCH 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
5	DATAR 82	CNTR	Light water reactor
6	VUILLEUMIER 81	CNTR	Reactor; $A^0 \rightarrow 2\gamma$

- <sup>1</sup> CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products  $G_{A\gamma\gamma} G_{ANN}$  and  $G_{Aee} G_{ANN}$  for  $m(A^0)$  less than the MeV range.
- <sup>2</sup> ALTMANN 95 looked for  $A^0$  decaying into  $e^+e^-$  from the Bugey 5 nuclear reactor. They obtain an upper limit on the  $A^0$  production rate of  $\omega(A^0)/\omega(\gamma) \times \text{B}(A^0 \rightarrow e^+e^-) < 10^{-16}$  for  $m_{A^0} = 1.5$  MeV at 90% CL. The limit is weaker for heavier  $A^0$ . In the case of a standard axion, this limit excludes a mass in the range  $2m_e < m_{A^0} < 4.8$  MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances  $Z^0$  in the  $(m_{X^0}, f_{X^0})$  plane.
- <sup>3</sup> KETOV 86 searched for  $A^0$  at the Rovno nuclear power plant. They found an upper limit on the  $A^0$  production probability of  $0.8 [100 \text{ keV}/m_{A^0}]^6 \times 10^{-6}$  per fission. In the standard axion model, this corresponds to  $m_{A^0} > 150$  keV. Not valid for  $m_{A^0} \gtrsim 1$  MeV.
- <sup>4</sup> KOCH 86 searched for  $A^0 \rightarrow \gamma\gamma$  at nuclear power reactor Biblis A. They found an upper limit on the  $A^0$  production rate of  $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$  (CL=95%). Standard axion with  $m_{A^0} = 250$  keV gives  $10^{-5}$  for the ratio. Not valid for  $m_{A^0} > 1022$  keV.
- <sup>5</sup> DATAR 82 looked for  $A^0 \rightarrow 2\gamma$  in neutron capture ( $n p \rightarrow d A^0$ ) at Tarapur 500 MW reactor. Sensitive to sum of  $l = 0$  and  $l = 1$  amplitudes. With ZEHNDER 81 [ $(l = 0) - (l = 1)$ ] result, assert nonexistence of standard  $A^0$ .
- <sup>6</sup> VUILLEUMIER 81 is at Grenoble reactor. Set limit  $m_{A^0} < 280$  keV.

### $A^0$ (Axion) and Other Light Boson ( $X^0$ ) Searches in Nuclear Transitions

Limits are for branching ratio.

## Gauge & Higgs Boson Particle Listings

### Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>1</sup> DERBIN 02 looked for the axion emission in an M1 transition in  $^{125m}\text{Te}$  decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.
- <sup>2</sup> DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into  $e^+e^-$  would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.
- <sup>3</sup> TSUNODA 95 looked for axion emission when  $^{252}\text{Cf}$  undergoes a spontaneous fission, with the axion decaying into  $e^+e^-$ . The bound is for  $m_{A^0}=40$  MeV. It improves to  $2.5 \times 10^{-5}$  for  $m_{A^0}=200$  MeV.
- <sup>4</sup> MINOWA 93 studied chain process,  $^{139}\text{Ce} \rightarrow ^{139}\text{La}^*$  by electron capture and M1 transition of  $^{139}\text{La}^*$  to the ground state. It does not assume decay modes of  $A^0$ . The bound applies for  $m_{A^0} < 166$  keV.
- <sup>5</sup> HICKS 92 bound is applicable for  $\tau_{X^0} < 4 \times 10^{-11}$  sec.
- <sup>6</sup> The ASANUMA 90 limit is for the branching fraction of  $X^0$  emission per  $^{241}\text{Am}$   $\alpha$  decay and valid for  $\tau_{X^0} < 3 \times 10^{-11}$  s.
- <sup>7</sup> The DEBOER 90 limit is for the branching ratio  $^8\text{Be}^* (18.15 \text{ MeV}, 1^+) \rightarrow ^8\text{Be} A^0, A^0 \rightarrow e^+e^-$  for the mass range  $m_{A^0} = 4\text{--}15$  MeV.
- <sup>8</sup> The BINI 89 limit is for the branching fraction of  $^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow ^{16}\text{O} X^0, X^0 \rightarrow e^+e^-$  for  $m_X = 1.5\text{--}3.1$  MeV.  $\tau_{X^0} \lesssim 10^{-11}$  s is assumed. The spin-parity of  $X$  is restricted to  $0^+$  or  $1^-$ .
- <sup>9</sup> AVIGNONE 88 looked for the 1115 keV transition  $C^* \rightarrow \text{Cu} A^0$ , either from  $A^0 \rightarrow 2\gamma$  in-flight decay or from the secondary  $A^0$  interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for  $m_{A^0} < 1.1$  MeV.
- <sup>10</sup> DATAR 88 rule out light pseudoscalar particle emission through its decay  $A^0 \rightarrow e^+e^-$  in the mass range 1.02–2.5 MeV and lifetime range  $10^{-13}\text{--}10^{-8}$  s. The above limit is for  $\tau = 5 \times 10^{-13}$  s and  $m = 1.7$  MeV; see the paper for the  $\tau$ - $m$  dependence of the limit.
- <sup>11</sup> The limit is for the branching fraction of  $^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow ^{16}\text{O} X^0, X^0 \rightarrow e^+e^-$  against internal pair conversion for  $m_{X^0} = 1.7$  MeV and  $\tau_{X^0} < 10^{-11}$  s. Similar limits are obtained for  $m_{X^0} = 1.3\text{--}3.2$  MeV. The spin parity of  $X^0$  must be either  $0^+$  or  $1^-$ . The limit at 1.7 MeV is translated into a limit for the  $X^0$ -nucleon coupling constant:  $g_{X^0 NN}^2/4\pi < 2.3 \times 10^{-9}$ .
- <sup>12</sup> The DOEHNER 88 limit is for  $m_{A^0} = 1.7$  MeV,  $\tau(A^0) < 10^{-10}$  s. Limits less than  $10^{-4}$  are obtained for  $m_{A^0} = 1.2\text{--}2.2$  MeV.
- <sup>13</sup> SAVAGE 88 looked for  $A^0$  that decays into  $e^+e^-$  in the decay of the 9.17 MeV  $J^P = 2^+$  state in  $^{14}\text{N}$ , 17.64 MeV state  $J^P = 1^+$  in  $^8\text{Be}$ , and the 18.15 MeV state  $J^P = 1^+$  in  $^8\text{Be}$ . This experiment constrains the isovector coupling of  $A^0$  to hadrons, if  $m_{A^0} = (1.1 \rightarrow 2.6)$  MeV and the isoscalar coupling of  $A^0$  to hadrons, if  $m_{A^0} = (1.1 \rightarrow 2.6)$  MeV. Both limits are valid only if  $\tau(A^0) \lesssim 1 \times 10^{-11}$  s.
- <sup>14</sup> Limits are for  $\Gamma(A^0(1.8 \text{ MeV}))/\Gamma(\pi\text{M1})$ ; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of  $e^+e^-$  pairs. Valid for  $\tau_{A^0} < 2 \times 10^{-11}$  s.  $^6\text{Li}$  isovector decay data strongly disfavor PECCEI 86 model I, whereas the  $^{10}\text{B}$  and  $^{14}\text{N}$  isoscalar decay data strongly reject PECCEI 86 model II and III.
- <sup>15</sup> SAVAGE 86b looked for  $A^0$  that decays into  $e^+e^-$  in the decay of the 9.17 MeV  $J^P = 2^+$  state in  $^{14}\text{N}$ . Limit on the branching fraction is valid if  $\tau_{A^0} \lesssim 1 \times 10^{-11}$  s for  $m_{A^0} = (1.1\text{--}1.7)$  MeV. This experiment constrains the iso-vector coupling of  $A^0$  to hadrons.
- <sup>16</sup> ANANEV 85 with IBR-2 pulsed reactor exclude standard  $A^0$  at CL = 95% masses below 470 keV ( $\text{Li}^*$  decay) and below  $2m_e$  for deuteron\* decay.
- <sup>17</sup> CAVAGNAC 83 at Bugey reactor exclude axion at any  $m_{97}\text{Nb}^*$  decay and axion with  $m_{A^0}$  between 275 and 288 keV (deuteron\* decay).
- <sup>18</sup> ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard  $A^0$  at CL = 95% mass-ranges  $m_{A^0} < 400$  keV ( $\text{Li}^*$  decay) and  $330 \text{ keV} < m_{A^0} < 2.2$  MeV. (deuteron\* decay).
- <sup>19</sup> LEHMANN 82 obtained  $A^0 \rightarrow 2\gamma$  rate  $< 6.2 \times 10^{-5}/\text{s}$  (CL = 95%) excluding  $m_{A^0}$  between 100 and 1000 keV.
- <sup>20</sup> ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check  $A^0$  production. No  $2\gamma$  peak in  $\text{Li}^*$ ,  $\text{Nb}^*$  decay (both single  $p$  transition) nor in  $n$  capture (combined with previous  $\text{Ba}^*$  negative result) rules out standard  $A^0$ . Set limit  $m_{A^0} < 60$  keV for any  $A^0$ .
- <sup>21</sup> ZEHNDER 81 looked for  $\text{Ba}^* \rightarrow A^0 \text{Ba}$  transition with  $A^0 \rightarrow 2\gamma$ . Obtained  $2\gamma$  coincidence rate  $< 2.2 \times 10^{-5}/\text{s}$  (CL = 95%) excluding  $m_{A^0} > 160$  keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.
- <sup>22</sup> CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

#### $A^0$ (Axion) Limits from Its Electron Coupling

Limits are for  $\tau(A^0 \rightarrow e^+e^-)$ .

VALUE (s)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none $4 \times 10^{-16}\text{--}4.5 \times 10^{-12}$	90	<sup>1</sup> BROSS	91	BDMP $eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
		<sup>2</sup> GUO	90	BDMP $eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
		<sup>3</sup> BJORKEN	88	CALO $A \rightarrow e^+e^-$ or $2\gamma$
		<sup>4</sup> BLINOV	88	MD1 $ee \rightarrow eeA^0$ ( $A^0 \rightarrow ee$ )
none $1 \times 10^{-14}\text{--}1 \times 10^{-10}$	90	<sup>5</sup> RIORDAN	87	BDMP $eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
none $1 \times 10^{-14}\text{--}1 \times 10^{-11}$	90	<sup>6</sup> BROWN	86	BDMP $eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
none $6 \times 10^{-14}\text{--}9 \times 10^{-11}$	95	<sup>7</sup> DAVIER	86	BDMP $eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
none $3 \times 10^{-13}\text{--}1 \times 10^{-7}$	90	<sup>8</sup> KONAKA	86	BDMP $eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )

- <sup>1</sup> The listed BROSS 91 limit is for  $m_{A^0} = 1.14$  MeV.  $B(A^0 \rightarrow e^+e^-) = 1$  assumed. Excluded domain in the  $\tau_{A^0}$ - $m_{A^0}$  plane extends up to  $m_{A^0} \approx 7$  MeV (see Fig. 5). Combining with electron  $g$ -2 constraint, axions coupling only to  $e^+e^-$  ruled out for  $m_{A^0} < 4.8$  MeV (90% CL).
- <sup>2</sup> GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with  $g$ -2 constraint, axions coupling only to  $e^+e^-$  are ruled out for  $m_{A^0} < 2.7$  MeV (90% CL).
- <sup>3</sup> BJORKEN 88 reports limits on axion parameters ( $f_A, m_A, \tau_A$ ) for  $m_{A^0} < 200$  MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.
- <sup>4</sup> BLINOV 88 assume zero spin,  $m = 1.8$  MeV and lifetime  $< 5 \times 10^{-12}$  s and find  $\Gamma(A^0 \rightarrow \gamma\gamma)B(A^0 \rightarrow e^+e^-) < 2$  eV (CL=90%).
- <sup>5</sup> Assumes  $A^0\gamma\gamma$  coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for  $m_{A^0} < 15$  MeV.
- <sup>6</sup> Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for  $m_{A^0} < 15$  MeV are shown in their figure 3.
- <sup>7</sup>  $m_{A^0} = 1.8$  MeV assumed. The excluded domain in the  $\tau_{A^0}$ - $m_{A^0}$  plane extends up to  $m_{A^0} \approx 14$  MeV, see their figure 4.
- <sup>8</sup> The limits are obtained from their figure 3. Also given is the limit on the  $A^0\gamma\gamma$ - $A^0e^+e^-$  coupling plane by assuming Primakoff production.

#### Search for $A^0$ (Axion) Resonance in Bhabha Scattering

The limit is for  $\Gamma(A^0)[B(A^0 \rightarrow e^+e^-)]^2$ .

- <sup>1</sup> HALLIN 92 quote limits on lifetime,  $8 \times 10^{-14} \text{--} 5 \times 10^{-13}$  sec depending on mass, assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . They say that TSERTOS 91 overstated their sensitivity by a factor of 3.
- <sup>2</sup> HENDERSON 92c exclude axion with lifetime  $\tau_{A^0} = 1.4 \times 10^{-12} \text{--} 4.0 \times 10^{-10}$  s, assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . HENDERSON 92c also exclude a vector boson with  $\tau = 1.4 \times 10^{-12} \text{--} 6.0 \times 10^{-10}$  s.
- <sup>3</sup> WU 92 quote limits on lifetime  $> 3.3 \times 10^{-13}$  s assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . They say that TSERTOS 89 overestimate the limit by a factor of  $\pi/2$ . WU 92 also quote a bound for vector boson,  $\tau > 8.2 \times 10^{-13}$  s.
- <sup>4</sup> WIDMANN 91 bound applies exclusively to the case  $B(A^0 \rightarrow e^+e^-) = 1$ , since the detection efficiency varies substantially as  $\Gamma(A^0)_{\text{total}}$  changes. See their Fig. 6.
- <sup>5</sup> JUDGE 90 excludes an elastic pseudoscalar  $e^+e^-$  resonance for  $4.5 \times 10^{-13} \text{ s} < \tau(A^0) < 7.5 \times 10^{-12} \text{ s}$  (95% CL) at  $m_{A^0} = 1.832$  MeV. Comparable limits can be set for  $m_{A^0} = 1.776\text{--}1.856$  MeV.
- <sup>6</sup> See also TSERTOS 88b in references.
- <sup>7</sup> The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88b, footnote 3.
- <sup>8</sup> VANKLINKEN 88 looked for relatively long-lived resonance ( $\tau = 10^{-10}\text{--}10^{-12}$  s). The sensitivity is not sufficient to exclude such a narrow resonance.
- <sup>9</sup> MAIER 87 obtained limits  $R\Gamma \lesssim 60$  eV (100 eV) at  $m_{A^0} \approx 1.64$  MeV (1.83 MeV) for energy resolution  $\Delta E_{\text{cm}} \approx 3$  keV, where  $R$  is the resonance cross section normalized to that of Bhabha scattering, and  $\Gamma = \Gamma_{e^+e^-}^2/\Gamma_{\text{total}}$ . For a discussion implying that  $\Delta E_{\text{cm}} \approx 10$  keV, see TSERTOS 89.
- <sup>10</sup> VONWIMMERSPERG 87 measured Bhabha scattering for  $E_{\text{cm}} = 1.37\text{--}1.86$  MeV and found a possible peak at 1.73 with  $\int \sigma dE_{\text{cm}} = 14.5 \pm 6.8$  keV-b. For a comment and a reply, see VANKLINKEN 88b and VONWIMMERSPERG 88. Also see CONNELL 88.

#### Search for $A^0$ (Axion) Resonance in $e^+e^- \rightarrow \gamma\gamma$

The limit is for  $\Gamma(A^0 \rightarrow e^+e^-)\Gamma(A^0 \rightarrow \gamma\gamma)/\Gamma_{\text{total}}$

VALUE ( $10^{-3}$ eV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>1</sup> VO 94 looked for  $X^0 \rightarrow \gamma\gamma\gamma$  decaying at rest. The precise limits depend on  $m_{X^0}$ . See Fig. 2(b) in paper.
- <sup>2</sup> VO 94 looked for  $X^0 \rightarrow \gamma\gamma\gamma$  decaying in flight.
- <sup>3</sup> SKALSEY 92 also give limits 4.3 for  $m_{X^0} = 1.54$  and 7.5 for 1.64 MeV. The spin of  $X^0$  is assumed to be one.

### Light Boson ( $X^0$ ) Search in Nonresonant $e^+e^-$ Annihilation at Rest

Limits are for the ratio of  $n\gamma + X^0$  production relative to  $\gamma\gamma$ .

VALUE (units $10^{-6}$ )	CL%	DOCUMENT ID	TECN	COMMENT
• • •		We do not use the following data for averages, fits, limits, etc. • • •		
< 4.2	90	<sup>1</sup> MITSUI	96	CNTR $\gamma X^0$
< 4	68	<sup>2</sup> SKALSEY	95	CNTR $\gamma X^0$
<40	68	<sup>3</sup> SKALSEY	95	RVUE $\gamma X^0$
< 0.18	90	<sup>4</sup> ADACHI	94	CNTR $\gamma\gamma X^0, X^0 \rightarrow \gamma\gamma$
< 0.26	90	<sup>5</sup> ADACHI	94	CNTR $\gamma\gamma X^0, X^0 \rightarrow \gamma\gamma$
< 0.33	90	<sup>6</sup> ADACHI	94	CNTR $\gamma X^0, X^0 \rightarrow \gamma\gamma\gamma$

- <sup>1</sup> MITSUI 96 looked for a monochromatic  $\gamma$ . The bound applies for a vector  $X^0$  with  $C=-1$  and  $m_{X^0} < 200$  keV. They derive an upper bound on  $eeX^0$  coupling and hence on the branching ratio  $B(o\text{-Ps} \rightarrow \gamma\gamma X^0) < 6.2 \times 10^{-6}$ . The bounds weaken for heavier  $X^0$ .
- <sup>2</sup> SKALSEY 95 looked for a monochromatic  $\gamma$  without an accompanying  $\gamma$  in  $e^+e^-$  annihilation. The bound applies for scalar and vector  $X^0$  with  $C=-1$  and  $m_{X^0} = 100\text{--}1000$  keV.
- <sup>3</sup> SKALSEY 95 reinterpreted the bound on  $\gamma A^0$  decay of  $o\text{-Ps}$  by ASAI 91 where 3% of delayed annihilations are not from  $^3S_1$  states. The bound applies for scalar and vector  $X^0$  with  $C=-1$  and  $m_{X^0} = 0\text{--}800$  keV.
- <sup>4</sup> ADACHI 94 looked for a peak in the  $\gamma\gamma$  invariant mass distribution in  $\gamma\gamma\gamma\gamma$  production from  $e^+e^-$  annihilation. The bound applies for  $m_{X^0} = 70\text{--}800$  keV.
- <sup>5</sup> ADACHI 94 looked for a peak in the missing-mass mass distribution in  $\gamma\gamma$  channel, using  $\gamma\gamma\gamma\gamma$  production from  $e^+e^-$  annihilation. The bound applies for  $m_{X^0} < 800$  keV.
- <sup>6</sup> ADACHI 94 looked for a peak in the missing mass distribution in  $\gamma\gamma\gamma$  channel, using  $\gamma\gamma\gamma\gamma$  production from  $e^+e^-$  annihilation. The bound applies for  $m_{X^0} = 200\text{--}900$  keV.

### Searches for Goldstone Bosons ( $X^0$ )

(Including Horizontal Bosons and Majorons.) Limits are for branching ratios.

		<sup>17</sup> DICUS	83	COSM $\nu(\text{hvy}) \rightarrow \nu(\text{light}) X^0$

- <sup>1</sup> BAYES 15 limits are the average over  $m_{X^0} = 13\text{--}80$  MeV for the isotropic decay distribution of positrons. See their Fig. 4 and Table II for the mass-dependent limits as well as the dependence on the decay anisotropy. In particular, they find a limit  $< 58 \times 10^{-6}$  at 90% CL for massless familons and for the same asymmetry as normal moon decay, a case not covered by JODIDIO 86.
- <sup>2</sup> LATTANZI 13 use WMAP 9 year data as well as X-ray and  $\gamma$ -ray observations to derive limits on decaying majoron dark matter. A limit on the decay width  $\Gamma(X^0 \rightarrow \nu\bar{\nu}) < 6.4 \times 10^{-19} \text{ s}^{-1}$  at 95% CL is found if majorons make up all of the dark matter.
- <sup>3</sup> LESSA 07 consider decays of the form Meson  $\rightarrow \ell\nu\text{Majoron}$  and  $\ell \rightarrow \ell'\nu\bar{\nu}\text{Majoron}$  and use existing data to derive limits on the neutrino-Majoron Yukawa couplings  $g_{\alpha\beta}$  ( $\alpha, \beta = e, \mu, \tau$ ). Their best limits are  $|g_{e\alpha}|^2 < 5.5 \times 10^{-6}$ ,  $|g_{\mu\alpha}|^2 < 4.5 \times 10^{-5}$ ,  $|g_{\tau\alpha}|^2 < 5.5 \times 10^{-2}$  at CL = 90%.
- <sup>4</sup> DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay  $Z \rightarrow H^0 A^0 \rightarrow X^0 X^0 X^0 X^0$  and  $e^+e^- \rightarrow Z H^0$  with  $H^0 \rightarrow X^0 X^0$ .
- <sup>5</sup> BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit  $x_e^2 < 2 \times 10^{-4}$  (95%CL) is found for the effective anomalous magneton parametrized as  $x_e(G_F/8\pi\sqrt{2})^{1/2}$ .
- <sup>6</sup> ALBRECHT 90E limits are for  $B(\tau \rightarrow \ell X^0)/B(\tau \rightarrow \ell\nu\bar{\nu})$ . Valid for  $m_{X^0} < 100$  MeV. The limits rise to 7.1% (for  $\mu$ ), 5.0% (for  $e$ ) for  $m_{X^0} = 500$  MeV.
- <sup>7</sup> ATIYA 90 limit is for  $m_{X^0} = 0$ . The limit  $B < 1 \times 10^{-8}$  holds for  $m_{X^0} < 95$  MeV.
- For the reduction of the limit due to finite lifetime of  $X^0$ , see their Fig. 3.
- <sup>8</sup> BOLTON 88 limit corresponds to  $F > 3.1 \times 10^9$  GeV, which does not depend on the chirality property of the coupling.
- <sup>9</sup> CHANDA 88 find  $v_T < 10$  MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and  $v_S > 5.8 \times 10^6$  GeV in the singlet Majoron model.
- <sup>10</sup> CHOI 88 used the observed neutrino flux from the supernova SN1987A to exclude the neutrino Majoron Yukawa coupling  $h$  in the range  $2 \times 10^{-5} < h < 3 \times 10^{-4}$  for the interaction  $L_{\text{int}} = \frac{1}{2}ih\bar{\psi}_\nu\gamma_5\psi_\nu\phi_X$ . For several families of neutrinos, the limit applies for  $(\Sigma h_i^4)^{1/4}$ .
- <sup>11</sup> PICCIOTTO 88 limit applies when  $m_{X^0} < 55$  MeV and  $\tau_{X^0} > 2\text{ns}$ , and it decreases to  $4 \times 10^{-7}$  at  $m_{X^0} = 125$  MeV, beyond which no limit is obtained.
- <sup>12</sup> GOLDMAN 87 limit corresponds to  $F > 2.9 \times 10^9$  GeV for the family symmetry breaking scale from the Lagrangian  $L_{\text{int}} = (1/F)\bar{\psi}_\mu\gamma^\mu(a + b\gamma_5)\psi_e\partial_\mu\phi_X$  with  $a^2 + b^2 = 1$ . This is not as sensitive as the limit  $F > 9.9 \times 10^9$  GeV derived from the search for  $\mu^+ \rightarrow e^+X^0$  by JODIDIO 86, but does not depend on the chirality property of the coupling.
- <sup>13</sup> Limits are for  $\Gamma(\mu \rightarrow eX^0)/\Gamma(\mu \rightarrow e\nu\bar{\nu})$ . Valid when  $m_{X^0} = 0\text{--}93.4, 98.1\text{--}103.5$  MeV.
- <sup>14</sup> EICHLER 86 looked for  $\mu^+ \rightarrow e^+X^0$  followed by  $X^0 \rightarrow e^+e^-$ . Limits on the branching fraction depend on the mass and lifetime of  $X^0$ . The quoted limits are valid when  $\tau_{X^0} \lesssim 3. \times 10^{-10} \text{ s}$  if the decays are kinematically allowed.
- <sup>15</sup> JODIDIO 86 corresponds to  $F > 9.9 \times 10^9$  GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian  $L_{\text{int}} = (1/F)\bar{\psi}_\mu\gamma^\mu\psi_e\partial^\mu\phi_X$ .
- <sup>16</sup> BALTRUSAITIS 85 search for light Goldstone boson( $X^0$ ) of broken  $U(1)$ . CL = 95% limits are  $B(\tau \rightarrow \mu^+X^0)/B(\tau \rightarrow \mu^+\nu\bar{\nu}) < 0.125$  and  $B(\tau \rightarrow e^+X^0)/B(\tau \rightarrow e^+\nu\bar{\nu}) < 0.04$ . Inferred limit for the symmetry breaking scale is  $m > 3000$  TeV.
- <sup>17</sup> The primordial heavy neutrino must decay into  $\nu$  and familon,  $f_A$ , early so that the red-shifted decay products are below critical density, see their table. In addition,  $K \rightarrow \pi f_A$  and  $\mu \rightarrow e f_A$  are unseen. Combining these excludes  $m_{\text{heavy}\nu}$  between  $5 \times 10^{-5}$  and  $5 \times 10^{-4}$  MeV ( $\mu$  decay) and  $m_{\text{heavy}\nu}$  between  $5 \times 10^{-5}$  and 0.1 MeV ( $K$ -decay).

### Majoron Searches in Neutrinoless Double $\beta$ Decay

Limits are for the half-life of neutrinoless  $\beta\beta$  decay with a Majoron emission.

No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported. Also see the reviews ZUBER 98 and FAESSLER 98B.

- 1 BERNATOWICZ 92 studied double- $\beta$  decays of  $^{128}\text{Te}$  and  $^{130}\text{Te}$ , and found the ratio  $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$  in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of  $^{128}\text{Te}$  of  $(7.7 \pm 0.4) \times 10^{24}$  year. We calculated 90% CL limit as  $(7.7-1.28 \times 0.4=7.2) \times 10^{24}$ .
- 2 AGOSTINI 15A analyze a 20.3 kg yr of data set of the GERDA calorimeter to determine  $g_{\nu\chi} < 3.4-8.7 \times 10^{-5}$  on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- 3 ARNOLD 15 use the NEMO-3 tracking calorimeter with 3.43 kg yr exposure to determine the limit on Majoron emission. The limit corresponds to  $g_{\nu\chi} < 1.6-3.0 \times 10^{-4}$ . The spread reflects different nuclear matrix elements. Supersedes ARNOLD 06.
- 4 ALBERT 14A utilize 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a limit on the  $g_{\nu\chi} < 0.8-1.7 \times 10^{-5}$  on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- 5 GANDO 12 use the KamLAND-Zen detector to obtain the limit on the  $0\nu\chi$  decay with Majoron emission. It implies that the coupling constant  $g_{\nu\chi} < 0.8-1.6 \times 10^{-5}$  depending on the nuclear matrix elements used.
- 6 ARNOLD 11 use the NEMO-3 detector to obtain the reported limit on Majoron emission. It implies that the coupling constant  $g_{\nu\chi} < 0.6-1.6 \times 10^{-4}$  depending on the nuclear matrix element used. Supersedes ARNOLDI 03.
- 7 ARGYRIADES 10 use the NEMO-3 tracking detector and  $^{96}\text{Zr}$  to derive the reported limit. No limit for the Majoron electron coupling is given.
- 8 ARGYRIADES 09 use  $^{150}\text{Nd}$  data taken with the NEMO-3 tracking detector. The reported limit corresponds to  $\langle g_{\nu\chi} \rangle < 1.7-3.0 \times 10^{-4}$  using a range of nuclear matrix elements that include the effect of nuclear deformation.
- 9 ARNOLD 06 use  $^{100}\text{Mo}$  data taken with the NEMO-3 tracking detector. The reported limit corresponds to  $\langle g_{\nu\chi} \rangle < (0.4-1.8) \times 10^{-4}$  using a range of matrix element calculations. Superseded by ARNOLD 15.
- 10 NEMO-3 tracking calorimeter is used in ARNOLD 06. Reported half-life limit for  $^{82}\text{Se}$  corresponds to  $\langle g_{\nu\chi} \rangle < (0.66-1.9) \times 10^{-4}$  using a range of matrix element calculations. Supersedes ARNOLD 04.
- 11 ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to  $\langle g_{\nu\chi} \rangle < (0.5-0.9)10^{-4}$  using the matrix elements of SIMKOVIĆ 99, STOICA 01 and CIVITARESE 03. Supersedes by ARNOLD 06.
- 12 ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to  $\langle g_{\nu\chi} \rangle < (0.7-1.6)10^{-4}$  using the matrix elements of SIMKOVIĆ 99, STOICA 01 and CIVITARESE 03.
- 13 Supersedes ALESSANDRELLO 00. Array of  $\text{TeO}_2$  crystals in high resolution cryogenic calorimeter. Some enriched in  $^{130}\text{Te}$ . Derive  $\langle g_{\nu\chi} \rangle < 17-33 \times 10^{-5}$  depending on matrix element.
- 14 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.
- 15 Limit for the  $0\nu\chi$  decay with Majoron emission of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators.  $\langle g_{\nu\chi} \rangle < 4.6-8.1 \times 10^{-5}$  depending on the matrix element. Supersedes DANEVICH 00.
- 16 Limit for the  $0\nu 2\chi$  decay of  $^{116}\text{Cd}$ . Supersedes DANEVICH 00.
- 17 BERNABEI 02p obtain limit for  $0\nu\chi$  decay with Majoron emission of  $^{136}\text{Xe}$  using liquid Xe scintillation detector. They derive  $\langle g_{\nu\chi} \rangle < 2.0-3.0 \times 10^{-5}$  with several nuclear matrix elements.
- 18 Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the  $0\nu\chi$  decay by means of tracking calorimeter ELEGANT V. Considering various matrix element calculations, a range of limits for the Majoron-neutrino coupling is given:  $\langle g_{\nu\chi} \rangle < (6.3-360) \times 10^{-5}$ .
- 19 ASHITKOV 01 result for  $0\nu\chi$  of  $^{100}\text{Mo}$  is less stringent than ARNOLD 00.
- 20 DANEVICH 01 obtain limit for the  $0\nu\chi$  decay with Majoron emission of  $^{160}\text{Gd}$  using  $\text{Gd}_2\text{SiO}_5:\text{Ce}$  crystal scintillators.
- 21 DANEVICH 01 obtain limit for the  $0\nu 2\chi$  decay with 2 Majoron emission of  $^{160}\text{Gd}$ .
- 22 ARNOLD 00 reports limit for the  $0\nu\chi$  decay with Majoron emission derived from tracking calorimeter NEMO 2. Using  $^{82}\text{Se}$  source:  $\langle g_{\nu\chi} \rangle < 1.6 \times 10^{-4}$ . Matrix element from GUENTHER 96.
- 23 Using  $^{96}\text{Zr}$  source:  $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$ . Matrix element from ARNOLD 99.
- 24 ARNOLD 00 reports limit for the  $0\nu 2\chi$  decay with two Majoron emission derived from tracking calorimeter NEMO 2.
- 25 ARNOLD 98 determine the limit for  $0\nu\chi$  decay with Majoron emission of  $^{82}\text{Se}$  using the NEMO-2 tracking detector. They derive  $\langle g_{\nu\chi} \rangle < 2.3-4.3 \times 10^{-4}$  with several nuclear matrix elements.
- 26 LUESCHER 98 report a limit for the  $0\nu$  decay with Majoron emission of  $^{136}\text{Xe}$  using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on  $\langle g_{\nu\chi} \rangle$  of  $2.0 \times 10^{-4}$ .
- 27 See Table I in GUENTHER 96 for limits on the Majoron coupling in different models.

### Invisible $A^0$ (Axion) MASS LIMITS from Astrophysics and Cosmology

$v_1 = v_2$  is usually assumed ( $v_i$  = vacuum expectation values). For a review of these limits, see RAFFELT 91 and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

- 1 ARCHIDIACONO 13A is analogous to HANNESTAD 05A. The limit is based on the CMB temperature power spectrum of the Planck data, the CMB polarization from the WMAP 9-yr data, the matter power spectrum from SDSS-DR7, and the local Hubble parameter measurement by the Carnegie Hubble program.
- 2 CADAMURO 11 use the deuterium abundance to show that the  $m_{A^0}$  range 0.7 eV – 300 keV is excluded for axions, complementing HANNESTAD 10.
- 3 DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of  $^{169}\text{Tm}$ , constraining the axion-electron  $\times$  axion-nucleon couplings.
- 4 ANDRIAMONJE 10 search for solar axions produced from  $^7\text{Li}$  (478 keV) and  $\text{D}(p,\gamma)^3\text{He}$  (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for  $m_A < 100$  eV.
- 5 This is an update of HANNESTAD 08 including 7 years of WMAP data.
- 6 ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of  $^{57}\text{Fe}$ . They show limits on the axion-nucleon  $\times$  axion-photon coupling assuming  $m_A < 0.03$  eV.
- 7 DERBIN 09A look for Primakoff-produced solar axions in the resonant excitation of  $^{169}\text{Tm}$ , constraining the axion-photon  $\times$  axion-nucleon couplings.
- 8 KEKEZ 09 look at axio-electric effect of solar axions in HPGe detectors. The one-loop axion-electron coupling for hadronic axions is used.
- 9 This is an update of HANNESTAD 07 including 5 years of WMAP data.
- 10 This is an update of HANNESTAD 05A with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman- $\alpha$  data are left out, in contrast to HANNESTAD 05A and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.
- 11 MELCHIORRI 07A is analogous to HANNESTAD 05A, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- neutrino hot dark matter component. Leaving out Lyman- $\alpha$  data, a conservative limit is 1.4 eV.
- <sup>12</sup> HANNESTAD 05A puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large scale structure, Lyman  $\alpha$ , and the prior Hubble parameter from HST Key Project. A  $\chi^2$  statistic is used. Neutrinos are assumed not to contribute to hot dark matter.
- <sup>13</sup> MOROI 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent  $g_{A\gamma}$  is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.
- <sup>14</sup> BORISOV 97 bound is on the axion-electron coupling  $g_{ae} < 1 \times 10^{-13}$  from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.
- <sup>15</sup> KACHELRIESS 97 bound is on the axion-electron coupling  $g_{ae} < 1 \times 10^{-10}$  from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit,  $g_{ae} < 9 \times 10^{-13}$  which is strongly dependent on the strength of the magnetic field in white dwarfs.
- <sup>16</sup> KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.
- <sup>17</sup> RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).
- <sup>18</sup> ALTHERR 94 bound is on the axion-electron coupling  $g_{ae} < 1.5 \times 10^{-13}$ , from energy loss via axion emission.
- <sup>19</sup> CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in  $z=m_u/m_d$  (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window  $f_A=3 \times 10^5 - 3 \times 10^6$  GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.
- <sup>20</sup> BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2 $\gamma$  decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.
- <sup>21</sup> KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of axion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.
- <sup>22</sup> RAFFELT 91B argue that previous SN1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.
- <sup>23</sup> RESSELL 91 uses absence of any intracluster line emission to set limit.
- <sup>24</sup> ENGEL 90 rule out  $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$ , which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to  $2.5 \times 10^{-3} \text{ eV} \lesssim m_{A^0} \lesssim 2.5 \times 10^4 \text{ eV}$ . The constraint is loose in the middle of the range, i.e. for  $g_{AN} \sim 10^{-6}$ .
- <sup>25</sup> RAFFELT 90D is a re-analysis of DEARBORN 86.
- <sup>26</sup> The region  $m_{A^0} \gtrsim 2 \text{ eV}$  is also allowed.
- <sup>27</sup> ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.
- <sup>28</sup> MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.
- <sup>29</sup> RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium-burning stars  $\epsilon < 100 \text{ erg g}^{-1} \text{ s}^{-1}$ , which gives a firmer basis for the axion limits based on red giant cooling.
- <sup>30</sup> RAFFELT 87 also gives a limit  $g_{A\gamma} < 1 \times 10^{-10} \text{ GeV}^{-1}$ .
- <sup>31</sup> DEARBORN 86 also gives a limit  $g_{A\gamma} < 1.4 \times 10^{-11} \text{ GeV}^{-1}$ .
- <sup>32</sup> RAFFELT 86 gives a limit  $g_{A\gamma} < 1.1 \times 10^{-10} \text{ GeV}^{-1}$  from red giants and  $< 2.4 \times 10^{-9} \text{ GeV}^{-1}$  from the sun.
- <sup>33</sup> KAPLAN 85 says  $m_{A^0} < 23 \text{ eV}$  is allowed for a special choice of model parameters.
- <sup>34</sup> FUKUGITA 82 gives a limit  $g_{A\gamma} < 2.3 \times 10^{-10} \text{ GeV}^{-1}$ .

### Search for Relic Invisible Axions

Limits are for  $[G_{A\gamma\gamma}/m_{A^0}]^2 \rho_A$  where  $G_{A\gamma\gamma}$  denotes the axion two-photon coupling,

$$L_{\text{int}} = -\frac{G_{A\gamma\gamma}}{4} F_{\mu\nu} \tilde{F}^{\mu\nu} = G_{A\gamma\gamma} \mathbf{E} \cdot \mathbf{B}, \text{ and } \rho_A \text{ is the axion energy density near the earth.}$$

$< 2.9 \times 10^{-43}$	90	3 ASZTALOS	10	ADMX $m_{A^0} = 3.34\text{--}3.53 \times 10^{-6} \text{ eV}$
$< 1.9 \times 10^{-43}$	97.7	4 DUFFY	06	ADMX $m_{A^0} = 1.98\text{--}2.17 \times 10^{-6} \text{ eV}$
$< 5.5 \times 10^{-43}$	90	5 ASZTALOS	04	ADMX $m_{A^0} = 1.9\text{--}3.3 \times 10^{-6} \text{ eV}$
		6 KIM	98	THEO
$< 2 \times 10^{-41}$		7 HAGMANN	90	CNTR $m_{A^0} = (5.4\text{--}5.9) \times 10^{-6} \text{ eV}$
$< 1.3 \times 10^{-42}$	95	8 WUENSCH	89	CNTR $m_{A^0} = (4.5\text{--}10.2) \times 10^{-6} \text{ eV}$
$< 2 \times 10^{-41}$	95	8 WUENSCH	89	CNTR $m_{A^0} = (11.3\text{--}16.3) \times 10^{-6} \text{ eV}$

<sup>1</sup> BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review B70 180503 (2004)] is interpreted in terms of subdominant dark matter axions with  $m_{A^0} = 0.11 \text{ MeV}$ .

<sup>2</sup> HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.

<sup>3</sup> ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the  $m_{A^0}$  dependence of the limit.

<sup>4</sup> DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.

<sup>5</sup> ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than

0.45  $\text{GeV}/\text{cm}^3$  in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.

<sup>6</sup> KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of  $G_{A\gamma\gamma}$  and hence the bound from relic axion search.

<sup>7</sup> HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

<sup>8</sup> WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with  $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2 \times 10^{-14} \text{ MeV}^{-4}$  (the three generation DFSZ model) and  $\rho_A = 300 \text{ MeV}/\text{cm}^3$  that makes up galactic halos gives  $(G_{A\gamma\gamma}/m_{A^0})^2 \rho_A = 4 \times 10^{-44}$ . Note that our definition of  $G_{A\gamma\gamma}$  is  $(1/4\pi)$  smaller than that of WUENSCH 89.

### Invisible $A^0$ (Axion) Limits from Photon Coupling

Limits are for the modulus of the axion-two-photon coupling  $G_{A\gamma\gamma}$  defined by

$L = -G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}$ . For scalars  $S^0$  the limit is on the coupling constant in

$L = G_{S\gamma\gamma} \phi_S (\mathbf{E}^2 - \mathbf{B}^2)$ . The relation between  $G_{A\gamma\gamma}$  and  $m_{A^0}$  is not used unless stated otherwise, i.e., many of these bounds apply to low-mass axion-like particles (ALPs), not to QCD axions.

<sup>1</sup> ANASTASSOPOULOS 15 search for solar chameleons with CAST and derived limits on the chameleon coupling to photons and matter. See their Fig. 12 for the exclusion region.

<sup>2</sup> ARIK 15 is analogous to ARIK 09, and search for solar axions for  $m_{A^0}$  around 0.2 and 0.4 eV. See their Figs. 1 and 3 for the mass-dependent limits.

See key on page 601

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>3</sup> Based on OSQAR photon regeneration experiment. See their Fig. 6 for mass-dependent limits on scalar and pseudoscalar bosons.
- <sup>4</sup> BRAX 15 derived limits on conformal and disformal couplings of a scalar to photons by searching for a chaotic absorption pattern in the X-ray and UV bands of the Hydra A galaxy cluster and a BL lac object, respectively. See their Fig. 8.
- <sup>5</sup> HASEBE 15 look for an axion via a four-wave mixing process at quasi-parallel colliding laser beams. They also derived limits on a scalar coupling to photons  $G_{S\gamma\gamma} < 2.62 \times 10^{-4} \text{ GeV}^{-1}$  at  $m_{S^0} = 0.15 \text{ eV}$ . See their Figs. 11 and 12 for mass-dependent limits.
- <sup>6</sup> MILLEA 15 is similar to CADAMURO 12, including the Planck data and the latest inferences of primordial deuterium abundance. See their Fig. 3 for mass-dependent limits.
- <sup>7</sup> VANTILBURG 15 look for harmonic variations in the dysprosium transition frequency data, induced by coherent oscillations of the fine-structure constant due to dilaton-like dark matter, and set the limits,  $G_{S\gamma\gamma} < 6 \times 10^{-27} \text{ GeV}^{-1}$  at  $m_{S^0} = 6 \times 10^{-23} \text{ eV}$ . See their Fig. 4 for mass-dependent limits between  $1 \times 10^{-24} < m_{S^0} < 1 \times 10^{-15} \text{ eV}$ .
- <sup>8</sup> VINOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations. See their Fig. 9.
- <sup>9</sup> ARIK 14 is similar to ARIK 11. See their Fig. 2 for mass-dependent limits.
- <sup>10</sup> AYALA 14 derived the limit from the helium-burning lifetime of horizontal-branch stars based on number counts in globular clusters.
- <sup>11</sup> DELLA-VALLE 14 use the new PVLAS apparatus to set a limit on vacuum magnetic birefringence induced by axion-like particles. See their Fig. 6 for the mass-dependent limits.
- <sup>12</sup> EULLI 14 set limits on a product of primordial magnetic field and the axion mass using CMB distortion induced by resonant axion production from CMB photons. See their Fig. 1 for limits applying specifically to the DFSZ and KSVZ axion models.
- <sup>13</sup> PUGNAT 14 is analogous to EHRET 10. See their Fig. 5 for mass-dependent limits on scalar and pseudoscalar bosons.
- <sup>14</sup> REESMAN 14 derive limits by requiring effects of axion-photon interconversion on gamma-ray spectra from distant blazars to be no larger than errors in the best-fit optical depth based on a certain extragalactic background light model. See their Fig. 5 for mass-dependent limits.
- <sup>15</sup> ABRAMOWSKI 13a look for irregularities in the energy spectrum of the BL Lac object PKS 2155-304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.
- <sup>16</sup> ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.
- <sup>17</sup> BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.
- <sup>18</sup> FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7-12 solar masses.
- <sup>19</sup> MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy  $\gamma$ -rays with respect to predictions based on extragalactic background light models. See their Fig. 4 for mass-dependent lower limits for various magnetic field configurations.
- <sup>20</sup> CADAMURO 12 derived cosmological limits on  $G_{A\gamma\gamma}$  for axion-like particles. See their Fig. 1 for mass-dependent limits.
- <sup>21</sup> PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.
- <sup>22</sup> ARIK 11 search for solar axions using  $^3\text{He}$  buffer gas in CAST, continuing from the  $^4\text{He}$  version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.
- <sup>23</sup> ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.
- <sup>24</sup> AHMED 09a is analogous to AVIGNONE 98.
- <sup>25</sup> ARIK 09 is the  $^4\text{He}$  filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.
- <sup>26</sup> CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at  $3\sigma$  the range  $2.6 \times 10^{-7} \text{ GeV}^{-1} < G_{A\gamma\gamma} < 4.2 \times 10^{-6} \text{ GeV}^{-1}$  for vacuum  $m_{A^0}$  roughly below  $6 \text{ MeV}$  for density scaling index exceeding 0.8.
- <sup>27</sup> GONDOLO 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.
- <sup>28</sup> LIPSS photon regeneration experiment, assuming scalar particle  $S^0$ . See Fig. 4 for mass-dependent limits.
- <sup>29</sup> CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
- <sup>30</sup> FOUCHÉ 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.
- <sup>31</sup> INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.
- <sup>32</sup> ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.
- <sup>33</sup> ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
- <sup>34</sup> ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
- <sup>35</sup> ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
- <sup>36</sup> INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X-ray.
- <sup>37</sup> MORALES 02b looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
- <sup>38</sup> BERNABE 01b looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.
- <sup>39</sup> ASTIER 00b looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
- <sup>40</sup> MASSO 00 studied limits on axion-photon coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound  $g_{p\gamma}^2/4\pi < 1.7 \times 10^{-9}$  for the coupling  $g_{p\gamma}^2 P \phi A$ .

- <sup>41</sup> AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
- <sup>42</sup> Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.
- <sup>43</sup> Experiment based on proposal by MAIANI 86.
- <sup>44</sup> Experiment based on proposal by VANBIBBER 87.
- <sup>45</sup> LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.
- <sup>46</sup> RUOSO 92 experiment is based on the proposal by VANBIBBER 87.
- <sup>47</sup> SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to  $m_{A^0} = 4 \times 10^{-3}$  where  $G_{A\gamma\gamma} < 1 \times 10^{-4} \text{ GeV}^{-1}$ .

### Limit on Invisible $A^0$ (Axion) Electron Coupling

The limit is for  $G_{Aee}\partial_\mu\phi A\bar{\psi}\gamma^\mu\psi$  in  $\text{GeV}^{-1}$ , or equivalently, the dipole-dipole potential  $\frac{G_{Aee}^2}{4\pi}((\sigma_1 \cdot \sigma_2) - 3(\sigma_1 \cdot \mathbf{n})(\sigma_2 \cdot \mathbf{n}))/r^3$  where  $\mathbf{n}=\mathbf{r}/r$ .

- <sup>1</sup> ABE 14F set limits on the axioelectric effect in the XMAS detector assuming the pseudoscalar constitutes all the local dark matter. See their Fig. 3 for limits between  $m_{A^0} = 40-120 \text{ keV}$ .
- <sup>2</sup> APRILE 14B look for solar axions using the XENON100 detector.
- <sup>3</sup> APRILE 14B is analogous to AHMED 09A. See their Fig. 7 for limits between  $1 \text{ keV} < m_{A^0} < 35 \text{ keV}$ .
- <sup>4</sup> DERBIN 14 is an update of DERBIN 13 with a BGO scintillating bolometer. See their Fig. 3 for mass-dependent limits.
- <sup>5</sup> MILLER-BERTOLAMI 14 studied the impact of axion emission on white dwarf cooling in a self-consistent way.
- <sup>6</sup> ABE 13D is analogous to DERBIN 12, using the XMAS detector.
- <sup>7</sup> ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between  $3 \text{ keV} < m_{A^0} < 100 \text{ keV}$ .
- <sup>8</sup> ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.
- <sup>9</sup> BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit,  $G_{Aee} \cdot G_{A\gamma\gamma} < 7.9 \times 10^{-20} \text{ GeV}^{-2}$  at 95%CL.
- <sup>10</sup> DERBIN 13 looked for 5.5 MeV solar axions produced in  $p d \rightarrow ^3\text{He} A^0$  in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.
- <sup>11</sup> HECKEL 13 studied the influence of 2 or 4 stationary sources each containing  $6.0 \times 10^{24}$  polarized electrons, on a rotating torsion pendulum containing  $9.8 \times 10^{24}$  polarized electrons. See their Fig. 4 for mass-dependent limits.
- <sup>12</sup> VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.
- <sup>13</sup> CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with  $G_{Aee} \simeq 5 \times 10^{-10}$ .
- <sup>14</sup> DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.
- <sup>15</sup> AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.
- <sup>16</sup> AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.
- <sup>17</sup> DAVOUDIASEL 09 use geophysical constraints on Earth cooling by axion emission.
- <sup>18</sup> These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.
- <sup>19</sup> These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them.
- <sup>20</sup> WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

<1.45 $\times 10^2$	95	14 BELLINI 08	CNTR	Solar axion
		15 ADELBERGER 07		Test of Newton's law

- <sup>1</sup> GAVRILYUK 15 look for solar axions emitted by the M1 transition of  $^{83}\text{Kr}$  (9.4 keV). The mass bound assumes  $m_U/m_d = 0.56$  and  $S = 0.5$ .
- <sup>2</sup> KLIMCHITSKAYA 15 use the measurement of differential forces between a test mass and rotating source masses of Au and Si to constrain the force due to two-axion exchange for  $1.7 \times 10^{-3} < m_{A^0} < 0.9$  eV. See their Figs. 1 and 2 for mass dependent limits.
- <sup>3</sup> BEZERRA 14 use the measurement of the thermal Casimir-Polder force between a Bose-Einstein condensate of  $^{87}\text{Rb}$  atoms and a  $\text{SiO}_2$  plate to constrain the force mediated by exchange of two pseudoscalars for  $0.1 \text{ meV} < m_{A^0} < 0.3$  eV. See their Fig. 2 for the mass-dependent limit on pseudoscalar coupling to nucleons.
- <sup>4</sup> BEZERRA 14A is analogous to BEZERRA 14. They use the measurement of the Casimir pressure between two Au-coated plates to constrain pseudoscalar coupling to nucleons for  $1 \times 10^{-3} \text{ eV} < m_{A^0} < 15$  eV. See their Figs. 1 and 2 for the mass-dependent limit.
- <sup>5</sup> BEZERRA 14B is analogous to BEZERRA 14. BEZERRA 14B use the measurement of the normal and lateral Casimir forces between sinusoidally corrugated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for  $1 \text{ eV} < m_{A^0} < 20$  eV. See their Figs. 1–3 for mass-dependent limits.
- <sup>6</sup> BEZERRA 14C is analogous to BEZERRA 14. They use the measurement of the gradient of the Casimir force between Au- and Ni-coated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for  $3 \times 10^{-5} \text{ eV} < m_{A^0} < 1$  eV. See their Figs. 1, 3, and 4 for the mass-dependent limits.
- <sup>7</sup> BLUM 14 studied effects of an oscillating strong  $CP$  phase induced by axion dark matter on the primordial  $^4\text{He}$  abundance. See their Fig. 1 for mass-dependent limits.
- <sup>8</sup> LEINSON 14 attributes the excessive cooling rate of the neutron star in Cassiopeia A to axion emission from the superfluid core, and found  $C_n^2 m_n^2 A^0 \simeq 5.7 \times 10^{-6} \text{ eV}^2$ , where  $C_n$  is the effective Peccei-Quinn charge of the neutron.
- <sup>9</sup> ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited  $^{57}\text{Fe}$  nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
- <sup>10</sup> ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.
- <sup>11</sup> BELLI 12 looked for solar axions emitted by the M1 transition of  $^7\text{Li}^*$  (478 keV) after the electron capture of  $^7\text{Be}$ , using the resonant excitation  $^7\text{Li}$  in the LiF crystal. The mass bound assumes  $m_U/m_d = 0.55$ ,  $m_U/m_S = 0.029$ , and the flavor-singlet axial vector matrix element  $S = 0.4$ .
- <sup>12</sup> BELLINI 12B looked for 5.5 MeV solar axions produced in the  $pd \rightarrow ^3\text{He} A^0$ . The limit assumes the hadronic axion model. See their Figs. 4 and 5 for mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
- <sup>13</sup> DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited  $^{57}\text{Fe}$  nuclei in the Sun, using their possible resonant capture on  $^{57}\text{Fe}$  in the laboratory. The mass bound assumes  $m_U/m_d = 0.56$  and the flavor-singlet axial vector matrix element  $S = 3F - D \simeq 0.5$ .
- <sup>14</sup> BELLINI 08 consider solar axions emitted in the M1 transition of  $^7\text{Li}^*$  (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For  $m_{A^0} < 450$  keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
- <sup>15</sup> ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for  $m_{A^0}$  below about 1 MeV.

### Axion Limits from $T$ -violating Medium-Range Forces

The limit is for the coupling  $g = g_p g_s$  in a  $T$ -violating potential between nucleons or nucleon and electron of the form  $V = \frac{g\hbar^2}{8\pi m_p} (\boldsymbol{\sigma} \cdot \hat{\mathbf{r}}) \left( \frac{1}{r^2} + \frac{1}{\lambda r} \right) e^{-r/\lambda}$ , where  $g_p$  and  $g_s$  are dimensionless scalar and pseudoscalar coupling constants and  $\lambda = \hbar/(m_A c)$  is the range of the force.

<sup>18</sup> VENEMA 92		nuclear spin-precession frequencies
<sup>19</sup> WINELAND 91	NMR	

- <sup>1</sup> AFACH 15 look for a change of spin precession frequency of ultracold neutrons when a magnetic field with opposite directions is applied, and find  $g < 2.2 \times 10^{-27} (\text{m}/\lambda)^2$  at 95% CL for  $1 \mu\text{m} < \lambda < 5$  mm. See their Fig. 3 for their limits.
- <sup>2</sup> STADNIK 15 studied proton and neutron spin contributions for nuclei and derive the limits  $g < 10^{-28} - 10^{-23}$  for  $\lambda > 3 \times 10^{-4}$  m using the data of TULLNEY 13. See their Figs. 1 and 2 for  $\lambda$ -dependent limits.
- <sup>3</sup> BULATOWICZ 13 looked for NMR frequency shifts in polarized  $^{129}\text{Xe}$  and  $^{131}\text{Xe}$  when a zirconia rod is positioned near the NMR cell, and find  $g < 1 \times 10^{-19} - 1 \times 10^{-24}$  for  $\lambda = 0.01$ –1 cm. See their Fig. 4 for their limits.
- <sup>4</sup> CHU 13 look for a shift of the spin precession frequency of polarized  $^3\text{He}$  in the presence of an unpolarized mass, in analogy to YODIN 96. See Fig. 3 for limits on  $g$  in the approximate  $m_{A^0}$  range 0.02–2 meV.
- <sup>5</sup> TULLNEY 13 look for a shift of the precession frequency difference between the colocated  $^3\text{He}$  and  $^{129}\text{Xe}$  in the presence an unpolarized mass, and derive limits  $g < 3 \times 10^{-29} - 2 \times 10^{-22}$  for  $\lambda > 3 \times 10^{-4}$  m. See their Fig. 3 for  $\lambda$ -dependent limits.
- <sup>6</sup> RAFFELT 12 show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on  $g$ . See their Figs. 2 and 3 for results.
- <sup>7</sup> HOEDL 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on  $g$  in the approximate  $m_{A^0}$  range 0.03–10 meV.
- <sup>8</sup> PETUKHOV 10 use spin relaxation of polarized  $^3\text{He}$  and find  $g < 3 \times 10^{-23} (\text{cm}/\lambda)^2$  at 95% CL for the force range  $\lambda = 10^{-4}$ –1 cm.
- <sup>9</sup> SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find  $g < 2 \times 10^{-21} (\text{cm}/\lambda)^2$  at 95% CL for the force range  $\lambda = 10^{-4}$ –1 cm.
- <sup>10</sup> IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show  $\lambda$ -dependent limits in their Fig. 1.
- <sup>11</sup> SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds  $g < 2.96 \times 10^{-21} (\text{cm}/\lambda)^2$  for the force range  $\lambda = 10^{-3}$ –1 cm and  $g < 3.9 \times 10^{-22} (\text{cm}/\lambda)^2$  for  $\lambda = 10^{-4}$ – $10^{-3}$  cm, each time at 95% CL, significantly improving on BAESSLER 07.
- <sup>12</sup> BAESSLER 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain  $g$  for an interaction range  $1 \mu\text{m}$ –a few mm. See their Fig. 3 for results.
- <sup>13</sup> HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about  $9 \times 10^{22}$  polarized electrons. See their Fig. 4 for limits on  $g$  as a function of interaction range.
- <sup>14</sup> NI 99 searched for a  $T$ -violating medium-range force acting on paramagnetic Tb F<sub>3</sub> salt. See their Fig. 1 for the result.
- <sup>15</sup> POSPELOV 98 studied the possible contribution of  $T$ -violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate  $CP$ . The size of the force among nucleons must be smaller than gravity by a factor of  $2 \times 10^{-10} (1 \text{ cm}/\lambda_A)$ , where  $\lambda_A = \hbar/m_A c$ .
- <sup>16</sup> YODIN 96 compared the precession frequencies of atomic  $^{199}\text{Hg}$  and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.
- <sup>17</sup> RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.
- <sup>18</sup> VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of  $^{199}\text{Hg}$  and  $^{201}\text{Hg}$  atoms.
- <sup>19</sup> WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored  $^9\text{Be}^+$  ions using nuclear magnetic resonance.

### Hidden Photons: Kinetic Mixing Parameter Limits

Hidden photons limits are listed for the first time, including only the most recent papers. Suggestions for previous important results are welcome. Limits are on the kinetic mixing parameter  $\chi$  which is defined by the Lagrangian

$$L = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \frac{1}{4} F'_{\mu\nu} F'^{\mu\nu} - \frac{\chi}{2} F_{\mu\nu} F'^{\mu\nu} + \frac{m^2}{2} A'_\mu A'^\mu,$$

where  $A_\mu$  and  $A'_\mu$  are the photon and hidden-photon fields with field strengths  $F_{\mu\nu}$  and  $F'_{\mu\nu}$ , respectively, and  $m_{\gamma'}$  is the hidden-photon mass.

- 1 KHACHATRYAN 16 look for  $\gamma' \rightarrow \mu^+ \mu^-$  in a dark SUSY scenario where the SM-like Higgs boson decays into a pair of the visible lightest neutralinos with mass 10 GeV, both of which decay into  $\gamma'$  and a hidden neutralino with mass 1 GeV. See the right panel in their Fig. 2.
- 2 AAD 15CD look for  $H \rightarrow Z\gamma' \rightarrow 4\ell$  with the ATLAS detector at LHC and find  $\chi < 4\text{--}17 \times 10^{-2}$  for  $m_{\gamma'} = 15\text{--}55$  GeV. See their Fig. 6.
- 3 ADARE 15 look for a hidden photon in  $\pi^0, \eta^0 \rightarrow \gamma e^+ e^-$  at the PHENIX experiment. See their Fig. 4 for mass-dependent limits.
- 4 AN 15A derived limits from the absence of ionization signals in the XENON10 and XENON100 experiments, assuming hidden photons constitute all the local dark matter. Their best limit is  $\chi < 1.3 \times 10^{-15}$  at  $m_{\gamma'} = 18$  eV. See their Fig. 1 for mass-dependent limits.
- 5 ANASTASI 15 look for a production of a hidden photon and a hidden Higgs boson with the KLOE detector at DAΦNE, where the hidden photon decays into a pair of muons and the hidden Higgs boson lighter than  $m_{\gamma'}$  escape detection. See their Figs. 6 and 7 for mass-dependent limits on a product of the hidden fine structure constant and the kinetic mixing.
- 6 ANASTASI 15A look for the decay  $\gamma' \rightarrow e^+ e^-$  in the reaction  $e^+ e^- \rightarrow e^+ e^- \gamma'$ . Limits between  $1.7 \times 10^{-3}$  and  $1 \times 10^{-2}$  are obtained for  $m_{\gamma'} = 5\text{--}320$  MeV (see their Fig. 7).
- 7 BATLEY 15A look for  $\pi^0 \rightarrow \gamma\gamma' (\gamma' \rightarrow e^+ e^-)$  at the NA48/2 experiment. Limits between  $4.2 \times 10^{-4}$  and  $8.8 \times 10^{-3}$  are obtained for  $m_{\gamma'} = 9\text{--}120$  MeV (see their Fig. 4).
- 8 JAEGLER 15 look for the decay  $\gamma' \rightarrow e^+ e^-, \mu^+ \mu^-,$  or  $\pi^+ \pi^-$  in the dark Higgs-gating channel,  $e^+ e^- \rightarrow \gamma' H' (H' \rightarrow \gamma' \gamma')$  at the BELLE experiment. They set limits on a product of the branching fraction and the Born cross section as well as a product of the hidden fine structure constant and the kinetic mixing. See their Figs. 3 and 4.
- 9 KAZANAS 15 set limits by studying the decay of hidden photons  $\gamma' \rightarrow e^+ e^-$  inside and near the progenitor star of SN1987A. See their Fig. 6 for mass-dependent limits.
- 10 SUZUKI 15 looked for hidden-photon dark matter with a dish antenna and derived limits assuming they constitute all the local dark matter. Their limits are  $\chi < 6 \times 10^{-12}$  for  $m_{\gamma'} = 1.9\text{--}4.3$  eV. See their Fig. 7 for mass-dependent limits.
- 11 VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations, and set the limits  $\chi m_{\gamma'} < 1.8 \times 10^{-12}$  eV for  $m_{\gamma'} = 3 \times 10^{-5}\text{--}8$  eV. See their Fig. 11.
- 12 ABE 14F look for the photoelectric-like interaction in the XMASS detector assuming the hidden photon constitutes all the local dark matter. Limits between  $2 \times 10^{-13}$  and  $1 \times 10^{-12}$  are obtained. See their Fig. 3 for mass-dependent limits.
- 13 AGAKISHIEV 14 look for hidden photons  $\gamma' \rightarrow e^+ e^-$  at the HADES experiment, and set limits on  $\chi$  for  $m_{\gamma'} = 0.02\text{--}0.6$  GeV. See their Fig. 5 for mass-dependent limits.
- 14 BABUSCI 14 look for the decay  $\gamma' \rightarrow \mu^+ \mu^-$  in the reaction  $e^+ e^- \rightarrow \mu^+ \mu^- \gamma'$ . Limits between  $4 \times 10^{-3}$  and  $9.0 \times 10^{-4}$  are obtained for  $520 \text{ MeV} < m_{\gamma'} < 980 \text{ MeV}$  (see their Fig. 7).
- 15 BATELL 14 derived limits from the electron beam dump experiment at SLAC (E-137) by searching for events with recoil electrons by sub-GeV dark matter produced from the decay of the hidden photon. Limits at the level of  $10^{-4}\text{--}10^{-1}$  are obtained for  $m_{\gamma'} = 10^{-3}\text{--}1$  GeV, depending on the dark matter mass and the hidden gauge coupling (see their Fig. 2).
- 16 BLUEMLEIN 14 analyzed the beam dump data taken at the U-70 accelerator to look for  $\gamma'$ -bremsstrahlung and the subsequent decay into muon pairs and hadrons. See their Fig. 4 for mass-dependent excluded regions.
- 17 FRADETTE 14 studied effects of decay of relic hidden photons on BBN and CMB to set constraints on very small values of the kinetic mixing. See their Figs. 4 and 7 for mass-dependent excluded regions.

- 18 LEES 14J look for hidden photons in the reaction  $e^+ e^- \rightarrow \gamma\gamma' (\gamma' \rightarrow e^+ e^-, \mu^+ \mu^-)$ . Limits at the level of  $10^{-4}\text{--}10^{-3}$  are obtained for  $0.02 \text{ GeV} < m_{\gamma'} < 10.2 \text{ GeV}$ . See their Fig. 4 for mass-dependent limits.
- 19 MERKEL 14 look for  $\gamma' \rightarrow e^+ e^-$  at the A1 experiment at the Mainz Microtron (MAMI). See their Fig. 3 for mass-dependent limits.
- 20 AN 13B examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.
- 21 AN 13C use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find  $\chi m_{\gamma'} < 3 \times 10^{-12}$  eV for  $m_{\gamma'} < 1$  eV. See their Fig. 2 for mass-dependent limits.
- 22 HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.
- 23 INADA 13 search for hidden photons using an intense X-ray beamline at SPring-8. See their Fig. 4 for mass-dependent limits.
- 24 MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.
- 25 PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig. 5 for mass-dependent limits.
- 26 PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.
- 27 REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13B, and also updated stellar-energy loss arguments. See their Fig. 3 for mass-dependent limits, including a review of the currently best limits from other arguments.
- 28 BLUEMLEIN 11 analyzed the beam dump data taken at the U-70 accelerator to look for  $\pi^0 \rightarrow \gamma\gamma' (\gamma' \rightarrow e^+ e^-)$ . See their Fig. 5 for mass-dependent limits.

## LEPTONS

e

$$J = \frac{1}{2}$$

**e MASS (atomic mass units u)**

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE ( $10^{-6}$ u)	DOCUMENT ID	TECN	COMMENT
<b>548.57990970 ± 0.00000016</b>	MOHR	16	RVUE 2014 CODATA value

<sup>1</sup> BEIER 02 compares Larmor frequency of the electron bound in a  $^{12}\text{C}^{5+}$  ion with the cyclotron frequency of a single trapped  $^{12}\text{C}^{5+}$  ion.

<sup>2</sup> FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped  $^{12}\text{C}^{6+}$  ion.

**e MASS**

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494 061 (21). Earlier values use the then-current conversion factor. The conversion error dominates the uncertainty of the masses given below.

<b>&lt; 8 × 10<sup>-9</sup></b>	90	<sup>1</sup> FEE	93	Positronium spectroscopy
• • • We do not use the following data for averages, fits, limits, etc. • • •				
< 4 × 10 <sup>-23</sup>	90	<sup>2</sup> DOLGOV	14	From photon mass limit
< 4 × 10 <sup>-8</sup>	90	CHU	84	CNTR Positronium spectroscopy

<sup>1</sup> FEE 93 value is obtained under the assumption that the positronium Rydberg constant is exactly half the hydrogen one.

<sup>2</sup> DOLGOV 14 result is obtained under the assumption that any mass difference between electron and positron would lead to a non-zero photon mass. The PDG 12 limit of  $1 \times 10^{-18}$  eV on the photon mass is in turn used to derive the value quoted here.

$$|q_{e^+} + q_{e^-}|/e$$

A test of *CPT* invariance. See also similar tests involving the proton.

<sup>1</sup> BARON 14 gives a measurement corresponding to this limit as  $(-0.21 \pm 0.37 \pm 0.25) \times 10^{-28}$  ecm.

<sup>2</sup> ECKEL 12 gives a measurement corresponding to this limit as  $(-1.07 \pm 3.06 \pm 1.74) \times 10^{-25}$  ecm.

<sup>3</sup> HUDSON 11 gives a measurement corresponding to this limit as  $(-2.4 \pm 5.7 \pm 1.5) \times 10^{-28}$  ecm.

<sup>4</sup> ABDULLAH 90, COMMINS 94, and REGAN 02 use the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

**e<sup>-</sup> MEAN LIFE / BRANCHING FRACTION**

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** 51 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in  $e^- \rightarrow \nu_e \gamma$ , (b) the (K) shell x-ray produced when an electron decays without additional energy deposit, e.g.,  $e^- \rightarrow \nu_e \bar{\nu}_e \nu_e$  ("disappearance" experiments), and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best  $e^- \rightarrow \nu_e \gamma$  limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported.

## μ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium (*μ*<sup>+</sup> *e*<sup>−</sup> atom). Since the electron's mass is most accurately known in *u*, the muon's mass is also most accurately known in *u*. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in *u*. In this datablock we give the result in *u*, and in the following datablock in MeV.

### $\mu/p$ MAGNETIC MOMENT RATIO

This ratio is used to obtain a precise value of the muon mass and to reduce experimental muon Larmor frequency measurements to the muon magnetic moment anomaly. Measurements with an error  $> 0.00001$  have been omitted. By convention, the minus sign on this ratio is omitted. CODATA values were fitted using their selection of data, plus other data from multiparameter fits.

### THE MUON ANOMALOUS MAGNETIC MOMENT

Updated August 2013 by A. Hoecker (CERN), and W.J. Marciano (BNL).

The Dirac equation predicts a muon magnetic moment,  $\vec{M} = g_\mu \frac{e}{2m_\mu} \vec{S}$ , with gyromagnetic ratio  $g_\mu = 2$ . Quantum loop effects lead to a small calculable deviation from  $g_\mu = 2$ , parameterized by the anomalous magnetic moment

$$a_\mu \equiv \frac{g_\mu - 2}{2}. \quad (1)$$

That quantity can be accurately measured and, within the Standard Model (SM) framework, precisely predicted. Hence, comparison of experiment and theory tests the SM at its quantum loop level. A deviation in  $a_\mu^{\text{exp}}$  from the SM expectation would signal effects of new physics, with current sensitivity reaching up to mass scales of  $\mathcal{O}(\text{TeV})$  [1,2]. For recent and very thorough muon  $g - 2$  reviews, see Refs. [3–5].

The E821 experiment at Brookhaven National Lab (BNL) studied the precession of  $\mu^+$  and  $\mu^-$  in a constant external magnetic field as they circulated in a confining storage ring. It found [7]<sup>1</sup>

$$\begin{aligned} a_{\mu^+}^{\text{exp}} &= 11\,659\,204(6)(5) \times 10^{-10}, \\ a_{\mu^-}^{\text{exp}} &= 11\,659\,215(8)(3) \times 10^{-10}, \end{aligned} \quad (2)$$

<sup>1</sup> The original results reported by the experiment have been updated in Eq. (2) and Eq. (3) to the newest value for the absolute muon-to-proton magnetic ratio  $\lambda = 3.183\,345\,107(84)$  [6]. The change induced in  $a_\mu^{\text{exp}}$  with respect to the value of  $\lambda = 3.183\,345\,39(10)$  used in Ref. 7 amounts to  $+1.12 \times 10^{-10}$ .

where the first errors are statistical and the second systematic. Assuming *CPT* invariance and taking into account correlations between systematic uncertainties, one finds for their average [6,7]

$$a_\mu^{\text{exp}} = 11\,659\,209.1(5.4)(3.3) \times 10^{-10}. \quad (3)$$

These results represent about a factor of 14 improvement over the classic CERN experiments of the 1970's [8]. Improvement of the measurement in Eq. (3) by a factor of four by moving the E821 storage ring to Fermilab, and utilizing a cleaner and more intense muon beam is in progress. An even more ambitious precision goal is set by an experiment based on a beam of ultra-cold muons proposed at the Japan Proton Accelerator Research Complex.

The SM prediction for  $a_\mu^{\text{SM}}$  is generally divided into three parts (see Fig. 1 for representative Feynman diagrams)

$$a_\mu^{\text{SM}} = a_\mu^{\text{QED}} + a_\mu^{\text{EW}} + a_\mu^{\text{Had}}. \quad (4)$$

The QED part includes all photonic and leptonic ( $e, \mu, \tau$ ) loops starting with the classic  $\alpha/2\pi$  Schwinger contribution. It has been computed through 5 loops [9]

$$\begin{aligned} a_\mu^{\text{QED}} &= \frac{\alpha}{2\pi} + 0.765\,857\,425(17) \left(\frac{\alpha}{\pi}\right)^2 + 24.050\,509\,96(32) \left(\frac{\alpha}{\pi}\right)^3 \\ &\quad + 130.879\,6(6.3) \left(\frac{\alpha}{\pi}\right)^4 + 753.3(1.0) \left(\frac{\alpha}{\pi}\right)^5 + \dots \end{aligned} \quad (5)$$

with a few significant changes in the coefficients since our previous update of this review in 2011. Employing<sup>2</sup>  $\alpha^{-1} = 137.035\,999\,049(90)$ , obtained [6] from the precise measurements of  $h/m_{\text{Rb}}$  [11], the Rydberg constant and  $m_{\text{Rb}}/m_e$  [6], leads to [9]

$$a_\mu^{\text{QED}} = 116\,584\,718.95(0.08) \times 10^{-11}, \quad (6)$$

where the small error results mainly from the uncertainty in  $\alpha$ .

Loop contributions involving heavy  $W^\pm, Z$  or Higgs particles are collectively labeled as  $a_\mu^{\text{EW}}$ . They are suppressed by at least a factor of  $\frac{\alpha}{\pi} \frac{m_\mu^2}{m_W^2} \simeq 4 \times 10^{-9}$ . At 1-loop order [12]

$$\begin{aligned} a_\mu^{\text{EW}}[1\text{-loop}] &= \frac{G_\mu m_\mu^2}{8\sqrt{2}\pi^2} \left[ \frac{5}{3} + \frac{1}{3} (1 - 4\sin^2\theta_W)^2 \right. \\ &\quad \left. + \mathcal{O}\left(\frac{m_\mu^2}{M_W^2}\right) + \mathcal{O}\left(\frac{m_\mu^2}{M_H^2}\right) \right], \\ &= 194.8 \times 10^{-11}, \end{aligned} \quad (7)$$

<sup>2</sup> In the previous versions of this review we used the precise  $\alpha$  value determined from the electron  $a_e$  measurement [9,10]. With the new measurement [11] of the recoil velocity of Rubidium,  $h/m_{\text{Rb}}$ , an  $a_e$ -independent determination of  $\alpha$  with sufficient precision is available and preferred.

# Lepton Particle Listings

$\mu$

for  $\sin^2\theta_W \equiv 1 - M_W^2/M_Z^2 \simeq 0.223$ , and where  $G_\mu \simeq 1.166 \times 10^{-5} \text{ GeV}^{-2}$  is the Fermi coupling constant. Two-loop corrections are relatively large and negative [13]. For a Higgs boson mass of  $\simeq 126 \text{ GeV}$  [13]

$$a_\mu^{\text{EW}}[\text{2-loop}] = -41.2(1.0) \times 10^{-11}, \quad (8)$$

where the uncertainty stems from quark triangle loops. The 3-loop leading logarithms are negligible [13,14],  $\mathcal{O}(10^{-12})$ , implying in total

$$a_\mu^{\text{EW}} = 153.6(1.0) \times 10^{-11}. \quad (9)$$

Hadronic (quark and gluon) loop contributions to  $a_\mu^{\text{SM}}$  give rise to its main theoretical uncertainties. At present, those effects are not calculable from first principles, but such an approach, at least partially, may become possible as lattice QCD matures. Instead, one currently relies on a dispersion relation approach to evaluate the lowest-order (*i.e.*,  $\mathcal{O}(\alpha^2)$ ) hadronic vacuum polarization contribution  $a_\mu^{\text{Had}}[\text{LO}]$  from corresponding cross section measurements [15]

$$a_\mu^{\text{Had}}[\text{LO}] = \frac{1}{3} \left( \frac{\alpha}{\pi} \right)^2 \int_{m_\pi^2}^{\infty} ds \frac{K(s)}{s} R^{(0)}(s), \quad (10)$$

where  $K(s)$  is a QED kernel function [16], and where  $R^{(0)}(s)$  denotes the ratio of the bare<sup>3</sup> cross section for  $e^+e^-$  annihilation into hadrons to the pointlike muon-pair cross section at center-of-mass energy  $\sqrt{s}$ . The function  $K(s) \sim 1/s$  in Eq. (10) gives a strong weight to the low-energy part of the integral. Hence,  $a_\mu^{\text{Had}}[\text{LO}]$  is dominated by the  $\rho(770)$  resonance.

Currently, the available  $\sigma(e^+e^- \rightarrow \text{hadrons})$  data give a leading-order hadronic vacuum polarization (representative) contribution of [17]

$$a_\mu^{\text{Had}}[\text{LO}] = 6923(42)(3) \times 10^{-11}, \quad (11)$$

where the first error is experimental (dominated by systematic uncertainties), and the second due to perturbative QCD, which is used at intermediate and large energies to predict the contribution from the quark-antiquark continuum. New multi-hadron data from the BABAR experiment have increased the constraints on unmeasured exclusive final states and led to a small reduction in the hadronic contribution compared to the 2009 PDG value.

Alternatively, one can use precise vector spectral functions from  $\tau \rightarrow \nu_\tau + \text{hadrons}$  decays [18] that can be related to isovector  $e^+e^- \rightarrow \text{hadrons}$  cross sections by isospin symmetry. Replacing  $e^+e^-$  data in the two-pion and four-pion channels by the corresponding isospin-transformed  $\tau$  data, and applying

<sup>3</sup> The bare cross section is defined as the measured cross section corrected for initial-state radiation, electron-vertex loop contributions and vacuum-polarization effects in the photon propagator. However, QED effects in the hadron vertex and final state, as photon radiation, are included.

isospin-violating corrections (from QED and  $m_d - m_u \neq 0$ ), one finds [17]

$$a_\mu^{\text{Had}}[\text{LO}] = 7015(42)(19)(3) \times 10^{-11} (\tau), \quad (12)$$

where the first error is experimental, the second estimates the uncertainty in the isospin-breaking corrections applied to the  $\tau$  data, and the third error is due to perturbative QCD. The current discrepancy between the  $e^+e^-$  and  $\tau$ -based determinations of  $a_\mu^{\text{Had}}[\text{LO}]$  has been reduced to  $1.8\sigma$  with respect to earlier evaluations. New  $e^+e^-$  and  $\tau$  data from the  $B$ -factory experiments BABAR and Belle have increased the experimental information. Reevaluated isospin-breaking corrections have also contributed to this improvement [19]. BABAR reported good agreement with the  $\tau$  data in the most important two-pion channel [20]. The remaining discrepancy with the older  $e^+e^-$  and  $\tau$  datasets may be indicative of problems with one or both data sets. It may also suggest the need for additional isospin-violating corrections to the  $\tau$  data. Several evaluations of  $a_\mu^{\text{Had}}[\text{LO}]$  have been published leading to similar results (see Fig. 2). The low-energy contribution to  $a_\mu^{\text{Had}}[\text{LO}]$  has also been evaluated with the use of additional theory or model constraints in Refs. [22] and [23], respectively.

Higher order,  $\mathcal{O}(\alpha^3)$ , hadronic contributions are obtained from dispersion relations using the same  $e^+e^- \rightarrow \text{hadrons}$  data [18,21,24], giving  $a_\mu^{\text{Had,Disp}}[\text{NLO}] = (-98.4 \pm 0.6) \times 10^{-11}$ , along with model-dependent estimates of the hadronic light-by-light scattering contribution,  $a_\mu^{\text{Had,LBL}}[\text{NLO}]$ , motivated by large- $N_C$  QCD [25–31].<sup>4</sup> Following [29], one finds for the sum of the two terms

$$a_\mu^{\text{Had}}[\text{NLO}] = 7(26) \times 10^{-11}, \quad (13)$$

where the error is dominated by hadronic light-by-light uncertainties.

Adding Eqs. (6), (9), (11) and (13) gives the representative  $e^+e^-$  data based SM prediction

$$a_\mu^{\text{SM}} = 116591803(1)(42)(26) \times 10^{-11}, \quad (14)$$

where the errors are due to the electroweak, lowest-order hadronic, and higher-order hadronic contributions, respectively. The difference between experiment and theory

$$\Delta a_\mu = a_\mu^{\text{exp}} - a_\mu^{\text{SM}} = 288(63)(49) \times 10^{-11}, \quad (15)$$

(with all errors combined in quadrature) represents an interesting but not yet conclusive discrepancy of 3.6 times the estimated  $1\sigma$  error. All the recent estimates for the hadronic contribution compiled in Fig. 2 exhibit similar discrepancies. Switching to  $\tau$  data reduces the discrepancy to  $2.4\sigma$ , assuming the isospin-violating corrections are under control within the

<sup>4</sup> Some representative recent estimates of the hadronic light-by-light scattering contribution,  $a_\mu^{\text{Had,LBL}}[\text{NLO}]$ , that followed after the sign correction of [27], are:  $105(26) \times 10^{-11}$  [29],  $110(40) \times 10^{-11}$  [25],  $136(25) \times 10^{-11}$  [26].

**Figure 2:** Compilation of recent published results for  $a_\mu$  (in units of  $10^{-11}$ ), subtracted by the central value of the experimental average (3). The shaded band indicates the size of the experimental uncertainty. The SM predictions are taken from: JN [4], DHMZ [17], HMNT [21]. Note that the quoted errors in the figure do not include the uncertainty on the subtracted experimental value. To obtain for each theory calculation a result equivalent to Eq. (15), the errors from theory and experiment must be added in quadrature.

estimated uncertainties (see Ref. 32 for an analysis leading to a different conclusion).

An alternate interpretation is that  $\Delta a_\mu$  may be a new physics signal with supersymmetric particle loops as the leading candidate explanation. Such a scenario is quite natural, since generically, supersymmetric models predict [1] an additional contribution to  $a_\mu^{\text{SM}}$

$$a_\mu^{\text{SUSY}} \simeq \text{sign}(\mu) \cdot 130 \times 10^{-11} \cdot \left( \frac{100 \text{ GeV}}{m_{\text{SUSY}}} \right)^2 \tan\beta, \quad (16)$$

where  $m_{\text{SUSY}}$  is a representative supersymmetric mass scale,  $\tan\beta \simeq 3\text{--}40$  a potential enhancement factor, and  $\text{sign}(\mu) = \pm 1$ . Supersymmetric particles in the mass range 100–500 GeV could be the source of the deviation  $\Delta a_\mu$ . If so, those particles should be directly observed at the Large Hadron Collider at CERN.

New physics effects [1] other than supersymmetry could also explain a non-vanishing  $\Delta a_\mu$ . A recent popular scenario involves the “dark photon”, a relatively light hypothetical vector boson from the dark matter sector that couples to our world of particle physics through mixing with the ordinary photon [33–35]. As a result, it couples to ordinary charged particles with strength  $\varepsilon \cdot e$  and gives rise to an additional muon anomalous magnetic moment contribution

$$a_\mu^{\text{dark photon}} = \frac{\alpha}{2\pi} \varepsilon^2 F(m_V/m_\mu), \quad (17)$$

where  $F(x) = \int_0^1 2z(1-z)^2 / [(1-z)^2 + x^2 z] dz$ . For values of  $\varepsilon \sim 1\text{--}2 \cdot 10^{-3}$  and  $m_V \sim 10\text{--}100 \text{ MeV}$ , the dark photon, which

was originally motivated by cosmology, can provide a viable solution to the muon  $g - 2$  discrepancy. Searches for the dark photon in that mass range are currently underway at Jefferson Lab, USA, and MAMI in Mainz, Germany.

 $\mu$  MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency  $\omega_a$  between the muon spin precession and the orbital angular frequency ( $e/m_\mu c \langle B \rangle$ ) is measured, as is the free proton NMR frequency  $\omega_p$ , thus determining the ratio  $R = \omega_a/\omega_p$ . Given the magnetic moment ratio  $\lambda = \mu_\mu/\mu_p$  (from hyperfine structure in muonium),  $(g-2)/2 = R/(\lambda - R)$ .

$$\mu_\mu/(e\hbar/2m_\mu) - 1 = (g_\mu - 2)/2$$

<sup>1</sup> This is the combination of the two BENNETT 09 results quoted here separately for  $\mu^+$  and  $\mu^-$ . BENNETT 09 uses the convention  $d = 1/2 \cdot (d_{\mu^-} - d_{\mu^+})$ .

<sup>2</sup> This is the combination of the two BAILEY 78 results quoted here separately for  $\mu^+$  and  $\mu^-$ . BAILEY 78 uses the convention  $d = 1/2 \cdot (d_{\mu^+} - d_{\mu^-})$  and reports  $3.7 \pm 3.4$ . We convert their result to use the same convention as BENNETT 09.

MUON-ELECTRON CHARGE RATIO ANOMALY  $q_{\mu^+}/q_{e^-} + 1$ 

VALUE	DOCUMENT ID	TECN	CHG	COMMENT
<b><math>(1.1 \pm 2.1) \times 10^{-9}</math></b>	<sup>1</sup> MEYER	00	CNTR	$+$ 1s–2s muonium interval

<sup>1</sup> MEYER 00 measure the 1s–2s muonium interval, and then interpret the result in terms of muon-electron charge ratio  $q_{\mu^+}/q_{e^-}$ .

 $\mu^-$  DECAY MODES

$\mu^+$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $e^- \bar{\nu}_e \nu_\mu$	$\approx 100\%$	
$\Gamma_2$ $e^- \bar{\nu}_e \nu_\mu \gamma$	[a] $(1.4 \pm 0.4)\%$	
$\Gamma_3$ $e^- \bar{\nu}_e \nu_\mu e^+ e^-$	[b] $(3.4 \pm 0.4) \times 10^{-5}$	

## Lepton Family number (LF) violating modes

Mode	LF	$\Gamma_i/\Gamma$	Confidence level
$\Gamma_4$ $e^- \nu_e \bar{\nu}_\mu$	LF	[c] $< 1.2\%$	90%
$\Gamma_5$ $e^- \gamma$	LF	$< 5.7 \times 10^{-13}$	90%
$\Gamma_6$ $e^- e^+ e^-$	LF	$< 1.0 \times 10^{-12}$	90%
$\Gamma_7$ $e^- 2\gamma$	LF	$< 7.2 \times 10^{-11}$	90%

[a] This only includes events with the  $\gamma$  energy  $> 10$  MeV. Since the  $e^- \bar{\nu}_e \nu_\mu$  and  $e^- \bar{\nu}_e \nu_\mu \gamma$  modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] A test of additive vs. multiplicative lepton family number conservation.

<sup>1</sup> This limit assumes a giant resonance excitation of the daughter Ca nucleus (mean energy and width both 20 MeV).

<sup>2</sup> KAULARD 98 obtained these same limits using the unified classical analysis of FELD-MAN 98.

<sup>3</sup> This limit assumes the daughter Ca nucleus is left in the ground state. However, the probability of this is unknown.

<sup>4</sup> Assuming a giant-resonance-excitation model.

### LIMIT ON MUONIUM $\rightarrow$ ANTIMUONIUM CONVERSION

Forbidden by lepton family number conservation.

$R_g = G_C / G_F$

The effective Lagrangian for the  $\mu^+ e^- \rightarrow \mu^- e^+$  conversion is assumed to be

$$\mathcal{L} = 2^{-1/2} G_C [\bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e] [\bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e] + \text{h.c.}$$

The experimental result is then an upper limit on  $G_C / G_F$ , where  $G_F$  is the Fermi coupling constant.

### MUON DECAY PARAMETERS

Revised September 2013 by W. Fetscher and H.-J. Gerber (ETH Zürich).

**Introduction:** All measurements in direct muon decay,  $\mu^- \rightarrow e^- + 2 \text{ neutrals}$ , and its inverse,  $\nu_\mu + e^- \rightarrow \mu^- + \text{neutral}$ , are successfully described by the "V-A interaction," which is a particular case of a local, derivative-free, lepton-number-conserving,

# Lepton Particle Listings

$\mu$

four-fermion interaction [1]. As shown below, within this framework, the Standard Model assumptions, such as the  $V-A$  form and the nature of the neutrals ( $\nu_\mu$  and  $\bar{\nu}_e$ ), and hence the doublet assignments ( $\nu_e e^-$ ) $_L$  and ( $\nu_\mu \mu^-$ ) $_L$ , have been determined from experiments [2,3]. All considerations on muon decay are valid for the leptonic tau decays  $\tau \rightarrow \ell + \nu_\tau + \bar{\nu}_e$  with the replacements  $m_\mu \rightarrow m_\tau$ ,  $m_e \rightarrow m_\ell$ .

**Parameters:** The differential decay probability to obtain an  $e^\pm$  with (reduced) energy between  $x$  and  $x + dx$ , emitted in the direction  $\hat{\mathbf{x}}_3$  at an angle between  $\vartheta$  and  $\vartheta + d\vartheta$  with respect to the muon polarization vector  $\mathbf{P}_\mu$ , and with its spin parallel to the arbitrary direction  $\hat{\boldsymbol{\zeta}}$ , neglecting radiative corrections, is given by

$$\begin{aligned} \frac{d^2\Gamma}{dx d\cos\vartheta} &= \frac{m_\mu}{4\pi^3} W_{e\mu}^4 G_F^2 \sqrt{x^2 - x_0^2} \\ &\times (F_{IS}(x) \pm P_\mu \cos\vartheta F_{AS}(x)) \\ &\times \left[ 1 + \hat{\boldsymbol{\zeta}} \cdot \mathbf{P}_e(x, \vartheta) \right] . \end{aligned} \quad (1)$$

Here,  $W_{e\mu} = \max(E_e) = (m_\mu^2 + m_e^2)/2m_\mu$  is the maximum  $e^\pm$  energy,  $x = E_e/W_{e\mu}$  is the reduced energy,  $x_0 = m_e/W_{e\mu} = 9.67 \times 10^{-3}$ , and  $P_\mu = |\mathbf{P}_\mu|$  is the degree of muon polarization.  $\hat{\boldsymbol{\zeta}}$  is the direction in which a perfect polarization-sensitive electron detector is most sensitive. The isotropic part of the spectrum,  $F_{IS}(x)$ , the anisotropic part  $F_{AS}(x)$ , and the electron polarization,  $\mathbf{P}_e(x, \vartheta)$ , may be parametrized by the Michel parameter  $\rho$  [1], by  $\eta$  [4], by  $\xi$  and  $\delta$  [5,6], *etc.* These are bilinear combinations of the coupling constants  $g_{e\mu}^2$ , which occur in the matrix element (given below).

If the masses of the neutrinos as well as  $x_0^2$  are neglected, the energy and angular distribution of the electron in the rest frame of a muon ( $\mu^\pm$ ) measured by a polarization insensitive detector, is given by

$$\begin{aligned} \frac{d^2\Gamma}{dx d\cos\vartheta} &\sim x^2 \cdot \left\{ 3(1-x) + \frac{2\rho}{3}(4x-3) + 3\eta x_0(1-x)/x \right. \\ &\quad \left. \pm P_\mu \cdot \xi \cdot \cos\vartheta \left[ 1 - x + \frac{2\delta}{3}(4x-3) \right] \right\} . \end{aligned} \quad (2)$$

Here,  $\vartheta$  is the angle between the electron momentum and the muon spin, and  $x \equiv 2E_e/m_\mu$ . For the Standard Model coupling, we obtain  $\rho = \xi\delta = 3/4$ ,  $\xi = 1$ ,  $\eta = 0$  and the differential decay rate is

$$\frac{d^2\Gamma}{dx d\cos\vartheta} = \frac{G_F^2 m_\mu^5}{192\pi^3} [3 - 2x \pm P_\mu \cos\vartheta(2x-1)] x^2 . \quad (3)$$

The coefficient in front of the square bracket is the total decay rate.

If only the neutrino masses are neglected, and if the  $e^\pm$  polarization is detected, then the functions in Eq. (1) become

$$\begin{aligned} F_{IS}(x) &= x(1-x) + \frac{2}{9} \rho(4x^2 - 3x - x_0^2) + \eta \cdot x_0(1-x) \\ F_{AS}(x) &= \frac{1}{3} \xi \sqrt{x^2 - x_0^2} \\ &\quad \times [1 - x + \frac{2}{3} \delta(4x - 3 + (\sqrt{1 - x_0^2} - 1))] \\ \mathbf{P}_e(x, \vartheta) &= P_{T1} \cdot \hat{\mathbf{x}}_1 + P_{T2} \cdot \hat{\mathbf{x}}_2 + P_L \cdot \hat{\mathbf{x}}_3 . \end{aligned} \quad (4)$$

Here  $\hat{\mathbf{x}}_1$ ,  $\hat{\mathbf{x}}_2$ , and  $\hat{\mathbf{x}}_3$  are orthogonal unit vectors defined as follows:

$$\begin{aligned} \hat{\mathbf{x}}_3 &\text{ is along the } e \text{ momentum } \mathbf{p}_e \\ \frac{\hat{\mathbf{x}}_3 \times \mathbf{P}_\mu}{|\hat{\mathbf{x}}_3 \times \mathbf{P}_\mu|} &= \hat{\mathbf{x}}_2 \text{ is transverse to } \mathbf{p}_e \text{ and perpendicular} \\ &\text{to the “decay plane”} \\ \hat{\mathbf{x}}_2 \times \hat{\mathbf{x}}_3 &= \hat{\mathbf{x}}_1 \text{ is transverse to the } \mathbf{p}_e \text{ and in the} \\ &\text{“decay plane.”} \end{aligned}$$

The components of  $\mathbf{P}_e$  then are given by

$$\begin{aligned} P_{T1}(x, \vartheta) &= P_\mu \sin\vartheta \cdot F_{T1}(x) / (F_{IS}(x) \pm P_\mu \cos\vartheta \cdot F_{AS}(x)) \\ P_{T2}(x, \vartheta) &= P_\mu \sin\vartheta \cdot F_{T2}(x) / (F_{IS}(x) \pm P_\mu \cos\vartheta \cdot F_{AS}(x)) \\ P_L(x, \vartheta) &= \left( \pm F_{IP}(x) + P_\mu \cos\vartheta \right. \\ &\quad \left. \times F_{AP}(x) \right) / (F_{IS}(x) \pm P_\mu \cos\vartheta \cdot F_{AS}(x)) , \end{aligned}$$

where

$$\begin{aligned} F_{T1}(x) &= \frac{1}{12} \left\{ -2 \left[ \xi'' + 12(\rho - \frac{3}{4}) \right] (1-x)x_0 \right. \\ &\quad \left. - 3\eta(x^2 - x_0^2) + \eta''(-3x^2 + 4x - x_0^2) \right\} \\ F_{T2}(x) &= \frac{1}{3} \sqrt{x^2 - x_0^2} \left\{ 3 \frac{\alpha'}{A} (1-x) + 2 \frac{\beta'}{A} \sqrt{1 - x_0^2} \right\} \\ F_{IP}(x) &= \frac{1}{54} \sqrt{x^2 - x_0^2} \left\{ 9\xi' \left( -2x + 2 + \sqrt{1 - x_0^2} \right) \right. \\ &\quad \left. + 4\xi(\delta - \frac{3}{4})(4x - 4 + \sqrt{1 - x_0^2}) \right\} \\ F_{AP}(x) &= \frac{1}{6} \left\{ \xi''(2x^2 - x - x_0^2) + 4(\rho - \frac{3}{4})(4x^2 - 3x - x_0^2) \right. \\ &\quad \left. + 2\eta''(1-x)x_0 \right\} . \end{aligned} \quad (5)$$

For the experimental values of the parameters  $\rho$ ,  $\xi$ ,  $\xi'$ ,  $\xi''$ ,  $\delta$ ,  $\eta$ ,  $\eta''$ ,  $\alpha/A$ ,  $\beta/A$ ,  $\alpha'/A$ ,  $\beta'/A$ , which are not all independent, see the Data Listings below. Experiments in the past have also been analyzed using the parameters  $a$ ,  $b$ ,  $c$ ,  $a'$ ,  $b'$ ,  $c'$ ,  $\alpha/A$ ,  $\beta/A$ ,  $\alpha'/A$ ,  $\beta'/A$  (and  $\eta = (\alpha - 2\beta)/2A$ ), as defined by Kinoshita and Sirlin [5,6]. They serve as a model-independent summary of all possible measurements on the decay electron (see Listings below). The relations between the two sets of parameters are

$$\begin{aligned} \rho - \frac{3}{4} &= \frac{3}{4}(-a + 2c)/A , \\ \eta &= (\alpha - 2\beta)/A , \\ \eta'' &= (3\alpha + 2\beta)/A , \\ \delta - \frac{3}{4} &= \frac{9}{4} \cdot \frac{(a' - 2c')/A}{1 - [a + 3a' + 4(b + b') + 6c - 14c']/A} , \\ 1 - \xi \frac{\delta}{\rho} &= 4 \frac{[(b + b') + 2(c - c')]/A}{1 - (a - 2c)/A} , \\ 1 - \xi' &= [(a + a') + 4(b + b') + 6(c + c')]/A , \\ 1 - \xi'' &= (-2a + 20c)/A , \end{aligned}$$

where

$$A = a + 4b + 6c . \quad (6)$$

The differential decay probability to obtain a *left-handed*  $\nu_e$  with (reduced) energy between  $y$  and  $y + dy$ , neglecting radiative

corrections as well as the masses of the electron and of the neutrinos, is given by [7]

$$\frac{d\Gamma}{dy} = \frac{m_\mu^5 G_F^2}{16\pi^3} \cdot Q_L^{\nu_e} \cdot y^2 \left\{ (1-y) - \omega_L \cdot (y - \frac{3}{4}) \right\}. \quad (7)$$

Here,  $y = 2 E_{\nu_e}/m_\mu$ ,  $Q_L^{\nu_e}$  and  $\omega_L$  are parameters.  $\omega_L$  is the neutrino analog of the spectral shape parameter  $\rho$  of Michel. Since in the Standard Model,  $Q_L^{\nu_e} = 1$ ,  $\omega_L = 0$ , the measurement of  $d\Gamma/dy$  has allowed a null-test of the Standard Model (see Listings below).

**Matrix element:** All results in direct muon decay (energy spectra of the electron and of the neutrinos, polarizations, and angular distributions), and in inverse muon decay (the reaction cross section) at energies well below  $m_W c^2$ , may be parametrized in terms of amplitudes  $g_{\varepsilon\mu}^\gamma$  and the Fermi coupling constant  $G_F$ , using the matrix element

$$\frac{4G_F}{\sqrt{2}} \sum_{\substack{\gamma=S,V,T \\ \varepsilon,\mu=R,L}} g_{\varepsilon\mu}^\gamma \langle \bar{e}_\varepsilon | \Gamma^\gamma | (\nu_e)_n \rangle \langle (\bar{\nu}_\mu)_m | \Gamma_\gamma | \mu_\mu \rangle. \quad (8)$$

We use the notation of Fetscher *et al.* [2], who in turn use the sign conventions and definitions of Scheck [8]. Here,  $\gamma = S, V, T$  indicates a scalar, vector, or tensor interaction; and  $\varepsilon, \mu = R, L$  indicate a right- or left-handed chirality of the electron or muon. The chiralities  $n$  and  $m$  of the  $\nu_e$  and  $\bar{\nu}_\mu$  are then determined by the values of  $\gamma, \varepsilon$ , and  $\mu$ . The particles are represented by fields of definite chirality [9].

As shown by Langacker and London [10], explicit lepton-number nonconservation still leads to a matrix element equivalent to Eq. (8). They conclude that it is not possible, even in principle, to test lepton-number conservation in (leptonic) muon decay if the final neutrinos are massless and are not observed.

The ten complex amplitudes  $g_{\varepsilon\mu}^\gamma$  ( $g_{RR}^T$  and  $g_{LL}^T$  are identically zero) and  $G_F$  constitute 19 independent (real) parameters to be determined by experiment. The Standard Model interaction corresponds to one single amplitude  $g_{LL}^V$  being unity and all the others being zero.

The (direct) muon decay experiments are compatible with an arbitrary mix of the scalar and vector amplitudes  $g_{LL}^S$  and  $g_{LL}^V$  – in the extreme even with purely scalar  $g_{LL}^S = 2$ ,  $g_{LL}^V = 0$ . The decision in favour of the Standard Model comes from the quantitative observation of inverse muon decay, which would be forbidden for pure  $g_{LL}^S$  [2].

**Experimental determination of V-A:** In order to determine the amplitudes  $g_{\varepsilon\mu}^\gamma$  uniquely from experiment, the following set of equations, where the left-hand sides represent experimental results, has to be solved.

$$\begin{aligned} a &= 16(|g_{RL}^V|^2 + |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 + |g_{LR}^S + 6g_{LR}^T|^2 \\ a' &= 16(|g_{RL}^V|^2 - |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 - |g_{LR}^S + 6g_{LR}^T|^2 \\ \alpha &= 8\text{Re} \left\{ g_{RL}^V (g_{RL}^{S*} + 6g_{RL}^{T*}) + g_{LR}^V (g_{LR}^{S*} + 6g_{LR}^{T*}) \right\} \\ \alpha' &= 8\text{Im} \left\{ g_{LR}^V (g_{RL}^{S*} + 6g_{RL}^{T*}) - g_{RL}^V (g_{LR}^{S*} + 6g_{LR}^{T*}) \right\} \\ b &= 4(|g_{RR}^V|^2 + |g_{LL}^V|^2) + |g_{RR}^S|^2 + |g_{LL}^S|^2 \end{aligned}$$

$$b' = 4(|g_{RR}^V|^2 - |g_{LL}^V|^2) + |g_{RR}^S|^2 - |g_{LL}^S|^2$$

$$\beta = -4\text{Re} \left\{ g_{RR}^V g_{LL}^{S*} + g_{LL}^V g_{RR}^{S*} \right\}$$

$$\beta' = 4\text{Im} \left\{ g_{RR}^V g_{LL}^{S*} - g_{LL}^V g_{RR}^{S*} \right\}$$

$$c = \frac{1}{2} \left\{ |g_{RL}^S - 2g_{RL}^T|^2 + |g_{LR}^S - 2g_{LR}^T|^2 \right\}$$

$$c' = \frac{1}{2} \left\{ |g_{RL}^S - 2g_{RL}^T|^2 - |g_{LR}^S - 2g_{LR}^T|^2 \right\}$$

and

$$Q_L^{\nu_e} = 1 - \left\{ \frac{1}{4}|g_{LR}^S|^2 + \frac{1}{4}|g_{LL}^S|^2 + |g_{RR}^V|^2 + |g_{RL}^V|^2 + 3|g_{LR}^T|^2 \right\}$$

$$\omega_L = \frac{3}{4} \frac{\{|g_{RR}^S|^2 + 4|g_{LR}^V|^2 + |g_{RL}^S + 2g_{RL}^T|^2\}}{|g_{RL}^S|^2 + |g_{RR}^S|^2 + 4|g_{LL}^V|^2 + 4|g_{LR}^V|^2 + 12|g_{RL}^T|^2}.$$

It has been noted earlier by C. Jarlskog [11], that certain experiments observing the decay electron are especially informative if they yield the  $V$ - $A$  values. The complete solution is now found as follows. Fetscher *et al.* [2] introduced four probabilities  $Q_{\varepsilon\mu}(\varepsilon, \mu = R, L)$  for the decay of a  $\mu$ -handed muon into an  $\varepsilon$ -handed electron, and showed that there exist upper bounds on  $Q_{RR}$ ,  $Q_{LR}$ , and  $Q_{RL}$ , and a lower bound on  $Q_{LL}$ . These probabilities are given in terms of the  $g_{\varepsilon\mu}^\gamma$ 's by

$$Q_{\varepsilon\mu} = \frac{1}{4}|g_{\varepsilon\mu}^S|^2 + |g_{\varepsilon\mu}^V|^2 + 3(1 - \delta_{\varepsilon\mu})|g_{\varepsilon\mu}^T|^2, \quad (9)$$

where  $\delta_{\varepsilon\mu} = 1$  for  $\varepsilon = \mu$ , and  $\delta_{\varepsilon\mu} = 0$  for  $\varepsilon \neq \mu$ . They are related to the parameters  $a$ ,  $b$ ,  $c$ ,  $a'$ ,  $b'$ , and  $c'$  by

$$\begin{aligned} Q_{RR} &= 2(b + b')/A, \\ Q_{LR} &= [(a - a') + 6(c - c')]/2A, \\ Q_{RL} &= [(a + a') + 6(c + c')]/2A, \\ Q_{LL} &= 2(b - b')/A, \end{aligned} \quad (10)$$

with  $A = 16$ . In the Standard Model,  $Q_{LL} = 1$  and the others are zero.

Since the upper bounds on  $Q_{RR}$ ,  $Q_{LR}$ , and  $Q_{RL}$  are found to be small, and since the helicity of the  $\nu_\mu$  in pion decay is known from experiment [12,13] to very high precision to be  $-1$  [14], the cross section  $S$  of *inverse* muon decay, normalized to the  $V$ - $A$  value, yields [2]

$$|g_{LL}^S|^2 \leq 4(1 - S) \quad (11)$$

and

$$|g_{LL}^V|^2 = S. \quad (12)$$

Thus the Standard Model assumption of a pure  $V$ - $A$  leptonic charged weak interaction of  $e$  and  $\mu$  is derived (within errors) from experiments at energies far below mass of the  $W^\pm$ : Eq. (12) gives a lower limit for  $V$ - $A$ , and Eqs. (9) and (11) give upper limits for the other four-fermion interactions. The existence of such upper limits may also be seen from  $Q_{RR} + Q_{RL} = (1 - \xi')/2$  and  $Q_{RR} + Q_{LR} = \frac{1}{2}(1 + \xi/3 - 16 \xi \delta/9)$ . Table 1 gives the current experimental limits on the magnitudes of the  $g_{\varepsilon\mu}^\gamma$ 's. More stringent limits on the six coupling constants  $g_{LR}^S$ ,  $g_{LR}^V$ ,

# Lepton Particle Listings

$\mu$

$g_{LR}^T$ ,  $g_{RL}^S$ ,  $g_{RL}^V$ , and  $g_{RL}^T$  have been derived from upper limits on the neutrino mass [18]. Limits on the “charge retention” coordinates, as used in the older literature (e.g., Ref. 19), are given by Burkard *et al.* [20].

**Table 1.** Coupling constants  $g_{\varepsilon\mu}^\gamma$  and some combinations of them. Ninety-percent confidence level experimental limits. The limits on  $|g_{LL}^S|$  and  $|g_{LL}^V|$  are from Ref. 15, and the others from a general analysis of muon decay measurements. Top three rows: Ref. 22, fourth row: Ref. 16, next three rows: Ref. 17, last row: Ref. 21. The experimental uncertainty on the muon polarization in pion decay is included. Note that, by definition,  $|g_{\varepsilon\mu}^S| \leq 2$ ,  $|g_{\varepsilon\mu}^V| \leq 1$  and  $|g_{\varepsilon\mu}^T| \leq 1/\sqrt{3}$ .

$ g_{RR}^S  < 0.035$	$ g_{RR}^V  < 0.017$	$ g_{RR}^T  \equiv 0$
$ g_{LR}^S  < 0.050$	$ g_{LR}^V  < 0.023$	$ g_{LR}^T  < 0.015$
$ g_{RL}^S  < 0.420$	$ g_{RL}^V  < 0.105$	$ g_{RL}^T  < 0.105$
$ g_{LL}^S  < 0.550$	$ g_{LL}^V  > 0.960$	$ g_{LL}^T  \equiv 0$
$ g_{LR}^S + 6g_{LR}^T  < 0.143$	$ g_{RL}^S + 6g_{RL}^T  < 0.418$	
$ g_{LR}^S + 2g_{LR}^T  < 0.108$	$ g_{RL}^S + 2g_{RL}^T  < 0.417$	
$ g_{LR}^S - 2g_{LR}^T  < 0.070$	$ g_{RL}^S - 2g_{RL}^T  < 0.418$	
$Q_{RR} + Q_{LR} < 8.2 \times 10^{-4}$

0.782 ± 0.031		KRUGER	61		
0.78 ± 0.05	8354	PLANO	60	HBC	+ Whole spectrum

<sup>1</sup> The quoted systematic error includes a contribution of 0.00006 (added in quadrature) from uncertainties on radiative corrections and on the Michel parameter  $\eta$ .

<sup>2</sup> BALKE 88 uses  $\rho = 0.752 \pm 0.003$ .

<sup>3</sup> VOSSLER 69 has measured the asymmetry below 10 MeV. See comments about radiative corrections in VOSSLER 69.

### $|\xi|$ (PARAMETER) $\times (\mu$ LONGITUDINAL POLARIZATION)

(V–A) theory predicts  $\xi = 1$ , longitudinal polarization = 1.

VALUE	DOCUMENT ID	TECN	CHG	COMMENT
<b>1.0009 ± 0.0016 OUR AVERAGE</b>				
1.00084 ± 0.00029 ± 0.00165	BUENO	11	TWST	Surface $\mu^+$ beam
1.0027 ± 0.0079 ± 0.0030	BELTRAMI	87	CNTR	SIN, $\pi$ decay in flight
• • • We do not use the following data for averages, fits, limits, etc. • • •				
1.0003 ± 0.0006 ± 0.0038	JAMIESON	06	TWST	+ surface $\mu^+$ beam
1.0013 ± 0.0030 ± 0.0053	<sup>1</sup> IMAZATO	92	SPEC	+ $K^+ \rightarrow \mu^+ \nu_\mu$
0.975 ± 0.015	AKHMANOV	68	EMUL	140 kG

0.903 ± 0.027	<sup>2</sup> ALI-ZADE	61	EMUL	+ 27 kG
0.93 ± 0.06	PLANO	60	HBC	+ 8.8 kG
0.97 ± 0.05	BARDON	59	CNTR	Bromoform target

<sup>1</sup> The corresponding 90% confidence limit from IMAZATO 92 is  $|\xi P_\mu| > 0.990$ . This measurement is of  $K^+$  decay, not  $\pi^+$  decay, so we do not include it in an average, nor do we yet set up a separate data block for  $K$  results.

<sup>2</sup> Depolarization by medium not known sufficiently well.

$\xi \times (\mu \text{ LONGITUDINAL POLARIZATION}) \times \delta / \rho$ 

VALUE	CL%	DOCUMENT ID	TECN	CHG	COMMENT
<b>1.00179<math>\pm</math>0.00156 -0.00071</b>		<sup>1</sup> BAYES	11	TWST +	Surface $\mu^+$ beam
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>0.99682	90	<sup>2</sup> JODIDIO	86	SPEC +	TRIUMF
>0.9966	90	<sup>3</sup> STOKER	85	SPEC +	$\mu$ -spin rotation
>0.9959	90	CARR	83	SPEC +	11 kG

<sup>1</sup> BAYES 11 obtains the limit  $> 0.99909$  (90% CL) with the constraint that  $\xi \times (\mu \text{ LONGITUDINAL POLARIZATION}) \times \delta / \rho \leq 1.0$ .

<sup>2</sup> JODIDIO 86 includes data from CARR 83 and STOKER 85. The value here is from the erratum.

<sup>3</sup> STOKER 85 find  $(\xi P_{\mu} \delta / \rho) > 0.9955$  and  $> 0.9966$ , where the first limit is from new  $\mu$  spin-rotation data and the second is from combination with CARR 83 data. In  $V-A$  theory,  $(\delta / \rho) = 1.0$ .

 $\xi' = \text{LONGITUDINAL POLARIZATION OF } e^+$ 

( $V-A$ ) theory predicts the longitudinal polarization =  $\pm 1$  for  $e^{\pm}$ , respectively. We have flipped the sign for  $e^-$  so our programs can average.

$\tau$

$$J = \frac{1}{2}$$

$\tau$  discovery paper was PERL 75.  $e^+e^- \rightarrow \tau^+\tau^-$  cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out  $J = 3/2$ . KIRKBY 79 also ruled out  $J$ =integer,  $J = 3/2$ .

$<2.7 \times 10^{-3}$	95	<sup>1</sup> HEISTER	03F ALEP	1990-1995 LEP runs
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$<9.9 \times 10^{-3}$	90	<sup>1</sup> ACCIARRI	98c L3	1991-1995 LEP runs
<sup>1</sup> Limit is on the absolute value of the imaginary part of the weak anomalous magnetic dipole moment.				

## $\tau^-$ DECAY MODES

$\tau^+$  modes are charge conjugates of the modes below. “ $h^\pm$ ” stands for  $\pi^\pm$  or  $K^\pm$ . “ $\ell$ ” stands for e or  $\mu$ . “Neutrals” stands for  $\gamma$ ’s and/or  $\pi^0$ ’s.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Modes with one charged particle</b>		
$\Gamma_1$ particle $^- \geq 0$ neutrals $\geq 0 K^0 \nu_\tau$ (“1-prong”)	(85.24 $\pm$ 0.06) %	
$\Gamma_2$ particle $^- \geq 0$ neutrals $\geq 0 K_L^0 \nu_\tau$	(84.58 $\pm$ 0.06) %	
$\Gamma_3$ $\mu^- \overline{\nu}_\mu \nu_\tau$	[a] (17.39 $\pm$ 0.04) %	
$\Gamma_4$ $\mu^- \overline{\nu}_\mu \nu_\tau \gamma$	[b] ( 3.68 $\pm$ 0.10 ) $\times 10^{-3}$	
$\Gamma_5$ $e^- \overline{\nu}_e \nu_\tau$	[a] (17.82 $\pm$ 0.04) %

Lepton Family number (LF), Lepton number (L),  
or Baryon number (B) violating modes

L means lepton number violation (e.g.  $\tau^- \rightarrow e^+ \pi^- \pi^-$ ). Following common usage, LF means lepton family violation and not lepton number violation (e.g.  $\tau^- \rightarrow e^- \pi^+ \pi^-$ ). B means baryon number violation.

### $\tau$ BRANCHING FRACTIONS

Revised April 2016 by S.Banerjee (University of Louisville), K.Hayes (Hillsdale College), A.Lusiani (Scuola Normale Superiore and INFN, sezione di Pisa)

In order to make optimal use of the experimental data to determine the  $\tau$  branching fractions, their uncertainties, and their correlations, we perform a global minimum  $\chi^2$  fit using the measured values, their uncertainties, their statistical correlations, their dependencies on external parameters and common systematics, and the relations that hold between the branching fractions, including a unitarity constraint on the sum of all the exclusive  $\tau$  decay branching fractions. Starting with this edition, we use a new fit procedure, which has been elaborated by the Tau Physics Group within the Heavy Flavour Averaging Group (HFAG) [1].

In the following, we use “branching fraction” to refer to the partial decay fraction of a particle like the  $\tau$  into a specific decay mode, and “branching ratio” to refer to quantities derived from the branching fractions [2], like for instance a ratio of two branching fractions, or a ratio of two linear combinations of branching fractions.

#### *The constrained fit to $\tau$ branching fractions.*

The  $\tau$  Listings contains 242  $\tau$  decay modes, out of which 61 are Lepton Family number, Lepton number, or Baryon number violating modes. The fit computes the branching fractions of 112 decay modes. Although no new  $\tau$  branching fraction and ratio measurements have been released since the 2015 edition, the fit in this edition includes more experimental measurements (169, up from 143 in 2015) and determines in the fit several additional  $\tau$  branching fractions and ratios, relying on a larger and updated set of constraints that relate the branching fractions and ratios between themselves. The measurements are treated as follows [1].

Many published measurements depend on external parameters such as the  $\tau$  pair production cross-section in  $e^+e^-$

annihilations at the  $\Upsilon(4S)$  peak. We compute the size and sign of these dependencies and update the measurements and their uncertainties to the current values of the external parameters. Accordingly, the measurements and their uncertainties are updated to account for updated values of external parameters. The dependencies on common systematic effects are also determined in size and sign, and all the common systematic dependencies of different measurements are used together with the published statistical and systematic uncertainties and correlations in order to compute a single all-inclusive variance and covariance matrix of the experimental measurements. All the measurements, their uncertainties, and their correlations were taken from the respective published papers. Their values and the constraints used in the fit are reported in the  $\tau$  Listings section that follows this review. If only a few measurements are correlated, the correlation coefficients are listed in the footnote for each measurement (see for example  $\Gamma(\text{particle}^- \geq 0 \text{ neutrals} \geq 0 K^0 \nu_\tau)$  (“1-prong”))/ $\Gamma_{\text{total}}$ ). If a large number of measurements are correlated, then the full correlation matrix is listed in the footnote to the measurement that first appears in the  $\tau$  Listings. Footnotes to the other measurements refer to the first measurement. For example, the large correlation matrices for the branching fraction or ratio measurements contained in Refs. [3,4] are listed in Footnotes to the  $\Gamma(e^- \bar{\nu}_e \nu_\tau)/\Gamma_{\text{total}}$  and  $\Gamma(h^- \nu_\tau)/\Gamma_{\text{total}}$  measurements respectively. The constraints between the  $\tau$  branching fractions and ratios include coefficients that correspond to physical quantities, like for instance the branching fractions of the  $\eta$  and  $\omega$  mesons. All quantities are taken from the 2015 edition of the Review of Particle Physics. Their uncertainties are neglected in the fit.

Compared to the 2015 edition, the fit now includes several additional modes, mainly related to the most recent BaBar papers on high multiplicity modes [5] and  $K_S^0 K_S^0$  modes [6] and the Belle paper on neutral kaon modes [7]:

$$B(\tau \rightarrow \pi^- \pi^0 K_S^0 K_S^0 \nu_\tau)$$

$$B(\tau \rightarrow K^- K^- K^+ \nu_\tau)$$

$$B(\tau \rightarrow K^- \pi^0 \eta \nu_\tau)$$

$$B(\tau \rightarrow \pi^- \bar{K}^0 \eta \nu_\tau) ;$$

Also, the following components of  $\tau$ -decay modes are now included [5,8,9]:

$$B(\tau \rightarrow \pi^- 2\pi^0 \eta \nu_\tau \text{ } (\eta \rightarrow \pi^+ \pi^- \pi^0) \text{ (ex. } K^0))$$

$$B(\tau \rightarrow 2\pi^- \pi^+ \eta \nu_\tau \text{ } (\eta \rightarrow \pi^+ \pi^- \pi^0) \text{ (ex. } K^0))$$

$$B(\tau \rightarrow 2\pi^- \pi^+ \eta \nu_\tau \text{ } (\eta \rightarrow \gamma \gamma) \text{ (ex. } K^0))$$

$$B(\tau \rightarrow \pi^- 2\pi^0 \omega \nu_\tau \text{ (ex. } K^0))$$

$$B(\tau \rightarrow 2\pi^- \pi^+ \omega \nu_\tau \text{ (ex. } K^0))$$

$$B(\tau \rightarrow \pi^- f_1 \nu_\tau \text{ } (f_1 \rightarrow 2\pi^- 2\pi^+)) .$$

$$B(\tau \rightarrow K^- \phi \nu_\tau) .$$

We obtain the branching fraction of  $\tau \rightarrow a_1^- (\rightarrow \pi^- \gamma) \nu_\tau$  using the ALEPH estimate for  $B(a_1^- \rightarrow \pi^- \gamma)$  [3], which uses the measurement of  $\Gamma(a_1^- \rightarrow \pi^- \gamma)$  [10]. In the fit, we assume that  $B(\tau^- \rightarrow a_1^- \nu_\tau)$  is equal to  $B(\tau \rightarrow \pi^- \pi^- \pi^+ \nu_\tau \text{ (ex. } K^0, \omega)) + B(\tau \rightarrow \pi^- 2\pi^0 \nu_\tau \text{ (ex. } K^0))$ .

**Figure 1:** Pulls of individual measurements against the respective fitted quantity. No scale factor is used.

In some cases, constraints describe approximate relations that nevertheless hold within the present experimental precision. For instance, the constraint  $B(\tau \rightarrow K^- K^- K^+ \nu_\tau) = B(\tau \rightarrow K^- \phi \nu_\tau) \times B(\phi \rightarrow K^+ K^-)$  is justified within the current experimental evidence.

In the fit, scale factors are applied to the published uncertainties of measurements only if significant inconsistency between different measurements remain after accounting for all relevant uncertainties and correlations. After examining the data and the fit pulls, it has been decided to apply just one scale factor of 5.4 on the measurements of  $B(\tau \rightarrow K^- K^- K^+ \nu_\tau)$ . The scale factor has been computed and applied according to the standard PDG procedure. Without the scale factor applied, the  $\chi^2$  probability of the fit is about 2%. On a per-measurement basis, the pull distribution in figure 1 indicates that just a few measurements have more than  $3\sigma$  pulls. (The uncertainties to obtain the pulls are computed using the measurements variance matrix and the variance matrix of the result, accounting for the fact that the variance matrix of the result is obtained from the measurement variance with the fit.) The pull probability distribution in figure 2 is reasonably flat. With many measurements some entries on the tails of the normal distribution must be expected. There are 169 pulls, one per measurement. They are partially correlated, and the effective number of independent pulls is equal to the number of degrees of freedom of the fit, 124. Only the  $\tau \rightarrow K^- K^- K^+ \nu_\tau$  decay mode has a pull that is inconsistent at the level of more than  $3\sigma$  even if considered as the largest pull in a set of 124. This confirms the choice of adopting just that one scale factor.

After scaling the error the 2016 constrained fit has a  $\chi^2$  of 134.9 for 124 degrees of freedom, corresponding to a  $\chi^2$  probability of 24%. We use 169 measurements and 84 constraints on the branching fractions and ratios to determine 129 quantities, consisting of 112 branching fractions and 17 branching ratios. A total of 85 quantities have at least one measurement in the fit. The constraints include the unitarity constraint on the sum of all the exclusive  $\tau$  decay modes,  $B_{\text{all}} = 1$ . If the unitarity

**Figure 2:** Probability of individual measurement pulls against the respective fitted quantity. No scale factor is used.

constraint is released, the fit result for  $B_{\text{all}}$  is consistent with unitarity with  $1 - B_{\text{all}} = (0.07 \pm 0.10)\%$ .

For the convenience of summarizing the fit results, we list in the following the values and uncertainties for a set of 46 “basis” decay modes, from which all remaining branching fractions and ratios can be obtained using the constraints. Unlike in previous editions, the basis decay modes are not intended to sum up to 1. The new unitarity constraint corresponds to a linear combination of the basis modes weighted by the coefficients listed in the following. The corresponding correlation matrix is listed in the  $\tau$  Listings.

decay mode	fit result (%)	coefficient

Applying the fit procedure on the PDG 2015 inputs, the fit results differ from the 2015 fit by at most 20% of their uncertainty, for fitted quantities that have measurements with asymmetric errors, and by at most 5% of their uncertainty for the other quantities. The differences originate from the different treatment of asymmetric errors. The present fit procedure symmetrizes the errors as  $\sigma_{\text{symm}}^2 = (\sigma_+^2 + \sigma_-^2)/2$ , while the PDG 2015 fit did model the asymmetric error distributions in the fit. Comparing the results of the previous edition with the current fit, there are differences up to 2.3 times the fitted quantity uncertainty ( $2.3\sigma$ ) for quantities that have no measurement included in the fit and are derived through the constraints. Those differences arise mainly from three changes: the unitarity constraint has been updated to accommodate several additional decay modes, the definitions of the respective quantities have been updated to use the additional decay modes, and the parameters of all constraints (typically,  $K, \eta, \omega$  branching fractions) have been updated to the values reported in the last published PDG edition. For quantities that have measurements in the fit, the fitted values changed at most by  $1.1\sigma$ , reflecting the inclusion of several additional measurements, especially on high-multiplicity decay modes. The uncertainties on the fit results are generally smaller than in 2015 because only one error scale factor is used and some additional measurements have been used.

In defining the fit constraints and in selecting the modes that sum up to one we made some assumptions and choices. We assume that some channels, like  $\tau^- \rightarrow \pi^- K^+ \pi^- \geq 0\pi^0 \nu_\tau$  and  $\tau^- \rightarrow \pi^+ K^- K^- \geq 0\pi^0 \nu_\tau$ , have negligible branching fractions as expected from the Standard Model, even if the experimental limits for these branching fractions are not very stringent. The 95% confidence level upper limits are  $B(\tau^- \rightarrow \pi^- K^+ \pi^- \geq$

$0\pi^0 \nu_\tau) < 0.25\%$  and  $B(\tau^- \rightarrow \pi^+ K^- K^- \geq 0\pi^0 \nu_\tau) < 0.09\%$ , values not so different from measured branching fractions for allowed 3-prong modes containing charged kaons. For decays to final states containing one neutral kaon we assume that the branching fraction with the  $K_L^0$  are the same as the corresponding one with a  $K_S^0$ . On decays with two neutral kaons we assume that the branching fractions with  $K_L^0 K_L^0$  are the same as the ones with  $K_S^0 K_S^0$ .

#### **BaBar and Belle measure on average lower branching fractions and ratios.**

We compare the BaBar and Belle measurements with the results of a fit where all their measurements have been excluded. We find that that BaBar and Belle tend to measure lower  $\tau$  branching fractions and ratios than the other experiments. Figure 3 shows histograms of the 27 normalized differences between the  $B$ -factory measurements and the respective non- $B$ -factory fit results. The normalization is the uncertainty on the difference. The average normalized difference between the two sets of measurements is  $-0.8\sigma$  ( $-0.8\sigma$  for the 16 Belle measurements and  $-0.9\sigma$  for the 11 BaBar measurements).

**Figure 3:** Distribution of the normalized difference between the 27  $B$ -factory measurements and non- $B$ -factory measurements. The list includes 16 measurements of branching fractions and ratios published by the Belle collaboration and 11 by the BaBar collaboration that are used in the fit and for which non- $B$ -factory measurements exist.

#### **Overconsistency of Leptonic Branching Fraction Measurements.**

As observed in the previous editions of this review, measurements of the leptonic branching fractions are more consistent with each other than expected from the quoted errors on the individual measurements. The  $\chi^2$  is 0.34 for  $B_e$  and 0.08 for

# Lepton Particle Listings

$\tau$

$B_\mu$ . Assuming normal errors, the probability of a smaller  $\chi^2$  is 1.3% for  $B_e$  and 0.08% for  $B_\mu$ .

## Technical implementation of the fit.

The fit computes a set of quantities denoted with  $q_i$  by minimizing a  $\chi^2$  while respecting a series of equality constraints on the  $q_i$ . The  $\chi^2$  is computed using the measurements  $m_i$  and their covariance matrix  $E_{ij}$  as  $\chi^2 = (m_i - A_{ik}q_k)^t E_{ij}^{-1} (m_j - A_{jl}q_l)$  where the model matrix  $A_{ij}$  is used to get the vector of the predicted measurements  $m'_i$  from the vector of the fit parameters  $q_j$  as  $m'_i = A_{ij}q_j$ . In this particular implementation the measurements are grouped by the quantity that they measure, and all quantities with at least one measurement correspond to a fit parameter. Therefore, the matrix  $A_{ij}$  has one row per measurement  $m_i$  and one column per fitted quantity  $q_j$ , with unity coefficients for the rows and column that identify a measurement  $m_i$  of the quantity  $q_j$ , respectively. The constraints are equations involving the fit parameters. The fit does not impose limitations on the functional form of the constraints. In summary, the fit requires:

$$\min(m_i - A_{ik}q_k)^t E_{ij}^{-1} (m_j - A_{jl}q_l), \quad (1a)$$

$$\text{subjected to } f_r(q_s) - c_r = 0, \quad (1b)$$

where the left term of Eq. (1b) defines the constraint expressions. Using the method of Lagrange multipliers, a set of equations is obtained by taking the derivatives with respect to the fitted quantities  $q_k$  and the Lagrange multipliers  $\lambda_r$  of the sum of the  $\chi^2$  and the constraint expressions multiplied by the Lagrange multipliers  $\lambda_r$ , one for each constraint:

$$\min \left[ (A_{ik}q_k - m_i)^t E_{ij}^{-1} (A_{jl}q_l - m_j) + 2\lambda_r (f_r(q_s) - c_r) \right] \quad (2a)$$

$$(\partial/\partial q_k, \partial/\partial \lambda_r)[\text{expression above}] = 0 \quad (2b)$$

Eq. (2b) defines a set of equations for the vector of the unknowns  $(q_k, \lambda_r)$ , some of which may be non-linear, in case of non-linear constraints. An iterative minimization procedure approximates at each step the non-linear constraint expressions by their first order Taylor expansion around the current values of the fitted quantities,  $\bar{q}_s$ :

$$f_r(q_s) - c_r = f_r(\bar{q}_s) + \frac{\partial f_r(q_s)}{\partial q_s} \bigg|_{\bar{q}_s} (q_s - \bar{q}_s) - c_r, \quad (3a)$$

which can be written as

$$B_{rs}q_s - c'_r, \quad (3b)$$

where  $c'_r$  are the resulting constant known terms, independent of  $q_s$  at first order. After linearization, the differentiation by  $q_k$  and  $\lambda_r$  is trivial and leads to a set of linear equations

$$A_{ki}^t E_{ij}^{-1} A_{jl} q_l + B_{kr}^t \lambda_r = A_{ki}^t E_{ij}^{-1} m_j \quad (4a)$$

$$B_{rs}q_s = c'_r, \quad (4b)$$

which can be expressed as:

$$F_{ij} u_j = v_i \quad (5)$$

where  $u_j = (q_k, \lambda_r)$  and  $v_i$  is the vector of the known constant terms running over the index  $k$  and then  $r$  in the right terms of Eq. (4a) and Eq. (4b), respectively. Solving the equation set in Eq. (5) by matrix inversion gives the the fitted quantities and their variance and covariance matrix, using the measurements and their variance and covariance matrix. The fit procedure starts by computing the linear approximation of the non-linear constraint expressions around the quantities seed values. With an iterative procedure, the unknowns are updated at each step by solving the equations and the equations are then linearized around the updated values, until the variation of the fitted unknowns is reduced below a numerically small threshold.

The charged particle here can be  $e$ ,  $\mu$ , or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below. The measurements used only for the average are marked "avg," whereas "f&a" marks a result used for the fit and the average.

## $\tau$ -DECAY PARAMETERS $\tau$ -LEPTON DECAY PARAMETERS

Updated August 2011 by A. Stahl (RWTH Aachen).

The purpose of the measurements of the decay parameters (also known as Michel parameters) of the  $\tau$  is to determine the structure (spin and chirality) of the current mediating its decays.

**Leptonic Decays:** The Michel parameters are extracted from the energy spectrum of the charged daughter lepton  $\ell = e, \mu$  in the decays  $\tau \rightarrow \ell \nu_\ell \nu_\tau$ . Ignoring radiative corrections, neglecting terms of order  $(m_\ell/m_\tau)^2$  and  $(m_\tau/\sqrt{s})^2$ , and setting the neutrino masses to zero, the spectrum in the laboratory frame reads

$$\frac{d\Gamma}{dx} = \frac{G_{\tau\ell}^2 m_\tau^5}{192 \pi^3} \times \left\{ f_0(x) + \rho f_1(x) + \eta \frac{m_\ell}{m_\tau} f_2(x) - P_\tau [\xi g_1(x) + \xi \delta g_2(x)] \right\}, \quad (1)$$

with

$$\begin{aligned} f_0(x) &= 2 - 6x^2 + 4x^3 \\ f_1(x) &= -\frac{4}{9} + 4x^2 - \frac{32}{9}x^3 & g_1(x) &= -\frac{2}{3} + 4x - 6x^2 + \frac{8}{3}x^3 \\ f_2(x) &= 12(1-x)^2 & g_2(x) &= \frac{4}{9} - \frac{16}{3}x + 12x^2 - \frac{64}{9}x^3. \end{aligned}$$

The quantity  $x$  is the fractional energy of the daughter lepton  $\ell$ , i.e.,  $x = E_\ell/E_{\ell, \text{max}} \approx E_\ell/(\sqrt{s}/2)$  and  $P_\tau$  is the polarization of the tau leptons. The integrated decay width is given by

$$\Gamma = \frac{G_{\tau\ell}^2 m_\tau^5}{192 \pi^3} \left( 1 + 4\eta \frac{m_\ell}{m_\tau} \right). \quad (2)$$

The situation is similar to muon decays  $\mu \rightarrow e \nu_e \nu_\mu$ . The generalized matrix element with the couplings  $g_{\tau\ell}^\gamma$  and their relations to the Michel parameters  $\rho$ ,  $\eta$ ,  $\xi$ , and  $\delta$  have been described in the “Note on Muon Decay Parameters.” The Standard Model expectations are 3/4, 0, 1, and 3/4, respectively. For more details, see Ref. 1.

**Hadronic Decays:** In the case of hadronic decays  $\tau \rightarrow h \nu_\tau$ , with  $h = \pi, \rho$ , or  $a_1$ , the ansatz is restricted to purely vectorial currents. The matrix element is

$$\frac{G_{\tau h}}{\sqrt{2}} \sum_{\lambda=R,L} g_\lambda \langle \bar{\Psi}_\omega(\nu_\tau) | \gamma^\mu | \Psi_\lambda(\tau) \rangle J_\mu^h \quad (3)$$

with the hadronic current  $J_\mu^h$ . The neutrino chirality  $\omega$  is uniquely determined from  $\lambda$ . The spectrum depends only on a single parameter  $\xi_h$

$$\frac{d^n \Gamma}{dx_1 dx_2 \dots dx_n} = f(\vec{x}) + \xi_h P_\tau g(\vec{x}), \quad (4)$$

with  $f$  and  $g$  being channel-dependent functions of the  $n$  observables  $\vec{x} = (x_1, x_2, \dots, x_n)$  (see Ref. 2). The parameter  $\xi_h$  is related to the couplings through

$$\xi_h = |g_L|^2 - |g_R|^2. \quad (5)$$

$\xi_h$  is the negative of the chirality of the  $\tau$  neutrino in these decays. In the Standard Model,  $\xi_h = 1$ . Also included in the Data Listings for  $\xi_h$  are measurements of the neutrino helicity which coincide with  $\xi_h$ , if the neutrino is massless (ASNER 00, ACKERSTAFF 97R, AKERS 95P, ALBRECHT 93C, and ALBRECHT 90I).

**Combination of Measurements:** The individual measurements are combined, taking into account the correlations between the parameters. In a first fit, universality between the two leptonic decays, and between all hadronic decays, is assumed. A second fit is made without these assumptions. The results of the two fits are provided as OUR FIT in the Data Listings below in the tables whose title includes “(e or mu)” or “(all hadronic modes),” and “(e),” “(mu)” etc., respectively. The measurements show good agreement with the Standard Model. The  $\chi^2$  values with respect to the Standard model predictions are 24.1 for 41 degrees of freedom and 26.8 for 56 degrees of freedom, respectively. The correlations are reduced through this combination to less than 20%, with the exception of  $\rho$  and  $\eta$  which are correlated by +23%, for the fit with universality and by +70% for  $\tau \rightarrow \mu \nu_\mu \nu_\tau$ .

**Model-independent Analysis:** From the Michel parameters, limits can be derived on the couplings  $g_{e\lambda}^\kappa$  without further model assumptions. In the Standard model  $g_{LL}^V = 1$  (leptonic decays), and  $g_L = 1$  (hadronic decays) and all other couplings vanish. First, the partial decay widths have to be compared to the Standard Model predictions to derive limits on the normalization of the couplings  $A_x = G_{\tau x}^2/G_F^2$  with Fermi’s constant  $G_F$ :

$$A_e = 1.0029 \pm 0.0046,$$

$$A_\mu = 0.981 \pm 0.018,$$

$$A_\pi = 1.0020 \pm 0.0073. \quad (6)$$

Then limits on the couplings (95% CL) can be extracted (see Ref. 3 and Ref. 4). Without the assumption of universality, the limits given in Table 1 are derived.

**Table 1:** Coupling constants  $g_{e\mu}^\gamma$ . 95% confidence level experimental limits. The limits include the quoted values of  $A_e$ ,  $A_\mu$ , and  $A_\pi$  and assume  $A_\rho = A_{a_1} = 1$ .

$\tau \rightarrow e\nu_e\nu_\tau$		
$ g_{RR}^S  < 0.70$	$ g_{RR}^V  < 0.17$	$ g_{RR}^T  \equiv 0$
$ g_{LR}^S  < 0.99$	$ g_{LR}^V  < 0.13$	$ g_{LR}^T  < 0.082$
$ g_{RL}^S  < 2.01$	$ g_{RL}^V  < 0.52$	$ g_{RL}^T  < 0.51$
$ g_{LL}^S  < 2.01$	$ g_{LL}^V  < 1.005$	$ g_{LL}^T  \equiv 0$
$\tau \rightarrow \mu\nu_\mu\nu_\tau$		
$ g_{RR}^S  < 0.72$	$ g_{RR}^V  < 0.18$	$ g_{RR}^T  \equiv 0$
$ g_{LR}^S  < 0.95$	$ g_{LR}^V  < 0.12$	$ g_{LR}^T  < 0.079$
$ g_{RL}^S  < 2.01$	$ g_{RL}^V  < 0.52$	$ g_{RL}^T  < 0.51$
$ g_{LL}^S  < 2.01$	$ g_{LL}^V  < 1.005$	$ g_{LL}^T  \equiv 0$
$\tau \rightarrow \pi\nu_\tau$		
$ g_R^V  < 0.15$	$ g_L^V  > 0.992$	
$\tau \rightarrow \rho\nu_\tau$		
$ g_R^V  < 0.10$	$ g_L^V  > 0.995$	
$\tau \rightarrow a_1\nu_\tau$		
$ g_R^V  < 0.16$	$ g_L^V  > 0.987$	

**Model-dependent Interpretation:** More stringent limits can be derived assuming specific models. For example, in the framework of a two Higgs doublet model, the measurements correspond to a limit of  $m_{H^\pm} > 1.9 \text{ GeV} \times \tan\beta$  on the mass of the charged Higgs boson, or a limit of 253 GeV on the mass of the second  $W$  boson in left-right symmetric models for arbitrary mixing (both 95% CL). See Ref. 4 and Ref. 5.

<sup>1</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95c, ALBRECHT 93g, and ALBRECHT 94e. ALBRECHT 98 use tau pair events of the type  $\tau^-\tau^+ \rightarrow (\ell^-\bar{\nu}_\ell\nu_\tau)(\pi^+\pi^0\nu_\tau)$ , and their charged conjugates.

<sup>2</sup> ABE 97o assume  $\eta = 0$  in their fit. Letting  $\eta$  vary in the fit gives a  $\rho$  value of  $0.69 \pm 0.13 \pm 0.05$ .

<sup>3</sup> Value is from a simultaneous fit for the  $\rho$  and  $\eta$  decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E ( $\rho(e \text{ or } \mu)$ ) value which assumes  $\eta = 0$ . Result is strongly correlated with ALBRECHT 95c.

<sup>4</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95c, ALBRECHT 93g, and ALBRECHT 94e.

## $\tau$

• • • We do not use the following data for averages, fits, limits, etc. • • •

$0.94 \pm 0.21 \pm 0.07$	18k	ACCIARRI	96H L3	Repl. by ACCIARRI 98R
$0.97 \pm 0.14$		<sup>3</sup> ALBRECHT	95C ARG	Repl. by ALBRECHT 98
$1.18 \pm 0.15 \pm 0.16$		BUSKULIC	95D ALEP	Repl. by HEISTER 01E
$0.90 \pm 0.15 \pm 0.10$	3230	<sup>4</sup> ALBRECHT	93G ARG	$E_{\text{cm}}^{\text{ee}} = 9.4\text{--}10.6$ GeV

<sup>1</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type  $\tau^- \tau^+ \rightarrow (\ell^- \overline{\nu}_\ell \nu_\tau)(\pi^+ \pi^0 \overline{\nu}_\tau)$ , and their charged conjugates.

<sup>2</sup> ABE 97o assume  $\eta = 0$  in their fit. Letting  $\eta$  vary in the fit gives a  $\xi$  value of  $1.02 \pm 0.36 \pm 0.05$ .

<sup>3</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 95C uses events of the type  $\tau^- \tau^+ \rightarrow (\ell^- \overline{\nu}_\ell \nu_\tau)(h^+ h^- h^+ \overline{\nu}_\tau)$  and their charged conjugates.

<sup>4</sup> ALBRECHT 93G measurement determines  $|\xi|$  for the case  $\xi(e) = \xi(\mu)$ , but the authors point out that other LEP experiments determine the sign to be positive.

## $\xi(e)$ PARAMETER

( $V\text{--}A$ ) theory predicts  $\xi = 1$ .

## Heavy Charged Lepton Searches, Neutrino Properties

<sup>7</sup> Assumes associated neutrino is approximately massless.  
<sup>8</sup> ADEVA 85 analyze one-isolated-muon data and sensitive to  $\tau < 10$  nanosec. Assume  $B(\text{lepton}) = 0.30$ .  $E_{\text{cm}} = 40\text{--}47$  GeV.  
<sup>9</sup> BARTEL 83 limit is from PETRA  $e^+e^-$  experiment with average  $E_{\text{cm}} = 34.2$  GeV.  
<sup>10</sup> BERGER 81b is DESY DORIS and PETRA experiment. Looking for  $e^+e^- \rightarrow L^+L^-$ .  
<sup>11</sup> BRANDELIK 81 is DESY-PETRA experiment. Looking for  $e^+e^- \rightarrow L^+L^-$ .  
<sup>12</sup> AZIMOV 80 estimated probabilities for  $M+N$  type events in  $e^+e^- \rightarrow L^+L^-$  deducing semi-hadronic decay multiplicities of  $L$  from  $e^+e^-$  annihilation data at  $E_{\text{cm}} = (2/3)m_L$ .  
Obtained above limit comparing these with  $e^+e^-$  data (BRANDELIK 80).  
<sup>13</sup> BARBER 80b looked for  $e^+e^- \rightarrow L^+L^-$ ,  $L \rightarrow \nu_L^+ X$  with MARK-J at DESY-PETRA.  
<sup>14</sup> ROTHE 69 examines previous data on  $\mu$  pair production and  $\pi$  and  $K$  decays.

## Neutrino Properties

### INTRODUCTION TO THE NEUTRINO PROPERTIES LISTINGS

Revised August 2013 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The following Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, all of which so far are limits, actually concern superpositions of the mass eigenstates  $\nu_i$ , which are in turn related to the weak eigenstates  $\nu_\ell$ , via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i} |\nu_i\rangle.$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a “dominant eigenstate” approximation. However, the results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles and a third angle that is not exceedingly small. We cannot, therefore, associate any particular state  $|\nu_i\rangle$  with any particular lepton label  $e, \mu$  or  $\tau$ . Nevertheless, note that in the standard labeling the  $|\nu_1\rangle$  has the largest  $|\nu_e\rangle$  component ( $\sim 2/3$ ),  $|\nu_2\rangle$  contains  $\sim 1/3$  of the  $|\nu_e\rangle$  component and  $|\nu_3\rangle$  contains only a small  $\sim 2.5\%$   $|\nu_e\rangle$  component.

Neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged lepton categories. Other properties (mean lifetime, magnetic moment, charge and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, *etc.*) all depend upon the mixing parameters  $|U_{\ell i}|^2$ , but to some extent also on experimental conditions (*e.g.*, on energy resolution). Most of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos, and are unaffected by  $CP$  phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity  $\langle m_\beta^2 \rangle = \sum_i |U_{ei}|^2 m_{\nu_i}^2$  is determined or constrained, where the sum is over all mass eigenvalues  $m_{\nu_i}$  that are too close together to be resolved experimentally. If the energy resolution is better than  $\Delta m_{ij}^2 \equiv m_{\nu_i}^2 - m_{\nu_j}^2$ , the corresponding heavier  $m_{\nu_i}$  and mixing

# Lepton Particle Listings

## Neutrino Properties

parameter could be determined by fitting the resulting spectral anomaly (step or kink).

A limit on  $\langle m_\beta^2 \rangle$  implies an upper limit on the minimum value  $m_{\min}^2$  of  $m_{\nu_i}^2$ , independent of the mixing parameters  $U_{ei}$ :  $m_{\min}^2 \leq \langle m_\beta^2 \rangle$ . However, if and when the value of  $\langle m_\beta^2 \rangle$  is determined then its combination with the results derived from neutrino oscillations that give us the values of the neutrino mass-squared differences  $\Delta m_{ij}^2 \equiv m_i^2 - m_j^2$  and the mixing parameters  $|U_{ei}|^2$ , the individual neutrino mass squares  $m_{\nu_j}^2 = \langle m_\beta^2 \rangle - \sum_i |U_{ei}|^2 \Delta m_{ij}^2$  can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting neutrino species that might be observable since they couple weakly to the flavor neutrinos  $|\nu_l\rangle$ .

Combined three neutrino analyses determine the squared mass differences and all three mixing angles to within reasonable accuracy. For given  $|\Delta m_{ij}^2|$  a limit on  $\langle m_\beta^2 \rangle$  from beta decay defines an upper limit on the maximum value  $m_{\max}$  of  $m_{\nu_i}$ :  $m_{\max}^2 \leq \langle m_\beta^2 \rangle + \sum_{i < j} |\Delta m_{ij}^2|$ . The analysis of the low energy beta decay of tritium, combined with the oscillation results, thus limits all active neutrino masses. Traditionally, experimental neutrino mass limits obtained from pion decay  $\pi^+ \rightarrow \mu^+ + \nu_\mu$  or the shape of the spectrum of decay products of the  $\tau$  lepton did not distinguish between flavor and mass eigenstates. These results are reported as limits of the  $\mu$  and  $\tau$  based neutrino mass. After the determination of the  $|\Delta m_{ij}^2|$ 's and the mixing angles  $\theta_{ij}$ , the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to  $\langle m_\beta \rangle \equiv \sqrt{\langle m_\beta^2 \rangle}$ . This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint on the sum of the neutrino masses can be obtained from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table (Sum of Neutrino Masses,  $m_{\text{tot}}$ ). Discussion concerning the model dependence of this limit is continuing.

### $\overline{\nu}$ MASS (electron based)

Those limits given below are for the square root of  $m_{\nu_e}^{2(\text{eff})} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$ . Limits that come from the kinematics of  ${}^3\text{H}\beta^- \overline{\nu}$  decay are the square roots of the limits for  $m_{\nu_e}^{2(\text{eff})}$ . Obtained from the measurements reported in the Listings for " $\overline{\nu}$  Mass Squared," below.

<sup>1</sup> ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of  $m_{\nu_e}$ , based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for  $m_{\nu_e}^2$ . Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.

<sup>2</sup> KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.

<sup>3</sup> PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.

<sup>4</sup> ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using  $\beta$ -decay of <sup>187</sup>Re. Bolometric AgReO<sub>4</sub> micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium  $\beta$ -decays but has different systematic uncertainties.

<sup>5</sup> LOREDO 02 updates LOREDO 89.

<sup>6</sup> LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to  $m_{\nu_e}^2$ , making unambiguous interpretation difficult. See the footnote under " $\overline{\nu}$  Mass Squared."

<sup>7</sup> WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable  $m_{\nu_e}^2$ . We report the most conservative limit, but the other is nearly the same. See the footnote under " $\overline{\nu}$  Mass Squared."

<sup>8</sup> BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields  $m_{\nu_e}^2 = -4.1 \pm 10.9 \text{ eV}^2$ , leading to this Bayesian limit.

<sup>9</sup> CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of  $m_{\nu_e}^2$  is given.

<sup>10</sup> HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean  $m_{\nu_e}^2 = 221 \pm 4244 \text{ eV}^2$  from the two runs listed below.

<sup>11</sup> STOEFL 95 (LLNL) result is the Bayesian limit obtained from the  $m_{\nu_e}^2$  errors given below but with  $m_{\nu_e}^2$  set equal to 0. The anomalous endpoint accumulation leads to a value of  $m_{\nu_e}^2$  which is negative by more than 5 standard deviations.

<sup>12</sup> WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium  $\beta$  spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

<sup>13</sup> HOLZSCHUH 92B (Zurich) result is obtained from the measurement  $m_{\nu_e}^2 = -24 \pm 48 \pm 61$  (1 $\sigma$  errors), in eV<sup>2</sup>, using the PDG prescription for conversion to a limit in  $m_{\nu_e}$ .

<sup>14</sup> KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the  $m_{\nu_e}^2$  limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.

<sup>15</sup> ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that  $m_{\nu_e}$  lies between 17 and 40 eV. However, the probability of a positive  $m_{\nu_e}^2$  is only 3% if statistical and systematic error are combined in quadrature.

<sup>16</sup> See also comment in BORIS 87B and erratum in BORIS 88.

### $\overline{\nu}$ MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimators of  $m_{\nu_e}^{2(\text{eff})} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$ , in many experiments, we use only KRAUS 05 and LOBASHEV 99 for our average.

<sup>1</sup> ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.

<sup>2</sup> KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.

<sup>3</sup> LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted  $m_\nu^2 \approx -(20-10) \text{ eV}^2$ . This problem is attributed to a discrete spectral anomaly of about  $6 \times 10^{-11}$  intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of  $m_\nu^2 = -1.9 \pm 3.4 \pm 2.2 \text{ eV}^2$  which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived  $m_\nu^2$  limit makes unambiguous interpretation of this result difficult.

<sup>4</sup> WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93. Using a lower temperature of the frozen tritium source eliminated the dewetting of the  $T_2$  film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable  $m_\nu^2$  fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.

<sup>5</sup> BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium source. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.

<sup>6</sup> HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.

<sup>7</sup> STOEFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for  $m_\nu^2$ . The authors acknowledge that “the negative value for the best fit of  $m_\nu^2$  has no physical meaning” and discuss possible explanations for this effect.

<sup>8</sup> SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.

<sup>9</sup> WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium  $\beta$  spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

<sup>10</sup> HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.

<sup>11</sup> KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.

<sup>12</sup> ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that  $m_\nu$  lies between 17 and 40 eV. However, the probability of a positive  $m_\nu^2$  is only 3% if statistical and systematic error are combined in quadrature.

### $\nu$ MASS (electron based)

These are measurement of  $m_{\nu\mu}$  (in contrast to  $m_{\tau\mu}$  given above). The masses can be different for a Dirac neutrino in the absence of  $CPT$  invariance. The possible distinction between  $\nu$  and  $\bar{\nu}$  properties is usually ignored elsewhere in these Listings.

VALUE (eV)	CL%	DOCUMENT ID	TECN	COMMENT
<460	68	YASUMI	94	CNTR $^{163}\text{Ho}$ decay
<225	95	SPRINGER	87	CNTR $^{163}\text{Ho}$ decay

### $\nu$ MASS (muon based)

Limits given below are for the square root of  $m_{\nu\mu}^{2(\text{eff})} \equiv \sum_i |\mathcal{U}_{\mu i}|^2 m_{\nu_i}^2$ .

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the  $\pi^\pm$  mass and the ASSAMAGAN 96 value for the muon momentum for the  $\pi^\pm$  decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since

$m_{\nu\mu}^{2(\text{eff})}$  is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt;0.19 (CL = 90%) OUR EVALUATION</b>				
<0.17	90	<sup>1</sup> ASSAMAGAN	96	SPEC $m_\nu^2 = -0.016 \pm 0.023$
• • • We do not use the following data for averages, fits, limits, etc. • • •

<0.65	90	CLARK	74	ASP K $K_{\mu 3}$ decay

<sup>1</sup> ASSAMAGAN 96 measurement of  $p_\mu$  from  $\pi^+ \rightarrow \mu^+ \nu$  at rest combined with JECKELMANN 94 Solution B pion mass yields  $m_\nu^2 = -0.016 \pm 0.023$  with corresponding Bayesian limit listed above. If Solution A is used,  $m_\nu^2 = -0.143 \pm 0.024 \text{ MeV}^2$ . Replaces ASSAMAGAN 94.

<sup>2</sup> DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below  $T_{\text{QCD}}$  for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.

<sup>3</sup> ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time,  $\sim 1 \text{ s}$ .

<sup>4</sup> Assumes neutrino lifetime  $> 1 \text{ s}$ . For Dirac neutrinos only. See also ENQVIST 93.

<sup>5</sup> ANDERHUB 82 kinematics is insensitive to the pion mass.

### $\nu$ MASS (tau based)

The limits given below are the square roots of limits for  $m_{\nu\tau}^{2(\text{eff})} \equiv \sum_i |\mathcal{U}_{\tau i}|^2 m_{\nu_i}^2$ .

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

## Neutrino Properties

- <sup>6</sup> FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region  $< 0.93$  or  $> 31$  MeV is excluded. These bounds assume  $N_\nu < 4$  from nucleosynthesis; a wider excluded region occurs with a smaller  $N_\nu$  upper limit.
- <sup>7</sup> SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for  $\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau$ ,  $\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau$ ,  $\tau^- \rightarrow \pi^- \nu_\tau$ , and  $\tau^- \rightarrow K^- \nu_\tau$ , and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO  $\tau$  mass measurement (BALEST 93) is included; see CLEO's more recent  $m_{\nu_\tau}$  limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields  $\sin^2 \theta_L < 0.016$  (95%CL).
- <sup>8</sup> ALEXANDER 96M bound comes from analyses of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow h^- h^- h^+ \nu_\tau$  decays.
- <sup>9</sup> BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.
- <sup>10</sup> HANNESTAD 96C limit is on the mass of a Majorana neutrino. This bound assumes  $N_\nu < 4$  from nucleosynthesis. A wider excluded region occurs with a smaller  $N_\nu$  upper limit. This paper is the corrected version of HANNESTAD 96; see the erratum: HANNESTAD 96B.
- <sup>11</sup> SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.
- <sup>12</sup> BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of  $\tau \rightarrow 5\pi(\pi^0)\nu_\tau$  decays. Replaced by BARATE 98F.
- <sup>13</sup> DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below  $T_{\text{QCD}}$  for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.
- <sup>14</sup> SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between  $10^{-3}$  and  $10^8$  seconds if the decay products are predominantly  $\gamma$  or  $e^+e^-$ .
- <sup>15</sup> DODELSON 94 calculate constraints on  $\nu_\tau$  mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for all decay modes of Majorana neutrinos with lifetime greater than about 300s. For Dirac neutrinos limits change to  $< 0.3$  or  $> 33$ .
- <sup>16</sup> KAWASAKI 94 excluded region is for Majorana neutrino with lifetime  $> 1000$  s. Other limits are given as a function of  $\nu_\tau$  lifetime for decays of the type  $\nu_\tau \rightarrow \nu_\mu \phi$  where  $\phi$  is a Nambu-Goldstone boson.
- <sup>17</sup> PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions,  $m_3 < 70$  MeV and  $140 \text{ MeV} < m_3 < 149$  MeV.
- <sup>18</sup> CINABRO 93 bound comes from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$  decay modes.
- <sup>19</sup> DOLGOV 93 assumes neutrino lifetime  $> 100$  s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.
- <sup>20</sup> ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time,  $\sim 1$  s.
- <sup>21</sup> ALBRECHT 92M reports measurement of a slightly lower  $\tau$  mass, which has the effect of reducing the  $\nu_\tau$  mass reported in ALBRECHT 88B. Bound is from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  mode.
- <sup>22</sup> Assumes neutrino lifetime  $> 1$  s. For Dirac neutrinos. See also ENQVIST 93.
- <sup>23</sup> KOLB 91 exclusion region is for Dirac neutrino with lifetime  $> 1$  s; other limits are given.

## SUM OF NEUTRINO MASSES

Revised January 2016 by K.A. Olive (University of Minnesota).

The limits on low mass ( $m_\nu \lesssim 1$  MeV) neutrinos apply to  $m_{\text{tot}}$  given by

$$m_{\text{tot}} = \sum_\nu (g_\nu/2) m_\nu,$$

where  $g_\nu$  is the number of spin degrees of freedom for  $\nu$  plus  $\bar{\nu}$ :  $g_\nu = 4$  for neutrinos with Dirac masses;  $g_\nu = 2$  for Majorana neutrinos. Stable neutrinos in this mass range make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\text{tot}} n_\nu = m_{\text{tot}} (3/11) n_\gamma,$$

where the factor 3/11 is the ratio of (light) neutrinos to photons. Writing  $\Omega_\nu = \rho_\nu/\rho_c$ , where  $\rho_c$  is the critical energy density of the Universe, and using  $n_\gamma = 412 \text{ cm}^{-3}$ , we have

$$\Omega_\nu h^2 = m_{\text{tot}} / (94 \text{ eV}).$$

While an upper limit to the matter density of  $\Omega_m h^2 < 0.12$  would constrain  $m_{\text{tot}} < 11$  eV, much stronger constraints are obtained from a combination of observations of the CMB, the amplitude of density fluctuations on smaller scales from the clustering of galaxies and the Lyman- $\alpha$  forest, baryon acoustic oscillations, and new Hubble parameter data. These combine to give an upper limit of around 0.2 eV, and may, in the near future, be able to provide a lower bound on the sum of the neutrino masses.

## SUM OF THE NEUTRINO MASSES, $m_{\text{tot}}$

(Defined in the above note), of effectively stable neutrinos (i.e., those with mean lives greater than or equal to the age of the universe). These papers assumed Dirac neutrinos. When necessary, we have generalized the results reported so they apply to  $m_{\text{tot}}$ . For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85.

<sup>1</sup> Constrains the total mass of neutrinos using the Lyman  $\alpha$  forest power spectrum obtained by BOSS. The analysis includes CMB data from Planck, WMAP, ACT, and SPT. Limit improves to 0.14 when BAO data are included. Superseded by PALANQUE-DELABROUILLE 15A.

<sup>2</sup> Constrains the total mass of neutrinos using the Lyman- $\alpha$  forest power spectrum obtained by BOSS. The analysis includes CMB data from Planck, ACT, and SPT. Limit is unchanged when BAO data are included. Supersedes PALANQUE-DELABROUILLE 15.

<sup>3</sup> Constrains the total mass of neutrinos from Planck CMB data along with WMAP polarization, high L, and BAO data.

<sup>4</sup> Finite neutrino mass fit to resolve discrepancy between CMB and lensing measurements.

<sup>5</sup> Fit to the total mass of neutrinos from BOSS data along with WMAP CMB data and data from other BAO constraints and weak lensing.

<sup>6</sup> Fit to the total mass of neutrinos from Planck CMB data along with BAO.

<sup>7</sup> Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS and HST data on the Hubble parameter.

<sup>8</sup> Fit based on the SPT-SZ survey combined with CMB, BAO, and  $H_0$  data.

<sup>9</sup> Constrains the total mass of neutrinos (marginalizing over the effective number of neutrino species) from CMB, CMB lensing, BAO, and galaxy clustering data.

# Lepton Particle Listings

## Neutrino Properties

- <sup>10</sup> Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS, 6dFGS, SDSS, WiggleZ data on the galaxy power spectrum, and HST data on the Hubble parameter. The limit is increased to 0.25 eV if a lower bound to the sum of neutrino masses of 0.04 eV is assumed.
- <sup>11</sup> Constrains the total mass of neutrinos from observational Hubble parameter data with seven-year WMAP data and the most recent estimate of  $H_0$ .
- <sup>12</sup> Constrains the total mass of neutrinos from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Limit is relaxed to 0.41 eV when small scales affected by non-linearities are removed.
- <sup>13</sup> Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.
- <sup>14</sup> Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.
- <sup>15</sup> Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of  $H_0$  (SHOES), and baryon acoustic oscillation data from SDSS.
- <sup>16</sup> Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter,  $w \neq -1$ .
- <sup>17</sup> Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes  $\Lambda$ CDM model.
- <sup>18</sup> Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the  $\Lambda$ CDM model. Supersedes SPERGEL 07.
- <sup>19</sup> Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to  $0.03 < \Sigma m_\nu < 0.54$  eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes  $\Lambda$ CDM model.
- <sup>20</sup> Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state,  $w$ .
- <sup>21</sup> Constraints the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes  $\Lambda$ CDM model. Limit degrades to 0.59 eV in a more general  $w$ CDM model.
- <sup>22</sup> Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.
- <sup>23</sup> Constrains the total mass of neutrinos from recent CMB, large scale structure, SNIa, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.
- <sup>24</sup> Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed.
- <sup>25</sup> Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SNIa data.
- <sup>26</sup> Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.
- <sup>27</sup> Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.
- <sup>28</sup> Constrains the total mass of neutrinos from the CMB experiments alone, assuming  $\Lambda$ CDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.
- <sup>29</sup> Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.
- <sup>30</sup> Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.
- <sup>31</sup> Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dFGRS data, and Lyman  $\alpha$  data. The limit does not noticeably change if the Lyman  $\alpha$  data are not used.
- <sup>32</sup> LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.
- <sup>33</sup> WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman  $\alpha$  forest.
- <sup>34</sup> FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale  $\sigma_8$  and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.
- <sup>35</sup> CROFT 99 result based on the power spectrum of the Ly  $\alpha$  forest. If  $\Omega_{\text{matter}} < 0.5$ , the limit is improved to  $m_\nu < 2.4$  ( $\Omega_{\text{matter}}/0.17-1$ ) eV.

### Limits on MASSES of Light Stable Right-Handed $\nu$ (with necessarily suppressed interaction strengths)

VALUE (eV)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
<100–200	<sup>1</sup> OLIVE	82	COSM Dirac $\nu$
<200–2000	<sup>1</sup> OLIVE	82	COSM Majorana $\nu$

<sup>1</sup> Depending on interaction strength  $G_R$  where  $G_R < G_F$ .

### Limits on MASSES of Heavy Stable Right-Handed $\nu$ (with necessarily suppressed interaction strengths)

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
> 10	<sup>1</sup> OLIVE	82	COSM $G_R/G_F < 0.1$
>100	<sup>1</sup> OLIVE	82	COSM $G_R/G_F < 0.01$

<sup>1</sup> These results apply to heavy Majorana neutrinos and are summarized by the equation:  $m_\nu > 1.2$  GeV ( $G_F/G_R$ ). The bound saturates, and if  $G_R$  is too small no mass range is allowed.

### $\nu$ CHARGE

VALUE (units: electron charge)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<2.1 $\times 10^{-12}$	90	<sup>1</sup> CHEN	14A	TEXO Nuclear reactor
<1.5 $\times 10^{-12}$	90	<sup>2</sup> STUDENIKIN	14	Nuclear reactor
<3.7 $\times 10^{-12}$	90	<sup>3</sup> GNINENKO	07	RVUE Nuclear reactor
<2 $\times 10^{-14}$		<sup>4</sup> RAFFELT	99	ASTR Red giant luminosity
<6 $\times 10^{-14}$		<sup>5</sup> RAFFELT	99	ASTR Solar cooling

<2 $\times 10^{-15}$		<sup>8</sup> BARBIELLINI	87	ASTR SN 1987A
<1 $\times 10^{-13}$		<sup>9</sup> BERNSTEIN	63	ASTR Solar energy losses

<sup>1</sup> CHEN 14A use the Multi-Configuration RPPA method to analyze reactor  $\bar{\nu}_e$  scattering on Ge atoms with 300 eV recoil energy threshold to obtain this limit.

<sup>2</sup> STUDENIKIN 14 uses the limit on  $\mu_\nu$  from BEDA 13 and the 2.8 keV threshold of the electron recoil energy to obtain this limit.

<sup>3</sup> GNINENKO 07 use limit on  $\bar{\nu}_e$  magnetic moment from Li 03b to derive this result. The limit is considerably weaker than the limits on the charge of  $\nu_e$  and  $\bar{\nu}_e$  from various astrophysics considerations.

<sup>4</sup> This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.

<sup>5</sup> This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.

<sup>6</sup> BABU 94 use COOPER-SARKAR 92 limit on  $\nu$  magnetic moment to derive quoted result. It applies to  $\nu_\tau$ .

<sup>7</sup> DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to  $\nu_\tau$ .

<sup>8</sup> Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to  $\nu_e$ .

<sup>9</sup> The limit applies to all flavors.

### $\nu$ (MEAN LIFE) / MASS

Measures  $[\sum |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$ , where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any  $\nu$  within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for  $\nu_i \rightarrow \nu_j + \gamma$

is constrained by  $\Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m_i^3} \mu_{ij}^2$  where  $\mu_{ij}$  is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

- 1 KRAKAUER 91 quotes the limit  $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3)\text{ s/eV}$ , where  $a$  is a parameter describing the asymmetry in the neutrino decay defined as  $dN_{\nu}/dcos\theta = (1/2)(1 + a\cos\theta)$ . The parameter  $a=0$  for a Majorana neutrino, but can vary from  $-1$  to  $1$  for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for  $a = -1$ ).
- 2 RAFFELT 85 limit on the radiative decay is from solar  $x$ - and  $\gamma$ -ray fluxes. Limit depends on  $\nu$  flux from  $pp$ , now established from GALLEX and SAGE to be  $> 0.5$  of expectation.
- 3 REINES 74 looked for  $\nu$  of nonzero mass decaying radiatively to a neutral of lesser mass  $+\gamma$ . Used liquid scintillator detector near fission reactor. Finds lab lifetime  $6 \times 10^7\text{ s}$  or more. Above value of (mean life)/mass assumes average effective neutrino energy of  $0.2\text{ MeV}$ . To obtain the limit  $6 \times 10^7\text{ s}$  REINES 74 assumed that the full  $\overline{\nu}_e$  reactor flux could be responsible for yielding decays with photon energies in the interval  $0.1\text{ MeV} - 0.5\text{ MeV}$ . This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.
- 4 CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of  $\nu_1$  masses between  $10^{-4}$  and  $0.1\text{ eV}$ .
- 5 MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay  $\nu_2 \rightarrow \nu_1$  the lifetime limit is  $\lesssim 4 \times 10^{20}\text{ s}$  for  $m_{\min} \lesssim 0.14\text{ eV}$ . For transition with the  $|\Delta m_{31}|$  mass difference the lifetime limit is  $\sim 2 \times 10^{19}\text{ s}$  for  $m_{\min} \lesssim 0.14\text{ eV}$  and  $\sim 5 \times 10^{20}\text{ s}$  for  $m_{\min} \gtrsim 0.14\text{ eV}$ .
- 6 MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the  $|\Delta m_{31}|$  mass difference they obtain the lifetime limit  $\sim 10^{20}\text{ s}$  for  $m_{\min} \lesssim 0.14\text{ eV}$ .
- 7 WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of  $\Delta m_{13}^2 \sim 2 \times 10^{-3}\text{ eV}^2$  to obtain  $\tau_{13}/m_1^3 > 3.2 \times 10^{27}\text{ s/eV}^3$  for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for  $\tau_{23}$  and  $\tau_{21}$ .
- 8 XIN 05 search for the  $\gamma$  from radiative decay of  $\nu_e$  produced by the electron capture on  $^{51}\text{Cr}$ . No events were seen and the limit on  $\tau/m_{\nu}$  was derived. This is a weaker limit on the decay of  $\nu_e$  than KRAKAUER 91.
- 9 XIN 05 use their limit on the neutrino magnetic moment of  $\nu_e$  together with the assumed experimental value of  $\Delta m_{13}^2 \sim 2 \times 10^{-3}\text{ eV}^2$  to obtain  $\tau_{13}/m_1^3 > 1 \times 10^{23}\text{ s/eV}^3$  for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for  $\tau_{23}$  and  $\tau_{21}$ . Again, this limit is specific for  $\nu_e$ .
- 10 AHARMIM 04 obtained these results from the solar  $\overline{\nu}_e$  flux limit set by the SNO measurement assuming  $\nu_2$  decay through nonradiative process  $\nu_2 \rightarrow \overline{\nu}_1 X$ , where  $X$  is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- 11 CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a  $\tau/m_{\nu_2}$  in  $\nu_2 \rightarrow \nu_1 \gamma$ . Limit ranges from  $\sim 100$  to  $10^7\text{ s/eV}$  for  $0.01 < m_{\nu_1} < 0.1\text{ eV}$ .
- 12 EGUCHI 04 obtained these results from the solar  $\overline{\nu}_e$  flux limit set by the KamLAND measurement assuming  $\nu_2$  decay through nonradiative process  $\nu_2 \rightarrow \overline{\nu}_1 X$ , where  $X$  is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- 13 The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for  $\nu_2$ . They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that  $\nu_1$  is the lowest mass, stable or nearly stable neutrino

state and  $\nu_2$  decays through nonradiative Majoron emission process,  $\nu_2 \rightarrow \overline{\nu}_1 + J$ , or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.

- 14 DERBIN 02b (also BACK 03b) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as  $dN_{\gamma}/dcos\theta = (1/2)(1 + \alpha\cos\theta)$  with  $\alpha=0$  for a Majorana neutrino, and  $\alpha$  varying to  $-1$  to  $1$  for a Dirac neutrino. The listed bound is for the case of  $\alpha=0$ . The most conservative bound  $1.5 \times 10^{13}\text{ s eV}^{-1}$  is obtained for the case of  $\alpha=-1$ .
- 15 The ratio of the lifetime over the mass derived by JOSHIPURA 02b is for  $\nu_2$ . They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that  $\nu_1$  is the lowest mass, stable or nearly stable neutrino state and  $\nu_2$  decays through nonradiative process like Majoron emission decay,  $\nu_2 \rightarrow \nu_1' + J$  where  $\nu_1'$  state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.
- 16 DOLGOV 99 places limits in the (Majorana)  $\tau$ -associated  $\nu$  mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.
- 17 BILLER 98 use the observed TeV  $\gamma$ -ray spectra to set limits on the mean life of any radiatively decaying neutrino between  $0.05$  and  $1\text{ eV}$ . Curve shows  $\tau_{\nu}/B_{\gamma} > 0.15 \times 10^{21}\text{ s}$  at  $0.05\text{ eV}$ ,  $> 1.2 \times 10^{21}\text{ s}$  at  $0.17\text{ eV}$ ,  $> 3 \times 10^{21}\text{ s}$  at  $1\text{ eV}$ , where  $B_{\gamma}$  is the branching ratio to photons.
- 18 BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.
- 19 Limit on the radiative decay based on nonobservation of  $\gamma$ 's in coincidence with  $\nu$ 's from SN 1987A.
- 20 DODELSON 92 range is for wrong-helicity keV mass Dirac  $\nu$ 's from the core of neutron star in SN 1987A decaying to  $\nu$ 's that would have interacted in KAM2 or LMB detectors.
- 21 GRANEK 91 considers heavy neutrino decays to  $\gamma\nu_L$  and  $3\nu_L$ , where  $m_{\nu_L} < 100\text{ keV}$ . Lifetime is calculated as a function of heavy neutrino mass, branching ratio into  $\gamma\nu_L$ , and  $m_{\nu_L}$ .
- 22 KRAKAUER 91 quotes the limit for  $\nu_e$ ,  $\tau/m_{\nu} > (0.3a^2 + 9.8a + 15.9)\text{ s/eV}$ , where  $a$  is a parameter describing the asymmetry in the radiative neutrino decay defined as  $dN_{\nu}/dcos\theta = (1/2)(1 + a\cos\theta)$   $a=0$  for a Majorana neutrino, but can vary from  $-1$  to  $1$  for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for  $a = -1$ ).
- 23 WALKER 90 uses SN 1987A  $\gamma$  flux limits after 289 days.
- 24 CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
- 25 RAFFELT 89 uses KYULDJIEV 84 to obtain  $\tau m^3 > 3 \times 10^{18}\text{ s eV}^3$  (based on  $\overline{\nu}_e e^-$  cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.
- 26 RAFFELT 89b analyze stellar evolution and exclude the region  $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21}\text{ s eV}^3$ .
- 27 Model-dependent theoretical analysis of SN 1987A neutrinos. Quoted limit is for  $[\sum_j |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$ , where  $\ell=\mu, \tau$ . Limit is  $3.3 \times 10^{14}\text{ s/eV}$  for  $\ell=e$ .
- 28 OBERAUER 87 looks for photons and  $e^+e^-$  pairs from radiative decays of reactor neutrinos.
- 29 BINETRUY 84 finds  $\tau < 10^8\text{ s}$  for neutrinos in a radiation-dominated universe.
- 30 These experiments look for  $\nu_k \rightarrow \nu_j \gamma$  or  $\overline{\nu}_k \rightarrow \overline{\nu}_j \gamma$ .
- 31 STECKER 80 limit based on UV background; result given is  $\tau > 4 \times 10^{22}\text{ s}$  at  $m_{\nu}=20\text{ eV}$ .
- 32 FALK 78 finds lifetime constraints based on supernova energetics.
- 33 COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require  $\tau > 10^{23}\text{ s}$  for  $m_{\nu} \sim 1\text{ eV}$ . See also COWSIK 79 and GOLDMAN 79.

## $\nu$ MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is a characterized by a  $3 \times 3$  matrix  $\lambda$  of the magnetic ( $\mu$ ) and electric ( $d$ ) dipole moments ( $\lambda = \mu - id$ ). For Majorana neutrinos the matrix  $\lambda$  is antisymmetric and only transition moments are allowed, while for Dirac neutrinos  $\lambda$  is a general  $3 \times 3$  matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80)  $\mu_{\nu} = 3eG_F m_{\nu}/(8\pi^2 \sqrt{2}) = 3.2 \times 10^{-19}(m_{\nu}/\text{eV})\mu_B$ , i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on  $\lambda$  are obtained via elastic  $\nu$ - $e$  scattering, where the scattered neutrino is not observed. The combinations of matrix elements of  $\lambda$  that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar  $\nu_e$  and reactor  $\overline{\nu}_e$  do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of  $e^+e^- \rightarrow \nu\overline{\nu}\gamma$  collider experiments.

See key on page 601

- 1 BEDA 13 report  $\bar{\nu}_e e^-$  scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.5 and 55 keV. Supersedes BEDA 07. Supersedes BEDA 10. This is the most stringent limit on the magnetic moment of reactor  $\bar{\nu}_e$ .
- 2 AUERBACH 01 limit is based on the LSND  $\nu_e$  and  $\nu_\mu$  electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.
- 3 SCHWIENHORST 01 quote an experimental sensitivity of  $4.9 \times 10^{-7}$ .
- 4 ARCEO-DIAZ 15 constrains the neutrino magnetic moment from observation of the tip of the red giant branch in the globular cluster  $\omega$ -Centauri.
- 5 CORSICO 14 constrains the neutrino magnetic moment from observations of white dwarf pulsations.
- 6 MILLER-BERTOLAMI 14B constrains the neutrino magnetic moment from observations of the white dwarf luminosity function of the Galactic disk.
- 7 VIAUX 13A constrains the neutrino magnetic moment from observations of the globular cluster M5.
- 8 BEDA 10 report  $\bar{\nu}_e e^-$  scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. Supersedes by BEDA 13.
- 9 DENIZ 10 observe reactor  $\bar{\nu}_e e^-$  scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on  $\bar{\nu}_e$  magnetic moment.

- 10 KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.
- 11 ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.
- 12 BEDA 07 performed search for electromagnetic  $\bar{\nu}_e e^-$  scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.
- 13 WONG 07 performed search for non-standard  $\bar{\nu}_e e^-$  scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor  $\bar{\nu}_e$ . Supersedes LI 03B.
- 14 DARAKTCHIEVA 05 present the final analysis of the search for non-standard  $\bar{\nu}_e e^-$  scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.
- 15 XIN 05 evaluated the  $\nu_e$  flux at the Kuo-Sheng nuclear reactor and searched for non-standard  $\nu_e e^-$  scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor  $\bar{\nu}_e$ , but is specific to  $\nu_e$ .
- 16 GRIFOLS 04 obtained this bound using the SNO data of the solar  $^8\text{B}$  neutrino flux measured with deuteron breakup. This bound applies to  $\mu_{\text{eff}} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$ .
- 17 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments,  $\mu_{\nu 1} = \mu_{\nu 2}$ . This limit corresponds to the oscillation parameters in the vacuum oscillation region.
- 18 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND.  $\mu_{\nu 1} = \mu_{\nu 2}$  is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.
- 19 BACK 03B obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This  $\mu_\nu$  can be different from the reactor  $\mu_\nu$  in certain oscillation scenarios (see BEACOM 99).
- 20 DARAKTCHIEVA 03 searched for non-standard  $\bar{\nu}_e e^-$  scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.
- 21 LI 03B used Ge detector in active shield near nuclear reactor to test for nonstandard  $\bar{\nu}_e e^-$  scattering.
- 22 GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of  $6.3 \times 10^{-10} \mu_B$  is obtained.
- 23 TANIMOTO 00 combined  $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$  data from VENUS, TOPAZ, and AMY.
- 24 AYALA 99 improves the limit of BARBIERI 88.
- 25 BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This  $\mu_\nu$  can be different from the reactor  $\mu_\nu$  in certain oscillation scenarios.
- 26 RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough ( $< 5$  keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 27 RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough ( $< 1$  keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 28 ACCIARRI 97Q result applies to both direct and transition magnetic moments and for  $q^2=0$ .
- 29 ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.
- 30 Applies to absolute value of magnetic moment.
- 31 DERBIN 93 determine the cross section for 0.6–2.0 MeV electron energy as  $(1.28 \pm 0.63) \times \sigma_{\text{weak}}$ . However, the (reactor on – reactor off)/(reactor off) is only  $\sim 1/100$ .
- 32 COOPER-SARKAR 92 assume  $f_{D_s}/f_\pi = 2$  and  $D_s, \bar{D}_s$  production cross section =  $2.6 \mu\text{b}$  to calculate  $\nu$  flux.
- 33 VIDYAKIN 92 limit is from a  $e\bar{\nu}_e$  elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses  $\sin^2 \theta_W = 0.23$  as input.
- 34 DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the  $\nu$  magnetic moment is  $< 1 \times 10^{-9}$  at the 95%CL. DORENBOSCH 89 measures both  $\nu_\mu e$  and  $\bar{\nu}_e e$  elastic scattering and assume  $\mu(\nu) = \mu(\bar{\nu})$ .
- 35 KRAKAUER 90 experiment fully reported in ALLEN 93.
- 36 RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives  $< 1.4 \times 10^{-12}$ . Limit at 95%CL obtained from  $\delta M_C$ .
- 37 Significant dependence on details of stellar models.
- 38 FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by  $\mu < 10^{-16} [10^{-9} G/B_0]$  where  $B_0$  is the present-day intergalactic field strength.
- 39 GROTH 88 combined data from MAC, ASP, CELLO, and Mark J.

# Lepton Particle Listings

## Neutrino Properties

- <sup>40</sup> For  $m_\nu = 8\text{--}200$  eV. NUSSINOV 87 examines transition magnetic moments for  $\nu_\mu \rightarrow \nu_e$  and obtain  $< 3 \times 10^{-15}$  for  $m_\nu > 16$  eV and  $< 6 \times 10^{-14}$  for  $m_\nu > 4$  eV.
- <sup>41</sup> We obtain above limit from SUTHERLAND 76 using their limit  $f < 1/3$ .
- <sup>42</sup> KIM 74 is a theoretical analysis of  $\bar{\nu}_\mu$  reaction data.

### NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77c), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

< 7.3	90	<sup>5</sup> VIDYAKIN	92 CNTR	Reactor $\bar{\nu} e \rightarrow \bar{\nu} e$
1.1 ± 2.3		ALLEN	91 CNTR	Repl. by ALLEN 93
-1.1 ± 1.0		<sup>6</sup> AHRENS	90 CNTR	$\nu_\mu e$ elastic scat.
-0.3 ± 1.5		<sup>6</sup> DORENBOS...	89 CHRM	$\nu_\mu e$ elastic scat.
		<sup>7</sup> GRIFOLS	89B ASTR	SN 1987A

- <sup>1</sup> DENIZ 10 observe reactor  $\bar{\nu}_e e$  scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on  $\bar{\nu}_e$  charge radius.
- <sup>2</sup> Based on analysis of CCFR 98 results. Limit is on  $\langle r_V^2 \rangle + \langle r_A^2 \rangle$ . The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as  $\nu_\mu$  charge radius it implies  $\langle r_V^2 \rangle + \langle r_A^2 \rangle = (4.20 \pm 1.64) \times 10^{-33}$  cm<sup>2</sup>.
- <sup>3</sup> Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana  $\nu_\mu$ . Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).
- <sup>4</sup> AUERBACH 01 measure  $\nu_e e$  elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.
- <sup>5</sup> VIDYAKIN 92 limit is from a  $e \bar{\nu}$  elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses  $\sin^2 \theta_W = 0.23$  as input.
- <sup>6</sup> Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain  $1\sigma$  errors.
- <sup>7</sup> GRIFOLS 89b sets a limit of  $\langle r^2 \rangle < 0.2 \times 10^{-32}$  cm<sup>2</sup> for right-handed neutrinos.

## Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard  $SU(2) \times U(1)$  Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with  $m < m_Z/2$ . The limits are on the number of neutrino mass eigenstates, including  $\nu_1$ ,  $\nu_2$ , and  $\nu_3$ .

## THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised March 2008 by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types,  $N_\nu$ , come from studies of  $Z$  production in  $e^+e^-$  collisions. The invisible partial width,  $\Gamma_{\text{inv}}$ , is determined by subtracting the measured visible partial widths, corresponding to  $Z$  decays into quarks and charged leptons, from the total  $Z$  width. The invisible width is assumed to be due to  $N_\nu$  light neutrino species each contributing the neutrino partial width  $\Gamma_\nu$  as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of

the neutrino to charged leptonic partial widths,  $(\Gamma_\nu/\Gamma_\ell)_{\text{SM}} = 1.991 \pm 0.001$ , is used instead of  $(\Gamma_\nu)_{\text{SM}}$  to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\text{inv}}}{\Gamma_\ell} \left( \frac{\Gamma_\ell}{\Gamma_\nu} \right)_{\text{SM}}. \quad (1)$$

The combined result from the four LEP experiments is  $N_\nu = 2.984 \pm 0.008$  [1].

In the past, when only small samples of  $Z$  decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in  $N_\nu$  was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the  $Z$  resonance. Since this method is much more dependent on the Standard Model, the approach described above is favored.

Before the advent of the SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy  $e^+e^-$  colliders by measuring the cross section of the process  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$ . The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [2], leading to a 95% CL limit of  $N_\nu < 4.8$ . This process has a much larger cross section at center-of-mass energies near the  $Z$  mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [3]. These experiments have observed several thousand such events, and the combined result is  $N_\nu = 3.00 \pm 0.08$ . The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [4]. Combined with the lower energy data, the result is  $N_\nu = 2.92 \pm 0.05$ .

Experiments at  $p\bar{p}$  colliders also placed limits on  $N_\nu$  by determining the total  $Z$  width from the observed ratio of  $W^\pm \rightarrow \ell^\pm \nu$  to  $Z \rightarrow \ell^+ \ell^-$  events [5]. This involved a calculation that assumed Standard Model values for the total  $W$  width and the ratio of  $W$  and  $Z$  leptonic partial widths, and used an estimate of the ratio of  $Z$  to  $W$  production cross sections. Now that the  $Z$  width is very precisely known from the LEP experiments, the approach is now one of those used to determine the  $W$  width.

**Double- $\beta$  Decay**

OMITTED FROM SUMMARY TABLE

**NEUTRINOLESS DOUBLE- $\beta$  DECAY**

Revised August 2015 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

Observation of neutrinoless double-beta ( $0\nu\beta\beta$ ) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of  $0\nu\beta\beta$ -decay requires Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating  $0\nu\beta\beta$ -decay can be obtained, independently of the actual mechanism by assuming that one of these “new physics” possibilities dominates. These limits are listed in the next three tables, together with a claimed  $0\nu\beta\beta$ -decay signal reported by part of the Heidelberg-Moscow collaboration. There is tension between that claim and several recent experiments which did not find evidence for  $0\nu\beta\beta$  decay.

In the following we assume that the exchange of light Majorana neutrinos ( $m_{\nu_i} \leq 10$  MeV) contributes dominantly to the decay rate. Besides a dependence on the phase space ( $G^{0\nu}$ ) and the nuclear matrix element ( $M^{0\nu}$ ), the observable  $0\nu\beta\beta$ -decay rate is proportional to the square of the effective Majorana mass  $\langle m_{\beta\beta} \rangle$ ,  $(T_{1/2}^{0\nu})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot \langle m_{\beta\beta} \rangle^2$ , with  $\langle m_{\beta\beta} \rangle^2 = |\sum_i U_{ei}^2 m_{\nu_i}|^2$ . The sum contains, in general, complex  $CP$ -phases in  $U_{ei}^2$ , i.e., cancellations may occur. For three neutrino flavors, there are three physical phases for Majorana neutrinos. There is only one phase if neutrinos are Dirac particles. The two additional Majorana phase differences affect only processes to which lepton-number-changing amplitudes contribute. Given the general  $3 \times 3$  mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities,  $\langle m_{\ell\ell'} \rangle = \sum_i U_{ei} U_{\ell'i} m_{\nu_i}$  ( $\ell$  or  $\ell' \neq e$ ). However, these are currently much less constrained than  $\langle m_{\beta\beta} \rangle$ .

Nuclear structure calculations are needed to deduce  $\langle m_{\beta\beta} \rangle$  from the decay rate. While  $G^{0\nu}$  can be calculated, the computation of  $M^{0\nu}$  is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor  $\sim 2$  to 3 spread in the calculated nuclear matrix elements. In addition, if the effective value of the axial current coupling constant  $g_A$  in nuclei is substantially smaller than its single nucleon value  $g_A = 1.2723 \pm 0.0023$ , the decay rate might be further reduced. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the more conventional  $2\nu\beta\beta$  decay serve to calibrate some nuclear models (e.g. QRPA-based calculations), results for this process are also given.

Oscillation experiments utilizing atmospheric-, accelerator-, solar-, and reactor-produced neutrinos and anti-neutrinos yield strong evidence that at least some neutrinos are massive. However, these findings shed no light on the mass hierarchy (i.e., on the sign of  $\Delta m_{31}^2$ ), the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana).

All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. Full three flavor analyses such as e.g. [1] yield:  $|\Delta m_{31}^2| = 2.48_{-0.07}^{+0.05} (2.38_{-0.06}^{+0.05}) \times 10^{-3}$  eV<sup>2</sup> and  $\sin^2 \theta_{23} = 0.567_{-0.124}^{+0.032} (0.573_{-0.039}^{+0.025})$  for the parameters observed in atmospheric and accelerator experiments, where the values correspond to the normal (inverted) hierarchies. Observations of solar  $\nu_e$  and reactor  $\bar{\nu}_e$  lead to  $\Delta m_{21}^2 = 7.60_{-0.18}^{+0.19} \times 10^{-5}$  eV<sup>2</sup> and  $\sin^2 \theta_{12} = 0.323 \pm 0.016$ . The investigation of reactor  $\bar{\nu}_e$  at  $\sim 1.5$  km baseline shows that electron type neutrinos couple only weakly to the third mass eigenstate with  $\sin^2 \theta_{13} = 0.0226 \pm 0.0012$  ( $0.0229 \pm 0.0012$ ). (All errors correspond to  $1\sigma$ .)

Based on the 3-neutrino analysis:  $\langle m_{\beta\beta} \rangle^2 = |\cos^2 \theta_{13} \cos^2 \theta_{12} m_1 + e^{i\Delta\alpha_{21}} \cos^2 \theta_{13} \sin^2 \theta_{12} m_2 + e^{i\Delta\alpha_{31}} \sin^2 \theta_{13} m_3|^2$ , with  $\Delta\alpha_{21}, \Delta\alpha_{31}$  denoting the physically relevant Majorana  $CP$ -phase differences (possible Dirac phase  $\delta$  is absorbed in these  $\Delta\alpha$ ). Given the present knowledge of the neutrino oscillation parameters one can derive the relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in the left panel of Fig. 1. The three mass hierarchies allowed by the oscillation data: normal ( $m_1 < m_2 < m_3$ ), inverted ( $m_3 < m_1 < m_2$ ), and degenerate ( $m_1 \approx m_2 \approx m_3$ ), result in different projections. The width of the innermost hatched bands reflects the uncertainty introduced by the unknown Majorana and Dirac phases. If the experimental errors of the oscillation parameters are taken into account, then the allowed areas are widened as shown by the outer bands of Fig. 1. Because of the overlap of the different mass scenarios a measurement of  $\langle m_{\beta\beta} \rangle$  in the degenerate or inversely hierarchical ranges would not determine the hierarchy. The middle panel of Fig. 1 depicts the relation of  $\langle m_{\beta\beta} \rangle$  with the summed neutrino mass  $m_{tot} = m_1 + m_2 + m_3$ , constrained by observational cosmology. The oscillation data thus allow to test whether observed values of  $\langle m_{\beta\beta} \rangle$  and  $m_{tot}$  are consistent within the 3 neutrino framework and the light neutrino-exchange dominance assumption. The right hand panel of Fig. 1, finally, shows  $\langle m_{\beta\beta} \rangle$  as a function of the kinematical mass  $\langle m_{\beta} \rangle = [\sum |U_{ei}|^2 m_{\nu_i}^2]^{1/2}$  determined through the analysis of the electron energy distribution in low energy beta decays. The rather large intrinsic width of the  $\beta\beta$ -decay constraint essentially does not allow to positively identify the inverted hierarchy, and thus the sign of  $\Delta m_{31}^2$ , even in combination with these other observables. Naturally, if the value of  $\langle m_{\beta\beta} \rangle \leq 0.01$  eV, but non-zero is ever established then normal hierarchy becomes the only possible scenario.

# Lepton Particle Listings

## Double- $\beta$ Decay

**Figure 1:** The left panel shows the dependence of  $\langle m_{\beta\beta} \rangle$  on the absolute mass of the lightest neutrino  $m_{\min}$ . The middle panel shows  $\langle m_{\beta\beta} \rangle$  as a function of the summed neutrino mass  $m_{\text{tot}}$ , while the right panel depicts  $\langle m_{\beta\beta} \rangle$  as a function of the mass  $\langle m_{\beta} \rangle$ . In all panels the width of the hatched areas is due to the unknown Majorana phases and thus irreducible. The allowed areas given by the solid lines are obtained by taking into account the errors of the oscillation parameters (at 90% confidence level [1]). The two sets of solid lines correspond to the normal (blue) and inverted (red) hierarchies. These sets merge into each other for  $\langle m_{\beta\beta} \rangle \geq 0.1$  eV, which corresponds to the degenerate mass pattern.

It should be noted that systematic uncertainties of the nuclear matrix elements are not folded into the mass projections shown in Fig. 1. Taking this additional uncertainty into account would further widen the allowed areas. The uncertainties in oscillation parameters affect the width of the allowed bands in an asymmetric manner, as shown in Fig. 1. For example, for the degenerate mass pattern ( $\langle m_{\beta\beta} \rangle \geq 0.1$  eV) the upper edge is simply  $\langle m_{\beta\beta} \rangle \sim m$ , where  $m$  is the common mass of the degenerate multiplet, independent of the oscillation parameters, while the lower edge is  $m \cos(2\theta_{12})$ . Similar arguments explain the other features of Fig. 1. The plots in Fig. 1 are based on a 3-neutrino analysis. If it turns out that additional, i.e. sterile light neutrinos exist, the allowed regions would be modified substantially.

If the neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses  $m_{\nu_i}$ . Unlike the direct neutrino mass measurements, however, a limit on  $\langle m_{\beta\beta} \rangle$  does not allow one to constrain the individual mass values  $m_{\nu_i}$  even when the mass differences  $\Delta m^2$  are known.

Neutrino oscillation data imply, for the first time, the existence of a lower limit  $\sim 0.014$  eV for the Majorana neutrino mass for the inverted hierarchy mass pattern while  $\langle m_{\beta\beta} \rangle$  could, by fine tuning, vanish in the case of the normal mass hierarchy. Several new double beta searches have been proposed to probe the interesting  $\langle m_{\beta\beta} \rangle$  mass range, with the prospect of full coverage of the inverted mass hierarchy region within the next decade.

The  $0\nu\beta\beta$  decay mechanism discussed so far is not the only way in which the decay can occur. Numerous other possible scenarios have been proposed, however, all of them requiring new physics. It will be a challenging task to decide which mechanism was responsible once  $0\nu\beta\beta$  decay is observed. LHC experiments may reveal corresponding signatures for new physics of lepton number violation. If lepton-number-violating right-handed current weak interactions exist, their strength can be characterized by the phenomenological coupling constants  $\eta$  and  $\lambda$  ( $\eta$  describes the coupling between the right-handed lepton current and left-handed quark current while  $\lambda$  describes the coupling when both currents are right-handed). The  $0\nu\beta\beta$  decay rate then depends on  $\langle \eta \rangle = \eta \sum_i U_{ei} V_{ei}$  and  $\langle \lambda \rangle = \lambda \sum_i U_{ei} V_{ei}$  that vanish for massless or unmixed neutrinos ( $V_{\ell j}$  is a matrix analogous to  $U_{\ell j}$  but describing the mixing with the hypothetical right-handed neutrinos). The observation of the single electron spectra could, in principle, allow to distinguish this mechanism of  $0\nu\beta\beta$  from the light Majorana neutrino exchange driven mode. The limits on  $\langle \eta \rangle$  and  $\langle \lambda \rangle$  are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between  $\eta$  and  $\lambda$ . In addition, see the section on Majoron searches for additional limits set by these experiments.

## Half-life Measurements and Limits for Double- $\beta$ Decay

In most cases the transitions  $(Z,A) \rightarrow (Z+2,A) + 2e^- + (0 \text{ or } 2) \bar{\nu}_e$  to the  $0^+$  ground state of the final nucleus are listed. However, we also list transitions that increase the nuclear charge ( $2e^+$ ,  $e^+$ /EC and ECEC) and transitions to excited states of the final nuclei ( $0_i^+$ ,  $2^+$ , and  $2_i^+$ ). In the following Listings, only best or comparable limits or lifetimes for each isotope are reported and only those with  $T_{1/2} > 10^{20}$  years that are relevant for particle physics. For  $2\nu$  decay, which is well established, only measured half-lives with the smallest (or comparable) error for each nucleus are reported.

## Double-β Decay

<sup>30</sup> Supersedes DANEVICH 03 and ARNOLD 96.

<sup>31</sup> Supersedes BRUDANIN 00 and BALYSH 96.

<sup>32</sup> BARABASH 11A use the NEMO-3 detector to measure  $2\nu\beta\beta$  rates and place limits on  $0\nu\beta\beta$  half lives for various nuclides.

<sup>33</sup> Supersedes ARNABOLDI 03.

<sup>34</sup> Supersedes ARNOLD 05A, ARNOLD 04, ARNOLD 98, and ELLIOTT 92.

<sup>35</sup> Less restrictive than ARNABOLDI 08.

<sup>36</sup> Less restrictive than DANEVICH 03.

<sup>37</sup> BELLI 11D use  $\text{ZnWO}_4$  scintillator calorimeters to search for various  $\beta\beta$  decay modes of  $^{64}\text{Zn}$ ,  $^{70}\text{Zn}$ ,  $^{180}\text{W}$ , and  $^{186}\text{W}$ .

<sup>38</sup> RUKHADZE 11 uses 13.6 g of enriched  $^{106}\text{Cd}$  to search for the neutrinoless ECEC decay into an excited state of  $^{106}\text{Pd}$  and its characteristic  $\gamma$ -radiation using the TGV2 detector. This decay mode is a candidate for resonant rate enhancement, however, hindered by the large spin difference.

<sup>39</sup> ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and identify its  $2\nu\beta\beta$  decay. The result is in agreement and supersedes ARNOLD 99.

<sup>40</sup> ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and obtain a limit of the  $0\nu\beta\beta$  decay. The result is in agreement and supersedes ARNOLD 99.

<sup>41</sup> ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and obtain a limit of the  $0\nu\beta\beta$  decay into the first excited  $0_1^+$  state in  $^{96}\text{Mo}$ .

<sup>42</sup> BELLI 10 use enriched  $^{100}\text{Mo}$  with 4 HP Ge detectors to record the 590.8 and 539.5 keV  $\gamma$  rays from the decay of the  $0_1^+$  state in  $^{100}\text{Ru}$  both in singles and coincidences. This result confirms the measurement of KIDD 09 and ARNOLD 07 and supersedes them.

<sup>43</sup> ARGYRIADES 09 use the NEMO-3 tracking calorimeter containing 36.5 g of  $^{150}\text{Nd}$ , a total exposure of 924.7 days, to derive a limit for the  $0\nu\beta\beta$  half-life. Supersedes DESILVA 97.

<sup>44</sup> ARGYRIADES 09 use the NEMO-3 tracking calorimeter containing 36.5 g of  $^{150}\text{Nd}$ , a total exposure of 924.7 days, to determine the value of the  $2\nu\beta\beta$  half-life. This result is in marginal agreement, but has somewhat smaller error bars, than DESILVA 97.

<sup>45</sup> BELLI 09A use  $\text{ZnWO}_4$  scintillating crystals to search for various modes of  $\beta\beta$  decay. This work improves the limits for different modes of  $^{64}\text{Zn}$  decay into the ground state of  $^{64}\text{Ni}$ , in this case for the  $0\nu\beta^+\text{EC}$  mode. Supersedes BELLI 08.

<sup>46</sup> BELLI 09A use  $\text{ZnWO}_4$  scintillating crystals to search for various modes of  $\beta\beta$  decay. This work improves the limits for different modes of  $^{64}\text{Zn}$  decay into the ground state of  $^{64}\text{Ni}$ , in this case for the  $0\nu\beta\beta$  ECEC mode. Supersedes BELLI 08.

<sup>47</sup> KIDD 09 combine past and new data with an improved coincidence detection efficiency determination. The result agrees with ARNOLD 95. Supersedes DEBRAECKELEER 01 and BARABASH 95.

<sup>48</sup> BELLI 08 use  $\text{ZnWO}_4$  scintillation calorimeter to search for neutrinoless  $\beta^+$  plus electron capture decay of  $^{64}\text{Zn}$ . The half-life limit for the  $2\nu\beta\beta$  mode is  $2.1 \times 10^{20}$  years.

<sup>49</sup> BELLI 08B use  $\text{CdWO}_4$  scintillation calorimeter to search for  $0\nu\beta\beta$  decay of  $^{114}\text{Cd}$ .

<sup>50</sup> UMEHARA 08 use  $\text{CaF}_2$  scintillation calorimeter to search for double beta decay of  $^{48}\text{Ca}$ . Limit is significantly more stringent than quoted sensitivity:  $18 \times 10^{21}$  years.

<sup>51</sup> First exclusive measurement of  $2\nu$ -decay to the first excited  $0_1^+$ -state of daughter nucleus. ARNOLD 07 use the NEMO-3 tracking calorimeter to detect all particles emitted in decay. Result agrees with the inclusive ( $0\nu + 2\nu$ ) measurement of DEBRAECKELEER 01.

<sup>52</sup> Limit on  $0\nu$ -decay to the first excited  $0_1^+$ -state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.

<sup>53</sup> Limit on  $0\nu$ -decay to the first excited  $2^+$ -state of daughter nucleus using NEMO-3 tracking calorimeter.

<sup>54</sup> KLAPDOR-KLEINGROTHAUS 06A present re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim improved  $6\sigma$  statistical evidence for observation of  $0\nu$ -decay, compared to  $4.2\sigma$  in KLAPDOR-KLEINGROTHAUS 04A. Analysis of the systematic uncertainty is not presented. This re-analysis is disputed in AGOSTINI 13A and SCHWINGENHEUER 13.

<sup>55</sup> Supersedes ARNABOLDI 04. Bolometric  $\text{TeO}_2$  detector array CUORICINO is used for high resolution search for  $0\nu\beta\beta$  decay. The half-life limit is derived from 3.09 kg yr  $^{130}\text{Te}$  exposure.

<sup>56</sup> NEMO-3 tracking calorimeter is used in ARNOLD 05A to place limit on  $0\nu\beta\beta$  half-life of  $^{82}\text{Se}$ . Detector contains 0.93 kg of enriched  $^{82}\text{Se}$ . Supersedes ARNOLD 04.

<sup>57</sup> ARNOLD 05A use the NEMO-3 tracking detector to determine the  $2\nu\beta\beta$  half-life of  $^{82}\text{Se}$  with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.

<sup>58</sup> ARNOLD 04 use the NEMO-3 tracking detector to determine the limit for  $0\nu\beta\beta$  half-life of  $^{82}\text{Se}$ . This represents an improvement, by a factor of  $\sim 10$ , when compared with ELLIOTT 92. It supersedes the limit of ARNOLD 98 for this decay using NEMO-2.

<sup>59</sup> BARABASH 04 perform an inclusive measurement of the  $\beta\beta$  decay of  $^{150}\text{Nd}$  into the first excited ( $0_1^+$ ) state of  $^{150}\text{Sm}$ . Gamma radiation emitted in decay of the excited state is detected.

<sup>60</sup> Decay into first excited state of daughter nucleus.

<sup>61</sup> Supersedes ALESSANDRELLO 00. Array of  $\text{TeO}_2$  crystals in high resolution cryogenic calorimeter. Some enriched in  $^{128}\text{Te}$ . Ground state to ground state decay.

<sup>62</sup> Calorimetric measurement of  $2\nu\beta\beta$  ground state decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DANEVICH 00.

<sup>63</sup> Limit on  $0\nu\beta\beta$  decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.

<sup>64</sup> Limit on  $0\nu\beta\beta$  decay of  $^{116}\text{Cd}$  into first excited  $2^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.

<sup>65</sup> Limit on  $0\nu\beta\beta$  decay of  $^{116}\text{Cd}$  into first excited  $0^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.

<sup>66</sup> Limit on  $0\nu\beta\beta$  decay of  $^{116}\text{Cd}$  into second excited  $0^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.

<sup>67</sup> Limit on the  $0\nu\beta\beta$  ground state decay of  $^{186}\text{W}$  using enriched  $\text{CdWO}_4$  scintillators.

<sup>68</sup> Limit on the  $0\nu\beta\beta$  decay of  $^{186}\text{W}$  to the first excited  $2^+$  state of the daughter nucleus using enriched  $\text{CdWO}_4$  scintillators.

<sup>69</sup> AALSETH 02b limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01b for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04b. The criticism was addressed and disputed in AALSETH 04.

<sup>70</sup> BERNABEI 02n report a limit for the  $0\nu, 0^+ \rightarrow 0^+$  decay of  $^{134}\text{Xe}$ , present in the source at 17%, by considering the maximum number of events for this mode compatible with the fitted smooth background.

<sup>71</sup> DANEVICH 01 place limit on  $0\nu\beta\beta$  decay of  $^{160}\text{Gd}$  using  $\text{Gd}_2\text{SiO}_5\text{:Ce}$  crystal scintillators. The limit is more stringent than KOBAYASHI 95.

<sup>72</sup> DANEVICH 01 place limits on  $0\nu\beta\beta$  decay of  $^{160}\text{Gd}$  into excited  $2^+$  state of daughter nucleus using  $\text{Gd}_2\text{SiO}_5\text{:Ce}$  crystal scintillators.

<sup>73</sup> KLAPDOR-KLEINGROTHAUS 01 is a continuation of the work published in BAUDIS 99. Isotopically enriched Ge detectors are used in calorimetric measurement. The most stringent bound is derived from the data set in which pulse-shape analysis has been used to reduce background. Exposure time is 35.5 kg y. Supersedes BAUDIS 99 as most stringent result.

<sup>74</sup> WIESER 01 reports an inclusive geochemical measurement of  $^{96}\text{Zr}$   $\beta\beta$  half life. Their result agrees within  $2\sigma$  with ARNOLD 99 but only marginally, within  $3\sigma$ , with KAWASHIMA 93.

<sup>75</sup> BRUDANIN 00 determine the  $2\nu\beta\beta$  half-life of  $^{48}\text{Ca}$ . Their value is less accurate than BALYSH 96.

<sup>76</sup> ARNOLD 99 measure directly the  $2\nu\beta\beta$  decay of Zr for the first time, using the NEMO-2 tracking detector and an isotopically enriched source. The lifetime is more accurate than the geochemical result of KAWASHIMA 93.

<sup>77</sup> ARNOLD 98 determine the limit for  $0\nu\beta\beta$  decay to the excited  $2^+$  state of  $^{82}\text{Se}$  using the NEMO-2 tracking detector.

<sup>78</sup> DESILVA 97 result for  $2\nu\beta\beta$  decay of  $^{150}\text{Nd}$  is in marginal agreement with ARTEMEV 93. It has smaller errors.

<sup>79</sup> BALYSH 96 measure the  $2\nu\beta\beta$  decay of  $^{48}\text{Ca}$ , using a passive source of enriched  $^{48}\text{Ca}$  in a TPC.

<sup>80</sup> BERNATOWICZ 92 finds  $^{128}\text{Te}/^{130}\text{Te}$  activity ratio from slope of  $^{128}\text{Xe}/^{132}\text{Xe}$  vs  $^{130}\text{Xe}/^{132}\text{Xe}$  ratios during extraction, and normalizes to lead-dated ages for the  $^{130}\text{Te}$  lifetime. The authors state that their results imply that “(a) the double beta decay of  $^{128}\text{Te}$  has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences. ... (b) Theoretical calculations ... underestimate the [long half-lives of  $^{128}\text{Te}$   $^{130}\text{Te}$ ] by 1 or 2 orders of magnitude, pointing to a real suppression in the  $2\nu\beta\beta$  decay rate of these isotopes. (c) Despite [this], most  $\beta\beta$ -models predict a ratio of  $2\nu\beta\beta$  decay widths ... in fair agreement with observation.” Further details of the experiment are given in BERNATOWICZ 93. Our listed half-life has been revised downward from the published value by the authors, on the basis of reevaluated cosmic-ray  $^{128}\text{Xe}$  production corrections.

<sup>81</sup> TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state “Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the  $^{238}\text{U}$  transition in the same range as deduced for  $^{130}\text{Te}$  and  $^{76}\text{Ge}$ . On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case.” See BOEHM 87 and STAUDT 90.

<sup>82</sup> Ratio of inclusive double beta half lives of  $^{128}\text{Te}$  and  $^{130}\text{Te}$  determined from minerals melonite ( $\text{NiTe}_2$ ) and altaite ( $\text{PbTe}$ ) by means of mass spectroscopic measurement of abundance of  $\beta\beta$ -decay products. As gas-retention-age could not be determined the authors use half life of  $^{130}\text{Te}$  (LIN 88) to infer the half life of  $^{128}\text{Te}$ . No estimate of the systematic uncertainty of this method is given. The directly determined half life ratio agrees with BERNATOWICZ 92. However, the inferred  $^{128}\text{Te}$  half life disagrees with KIRSTEN 83 and BERNATOWICZ 92.

### $\langle m_\nu \rangle$ , The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double-β Decay

$\langle m_\nu \rangle = |\sum U_{ej}^2 m_\nu|$ , where the sum goes from 1 to  $n$  and where  $n$  = number of neutrino generations, and  $\nu_j$  is a Majorana neutrino. Note that  $U_{ej}^2$ , not  $|U_{ej}|^2$ , occurs in the sum. The possibility of cancellations has been stressed. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

- ALFONSO 15 report a range of mass limits using the combined data of the CUORICINO and CUORE-0 experiments. The reported mass range reflects the variability of the nuclear matrix element calculations.
- ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the neutrino mass limit based on the 0 $\nu\beta\beta$ -half life of <sup>100</sup>Mo. The spread range reflects different nuclear matrix elements. Supersedes ARNOLD 14 and BARABASH 11A.
- ALBERT 14B is based on 100 kg yr of exposure of the EXO-200 tracking calorimeter. The mass range reflects the nuclear matrix element calculations. Supersedes AUGER 12.
- AGOSTINI 13A is based on 21.6 kg yr of data collected by the GERDA detector. The reported range reflects different nuclear matrix elements. This result is in tension with the evidence for 0 $\nu\beta\beta$ -decay reported in KLAPDOR-KLEINGROTHAUS 06A and earlier references to that work.
- GANDO 13A limit is based on a combination of KamLAND-Zen and EXO-200 (AUGER 12) data. The reported range reflects different nuclear matrix elements. Supersedes GANDO 12A.
- GANDO 12A limit is based on the KamLAND-Zen data. The reported range reflects different nuclear matrix elements. Superseded by GANDO 13A.
- BARABASH 11A limit is based on NEMO-3 data for <sup>82</sup>Se. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.
- ARGYRIADES 10 use <sup>96</sup>Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.
- ARGYRIADES 09 limit is based on data taken with the NEMO-3 detector and <sup>150</sup>Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used.
- Limit was obtained using CaF<sub>2</sub> scintillation calorimeter to search for double beta decay of <sup>48</sup>Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.
- ARNOLD 07 use NEMO-3 half life limit for 0 $\nu$ -decay of <sup>100</sup>Mo to the first excited 0 $^+_{1/2}$ -state of daughter nucleus to obtain neutrino mass limit. The spread reflects the choice of two different nuclear matrix elements. This limit is not competitive when compared to the decay to the ground state.
- ARNOLD 07 use NEMO-3 half life limit for 0 $\nu$ -decay of <sup>100</sup>Mo to the first excited 2 $^+_{1/2}$ -state of daughter nucleus to obtain neutrino mass limit. This limit is not competitive when compared to the decay to the ground state.
- Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6 $\sigma$  statistical evidence for observation of 0 $\nu$ -decay. Authors use matrix element of STAUDT 90. Uncertainty of nuclear matrix element is not reflected in stated error. Supersedes KLAPDOR-KLEINGROTHAUS 04A.
- Supersedes ARNABOLDI 04. Reported range of limits due to use of different nuclear matrix element calculations.
- Mass limits reported in ARNOLD 05A are derived from <sup>100</sup>Mo data, obtained by the NEMO-3 collaboration. The range reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.
- Neutrino mass limits based on <sup>82</sup>Se data utilizing the NEMO-3 detector. The range reported in ARNOLD 05A reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.
- Supersedes ARNABOLDI 03. Reported range of limits due to use of different nuclear matrix element calculations.
- ARNOLD 04 limit is based on the nuclear matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.
- Supersedes KLAPDOR-KLEINGROTHAUS 02D. Event excess at  $\beta\beta$ -decay energy is used to derive Majorana neutrino mass using the nuclear matrix elements of STAUDT 90. The mass range shown is based on the authors evaluation of the uncertainties of the STAUDT 90 matrix element calculation. If this uncertainty is neglected, and only statistical errors are considered, the range in  $\langle m \rangle$  becomes (0.2–0.6) eV at the 3  $\sigma$  level.
- Calorimetric CaF<sub>2</sub> scintillator. Range of limits reflects authors' estimate of the uncertainty of the nuclear matrix elements. Replaces YOU 91 as the most stringent limit based on <sup>48</sup>Ca.
- Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.

- Limit for  $\langle m_{\nu} \rangle$  is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.
- AALSETH 02B reported range of limits on  $\langle m_{\nu} \rangle$  reflects the spread of theoretical nuclear matrix elements. Excludes part of allowed mass range reported in KLAPDOR-KLEINGROTHAUS 01B.
- BERNABEI 02D limit is based on the matrix elements of SIMKOVIC 02. The range of neutrino masses based on a variety of matrix elements is 1.1–2.9 eV.
- KLAPDOR-KLEINGROTHAUS 02D is a detailed description of the analysis of the data collected by the Heidelberg-Moscow experiment, previously presented in KLAPDOR-KLEINGROTHAUS 01B. Matrix elements in STAUDT 90 have been used. See the footnote in the preceding table for further details. See also KLAPDOR-KLEINGROTHAUS 02B.
- The range of the reported  $\langle m_{\nu} \rangle$  values reflects the spread of the nuclear matrix elements. On axis value assuming  $\langle \lambda \rangle = \langle \eta \rangle = 0$ .
- KLAPDOR-KLEINGROTHAUS 01 uses the calculation by STAUDT 90. Using several other models in the literature could worsen the limit up to 1.2 eV. This is the most stringent experimental bound on  $m_{\nu}$ . It supersedes BAUDIS 99B.
- ARNOLD 99 limit based on the nuclear matrix elements of STAUDT 90.
- BERNATOWICZ 92 finds these majorana neutrino mass limits assuming that the measured geochemical decay width is a limit on the 0 $\nu$  decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.
- ELLIOTT 92 uses the matrix elements of HAXTON 84.

### Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later.  $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$  and  $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$ , where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

$\langle \lambda \rangle$ ( $10^{-6}$ )	CL%	$\langle \eta \rangle$ ( $10^{-8}$ )	CL%	ISOTOPE	METHOD	DOCUMENT ID

		< 5.3		<sup>128</sup> Te	Geochem	13 BERNATOW... 92

- ARNOLD 14 is based on 34.7 kg yr of exposure of the NEMO-3 tracking calorimeter. The reported range limit on  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  reflects the nuclear matrix element uncertainty in <sup>100</sup>Mo.
- ARNOLD 07 use NEMO-3 half life limit for 0 $\nu$ -decay of <sup>100</sup>Mo to the first excited 2 $^+_{1/2}$ -state of daughter nucleus to limit the right-right handed admixture of weak currents  $\langle \lambda \rangle$ . This limit is not competitive when compared to the decay to the ground state.
- Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6 $\sigma$  statistical evidence for observation of 0 $\nu$ -decay. Authors use matrix element of MUTO 89 to determine  $\langle \lambda \rangle$  and  $\langle \eta \rangle$ . Uncertainty of nuclear matrix element is not reflected in stated errors.
- ARNOLD 05A derive limit for  $\langle \lambda \rangle$  based on <sup>100</sup>Mo data collected with NEMO-3 detector. No limit for  $\langle \eta \rangle$  is given. Supersedes ARNOLD 04.
- ARNOLD 05A derive limit for  $\langle \lambda \rangle$  based on <sup>82</sup>Se data collected with NEMO-3 detector. No limit for  $\langle \eta \rangle$  is given. Supersedes ARNOLD 04.
- ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for  $\langle \lambda \rangle$ , no limit for  $\langle \eta \rangle$  is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.
- ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for  $\langle \lambda \rangle$ , no limit for  $\langle \eta \rangle$  is given.
- Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.
- Limits for  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.
- The range of the reported  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  values reflects the spread of the nuclear matrix elements. On axis value assuming  $\langle m_{\nu} \rangle = 0$  and  $\langle \lambda \rangle = \langle \eta \rangle = 0$ , respectively.
- GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.
- VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit  $2.6 \times 10^{23}$  y at 90%CL.
- BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0 $\nu$  width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on  $\eta$ . Further details of the experiment are given in BERNATOWICZ 93.

## Neutrino Mixing

With the exception of a few possible anomalies such as LSND, current neutrino data can be described within the framework of a  $3\times 3$  mixing matrix between the flavor eigenstates  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$  and the mass eigenstates  $\nu_1$ ,  $\nu_2$ , and

$\nu_3$ . (See Eq. (14.6) of the review “Neutrino Mass, Mixing, and Oscillations” by K. Nakamura and S.T. Petcov.) The Listings are divided into the following sections:

**(A) Neutrino fluxes and event ratios:** shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

**(B) Three neutrino mixing parameters:** shows measurements of  $\sin^2(2\theta_{12})$ ,  $\sin^2(2\theta_{23})$ ,  $\Delta m_{21}^2$ ,  $\Delta m_{32}^2$ , and  $\sin^2(2\theta_{13})$  which are all interpretations of data based on the three neutrino mixing scheme described in the review “Neutrino Mass, Mixing, and Oscillations.” by K. Nakamura and S.T. Petcov. Many parameters have been calculated in the two-neutrino approximation.

**(C) Other neutrino mixing results:** shows measurements and limits for the probability of oscillation for experiments which might be relevant to the LSND oscillation claim. Included are experiments which are sensitive to  $\nu_\mu \rightarrow \nu_e$ ,  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ , sterile neutrinos, and CPT tests.

### (A) Neutrino fluxes and event ratios

#### Events (observed/expected) from accelerator $\nu_\mu$ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1.01 ± 0.10	<sup>1</sup> ABE	14B T2K	$\nu_e$ rate in T2K near detect.
0.71 ± 0.08	<sup>2</sup> AHN	06A K2K	K2K to Super-K
0.64 ± 0.05	<sup>3</sup> MICHAEL	06 MINS	All charged current events
0.71 +0.08 -0.09	<sup>4</sup> ALIU	05 K2K	KEK to Super-K
0.70 +0.10 -0.11	<sup>5</sup> AHN	03 K2K	KEK to Super-K

<sup>1</sup> The rate of  $\nu_e$  from  $\mu$  decay was measured to be  $0.68 \pm 0.30$  compared to the predicted flux. From  $K$  decay  $1.10 \pm 0.14$  compared to the predicted flux.

<sup>2</sup> Based on the observation of 112 events when  $158.1^{+9.2}_{-8.6}$  were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about  $4.3 \sigma$ . Supersedes ALIU 05.

<sup>3</sup> This ratio is based on the observation of 215 events compared to an expectation of  $336 \pm 14$  without oscillations. See also ADAMSON 08.

<sup>4</sup> This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of  $151^{+12}_{-10}$ .

<sup>5</sup> This ratio is based on the observation of 56 events with an expectation of  $80.1^{+6.2}_{-5.4}$ .

#### Events (observed/expected) from reactor $\bar{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor  $\bar{\nu}_e$  event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels ( $^{235}\text{U}$ ,  $^{239}\text{Pu}$ ,  $^{241}\text{Pu}$ ) and on calculations for  $^{238}\text{U}$ .

A recent re-evaluation of the spectral conversion of electron to  $\bar{\nu}_e$  in MUELLER 11 results in an upward shift of the reactor  $\bar{\nu}_e$  spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

0.955±0.035±0.110	<sup>12</sup> KWON 81	$\bar{\nu}_e p \rightarrow e^+ n$
0.89 ±0.15	<sup>12</sup> BOEHM 80	$\bar{\nu}_e p \rightarrow e^+ n$

<sup>1</sup> AN 13 use six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 470 and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\bar{\nu}_e$  observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 7.7 standard deviations. The value of  $\Delta m_{31}^2 = 2.32 \times 10^{-3} \text{ eV}^2$  was assumed in the analysis. This is an improved result (2.5 times increase in statistics) compared to AN 12.

<sup>2</sup> ABE 12 determine the  $\bar{\nu}_e$  interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations.

<sup>3</sup> AHN 12 use two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99m from six reactor cores, to determine the  $\bar{\nu}_e$  interaction rate ratio.

<sup>4</sup> AN 12 use six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the  $\bar{\nu}_e$  interaction rate ratios. Superseded by AN 13.

<sup>5</sup> DENIZ 10 observe reactor  $\bar{\nu}_e e$  scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on  $\sin^2 2\theta_{\text{eff}} = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$ .

<sup>6</sup> Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.

<sup>7</sup> EGUCHI 03 observe reactor neutrino disappearance at  $\sim 180 \text{ km}$  baseline to various Japanese nuclear power reactors.

<sup>8</sup> BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.

<sup>9</sup> APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use  $\bar{\nu}_e p \rightarrow e^+ n$  in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.

<sup>10</sup> GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.

<sup>11</sup> DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.

<sup>12</sup> KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

### Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce  $\mu$ -like and  $e$ -like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as  $\mu/e$ . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical  $\mu/e$ ,  $R(\mu/e)$ , or that of experimental to theoretical  $\mu/\text{total}$ ,  $R(\mu/\text{total})$  with  $\text{total} = \mu + e$ , is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for  $\mu$  ( $N_{\text{up}}(\mu)/N_{\text{down}}(\mu)$ ) or  $e$  ( $N_{\text{up}}(e)/N_{\text{down}}(e)$ ) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

### $R(\mu/e) = (\text{Measured Ratio } \mu/e) / (\text{Expected Ratio } \mu/e)$

<sup>1</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring  $e$ -like events with  $0.1 \text{ GeV}/c < p_e$  and  $\mu$ -like events  $0.2 \text{ GeV}/c < p_\mu$ , both having a visible energy  $< 1.33 \text{ GeV}$ . These criteria match the definition used by FUKUDA 94.

<sup>2</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy  $> 1.33 \text{ GeV}$  and partially-contained events. All partially-contained events are classified as  $\mu$ -like.

<sup>3</sup> SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained  $e$ -flavor and  $\mu$ -flavor events having lepton momentum  $> 0.3 \text{ GeV}/c$ .

<sup>4</sup> FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

<sup>5</sup> DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report  $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$  for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

<sup>6</sup> FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained  $e$ -like events with  $0.1 < p_e < 1.33 \text{ GeV}/c$  and fully-contained  $\mu$ -like events with  $0.2 < p_\mu < 1.5 \text{ GeV}/c$ .

<sup>7</sup> FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy  $> 1.33 \text{ GeV}$  and partially contained  $\mu$ -like events.

<sup>8</sup> BECKER-SZENDY 92B reports the fraction of nonshowing events (mostly muons from atmospheric neutrinos) as  $0.36 \pm 0.02 \pm 0.02$ , as compared with expected fraction  $0.51 \pm 0.01 \pm 0.05$ . After cutting the energy range to the Kamiokande limits, BEIER 92 finds  $R(\mu/e)$  very close to the Kamiokande value.

### $R(\nu_\mu) = (\text{Measured Flux of } \nu_\mu) / (\text{Expected Flux of } \nu_\mu)$

0.95±0.22	<sup>8</sup> BOLIEV 81		Baksan
0.62±0.17	CROUCH 78		Case Western/UCI

<sup>1</sup> ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of 127 ± 13 without oscillations.

<sup>2</sup> AMBROSIO 01 result is based on the upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

<sup>3</sup> AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

<sup>4</sup> AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

<sup>5</sup> AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of  $\approx 0.13$ . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) \sim$  a few times  $10^{-3} \text{ eV}^2$ . However, the fit to the observed zenith distribution gives a maximum probability for  $\chi^2$  of only 5% for the best oscillation hypothesis.

<sup>6</sup> CASPER 91 correlates showering/nonshowing signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowing ( $\approx \nu_\mu$  induced) fraction is  $0.41 \pm 0.03 \pm 0.02$ , as compared with expected  $0.51 \pm 0.05$  (syst).

<sup>7</sup> AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define  $\rho = (\text{measured number of } \nu_e \text{'s})/(\text{measured number of } \nu_\mu \text{'s})$ . They report  $\rho(\text{measured}) = \rho(\text{expected}) = 0.96 \pm 0.32$ .

<sup>8</sup> From this data BOLIEV 81 obtain the limit  $\Delta(m^2) \leq 6 \times 10^{-3} \text{ eV}^2$  for maximal mixing,  $\nu_\mu \not\leftrightarrow \nu_\mu$  type oscillation.

## Neutrino Mixing

$0.71 \pm 0.06$	<sup>1</sup> ADAMSON	12B	MINS	contained-vertex muons
$0.551 \pm 0.035$ $-0.033 \pm 0.004$	<sup>2</sup> ASHIE	05	SKAM	multi-GeV

<sup>1</sup> ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). This result is obtained with a sample of high resolution contained-vertex muons. The quoted error is statistical only.

<sup>2</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring  $\mu$ -like events with visible energy  $> 1.33$  GeV and partially-contained events. All partially-contained events are classified as  $\mu$ -like. Upward-going events are those with  $-1 < \cos(\text{zenith angle}) < -0.2$  and downward-going events are those with  $0.2 < \cos(\text{zenith angle}) < 1$ . The  $\mu$ -like up-down ratio for the multi-GeV data deviates from 1 (the expectation for no atmospheric  $\nu_\mu$  oscillations) by more than 12 standard deviations.

<sup>1</sup> ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio  $N(\mu^+)/N(\mu^-)$  represents the  $\overline{\nu}_\mu/\nu_\mu$  ratio.

<sup>2</sup> This result is obtained with a charge-separated sample of high resolution contained-vertex muons. The quoted error is statistical only.

<sup>3</sup> This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons. The quoted error is statistical only.

### $R(\mu^+/\mu^-) = (\text{Measured } N(\mu^+)/N(\mu^-)) / (\text{Expected } N(\mu^+)/N(\mu^-))$

VALUE	DOCUMENT ID	TECN	COMMENT
-------	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$0.93 \pm 0.09 \pm 0.09$	<sup>1,2</sup> ADAMSON	12B	MINS	contained-vertex muons
$1.29 \pm 0.19$ $-0.17 \pm 0.16$	<sup>1,3</sup> ADAMSON	12B	MINS	$\nu$ -induced rock-muons
$1.03 \pm 0.08 \pm 0.08$	<sup>1,4</sup> ADAMSON	12B	MINS	contained
$1.39 \pm 0.35 \pm 0.08$ $-0.46 \pm 0.14$	<sup>5</sup> ADAMSON	07	MINS	Upward and horizontal $\mu$ with far detector
$0.96 \pm 0.38$ $-0.27 \pm 0.15$	<sup>6</sup> ADAMSON	06	MINS	atmospheric $\nu$ with far detector

<sup>1</sup> ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio  $N(\mu^+)/N(\mu^-)$  represents the  $\overline{\nu}_\mu/\nu_\mu$  ratio. As far as the same oscillation parameters are used for  $\nu_s$  and  $\overline{\nu}_s$ , the expected  $\overline{\nu}_\mu/\nu_\mu$  ratio is almost entirely independent of any input oscillations.

<sup>2</sup> This result is obtained with a charge-separated sample of high resolution contained-vertex muons.

<sup>3</sup> This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons.

<sup>4</sup> The charge-separated samples of high resolution contained-vertex muons and neutrino-induced rock-muons are combined to obtain this result which is consistent with unity.

<sup>5</sup> ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with  $CPT$  conservation.

<sup>6</sup> ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

## Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of  $^8\text{B}$ . Solar neutrino fluxes are composed of all active neutrino species,  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ . In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes. For details, see Section 13.4 of Reviews, Tables, and Plots.

### $\nu_e$ Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) =  $10^{-36}$  captures per atom per second.

VALUE (SNU)	DOCUMENT ID	TECN	COMMENT
-------------	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$73.4 \pm 6.1 \pm 3.7$ $-6.0 \pm 4.1$	<sup>1</sup> KAETHER	10		GALX reanalysis
$67.6 \pm 4.0 \pm 3.2$	<sup>2</sup> KAETHER	10		GNO+GALX reanalysis combined
$65.4 \pm 3.1 \pm 2.6$ $-3.0 \pm 2.8$	<sup>3</sup> ABDURASHI...	09	SAGE	$^{71}\text{Ga} \rightarrow ^{71}\text{Ge}$
$62.9 \pm 5.5 \pm 2.5$ $-5.3$	<sup>4</sup> ALTMANN	05	GNO	$^{71}\text{Ga} \rightarrow ^{71}\text{Ge}$
$69.3 \pm 4.1 \pm 3.6$	<sup>5</sup> ALTMANN	05	GNO	GNO + GALX combined
$77.5 \pm 6.2 \pm 4.3$ $-4.7$	<sup>6</sup> HAMPEL	99	GALX	$^{71}\text{Ga} \rightarrow ^{71}\text{Ge}$
$2.56 \pm 0.16 \pm 0.16$	<sup>7</sup> CLEVELAND	98	HOME	$^{37}\text{Cl} \rightarrow ^{37}\text{Ar}$

<sup>1</sup> KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.

<sup>2</sup> Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).

<sup>3</sup> ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a  $\sim 15\%$  systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense  $^{51}\text{Cr}$  (twice by GALLEX and once by SAGE) and  $^{37}\text{Ar}$  (by SAGE) result in an average ratio of  $0.87 \pm 0.05$  of the observed to calculated rates.

<sup>4</sup> ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.

<sup>5</sup> Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.

<sup>6</sup> HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is  $118.4 \pm 17.8 \pm 6.6$  SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300  $^{71}\text{Ge}$  events were observed. Note that a  $\sim 15\%$  systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense  $^{51}\text{Cr}$  (twice by GALLEX and once by SAGE) and  $^{37}\text{Ar}$  (by SAGE) result in an average ratio of  $0.87 \pm 0.05$  of the observed to calculated rates.

<sup>7</sup> CLEVELAND 98 is a detailed report of the  $^{37}\text{Cl}$  experiment at the Homestake Mine. The average solar neutrino-induced  $^{37}\text{Ar}$  production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

### $\Phi_{\text{ES}} (^8\text{B})$

$^8\text{B}$  solar-neutrino flux measured via  $\nu e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu$ ,  $\nu_\tau$  due to the cross-section difference,  $\sigma(\nu_\mu, \tau e) \sim 0.16\sigma(\nu_e e)$ . If the  $^8\text{B}$  solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is  $\sim 0.16$  times of  $\nu_e$ .

<sup>1</sup> ABE 11 reports the Super-Kamiokande-III results for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron range has a total live time of 298 days.

<sup>2</sup> ABE 11 recalculated the Super-Kamiokande-II results using <sup>8</sup>B spectrum of WINTER 06A.

<sup>3</sup> ABE 11 recalculated the Super-Kamiokande-I results using <sup>8</sup>B spectrum of WINTER 06A.

<sup>4</sup> ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the <sup>8</sup>B solar neutrino flux. They utilize  $\nu - e$  elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which  $157 \pm 23.6$  are assigned to background.

<sup>5</sup> BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.

<sup>6</sup> AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.

<sup>7</sup> CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.

<sup>8</sup> HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

<sup>9</sup> AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.

<sup>10</sup> AHMAD 02 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.

<sup>11</sup> AHMAD 01 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

<sup>12</sup> FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold  $E_e > 9.3$  MeV (first 449 days),  $> 7.5$  MeV (middle 794 days), and  $> 7.0$  MeV (last 836 days). These results update the HIRATA 90 result for the average <sup>8</sup>B solar-neutrino flux and HIRATA 91 result for the day-night variation in the <sup>8</sup>B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

### $\phi_{CC}$ (<sup>8</sup>B)

<sup>8</sup>B solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to  $\nu_e$ .

<sup>1</sup> AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.

<sup>2</sup> AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.

<sup>3</sup> AHMAD 02 reports the SNO result of the <sup>8</sup>B solar-neutrino flux measured with charged-current reaction on deuterium,  $\nu_e d \rightarrow ppe^-$ , above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results. The complete description of the SNO Phase I data set is given in AHARMIM 07.

<sup>4</sup> AHMAD 01 reports the first SNO result of the <sup>8</sup>B solar-neutrino flux measured with the charged-current reaction on deuterium,  $\nu_e d \rightarrow ppe^-$ , above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

### $\phi_{NC}$ (<sup>8</sup>B)

<sup>8</sup>B solar neutrino flux measured with neutral-current reaction, which is equally sensitive to  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ .

VALUE ( $10^6 \text{ cm}^{-2}\text{s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
$5.25 \pm 0.16^{+0.11}_{-0.13}$	1 AHARMIM	13	SNO All three phases combined
$5.140^{+0.160+0.132}_{-0.158-0.117}$	2 AHARMIM	10	SNO Phase I+II, low threshold
$5.54^{+0.33+0.36}_{-0.31-0.34}$	3 AHARMIM	08	SNO Phase III, prop. counter + PMT
$4.94 \pm 0.21^{+0.38}_{-0.34}$	4 AHARMIM	05A	SNO Salty D <sub>2</sub> O; <sup>8</sup> B shape not const.
$4.81 \pm 0.19^{+0.28}_{-0.27}$	4 AHARMIM	05A	SNO Salty D <sub>2</sub> O; <sup>8</sup> B shape constrained
$5.09^{+0.44+0.46}_{-0.43-0.43}$	5 AHMAD	02	SNO average flux; <sup>8</sup> B shape const.
$6.42 \pm 1.57^{+0.55}_{-0.58}$	5 AHMAD	02	SNO average flux; <sup>8</sup> B shape not const.

<sup>1</sup> AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the <sup>8</sup>B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

<sup>2</sup> AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.

<sup>3</sup> AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.

<sup>4</sup> AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.

<sup>5</sup> AHMAD 02 reports the first SNO result of the <sup>8</sup>B solar-neutrino flux measured with the neutral-current reaction on deuterium,  $\nu_\ell d \rightarrow np\nu_\ell$ , above the neutral-current reaction threshold of 2.2 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001. The complete description of the SNO Phase I data set is given in AHARMIM 07.

### $\phi_{\nu_\mu+\nu_\tau}$ (<sup>8</sup>B)

Nonelectron-flavor active neutrino component ( $\nu_\mu$  and  $\nu_\tau$ ) in the <sup>8</sup>B solar-neutrino flux.

VALUE ( $10^6 \text{ cm}^{-2}\text{s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT

## Neutrino Mixing

$5.25 \pm 0.16 \pm^{+0.11}_{-0.13}$	<sup>1</sup> AHARMIM	13	SNO	All three phases combined
$5.046 \pm^{+0.159}_{-0.152} \pm^{+0.107}_{-0.123}$	<sup>2</sup> AHARMIM	10	SNO	From $\phi_{NC}$ in Phase I+II, low threshold
$5.54 \pm^{+0.33}_{-0.31} \pm^{+0.36}_{-0.34}$	<sup>3</sup> AHARMIM	08	SNO	$\phi_{NC}$ in Phase III
$4.94 \pm 0.21 \pm^{+0.38}_{-0.34}$	<sup>4</sup> AHARMIM	05A	SNO	From $\phi_{NC}$ ; $^8\text{B}$ shape not const.
$4.81 \pm 0.19 \pm^{+0.28}_{-0.27}$	<sup>4</sup> AHARMIM	05A	SNO	From $\phi_{NC}$ ; $^8\text{B}$ shape constrained
$5.09 \pm^{+0.44}_{-0.43} \pm^{+0.46}_{-0.43}$	<sup>5</sup> AHMAD	02	SNO	Direct measurement from $\phi_{NC}$
$5.44 \pm 0.99$	<sup>6</sup> AHMAD	01		Derived from SNO+SuperKam, water Cherenkov

- <sup>1</sup> AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the  $^8\text{B}$  flux mostly comes from the NC signal, however, CC contribution is included in the fit.
- <sup>2</sup> AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total  $^8\text{B}$  neutrino flux and the energy-dependent  $\nu_e$  survival probability.
- <sup>3</sup> AHARMIM 08 reports the results from SNO Phase III measurement using an array of  $^3\text{He}$  proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the  $^8\text{B}$  shape.
- <sup>4</sup> AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the  $^8\text{B}$  energy spectrum was not constrained. In the other method, the constraint of an undistorted  $^8\text{B}$  energy spectrum was added for comparison with AHMAD 02 results.
- <sup>5</sup> AHMAD 02 determined the total flux of active  $^8\text{B}$  solar neutrinos by directly measuring the neutral-current reaction,  $\nu_e d \rightarrow np\nu_e$ , which is equally sensitive to  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ . The complete description of the SNO Phase I data set is given in AHARMIM 07.
- <sup>6</sup> AHMAD 01 deduced the total flux of active  $^8\text{B}$  solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande  $\nu e$  elastic-scattering result (FUKUDA 01).

### Day-Night Asymmetry ( $^8\text{B}$ )

$$A = (\phi_{\text{night}} - \phi_{\text{day}}) / \phi_{\text{average}}$$

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •

$-0.037 \pm 0.063 \pm 0.032$	<sup>5</sup> AHARMIM	05A	SNO From salty SNO $\phi_{CC}$ ; const. of no $\phi_{NC}$ asymmetry
$0.14 \pm 0.063 \pm^{+0.015}_{-0.014}$	<sup>6</sup> AHMAD	02B	SNO Derived from SNO $\phi_{CC}$
$0.07 \pm 0.049 \pm^{+0.013}_{-0.012}$	<sup>7</sup> AHMAD	02B	SNO Const. of no $\phi_{NC}$ asymmetry

- <sup>1</sup> RENSHAW 14 obtains this result by using the "amplitude fit" introduced in SMY 04. The data from the Super-Kamiokande(SK)-I, -II, and 1306 live days of the SK-IV measurements are used. The analysis threshold is recoil-electron kinetic energy of 4.5 MeV for SK-III, and SK-IV except for 250 live days in SK-III (6.0 MeV). The analysis threshold for SK-I and SK-II is the same as in the previous reports. (Note that in the previous SK solar-neutrino results, the analysis threshold is quoted as recoil-electron total energy.) This day-night asymmetry result is consistent with neutrino oscillations for  $4 \times 10^{-5} \text{ eV}^2 < \Delta m_{21}^2 < 7 \times 10^{-5} \text{ eV}^2$  and large mixing values of  $\theta_{12}$  at the 68% CL.
- <sup>2</sup> CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV except for the first 159 live days (8.0 MeV).
- <sup>3</sup> HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- <sup>4</sup> This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via  $\nu_e$  elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of  $\pm 0.0004$  coming from uncertainty of oscillation parameters.
- <sup>5</sup> AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the  $^8\text{B}$  shape.
- <sup>6</sup> AHMAD 02B results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

<sup>7</sup> AHMAD 02B results are derived from the charged-current interactions, neutral-current interactions, and  $\nu e$  elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

### $\phi_{ES} (^8\text{Be})$

$^7\text{Be}$  solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu$ ,  $\nu_\tau$  due to the cross-section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the  $^7\text{Be}$  solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

$3.26 \pm 0.52$	<sup>1</sup> GANDO	15	KLND average flux
$3.10 \pm 0.15$	<sup>2</sup> BELLINI	11A	BORX average flux

- <sup>1</sup> GANDO 15 uses 165.4 kton-day exposure of the KamLAND liquid scintillator detector to measure the 862 keV  $^7\text{Be}$  solar neutrino flux via  $\nu - e$  elastic scattering
- <sup>2</sup> BELLINI 11A reports the  $^7\text{Be}$  solar neutrino flux measured via  $\nu - e$  elastic scattering. The data correspond to 740.7 live days between May 16, 2007 and May 8, 2010, and also correspond to 153.6 ton-year fiducial exposure. BELLINI 11A measured the 862 keV  $^7\text{Be}$  solar neutrino flux, which is an 89.6% branch of the  $^7\text{Be}$  solar neutrino flux, to be  $(2.78 \pm 0.13) \times 10^9 \text{ cm}^{-2} \text{ s}^{-1}$ . Supercedes ARPESELLA 08A.

### $\phi_{ES} (p \bar{p})$

$p \bar{p}$  solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu$ ,  $\nu_\tau$  due to the cross section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the  $p \bar{p}$  solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

VALUE ( $10^8 \text{ cm}^{-2} \text{ s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
$1.0 \pm 0.2$	<sup>1</sup> BELLINI	12A	BORX average flux

- <sup>1</sup> BELLINI 12A reports 1.44 MeV  $p \bar{p}$  solar-neutrino flux measured via  $\nu_e$  elastic scattering. The data were collected between January 13, 2008 and May 9, 2010, corresponding to 20,4009 ton-day fiducial exposure. The listed flux value is calculated from the observed rate of  $p \bar{p}$  solar neutrino interactions in Borexino ( $3.1 \pm 0.6 \pm 0.3$  counts/(day-100 ton)) and the corresponding rate expected for no neutrino flavor oscillations ( $4.47 \pm 0.05$  counts/(day-100 ton)), using the SSM prediction for the  $p \bar{p}$  solar neutrino flux of  $(1.441 \pm 0.012) \times 10^8 \text{ cm}^{-2} \text{ s}^{-1}$ .

### $\phi_{ES} (\text{CNO})$

CNO solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu$ ,  $\nu_\tau$  due to the cross section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the CNO solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

## (B) Three-neutrino mixing parameters

## INTRODUCTION TO THREE-NEUTRINO MIXING PARAMETERS LISTINGS

Updated November 2015 by M. Goodman (ANL).

**Introduction and Notation:** With the exception of possible short-baseline anomalies (such as LSND), current accelerator, reactor, solar and atmospheric neutrino data can be described within the framework of a  $3 \times 3$  mixing matrix between the flavor eigenstates  $\nu_e$ ,  $\nu_\mu$  and  $\nu_\tau$  and mass eigenstates  $\nu_1$ ,  $\nu_2$  and  $\nu_3$ . (See equation 14.6 of the review “Neutrino Mass, Mixing and Oscillations” by K. Nakamura and S.T. Petcov.) Whether or not this is the ultimately correct framework, it is currently widely used to parametrize neutrino mixing data and to plan new experiments.

The mass differences are called  $\Delta m_{21}^2 \equiv m_2^2 - m_1^2$  and  $\Delta m_{32}^2 \equiv m_3^2 - m_2^2$ . In these listings, we assume

$$\Delta m_{32}^2 \sim \Delta m_{31}^2 \quad (1)$$

even though the experimental error is comparable to the difference  $\Delta m_{31}^2 - \Delta m_{32}^2 = \Delta m_{21}^2$ . The measurements made by  $\nu_\mu$  disappearance at accelerators and by  $\nu_e$  disappearance at reactors are slightly different mixtures of  $\Delta m_{32}^2$  and  $\Delta m_{31}^2$ . The angles are labeled  $\theta_{12}$ ,  $\theta_{23}$  and  $\theta_{13}$ . The CP violating phase is called  $\delta$ . The familiar two neutrino form for oscillations is

$$P(\nu_a \rightarrow \nu_b; a \neq b) = \sin^2(2\theta) \sin^2(\Delta m^2 L/4E). \quad (2)$$

Despite the fact that the mixing angles have been measured to be much larger than in the quark sector, the two neutrino form is often a very good approximation and is used in many situations.

The angles appear in the equations below in many forms. They most often appear as  $\sin^2(2\theta)$ . The listings currently now use  $\sin^2(\theta)$  because this distinguishes whether  $\theta_{23}$  is larger or smaller than  $45^\circ$ .

**Accelerator neutrino experiments:** Ignoring  $\Delta m_{21}^2$ , CP violation, and matter effects, the equations for the probability of appearance in an accelerator oscillation experiment are:

$$P(\nu_\mu \rightarrow \nu_\tau) = \sin^2(2\theta_{23}) \cos^4(\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \quad (3)$$

$$P(\nu_\mu \rightarrow \nu_e) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (4)$$

$$P(\nu_e \rightarrow \nu_\mu) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (5)$$

$$P(\nu_e \rightarrow \nu_\tau) = \sin^2(2\theta_{13}) \cos^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E). \quad (6)$$

Current and future long-baseline accelerator experiments are studying non-zero  $\theta_{13}$  through  $P(\nu_\mu \rightarrow \nu_e)$ . Including the CP terms and low mass scale, the equation for neutrino oscillation in vacuum is:

$$\begin{aligned} P(\nu_\mu \rightarrow \nu_e) &= P1 + P2 + P3 + P4 \\ P1 &= \sin^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \\ P2 &= \cos^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{21}^2 L/4E) \\ P3 &= -/+ J \sin(\delta) \sin(\Delta m_{32}^2 L/4E) \\ P4 &= J \cos(\delta) \cos(\Delta m_{32}^2 L/4E) \end{aligned} \quad (7)$$

where

$$\begin{aligned} J &= \cos(\theta_{13}) \sin(2\theta_{12}) \sin(2\theta_{13}) \sin(2\theta_{23}) \times \\ &\quad \sin(\Delta m_{32}^2 L/4E) \sin(\Delta m_{21}^2 L/4E) \end{aligned} \quad (8)$$

and the sign in P3 is negative for neutrinos and positive for anti-neutrinos respectively. For most new long-baseline accelerator experiments, P2 can safely be neglected but the other three terms can all be large. Also, depending on the distance and the mass hierarchy, matter effects will need to be included.

**Reactor neutrino experiments:** Nuclear reactors are prolific sources of  $\bar{\nu}_e$  with an energy near 4 MeV. The oscillation probability can be expressed

$$\begin{aligned} P(\bar{\nu}_e \rightarrow \bar{\nu}_e) &= 1 - \cos^4(\theta_{13}) \sin^2(2\theta_{12}) \sin^2(\Delta m_{21}^2 L/4E) \\ &\quad - \cos^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{31}^2 L/4E) \\ &\quad - \sin^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \end{aligned} \quad (9)$$

not using the approximation in Eq. (1). For short distances ( $L < 5 \text{ km}$ ) we can ignore the second term on the right and can reimpose approximation Eq. (1). This takes the familiar two neutrino form with  $\theta_{13}$  and  $\Delta m_{32}^2$ :

$$P(\bar{\nu}_e \rightarrow \bar{\nu}_e) = 1 - \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E). \quad (10)$$

**Solar and Atmospheric neutrino experiments:** Solar neutrino experiments are sensitive to  $\nu_e$  disappearance and have

# Lepton Particle Listings

## Neutrino Mixing

allowed the measurement of  $\theta_{12}$  and  $\Delta m_{21}^2$ . They are also sensitive to  $\theta_{13}$ . We identify  $\Delta m_{\odot}^2 = \Delta m_{21}^2$  and  $\theta_{\odot} = \theta_{12}$ .

Atmospheric neutrino experiments are primarily sensitive to  $\nu_{\mu}$  disappearance through  $\nu_{\mu} \rightarrow \nu_{\tau}$  oscillations, and have allowed the measurement of  $\theta_{23}$  and  $\Delta m_{32}^2$ . We identify  $\Delta m_A^2 = \Delta m_{32}^2$  and  $\theta_A = \theta_{23}$ . Despite the large  $\nu_e$  component of the atmospheric neutrino flux, it is difficult to measure  $\Delta m_{21}^2$  effects. This is because of a cancellation between  $\nu_{\mu} \rightarrow \nu_e$  and  $\nu_e \rightarrow \nu_{\mu}$  together with the fact that the ratio of  $\nu_{\mu}$  and  $\nu_e$  atmospheric fluxes, which arise from sequential  $\pi$  and  $\mu$  decay, is near 2.

**Oscillation Parameter Listings:** In Section (B) we encode the three mixing angles  $\theta_{12}$ ,  $\theta_{23}$ ,  $\theta_{13}$  and two mass squared differences  $\Delta m_{21}^2$  and  $\Delta m_{32}^2$ . Our knowledge of  $\theta_{12}$  and  $\Delta m_{21}^2$  comes from the KamLAND reactor neutrino experiment together with solar neutrino experiments. Our knowledge of  $\theta_{23}$  and  $\Delta m_{32}^2$  comes from atmospheric, reactor and long-baseline accelerator neutrino experiments. For the earlier experiments, we identified the large mass splitting as  $\Delta m_{32}^2$ . Now that  $\sigma(\Delta m_{32}^2) \approx \Delta m_{21}^2$ , some experiments report separate values for the two hierarchies. Results on  $\theta_{13}$  come from reactor antineutrino disappearance experiments. There are also results from long-baseline accelerator experiments looking for  $\nu_e$  appearance. The interpretation of both kinds of results depends on  $\Delta m_{32}^2$ , and the accelerator results also depend on the mass hierarchy,  $\theta_{23}$  and the CP violating phase  $\delta$ .

Accelerator and atmospheric experiments are beginning to have some sensitivity to the CP violation phase  $\delta$  through Eq. (7). Note that P3 depends on the sign of  $\Delta m_{32}^2$  so the sensitivity depends on the mass hierarchy. For non-maximal  $\theta_{23}$  mixing, it also depends on the octant of  $\theta_{23}$ , i.e. whether  $\theta_{23} > \pi/4$  or  $\theta_{23} < \pi/4$ .

### $\sin^2(\theta_{12})$

<sup>1</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.

<sup>2</sup> FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

<sup>3</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $0.304^{+0.013}_{-0.012}$  for normal and  $0.305^{+0.012}_{-0.013}$  for inverted mass ordering.

<sup>4</sup> AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>5</sup> AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8\text{B}$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and  $^7\text{Be}$  (BELLINI 11A) rates, and  $^8\text{B}$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

<sup>6</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>7</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino and KamLAND (GANDO 11) data. CPT invariance is assumed.

<sup>8</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

<sup>9</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

<sup>10</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

<sup>11</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

<sup>12</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.

<sup>13</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

<sup>14</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free. CPT invariance is assumed.

<sup>15</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free.

<sup>16</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

<sup>17</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GANDO 13.

<sup>18</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

## Neutrino Mixing

- <sup>19</sup>AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>20</sup>AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- <sup>21</sup>AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>22</sup>AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.
- <sup>23</sup>ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for  $\Delta m_{21}^2$  and  $\tan^2 \theta_{12}$ , using KamLAND data only. Superseded by GANDO 11.
- <sup>24</sup>ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO  $\chi^2$ -map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.
- <sup>25</sup>The result given by AHARMIM 08 is  $\theta = (34.4^{+1.3}_{-1.2})^\circ$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>26</sup>HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK  $\nu_e$  data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). *CPT* invariance is assumed.
- <sup>27</sup>HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.
- <sup>28</sup>HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.
- <sup>29</sup>The result given by AHARMIM 05A is  $\theta = (33.9 \pm 1.6)^\circ$ . This result is obtained by a two-neutrino oscillation analysis using SNO pure deuteron and salt phase data, SK  $\nu_e$  data, CI and Ga CC data, and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes  $\theta = (33.9^{+2.4}_{-2.2})^\circ$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$ .
- <sup>30</sup>AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes  $\tan^2 \theta = 0.45^{+0.09}_{-0.08}$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$ .
- <sup>31</sup>ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The  $1\sigma$  error shown here is translated from the number provided by the KamLAND collaboration,  $\tan^2 \theta = 0.40^{+0.07}_{-0.05}$ . The corresponding number quoted in ARAKI 05 is  $\tan^2 \theta = 0.40^{+0.10}_{-0.07}$  ( $\sin^2 2\theta = 0.82 \pm 0.07$ ), which envelops the 68% CL two-dimensional region.
- <sup>32</sup>The result given by AHMED 04A is  $\theta = (32.5^{+1.7}_{-1.6})^\circ$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes  $\theta = (32.5^{+2.4}_{-2.3})^\circ$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.82 \pm 0.06$ .
- <sup>33</sup>AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is  $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$ ,  $\tan^2 \theta = 0.40$  ( $\sin^2 2\theta = 0.82$ ).
- <sup>34</sup>The result given by SMY 04 is  $\tan^2 \theta = 0.44 \pm 0.08$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.
- <sup>35</sup>SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>36</sup>SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>37</sup>AHMAD 02b obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02b. The best fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan \theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).
- <sup>38</sup>FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is  $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$  and  $\tan^2 \theta = 0.38$  ( $\sin^2 2\theta = 0.80$ ).

<sup>1</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming *CPT* invariance. Supersedes GANDO 11.

<sup>2</sup> FORERO 14 performs a global fit to  $\Delta m_{21}^2$  using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

<sup>3</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $(7.50^{+0.19}_{-0.17}) \times 10^{-5} \text{ eV}^2$  for normal and  $(7.50^{+0.18}_{-0.17}) \times 10^{-5} \text{ eV}^2$  for inverted mass ordering.

<sup>4</sup> AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>5</sup> AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8\text{B}$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09) which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether), and  $^7\text{Be}$  (BELLINI 11A) rates, and  $^8\text{B}$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

<sup>6</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>7</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino and KamLAND data (GANDO 11). *CPT* invariance is assumed.

<sup>8</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming *CPT* invariance. Supersedes GANDO 11.

<sup>9</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

<sup>10</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. *CPT* invariance is assumed.

<sup>11</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

<sup>12</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and *CPT* invariance are assumed.

<sup>13</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

# Lepton Particle Listings

## Neutrino Mixing

- <sup>14</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free. CPT invariance is assumed.
- <sup>15</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free.
- <sup>16</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.
- <sup>17</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.
- <sup>18</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CL (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- <sup>19</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.
- <sup>20</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- <sup>21</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.
- <sup>22</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.
- <sup>23</sup> ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for  $\Delta m_{21}^2$  and  $\tan^2 \theta_{12}$ , using KamLAND data only. Superseded by GANDO 11.
- <sup>24</sup> ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO  $\chi^2$ -map, and solar flux data. CPT invariance is assumed. Superseded by GANDO 11.
- <sup>25</sup> AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.
- <sup>26</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). CPT invariance is assumed.
- <sup>27</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.
- <sup>28</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.
- <sup>29</sup> HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the  $1\sigma$  boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at  $\tan^2 \theta = 0.44$  because the fit depends only very weakly on it.
- <sup>30</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes  $\Delta(m^2) = (8.0^{+0.6}_{-0.4}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.
- <sup>31</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes  $\Delta(m^2) = (6.5^{+1.4}_{-2.3}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.
- <sup>32</sup> ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The  $1\sigma$  error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05,  $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$ , envelops the 68% CL two-dimensional region.
- <sup>33</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes  $\Delta(m^2) = (7.1^{+1.2}_{-0.6}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.
- <sup>34</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMED 04A. The best-fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan \theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).
- <sup>35</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). CPT invariance is assumed.
- <sup>36</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>37</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>38</sup> AHMAD 02b obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02b. The best fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan \theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).
- <sup>39</sup> FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95%

CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is  $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$  and  $\tan^2 \theta = 0.38$  ( $\sin^2 2\theta = 0.80$ ).

### $\sin^2(\theta_{23})$

The reported limits below correspond to the projection onto the  $\sin^2(\theta_{23})$  axis of the 90% CL contours in the  $\sin^2(\theta_{23}) - \Delta m_{32}^2$  plane presented by the authors. Unless otherwise specified, the limits are 90% CL and the reported uncertainties are 68% CL.

<sup>1</sup> AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

<sup>2</sup> ABE 14 results are based on  $\nu_\mu$  disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods.

<sup>3</sup> ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the  $\nu_\mu$  disappearance and  $\nu_e$  appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions. The best fit is for lower  $\theta_{23}$  quadrant and inverted mass ordering.

<sup>4</sup> FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

<sup>5</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 0.433–0.496 or 0.530–0.594 for normal and 0.514–0.612 for inverted mass ordering.

<sup>6</sup> AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

<sup>7</sup> The best fit value is  $\sin^2(\theta_{23}) = 0.514 \pm 0.082$ . Superseded by ABE 14.

<sup>8</sup> ADAMSON 13b obtained this result from  $\nu_\mu$  and  $\bar{\nu}_\mu$  disappearance using  $\nu_\mu$  ( $10.71 \times 10^{20}$  POT) and  $\bar{\nu}_\mu$  ( $3.36 \times 10^{20}$  POT) beams, and atmospheric (37.88kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical  $\nu_\mu$  and  $\bar{\nu}_\mu$  oscillation parameters. Superseded by ADAMSON 14.

<sup>9</sup> ABE 12a obtained this result by a two-neutrino oscillation analysis. The best-fit point is  $\sin^2(2\theta_{23}) = 0.98$ .

<sup>10</sup> ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is  $\sin^2(2\theta_{23}) = 0.95^{+0.10}_{-0.11} \pm 0.01$ .

<sup>11</sup> ADAMSON 12b obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.

<sup>12</sup> The best fit point is  $\Delta m^2 = 0.0019 \text{ eV}^2$  and  $\sin^2 2\theta = 0.99$ . The 90% single-parameter confidence interval at the best fit point is  $\sin^2 2\theta > 0.86$ .

<sup>13</sup> The data are separated into pure samples of  $\nu$ s and  $\bar{\nu}$ s, and separate oscillation parameters for  $\nu$ s and  $\bar{\nu}$ s are fit to the data. The best fit point is  $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$  and  $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$ . The quoted result is taken from the 90% C.L. contour in the  $(\Delta m^2, \sin^2 2\theta)$  plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

<sup>14</sup> ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time).

<sup>15</sup> ABE 11c obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11c also reported results under a two-neutrino disappearance model with separate mixing parameters between  $\nu$  and  $\bar{\nu}$ , and obtained  $\sin^2 2\theta > 0.93$  for  $\nu$  and  $\sin^2 2\theta > 0.83$  for  $\bar{\nu}$  at 90% C.L.

<sup>16</sup> ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with  $1.71 \times 10^{20}$  protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

<sup>17</sup> WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.407\text{--}0.583$ ) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming  $\theta_{13} = 0$  but including the solar oscillation parameters  $\Delta m_{21}^2$  and  $\sin^2 \theta_{12}$  in the fit.

<sup>18</sup> WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.43\text{--}0.61$ ) by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.

<sup>19</sup> WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.44\text{--}0.63$ ) by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.

<sup>20</sup> ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.

<sup>21</sup> Supercedes ALIU 05.

<sup>22</sup> MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.

<sup>23</sup> The best fit is for maximal mixing.

<sup>24</sup> ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is  $\Delta m^2 = 0.0017 \text{ eV}^2$  and  $\sin^2(2\theta) = 0.97$ .

<sup>25</sup> ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.

<sup>26</sup> AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ ,  $N_{\text{low}}$  and  $N_{\text{high}}$ , and the numbers of InDown + UpStop and InUp events. Here,  $N_{\text{low}}$  and  $N_{\text{high}}$  are the number of events with reconstructed neutrino energies  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.

<sup>27</sup> ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of  $\nu_\mu$  disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.

<sup>28</sup> There are several islands of allowed region from this K2K analysis, extending to high values of  $\Delta m^2$ . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.

<sup>29</sup> AMBROSIO 03 obtained this result on the basis of the ratio  $R = N_{\text{low}}/N_{\text{high}}$ , where  $N_{\text{low}}$  and  $N_{\text{high}}$  are the number of upward through-going muon events with reconstructed neutrino energy  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.

<sup>30</sup> AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.

<sup>31</sup> SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection  $\mu$  flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is  $\sin^2(2\theta) = 0.97$ .

<sup>32</sup> AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.

<sup>33</sup> AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . See the previous footnote.

<sup>34</sup> FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is  $\sin^2(2\theta) = 0.95$ .

<sup>35</sup> FUKUDA 99d obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is to maximal mixing.

<sup>36</sup> FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.

<sup>37</sup> FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.

<sup>38</sup> HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux of upward through-going muons is  $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for maximal mixing.

<sup>39</sup> HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is  $\sin^2(2\theta) = 0.95$ .

<sup>40</sup> FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

### $\Delta m_{32}^2$

The sign of  $\Delta m_{32}^2$  is not known at this time. Only the absolute value is quoted below. Unless otherwise specified, the ranges below correspond to the projection onto the  $\Delta m_{32}^2$  axis of the 90% CL contours in the  $\sin^2(2\theta_{23}) - \Delta m_{32}^2$  plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

- 1 AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurements with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
- 2 AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine prompt energy spectra. The results correspond to the exposure of  $6.9 \times 10^5$  GW<sub>th</sub>-ton-days. They derive  $\Delta m^2 = (2.42 \pm 0.11) \times 10^{-3}$  eV<sup>2</sup>. Assuming the normal (inverted) ordering, the fitted  $\Delta m^2_{32} = (2.37 \pm 0.11) \times 10^{-3}$  (( $2.47 \pm 0.11$ )  $\times 10^{-3}$ ) eV<sup>2</sup>. Supersedes AN 14.
- 3 ABE 14 results are based on  $\nu_\mu$  disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass ordering result is reported as  $\Delta m^2_{13} = (2.48 \pm 0.10) \times 10^{-3}$  eV<sup>2</sup> which we converted to  $\Delta m^2_{32}$  by adding PDG 14 value of  $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$  eV<sup>2</sup>.
- 4 ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the analysis combines the  $\nu_\mu$  disappearance and  $\nu_e$  appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions.
- 5 AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive  $\Delta m^2_{ee} = (2.59 \pm 0.19) \times 10^{-3}$  eV<sup>2</sup>. Assuming the normal (inverted) ordering, the fitted  $\Delta m^2_{32} = (2.54 \pm 0.19) \times 10^{-3}$  (( $2.64 \pm 0.19$ )  $\times 10^{-3}$ ) eV<sup>2</sup>. Superseded by AN 15.
- 6 FORERO 14 performs a global fit to  $\Delta m^2_{31}$  using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
- 7 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as ( $2.460 \pm 0.046$ )  $\times 10^{-3}$  eV<sup>2</sup> for normal and ( $2.445 \pm 0.047$ )  $\times 10^{-3}$  eV<sup>2</sup> for inverted mass ordering.
- 8 The value for normal mass ordering is actually a measurement of  $\Delta m^2_{31}$  which differs from  $\Delta m^2_{32}$  by a much smaller value of  $\Delta m^2_{12}$ .
- 9 AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
- 10 Based on the observation of 58  $\nu_\mu$  events with  $205 \pm 17$ (syst) expected in the absence of neutrino oscillations. Superseded by ABE 14.
- 11 ADAMSON 13b obtained this result from  $\nu_\mu$  and  $\bar{\nu}_\mu$  disappearance using  $\nu_\mu$  ( $10.71 \times 10^{20}$  POT) and  $\bar{\nu}_\mu$  ( $3.36 \times 10^{20}$  POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical  $\nu_\mu$  and  $\bar{\nu}_\mu$  oscillation parameters.
- 12 ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is  $\Delta m^2_{32} = 2.65 \times 10^{-3}$  eV<sup>2</sup>.
- 13 ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.
- 14 ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
- 15 The 90% single-parameter confidence interval at the best fit point is  $\Delta m^2 = 0.0019 \pm 0.0004$  eV<sup>2</sup>.
- 16 The data are separated into pure samples of  $\nu_s$  and  $\bar{\nu}_s$ , and separate oscillation parameters for  $\nu_s$  and  $\bar{\nu}_s$  are fit to the data. The best fit point is ( $\Delta m^2, \sin^2 2\theta$ ) = (0.0022 eV<sup>2</sup>, 0.99) and ( $\Delta \bar{m}^2, \sin^2 2\bar{\theta}$ ) = (0.0016 eV<sup>2</sup>, 1.00). The quoted result is taken from the 90% C.L. contour in the ( $\Delta m^2, \sin^2 2\theta$ ) plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- 17 ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time).
- 18 ABE 11c obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is  $\Delta m^2 = 1.7\text{--}3.0 \times 10^{-3}$  eV<sup>2</sup>.
- 19 ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with  $1.71 \times 10^{20}$  protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- 20 ADAMSON 11c obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.
- 21 WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m^2_{21} = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

- 22 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- 23 The best fit in the physical region is for  $\Delta m^2 = 2.8 \times 10^{-3}$  eV<sup>2</sup>.
- 24 Supersedes ALIU 05.
- 25 MICHAEL 06 best fit is  $2.74 \times 10^{-3}$  eV<sup>2</sup>. See also ADAMSON 08.
- 26 ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is  $\Delta m^2 = 0.0017$  eV<sup>2</sup> and  $\sin^2 2\theta = 0.97$ .
- 27 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande-I running period. The best fit is for  $\Delta m^2 = 2.1 \times 10^{-3}$  eV<sup>2</sup>.
- 28 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with  $E_\mu > 1$  GeV,  $N_{low}$  and  $N_{high}$ , and the numbers of InDown + UpStop and InUp events. Here,  $N_{low}$  and  $N_{high}$  are the number of events with reconstructed neutrino energies  $< 30$  GeV and  $> 130$  GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for  $\Delta m^2 = 2.3 \times 10^{-3}$  eV<sup>2</sup>.
- 29 ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of  $\nu_\mu$  disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for  $\Delta m^2 = 2.1 \times 10^{-3}$  eV<sup>2</sup>.
- 30 There are several islands of allowed region from this K2K analysis, extending to high values of  $\Delta m^2$ . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for  $\Delta m^2 = 2.8 \times 10^{-3}$  eV<sup>2</sup>.
- 31 AMBROSIO 03 obtained this result on the basis of the ratio  $R = N_{low}/N_{high}$ , where  $N_{low}$  and  $N_{high}$  are the number of upward through-going muon events with reconstructed neutrino energy  $< 30$  GeV and  $> 130$  GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for  $\Delta m^2 = 2.5 \times 10^{-3}$  eV<sup>2</sup>.
- 32 AMBROSIO 03 obtained this result by using the ratio  $R$  and the angular distribution of the upward through-going muons.  $R$  is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for  $\Delta m^2 = 2.5 \times 10^{-3}$  eV<sup>2</sup>.
- 33 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection  $\mu$  flavor sample while the  $e$ -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for  $\Delta m^2 = 5.2 \times 10^{-3}$  eV<sup>2</sup>.
- 34 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_\mu > 1$  GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.
- 35 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_\mu > 1$  GeV. See the previous footnote.
- 36 FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_\mu > 1.6$  GeV, the observed flux is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. The best fit is for  $\Delta m^2 = 5.9 \times 10^{-3}$  eV<sup>2</sup>.
- 37 FUKUDA 99d obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. This is compared to the expected flux of  $(0.73 \pm 0.16$  (theoretical error))  $\times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. The best fit is for  $\Delta m^2 = 3.9 \times 10^{-3}$  eV<sup>2</sup>.
- 38 FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for  $\Delta m^2 = 3.1 \times 10^{-3}$  eV<sup>2</sup>.
- 39 FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for  $\Delta m^2 = 2.2 \times 10^{-3}$  eV<sup>2</sup>.
- 40 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_\mu > 1.6$  GeV, the observed flux of upward through-going muons is  $(1.94 \pm 0.10 \pm 0.07) \times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. This is compared to the expected flux of  $(2.46 \pm 0.54$  (theoretical error))  $\times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. The best fit is for  $\Delta m^2 = 2.2 \times 10^{-3}$  eV<sup>2</sup>.
- 41 HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for  $\Delta m^2 = 13 \times 10^{-3}$  eV<sup>2</sup>.
- 42 FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for  $\Delta m^2 = 16 \times 10^{-3}$  eV<sup>2</sup>.

### $\sin^2(\theta_{13})$

At present time direct measurements of  $\sin^2(\theta_{13})$  are derived from the reactor  $\bar{\nu}_e$  disappearance at distances corresponding to the  $\Delta m^2_{32}$  value, i.e.  $L \sim 1$  km. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based  $\nu_\mu \rightarrow \nu_e$  experiments.

<15	<sup>90</sup> <sup>42</sup> APOLLONIO	99	CHOZ	Reactor Experiment

<sup>1</sup> AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine the mixing angle  $\theta_{13}$  using the  $\overline{\nu}_e$  observed interaction rates with neutron capture on Gd and energy spectra. The result corresponds to the exposure of  $6.9 \times 10^5$  GW<sub>th</sub>-ton-days. Supersedes AN 14.

<sup>2</sup> ABE 14H uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter  $\sin^2(2\theta_{13})$ . The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A rate and shape analysis is performed. Supersedes ABE 14A.

<sup>3</sup> AN 14B uses six identical anti-neutrino detectors with flux-weighted baselines of  $\sim 500$  m and  $\sim 1.6$  km to six power reactors. This rate analysis uses a 217-day data set and neutron capture on protons (not Gd) only.  $\Delta m_{31}^2 = 2.32 \times 10^{-3}$  eV<sup>2</sup> is assumed.

<sup>4</sup> ABE 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The physical volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux.

<sup>5</sup> AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle  $\theta_{13}$ . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of  $\Delta m_{31}^2 = (2.32 \pm 0.12 \pm 0.08) \times 10^{-3}$  eV<sup>2</sup> was assumed in the analysis.

<sup>6</sup> ABE 14A uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter  $\sin^2(2\theta_{13})$ . The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A "rate-modulation" analysis is performed. Supersedes ABE 12B.

<sup>7</sup> ABE 14C result is for  $\nu_e$  appearance and assumes  $\Delta m_{32}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup>,  $\sin^2(\theta_{23}) = 0.5$ , and  $\delta = 0$ .

<sup>8</sup> AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\overline{\nu}_e$  observed interaction rates with neutron capture on Gd and energy spectra. Supersedes AN 13 and superseded by AN 15.

<sup>9</sup> FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

<sup>10</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $(2.18 \pm 0.10 \pm 0.11) \times 10^{-2}$  eV<sup>2</sup> for normal and  $(2.19 \pm 0.12 \pm 0.10) \times 10^{-2}$  eV<sup>2</sup> for inverted mass ordering.

<sup>11</sup> ABE 13E assumes maximal  $\theta_{23}$  mixing and  $CP$  phase  $\delta = 0$ .

<sup>12</sup> ADAMSON 13A results obtained from  $\nu_e$  appearance, assuming  $\delta = 0$ , and  $\sin^2(2\theta_{23}) = 0.957$ .

<sup>13</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8B$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and  $^7Be$  (BELLINI 11A) rates, and  $^8B$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is  $\sin^2(2\theta_{13}) = (9.1 \pm 2.9 \pm 3.1) \times 10^{-2}$ .

<sup>14</sup> AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the  $\overline{\nu}_e$  interaction rate ratios. Superseded by AN 14.

<sup>15</sup> ABE 12 determines the  $\overline{\nu}_e$  interaction rate in a single detector, located 1050 m from the cores of two reactors. A rate and shape analysis is performed. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of  $\Delta m_{31}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup> is used in the analysis. Superseded by ABE 12B.

<sup>16</sup> ABE 12B determines the neutrino mixing angle  $\theta_{13}$  using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 14A.

<sup>17</sup> AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\overline{\nu}_e$  observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of  $\Delta m_{31}^2 = (2.32 \pm 0.12 \pm 0.08) \times 10^{-3}$  eV<sup>2</sup> was assumed in the analysis. Superseded by AN 13.

<sup>18</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of  $\sin^2\theta_{13} < 0.059$  (95% CL) or  $\sin^2 2\theta_{13} < 0.22$  (95% CL). The normal neutrino mass ordering and  $CP$  invariance are assumed.

<sup>19</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

<sup>20</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the normal mass ordering. For other values of  $\delta$ , the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.

<sup>21</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the inverted mass ordering. For other values of  $\delta$ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.

<sup>22</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.32 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the normal mass ordering. For other values of  $\delta$ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.

<sup>23</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.32 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the inverted mass ordering. For other values of  $\delta$ , the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.

<sup>24</sup> FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor  $\overline{\nu}_e$  fluxes, and using these fluxes, the fitted result becomes  $0.10 \pm 0.03$ .

<sup>25</sup> GANDO 11 report  $\sin^2\theta_{13} = 0.020 \pm 0.016$ . This result was obtained with three-neutrino fit using the KamLAND + solar data.

<sup>26</sup> GANDO 11 report  $\sin^2\theta_{13} = 0.032 \pm 0.037$ . This result was obtained with three-neutrino fit using the KamLAND data only.

<sup>27</sup> This result corresponds to the limit of  $<0.12$  at 90% CL for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 90% CL region spans from 0 to 0.16.

<sup>28</sup> This result corresponds to the limit of  $<0.20$  at 90% CL for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 90% CL region spans from 0 to 0.21.

<sup>29</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), GALLEX/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

<sup>30</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data and KamLAND data (ABE 08A).  $CP$  invariance is assumed. This result implies an upper bound of  $\sin^2\theta_{13} < 0.057$  (95% CL) or  $\sin^2 2\theta_{13} < 0.22$  (95% CL).

## Neutrino Mixing

- <sup>31</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.
- <sup>32</sup> WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- <sup>33</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 68% CL region spans from 0.02 to 0.26.
- <sup>34</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 68% CL region spans from 0.04 to 0.34.
- <sup>35</sup> FOGLI 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.
- <sup>36</sup> FOGLI 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.
- <sup>37</sup> FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.
- <sup>38</sup> YAMAMOTO 06 searched for  $\nu_\mu \rightarrow \nu_e$  appearance. Assumes  $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$ . The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the one- $\sigma$  low value for AHN 06A. For the AHN 06A best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2(2\theta_{13})$  limit is  $< 0.26$ . Supersedes AHN 04.
- <sup>39</sup> AHN 04 searched for  $\nu_\mu \rightarrow \nu_e$  appearance. Assuming  $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$ , a limit on  $\sin^2(2\theta_{\mu e})$  is converted to a limit on  $\sin^2(2\theta_{13})$ . The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the one- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2(2\theta_{13})$  limit is  $< 0.30$ .
- <sup>40</sup> The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the 1- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2 2\theta_{13}$  limit is  $< 0.19$ . In this range, the  $\theta_{13}$  limit is larger for lower values of  $\Delta m_{32}^2$ , and smaller for higher values of  $\Delta m_{32}^2$ .
- <sup>41</sup> The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the 1- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2 2\theta_{13}$  limit is  $< 0.23$ .
- <sup>42</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the central value for ADAMSON 08. For the ADAMSON 08 1- $\sigma$  low value of  $2.30 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2 2\theta_{13}$  limit is  $< 0.16$ . See also APOLLONIO 03 for a detailed description of the experiment.

### CP violating phase

#### $\delta$ , CP violating phase

Measurements of  $\delta$  come from atmospheric and accelerator experiments looking at  $\nu_e$  appearance. We encode values between 0 and  $2\pi$ , though it is equivalent to use  $-\pi$  to  $\pi$ .

- <sup>1</sup> Based on three-flavor formalism and  $\theta_{23} > \pi/4$ . Likelihood as a function of  $\delta$  is also shown for the other three combinations of hierarchy and  $\theta_{23}$  quadrant; all values of  $\delta$  are allowed at 90% C.L.
- <sup>2</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 1.24–1.94 for normal and 1.15–1.77 for inverted mass ordering.
- <sup>3</sup> Based on  $\nu_e$  appearance in MINOS and the calculated  $\sin^2(2\theta_{23}) = 0.957$ ,  $\theta_{23} > \pi/4$ , and normal mass hierarchy. Likelihood as a function of  $\delta$  is also shown for the other three combinations of hierarchy and  $\theta_{23}$  quadrant; all values of  $\delta$  are allowed at 90% C.L.

### (C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations. In a three neutrino framework, this would be a measurement of  $\theta_{12}$  and  $\Delta m_{21}^2$ . This does not appear to be consistent with most of the other neutrino data. The MiniBooNE experiment, reported in AGUILAR-AREVALO 07, does a two-neutrino analysis which, assuming  $CP$  conservation, rules out AGUILAR 01. However, the MiniBooNE antineutrino data reported in AGUILAR-AREVALO 13A are consistent with the signal reported in AGUILAR 01. The following listings include results which might be relevant towards understanding these observations. They include searches for  $\nu_\mu \rightarrow \nu_e$ ,  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ , sterile neutrino oscillations, and  $CPT$  violation.

### $\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ( $\nu_\mu \rightarrow \nu_e$ )

VALUE (eV <sup>2</sup> )	CL%	DOCUMENT ID	TECN	COMMENT

$< 2.3$	90	VILAIN 94c	CHM2	CERN SPS
$< 0.9$	90	ANGELINI 86	HLBC	BEBC CERN PS

- <sup>1</sup> Based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $162.0 \pm 47.8$  events; marginally compatible with two neutrino oscillations. The best fit value is  $\Delta m^2 = 3.14 \text{ eV}^2$ .
- <sup>2</sup> MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of  $\Delta m^2$  up to  $25 \text{ eV}^2$ . The best limit is 0.04 at  $7 \text{ eV}^2$ .
- <sup>3</sup> AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the  $\nu_\mu \rightarrow \nu_e$  oscillations using  $\nu_\mu$  from  $\pi^+$  decay in flight by observing beam-on electron events from  $\nu_e C \rightarrow e^- X$ . Present analysis results in  $8.1 \pm 12.2 \pm 1.7$  excess events in the  $60 < E_e < 200 \text{ MeV}$  energy range, corresponding to oscillation probability of  $0.10 \pm 0.16 \pm 0.04\%$ . This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above  $60 \text{ MeV}$  than ATHANASSOPOULOS 98.
- <sup>4</sup> ATHANASSOPOULOS 98 is a search for the  $\nu_\mu \rightarrow \nu_e$  oscillations using  $\nu_\mu$  from  $\pi^+$  decay in flight. The 40 observed beam-on electron events are consistent with  $\nu_e C \rightarrow e^- X$ ; the expected background is  $21.9 \pm 2.1$ . Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability  $(0.26 \pm 0.10 \pm 0.05)\%$ . Although the significance is only  $2.3\sigma$ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations from  $\mu^+$  decay at rest. See also ATHANASSOPOULOS 98b.
- <sup>5</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

- <sup>1</sup> Based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $162.0 \pm 47.8$  events; marginally compatible with two neutrino oscillations. The best fit value is  $\sin^2 2\theta = 0.002$ .
- <sup>2</sup> ANTONELLO 13 use the ICARUS T600 detector at LNGS and  $\sim 20 \text{ GeV}$  beam of  $\nu_\mu$  from CERN 730 km away to search for an excess of  $\nu_e$  events. Two events are found with  $3.7 \pm 0.6$  expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13A.
- <sup>3</sup> Based on four events with a background of  $6.4 \pm 0.9$  from conventional sources with an average energy of  $20 \text{ GeV}$  and  $730 \text{ km}$  from the source of  $\nu_\mu$ .
- <sup>4</sup> MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data.
- <sup>5</sup> The limit is  $\sin^2 2\theta < 0.9 \times 10^{-3}$  at  $\Delta m^2 = 2 \text{ eV}^2$ . That value of  $\Delta m^2$  corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.
- <sup>6</sup> The limit becomes  $\sin^2 2\theta < 0.15$  at  $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$ , the best-fit value of the  $\nu_\mu$  disappearance analysis in K2K.
- <sup>7</sup> AGUILAR 01 is the final analysis of the LSND full data set of the search for the  $\nu_\mu \rightarrow \nu_e$  oscillations. See footnote in preceding table for further details.
- <sup>8</sup> ATHANASSOPOULOS 98 report  $(0.26 \pm 0.10 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta m^2$  is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate  $\sin^2 2\theta$  and  $\Delta m^2$ . See also ATHANASSOPOULOS 98b.
- <sup>9</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.
- <sup>10</sup> VILAIN 94c limit derived by combining the  $\nu_\mu$  and  $\bar{\nu}_\mu$  data assuming  $CP$  conservation.

See key on page 601

<sup>1</sup> Based on  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  appearance of  $78.4 \pm 28.5$  events. The best fit values are  $\Delta m^2 = 0.043$  eV<sup>2</sup> and  $\sin^2 2\theta = 0.88$ .

<sup>2</sup> CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

<sup>3</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 475$  MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09B.

<sup>4</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 200$  MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for  $\Delta(m^2) = 4.4$  eV<sup>2</sup>.

<sup>5</sup> ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for  $\bar{\nu}_e$ , detected by the inverse  $\beta$ -decay reaction on protons and <sup>12</sup>C. 15 candidate events are observed, and  $15.8 \pm 0.5$  background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

<sup>6</sup> AGUILAR 01 is the final analysis of the LSND full data set. It is a search for  $\bar{\nu}_e$  30 m from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\bar{\nu}_e$  are detected through  $\bar{\nu}_e p \rightarrow e^+ n$  ( $20 < E_{e^+} < 60$  MeV) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe  $87.9 \pm 22.4 \pm 6.0$  total excess events. The observation is attributed to  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations with the oscillation probability of  $0.264 \pm 0.067 \pm 0.045\%$ , consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of  $\Delta(m^2)$  from 0.2–2.0 eV<sup>2</sup>. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

<sup>7</sup> ATHANASSOPOULOS 96 is a search for  $\bar{\nu}_e$  30 m from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\bar{\nu}_e$  could come from either  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  or  $\nu_e \rightarrow \bar{\nu}_e$ ; our entry assumes the first interpretation. They are detected through  $\bar{\nu}_e p \rightarrow e^+ n$  ( $20 \text{ MeV} < E_{e^+} < 60 \text{ MeV}$ ) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe  $51 \pm 20 \pm 8$  total excess events over an estimated background  $12.5 \pm 2.9$ . ATHANASSOPOULOS 96B is a shorter version of this paper.

<sup>8</sup> ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is  $2.7 \pm 0.4$  events. Corresponds to an oscillation probability of  $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

<sup>9</sup> HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and obtains only upper limits.

<sup>10</sup> FREEDMAN 93 is a search at LAMPF for  $\bar{\nu}_e$  generated from any of the three neutrino types  $\nu_\mu$ ,  $\bar{\nu}_\mu$ , and  $\nu_e$  which come from the beam stop. The  $\bar{\nu}_e$ 's would be detected by the reaction  $\bar{\nu}_e p \rightarrow e^+ n$ . FREEDMAN 93 replaces DURKIN 88.

### $\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ ( $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ )

< 6	90	<sup>10</sup> HILL 95		

<sup>1</sup> ANTONELLO 13A obtained the limit by assuming  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillation from the  $\sim 2\%$  of  $\bar{\nu}_\mu$  evnsts contamination in the CNGS beam.

<sup>2</sup> CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

<sup>3</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 475$  MeV. At 90% CL there is no solution at high  $\Delta(m^2)$ . The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09B.

<sup>4</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 200$  MeV with subtraction of the expected 12 events low energy excess seen in the

neutrino component of the beam. At 90% CL there is no solution at high  $\Delta(m^2)$ . The best fit value is 0.007 for  $\Delta(m^2) = 4.4$  eV<sup>2</sup>.

<sup>5</sup> This result is inconclusive with respect to small amplitude mixing suggested by LSND.

<sup>6</sup> ARMBRUSTER 02 is the final analysis of the KARMEN 2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.

<sup>7</sup> AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is  $0.264 \pm 0.067 \pm 0.045\%$ ; the value of  $\sin^2 2\theta$  for large  $\Delta(m^2)$  is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

<sup>8</sup> ATHANASSOPOULOS 96 reports  $(0.31 \pm 0.12 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta(m^2)$  should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.

<sup>9</sup> ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is  $2.7 \pm 0.4$  events. Corresponds to an oscillation probability of  $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

<sup>10</sup> HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and obtains only upper limits.

## Neutrino Mixing

<sup>1</sup> AMBROSIO 01 tested the pure 2-flavor  $\nu_\mu \rightarrow \nu_s$  hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and  $\Delta(m^2)$  around  $0.0024\text{ eV}^2$ , the  $\nu_\mu \rightarrow \nu_s$  oscillation is disfavored with 99% confidence level with respect to the  $\nu_\mu \rightarrow \nu_\tau$  hypothesis.

<sup>2</sup> FUKUDA 00 tested the pure 2-flavor  $\nu_\mu \rightarrow \nu_s$  hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the  $(\Delta(m^2))$  and  $\sin^2 2\theta$  region preferred by the Super-Kamiokande data, the  $\nu_\mu \rightarrow \nu_s$  hypothesis is rejected at the 99% confidence level, while the  $\nu_\mu \rightarrow \nu_\tau$  hypothesis consistently fits all of the data sample.

<sup>11</sup>BRITTON 92B is from a search for additional peaks in the  $e^+$  spectrum from  $\pi^+ \rightarrow e^+ \nu_e$  decay at TRIUMF. See also BRITTON 92.

<sup>12</sup>BRYMAN 83B obtain upper limits from both direct peak search and analysis of  $B(\pi \rightarrow e\nu)/B(\pi \rightarrow \mu\nu)$ . Latter limits are not listed, except for this entry (i.e. — we list the most stringent limits for given mass).

<sup>13</sup>Analysis of  $(\pi^+ \rightarrow e^+ \nu_e)/(\pi^+ \rightarrow \mu^+ \nu_\mu)$  and  $(K^+ \rightarrow e^+ \nu_e)/(K^+ \rightarrow \mu^+ \nu_\mu)$  decay ratios.

<sup>14</sup>Analysis of  $(K^+ \rightarrow e^+ \nu_e)$  spectrum.

##### Kink search in nuclear $\beta$ decay

High-sensitivity follow-up experiments show that indications for a neutrino with mass 17 keV (Simpson, Hime, and others) were not valid. Accordingly, we no longer list the experiments by these authors and some others which made positive claims of 17 keV neutrino emission. Complete listings are given in the 1994 edition (Physical Review **D50** 1173 (1994)) and in the 1998 edition (The European Physical Journal **C3** 1 (1998)). We list below only the best limits on  $|U_{ex}|^2$  for each  $m_{\nu_x}$ . See WIETFELDT 96 for a comprehensive review.

# Lepton Particle Listings

## Heavy Neutral Leptons, Searches for

15 TRINCEK 03 is a search for admixture of heavy neutrino to  $\nu_e$ , in contrast to  $\bar{\nu}_e$  used in many other searches. Full kinematic reconstruction of the neutrino momentum by use of a magneto optical trap.

16 GALEAZZI 01 use an cryogenic microcalorimeter to search for mass 50–1000 eV neutrino admixtures using the  $^{187}\text{Re}$  beta spectrum with 2.4 keV endpoint. They derive limits for the admixture of heavy neutrinos, ranging from  $9 \times 10^{-3}$  for mass 1 keV to 0.116 for mass 100 eV. This is a significant improvement with respect to HIDDEMANN 95, especially for masses below  $\sim 500$  MeV, where the limit is about a factor of  $\sim 2$  higher.

17 HOLZSCHUH 00 use an iron-free  $\beta$  spectrometer to measure the  $^{35}\text{S}$   $\beta$  decay spectrum. An analysis of the spectrum in the energy range 56–173 keV is used to derive limits for the admixture of heavy neutrinos. This extends the range of neutrino masses explored in HOLZSCHUH 99.

18 DRAGOUN 99 analyze the  $\beta$  decay spectrum of  $^{241}\text{Pu}$  in the energy range 0.2–9.2 keV to derive limits for the admixture of heavy neutrinos. It is not competitive with HOLZSCHUH 99.

19 HOLZSCHUH 99 use an iron-free  $\beta$  spectrometer to measure the  $^{63}\text{Ni}$   $\beta$  decay spectrum. An analysis of the spectrum in the energy range 33–67.8 keV is used to derive limits for the admixture of heavy neutrinos.

20 HINDI 98 obtain a limit on heavy neutrino admixture from EC decay of  $^{37}\text{Ar}$  by measuring the time-of-flight distribution of the recoiling ions in coincidence with x-rays or Auger electrons. The authors report upper limit for  $|U_{ex}|^2$  of  $\approx 3\%$  for  $m_{\nu_x}=500$  keV, 1% for  $m_{\nu_x}=550$  keV, 2% for  $m_{\nu_x}=600$  keV, and 4% for  $m_x=650$  keV. Their reported limits for  $m_{\nu_x} \leq 450$  keV are inferior to the limits of SCHRECKENBACH 83.

21 In the beta spectrum from tritium  $\beta$  decay nonvanishing or mixed  $m_{\bar{\nu}_1}$  state in the mass region 0.01–4 keV. For  $m_{\nu_x} < 1$  keV, their upper limit on  $|U_{ex}|^2$  becomes less

22 KALBFLEISCH 93 extends the 17 keV neutrino search of BAHRAN 92, using an improved proportional chamber to which a small amount of  $^3\text{H}$  is added. Systematics are significantly reduced, allowing for an improved upper limit. The authors give a 99% confidence limit on  $|U_{ex}|^2$  as a function of  $m_{\nu_x}$  in the range from 13.5 keV to 17.5 keV. See also the related papers BAHRAN 93, BAHRAN 93b, and BAHRAN 95 on theoretical aspects of beta spectra and fitting methods for heavy neutrinos.

23 MORTARA 93 limit is from study using a high-resolution solid-state detector with a superconducting solenoid. The authors note that “The sensitivity to neutrino mass is verified by measurement with a mixed source of  $^{35}\text{S}$  and  $^{14}\text{C}$ , which artificially produces a distortion in the beta spectrum similar to that expected from the massive neutrino.”

24 DEUTSCH 90 search for emission of heavy  $\bar{\nu}_e$  in super-allowed beta decay of  $^{20}\text{F}$  by spectral analysis of the electrons.

25 This limit was taken from the figure 3 of APALIKOV 85; the text gives a more restrictive limit of  $1.7 \times 10^{-3}$  at CL = 90%.

26 SCHRECKENBACH 83 is a combined measurement of the  $\beta^+$  and  $\beta^-$  spectrum.

27 SHROCK 80 was a retroactive analysis of data on several superallowed  $\beta$  decays to search for kinks in the Kurie plot.

28 Application of test to search for kinks in  $\beta$  decay Kurie plots.

29 BACK 03A searched for heavy neutrinos emitted from  $^8\text{B}$  decay in the Sun using the decay  $\nu_h \rightarrow \nu_e e^+ e^-$  in the Counting Test Facility (the prototype of the Borexino detector) and obtained limits on heavy neutrino admixture for the  $\nu_h$  mass range 1.1–12 MeV.

30 ABREU 97I long-lived  $\nu_x$  analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

31 HAGNER 95 obtain limits on heavy neutrino admixture from the decay  $\nu_h \rightarrow \nu_e e^+ e^-$  at a nuclear reactor for the  $\nu_h$  mass range 2–9 MeV.

32 BARANOV 93 is a search for neutrino decays into  $e^+ e^- \nu_e$  using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. The limits are not as good as those achieved earlier by BERGSMA 83 and BERNARDI 86, BERNARDI 88.

33 BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

34 OBERAUER 87 bounds from search for  $\nu \rightarrow \nu' ee$  decay mode using reactor (anti)neutrinos.

35 COOPER-SARKAR 85 also give limits based on model-dependent assumptions for  $\nu_\tau$  flux. We do not list these. Note that for this bound to be nontrivial,  $x$  is not equal to 3, i.e.  $\nu_x$  cannot be the dominant mass eigenstate in  $\nu_\tau$  since  $m_{\nu_3} < 70$  MeV (ALBRECHT 85i). Also, of course,  $x$  is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

36 BERGSMA 83B also quote limits on  $|U_{e3}|^2$  where the index 3 refers to the mass eigenstate dominantly coupled to the  $\tau$ . Those limits were based on assumptions about the  $D_s$  mass and  $D_s \rightarrow \tau \nu_\tau$  branching ratio which are no longer valid. See COOPER-SARKAR 85.

### Limits on Coupling of $\mu$ to $\nu_x$ as Function of $m_{\nu_x}$

### Heavy Neutral Leptons, Searches for

<1	$\times 10^{-1}$	90	44 ABELA	81	$m_{\nu_X}=4$ MeV
<7	$\times 10^{-5}$	90	44 ABELA	81	$m_{\nu_X}=10.5$ MeV
<2	$\times 10^{-4}$	90	44 ABELA	81	$m_{\nu_X}=11.5$ MeV
<2	$\times 10^{-5}$	90	44 ABELA	81	$m_{\nu_X}=16-30$ MeV

<sup>37</sup> ASTIER 02 search for anomalous pion decay into a 33.9 MeV neutral particle. No evidence was found and the sensitivity to the branching ratio  $B(\pi \rightarrow \mu X) \cdot B(X \rightarrow \nu e^+ e^-)$  is as low as  $3.7 \times 10^{-15}$ , depending on the  $X$  lifetime.

<sup>38</sup> DAUM 00 search for anomalous pion decay into a 33.9 MeV neutral particle that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration.

<sup>39</sup> FORMAGGIO 00 search for anomalous pion decay into a 33.9 MeV neutral particle  $Q^0$  that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration. In the E815 (NuTeV) experiment at Fermilab no evidence was found, with sensitivity for the pion branching ratio  $B(\pi \rightarrow \mu Q^0) \cdot B(Q^0 \rightarrow \text{visible})$  as low as  $10^{-13}$ .

<sup>40</sup> ASSAMAGAN 98 obtain a limit on heavy neutrino admixture from  $\pi^+$  decay essentially at rest, by measuring with good resolution the momentum distribution of the muons. However, the search uses an ad hoc shape correction. The authors report upper limit for  $|U_{\mu X}|^2$  of 0.22 for  $m_{\nu} = 0.53$  MeV, 0.029 for  $m_{\nu} = 0.75$  MeV, and 0.016 for  $m_{\nu} = 1.0$  MeV at 90%CL.

<sup>41</sup> BRYMAN 96 search for massive unconventional neutrinos of mass  $m_{\nu_X}$  in  $\pi^+$  decay.

<sup>42</sup> ARMBRUSTER 95 study the reactions  $^{12}\text{C}(\nu_e, e^-)^{12}\text{N}$  and  $^{12}\text{C}(\nu, \nu')^{12}\text{C}^*$  induced by neutrinos from  $\pi^+$  and  $\mu^+$  decay at the ISIS neutron spallation source at the Rutherford-Appleton laboratory. An anomaly in the time distribution can be interpreted as the decay  $\pi^+ \rightarrow \mu^+ \nu_X$ , where  $\nu_X$  is a neutral weakly interacting particle with mass  $\approx 33.9$  MeV and spin 1/2. The lower limit to the branching ratio is a function of the lifetime of the new massive neutral particle, and reaches a minimum of a few  $\times 10^{-16}$  for  $\tau_X \sim 5$  s.

<sup>43</sup> From experiments of  $\pi^+$  and  $\pi^-$  decay in flight at PSI, to check the claim of the KARMEN Collaboration quoted above (ARMBRUSTER 95).

<sup>44</sup>  $\pi^+ \rightarrow \mu^+ \nu_\mu$  peak search experiment.

<sup>45</sup>  $K^+ \rightarrow \mu^+ \nu_\mu$  peak search experiment.

## QUARKS

**QUARK MASSES**

Updated Jan 2016 by A.V. Manohar (University of California, San Diego), C.T. Sachrajda (University of Southampton), and R.M. Barnett (LBNL).

**A. Introduction**

This note discusses some of the theoretical issues relevant for the determination of quark masses, which are fundamental parameters of the Standard Model of particle physics. Unlike the leptons, quarks are confined inside hadrons and are not observed as physical particles. Quark masses therefore cannot be measured directly, but must be determined indirectly through their influence on hadronic properties. Although one often speaks loosely of quark masses as one would of the mass of the electron or muon, any quantitative statement about the value of a quark mass must make careful reference to the particular theoretical framework that is used to define it. It is important to keep this *scheme dependence* in mind when using the quark mass values tabulated in the data listings.

Historically, the first determinations of quark masses were performed using quark models. The resulting masses only make sense in the limited context of a particular quark model, and cannot be related to the quark mass parameters of the Standard Model. In order to discuss quark masses at a fundamental level, definitions based on quantum field theory must be used, and the purpose of this note is to discuss these definitions and the corresponding determinations of the values of the masses.

**B. Mass parameters and the QCD Lagrangian**

The QCD [1] Lagrangian for  $N_F$  quark flavors is

$$\mathcal{L} = \sum_{k=1}^{N_F} \bar{q}_k (i \not{D} - m_k) q_k - \frac{1}{4} G_{\mu\nu} G^{\mu\nu}, \quad (1)$$

where  $\not{D} = (\partial_\mu - ig A_\mu) \gamma^\mu$  is the gauge covariant derivative,  $A_\mu$  is the gluon field,  $G_{\mu\nu}$  is the gluon field strength,  $m_k$  is the mass parameter of the  $k^{\text{th}}$  quark, and  $q_k$  is the quark Dirac field. After renormalization, the QCD Lagrangian Eq. (1) gives finite values for physical quantities, such as scattering amplitudes. Renormalization is a procedure that invokes a subtraction scheme to render the amplitudes finite, and requires the introduction of a dimensionful scale parameter  $\mu$ . The mass parameters in the QCD Lagrangian Eq. (1) depend on the renormalization scheme used to define the theory, and also on the scale parameter  $\mu$ . The most commonly used renormalization scheme for QCD perturbation theory is the  $\overline{\text{MS}}$  scheme.

The QCD Lagrangian has a chiral symmetry in the limit that the quark masses vanish. This symmetry is spontaneously

broken by dynamical chiral symmetry breaking, and explicitly broken by the quark masses. The nonperturbative scale of dynamical chiral symmetry breaking,  $\Lambda_\chi$ , is around 1 GeV [2]. It is conventional to call quarks heavy if  $m > \Lambda_\chi$ , so that explicit chiral symmetry breaking dominates ( $c$ ,  $b$ , and  $t$  quarks are heavy), and light if  $m < \Lambda_\chi$ , so that spontaneous chiral symmetry breaking dominates (the  $u$  and  $d$  are light and  $s$  quarks are considered to be light when using  $\text{SU}(3)_L \times \text{SU}(3)_R$  chiral perturbation theory). The determination of light- and heavy-quark masses is considered separately in sections D and E below.

At high energies or short distances, nonperturbative effects, such as chiral symmetry breaking, become small and one can, in principle, determine quark masses by analyzing mass-dependent effects using QCD perturbation theory. Such computations are conventionally performed using the  $\overline{\text{MS}}$  scheme at a scale  $\mu \gg \Lambda_\chi$ , and give the  $\overline{\text{MS}}$  “running” mass  $\overline{m}(\mu)$ . We use the  $\overline{\text{MS}}$  scheme when reporting quark masses; one can readily convert these values into other schemes using perturbation theory.

The  $\mu$  dependence of  $\overline{m}(\mu)$  at short distances can be calculated using the renormalization group equation,

$$\mu^2 \frac{d\overline{m}(\mu)}{d\mu^2} = -\gamma(\overline{\alpha}_s(\mu)) \overline{m}(\mu), \quad (2)$$

where  $\gamma$  is the anomalous dimension which is now known to four-loop order in perturbation theory [3,4].  $\overline{\alpha}_s$  is the coupling constant in the  $\overline{\text{MS}}$  scheme. Defining the expansion coefficients  $\gamma_r$  by

$$\gamma(\overline{\alpha}_s) \equiv \sum_{r=1}^{\infty} \gamma_r \left( \frac{\overline{\alpha}_s}{4\pi} \right)^r,$$

the first four coefficients are given by

$$\begin{aligned} \gamma_1 &= 4, \\ \gamma_2 &= \frac{202}{3} - \frac{20N_L}{9}, \\ \gamma_3 &= 1249 + \left( -\frac{2216}{27} - \frac{160}{3}\zeta(3) \right) N_L - \frac{140}{81} N_L^2, \\ \gamma_4 &= \frac{4603055}{162} + \frac{135680}{27}\zeta(3) - 8800\zeta(5) \\ &\quad + \left( -\frac{91723}{27} - \frac{34192}{9}\zeta(3) + 880\zeta(4) + \frac{18400}{9}\zeta(5) \right) N_L \\ &\quad + \left( \frac{5242}{243} + \frac{800}{9}\zeta(3) - \frac{160}{3}\zeta(4) \right) N_L^2 \\ &\quad + \left( -\frac{332}{243} + \frac{64}{27}\zeta(3) \right) N_L^3, \end{aligned}$$

where  $N_L$  is the number of active light quark flavors at the scale  $\mu$ , i.e. flavors with masses  $< \mu$ , and  $\zeta$  is the Riemann

# Quark Particle Listings

## Quarks

zeta function ( $\zeta(3) \simeq 1.2020569$ ,  $\zeta(4) \simeq 1.0823232$ , and  $\zeta(5) \simeq 1.0369278$ ). In addition, as the renormalization scale crosses quark mass thresholds one needs to match the scale dependence of  $\overline{m}$  below and above the threshold. There are finite threshold corrections; the necessary formulae can be found in Ref. [5].

The quark masses for light quarks discussed so far are often referred to as current quark masses. Nonrelativistic quark models use constituent quark masses, which are of order 350 MeV for the  $u$  and  $d$  quarks. Constituent quark masses model the effects of dynamical chiral symmetry breaking, and are not directly related to the quark mass parameters  $m_k$  of the QCD Lagrangian Eq. (1). Constituent masses are only defined in the context of a particular hadronic model.

### C. Lattice Gauge Theory

The use of the lattice simulations for *ab initio* determinations of the fundamental parameters of QCD, including the coupling constant and quark masses (except for the top-quark mass) is a very active area of research (see the review on Lattice Quantum Chromodynamics in this *Review*). Here we only briefly recall those features which are required for the determination of quark masses. In order to determine the lattice spacing ( $a$ , i.e. the distance between neighboring points of the lattice) and quark masses, one computes a convenient and appropriate set of physical quantities (frequently chosen to be a set of hadronic masses) for a variety of input values of the quark masses. The true (physical) values of the quark masses are those which correctly reproduce the set of physical quantities being used for the calibration.

The values of the quark masses obtained directly in lattice simulations are bare quark masses, corresponding to a particular discretization of QCD and with the lattice spacing as the ultraviolet cut-off. In order for these results to be useful in phenomenological applications, it is necessary to relate them to renormalized masses defined in some standard renormalization scheme such as  $\overline{\text{MS}}$ . Provided that both the ultraviolet cut-off  $a^{-1}$  and the renormalization scale  $\mu$  are much greater than  $\Lambda_{\text{QCD}}$ , the bare and renormalized masses can be related in perturbation theory. However, in order to avoid uncertainties due to the unknown higher-order coefficients in lattice perturbation theory, most results obtained recently use *non-perturbative renormalization* to relate the bare masses to those defined in renormalization schemes which can be simulated directly in lattice QCD (e.g. those obtained from quark and gluon Green functions at specified momenta in the Landau gauge [62] or those defined using finite-volume techniques and the Schrödinger functional [63]). The conversion to the  $\overline{\text{MS}}$  scheme (which cannot be simulated) is then performed using continuum perturbation theory.

The determination of quark masses using lattice simulations is well established and the current emphasis is on the reduction and control of the systematic uncertainties. With improved algorithms and access to more powerful computing resources, the precision of the results has improved immensely in recent years.

Vacuum polarisation effects are included with  $N_f = 2, 2 + 1$  or  $N_f = 2 + 1 + 1$  flavors of sea quarks. The number 2 here indicates that the up and down quarks are degenerate. In earlier *reviews*, results were presented from simulations in which vacuum polarization effects were completely neglected (this is the so-called *quenched* approximation), leading to systematic uncertainties which could not be estimated reliably. It is no longer necessary to include quenched results in compilations of quark masses. Particularly pleasing is the observation that results obtained using different formulations of lattice QCD, with different systematic uncertainties, give results which are largely consistent with each other. This gives us broad confidence in the estimates of the systematic errors. As the precision of the results approaches (or even exceeds in some cases) 1%, isospin breaking effects, including electromagnetic corrections need to be included and this is beginning to be done as will be discussed below. The results however, are still at an early stage and therefore, unless explicitly stated otherwise, the results presented below will neglect isospin breaking.

Members of the lattice QCD community have organised a Flavour Lattice Averaging Group (FLAG) which critically reviews quantities computed in lattice QCD relevant to flavor physics, including the determination of light quark masses, against stated quality criteria and presents its view of the current status of the results. The latest (2nd) edition reviewed lattice results published before November 30th 2013 [16].

### D. Light quarks

In this section we review the determination of the masses of the light quarks  $u$ ,  $d$  and  $s$  from lattice simulations and then discuss the consequences of the approximate chiral symmetry.

**Lattice Gauge Theory:** The most reliable determinations of the strange quark mass  $m_s$  and of the average of the up and down quark masses  $m_{ud} = (m_u + m_d)/2$  are obtained from lattice simulations. As explained in section C above, the simulations are generally performed with degenerate up and down quarks ( $m_u = m_d$ ) and so it is the average which is obtained directly from the computations. Below we discuss attempts to derive  $m_u$  and  $m_d$  separately using lattice results in combination with other techniques, but we start by briefly present our estimate of the current status of the latest lattice results in the isospin symmetric limit. Based largely on references [21–25], which its authors considered to have the most reliable estimates of the systematic uncertainties, the FLAG Review [16] quoted as its summary of results obtained with  $N_f = 2 + 1$  flavors of sea quarks:

$$\overline{m}_s = (93.8 \pm 1.5 \pm 1.9) \text{ MeV}, \quad (3)$$

$$\overline{m}_{ud} = (3.42 \pm 0.06 \pm 0.07) \text{ MeV} \quad (4)$$

and

$$\frac{\overline{m}_s}{\overline{m}_{ud}} = 27.46 \pm 0.15 \pm 0.41. \quad (5)$$

The masses are given in the  $\overline{\text{MS}}$  scheme at a renormalization scale of 2 GeV. The first error comes from averaging the lattice results and the second is an estimate of the neglect of sea-quark effects from the charm and more massive quarks. Because of the systematic errors, these results are not simply the combinations of all the results in quadrature, but include a judgement of the remaining uncertainties. Since the different collaborations use different formulations of lattice QCD, the (relatively small) variations of the results between the groups provides important information about the reliability of the estimates.

Since the publication of the FLAG review [16] there have been a number of studies with  $N_f = 2 + 1 + 1$  [26–28] and  $N_f = 2 + 1$  [29] and a reasonable summary of the current status may be  $\overline{m}_{ud} = (3.4 \pm 0.1) \text{ MeV}$ ,  $\overline{m}_s = (93.5 \pm 2) \text{ MeV}$  and  $\overline{m}_s/\overline{m}_{ud} = 27.5 \pm 0.3$ .

To obtain the individual values of  $\overline{m}_u$  and  $\overline{m}_d$  requires the introduction of isospin breaking effects, including electromagnetism. In principle this can be done completely using lattice field theory. Such calculations are indeed beginning (note the recent computation of the neutron-proton mass splitting [30]) but are still at a relatively early stage. In practice therefore,  $\overline{m}_u$  and  $\overline{m}_d$  are extracted by combining lattice results with some elements of continuum phenomenology, most frequently based on chiral perturbation theory. Such studies include references [32,17,24,28,33,34] as well the Flavianet Lattice Averaging Group [43]. Based on these results we summarise the current status as

$$\frac{\overline{m}_u}{\overline{m}_d} = 0.46(5), \quad \overline{m}_u = 2.15(15) \text{ MeV}, \quad \overline{m}_d = 4.70(20) \text{ MeV}. \quad (6)$$

Again the masses are given in the  $\overline{\text{MS}}$  scheme at a renormalization scale of 2 GeV. Of particular importance is the fact that  $m_u \neq 0$  since there would have been no strong  $CP$  problem had  $m_u$  been equal to zero.

The quark mass ranges for the light quarks given in the listings combine the lattice and continuum values and use the PDG method for determining errors given in the introductory notes.

**Chiral Perturbation Theory:** For light quarks, one can use the techniques of chiral perturbation theory [6–8] to extract quark mass ratios. The mass term for light quarks in the QCD Lagrangian is

$$\overline{\Psi} M \Psi = \overline{\Psi}_L M \Psi_R + \overline{\Psi}_R M^\dagger \Psi_L, \quad (7)$$

where  $M$  is the light quark mass matrix,

$$M = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_d & 0 \\ 0 & 0 & m_s \end{pmatrix}, \quad (8)$$

$\Psi = (u, d, s)$ , and  $L$  and  $R$  are the left- and right-chiral components of  $\Psi$  given by  $\Psi_{L,R} = P_{L,R} \Psi$ ,  $P_L = (1 - \gamma_5)/2$ ,  $P_R = (1 + \gamma_5)/2$ . The mass term is the only term in the QCD Lagrangian that mixes left- and right-handed quarks. In the

limit  $M \rightarrow 0$ , there is an independent  $SU(3) \times U(1)$  flavor symmetry for the left- and right-handed quarks. The vector  $U(1)$  symmetry is baryon number; the axial  $U(1)$  symmetry of the classical theory is broken in the quantum theory due to the anomaly. The remaining  $G_\chi = SU(3)_L \times SU(3)_R$  chiral symmetry of the QCD Lagrangian is spontaneously broken to  $SU(3)_V$ , which, in the limit  $M \rightarrow 0$ , leads to eight massless Goldstone bosons, the  $\pi$ 's,  $K$ 's, and  $\eta$ .

The symmetry  $G_\chi$  is only an approximate symmetry, since it is explicitly broken by the quark mass matrix  $M$ . The Goldstone bosons acquire masses which can be computed in a systematic expansion in  $M$ , in terms of low-energy constants, which are unknown nonperturbative parameters of the effective theory, and are not fixed by the symmetries. One treats the quark mass matrix  $M$  as an external field that transforms under  $G_\chi$  as  $M \rightarrow L M R^\dagger$ , where  $\Psi_L \rightarrow L \Psi_L$  and  $\Psi_R \rightarrow R \Psi_R$  are the  $SU(3)_L$  and  $SU(3)_R$  transformations, and writes down the most general Lagrangian invariant under  $G_\chi$ . Then one sets  $M$  to its given constant value Eq. (8), which implements the symmetry breaking. To first order in  $M$  one finds that [9]

$$\begin{aligned} m_{\pi^0}^2 &= B(m_u + m_d), \\ m_{\pi^\pm}^2 &= B(m_u + m_d) + \Delta_{\text{em}}, \\ m_{K^0}^2 &= m_{K^\pm}^2 = B(m_d + m_s), \\ m_{K^\pm}^2 &= B(m_u + m_s) + \Delta_{\text{em}}, \\ m_\eta^2 &= \frac{1}{3} B(m_u + m_d + 4m_s), \end{aligned} \quad (9)$$

with two unknown constants  $B$  and  $\Delta_{\text{em}}$ , the electromagnetic mass difference. From Eq. (9), one can determine the quark mass ratios [9]

$$\begin{aligned} \frac{m_u}{m_d} &= \frac{2m_{\pi^0}^2 - m_{\pi^+}^2 + m_{K^+}^2 - m_{K^0}^2}{m_{K^0}^2 - m_{K^+}^2 + m_{\pi^+}^2} = 0.56, \\ \frac{m_s}{m_d} &= \frac{m_{K^0}^2 + m_{K^+}^2 - m_{\pi^+}^2}{m_{K^0}^2 + m_{\pi^+}^2 - m_{K^+}^2} = 20.2, \end{aligned} \quad (10)$$

to lowest order in chiral perturbation theory, with an error which will be estimated below. Since the mass ratios extracted using chiral perturbation theory use the symmetry transformation property of  $M$  under the chiral symmetry  $G_\chi$ , it is important to use a renormalization scheme for QCD that does not change this transformation law. Any mass independent subtraction scheme such as  $\overline{\text{MS}}$  is suitable. The ratios of quark masses are scale independent in such a scheme, and Eq. (10) can be taken to be the ratio of  $\overline{\text{MS}}$  masses. Chiral perturbation theory cannot determine the overall scale of the quark masses, since it uses only the symmetry properties of  $M$ , and any multiple of  $M$  has the same  $G_\chi$  transformation law as  $M$ .

Chiral perturbation theory is a systematic expansion in powers of the light quark masses. The typical expansion parameter is  $m_K^2/\Lambda_\chi^2 \sim 0.25$  if one uses  $SU(3)$  chiral symmetry, and  $m_\pi^2/\Lambda_\chi^2 \sim 0.02$  if instead one uses  $SU(2)$  chiral symmetry. Electromagnetic effects at the few percent level also break

## Quarks

$SU(2)$  and  $SU(3)$  symmetry. The mass formulae Eq. (9) were derived using  $SU(3)$  chiral symmetry, and are expected to have approximately a 25% uncertainty due to second order corrections. This estimate of the uncertainty is consistent with the lattice results found in Eq. (3)-Eq. (5) and more recent calculations.

**Figure 1:** The analytic structure of  $\Pi(s)$  in the complex  $s$ -plane. The contours  $C_1$  and  $C_2$  are the integration contours discussed in the text.

There is a subtlety which arises when one tries to determine quark mass ratios at second order in chiral perturbation theory. The second order quark mass term [10]

$$\left(M^\dagger\right)^{-1} \det M^\dagger \quad (11)$$

(which can be generated by instantons) transforms in the same way under  $G_\chi$  as  $M$ . Chiral perturbation theory cannot distinguish between  $M$  and  $\left(M^\dagger\right)^{-1} \det M^\dagger$ ; one can make the replacement  $M \rightarrow M(\lambda) = M + \lambda M \left(M^\dagger M\right)^{-1} \det M^\dagger$  in the chiral Lagrangian,

$$\begin{aligned} M(\lambda) &= \text{diag}(m_u(\lambda), m_d(\lambda), m_s(\lambda)) \\ &= \text{diag}(m_u + \lambda m_d m_s, m_d + \lambda m_u m_s, m_s + \lambda m_u m_d), \end{aligned} \quad (12)$$

and leave all observables unchanged.

The combination

$$\left(\frac{m_u}{m_d}\right)^2 + \frac{1}{Q^2} \left(\frac{m_s}{m_d}\right)^2 = 1 \quad (13)$$

where

$$Q^2 = \frac{m_s^2 - \hat{m}^2}{m_d^2 - m_u^2}, \quad \hat{m} = \frac{1}{2}(m_u + m_d),$$

is insensitive to the transformation in Eq. (12). Eq. (13) gives an ellipse in the  $m_u/m_d - m_s/m_d$  plane. The ellipse is well-determined by chiral perturbation theory, but the exact location on the ellipse, and the absolute normalization of the quark masses, has large uncertainties.  $Q$  is determined to be

in the range 21–25 from  $\eta \rightarrow 3\pi$  decay and the electromagnetic contribution to the  $K^+ - K^0$  and  $\pi^+ - \pi^0$  mass differences [11].

The absolute normalization of the quark masses cannot be determined using chiral perturbation theory. Other methods, such as lattice simulations discussed above or spectral function sum rules [12,13] for hadronic correlation functions, which we review next are necessary.

**Sum Rules:** Sum rule methods have been used extensively to determine quark masses and for illustration we briefly discuss here their application to hadronic  $\tau$  decays [14]. Other applications involve very similar techniques.

The experimentally measured quantity is  $R_\tau$ ,

$$\frac{dR_\tau}{ds} = \frac{d\Gamma/ds(\tau^- \rightarrow \text{hadrons} + \nu_\tau(\gamma))}{\Gamma(\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau(\gamma))} \quad (14)$$

the hadronic invariant mass spectrum in semihadronic  $\tau$  decay, normalized to the leptonic  $\tau$  decay rate. It is useful to define  $q$  as the total momentum of the hadronic final state, so  $s = q^2$  is the hadronic invariant mass. The total hadronic  $\tau$  decay rate  $R_\tau$  is then given by integrating  $dR_\tau/ds$  over the kinematically allowed range  $0 \leq s \leq M_\tau^2$ .

$R_\tau$  can be written as

$$\begin{aligned} R_\tau &= 12\pi \int_0^{M_\tau^2} \frac{ds}{M_\tau^2} \left(1 - \frac{s}{M_\tau^2}\right)^2 \\ &\times \left[ \left(1 + 2\frac{s}{M_\tau^2}\right) \text{Im} \Pi^T(s) + \text{Im} \Pi^L(s) \right] \end{aligned} \quad (15)$$

where  $s = q^2$ , and the hadronic spectral functions  $\Pi^{L,T}$  are defined from the time-ordered correlation function of two weak currents is the time-ordered correlator of the weak interaction current ( $j^\mu(x)$  and  $j^\nu(0)$ ) by

$$\Pi^{\mu\nu}(q) = i \int d^4x e^{iq \cdot x} \langle 0 | T \left( j^\mu(x) j^\nu(0)^\dagger \right) | 0 \rangle, \quad (16)$$

$$\Pi^{\mu\nu}(q) = (-g^{\mu\nu} + q^\mu q^\nu) \Pi^T(s) + q^\mu q^\nu \Pi^L(s), \quad (17)$$

and the decomposition Eq. (17) is the most general possible structure consistent with Lorentz invariance.

By the optical theorem, the imaginary part of  $\Pi^{\mu\nu}$  is proportional to the total cross-section for the current to produce all possible states. A detailed analysis including the phase space factors leads to Eq. (15). The spectral functions  $\Pi^{L,T}(s)$  are analytic in the complex  $s$  plane, with singularities along the real axis. There is an isolated pole at  $s = m_\pi^2$ , and single- and multi-particle singularities for  $s \geq 4m_\pi^2$ , the two-particle threshold. The discontinuity along the real axis is  $\Pi^{L,T}(s + i0^+) - \Pi^{L,T}(s - i0^+) = 2i \text{Im} \Pi^{L,T}(s)$ . As a result, Eq. (15) can be rewritten with the replacement  $\text{Im} \Pi^{L,T}(s) \rightarrow -i \Pi^{L,T}(s)/2$ , and the integration being over the contour  $C_1$ . Finally, the contour  $C_1$  can be deformed to  $C_2$  without crossing any singularities, and so leaving the integral unchanged. One can derive a series of sum rules analogous to Eq. (15) by

weighting the differential  $\tau$  hadronic decay rate by different powers of the hadronic invariant mass,

$$R_{\tau}^{kl} = \int_0^{M_{\tau}^2} ds \left(1 - \frac{s}{M_{\tau}^2}\right)^k \left(\frac{s}{M_{\tau}^2}\right)^l \frac{dR_{\tau}}{ds} \quad (18)$$

where  $dR_{\tau}/ds$  is the hadronic invariant mass distribution in  $\tau$  decay normalized to the leptonic decay rate. This leads to the final form of the sum rule(s),

$$R_{\tau}^{kl} = -6\pi i \int_{C_2} \frac{ds}{M_{\tau}^2} \left(1 - \frac{s}{M_{\tau}^2}\right)^{2+k} \left(\frac{s}{M_{\tau}^2}\right)^l \times \left[ \left(1 + 2\frac{s}{M_{\tau}^2}\right) \Pi^T(s) + \Pi^L(s) \right]. \quad (19)$$

The manipulations so far are completely rigorous and exact, relying only on the general analytic structure of quantum field theory. The left-hand side of the sum rule Eq. (19) is obtained from experiment. The right hand-side can be computed for  $s$  far away from any physical cuts using the operator product expansion (OPE) for the time-ordered product of currents in Eq. (16), and QCD perturbation theory. The OPE is an expansion for the time-ordered product Eq. (16) in a series of local operators, and is an expansion about the  $q \rightarrow \infty$  limit. It gives  $\Pi(s)$  as an expansion in powers of  $\alpha_s(s)$  and  $\Lambda_{\text{QCD}}^2/s$ , and is valid when  $s$  is far (in units of  $\Lambda_{\text{QCD}}^2$ ) from any singularities in the complex  $s$ -plane.

The OPE gives  $\Pi(s)$  as a series in  $\alpha_s$ , quark masses, and various non-perturbative vacuum matrix element. By computing  $\Pi(s)$  theoretically, and comparing with the experimental values of  $R_{\tau}^{kl}$ , one determines various parameters such as  $\alpha_s$  and the quark masses. The theoretical uncertainties in using Eq. (19) arise from neglected higher order corrections (both perturbative and non-perturbative), and because the OPE is no longer valid near the real axis, where  $\Pi$  has singularities. The contribution of neglected higher order corrections can be estimated as for any other perturbative computation. The error due to the failure of the OPE is more difficult to estimate. In Eq. (19), the OPE fails on the endpoints of  $C_2$  that touch the real axis at  $s = M_{\tau}^2$ . The weight factor  $(1 - s/M_{\tau}^2)$  in Eq. (19) vanishes at this point, so the importance of the endpoint can be reduced by choosing larger values of  $k$ .

### E. Heavy quarks

For heavy-quark physics one can exploit the fact that  $m_Q \gg \Lambda_{\text{QCD}}$  to construct effective theories ( $m_Q$  is the mass of the heavy quark  $Q$ ). The masses and decay rates of hadrons containing a single heavy quark, such as the  $B$  and  $D$  mesons can be determined using the heavy quark effective theory (HQET) [45]. The theoretical calculations involve radiative corrections computed in perturbation theory with an expansion in  $\alpha_s(m_Q)$  and non-perturbative corrections with an expansion in powers of  $\Lambda_{\text{QCD}}/m_Q$ . Due to the asymptotic nature of the QCD perturbation series, the two kinds of corrections are intimately related; an example of this are renormalon effects

in the perturbative expansion which are associated with non-perturbative corrections.

Systems containing two heavy quarks such as the  $\Upsilon$  or  $J/\Psi$  are treated using non-relativistic QCD (NRQCD) [46]. The typical momentum and energy transfers in these systems are  $\alpha_s m_Q$ , and  $\alpha_s^2 m_Q$ , respectively, so these bound states are sensitive to scales much smaller than  $m_Q$ . However, smeared observables, such as the cross-section for  $e^+e^- \rightarrow b\bar{b}$  averaged over some range of  $s$  that includes several bound state energy levels, are better behaved and only sensitive to scales near  $m_Q$ . For this reason, most determinations of the  $c, b$  quark masses using perturbative calculations compare smeared observables with experiment [47–49].

There are many continuum extractions of the  $c$  and  $b$  quark masses, some with quoted errors of 10 MeV or smaller. There are systematic effects of comparable size, which are typically not included in these error estimates. Reference [41], for example, shows that even though the error estimate of  $m_c$  using the rapid convergence of the  $\alpha_s$  perturbation series is only a few MeV, the central value of  $m_c$  can differ by a much larger amount depending on which algorithm (all of which are formally equally good) is used to determine  $m_c$  from the data. This leads to a systematic error from perturbation theory of around 20 MeV for the  $c$  quark and 25 MeV for the  $b$  quark. Electromagnetic effects, which also are important at this precision, are often not included. For this reason, we inflate the errors on the continuum extractions of  $m_c$  and  $m_b$ . The average values of  $m_c$  and  $m_b$  from continuum determinations are (see Sec. G for the 1S scheme)

$$\overline{m}_c(\overline{m}_c) = (1.28 \pm 0.025) \text{ GeV}$$

$$\overline{m}_b(\overline{m}_b) = (4.18 \pm 0.03) \text{ GeV}, \quad m_b^{1S} = (4.65 \pm 0.03) \text{ GeV}.$$

Lattice simulations of QCD lead to discretization errors which are powers of  $m_Q a$  (modulated by logarithms); the power depends on the formulation of lattice QCD being used and in most cases is quadratic. Clearly these errors can be reduced by performing simulations at smaller lattice spacings, but also by using *improved* discretizations of the theory. Recently, with more powerful computing resources, better algorithms and techniques, it has become possible to perform simulations in the charm quark region and beyond, also decreasing the extrapolation which has to be performed to reach the  $b$ -quark. A novel approach proposed in [64] has been to compare the lattice results for moments of correlation functions of  $c\bar{c}$  quark-bilinear operators to perturbative calculations of the same quantities at 4-loop order. In this way both the strong coupling constant and the charm quark mass can be determined with remarkably small errors; in particular  $\overline{m}_c(\overline{m}_c) = 1.273(6) \text{ GeV}$  [36]. This lattice determination also uses the perturbative expression for the current-current correlator, and so has the perturbation theory systematic error discussed above. Recent updates using this correlator method, both with a very similar result, can be found in [27,37]. It should be remembered that these results

# Quark Particle Listings

## Quarks

were obtained in QCD with exact isospin symmetry; isospin breaking effects, including electromagnetism may well be larger or of the order of the quoted uncertainty.

As the range of heavy-quark masses which can be used in numerical simulations increases, results obtained by extrapolating the results to  $b$ -physics are becoming ever more reliable (see e.g. [27]). Traditionally however, the main approach to controlling the discretization errors in lattice studies of heavy quark physics has been to perform simulations of the effective theories such as HQET and NRQCD. This remains an important technique, both in its own right and in providing additional information for extrapolations from lower masses to the bottom region. Using effective theories,  $m_b$  is obtained from what is essentially a computation of the difference of  $M_{H_b} - m_b$ , where  $M_{H_b}$  is the mass of a hadron  $H_b$  containing a  $b$ -quark. The relative error on  $m_b$  is therefore much smaller than that for  $M_{H_b} - m_b$ . The principal systematic errors are the matching of the effective theories to QCD and the presence of power divergences in  $a^{-1}$  in the  $1/m_b$  corrections which have to be subtracted numerically. The use of HQET or NRQCD is less precise for the charm quark, but in this case, as mentioned above, direct QCD simulations are now possible.

### F. Pole Mass

For an observable particle such as the electron, the position of the pole in the propagator is the definition of its mass. In QCD this definition of the quark mass is known as the pole mass. It is known that the on-shell quark propagator has no infrared divergences in perturbation theory [52,53], so this provides a perturbative definition of the quark mass. The pole mass cannot be used to arbitrarily high accuracy because of nonperturbative infrared effects in QCD. The full quark propagator has no pole because the quarks are confined, so that the pole mass cannot be defined outside of perturbation theory. The relation between the pole mass  $m_Q$  and the  $\overline{\text{MS}}$  mass  $\overline{m}_Q$  is known to three loops [54,55,56,57]

$$m_Q = \overline{m}_Q(\overline{m}_Q) \left\{ 1 + \frac{4\overline{\alpha}_s(\overline{m}_Q)}{3\pi} + \left[ -1.0414 \sum_k \left( 1 - \frac{4}{3} \frac{\overline{m}_{Q_k}}{\overline{m}_Q} \right) + 13.4434 \right] \left[ \frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi} \right]^2 + [0.6527N_L^2 - 26.655N_L + 190.595] \left[ \frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi} \right]^3 \right\}, \quad (20)$$

where  $\overline{\alpha}_s(\mu)$  is the strong interaction coupling constants in the  $\overline{\text{MS}}$  scheme, and the sum over  $k$  extends over the  $N_L$  flavors  $Q_k$  lighter than  $Q$ . The complete mass dependence of the  $\alpha_s^2$  term can be found in [54]; the mass dependence of the  $\alpha_s^3$  term is not known. For the  $b$ -quark, Eq. (20) reads

$$m_b = \overline{m}_b(\overline{m}_b) [1 + 0.10 + 0.05 + 0.03], \quad (21)$$

where the contributions from the different orders in  $\alpha_s$  are shown explicitly. The two and three loop corrections are comparable in size and have the same sign as the one loop term. This is a signal of the asymptotic nature of the perturbation series [there is a renormalon in the pole mass]. Such a badly behaved perturbation expansion can be avoided by directly extracting the  $\overline{\text{MS}}$  mass from data without extracting the pole mass as an intermediate step.

**Figure 2:** The allowed region (shown in white) for up quark and down quark masses. This region was determined in part from papers reporting values for  $m_u$  and  $m_d$  (data points shown) and in part from analysis of the allowed ranges of other mass parameters (see Fig. 3). The parameter  $(m_u + m_d)/2$  yields the two downward-sloping lines, while  $m_u/m_d$  yields the two rising lines originating at  $(0,0)$ .

### G. Numerical values and caveats

The quark masses in the particle data listings have been obtained by using a wide variety of methods. Each method involves its own set of approximations and uncertainties. In most cases, the errors are an estimate of the size of neglected higher-order corrections or other uncertainties. The expansion parameters for some of the approximations are not very small (for example, they are  $m_K^2/\Lambda_\chi^2 \sim 0.25$  for the chiral expansion

**Figure 3.** The values of each quark mass parameter taken from the Data Listings. The points are in chronological order with the more recent measurements at the top. Points from papers reporting no error bars are colored grey. The shaded regions indicate values excluded by our evaluations; some regions were determined in part through examination of Fig. 2.

and  $\Lambda_{\text{QCD}}/m_b \sim 0.1$  for the heavy-quark expansion), so an unexpectedly large coefficient in a neglected higher-order term could significantly alter the results. It is also important to note that the quark mass values can be significantly different in the different schemes.

The heavy quark masses obtained using HQET, QCD sum rules, or lattice gauge theory are consistent with each other if they are all converted into the same scheme and scale. We have specified all masses in the  $\overline{\text{MS}}$  scheme. For light quarks, the renormalization scale has been chosen to be  $\mu = 2 \text{ GeV}$ . The light quark masses at 1 GeV are significantly different from those at 2 GeV,  $\overline{m}(1 \text{ GeV})/\overline{m}(2 \text{ GeV}) \sim 1.33$ . It is conventional to choose the renormalization scale equal to the quark mass for

a heavy quark, so we have quoted  $\overline{m}_Q(\mu)$  at  $\mu = \overline{m}_Q$  for the  $c$  and  $b$  quarks. Recent analyses of inclusive  $B$  meson decays have shown that recently proposed mass definitions lead to a better behaved perturbation series than for the  $\overline{\text{MS}}$  mass, and hence to more accurate mass values. We have chosen to also give values for one of these, the  $b$  quark mass in the 1S-scheme [58,59]. Other schemes that have been proposed are the PS-scheme [60] and the kinetic scheme [61].

If necessary, we have converted values in the original papers to our chosen scheme using two-loop formulae. It is important to realize that our conversions introduce significant additional errors. In converting to the  $\overline{\text{MS}}$   $b$ -quark mass, for example, the three-loop conversions from the 1S and pole masses give values about 35 MeV and 135 MeV lower than the two-loop

# Quark Particle Listings

## Quarks, $u$

conversions. The uncertainty in  $\alpha_s(M_Z) = 0.1181(13)$  gives an uncertainty of  $\pm 10$  MeV and  $\pm 35$  MeV respectively in the same conversions. We have not added these additional errors when we do our conversions. The  $\alpha_s$  value in the conversion is correlated with the  $\alpha_s$  value used in determining the quark mass, so the conversion error is not a simple additional error on the quark mass.

OMITTED FROM SUMMARY TABLE

### $u$ -QUARK MASS

The  $u$ -,  $d$ -, and  $s$ -quark masses are estimates of so-called “current-quark masses,” in a mass-independent subtraction scheme such as  $\overline{\text{MS}}$ . The ratios  $m_u/m_d$  and  $m_s/m_d$  are extracted from pion and kaon masses using chiral symmetry. The estimates of  $d$  and  $u$  masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the  $u$  quark could be essentially massless. The  $s$ -quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the  $\overline{\text{MS}}$  masses at a renormalization scale of  $\mu = 2$  GeV. Results quoted in the literature at  $\mu = 1$  GeV have been rescaled by dividing by 1.35. The values of “Our Evaluation” were determined in part via Figures 1 and 2.

1 CARRASCO 14 is a lattice QCD computation of light quark masses using  $2 + 1 + 1$  dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.

2 AOKI 12 is a lattice computation using  $1 + 1 + 1$  dynamical quark flavors.

3 DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $N_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual  $m_u, m_d$  values are obtained using the lattice determination of the average mass  $m_{ud}$  and of the ratio  $m_s/m_{ud}$  and the value of  $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$  as determined from  $\eta \rightarrow 3\pi$  decays.

4 BAZAVOV 10 is a lattice computation using  $2+1$  dynamical quark flavors.

5 BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use  $2+1$  dynamical quark flavors.

6 DAVIES 10 and MCNEILE 10 determine  $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $N_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_p$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios,  $m_s/\overline{m}$  and  $m_u/m_d$ .

7 DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .

8 DEANDREA 08 determine  $m_u - m_d$  from  $\eta \rightarrow 3\pi^0$ , and combine with the PDG 06 lattice average value of  $m_u + m_d = 7.6 \pm 1.6$  to determine  $m_u$  and  $m_d$ .

9 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

10 JAMIN 06 determine  $m_u(2 \text{ GeV})$  by combining the value of  $m_s$  obtained from the spectral function for the scalar  $K\pi$  form factor with other determinations of the quark mass ratios.

11 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order. The quark masses  $m_u$  and  $m_d$  were determined from their  $(m_u + m_d)/2$  measurement and AUBIN 04A  $m_u/m_d$  value.

12 NARISON 06 uses sum rules for  $e^+e^- \rightarrow$  hadrons to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.

13 AUBIN 04A employ a partially quenched lattice calculation of the pseudoscalar meson masses.

1 CARRASCO 14 is a lattice QCD computation of light quark masses using  $2 + 1 + 1$  dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.

2 ARTHUR 13 is a lattice computation using  $2+1$  dynamical domain wall fermions. Masses at  $\mu = 3$  GeV have been converted to  $\mu = 2$  GeV using conversion factors given in their paper.

3 AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $N_f = 2 + 1$  dynamical flavors of domain wall fermions.

4 DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $N_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

5 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $N_f=2$  dynamical twisted-mass Wilson fermions.

6 DAVIES 10 and MCNEILE 10 determine  $\bar{m}_C(\mu)/\bar{m}_S(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $N_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $\bar{m}$  is obtained from this using the value of  $m_C$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio,  $m_s/\bar{m}$ .

7 DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .

8 ALLTON 08 use a lattice computation of the  $\pi$ ,  $K$ , and  $\Omega$  masses with  $2+1$  dynamical flavors of domain wall quarks, and non-perturbative renormalization.

9 ISHIKAWA 08 use a lattice computation of the light meson spectrum with  $2+1$  dynamical flavors of  $\mathcal{O}(a)$  improved Wilson quarks, and one-loop perturbative renormalization.

10 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

11 BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.

12 DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-point correlator.

13 NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.

14 GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization, to obtain  $\bar{m}(2 \text{ GeV}) = 4.08 \pm 0.25 \pm 0.19 \pm 0.23 \text{ MeV}$ , where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.

15 GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization.

16 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order.

17 NARISON 06 uses sum rules for  $e^+e^- \rightarrow \text{hadrons}$  to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.

18 AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.

19 AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.

20 The errors given in AOKI 03B were  $+0.046$   
 $-0.069$ . We changed them to  $\pm 0.3$  for calculating the overall best values. AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the  $\mathcal{O}(a)$  improved Wilson action.

21 BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses  $\mathcal{O}(a)$  improved Wilson action and nonperturbative renormalization.

22 CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

<sup>1</sup> CHAKRABORTY 15 is a lattice QCD computation that determines  $m_c$  and  $m_c/m_s$  using pseudoscalar meson masses tuned on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with  $u/d$  masses down to the physical value.

<sup>2</sup> CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.

<sup>3</sup> ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at  $\mu = 3$  GeV have been converted to  $\mu = 2$  GeV using conversion factors given in their paper.

<sup>4</sup> BODENSTEIN 13 determines  $m_s$  from QCD finite energy sum rules, and the perturbative computation of the pseudoscalar correlator to five-loop order.

<sup>5</sup> FRITZSCH 12 determine  $m_s$  using a lattice computation with  $N_f = 2$  dynamical flavors.

<sup>6</sup> AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $N_f = 2 + 1$  dynamical flavors of domain wall fermions.

<sup>7</sup> DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $N_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

<sup>8</sup> BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $N_f = 2$  dynamical twisted-mass Wilson fermions.

<sup>9</sup> BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

<sup>10</sup> ALLTON 08 use a lattice computation of the  $\pi$ ,  $K$ , and  $\Omega$  masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.

<sup>11</sup> DOMINGUEZ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order  $\alpha_s^4$ .

<sup>12</sup> ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of  $\mathcal{O}(a)$  improved Wilson quarks, and one-loop perturbative renormalization.

<sup>13</sup> DAVIES 10 and MCNEILE 10 determine  $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $N_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_c$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10.

<sup>14</sup> BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.

<sup>15</sup> NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.

<sup>16</sup> BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

<sup>17</sup> CHETYSKIN 06 use QCD sum rules in the pseudoscalar channel to order  $\alpha_s^4$ .

<sup>18</sup> GOKKELER 06 use an unquenched lattice computation of the axial Ward Identity with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization, to obtain  $\overline{m}_s(2 \text{ GeV}) = 111 \pm 6 \pm 4 \pm 6 \text{ MeV}$ , where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.

<sup>19</sup> GOKKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization.

<sup>20</sup> JAMIN 06 determine  $\overline{m}_s(2 \text{ GeV})$  from the spectral function for the scalar  $K\pi$  form factor.

<sup>21</sup> MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order.

<sup>22</sup> NARISON 06 uses sum rules for  $e^+e^- \rightarrow \text{hadrons}$  to order  $\alpha_s^3$ .

<sup>23</sup> NARISON 06 obtains the quoted range from positivity of the spectral functions.

<sup>24</sup> BAIKOV 05 determines  $\overline{m}_s(M_\tau) = 100^{+5}_{-3} + 17$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^3$ , with an estimate of the  $\alpha_s^4$  terms. We have converted the result to  $\mu = 2$  GeV.

<sup>25</sup> GAMIZ 05 determines  $\overline{m}_s(2 \text{ GeV})$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^2$ , with an estimate of the  $\alpha_s^3$  terms.

<sup>26</sup> GORBUNOV 05 use hadronic tau decays to N<sup>3</sup>LO, including power corrections.

<sup>27</sup> NARISON 05 determines  $\overline{m}_s(2 \text{ GeV})$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^3$ .

<sup>28</sup> AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.

<sup>29</sup> AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines  $m_s = 113.8 \pm 2.3^{+5.8}_{-2.9}$  using  $K$  mass as input and  $m_s = 142.3 \pm 5.8^{+22}_{-0}$  using  $\phi$  mass as input. We have performed a weighted average of these values.

<sup>30</sup> AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the  $\mathcal{O}(a)$  improved Wilson action.

<sup>31</sup> BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses  $\mathcal{O}(a)$  improved Wilson action and nonperturbative renormalization. They also quote  $\overline{m}/m_s = 24.3 \pm 0.2 \pm 0.6$ .

<sup>32</sup> CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

<sup>33</sup> GAMIZ 03 determines  $m_s$  from SU(3) breaking in the  $\tau$  hadronic width. The value of  $V_{us}$  is chosen to satisfy CKM unitarity.

<sup>34</sup> GAMIZ 03 determines  $m_s$  from SU(3) breaking in the  $\tau$  hadronic width. The value of  $V_{us}$  is taken from the PDG.

18 to 23	5 LEUTWYLER 90b	THEO	

- 1 GAO 97 uses electromagnetic mass splittings of light mesons.
- 2 LEUTWYLER 96 uses a combined fit to  $\eta \rightarrow 3\pi$  and  $\psi' \rightarrow J/\psi(\pi, \eta)$  decay rates, and the electromagnetic mass differences of the  $\pi$  and  $K$ .
- 3 DONOGHUE 92 result is from a combined analysis of meson masses,  $\eta \rightarrow 3\pi$  using second-order chiral perturbation theory including nonanalytic terms, and  $(\psi(2S) \rightarrow J/\psi(1S)\pi)/(\psi(2S) \rightarrow J/\psi(1S)\eta)$ .
- 4 GERARD 90 uses large  $N$  and  $\eta$ - $\eta'$  mixing.
- 5 LEUTWYLER 90b determines quark mass ratios using second-order chiral perturbation theory for the meson and baryon masses, including nonanalytic corrections. Also uses Weinberg sum rules to determine  $L_7$ .

### c-QUARK MASS

The  $c$ -quark mass corresponds to the “running” mass  $m_c(\mu = m_c)$  in the  $\overline{MS}$  scheme. We have converted masses in other schemes to the  $\overline{MS}$  scheme using two-loop QCD perturbation theory with  $\alpha_s(\mu=m_c) = 0.38 \pm 0.03$ . The value  $1.27 \pm 0.03$  GeV for the  $\overline{MS}$  mass corresponds to  $1.67 \pm 0.07$  GeV for the pole mass (see the “Note on Quark Masses”).

- <sup>1</sup> KIYO 16 determine  $\overline{m}_c(\overline{m}_c)$  from the  $J/\psi(1S)$  mass at order  $\alpha_s^3$  (N3LO).
- <sup>2</sup> CHAKRABORTY 15 is a lattice QCD computation using 2+1+1 dynamical flavors. Moments of pseudoscalar current-current correlators are matched to  $\alpha_s^3$ -accurate QCD perturbation theory with the  $\eta_c$  meson mass tuned to experiment.
- <sup>3</sup> DEHNADI 15 determine  $\overline{m}_c(\overline{m}_c)$  using sum rules for  $e^+e^- \rightarrow$  hadrons at order  $\alpha_s^3$  (N3LO), and fitting to both experimental data and lattice results.
- <sup>4</sup> CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.
- <sup>5</sup> ABRAMOWICZ 13c determines  $m_c$  from charm production in deep inelastic  $ep$  scattering, using the QCD prediction at NLO order. The uncertainties from model and parameterization assumptions, and the value of  $\alpha_s$ , of  $\pm 0.03$ ,  $\pm 0.02$ , and  $\pm 0.02$  respectively, have been combined in quadrature.
- <sup>6</sup> ALEKHIN 13 determines  $m_c$  from charm production in deep inelastic scattering at HERA using approximate NNLO QCD.
- <sup>7</sup> DEHNADI 13 determines  $m_c$  using QCD sum rules for the charmonium spectrum and charm continuum to order  $\alpha_s^3$  (N3LO). The statistical and systematic experimental errors of  $\pm 0.006$  and  $\pm 0.009$  have been combined in quadrature. The theoretical uncertainties  $\pm 0.019$  from truncation of the perturbation series,  $\pm 0.010$  from  $\alpha_s$ , and  $\pm 0.002$  from the gluon condensate have been combined in quadrature.
- <sup>8</sup> NARISON 13 determines  $m_c$  using QCD spectral sum rules to order  $\alpha_s^2$  (NNLO) and including condensates up to dimension 6.
- <sup>9</sup> SAMOYLOV 13 determines  $m_c$  from a study of charm dimuon production in neutrino-ion scattering using the NLO QCD result for the charm quark production cross section.
- <sup>10</sup> ALEKHIN 12 determines  $m_c$  from heavy quark production in deep inelastic scattering at HERA using approximate NNLO QCD.
- <sup>11</sup> NARISON 12A determines  $m_c$  using sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight.
- <sup>12</sup> BODENSTEIN 11 determine  $\overline{m}_c(3 \text{ GeV}) = 0.987 \pm 0.009 \text{ GeV}$  and  $\overline{m}_c(\overline{m}_c) = 1.278 \pm 0.009 \text{ GeV}$  using QCD sum rules for the charm quark vector current correlator.
- <sup>13</sup> LASCHKA 11 determine the  $c$  mass from the charmonium spectrum. The theoretical computation uses the heavy  $Q\overline{Q}$  potential to order  $1/m_Q$  obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- <sup>14</sup> AUBERT 10A determine the  $b$ - and  $c$ -quark masses from a fit to the inclusive decay spectra in semileptonic  $B$  decays in the kinetic scheme (and convert it to the  $\overline{MS}$  scheme).
- <sup>15</sup> BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $N_f=2$  dynamical twisted-mass Wilson fermions.
- <sup>16</sup> CHETYRKIN 09 determine  $m_c$  and  $m_b$  from the  $e^+e^- \rightarrow Q\overline{Q}$  cross-section and sum rules, using an order  $\alpha_s^3$  computation of the heavy quark vacuum polarization. They also determine  $m_c(3 \text{ GeV}) = 0.986 \pm 0.013 \text{ GeV}$ .
- <sup>17</sup> SIGNER 09 determines the  $c$ -quark mass using non-relativistic sum rules to analyze the  $e^+e^- \rightarrow c\overline{c}$  cross-section near threshold. Also determine the PS mass  $m_{PS}(\mu_F = 0.7 \text{ GeV}) = 1.50 \pm 0.04 \text{ GeV}$ .
- <sup>18</sup> ALEKHIN 11 determines  $m_c$  from heavy quark production in deep inelastic scattering using fixed target and HERA data, and approximate NNLO QCD.
- <sup>19</sup> BODENSTEIN 10 determines  $\overline{m}_c(3 \text{ GeV}) = 1.008 \pm 0.026 \text{ GeV}$  using finite energy sum rules for the vector current correlator. The authors have converted this to  $\overline{m}_c(\overline{m}_c)$  using  $\alpha_s(M_Z) = 0.1189 \pm 0.0020$ .
- <sup>20</sup> MCNEILE 10 determines  $m_c$  by comparing the order  $\alpha_s^3$  perturbative results for the pseudo-scalar current to lattice simulations with  $N_f = 2+1$  sea-quarks by the HPQCD collaboration.
- <sup>21</sup> NARISON 10 determines  $m_c$  from ratios of moments of vector current correlators computed to order  $\alpha_s^3$  and including the dimension-six gluon condensate.
- <sup>22</sup> ALLISON 08 determine  $m_c$  by comparing four-loop perturbative results for the pseudo-scalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.
- <sup>23</sup> KUHN 07 determine  $\overline{m}_c(\mu = 3 \text{ GeV}) = 0.986 \pm 0.013 \text{ GeV}$  and  $\overline{m}_c(\overline{m}_c)$  from a four-loop sum-rule computation of the cross-section for  $e^+e^- \rightarrow$  hadrons in the charm threshold region.
- <sup>24</sup> BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order  $\alpha_s^3$ .
- <sup>25</sup> BUCHMUELLER 06 determine  $m_b$  and  $m_c$  by a global fit to inclusive  $B$  decay spectra.
- <sup>26</sup> HOANG 06 determines  $\overline{m}_c(\overline{m}_c)$  from a global fit to inclusive  $B$  decay data. The  $B$  decay distributions were computed to order  $\alpha_s^2\beta_0$ , and the conversion between different  $m_c$  mass schemes to order  $\alpha_s^3$ .
- <sup>27</sup> AUBERT 04x obtain  $m_c$  from a fit to the hadron mass and lepton energy distributions in semileptonic  $B$  decay. The paper quotes values in the kinetic scheme. The  $\overline{MS}$  value has been provided by the BABAR collaboration.
- <sup>28</sup> HOANG 04 determines  $\overline{m}_c(\overline{m}_c)$  from moments at order  $\alpha_s^2$  of the charm production cross-section in  $e^+e^-$  annihilation.
- <sup>29</sup> DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
- <sup>30</sup> EIDEMULLER 03 determines  $m_b$  and  $m_c$  using QCD sum rules.
- <sup>31</sup> ERLER 03 determines  $m_b$  and  $m_c$  using QCD sum rules. Includes recent BES data.
- <sup>32</sup> ZYABLYUK 03 determines  $m_c$  by using QCD sum rules in the pseudoscalar channel and comparing with the  $\eta_c$  mass.

 **$m_c/m_s$  MASS RATIO**

- <sup>1</sup> CHAKRABORTY 15 is a lattice QCD computation on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with  $u/d$  masses down to the physical value.  $m_c$  and  $m_s$  are tuned from pseudoscalar meson masses.
- <sup>2</sup> BAZAVOV 14A is a lattice computation using 4 dynamical flavors of HISQ fermions.
- <sup>3</sup> CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.
- <sup>4</sup> DURR 12 determine  $m_c/m_s$  using a lattice computation with  $N_f = 2$  dynamical fermions. The result is combined with other determinations of  $m_c$  to obtain  $m_s(2 \text{ GeV}) = 97.0 \pm 2.6 \pm 2.5 \text{ MeV}$ .
- <sup>5</sup> BLOSSIER 10 determine  $m_c/m_s$  from a computation of the hadron spectrum using  $N_f = 2$  dynamical twisted-mass Wilson fermions.
- <sup>6</sup> DAVIES 10 determine  $m_c/m_s$  from meson masses calculated on gluon fields including  $u$ ,  $d$ , and  $s$  sea quarks with lattice spacing down to 0.045 fm. The Highly Improved Staggered quark formalism is used for the valence quarks.

## b-QUARK MASS

The first value is the “running mass”  $\overline{m}_b(\mu = \overline{m}_b)$  in the  $\overline{MS}$  scheme, and the second value is the  $1S$  mass, which is half the mass of the  $\Upsilon(1S)$  in perturbation theory. For a review of different quark mass definitions and their properties, see EL-KHADRA 02. The  $1S$  mass is better suited for use in analyzing  $B$  decays than the  $\overline{MS}$  mass because it gives a stable perturbative expansion. We have converted masses in other schemes to the  $\overline{MS}$  mass and  $1S$  mass using two-loop QCD perturbation theory with  $\alpha_s(\mu = \overline{m}_b) = 0.223 \pm 0.008$ . The values  $4.18^{+0.04}_{-0.03}$  GeV for the  $\overline{MS}$  mass and  $4.66^{+0.04}_{-0.03}$  GeV for the  $1S$  mass correspond to  $4.78 \pm 0.06$  GeV for the pole mass, using the two-loop conversion formula. A discussion of masses in different schemes can be found in the “Note on Quark Masses.”

- KIYO 16 determine  $\overline{m}_b(\overline{m}_b)$  from the  $\Upsilon(1S)$  mass at order  $\alpha_s^3$  (N3LO). We have converted this to the  $1S$  scheme.
- ALBERTI 15 determine  $\overline{m}_b(\overline{m}_b)$  from fits to inclusive  $B \rightarrow X_c e \overline{\nu}$  decay. We have converted this to the  $1S$  scheme. They also find  $m_b^{\text{kin}}(1 \text{ GeV}) = 4.553 \pm 0.020 \text{ GeV}$ .
- BENEKE 15 determine  $\overline{m}_b(\overline{m}_b)$  using sum rules for  $e^+e^- \rightarrow \text{hadrons}$  at order N3LO including finite  $m_c$  effects. We have converted this to the  $1S$  scheme. They also find  $m_b^{\text{PS}}(2 \text{ GeV}) = 4.532^{+0.013}_{-0.039} \text{ GeV}$ . When the four-loop conversion between the pole and the  $\overline{MS}$  mass is applied in BENEKE 16, the  $\overline{m}_b(\overline{m}_b)$  mass changes to  $4.203^{+0.016}_{-0.034} \text{ GeV}$ .
- DEHNADI 15 determine  $\overline{m}_b(\overline{m}_b)$  using sum rules for  $e^+e^- \rightarrow \text{hadrons}$  at order  $\alpha_s^3$  (N3LO), and fitting to both experimental data and lattice results. We have converted this to the  $1S$  scheme.
- ABRAMOWICZ 14A determine  $\overline{m}_b(\overline{m}_b) = 4.07 \pm 0.14^{+0.01+0.05+0.08}_{-0.07-0.00-0.05}$  from the production of  $b$  quarks in  $ep$  collisions at HERA. The errors due to fitting, modeling, PDF parameterization, and theoretical QCD uncertainties due to the values of  $\alpha_s$ ,  $m_c$ , and the renormalization scale  $\mu$  have been combined in quadrature. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- AYALA 14A determine  $\overline{m}_b(\overline{m}_b)$  from the  $\Upsilon(1S)$  mass computed to N<sup>3</sup>LO order in perturbation theory using a renormalon subtracted scheme. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- BERNARDONI 14 determine  $m_b$  from  $N_f = 2$  lattice calculations using heavy quark effective theory non-perturbatively renormalized and matched to QCD at  $1/m$  order. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- PENIN 14 determine  $\overline{m}_b(\overline{m}_b) = 4.169 \pm 0.008 \pm 0.002 \pm 0.002$  using an estimate of the order  $\alpha_s^3$   $b$ -quark vacuum polarization function in the threshold region, including finite  $m_c$  effects. The errors of  $\pm 0.008$  from theoretical uncertainties, and  $\pm 0.002$  from  $\alpha_s$  have been combined in quadrature. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- LEE 130 determines  $m_b$  using lattice calculations of the  $\Upsilon$  and  $B_s$  binding energies in NRQCD, including three light dynamical quark flavors. The quark mass shift in NRQCD is determined to order  $\alpha_s^2$ , with partial  $\alpha_s^3$  contributions.
- LUCHA 13 determines  $m_b$  from QCD sum rules for heavy-light currents using the lattice value for  $\Gamma_B$  of  $191.5 \pm 7.3 \text{ GeV}$ .
- NARISON 13 determines  $m_b$  using QCD spectral sum rules to order  $\alpha_s^2$  (NNLO) and including condensates up to dimension 6. We have converted the  $\overline{MS}$  value to the  $1S$  scheme.
- NARISON 13A determines  $m_b$  using HQET sum rules to order  $\alpha_s^2$  (NNLO) and the  $B$  meson mass and decay constant.
- BODENSTEIN 12 determine  $m_b$  using sum rules for the vector current correlator and the  $e^+e^- \rightarrow Q\overline{Q}$  total cross-section. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- DIMOPOULOS 12 determine quark masses from a lattice computation using  $N_f = 2$  dynamical flavors of twisted mass fermions. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- HOANG 12 determine  $m_b$  using non-relativistic sum rules for the  $\Upsilon$  system at order  $\alpha_s^2$  (NNLO) with renormalization group improvement.
- Determines  $m_b$  to order  $\alpha_s^3$  (N3LO), including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12A. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- LASCHKA 11 determine the  $b$  mass from the charmonium spectrum. The theoretical computation uses the heavy  $Q\overline{Q}$  potential to order  $1/m_Q$  obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- AUBERT 10A determine the  $b$ - and  $c$ -quark masses from a fit to the inclusive decay spectra in semileptonic  $B$  decays in the kinetic scheme (and convert it to the  $\overline{MS}$  scheme). We have converted this to the  $1S$  scheme.
- MCNEILE 10 determines  $m_b$  by comparing order  $\alpha_s^3$  (N3LO) perturbative results for the pseudo-scalar current to lattice simulations with  $N_f = 2+1$  sea-quarks by the HPQCD collaboration. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- CHETYRKIN 09 determine  $m_c$  and  $m_b$  from the  $e^+e^- \rightarrow Q\overline{Q}$  cross-section and sum rules, using an order  $\alpha_s^3$  (N3LO) computation of the heavy quark vacuum polarization. We have converted their  $m_b$  to the  $1S$  scheme.
- SCHWANDA 08 measure moments of the inclusive photon spectrum in  $B \rightarrow X_s \gamma$  decay to determine  $m_b^{1S}$ . We have converted this to  $\overline{MS}$  scheme.
- NARISON 12 determines  $m_b$  using exponential sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- NARISON 12A determines  $m_b$  using sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight. We have converted  $\overline{m}_b(\overline{m}_b)$  to the  $1S$  scheme.
- NARISON 10 determines  $m_b$  from ratios of moments of vector current correlators computed to order  $\alpha_s^3$  and including the dimension-six gluon condensate. These values are taken from the erratum to that reference.

- 25 ABDALLAH 08d determine  $\overline{m}_b(M_Z) = 3.76 \pm 1.0$  GeV from a leading order study of four-jet rates at LEP. We have converted this to  $\overline{m}_b(\overline{m}_b)$  and  $m_b^{1S}$ .
- 26 GUAZZINI 08 determine  $\overline{m}_b(\overline{m}_b)$  from a quenched lattice simulation of heavy meson masses. The  $\pm 0.08$  is an estimate of the quenching error. We have converted these values to the 1S scheme.
- 27 DELLA-MORTE 07 determine  $\overline{m}_b(\overline{m}_b)$  from a computation of the spin-averaged  $B$  meson mass using quenched lattice HQET at order  $1/m$ . The  $\pm 0.08$  is an estimate of the quenching error.
- 28 KUHN 07 determine  $\overline{m}_b(\mu = 10 \text{ GeV}) = 3.609 \pm 0.025$  GeV and  $\overline{m}_b(\overline{m}_b)$  from a four-loop sum-rule computation of the cross-section for  $e^+e^- \rightarrow$  hadrons in the bottom threshold region. We have converted this to the 1S scheme.
- 29 ABDALLAH 06d determine  $m_b(M_Z) = 2.85 \pm 0.32$  GeV from  $Z$ -decay three-jet events containing a  $b$ -quark. We have converted this to  $\overline{m}_b(\overline{m}_b)$  and  $m_b^{1S}$ .
- 30 BOUGHEZAL 06  $\overline{MS}$  scheme result comes from the first moment of the hadronic production cross-section to order  $\alpha_s^3$ . We have converted it to the 1S scheme.
- 31 BUCHMUELLER 06 determine  $m_b$  and  $m_c$  by a global fit to inclusive  $B$  decay spectra. We have converted this to the 1S scheme.
- 32 PINEDA 06  $\overline{MS}$  scheme result comes from a partial NNLL evaluation (complete at order  $\alpha_s^2$  (NNLO)) of sum rules of the bottom production cross-section in  $e^+e^-$  annihilation. We have converted it to the 1S scheme.
- 33 GRAY 05 determines  $\overline{m}_b(\overline{m}_b)$  from a lattice computation of the  $\Upsilon$  spectrum. The simulations have 2+1 dynamical light flavors. The  $b$  quark is implemented using NRQCD. We have converted  $m_b$  to the 1S scheme.
- 34 AUBERT 04x obtain  $m_b$  from a fit to the hadron mass and lepton energy distributions in semileptonic  $B$  decay. The paper quotes values in the kinetic scheme. The  $\overline{MS}$  value has been provided by the BABAR collaboration, and we have converted this to the 1S scheme.
- 35 BAUER 04 determine  $m_b$ ,  $m_c$  and  $m_b - m_c$  by a global fit to inclusive  $B$  decay spectra.
- 36 HOANG 04 determines  $\overline{m}_b(\overline{m}_b)$  from moments at order  $\alpha_s^2$  of the bottom production cross-section in  $e^+e^-$  annihilation.
- 37 MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.
- 38 BAUER 03 determine the  $b$  quark mass by a global fit to  $B$  decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic  $B \rightarrow X_c \ell \nu_\ell$  decay, and the inclusive photon spectrum in  $B \rightarrow X_s \gamma$  decay. The theoretical expressions used are of order  $1/m^3$ , and  $\alpha_s^2 \beta_0$ .
- 40 BORDES 03 determines  $m_b$  using QCD finite energy sum rules to order  $\alpha_s^2$ .
- 41 CORCELLA 03 determines  $\overline{m}_b$  using sum rules computed to order  $\alpha_s^2$ . Includes charm quark mass effects.
- 42 DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
- 43 EIDEMULLER 03 determines  $\overline{m}_b$  and  $\overline{m}_c$  using QCD sum rules.
- 44 ERLER 03 determines  $\overline{m}_b$  and  $\overline{m}_c$  using QCD sum rules. Includes recent BES data.
- 45 MAHMOOD 03 determines  $m_b^{1S}$  by a fit to the lepton energy moments in  $B \rightarrow X_c \ell \nu_\ell$  decay. The theoretical expressions used are of order  $1/m^3$  and  $\alpha_s^2 \beta_0$ . We have converted their result to the  $\overline{MS}$  scheme.
- 46 BRAMBILLA 02 determine  $\overline{m}_b(\overline{m}_b)$  from a computation of the  $\Upsilon(1S)$  mass to order  $\alpha_s^4$ , including finite  $m_c$  corrections. We have converted this to the 1S scheme.
- 47 PENIN 02 determines  $\overline{m}_b$  from the spectrum of the  $\Upsilon$  system.

## THE TOP QUARK

Updated September 2015 by T.M. Liss (The City College of New York), F. Maltoni (Univ. Catholique de Louvain), and A. Quadt (Univ. Göttingen).

## A. Introduction

The top quark is the  $Q = 2/3$ ,  $T_3 = +1/2$  member of the weak-isospin doublet containing the bottom quark (see the review on the “Electroweak Model and Constraints on New Physics” for more information). Its phenomenology is driven by its large mass. Being heavier than a  $W$  boson, it is the only quark that decays semi-weakly, i.e., into a real  $W$  boson and a  $b$  quark. Therefore, it has a very short lifetime and decays before hadronization can occur. In addition, it is the only quark whose Yukawa coupling to the Higgs boson is order of unity. For these reasons the top quark plays a special role in the Standard Model (SM) and in many extensions thereof. Its phenomenology provides a unique laboratory where our understanding of the strong interactions, both in the perturbative and non-perturbative regimes, can be tested. An accurate knowledge of its properties (mass, couplings, production cross section, decay branching ratios, *etc.*) can bring key information on fundamental interactions at the electroweak breaking scale and beyond. This review provides a concise discussion of the experimental and theoretical issues involved in the determination the top-quark properties.

## B. Top-quark production at the Tevatron and LHC

In hadron collisions, top quarks are produced dominantly in pairs through the processes  $q\bar{q} \rightarrow t\bar{t}$  and  $gg \rightarrow t\bar{t}$ , at leading order in QCD. Approximately 85% of the production cross section at the Tevatron is from  $q\bar{q}$  annihilation, with

# Quark Particle Listings

*t*

the remainder from gluon-gluon fusion, while at LHC energies about 90% of the production is from the latter process at  $\sqrt{s} = 14$  TeV ( $\approx 80\%$  at  $\sqrt{s} = 7$  TeV).

Predictions for the total cross sections are now available at next-to-next-to leading order (NNLO) with next-to-next-to-leading-log (NNLL) soft gluon resummation [1]. These results supersede previous approximate ones [2]. Assuming a top-quark mass of 173.3 GeV/c<sup>2</sup>, close to the Tevatron + LHC average [3] (LHC results not yet included), the resulting theoretical prediction of the top-quark pair cross-section at NNLO+NNLL accuracy at the Tevatron at  $\sqrt{s} = 1.96$  TeV is  $\sigma_{t\bar{t}} = 7.16^{+0.11+0.17}_{-0.20-0.12}$  pb where the first uncertainty is from scale dependence and the second from parton distribution functions. At the LHC, assuming a top-quark mass of 173.2 GeV/c<sup>2</sup> the cross sections are:  $\sigma_{t\bar{t}} = 173.6^{+4.5+8.9}_{-5.9-8.9}$  pb, at  $\sqrt{s} = 7$  TeV,  $\sigma_{t\bar{t}} = 247.7^{+6.3+11.5}_{-8.5-11.5}$  pb at  $\sqrt{s} = 8$  TeV, and  $\sigma_{t\bar{t}} = 816.0^{+19.4+34.4}_{-28.6-34.4}$  pb at  $\sqrt{s} = 13$  TeV [1].

Electroweak single top-quark production mechanisms, namely from  $q\bar{q}' \rightarrow t\bar{b}$  [4],  $qb \rightarrow q't$  [5], mediated by virtual *s*-channel and *t*-channel *W*-bosons, and *Wt*-associated production, through  $bg \rightarrow W^-t$ , lead to somewhat smaller cross sections. For example, *t*-channel production, while suppressed by the weak coupling with respect to the strong pair production, is kinematically enhanced, resulting in a sizable cross section both at Tevatron and LHC energies. At the Tevatron, the *t*- and *s*-channel cross sections of top and antitop are identical, while at the LHC they are not, due to the charge-asymmetric initial state. Approximate NNLO cross sections for *t*-channel single top-quark production ( $t + \bar{t}$ ) are calculated for  $m_t = 173.3$  GeV/c<sup>2</sup> to be  $2.06^{+0.13}_{-0.13}$  pb in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV (scale and parton distribution functions uncertainties are combined in quadrature) and  $65.7^{+1.9}_{-1.9}$  ( $87.1^{+0.24}_{-0.24}$ ) pb in  $pp$  collisions at  $\sqrt{s} = 7$  (8) TeV, where 65% and 35% are the relative proportions of *t* and  $\bar{t}$  [6]. A calculation at NNLO accuracy for the *t*-channel cross section has been recently performed predicting a cross section of  $85.1^{+2.5}_{-1.4}$  pb at 8 TeV [7]. For the *s*-channel, these calculations yield  $1.03^{+0.05}_{-0.05}$  pb for the Tevatron, and  $4.5^{+0.2}_{-0.2}$  ( $5.5^{+0.2}_{-0.2}$ ) pb for  $\sqrt{s} = 7$  (8) TeV at the LHC, with 69% (31%) of top (anti-top) quarks [8]. While negligible at the Tevatron, at LHC energies the *Wt*-associated production becomes relevant. At  $\sqrt{s} = 7$  (8) TeV, an approximate NNLO calculation gives  $15.5^{+1.2}_{-1.2}$  ( $22.1^{+1.5}_{-1.5}$ ) pb ( $t + \bar{t}$ ), with an equal proportion of top and anti-top quarks [9].

Assuming  $|V_{tb}| \gg |V_{td}|, |V_{ts}|$  (see the review “The CKM Quark-Mixing Matrix” for more information), the cross sections for single top production are proportional to  $|V_{tb}|^2$ , and no extra hypothesis is needed on the number of quark families or on the unitarity of the CKM matrix in extracting  $|V_{tb}|$ . Separate measurements of the *s*- and *t*-channel processes provide sensitivity to physics beyond the Standard Model [10].

With a mass above the *Wb* threshold, and  $|V_{tb}| \gg |V_{td}|, |V_{ts}|$ , the decay width of the top quark is expected to be dominated by the two-body channel  $t \rightarrow Wb$ . Neglecting terms

of order  $m_b^2/m_t^2$ ,  $\alpha_s^2$ , and  $(\alpha_s/\pi)M_W^2/m_t^2$ , the width predicted in the SM at NLO is [11]:

$$\Gamma_t = \frac{G_F m_t^3}{8\pi\sqrt{2}} \left(1 - \frac{M_W^2}{m_t^2}\right)^2 \left(1 + 2\frac{M_W^2}{m_t^2}\right) \left[1 - \frac{2\alpha_s}{3\pi} \left(\frac{2\pi^2}{3} - \frac{5}{2}\right)\right], \quad (1)$$

where  $m_t$  refers to the top-quark pole mass. The width for a value of  $m_t = 173.3$  GeV/c<sup>2</sup> is 1.35 GeV/c<sup>2</sup> (we use  $\alpha_s(M_Z) = 0.118$ ) and increases with mass. With its correspondingly short lifetime of  $\approx 0.5 \times 10^{-24}$  s, the top quark is expected to decay before top-flavored hadrons or  $t\bar{t}$ -quarkonium-bound states can form [12]. In fact, since the decay time is close to the would-be-resonance binding time, a peak will be visible in  $e^+e^-$  scattering at the  $t\bar{t}$  threshold [13] and it is in principle present (yet very difficult to measure) in hadron collisions, too [14]. The order  $\alpha_s^2$  QCD corrections to  $\Gamma_t$  are also available [15], thereby improving the overall theoretical accuracy to better than 1%.

The final states for the leading pair-production process can be divided into three classes:

- A.  $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow q\bar{q}' b q'' \bar{q}'' \bar{b}$ , (45.7%)
- B.  $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow q\bar{q}' b \ell^- \bar{\nu}_\ell \bar{b} + \ell^+ \nu_\ell b q'' \bar{q}'' \bar{b}$ , (43.8%)
- C.  $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow \ell^+ \nu_\ell b \ell'^- \bar{\nu}_{\ell'}$ . (10.5%)

The quarks in the final state evolve into jets of hadrons. A, B, and C are referred to as the all-jets, lepton+jets ( $\ell$ +jets), and dilepton ( $\ell\ell$ ) channels, respectively. Their relative contributions, including hadronic corrections, are given in parentheses assuming lepton universality. While  $\ell$  in the above processes refers to *e*,  $\mu$ , or  $\tau$ , most of the analyses distinguish the *e* and  $\mu$  from the  $\tau$  channel, which is more difficult to reconstruct. Therefore, in what follows, we will use  $\ell$  to refer to *e* or  $\mu$ , unless otherwise noted. Here, typically leptonic decays of  $\tau$  are included. In addition to the quarks resulting from the top-quark decays, extra QCD radiation (quarks and gluons) from the colored particles in the event can lead to extra jets.

The number of jets reconstructed in the detectors depends on the decay kinematics, as well as on the algorithm for reconstructing jets used by the analysis. Information on the transverse momenta of neutrinos is obtained from the imbalance in transverse momentum measured in each event (missing  $p_T$ , which is here also called missing  $E_T$ ).

The identification of top quarks in the electroweak single top channel is much more difficult than in the QCD  $t\bar{t}$  channel, due to a less distinctive signature and significantly larger backgrounds, mostly due to  $t\bar{t}$  and *W*+jets production.
