$\Gamma(\text{baryons anything})/\Gamma_{\text{total}}$	$\Gamma_{117}/\Gamma$
VALUE	DOCUMENT ID TECN COMMENT
<b><math>0.068 \pm 0.005 \pm 0.003</math></b>	<sup>1</sup> ALBRECHT 92o ARG $e^+e^- \rightarrow \gamma(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •	
$0.076 \pm 0.014$	<sup>2</sup> ALBRECHT 89K ARG $e^+e^- \rightarrow \gamma(4S)$

<sup>1</sup> ALBRECHT 92o result is from simultaneous analysis of  $p$  and  $\Lambda$  yields,  $p\bar{p}$  and  $\Lambda\bar{\Lambda}$  correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89K.

<sup>2</sup> ALBRECHT 89K obtain this result by adding their their measurements ( $5.5 \pm 1.6$ )% for direct protons and ( $4.2 \pm 0.5 \pm 0.6$ )% for inclusive  $\Lambda$  production. They then assume ( $5.5 \pm 1.6$ )% for neutron production and add it in also. Since each  $B$  decay has two baryons, they divide by 2 to obtain ( $7.6 \pm 1.4$ )%.

$0.60^{+0.31+0.05}_{-0.29-0.04}$	<sup>1</sup> LEES	14D BABR	$e^+e^- \rightarrow \gamma(4S)$

<sup>1</sup> Measured from sum of exclusive modes through  $K^+$ ,  $K^+\pi^0$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+$ ,  $K_S^0$ ,  $K_S^0\pi^0$ ,  $K_S^0\pi^+$ ,  $K_S^0\pi^+\pi^0$ , and  $K_S^0\pi^+\pi^-\pi^0$  corrected for unobserved modes.

### LEPTON (HADRON) FORWARD-BACKWARD ASYMMETRY IN $B \rightarrow K^{(*)} \ell^+ \ell^- (B \rightarrow K/\pi h^+ h^-)$ DECAY

The forward-backward angular asymmetry of the lepton pair in  $B \rightarrow K^{(*)} \ell^+ \ell^- (B \rightarrow K/\pi h^+ h^-)$  decay is defined as

$$A_{FB}(s) = \frac{N(\cos\theta > 0) - N(\cos\theta < 0)}{N(\cos\theta > 0) + N(\cos\theta < 0)},$$

where  $s=q^2/m_B^2$ , and  $\theta$  is the angle of the  $\ell^- (h^-)$  with respect to the flight direction of the  $B$  meson, measured in the dilepton (dihadron) rest frame. In addition, the fraction of longitudinal polarization  $F_L$  of the  $K^*$  and  $F_S$ , the relative contribution from scalar and pseudoscalar penguin amplitudes in  $B \rightarrow K \ell^+ \ell^-$ , can be measured from the angular distribution of its decay products.

## $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

0.98 ±0.12 ±0.13	ONG	89	MRK2	$E_{\text{cm}}^{\text{ee}} = 29 \text{ GeV}$
1.17 $\begin{smallmatrix} +0.27 \\ -0.22 \end{smallmatrix}$ $\begin{smallmatrix} +0.17 \\ -0.16 \end{smallmatrix}$	KLEM	88	DLCO	$E_{\text{cm}}^{\text{ee}} = 29 \text{ GeV}$
1.29 ±0.20 ±0.21	25 ASH	87	MAC	$E_{\text{cm}}^{\text{ee}} = 29 \text{ GeV}$
1.02 $\begin{smallmatrix} +0.42 \\ -0.39 \end{smallmatrix}$	301 26 BROM	87	HRS	$E_{\text{cm}}^{\text{ee}} = 29 \text{ GeV}$
1 Measurement performed using an inclusive reconstruction and $B$ flavor identification technique.				
2 Measured using inclusive $J/\psi(1S) \rightarrow \mu^+ \mu^-$ vertex.				
3 ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.				
4 ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.				
5 Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.				
6 BUSKULIC 96F analyzed using 3D impact parameter.				
7 ABE,K 95B uses an inclusive topological technique.				
8 ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.				
9 From proper time distribution of $b \rightarrow J/\psi(1S)$ anything.				
10 ABE 93J analyzed using $J/\psi(1S) \rightarrow \mu \mu$ vertices.				
11 ABREU 93D data analyzed using $D/D^* \ell$ anything event vertices.				
12 ABREU 93G data analyzed using charged and neutral vertices.				
13 ACTON 93C analysed using $D/D^* \ell$ anything event vertices.				
14 ACTON 93L and ADRIANI 93K analyzed using lepton ( $e$ and $\mu$ ) impact parameter at Z.				
15 BUSKULIC 93O analyzed using dipole method.				
16 ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of $B$ species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.				
17 ACTON 92 is combined result of muon and electron impact parameter analyses.				
18 BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.				
19 BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average $b$ lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different $b$ -flavored hadrons are in the same ratio.				
20 Using $Z \rightarrow e^+ X$ or $\mu^+ X$ , ADEVA 91H determined the average lifetime for an admixture of $B$ hadrons from the impact parameter distribution of the lepton.				
21 Using $Z \rightarrow J/\psi(1S) X$ , $J/\psi(1S) \rightarrow \ell^+ \ell^-$ , ALEXANDER 91G determined the average lifetime for an admixture of $B$ hadrons from the decay point of the $J/\psi(1S)$ .				
22 Using $Z \rightarrow e X$ or $\mu X$ , DECAMP 91C determines the average lifetime for an admixture of $B$ hadrons from the signed impact parameter distribution of the lepton.				
23 HAGEMANN 90 uses electrons and muons in an impact parameter analysis.				
24 LYONS 90 combine the results of the $B$ lifetime measurements of ONG 89, BRAUN-SCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.				
25 We have combined an overall scale error of 15% in quadrature with the systematic error of $\pm 0.7$ to obtain $\pm 2.1$ systematic error.				
26 Statistical and systematic errors were combined by BROM 87.

### $\overline{b}$ PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of  $B$  mesons and baryons at energies above the  $T(4S)$ . Only the highest energy results (LHC, LEP, Tevatron,  $Sp\overline{p}S$ ) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a  $\overline{b}$  initial state.  $b$  modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
------	--------------------------------	-----------------------------------

### PRODUCTION FRACTIONS

The production fractions for weakly decaying  $b$ -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note “ $B^0$ - $\overline{B}^0$  Mixing” in the  $B^0$  Particle Listings. The production fractions in  $b$ -hadronic  $Z$  decay or  $p\overline{p}$  collisions at the Tevatron are also listed at the end of the section. Values assume

$$\begin{aligned} B(\overline{b} \rightarrow B^+) &= B(\overline{b} \rightarrow B^0) \\ B(\overline{b} \rightarrow B^+) + B(\overline{b} \rightarrow B^0) + B(\overline{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) &= 100\%. \end{aligned}$$

The correlation coefficients between production fractions are also reported:

$$\begin{aligned} \text{cor}(B_s^0, b\text{-baryon}) &= -0.240 \\ \text{cor}(B_s^0, B^\pm=B^0) &= -0.161 \\ \text{cor}(b\text{-baryon}, B^\pm=B^0) &= -0.920. \end{aligned}$$

The notation for production fractions varies in the literature ( $f_d$ ,  $d_{B^0}$ ,  $f(b \rightarrow \overline{B}^0)$ ,  $\text{Br}(b \rightarrow \overline{B}^0)$ ). We use our own branching fraction notation here,  $B(\overline{b} \rightarrow B^0)$ .

Note these production fractions are  $b$ -hadronization fractions, not the conventional branching fractions of  $b$ -quark to a  $B$ -hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

$\Gamma_1$	$B^+$	( 40.4 ± 0.6 ) %
$\Gamma_2$	$B^0$	( 40.4 ± 0.6 ) %
$\Gamma_3$	$B_s^0$	( 10.3 ± 0.5 ) %
$\Gamma_4$	$b$ -baryon	( 8.9 ± 1.3 ) %

<b>0.134 <math>\pm 0.008</math> OUR AVERAGE</b>			

0.134 $\pm 0.004 \pm_{-0.010}^{+0.011}$	<sup>1</sup> AAIJ	12J	LHCB $pp$ at 7 TeV
0.1265 $\pm 0.0085 \pm 0.0131$	<sup>2</sup> AAIJ	11F	LHCB $pp$ at 7 TeV
0.128 $\pm_{-0.010}^{+0.011}$	<sup>3</sup> AALTONEN	08N	CDF $p\bar{p}$ at 1.96 TeV
0.213 $\pm 0.068$	<sup>4</sup> AFFOLDER	00E	CDF $p\bar{p}$ at 1.8 TeV
0.21 $\pm_{-0.030}^{+0.036}$	<sup>5</sup> ABE	99P	CDF $p\bar{p}$ at 1.8 TeV

<sup>1</sup> Measured using  $b$ -hadron semileptonic decays and assuming isospin symmetry.

<sup>2</sup> AAIJ 11F measured  $f_s/f_d = 0.253 \pm 0.017 \pm 0.017 \pm 0.020$ , where the errors are statistical, systematic, and theoretical. We divide their value by 2. Our second error combines systematic and theoretical uncertainties.

<sup>3</sup> AALTONEN 08N reports  $[\Gamma(\bar{b} \rightarrow B_s^0)/[\Gamma(\bar{b} \rightarrow B^+) + \Gamma(\bar{b} \rightarrow B^0)]] \times [B(D_s^+ \rightarrow \phi\pi^+)] = (5.76 \pm 0.18 \pm_{-0.42}^{+0.45}) \times 10^{-3}$  which we divide by our best value  $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>4</sup> AFFOLDER 00E uses several electron-charm final states in  $b \rightarrow ce^-X$ .

<sup>5</sup> ABE 99P uses the numbers of  $K^*(892)^0$ ,  $K^*(892)^+$ , and  $\phi(1020)$  events produced in association with the double semileptonic decays  $b \rightarrow c\mu^-X$  with  $c \rightarrow s\mu^+X$ .

0.105 $\pm$ 0.006 $\pm$ 0.005	<sup>10</sup> AKERS	93B	OPAL Repl. by ABBI- ENDI 00E

- <sup>1</sup> Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.  
<sup>2</sup> The experimental systematic and model uncertainties are combined in quadrature.  
<sup>3</sup> ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged  $Z \rightarrow b\bar{b}$  sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.  
<sup>4</sup> ACCIARRI 00 result obtained from a combined fit of  $R_D = \Gamma(Z \rightarrow b\bar{b})/\Gamma(Z \rightarrow \text{hadrons})$  and  $B(b \rightarrow \ell\nu X)$ , using double-tagging method.  
<sup>5</sup> ACCIARRI 96c result obtained by a fit to the single lepton spectrum.  
<sup>6</sup> Assumes Standard Model value for  $R_B$ .  
<sup>7</sup> ABREU 95D give systematic errors  $\pm 0.0019$  (model) and 0.0012 ( $R_C$ ). We combine these in quadrature.  
<sup>8</sup> BUSKULIC 94G uses  $e$  and  $\mu$  events. This value is from a global fit to the lepton  $p_T$  (relative to jet) spectra which also determines the  $b$  and  $c$  production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high  $p_T$ , but the lower  $p_T$  portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is  $\pm 0.0026$  and is included in the systematic error.  
<sup>9</sup> ABREU 93c event count includes  $ee$  events. Combining  $ee$ ,  $\mu\mu$ , and  $e\mu$  events, they obtain  $0.100 \pm 0.007 \pm 0.007$ .  
<sup>10</sup> AKERS 93B analysis performed using single and dilepton events.

- <sup>1</sup> ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged  $Z \rightarrow b\bar{b}$  sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.  
<sup>2</sup> ACCIARRI 96c result obtained by a fit to the single lepton spectrum.  
<sup>3</sup> Assumes Standard Model value for  $R_B$ .  
<sup>4</sup> ABREU 93c event count includes  $ee$  events. Combining  $ee$ ,  $\mu\mu$ , and  $e\mu$  events, they obtain  $0.100 \pm 0.007 \pm 0.007$ .  
<sup>5</sup> ADEVA 91c measure the average  $B(b \rightarrow eX)$  branching ratio using single and double tagged  $b$  enhanced  $Z$  events. Combining  $e$  and  $\mu$  results, they obtain  $0.113 \pm 0.010 \pm 0.006$ . Constraining the initial number of  $b$  quarks by the Standard Model prediction ( $378 \pm 3 \text{ MeV}$ ) for the decay of the  $Z$  into  $b\bar{b}$ , the electron result gives  $0.112 \pm 0.004 \pm 0.008$ . They obtain  $0.119 \pm 0.003 \pm 0.006$  when  $e$  and  $\mu$  results are combined. Used to measure the  $b\bar{b}$  width itself, this electron result gives  $370 \pm 12 \pm 24 \text{ MeV}$  and combined with the muon result gives  $385 \pm 7 \pm 22 \text{ MeV}$ .  
<sup>6</sup> ABE 93E experiment also measures forward-backward asymmetries and fragmentation functions for  $b$  and  $c$ .  
<sup>7</sup> AKERS 93B analysis performed using single and dilepton events.

- <sup>1</sup> ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged  $Z \rightarrow b\bar{b}$  sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.  
<sup>2</sup> ACCIARRI 96c result obtained by a fit to the single lepton spectrum.  
<sup>3</sup> Assumes Standard Model value for  $R_B$ .  
<sup>4</sup> ABREU 93c event count includes  $\mu\mu$  events. Combining  $ee$ ,  $\mu\mu$ , and  $e\mu$  events, they obtain  $0.100 \pm 0.007 \pm 0.007$ .  
<sup>5</sup> ADEVA 91c measure the average  $B(b \rightarrow eX)$  branching ratio using single and double tagged  $b$  enhanced  $Z$  events. Combining  $e$  and  $\mu$  results, they obtain  $0.113 \pm 0.010 \pm 0.006$ . Constraining the initial number of  $b$  quarks by the Standard Model prediction ( $378 \pm 3 \text{ MeV}$ ) for the decay of the  $Z$  into  $b\bar{b}$ , the muon result gives  $0.123 \pm 0.003 \pm 0.006$ . They obtain  $0.119 \pm 0.003 \pm 0.006$  when  $e$  and  $\mu$  results are combined. Used to measure the  $b\bar{b}$  width itself, this muon result gives  $394 \pm 9 \pm 22 \text{ MeV}$  and combined with the electron result gives  $385 \pm 7 \pm 22 \text{ MeV}$ .  
<sup>6</sup> AKERS 93B analysis performed using single and dilepton events.

 $V_{cb}$  and  $V_{ub}$  CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

SEMILEPTONIC BOTTOM HADRON DECAYS AND THE DETERMINATION OF  $V_{cb}$  AND  $V_{ub}$ 

Updated November 2015 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

## INTRODUCTION

Precision determinations of  $|V_{ub}|$  and  $|V_{cb}|$  are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in  $B$  decays. The length of the side of the unitarity triangle opposite the well-measured angle  $\beta$  is proportional to the ratio  $|V_{ub}|/|V_{cb}|$ ; its determination is a high priority of the heavy-flavor physics program.

The semileptonic transitions  $b \rightarrow c\ell\bar{\nu}_\ell$  and  $b \rightarrow u\ell\bar{\nu}_\ell$  (where  $\ell$  refers to an electron or muon) each provide two avenues

for determining these CKM matrix elements, namely through inclusive and exclusive final states. Recent measurements and calculations are reflected in the values quoted in this article, which is an update of the previous review [1]. The leptonic decay  $B^- \rightarrow \tau\bar{\nu}$  can also be used to extract  $|V_{ub}|$ ; we do not use this information at present since none of the experimental measurements has reached the significance level of an observation.

The theory underlying the determination of  $|V_{qb}|$  is mature, in particular for  $|V_{cb}|$ . Most of the theoretical approaches use the fact that the mass  $m_b$  of the  $b$  quark is large compared to the scale  $\Lambda_{\text{QCD}}$  that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of  $\Lambda/m_b$ , where  $\Lambda \sim 500 - 700$  MeV is a hadronic scale of the order of  $\Lambda_{\text{QCD}}$ , based on effective-field-theory methods described in a separate RPP mini-review [2]. The use of lattice QCD for calculations of non-perturbative quantities plays an essential role in many of the determinations discussed here; lattice methods are discussed in a separate RPP mini-review [3].

The measurements discussed in this review are of branching fractions or ratios of branching fractions. The determination of the  $|V_{cb}|$  and  $|V_{ub}|$  also requires a measurement of the total decay widths of the corresponding  $b$  hadrons, which is the subject of a separate RPP mini-review [4]. The measurements of inclusive semileptonic decays relevant to this review come primarily from  $e^+e^- B$  factories operating at the  $\Upsilon(4S)$  resonance, where  $B\bar{B}$  pairs are produced nearly at rest in the center-of-mass frame. Measurements of exclusive semileptonic decays come from the  $e^+e^- B$  factories and from the LHCb experiment at CERN.

Semileptonic  $B$  meson decay amplitudes to electrons and muons are assumed to be largely free from any impact of non-Standard Model physics, since they are dominated by Standard-Model  $W$  boson exchange. The decays  $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_\tau$ , however, provide sensitivity to possible non-universalities in the couplings to the third generation leptons that are present at tree level in models involving new charged mediators. For example, a charged Higgs boson, present in many models of new physics, couples to the mass of the lepton and breaks lepton universality. If the enhanced decay rates seen in recent measurements of these decay modes turn out to be robust, they are an indication of new physics.

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [5] using updated values from Ref. 6.

DETERMINATION OF  $|V_{cb}|$ 

*Summary:* The determination of  $|V_{cb}|$  from  $\bar{B} \rightarrow D^*\ell\bar{\nu}_\ell$  decays has a relative precision of about 2%, with comparable contributions from theory and experiment. The value determined from  $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$  decays is consistent and has an uncertainty of 4%. Inclusive decays provide a determination of  $|V_{cb}|$  with a relative uncertainty of about 2%; the limitations

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

arise mainly from our ignorance of higher-order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are only marginally consistent with each other:

$$|V_{cb}| = (42.2 \pm 0.8) \times 10^{-3} \quad (\text{inclusive}) \quad (1)$$

$$|V_{cb}| = (39.2 \pm 0.7) \times 10^{-3} \quad (\text{exclusive}); \quad (2)$$

as a result, their combination should be treated with caution. An average of these determinations has  $p(\chi^2) = 0.33\%$ , so we scale the error by  $\sqrt{\chi^2/1} = 2.9$  to find

$$|V_{cb}| = (40.5 \pm 1.5) \times 10^{-3} \quad (\text{average}). \quad (3)$$

### $|V_{cb}|$ from exclusive decays

Exclusive determinations of  $|V_{cb}|$  make use of semileptonic  $B$  decays into the ground state charmed mesons  $D$  and  $D^*$  and are based on the distribution of the variable  $w \equiv v \cdot v'$ , where  $v$  and  $v'$  are the four velocities of the initial and final-state hadrons. In the rest frame of the decay this variable corresponds to the energy of the final state  $D^{(*)}$  meson. Heavy Quark Symmetry (HQS) [7,8] predicts these decay rates in the infinite mass limit in terms of a single form factor, which is normalized at  $w = 1$ , the point of maximum momentum transfer to the leptons. Measured decay rates and calculations of the form factors are used to determine  $|V_{cb}|$ .

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the shape of the form factors near the point  $w = 1$ . These calculations utilize Heavy Quark Effective Theory, which is discussed in a separate RPP mini-review [2]. Form factors that are normalized due to HQS are protected against linear corrections [9], and thus the leading corrections are of order  $\Lambda_{\text{QCD}}^2/m_c^2$ . For the form factors that vanish in the infinite mass limit the corrections are in general linear in  $\Lambda_{\text{QCD}}/m_c$ . In addition to these corrections, there are perturbatively calculable radiative corrections from hard gluons and photons, which will be discussed in the relevant sections.

### $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$

The decay rate for  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$  is given by

$$\frac{d\Gamma}{dw}(\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell) = \frac{G_F^2 m_B^5}{48\pi^3} |V_{cb}|^2 (w^2 - 1)^{1/2} P(w) (\eta_{\text{ew}} \mathcal{F}(w))^2, \quad (4)$$

where  $P(w)$  is a phase space factor,

$$P(w) = r^3 (1 - r)^2 (w + 1)^2 \left( 1 + \frac{4w}{w + 1} \frac{1 - 2rw + r^2}{(1 - r)^2} \right).$$

with  $r = m_{D^*}/m_B$ . The form factor  $\mathcal{F}(w)$ , which is unity by HQS in the infinite-mass limit, is dominated by the axial vector form factor  $h_{A_1}$  as  $w \rightarrow 1$ . For the definitions of the vector and axial vector form factors as a function of  $w$  see Eq. (2.84) of Ref. 10. The factor  $\eta_{\text{ew}} = 1.015 \pm 0.005$  accounts for the leading electroweak corrections to the four-fermion operator mediating the semileptonic decay [11], and includes an

estimated uncertainty for missing long-distance QED radiative corrections [12].

The determination of  $V_{cb}$  involves an extrapolation to the zero-recoil point. A frequently used one-parameter form for  $\mathcal{F}(w)$  is [13,14]

$$h_{A_1}(w) = \eta_A \left[ 1 + \delta_{1/m^2} + \dots \right] \\ [1 - 8\rho_{A_1}^2 z + (53\rho_{A_1}^2 - 15)z^2 - (231\rho_{A_1}^2 - 91)z^3] \quad (5)$$

with

$$z = (\sqrt{w + 1} - \sqrt{2})/(\sqrt{w + 1} + \sqrt{2}). \quad (6)$$

The use of the variable  $z$  originates from a conformal transformation, which is motivated by analyticity and unitarity. The expansion in this variable converges rapidly in the kinematical region of heavy hadron decays. Expanding in  $w - 1$  one sees that the parameter  $\rho_{A_1}^2$  is the slope of the form factor at  $w = 1$ , and the one parameter form (Eq. (5)) links the curvature (i.e. the coefficient of the second order in the  $w - 1$  expansion) to the slope. All current analyses use the form given in Eq. (5); however, as data become more precise, this simple assumption on the curvature needs to be revised.

The factor  $\eta_A$  is the QCD short-distance radiative correction [15] to the form factor

$$\eta_A = 0.960 \pm 0.007, \quad (7)$$

and  $\delta_{1/m^2}$  comes from non-perturbative  $1/m^2$  corrections, which can be calculated on the lattice (see below).

Precise lattice determinations of the  $B \rightarrow D^{(*)}$  form factors use heavy-quark symmetries, so all uncertainties scale with the deviation of the form factor from unity. The state-of-the-art calculations are “unquenched”, i.e. calculations with realistic sea quarks using  $2 + 1$  flavors. The relevant calculations for the form factor  $\mathcal{F}(w)$  in Ref. 12 quote a total uncertainty at the (1-2)% level. The main contributions to this uncertainty are from the chiral extrapolation from the light quark masses used in the numerical lattice computation to realistic up and down quark masses, and from discretization errors. These sources of uncertainty will be reduced with larger lattice sizes and smaller lattice spacings. Including effects from finite quark masses to calculate the deviation of  $\mathcal{F}(1)$  from unity, the current lattice prediction [12] is

$$\mathcal{F}(1) = 0.906 \pm 0.013, \quad (8)$$

where we take  $\eta_{\text{ew}} = 1.015 \pm 0.005$  [12], appropriate to the mix of  $B^0$  and  $B^+$  decays in the HFAG average, and the errors have been added in quadrature.

Non-lattice estimates based on sum rules for the form factor tend to yield lower values for  $\mathcal{F}(1)$  [16,17,18]. Omitting the contributions from excited states, the sum rules indicate that  $\mathcal{F}(1) < 0.93$ . Including an estimate for the contribution of the excited states yields  $\mathcal{F}(1) = 0.86 \pm 0.01 \pm 0.02$  [18,19] where the second uncertainty accounts for the excited states.

Many experiments [20–28] have measured the differential decay rate as a function of  $w$ , employing a variety of methods:

using either  $B^+$  or  $B^0$  decays, with or without  $B$ -tagging, and with or without explicit reconstruction of the transition pion from  $D^* \rightarrow D$  decays. These measurements are input to a four-dimensional fit [6] for  $\eta_{\text{ew}}\mathcal{F}(1)|V_{cb}|$ ,  $\rho_{A_1}^2$  and the form-factor ratios  $R_1 \propto A_2/A_1$  and  $R_2 \propto V/A_1$ . The fit gives [6]  $\eta_{\text{ew}}\mathcal{F}(1)|V_{cb}| = (35.81 \pm 0.45) \times 10^{-3}$  with a  $p$ -value of 0.15. The leading sources of uncertainty on  $\eta_{\text{ew}}\mathcal{F}(1)|V_{cb}|$  are due to detection efficiencies and  $D^{(*)}$  decay branching fractions.

Along with the lattice value given above for  $\mathcal{F}(1)$  this yields

$$|V_{cb}| = (38.9 \pm 0.5 \pm 0.5 \pm 0.2) \times 10^{-3} \quad (\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell, \text{ LQCD}). \quad (9)$$

where the first error is experimental, the second from lattice QCD and the third from the electroweak and Coulomb correction. The value of  $\mathcal{F}(1)$  obtained from QCD sum rules results in a larger value for  $|V_{cb}|$ :

$$|V_{cb}| = (41.0 \pm 0.5 \pm 1.0) \times 10^{-3} \quad (\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell, \text{ SR}), \quad (10)$$

where the errors are from experiment and theory, respectively.

### $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$

The differential rate for  $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$  is given by

$$\frac{d\Gamma}{dw}(\bar{B} \rightarrow D \ell \bar{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 (m_B + m_D)^2 m_D^3 (w^2 - 1)^{3/2} (\eta_{\text{ew}} \mathcal{G}(w))^2. \quad (11)$$

The form factor is

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D} h_-(w), \quad (12)$$

where  $h_+$  is normalized to unity due to HQS and  $h_-$  vanishes in the infinite-mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D} \frac{\Lambda_{\text{QCD}}}{m_c}\right) \quad (13)$$

and the corrections to the HQET predictions are parametrically larger than was the case for  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$ .

Lattice calculations including effects beyond the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$  is irrelevant. These unquenched calculations provide information over a range of  $z$  values (see Eq. (6)) and can be used in a simultaneous fit, along with the differential branching fraction, in a form-factor expansion in  $z$  [29,30]. This is important, since the experimental precision near  $w = 1$  is poor given the low decay rate in this region.

From the lattice simulations one obtains the form factor normalization at zero recoil:  $\mathcal{G}(1) = 1.033 \pm 0.095$  [31],  $\mathcal{G}(1) = 1.035 \pm 0.040$  [32] and, from Ref. 33,

$$\mathcal{G}(1) = 1.0528 \pm 0.0082. \quad (14)$$

The most precise measurements of  $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$  [27,34] dominate the average [6] value,  $\eta_{\text{ew}}\mathcal{G}(1)|V_{cb}| = (42.65 \pm 1.53) \times 10^{-3}$ . Using the value from Eq. (14) for  $\mathcal{G}(1)$  and accounting for the

electroweak correction [33],  $\eta_{\text{ew}} = 1.012 \pm 0.005$ , appropriate to the mix of  $B^0$  and  $B^+$  decays in the average, gives

$$|V_{cb}| = (40.0 \pm 1.4 \pm 0.3 \pm 0.2) \times 10^{-3} \quad (\bar{B} \rightarrow D \ell \bar{\nu}_\ell, \text{ LQCD}), \quad (15)$$

where the first uncertainty is from experiment, the second from lattice QCD and the third from the QED and Coulomb corrections.

The first  $|V_{cb}|$  determinations using combined fits to experimental and lattice data over a range of  $q^2$  were reported in Refs. 32 and 33; they find values compatible with the result quoted above. A new preliminary result from Belle [35] provides the most precise single determination,  $\eta_{\text{ew}}|V_{cb}| = (41.10 \pm 1.14) \times 10^{-3}$ . Using the same value for  $\eta_{\text{ew}}$  quoted above results in  $|V_{cb}| = (40.6 \pm 1.1) \times 10^{-3}$ . This new determination has not yet been included in the  $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$  average quoted above.

The  $|V_{cb}|$  averages from  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$  and  $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$  decays are consistent, and their uncertainties are largely uncorrelated. Averaging the results from Eqs. (9) and (15) gives

$$|V_{cb}| = (39.2 \pm 0.7) \times 10^{-3} \quad (\text{exclusive}). \quad (16)$$

### $|V_{cb}|$ from inclusive decays

Measurements of the total semileptonic branching decay rate, along with moments of the lepton energy and hadronic invariant mass spectra in inclusive semileptonic  $b \rightarrow c$  transitions, can be used to determine  $|V_{cb}|$ . The total semileptonic decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the moments.

### Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE) [36,37]. Details can be found in the RPP mini-review on Effective Theories [2].

The OPE result for the total rate can be written schematically (details can be found, *e.g.*, in Ref. 38) as

$$\begin{aligned} \Gamma = & |V_{cb}|^2 \frac{G_F^2 m_b^5(\mu)}{192\pi^3} (1 + A_{\text{ew}}) \times \\ & \left[ z_0^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_0^{(1)}(r) + \left( \frac{\alpha_s(\mu)}{\pi} \right)^2 z_0^{(2)}(r) + \dots \right. \\ & + \frac{\mu_\pi^2}{m_b^2} \left( z_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_2^{(1)}(r) + \dots \right) \\ & + \frac{\mu_G^2}{m_b^2} \left( y_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_2^{(1)}(r) + \dots \right) \\ & + \frac{\rho_D^3}{m_b^3} \left( z_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_3^{(1)}(r) + \dots \right) \\ & \left. + \frac{\rho_{\text{LS}}^3}{m_b^3} \left( y_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_3^{(1)}(r) + \dots \right) + \dots \right] \quad (17) \end{aligned}$$

where  $\eta_{\text{ew}} = 1 + A_{\text{ew}}$  denotes the electroweak corrections,  $r$  is the ratio  $m_c/m_b$  and the  $y_i$  and  $z_i$  are functions that appear in the perturbative expansion at different orders of the heavy mass

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

expansion. The parameters  $\mu_\pi$ ,  $\mu_G$ ,  $\rho_D$  and  $\rho_{LS}$  constitute the non-perturbative input into the heavy quark expansion; they correspond to certain matrix elements to be discussed below. Similar expansions give the moments of distributions of charged-lepton energy, hadronic invariant mass and hadronic energy, e.g.

$$\langle E_e^n \rangle_{E_e > E_{\text{cut}}} = \int_{E_{\text{cut}}}^{E_{\text{max}}} \frac{d\Gamma}{dE_e} E_e^n dE_e \bigg/ \int_{E_{\text{cut}}}^{E_{\text{max}}} \frac{d\Gamma}{dE_e} dE_e.$$

The OPE result is known up to order  $1/m_b^5$  at tree level [39–42]. The leading term is the parton model, and is known completely to order  $\alpha_s$  and  $\alpha_s^2$  [43–45]; the terms of order  $\alpha_s^{n+1}\beta_0^n$  (where  $\beta_0$  is the first coefficient of the QCD  $\beta$  function,  $\beta_0 = (33 - 2n_f)/3$ ) have been included by the usual BLM procedure [38,46,47]. Corrections of order  $\alpha_s\mu_\pi^2/m_b^2$  have been computed in Refs. 48 and 49, while the  $\alpha_s\mu_G^2/m_b^2$  terms have been calculated in Refs. 50 and 51.

Starting at order  $1/m_b^3$  contributions with an infrared sensitivity to the charm mass,  $m_c$ , appear [41,52,53]. At order  $1/m_b^3$  this “intrinsic charm” contribution manifests as a  $\log(m_c)$  in the coefficient of the Darwin term  $\rho_D^3$ . At higher orders, terms such as  $1/m_b^3 \times 1/m_c^2$  and  $\alpha_s(m_c)1/m_b^3 \times 1/m_c$  appear, which are comparable in size to the contributions of order  $1/m_b^4$ .

The HQE parameters are given in terms of forward matrix elements; the parameters entering the expansion for orders up to  $1/m_b^3$  are ( $D_\perp^\mu = (g_{\mu\nu} - v_\mu v_\nu)D^\nu$ )

$$\begin{aligned} \bar{\Lambda} &= M_B - m_b, \\ \mu_\pi^2 &= -\langle B | \bar{b} (iD_\perp)^2 b | B \rangle, \\ \mu_G^2 &= \langle B | \bar{b} (iD_\perp^\mu) (iD_\perp^\mu) \sigma_{\mu\nu} b | B \rangle, \\ \rho_D^3 &= \langle B | \bar{b} (iD_{\perp\mu}) (ivD) (iD_\perp^\nu) b | B \rangle, \\ \rho_{LS}^3 &= \langle B | \bar{b} (iD_\perp^\mu) (ivD) (iD_\perp^\nu) \sigma_{\mu\nu} b | B \rangle. \end{aligned} \quad (18)$$

These parameters still depend on the heavy quark mass. Sometimes the infinite mass limits of these parameters  $\bar{\Lambda} \rightarrow \bar{\Lambda}_{\text{HQET}}$ ,  $\mu_\pi^2 \rightarrow -\lambda_1$ ,  $\mu_G^2 \rightarrow 3\lambda_2$ ,  $\rho_D^3 \rightarrow \rho_1$  and  $\rho_{LS}^3 \rightarrow 3\rho_2$ , are used instead. The hadronic parameters of the orders  $1/m_b^4$  and  $1/m_b^5$  have been defined and estimated in Ref. 42. The five hadronic parameters  $s_i$  of the order  $1/m_b^4$  can be found in Ref. 40. These terms have not yet been included in the fits.

The rates and the spectra depend strongly on  $m_b$  (or equivalently on  $\bar{\Lambda}$ ). This makes the discussion of renormalization issues mandatory, since the size of QCD corrections is strongly correlated with the definitions used for the quark masses. For example, it is well known that using the pole mass definition for heavy quark masses leads to a perturbative series for the decay rates that does not converge very well, making a precision determination of  $|V_{cb}|$  in such a scheme impossible.

This motivates the use of “short-distance” mass definitions, such as the kinetic scheme [16] or the 1S scheme [54]. Both schemes have been applied to semileptonic  $b \rightarrow c$  transitions and yield comparable results and uncertainties. The 1S scheme eliminates the  $b$  quark pole mass by relating it to the perturbative expression for the mass of the 1S state of the  $\Upsilon$  system.

The physical mass of the  $\Upsilon(1S)$  contains non-perturbative contributions, which have been estimated in Ref. 55. These non-perturbative contributions are small; nevertheless, the best determination of the  $b$  quark mass in the 1S scheme is obtained from sum rules for  $e^+e^- \rightarrow b\bar{b}$  [56]. Alternatively one may use a short-distance mass definition such as the  $\overline{\text{MS}}$  mass,  $m_b^{\overline{\text{MS}}}(m_b)$ . However, it has been argued that the scale  $m_b$  is unnaturally high for  $B$  decays, while for smaller scales  $\mu \sim 1 \text{ GeV}$   $m_b^{\overline{\text{MS}}}(\mu)$  is under poor control. For this reason the so-called “kinetic mass”  $m_b^{\text{kin}}(\mu)$ , has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy-quark sum rules [16].

### Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays [57–65] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum (0<sup>th</sup>–3<sup>rd</sup>) and of the squared hadronic mass spectrum (0<sup>th</sup>–2<sup>nd</sup>) have statistical uncertainties that are roughly equal to their systematic uncertainties. The sets of moments measured within each experiment have strong correlations; their use in a global fit requires fully specified statistical and systematic covariance matrices. Measurements of photon energy moments (0<sup>th</sup>–2<sup>nd</sup>) in  $B \rightarrow X_s \gamma$  decays [66–70] as a function of the minimum accepted photon energy are also used in some fits; the dominant uncertainties on these measurements are statistical.

Global fits to the full set of moments [65,67,71–76] have been performed in the 1S and kinetic schemes. The semileptonic moments alone determine a linear combination of  $m_b$  and  $m_c$  very accurately but leave the orthogonal combination poorly determined [77]; additional input is required to allow a precise determination of  $m_b$ . This additional information can come from the radiative  $B \rightarrow X_s \gamma$  moments (with the caveat that the OPE for  $b \rightarrow s \gamma$  breaks down beyond leading order in  $\Lambda_{\text{QCD}}/m_b$ ), which provide complementary information on  $m_b$  and  $\mu_\pi^2$ , or from precise determinations of the charm quark mass [78,79]. The values obtained in the kinetic scheme fits [73,75,76] with these two constraints are consistent. Based on the charm quark mass constraint  $m_c^{\overline{\text{MS}}}(3 \text{ GeV}) = 0.986 \pm 0.013 \text{ GeV}$  [80], a recent analysis [76] obtains

$$|V_{cb}| = (42.21 \pm 0.78) \times 10^{-3} \quad (19)$$

$$m_b^{\text{kin}} = 4.553 \pm 0.020 \text{ GeV} \quad (20)$$

$$\mu_\pi^2(\text{kin}) = 0.465 \pm 0.068 \text{ GeV}^2, \quad (21)$$

where the errors include experimental and theoretical uncertainties.

Theoretical uncertainties are estimated and included in performing the fits. Similar values for the parameters are obtained with a variety of assumptions about the theoretical uncertainties and their correlations. The  $\chi^2/\text{dof}$  is substantially below unity in all fits, suggesting that the theoretical uncertainties may be overestimated. While one could obtain a satisfactory fit with smaller uncertainties, this would result in unrealistically small uncertainties on the extracted HQE parameters, which

are used as input to other calculations (e.g. the determination of  $|V_{ub}|$ ). In any case, the low  $\chi^2$  shows no evidence for duality violations at a significant level. The mass in the  $\overline{\text{MS}}$  scheme corresponding to Eq. (20) is  $m_b^{\overline{\text{MS}}} = 4.18 \pm 0.04 \text{ GeV}$ , which can be compared with a value obtained using relativistic sum rules [80],  $m_b^{\overline{\text{MS}}} = 4.163 \pm 0.016 \text{ GeV}$ , and provides a non-trivial cross-check.

A fit to the measured moments in the 1S scheme [74,5] gives

$$|V_{cb}| = (41.98 \pm 0.45) \times 10^{-3} \quad (22)$$

$$m_b^{1\text{S}} = 4.691 \pm 0.037 \text{ GeV} \quad (23)$$

$$\lambda_1(1\text{S}) = -0.362 \pm 0.067 \text{ GeV}^2, \quad (24)$$

This fit uses semileptonic and radiative moments and constrains the chromomagnetic operator using the  $B^*-B$  and  $D^*-D$  mass differences, but does not include the constraint on  $m_c$  nor the full NNLO corrections.

The fits in the two renormalization schemes give consistent results for  $|V_{cb}|$  and, after translation to a common renormalization scheme, for  $m_b$  and  $\mu_\pi^2$ . We take the fit in the kinetic scheme [76], which includes higher-order corrections and results in a more conservative uncertainty, as the inclusive determination of  $|V_{cb}|$ :

$$|V_{cb}| = (42.2 \pm 0.8) \times 10^{-3} \text{ (inclusive)}. \quad (25)$$

The precision of the global fit results can be further improved by calculating higher-order perturbative corrections to the coefficients of the HQE parameters, in particular the still-missing  $\alpha_s \mu_G^2$  corrections, which are presently only known for  $B \rightarrow X_s \gamma$  [81]. The inclusion of still-higher-order moments, if they can be measured with the required precision, may improve the sensitivity of the fits to higher-order terms in the HQE.

## DETERMINATION OF $|V_{ub}|$

*Summary:* The best determinations of  $|V_{ub}|$  are from  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  decays, where combined fits to theory and experimental data as a function of  $q^2$  provide a precision below 5%; the uncertainties from experiment and theory are comparable in size. Determinations based on inclusive semileptonic decays are done based on different observables and using different calculational ansatzes. All determinations are consistent and provide a precision of about 6%, with comparable contributions to the uncertainty from experiment and theory.

The values obtained from inclusive and exclusive determinations are

$$|V_{ub}| = (4.49 \pm 0.16 \pm_{0.18}^{0.16}) \times 10^{-3} \text{ (inclusive)}, \quad (26)$$

$$|V_{ub}| = (3.72 \pm 0.19) \times 10^{-3} \text{ (exclusive)}. \quad (27)$$

The two determinations are independent, and the dominant uncertainties are on multiplicative factors. To combine these values, the inclusive and exclusive values are weighted by their relative errors and the uncertainties are treated as normally

distributed. The resulting average has  $p(\chi^2) = 1.0\%$ , so we scale the error by  $\sqrt{\chi^2/1} = 2.6$  to find

$$|V_{ub}| = (4.09 \pm 0.39) \times 10^{-3} \text{ (average)}. \quad (28)$$

Given the poor consistency between the two determinations, this average should be treated with caution.

### $|V_{ub}|$ from inclusive decays

The theoretical description of inclusive  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays is based on the Heavy Quark Expansion, as for  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays, and leads to a predicted total decay rate with uncertainties below 5% [82,83]. Unfortunately, the total decay rate is hard to measure due to the large background from CKM-favored  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  transitions. Technically, the calculation of the partial decay rate in regions of phase space where  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays are suppressed requires the introduction of a non-perturbative distribution function, the “shape function” (SF) [84,85], whose form is unknown. The shape function becomes important when the light-cone momentum component  $P_+ \equiv E_X - |P_X|$  is not large compared to  $\Lambda_{QCD}$ , as is the case near the endpoint of the  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  lepton spectrum. Partial rates for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  are predicted and measured in a variety of kinematic regions that differ in their sensitivity to shape-function effects.

At leading order a single shape function appears, which is universal for all heavy-to-light transitions [84,85] and can be measured in  $\bar{B} \rightarrow X_s \gamma$  decays. At subleading order in  $1/m_b$ , several shape functions appear [86]. Thus, prescriptions that relate directly the partial rates for  $\bar{B} \rightarrow X_s \gamma$  and  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays [87–90] are limited to leading order in  $1/m_b$ .

Existing approaches have tended to use parameterizations of the leading SF that respect constraints on the normalization and on the first and second moments, which are given in terms of the HQE parameters  $\bar{\Lambda} = M_B - m_b$  and  $\mu_\pi^2$ , respectively. The relations between SF moments and HQE parameters are known to second order in  $\alpha_s$  [91]. As a result, measurements of HQE parameters from global fits to  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  and  $\bar{B} \rightarrow X_s \gamma$  moments can be used to constrain the SF moments, as well as to provide accurate values of  $m_b$  and other parameters for use in determining  $|V_{ub}|$ . The authors of Ref. 92 propose the use of a set of orthogonal basis functions to approximate the SF and thereby include the known short-distance contributions and renormalization properties of the SF; this would allow a global fit of all inclusive  $B$  meson decay data.

The calculations used for the fits performed by HFAG are documented in Ref. 93 (BLNP), Ref. 94 (GGOU), Ref. 95 (DGE) and Ref. 96 (BLL).

The triple differential rate in the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (29)$$

is

$$\frac{d^3\Gamma}{dP_+ dP_- dP_l} = \frac{G_F^2 |V_{ub}|^2}{16\pi^2} (M_B - P_+) \left\{ (P_- - P_l)(M_B - P_- + P_l - P_+) \mathcal{F}_1 \right. \\ \left. + (M_B - P_-)(P_- - P_+) \mathcal{F}_2 + (P_- - P_l)(P_l - P_+) \mathcal{F}_3 \right\}. \quad (30)$$

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

The “structure functions”  $\mathcal{F}_i$  can be calculated using factorization theorems that have been proven to subleading order in the  $1/m_b$  expansion.

The BLNP [93] calculation uses these factorization theorems to write the  $\mathcal{F}_i$  in terms of perturbatively calculable hard coefficients  $H$  and jet functions  $J$ , which are convolved with the (soft) light-cone distribution functions  $S$ , the shape functions of the  $B$  meson. The calculation of  $\mathcal{O}(\alpha_s^2)$  contributions [97,98] is not yet complete and is not included in the  $|V_{ub}|$  determination given below.

The leading order term in the  $1/m_b$  expansion of the  $\mathcal{F}_i$  contains a single non-perturbative function and is calculated to subleading order in  $\alpha_s$ , while at subleading order in the  $1/m_b$  expansion there are several independent non-perturbative functions that have been calculated only at tree level in the  $\alpha_s$  expansion.

A distinct approach (GGOU) [94] uses a hard, Wilsonian cut-off that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite  $m_b$  and depend on the light-cone component  $k_+$  of the  $b$  quark momentum and on the momentum transfer  $q^2$  to the leptons. These functions include subleading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (30). Their  $k_+$  moments can be computed in the OPE and related to observables and to the shape functions defined in Ref. 93.

Going to subleading order in  $\alpha_s$  requires the definition of a renormalization scheme for the HQE parameters and for the SF. The relation between the moments of the SF and the forward matrix elements of local operators is plagued by ultraviolet problems and requires additional renormalization. A scheme for improving this behavior was suggested in Refs. 93 and 99, which introduce a definition of the quark mass (the so-called shape-function scheme) based on the first moment of the measured  $\bar{B} \rightarrow X_s \gamma$  photon energy spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

One can attempt to calculate the SF by using additional assumptions. One approach (DGE) is the so-called “dressed gluon exponentiation” [95], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large  $\beta_0$  limit, where  $\beta_0$  has been defined following Eq. (17).

In order to reduce sensitivity to SF uncertainties, measurements that use a combination of cuts on the leptonic momentum transfer  $q^2$  and the hadronic invariant mass  $m_X$ , as suggested in Ref. 96, have been made. In general, efforts to extend the experimental measurements of  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  into charm-dominated regions (in order to reduce SF uncertainties) lead to an increased experimental sensitivity to the modeling of  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays, resulting in measured partial rates with an undesirable level of model dependence. The measurements quoted below have used

a variety of functional forms to parameterize the leading SF; in no case does this lead to more than a 2% uncertainty on  $|V_{ub}|$ .

Weak Annihilation [100,101,94] (WA) can in principle contribute significantly in the high- $q^2$  region of  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays. Estimates based on semileptonic  $D_s$  decays [101,53,96] lead to a  $\sim 2\%$  uncertainty on the total  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  rate from the  $\Upsilon(4S)$ . The  $q^2$  spectrum of the WA contribution is not well known, but from the OPE it is expected to contribute predominantly at high  $q^2$ . More recent investigations [53,102,103] indicate that WA is a small effect, but may become a significant source of uncertainty for  $|V_{ub}|$  measurements that accept only a small fraction of the full  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  phase space.

### Measurements

We summarize the measurements used in the determination of  $|V_{ub}|$  below. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [104–107] will not be considered in this review.

Inclusive electron momentum measurements [108–110] reconstruct a single charged electron to determine a partial decay rate for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  near the kinematic endpoint. This results in a selection efficiency of order 50% and only modest sensitivity to the modeling of detector response. The inclusive electron momentum spectrum from  $B\bar{B}$  events, after subtraction of the  $e^+e^- \rightarrow q\bar{q}$  continuum background, is fitted to a model  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  spectrum and several components ( $D\ell\bar{\nu}_\ell$ ,  $D^*\ell\bar{\nu}_\ell$ , ...) of the  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  background; the dominant uncertainties are related to this subtraction and modelling. The decay rate can be cleanly extracted for  $E_e > 2.3$  GeV, but this is deep in the SF region, where theoretical uncertainties are large. Measurements with  $E_e > 2.0$  GeV have a low ( $< 1/10$ ) but usable signal-to-background (S/B) ratio. The resulting  $|V_{ub}|$  values for various  $E_e$  cuts are given in Table 1.

An untagged “neutrino reconstruction” measurement [111] from BABAR uses a combination [112] of a high-energy electron with a measurement of the missing momentum vector. This allows S/B  $\sim 0.7$  for  $E_e > 2.0$  GeV and a  $\approx 5\%$  selection efficiency, but at the cost of a smaller accepted phase space for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays and uncertainties associated with the determination of the missing momentum. The corresponding values for  $|V_{ub}|$  are given in Table 1.

The large samples accumulated at the  $B$  factories allow studies in which one  $B$  meson is fully reconstructed and the recoiling  $B$  decays semileptonically [113–117]. The experiments can fully reconstruct a “tag”  $B$  candidate in about 0.5% (0.3%) of  $B^+B^-$  ( $B^0\bar{B}^0$ ) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag  $B$  and the remaining particles are assigned to the  $X_u$  system. The full set of kinematic properties ( $E_\ell$ ,  $m_X$ ,  $q^2$ , etc.) are available for studying the semileptonically decaying  $B$ , making possible selections that accept up to 90% of the full  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  rate. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with additional missing particles, undetected

## Meson Particle Listings

### $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

or mis-measured particles from  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decay (e.g.,  $K_L^0$  and additional neutrinos) remain an important source of uncertainty. Measurements with the largest kinematic acceptance (i.e.  $E_\ell > 1 \text{ GeV}$ ) lead to the smallest overall uncertainties on  $|V_{ub}|$ .

BABAR [113] and Belle [114,115] have measured partial rates with cuts on  $m_X$ ,  $m_X$  and  $q^2$ ,  $P_+$  and  $E_\ell$  using the recoil method. In each case the experimental systematics have significant contributions from the modeling of  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  and  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays and from the detector response to charged particles, photons and neutral hadrons. The corresponding  $|V_{ub}|$  values are given in Table 1.

#### $|V_{ub}|$ from inclusive partial rates

The measured partial rates and theoretical calculations from BLNP, GGOU and DGE described previously are used to determine  $|V_{ub}|$  from all measured partial  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  rates [6]; selected values are given in Table 1. The correlations amongst the multiple BABAR recoil-based measurements [113] are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments. As an illustration of the relative sizes of the uncertainties entering  $|V_{ub}|$  we give the error breakdown for the GGOU average: statistical—1.9%; experimental—1.7%;  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  modeling—1.3%;  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  modeling—1.9%; HQE parameters ( $m_b$ ) —1.6%; higher-order corrections—1.5%;  $q^2$  modeling—1.4%; Weak Annihilation— $^{+0.0\%}_{-2.0\%}$ ; SF parameterization—0.2%.

The averages quoted here are based on the following  $m_b$  values:  $m_b^{SF} = 4.569 \pm 0.029 \text{ GeV}$  for BLNP,  $m_b^{\text{kin}} = 4.541 \pm 0.023 \text{ GeV}$  for GGOU, and  $m_b^{MS} = 4.177 \pm 0.043 \text{ GeV}$  for DGE. The  $m_b^{\text{kin}}$  value is determined in a global fit to moments in the kinetic scheme; this value is translated into  $m_b^{SF}$  and  $m_b^{MS}$  at fixed order in  $\alpha_s$ . These input values are based on an earlier determination of  $m_b^{\text{kin}}$  than is quoted in equation Eq. (20); using the latest value would decrease the  $|V_{ub}|$  averages by 1-2%.

The theoretical calculations produce very similar results for  $|V_{ub}|$ ; the standard deviation of the  $|V_{ub}|$  values for the  $E_\ell > 2.1 \text{ GeV}$  rate is 4.9%, for the  $m_X - q^2$  rate is 0.6%, and for the  $E_\ell > 1 \text{ GeV}$  rate is 1.6%. The  $|V_{ub}|$  values do not show a marked trend versus the kinematic acceptance,  $f_u$ , for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays. The  $p$ -values of the averages are in the range 55-62%, indicating that the ratios of calculated partial widths in the different phase space regions are in good agreement with ratios of measured partial branching fractions.

Hadronization uncertainties also impact the  $|V_{ub}|$  determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (e.g.  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ ); this must be added to the simulated  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The

**Table 1:**  $|V_{ub}|$  (in units of  $10^{-5}$ ) from inclusive  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  measurements. The first uncertainty on  $|V_{ub}|$  is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are listed in order of increasing kinematic acceptance  $f_u$  (0.19 to 0.90); those below the horizontal bar are based on recoil methods.

experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables ( $q^2, E_\ell, m_X$ ) averaged over the sample, but these prescriptions are *ad hoc*. The resulting uncertainties have been estimated to be  $\sim 1\text{-}2\%$  on  $|V_{ub}|$ .

All calculations yield compatible  $|V_{ub}|$  values and similar error estimates. We take the arithmetic mean of the values and errors to find

$$|V_{ub}| = (4.49 \pm 0.16_{\text{exp}} \begin{smallmatrix} +0.16 \\ -0.18 \end{smallmatrix}_{\text{theo}}) \times 10^{-3} \quad (\text{inclusive}). \quad (31)$$

The BLL [96] calculation has been used along with measurements [113,114,118] with cuts on  $m_X$  and  $q^2$  to determine  $|V_{ub}|$ . Using  $m_b^{\text{IS}} = 4.704 \pm 0.029 \text{ GeV}$  yields a  $|V_{ub}|$  value of  $(4.62 \pm 0.20 \pm 0.29) \times 10^{-3}$ , which is somewhat larger than the corresponding values listed in Table 1.

#### $|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining  $|V_{ub}|$ . For the experiments, the specification of the final state provides better background rejection, but the branching fraction to a specific final state is typically only a few percent of that for inclusive decays. For theory, the calculation of the form factors for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ , as it is the most promising mode for both experiment and theory. Measurements of other exclusive  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  states can be found in Refs. [119–126].

#### $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ form factor calculations

The relevant form factors for the decay  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  are usually defined as

$$\langle \pi(p_\pi) | V^\mu | B(p_B) \rangle = \quad (32)$$

$$f_+(q^2) \left[ p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \right] + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q^\mu$$

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

in terms of which the rate becomes (in the limit  $m_\ell \rightarrow 0$ )

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_\pi|^3 |f_+(q^2)|^2, \quad (33)$$

where  $p_\pi$  is the pion momentum in the  $B$  meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD (LQCD) and light-cone sum rules (LCSR). The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer  $q^2$  to the leptons, while light-cone sum rules provide information near  $q^2 = 0$ . Interpolations between these two regions can be constrained by unitarity and analyticity.

Unquenched simulations, i.e. where quark loop effects are fully incorporated, are now standard, and have been performed by the Fermilab/MILC [127], the HPQCD [128] and the RBC/UKQCD [129] collaborations. The calculations differ in the way the  $b$  quark is simulated, with HPQCD using nonrelativistic QCD, and Fermilab/MILC and RBC/UKQCD using relativistic  $b$  quarks with the Fermilab and Columbia heavy-quark formulations; they agree within the quoted errors. The result from Ref. 127 represents a significant improvement in precision. The form factor  $f_+$  evaluated at  $q^2 = 20 \text{ GeV}^2$  has an estimated uncertainty of 3.4%, where the leading contribution is due to the chiral-continuum extrapolation fit, which includes statistical and heavy-quark discretization errors. However, the lattice simulations are restricted to the region of large  $q^2$ , i.e. the region  $q_{\text{max}}^2 > q^2 \gtrsim 15 \text{ GeV}^2$ .

The extrapolation to small values of  $q^2$  is performed using guidance from analyticity and unitarity. Making use of the heavy-quark limit, stringent constraints on the shape of the form factor can be derived [130], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in the variable

$$z = \frac{\sqrt{t_+ - t_-} - \sqrt{t_+ - q^2}}{\sqrt{t_+ - t_-} + \sqrt{t_+ - q^2}}$$

where  $t_\pm = (M_B \pm m_\pi)^2$ . The use of lattice data in combination with experimental measurements of the differential decay rate provides a stringent constraint on the shape of the form factor in addition to precise determination of  $|V_{ub}|$  [131].

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR). The sum-rule approach provides an estimate for the product  $f_B f_+(q^2)$ , valid in the region  $0 < q^2 \lesssim 12 \text{ GeV}^2$ . The determination of  $f_+(q^2)$  itself requires knowledge of the decay constant  $f_B$ , which is usually obtained by replacing  $f_B$  by its two-point QCD (SVZ) sum rule [132] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio  $(f_B f_+)/f_B$ .

The LCSR for  $f_B f_+$  is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite  $b$ -quark mass. The resulting expressions actually

**Table 2:** Total and partial branching fractions for  $\bar{B}^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$ .  $B$ -tagged analyses are indicated (SL for *semileptonic*, Had for *hadronic*). The first uncertainty listed is from statistics, the second from systematics. Measurements of  $\mathcal{B}(B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell)$  have been multiplied by a factor  $2\tau_{B^0}/\tau_{B^+}$  to obtain the values below.

comprise a triple expansion: in the twist  $t$  of the operators near the light-cone, in  $\alpha_s$ , and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry. The sources of uncertainties in the LCSR calculation are discussed in Refs. 133 and 134; currently the total uncertainty slightly larger than 10% on  $|V_{ub}|$  is obtained from a LCSR calculation of

$$\begin{aligned} \Delta\zeta(0, q_{\text{max}}^2) &= \frac{G_F^2}{24\pi^3} \int_0^{q_{\text{max}}^2} dq^2 p_\pi^3 |f_+(q^2)|^2 \\ &= \frac{1}{|V_{ub}|^2 \tau_{B^0}} \int_0^{q_{\text{max}}^2} dq^2 \frac{d\mathcal{B}(B \rightarrow \pi \ell \nu)}{dq^2} \end{aligned} \quad (34)$$

which gives [135]

$$\Delta\zeta(0, 12 \text{ GeV}^2) = 4.59_{-0.85}^{+1.00} \text{ ps}^{-1}. \quad (35)$$

The recent calculation of two loop contributions to the LCQCD sum rules [136] and the estimation of statistical correlations [137] results in only small changes to the central value and uncertainty.

### $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ measurements

The  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second  $B$  meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance and S/B as high as 10, but low statistics. The untagged measurements have somewhat higher background levels ( $S/B < 1$ ) and make slightly more restrictive kinematic cuts, but provide better precision on the  $q^2$  dependence of the form factor.

CLEO has analyzed  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  and  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$  using an untagged analysis [124]. Similar analyses have been done at BABAR [125,126] and Belle [139]. The leading systematic uncertainties in the untagged  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  analyses are associated with modeling the missing momentum reconstruction, with backgrounds from  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays and  $e^+e^- \rightarrow q\bar{q}$  continuum events, and with varying the form factor for the  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$  decay. The values obtained for the full and partial branching fractions [6] are listed in Table 2 above the horizontal line. These BABAR and Belle measurements provide the differential  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  rate versus  $q^2$ , shown in Fig. 1, which is used in the determination of  $|V_{ub}|$  discussed below.

Analyses [140,141] based on reconstructing a  $B$  in the  $\bar{D}^{(*)} \ell^+ \nu_\ell$  decay mode and looking for a  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  or  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$  decay amongst the remaining particles in the event make use of the fact that the  $B$  and  $\bar{B}$  are back-to-back in the  $\Upsilon(4S)$  frame to construct a discriminant variable that provides a signal-to-noise ratio above unity for all  $q^2$  bins. A related technique was discussed in Ref. 143. BABAR [141] and Belle [119] have also used their samples of  $B$  mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays, resulting in very clean but small samples. The corresponding full and partial branching fractions are given in Table 2. The averages take account of correlations and common systematic uncertainties, and have  $p(\chi^2) > 0.5$  in each case.

**Figure 1:** The differential  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  branching fraction versus  $q^2$  for untagged measurements along with a combined fit to lattice calculations from Ref. 127.

$|V_{ub}|$  can be obtained from the average  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  branching fraction and the measured  $q^2$  spectrum. Fits to the  $q^2$  spectrum using a theoretically motivated parameterization (e.g. "BCL" from Ref. 138) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum. The most sensitive method for determining  $|V_{ub}|$  from  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  decays employs a simultaneous fit [6,127,144] to measured

experimental partial rates and lattice points versus  $q^2$  (or  $z$ ) to determine  $|V_{ub}|$  and the first few coefficients of the expansion of the form factor in  $z$ . The most precise determination at present is from Ref. 127, which uses as experimental input the measurements in Refs. [119,125,126,139], and finds  $|V_{ub}| = (3.72 \pm 0.16) \times 10^{-3}$ . This fit, shown in Fig. 1, has  $p(\chi^2) = 2\%$ . We scale the quoted uncertainty by  $\sqrt{\chi^2/\text{d.o.f.}} = 1.2$  to find

$$|V_{ub}| = (3.72 \pm 0.19) \times 10^{-3} \quad (\text{exclusive}). \quad (36)$$

We note that fits that exclude the data of Ref. 125 have larger  $p(\chi^2)$  and result in higher  $|V_{ub}|$  values between  $3.8 \times 10^{-3}$  and  $4.0 \times 10^{-3}$ . The contributions to the uncertainty from the lattice calculation and from the experimental measurements are comparable.

An alternative approach using the average [6] of partial branching fractions in the  $q^2 < 12 \text{ GeV}^2$  region,  $(0.81 \pm 0.02 \pm 0.02) \times 10^{-4}$ , along with an LCSR calculation of the theoretical rate [135], gives

$$|V_{ub}| = (3.41 \pm 0.06_{\text{exp}}^{+0.37}_{-0.32} \text{theo}) \times 10^{-3} \quad (\text{LCSR}, q^2 < 12 \text{ GeV}^2). \quad (37)$$

#### SEMILEPTONIC $B$ -BARYON DECAYS AND DETERMINATION OF $|V_{ub}|/|V_{cb}|$

*Summary:* A significant sample of  $\Lambda_b^0$  baryons is available at the LHCb experiment, and methods have been developed to study their semileptonic decays. Both  $\Lambda_b^0 \rightarrow p \mu \bar{\nu}$  and  $\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \bar{\nu}$  decays have been measured at LHCb, and the ratio of branching fractions to these two decay modes is used to determine the ratio  $|V_{ub}|/|V_{cb}|$ . Averaging the LHCb determination with those obtained from inclusive and exclusive  $B$  meson decays, we find

$$|V_{ub}|/|V_{cb}| = 0.096 \pm 0.007 \quad (\text{average})$$

where the uncertainty has been scaled by a factor  $\sqrt{\chi^2/\text{ndf}} = 2.0$ . In light of the poor consistency of the three determinations considered, the average should be treated with caution.

#### $\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \bar{\nu}$ and $\Lambda_b^0 \rightarrow p \mu \bar{\nu}$

The  $\Lambda_b^0 \rightarrow \Lambda_c^+$  and  $\Lambda_b^0 \rightarrow p$  semileptonic transitions are described in terms of six form factors each. The three form factors corresponding to the vector current can be defined as [145]

$$\begin{aligned} \langle F(p', s') | \bar{q} \gamma_\mu b | \Lambda_b^0(p, s) \rangle = & \bar{u}_F(p', s') \left\{ f_0(q^2) (M_{\Lambda_b^0} - m_F) \frac{q_\mu}{q^2} \right. \\ & + f_+(q^2) \frac{M_{\Lambda_b^0} + m_F}{s_+} \left( p_\mu + p'_\mu - \frac{q_\mu}{q^2} (M_{\Lambda_b^0}^2 - m_F^2) \right) \\ & \left. + f_\perp(q^2) \left( \gamma_\mu - \frac{2m_F}{s_+} p_\mu - \frac{2M_{\Lambda_b^0}}{s_+} p'_\mu \right) \right\} u_{\Lambda_b^0}(p, s), \quad (38) \end{aligned}$$

where  $F = p$  or  $\Lambda_c^+$  and where we define  $s_\pm = (M_{\Lambda_b^0} \pm m_F)^2 - q^2$ . At vanishing momentum transfer,  $q^2 \rightarrow 0$ , the kinematic constraint  $f_0(0) = f_+(0)$  holds. The form factors are defined in such a way that they correspond to time-like

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

(scalar), longitudinal and transverse polarization with respect to the momentum-transfer  $q^\mu$  for  $f_0$ ,  $f_+$  and  $f_\perp$ , respectively. Furthermore we have chosen the normalization in such a way that for  $f_0, f_+, f_\perp \rightarrow 1$  one recovers the expression for point-like baryons.

Likewise, the expression for the axial-vector current is

$$\begin{aligned} \langle F(p', s') | \bar{q} \gamma_\mu \gamma_5 b | \Lambda_b^0(p, s) \rangle = & -\bar{u}_F(p', s') \gamma_5 \\ & \left\{ g_0(q^2) (M_{\Lambda_b^0} + m_F) \frac{q_\mu}{q^2} \right. \\ & + g_+(q^2) \frac{M_{\Lambda_b^0} - m_F}{s_-} \left( p_\mu + p'_\mu - \frac{q_\mu}{q^2} (M_{\Lambda_b^0}^2 - m_F^2) \right) \\ & \left. + g_\perp(q^2) \left( \gamma_\mu + \frac{2m_F}{s_-} p_\mu - \frac{2M_{\Lambda_b^0}}{s_-} p'_\mu \right) \right\} u_{\Lambda_b^0}(p, s), \quad (39) \end{aligned}$$

with the kinematic constraint  $g_0(0) = g_+(0)$  at  $q^2 \rightarrow 0$ .

The form factors have been discussed in the heavy quark limit; assuming both  $b$  and  $c$  as heavy, all the form factors  $f_i$  and  $g_i$  turn out to be identical [145]

$$f_0 = f_+ = f_\perp = g_0 = g_+ = g_\perp = \xi_B \quad (40)$$

and equal to the Isgur Wise function  $\xi_B$  for baryons. In the limit of a light baryon in the final state, the number of independent form factors is still reduced to two through the heavy quark symmetries of the  $\Lambda_b^0$ . It should be noted that the  $\Lambda_b^0 \rightarrow (p/\Lambda_c^+) \mu \nu$  decay rates peak at high  $q^2$ , which facilitates both lattice QCD calculations and experimental measurements.

The form factors for  $\Lambda_b^0$  decays have been studied on the lattice [146]. Based on these results the differential rates for both  $\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \nu$  as well as for  $\Lambda_b^0 \rightarrow p \mu \nu$  can be predicted in the full phase space. In particular, for the experimentally interesting region they find the ratio of decay rates to be [146]

$$\frac{\mathcal{B}(\Lambda_b^0 \rightarrow p \mu \bar{\nu})_{q^2 > 15 \text{ GeV}^2}}{\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \bar{\nu})_{q^2 > 7 \text{ GeV}^2}} = (1.471 \pm 0.095 \pm 0.109) \left| \frac{V_{ub}}{V_{cb}} \right|^2 \quad (41)$$

where the first uncertainty is statistical and the second, systematic.

### Measurements at LHCb

The LHCb experiment has measured the branching fractions of the semileptonic decays  $\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \bar{\nu}$  and  $\Lambda_b^0 \rightarrow p \mu \bar{\nu}$ , from which they determine  $|V_{ub}|/|V_{cb}|$ . This is the first such determination at a hadron collider, the first to use a  $b$  baryon decay, and the first observation of  $\Lambda_b^0 \rightarrow p \mu \bar{\nu}$ . Excellent vertex resolution allows the  $p\mu$  and production vertices to be separated, which permits the calculation of the transverse momentum  $p_\perp$  of the  $p\mu$  pair relative to the  $\Lambda_b^0$  flight direction. The corrected mass,  $m_{\text{corr}} = \sqrt{p_\perp^2 + m_{p\mu}^2}$ , peaks at the  $\Lambda_b^0$  mass for signal decays and provides good discrimination against background combinations. The topologically similar decay  $\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \bar{\nu}$  is also measured, which eliminates the need to know the production cross-section or absolute efficiencies. Using vertex and  $\Lambda_b^0$  mass constraints,  $q^2$  can be determined up to a two-fold ambiguity. The LHCb analysis requires both solutions to be in

the high  $q^2$  region to minimise contamination from the low  $q^2$  region. They find [147]

$$\frac{\mathcal{B}(\Lambda_b^0 \rightarrow p \mu \bar{\nu})_{q^2 > 15 \text{ GeV}^2}}{\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \mu \bar{\nu})_{q^2 > 7 \text{ GeV}^2}} = (1.00 \pm 0.04 \pm 0.08) \times 10^{-2} \quad (42)$$

The largest systematic uncertainty is from knowledge of the branching fraction  $\mathcal{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)$ ; uncertainties due to trigger, tracking and the  $\Lambda_c^+$  selection efficiency are each about 3%.

### The ratio $|V_{ub}|/|V_{cb}|$

The ratio of matrix elements,  $|V_{ub}|/|V_{cb}|$ , is often required when testing the compatibility of a set of measurements with theoretical predictions. It can be determined from the ratio of branching fractions measured by the LHCb experiment, quoted in the previous section. It can also be calculated based on the  $|V_{ub}|$  and  $|V_{cb}|$  values quoted earlier in this review.

As previously noted, the decay rate for  $\Lambda_b^0 \rightarrow p \mu \bar{\nu}$  peaks at high  $q^2$  where the calculation of the associated form factors using lattice QCD is under good control. Using the measured ratio from Eq. (42) along with the calculations of Ref. 146 results in

$$|V_{ub}|/|V_{cb}| = 0.083 \pm 0.006 \quad (\text{LHCb}). \quad (43)$$

Given the similarities in the theoretical frameworks used for charmed and charmless decays, we choose to quote the ratio  $|V_{ub}|/|V_{cb}|$  separately for inclusive and exclusive decays:

$$|V_{ub}|/|V_{cb}| = 0.107 \pm 0.006 \quad (\text{inclusive}), \quad (44)$$

$$|V_{ub}|/|V_{cb}| = 0.095 \pm 0.005 \quad (\text{exclusive}). \quad (45)$$

We average these values, along with the result in Eq. (43), weighting by relative errors. The average has  $p(\chi^2) = 1.8\%$ , so we scale the uncertainty by a factor 2.0 to find

$$|V_{ub}|/|V_{cb}| = 0.096 \pm 0.007 \quad (\text{average}). \quad (46)$$

### SEMITAUONIC DECAYS

*Summary:* Semileptonic decays to third-generation leptons provide sensitivity to non-Standard Model amplitudes, such as from a charged Higgs boson [148]. The ratios of branching fractions of semileptonic decays involving tau leptons to those involving  $e/\mu$ ,  $\mathcal{R}_{D^{(*)}} \equiv \mathcal{B}(\bar{B} \rightarrow D^{(*)} \tau \bar{\nu}_\tau) / \mathcal{B}(\bar{B} \rightarrow D^{(*)} \ell \bar{\nu}_\ell)$ , are predicted with good precision in the Standard Model [32,33,149,150]. We use the most precise values from lattice QCD for  $\mathcal{R}_D$  [32], and for  $\mathcal{R}_{D^*}$  we use a calculation based on the heavy quark expansion, combined with the measurements for  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$  [150]

$$\begin{aligned} \mathcal{R}_D^{\text{SM}} &= 0.300 \pm 0.008, \\ \mathcal{R}_{D^*}^{\text{SM}} &= 0.252 \pm 0.003. \end{aligned} \quad (47)$$

Measurements [151–157] of these ratios yield higher values; averaging B-tagged measurements of  $\mathcal{R}_D$  and  $\mathcal{R}_{D^*}$  at the  $\Upsilon(4S)$  and the LHCb measurement of  $\mathcal{R}_D$  yields

$$\begin{aligned} \mathcal{R}_D^{\text{meas}} &= 0.391 \pm 0.050 \\ \mathcal{R}_{D^*}^{\text{meas}} &= 0.322 \pm 0.022 \end{aligned} \quad (48)$$

These values exceed Standard Model predictions by  $1.7\sigma$  and  $3.0\sigma$ , respectively. A variety of new physics models have been proposed [148,156–160] to explain this excess. The potential impact of any new physics in this decay mode on the  $|V_{ub}|$  and  $|V_{cb}|$  results given above is expected to be negligible.

#### Sensitivity of $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_\tau$ to additional amplitudes

In addition to the helicity amplitudes present for decays to  $e\bar{\nu}_e$  and  $\mu\bar{\nu}_\mu$ , decays proceeding through  $\tau\bar{\nu}_\tau$  include a scalar amplitude  $H_s$ . The differential decay rate is given by [161]

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{cb}|^2 |\mathbf{p}_{D^{(*)}}^*|^2}{96\pi^3 m_B^2} \left(1 - \frac{m_\tau^2}{q^2}\right)^2 \left[ (|H_+|^2 + |H_-|^2 + |H_0|^2) \left(1 + \frac{m_\tau^2}{2q^2}\right) + \frac{3m_\tau^2}{2q^2} |H_s|^2 \right], \quad (49)$$

where  $|\mathbf{p}_{D^{(*)}}^*|$  is the 3-momentum of the  $D^{(*)}$  in the  $\bar{B}$  rest frame and the helicity amplitudes  $H$  depend on the four-momentum transfer  $q^2$ . All four helicity amplitudes contribute to  $\bar{B} \rightarrow D^*\tau\bar{\nu}_\tau$ , while only  $H_0$  and  $H_s$  contribute to  $\bar{B} \rightarrow D\tau\bar{\nu}_\tau$ ; as a result, new physics contributions tend to produce larger effects in the latter mode.

The (semi)-leptonic  $B$  decays into a  $\tau$  lepton provide a stringent test of the two-Higgs doublet model of type II (2HDMII), i.e. where the two Higgs doublets couple separately to up- and down-type quarks. This is also of relevance for Supersymmetry, since this corresponds to the Higgs sector of any commonly used supersymmetric model. These models involve additional charged scalar particles, which contribute at tree level to the (semi)-leptonic  $B$  decays into a  $\tau$ . The distinct feature of the 2HDMII is that the contributions of the charged scalars scale as  $m_\tau^2/m_{H^\pm}^2$ , since the couplings to the charged Higgs particles are proportional to the mass of the lepton. As a consequence, one may expect visible effects in decays into a  $\tau$ , but only small effects for decays into  $e$  and  $\mu$ .

As discussed in the next section, the 2HDMII does not describe the observations any better than the Standard Model. To achieve a better description one has to extend the analysis to other models, where the scaling of the new contributions with the lepton mass is different.

#### Measurement of $\mathcal{R}_{D^{(*)}}$

$\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_\tau$  decays have been studied at the  $\Upsilon(4S)$  resonance and in  $pp$  collisions.

At the  $\Upsilon(4S)$ , the experimental signature consists of a  $D$  or  $D^*$  meson, an electron or muon (denoted here by  $\ell$ ) from the decay  $\tau \rightarrow \ell\nu_\tau\bar{\nu}_\ell$ , a fully-reconstructed hadronic decay of the second  $B$  meson in the event, and multiple missing neutrinos. The signal decays are separated from  $\bar{B} \rightarrow D^{(*)}\ell\bar{\nu}_\ell$  decays using the lepton momentum and the measured missing mass squared; decays with only a single missing neutrino peak sharply at zero in this variable, while the signal is spread out to positive values. Background from  $\bar{B} \rightarrow D^{**}\ell\bar{\nu}_\ell$  decays with one or more unreconstructed particles is harder to separate from signal, as is background from  $\bar{B} \rightarrow D^{(*)}H_c X$  (where  $H_c$  is a hadron containing a  $\bar{c}$  quark) decays. The leading sources of

systematic uncertainty are due to the limited size of simulation samples used in constructing the PDFs, the composition of the  $D^{**}$  states, efficiency corrections, and cross-feed (swapping soft particles between the signal and tag  $B$ ).

The LHCb experiment has studied the decay  $\bar{B} \rightarrow D^{*+}\tau\bar{\nu}_\tau$  with  $D^{*+} \rightarrow D^0\pi^+$ ,  $D^0 \rightarrow K^-\pi^+$  and  $\tau \rightarrow \mu\nu_\tau\bar{\nu}_\mu$  in  $pp$  collisions. Their analysis takes advantage of the measurable flight lengths of  $b$  and  $c$  hadrons and  $\tau$  leptons. A multivariate discriminant is used to select decays where no additional charged particles are consistent with coming from the signal decay vertices. The separation between the primary and  $B$  decay vertices is used to calculate the momentum of the  $B$  decay products transverse to the  $B$  flight direction. The longitudinal component of the  $B$  momentum can be estimated based on the visible decay products; this allows a determination of the  $B$  rest frame, with modest resolution, and enables the calculation of the same discrimination variables available at the  $e^+e^- B$  factories. The (rest frame) muon energy, missing mass-squared and  $q^2$  are used in a 3- $d$  fit. The leading sources of systematic uncertainty are due to the size of the simulation sample used in constructing the fit templates, the shape of the muon misidentification template, and uncertainties in modelling the background from  $\bar{B} \rightarrow D^{**}\ell\bar{\nu}_\ell$  and  $\bar{B} \rightarrow D^{(*)}H_c X$  decays.

Measurements from Belle [152–154], BABAR [155,151] and LHCb [157] result in values for  $\mathcal{R}_D$  and  $\mathcal{R}_{D^*}$  that exceed Standard Model predictions. Table 3 lists these values and their average. The measurements of  $\mathcal{R}_D$  and  $\mathcal{R}_{D^*}$  have linear correlation coefficients of  $-0.27$  (BABAR) and  $-0.49$  (Belle); the averaged values have a correlation of  $-0.29$ . Two untagged Belle measurements [152,153] are subject to larger systematic uncertainties; we do not include them in our average.

**Table 3:** Measurements of  $\mathcal{R}_D$  and  $\mathcal{R}_{D^*}$ . The averages correspond to the values in the upper portion of the table.

	$\mathcal{R}_D \times 10^2$	$\mathcal{R}_{D^*} \times 10^2$
BABAR [151] $B^0, B^+$	$44.0 \pm 5.8 \pm 4.2$	$33.2 \pm 2.4 \pm 1.8$
Belle [154] $B^0, B^+$	$37.5 \pm 6.4 \pm 2.6$	$29.3 \pm 3.8 \pm 1.5$
LHCb [157] $B^0$		$33.6 \pm 2.7 \pm 3.0$
Average $B^0, B^+$	$39.1 \pm 4.1 \pm 2.8$	$32.2 \pm 1.8 \pm 1.2$

The tension between the SM prediction and the measurements is at the level of  $1.7\sigma$  ( $\mathcal{R}_D$ ) and  $3.0\sigma$  ( $\mathcal{R}_{D^*}$ ); if one considers these deviations together the significance rises to  $3.9\sigma$ . This motivates speculation on possible new physics contributions. It is striking that an interpretation in terms of the 2HDMII seems to be ruled out by the data. Fig. 2 shows that the interpretation of the deviation of  $\mathcal{R}_D$  in terms of the 2HDMII requires vastly different values of the relevant parameter  $\tan\beta/m_{H^\pm}$  than for  $\mathcal{R}_{D^*}$ , excluding this possibility. All three experiments assume the Standard Model kinematic distributions for  $\bar{B} \rightarrow D^{(*)}\tau\bar{\nu}_\tau$  in their determinations of the branching fraction ratio. The BABAR [151] and Belle [154] analyses use

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

kinematical distributions from the 2HDMII when comparing the compatibility of their measurements with predictions; this is why the band in Fig. 2 corresponding to the measurement varies with  $\tan\beta/m_{H^+}$ . In general, new physics contributions with a different operator structure to the SM could modify  $R_{D^{(*)}}$  from the measured values, and could have a different effect in different experiments.

**Figure 2:** The  $R_{D^{(*)}}$  measured in Ref. 151 along with expectations in the 2HDMII as a function of  $\tan\beta/m_{H^+}$ .

A more general approach has been formulated in Ref. 159 on the basis of an effective field theory. Assuming lepton-flavour-universality-violating operators of dimension six and eight, the coefficients of these operators can be fitted to the observed values. Although a detailed analysis along these lines requires more data on related decays (such as  $B \rightarrow \pi\tau\bar{\nu}$ ), there are indications that the tension in  $R_{D^{(*)}}$  cannot be explained by a minimally flavor-violating scenario with only left-handed interactions; a better fit is obtained once right-handed and scalar currents are included.

## CONCLUSION

The study of semileptonic  $B$  meson decays continues to be an active area for both theory and experiment. The application of HQE calculations to inclusive decays is mature, and fits to moments of  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays provide precise values for  $|V_{cb}|$  and, in conjunction with input on  $m_c$  or from  $B \rightarrow X_s \gamma$  decays, provide precise and consistent values for  $m_b$ .

The determination of  $|V_{ub}|$  from inclusive  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays is based on multiple calculational approaches and independent measurements over a variety of kinematic regions, all of which provide consistent results. Further progress in this area is possible, but will require better theoretical control over higher-order terms, improved experimental knowledge of the  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  background and improvements to the modeling of the  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  signal distributions.

In both  $b \rightarrow u$  and  $b \rightarrow c$  exclusive channels there has been significant recent progress in lattice-QCD calculations, resulting in improved precision on both  $|V_{ub}|$  and  $|V_{cb}|$ . These calculations now provide information on the form factors well away from the high  $q^2$  region, allowing better use of experimental data. Projections for future uncertainties from lattice calculations can be found in Ref. 162.

The values from the inclusive and exclusive determinations of both  $|V_{cb}|$  and  $|V_{ub}|$  are only marginally consistent. This is a long-standing puzzle, and the new measurement of  $|V_{ub}|/|V_{cb}|$  from LHCb based on  $\Lambda_b^0$  decays does not simplify the picture.

Both  $|V_{cb}|$  and  $|V_{ub}|$  are indispensable inputs into unitarity triangle fits. In particular, knowing  $|V_{ub}|$  with good precision allows a test of CKM unitarity in a most direct way, by comparing the length of the  $|V_{ub}|$  side of the unitarity triangle with the measurement of  $\sin(2\beta)$ . This comparison of a “tree” process ( $b \rightarrow u$ ) with a “loop-induced” process ( $B^0 - \bar{B}^0$  mixing) provides sensitivity to possible contributions from new physics.

The observation of semileptonic decays into  $\tau$  leptons has opened a new window to the physics of the third generation. The measurements indicate a tension between the data and the Standard Model prediction, which could be a hint to new physics. However, the most prominent and simplest candidate, the 2HDMII, cannot explain the current data. More general ansatzes fit the data, but do not provide deeper insight until measurements of related processes (such as  $B \rightarrow \pi\tau\bar{\nu}$ ) are available.

The authors would like to acknowledge helpful input from C. Bozzi, P. Gambino, A. Kronfeld, P. Owen, C. Schwanda, S. Stone and R. Van de Water.

<sup>1</sup> Uses fully reconstructed  $D^{*-}\ell^+\nu$  events ( $\ell = e$  or  $\mu$ ).

<sup>2</sup> Obtained from a global fit to  $B \rightarrow D^{(*)}\ell\nu_\ell$  events, with reconstructed  $D^0\ell$  and  $D^+\ell$  final states and  $\rho^2 = 1.22 \pm 0.02 \pm 0.07$ .

<sup>3</sup> Measured using the dependence of  $B^- \rightarrow D^{*0}e^-\bar{\nu}_e$  decay differential rate and the form factor description by CAPRINI 98 with  $\rho^2 = 1.16 \pm 0.06 \pm 0.08$ .

<sup>4</sup> Measurement using fully reconstructed  $D^*$  sample with a  $\rho^2 = 1.32 \pm 0.15 \pm 0.33$ .

<sup>5</sup> Average of the  $B^0 \rightarrow D^{*}(2010)^-\ell^+\nu$  and  $B^+ \rightarrow \bar{D}^{*}(2007)\ell^+\nu$  modes with  $\rho^2 = 1.61 \pm 0.09 \pm 0.21$  and  $f_{+,-} = 0.521 \pm 0.012$ .

<sup>6</sup> ABREU 01H measured using about 5000 partial reconstructed  $D^*$  sample with a  $\rho^2 = 1.34 \pm 0.14 \pm \begin{smallmatrix} +0.24 \\ -0.22 \end{smallmatrix}$ .

<sup>7</sup> ABBIENDI 00Q: measured using both inclusively and exclusively reconstructed  $D^{*\pm}$  samples with a  $\rho^2 = 1.21 \pm 0.12 \pm 0.20$ . The statistical and systematic correlations between  $|V_{cb}| \times F(1)$  and  $\rho^2$  are 0.90 and 0.54 respectively.

<sup>8</sup> BUSKULIC 97: measured using exclusively reconstructed  $D^{*\pm}$  with a  $a^2 = 0.31 \pm 0.17 \pm 0.08$ . The statistical correlation is 0.92.

<sup>9</sup> Measured using fully reconstructed  $D^*$  sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters:  $\rho^2 = 1.191 \pm 0.048 \pm 0.028$ ,  $R_1(1) = 1.429 \pm 0.061 \pm 0.044$ , and  $R_2(1) = 0.827 \pm 0.038 \pm 0.022$ .

<sup>10</sup> Measurement using fully reconstructed  $D^*$  sample with a  $\rho^2 = 1.29 \pm 0.03 \pm 0.10$ .

<sup>11</sup> Combines with previous partial reconstructed  $D^*$  measurement with a  $\rho^2 = 1.39 \pm 0.10 \pm 0.33$ .

<sup>12</sup> Measured using exclusive  $B^0 \rightarrow D^{*}(892)^-\ell^+\nu$  decays with  $\rho^2 = 1.35 \pm 0.17 \pm 0.19$  and a correlation of 0.91.

<sup>13</sup> BRIERE 02 result is based on the same analysis and data sample reported in ADAM 03.

<sup>14</sup> ABREU 96P: measured using both inclusively and exclusively reconstructed  $D^{*\pm}$  samples.

<sup>15</sup> BARISH 95: measured using both exclusive reconstructed  $B^0 \rightarrow D^{*-}\ell^+\nu$  and  $B^+ \rightarrow D^{*0}\ell^+\nu$  samples. They report their experiment's uncertainties  $\pm 0.0019 \pm 0.0018 \pm 0.0008$ , where the first error is statistical, the second is systematic, and the third is the uncertainty in the lifetimes. We combine the last two in quadrature.

### $V_{cb}$ MEASUREMENTS

For the discussion of  $V_{cb}$  measurements, which is not repeated here, see the review on "Determination of  $|V_{cb}|$  and  $|V_{ub}|$ ."

The CKM matrix element  $|V_{cb}|$  can be determined by studying the rate of the semileptonic decay  $B \rightarrow D^{(*)}\ell\nu$  as a function of the recoil kinematics of  $D^{(*)}$  mesons. Taking advantage of theoretical constraints on the normalization and a linear  $\omega$  dependence of the form factors ( $F(\omega)$ ,  $G(\omega)$ ) provided by Heavy Quark Effective Theory (HQET), the  $|V_{cb}| \times F(\omega)$  and  $\rho^2$  ( $a^2$ ) can be simultaneously extracted from data, where  $\omega$  is the scalar product of the two-meson four velocities,  $F(1)$  is the form factor at zero recoil ( $\omega=1$ ) and  $\rho^2$  is the slope, sometimes denoted as  $a^2$ . Using the theoretical input of  $F(1)$ , a value of  $|V_{cb}|$  can be obtained.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

5713± 2		<sup>4</sup> ACCIARRI	99N L3	$e^+e^- \rightarrow Z$

- <sup>1</sup> AFFOLDER 01F uses the reconstructed  $B$  meson through semileptonic decay channels. The fraction of light  $B$  mesons that are produced at  $L=1$   $B^{**}$  states is measured to be  $0.28 \pm 0.06 \pm 0.03$ .
- <sup>2</sup> BARATE 98L uses fully reconstructed  $B$  mesons to search for  $B^{**}$  production in the  $B\pi^\pm$  system. In the framework of heavy quark symmetry (HQS), they also measured the mass of  $B_2^*$  to be  $5739^{+8+6}_{-11-4}$  MeV/ $c^2$  and the relative production rate of  $B(b \rightarrow B_2^* \rightarrow B^{(*)}\pi)/B(b \rightarrow B_{u,d}) = (31 \pm 9^{+6}_{-5})\%$ .
- <sup>3</sup> Using  $m_{B\pi^-} - m_B = 424 \pm 4 \pm 10$  MeV.
- <sup>4</sup> ACCIARRI 99N uses inclusive reconstructed  $B$  mesons to search for  $B^{**}$  production in the  $B^{(*)}\pi^\pm$  system. In the framework of HQET, they measured the mass of  $B_1^*$  and  $B_2^*$  to be  $5670 \pm 10 \pm 13$  MeV and  $5768 \pm 5 \pm 6$  with the  $B(b \rightarrow B^{**}) = (32 \pm 3 \pm 6) \times 10^{-2}$ . They also reported the evidence for the existence of an excited  $B$ -meson state or mixture of states in the region 5.9–6.0 GeV.

## $B_s^0$ MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

"OUR EVALUATION" is an average of  $1 / [0.5 (\Gamma_{B_{sL}^0} + \Gamma_{B_{sH}^0})]$ .

- Measured using a pure CP-odd final state  $J/\psi K_S^0$  with the assumption that contributions from penguin diagrams are small.
- Measured using a pure CP-odd final state  $J/\psi f_0(980)$ .
- Uses the time-dependent angular analysis of  $B_S^0 \rightarrow J/\psi \phi$  decays assuming CP-violating angle  $\beta_S(B^0 \rightarrow J/\psi \phi) = 0.02$ .
- Obtained from  $\Delta\Gamma_S$  and  $\Gamma_S$  fit with a correlation of 0.6.
- Measured using the time-dependent angular analysis of  $B_S^0 \rightarrow J/\psi \phi$  decays.

 $B_{sL}^0$  MEAN LIFE

$B_{sL}^0$  is the light mass state of two  $B_S^0$  CP eigenstates.

“OUR EVALUATION” has been obtained by the Heavy Flavor Averaging Group (HFAG) using the constraint of the flavor-specific lifetime average in a way similar to  $\Delta\Gamma_{B_S^0}/\Gamma_{B_S^0}$ .

	<sup>6</sup> BARATE	00K	ALEP $e^+e^- \rightarrow Z$

- Measured using  $B_S^0 \rightarrow D_S^- D_S^+$ . The effective lifetime is translated into a decay width of  $\Gamma_L = 0.725 \pm 0.014 \pm 0.009 \text{ ps}^{-1}$ .
- Measured using  $B_S^0 \rightarrow K^+ K^-$  decays. There may still be CPV in the decay.
- Uses the time-dependent angular analysis of  $B_S^0 \rightarrow J/\psi \phi$  decays and assuming CP-violating angle  $\beta_S(B^0 \rightarrow J/\psi \phi) = 0.02$ .
- Obtained from  $\Delta\Gamma_S$  and  $\Gamma_S$  fit with a correlation of 0.6.
- Measured using the time-dependent angular analysis of  $B_S^0 \rightarrow J/\psi \phi$  decays.
- Uses  $\phi \phi$  correlations from  $B_S^0 \rightarrow D_S^{(*)+} D_S^{(*)-}$ .

 $\Delta\Gamma_{B_S^0}/\Gamma_{B_S^0}$ 

$\Gamma_{B_S^0}$  and  $\Delta\Gamma_{B_S^0}$  are the decay rate average and difference between two  $B_S^0$  CP eigenstates (light – heavy).

“OUR EVALUATION” is an average of all available  $B_S$  flavor-specific lifetime measurements with the  $\Delta\Gamma_{B_S^0}/\Gamma_S$  analyses performed by the Heavy

Flavor Averaging Group (HFAG) as described in our “Review on  $B-\bar{B}$  Mixing” in the  $B^0$  Section of these Listings.

## Meson Particle Listings

 $B_s^0$ 

- <sup>1</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays.  
<sup>2</sup> Measured using fully reconstructed  $B_s \rightarrow J/\psi\phi$  decays.  
<sup>3</sup> Assumes  $CP$  violation is negligible.  
<sup>4</sup> Uses the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays and assuming  $CP$ -violating angle  $\beta_s(B^0 \rightarrow J/\psi\phi) = 0.02$ .  
<sup>5</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays.  
<sup>6</sup> Uses  $|A_0|^2 - |A_{||}|^2 = 0.355 \pm 0.066$  from ACOSTA 05.  
<sup>7</sup> Uses  $D_s^- \ell^+$  and  $\phi \ell^+$  vertices.  
<sup>8</sup> Measured using  $D_s$  hadron vertices.  
<sup>9</sup> ABE 99d assumes  $\tau_{B_s^0} = 1.55 \pm 0.05$  ps.  
<sup>10</sup> ACCIARRI 98s assumes  $\tau_{B_s^0} = 1.49 \pm 0.06$  ps and PDG 98 values of  $b$  production fraction.

 $\Delta\Gamma_{B_s^0}$ 

"OUR EVALUATION" has been obtained by the Heavy Flavor Averaging Group (HFAG) using the constraint of the flavor-specific lifetime average in a way similar to  $\Delta\Gamma_{B_s^0}/\Gamma_{B_s^0}$ .

- <sup>1</sup> Measured using time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi K^+ K^-$  decays.  
<sup>2</sup> Measured using the flavor tagged time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays.  
<sup>3</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays.  
<sup>4</sup> The error includes both statistical and systematic uncertainties.  
<sup>5</sup> Measured using fully reconstructed  $B_s \rightarrow J/\psi\phi$  decays.  
<sup>6</sup> AAIJ 13AR result comes from a combined fit to  $B_s^0 \rightarrow J/\psi K^+ K^-$  and  $B_s^0 \rightarrow J/\psi\pi^+\pi^-$  data sets. Also reports  $\Delta\Gamma_s = 0.100 \pm 0.016 \pm 0.003 \text{ ps}^{-1}$  from a fit to  $B_s^0 \rightarrow J/\psi K^+ K^-$  decays.  
<sup>7</sup> Uses the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays and assuming  $CP$ -violating angle  $\beta_s(B^0 \rightarrow J/\psi\phi) = 0.02$ .  
<sup>8</sup> Measured the angular and lifetime parameters for the time-dependent angular untagged decays  $B_d^0 \rightarrow J/\psi K^{*0}$  and  $B_s^0 \rightarrow J/\psi\phi$ .  
<sup>9</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays and assuming  $CP$ -violating phase  $\phi_s = 0$ .  
<sup>10</sup> Obtains 90% CL interval  $-0.06 < \Delta\Gamma_s < 0.30$ .  
<sup>11</sup> ABAZOV 07 reports  $0.17 \pm 0.09 \pm 0.02$  with  $CP$ -violating phase  $\phi_s$  as a free parameter.  
<sup>12</sup> Combines  $D^0$  measurements of time-dependent angular distributions in  $B_s^0 \rightarrow J/\psi\phi$  and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

 $\Delta\Gamma_s^{CP} / \Gamma_s$ 

$\Gamma_s$  and  $\Delta\Gamma_s^{CP}$  are the decay rate average and difference between even,  $\Gamma_s^{CP\text{-even}}$ , and odd,  $\Gamma_s^{CP\text{-odd}}$ ,  $CP$  eigenstates.

<sup>7</sup> AAIJ 12D reports average decay width of  $B_s^0$ ,  $\Gamma_{B_s^0} = 0.657 \pm 0.009 \pm 0.008 \text{ ps}^{-1}$  that we converted to  $1/\Gamma_{B_s^0}$ .

WEIGHTED AVERAGE  
1.509 $\pm 0.010$  (Error scaled by 1.5)

 $B_s^0$  DECAY MODES

These branching fractions all scale with  $\text{B}(\bar{b} \rightarrow B_s^0)$ .

The branching fraction  $\text{B}(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$  is not a pure measurement since the measured product branching fraction  $\text{B}(\bar{b} \rightarrow B_s^0) \times \text{B}(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$  was used to determine  $\text{B}(\bar{b} \rightarrow B_s^0)$ , as described in the note on " $B^0$ - $\bar{B}^0$  Mixing"

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{ anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

- [a] Not a pure measurement. See note at head of  $B_s^0$  Decay Modes.  
 [b] Here  $S$  and  $P$  are the hypothetical scalar and pseudoscalar particles with masses of 2.5 GeV/ $c^2$  and 214.3 MeV/ $c^2$ , respectively.  
 [c] The value is for the sum of the charge states or particle/antiparticle states indicated.

### CONSTRAINED FIT INFORMATION

An overall fit to 10 branching ratios uses 16 measurements and one constraint to determine 7 parameters. The overall fit has a  $\chi^2 = 3.3$  for 10 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

### $B_s^0$ BRANCHING RATIOS

$\Gamma(D_s^- \text{ anything}) / \Gamma_{\text{total}}$				$\Gamma_1 / \Gamma$
VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN	COMMENT
<b>0.93 ± 0.25 OUR AVERAGE</b>				
0.91 ± 0.18 ± 0.41		1 DRUTSKOY	07 BELL	$e^+e^- \rightarrow \gamma(4S)$
0.81 ± 0.24 ± 0.22	90	2 BUSKULIC	96E ALEP	$e^+e^- \rightarrow Z$
1.56 ± 0.58 ± 0.44	147	3 ACTON	92N OPAL	$e^+e^- \rightarrow Z$

- <sup>1</sup> The extraction of this result takes into account the correlation between the measurements of  $B(\gamma(5S) \rightarrow D_s X)$  and  $B(\gamma(5S) \rightarrow D^0 X)$ .  
<sup>2</sup> BUSKULIC 96E separate  $c\bar{c}$  and  $b\bar{b}$  sources of  $D_s^+$  mesons using a lifetime tag, subtract generic  $\bar{D} \rightarrow W^+ \rightarrow D_s^+ \text{ events}$ , and obtain  $B(\bar{D} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \text{ anything}) = 0.088 \pm 0.020 \pm 0.020$  assuming  $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$  and PDG 1994 values for the relative partial widths to other  $D_s$  channels. We evaluate using our current values  $B(\bar{D} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{D} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .  
<sup>3</sup> ACTON 92N assume that excess of  $147 \pm 48 D_s^0$  events over that expected from  $B^0, B^+,$  and  $c\bar{c}$  is all from  $B_s^0$  decay. The product branching fraction is measured to be  $B(\bar{D} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1) \times 10^{-3}$ . We evaluate using our current values  $B(\bar{D} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{D} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .

- <sup>1</sup> The measurement corresponds to the average of the electron and muon branching fractions.  
<sup>2</sup> The measurement corresponds to a branching fraction where the lepton originates from bottom decay and is the average between the electron and muon branching fractions. LEES 12A uses the correlation of the production of  $\phi$  mesons in association with a lepton in  $e^+e^-$  data taken at center-of-mass energies between 10.54 and 11.2 GeV.

13 ± 4 ± 4	27	5 BUSKULIC	92E ALEP	$e^+e^- \rightarrow Z$

- The values and averages in this section serve only to show what values result if one assumes our  $B(\bar{D} \rightarrow B_s^0)$ . They cannot be thought of as measurements since the underlying product branching fractions were also used to determine  $B(\bar{D} \rightarrow B_s^0)$  as described in the note on "Production and Decay of  $b$ -Flavored Hadrons."
- <sup>1</sup> Obtains  $B_s \rightarrow D_s X e \nu$ , and  $D_s X \mu \nu$  separately, then combines them by assuming systematic uncertainties are fully correlated, except for the one on lepton identification. The third uncertainty adds in quadrature systematic uncertainties from external sources (number of  $B_s$  events, and  $D_s^{(*)}$  branching fractions). OSWALD 15 also measures the cross-section  $\sigma(e^+e^- \rightarrow B_s^{(*)} \bar{B}_s^{(*)}) = 53.8 \pm 1.4 \pm 5.3$  pb at  $\sqrt{s} = 10.86$  GeV.  
<sup>2</sup> BUSKULIC 95O use  $D_s \ell$  correlations. The measured product branching ratio is  $B(\bar{D} \rightarrow B_s) \times B(B_s \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = (0.82 \pm 0.09 \pm 0.13 \pm 0.14)\%$  assuming  $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$  and PDG 1994 values for the relative partial widths to the six other  $D_s$  channels used in this analysis. Combined with results from  $\gamma(4S)$  experiments this can be used to extract  $B(\bar{D} \rightarrow B_s) = (11.0 \pm 1.2 \pm 2.5 \pm 2.6)\%$ . We evaluate using our current values  $B(\bar{D} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{D} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .  
<sup>3</sup> ABREU 92M measured muons only and obtained product branching ratio  $B(Z \rightarrow b \text{ or } \bar{b}) \times B(\bar{D} \rightarrow B_s) \times B(B_s \rightarrow D_s \mu^+ \nu_\mu \text{ anything}) \times B(D_s \rightarrow \phi\pi) = (18 \pm 8) \times 10^{-5}$ . We evaluate using our current values  $B(\bar{D} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{D} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .  
<sup>4</sup> ACTON 92N is measured using  $D_s \rightarrow \phi\pi^+$  and  $K^*(892)^0 K^+$  events. The product branching fraction measured is measured to be  $B(\bar{D} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$ . We evaluate using our current values  $B(\bar{D} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{D} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .  
<sup>5</sup> BUSKULIC 92E is measured using  $D_s \rightarrow \phi\pi^+$  and  $K^*(892)^0 K^+$  events. They use  $2.7 \pm 0.7\%$  for the  $\phi\pi^+$  branching fraction. The average product branching fraction is measured to be  $B(\bar{D} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = 0.020 \pm 0.0055 \pm 0.005 - 0.006$ . We evaluate using our current values  $B(\bar{D} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{D} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ . Superseded by BUSKULIC 95O.

## $B_s^0\text{-}\bar{B}_s^0$ MIXING

For a discussion of  $B_s^0\text{-}\bar{B}_s^0$  mixing see the note on “ $B^0\text{-}\bar{B}^0$  Mixing” in the  $B^0$  Particle Listings above.

$\chi_s$  is a measure of the time-integrated  $B_s^0\text{-}\bar{B}_s^0$  mixing probability that produced  $B_s^0(\bar{B}_s^0)$  decays as a  $\bar{B}_s^0(B_s^0)$ . Mixing violates  $\Delta B \neq 2$  rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$x_s = \frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = (m_{B_{sH}^0} - m_{B_{sL}^0}) \tau_{B_s^0},$$

where  $H, L$  stand for heavy and light states of two  $B_s^0$  CP eigenstates and

$$\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_{sH}^0} + \Gamma_{B_{sL}^0})}.$$

$$\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$$

$\Delta m_{B_s^0}$  is a measure of  $2\pi$  times the  $B_s^0\text{-}\bar{B}_s^0$  oscillation frequency in time-dependent mixing experiments.

“OUR EVALUATION” is provided by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

1 Measured using time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi K^+ K^-$  decays.

2 Measured using  $B_s^0 \rightarrow D_s^- \pi^+$  decays.

3 Measured using  $B_s^0 \rightarrow D_s^- \mu^+ \nu_\mu X$  decays.

4 Measured using  $B_s^0 \rightarrow D_s^- \pi^+$  and  $D_s^- \pi^+ \pi^- \pi^+$  decays.

5 Significance of oscillation signal is  $5.4 \sigma$ . Also reports  $|V_{td}/V_{ts}| = 0.2060 \pm 0.0007^{+0.0081}_{-0.0060}$ .

6 A likelihood scan over the oscillation frequency,  $\Delta m_s$ , gives a most probable value of  $19 \text{ ps}^{-1}$  and a range of  $17 < \Delta m_s < 21 (\text{ps}^{-1})$  at 90% C.L. assuming Gaussian uncertainties. Also excludes  $\Delta m_s < 14.8 \text{ ps}^{-1}$  at 95% C.L.

7 Significance of oscillation signal is 0.2%. Also reported the value  $|V_{td}/V_{ts}| = 0.208^{+0.001+0.008}_{-0.002-0.006}$ .

8 Uses leptons emitted with large momentum transverse to a jet and improved techniques for vertexing and flavor-tagging.

9 Updates of  $D_s$ -lepton analysis.

10 Combined results from all Delphi analyses.

11 Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

12 ABE 03 uses the novel “charge dipole” technique to reconstruct separate secondary and tertiary vertices originating from the  $B \rightarrow D$  decay chain. The analysis excludes  $\Delta m_s < 4.9 \text{ ps}^{-1}$  and  $7.9 < \Delta m_s < 10.3 \text{ ps}^{-1}$ .

13 Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with  $D_s$  exclusively reconstructed; (3) inclusive semileptonic decays.

14 ABE 02v uses exclusively reconstructed  $D_s^-$  mesons and excludes  $\Delta m_s < 1.4 \text{ ps}^{-1}$  and  $2.4 < \Delta m_s < 5.3 \text{ ps}^{-1}$  at 95%CL.

15 Uses fully or partially reconstructed  $D_s \ell$  vertices and a mixing tag as a flavor tagging.

16 Replaced by ABDALLAH 04A. Uses  $D_s^- \ell^+$ , and  $\phi \ell^+$  vertices, and a multi-variable discriminant as a flavor tagging.

17 Uses inclusive  $D_s$  vertices and fully reconstructed  $B_s$  decays and a multi-variable discriminant as a flavor tagging.

18 Uses  $\ell\text{-}Q_{\text{hem}}$  and  $\ell\text{-}\ell$ .

19 ABE 99d assumes  $\tau_{B_s^0} = 1.55 \pm 0.05 \text{ ps}$  and  $\Delta\Gamma/\Delta m = (5.6 \pm 2.6) \times 10^{-3}$ .

20 ABE 99j uses  $\phi \ell\text{-}\ell$  correlation.

21 BARATE 99j uses combination of an inclusive lepton and  $D_s^-$ -based analyses.

22 BARATE 98c combines results from  $D_s \ell\text{-}\ell/Q_{\text{hem}}$ ,  $D_s \ell\text{-}K$  in the same side,  $D_s \ell\text{-}\ell/Q_{\text{hem}}$  and  $D_s \ell\text{-}K$  in the same side.

23 Uses  $\ell\text{-}Q_{\text{hem}}$ .

24 Uses  $\ell\text{-}\ell$ .

25 ADAM 97 combines results from  $D_s \ell\text{-}Q_{\text{hem}}$ ,  $\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$ .

26 BUSKULIC 96M uses  $D_s$  lepton correlations and lepton, kaon, and jet charge tags.

27 BUSKULIC 95i uses  $\ell\text{-}Q_{\text{hem}}$ . They find  $\Delta m_s > 5.6 [ > 6.1]$  for  $f_s=10\%$  [12%]. We interpolate to our central value  $f_s=10.5\%$ .

$$\chi_s = \Delta m_{B_s^0} / \Gamma_{B_s^0}$$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on  $\Delta m_{B_s^0}$  and “OUR EVALUATION” of the  $B_s^0$  mean lifetime.

## CP VIOLATION PARAMETERS in $B_s^0$

$$\text{Re}(\epsilon_{B_s^0}) / (1 + |\epsilon_{B_s^0}|^2)$$

CP impurity in  $B_s^0$  system.

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/scaling procedure takes into account correlation between the measurements. The value has been obtained from a 2D fit of the  $B_d$  and  $B_s$  asymmetries, which includes the  $B_s$  measurements listed below and the  $B$  factory average for the  $B_d$ .

<b><math>65\pm 7</math> OUR AVERAGE</b>			
$63.5^{+7.2}_{-6.7}$	<sup>1,2</sup> AAIJ	15K LHCB	$pp$ at 7, 8 TeV
$115^{+28}_{-43}$	<sup>3</sup> AAIJ	14Bf LHCB	$pp$ at 7 TeV

- <sup>1</sup> Obtained by measuring time-dependent  $CP$  asymmetry in  $B_S^0\rightarrow K^+K^-$  and using a U-spin relation between  $B_S^0\rightarrow K^+K^-$  and  $B^0\rightarrow \pi^+\pi^-$ .
- <sup>2</sup> Results are also presented using additional inputs on  $B^0\rightarrow \pi^0\pi^0$  and  $B^+\rightarrow \pi^+\pi^0$  decays from other experiments and isospin symmetry assumptions. The dependence of the results on the maximum allowed amount of U-spin breaking up to 50% is also included.
- <sup>3</sup> Measured in  $B_S^0\rightarrow D_S^\mp K^\pm$  decays, constraining  $-2\beta_S$  by the measurement of  $\phi_S=0.01\pm 0.07\pm 0.0$  from AAIJ 13AR. The value is modulo  $180^\circ$  at 68% CL.

### $\delta_B(B_S^0\rightarrow D_S^\pm K^\mp)$

VALUE(°)	DOCUMENT ID	TECN	COMMENT
<b><math>3^{+19}_{-20}</math></b>	<sup>1</sup> AAIJ	14Bf LHCB	$pp$ at 7 TeV

- <sup>1</sup> Measured in  $B_S^0\rightarrow D_S^\mp K^\pm$  decays, constraining  $-2\beta_S$  by the measurement of  $\phi_S=0.01\pm 0.07\pm 0.0$  from AAIJ 13AR. The value is modulo  $180^\circ$  at 68% CL.

### $r_B(B_S^0\rightarrow D_S^\mp K^\pm)$

$r_B$  and  $\delta_B$  are the amplitude ratio and relative strong phase between the amplitudes of  $A(B_S^0\rightarrow D_S^+K^-)$  and  $A(B_S^0\rightarrow D_S^-K^+)$ ,

VALUE	DOCUMENT ID	TECN	COMMENT
<b><math>0.53^{+0.17}_{-0.16}</math></b>	<sup>1</sup> AAIJ	14Bf LHCB	$pp$ at 7 TeV

- <sup>1</sup> Measured in  $B_S^0\rightarrow D_S^\mp K^\pm$  decays, constraining  $-2\beta_S$  by the measurement of  $\phi_S=0.01\pm 0.07\pm 0.0$  from AAIJ 13AR. At 68% CL.

## $CP$ Violation phase $\beta_s$

$-2\beta_s$  is the weak phase difference between  $B_S^0$  mixing amplitude and the  $B_S^0\rightarrow J/\psi\phi$  decay amplitude driven by the  $b\rightarrow c\overline{c}s$  transition (such as  $B_S\rightarrow J/\psi\phi$ ,  $J/\psi K^+K^-$ ,  $J/\psi\pi^+\pi^-$ , and  $D_S^+D_S^-$ ). The Standard Model value of  $\beta_s$  is  $\arg(-\frac{V_{ts}V_{cb}^*}{V_{cs}V_{tb}^*})$  if penguin contributions are neglected.

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. - <sup>1</sup> AAIJ 15i reports  $\phi_s=-2\beta_s=-0.058\pm 0.049\pm 0.006$  rad. that was measured using a tagged, time-dependent angular analysis of  $B_S^0\rightarrow J/\psi K^+K^-$  decays. It also combines this result with that of AAIJ 14s and quotes  $\phi_s=-2\beta_s=-0.010\pm 0.039$  rad.
- <sup>2</sup> AAIJ 15K reports  $-2\beta_s=-0.12^{+0.14}_{-0.16}$  rad. The value was obtained by measuring time-dependent  $CP$  asymmetry in  $B_S^0\rightarrow K^+K^-$  and using a U-spin relation between  $B_S^0\rightarrow K^+K^-$  and  $B^0\rightarrow \pi^+\pi^-$ .
- <sup>3</sup> Results are also presented using additional inputs on  $B^0\rightarrow \pi^0\pi^0$  and  $B^+\rightarrow \pi^+\pi^0$  decays from other experiments and isospin symmetry assumptions. The dependence of the results on the maximum allowed amount of U-spin breaking up to 50% is also included.
- <sup>4</sup> AAD 14U reports  $\phi_s=-2\beta_s=0.12\pm 0.25\pm 0.05$  rad. that was measured using a tagged, time-dependent angular analysis of  $B_S^0\rightarrow J/\psi\phi$  decays.
- <sup>5</sup> AAIJ 14AY reports  $-2\beta_s=0.02\pm 0.17\pm 0.02$  rad. in tagged, time-dependent fit to  $B_S^0\rightarrow D_S^+D_S^-$ , while allowing  $CP$  violation in decay.
- <sup>6</sup> AAIJ 14s reports  $\phi_s=-2\beta_s=0.070\pm 0.068\pm 0.008$  rad. and  $|\lambda|=0.89\pm 0.05\pm 0.01$ , when direct  $CP$  violation is allowed. Measured using a tagged, time-dependent fit to  $B_S^0\rightarrow J/\psi\pi^+\pi^-$  decays.
- <sup>7</sup> AALTONEN 12AJ reports  $-\pi/2<\beta_s<-1.51$  or  $-0.06<\beta_s<0.30$ , or  $1.26<\beta_s<\pi/2$  rad. at 68% CL. Measured using the time-dependent angular analysis of  $B_S^0\rightarrow J/\psi\phi$  decays.
- <sup>8</sup> Measured using fully reconstructed  $B_S\rightarrow J/\psi\phi$  decays. A single error includes both statistical and systematic uncertainties.
- <sup>9</sup> Reports  $\phi_s$  which equals to  $-2\beta_s$ .
- <sup>10</sup> Measured in  $B_S^0\rightarrow \phi\phi$  decays. This is a  $b\rightarrow s\overline{s}s$  transition with a decay amplitude phase different from that of  $b\rightarrow c\overline{c}s$  transition.
- <sup>11</sup> AAIJ 13AR reports  $\phi_s=-2\beta_s=0.01\pm 0.07\pm 0.01$  rad. obtained from combined fit to  $B_S^0\rightarrow J/\psi K^+K^-$  and  $B_S^0\rightarrow J/\psi\pi^+\pi^-$  data sets. Also reports separate results of  $\phi_s=0.07\pm 0.09\pm 0.01$  rad. from  $B_S^0\rightarrow J/\psi K^+K^-$  decays and  $\phi_s=-0.14^{+0.17}_{-0.16}\pm 0.01$  rad. from  $B_S^0\rightarrow J/\psi\pi^+\pi^-$  decays.
- <sup>12</sup> AAIJ 13AY uses  $B_S^0\rightarrow \phi\phi$  mode, and reports the 68% CL interval of  $\phi_s=-2\beta_s$  as  $[-2.46,-0.76]$  rad.
- <sup>13</sup> AAD 12CV reports  $\phi_s=-2\beta_s=0.22\pm 0.41\pm 0.10$  rad. that was measured using a time-dependent angular analysis of  $B_S^0\rightarrow J/\psi\phi$  decays.
- <sup>14</sup> Reports  $\phi_s=-2\beta_s=-0.44\pm 0.44\pm 0.02$  rad. that was measured using a time-dependent fit to  $B_S^0\rightarrow J/\psi f_0(980)$  decays.
- <sup>15</sup> Reports  $\phi_s=-2\beta_s=0.15\pm 0.18\pm 0.06$  rad. that was measured using a time-dependent angular analysis of  $B_S^0\rightarrow J/\psi\phi$  decays.
- <sup>16</sup> Reports  $\phi_s=-2\beta_s=-0.019^{+0.173+0.004}_{-0.174-0.003}$  rad. which was measured using a time-dependent fit to  $B_S^0\rightarrow J/\psi\pi^+\pi^-$  decays, with the  $\pi^+\pi^-$  mass within 775–1550 MeV. Searches for, but finds no evidence, for direct  $CP$  violation in  $B_S^0\rightarrow J/\psi\pi\pi$  decays.
- <sup>17</sup> Reports  $0.02<\phi_s<0.52$  or  $1.08<\phi_s<1.55$  rad. at 68% C.L. confidence regions in the two-dimensional space of  $\phi_s$  and  $\Delta\Gamma_{B_S^0}$  from  $B_S^0\rightarrow J/\psi\phi$  decays.
- <sup>18</sup> Reports  $0.32<2\beta_s<2.82$  rad. at 68% C.L. and confidence regions in the two-dimensional space of  $2\beta_s$  and  $\Delta\Gamma$  from the first measurement of  $B^0\rightarrow J/\psi\phi$  decays using flavor tagging. The probability of a deviation from SM prediction as large as the level of observed data is 15%.
- <sup>19</sup> Reports  $\phi_s=-2\beta_s$  and obtains 90% CL interval  $-0.03<\beta_s<0.60$  rad.
- <sup>20</sup> The first direct measurement of the  $CP$ -violating mixing phase is reported from the time-dependent analysis of flavor untagged  $B_S^0\rightarrow J/\psi\phi$  decays.
- <sup>21</sup> Combines D0 collaboration measurements of time-dependent angular distributions in  $B_S^0\rightarrow J/\psi\phi$  and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

## CPT VIOLATION PARAMETERS

In the  $B_s^0$  mixing, propagating mass eigenstates can be written as

$$\begin{aligned} |B_{sL}\rangle &\propto p \sqrt{1-\xi} |B_s^0\rangle + q \sqrt{1+\xi} |\bar{B}_s^0\rangle \\ |B_{sH}\rangle &\propto p \sqrt{1+\xi} |B_s^0\rangle - q \sqrt{1-\xi} |\bar{B}_s^0\rangle \end{aligned}$$

where parameter  $\xi$  controls  $CPT$  violation. If  $\xi$  is zero, then  $CPT$  is conserved. The parameter  $\xi$  can be written as

$$\xi = \frac{2(M_{11}-M_{22})-i(\Gamma_{11}-\Gamma_{22})}{-2\Delta m_s + i\Delta\Gamma_s} \approx \frac{-2\beta^\mu \Delta a_\mu}{2\Delta m_s - i\Delta\Gamma_s},$$

where  $M_{ii}$ ,  $\Gamma_{ii}$ ,  $\Delta m_s$ , and  $\Delta\Gamma_s$  are parameters of Hamiltonian governing  $B_s^0$  oscillations,  $\beta^\mu$  is the  $B_s^0$  meson velocity and  $\Delta a_\mu$  characterizes Lorentz-invariance violation. $\Delta a_\perp$

The mass value is estimated from  $m(J/\psi(1S) \ell)$ .<sup>6</sup> ACKERSTAFF 98O observed 2 candidate events in the  $B_c^+ \rightarrow J/\psi(1S) \pi^+$  channel with an estimated background of  $0.63 \pm 0.20$  events. $B_c^+$  MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

## POLARIZATION IN $B_c^+$ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (||) or perpendicular ( $\perp$ ) to each other with the parameters  $\Gamma_L/\Gamma$ ,  $\Gamma_{\perp}/\Gamma$ , and the relative phases  $\phi_{||}$  and  $\phi_{\perp}$ . See the definitions in the note on “Polarization in  $B$  Decays” review in the  $B^0$  Particle Listings.

## SPECTROSCOPY OF MESONS CONTAINING TWO HEAVY QUARKS

Updated March 2016 by S. Eidelman (Budker Inst. and Novosibirsk State Univ.), C. Hanhart (Forschungszentrum Jülich), B.K. Heltsley (Cornell Univ.), J.J. Hernandez-Rey (Univ. Valencia-CSIC), R.E. Mitchell (Indiana Univ.), S. Navas (Univ. Granada), and C. Patrignani (Bologna Univ., INFN).

A golden age for heavy quarkonium physics dawned at the turn of this century, initiated by the confluence of exciting advances in quantum chromodynamics (QCD) and an explosion of related experimental activity. The subsequent broad spectrum of breakthroughs, surprises, and continuing puzzles had not been anticipated. In that period, the BESIII program concluded only to give birth to BESIII; the  $B$ -factories and CLEO-c flourished; quarkonium production and polarization measurements at HERA and the Tevatron matured; and heavy-ion collisions at RHIC opened a window on the deconfinement regime. Recently also ATLAS, CMS and LHCb started to contribute to the field. For an extensive presentation of the status of heavy quarkonium physics, the reader is referred to several reviews [1–8]. This note focuses on experimental developments in heavy quarkonium spectroscopy with very few theoretical comments. Some other comments on possible theoretical interpretations of the states not predicted by the quark model are presented in the mini-review on non  $\bar{q}q$ -states.

In this mini-review we display the newly discovered states, where “newly” is interpreted to include the period since 2002. In earlier versions of this write-up the particles were sorted according to an assumed *conventional* or *unconventional* nature

with respect to the quark model. However, since this classification is not always unambiguous, we here follow Ref. [8] and sort the states into three groups, namely states below (*cf.* Table 1), near (*cf.* Table 2) and above (*cf.* Table 3) the lowest open flavor thresholds.

Table 1 lists properties of newly observed heavy quarkonium states located below the lowest open flavor thresholds. Those are expected to be (at least prominently) conventional quarkonia. The  $h_c(1P)$  is the  $^1P_1$  state of charmonium, singlet partner of the long-known  $\chi_{cJ}$  triplet  $^3P_J$ . The  $\eta_c(2S)$  is the first excited state of the pseudoscalar ground state  $\eta_c(1S)$ , lying just below the mass of its vector counterpart,  $\psi(2S)$ .

Although  $\eta_c(2S)$  measurements began to converge towards a mass and a width some time ago, refinements are still in progress. In particular, Belle [16] has revisited its analysis of  $B \rightarrow K\eta_c(2S)$ ,  $\eta_c(2S) \rightarrow KK\pi$  decays with more data and methods that account for interference between the above decay chain, an equivalent one with the  $\eta_c(1S)$  instead, and one with no intermediate resonance. The net effect of this interference is far from trivial; it shifts the apparent mass by  $\sim +10$  MeV and blows up the apparent width by a factor of six. The updated  $\eta_c(2S)$  mass and width are in better accordance with other measurements than the previous treatment [15], which did not include interference. Complementing this measurement in  $B$ -decay, BaBar [17] updated their previous [18]  $\eta_c(2S)$  mass and width measurements in two-photon production, where interference effects, judging from studies of  $\eta_c(1S)$ , appear to be small. In combination, precision on the  $\eta_c(2S)$  mass has improved dramatically. In addition, Belle recently reported a measurement of  $\psi_2(1D)$  which would be a  $J^{PC} = 2^{+-}$  state [23]. Its existence was confirmed with high significance by BESIII [24]. While the negative C-parity is indeed established by the measurement, the assignment of  $J = 2$  was done by matching to the closest quark model state. In the table this state is therefore simply called  $X(3823)$ , according to the PDG name convention.

A new  $\bar{c}b$  state was discovered by the ATLAS Collaboration [28]. They observed an excited  $B_c^\pm$  state, which properties are consistent with expectations for the second  $S$ -wave state of the  $B_c^\pm$  meson,  $B_c^\pm(2S)$ .

The ground state of bottomonium is the  $\eta_b(1S)$ , recently confirmed with a second observation of more than  $5\sigma$  significance at Belle. In addition, in the same experiment strong evidence was collected for  $\eta_b(2S)$  [32], but it still needs experimental confirmation at the  $5\sigma$  level. The  $\Upsilon(1D)$  is the lowest-lying  $D$ -wave triplet of the  $b\bar{b}$  system. Both the  $h_b(1P)$ , the bottomonium counterpart of  $h_c(1P)$ , and the next excited state,  $h_b(2P)$ , were recently observed by Belle [35], as described further below, in dipion transitions from the  $\Upsilon(10860)$ . We no longer mention a hypothetical  $Y_b(10888)$  state since new analysis of the  $\Upsilon(10860)$  energy range does not show evidence for an additional state with mass shifted from the  $\Upsilon(10860)$  [111]. After the mass of the  $\eta_b(1S)$  was shifted upwards by about 10 MeV based on the new Belle measurements [32,33], all states

# Meson Particle Listings

## Heavy Quarkonium Spectroscopy

mentioned in this paragraph fit into their respective spectroscopies roughly where expected. Their exact masses, production mechanisms, and decay modes provide guidance to their descriptions within QCD.

them have been confirmed experimentally as indicated in the last column of the tables. With the possible exception of the tensor state located at 3930 MeV, neither can unambiguously be assigned a place in the hierarchy of

**Table 1:** New states below the open flavor thresholds in the  $c\bar{c}$ ,  $b\bar{c}$ , and  $b\bar{b}$  regions, ordered by mass. Masses  $m$  and widths  $\Gamma$  represent the PDG16 weighted averages. Ellipses (...) in the Process column indicate inclusively selected event topologies; *i.e.*, additional particles not required by the Experiments to be present. A question mark (?) indicates an unmeasured value. For each Experiment a citation is given, as well as the statistical significance ( $\#\sigma$ ), or “(np)” for “not provided”. The Year column gives the date of the first measurement cited. The Status column indicates that the state has been observed by at most one (NC!=needs confirmation) or at least two independent experiments with significance of  $>5\sigma$  (OK).

There is a large number of newly discovered states both near and above the lowest open flavor thresholds. They are displayed in Table 2 and Table 3, respectively\*; notice that just a few of

\* For consistency with the literature, we preserve the use of  $X$ ,  $Y$  and  $Z$ , contrary to the practice of the PDG, which exclusively uses  $X$  for states with undetermined quantum numbers.

charmonia or bottomonia. However, besides the charged states, none has a universally accepted unconventional origin either. The  $X(3872)$  is widely studied, yet its interpretation demands additional experimental attention: after the quantum numbers were fixed at LHCb [59,60], the next experimental challenge will be a measurement of its line shape. The state originally

dubbed  $Z(3930)$  is now regarded by many as the first observed  $2P$  state of  $\chi_{cJ}$ , the  $\chi_{c2}(2P)$ . Another state was discovered at 3915 MeV [75] and from a subsequent measurement its quantum numbers were determined to be  $J^{PC} = 0^{++}$  [77] suggesting it to be the  $\chi_{c0}(2P)$  quark model state, but this interpretation is not generally accepted [114,115]. In addition, it was pointed out in Ref. [116] that if the assumption of a helicity-2 dominance is abandoned and instead one allows for a sizable helicity-0 component, a  $J^{PC} = 2^{++}$  assignment is possible. This could imply that the state at 3930 MeV is actually identical to the one at 3915 MeV—but to explain the large helicity-0 component a sizable portion of non- $\bar{q}q$  is necessary [116]. Because of this analysis the name of the state was changed back from  $\chi_{c0}(2P)$  to  $X(3915)$ .

Based on a full amplitude analysis of the  $B^0 \rightarrow K^+ \pi^- \psi(2S)$  decays, Belle determined the spin-parity of the  $Z(4430)^{\pm**}$  to be  $J^P = 1^+$  [105]. Very recently this state as well as its quantum numbers were confirmed at LHCb [107] with much higher statistics. Improved values for mass and width from LHCb are consistent with earlier measurements; our new average is in Table 3; the experiment even reports a resonant behavior of the  $Z(4430)^{\pm}$  amplitude. This state as well as  $Z(4050)^{\pm}$  and  $Z(4250)^{\pm}$  seen in  $\pi^{\pm}\chi_{c1}$  is, however, not confirmed (nor excluded) by BaBar (see [106] for the  $Z(4430)$  and [83] for the  $Z(4050)^{\pm}$  and  $Z(4250)^{\pm}$ ). Belle observes signals of significances  $5.0\sigma$ ,  $5.0\sigma$ , and  $6.4\sigma$  for  $Z_1(4050)^+$ ,  $Z_2(4250)^+$ , and  $Z(4430)^+$ , respectively, whereas BABAR reports  $1.1\sigma$ ,  $2.0\sigma$ , and  $2.4\sigma$  effects, setting upper limits on product branching

**Table 2:** As in Table 1, but for new states near the first open flavor thresholds in the  $c\bar{c}$  and  $b\bar{b}$  regions, ordered by mass. For  $X(3872)$ , the values given are based only upon decays to  $\pi^+\pi^-J/\psi$ . The  $Y(4260)$  and  $Y(4360)$  are vector states decaying to  $\pi^+\pi^-J/\psi$  and  $\pi^+\pi^-\psi(2S)$ , respectively, yet, unlike most conventional vector charmonia, do not correspond to enhancements in the  $e^+e^-$  hadronic cross section. Another interesting question is whether a heavier  $\pi^+\pi^-\psi(2S)$  state, the  $Y(4660)$ , discovered by Belle [101,102] and confirmed by BaBar [100], is identical to the  $\Lambda_c^+\Lambda_c^-$  state with close parameters observed by Belle using initial-state radiation [108].

fractions that are not inconsistent with Belle’s and LHCb’s measured rates. For the  $Z_1(4050)^+$  and  $Z_2(4250)^+$  states the situation remains unresolved.

\*\* There are currently various candidates for isotriplet states in the spectrum. For some of them both charged states are already established and sometimes there is also evidence for the neutral partner. We still chose to put the charge as superscript since it is an explicit marker of the exotic nature of the states.

## Heavy Quarkonium Spectroscopy

**Table 3:** As in Table 1, but for new states above the first open flavor thresholds in the  $c\bar{c}$  and  $b\bar{b}$  regions, ordered by mass.  $X(3945)$  and  $Y(3940)$  have been subsumed under  $X(3940)$  due to compatible properties. The  $\chi_{c0}(3915)$  is now changed back to  $X(3915)$  as explained in the main text. The state known as  $Z(3930)$  appears as the  $\chi_{c2}(2P)$  in Table 1. In some cases experiment still allows two  $J^{PC}$  values, in which case both appear. See also the reviews in [1–8].

In addition to the three  $Z_c^+$  discussed in the previous paragraph, in 2013 two more states named  $Z_c(3900)^+$  and  $Z_c(4020)^+$  were unearthed in the charmonium region. Note that in this write-up as well as the RPP listings we combined  $Z_c(3900)^+$  (seen in  $J/\psi \pi \pi$ ) and  $Z_c(3885)^+$  (seen in  $D\bar{D}^*$ ) as well as  $Z_c(4020)^+$  (seen in  $h_c \pi \pi$ ) and  $Z_c(4025)^+$  (seen in  $D^* \bar{D}^*$ ) into only two states due to their close proximity in mass. In various respects  $Z_c(3900)^+$  and  $Z_c(4020)^+$  seem to be the charmed partners of  $Z_b(10610)^+$  and  $Z_b(10650)^+$  as will be outlined below. Finally, from their study of  $\bar{B}^0 \rightarrow J/\psi K^- \pi^+$

decays Belle reported evidence for one more charged state, dubbed  $Z_c(4200)^+$  [92]. This very analysis gave evidence for the decay mode  $Z(4430) \rightarrow J/\psi \pi$ , which has an order of magnitude lower branching fraction than the discovery mode  $Z(4430) \rightarrow \psi(2S) \pi$ .

The  $Y(4140)$  observed in 2008 by CDF [84,85] was confirmed at D0 and CMS [86,87], however, a second structure related to  $Y(4274)$  could not be established unambiguously. The two states were neither seen in  $B$  decays at Belle [88], LHCb [89]

See key on page 601

### Heavy Quarkonium Spectroscopy

and BaBar [90] nor in  $\gamma\gamma$  collisions at Belle [91]. Thus the situation for the  $Y(4140)$  and  $Y(4274)$  is still controversial.

New results on  $\eta_b$ ,  $h_b$ , and  $Z_b^+$  mostly come from Belle [32–35], [71–74], [110–113], all from analyses of  $121.4 \text{ fb}^{-1}$  of  $e^+e^-$  collision data collected near the peak of the  $Y(10860)$  resonance as well as from additional  $25 \text{ fb}^{-1}$  of data collected during the scans of the c.m. energy range 10.63–11.05 GeV. They all appear in the decay chains:  $Y(10860) \rightarrow \pi^- Z_b^+$ ,  $Z_b^+ \rightarrow \pi^+(b\bar{b})$ , and, when the  $b\bar{b}$  forms an  $h_b(1P)$ , frequently decaying as  $h_b(1P) \rightarrow \gamma\eta_b$ .

**Figure 1:** From Belle [35], the mass recoiling against  $\pi^+\pi^-$  pairs,  $M_{\text{miss}}$ , in  $e^+e^-$  collision data taken near the peak of the  $Y(10860)$  (points with error bars). The smooth combinatorial and  $K_S^0 \rightarrow \pi^+\pi^-$  background contributions have been subtracted. The fit to the various labeled signal contributions is overlaid (curve). Adapted from [35] with kind permission, copyright (2011) The American Physical Society.

The Belle  $h_b$  discovery analysis [35] selects hadronic events and searches for peaks in the mass recoiling against  $\pi^+\pi^-$  pairs, the spectrum for which, after subtraction of smooth combinatorial and  $K_S^0 \rightarrow \pi^+\pi^-$  backgrounds, appears in Fig. 1. Prominent and unmistakable  $h_b(1P)$  and  $h_b(2P)$  peaks are present. This search was directly inspired by a CLEO result [117], which found the surprisingly copious transitions  $\psi(4160) \rightarrow \pi^+\pi^-h_c(1P)$  and an indication that  $Y(4260) \rightarrow \pi^+\pi^-h_c(1P)$  occurs at a comparable rate as the signature mode,  $Y(4260) \rightarrow \pi^+\pi^-J/\psi$ . The presence of  $Y(nS)$  peaks in Fig. 1 at rates two orders of magnitude larger than expected, along with separate studies with exclusive decays  $Y(nS) \rightarrow \mu^+\mu^-$ , allow precise calibration of the  $\pi^+\pi^-$  recoil mass spectrum and very accurate measurements of  $h_b(1P)$  and  $h_b(2P)$  masses. Both corresponding hyperfine splittings are consistent with zero within an uncertainty of about 1.5 MeV (lowered to  $\pm 1.1 \text{ MeV}$  for  $h_b(1P)$  in Ref. [34]).

Belle soon noticed that, for events in the peaks of Fig. 1, there seemed to be two intermediate charged states nearby. For example, Fig. 2 shows a Dalitz plot for events restricted to the  $Y(2S)$  region of  $\pi^+\pi^-$  recoil mass, with  $Y(2S) \rightarrow \mu^+\mu^-$ . The two bands observed in the maximum of the two  $M[\pi^\pm Y(2S)]^2$  values also appear for  $Y(1S)$ ,  $Y(3S)$ ,  $h_b(1P)$ , and  $h_b(2P)$

**Figure 2:** From Belle [71]  $e^+e^-$  collision data taken near the peak of the  $Y(10860)$  for events with a  $\pi^+\pi^-$ -missing mass consistent with an  $Y(2S) \rightarrow \mu^+\mu^-$ , (a) the maximum of the two possible single  $\pi^\pm$ -missing-mass-squared combinations vs. the  $\pi^+\pi^-$ -mass-squared; and (b) projection of the maximum of the two possible single  $\pi^\pm$ -missing-mass combinations (points with error bars) overlaid with a fit (curve). Events to the left of the vertical line in (a) are excluded from amplitude analysis. The hatched histogram in (b) corresponds to the combinatorial background. The two horizontal stripes in (a) and two peaks in (b) correspond to the two  $Z_b^+$  states. Adapted from [71] with kind permission, copyright (2011) The American Physical Society.

**Figure 3:** From Belle [34]  $e^+e^-$  collision data taken near the peak of the  $Y(10860)$ , the  $h_b(1P)$  event yield vs. the mass recoiling against the  $\pi^+\pi^-\gamma$  (corrected for misreconstructed  $\pi^+\pi^-$ ), where the  $h_b(1P)$  yield is obtained by fitting the mass recoiling against the  $\pi^+\pi^-$  (points with error bars). The fit results (solid histograms) for signal plus background and background alone are superimposed.

samples. Belle fits all subsamples to resonant plus non-resonant amplitudes, allowing for interference (notably, between  $\pi^- Z_b^+$  and  $\pi^+ Z_b^-$ ), and finds consistent pairs of  $Z_b^+$  masses for all bottomonium transitions, and comparable strengths of the two states. A recent angular analysis assigned  $J^P = 1^+$  for both  $Z_b^+$

## Meson Particle Listings

### Heavy Quarkonium Spectroscopy

states [72], which must also have negative  $G$ -parity. Transitions through  $Z_b^+$  to the  $h_b(nP)$  saturate the observed  $\pi^+\pi^-h_b(nP)$  cross sections. While the two masses of the  $Z_b^+$  states as extracted from Breit-Wigner fits for the various channels are just a few MeV above the  $B^*\bar{B}$  and  $B^*\bar{B}^*$  thresholds, respectively, more refined analyses find pole locations right below the corresponding thresholds either on the physical [118] or the unphysical sheet [119]. Regardless their proximity to the corresponding thresholds, both states predominantly decay into these open flavor channels [74], regardless the small phase space, with branching fractions that exceed 80% and 70%, respectively, at 90% CL. This feature provides strong evidence for their molecular nature—note that the  $Z_b^+$  states cannot be simple mesons because they are charged and have  $b\bar{b}$  content.

**Figure 4:** From ATLAS [39]  $pp$  collision data (points with error bars) taken at  $\sqrt{s} = 7$  TeV, the effective mass of  $\chi_{bJ}(1P, 2P, 3P) \rightarrow \gamma Y(1S, 2S)$  candidates in which  $Y(1S, 2S) \rightarrow \mu^+\mu^-$  and the photon is reconstructed as an  $e^+e^-$  conversion in the tracking system. Fits (smooth curves) show significant signals for each triplet (merged- $J$ ) on top of a smooth background. From [39] with kind permission, copyright (2012) The American Physical Society.

The third Belle result to follow from these data is the confirmation of the  $\eta_b(1S)$  and measurement of the  $h_b(1P) \rightarrow \gamma\eta_b(1S)$  branching fraction, expected to be several tens of percent. To accomplish this, events with the  $\pi^+\pi^-$  recoil mass in the  $h_b(1P)$  mass window and a radiative photon candidate are selected, and the  $\pi^+\pi^-\gamma$  recoil mass queried for correlation with non-zero  $h_b(1P)$  population in the  $\pi^+\pi^-$  missing mass spectrum, as shown in Fig. 3. A clear peak is observed, corresponding to the  $\eta_b(1S)$ . A fit is performed to extract the  $\eta_b(1S)$  mass, and determine its width and the branching fraction for  $h_b(1P) \rightarrow \gamma\eta_b(1S)$

(the latter of which is  $(49.8 \pm 6.8_{-5.2}^{+10.9})\%$ ) for the first time. The mass determination has comparable uncertainty and a larger central value (by 10 MeV, or  $2.4\sigma$ ) than the average of previous measurements, thereby reducing the new world average hyperfine splitting by nearly 5 MeV. An independent experimental confirmation of the shifted mass recently came from the Belle observation of the  $Y(4S) \rightarrow \eta h_b(1P)$  [33].

The  $\chi_{bJ}(nP)$  states have recently been observed at the LHC by ATLAS [39] and confirmed by D0 [40] for  $n = 1, 2, 3$ , although in each case the three  $J$  states are not distinguished from one another. Events are sought which have both a photon and an  $Y(1S, 2S) \rightarrow \mu^+\mu^-$  candidate which together form a mass in the  $\chi_b$  region. Observation of all three  $J$ -merged peaks is seen with significance in excess of  $6\sigma$  for both unconverted and converted photons. The mass plot for converted photons, which provide better mass resolution, is shown in Fig. 4. This marks the first observation of the  $\chi_{bJ}(3P)$  triplet, quite near the expected mass. A precise confirmation of this result came from LHCb [41].

**Figure 5:**  $J/\psi\pi$  invariant mass distributions from BES-III [61]  $e^+e^-$  collision data taken near the peak of the  $Y(4260)$ . Adapted from [61] with kind permission, copyright (2013) The American Physical Society.

In 2013 at BESIII [61] and shortly after at Belle [62] a charged state called  $Z_c(3900)^+$  was found near the  $D\bar{D}^*$  threshold—the corresponding spectrum from BESIII is shown in Fig. 5. In addition to confirming these findings, Ref. [63] also provided evidence for a neutral partner. A nearby signal was also seen in the  $D\bar{D}^*$  channel [65] whose quantum numbers were fixed to  $1^{+-}$ . The masses extracted from these experiments agree only within  $2\sigma$ . However, since the extraction did not allow for an interference with the background and used Breit-Wigner line shapes, which is not justified near thresholds, there might be some additional systematic uncertainty in the mass values. Therefore in the RPP listings as well as Table 2

both structures appear under the name  $Z_c(3900)^+$ . Analogously,  $Z_c(4020)^+$  (seen in in  $h_c\pi\pi$  [67]) and  $Z_c^+(4025)$  (seen in  $D^*\bar{D}^*$  [69]) are listed as one state,  $Z_c(4020)^+$ . The  $Z_c^+$  states show some remarkable similarities to the  $Z_b^+$  states, e.g. they decay dominantly to the  $D^{(*)}\bar{D}^*$  channels. However, current analyses suggest that the mass of especially the  $Z_c(3900)^+$  might be somewhat above the  $D\bar{D}^*$  threshold. If confirmed, this feature would clearly challenge a possible  $D\bar{D}^*$ -molecular interpretation.

## $c\bar{c}$ MESONS

[illegible]

The level scheme of the  $c\bar{c}$  states showing experimentally established states with solid lines. Singlet states are called  $\eta_c$  and  $h_c$ , triplet states  $\psi$  and  $\chi_{cJ}$ , and unassigned charmonium-like states  $X$ . In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. Only observed hadronic transitions are shown; the single photon transitions  $\psi(nS) \rightarrow \gamma\eta_c(mP)$ ,  $\psi(nS) \rightarrow \gamma\chi_{cJ}(mP)$ , and  $\chi_{cJ}(1P) \rightarrow \gamma J/\psi$  are omitted for clarity.

 $\eta_c(1S)$ 

$$1^G(J^{PC}) = 0^+(0^--)$$

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, 8 combinations of partial widths obtained from integrated cross section, and 19 branching ratios uses 85 measurements and one constraint to determine 13 parameters. The overall fit has a  $\chi^2 = 118.3$  for 73 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

### BRANCHING RATIOS OF $\psi(2S)$ AND $\chi_{c0,1,2}$

Updated August 2015 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Bologna Univ.)

Since 2002, the treatment of the branching ratios of the  $\psi(2S)$  and  $\chi_{c0,1,2}$  has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the *Review of Particle Physics* (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles Ref. 1, Ref. 2 as discussed in more detail in earlier editions of this mini-review.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles,  $\psi(2S)$ ,  $\chi_{c0}$ ,  $\chi_{c1}$ , and  $\chi_{c2}$ , and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [3].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by

using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the  $\chi_{c0,1,2}$  are measured independently of the  $\psi(2S)$  radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

### FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 25 combinations of partial widths, 10 branching ratios, and 80 combinations of branching ratios. Of the latter 57 involve decays of more than one particle.

The overall fit uses 239 measurements to determine 49 parameters and has a  $\chi^2$  of 341.3 for 190 degrees of freedom.

The relatively high  $\chi^2$  of the fit, 1.8 per d.o.f., can be traced back to a few specific discrepancies in the data. No scaling factors to fit uncertainties have been applied.

In the listing we provide the inter-particle correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the corresponding parameter  $x_i$ .

<b>20.7±1.7 OUR AVERAGE</b>				
23.9±2.7±4.1	97 ± 11	1 BAI 03c	BES	$\psi(2S) \rightarrow \gamma\chi_{c0} \rightarrow \gamma\pi^0\pi^0$
20.2±1.1±1.5	720 ± 32	2 BAI 98i	BES	$\psi(2S) \rightarrow \gamma\chi_{c0} \rightarrow \gamma\pi^+\pi^-$

1 We have multiplied  $\pi^0\pi^0$  measurement by 3 to obtain  $\pi\pi$ .

2 Calculated by us. The value for  $B(\chi_{c0} \rightarrow \pi^+\pi^-)$  reported in BAI 98i is derived using  $B(\psi' \rightarrow \gamma\chi_{c0}) = (9.3 \pm 0.8)\%$  and  $B(\psi' \rightarrow J/\psi\pi^+\pi^-) = (32.4 \pm 2.6)\%$  [BAI 98D]. We have multiplied  $\pi^+\pi^-$  measurement by 3/2 to obtain  $\pi\pi$ .

## CONSTRAINED FIT INFORMATION

A multiparticle fit to  $\chi_{c1}(1P)$ ,  $\chi_{c0}(1P)$ ,  $\chi_{c2}(1P)$ , and  $\psi(2S)$  with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 240 measurements to determine 49 parameters. The overall fit has a  $\chi^2 = 342.4$  for 191 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle\delta p_i \delta p_j\rangle/(\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ .

### CONSTRAINED FIT INFORMATION

A multiparticle fit to  $\chi_{C1}(1P)$ ,  $\chi_{C0}(1P)$ ,  $\chi_{C2}(1P)$ , and  $\psi(2S)$  with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 240 measurements to determine 49 parameters. The overall fit has a  $\chi^2 = 342.4$  for 191 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ .

## $\psi(2S)$

• • • We do not use the following data for averages, fits, limits, etc. • • •

$3686.114 \pm 0.007^{+0.011}_{-0.016}$	<sup>4</sup> ANASHIN	12	KEDR	$e^+e^- \rightarrow \text{hadrons}$
$3686.111 \pm 0.025 \pm 0.009$	AULCHENKO	03	KEDR	$e^+e^- \rightarrow \text{hadrons}$
$3686.00 \pm 0.10$	<sup>413</sup> <sup>5</sup> ZHOLENTZ	80	OLYA	$e^+e^-$
<sup>1</sup> Supersedes AULCHENKO 03 and ANASHIN 12.				
<sup>2</sup> Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85).				
<sup>3</sup> Mass central value and systematic error recalculated by us according to Eq.(16) in ARMSTRONG 93B, using the value for the $J/\psi(1S)$ mass from AULCHENKO 03.				
<sup>4</sup> From the scans in 2004 and 2006. ANASHIN 12 reports the value $3686.114 \pm 0.007 \pm 0.011^{+0.002}_{-0.012}$ MeV, where the third uncertainty is due to assumptions on the interference between the resonance and hadronic continuum. We combined the two systematic uncertainties.				
<sup>5</sup> Superseded by ARTAMONOV 00.				

### $m_{\psi(2S)} - m_{J/\psi(1S)}$

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b>589.188 ± 0.028 OUR AVERAGE</b>			
$589.194 \pm 0.027 \pm 0.011$	<sup>1</sup> AULCHENKO 03	KEDR	$e^+e^- \rightarrow \text{hadrons}$

## CONSTRAINED FIT INFORMATION

A multiparticle fit to  $\chi_{c1}(1P)$ ,  $\chi_{c0}(1P)$ ,  $\chi_{c2}(1P)$ , and  $\psi(2S)$  with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 240 measurements to determine 49 parameters. The overall fit has a  $\chi^2 = 342.4$  for 191 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ .

## $\psi(2S)$

### $\psi(2S) \Gamma(i) \Gamma(e^+ e^-) / \Gamma(\text{total})$

This combination of a partial width with the partial width into  $e^+ e^-$  and with the total width is obtained from the integrated cross section into channel(i) in the  $e^+ e^-$  annihilation. We list only data that have not been used to determine the partial width  $\Gamma(i)$  or the branching ratio  $\Gamma(i)/\text{total}$ .

### $\Gamma(\text{hadrons}) \times \Gamma(e^+ e^-) / \Gamma(\text{total})$

 $\psi(3770)$  DECAY MODES

In addition to the dominant decay mode to  $D\bar{D}$ ,  $\psi(3770)$  was found to decay into the final states containing the  $J/\psi$  (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to  $\phi\eta$  only (ADAMS 06).

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor / Confidence level
$\Gamma_1 D\bar{D}$	(93 <sup>+8</sup> <sub>-9</sub> ) %	S=2.0
$\Gamma_2 D^0\bar{D}^0$	(52 <sup>+4</sup> <sub>-5</sub> ) %	S=2.0
$\Gamma_3 D^+D^-$	(41 ± 4) %	S=2.0
$\Gamma_4 J/\psi\pi^+\pi^-$	(1.93 ± 0.28) × 10 <sup>-3</sup>

## CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 3 branching ratios uses 23 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 20.1$  for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

9 Solution I of the two solutions.						
10 Taking into account interference between the resonant and non-resonant $D \bar{D}$ production.						
11 Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$ , $\psi(4040)$ , $\psi(4160)$ , and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = 0^\circ$ .						
12 Interference between the resonant and non-resonant $D \bar{D}$ production not taken into account.						
13 BESSION 06 (as corrected in BESSION 10) measure $\sigma(e^+ e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = 6.36 \pm 0.08 \pm 0.41$ nb at $\sqrt{s} = 3773 \pm 1$ MeV, and obtain $\Gamma_{ee}$ from the Born-level cross section calculated using $\psi(3770)$ mass and width from our 2004 edition, PDG 04.						
14 Solution II of the two solutions.						
15 See also $\Gamma(e^+ e^-) / \Gamma_{\text{total}}$ below.

<sup>16</sup> Neglecting interference.				
<sup>17</sup> Obtained by comparing a measurement of the total cross section (corrected in BESSON 10) with that of $D\bar{D}$ reported by CLEO in DOBBS 07.				
<sup>18</sup> Using $\sigma^{obs} = 7.07 \pm 0.58$ nb and neglecting interference.				
<sup>19</sup> Not independent of ABLIKIM 08b.				
<sup>20</sup> From a measurement of $\sigma(e^+e^- \rightarrow D\bar{D})$ at $\sqrt{s} = 3773$ MeV, using the $\psi(3770)$ resonance parameters measured by ABLIKIM 06L.				
<sup>21</sup> See ADLER 88c for older measurements of this quantity.				
<sup>22</sup> Superseded by BONVICINI 14.

- 23 Comparing cross sections at  $\sqrt{s} = 3.773$  GeV and  $\sqrt{s} = 3.671$  GeV, neglecting interference, and using  $\sigma(\psi(3770) \rightarrow D\overline{D}) = 6.39 \pm 0.20$  nb.
- 24 Assuming that interference effects between resonance and continuum can be neglected and using  $\sigma^{obs}(e^+e^- \rightarrow \psi(3770)) = 7.15 \pm 0.38$  nb.
- 25 Data suggest possible destructive interference with continuum.
- 26 DRUZHININ 15 uses BABAR and CLEO data takitaking into account interference of the processes  $e^+e^- \rightarrow K^+K^-$  and  $e^+e^- \rightarrow K_S^0\overline{K}_L^0$ .
- 27 Using  $\sigma(e^+e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = (6.38 \pm 0.08^{+0.41}_{-0.30})$  nb from BESSON 06 and  $B(K_S^0 \rightarrow \pi^+\pi^-) = 0.6895 \pm 0.0014$ .
- 28 Using  $B(K_S^0 \rightarrow \pi^+\pi^-) = 0.6860 \pm 0.0027$ .
- 29 Using  $\sigma_{tot}(e^+e^- \rightarrow \psi(3770)) = 7.9 \pm 0.6$  nb at the resonance.
- 30 Solution I of two equivalent solutions in a fit with a resonance interfering with continuum.
- 31 Solution II of two equivalent solutions in a fit with a resonance interfering with continuum.
- 32 Calculated by the authors using  $\sigma(e^+e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = 6.36 \pm 0.08^{+0.41}_{-0.30}$  nb from BESSON 10.
- 33 Solution I of two equivalent solutions in a fit with a resonance interfering with continuum.
- 34 Solution II of two equivalent solutions in a fit with a resonance interfering with continuum.
- 35 Using  $\sigma^{obs} = 7.15 \pm 0.27 \pm 0.27$  nb and neglecting interference.
- 36 Assuming that interference effects between resonance and continuum can be neglected.

- <sup>37</sup> This limit is equivalent to  $(0.25 \pm 0.21 \pm 0.18) \times 10^{-3}$  branching fraction value.
- <sup>38</sup> Uses  $B(\psi(2S) \rightarrow \gamma\chi_{c2}) = 9.22 \pm 0.11 \pm 0.46\%$  from ATHAR 04,  $\psi(2S)$  mass and width from PDG 04, and  $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$  keV from ADAM 06.
- <sup>39</sup> Using  $\Gamma_{ee}(\psi(2S)) = (2.54 \pm 0.03 \pm 0.11)$  keV from ADAM 06 and taking  $\sigma(e^+e^- \rightarrow D\bar{D})$  from HE 05 for  $\sigma(e^+e^- \rightarrow \psi(3770))$ .
- <sup>40</sup> ABLIKIM 16B reports  $(1.94 \pm 0.42 \pm 0.64) \times 10^{-3}$  from a measurement of  $[\Gamma(\psi(3770) \rightarrow \gamma\chi_{c1})/\Gamma_{\text{total}}] / [B(\psi(2S) \rightarrow \gamma\chi_{c1}(1P))]$  assuming  $B(\psi(2S) \rightarrow \gamma\chi_{c1}(1P)) = (9.55 \pm 0.31) \times 10^{-2}$ .
- <sup>41</sup> ABLIKIM 14H reports  $[\Gamma(\psi(3770) \rightarrow \gamma\chi_{c1})/\Gamma_{\text{total}}] \times [B(\chi_{c1}(1P) \rightarrow K_S^0 K^\pm \pi^\mp)] = (8.51 \pm 2.39 \pm 1.42) \times 10^{-6}$  which we divide by our best value  $B(\chi_{c1}(1P) \rightarrow K_S^0 K^\pm \pi^\mp) = 0.00356 \pm 0.00030$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. We have calculated the best value of  $B(\chi_{c1}(1P) \rightarrow K_S^0 K^\pm \pi^\mp)$  as  $1/2$  of  $B(\chi_{c1}(1P) \rightarrow \bar{K}^0 K^+ \pi^- + \text{c.c.}) = (7.1 \pm 0.6) \times 10^{-3}$ .
- <sup>42</sup> Averages the two measurements from COAN 06A and BRIERE 06.
- <sup>43</sup> Uses  $B(\psi(2S) \rightarrow \gamma\chi_{c1}) = 9.07 \pm 0.11 \pm 0.54\%$  from ATHAR 04,  $\psi(2S)$  mass and width from PDG 04, and  $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$  keV from ADAM 06.
- <sup>44</sup> Using  $B(\psi(3770) \rightarrow J/\psi\pi^+\pi^-) = (1.89 \pm 0.20 \pm 0.20) \times 10^{-3}$  from ADAM 06.
- <sup>45</sup> ABLIKIM 16B reports  $(6.88 \pm 0.28 \pm 0.67) \times 10^{-3}$  from a measurement of  $[\Gamma(\psi(3770) \rightarrow \gamma\chi_{c0})/\Gamma_{\text{total}}] / [B(\psi(2S) \rightarrow \gamma\chi_{c0}(1P))]$  assuming  $B(\psi(2S) \rightarrow \gamma\chi_{c0}(1P)) = (9.99 \pm 0.27) \times 10^{-2}$ .

<sup>46</sup> Not independent of other results in BRIERE 06.

<sup>47</sup> ABLIKIM 14H reports  $[\Gamma(\psi(3770) \rightarrow \gamma\eta_c)/\Gamma_{\text{total}}] \times [B(\eta_c(1S) \rightarrow K_S^0 K^\pm \pi^\mp)] < 16 \times 10^{-6}$  which we divide by our best value  $B(\eta_c(1S) \rightarrow K_S^0 K^\pm \pi^\mp) = 2.43 \times 10^{-2}$ . We have calculated the best value of  $B(\eta_c(1S) \rightarrow K_S^0 K^\pm \pi^\mp)$  as  $1/3$  of  $B(\eta_c(1S) \rightarrow K\bar{K}\pi) = 7.3 \times 10^{-2}$ .

<sup>48</sup> ABLIKIM 14H reports  $[\Gamma(\psi(3770) \rightarrow \gamma\eta_c(2S))/\Gamma_{\text{total}}] \times [B(\eta_c(2S) \rightarrow K_S^0 K^\pm \pi^\mp)] < 5.6 \times 10^{-6}$  which we divide by our best value  $B(\eta_c(2S) \rightarrow K_S^0 K^\pm \pi^\mp) = 6 \times 10^{-3}$ . We have calculated the best value of  $B(\eta_c(2S) \rightarrow K_S^0 K^\pm \pi^\mp)$  as  $1/3$  of  $B(\eta_c(2S) \rightarrow K\bar{K}\pi) = 1.9 \times 10^{-2}$ .

<sup>49</sup> Assuming maximal destructive interference between  $\psi(3770)$  and continuum sources.

$\psi(3823)$   
was  $X(3823)$ .

$I_G(J^{PC}) = ?^?(2^{-}-)$   
 $J, P$  need confirmation.

Seen by BHARDWAJ 13 in  $B \rightarrow \chi_{c1} \gamma K$  and ABLIKIM 15S in  $e^+e^- \rightarrow \pi^+\pi^-\gamma\chi_{c1}$  decays as a narrow peak in the invariant mass distribution of the  $\chi_{c1} \gamma$  system. Properties consistent with the  $\psi_2(1^3D_2) c\bar{c}$  state.

## $\psi(3823)$ MASS

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>3822.2±1.2 OUR AVERAGE</b>				
3821.7±1.3±0.7	19 ± 5	<sup>1</sup> ABLIKIM	15s BES3	$e^+e^- \rightarrow \pi^+\pi^-\chi_{c1}\gamma$
3823.1±1.8±0.7	33 ± 10	<sup>2</sup> BHARDWAJ	13 BELL	$B \rightarrow \chi_{c1}\gamma K$

- <sup>1</sup> From a simultaneous unbinned maximum likelihood fit of  $e^+e^- \rightarrow \pi^+\pi^-\chi_{c1} \gamma$  data (the  $\pi^+\pi^-$  recoil mass) taken at  $\sqrt{s}$  values of 4.23, 4.26, 4.36, 4.42, and 4.60 GeV to simulated events including both  $\psi(2S) \rightarrow \chi_{c1} \gamma$  and  $\psi(3823) \rightarrow \chi_{c1} \gamma$  together, with floating mass scale offset for  $\psi(2S)$ , floating  $\psi(3823)$  mass, and zero  $\psi(3823)$  width, resulting in a significance of 5.9 $\sigma$  when including systematic uncertainties.
- <sup>2</sup> From a simultaneous fit to  $B^\pm \rightarrow (\chi_{c1} \gamma) K^\pm$  and  $B^0 \rightarrow (\chi_{c1} \gamma) K_S^0$  with significance 4.0 $\sigma$  including systematics. Corrected for the measured  $\psi(2S)$  mass using  $B \rightarrow \psi(2S) K \rightarrow (\gamma\chi_{c1}) K$  decays.

## X(3872)

$$I^G(J^{PC}) = 0^+(1^{++})$$

First observed by CHOI 03 in  $B \rightarrow K\pi^+\pi^-J/\psi(1S)$  decays as a narrow peak in the invariant mass distribution of the  $\pi^+\pi^-J/\psi(1S)$  final state. Isovector hypothesis excluded by AUBERT 05B and CHOI 11.

AAIJ 13Q perform a full five-dimensional amplitude analysis of the angular correlations between the decay products in  $B^+ \rightarrow X(3872)K^+$  decays, where  $X(3872) \rightarrow J/\psi\pi^+\pi^-$  and  $J/\psi \rightarrow \mu^+\mu^-$ , which unambiguously gives the  $J^{PC} = 1^{++}$  assignment under the assumption that the  $\pi^+\pi^-$  and  $J/\psi$  are in an  $S$ -wave. AAIJ 15AO extend this analysis with more data to limit  $D$ -wave contributions to < 4% at 95% CL.

See our note on “Developments in Heavy Quarkonium Spectroscopy”.

<b>&lt;0.4</b>	90	<sup>1,2</sup> IWASHITA	14 BELL	$B \rightarrow K\eta J/\psi$	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.6 90 AUBERT 04Y BABR				$B \rightarrow K\eta J/\psi$	
<sup>1</sup> IWASHITA 14 reports $[\Gamma(X(3872) \rightarrow \eta J/\psi)/\Gamma(X(3872) \rightarrow \pi^+\pi^- J/\psi(1S))] \times [B(B^+ \rightarrow X(3872) K^+, X \rightarrow J/\psi\pi^+\pi^-)] < 3.8 \times 10^{-6}$ which we divide by our best value $B(B^+ \rightarrow X(3872) K^+, X \rightarrow J/\psi\pi^+\pi^-) = 8.6 \times 10^{-6}$ .					
<sup>2</sup> IWASHITA 14 also scans the $\eta J/\psi$ mass range 3.8–4.75 GeV and sets upper limits for $B(B^\pm \rightarrow X(3872) K^\pm) \times B(X(3872) \rightarrow \eta J/\psi)$ in 5 MeV intervals.

## X(3900)

$I^G(J^{PC}) = 1^+(1^{+-})$

Charged X(3900) seen as a peak in the invariant mass distribution of the  $J/\psi\pi^\pm$  system by BES III (ABLIKIM 13T) in  $e^+e^- \rightarrow \pi^+\pi^- J/\psi$  at c.m. energy of 4.26 GeV and by radiative return from  $e^+e^-$  collisions at  $\sqrt{s}$  from 9.46 to 10.86 GeV at Belle (LIU 13B). Angular analysis of ABLIKIM 14A and ABLIKIM 15AC favor the  $J^P = 1^+$  assignment. Neutral X(3900) seen in the  $J/\psi\pi^0$  invariant mass distribution in  $e^+e^- \rightarrow \pi^0\pi^0 J/\psi$  at c.m. energies of 4.23, 4.26, and 4.36 GeV by BES III (ABLIKIM 15U) and at 4.17 GeV by XIAO 13A. Peaks in  $(D\overline{D}^*)^{0,\pm}$  reported by BES III (ABLIKIM 14A, ABLIKIM 15AB) are assumed to be related.

## X(3915)

was  $\chi_{c0}(3915)$ 

$$J^G(J^{PC}) = 0^+(0 \text{ or } 2^{++})$$

The experimental analysis prefers  $J^{PC} = 0^{++}$ . However, a re-analysis presented in ZHOU 15C shows that if helicity-2 dominance assumption is abandoned and a sizable helicity-0 component is allowed, a  $J^{PC} = 2^{++}$  assignment is possible.

## X(4020), $\psi(4040)$

### X(4020)

$$I(J^P) = 1(?)^?$$

Charged X(4020) seen by ABLIKIM 13X from  $e^+e^- \rightarrow \pi^+\pi^-h_c(1P)$  at c.m. energy from 3.90 to 4.42 GeV as a peak in the invariant mass distribution of the  $\pi^\pm h_c(1P)$  system, and by ABLIKIM 14B from  $e^+e^- \rightarrow (D^*\bar{D}^*)^\pm\pi^\mp$  events in  $(D^*\bar{D}^*)^\pm$  mass. A neutral X(4020) seen by ABLIKIM 14P at three c.m. energies in the same range in  $e^+e^- \rightarrow \pi^0\pi^0h_c(1P)$  as a peak in the larger of the two masses recoiling against a  $\pi^0$ . ABLIKIM 15AA observes a  $5.9\sigma$  signal in  $(D^*\bar{D}^*)^0$  in  $e^+e^- \rightarrow (D^*\bar{D}^*)^0\pi^0$  events using collisions at two c.m. energies. Production rates and mass values support grouping neutral and charged X(4020) together as manifestations of a single  $I = 1$  particle.

### $\psi(4040)$ DECAY MODES

Due to the complexity of the  $c\bar{c}$  threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle's central mass value, more (less) than  $2\sigma$  above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

$\psi(4160)$  DECAY MODES

Due to the complexity of the  $c\bar{c}$  threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle’s central mass value, more (less) than  $2\sigma$  above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

$\psi(4415)$  DECAY MODES

Due to the complexity of the  $c\bar{c}$  threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle’s central mass value, more (less) than  $2\sigma$  above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

**$b\bar{b}$  MESONS**
**THE BOTTOMONIUM SYSTEM**

The level scheme of the  $b\bar{b}$  states showing experimentally established states with solid lines. Singlet states are called  $\eta_b$  and  $h_b$ , triplet states  $\Upsilon$  and  $\chi_{bJ}$ . In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*,  $h_b(2P)$  means  $2^1P_1$  with  $n = 2$ ,  $L = 1$ ,  $S = 0$ ,  $J = 1$ ,  $PC = +-$ . The figure shows observed hadronic transitions. The single photon transitions  $\Upsilon(nS) \rightarrow \gamma\eta_b(mS)$ ,  $\Upsilon(nS) \rightarrow \gamma\chi_{bJ}(mP)$ , and  $\chi_{bJ}(nP) \rightarrow \gamma\Upsilon(mS)$  are omitted for clarity.

**WIDTH DETERMINATIONS OF THE  $\Upsilon$  STATES**

As is the case for the  $J/\psi(1S)$  and  $\psi(2S)$ , the full widths of the  $b\bar{b}$  states  $\Upsilon(1S)$ ,  $\Upsilon(2S)$ , and  $\Upsilon(3S)$  are not directly measurable, since they are much narrower than the energy resolution of the  $e^+e^-$  storage rings where these states are produced. The common indirect method to determine  $\Gamma$  starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \ , \quad (1)$$

where  $\Gamma_{\ell\ell}$  is one leptonic partial width and  $B_{\ell\ell}$  is the corresponding branching fraction ( $\ell = e, \mu$ , or  $\tau$ ). One then assumes  $e$ - $\mu$ - $\tau$  universality and uses

$$\begin{aligned} \Gamma_{\ell\ell} &= \Gamma_{ee} \\ B_{\ell\ell} &= \text{average of } B_{ee}, B_{\mu\mu}, \text{ and } B_{\tau\tau} \ . \end{aligned} \quad (2)$$

The electronic partial width  $\Gamma_{ee}$  is also not directly measurable at  $e^+e^-$  storage rings, only in the combination  $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$ , where  $\Gamma_{\text{had}}$  is the hadronic partial width and

$$\Gamma_{\text{had}} + 3\Gamma_{ee} = \Gamma \ . \quad (3)$$

This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\begin{aligned} \int_{\text{resonance}} \sigma(e^+e^- \rightarrow \Upsilon \rightarrow \text{hadrons})dE \\ = \frac{6\pi^2 \Gamma_{ee}\Gamma_{\text{had}}}{M^2 \Gamma} C_r = \frac{6\pi^2 \Gamma_{ee}^{(0)}\Gamma_{\text{had}}}{M^2 \Gamma} C_r^{(0)} \ , \end{aligned} \quad (4)$$

where  $M$  is the  $\Upsilon$  mass, and  $C_r$  and  $C_r^{(0)}$  are radiative correction factors.  $C_r$  is used for obtaining  $\Gamma_{ee}$  as defined in Eq. (1), and contains corrections from all orders of QED for describing  $(b\bar{b}) \rightarrow e^+e^-$ . The lowest order QED value  $\Gamma_{ee}^{(0)}$ , relevant for comparison with potential-model calculations, is defined by the lowest order QED graph (Born term) alone, and is about 7% lower than  $\Gamma_{ee}$ .

The Listings give experimental results on  $B_{ee}$ ,  $B_{\mu\mu}$ ,  $B_{\tau\tau}$ , and  $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$ . The entries of the last quantity have been re-evaluated consistently using the correction procedure of KU-RAEV 85. The partial width  $\Gamma_{ee}$  is obtained from the average values for  $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$  and  $B_{\ell\ell}$  using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{\text{had}}}{\Gamma(1 - 3B_{\ell\ell})} \ . \quad (5)$$

See key on page 601

# Meson Particle Listings

## Bottomonium, $\eta_b(1S)$

The total width  $\Gamma$  is then obtained from Eq. (1). We do not list  $\Gamma_{ee}$  and  $\Gamma$  values of individual experiments. The  $\Gamma_{ee}$  values in the Meson Summary Table are also those defined in Eq. (1).

<b><math>\eta_b(1S)</math></b>	$I^G(J^{PC}) = 0^+(0^{-+})$
Quantum numbers shown are quark-model predictions. Observed in radiative decay of the $\Upsilon(3S)$ , therefore $C = +$ .

## $\chi_{b1}(1P)$ $I^G(J^{PC}) = 0^+(1^+ +)$ $J$ needs confirmation.

Observed in radiative decay of the  $\Upsilon(2S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ ,  $J = 1$  from SKWARNICKI 87.

## $\chi_{b2}(1P)$

$$I^G(J^{PC}) = 0^+(2^{++})$$

$J$  needs confirmation.

Observed in radiative decay of the  $\Upsilon(2S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .  $J = 2$  from SKWARNICKI 87.

## CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 11.8$  for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle\delta x_i\delta x_j\rangle/(\delta x_i\delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$x_7 \begin{array}{|c|} \hline x_1 \\ \hline \end{array}$$

DEL-AMO-SA..10R	PR D82 111102	P. del Amo Sanchez et al.	(BABAR Collab.)
BONVICINI 04	PR D70 032001	G. Bonvicini et al.	(CLEO Collab.)

$$\chi_{b0}(2P) \quad J^G(J^{PC}) = 0^+(0^{++})$$

$J$  needs confirmation.

Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .

## $\chi_{b1}(2P)$

$$J^G(J^{PC}) = 0^+(1^++)$$

$J$  needs confirmation.

Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .

## $\chi_{b2}(2P)$

$$J^G(J^{PC}) = 0^+(2^{++})$$

$J$  needs confirmation.

Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .

### $\chi_{b2}(2P)$ MASS

VALUE (MeV)	DOCUMENT ID
<b><math>10268.65\pm0.22\pm0.50</math> OUR EVALUATION</b>	From $\gamma$ energy below, using $\Upsilon(3S)$ mass = $10355.2 \pm 0.5$ MeV

$\chi_{b1}(3P)$

$$J^G(J^{PC}) = 0^+(1^{++})$$

Observed in the radiative decay to  $\Upsilon(1S, 2S, 3S)$ , therefore  $C = +$ .  
 $J$  needs confirmation.

### $\chi_{b1}(3P)$ MASS

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>10512.1<math>\pm</math> 2.1<math>\pm</math> 0.9</b>	351	<sup>1</sup> AAIJ	14BG LHCb	$pp \rightarrow \gamma \mu^+ \mu^- X$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
10515.7 $^{+2.2+1.5}_{-3.9-2.1}$	169	<sup>2</sup> AAIJ	14BG LHCb	$pp \rightarrow \gamma \mu^+ \mu^- X$

<sup>1</sup> The mass of the  $\chi_{b1}(3P)$  state obtained by combining the results of AAIJ 14BG with that of AAIJ 14BI. The first uncertainty is experimental and the second attributable to the unknown mass splitting, assumed to be  $m_{\chi_{b2}(3P)} - m_{\chi_{b1}(3P)} = 10.5 \pm 1.5$  MeV.

<sup>2</sup> From  $\chi_{b1}(3P) \rightarrow \Upsilon(1S, 2S) \gamma$  transitions assuming  $m_{\chi_{b2}(3P)} - m_{\chi_{b1}(3P)} = 10.5 \pm 1.5$  MeV and allowing for  $\pm 30\%$  variation in the  $\chi_{b2}(3P)$  production rate relative to that of  $\chi_{b1}(3P)$ .

<sup>3</sup> From  $\chi_{b1}(3P) \rightarrow \Upsilon(3S) \gamma$  transition assuming  $m_{\chi_{b2}(3P)} - m_{\chi_{b1}(3P)} = 10.5 \pm 1.5$  MeV.

<sup>4</sup> The mass barycenter of the merged lineshapes from the  $J = 1$  and 2 states.

 $\Upsilon(4S)$ WEIGHTED AVERAGE  
0.272±0.029 (Error scaled by 1.5) $\Upsilon(4S)$  BRANCHING RATIOS $B\bar{B}$  DECAYS

The ratio of branching fraction to charged and neutral B mesons is often derived assuming isospin invariance in the decays, and relies on the knowledge of the  $B^+/B^0$  lifetime ratio. "OUR EVALUATION" is obtained based on averages of rescaled data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account the common dependence of the measurement on the value of the lifetime ratio.

$X(10610)^{\pm}$

$I^G(J^P) = 1^+(1^+)$

Observed by BONDAR 12 in  $\Upsilon(5S)$  decays to  $\Upsilon(nS)\pi^+\pi^-$  (n = 1, 2, 3) and  $h_b(mP)\pi^+\pi^-$  (m = 1, 2).  $J^P = 1^+$  is favored from angular analyses. Isospin = 1 is favored due to observation by KROKOVNY 13 of a corresponding neutral state produced in  $\Upsilon(10860) \rightarrow \Upsilon(2S)/\Upsilon(3S)\pi^0\pi^0$  decays at a consistent mass.

$X(10610)^0$

$J^G(J^P) = 1^+(1^+)$

Observed by KROKOVNY 13 in  $\Upsilon(10860) \rightarrow \Upsilon(nS)\pi^0\pi^0$  ( $n=2,3$ ). Isospin 1 is favored from the proximity in mass to  $X(10610)^{\pm}$  and their similarity of observed decay modes and cross sections.  $J^P = 1^+$  is favored from angular analysis of  $X(10610)^{\pm}$  decays by BONDAR 12.

<sup>19</sup>Not independent of DRUTSKOY 10 values for  $\Upsilon(5S) \rightarrow B^{\pm,0} \text{ anything}$ .

<sup>20</sup>Using measurements or limits from AQUINES 06.

<sup>21</sup>Assuming isospin conservation.

<sup>22</sup>Supersedes DRUTSKOY 07.

<sup>23</sup>Supersedes ARTUSO 05B. Combining inclusive  $\phi$ ,  $D_s$ , and  $B$  measurements. Using  $B(D_s^+ \rightarrow \phi\pi^+) = 4.4 \pm 0.6\%$  from PDG 06.

<sup>24</sup>Using  $B(D_s^+ \rightarrow \phi\pi^+) = (4.4 \pm 0.6)\%$  from PDG 06.

<sup>25</sup>Uses a model-dependent estimate  $B(B_S \rightarrow D_s X) = (92 \pm 11)\%$ .

<sup>26</sup>Supersedes LOUVOT 09.

<sup>27</sup>With  $N(B_S^{(*)}\overline{B}_S^{(*)}) = (7.11 \pm 1.30) \times 10^6$ .

<sup>28</sup>The ratios  $N(B_S^{(*)}\overline{B}_S^{(*)})/N(B_S^{(*)}\overline{B}_S^{(*)})$  and  $N(B_S^{(*)}\overline{B}_S^0)/N(B_S^{(*)}\overline{B}_S^{(*)})$  are measured with a correlation coefficient of  $-0.72$ .

<sup>29</sup>From a measurement of  $\sigma(e^+e^- \rightarrow B_S^* \overline{B}_S^*)/\sigma(e^+e^- \rightarrow B_S^{(*)} \overline{B}_S^{(*)})$  at  $\sqrt{s} = 10.86$  GeV.

<sup>30</sup>Assuming that the observed events are solely due to the  $\Upsilon(5S)$  resonance.

<sup>31</sup>Assuming that all the  $b\overline{b}$  events are from  $\Upsilon(5S)$  resonance decays and using  $\sigma(e^+e^- \rightarrow b\overline{b}) = 0.340 \pm 0.016$  nb from ESEN 13. Correlated with other results from HE 14.

<sup>32</sup>Accounting for correlated systematics.

<sup>33</sup>Assuming that all the  $b\overline{b}$  events are from  $\Upsilon(5S)$  resonance decays and using  $\sigma(e^+e^- \rightarrow b\overline{b}) = 0.340 \pm 0.016$  nb from ESEN 13. Correlated with other results from HE 14. For a state  $X_b$  with mass between  $10.55$  GeV/ $c^2$  and  $10.65$  GeV/ $c^2$ , the obtained 90% upper limit as a function of  $m_{X_b}$  varies from  $2.6 \times 10^{-5}$  to  $3.8 \times 10^{-5}$ .

<sup>34</sup>ARTUSO 05B reports  $[\Gamma(\Upsilon(10860) \rightarrow D_s \text{ anything} + \text{c.c.})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)] = 0.0198 \pm 0.0019 \pm 0.0038$  which we divide by our best value  $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>19</sup> Not independent of DRUTSKOY 10 values for  $\Upsilon(5S) \rightarrow B^{\pm,0} \text{ anything}$ .  
<sup>20</sup> Using measurements or limits from AQUINES 06.  
<sup>21</sup> Assuming isospin conservation.  
<sup>22</sup> Supersedes DRUTSKOY 07.  
<sup>23</sup> Supersedes ARTUSO 05B. Combining inclusive  $\phi$ ,  $D_s$ , and  $B$  measurements. Using  $B(D_s^+ \rightarrow \phi\pi^+) = 4.4 \pm 0.6\%$  from PDG 06.  
<sup>24</sup> Using  $B(D_s^+ \rightarrow \phi\pi^+) = (4.4 \pm 0.6)\%$  from PDG 06.

## Non- $q\bar{q}$ Candidates

### NON- $q\bar{q}$ CANDIDATES

#### NON- $q\bar{q}$ MESONS

Revised August 2015 by C. Amsler (University of Bern and Stefan Meyer Institute for Subatomic Physics, Vienna) and C. Hanhart (Forschungszentrum Jülich).

The constituent quark model describes the observed meson spectrum as bound  $q\bar{q}$  states grouped into SU(N) flavor multiplets (see our review on the ‘Quark Model’ in this issue of the *Review*). However, the self-coupling of gluons in QCD suggests that additional mesons made of bound gluons (glueballs), or  $q\bar{q}$ -pairs with an excited gluon (hybrids), may exist. Multiquark color singlet states such as  $qq\bar{q}\bar{q}$  (tetraquarks as compact diquark-antidiquark systems and ‘molecular’ bound states of two mesons) or  $qqq\bar{q}\bar{q}\bar{q}$  (six-quark and ‘baryonium’ bound states of two baryons) have also been predicted. For a more detailed discussion on exotic mesons we refer to [1,2].

In recent years experimental evidence for states beyond the quark model has accumulated in the heavy quark sector. We therefore split this mini-review into three parts discussing separately light systems, heavy-light systems and heavy-heavy systems.

#### 1. Light systems

##### 1.1. Glueball candidates

Among the signatures naively expected for glueballs are (i) no free space in  $q\bar{q}$  nonets, (ii) enhanced production in gluon-rich channels such as central production and radiative  $J/\psi(1S)$  decay, (iii) decay branching fractions incompatible with SU(N) predictions for  $q\bar{q}$  states, and (iv) reduced  $\gamma\gamma$  couplings. However, mixing effects with isoscalar  $q\bar{q}$  mesons [3–10] and decay form factors [11] obscure these simple signatures.

Lattice calculations, QCD sum rules, flux tube, and constituent glue models agree that the lightest glueballs have quantum numbers  $J^{PC} = 0^{++}$  and  $2^{++}$ . Lattice calculations predict for the ground state (a  $0^{++}$  glueball) a mass around 1600 – 1700 MeV [8,12–14]) with an uncertainty of about 100 MeV, while the first excited state ( $2^{++}$ ) has a mass of about 2300 MeV. Hence, the low-mass glueballs lie in the same mass region as ordinary isoscalar  $q\bar{q}$  states, in the mass range of the  $1^3P_0(0^{++})$ ,  $2^3P_2(2^{++})$ ,  $3^3P_2(2^{++})$ , and  $1^3F_2(2^{++})$   $q\bar{q}$  states. The  $0^{-+}$  state and exotic glueballs (with non- $q\bar{q}$  quantum numbers such as  $0^{--}$ ,  $0^{+-}$ ,  $1^{-+}$ ,  $2^{-+}$ , etc.) are expected above 2 GeV [14]. The lattice calculations were performed so far in the quenched approximation. Thus neither quark loops nor mixing with conventional mesons were included, although quenching effects seem to be small [15]. For a recent comparison between quenched and unquenched lattice studies see [16].

However, one expects that glueballs will mix with nearby  $q\bar{q}$  states of the same quantum numbers. The presence of a glueball mixed with  $q\bar{q}$  would lead to a supernumerary isoscalar

state in the SU(3) classification of  $q\bar{q}$  mesons. A lattice study in full QCD (performed at unphysical quark masses corresponding to a pion mass of 400 MeV) did not identify any state with sizable overlap with pure gluonic sources [17].

In the following we focus on glueball candidates in the scalar sector. For the  $2^{++}$  sector we refer to the section on non- $q\bar{q}$  mesons in the 2006 issue of this *Review* [18], and for the  $0^{-+}$  glueball to the note on ‘The Pseudoscalar and Pseudovector Mesons in the 1400 MeV Region’ in the *Meson Listings*.

Five isoscalar resonances are well established: the very broad  $f_0(500)$  (or  $\sigma$ ), the  $f_0(980)$ , the broad  $f_0(1370)$ , and the comparatively narrow  $f_0(1500)$  and  $f_0(1710)$ , see the note on ‘Scalar Mesons below 2 GeV’ in the *Meson Listings*, and also [19]. The  $f_0(1370)$  and  $f_0(1500)$  decay mostly into pions ( $2\pi$  and  $4\pi$ ) while the  $f_0(1710)$  decays mainly into  $K\bar{K}$  final states. Naively, this suggests an  $n\bar{n}$  ( $= u\bar{u} + d\bar{d}$ ) structure for the  $f_0(1370)$  and  $f_0(1500)$ , and  $s\bar{s}$  for the  $f_0(1710)$ . The latter is not observed in  $p\bar{p}$  annihilation [20], as expected from the OZI suppression for an  $s\bar{s}$  state.

In  $\gamma\gamma$  collisions leading to  $K_S K_S$  [21] and  $K^+ K^-$  [22] a spin-0 signal is observed at the  $f_0(1710)$  mass (together with a dominant spin-2 component), while the  $f_0(1500)$  is not observed in  $\gamma\gamma \rightarrow K\bar{K}$  nor  $\pi^+\pi^-$  [23]. The  $f_0(1500)$  is also not observed by Belle in  $\gamma\gamma \rightarrow \pi^0\pi^0$ , although a shoulder is seen which could also be due to the  $f_0(1370)$  [24]. The absence of a signal in the  $\pi\pi$  channel in  $\gamma\gamma$  collisions does not favor an  $\bar{n}n$  interpretation for the  $f_0(1500)$ . The upper limit from  $\pi^+\pi^-$  excludes a large  $n\bar{n}$  content, and hence points to a mainly  $s\bar{s}$  content [25]. This is in contradiction with the small  $K\bar{K}$  decay branching ratio of the  $f_0(1500)$  [26–28]. Hence, the  $f_0(1500)$  is hard to accommodate as a  $q\bar{q}$  state. This state could be mainly glue due its absence of  $2\gamma$ -coupling, while the  $f_0(1710)$  coupling to  $2\gamma$  would be compatible with an  $s\bar{s}$  state. Indeed, Belle finds that in  $\gamma\gamma \rightarrow K_S K_S$  collisions the 1500 MeV region is dominated by the  $f'_2(1525)$ . The  $f_0(1710)$  is also observed but its production  $\times$  decay rate is too large for a glueball [29]. However, the  $2\gamma$ -couplings are sensitive to glue mixing with  $q\bar{q}$  [30].

Since the  $f_0(1370)$  does not couple strongly to  $s\bar{s}$  [28], the  $f_0(1370)$  or  $f_0(1500)$  appear to be supernumerary. The narrow width of the  $f_0(1500)$ , and its enhanced production at low transverse momentum transfer in central collisions [31–33] also favor the  $f_0(1500)$  to be non- $q\bar{q}$ . In [3] the ground state scalar nonet is made of the  $a_0(1450)$ ,  $f_0(1370)$ ,  $K_0^*(1430)$ , and  $f_0(1710)$ . The isoscalars  $f_0(1370)$  and  $f_0(1710)$  contain a small fraction of glue, while the  $f_0(1500)$  is mostly gluonic. The light scalars  $f_0(500)$ ,  $f_0(980)$ ,  $a_0(980)$ , and  $\kappa(800)$  are four-quark states or two-meson resonances (see [1] for a review). In the mixing scheme of [30], which uses central production data from WA102 and the recent hadronic  $J/\psi$  decay data from BES [34,35], glue is shared between the  $f_0(1370)$ ,  $f_0(1500)$  and  $f_0(1710)$ . The  $f_0(1370)$  is mainly  $n\bar{n}$ , the  $f_0(1500)$  mainly glue and the  $f_0(1710)$  dominantly  $s\bar{s}$ . This agrees with previous analyses [3,9], but, as already pointed out, alternative schemes

have been proposed, see, e.g. [8,36]. In particular, for a scalar glueball the two-gluon coupling to  $n\bar{n}$  appears to be suppressed by chiral symmetry [37] and therefore  $K\bar{K}$  decay could be enhanced. It was argued that chiral symmetry constraints in a multichannel analysis imply that the  $f_0(1710)$  is an unmixed scalar glueball [38], a view that is challenged [39].

The contribution of  $f_0(1500)$  production in (the supposedly gluon rich) radiative  $J/\psi$  decay is not well known. The  $f_0(1500)$  is observed by BESII in  $J/\psi \rightarrow \gamma\pi\pi$  [40] and by BESIII in  $J/\psi \rightarrow \gamma\eta\eta$  [41] with a much smaller rate than for the  $f_0(1710)$ , which speaks against a glueball interpretation for the former. However, the mass found by BES is significantly lower than the expected value. The overlap with the  $f_0(1370)$  and  $f'_2(1525)$  and the statistically limited data sample prevent a proper  $K$ -matrix analysis to be performed. Hence more data are needed in radiative  $J/\psi$  decay and in  $\gamma\gamma$  collisions to clarify the spectrum of scalar mesons.

The Dalitz plots of  $B^\pm \rightarrow \pi^\pm\pi^\pm\pi^\mp$  have been studied by BaBar [42]. A broad  $2\pi$  signal is observed around 1400 MeV which is attributed to the  $f_0(1370)$ , but could also be due to the  $f_0(1500)$ . In  $B^\pm \rightarrow K^\pm K^\pm K^\mp$  both BaBar [43] and Belle [44] observe a strong spin-0 activity in  $K\bar{K}$  around 1550 MeV.  $B^0$  decay into  $J/\psi X$  filters out the  $d\bar{d}$  content of  $X$  while  $B_s^0$  decay selects its  $s\bar{s}$  component.  $B$  decay into  $J/\psi X$  may therefore be the ideal environment to determine the flavor content of neutral mesons [45], or to distinguish  $q\bar{q}$  from tetraquark states [46]. LHCb has analyzed  $\bar{B}^0$  decay into  $J/\psi\pi^+\pi^-$  [47]. The fit to the  $\pi\pi$  mass spectrum above  $\sim 1.2$  GeV does not show any significant scalar component. However, the data analysis has been challenged [48]. For  $\bar{B}_s^0 \rightarrow J/\psi\pi^+\pi^-$  a scalar contribution from the  $f_0(1370)$  [49] or the  $f_0(1500)$  [50] is required in the 1400–1500 MeV region.

### 1.2. Tetraquark candidates and molecular bound states

The  $a_0(980)$  and  $f_0(980)$  could be tetraquark states [51–53] or  $K\bar{K}$  molecular states [54–56] due to their strong affinity for  $K\bar{K}$ , in spite of their masses being very close to threshold. For  $q\bar{q}$  states, the expected  $\gamma\gamma$  widths [57,58] are not significantly larger than for molecular states [57,59], both predictions being consistent with data. Radiative decays of the  $\phi(1020)$  into  $a_0(980)$  and  $f_0(980)$  were claimed to enable disentangling compact from molecular structures. Interpreting the data from DAPHNE [60,61] and VEPP - 2M [62,63] along the lines of [64,65] seems to favor these mesons to be tetraquark states. In [66] they are made of a four-quark core and a virtual  $K\bar{K}$  cloud at the periphery. This is challenged in [67] showing that  $\phi$  radiative decay data are consistent with a molecular structure of the light scalars. The  $f_0(980)$  is strongly produced in  $D_s^+$  decay [68]. This points to a large  $s\bar{s}$  component, assuming Cabibbo favored  $c \rightarrow s$  decay. However, the mainly  $n\bar{n}$   $f_0(1370)$  is also strongly produced in  $D_s^+$  decay, indicating that other graphs must contribute [69]. On the other hand, the contributions

from the  $f_0(500)$  and  $f_0(980)$  in the decay  $\bar{B}^0 \rightarrow J/\psi\pi^+\pi^-$  seem to exclude a tetraquark structure for these states [47], while the corresponding ones in  $\bar{B}_s^0 \rightarrow J/\psi\pi^+\pi^-$  are compatible with tetraquarks [50].

COMPASS reports a new  $1^{++}$  isovector meson at 1414 MeV, decaying into  $f_0(980)\pi$  [70]. The resonance is observed in diffractive dissociation  $\pi^-p \rightarrow \pi^-(\pi^+\pi^-)p$ . Traditionally, the  $1^{++}$  ground state nonet is believed to contain the  $a_1(1260)$ ,  $f_1(1285)$  and  $f_1(1420)$  (see the mini-review on ‘The Pseudoscalar and Pseudovector Mesons in the 1400 MeV Region’ in the *Meson Listings*). However, a molecular  $K\bar{K}\pi$  structure has been proposed for the  $f_1(1420)$  [71] in view of the proximity of the  $K^*\bar{K}$  threshold. The new  $a_1(1414)$  could then also be a molecular state, the isovector partner of the  $f_1(1420)$ .

### 1.3. Baryonia

Bound states of two nucleons have been predicted, but have remained elusive. The  $f_2(1565)$  which is only observed in  $\bar{p}p$  annihilation [72,73] is a good candidate for a  $2^{++}$   $\bar{p}p$  bound state. Enhancements in the  $\bar{p}p$  mass spectrum have also been reported below  $\bar{p}p$  threshold, in  $J/\psi \rightarrow \gamma\bar{p}p$  [74–76] and in  $B^+ \rightarrow K^+\bar{p}p$ ,  $B^0 \rightarrow K_S^0\bar{p}p$  [77,78] and  $\bar{B}^0 \rightarrow D^0\bar{p}p$  [79]. This enhancement could be due to a  $0^{-+}$  baryonium [80] but other explanations have been proposed, such as the dynamics of the fragmentation mechanism [78] or the attractive  $^1S_0$  ( $\bar{p}p$ ) wave [81–83].

The pronounced signal observed in  $e^+e^- \rightarrow \Lambda_c^+\Lambda_c^-$  around  $\sqrt{s} = 4.63$  GeV by Belle [84] was argued to be a strong evidence in favor of an interpretation of  $Y(4660)$  as charmed baryonium [85]. However, this picture was challenged in [86].

### 1.4. Hybrid mesons

Hybrids may be viewed as  $q\bar{q}$  mesons with a vibrating gluon flux tube. In contrast to glueballs, they can have isospin 0 or 1. The mass spectrum of hybrids with exotic (non- $q\bar{q}$ ) quantum numbers was predicted in [87], while [88] also deals with non-exotic quantum numbers. The ground state hybrids with quantum numbers ( $0^{-+}$ ,  $1^{-+}$ ,  $1^{--}$ , and  $2^{-+}$ ) are expected around 1.7 to 1.9 GeV. Lattice calculations predict that the hybrid with exotic quantum numbers  $1^{-+}$  lies at a mass of  $1.9 \pm 0.2$  GeV [89,90]. Most hybrids are expected to be rather broad, but some can be as narrow as 100 MeV [91]. They prefer to decay into a pair of  $S$ - and  $P$ -wave mesons. The lattice study in [17], based on full QCD with pion masses around 400 MeV, finds that several of the high-lying states observed in their spectrum show significant overlap with gluon rich source terms.

A  $J^{PC} = 1^{-+}$  exotic meson,  $\pi_1(1400)$ , was reported in  $\pi^-p \rightarrow \eta\pi^-p$  [92,93] and in  $\pi^-p \rightarrow \eta\pi^0n$  [94]. It was observed as an interference between the angular momentum  $L = 1$  and  $L = 2$   $\eta\pi$  amplitudes, leading to a forward/backward asymmetry in the  $\eta\pi$  angular distribution. This state has been reported earlier in  $\pi^-p$  reactions [95], but ambiguous solutions

# Meson Particle Listings

## Non- $q\bar{q}$ Candidates

in the partial wave analysis were pointed out in [96,97]. A resonating  $1^{-+}$  contribution to the  $\eta\pi$   $P$ -wave is also required in the Dalitz plot analysis of  $\bar{p}n$  annihilation into  $\pi^-\pi^0\eta$  [98], and in  $\bar{p}p$  annihilation into  $\pi^0\pi^0\eta$  [99]. Mass and width are consistent with the results of Ref. [92].

Another  $1^{-+}$  state,  $\pi_1(1600)$ , decaying into  $\rho\pi$ , was reported by COMPASS with 190 GeV pions hitting a lead target [100]. It was observed earlier in  $\pi^-p$  interactions in the decay modes  $\eta'\pi$  [101],  $f_1(1285)\pi$  [102], and  $\omega\pi\pi$  [103],  $b_1(1235)\pi$ , but not  $\eta\pi$  [104]. A strong enhancement in the  $1^{-+}$   $\eta'\pi$  wave, compared to  $\eta\pi$ , was reported at this mass in [105]. Ref. [106] suggests that a Deck-generated  $\eta\pi$  background from final state rescattering in  $\pi_1(1600)$  decay could mimic  $\pi_1(1400)$ . However, this mechanism is absent in  $\bar{p}p$  annihilation. The  $\eta\pi\pi$  data require  $\pi_1(1400)$  and cannot accommodate a state at 1600 MeV [107]. Finally, evidence for a  $\pi_1(2015)$  has also been reported [102,103].

The flux tube model and the lattice concur to predict a hybrid mass of about 1.9 GeV while the  $\pi_1(1400)$  and  $\pi_1(1600)$  are lighter. As isovectors,  $\pi_1(1400)$  and  $\pi_1(1600)$  cannot be glueballs. The coupling to  $\eta\pi$  of the former points to a four-quark state [108], while the strong  $\eta'\pi$  coupling of the latter is favored for hybrid states [109,110]. The mass of  $\pi_1(1600)$  is also not far below the lattice prediction.

Hybrid candidates with  $J^{PC} = 0^{-+}$ ,  $1^{--}$ , and  $2^{-+}$  have also been reported. The  $\pi(1800)$  decays mostly to a pair of  $S$ - and  $P$ -wave mesons [100,111], in line with expectations for  $0^{-+}$  hybrid mesons. This meson is also somewhat narrow if interpreted as the second radial excitation of the pion. The evidence for  $1^{--}$  hybrids required in  $e^+e^-$  annihilation and in  $\tau$  decays has been discussed in Ref. [112]. A candidate for the  $2^{-+}$  hybrid, the  $\eta_2(1870)$ , was reported in  $\gamma\gamma$  interactions [113], in  $\bar{p}p$  annihilation [114], and in central production [115]. The near degeneracy of  $\eta_2(1645)$  and  $\pi_2(1670)$  suggests ideal mixing in the  $2^{-+}$   $q\bar{q}$  nonet, and hence, the second isoscalar should be mainly  $s\bar{s}$ . However,  $\eta_2(1870)$  decays mainly to  $a_2(1320)\pi$  and  $f_2(1270)\pi$  [114], with a relative rate compatible with a hybrid state [88].

## 2. Heavy-light systems

Two very narrow states,  $D_{s0}^*(2317)^\pm$  and  $D_{s1}(2460)^\pm$ , were observed at B factories [116,117]. They lie far below the predicted masses for the two expected broad  $P$ -wave  $c\bar{s}$  mesons. These states have hence been interpreted as four-quark states [118–120] or  $DK$  ( $DK^*$ ) molecules [121–123]. However, strong cusp effects, due to the nearby  $DK$  ( $DK^*$ ) thresholds, could shift their masses downwards and quench the observed widths, an effect similar to that occurring for the  $a_0(980)$  and  $f_0(980)$  mesons, which lie just below  $K\bar{K}$  threshold. A hadronic width of typically 100 keV would be the unequivocal signature for the molecular nature of  $D_{s0}^*(2317)^\pm$  [123,124]. Its measured width is currently less than 3.8 MeV.

## 3. Heavy-heavy systems

A search for multiquark states containing a  $c$  (or a  $b$ ) quark is promising since the charmonium spectrum can be predicted accurately, and because those mesons lying below the  $D\bar{D}$  or  $D\bar{D}^*$  thresholds should be narrow. Several states have been observed recently in the charmonium region. With the discovery of the  $X(3872)$  in  $B^\pm \rightarrow K^\pm X$  ( $X \rightarrow J/\psi \pi^+\pi^-$ ) by Belle [126], soon confirmed by BaBar [127], many searches for states beyond the standard quark model were initiated both in the charm and in the bottom sectors. In the decay  $\Lambda_b^0 \rightarrow J/\psi K^- p$  the LHCb collaboration has recently reported the observation of two new baryons decaying into  $J/\psi p$ , which are candidates for heavy pentaquark states [128]. For an updated collection of the currently available experimental information on multiquark states we refer to the mini-review on ‘Spectroscopy of mesons containing two heavy quarks’ in the *Meson Listings*.

When restricting ourselves to confirmed states we are faced with eight states that do not seem to fit into the standard quark model. This is clear for the four established charged states ( $Z_c(3900)^\pm$  and  $Z_c(4430)^\pm$  in the charmonium sector, and  $Z_b(10610)^\pm$  and  $Z_b(10650)^\pm$  in the bottomonium sector). The neutral ones ( $X(3872)$ ,  $Y(4260)$ ,  $Y(4360)$ ,  $Y(4660)$ ) also challenge the standard quark model since their masses and decay properties are in conflict with expectations.

The quantum numbers of the  $X(3872)$  have been determined by LHCb to be  $J^{PC} = 1^{++}$ , first by assuming the angular momentum zero between the  $J/\psi$  and the dipion [129] and then by relaxing this constraint [130]. The  $X(3872)$  can hardly be identified with the  $2^3P_1$   $\chi'_{c1}$  since the latter is predicted to lie about 100 MeV higher in mass [131]. Instead, the  $X(3940)$  reported by Belle in  $e^+e^- \rightarrow J/\psi X$ , decaying into  $D^*\bar{D}$  but not into  $D\bar{D}$  [132], and also observed in  $B \rightarrow K(X \rightarrow \omega J/\psi)$  [133] could be the  $\chi'_{c1}$ . The  $2^3P_2$  tensor partner ( $\chi'_{c2}$ ) was reported by Belle at 3931 MeV in  $\gamma\gamma$  interactions [134].

The  $X(3872)$  lies close to the  $D^0\bar{D}^{*0}$  threshold and therefore the most natural explanation for this state is a  $1^{++}$   $D\bar{D}^*$  molecule [135] for which strong isospin breaking is predicted [135,136] due to the nearby  $D^+D^{*-}$  threshold. Indeed, the comparable rates for  $\omega J/\psi$  and  $\rho^0 J/\psi$  are consistent with an interpretation of  $X(3872)$  as an isoscalar  $D\bar{D}^*$  molecule when the different widths of the  $\rho$  and  $\omega$  are taken into account [137]. A four-quark state  $cq\bar{c}\bar{q}'$  is also possible [120] but unlikely, since the charged partner of the  $X(3872)$  has not been observed (e.g. in  $B^- \rightarrow \bar{K}^0 X^-$  nor in  $B^0 \rightarrow K^+ X^-$ , where  $X^- \rightarrow J/\psi \pi^-\pi^0$  [138]). The claim that  $X(3872)$  must be a compact (tetraquark) state, since it is also produced at very high  $p_T$  in  $\bar{p}p$  collisions [139], was challenged in [140] which stresses the importance of rescattering, see also Ref. [141].

A broad structure,  $Y(4260)$ , decaying into  $J/\psi \pi^+\pi^-$  was reported by BaBar in initial state radiation  $e^+e^- \rightarrow \gamma(e^+e^- \rightarrow Y(4260))$  [142]. A charmonium state with the quantum numbers  $1^{--}$  is not expected in this mass region. In addition,

See key on page 601

a charmonium at this mass should have a significant coupling to  $\bar{D}D$ , a decay channel that is not observed for the  $Y(4260)$ . This state could be a hybrid charmonium with a spin-1  $\bar{c}c$  core [143,144]. However, provided that the observation of  $Y(4260)$  decay into  $h_c(1P)\pi\pi$  by BESIII [145] is confirmed, the hybrid hypothesis would be under pressure, since the spin of the heavy quarks (coupled to zero in the  $h_c(1P)$ ) should be conserved in leading order in the expansion in  $(\Lambda_{\text{QCD}}/m_c)$ . (The individual conservation of the heavy quark spin and the total angular momentum of the light quark cloud is a consequence of the heavy quark spin symmetry, see the review on ‘Heavy-Quark and Soft-Collinear Effective Theory’ in this issue of the *Review*.)

The same criticism applies to the hadrocharmonium interpretation of the  $Y(4260)$  which describes this state as spin-1 quarkonium surrounded by a light quark cloud [146]. To circumvent the spin symmetry argument Ref. [147] argues that  $Y(4260)$  and  $Y(4360)$  could be mixtures of two hadrocharmonia with spin-triplet and spin-singlet heavy quark pairs. The same kind of mixing could also operate for a hybrid.

A dominant  $D_1\bar{D}$  component in the  $Y(4260)$  [148] would explain naturally why  $Z_c(3900)^\pm$  (interpreted by the authors as a  $\bar{D}D^*$  bound state) is seen in  $Y(4260) \rightarrow \pi^\mp Z_c(3900)^\pm$ . A prominent  $D_1\bar{D}$  component in the  $Y(4260)$  would in addition explain the copious production of  $X(3872)$  in  $Y(4260)$  radiative decays [149]. The  $Y(4360)$  as  $D_1\bar{D}^*$  bound state could be the spin partner of the  $Y(4260)$  [150,151], but a detailed microscopic calculation is still lacking.

The tetraquark picture explains the observed  $Y$  states and, when including a tailor-made spin-spin interaction, is also capable to describe both  $Z_c(3900)^{\pm,0}$  and  $Z_c(4020)^\pm$  [152], and even the recently confirmed  $Z(4430)^\pm$  by Belle [153]. However, the model predicts many additional charged and neutral states which have not yet been discovered.

The charged states  $Z_c(3900)^\pm$ , first observed by BESIII [154] and the to be confirmed  $Z_c(4020)^\pm$  [155] decay predominantly into  $\bar{D}D^*$  and  $\bar{D}^*D^*$ , respectively, while  $Z_b(10610)^{\pm,0}$  and  $Z_b(10650)^\pm$  [156,157] decay predominantly into  $\bar{B}B^*$  and  $\bar{B}^*B^*$ , respectively, although all of them were discovered in the decay mode heavy quarkonium and pion. This suggests that the states are close relatives and their interactions are connected via heavy quark flavor symmetry. A molecular interpretation for the bottomonium states was proposed shortly after the discovery of the  $Z_b^\pm$  states [158] and also shortly after that of the  $Z_c(3900)^\pm$  [148]. However, their properties also appear to be consistent with tetraquark structures [159].

The heaviest confirmed charged state in the charmonium sector is the  $Z(4430)^\pm$  observed by Belle [153]. It is interpreted as hadrocharmonium [146],  $\bar{D}_1D^*$  molecule [160] as well as tetraquark state [152]. Alternatively, in [161] the  $Z(4430)^\pm$  can be explained as a cross-channel effect.

It should be stressed that the various scenarios, while describing the data, also make decisive predictions, e.g. for other decay channels. The forthcoming data on heavy meson spectroscopy from various facilities should soon provide a much

deeper understanding on how QCD forms matter out of quarks and gluons.

1.00727646688 ± 0.000000000013	MOHR 99	RVUE	1998 CODATA value
1.007276470 ± 0.0000000012	COHEN 87	RVUE	1986 CODATA value

### p MASS (MeV)

The mass is known much more precisely in u (atomic mass units) than in MeV. The conversion from u to MeV,  $1 \text{ u} = 931.494 \text{ 0054(57) MeV}/c^2$  (MOHR 16, the 2014 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b>938.2720813 ± 0.0000058</b>	MOHR 16	RVUE	2014 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •

938.2796 ± 0.0027	COHEN 73	RVUE	1973 CODATA value

$$|m_p - m_{\bar{p}}|/m_p$$

A test of *CPT* invariance. Note that the comparison of the  $\bar{p}$  and  $p$  charge-to-mass ratio, given in the next data block, is much better determined.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt;7 × 10<sup>-10</sup></b>	90	<sup>1</sup> HORI	11	SPEC $\bar{p}e^-$ -He atom
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<2 × 10 <sup>-9</sup>	90	<sup>1</sup> HORI	06	SPEC $\bar{p}e^-$ -He atom
<1.0 × 10 <sup>-8</sup>	90	<sup>1</sup> HORI	03	SPEC $\bar{p}e^-$ <sup>4</sup> He, $\bar{p}e^-$ <sup>3</sup> He
<6 × 10 <sup>-8</sup>	90	<sup>1</sup> HORI	01	SPEC $\bar{p}e^-$ -He atom
<5 × 10 <sup>-7</sup>		<sup>2</sup> TORII	99	SPEC $\bar{p}e^-$ -He atom

<sup>1</sup> HORI 01, HORI 03, HORI 06, and HORI 11 use the more-precisely-known constraint on the  $\bar{p}$  charge-to-mass ratio of GABRIELSE 99 (see below) to get their results. Their results are not independent of the HORI 01, HORI 03, HORI 06, and HORI 11 values for  $|q_p + q_{\bar{p}}|/e$ , below.

<sup>2</sup> TORII 99 uses the more-precisely-known constraint on the  $\bar{p}$  charge-to-mass ratio of GABRIELSE 95 (see below) to get this result. This is not independent of the TORII 99 value for  $|q_p + q_{\bar{p}}|/e$ , below.

### $\bar{p}/p$ CHARGE-TO-MASS RATIO, $|q_{\bar{p}}/m_{\bar{p}}|/(q_p/m_p)$

A test of *CPT* invariance. Listed here are measurements involving the *inertial* masses. For a discussion of what may be inferred about the ratio of  $\bar{p}$  and  $p$  *gravitational* masses, see ERICSON 90; they obtain an upper bound of  $10^{-6}$ – $10^{-7}$  for violation of the equivalence principle for  $\bar{p}$ 's.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.99999999991 ± 0.00000000009</b>	GABRIELSE 99	TRAP	Penning trap
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1.0000000015 ± 0.0000000011	<sup>1</sup> GABRIELSE 95	TRAP	Penning trap
1.0000000023 ± 0.0000000042	<sup>2</sup> GABRIELSE 90	TRAP	Penning trap

<sup>1</sup> Equation (2) of GABRIELSE 95 should read  $M(\bar{p})/M(p) = 0.999\,999\,9985(11)$  (G. Gabrielse, private communication).

<sup>2</sup> GABRIELSE 90 also measures  $m_{\bar{p}}/m_{e^-} = 1836.152660 \pm 0.000083$  and  $m_p/m_{e^-} = 1836.152680 \pm 0.000088$ . Both are completely consistent with the 1986 CODATA (COHEN 87) value for  $m_p/m_{e^-}$  of  $1836.152701 \pm 0.000037$ .

$$(|q_{\bar{p}}/m_{\bar{p}} - q_p/m_p)/q_p/m_p$$

A test of *CPT* invariance. Taken from the  $\bar{p}/p$  charge-to-mass ratio, above.

VALUE	DOCUMENT ID
<b>(−9 ± 9) × 10<sup>-11</sup></b>	OUR EVALUATION

$$|q_p + q_{\bar{p}}|/e$$

A test of *CPT* invariance. Note that the comparison of the  $\bar{p}$  and  $p$  charge-to-mass ratios given above is much better determined. See also a similar test involving the electron.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt;7 × 10<sup>-10</sup></b>	90	<sup>1</sup> HORI	11	SPEC $\bar{p}e^-$ -He atom
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<2 × 10 <sup>-9</sup>	90	<sup>1</sup> HORI	06	SPEC $\bar{p}e^-$ -He atom
<1.0 × 10 <sup>-8</sup>	90	<sup>1</sup> HORI	03	SPEC $\bar{p}e^-$ <sup>4</sup> He, $\bar{p}e^-$ <sup>3</sup> He
<6 × 10 <sup>-8</sup>	90	<sup>1</sup> HORI	01	SPEC $\bar{p}e^-$ -He atom
<5 × 10 <sup>-7</sup>		<sup>2</sup> TORII	99	SPEC $\bar{p}e^-$ -He atom
<2 × 10 <sup>-5</sup>		<sup>3</sup> HUGHES	92	RVUE

<sup>1</sup> HORI 01, HORI 03, HORI 06, and HORI 11 use the more-precisely-known constraint on the  $\bar{p}$  charge-to-mass ratio of GABRIELSE 99 (see above) to get their results. Their results are not independent of the HORI 01, HORI 03, HORI 06, and HORI 11 values for  $|m_p - m_{\bar{p}}|/m_p$ , above.

<sup>2</sup> TORII 99 uses the more-precisely-known constraint on the  $\bar{p}$  charge-to-mass ratio of GABRIELSE 95 (see above) to get this result. This is not independent of the TORII 99 value for  $|m_p - m_{\bar{p}}|/m_p$ , above.

<sup>3</sup> HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

$$|q_p + q_e|/e$$

See BRESSI 11 for a summary of experiments on the neutrality of matter. See also “*n* CHARGE” in the neutron Listings.

VALUE	DOCUMENT ID	COMMENT
<b>&lt;1 × 10<sup>-21</sup></b>	<sup>1</sup> BRESSI	11 Neutrality of SF <sub>6</sub>
• • • We do not use the following data for averages, fits, limits, etc. • • •		
<3.2 × 10 <sup>-20</sup>	<sup>2</sup> SENGUPTA	00 binary pulsar
<0.8 × 10 <sup>-21</sup>	MARINELLI	84 Magnetic levitation
<1.0 × 10 <sup>-21</sup>	<sup>1</sup> DYLLA	73 Neutrality of SF <sub>6</sub>

<sup>1</sup> BRESSI 11 uses the method of DYLLA 73 but finds serious errors in that experiment that greatly reduce its accuracy. The BRESSI 11 limit assumes that  $n \rightarrow p e^- \nu_e$  conserves charge. Thus the limit applies equally to the charge of the neutron.

<sup>2</sup> SENGUPTA 00 uses the difference between the observed rate of rotational energy loss by the binary pulsar PSR B1913+16 and the rate predicted by general relativity to set this limit. See the paper for assumptions.

MBR Molecular beam
- <sup>1</sup>DMITRIEV 03 calculates this limit from the limit on the electric dipole moment of the <sup>199</sup>Hg atom.
- <sup>2</sup>This WILKENING 84 value includes a finite-size effect and a magnetic effect.
- <sup>3</sup>This WILKENING 84 value is more cautious than the other and excludes the finite-size effect, which relies on uncertain nuclear integrals.

### p ELECTRIC POLARIZABILITY α<sub>p</sub>

For a very complete review of the “polarizability of the nucleon and Compton scattering,” see SCHUMACHER 05. His recommended values for the proton are α<sub>p</sub> = (12.0 ± 0.6) × 10<sup>−4</sup> fm<sup>3</sup> and β<sub>p</sub> = (1.9 ± 0.6) × 10<sup>−4</sup> fm<sup>3</sup>, almost exactly our averages.

VALUE (10 <sup>−4</sup> fm <sup>3</sup> )	DOCUMENT ID	TECN	COMMENT
<b>11.2 ±0.4 OUR AVERAGE</b>			
10.65±0.35±0.36	MCGOVERN	13	RVUE χEFT + Compton scattering
12.1 ±1.1 ±0.5	<sup>1</sup> BEANE	03	EFT + γp
11.82±0.98± <sub>−0.98</sub> <sup>0.52</sup>	<sup>2</sup> BLANPIED	01	LEGS p( <i>γ</i> ,γ), p( <i>γ</i> ,π <sup>0</sup> ), p( <i>γ</i> ,π <sup>+</sup> )
11.9 ±0.5 ±1.3	<sup>3</sup> OLMOSDEL...	01	CNTR γp Compton scattering
12.1 ±0.8 ±0.5	<sup>4</sup> MACGIBBON	95	RVUE global average
• • • We do not use the following data for averages, fits, limits, etc. • • •			
11.7 ±0.8 ±0.7	<sup>5</sup> BARANOV	01	RVUE Global average
12.5 ±0.6 ±0.9	MACGIBBON	95	CNTR γp Compton scattering
9.8 ±0.4 ±1.1	HALLIN	93	CNTR γp Compton scattering
10.62±1.25+1.07 −1.19−1.03	ZIEGER	92	CNTR γp Compton scattering
10.9 ±2.2 ±1.3	<sup>6</sup> FEDERSPIEL	91	CNTR γp Compton scattering
<sup>1</sup> BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) α <sub>N</sub> = (13.0 ± 1.9+3.9) −1.5 × 10 <sup>−4</sup> fm <sup>3</sup> and β <sub>N</sub> = (−1.8 ± 1.9±2.1) 0.9 × 10 <sup>−4</sup> fm <sup>3</sup> .			
<sup>2</sup> BLANPIED 01 gives α <sub>p</sub> + β <sub>p</sub> and α <sub>p</sub> − β <sub>p</sub> . The separate α <sub>p</sub> and β <sub>p</sub> are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.			
<sup>3</sup> This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that α + β = (13.8 ± 0.4) × 10 <sup>−4</sup> fm <sup>3</sup> . See the paper for a discussion.			
<sup>4</sup> MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a “global average” in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.			
<sup>5</sup> BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum α <sub>p</sub> + β <sub>p</sub> .			
<sup>6</sup> FEDERSPIEL 91 obtains for the (static) electric polarizability α <sub>p</sub> , defined in terms of the induced electric dipole moment by <b>D</b> = 4πε <sub>0</sub> α <sub>p</sub> <b>E</b> , the value (7.0 ± 2.2 ± 1.3) × 10 <sup>−4</sup> fm <sup>3</sup> .			

### p MAGNETIC POLARIZABILITY β<sub>p</sub>

The electric and magnetic polarizabilities are subject to a dispersion sum-rule constraint α + β = (14.2 ± 0.5) × 10<sup>−4</sup> fm<sup>3</sup>. Errors here are anticorrelated with those on α<sub>p</sub> due to this constraint.

2.1 ±0.8 ±0.5	<sup>4</sup> MACGIBBON	95	RVUE global average
• • • We do not use the following data for averages, fits, limits, etc. • • •			
2.3 ±0.9 ±0.7	<sup>5</sup> BARANOV	01	RVUE Global average
1.7 ±0.6 ±0.9	MACGIBBON	95	CNTR γp Compton scattering
4.4 ±0.4 ±1.1	HALLIN	93	CNTR γp Compton scattering
3.58±1.19+1.03 −1.25−1.07	ZIEGER	92	CNTR γp Compton scattering
3.3 ±2.2 ±1.3	FEDERSPIEL	91	CNTR γp Compton scattering
<sup>1</sup> BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) α <sub>N</sub> = (13.0 ± 1.9+3.9) −1.5 × 10 <sup>−4</sup> fm <sup>3</sup> and β <sub>N</sub> = (−1.8 ± 1.9±2.1) 0.9 × 10 <sup>−4</sup> fm <sup>3</sup> .			
<sup>2</sup> BLANPIED 01 gives α <sub>p</sub> + β <sub>p</sub> and α <sub>p</sub> − β <sub>p</sub> . The separate α <sub>p</sub> and β <sub>p</sub> are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.			
<sup>3</sup> This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that α + β = (13.8 ± 0.4) × 10 <sup>−4</sup> fm <sup>3</sup> . See the paper for a discussion.			
<sup>4</sup> MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a “global average” in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.			
<sup>5</sup> BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum α <sub>p</sub> + β <sub>p</sub> .			

### p CHARGE RADIUS

This is the rms electric charge radius, √⟨r<sub>E</sub><sup>2</sup>⟩.

Most measurements of the radius of the proton involve electron-proton interactions, and most of the more recent values agree with one another. The most precise of these is r<sub>p</sub> = 0.879(8) fm (BERNAUER 10). The CODATA 14 value (MOHR 16), obtained from the electronic results, is 0.8751(61). Compared to this CODATA value, however, a measurement using muonic hydrogen finds r<sub>p</sub> = 0.84087(39) fm (ANTOGNINI 13), which is 16 times more precise but differs by 5.6 standard deviations (using the CODATA 14 error).

Since POHL 10 (the first μp result), there has been a lot of discussion about the disagreement, especially concerning the modeling of muonic hydrogen. Here is an incomplete list of papers: DERUJULA 10, CLOET 11, DISTLER 11, DERUJULA 11, ARRINGTON 11, BERNAUER 11, HILL 11, LORENZ 14, KARSHENBOIM 14A, and PESET 15.

Until the difference between the ep and μp values is understood, it does not make sense to average the values together. For the present, we give both values. It is up to workers in this field to solve this puzzle.

See our 2014 edition (Chinese Physics C **38** 070001 (2014)) for values published before 2003.

### p MEAN LIFE

A test of baryon conservation. See the “p Partial Mean Lives” section below for limits for identified final states. The limits here are to “anything” or are for “disappearance” modes of a bound proton (p) or (n). See also the 3ν modes in the “Partial Mean Lives” section. Table 1 of BACK 03 is a nice summary.

# Baryon Particle Listings

*p*

- <sup>1</sup> ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of a neutron from the  $s$  shell of  $^{12}\text{C}$ .
- <sup>2</sup> AHMED 04 looks for  $\gamma$  rays from the de-excitation of a residual  $^{15}\text{O}^*$  or  $^{15}\text{N}^*$  following the disappearance of a neutron or proton in  $^{16}\text{O}$ .
- <sup>3</sup> BACK 03 looks for decays of unstable nuclides left after  $N$  decays of parent  $^{12}\text{C}$ ,  $^{13}\text{C}$ ,  $^{16}\text{O}$  nuclei. These are "invisible channel" limits.
- <sup>4</sup> ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.
- <sup>5</sup> AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.
- <sup>6</sup> BERNABEI 00b looks for the decay of a  $^{128}_{53}\text{I}$  nucleus following the disappearance of a proton in the otherwise-stable  $^{129}_{54}\text{Xe}$  nucleus.
- <sup>7</sup> EVANS 77 looks for the daughter nuclide  $^{129}\text{Xe}$  from possible  $^{130}\text{Te}$  decays in ancient Te ore samples.
- <sup>8</sup> This mean-life limit has been obtained from a half-life limit by dividing the latter by  $\ln(2) = 0.693$ .
- <sup>9</sup> FLEROV 58 looks for the spontaneous fission of a  $^{232}\text{Th}$  nucleus after the disappearance of one of its nucleons.

## $\bar{p}$ MEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also " $\bar{p}$  Partial Mean Lives" after " $p$  Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is  $7 \times 10^5$  years, for  $\bar{p} \rightarrow e^- \gamma$ . We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	EVTs	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>8 $\times 10^5$	90		<sup>1</sup> GEER 00D		$\bar{p}/p$ ratio, cosmic rays
>0.28			GABRIELSE 90	TRAP	Penning trap
>0.08	90	1	BELL 79	CNTR	Storage ring
>1 $\times 10^7$			GOLDEN 79	SPEC	$\bar{p}/p$ ratio, cosmic rays
>3.7 $\times 10^{-3}$			BREGMAN 78	CNTR	Storage ring
<sup>1</sup> GEER 00D uses agreement between a model of galactic $\bar{p}$ production and propagation and the observed $\bar{p}/p$ cosmic-ray spectrum to set this limit.					

## $p$ DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on  $\tau/B_j$ , where  $\tau$  is the total mean life and  $B_j$  is the branching fraction for the mode in question. For  $N$  decays,  $p$  and  $n$  indicate proton and neutron partial lifetimes.

Mode	Partial mean life ( $10^{30}$ years)	Confidence level
<b>Antilepton + meson</b>		
$\tau_1 \quad N \rightarrow e^+ \pi$	> 2000 ( $n$ ), > 8200 ( $p$ )	90%
$\tau_2 \quad N \rightarrow \mu^+ \pi$	> 1000 ( $n$ ), > 6600 ( $p$ )	90%
$\tau_3 \quad N \rightarrow \nu \pi$	> 1100 ( $n$ ), > 390 ( $p$ )	90%
$\tau_4 \quad p \rightarrow e^+ \eta$	> 4200	90%
$\tau_5 \quad p \rightarrow \mu^+ \eta$	> 1300	90%
$\tau_6 \quad n \rightarrow \nu \eta$	> 158	90%
$\tau_7 \quad N \rightarrow e^+ \rho$	> 217 ( $n$ ), > 710 ( $p$ )	90%
$\tau_8 \quad N \rightarrow \mu^+ \rho$	> 228 ( $n$ ), > 160 ( $p$ )	90%
$\tau_9 \quad N \rightarrow \nu \rho$	> 19 ( $n$ ), > 162 ( $p$ )	90%

$\tau_{19} \quad N \rightarrow \nu K$	> 86 ( $n$ ), > 5900 ( $p$ )	90%
$\tau_{20} \quad n \rightarrow \nu K_S^0$	> 260	90%
$\tau_{21} \quad p \rightarrow e^+ K^*(892)^0$	> 84	90%
$\tau_{22} \quad N \rightarrow \nu K^*(892)$	> 78 ( $n$ ), > 51 ( $p$ )	90%

## Antilepton + mesons

Mode	Partial mean life (years)	Confidence level
$\tau_{23} \quad p \rightarrow e^+ \pi^+ \pi^-$	> 82	90%
$\tau_{24} \quad p \rightarrow e^+ \pi^0 \pi^0$	> 147	90%
$\tau_{25} \quad n \rightarrow e^+ \pi^- \pi^0$	> 52	90%
$\tau_{26} \quad p \rightarrow \mu^+ \pi^+ \pi^-$	> 133	90%
$\tau_{27} \quad p \rightarrow \mu^+ \pi^0 \pi^0$	> 101	90%
$\tau_{28} \quad n \rightarrow \mu^+ \pi^- \pi^0$	> 74	90%
$\tau_{29} \quad n \rightarrow e^+ K^0 \pi^-$	> 18	90%

## Lepton + meson

$\tau_{30} \quad n \rightarrow e^- \pi^+$	> 65	90%
$\tau_{31} \quad n \rightarrow \mu^- \pi^+$	> 49	90%
$\tau_{32} \quad n \rightarrow e^- \rho^+$	> 62	90%
$\tau_{33} \quad n \rightarrow \mu^- \rho^+$	> 7	90%
$\tau_{34} \quad n \rightarrow e^- K^+$	> 32	90%
$\tau_{35} \quad n \rightarrow \mu^- K^+$	> 57	90%

## Lepton + mesons

$\tau_{36} \quad p \rightarrow e^- \pi^+ \pi^+$	> 30	90%
$\tau_{37} \quad n \rightarrow e^- \pi^+ \pi^0$	> 29	90%
$\tau_{38} \quad p \rightarrow \mu^- \pi^+ \pi^+$	> 17	90%
$\tau_{39} \quad n \rightarrow \mu^- \pi^+ \pi^0$	> 34	90%
$\tau_{40} \quad p \rightarrow e^- \pi^+ K^+$	> 75	90%
$\tau_{41} \quad p \rightarrow \mu^- \pi^+ K^+$	> 245	90%

## Antilepton + photon(s)

$\tau_{42} \quad p \rightarrow e^+ \gamma$	> 670	90%
$\tau_{43} \quad p \rightarrow \mu^+ \gamma$	> 478	90%
$\tau_{44} \quad n \rightarrow \nu \gamma$	> 550	90%
$\tau_{45} \quad p \rightarrow e^+ \gamma \gamma$	> 100	90%
$\tau_{46} \quad n \rightarrow \nu \gamma \gamma$	> 219	90%

## Antilepton + single massless

$\tau_{47} \quad p \rightarrow e^+ X$	> 790	90%
$\tau_{48} \quad p \rightarrow \mu^+ X$	> 410	90%

## Three (or more) leptons

$\tau_{49} \quad p \rightarrow e^+ e^+ e^-$	> 793	90%
$\tau_{50} \quad p \rightarrow e^+ \mu^+ \mu^-$	> 359	90%
$\tau_{51} \quad p \rightarrow e^+ \nu \nu$	> 170	90%
$\tau_{52} \quad n \rightarrow e^+ e^- \nu$	> 257	90%
$\tau_{53} \quad n \rightarrow \mu^+ e^- \nu$	> 83	90%
$\tau_{54} \quad n \rightarrow \mu^+ \mu^- \nu$	> 79	90%
$\tau_{55} \quad p \rightarrow \mu^+ e^+ e^-$	> 529	90%
$\tau_{56} \quad p \rightarrow \mu^+ \mu^+ \mu^-$	> 675	90%
$\tau_{57} \quad p \rightarrow \mu^+ \nu \nu$	> 220	90%
$\tau_{58} \quad p \rightarrow e^- \mu^+ \mu^+$	> 6	90%
$\tau_{59} \quad n \rightarrow 3\nu$	> $5 \times 10^{-4}$	90%
$\tau_{60} \quad n \rightarrow 5\nu$		

## Inclusive modes

$\tau_{61} \quad N \rightarrow e^+ \text{anything}$	> 0.6 ( $n, p$ )	90%
$\tau_{62} \quad N \rightarrow \mu^+ \text{anything}$	> 12 ( $n, p$ )	90%
$\tau_{63} \quad N \rightarrow \nu \text{anything}$		
$\tau_{64} \quad N \rightarrow e^+ \pi^0 \text{anything}$	> 0.6 ( $n, p$ )	90%
$\tau_{65} \quad N \rightarrow 2 \text{ bodies, } \nu\text{-free}$		

## $\Delta B = 2$ dinucleon modes

The following are lifetime limits per iron nucleus.

$\tau_{66} \quad pp \rightarrow \pi^+ \pi^+$	> 72.2	90%
$\tau_{67} \quad pn \rightarrow \pi^+ \pi^0$	> 170	90%
$\tau_{68} \quad nn \rightarrow \pi^+ \pi^-$	> 0.7	90%
$\tau_{69} \quad nn \rightarrow \pi^0 \pi^0$	> 404	90%
$\tau_{70} \quad pp \rightarrow K^+ K^+$	> 170	90%
$\tau_{71} \quad pp \rightarrow e^+ e^+$	> 5.8	90%
$\tau_{72} \quad pp \rightarrow e^+ \mu^+$	> 3.6	90%
$\tau_{73} \quad pp \rightarrow \mu^+ \mu^+$	> 1.7	90%
$\tau_{74} \quad pn \rightarrow e^+ \bar{\nu}$	> 260	90%
$\tau_{75} \quad pn \rightarrow \mu^+ \bar{\nu}$	> 200	90%
$\tau_{76} \quad pn \rightarrow \tau^+ \bar{\nu}_\tau$	> 29	90%
$\tau_{77} \quad nn \rightarrow \nu_e \bar{\nu}_e$	> 1.4	90%
$\tau_{78} \quad nn \rightarrow \nu_\mu \bar{\nu}_\mu$	> 1.4	90%
$\tau_{79} \quad pn \rightarrow \text{invisible}$	> $2.1 \times 10^{-5}$	90%
$\tau_{80} \quad pp \rightarrow \text{invisible}$	> $5 \times 10^{-5}$	90%

## $\bar{p}$ DECAY MODES

## $\rho$ PARTIAL MEAN LIVES

The “partial mean life” limits tabulated here are the limits on  $\tau/B_i$ , where  $\tau$  is the total mean life for the proton and  $B_i$  is the branching fraction for the mode in question.

Decaying particle:  $p$  = proton,  $n$  = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

<sup>1</sup> In estimating the background, this HIRATA 89c limit (as opposed to the later limits of WALL 00B and MCGREW 99) does not take into account present understanding that the flux of  $\nu_\mu$  originating in the upper atmosphere is depleted. Doing so would reduce the background and thus also would reduce the limit here.

<sup>2</sup> We have calculated 90% CL limit from 1 confined event.

<sup>3</sup> We have converted 2 possible events to 90% CL limit.

<sup>4</sup> We have converted half-life to 90% CL mean life.

> 5.8	$p$	90	1		<sup>4</sup> KRISHNA... 82	KOLR
> 0.3	$n$	90	2		<sup>5</sup> CHERRY 81	HOME

<sup>1</sup> This ALLISON 98 limit is with no background subtraction; with subtraction the limit becomes  $> 46 \times 10^{30}$  years.

<sup>2</sup> BARTELT 87 limit applies to  $n \rightarrow \nu K_S^0$ .

<sup>3</sup> Limit based on zero events.

<sup>4</sup> We have calculated 90% CL limit from 1 confined event.

<sup>5</sup> We have converted 2 possible events to 90% CL limit.

## $\tau(n \rightarrow \nu K_S^0)$

>0.000012	90	5	9.7	BERGER	91B	FREJ $\tau$ per iron nucleus
<sup>1</sup> ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of two neutrons from the s shell of <sup>12</sup> C.						
<sup>2</sup> TRETYAK 04 uses data from an old Homestake-mine radiochemical experiment on limits for invisible decays of <sup>39</sup> K to <sup>37</sup> Ar.						
<sup>3</sup> BACK 03 looks for decays of unstable nuclides left after $NN$ decays of parent <sup>12</sup> C, <sup>13</sup> C, <sup>16</sup> O nuclei. These are “invisible channel” limits.						
<sup>4</sup> BERNABEI 00b looks for the decay of a <sup>127</sup> Xe nucleus following the disappearance of an $nn$ pair in the otherwise-stable <sup>129</sup> Xe nucleus. The limit here applies as well to $nn \rightarrow \nu_\mu \bar{\nu}_\mu$ , $nn \rightarrow \nu_\tau \bar{\nu}_\tau$ , or any “disappearance” mode.						

$\tau(n n \rightarrow \nu_\mu \bar{\nu}_\mu)$							778
See the proceeding data block. "Invisible modes" would include any multi-neutrino mode.

<sup>2</sup> BERNABEI 00b looks for the decay of a <sup>127</sup> Te nucleus following the disappearance of a $pp$ pair in the otherwise-stable <sup>129</sup> Xe nucleus.						

**$\bar{p}$  PARTIAL MEAN LIVES**

The “partial mean life” limits tabulated here are the limits on  $\bar{\tau}/B_j$ , where  $\bar{\tau}$  is the total mean life for the antiproton and  $B_j$  is the branching fraction for the mode in question.

*n*  $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$  Status: \* \* \* \*

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Anyone interested in the neutron should look at these two new review articles: D. Dubbers and M.G. Schmidt, "The neutron and its role in cosmology and particle physics," *Reviews of Modern Physics* **83** 1111 (2011); and F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," *Reviews of Modern Physics* **83** 1173 (2011).

*n* MASS (atomic mass units u)

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

VALUE (u)	DOCUMENT ID	TECN	COMMENT
<b>1.00866491588 ± 0.00000000049</b>	MOHR	16	RVUE 2014 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> The 2014 CODATA mass difference in *u* is  $m_n - m_p = 1.001\,388\,449\,00(51) \times 10^{-3} u$ .

<sup>2</sup> The 2010 CODATA mass difference in *u* is  $m_n - m_p = 1.388\,449\,19(45) \times 10^{-3} u$ .

<sup>3</sup> Calculated by us from the MOHR 08 ratio  $m_n/m_p = 1.00137841918(46)$ . In *u*,  $m_n - m_p = 1.38844920(46) \times 10^{-3} u$ .

<sup>4</sup> Calculated by us from the MOHR 05 ratio  $m_n/m_p = 1.00137841870 \pm 0.00000000058$ . In *u*,  $m_n - m_p = (1.3884487 \pm 0.00000006) \times 10^{-3} u$ .

<sup>5</sup> Calculated by us from the MOHR 99 ratio  $m_n/m_p = 1.00137841887 \pm 0.00000000058$ . In *u*,  $m_n - m_p = (1.3884489 \pm 0.00000006) \times 10^{-3} u$ .

<sup>6</sup> Calculated by us from the COHEN 87 ratio  $m_n/m_p = 1.001378404 \pm 0.000000009$ . In *u*,  $m_n - m_p = 0.001388434 \pm 0.000000009 u$ .

*n* MEAN LIFE

Limits on lifetimes for *bound* neutrons are given in the section “p PARTIAL MEAN LIVES.”

We average the best seven measurements. The result,  $880.2 \pm 1.0$  s (including a scale factor of 1.9), is 5.5 seconds lower than the value we gave in 2010—a drop of 6.9 old and 5.5 new standard deviations.

For a full review of all matters concerning the neutron lifetime, see F.E. Wietfeldt and G.L. Greene, “The neutron lifetime,” *Reviews of Modern Physics* **83** 1173 (2011). In particular, there is a full discussion of the experimental methods and results; and an average lifetime is obtained making several different selections of the results then available.

<sup>1</sup> ARZUMANOV 15 is a reanalysis of their 2008–2010 dataset, with improved systematic corrections of ARZUMANOV 00 and ARZUMANOV 12.

<sup>2</sup> YUE 13 differs from NICO 05 in that a different and better method was used to measure the neutron density in the fiducial volume. This shifted the lifetime by +1.4 seconds and reduced the previously largest source of systematic uncertainty by a factor of five.

<sup>3</sup> STEYERL 12 is a detailed reanalysis of neutron storage loss corrections to the raw data of MAMPE 89, and it replaces that value.

<sup>4</sup> IGNATOVICH 95 calls into question some of the corrections and averaging procedures used by MAMPE 93. The response, BONDARENKO 96, denies the validity of the criticisms.

<sup>5</sup> ARZUMANOV 12 reanalyzes its systematic corrections in ARZUMANOV 00 and obtains this corrected value.

<sup>6</sup> The NESVIZHEVSKII 92 measurement has been withdrawn by A. Serebrov.

<sup>7</sup> The BYRNE 80 measurement has been withdrawn (J. Byrne, private communication, 1990).

WEIGHTED AVERAGE  
880.2 ± 1.0 (Error scaled by 1.9)

*n* MAGNETIC MOMENT

See the “Note on Baryon Magnetic Moments” in the *A* Listings.

VALUE ( $\mu_N$ )	DOCUMENT ID	TECN	COMMENT
<b>–1.91304273 ± 0.00000045</b>	MOHR 16	RVUE	2014 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •

< 16	90	ALTAREV 79	MRS	$d = (4.0 \pm 7.5) \times 10^{-25}$

<sup>1</sup> SEREBROV 14 includes the data of ALTAREV 96.

<sup>2</sup> LAMOREAUX 07 faults BAKER 06 for not including in the estimate of systematic error an effect due to the Earth's rotation. BAKER 07 replies (1) that the effect was included implicitly in the analysis and (2) that further analysis confirms that the BAKER 06 limit is correct as is. See also SILENKO 07.

<sup>3</sup> This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the results of these two experiments has been criticized by LAMOREAUX 00.

*n* MEAN-SQUARE CHARGE RADIUS

The mean-square charge radius of the neutron,  $\langle r_n^2 \rangle$ , is related to the neutron-electron scattering length  $b_{ne}$  by  $\langle r_n^2 \rangle = 3(m_e a_0 / m_n) b_{ne}$ , where  $m_e$  and  $m_n$  are the masses of the electron and neutron, and  $a_0$  is the Bohr radius. Numerically,  $\langle r_n^2 \rangle = 86.34 b_{ne}$ , if we use  $a_0$  for a nucleus with infinite mass.

LIMIT ON  $n\bar{n}$  OSCILLATIONSMean Time for  $n\bar{n}$  Transition in Vacuum

A test of  $\Delta B=2$  baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for  $n\bar{n}$  oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for  $n \rightarrow \bar{n}$  transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table. See MOHAPATRA 09 for a recent review.

<sup>1</sup> Losses of neutrons due to oscillations to mirror neutrons would be maximal when the magnetic fields  $B$  and  $B'$  in the two worlds were equal. Hence the scan over  $B$  by ALTAREV 09a: the limit applies for any  $B'$  over the given range. At  $B' = 0$ , the limit is 141 s (95% CL).

<sup>1</sup> NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition  $^{71}\text{Ga} \rightarrow ^{71}\text{Ge} + \text{neutrals}$  rather than to solar-neutrino reactions.

## BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

## Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\bar{B}_f [f_1(q^2)\gamma_\lambda + i f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5q_\lambda] B_i. \quad (1)$$

Here  $B_i$  and  $\bar{B}_f$  are spinors describing the initial and final baryons, and  $q = p_i - p_f$ , while the terms in  $f_1$ ,  $f_2$ ,  $g_1$ , and  $g_3$  account for vector, induced tensor (“weak magnetism”), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer,  $f_1$  reduces to the vector coupling constant  $g_V$ , and  $g_1$  reduces to the axial-vector coupling constant  $g_A$ . The latter coefficients are related by Cabibbo’s theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The  $g_3$  term is negligible for transitions in which an  $e^\pm$  is emitted, and gives a very small correction, which can be estimated by PCAC [4], for  $\mu^\pm$  modes. Recoil effects

include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f}, \quad (2)$$

where  $m_i$  and  $m_f$  are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher  $q^2$ , it is necessary to modify the form factors at  $q^2 = 0$  by a “dipole”  $q^2$  dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio  $g_A/g_V$  may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}. \quad (3)$$

The presence of a “triple correlation” term in the transition probability, proportional to  $\text{Im}(g_A/g_V)$  and of the form

$$\sigma_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (4)$$

for initial baryon polarization or

$$\sigma_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (5)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle  $\phi$  has been measured precisely only in neutron decay (and in  $^{19}\text{Ne}$  nuclear beta decay), and the results are consistent with  $T$  invariance.

## Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_\pi^2 \cdot \bar{B}_f (A - B\gamma_5) B_i, \quad (6)$$

where  $A$  and  $B$  are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma \hat{\omega}_f \cdot \hat{\omega}_i + (1 - \gamma)(\hat{\omega}_f \cdot \hat{\mathbf{n}})(\hat{\omega}_i \cdot \hat{\mathbf{n}}) + \alpha(\hat{\omega}_f \cdot \hat{\mathbf{n}} + \hat{\omega}_i \cdot \hat{\mathbf{n}}) + \beta \hat{\mathbf{n}} \cdot (\hat{\omega}_f \times \hat{\omega}_i), \quad (7)$$

where  $\hat{\mathbf{n}}$  is a unit vector in the direction of the final baryon momentum, and  $\hat{\omega}_i$  and  $\hat{\omega}_f$  are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  are defined as

$$\begin{aligned} \alpha &= 2 \text{Re}(s^*p)/(|s|^2 + |p|^2), \\ \beta &= 2 \text{Im}(s^*p)/(|s|^2 + |p|^2), \\ \gamma &= (|s|^2 - |p|^2)/(|s|^2 + |p|^2), \end{aligned} \quad (8)$$

# Baryon Particle Listings

$n$

where  $s = A$  and  $p = |\mathbf{p}_f| B/(E_f + m_f)$ ; here  $E_f$  and  $\mathbf{p}_f$  are the energy and momentum of the final baryon. The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1. \quad (9)$$

If the hyperon polarization is  $\mathbf{P}_Y$ , the polarization  $\mathbf{P}_B$  of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \hat{\mathbf{n}}) + \gamma\hat{\mathbf{n}} \times (\mathbf{P}_Y \times \hat{\mathbf{n}})}{1 + \alpha\mathbf{P}_Y \cdot \hat{\mathbf{n}}}. \quad (10)$$

Here  $\mathbf{P}_B$  is defined in the rest system of the baryon, obtained by a Lorentz transformation along  $\hat{\mathbf{n}}$  from the hyperon rest frame, in which  $\hat{\mathbf{n}}$  and  $\mathbf{P}_Y$  are defined.

An additional useful parameter  $\phi$  is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi. \quad (11)$$

In the Listings, we compile  $\alpha$  and  $\phi$  for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give  $\alpha$ ,  $\phi$ , and  $\Delta$  (defined below) with errors, and also give the value of  $\gamma$  without error.

Time-reversal invariance requires, in the absence of final-state interactions, that  $s$  and  $p$  be relatively real, and therefore that  $\beta = 0$ . However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s|e^{i\delta_s} \text{ and } p = |p|e^{i\delta_p}, \quad (12)$$

where  $\delta_s$  and  $\delta_p$  are the pion-baryon  $s$ - and  $p$ -wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p). \quad (13)$$

One also defines  $\Delta = -\tan^{-1}(\beta/\alpha)$ . If  $T$  invariance holds,  $\Delta = \delta_s - \delta_p$ . For  $\Lambda \rightarrow p\pi^-$  decay, the value of  $\Delta$  may be compared with the  $s$ - and  $p$ -wave phase shifts in low-energy  $\pi^-p$  scattering, and the results are consistent with  $T$  invariance.

See also the note on "Radiative Hyperon Decays" in the  $\Xi^0$  Listings in this *Review*.

$\lambda \equiv g_A / g_V$

See key on page 601

# Baryon Particle Listings

*n*

## $e^-$ ASYMMETRY PARAMETER $A$

This is the neutron-spin electron-momentum correlation coefficient. Unless otherwise noted, the values are corrected for radiative effects and weak magnetism. In the Standard Model,  $A$  is related to  $\lambda \equiv g_A/g_V$  by  $A = -2\lambda(\lambda+1)/(1+3\lambda^2)$ ; this assumes that  $g_A$  and  $g_V$  are real.

<sup>1</sup> KROPF 74 reviews all data through 1972.

## TRIPLE CORRELATION COEFFICIENT $D$

These are measurements of the component of  $n$  spin perpendicular to the decay plane in  $\beta$  decay. Should be zero if  $T$  invariance is not violated.

VALUE (units $10^{-4}$ )	DOCUMENT ID	TECN	COMMENT
<b>-1.2 ± 2.0 OUR AVERAGE</b>			
-0.94 ± 1.89 ± 0.97	CHUPP 12	CNTR	Cold <i>n</i> , polarized > 91%
-2.8 ± 6.4 ± 3.0	SOLDNER 04	CNTR	Cold <i>n</i> , polarized
-6 ± 12 ± 5	LISING 00	CNTR	Polarized > 93%
• • • We do not use the following data for averages, fits, limits, etc. • • •			
-0.96 ± 1.89 ± 1.01	MUMM 11	CNTR	See CHUPP 12
+22 ± 30	EROZOLIM... 78	CNTR	Cold <i>n</i> , polarized
-27 ± 50	<sup>1</sup> EROZOLIM... 74	CNTR	Cold <i>n</i> , polarized
-11 ± 17	STEINBERG 74	CNTR	Cold <i>n</i> , polarized

<sup>1</sup> EROZOLIMSKII 78 says asymmetric proton losses and nonuniform beam polarization may give a systematic error up to  $30 \times 10^{-4}$ , thus increasing the EROZOLIMSKII 74 error to  $50 \times 10^{-4}$ . STEINBERG 74 and STEINBERG 76 estimate these systematic errors to be insignificant in their experiment.

## TRIPLE CORRELATION COEFFICIENT $R$

Another test of time-reversal invariance.  $R$  measures the polarization of the electron in the direction perpendicular to the plane defined by the neutron spin and the electron momentum.  $R = 0$  for  $T$  invariance.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>+0.004 ± 0.012 ± 0.005</b>	<sup>1</sup> KOZELA 12	CNTR	Mott polarimeter
• • • We do not use the following data for averages, fits, limits, etc. • • •			
+0.008 ± 0.015 ± 0.005	KOZELA 09	CNTR	See KOZELA 12

<sup>1</sup> KOZELA 12 also measures the polarization of the electron along the direction of the neutron spin. This is nonzero in the Standard Model; the correlation coefficient is  $N = +0.067 \pm 0.011 \pm 0.004$ .

## *n* REFERENCES

We have omitted some papers that have been superseded by later experiments. See our earlier editions.

## N AND Δ RESONANCES

Revised May 2015 by V. Burkert (Jefferson Lab), E. Klempt (University of Bonn), M.R. Pennington (Jefferson Lab), L. Tiator (University of Mainz), and R.L. Workman (George Washington University).

### I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The Breit-Wigner masses and widths, the pole positions, and the elasticities of the *N* and  $\Delta$  resonances in the Baryon Summary Table come largely from partial-wave analyses of  $\pi N$  total, elastic, and charge-exchange scattering data. The most comprehensive analyses were carried out by the Karlsruhe-Helsinki (KH80) [1], Carnegie Mellon-Berkeley (CMB80) [2], and George Washington U (GWU) [3] groups. Partial-wave analyses have also been performed on much smaller  $\pi N$  reaction data sets to get  $\eta N$ ,  $K\Lambda$ , and  $K\Sigma$  branching fractions (see the Listings for references). Other branching fractions come from analyses of  $\pi N \rightarrow \pi\pi N$  data.

In recent years, a large amount of data on photoproduction of many final states has been accumulated, and these data are beginning to tell us much about the properties of baryon resonances. A survey of data on photoproduction can be found in the proceedings of recent conferences [4] and workshops [5], and in recent reviews [6,7].

*	Evidence of existence is poor.										

## II. Naming scheme for baryon resonances

In the past, when nearly all resonance information came from elastic  $\pi N$  scattering, it was common to label resonances with the incoming partial wave  $L_{2I,2J}$ , as in  $\Delta(1232)P_{33}$  and  $N(1680)F_{15}$ . However, most recent information has come from  $\gamma N$  experiments. Therefore, we have replaced  $L_{2I,2J}$  with the spin-parity  $J^P$  of the state, as in  $\Delta(1232)3/2^+$  and  $N(1680)5/2^+$ ; this name gives intrinsic properties of the resonance that are independent of the specific particles and reactions used to study them. This applies equally to all baryons, including  $\Xi$  resonances and charm baryons that are not produced in formation experiments. We do not, however, attach the mass or spin-parity to the names of the ground-state (“stable”) baryons  $N, \Lambda, \Sigma, \Xi, \Omega, \Lambda_c, \dots$ .

## III. Using the $N$ and $\Delta$ listings

Tables 1 and 2 list all the  $N$  and  $\Delta$  entries in the Baryon Listings and give our evaluation of the overall status and the status channel by channel. Only the established resonances (overall status 3 or 4 stars) are promoted to the Baryon Summary Table. We long ago omitted from the Listings information from old

analyses, prior to KH80 and CMB80, which can be found in earlier editions. A rather complete survey of older results was given in our 1982 edition [8].

Table 2. The status of the  $\Delta$  resonances. Only those with an overall status of \*\*\* or \*\*\*\* are included in the main Baryon Summary Table.

Status as seen in

*	Evidence of existence is poor.										

As a rule, we award an overall status \*\*\*\* or \*\*\* only to those resonances which are derived from analyses of data sets that include precision differential cross sections and polarization observables, and are confirmed by independent analyses. All other signals are given \*\* or \* status. We do not consider new results that are not accompanied by proper error evaluation. The following criteria are guidelines for future error analysis.

1. Uncertainties in resonance parameters: The publication must have a detailed discussion on how the uncertainties of parameters were estimated and why the author(s) believe that they approximately represent real uncertainties. This requires that the error estimates go beyond the simple fit error as e.g. given by MINUIT, and the robustness of the results must be demonstrated.

2. Fit quality: Concrete measures for the fit quality must be provided. The reduced global  $\chi^2$  value of the fit, while useful, is insufficient. Other possibilities include quoting variations of local  $\chi^2$  value in kinematic regions where evidence for new states or significantly improved information on resonance parameters is claimed.

3. Weight factors in observables: Analyses often use weight factors for certain data sets to either increase or reduce their

# Baryon Particle Listings

## $N$ 's and $\Delta$ 's

impact on the results. This has been particularly important when polarization observables are involved, which usually are very sensitive to amplitude interferences but often have much poorer statistics than differential cross section data. To evaluate sensitivities, the resulting resonance parameters should be checked against variations of the specific weight factors.

Claims of evidence for new baryon states must be based on a sufficiently complete set of partial waves in the fit. The robustness of signals must be demonstrated, e.g. by examining the effect of higher waves in the fit.

### IV. Properties of resonances

Resonances are defined by poles of the  $S$ -matrix, whether in scattering, production or decay matrix elements. These are poles in the complex plane in  $s$ , as discussed in the new review on *Resonances*. As traditional we quote here the pole positions in the complex energy  $w = \sqrt{s}$  plane. Crucially, the position of the pole of the  $S$ -matrix is independent of the process, and the production and decay properties factorize. This is the rationale for listing the pole position first for each resonance.

These key properties of the  $S$ -matrix pole are in contrast to other quantities related to resonance phenomena, such as Breit-Wigner parameters or any  $K$ -matrix pole. Thus, Breit-Wigner parameters depend on the formalism used such as angular-momentum barrier factors, or cut-off parameters, and the assumed or modeled background. However, the accurate determination of pole parameters from the analysis of data on the real energy axis is not necessarily simple, or even straightforward. It requires the implementation of the correct analytic structure of the relevant (often coupled) channels. The example in the meson sector of the  $\sigma$ -pole highlights the need to incorporate right and left hand cut analyticity (and their relation imposed by crossing symmetry) into a dispersive analysis to obtain a robust determination of the pole position, for a very short-lived state close to the lowest threshold. The development of general methods that are simpler to implement in the baryon sector is a research problem of current interest, often exploiting techniques introduced long ago when the experimental data were far poorer than those presently available for reactions like  $\gamma N \rightarrow \pi N$  [9]. No consensus yet exists for the use of any particular method, beyond the need to incorporate the general properties mentioned here and discussed more fully in the review of *Resonances*.

The tables will change in the following way: Pole positions, elastic and normalized inelastic residues appear first, followed by the Breit-Wigner mass, width, decay modes and branching ratios. Finally, we give the photon decay amplitudes first as complex values at the pole position and then as real numbers at the Breit-Wigner mass.

### V. Photoproduction

A new approach to the nucleon excitation spectrum is provided by dedicated facilities at the Universities of Bonn, Grenoble, and Mainz, and at the national laboratories Jefferson

Lab in the US and SPring-8 in Japan. High-precision cross sections and polarization observables for the photoproduction of pseudoscalar mesons provide a data set that is nearly a “complete experiment,” one that fully constrains the four complex amplitudes describing the spin-structure of the reaction [11]. A large number of photoproduction reactions has been studied.

In pseudo-scalar meson photoproduction, the four independent helicity amplitudes can be expressed in terms of the four CGLN [12] amplitudes allowed by Lorentz and gauge invariance. These amplitudes can be expanded in a series of electric and magnetic multipoles. Except for  $J=1/2$ , one electric and one magnetic multipole contributes to each  $J^P$  combination.

For a given state, these two amplitudes determine the resonance photo-decay helicity amplitudes  $A_{1/2}$  and  $A_{3/2}$ . As described below, this resonance extraction has been carried out either assuming a Breit-Wigner resonance or at the pole.

If a Breit-Wigner parametrization is used, the  $N\gamma$  partial width,  $\Gamma_\gamma$ , is given in terms of the helicity amplitudes  $A_{1/2}$  and  $A_{3/2}$  by

$$\Gamma_\gamma = \frac{k_{\text{BW}}^2}{\pi} \frac{2m_N}{(2J+1)m_{\text{BW}}} \left( |A_{1/2}|^2 + |A_{3/2}|^2 \right). \quad (1)$$

Here  $m_N$  and  $m_{\text{BW}}$  are the nucleon and resonance masses,  $J$  is the resonance spin, and  $k_{\text{BW}}$  is the photon c.m. decay momentum. Most earlier analyses have quoted these real quantities  $A_{1/2}$  and  $A_{3/2}$ .

More recent studies have quoted related complex quantities, evaluated at the T-matrix pole. These complex helicity amplitudes,  $\tilde{A}_{1/2}$  and  $\tilde{A}_{3/2}$ , can be cast onto the form

$$\tilde{A}_h = \sqrt{\frac{\pi(2J+1)w_{\text{pole}}}{m_N k_{\text{pole}}^2}} \frac{\text{Res}(T_h(\gamma N \rightarrow N b))}{\sqrt{\text{Res}(T(N b \rightarrow N b))}} \quad (2)$$

where the residues ( $\text{Res}$ ) are evaluated at the pole position,  $w_{\text{pole}}$ , and  $k_{\text{pole}}^2 = (w_{\text{pole}}^2 - m_N^2)/4w_{\text{pole}}^2$  [13]. For Breit-Wigner amplitudes,  $w_{\text{pole}} = m_{\text{BW}}$  and  $\tilde{A}_h = A_h$ . Similar relations for the photo- and electrocouplings at the pole position can be found in [14,15].

The determination of eight real numbers from four complex amplitudes (with one overall phase undetermined) requires at least seven independent measurements. At least one further measurement is required to resolve discrete ambiguities that result from the fact that data are proportional to squared amplitudes. Photon beams and nucleon targets can be polarized (with linear or circular polarization  $P_\perp$ ,  $P_\odot$  and  $\vec{T}$ , respectively); the recoil polarization of the outgoing baryon  $\vec{R}$  can be measured. The experiments can be divided into three classes: (1) the beam and target are polarized (BT); (2) the beam is polarized and the recoil baryon polarization is measured (BR); (3) the target is polarized and the recoil polarization is measured (TR). Different sign conventions are used in the literature, as summarized in [16].

One of the best studied reactions is  $\gamma p \rightarrow \Lambda K^+$ . Published data include differential cross sections, the beam asymmetry  $\Sigma$ , the target asymmetry  $T$ , the recoil polarization  $P$ , and the BR double-polarization variables  $C'_x, C'_z, O'_x$ , and  $O'_z$ . For the photoproduction of pions and etas, off proton and neutron targets, differential cross sections, single- and double-polarization asymmetries have been measured, mainly for pions.

## VI. Electroproduction

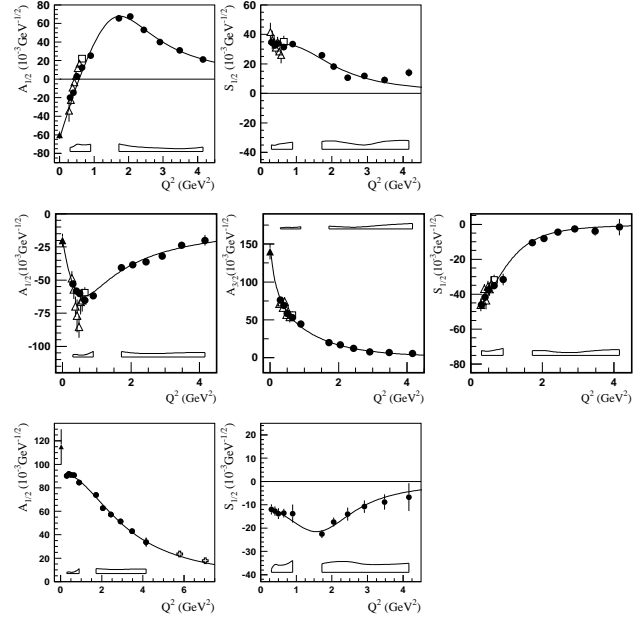

Electro-production of mesons provides information on the internal structure of resonances. The helicity amplitudes are functions of the (squared) momentum transfer  $Q^2 = -(e - e')^2$ , where  $e$  and  $e'$  are the 4-momenta of the incident and scattered electron, and a third amplitude,  $S_{1/2}$ , measures the resonance response to the longitudinal component of the virtual photon. Most data stem from the reactions  $e^- p \rightarrow e^- n \pi^+$  and  $e^- p \rightarrow e^- p \pi^0$  but also the reactions  $e^- p \rightarrow e^- p \eta$ ,  $e^- p \rightarrow e^- p \pi^+ \pi^-$ , and  $e^- p \rightarrow e^- \Lambda(\Sigma^0) K^+$  have been studied. The data and their interpretation are reviewed in Refs. 18,19.

The transition to the  $\Delta(1232)3/2^+$  is often quantified in terms of the magnetic dipole transition moment  $M_{1+}$  (or the magnetic transition form factor  $G_{M,Ash}^*(Q^2)$ ) [20], and the electric and scalar quadrupole transition moments  $E_{1+}$  and  $S_{1+}$ . Figure 1 shows the strength of the  $p \rightarrow \Delta^+$  transition plotted versus the photon virtuality  $Q^2$ . At  $Q^2 = 0$ ,  $M_{1+}$  dominates the resonance transition strength. The two amplitudes  $E_{1+}$  and  $S_{1+}$  imply a quadrupole deformation of the transition to the lowest excited state. The magnitude of  $R_{EM} = E_{1+}/M_{1+}$  remains nearly constant, while the magnitude of  $R_{SM} = S_{1+}/M_{1+}$  increases rapidly up to 25% at the highest  $Q^2$  value. Dynamical models assign most of the quadrupole strength in the  $p \Delta^+$  transition to the effect of a meson cloud around the bare  $\Delta$  states.

**Figure 1:** Left: The magnetic transition form factor for the  $\gamma^* p \rightarrow \Delta^+(1232)$  transition versus the photon virtuality  $Q^2$ . Right: The electric and scalar quadrupole ratios  $R_{EM}$  and  $R_{SM}$ . The different symbols are results from different experiments at JLab (squares, diamonds, circle) and MAMI (triangle, cross). The boxes near the horizontal axis indicate model uncertainties of the squares. Curves to guide the eyes.

Figure 2 shows the transverse and scalar helicity amplitudes for the  $N(1440)1/2^+$ ,  $N(1520)3/2^-$ , and  $N(1535)1/2^-$  resonances from JLab [18]. Similar results have been achieved at Mainz [19]. For the states  $N(1440)1/2^+$  and  $N(1520)3/2^-$ , helicity amplitudes and  $\pi\Delta$  and  $\rho p$  decays were determined at JLab in an analysis of  $\pi^+ \pi^- p$  electroproduction [21]. The data show distinctly different  $Q^2$  dependencies that indicate different internal structures.

**Figure 2:** Transverse and scalar (longitudinal) helicity amplitudes for  $\gamma p \rightarrow N(1440)1/2^+$  (top),  $\gamma p \rightarrow N(1520)3/2^-$  (center), and  $\gamma p \rightarrow N(1535)1/2^-$  (bottom) as extracted from the JLab/CLAS data in  $n\pi^+$  production (full circles), in  $\pi\pi^+\pi^-$  (open triangles), combined single and double pion production (open squares). The solid triangle is the PDG 2014 value at  $Q^2 = 0$ . The open boxes are the model uncertainties of the full circles.

The  $N(1520)3/2^-$  helicity amplitudes reveal the dominance of its three-quark nature: the  $A_{3/2}$  amplitude is large at the photon point and decreases rapidly  $\sim Q^{-5}$  with increasing  $Q^2$ ;  $A_{1/2}$  is small at the photon point, increases rapidly with  $Q^2$  and then falls off with  $\sim Q^{-3}$ . Quantitative agreement with the data is, however, achieved only when meson cloud effects are included.

At high  $Q^2$ , both amplitudes for  $N(1440)1/2^+$  are qualitatively described by light front quark models [22]: at short distances the resonance behaves as expected from a radial excitation of the nucleon. On the other hand,  $A_{1/2}$  changes sign at about  $0.6 \text{ GeV}^2$ . This remarkable behavior has not been observed before for any nucleon form factor or transition amplitude. Obviously, an important change in the structure occurs when the resonance is probed as a function of  $Q^2$ .

# Baryon Particle Listings

## $N$ 's and $\Delta$ 's

The  $Q^2$  dependence of  $A_{1/2}$  of the  $N(1535)1/2^-$  resonance exhibits the expected  $\sim Q^{-3}$  dependence, except for small  $Q^2$  values where meson cloud effects set in.

**Figure 3:** Transverse and scalar helicity amplitudes for  $\gamma p \rightarrow N(1675)5/2^-$  (top), and  $\gamma p \rightarrow N(1680)5/2^+$  (bottom) as extracted from the JLab/CLAS data in  $n\pi^+$  production (full circles), combined single and double pion production (open square). The solid triangle is the 2014 PDG value at  $Q^2 = 0$ . The open boxes are the model uncertainties of the full circles. The curves are to guide the eye.

Figure 3 shows the transverse and scalar amplitudes for two states in the 3rd nucleon resonance region around 1700 MeV, the  $N(1675)5/2^-$  and  $N(1680)5/2^+$ . These states have nearly degenerate masses and are parity partners. In the quark model picture, the transverse amplitudes for  $N(1675)5/2^-$  on the proton are suppressed due to the Moorhouse selection rule, allowing for a quantitative evaluation of the meson-baryon contributions. The data show significant meson-baryon strength in the  $A_{1/2}$  amplitude even at quite high  $Q^2$ , while  $A_{3/2}$  drops much faster with  $Q^2$ .  $N(1680)5/2^+$  shows qualitatively the features predicted in constituent quark models, a dominant  $A_{3/2}$  at the real photon point that drops rapidly with increasing  $Q^2$ , while  $A_{1/2}$  becomes the dominant contribution at high  $Q^2$ , indicating a switch of the helicity structure in the resonance transition at short distances.

### VII. Partial wave analyses

Several PWA groups are now actively involved in the analysis of the new data. The GWU group maintains a nearly complete database covering reactions from  $\pi N$  and  $KN$  elastic scattering to  $\gamma N \rightarrow N\pi$ ,  $N\eta$ , and  $N\eta'$ . It is presently the only group determining  $\pi N$  elastic amplitudes from scattering data in sliced energy bins. Given the high-precision of photoproduction data already or soon to be collected, the spectrum of  $N$  and  $\Delta$  resonances will in the near future be better known.

Fits to the data are performed by various groups with the aim to understand the reaction dynamics and to identify  $N$  and  $\Delta$  resonances. For practical reasons, approximations have to be made. We mention several analyses here: (1) The Mainz

unitary isobar model [23] focusses on the correct treatment of the low-energy domain. Resonances are added to the unitary amplitude as a sum of Breit-Wigner amplitudes. This model also obtains resonance transition form factors and helicity amplitudes from electroproduction [19]. (2) For  $N\pi$  electroproduction, the Yerevan/JLab group uses both the unitary isobar model and the dispersion relation approach developed in [22]. A phenomenological model was developed to extract resonance couplings and partial decay widths from exclusive  $\pi^+\pi^-p$  electroproduction [21]. (3) Multichannel analyses using K-matrix parameterizations derive background terms from a chiral Lagrangian - providing a microscopical description of the background - (Giessen [24,25]) or from phenomenology (KSU [26,27], Bonn-Gatchina [28]). (4.) Several groups (EBAC-Jlab [29,30], ANL-Osaka [31], Dubna-Mainz-Taipeh [32], Bonn-Jülich [33,34,35], Valencia [36]) use dynamical reaction models, driven by chiral Lagrangians, which take dispersive parts of intermediate states into account. Several other groups have made important contributions. The Giessen group pioneered multichannel analyses of large data sets on pion- and photo-induced reactions [24,25]. The Bonn-Gatchina group included recent high-statistics data and reported systematic searches for new baryon resonances in all relevant partial waves. A summary of their results can be found in Ref. 28.

### $N(1520)$ FOOTNOTES

- <sup>1</sup> Fit to the amplitudes of HOEHLER 79.  
<sup>2</sup> MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze  $\eta$  photoproduction data. The ratio of the  $A_{3/2}$  and  $A_{1/2}$  amplitudes is determined, with less model dependence than the amplitudes themselves, to be  $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$ .

### N(1650) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	50–70 %
$\Gamma_2$ $N\eta$	14–22 %
$\Gamma_3$ $\Lambda K$	5–15 %
$\Gamma_4$ $N\pi\pi$	8–36 %
$\Gamma_5$ $\Delta(1232)\pi$	
$\Gamma_6$ $\Delta(1232)\pi, D\text{-wave}$	6–18 %
$\Gamma_7$ $N\sigma$	2–18 %
$\Gamma_8$ $N(1440)\pi$	6–26 %
$\Gamma_9$ $p\gamma, \text{ helicity}=1/2$	0.04–0.20 %
$\Gamma_{10}$ $n\gamma, \text{ helicity}=1/2$	0.003–0.17 %

*N*(1675) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	35–45 %
$\Gamma_2$ $N\eta$	< 1 %
$\Gamma_3$ $N\pi\pi$	25–45 %
$\Gamma_4$ $\Delta(1232)\pi$	
$\Gamma_5$ $\Delta(1232)\pi, D\text{-wave}$	23–37 %
$\Gamma_6$ $N\sigma$	3–7 %
$\Gamma_7$ $p\gamma$	0–0.02 %
$\Gamma_8$ $p\gamma$ , helicity=1/2	0–0.01 %
$\Gamma_9$ $p\gamma$ , helicity=3/2	0–0.01 %
$\Gamma_{10}$ $n\gamma$	0–0.15 %
$\Gamma_{11}$ $n\gamma$ , helicity=1/2	0–0.05 %
$\Gamma_{12}$ $n\gamma$ , helicity=3/2	0–0.10 %

$N(1860) 5/2^+$

$I(J^P) = \frac{1}{2}(\frac{5}{2}^+)$  Status: \*\*

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a  $J^P = 5/2^+$  state with a mass above 1800 MeV was filed under a two-star  $N(2000)$ . There is now some evidence from ANISOVICH 12A for two  $5/2^+$  states in this region, so we have split the older data (according to mass) between two two-star  $5/2^+$  states, an  $N(1860)$  and an  $N(2000)$ .

## *N*(1875) 3/2<sup>−</sup>

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$  Status: \*\*\*

Before the 2012 *Review*, all the evidence for a  $J^P = 3/2^-$  state with a mass above 1800 MeV was found under a two-star *N*(2080). There is now evidence from ANISOVICH 12A for two 3/2<sup>−</sup> states in this region, so we have split the older data (according to mass) between a three-star *N*(1875) and a two-star *N*(2120).

*I*(*J*<sup>*P*</sup>) =  $\frac{1}{2}(\frac{5}{2}^+)$  Status: \*\*

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a *J*<sup>*P*</sup> = 5/2<sup>+</sup> state with a mass above 1800 MeV was filed under a two-star *N*(2000). There is now some evidence from ANISOVICH 12A for two 5/2<sup>+</sup> states in this region, so we have split the older data (according to mass) between two two-star 5/2<sup>+</sup> states, an *N*(1860) and an *N*(2000).

−31	ARNDT 91	DPWA	$\pi N \rightarrow \pi N$ Soln SM90

<sup>4</sup> Fit to the amplitudes of HOEHLER 79.  
<sup>5</sup> This ARNDT 95 value is in error, as pointed out by HOHLER 01. The corrected value is in line with the ARNDT 91 value (R.A. Arndt, private communication).

Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE  
We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.  
  
Our 1982 edition also had a  $\Delta(2850)$  and a  $\Delta(3230)$ . The evidence for them was deduced from total cross-section and  $180^\circ$  elastic cross-section measurements. The  $\Delta(2850)$  has been resolved into the  $\Delta(2750) \, l_{3,13}$  and  $\Delta(2950) \, K_{3,15}$ . The  $\Delta(3230)$  is perhaps related to the  $K_{3,13}$  of HENDRY 78 and to the  $L_{3,17}$  of KOCH 80.

$\Delta(\sim 3000)$ BREIT-WIGNER MASS			
VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
3300	<sup>1</sup> KOCH	80	IPWA $\pi N \rightarrow \pi N \, L_{3,17}$ wave
3500	<sup>1</sup> KOCH	80	IPWA $\pi N \rightarrow \pi N \, M_{3,19}$ wave
$2850 \pm 150$	HENDRY	78	MPWA $\pi N \rightarrow \pi N \, l_{3,11}$ wave
$3200 \pm 200$	HENDRY	78	MPWA $\pi N \rightarrow \pi N \, K_{3,13}$ wave
$3300 \pm 200$	HENDRY	78	MPWA $\pi N \rightarrow \pi N \, L_{3,17}$ wave
$3700 \pm 200$	HENDRY	78	MPWA $\pi N \rightarrow \pi N \, M_{3,19}$ wave
$4100 \pm 300$	HENDRY	78	MPWA $\pi N \rightarrow \pi N \, N_{3,21}$ wave

$\Delta(\sim 3000)$ BREIT-WIGNER WIDTH

BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure below shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest

quark model, using the measured  $p$ ,  $n$ , and  $\Lambda$  moments as input. In this model, the moments are [1]

$$\begin{aligned} \mu_p &= (4\mu_u - \mu_d)/3 & \mu_n &= (4\mu_d - \mu_u)/3 \\ \mu_{\Sigma^+} &= (4\mu_u - \mu_s)/3 & \mu_{\Sigma^-} &= (4\mu_d - \mu_s)/3 \\ \mu_{\Sigma^0} &= (4\mu_s - \mu_u)/3 & \mu_{\Xi^-} &= (4\mu_s - \mu_d)/3 \\ \mu_\Lambda &= \mu_s & \mu_{\Sigma^0} &= (2\mu_u + 2\mu_d - \mu_s)/3 \\ \mu_{\Omega^-} &= 3\mu_s \end{aligned}$$

and the  $\Sigma^0 \rightarrow \Lambda$  transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}.$$

The quark moments that result from this model are  $\mu_u = +1.852 \mu_N$ ,  $\mu_d = -0.972 \mu_N$ , and  $\mu_s = -0.613 \mu_N$ . The corresponding effective quark masses, taking the quarks to be Dirac point particles, where  $\mu = q\hbar/2m$ , are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

[a] See the Listings below for the pion momentum range used in this measurement.

## CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 10.5$  for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

<sup>1</sup> CHAUVAT 85 actually gives  $\alpha_+(\bar{\Lambda})/\alpha_-(\Lambda) = -1.04 \pm 0.29$ . Assumes polarization is same in  $\bar{p}p \rightarrow \bar{\Lambda}X$  and  $pp \rightarrow \Lambda X$ . Tests of this assumption, based on  $C$ -invariance and fragmentation, are satisfied by the data.

### $g_A / g_V$ FOR $\Lambda \rightarrow pe^-\bar{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the “Note on Baryon Decay Parameters” in the neutron Listings. The measurements all assume that the form factor  $g_2 = 0$ . See also the footnote on DWORKIN 90.

<sup>1</sup> The tabulated result assumes the weak-magnetism coupling  $w \equiv g_W(0)/g_V(0)$  to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 *measures*  $w$  to be  $0.15 \pm 0.30$ , and then  $g_A/g_V = -0.731 \pm 0.016$ .

<sup>2</sup> This experiment measures only the absolute value of  $g_A/g_V$ .

## $\Lambda$ AND $\Sigma$ RESONANCES

**Introduction:** Since our last edition, there have been a few measurements of properties of the lowest  $\Lambda$  and  $\Sigma$  resonances—mostly of masses and widths. But the field remains at a standstill. What follows is a much abbreviated version of the note on  $\Lambda$  and  $\Sigma$  Resonances from our 1990 edition [1]. In particular, see that edition for some representative Argand plots from partial-wave analyses.

the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the “first” particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the  $\Sigma(1775)D_{15}$  amplitude at resonance points along the positive imaginary axis (points “up”), then any  $\Sigma$  at resonance will point “up” and any  $\Lambda$  at resonance will point “down” (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the  $\bar{K}N \rightarrow \Lambda\pi$  and  $\bar{K}N \rightarrow \Sigma\pi$  amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is “up”? Our convention is that of Levi-Setti [2] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or – sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign

**Figure 1.** The signs of the imaginary parts of resonating amplitudes in the  $\bar{K}N \rightarrow \Lambda\pi$  and  $\Sigma\pi$  channels. The signs of the  $\Sigma(1385)$  and  $\Lambda(1405)$ , marked with a ●, are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an ×.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each  $\Lambda$  and  $\Sigma$  resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

**Sign conventions for resonance couplings:** In terms of the isospin-0 and -1 elastic scattering amplitudes  $A_0$  and  $A_1$ , the amplitude for  $K^-p \rightarrow \bar{K}^0 n$  scattering is  $\pm(A_1 - A_0)/2$ , where

means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [3].

**Errors on masses and widths:** The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a

# Baryon Particle Listings

## $\Lambda$ 's and $\Sigma$ 's, $\Lambda(1405)$

range reflecting the spread of the values rather than a particular value with error.

For three states, the  $\Lambda(1520)$ , the  $\Lambda(1820)$ , and the  $\Sigma(1775)$ , there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

Table 1. The status of the  $\Lambda$  and  $\Sigma$  resonances. Only those with an overall status of \*\*\* or \*\*\*\* are included in the main Baryon Summary Table.

****	Existence is certain, and properties are at least fairly well explored.					
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.					
**	Evidence of existence is only fair.					
*	Evidence of existence is poor.					

**Production experiments:** Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and

more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The  $\Sigma(1385)$  and  $\Lambda(1405)$  of course lie below the  $\bar{K}N$  threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of  $\Lambda(1520)$  and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the  $\Sigma(1670)$ .

## $\Lambda(1405) \ 1/2^-$

$I(J^P) = 0(\frac{1}{2}^-)$  Status: \*\*\*\*

The nature of the  $\Lambda(1405)$  has been a puzzle for decades: three-quark state or hybrid; two poles or one. We cannot here survey the rather extensive literature. See, for example, CIEPLY 10, KISSLINGER 11, SEKIYARA 11, and SHEVCHENKO 12A for discussions and earlier references.

It seems to be the universal opinion of the chiral-unitary community that there are two poles in the 1400-MeV region. ZYCHOR 08 presents experimental evidence against the two-pole model, but this is disputed by GENG 07A. See also REVAI 09, which finds little basis for choosing between one- and two-pole models; and IKEDA 12, which favors the two-pole model.

A single, ordinary three-quark  $\Lambda(1405)$  fits nicely into a  $J^P = 1/2^-$   $SU(4)$   $\bar{4}$  multiplet, whose other members are the  $\Lambda_c(2595)^+$ ,  $\Xi_c(2790)^+$ , and  $\Xi_c(2790)^0$ ; see Fig. 1 of our note on “Charmed Baryons.”

## POLE STRUCTURE OF THE $\Lambda(1405)$ REGION

Written November 2015 by Ulf-G. Meißner (Bonn Univ. / FZ Jülich) and Tetsuo Hyodo (YITP, Kyoto Univ.).

The  $\Lambda(1405)$  resonance emerges in the meson-baryon scattering amplitude with the strangeness  $S = -1$  and isospin  $I = 0$ . It is the archetype of what is called a dynamically generated resonance, as pioneered by Dalitz and Tuan [1]. The most powerful and systematic approach for the low-energy regime of the strong interactions is chiral perturbation theory (ChPT), see e.g. Ref. 2. A perturbative calculation is, however, not applicable to this sector because of the existence of the  $\Lambda(1405)$  just below the  $\bar{K}N$  threshold. In this case, ChPT has to be combined with a non-perturbative resummation technique, just as in the case of the nuclear forces. By solving the Lippmann-Schwinger equation with the interaction kernel determined by ChPT and using a particular regularization, in Ref. 3 a successful description of the low-energy  $K^-p$  scattering data as well as the mass distribution of the  $\Lambda(1405)$  was achieved (for further developments, see Ref. 4 and references therein).

The study of the pole structure was initiated by Ref. 5, which finds two poles of the scattering amplitude in the complex energy plane between the  $\bar{K}N$  and  $\pi\Sigma$  thresholds. The spectrum in experiments exhibits one effective resonance shape,

while the existence of two poles results in the reaction-dependent lineshape [6]. The origin of this two-pole structure is attributed to the two attractive channels of the leading order interaction in the SU(3) basis (singlet and octet) [6] and in the isospin basis ( $\bar{K}N$  and  $\pi\Sigma$ ) [7]. It is remarkable that the sign and the strength of the leading order interaction is determined by a low-energy theorem of chiral symmetry, i.e. the so-called Weinberg-Tomozawa term. The two-pole nature of the  $\Lambda(1405)$  is qualitatively different from the case of the N(1440) resonance. Two poles of the N(1440) appear on different Riemann sheets of the complex energy plane separated by the  $\pi\Delta$  branch point. These poles reflect a single state, with a nearby pole and a more distant shadow pole. In contrast, the two poles in the  $\Lambda(1405)$  region on the same Riemann sheet (where  $\pi\Sigma$  channels are unphysical and all other channels physical, correspondingly to the one, connected to the real axis between the  $\pi\Sigma$  and  $\bar{K}N$  thresholds) are generated from two attractive forces mentioned above [6,7].

Recently, various new experimental results on the  $\Lambda(1405)$  have become available [4]. Among these, the most striking measurement is the precise determination of the energy shift and width of kaonic hydrogen by the SIDDHARTA collaboration [8], [9], which provides a quantitative and stringent constraint on the  $K^-p$  amplitude at threshold through the improved Deser formula [10]. Systematic studies with error analyses based on the next-to-leading order ChPT interaction including the SIDDHARTA constraint have been performed by various groups [11–15]. All these studies confirm that the new kaonic hydrogen data are compatible with the scattering data above threshold.

**Table 1:** Comparison of the pole positions of  $\Lambda(1405)$  in the complex energy plane from next-to-leading order chiral unitary coupled-channel approaches including the SIDDHARTA constraint.

approach	pole 1 [MeV]	pole 2 [MeV]
Refs. 11,12, NLO	$1424^{+7}_{-23} - i 26^{+3}_{-14}$	$1381^{+18}_{-6} - i 81^{+19}_{-8}$
Ref. 14, Fit II	$1421^{+3}_{-2} - i 19^{+8}_{-5}$	$1388^{+9}_{-9} - i 114^{+24}_{-25}$
Ref. 15, solution #2	$1434^{+2}_{-2} - i 10^{+2}_{-1}$	$1330^{+4}_{-5} - i 56^{+17}_{-11}$
Ref. 15, solution #4	$1429^{+8}_{-7} - i 12^{+2}_{-3}$	$1325^{+15}_{-15} - i 90^{+12}_{-18}$

The results of the pole positions of  $\Lambda(1405)$  in the various approaches are summarized in Table 1. We may regard the difference among the calculations as a systematic error, which stems from the various approximations of the Bethe-Salpeter equation, the fitting procedure, and also the inclusion of SU(3) breaking effects such as the choice of the various meson decay constants, and so on. The main component for the  $\Lambda(1405)$  is the pole 1, whose position converges within a relatively small region near the  $\bar{K}N$  threshold. On the other hand, the position of the pole 2 shows a sizeable scatter. Detailed studies of the  $\pi\Sigma$  spectrum in various reaction processes, together with

the precise experimental lineshape (see e.g. the recent precise photoproduction data from the LEPS collaboration [16] and from the CLAS collaboration [17,18], electroproduction data from the CLAS collaboration [19], and proton-proton collision data from COSY [20] and the HADES collaboration [21]), will shed light on the position of the second pole. The  $\pi\Sigma$  spectra from the CLAS data and the HADES data are analyzed in Ref. 22 and Ref. 23, respectively. Although the result of the pole positions in Ref. 22 is similar to those in Table 1, the pole found in Ref. 23 is not compatible with other results. Therefore, the analysis with only the  $\pi\Sigma$  spectrum is not completely conclusive. It is thus desirable to perform a comprehensive analysis of  $\pi\Sigma$  spectra together with the systematic error analysis of the scattering data as done in Ref. 15. It was shown there that several solutions, which agree with the scattering data are ruled out, if confronted with the recent CLAS data. The remaining solutions are collected as solution #2 and solution #4 of Ref. 15 in Table 1.

### $\Lambda(1405)$ FOOTNOTES

- <sup>1</sup> DALITZ 91 fits the HEMINGWAY 85 data.
- <sup>2</sup> THOMAS 73 data is fit by CHAO 73 (see next section).
- <sup>3</sup> The KIMURA 00 values are from fits A and B from a coupled-channel potential model using low-energy  $\bar{K} N$  and  $\Sigma \pi$  data, kaonic-hydrogen x-ray measurements, and our  $\Lambda(1405)$  mass and width. The results bear mainly on the *nature* of the  $\Lambda(1405)$ : three-quark state or  $\bar{K} N$  bound state.
- <sup>4</sup> The MARTIN 81 fit includes the  $K^\pm p$  forward scattering amplitudes and the dispersion relations they must satisfy.
- <sup>5</sup> See also the accompanying paper of THOMAS 73.
- <sup>6</sup> Data of SAKITT 65 are used in the fit by KITTEL 66.
- <sup>7</sup> An asymmetric shape, with  $\Gamma/2 = 41$  MeV below resonance, 14 MeV above.

## $\Lambda(1520) \ 3/2^-$

$$I(J^P) = 0(\frac{3}{2}^-) \text{ Status: } ***$$

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** 1 (1982).

Production and formation experiments agree quite well, so they are listed together here.

See key on page 601

**CONSTRAINED FIT INFORMATION**

An overall fit to 9 branching ratios uses 28 measurements and one constraint to determine 6 parameters. The overall fit has a  $\chi^2 = 18.9$  for 23 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$\Gamma(\Sigma(1385)\pi(\rightarrow\Lambda\pi\pi))/\Gamma(\Lambda\pi\pi)$	$\Gamma_5/\Gamma_3$
The $\Lambda\pi\pi$ mode is largely due to $\Sigma(1385)\pi$ . Only the values of $(\Sigma(1385)\pi)/(\Lambda 2\pi)$ given by MAST 73b and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{\text{S-wave}}$ state.

 $\Lambda(1670)$  FOOTNOTES

- <sup>1</sup> GARCIA-RECIO 03 gives pole, not Breit-Wigner, parameters, but the narrow width of the  $\Lambda(1670)$  means there will be little difference.  
<sup>2</sup> MARTIN 77 obtains identical resonance parameters from a T-matrix pole and from a Breit-Wigner fit.

53	ZHANG	13A	DPWA Multichannel

$\Lambda(1690)$ DECAY MODES	
Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1 \ N\overline{K}$	20-30 %
$\Gamma_2 \ \Sigma \pi$	20-40 %
$\Gamma_3 \ \Lambda \pi \pi$	$\sim 25$ %
$\Gamma_4 \ \Sigma \pi \pi$	$\sim 20$ %
$\Gamma_5 \ \Lambda \eta$	
$\Gamma_6 \ \Sigma(1385) \pi, S\text{-wave}$	
The above branching fractions are our estimates, not fits or averages.	

$\Lambda(1690)$ BRANCHING RATIOS			
The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma \pi \pi$ bump looks more significant. (The error given for the $\Lambda \pi \pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma \pi \pi$ decay can be via $\Sigma(1385)$ , for then seven times as much $\Lambda \pi \pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on $\Lambda$ and $\Sigma$ Resonances.

- $\Lambda(1690)$  FOOTNOTES**
- <sup>1</sup> The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another  $D_{03} \ \Lambda$  at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.

<sup>2</sup> BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

$\Lambda(1820) \ 5/2^+$

$I(J^P) = 0(\frac{5}{2}^+)$  Status: \*\*\*

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

 **$\Lambda(1820)$  FOOTNOTES**

- <sup>1</sup> The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.  
<sup>2</sup> There is a suggestion of a bump, enough to be consistent with what is expected from  $\Sigma(1385) \rightarrow \Sigma\pi$  decay.  
<sup>3</sup> The published sign has been changed to be in accord with the baryon-first convention.

## $\Lambda(2000)$

$$I(J^P) = 0(?)^? \quad \text{Status: } *$$

OMITTED FROM SUMMARY TABLE

ZHANG 13A claims a  $J^P = 1/2^-$  state.

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are  $D_3$  (BARBARO-GALTIERI 70 in  $\Sigma\pi$ ),  $D_3+F_5$ ,  $P_3+D_5$ , or  $P_1+D_3$  (BRANDSTETER 72 in  $\Lambda\omega$ ), and  $S_1$  (CAMERON 78B in  $N\bar{K}^*$ ). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

## $\Lambda(2020)$ 7/2<sup>+</sup>

$$I(J^P) = 0(\frac{7}{2}^+) \quad \text{Status: } *$$

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either  $N\bar{K}$  or  $\Sigma\pi$ . With new  $K^- n$  angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

### $\Lambda(2100)$ FOOTNOTES

- <sup>1</sup> The NAKKASYAN 75 values are from the two best solutions found. Each has the  $\Lambda(2100)$  and one additional resonance ( $P_3$  or  $F_5$ ).  
<sup>2</sup> Note that the three for BACCARI 77 entries are for three different waves.  
<sup>3</sup> The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the  $G_3$  wave is 0.03.

## $\Lambda(2325)$ $3/2^-$

$$I(J^P) = 0(\frac{3}{2}^-) \text{ Status: } *$$

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either  $J^P = 3/2^-$  or  $3/2^+$  in a energy-dependent partial-wave analyses of  $K^-p \rightarrow \Lambda\omega$  from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects  $3/2^-$ . DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of  $K^-p \rightarrow \bar{K}N$  data, and finds  $J^P = 3/2^-$  or  $3/2^+$ . They again prefer  $J^P = 3/2^-$ , but only on the basis of model-dependent considerations.

## $\Lambda(2350)$ $9/2^+$

$$I(J^P) = 0(\frac{9}{2}^+) \text{ Status: } ***$$

DAUM 68 favors  $J^P = 7/2^-$  or  $9/2^+$ . BRICMAN 70 favors  $9/2^+$ . LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find  $9/2^+$  in energy-dependent partial-wave analyses of  $\bar{K}N \rightarrow \Sigma\pi$ ,  $\Lambda\omega$ , and  $N\bar{K}$ .

$\Sigma^+$  MAGNETIC MOMENT

See the "Note on Baryon Magnetic Moments" in the  $\Lambda$  Listings. Measurements with an error  $\geq 0.1 \mu_N$  have been omitted.

VALUE ( $\mu_N$ )	EVTS	DOCUMENT ID	TECN	COMMENT
<b>2.458 ± 0.010 OUR AVERAGE</b>				Error includes scale factor of 2.1. See the ideogram below.
2.4613 ± 0.0034 ± 0.0040	250k	MORELOS	93	SPEC $p$ Cu 800 GeV
2.428 ± 0.036 ± 0.007	12k	<sup>5</sup> MORELOS	93	SPEC $p$ Cu 800 GeV
2.479 ± 0.012 ± 0.022	137k	WILKINSON	87	SPEC $p$ Be 400 GeV
2.4040 ± 0.0198	44k	<sup>6</sup> ANKENBRA...	83	CNTR $p$ Cu 400 GeV

<sup>5</sup> We assume  $CPT$  invariance: this is (minus) the  $\Sigma^-$  magnetic moment as measured by MORELOS 93. See below for the moment difference testing  $CPT$ .  
<sup>6</sup> ANKENBRANDT 83 gives the value  $2.38 \pm 0.02 \mu_N$ . MORELOS 93 uses the same hyperon magnet and channel and claims to determine the field integral better, leading to the revised value given here.

$(\mu_{\Sigma^+} + \mu_{\Sigma^-}) / \mu_{\Sigma^+}$

A test of  $CPT$  invariance.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.014 ± 0.015</b>	<sup>7</sup> MORELOS	93	SPEC $p$ Cu 800 GeV

<sup>7</sup> This is our calculation from the MORELOS 93 measurements of the  $\Sigma^+$  and  $\Sigma^-$  magnetic moments given above. The statistical error on  $\mu_{\Sigma^-}$  dominates the error here.

$\Sigma^+$  DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $p \pi^0$	(51.57 ± 0.30) %	
$\Gamma_2$ $n \pi^+$	(48.31 ± 0.30) %	
$\Gamma_3$ $p \gamma$	( 1.23 ± 0.05 ) × 10 <sup>-3</sup>	
$\Gamma_4$ $n \pi^+ \gamma$	[a] ( 4.5 ± 0.5 ) × 10 <sup>-4</sup>	
$\Gamma_5$ $\Lambda e^+ \nu_e$	( 2.0 ± 0.5 ) × 10 <sup>-5</sup>	

$\Delta S = \Delta Q$  (SQ) violating modes or  
 $\Delta S = 1$  weak neutral current (S1) modes

$\Gamma_6$ $n e^+ \nu_e$	SQ	< 5	× 10 <sup>-6</sup>	90%
$\Gamma_7$ $n \mu^+ \nu_\mu$	SQ	< 3.0	× 10 <sup>-5</sup>	90%
$\Gamma_8$ $p e^+ e^-$	S1	< 7	× 10 <sup>-6</sup>	
$\Gamma_9$ $p \mu^+ \mu^-$	S1	( 9 <sup>+9</sup> / <sub>-8</sub> )	× 10 <sup>-8</sup>	

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 7.7$  for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.
