<sup>9</sup> The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\bar{D}^0 \rightarrow K^{*+} \pi^-$ . This value allows  $CP$  violation and is sensitive to the sign of  $\Delta m$ .

<sup>10</sup> The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^-)/\Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows  $CP$  violation. AUBERT 03Z assumes the strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$  amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.

<sup>11</sup> This LINK 05H limit is inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^-)$  (via  $\bar{D}^0$ )/ $\Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows  $CP$  violation. The strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$  is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

<sup>12</sup> This GODANG 00 limit is inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^-)$  (via  $\bar{D}^0$ )/ $\Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows  $CP$  violation. The strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$  is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

<sup>13</sup> AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows  $CP$  violation in this term, but assumes that  $A_D = A_R = 0$ . See the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above.

<sup>14</sup> This limit is inferred from  $R_M$  for  $f = K^+ \pi^-$  and  $f = K^+ \pi^- \pi^+ \pi^-$ . See the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from  $D^0$ - $\bar{D}^0$  mixing.

<sup>15</sup> This limit is inferred from  $R_M$  for  $f = K^+ \ell^- \pi_\ell$ . See the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above.

<sup>16</sup> ANJOS 88c assumes that  $y = 0$ . See the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above. Without this assumption, the limit degrades by about a factor of two.

$$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$$

The  $D_1^0$  and  $D_2^0$  are the mass eigenstates of the  $D^0$  meson, as described in the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above.

Due to the strong phase difference between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$ , we exclude from the average those measurements of  $y'$  that are inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^-)$  (via  $\bar{D}^0$ ) /  $\Gamma(K^+ \pi^-)$  given near the end of this  $D^0$  Listings.

Some early results have been omitted. See our 2006 *Review* (Journal of Physics **G33** 1 (2006)).

“OUR EVALUATION” comes from CPV allowing averages provided by the Heavy Flavor Averaging Group, see the note on “ $D^0$ - $\bar{D}^0$  Mixing.”

## Meson Particle Listings

 $D^0$ WEIGHTED AVERAGE  
1.11±0.27 (Error scaled by 1.4)

$$(\Gamma_1 - \Gamma_2)/\Gamma = 2\gamma$$

- 1 An improved measurement of  $\overline{D}^0 - D^0$  mixing and a search for  $CP$  violation in  $D^0$  decays to  $CP$ -even final states  $K^+ K^-$  and  $\pi^+ \pi^-$  using the final Belle data sample of 976 fb $^{-1}$ .
- 2 ABLIKIM 15D uses quantum correlations in  $e^+ e^- \rightarrow D^0 \overline{D}^0$  at the  $\psi(3770)$ .
- 3 Based on 976 fb $^{-1}$  of data collected at  $Y(nS)$  resonances. Assumes no  $CP$  violation. Reported  $x'^2 = (0.09 \pm 0.22) \times 10^{-3}$  and  $y' = (4.6 \pm 3.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\overline{D}^0 \rightarrow K^+ \pi^-$ .
- 4 The time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$  is employed. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\overline{D}^0 \rightarrow K^{*+} \pi^-$ . This value allows  $CP$  violation and is sensitive to the sign of  $\Delta m$ .
- 5 Based on 3 fb $^{-1}$  of data collected at  $\sqrt{s} = 7, 8$  TeV. Assumes no  $CP$  violation. Reported  $x'^2 = (5.5 \pm 4.9) \times 10^{-4}$  and  $y' = (4.8 \pm 1.0) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+ \pi^-$  and  $\overline{D}^0 \rightarrow K^+ \pi^-$ .
- 6 Based on 9.6 fb $^{-1}$  of data collected at the Tevatron. Assumes no  $CP$  violation. Reported  $x'^2 = (0.08 \pm 0.18) \times 10^{-3}$  and  $y' = (4.3 \pm 4.3) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+ \pi^-$  and  $\overline{D}^0 \rightarrow K^+ \pi^-$ .
- 7 Obtained  $y_{CP} = (0.72 \pm 0.18 \pm 0.12)\%$  based on three effective  $D^0$  lifetimes measured in  $K^+ \pi^-$ ,  $K^- K^+$ , and  $\pi^- \pi^+$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .
- 8 Compared the lifetimes of  $D^0$  decay to the  $CP$  eigenstate  $K^+ K^-$  with  $D^0$  decay to  $\pi^+ \pi^-$ . The values here assume no  $CP$  violation.
- 9 DEL-AMO-SANCHEZ 10D uses 540,800  $\pm 800$   $K_S^0 \pi^+ \pi^-$  and 79,900  $\pm 300$   $K_S^0 K^+ K^-$  events in a time-dependent amplitude analyses of the  $D^0$  and  $\overline{D}^0$  Dalitz plots. No evidence was found for  $CP$  violation, and the values here assume no such violation.
- 10 ZUPANC 09 uses a method based on measuring the mean decay time of  $D^0 \rightarrow K_S^0 K^+ K^-$  events for different  $K^+ K^-$  mass intervals.
- 11 LINK 00, AITALA 99E, and ABE 021 measure the lifetime difference between  $D^0 \rightarrow K^- K^+$  ( $CP$ -even) decays and  $D^0 \rightarrow K^- \pi^+$  ( $CP$ -mixed) decays, or  $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .
- 12 CSORNA 02 measures the lifetime difference between  $D^0 \rightarrow K^- K^+$  and  $\pi^- \pi^+$  ( $CP$ -even) decays and  $D^0 \rightarrow K^- \pi^+$  ( $CP$ -mixed) decays, or  $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .
- 13 Based on 1 fb $^{-1}$  of data collected at  $\sqrt{s} = 7$  TeV in 2011. Assumes no  $CP$  violation. Reported  $x'^2 = (-0.9 \pm 1.3) \times 10^{-4}$  and  $y' = (7.2 \pm 2.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+ \pi^-$  and  $\overline{D}^0 \rightarrow K^+ \pi^-$ .
- 14 This combines the  $y_{CP} = (\tau_{K^+ \pi^+} / \tau_{K^+ K^+}) - 1$  using untagged  $K^- \pi^+$  and  $K^- K^+$  events of AUBERT 09AI with the disjoint  $y_{CP}$  using tagged  $K^- \pi^+$ ,  $K^- K^+$ , and  $\pi^- \pi^+$  events of AUBERT 08U.
- 15 The AUBERT 09AN values are inferred from the branching ratio  $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0)$  via  $\overline{D}^0 / \Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$  given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between  $D^0 \rightarrow K^+ \pi^- \pi^0$  and  $\overline{D}^0 \rightarrow K^+ \pi^- \pi^0$  is assumed to be small. The width difference here is  $y'$ , which is not the same as  $y_{CP}$  in the note on  $D^0 - \overline{D}^0$  mixing.
- 16 LOWREY 09 uses quantum correlations in  $e^+ e^- \rightarrow D^0 \overline{D}^0$  at the  $\psi(3770)$ . See below for coherence factors and average relative strong phases for both  $D^0 \rightarrow K^- \pi^+ \pi^0$  and  $D^0 \rightarrow K^- \pi^- 2\pi^+$ . A fit that includes external measurements of charm mixing parameters gets  $2y = (1.62 \pm 0.32) \times 10^{-2}$ .
- 17 The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07W, and AALTONEN 08E limits are inferred from the  $D^0 - \overline{D}^0$  mixing ratio  $\Gamma(K^+ \pi^-)$  (via  $\overline{D}^0) / \Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0 - \overline{D}^0$  mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07W and AALTONEN 08E also allow  $CP$  violation. The phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\overline{D}^0 \rightarrow K^+ \pi^-$  is assumed to be small. This is a measurement of  $y'$  and is not the same as the  $y_{CP}$  of our note above on " $D^0 - \overline{D}^0$  Mixing."
- 18 This value combines the results of AUBERT 08U and AUBERT 03P.

- 19 STARIC 07 compares the lifetimes of  $D^0$  decay to the  $CP$  eigenstates  $K^+ K^-$  and  $\pi^+ \pi^-$  with  $D^0$  decay to  $K^- \pi^+$ .
- 20 The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\overline{D}^0 \rightarrow K^{*+} \pi^-$ . This limit allows  $CP$  violation.
- 21 The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.
- 22 AUBERT 03P measures  $Y \equiv 2 \tau^0 / (\tau^+ + \tau^-) - 1$ , where  $\tau^0$  is the  $D^0 \rightarrow K^- \pi^+$  (and  $\overline{D}^0 \rightarrow K^+ \pi^-$ ) lifetime, and  $\tau^+$  and  $\tau^-$  are the  $D^0$  and  $\overline{D}^0$  lifetimes to  $CP$ -even states (here  $K^- K^+$  and  $\pi^- \pi^+$ ). In the limit of  $CP$  conservation,  $Y = y \equiv \Delta\Gamma / 2\Gamma$  (we list  $2y = \Delta\Gamma/\Gamma$ ). AUBERT 03P also uses  $\tau^+ - \tau^-$  to get  $\Delta Y = -0.008 \pm 0.006 \pm 0.002$ .

 $|q/p|$ 

The mass eigenstates  $D_1^0$  and  $D_2^0$  are related to the  $C = \pm 1$  states by  $|D_{1,2}^0\rangle = p|D^0\rangle + q|\overline{D}^0\rangle$ . See the note on " $D^0 - \overline{D}^0$  Mixing" above.

"OUR EVALUATION" comes from CPV allowing averages provided by the Heavy Flavor Averaging Group. This would include as-yet-unpublished results, see the note on " $D^0 - \overline{D}^0$  Mixing."

0.86 $^{+0.30+0.10}_{-0.29-0.08}$	3 ZHANG	07B BELL	Repl. by PENG 14

- 1 The time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$  is employed. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\overline{D}^0 \rightarrow K^{*+} \pi^-$ . This value allows  $CP$  violation and is sensitive to the sign of  $\Delta m$ .
- 2 Based on 3 fb $^{-1}$  of data collected at  $\sqrt{s} = 7, 8$  TeV. Allowing for  $CP$  violation, the direct  $CP$  violation in mixing is reported  $0.75 < |q/p| < 1.24$  at the 68.3% CL for the  $D^0 \rightarrow K^+ \pi^-$  and  $\overline{D}^0 \rightarrow K^+ \pi^-$ .
- 3 The phase of  $p/q$  is  $(-14 \pm 16 \pm 5)^\circ$ . The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\overline{D}^0 \rightarrow K^{*+} \pi^-$ . This value allows  $CP$  violation.

 $A_\Gamma$ 

$A_\Gamma$  is the decay-rate asymmetry for  $CP$ -even final states  $A_\Gamma = (\overline{\tau}_+ - \tau_+) / (\overline{\tau}_+ + \tau_+)$ . See the note on " $D^0 - \overline{D}^0$  Mixing" above.

## D<sup>0</sup>

<sup>1</sup> Uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$  to measure the asymmetry of the branching fraction of  $D^0 \rightarrow K^-\pi^+$  in  $CP$ -odd and  $CP$ -even eigenstates to be  $(12.7 \pm 1.3 \pm 0.7)\%$ . A fit that includes external measurements of charm mixing parameters finds the value quoted above.

<sup>2</sup> Uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ , where decay rates of  $CP$ -tagged  $K\pi$  final states depend on the strong phases between the decays of  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ . The measurements obtained  $\sin(\delta) = -0.01 \pm 0.41 \pm 0.04$  and  $|\delta| = (10^{+28+13}_{-53-00})^\circ$  as well. A fit that includes external measurements of charm mixing parameters finds  $\cos(\delta) = 1.15^{+0.19+0.00}_{-0.17-0.08}$ ,  $\sin(\delta) = 0.56^{+0.32+0.21}_{-0.31-0.20}$ , and  $|\delta| = (18^{+11}_{-17})^\circ$ .

<sup>3</sup> ASNER 08 uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ , where decay rates of  $CP$ -tagged  $K\pi$  final states depend on  $\cos\delta$  because of interfering amplitudes. The above measurement implies  $|\delta| < 75^\circ$  with a confidence level of 95%. A fit that includes external measurements of charm mixing parameters finds  $\cos\delta = 1.10 \pm 0.35 \pm 0.07$ . See also the note on “ $D^0$ - $\bar{D}^0$  Mixing” p. 783 in our 2008 Review (PDG 08).

### D<sup>0</sup> → K<sup>-</sup>π<sup>+</sup>π<sup>0</sup> COHERENCE FACTOR R<sub>Kππ<sup>0</sup></sub>

See the note on ‘ $D^0$ - $\bar{D}^0$  Mixing’ for the definition.  $R_{K\pi\pi^0}$  can have any value between 0 and 1. A value near 1 indicates the decay is dominated by a few intermediate states with limited interference.

## D<sup>0</sup> DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K^0_S$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K^0_S$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K^0_S) = \Gamma(\bar{K}^0)$ .

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level

[k] The value is for the sum of the charge states or particle/antiparticle states indicated.

[1] This limit is for either  $D^0$  or  $\bar{D}^0$  to  $p e^-$ .

[n] This limit is for either  $D^0$  or  $\bar{D}^0$  to  $\bar{p}e^+$ .

### CONSTRAINED FIT INFORMATION

An overall fit to 55 branching ratios uses 110 measurements and one constraint to determine 31 parameters. The overall fit has a  $\chi^2 = 108.0$  for 80 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

[illegible]

$\Gamma_{281}$ Unaccounted decay modes	$(37.5 \pm 1.5) \%$	S=1.3
--	---------------------	-------

[a] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.

[b] This is the sum of our  $K^-2\pi^+\pi^-$ ,  $K^-2\pi^+\pi^-\pi^0$ ,  $\overline{K}^02\pi^+2\pi^-$ ,  $K^+2K^-\pi^+$ ,  $2\pi^+2\pi^-$ ,  $2\pi^+2\pi^-\pi^0$ ,  $K^+K^-\pi^+\pi^-$ , and  $K^+K^-\pi^+\pi^-\pi^0$ , branching fractions.

[c] This is the sum of our  $K^- 3\pi^+ 2\pi^-$  and  $3\pi^+ 3\pi^-$  branching fractions.

[d] The branching fractions for the  $K^- e^+ \nu_e$ ,  $K^*(892)^- e^+ \nu_e$ ,  $\pi^- e^+ \nu_e$ , and  $\rho^- e^+ \nu_e$  modes add up to  $6.19 \pm 0.17$  %.

[e] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[f] This is a doubly Cabibbo-suppressed mode.

[g] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[h] Submodes of the  $D^0 \rightarrow K_S^0 \pi^+ \pi^- \pi^0$  mode with a  $K^*$  and/or  $\rho$  were studied by COFFMAN 92B, but with only 140 events. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

[i] This branching fraction includes all the decay modes of the resonance in the final state.

[j] This mode is not a useful test for a  $\Delta C=1$  weak neutral current because both quarks must change flavor in this decay.

## CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 3 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.0$  for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

4.1 ±0.6	0.3k	<sup>8</sup> SCHINDLER	81 MRK2	$e^+ e^-$ 3.771 GeV	
4.3 ±1.0	130	<sup>9</sup> PERUZZI	77 LGW	$e^+ e^-$ 3.77 GeV	

- <sup>1</sup> This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.
- <sup>2</sup> ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97c use  $D^*(2010)^+ \rightarrow D^0 \pi^+$  decays. The  $\pi^+$  is both slow and of low  $p_T$  with respect to the event thrust axis or nearest jet ( $\approx D^{*+}$  direction). The excess number of such  $\pi^+$ 's over background gives the number of  $D^*(2010)^+ \rightarrow D^0 \pi^+$  events, and the fraction with  $D^0 \rightarrow K^- \pi^+$  gives the  $D^0 \rightarrow K^- \pi^+$  branching fraction.
- <sup>3</sup> DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.
- <sup>4</sup> ARTUSO 98, following ALBRECHT 94, uses  $D^0$  mesons from  $\overline{B}^0 \rightarrow D^*(2010)^+ X \ell^- \overline{\nu}_\ell$  decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.
- <sup>5</sup> COAN 98 assumes that  $\Gamma(B \rightarrow \overline{D} X \ell^+ \nu)/\Gamma(B \rightarrow X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$ , the last term accounting for  $\overline{B} \rightarrow D_s^+ K X \ell^- \overline{\nu}$ . COAN 98 is included in the CLEO average in ARTUSO 98.
- <sup>6</sup> ALBRECHT 94 uses  $D^0$  mesons from  $\overline{B}^0 \rightarrow D^{*+} \ell^- \overline{\nu}_\ell$  decays. This is a different set of events than used by ALBRECHT 94F.
- <sup>7</sup> This AKERIB 93 value includes radiative corrections; without them, the value is  $0.0391 \pm 0.0008 \pm 0.0017$ . AKERIB 93 is included in the CLEO average in ARTUSO 98.
- <sup>8</sup> SCHINDLER 81 (MARK-2) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.24 \pm 0.02$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.
- <sup>9</sup> PERUZZI 77 (MARK-1) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.25 \pm 0.05$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.

## Meson Particle Listings

 $D^0$  $\Gamma(K_S^0(\pi^+\pi^-)_{S\text{-wave}})/\Gamma(K_S^0\pi^+\pi^-)$   $\Gamma_{38}/\Gamma_{35}$ 

This is the “fit fraction” from the Dalitz-plot analysis. The  $(\pi^+\pi^-)_{S\text{-wave}}$  includes what in isobar models are the  $f_0(980)$  and  $f_0(1370)$ ; see the following two data blocks.

6.7+1.6  
-1.7 <sup>1</sup> BARLAG 92c computes the branching fraction using topological normalization.

 $\Gamma(K_S^0 \pi^+ \pi^- \pi^0)/\Gamma(K_S^0 \pi^+ \pi^-)$   $\Gamma_{76}/\Gamma_{35}$ 

Branching fractions for submodes of this mode with narrow resonances (the  $\eta$ ,  $\omega$ ,  $\eta'$ ) are fairly well determined (see below). COFFMAN 92B gives fractions of  $K^*$  and  $\rho$  submodes, but with only 140±28 events above background could not determine them with much accuracy. We omit those measurements here; they are in our 2008 Review (Physics Letters **B667** 1 (2008)).

• • • We do not use the following data for averages, fits, limits, etc. • • •	
<0.026 95 <sup>1</sup> CRONIN-HEN..05 CLEO $e^+e^-\approx 10$ GeV	
<sup>1</sup> The CRONIN-HENNESSY 05 fit here includes, in addition to the three $\rho\pi$ charged states, only the $f_0(980)\pi^0$ mode. See also the next entries for limits obtained in the same way for the $f_0(500)\pi^0$ mode and for an S-wave $\pi^+\pi^-$ parametrized using a $K$ -matrix. Our $\rho\pi$ branching ratios, given above, use the fit with the $K$ -matrix S wave.	
$\Gamma(f_0(500)\pi^0,f_0(500)\rightarrow\pi^+\pi^-)/\Gamma(\pi^+\pi^-\pi^0)$	$\Gamma_{145}/\Gamma_{134}$
The $f_0(500)$ is the $\sigma$ .

## Doubly Cabibbo-suppressed / Mixing modes

$\Gamma(K^+ \ell^- \bar{\nu}_\ell \text{ via } \bar{D}^0) / \Gamma(K^- \ell^+ \nu_\ell)$	$\Gamma_{220}/\Gamma_{17}$
This is a limit on $R_M$ without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. For the limits on $ m_1 - m_2 $ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these $D^0$ Listings.	

VALUE	DOCUMENT ID
$< 6.1 \times 10^{-4}$	<sup>1</sup> BITENC 08 BELL $e^+ e^-$ , 10.58 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •	
$<50 \times 10^{-4}$	<sup>2</sup> AITALA 96c E791 $\pi^-$ nucleus, 500 GeV

<sup>1</sup> The BITENC 08 right-sign sample includes about 15% of  $D^0 \rightarrow K^- \pi^0 \ell^+ \nu_\ell$  and other decays.

<sup>2</sup> AITALA 96c uses  $D^{*+} \rightarrow D^0 \pi^+$  (and charge conjugate) decays to identify the charm at production and  $D^0 \rightarrow K^- \ell^+ \nu_\ell$  (and charge conjugate) decays to identify the charm at decay.

$\Gamma(K^+ \alpha K^*(892)^+ e^- \bar{\nu}_e \text{ via } \bar{D}^0) / [\Gamma(K^- e^+ \nu_e) + \Gamma(K^*(892)^- e^+ \nu_e)]$	$\Gamma_{221}/(\Gamma_{18} + \Gamma_{20})$
---	--

This is a limit on  $R_M$  without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. The experiments use  $D^{*+} \rightarrow D^0 \pi^+$  (and charge conjugate) decays to identify the charm at production and the charge of the  $e$  to identify the charm at decay. These limits do not allow  $CP$  violation. For the limits on  $|m_1 - m_2|$  and  $(\Gamma_1 - \Gamma_2)/\Gamma$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

$\Gamma(K^+ \pi^-) / \Gamma(K^- \pi^+)$	$\Gamma_{222}/\Gamma_{31}$
This is $R$ , the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " $D^0$ - $\bar{D}^0$ Mixing," near the start of the $D^0$ Listings.	

The experiments here use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0) \pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born. The  $D^0 \rightarrow K^+ \pi^-$  decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by  $D^0 \rightarrow \bar{D}^0$  mixing followed by  $\bar{D}^0 \rightarrow K^+ \pi^-$  decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio  $R_D$ , and the following data block for limits on the mixing ratio  $R_M$ . See the section on  $CP$ -violating asymmetries near the end of this  $D^0$  Listing for values of  $A_D$ , and the note on " $D^0$ - $\bar{D}^0$  Mixing" for limits on  $x'$  and  $y'$ .

Some early limits have been omitted from this Listing; see our 1998 edition (The European Physical Journal **C3** (1998)) and our 2006 edition (Journal of Physics **G33** 1 (2006)).

### $D^0$ CP-VIOLATING DECAY-RATE ASYMMETRIES

This is the difference between  $D^0$  and  $\bar{D}^0$  partial widths for the decay to state  $f$ , divided by the sum of the widths:

$$A_{CP}(f) = [\Gamma(D^0 \rightarrow f) - \Gamma(\bar{D}^0 \rightarrow \bar{f})] / [\Gamma(D^0 \rightarrow f) + \Gamma(\bar{D}^0 \rightarrow \bar{f})].$$

$A_{CP}(K^+ K^-)$  in  $D^0, \bar{D}^0 \rightarrow K^+ K^-$

### $D^0$ CP-EVEN FRACTIONS

The  $CP$ -even fraction  $F_+$ , defined for self-conjugate final states, like the coherence factor is useful for measuring the unitary triangle angle  $\gamma$  in  $B \rightarrow DK$  decays. A purely  $CP$ -even state has  $F_+ = 1$ , a  $CP$ -odd one has  $F_+ = 0$ . For details, see NAYAK 15.

### $D^0$ CP-VIOLATING ASYMMETRY DIFFERENCES

$$\Delta A_{CP} = A_{CP}(K^+ K^-) - A_{CP}(\pi^+ \pi^-)$$

$CP$  violation in these modes can come from the decay amplitudes (direct) and/or from mixing or interference of mixing and decay (indirect). The difference  $\Delta A_{CP}$  is primarily sensitive to the direct component, and only retains a second-order dependence on the indirect component for measurements where the mean decay time of the  $K^+ K^-$  and  $\pi^+ \pi^-$  samples are not identical. The results below are averaged assuming the indirect component can be neglected.

### $D^0$ $\chi^2$ TESTS OF $CP$ -VIOLATION ( $CPV$ )

We list model-independent searches for local  $CP$  violation in phase-space distributions of multi-body decays.

Most of these searches divide phase space (Dalitz plot for 3-body decays, five-dimensional equivalent for 4-body decays) into bins, and perform a  $\chi^2$  test comparing normalised yields  $N_i, \bar{N}_i$  in  $CP$ -conjugate bin pairs  $i$ :  $\chi^2 = \sum_i (N_i - \alpha \bar{N}_i) / \sigma(N_i - \alpha \bar{N}_i)$ . The factor  $\alpha = (\sum_i N_i) / (\sum_i \bar{N}_i)$  removes the dependence on phase-space-integrated rate asymmetries. The result is used to obtain the probability (p-value) to obtain the measured  $\chi^2$  or larger under the assumption of  $CP$  conservation [AUBERT 08A0, BEDIAGA 09]. Alternative methods obtain p-values from other test variables based on unbinned analyses [WILLIAMS 11, AAJ 14C]. Results can be combined using Fisher's method [MOSTELLER 48].

### $CP$ VIOLATING ASYMMETRIES OF $P$ -ODD ( $T$ -ODD) MOMENTS

The  $CP$ -sensitive  $P$ -odd ( $T$ -odd) correlation in  $D^0, \bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^-$  decays.  $D^0$  and  $\bar{D}^0$  are distinguished by the charge of the parent  $D^*$ :  $D^{*+} \rightarrow D^0 \pi^+$  and  $D^{*-} \rightarrow \bar{D}^0 \pi^-$ .

$A_{Tviol}(K^+ K^- \pi^+ \pi^-)$ in $D^0, \bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^-$	EVTS	DOCUMENT ID	TECN	COMMENT
$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a parity-odd correlation of the $K^+$ , $\pi^+$ , and $\pi^-$ momenta (evaluated in the $D^0$ rest frame) for the $D^0$ . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the $\bar{D}^0$ . Then				
$A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ , and				
$\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ , and				
$A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ . $C_T$ and $\bar{C}_T$ are commonly referred to as $T$ -odd moments, because they are odd under $T$ reversal. However, the $T$ -conjugate process $K^+ K^- \pi^+ \pi^- \rightarrow D^0$ is not accessible, while the $P$ -conjugate process is.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
$10 \pm 57 \pm 37$	0.8k	LINK	05E FOCS	$\gamma A, \bar{E}_\gamma \approx 180$ GeV

$D^0$  CPT-VIOLATING DECAY-RATE ASYMMETRIES $A_{CP\mathcal{T}}(K^\mp\pi^\pm)$  in  $D^0 \rightarrow K^\mp\pi^\pm$ ,  $\bar{D}^0 \rightarrow K^\pm\pi^\mp$ 

$A_{CP\mathcal{T}}(t)$  is defined in terms of the time-dependent decay probabilities  $P(D^0 \rightarrow K^\mp\pi^\pm)$  and  $\bar{P}(\bar{D}^0 \rightarrow K^\pm\pi^\mp)$  by  $A_{CP\mathcal{T}}(t) = (\bar{P} - P)/(\bar{P} + P)$ . For small mixing parameters  $x \equiv \Delta m/\Gamma$  and  $y \equiv \Delta\Gamma/2\Gamma$  (as is the case), and times  $t$ ,  $A_{CP\mathcal{T}}(t)$  reduces to  $[y \operatorname{Re} \xi - x \operatorname{Im} \xi] \Gamma t$ , where  $\xi$  is the CPT-violating parameter.

The following is actually  $y \operatorname{Re} \xi - x \operatorname{Im} \xi$ .

$\Gamma_2 \quad D^0\gamma$	(35.3 ± 0.9) %

## CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 5 measurements and one constraint to determine 2 parameters. The overall fit has a  $\chi^2 = 2.5$  for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$\begin{array}{c|c} x_2 & -100 \\ \hline & x_1 \end{array}$$

### $D_1(2420)^0$ POLARIZATION AMPLITUDE $A_{D_1}$

A polarization amplitude  $A_{D_1}$  is a parameter that depends on the initial polarization of the  $D_1$  and is sensitive to a possible S-wave contribution to its decay. For  $D_1$  decays the helicity angle,  $\theta_h$ , distribution varies like  $1 + A_{D_1}\cos^2\theta_h$ , where  $\theta_h$  is the angle in the  $D^*$  rest frame between the two pions emitted by the  $D_1 \rightarrow D^*\pi$  and the  $D^* \rightarrow D\pi$ .

Unpolarized  $D_1$  decaying purely via D-wave is predicted to give  $A_{D_1} = 3$ .

$D_1(2420)^\pm$  POLARIZATION AMPLITUDE  $A_{D_1}$

A polarization amplitude  $A_{D_1}$  is a parameter that depends on the initial polarization of the  $D_1$  and is sensitive to a possible S-wave contribution to its decay. For  $D_1$  decays the helicity angle,  $\theta_h$ , distribution varies like  $1 + A_{D_1} \cos^2 \theta_h$ , where  $\theta_h$  is the angle in the  $D^*$  rest frame between the two pions emitted by the  $D_1 \rightarrow D^* \pi$  and the  $D^* \rightarrow D \pi$ .

Unpolarized  $D_1$  decaying purely via D-wave is predicted to give  $A_{D_1} = 3$ .

## Meson Particle Listings

 $D_s^\pm$ 

# CHARMED, STRANGE MESONS ( $C = S = \pm 1$ )

 $D_s^+ = c\bar{s}, D_s^- = \bar{c}s$ , similarly for  $D_s^{* \pm}$ 's
 $D_s^\pm$ 

$$J(P) = 0(0^-)$$

The angular distributions of the decays of the  $\phi$  and  $\bar{K}^*(892)^0$  in the  $\phi\pi^+$  and  $K^+\bar{K}^*(892)^0$  modes strongly indicate that the spin is zero. The parity given is that expected of a  $c\bar{s}$  ground state.

## $D_s^\pm$ MASS

The fit includes  $D_s^\pm, D^0, D_s^{* \pm}, D^{*0}, D_s^{* \pm}, D_1(2420)^0, D_2^*(2460)^0$ , and  $D_{s1}(2536)^\pm$  mass and mass difference measurements. Measurements of the  $D_s^\pm$  mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

## $D_s^\pm$ DECAY MODES

Unless otherwise noted, the branching fractions for modes with a resonance in the final state include all the decay modes of the resonance.  $D_s^\pm$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor / Confidence level
<b>Inclusive modes</b>		
$\Gamma_1$ $e^+$ semileptonic	[a] ( 6.5 ± 0.4 ) %	
$\Gamma_2$ $\pi^+$ anything	( 119.3 ± 1.4 ) %	
$\Gamma_3$ $\pi^-$ anything	( 43.2 ± 0.9 ) %	
$\Gamma_4$ $\pi^0$ anything	( 123 ± 7 ) %	
$\Gamma_5$ $K^-$ anything	( 18.7 ± 0.5 ) %	
$\Gamma_6$ $K^+$ anything	( 28.9 ± 0.7 ) %	
$\Gamma_7$ $K_S^0$ anything	( 19.0 ± 1.1 ) %	
$\Gamma_8$ $\eta$ anything	[b] ( 29.9 ± 2.8 ) %	
$\Gamma_9$ $\omega$ anything	( 6.1 ± 1.4 ) %	
$\Gamma_{10}$ $\eta'$ anything	[c] ( 10.3 ± 1.4 ) %	S=1.1
$\Gamma_{11}$ $f_0(980)$ anything, $f_0 \rightarrow \pi^+\pi^-$	< 1.3 %	CL=90%
$\Gamma_{12}$ $\phi$ anything	( 15.7 ± 1.0 ) %	
$\Gamma_{13}$ $K^+K^-$ anything	( 15.8 ± 0.7 ) %	
$\Gamma_{14}$ $K_S^0K^+$ anything	( 5.8 ± 0.5 ) %	
$\Gamma_{15}$ $K_S^0K^-$ anything	( 1.9 ± 0.4 ) %	
$\Gamma_{16}$ $2K_S^0$ anything	( 1.70 ± 0.32 ) %	
$\Gamma_{17}$ $2K^+$ anything	< 2.6 × 10 <sup>-3</sup>	CL=90%
$\Gamma_{18}$ $2K^-$ anything	< 6 × 10 <sup>-4</sup>	CL=90%
<b>Leptonic and semileptonic modes</b>		
$\Gamma_{19}$ $e^+\nu_e$	< 8.3 × 10 <sup>-5</sup>	CL=90%
$\Gamma_{20}$ $\mu^+\nu_\mu$	( 5.56 ± 0.25 ) × 10 <sup>-3</sup>	
$\Gamma_{21}$ $\tau^+\nu_\tau$	( 5.55 ± 0.24 ) %	
$\Gamma_{22}$ $K^+K^-e^+\nu_e$	—	
$\Gamma_{23}$ $\phi e^+\nu_e$	[d] ( 2.39 ± 0.23 ) %	S=1.8
$\Gamma_{24}$ $\eta e^+\nu_e + \eta'(958) e^+\nu_e$	[d] ( 2.96 ± 0.29 ) %	
$\Gamma_{25}$ $\eta e^+\nu_e$	[d] ( 2.28 ± 0.24 ) %	
$\Gamma_{26}$ $\eta'(958) e^+\nu_e$	[d] ( 6.8 ± 1.6 ) × 10 <sup>-3</sup>	
$\Gamma_{27}$ $\omega e^+\nu_e$	[e] < 2.0 × 10 <sup>-3</sup>	CL=90%
$\Gamma_{28}$ $K^0 e^+\nu_e$	( 3.9 ± 0.9 ) × 10 <sup>-3</sup>

[a] This is the purely  $e^+$  semileptonic branching fraction: the  $e^+$  fraction from  $\tau^+$  decays has been subtracted off. The sum of our (non- $\tau$ )  $e^+$  exclusive fractions — an  $e^+ \nu_e$  with an  $\eta, \eta', \phi, K^0, K^{*0}$ , or  $f_0(980)$  — is  $7.0 \pm 0.4$  %

[b] This fraction includes  $\eta$  from  $\eta'$  decays.

[c] Two times (to include  $\mu$  decays) the  $\eta' e^+ \nu_e$  branching fraction, plus the  $\eta' \pi^+, \eta' \rho^+$ , and  $\eta' K^+$  fractions, is  $(18.6 \pm 2.3)\%$ , which considerably exceeds the inclusive  $\eta'$  fraction of  $(11.7 \pm 1.8)\%$ . Our best guess is that the  $\eta' \rho^+$  fraction,  $(12.5 \pm 2.2)\%$ , is too large.

[d] This branching fraction includes all the decay modes of the final-state resonance.

[e] A test for  $u\bar{u}$  or  $d\bar{d}$  content in the  $D_s^+$ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and  $\omega$ - $\phi$  mixing is an unlikely explanation for any fraction above about  $2 \times 10^{-4}$ .

[f] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[g] We decouple the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the  $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$  branching fraction obtained from the Dalitz-plot analysis of  $D_s^+ \rightarrow K^+ K^- \pi^+$ . That is, the ratio of these two branching fractions is not exactly the  $\phi \rightarrow K^+ K^-$  branching fraction 0.491.

[h] This is the average of a model-independent and a  $K$ -matrix parametrization of the  $\pi^+ \pi^-$   $S$ -wave and is a sum over several  $f_0$  mesons.

[i] This mode is not a useful test for a  $\Delta C=1$  weak neutral current because both quarks must change flavor in this decay.

[j] This is *not* a test for the  $\Delta C=1$  weak neutral current, but leads to the  $\pi^+ \ell^+ \ell^-$  final state.

## CONSTRAINED FIT INFORMATION

An overall fit to 14 branching ratios uses 18 measurements and one constraint to determine 12 parameters. The overall fit has a  $\chi^2 = 8.1$  for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

## $D_s^+$ BRANCHING FRACTIONS

Updated November 2015 by J.L. Rosner (University of Chicago) and C.G. Wohl (LBNL).

Figure 1 shows a partial breakdown of the  $D_s^+$  branching fractions. The rest of this note is about how the figure was constructed. The values shown make heavy use of CLEO measurements of inclusive branching fractions [1]. For references to other data cited in the following, see the Listings.

**Modes with leptons:** The bottom  $(19.9 \pm 0.9)\%$  of Fig. 1 shows the fractions for the modes that include leptons. Measured  $Xe^+\nu_e$  semileptonic fractions have been doubled to include the  $X\mu^+\nu_\mu$  fractions. The sum of the exclusive  $Xe^+\nu_e$  fractions is  $(6.9 \pm 0.4)\%$ , consistent with an inclusive semileptonic measurement of  $(6.5 \pm 0.4)\%$ . There seems to be little missing here.

**Inclusive hadronic  $K\bar{K}$  fractions:** The Cabibbo-favored  $c \rightarrow s$  decay in  $D_s^+$  decay produces a final state with both an  $s$  and an  $\bar{s}$ ; and thus modes with a  $K\bar{K}$  pair or with an  $\eta$ ,  $\omega$ ,  $\eta'$ , or  $\phi$  predominate (as may already be seen in Fig. 1 in the semileptonic fractions). We consider the  $K\bar{K}$  modes first. A complete picture of the exclusive  $K\bar{K}$  charge modes is not yet possible, because branching fractions for many of those modes have not yet been measured. However, CLEO has measured the inclusive  $K^+$ ,  $K^-$ ,  $K_S^0$ ,  $K^+K^-$ ,  $K^+K_S^0$ ,  $K^-K_S^0$ , and  $2K_S^0$  fractions (these include modes with leptons) [1]. And each of these inclusive fractions with a  $K_S^0$  is equal to the corresponding fraction with a  $K_L^0$ :  $f(K^+K_L^0) = f(K^+K_S^0)$ ,  $f(2K_L^0) = f(2K_S^0)$ , *etc.* Therefore, of all inclusive fractions pairing a  $K^+$ ,  $K_S^0$ , or  $K_L^0$  with a  $K^-$ ,  $K_S^0$ , or  $K_L^0$ , we know all but  $f(K_S^0K_L^0)$ .

We can get that fraction. The total  $K_S^0$  fraction is

$$f(K_S^0) = f(K^+K_S^0) + f(K^-K_S^0) + 2f(2K_S^0) + f(K_S^0K_L^0) + f(\text{single } K_S^0),$$

where  $f(\text{single } K_S^0)$  is the sum of the branching fractions for modes such as  $K_S^0\pi^+2\pi^0$  with a  $K_S^0$  and no second  $K$ . The  $K_S^0\pi^+2\pi^0$  mode is in fact the only unmeasured single- $K_S^0$  mode

**Figure 1:** A partial breakdown of  $D_s^+$  branching fractions. The hadronic bins in the left column show inclusive fractions. Shading within a bin shows how much of the inclusive fraction is not yet accounted for by adding up all the relevant exclusive fractions. The inclusive hadronic  $\phi$  fraction is spread over three bins, in proportion to its decay fractions into  $K^+K^-$ ,  $K_S^0K_L^0$ , and no- $K\bar{K}$  modes.

(throughout, we shall assume that fractions for modes with a  $K$  or  $K\bar{K}$  and more than three pions are negligible), and we shall take its fraction to be the same as for the  $K_S^0 2\pi^+\pi^-$  mode,  $(0.30 \pm 0.11)\%$ . Any reasonable deviation from this value would be too small to matter much in the following. Adding the several small single- $K_S^0$  branching fractions, including those from semileptonic modes, we get  $f(\text{single } K_S^0) = (1.65 \pm 0.26)\%$ .

Using this, we have:

$$\begin{aligned} f(K_S^0K_L^0) &= f(K_S^0) - f(K^+K_S^0) - f(K^-K_S^0) \\ &\quad - 2f(2K_S^0) - f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \end{aligned}$$

$$\begin{aligned}
& -2 \times (1.7 \pm 0.3) - (1.7 \pm 0.3) \\
& = (6.2 \pm 1.4)\% .
\end{aligned}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors are secondary.

There is a check on our result: The  $\phi$  inclusive branching fraction is  $(15.7 \pm 1.0)\%$ , of which 34%, or  $(5.34 \pm 0.34)\%$  of  $D_s^+$  decays, produces a  $K_S^0 K_L^0$ . Our  $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$  has to be at least this large—and it is.

We now have all the inclusive  $K\bar{K}$  fractions. We use  $f(K^+ \bar{K}^0) = 2 f(K^+ K_S^0)$ , and likewise for  $f(K^- K^0)$ . For  $K^+ K^-$  and  $K_S^0 K_L^0$ , we subtract off the contributions from  $\phi \ell^+ \nu$  decay to get the purely hadronic  $K\bar{K}$  inclusive fractions:

$$\begin{aligned}
f(K^+ K^-, \text{hadronic}) &= (15.8 \pm 0.7) - (2.44 \pm 0.14) \\
&= (13.4 \pm 0.7)\% \\
f(K^+ \bar{K}^0, \text{hadronic}) &= (11.6 \pm 1.0)\% \\
f(K^- K^0, \text{hadronic}) &= (3.8 \pm 0.8)\% \\
f(2K_S^0 + 2K_L^0, \text{hadronic}) &= (3.4 \pm 0.64)\% \\
f(K_S^0 K_L^0, \text{hadronic}) &= (6.2 \pm 1.4) - (1.70 \pm 0.10) \\
&= (4.5 \pm 1.4)\% .
\end{aligned}$$

The fractions are shown in Fig. 1. They total  $(36.7 \pm 2.1)\%$  of  $D_s^+$  decays.

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

**$K^+ K^-$  modes**—The sum of measured  $K^+ K^- \pi^+$ ,  $K^+ K^- \pi^+ \pi^0$ , and  $K^+ K^- 2\pi^+ \pi^-$  branching fractions is  $(12.6 \pm 0.6)\%$ . That leaves  $(0.8 \pm 0.9)\%$  for the  $K^+ K^- \pi^+ 2\pi^0$  mode, which is the only other  $K^+ K^-$  mode with three or fewer pions. In Fig. 1, this unmeasured part of the  $K^+ K^-$  bin is shaded.

**$K^+ \bar{K}^0$  modes**—Two times the sum of the measured  $K^+ K_S^0$ ,  $K^+ K_S^0 \pi^0$ , and  $K^+ K_S^0 \pi^+ \pi^-$  branching fractions is  $(8.1 \pm 0.5)\%$ . This leaves  $(3.5 \pm 1.1)\%$  for the unmeasured  $K^+ \bar{K}^0$  modes (there are three such modes with three or fewer pions). This is shaded in the figure.

**$K^- K^0$  modes**—Twice the  $K^- K_S^0 2\pi^+$  fraction is  $(3.34 \pm 0.20)\%$ , which leaves about  $(0.5 \pm 0.8)\%$  for  $K^- K^0 2\pi^+ \pi^0$ , the only other  $K^- K^0$  mode with three or fewer pions.

**$2K_S^0 + 2K_L^0$  modes**—The  $2K_S^0 \pi^+$  and  $2K_S^0 2\pi^+ \pi^-$  fractions sum to  $(0.86 \pm 0.07)\%$ ; this times two (for the corresponding  $2K_L^0$  modes) is  $(1.72 \pm 0.14)\%$ . This leaves about  $(1.7 \pm 0.7)\%$  for other  $2K_S^0 + 2K_L^0$  modes.

**$K_S^0 K_L^0$  modes**—Most of the  $K_S^0 K_L^0$  fraction is accounted for by  $\phi$  decays (see below).

**Inclusive hadronic  $\eta$ ,  $\omega$ ,  $\eta'$ , and  $\phi$  fractions:** These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2)  $\eta$  mesons that are included in the inclusive  $\eta'$  fraction; and (3)  $K^+ K^-$  and  $K_S^0 K_L^0$  from  $\phi$  decays:

$$\begin{aligned}
f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 f(\eta' \text{ inclusive}) \\
&\quad - f(\eta \ell^+ \nu) = (17.0 \pm 3.1)\% \\
f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.0275 f(\eta' \text{ inclusive}) \\
&\quad = (5.8 \pm 1.4)\% \\
f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\
&\quad = (9.7 \pm 1.9)\% \\
f(\phi \text{ hadronic}, \not\rightarrow K\bar{K}) &= 0.17 [f(\phi \text{ inclusive}) - f(\phi \ell^+ \nu)] \\
&\quad = (1.8 \pm 0.2)\% .
\end{aligned}$$

The factors 0.65, 0.0275, and 0.17 are the  $\eta' \rightarrow \eta$ ,  $\eta' \rightarrow \omega$ , and  $\phi \rightarrow K\bar{K}$  branching fractions. Figure 1 shows the results; the sum is  $(34.2 \pm 3.9)\%$ , which is about equal to the hadronic  $K\bar{K}$  total.

Note that the bin marked  $\phi$  near the top of Fig. 1 includes neither the  $\phi \ell^+ \nu$  decays nor the 83% of other  $\phi$  decays that produce a  $K\bar{K}$  pair. There is twice as much  $\phi$  in the  $K_S^0 K_L^0$  bin, and nearly three times as much in the  $K^+ K^-$  bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

**$\eta$  modes**—The sum of  $\eta \pi^+$ ,  $\eta \rho^+$ , and  $\eta K^+$  branching fractions is  $(11.1 \pm 1.2)\%$ , which leaves a good part of the inclusive hadronic  $\eta$  fraction,  $(17.0 \pm 3.1)\%$ , to be accounted for. This is shaded in the figure.

**$\omega$  modes**—The sum of  $\omega \pi^+$ ,  $\omega \pi^+ \pi^0$ , and  $\omega 2\pi^+ \pi^-$  fractions is  $(4.6 \pm 0.9)\%$ , which is nearly as large as the inclusive hadronic  $\omega$  fraction,  $(5.8 \pm 1.4)\%$ .

**$\eta'$  modes**—The sum of  $\eta' \pi^+$ ,  $\eta' \rho^+$ , and  $\eta' K^+$  fractions is  $(9.7 \pm 1.9)\%$ , which agrees with the inclusive hadronic  $\eta'$  fraction,  $(9.7 \pm 1.9)\%$ . (An old measurement of the  $\eta' \rho^+$  fraction,  $(12.5 \pm 2.2)\%$ , has been abandoned [2].)

**Cabibbo-suppressed modes:** The sum of the fractions for modes with a  $K\bar{K}$ ,  $\eta$ ,  $\omega$ ,  $\eta'$ , or leptons is  $(90.8 \pm 4.5)\%$ . The remaining  $(9.2 \pm 4.5)\%$  is to Cabibbo-suppressed modes, mainly single- $K$ + pions and multiple-pion modes (see below). However, it should be noted that some small parts of the modes already discussed are Cabibbo-suppressed. For example, the  $(1.10 \pm 0.24)\%$  of  $D_s^+$  decays to  $K^0 \ell \nu$  or  $K^{*0} \ell \nu$  is already in the  $X \ell \nu$  bin in Fig. 1. And the inclusive measurements of  $\eta$ ,  $\omega$ , and  $\eta'$  fractions do not distinguish between (and therefore include both) Cabibbo-allowed and -suppressed modes. We shall not try to make a separation here.

**$K^0$  + pions**—Above, we found that  $f(\text{single } K_S^0) = (1.65 \pm 0.26)\%$ . Subtracting leptonic fractions with a  $K_S^0$  leaves  $(1.22 \pm 0.28)\%$ . The hadronic single- $K^0$  fraction is twice this,  $(2.44 \pm 0.56)\%$ . The sum of measured  $K^0 \pi^+$ ,  $K^0 \pi^+ \pi^0$ , and  $K^0 2\pi^+ \pi^-$  fractions is  $(1.84 \pm 0.28)\%$ .

**$K^+ + \text{pions}$** —The  $K^+ \pi^0$  and  $K^+ \pi^+ \pi^-$  fractions sum to  $(0.72 \pm 0.05)\%$ . Much of the  $K^+ n \pi$  modes, where  $n \geq 3$ , is

# Meson Particle Listings

$D_s^\pm$

already in the  $\eta$ ,  $\omega$ , and  $\eta'$  bins, and the rest is not measured. The total  $K^+$  fraction wanted here is probably in the 1-to-2% range.

*Multi-pions*—The  $2\pi^+\pi^-$ ,  $\pi^+2\pi^0$ , and  $3\pi^+2\pi^-$  fractions total  $(2.54 \pm 0.16)\%$ . Modes not measured might double this.

The sum of the actually measured fractions is  $(5.1 \pm 0.3)\%$ , which is not inconsistent with the Cabibbo-suppressed total of  $(9.2 \pm 4.5)\%$ .

**A model:** With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a “statistical isospin” model [3]. Consider, say, the  $D_s^+ \rightarrow K\bar{K}\pi$  charge modes: the  $K^+K^-\pi^+$  branching fraction is measured, the  $K^+\bar{K}^0\pi^0$  and  $K^0\bar{K}^0\pi^+$  fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for  $D_s^+ \rightarrow K\bar{K}\pi$  decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that  $D_s^+ \rightarrow K\bar{K}\pi$  decay is dominated by  $\phi\pi^+$ ,  $K^+\bar{K}^{*0}$ , and  $K^{*+}\bar{K}^0$  submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of  $D_s^+$  decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of  $\pi^+$ ,  $K_S^0$ , *etc.*, were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

### Leptonic and semileptonic modes

## LEPTONIC DECAYS OF CHARGED PSEUDO-SCALAR MESONS

Revised March 2016 by J. Rosner (Univ. Chicago), S. Stone (Syracuse Univ.), and R. Van de Water (FNAL).

We review the physics of purely leptonic decays of  $\pi^\pm$ ,  $K^\pm$ ,  $D^\pm$ ,  $D_s^\pm$ , and  $B^\pm$  pseudoscalar mesons. The measured decay rates are related to the product of the relevant weak-interaction-based CKM matrix element of the constituent quarks and a strong interaction parameter related to the overlap of the quark and antiquark wave-functions in the meson, called the decay constant  $f_P$ . The leptonic decay constants for  $\pi^\pm$ ,  $K^\pm$ ,  $D^\pm$ ,  $D_s^\pm$ , and  $B^\pm$  mesons can be obtained with controlled theoretical uncertainties and high precision from *ab initio* lattice-QCD simulations. The combination of experimental leptonic decay-rate measurements and theoretical decay-constant calculations enables the determination of several elements of the CKM matrix within the standard model. These determinations are competitive with those obtained from semileptonic decays, and also complementary because they are sensitive to axial-vector (as opposed to vector) quark flavor-changing currents. They can also be used to test the unitarity of the first and second rows of the CKM matrix. Conversely, taking the CKM elements predicted by unitarity, one can infer “experimental” values for  $f_P$  that can be compared with theory. These provide tests of lattice-QCD methods, provided new-physics contributions to leptonic decays are negligible at the current level of precision. This review was prepared for the Particle Data Group’s 2016 edition, updating the versions in Refs. 1–3.

## I. INTRODUCTION

Charged mesons formed from a quark and an antiquark can decay to a charged lepton pair when these objects annihilate via a virtual  $W$  boson. Fig. 1 illustrates this process for the purely leptonic decay of a  $D^+$  meson.

**Figure 1:** The annihilation process for pure  $D^+$  leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual  $W^+$  to the  $\ell^+\nu$  final states occur for the  $\pi^+$ ,  $K^+$ ,  $D_s^+$ , and  $B^+$  mesons. (Whenever pseudoscalar-meson charges are specified in this article, use of the charge-conjugate particles and corresponding decays are also implied.) Let  $P$  be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \rightarrow \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2}\right)^2 |V_{q_1 q_2}|^2 \quad (1)$$

Here  $M_P$  is the  $P$  mass,  $m_\ell$  is the  $\ell$  mass,  $V_{q_1 q_2}$  is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks  $q_1 \bar{q}_2$  in  $P$ , and  $G_F$  is the Fermi coupling constant. The decay constant  $f_P$  is proportional to the matrix element of the axial current between the one- $P$ -meson state and the vacuum:

$$\langle 0 | \bar{q}_1 \gamma_\mu \gamma_5 q_2 | P(p) \rangle = i p_\mu f_P, \quad (2)$$

and can be thought of as the “wavefunction overlap” of the quark and antiquark. In this article we use the convention in which  $f_\pi \approx 130$  MeV.

The decay  $P^\pm$  starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the  $\ell^\pm$  must then also be left-handed or right-handed, respectively. In the  $m_\ell = 0$  limit, the decay is forbidden, and can only occur as a result of the finite  $\ell$  mass. This helicity suppression is the origin of the  $m_\ell^2$  dependence of the decay width. Radiative corrections are needed when the final charged particle is an electron or muon; for the  $\tau$  they are greatly suppressed due to the large lepton mass, and hence negligible.

Measurements of purely leptonic decay branching fractions and lifetimes allow an experimental determination of the product  $|V_{q_1 q_2}| f_P$ . If the decay constant  $f_P$  is known to sufficient precision from theory, one can obtain the corresponding CKM element within the standard model. If, on the other hand, one takes the value of  $|V_{q_1 q_2}|$  assuming CKM unitarity, one can infer an “experimental measurement” of the decay constant that can then be compared with theory.

The importance of measuring  $\Gamma(P \rightarrow \ell\nu)$  depends on the particle being considered. Leptonic decays of charged pseudoscalar mesons occur at tree level within the standard model. Thus one does not expect large new-physics contributions to measurements of  $\Gamma(P \rightarrow \ell\nu)$  for the lighter mesons  $P = \pi^+, K^+$ , and these processes in principle provide clean standard-model determinations of  $V_{ud}$  and  $V_{us}$ . The situation is different for leptonic decays of charm and bottom mesons. The presence of new heavy particles such as charged Higgs bosons or leptoquarks could lead to observable effects in  $\Gamma(P \rightarrow \ell\nu)$  for  $P = D_{(s)}^+, B^+$  [4–8]. Thus the determination of  $|V_{ub}|$  from  $B^+ \rightarrow \tau\nu$  decay, in particular, should be considered a probe of new physics. More generally, the ratio of leptonic decays to  $\tau\nu$  over  $\mu\nu$  final states probes lepton universality [4,9].

The determinations of CKM elements from leptonic decays of charged pseudoscalar mesons provide complementary

# Meson Particle Listings

$D_s^\pm$

information to those from other decay processes. The decay  $P \rightarrow \ell\nu$  proceeds in the standard model via the axial-vector current  $\bar{q}_1\gamma_\mu\gamma_5q_2$ , whereas semileptonic pseudoscalar meson decays  $P_1 \rightarrow P_2\ell\nu$  proceed via the vector current  $\bar{q}_1\gamma_\mu q_2$ . Thus the comparison of determinations of  $|V_{q_1q_2}|$  from leptonic and semileptonic decays tests the  $V - A$  structure of the standard-model electroweak charged-current interaction. More generally, a small right-handed admixture to the standard-model weak current would lead to discrepancies between  $|V_{q_1q_2}|$  obtained from leptonic pseudoscalar-meson decays, exclusive semileptonic pseudoscalar-meson decays, exclusive semileptonic baryon decays, and inclusive semileptonic decays [10,11].

Both measurements of the decay rates  $\Gamma(P \rightarrow \ell\nu)$  and theoretical calculations of the decay constants  $f_P$  for  $P = \pi^+, K^+, D_{(s)}^+$  from numerical lattice-QCD simulations are now quite precise. As a result, the elements of the first row of the CKM matrix  $|V_{ud}|$  and  $|V_{us}|$  can be obtained to sub-percent precision from  $\pi^+ \rightarrow \ell\nu$  and  $K^+ \rightarrow \ell\nu$ , where the limiting error is from theory. The elements of the second row of the CKM matrix  $|V_{cd(s)}|$  can be obtained from leptonic decays of charged pseudoscalar mesons to few-percent precision, where here the limiting error is from experiment. These enable stringent tests of the unitarity of the first and second rows of the CKM matrix.

This review is organized as follows. Because the experimental and theoretical issues associated with measurements of pions and kaons, charmed mesons, and bottom mesons differ, we discuss each one separately. We begin with the pion and kaon system in Sec. II. First, in Sec. II.A we review current measurements of the experimental decay rates. We provide tables of branching-ratio measurements and determinations of the product  $|V_{ud(s)}|f_{\pi^+(K^+)}$ , as well as average values for these quantities including correlations and other effects needed to combine results. Then, in Sec. II.B we summarize the status of theoretical calculations of the decay constants. We provide tables of recent lattice-QCD results for  $f_{\pi^+}$ ,  $f_{K^+}$ , and their ratio from simulations including dynamical  $u, d, s$ , and (in some cases  $c$ ) quarks, and present averages for each of these quantities including correlations and strong SU(2)-isospin corrections as needed. We note that, for the leptonic decay constants in Sec. II.B, Sec. III.B, and Sec. IV.B, when available we use preliminary averages from the Flavor Lattice Averaging Group [12,13] that update the determinations in Ref. 14 to include results that have appeared since their most recent review, which dates from 2013. We next discuss the charmed meson system in Sec. III, again reviewing current experimental rate measurements in Sec. III.A and theoretical decay-constant calculations in Sec. III.B. Last, we discuss the bottom meson system in Sec. IV, following the same organization as the two previous sections.

After having established the status of both experimental measurements and theoretical calculations of leptonic charged pseudoscalar-meson decays, we discuss some implications for phenomenology in Sec. V. We combine the average  $\mathcal{B}(P \rightarrow \ell\nu)$  with the average  $f_P$  to obtain the relevant CKM elements from

leptonic decays, and then compare them with determinations from other processes. We also use the CKM elements obtained from leptonic decays to test the unitarity of the first and second rows of the CKM matrix. Further, as in previous reviews, we combine the experimental  $\mathcal{B}(P \rightarrow \ell\nu)$ s with the associated CKM elements obtained from CKM unitarity to infer “experimental” values for the decay constants; the comparison with theory provides a test of lattice and other QCD approaches assuming that new-physics contributions to these processes are not significant.

## II. PIONS AND KAONS

### A. Experimental rate measurements

The leading-order expression for  $\Gamma(P \rightarrow \ell\nu)$  in Eq. (1) is modified by radiative corrections arising from diagrams involving photons, in some cases with additional quark loops. These electroweak and “hadronic” contributions can be combined into an overall factor that multiplies the rate in the presence of only the strong interaction ( $\Gamma^{(0)}$ ) as follows (cf. Refs. 15,16, and references therein):

$$\Gamma(P \rightarrow \ell\nu) = \Gamma^{(0)} \left[ 1 + \frac{\alpha}{\pi} C_P \right], \quad (3)$$

where  $C_P$  differs for  $P = \pi, K$ . The inclusion of these corrections is numerically important given the level of precision achieved on the experimental measurements of the  $\pi^\pm \rightarrow \mu^\pm\nu$  and  $K^\pm \rightarrow \mu^\pm\nu$  decay widths. The explicit expression for the term in brackets above including all known electroweak and hadronic contributions is given in Eq. (114) of Ref. 17. It includes the universal short-distance electroweak correction obtained by Sirlin [18], the universal long-distance correction for a point-like meson from Kinoshita [19], and corrections that depend on the hadronic structure [20]. We evaluate  $\delta_P \equiv (\alpha/\pi)C_P$  using the latest experimentally-measured meson and lepton masses and coupling constants from the Particle Data Group [3], and taking the low-energy constants (LECs) that parameterize the hadronic contributions from Refs. 17,21,22. The finite non-logarithmic parts of the LECs were estimated within the large- $N_C$  approximation assuming that contributions from the lowest-lying resonances dominate. We therefore conservatively assign a 100% uncertainty to the LECs, which leads to a  $\pm 0.9$  error in  $C_{\pi,K}$ .<sup>1</sup> We obtain the following correction factors to the individual charged pion and kaon decay widths:

$$\delta_\pi = 0.0176(21) \quad \text{and} \quad \delta_K = 0.0107(21). \quad (4)$$

<sup>1</sup> This uncertainty on  $C_{\pi,K}$  is smaller than the error estimated by Marciano and Sirlin in Ref. 23, which predates the calculations of the hadronic-structure contributions in Refs. 17, 20–22. The hadronic LECs incorporate the large short-distance electroweak logarithm discussed in Ref. 23, and their dependence on the chiral renormalization scale cancels the scale-dependence induced by chiral loops, thereby removing the dominant scale uncertainty of the Marciano–Sirlin analysis [23].

The error on the ratio of kaon-to-pion leptonic decay widths is under better theoretical control because the hadronic contributions from low-energy constants estimated within the large- $N_c$  framework cancel at lowest order in the chiral expansion. For the ratio, we use the correction factor

$$\delta_{K/\pi} = -0.0069(17), \quad (5)$$

where we take the estimated error due to higher-order corrections in the chiral expansion from Ref. 24.

The sum of branching fractions for  $\pi^- \rightarrow \mu^- \bar{\nu}$  and  $\pi^- \rightarrow \mu^- \bar{\nu} \gamma$  is 99.98770(4)% [3]. The two modes are difficult to separate experimentally, so we use this sum. Together with the lifetime 26.033(5) ns [3] this implies  $\Gamma(\pi^- \rightarrow \mu^- \bar{\nu}[\gamma]) = 3.8408(7) \times 10^7 \text{ s}^{-1}$ . The right-hand side of Eq. (1) is modified by the factor  $1.0176 \pm 0.0021$  mentioned above to include photon emission and radiative corrections [23,25]. The decay rate together with the masses from the 2014 PDG review [3] gives

$$f_{\pi^-} |V_{ud}| = (127.13 \pm 0.02 \pm 0.13) \text{ MeV}, \quad (6)$$

where the errors are from the experimental rate measurement and the radiative correction factor  $\delta_\pi$  in Eq. (4), respectively. The uncertainty is dominated by that from theoretical estimate of the hadronic structure-dependent radiative corrections, which include next-to-leading order contributions of  $\mathcal{O}(e^2 p_{\pi,K}^2)$  in chiral perturbation theory [17].

The data on  $K_{\mu 2}$  decays have been updated recently through a global fit to branching ratios and lifetime measurements [26]:  $\mathcal{B}(K^- \rightarrow \mu^- \bar{\nu}[\gamma]) = 63.58(11)\%$  and  $\tau_{K^\pm} = 12.384(15) \text{ ns}$ . The improvement in the branching ratio is primarily due to a new measurement of  $\mathcal{B}(K^\pm \rightarrow \pi^\pm \pi^+ \pi^-)$  from KLOE-2 [27], which is correlated with  $\mathcal{B}(K_{\mu 2}^\pm)$  through the constraint that the sum of individual branching ratios must equal unity. The sum of branching fractions for  $K^- \rightarrow \mu^- \bar{\nu}$  and  $K^- \rightarrow \mu^- \bar{\nu} \gamma$  and the lifetime imply  $\Gamma(K^- \rightarrow \mu^- \bar{\nu}[\gamma]) = 5.134(11) \times 10^7 \text{ s}^{-1}$ . Again taking the 2014 PDG masses [3], this decay rate implies

$$f_{K^+} |V_{us}| = (35.09 \pm 0.04 \pm 0.04) \text{ MeV}, \quad (7)$$

where the errors are from the experimental rate measurement and the radiative correction factor  $\delta_K$ , respectively.

Short-distance radiative corrections cancel in the ratio of pion-to-kaon decay rates [28]:

$$\frac{\Gamma_{K_{\ell 2}[\gamma]}}{\Gamma_{\pi_{\ell 2}[\gamma]}} = \frac{|V_{us}|^2 f_{K^-}^2}{|V_{ud}|^2 f_{\pi^-}^2} \frac{m_K(1 - m_\ell^2/m_K^2)^2}{m_\pi(1 - m_\ell^2/m_\pi^2)^2} (1 + \delta_{K/\pi}), \quad (8)$$

where  $\delta_{K/\pi}$  is given in Eq. (5). The left-hand side of Eq. (8) is 1.3367(28), yielding

$$\frac{|V_{us}| f_{K^-}}{|V_{ud}| f_{\pi^-}} = 0.27599 \pm 0.00029 \pm 0.00024, \quad (9)$$

where the first uncertainty is due to the branching fractions and the second is due to  $\delta_{K/\pi}$ . Here the estimated error on the hadronic structure-dependent radiative corrections is commensurate with the experimental error.

In summary, the main experimental results pertaining to charged pion and kaon leptonic decays are

$$|V_{ud}| f_{\pi^-} = (127.13 \pm 0.02 \pm 0.13) \text{ MeV}, \quad (10)$$

$$|V_{us}| f_{K^+} = (35.09 \pm 0.04 \pm 0.04) \text{ MeV}, \quad (11)$$

$$\frac{|V_{us}| f_{K^+}}{|V_{ud}| f_{\pi^-}} = 0.27599 \pm 0.00029 \pm 0.00024, \quad (12)$$

where the errors are from the experimental uncertainties in the branching fractions and the theoretical uncertainties in the radiative correction factors  $\delta_P$ , respectively.

### B. Theoretical decay-constant calculations

Table 1 presents recent lattice-QCD calculations of the charged pion and kaon decay constants and their ratio from simulations with three ( $N_f = 2+1$ ) or four flavors ( $N_f = 2+1+1$ ) of dynamical quarks. The results have been obtained using several independent sets of gauge-field configurations, and a variety of lattice fermion actions that are sensitive to different systematic uncertainties.<sup>2</sup> The lattice-QCD uncertainties on both the individual decay constants and their ratio have now reached sub-percent precision. The SU(3)-breaking ratio  $f_{K^+}/f_{\pi^+}$  can be obtained with especially small errors because statistical errors associated with the Monte Carlo simulations are correlated between the numerator and denominator, as are some systematics. The good agreement between these largely independent determinations indicates that the lattice-QCD uncertainties are controlled and that the associated error estimates are reliable.<sup>3</sup>

Table 1 also shows the 2015 preliminary three- and four-flavor averages for the pion and kaon decay constants and their ratio from the Flavour Lattice Averaging Group (FLAG) [12,13] in the lines labeled “FLAG 15 average.” These preliminary updates of the 2013 FLAG averages [14] include only those results from Table 1 that are published in refereed journals, or that are straightforward conference updates of published analyses. In the (2+1+1)-flavor averages, the statistical errors of HPQCD and Fermilab/MILC were conservatively treated as 100% correlated because the calculations employed some of the same gauge-field configurations. The errors have also been increased by the  $\sqrt{\chi^2/\text{dof}}$  to reflect a slight tension between the results. There are no four-flavor lattice-QCD results for the pion decay constant in Table 1 because all of the calculations listed use the quantity  $f_{\pi^+}$  to fix the absolute lattice scale needed to convert from lattice-spacing units to GeV [31–33].

<sup>2</sup> See the PDG mini-review on “Lattice Quantum Chromodynamics” [29] for a general review of numerical lattice-QCD simulations. Details on the different methods used in modern lattice-QCD calculations are provided in Appendix A of the FLAG “Review of lattice results concerning low energy particle physics” [14].

<sup>3</sup> The recent review [30] summarizes the large body of evidence validating the methods employed in modern lattice-QCD simulations.

## Meson Particle Listings

‡ Lattice 2011 conference proceedings.

All of the results in Table 1 were obtained using isospin-symmetric gauge-field configurations, *i.e.*, the dynamical up and down quarks have the same mass. Most calculations of pion and kaon decay constants now include the dominant effect of nondegenerate up- and down-quark masses by evaluating the masses of the constituent light (valence) quarks in the pion at the physical up- and down-quark masses, respectively, and evaluating the mass of the valence light quark in the kaon at the physical  $m_u$ . Those results obtained with degenerate up and down valence quarks are corrected for isospin breaking using chiral perturbation theory ( $\chi$ PT) before being averaged. The isospin-breaking corrections at next-to-leading order in  $\chi$ PT can be parameterized as [24,40]

$$f_\pi = f_{\pi^+}, \quad (13)$$

$$f_K = f_{K^+} (1 - \delta_{\text{SU}(2)}/2), \quad (14)$$

$$\frac{f_K}{f_\pi} = \frac{1}{\sqrt{\delta_{\text{SU}(2)} + 1}} \frac{f_{K^+}}{f_{\pi^+}} \quad (15)$$

where the expression for  $\delta_{\text{SU}(2)}$  in terms of the quark masses, meson masses, and decay constants, is given in Eq. (37) of Ref. 14. Numerically, values of  $\delta_{\text{SU}(2)} \approx -0.004$  were employed by FLAG to obtain the  $(2+1)$ -flavor averages in Table 1,

but some direct lattice-QCD calculations of  $\delta_{\text{SU}(2)}$  give larger values [31,33,41] and further studies are needed.

To obtain the best decay-constant values for comparison with experimental rate measurements and other phenomenological applications, we combine the available  $(2+1)$ - and  $(2+1+1)$ -flavor lattice-QCD results, first accounting for the omission of charm sea quarks in the three-flavor simulations. The error introduced by omitting charm sea quarks can be roughly estimated by expanding the charm-quark determinant in powers of  $1/m_c$  [42]; the resulting leading contribution is of order  $\alpha_s (\Lambda_{\text{QCD}}/2m_c)^2$  [43]. Taking the  $\overline{\text{MS}}$  values  $\overline{m}_c(\overline{m}_c) = 1.275$  GeV,  $\overline{\Lambda}_{\text{QCD}} \sim 340$  MeV from FLAG [14], and  $\overline{\alpha}(\overline{m}_c) \sim 0.4$ , leads to an estimate of about 0.7% for the contribution to the decay constants from charm sea quarks. The charm sea-quark contribution to ratios of decay constants is expected to be further suppressed by the  $\text{SU}(3)$ -breaking factor  $(m_s - m_d)/\Lambda_{\text{QCD}}$ , and hence about 0.2%.

We can compare these power-counting estimates of charm sea-quark contributions to the observed differences between the  $(2+1)$ - and  $(2+1+1)$ -flavor lattice-QCD averages for kaon,  $D_{(s)}$ -meson, and  $B_{(s)}$ -decay constants and ratios in Table 1, Table 4, and Table 6. Of these, the kaon decay constants have been calculated most precisely, and the two- and three- and four-flavor averages for  $f_{K^+}$  and  $f_{K^+}/f_{\pi^+}$  agree within sub-percent errors. Within present uncertainties, however, effects of this

size in pseudoscalar-meson decay constants cannot be ruled out. Therefore, to be conservative, in this review we add in quadrature additional systematic errors of 0.7% and 0.2% to all (2+1)-flavor decay-constant and decay-constant-ratio averages, respectively, to account for the omission of charm sea quarks. Numerically, this increases the errors by at most about 50% for  $f_{K^+}$  and less for all other decay constants and ratios, indicating that the published (2+1)-flavor lattice-QCD results and uncertainties are reliable.

Our final preferred theoretical values for the charged pion and kaon decay constants are

$$\begin{aligned} \text{Our averages : } f_{\pi^+} &= 130.2(1.7) \text{ MeV}, \\ f_{K^+} &= 155.6(0.4) \text{ MeV}, \\ \frac{f_{K^+}}{f_{\pi^+}} &= 1.1928(26), \end{aligned} \quad (16)$$

where  $f_{\pi^+}$  is simply the (2+1)-flavor FLAG average with the error increased by the estimated 0.7% charm sea-quark contribution. For  $f_{K^+}$  and  $f_{K^+}/f_{\pi^+}$ , we take a simple weighted average of the (2+1)- and (2+1+1)-flavor FLAG values, because they are each obtained from a sufficient number of independent calculations that we do not expect there to be significant correlations. In practice, the addition of the charm sea-quark error has a tiny impact on our final values in Eq. (16), increasing the uncertainty on  $f_{\pi^+}$  by 0.3 MeV, and the central value for  $f_{K^+}/f_{\pi^+}$  by one in the last digit.

### III. CHARMED MESONS

#### A. Experimental rate measurements

Measurements have been made for  $D^+ \rightarrow \mu^+\nu$ ,  $D_s^+ \rightarrow \mu^+\nu$ , and  $D_s^+ \rightarrow \tau^+\nu$ . Only an upper limit has been determined for  $D^+ \rightarrow \tau^+\nu$ . Both CLEO-c and BES have made measurements of  $D^+$  decay using  $e^+e^-$  collisions at the  $\psi(3770)$  resonant energy where  $D^-D^+$  pairs are copiously produced. They fully reconstruct one of the  $D$ 's, say the  $D^-$ . Counting the number of these events provides the normalization for the branching fraction measurement. They then find a candidate  $\mu^+$ , and then form the missing-mass squared,  $MM^2 = (E_{\text{CM}} - E_{D^-})^2 - (\vec{p}_{\text{CM}} - \vec{p}_{D^-} - \vec{p}_{\mu^+})^2$ , taking into account their knowledge of the center-of-mass energy,  $E_{\text{CM}}$ , and momentum,  $p_{\text{CM}}$ , that equals zero in  $e^+e^-$  collisions. A peak at zero  $MM^2$  implies the existence of a missing neutrino and hence the  $\mu^+\nu$  decay of the  $D^+$ . CLEO-c does not explicitly identify the muon, so their data consists of a combination of  $\mu^+\nu$  and  $\tau^+\nu$ ,  $\tau^+ \rightarrow \pi^+\nu$  events. This permits them to do two fits: in one they fit for the individual components, and in the other they fix the ratio of  $\tau^+\nu/\mu^+\nu$  events to be that given by the standard-model expectation. Thus, the latter measurement should be used for standard-model comparisons and the other for new-physics searches. Our average uses the fixed ratio value. The measurements are shown in Table 2.

**Table 2:** Experimental results for  $\mathcal{B}(D^+ \rightarrow \mu^+\nu)$ ,  $\mathcal{B}(D^+ \rightarrow \tau^+\nu)$ , and  $|V_{cd}|f_{D^+}$ . Numbers for  $|V_{cd}|f_{D^+}$  have been extracted using updated values for masses (see text). Radiative corrections are included. Systematic uncertainties arising from the  $D^+$  lifetime and mass are included. For the average  $\mu^+\nu$  number we use the CLEO-c result for  $\mu^+\nu + \tau^+\nu$ .

Experiment	Mode	$\mathcal{B}$	$ V_{cd} f_{D^+}$ (MeV)
CLEO-c [44,45]	$\mu^+\nu$	$(3.93 \pm 0.35 \pm 0.09) \times 10^{-4}$	$47.07 \pm 2.10 \pm 0.57$
CLEO-c [44,45]	$\mu^+\nu + \tau^+\nu$	$(3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$	$46.41 \pm 1.94 \pm 0.57$
BES [46]	$\mu^+\nu$	$(3.71 \pm 0.19 \pm 0.06) \times 10^{-4}$	$45.73 \pm 1.17 \pm 0.38$
Our average	Lines 2+3	$(3.74 \pm 0.17) \times 10^{-4}$	$45.91 \pm 1.05$
CLEO-c [47,48]	$\tau^+\nu$	$< 1.2 \times 10^{-3}$	

To extract the value of  $|V_{cd}|f_{D^+}$  we use the well-measured  $D^+$  lifetime of 1.040(7) ps. The  $\mu^+\nu$  results include a 1% correction (lowering) of the rate due to the presence of the radiative  $\mu^+\nu\gamma$  final state based on the estimate by Dobrescu and Kronfeld [8].

We now discuss the  $D_s^+$ . Measurements of the leptonic decay rate have been made by several groups and are listed in Table 3 [47–53]. We exclude older values obtained by normalizing to  $D_s^+$  decay modes that are not well defined. Many measurements, for example, used the  $\phi\pi^+$  mode. This decay is a subset of the  $D_s^+ \rightarrow K^+K^-\pi^+$  channel which has interferences from other modes populating the  $K^+K^-$  mass region near the  $\phi$ , the most prominent of which is the  $f_0(980)$ . Thus the extraction of the effective  $\phi\pi^+$  rate is sensitive to the mass resolution of the experiment and the cuts used to define the  $\phi$  mass region [54].<sup>4</sup>

To find decays in the  $\mu^+\nu$  signal channels, CLEO, BaBar and Belle rely on fully reconstructing all the final state particles except for neutrinos and using a missing-mass technique to infer the existence of the neutrino. CLEO uses  $e^+e^- \rightarrow D_s D_s^*$  collisions at 4170 MeV, while Babar and Belle use  $e^+e^- \rightarrow DK n \pi D_s^*$  collisions at energies near the  $\Upsilon(4S)$ . CLEO does a similar analysis as was done for the  $D^+$  above. Babar and Belle do a similar  $MM^2$  calculation by using the reconstructed hadrons, the photon from the  $D_s^{*+}$  decay and a detected  $\mu^+$ . To get the normalization they do a  $MM^2$  fit without the  $\mu^+$  and use the signal at the  $D_s^+$  mass squared to determine the total  $D_s^+$  yield.

When selecting the  $\tau^+ \rightarrow \pi^+\bar{\nu}$  and  $\tau^+ \rightarrow \rho^+\bar{\nu}$  decay modes, CLEO uses both the calculation of the missing mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged  $D_s^-$  and the  $\tau^+$  decay products. The  $\tau^+ \rightarrow e^+\nu\bar{\nu}$  mode, however, uses only extra energy. Babar and Belle also use the extra energy to discriminate signal from background in their  $\tau^+\nu$  measurements.

<sup>4</sup> We have not included the BaBar result for  $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$  reported in Ref. 55 because this measurement determined the ratio of the leptonic decay rate to the hadronic decay rate  $\Gamma(D_s^+ \rightarrow \ell^+\nu)/\Gamma(D_s^+ \rightarrow \phi\pi^+)$ .

## Meson Particle Listings

 $D_s^\pm$ 

**Table 3:** Experimental results for  $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$ ,  $\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)$ , and  $|V_{cs}|f_{D_s^+}$ . Numbers for  $|V_{cs}|f_{D_s^+}$  have been extracted using updated values for masses (see text). The systematic uncertainty for correlated error on the  $D_s^+$  lifetime is included. The mass uncertainties are also common, but negligible. Common systematic errors in each experiment have been taken into account in the averages.

Experiment	Mode	$\mathcal{B}(\%)$	$ V_{cs} f_{D_s^+}$ (MeV)
CLEO-c [47,48]	$\mu^+\nu$	$0.565 \pm 0.045 \pm 0.017$	$250.8 \pm 10.0 \pm 4.2$
BaBar <sup>a</sup> [53]	$\mu^+\nu$	$0.602 \pm 0.038 \pm 0.034$	$258.9 \pm 8.2 \pm 7.5$
Belle [49]	$\mu^+\nu$	$0.531 \pm 0.028 \pm 0.020$	$243.1 \pm 6.4 \pm 4.9$
Our average	$\mu^+\nu$	$0.556 \pm 0.024$	$248.8 \pm 5.8$
CLEO-c [47,48]	$\tau^+\nu$ ( $\pi^+\bar{\nu}$ )	$6.42 \pm 0.81 \pm 0.18$	$270.8 \pm 17.1 \pm 4.2$
CLEO-c [50]	$\tau^+\nu$ ( $\rho^+\bar{\nu}$ )	$5.52 \pm 0.57 \pm 0.21$	$251.1 \pm 13.0 \pm 5.1$
CLEO-c [51,52]	$\tau^+\nu$ ( $e^+\nu\bar{\nu}$ )	$5.30 \pm 0.47 \pm 0.22$	$246.1 \pm 10.9 \pm 5.4$
BaBar [53]	$\tau^+\nu$ ( $e^+(\mu^+)\nu\bar{\nu}$ )	$5.00 \pm 0.35 \pm 0.49$	$239.0 \pm 8.4 \pm 11.9$
Belle [49]	$\tau^+\nu$ ( $\pi^+\bar{\nu}$ )	$6.04 \pm 0.43^{+0.46}_{-0.40}$	$262.7 \pm 9.3^{+10.2}_{-8.9}$
Belle [49]	$\tau^+\nu$ ( $e^+\nu\bar{\nu}$ )	$5.37 \pm 0.33^{+0.35}_{-0.31}$	$247.7 \pm 7.6^{+8.3}_{-7.4}$
Belle [49]	$\tau^+\nu$ ( $\mu^+\nu\bar{\nu}$ )	$5.86 \pm 0.37^{+0.34}_{-0.59}$	$258.7 \pm 8.2^{+7.7}_{-13.2}$
Our average	$\tau^+\nu$	$5.56 \pm 0.22$	$252.1 \pm 5.2$
Our average	$\mu^+\nu + \tau^+\nu$		$250.9 \pm 4.0$

<sup>a</sup>We do not use a previous unpublished BaBar result from a subsample of data that uses a different technique for obtaining the branching fraction normalization [56].

We extract the decay constant times the CKM factor from the measured branching ratios using the  $D_s^+$  mass of 1.96830(11) GeV, the  $\tau^+$  mass of 1.77682(16) GeV, and a  $D_s^+$  lifetime of 0.500(7) ps [3]. CLEO has included the radiative correction of 1% in the  $\mu^+\nu$  rate listed in the Table [8] (the  $\tau^+\nu$  rates need not be corrected). Other theoretical calculations show that the  $\gamma\mu^+\nu$  rate is a factor of 40–100 below the  $\mu^+\nu$  rate for charm [57–66]. As this is a small effect we do not attempt to correct the other measurements. The values for  $f_{D_s^+}|V_{cs}|$  are in good agreement for the two decay modes. Our average value including both the  $\mu^+\nu$  and  $\tau^+\nu$  final states is  $250.9 \pm 4.0$  MeV.

### B. Theoretical decay-constant calculations

Table 4 presents recent theoretical calculations of the charged  $D^{*-}$  and  $D_s$ -meson decay constants and their ratio. The upper two panels show results from lattice-QCD simulations with three ( $N_f = 2 + 1$ ) or four flavors ( $N_f = 2 + 1 + 1$ ) of dynamical quarks. Although there are fewer available results than for the pion and kaon sector, both  $f_{D^+}$  and  $f_{D_s}$  have been obtained using multiple sets of gauge-field configurations with different lattice fermion actions, providing independent confirmation. For comparison, the bottom panel of Table 4 shows non-lattice determinations from QCD sum rules and the light-front quark model; only results which include uncertainty estimates are shown. The lattice and non-lattice results agree, but the uncertainties on  $D_{(s)}^+$ -meson decay constants from lattice QCD have now reached significantly greater precision than those from other approaches.

The lattice-QCD results in Table 4 were all obtained using isospin-symmetric gauge-field configurations. The two calculations by the Fermilab Lattice and MILC Collaborations [69,32], however, include the dominant strong isospin-breaking contribution by evaluating the mass of the valence light quark in the  $D^+$ -meson decay constant at the physical down-quark mass. Reference 32 provides a determination of the size of this correction,

$$f_{D^+} - f_D = 0.47(1)_{(-6)}^{(+25)} \text{ MeV}, \quad (17)$$

where  $f_D$  is the value of the  $D$ -meson decay constant evaluated at the average up-down quark mass. Eq. (17) implies that the correction to the  $SU(3)_f$ -breaking ratio is

$$\frac{f_{D_s}}{f_{D^+}} - \frac{f_{D_s}}{f_D} = -0.0026, \quad (18)$$

taking the central values for  $f_{D^+}$  and  $f_{D_s}$  from the same work. Because the errors on the calculations listed in Table 4 that neglect isospin breaking are still about  $5\text{--}8 \times$  larger than the sizes of the shifts in Eqs. (17)–(18), we do not correct any results *a posteriori* for this effect in the current review. Nevertheless, we strongly encourage future lattice-QCD publications to present results for both the  $D^{*-}$  and  $D^0$ -meson decay constants. Including the effect of isospin breaking will be essential once lattice-QCD calculations of  $f_D$  and  $f_{D_s}/f_D$  reach the level of precision in Eqs. (17)–(18).

We average the lattice-QCD results in Table 4 accounting for possible correlations between them following the approach established by Laiho *et al.* [77]. Whenever we have reason to believe that a source of uncertainty is correlated between two

**Table 4:** Recent theoretical determinations of  $f_{D^+}$ ,  $f_{D_s}$ , and their ratio. The upper panels show results from lattice-QCD simulations with  $(2+1+1)$  and  $(2+1)$  dynamical quark flavors, respectively. Statistical and systematic errors are quoted separately. Lattice-QCD results for  $f_D$  and  $f_{D_s}/f_D$  in the isospin-symmetric limit  $m_u = m_d$  are noted with an “\*”. The bottom panel shows estimates from QCD sum rules (QCD SR) and the light-front quark model (LFQM). These are not used to obtain our preferred decay-constant values.

¶ Obtained by combining PDG value  $f_D = 205.8(8.9)$  MeV [76] with  $f_{D_s}/f_D$  from this work.

results, we conservatively take the correlation to be 100% when calculating the average. We then construct the correlation matrix for the set of lattice-QCD results using the prescription of Schmelling [78].

We first separately average the three- and four-flavor results for the charged  $D_{(s)}^+$ -meson decay constants and their ratio. There have been no new three-flavor lattice-QCD calculations of  $f_{D^+}$  or  $f_{D_s^+}/f_{D^+}$  since 2013, so we take the  $(2+1)$ -flavor averages from FLAG [14]. In this average, the statistical errors were treated as 100% correlated between the results of Fermilab/MILC [69] and HPQCD [68] because the calculations employed some of the same ensembles of gauge-field configurations. For  $f_{D_s}$ , we average the  $(2+1)$ -flavor results given in Table 4, again treating the Fermilab/MILC [69] and HPQCD [70] statistical errors as correlated, and taking the  $\chi$ QCD result [67] to be independent. For the  $(2+1+1)$ -flavor  $D_{(s)}$ -meson decay constants, we take a simple weighted average of the ETM [31] and Fermilab/MILC 14 results [32] in Table 4. We expect them to be independent because the calculations use different light-quark and gluon actions and different treatments of the chiral-continuum extrapolation. Our separate three- and four-flavor averages are listed in the lines labeled “Average” in Table 4, where the errors on the  $(2+1)$ -flavor  $f_{D_s}$  and

$(2+1+1)$ -flavor  $f_D$  averages have been rescaled by the factors  $\sqrt{(\chi^2/\text{dof})} = 1.1$  and  $\sqrt{(\chi^2/\text{dof})} = 1.3$ , respectively.<sup>5</sup>

To obtain the single-best values of the  $D_{(s)}^+$ -meson decay constants for phenomenology applications, we combine the available  $(2+1)$ - and  $(2+1+1)$ -flavor lattice-QCD results, which are compatible within the current level of precision. We account for the omission of charm sea-quark contributions in the three-flavor calculations by adding to the errors on the  $(2+1)$ -flavor averages in Table 4 our power-counting estimates of charm sea-quark errors from Sec. II.B. Because the estimated charm sea-quark errors of 0.7% for decay constants and 0.2% for decay-constant ratios are less than those on the  $(2+1)$ -flavor averages, adding them in quadrature has a small impact on the total uncertainties. The error increase is at most about 25% for  $f_{D_s}$ , and below 10% for both  $f_{D^+}$  and  $f_{D_s}/f_{D^+}$ . Our final preferred theoretical values for the charged  $D_{(s)}^+$ -meson decay constants are given by the weighted average of the entries in the two lines labeled “Average” in Table 4, after including the additional charm sea-quark errors in the  $(2+1)$ -flavor entries:

Our averages :  $f_{D^+} = 211.9(1.1)$  MeV ,

<sup>5</sup> After this article was submitted for review, preliminary  $(2+1)$ - and  $(2+1+1)$ -flavor FLAG averages for  $f_D$ ,  $f_{D_s}$ , and  $f_{D_s}/f_D$  were presented in Ref. 79 that are identical to our separate averages in Table 4.

# Meson Particle Listings

$D_s^\pm$

$$\begin{aligned} f_{D_s} &= 249.0(1.2) \text{ MeV}, \\ \frac{f_{D_s}}{f_{D^+}} &= 1.173(3). \end{aligned} \quad (19)$$

In practice, the errors on the (2+1+1)-flavor averages are so much smaller than on the (2+1)-flavor averages that the combination in Eq. (19) is almost identical to the (2+1+1)-flavor average in Table 4. The most precise result from Fermilab/MILC, in particular, has a large weight in the average.

## IV. BOTTOM MESONS

### A. Experimental rate measurements

The Belle and BaBar collaborations have found evidence for  $B^- \rightarrow \tau^- \bar{\nu}$  decay in  $e^+e^- \rightarrow B^- B^+$  collisions at the  $\Upsilon(4S)$  energy. The analysis relies on reconstructing a hadronic or semileptonic  $B$  decay tag, finding a  $\tau$  candidate in the remaining track and photon candidates, and examining the extra energy in the event which should be close to zero for a real  $\tau^-$  decay to  $e^- \nu \bar{\nu}$  or  $\mu^- \nu \bar{\nu}$  opposite a  $B^+$  tag. While the BaBar results have remained unchanged, Belle reanalyzed both samples of their data. The branching fraction using hadronic tags changed from  $1.79^{+0.56+0.46}_{-0.49-0.51} \times 10^{-4}$  [80] to  $0.72^{+0.27}_{-0.25} \pm 0.11 \times 10^{-4}$  [81], while the corresponding change using semileptonic tags was from  $1.54^{+0.38+0.29}_{-0.37-0.31}$  to  $1.25 \pm 0.28 \pm 0.27$ . These changes demonstrate the difficulty of the analysis. The results are listed in Table 5.

There are large backgrounds under the signals in all cases. The systematic errors are also quite large. Thus, the significances are not that large. Belle quotes  $4.6\sigma$  for their combined hadronic and semileptonic tags, while BaBar quotes  $3.3\sigma$  and  $2.3\sigma$ , for hadronic and semileptonic tags. Greater precision is necessary to determine if any effects beyond the Standard Model are present.

**Table 5:** Experimental results for  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$  and  $|V_{ub}|f_{B^+}$ .

Experiment	Tag	$\mathcal{B}$ (units of $10^{-4}$ )	$ V_{ub} f_{B^+}$ (MeV)
Belle [81]	Hadronic	$0.72^{+0.27}_{-0.25} \pm 0.11$	
Belle [82]	Semileptonic	$1.25 \pm 0.28 \pm 0.27$	
Belle [82]	Average	$0.91 \pm 0.22$	$0.72 \pm 0.09$
BaBar [83]	Hadronic	$1.83^{+0.53}_{-0.49} \pm 0.24$	
BaBar [84]	Semileptonic	$1.7 \pm 0.8 \pm 0.2$	
BaBar [83]	Average	$1.79 \pm 0.48$	$1.01 \pm 0.14$
Our average		$1.06 \pm 0.20$	$0.77 \pm 0.07$

To extract the value of  $|V_{ub}|f_{B^+}$  we use the PDG 2014 value of the  $B^+$  lifetime of  $1.638 \pm 0.004$  ps, and the  $\tau^+$  and  $B^+$  masses of 1.77684 and 5.27926 GeV, respectively.

### B. Theoretical decay-constant calculations

Table 6 and Table 7 present theoretical calculations of the  $B^+$ -,  $B^0$ -, and  $B_s$ -meson decay constants and their ratios. (The decay constants of the neutral  $B^0$  and  $B_s$  mesons enter the rates for the rare leptonic decays  $B_{d,s} \rightarrow \mu^+ \mu^-$ .) The upper

two panels show results from lattice-QCD simulations with three ( $N_f = 2+1$ ) or four flavors ( $N_f = 2+1+1$ ) of dynamical quarks. For all decay constants, calculations using different gauge-field configurations, light-quark actions, and  $b$ -quark actions provide independent confirmation. For comparison, the bottom panel of Table 6 shows non-lattice determinations of the  $B_{(s)}$ -meson decay constants which include error estimates. These are consistent with the lattice values, but with much larger uncertainties.

The lattice-QCD results in Table 6 and Table 7 were all obtained using isospin-symmetric gauge-field configurations. The most recent calculations of  $f_{B^+}$  by the HPQCD, Fermilab/MILC, and RBC/UKQCD Collaborations [69,86,88], however, include the dominant effect of nondegenerate up- and down-quark masses by evaluating the decay constant with the valence light-quark mass fixed to the physical up-quark mass. HPQCD and RBC/UKQCD also calculate  $f_{B^0}$  by fixing the valence light-quark mass equal to the physical down-quark mass [86,88]; they find differences between the  $B^+$ - and  $B^0$ -meson decay constants of  $f_{B^0} - f_{B^+} \approx 4$  MeV and  $f_{B_s}/f_{B^+} - f_{B_s}/f_{B^0} \approx 0.025$ . Inspection of Table 6 and Table 7 shows that these differences are comparable to the error on the HPQCD 12 result for  $f_B$  [89], and to the errors on the Fermilab/MILC, HPQCD 12, and ETM results for  $f_{B_s}/f_B$  [69,89,85], none of which account for isospin breaking. Therefore, to enable comparison with experimental measurements, in this review we correct those lattice-QCD results for  $B$ -meson decay constants obtained with degenerate up and down valence quarks *a posteriori* for isospin breaking before computing our averages. For the correction factors, we use the differences obtained empirically by HPQCD in Ref. 86<sup>6</sup>

$$f_{B^+} - f_B = -1.9(5) \text{ MeV}, \quad (20)$$

$$\frac{f_{B_s}}{f_{B^+}} - \frac{f_{B_s}}{f_B} = 0.012(4), \quad (21)$$

$$f_{B^0} - f_B = 1.7(5) \text{ MeV}, \quad (22)$$

$$\frac{f_{B_s}}{f_{B^0}} - \frac{f_{B_s}}{f_B} = -0.011(4). \quad (23)$$

The isospin-breaking correction factors in Eqs. (20)–(23) are well determined because of cancellations between correlated errors in the differences.

We first average the published (2+1)-flavor lattice-QCD results for the charged and neutral  $B_{(s)}$ -meson decay constants and their ratios in Table 6 and Table 7, accounting for possibly correlated uncertainties. We treat the statistical errors as correlated between the calculations of Aoki *et al.* and RBC/UKQCD because they employ the same gauge-field

<sup>6</sup> The correlated uncertainties were provided by HPQCD via private communication.

**Table 6:** Recent theoretical determinations of  $f_{B^+}$ ,  $f_{B_s}$ , and their ratio. The upper panels show results from lattice-QCD simulations with  $(2+1+1)$  and  $(2+1)$  dynamical quark flavors, respectively. For some of the lattice-QCD results, statistical and systematic errors are quoted separately. Lattice-QCD results for  $f_B$  and  $f_{B_s}/f_B$  in the isospin-symmetric limit  $m_u = m_d$  are noted with an “\*”; they are corrected by the factors in Eq. (20) and Eq. (21), respectively, before computing the averages. Preliminary conference results noted with a “†” are not included in the averages. The bottom panel shows estimates from QCD sum rules and the light-front quark model, which are not used to obtain our preferred decay-constant values.

‡ Obtained with static  $b$  quarks (*i.e.*  $m_b \rightarrow \infty$ ).

\* Obtained by combining  $f_{B_s}$  from HPQCD 11 with  $f_{B_s}/f_B$  from this work. Approximate statistical (systematic) error obtained from quadrature sum of individual statistical (systematic) errors.

§ Obtained using  $m_b^{\text{MS}}$ ; results using  $m_b^{\text{pole}}$  are also given in the paper.

¶ Obtained by combining PDG value  $f_B = 204(31)$  MeV [76] with  $f_{B_s}/f_B$  from this work.

configurations<sup>7</sup> [87,88]. We also treat the statistical errors as correlated between the HPQCD and Fermilab/MILC calculations because they analyze an overlapping set of gauge-field configurations [69,89,90]. For  $f_{B_s}$ , we include HPQCD’s results from both 2011 [90] and 2012 [89], which were obtained using different  $b$ -quark actions, but on some of the same gauge-field configurations. HPQCD 11 and 12 also use the same determination of the absolute lattice scale, which is the second-largest

<sup>7</sup> There may be mild correlations between some sub-dominant systematic errors of Aoki *et al.* and RBC/UKQCD, who use the same determinations of the absolute lattice scale and the physical light- and strange-quark masses from Ref. 93, and who use the same power-counting estimates for the light-quark and gluon discretization errors. The effects of any correlations between these systematics, however, would be too small to impact the numerical values of the averages.

source of systematic uncertainty in both calculations. We therefore treat the statistical and scale errors as correlated between HPQCD’s  $(2+1)$ -flavor  $f_{B_s}$  results. HPQCD also presents two results for  $f_B$  in Ref. 89. The more precise value is obtained by combining the ratio  $f_{B_s}/f_B$  from this work with  $f_{B_s}$  from Ref. 90, but an associated error budget is not provided. Because this would be needed to estimate correlations between the two  $f_B$  determinations, we include only HPQCD’s more precise  $(2+1)$ -flavor result for  $f_B$  in our average. Our separate three- and four-flavor averages for the  $B^{+-}$ ,  $B^{0-}$ , and  $B_s$ -meson decay constants and ratios are listed in the lines labeled “Average” in Table 6 and Table 7, where the error on the  $(2+1)$ -flavor  $f_{B_s}$  average has been rescaled by the factor  $\sqrt{\chi^2/\text{dof}} = 1.2$  to account for the tension among results. Our  $(2+1+1)$ -flavor “averages” are identical to the “HPQCD 13” entries in Table 6

$^\ddagger$  Obtained with static  $b$  quarks (*i.e.*,  $m_b \rightarrow \infty$ ).

\* Obtained by combining  $f_{B_s}$  from HPQCD 11 with  $f_{B_s}/f_B$  from this work. Approximate statistical (systematic) error obtained from quadrature sum of individual statistical (systematic) errors.

To obtain the single-best values of the  $B_{(s)}$ -meson decay constants for phenomenology applications, we combine the available  $(2+1)$ - and  $(2+1+1)$ -flavor lattice-QCD results, which are compatible within the current level of precision. Because the four-flavor “average” is obtained from only a single result, we do not simply combine the two lines labeled “Average” in Table 6 and Table 7, which would weight the four-flavor result too heavily. Instead, we form a single average including the published  $(2+1)$ -flavor results and the  $(2+1+1)$ -flavor result from HPQCD 13. We account for the omission of charm sea-quark contributions in the three-flavor calculations by adding to the errors on the  $(2+1)$ -flavor averages in Table 6 and Table 7 our power-counting estimates of charm sea-quark errors from Sec. II.B, taking charm sea-quark error to be 100% correlated between the three-flavor results. Because the estimated charm sea-quark errors of 0.7% for decay constants and 0.2% for decay-constant ratios are much less than those on the  $(2+1)$ -flavor averages, adding them in quadrature has a tiny impact on the total uncertainties. The largest observed change is an 0.3 MeV increase on the error  $f_{B_s}$  from HPQCD 11, and most are negligible. In the combined three- and four-flavor average we also consider correlations between the results of HPQCD 12 and HPQCD 13 because, although they employ different gauge-field configurations, they both use NRQCD for the  $b$ -quark action and the bottom-light axial-vector current.<sup>8</sup> We

<sup>8</sup> HPQCD 13 uses a 1-loop radiatively improved  $b$ -quark action, whereas HPQCD 12 uses tree-level action coefficients.

take both the operator-matching and relativistic errors, which are the dominant uncertainties in the decay constants, to be correlated between the two calculations. Our final preferred theoretical values for the charged  $B^+$  and neutral  $B_{(s)}^0$ -meson decay constants and their ratio are

$$\text{Our averages : } f_{B^+} = 187.1(4.2) \text{ MeV ,}$$

$$f_{B_s} = 227.2(3.4) \text{ MeV , } \frac{f_{B_s}}{f_{B^+}} = 1.215(7) , \quad (24)$$

$$f_{B^0} = 190.9(4.1) \text{ MeV , } \frac{f_{B_s}}{f_{B^0}} = 1.192(6) . \quad (25)$$

The errors on  $f_B^+$ ,  $f_B^0$ , and  $f_{B_s}$  after combining the three- and four-flavor results are only slightly smaller than those of the separate averages due to the correlations assumed.

## V. PHENOMENOLOGICAL IMPLICATIONS

### A. $|V_{ud}|$ , $|V_{us}|$ , and status of first-row unitarity

Using the average values for  $f_{\pi^+}|V_{ud}|$ ,  $f_{K^+}|V_{us}|$ , and their ratio from Eq. (10)–Eq. (12) and for  $f_{\pi^+}$ ,  $f_{K^+}$ , and their ratio from Eq. (16), we obtain the following determinations of the CKM matrix elements  $|V_{ud}|$ ,  $|V_{us}|$ , and their ratio from leptonic decays within the standard model:

$$|V_{ud}| = 0.9764(2)(127)(10) , \quad |V_{us}| = 0.2255(3)(6)(3) ,$$

$$\frac{|V_{us}|}{|V_{ud}|} = 0.2314(2)(5)(2) , \quad (26)$$

where the errors are from the experimental branching fraction(s), the pseudoscalar decay constant(s), and radiative corrections, respectively. These results enable a precise test of the unitarity of the first row of the CKM matrix from leptonic decays alone (the contribution from  $|V_{ub}|$  is negligible). Using the values of  $|V_{ud}|$  and  $|V_{us}|$  from Eq. (26), we find

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 - 1 = 0.004(25) , \quad (27)$$

which is consistent with three-generation unitarity at the sub-percent level.

The determinations of  $|V_{ud}|$  and  $|V_{us}|$  from leptonic decays in Eq. (26) can be compared to those obtained from other processes. The result above for  $|V_{ud}|$  agrees with the determination from superallowed  $\beta$ -decay,  $|V_{ud}| = 0.97417(21)$  [94], but has an error more than fifty times larger that is primarily due to the uncertainty in the theoretical determination of  $f_{\pi^+}$ . The CKM element  $|V_{us}|$  can be determined from semileptonic  $K^+ \rightarrow \pi^0 \ell^+ \nu$  decay. Here experimental measurements provide a value for the product  $f_+^{K\pi}(0)|V_{us}|$ , where  $f_+^{K\pi}(0)$  is the form-factor at zero four-momentum transfer between the initial state kaon and the final state pion. Taking the most recent experimental determination of  $|V_{us}|f_+^{K\pi}(0) = 0.2165(4)$

Both include the same contributions to the currents at one loop, but renormalization details differ.

from Moulson [26]<sup>9</sup> and the preliminary 2015 (2+1+1)-flavor FLAG average for  $f_+(0)^{K\pi} = 0.9704(24)(22)$  [12,13]<sup>10</sup> gives  $|V_{us}| = 0.22310(74)_{\text{thy}}(41)_{\text{exp}}$  from  $K_{\ell 3}$  decay. The determinations of  $|V_{us}|$  from leptonic and semileptonic kaon decays are both quite precise (with the error from leptonic decay being about 20% smaller), but the central values differ by  $2.2\sigma$ . Finally, the combination of the ratio  $|V_{us}|/|V_{ud}|$  from leptonic decays [Eq. (26)] with  $|V_{ud}|$  from  $\beta$  decay implies an alternative determination of  $|V_{us}| = 0.2254(6)$  which agrees with the value from leptonic kaon decay, but disagrees with the  $K_{\ell 3}$ -decay result at the  $2.2\sigma$  level. Collectively, these results indicate that there is some tension between theoretical calculations and/or measurements of leptonic pion and kaon decays, semileptonic kaon decays, and superallowed  $\beta$ -decay. Although this may be due to the presence of new physics, it is also important to revisit the quoted uncertainties on both the theoretical and experimental inputs.

Finally, we combine the experimental measurements of  $f_{\pi^+}|V_{ud}|$ ,  $f_{K^+}|V_{us}|$  from leptonic pseudoscalar-meson decays in Eq. (10) and Eq. (11) with determinations of the CKM elements from other decays or unitarity to infer “experimental” values for the decay constants. Assuming that there are no significant new-physics contributions to any of the input processes, the comparison of these results with theoretical calculations of the decay constants enables a test of lattice-QCD methods. Taking  $|V_{ud}|$  from superallowed  $\beta$ -decay [100] leads to

$$f_{\pi^-}^{\text{“exp”}} = 130.50(1)(3)(13) \text{ MeV}, \quad (28)$$

where the uncertainties are from the errors on  $\Gamma$ ,  $|V_{ud}|$ , and higher-order corrections, respectively. This agrees with the theoretical value  $f_{\pi^+} = 130.2(1.7) \text{ MeV}$  in Eq. (16) obtained from an average of recent (2+1)-flavor lattice-QCD results [39,37,35]. We take the value  $|V_{us}| = 0.22534(65)$  from the most recent global unitarity-triangle fit of the UTfit Collaboration [101] because there is tension between the values of  $|V_{us}|$  obtained from leptonic and semileptonic kaon decays. This implies

$$f_{K^-}^{\text{“exp”}} = 155.72(17)(45)(16) \text{ MeV} \quad (29)$$

where the uncertainties are from the errors on  $\Gamma$ ,  $|V_{us}|$ , and higher-order corrections, respectively. This agrees with the theoretical value  $f_{K^+} = 155.6(0.4) \text{ MeV}$  in Eq. (16) obtained from an average of recent three and four-flavor lattice-QCD results [31–33,35,37,39].

<sup>9</sup> This is an update of the 2010 Flavianet review [28] that includes new measurements of the  $K_s$  lifetime [95,96],  $\text{Re}(\epsilon'/\epsilon)$  [96], and  $\mathcal{B}(K^\pm \rightarrow \pi^\pm \pi^+ \pi^-)$  [27]. The latter measurement is the primary source of the reduced error on  $\mathcal{B}(K_{\ell 3})$ , via the constraint that the sum of all branching ratios must equal unity.

<sup>10</sup> This result comes from the calculation of FNAL/MILC in Ref. 97. For comparison, the 2015 preliminary (2+1)-flavor FLAG average based on the calculations of FNAL/MILC [98] and RBC/UKQCD [99] is  $f_+(0)^{K\pi} = 0.9677(37)$ .

### B. $|V_{cd}|$ , $|V_{cs}|$ , and status of second-row unitarity

Using the average values for  $|V_{cd}|f_{D^+}$  and  $|V_{cs}|f_{D_s^+}$  from Table 2 and Table 3, and for  $f_{D^+}$  and  $f_{D_s^+}$  from Eq. (19), we obtain the following determinations of the CKM matrix elements  $|V_{cd}|$  and  $|V_{cs}|$ , and from leptonic decays within the standard model:

$$|V_{cd}| = 0.217(5)(1) \quad \text{and} \quad |V_{cs}| = 1.007(16)(5), \quad (30)$$

where the errors are from experiment and theory, respectively, and are currently limited by the measured uncertainties on the decay rates. The central value of  $|V_{cs}|$  is greater than one, but is compatible with unity within the error. The above results for  $|V_{cd}|$  and  $|V_{cs}|$  do not include higher-order electroweak and hadronic corrections to the rate, in analogy to Eq. (3). These corrections have not been computed for  $D_{(s)}^+$ -meson leptonic decays, but are estimated to be about 1–2% for charged pion and kaon decays (see Sec. II.A). Now that the uncertainties on  $|V_{cd}|$  and  $|V_{cs}|$  from leptonic decays are at this level, we hope that the needed theoretical calculations will be undertaken.

The CKM elements  $|V_{cd}|$  and  $|V_{cs}|$  can also be obtained from semileptonic  $D^+ \rightarrow \pi^0 \ell^+ \nu$  and  $D_s^+ \rightarrow K^0 \ell^+ \nu$  decays, respectively. Here experimental measurements determine the product of the form factor times the CKM element, and theory provides the value for the form factor at zero four-momentum transfer between the initial  $D_{(s)}$  meson and the final pion or kaon. We combine the latest experimental averages for  $f_+^{D\pi}(0)|V_{cd}| = 0.1425(19)$  and  $f_+^{D_s K}(0)|V_{cs}| = 0.728(5)$  from the Heavy Flavor Averaging Group (HFAG) [102] with the zero-momentum-transfer form factors  $f_+^{D\pi}(0) = 0.666(29)$  and  $f_+^{D_s K}(0) = 0.747(19)$  calculated in (2+1)-flavor lattice QCD by the HPQCD Collaboration [103,104] to obtain  $|V_{cd}| = 0.2140(97)$  and  $|V_{cs}| = 0.9746(257)$  from semileptonic  $D_{(s)}$ -meson decays. The values of  $|V_{cd}|$  from leptonic and semileptonic decays agree, while those for  $|V_{cs}|$  are compatible at the  $1.1\sigma$  level. The determinations of  $|V_{cd}|$  and  $|V_{cs}|$  from leptonic decays in Eq. (30), however, are  $2.0\times$  and  $1.6\times$  more precise than those from semileptonic decays, respectively.

The results for  $|V_{cd}|$  and  $|V_{cs}|$  from Eq. (30) enable a test of the unitarity of the second row of the CKM matrix. We obtain

$$|V_{cd}|^2 + |V_{cs}|^2 + |V_{cb}|^2 - 1 = 0.064(36), \quad (31)$$

which is in slight tension with three-generation unitarity at the  $2\sigma$  level. Because the contribution to Eq. (31) from  $|V_{cb}|$  is so small, we obtain the same result taking  $|V_{cb}|^{\text{incl.}} \times 10^3 = 42.21(78)$  from inclusive  $B \rightarrow X_c \ell \nu$  decay [105] or  $|V_{cb}|^{\text{excl.}} \times 10^3 = 39.04(75)$  from exclusive  $B \rightarrow D^* \ell \nu$  decay at zero recoil [106].

We can also combine the experimental measurements of  $f_{D^+}|V_{cd}| = 45.91(1.05) \text{ MeV}$  and  $f_{D_s^+}|V_{cs}| = 250.9(4.0) \text{ MeV}$  from leptonic pseudoscalar-meson decays from Table 2 and Table 3 with determinations of  $|V_{cd}|$  and  $|V_{cs}|$  from CKM unitarity to infer “experimental” values for the decay constants within

# Meson Particle Listings

$D_s^\pm$

the standard model. For this purpose, we obtain the values of  $|V_{cd}|$  and  $|V_{cs}|$  by relating them to other CKM elements using the Wolfenstein parameterization [107]. We take  $|V_{cd}|$  to equal the value of  $|V_{us}|$  minus the leading correction [108]:

$$|V_{cd}| = |V_{us}| \left| -1 + \frac{|V_{cb}|^2}{2}(1 - 2(\rho + i\eta)) \right| \quad (32)$$

$$= |V_{us}| \left( \left[ -1 + (1 - 2\rho) \frac{|V_{cb}|^2}{2} \right]^2 + \eta^2 |V_{cb}|^4 \right)^{1/2}. \quad (33)$$

Using  $|V_{us}| = 0.2255(3)(6)(3)$  from leptonic kaon decay, Eq. (26), inclusive  $|V_{cb}|$  as above, and  $(\rho, \eta) = (0.136(24), 0.361(14))$  from CKM unitarity [101]  $|V_{cd}| = 0.2254(7)$ . We take  $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$  [108], using  $|V_{ud}| = 0.97417(21)$  from  $\beta$  decay [94], giving  $|V_{cs}| = 0.9733(2)$ . Given these choices, we find

$$f_{D^+}^{\text{exp}} = 203.7(4.7)(0.6) \text{ MeV} \quad \text{and} \quad f_{D_s^+}^{\text{exp}} = 257.8(4.1)(0.1) \text{ MeV}, \quad (34)$$

where the uncertainties are from the errors on  $\Gamma$  and  $|V_{us}|$  (or  $|V_{ud}|$ ), respectively. These disagree with the theoretical values  $f_{D^+} = 211.9(1.1) \text{ MeV}$  and  $f_{D_s^+} = 249.0(1.2) \text{ MeV}$  in Eq. (19) obtained from averaging recently published three and four-flavor lattice-QCD results at the  $1.7\sigma$  and  $2.0\sigma$  levels, respectively. The significances of the tensions are sensitive, however, to the choices made for  $|V_{us}|$  and  $|V_{ud}|$ . Thus resolving the inconsistencies between determinations of elements of the first row of the CKM matrix discussed previously in Sec. V.A may also reduce the mild tensions observed here.

## C. $|V_{ub}|$ and other applications

Using the average value for  $|V_{ub}|f_{B^+}$  from Table 5, and for  $f_{B^+}$  from Eq. (24), we obtain the following determination of the CKM matrix element  $|V_{ub}|$  from leptonic decays within the standard model:

$$|V_{ub}| = 4.12(37)(9) \times 10^{-3}, \quad (35)$$

where the errors are from experiment and theory, respectively. We note, however, that decays involving the third generation of quarks and leptons may be particularly sensitive to new physics associated with electroweak symmetry breaking due to their larger masses [4,6], so Eq. (35) is more likely to be influenced by new physics than the determinations of the elements of the first and second rows of the CKM matrix in the previous sections.

The CKM element  $|V_{ub}|$  can also be obtained from semileptonic  $B$ -meson decays. Over the past several years there has remained a persistent  $2\text{--}3\sigma$  tension between the determinations of  $|V_{ub}|$  from exclusive  $B \rightarrow \pi \ell \nu$  decay and from inclusive  $B \rightarrow X_u \ell \nu$  decay, where  $X_u$  denotes all hadrons which contain a constituent up quark [3,102,109–111]. The currently most precise determination of  $|V_{ub}|^{\text{excl}} = 3.72(16) \times 10^{-3}$  is obtained from a joint  $z$ -fit of the vector and scalar form

factors  $f_+^{B\pi}(q^2)$  and  $f_0^{B\pi}(q^2)$  calculated in (2+1)-flavor lattice QCD by the FNAL/MILC Collaboration [112] and experimental measurements of the differential decay rate from BaBar [113,114] and Belle [115,116]. On the other hand, the most recent PDG average of inclusive determinations obtained using the theoretical frameworks in Refs. 117–119 is  $|V_{ub}|^{\text{incl}} = 4.49(16) \left( \begin{smallmatrix} +16 \\ -18 \end{smallmatrix} \right) \times 10^{-3}$  [120]. The result for  $|V_{ub}|$  from leptonic  $B \rightarrow \tau \nu$  decay in Eq. (35) is compatible with determinations from both exclusive and inclusive semileptonic  $B$ -meson decays.

The CKM element  $|V_{ub}|$  can now also be obtained from semileptonic  $\Lambda_b$  decays. Specifically, the recent LHCb measurement of the ratio of decay rates for  $\Lambda_b \rightarrow p \ell \nu$  over  $\Lambda_b \rightarrow \Lambda_c \ell \nu$  [121], when combined with the ratio of form factors from (2+1)-flavor lattice QCD [122], enables the first determination of the ratio of CKM elements  $|V_{ub}|/|V_{cb}| = 0.083(4)(4)$  from baryonic decay. Taking  $|V_{cb}|^{\text{incl}} = 42.21(78) \times 10^{-3}$  [105] for the denominator,<sup>1</sup> we obtain  $|V_{ub}| = 3.50(17)(17)(6) \times 10^{-3}$  from exclusive  $\Lambda_b$  semileptonic decays, where the errors are from experiment, the form factors, and  $|V_{cb}|$ , respectively. The result for  $|V_{ub}|$  from leptonic  $B \rightarrow \tau \nu$  decay in Eq. (35) is  $1.4\sigma$  higher than the determination from  $b$ -baryon decays.

Given these results, the “ $V_{ub}$ ” puzzle still stands, and the determination from leptonic  $B^+$ -meson decay is not yet sufficiently precise to weigh in on the discrepancy. New and improved experimental measurements and theoretical calculations of other  $b \rightarrow u$  flavor-changing processes, however, are providing additional information and sharpening the picture of the various tensions. Further, the error on  $|V_{ub}|$  from  $B \rightarrow \tau \nu$  decay will shrink once improved rate measurements from the Belle II experiment are available.

Finally, we can combine the experimental measurement of  $|V_{ub}|f_{B^+}$  from leptonic  $B^+$ -meson decays in Table 5 with a determination of the CKM element  $|V_{ub}|$  from elsewhere to infer an “experimental” values for  $f_{B^+}$  within the standard model. This, of course, assumes that there are no significant new-physics contributions to  $B^+ \rightarrow \tau \nu$ , which may turn out not to be the case. Further, one does not know *a priori* what value to take for  $|V_{ub}|$  given the inconsistencies between the various determinations discussed above. We therefore take the PDG weighted average of the determinations from inclusive and exclusive semileptonic  $B$ -meson decays  $|V_{ub}|^{\text{excl+incl}} = 4.09(39) \times 10^{-3}$  [120], where

<sup>1</sup>This differs from the choice for  $|V_{cb}|$  made by LHCb [121], who use the determination from exclusive  $B \rightarrow D^{(*)} \ell \nu$  decays at zero recoil [123]. The Belle Experiment recently obtained a new measurement of the  $B \rightarrow D \ell \nu$  differential decay rate [124] and determination of  $|V_{cb}| = 40.83(1.13) \times 10^{-3}$ . They find that the inclusion of experimental and theoretical nonzero-recoil information increases the value for  $|V_{cb}|$  compared to when only zero-recoil information is used, and leads to agreement with the inclusive result.

the error has been rescaled by the  $\sqrt{\chi^2/\text{dof}} = 2.6$  to account for the disagreement. Using this result we obtain

$$f_{B^+}^{\text{exp}} = 188(17)(18) \text{ MeV}, \quad (36)$$

where the uncertainties are from the errors on  $\Gamma$  and  $|V_{ub}|$ , respectively. This agrees within large uncertainties with the theoretical value  $f_{B^+} = 187.1(4.2) \text{ MeV}$  in Eq. (24) obtained from an average of recent three and four-flavor lattice-QCD results [69,86,88,89].

## ACKNOWLEDGEMENTS

We thank V. Cirigliano, C. Davies, A. El Khadra, A. Khodjamirian, J. Laiho, W. Marciano, M. Moulson, S. Narison, S. Sharpe, and Z.-G. Wang for useful discussions and references. We thank P. Boyle, M. Della Morte, D. Lin and S. Simula for providing information on the preliminary FLAG-3 lattice averages. We gratefully acknowledge support of the U. S. National Science Foundation and the U. S. Department of Energy through Grant No. DE-FG02-13ER41598. The work of J. L. R. was performed in part at the Aspen Center for Physics, which is supported by National Science Foundation grant PHY-1066293. Fermilab is operated by Fermi Research Alliance, LLC, under Contract No. DE-AC02-07CH11359 with the U.S. Department of Energy.

5.94 ± 0.66 ± 0.31	88	<sup>4</sup> PEDLAR	07A CLEO See ALEXANDER 09
6.8 ± 1.1 ± 1.8	553	<sup>5</sup> HEISTER	02i ALEP Z decays

- <sup>1</sup> ZUPANC 13 uses both  $\mu^+ \nu$  and  $\tau^+ \nu$  events to get  $f_{D_s} = (255.5 \pm 4.2 \pm 5.1)$  MeV.  
<sup>2</sup> DEL-AMO-SANCHEZ 10J uses  $\mu^+ \nu_\mu$  and  $\tau^+ \nu_\tau$  events together to get  $f_{D_s} = (258.6 \pm 6.4 \pm 7.5)$  MeV.  
<sup>3</sup> WIDHALM 08 gets  $f_{D_s} = (275 \pm 16 \pm 12)$  MeV from the branching fraction.  
<sup>4</sup> PEDLAR 07A also fits  $\mu^+$  and  $\tau^+$  events together and gets an effective  $\mu^+ \nu_\mu$  branching fraction of  $(6.38 \pm 0.59 \pm 0.33) \times 10^{-3}$   
<sup>5</sup> This HEISTER 02i result is not actually an independent measurement of the absolute  $\mu^+ \nu_\mu$  branching fraction, but is in fact based on our  $\phi \pi^+$  branching fraction of 3.6 ± 0.9%, so it cannot be included in our overall fit. HEISTER 02i combines its  $D_s^+ \rightarrow \tau^+ \nu_\tau$  and  $\mu^+ \nu_\mu$  branching fractions to get  $f_{D_s} = (285 \pm 19 \pm 40)$  MeV.

$\Gamma(\mu^+ \nu_\mu)/\Gamma(\phi \pi^+)$	$\Gamma_{20}/\Gamma_{34}$
See the note on "Decay Constants of Charged Pseudoscalar Mesons" above.

7.4 ± 2.8 ± 2.4	16	<sup>7</sup> ACCIARRI	97F L3 $D_s^{*+} \rightarrow \gamma D_s^+ \text{ from } Z^0$ 's

- <sup>1</sup> ZUPANC 13 uses both  $\mu^+ \nu$  and  $\tau^+ \nu$  events to get  $f_{D_s} = (255.5 \pm 4.2 \pm 5.1)$  MeV.  
<sup>2</sup> DEL-AMO-SANCHEZ 10J (with a small correction; see LEES 15d) uses  $\mu^+ \nu_\mu$  and  $\tau^+ \nu_\tau$  events together to get  $f_{D_s} = (259.9 \pm 6.6 \pm 7.6)$  MeV.  
<sup>3</sup> ALEXANDER 09, NAIK 09A, and ONYISI 09 use different  $\tau$  decay modes and are independent. The three papers combined give  $f_{D_s} = (259.7 \pm 7.8 \pm 3.4)$  MeV.  
<sup>4</sup> ECKLUND 08 and PEDLAR 07A are independent: ECKLUND 08 uses  $\tau^+ \rightarrow e^+ \nu_e \bar{\nu}_\tau$  events, PEDLAR 07A uses  $\tau^+ \rightarrow \pi^+ \bar{\nu}_\tau$  events.  
<sup>5</sup> HEISTER 02i combines its  $D_s^+ \rightarrow \tau^+ \nu_\tau$  and  $\mu^+ \nu_\mu$  branching fractions to get  $f_{D_s} = (285 \pm 19 \pm 40)$  MeV.  
<sup>6</sup> This ABBIENDI 01L value gives a decay constant  $f_{D_s}$  of  $(286 \pm 44 \pm 41)$  MeV.  
<sup>7</sup> The second ACCIARRI 97F error here combines in quadrature systematic (0.016) and normalization (0.018) errors. The branching fraction gives  $f_{D_s} = (309 \pm 58 \pm 33 \pm 38)$  MeV.

$\Gamma(\phi \pi^+)/\Gamma_{\text{total}}$   $\Gamma_{34}/\Gamma$   
The results here are model-independent. For earlier, model-dependent results, see our PDG 06 edition. We decouple the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the  $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$  branching fraction obtained from the Dalitz-plot analysis of  $D_s^+ \rightarrow K^+ K^- \pi^+$ . That is, the ratio of these two branching fractions is not exactly the  $\phi \rightarrow K^+ K^-$  branching fraction 0.491.

VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN	COMMENT
<b><math>4.5 \pm 0.4</math> OUR AVERAGE</b>				
$4.62 \pm 0.36 \pm 0.51$		<sup>1</sup> AUBERT	06N BABR	$e^+ e^-$ at $\Upsilon(4S)$
$4.81 \pm 0.52 \pm 0.38$	212 ± 19	<sup>2</sup> AUBERT	05v BABR	$e^+ e^- \approx \Upsilon(4S)$
$3.59 \pm 0.77 \pm 0.48$		<sup>3</sup> ARTUSO	96 CLE2	$e^+ e^-$ at $\Upsilon(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$3.9 \pm 5.1 \pm 1.8$		<sup>4</sup> BAI	95c BES	$e^+ e^-$ 4.03 GeV

<sup>1</sup>This AUBERT 06N measurement uses  $\bar{B}^0 \rightarrow D_s^{(*)-} D^{(*)+}$  and  $B^- \rightarrow D_s^{(*)-} D^{(*)0}$  decays, including some from other papers. However, the result is independent of AUBERT 05v.  
<sup>2</sup>AUBERT 05v uses the ratio of  $B^0 \rightarrow D^{*-} D_s^{*+}$  events seen in two different ways, in both of which the  $D^{*-} \rightarrow \bar{D}^0 \pi^-$  decay is fully reconstructed: (1) The  $D_s^{*+} \rightarrow D_s^+ \gamma$ ,  $D_s^+ \rightarrow \phi \pi^+$  decay is fully reconstructed. (2) The number of events in the  $D_s^+$  peak in the missing mass spectrum against the  $D^{*-} \gamma$  is measured.  
<sup>3</sup>ARTUSO 96 uses partially reconstructed  $\bar{B}^0 \rightarrow D^{*+} D_s^{*-}$  decays to get a model-independent value for  $\Gamma(D_s^- \rightarrow \phi \pi^-)/\Gamma(D^0 \rightarrow K^- \pi^+)$  of  $0.92 \pm 0.20 \pm 0.11$ .  
<sup>4</sup>BAI 95c uses  $e^+ e^- \rightarrow D_s^+ D_s^-$  events in which one or both of the  $D_s^\pm$  are observed to obtain the first model-independent measurement of the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction, without assumptions about  $\sigma(D_s^\pm)$ . However, with only two “doubly-tagged” events, the statistical error is very large.

$\Gamma(\phi \pi^+, \phi \rightarrow K^+ K^-)/\Gamma(K^+ K^- \pi^+)$   $\Gamma_{35}/\Gamma_{33}$   
This is the “fit fraction” from the Dalitz-plot analysis. We decouple the  $D^+ \rightarrow \phi \pi^+$  branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the  $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$  branching fraction obtained from the Dalitz-plot analysis of  $D_s^+ \rightarrow K^+ K^- \pi^+$ . That is, the ratio of these two branching fractions is not exactly the  $\phi \rightarrow K^+ K^-$  branching fraction 0.491.

## $D_s^+ - D_s^-$ CP-VIOLATING DECAY-RATE ASYMMETRIES

This is the difference between  $D_s^+$  and  $D_s^-$  partial widths for the decay to state  $f$ , divided by the sum of the widths:

$A_{CP}(f)=[\Gamma(D_s^+ \rightarrow f)-\Gamma(D_s^- \rightarrow \bar{f})]/[\Gamma(D_s^+ \rightarrow f)+\Gamma(D_s^- \rightarrow \bar{f})]$ .

$A_{CP}(\mu^\pm \nu)$ in $D_s^+ \rightarrow \mu^+ \nu, D_s^- \rightarrow \mu^- \bar{\nu}_\mu$

## CP VIOLATING ASYMMETRIES OF P-ODD (T-ODD) MOMENTS

 $A_{T\text{viol}}(K_S^0 K^\pm\pi^+\pi^-)$  in  $D_s^\pm \rightarrow K_S^0 K^\pm\pi^+\pi^-$ 

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a parity-odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta for the  $D_s^\pm$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $D_s^-$ . Then

$$A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)], \text{ and}$$

$$\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)], \text{ and}$$

$A_{T\text{viol}} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ .  $C_T$  and  $\bar{C}_T$  are commonly referred to as  $T$ -odd moments, because they are odd under  $T$  reversal. However, the  $T$ -conjugate process  $K_S^0 K^\pm\pi^+\pi^- \rightarrow D_s^\pm$  is not accessible, while the  $P$ -conjugate process is.

### $D_s^{*+}$ DECAY MODES

$D_s^{*-}$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1 \quad D_s^+ \gamma$	(93.5±0.7) %
$\Gamma_2 \quad D_s^+ \pi^0$	( 5.8±0.7) %
$\Gamma_3 \quad D_s^+ e^+ e^-$	( 6.7±1.6) × 10 <sup>−3</sup>

### CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 3 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 0.0$  for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_j \equiv \Gamma_j/\Gamma_{\rm total}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	−97	
$x_3$	−19	−4
	$x_1$	$x_2$

$\Gamma_6$ $D_s^+\pi^0$		
$\Gamma_7$ $D_s^+\pi^0\pi^0$		
$\Gamma_8$ $D_s^+\gamma\gamma$		

### CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 8 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 3.4$  for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	80		
$x_3$	68	62	
$x_5$	−3	25	26
	$x_1$	$x_2$	$x_3$

$D_{s2}^*(2573)$

$I(J^P) = 0(2^+)$

$J^P$  is natural, width and decay modes consistent with  $2^+$ .  
AAIJ 14BJ confirms  $J^P = 2^+$ .

**BOTTOM MESONS**

$$(B = \pm 1)$$

$$B^+ = u\bar{b}, B^0 = d\bar{b}, \bar{B}^0 = \bar{d}b, B^- = \bar{u}b, \text{ similarly for } B^{*'}s$$

***B*-particle organization**

Many measurements of *B* decays involve admixtures of *B* hadrons. Previously we arbitrarily included such admixtures in the  $B^\pm$  section, but because of their importance we have created two new sections: “ $B^\pm/B^0$  Admixture” for  $T(4S)$  results and “ $B^\pm/B^0/B_s^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and  $\chi_b$  at high energy are found in the Admixture sections.  $B^0\text{--}\bar{B}^0$  mixing data are found in the  $B^0$  section, while  $B_s^0\text{--}\bar{B}_s^0$  mixing data and  $B\text{--}\bar{B}$  mixing data for a  $B^0/B_s^0$  admixture are found in the  $B_s^0$  section. *CP*-violation data are found in the  $B^\pm$ ,  $B^0$ , and  $B^\pm/B^0$  Admixture sections. *b*-baryons are found near the end of the Baryon section. Recently, we also created a new section: “ $V_{cb}$  and  $V_{ub}$  CKM Matrix Elements.”

The organization of the *B* sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

**PRODUCTION AND DECAY OF *b*-FLAVORED HADRONS**

Updated May 2016 by P. Eerola (U. of Helsinki, Helsinki, Finland), M. Kreps (U. of Warwick, Coventry, UK) and Y. Kwon (Yonsei U., Seoul, Korea).

The *b* quark belongs to the third generation of quarks and is the weak-doublet partner of the *t* quark. The existence of the third-generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix (“CKM” matrix), and confirmed four years later by the first observation of a  $b\bar{b}$  meson [2]. In the KM model, *CP* violation is explained within the Standard Model (SM) by an irreducible phase of the  $3 \times 3$  unitary matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the SM, including the fermion masses, and the elements of the CKM matrix.

Since the *b* quark is the lighter element of the third-generation quark doublet, the decays of *b*-flavored hadrons occur via generation-changing processes through this matrix. Because of this, and the fact that the CKM matrix is close to a  $3 \times 3$  unit matrix, many interesting features such as loop and box diagrams, flavor oscillations, as well as large *CP* asymmetries, can be observed in the weak decays of *b*-flavored hadrons.

The CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of *CP* violation in *B* meson decays. A crucial milestone was the first observation of *CP* violation in the *B* meson system in 2001, by the BaBar [3] and Belle [4] collaborations. They measured a large value for the parameter  $\sin 2\beta$  ( $= \sin 2\phi_1$ ) [5], almost four decades after the discovery of a small *CP* asymmetry in neutral kaons. A more detailed discussion of the CKM matrix and *CP* violation can be found elsewhere in this *Review* [6,7].

Recent developments in the physics of *b*-hadrons include the significant improvement in experimental determination of the CKM angle  $\gamma$ , the increased information on  $B_s$ ,  $B_c$  and  $\Lambda_b$  decays, the precise determination of  $\Lambda_b$  lifetime, the wealth of information in the  $B^0 \rightarrow K^{*0}(892)\ell^+\ell^-$  decays and after many years of search, the observation of  $B_s \rightarrow \mu^+\mu^-$  decays along with ever increasing precision on the CKM matrix parameters.

## *b*-flavored hadrons

The structure of this mini-review is organized as follows. After a brief description of theory and terminology, we discuss *b*-quark production and current results on spectroscopy and lifetimes of *b*-flavored hadrons. We then discuss some basic properties of *B*-meson decays, followed by summaries of hadronic, rare, and electroweak penguin decays of *B*-mesons. There are separate mini-reviews for  $B\bar{B}$  mixing [8] and the extraction of the CKM matrix elements  $V_{cb}$  and  $V_{ub}$  from *B*-meson decays [9] in this *Review*.

**Theory and terminology:** The ground states of *b*-flavored hadrons decay via weak interactions. In most hadrons, the *b*-quark is accompanied by light-partner quarks (*d*, *u*, or *s*), and the decay modes are well described by the decay of the *b* quark (spectator model) [10]. The dominant decay mode of a *b* quark is  $b \rightarrow cW^{*-}$  (referred to as a “tree” or “spectator” decay), where the virtual *W* materializes either into a pair of leptons  $\ell\bar{\nu}$  (“semileptonic decay”), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from  $W^*$  to form one of the final state hadrons are suppressed by a factor  $\sim (1/3)^2$ , because the colors of the two quarks from different sources must match (“color-suppression”).

Many aspects of *B* decays can be understood through the Heavy Quark Effective Theory (HQET) [11]. This has been particularly successful for semileptonic decays. For further discussion of HQET, see for instance Ref. 12. For hadronic decays, one typically uses effective Hamiltonian calculations that rely on a perturbative expansion with Wilson coefficients. In addition, some form of the factorization hypothesis is commonly used, where, in analogy with semileptonic decays, two-body hadronic decays of *B* mesons are expressed as the product of two independent hadronic currents, one describing the formation of a charm meson (in case of the dominant  $b \rightarrow cW^{*-}$  decays), and the other the hadronization of the remaining  $\bar{u}d$  (or  $\bar{c}s$ ) system from the virtual  $W^-$ . Qualitatively, for a *B* decay with a large energy release, the  $\bar{u}d$  pair (produced as a color singlet) travels fast enough to leave the interaction region without influencing the charm meson. This is known to work well for the dominant spectator decays [13]. There are several common implementations of these ideas for hadronic *B* decays, the most common of which are QCD factorization (QCDF) [14], perturbative QCD (pQCD) [15], and soft collinear effective theory (SCET) [16].

The transition  $b \rightarrow u$  is suppressed by  $|V_{ub}/V_{cb}|^2 \sim (0.1)^2$  relative to  $b \rightarrow c$  transitions. The transition  $b \rightarrow s$  is a flavor-changing neutral-current (FCNC) process, and although not allowed in the SM as a tree-process, can occur via more complex loop diagrams (denoted “penguin” decays). The rates for such processes are comparable or larger than CKM-suppressed  $b \rightarrow u$  processes. Penguin processes involving  $b \rightarrow d$  transitions are also possible, and have been observed [17,18]. Other decay processes discussed in this *Review* include *W*-exchange (a *W* is exchanged between initial-state quarks), penguin annihilation (the gluon from a penguin loop attaches to the spectator quark,

similar to an exchange diagram), and pure-annihilation (the initial quarks annihilate to a virtual *W*, which then decays).

**Production and spectroscopy:** The bound states of a  $\bar{b}$  antiquark and a *u*, *d*, *s*, or *c* quark are referred to as the  $B_u$  ( $B^+$ ),  $B_d$  ( $B^0$ ),  $B_s$ , and  $B_c$  mesons, respectively. The  $B_c$  is the heaviest of the ground-state *b*-flavored mesons, and the most difficult to produce: it was observed for the first time in the semileptonic mode by CDF in 1998 [19], but its mass was accurately determined only in 2006, from the fully reconstructed mode  $B_c^+ \rightarrow J/\psi\pi^+$  [20]. One of the best determination up to date uses  $B_c^+ \rightarrow J/\psi D_s^+$  decay and yields  $m(B_c^+) = 6276.28 \pm 1.44 \pm 0.36$  MeV/ $c^2$  [21]. As this decay has very low energy release, it allows to decrease systematic uncertainty and thus offers prospects for future increase in precision.

The first excited meson is called the  $B^*$  meson, while  $B^{**}$  is the generic name for the four orbitally excited ( $L = 1$ ) *B*-meson states that correspond to the *P*-wave mesons in the charm system,  $D^{**}$ . Excited states of the  $B_s$  meson are similarly named  $B_s^*$  and  $B_s^{**}$ . Of the possible bound  $\bar{b}b$  states, the  $\Upsilon$  series (S-wave) and the  $\chi_b$  (P-wave) are well studied. The pseudoscalar ground state  $\eta_b$  also has been observed by BaBar [22] (and confirmed by CLEO [23]), indirectly through the decay  $\Upsilon(3S) \rightarrow \gamma\eta_b$ . See Ref. 24 for classification and naming of these and other states.

Experimental studies of *b* decays have been performed in  $e^+e^-$  collisions at the  $\Upsilon(4S)$  (ARGUS, CLEO, Belle, BaBar) and  $\Upsilon(5S)$  (CLEO, Belle) resonances, as well as at higher energies, at the *Z* resonance (SLC, LEP), in  $p\bar{p}$  (Tevatron) and  $pp$  collisions (LHC). The  $e^+e^- \rightarrow \bar{b}b$  production cross-section at the *Z*,  $\Upsilon(4S)$ , and  $\Upsilon(5S)$  resonances are about 6.6 nb, 1.1 nb, and 0.3 nb respectively. High-energy hadron collisions produce *b*-flavored hadrons of all species with much larger cross-sections:  $\sigma(p\bar{p} \rightarrow bX, |\eta| < 1) \sim 30$   $\mu\text{b}$  at the Tevatron ( $\sqrt{s} = 1.96$  TeV), and even higher at the energies of the LHC  $pp$  collider (at  $\sqrt{s} = 7$  TeV, at the LHCb experiment with pseudorapidity acceptance  $2 < \eta < 5$  visible *b*-hadron cross section is  $\sim 100$   $\mu\text{b}$ ).

BaBar and Belle have accumulated respectively 560 fb $^{-1}$  and 1020 fb $^{-1}$  of data, of which 433 fb $^{-1}$  and 710 fb $^{-1}$  respectively are at the  $\Upsilon(4S)$  resonance; CDF and D0 have accumulated by the end of their running about 10 fb $^{-1}$  each. At the LHC, CMS and ATLAS have collected 5 fb $^{-1}$  (20 fb $^{-1}$ ) of data at  $\sqrt{s} = 7$  (8) TeV respectively and LHCb has collected about 1 fb $^{-1}$  and 2 fb $^{-1}$  at the two energies. Further data was collected at  $\sqrt{13}$  TeV, but amount is limited at the moment. These numbers indicate that the majority of *b*-quarks have been produced in hadron collisions, but the large backgrounds cause the hadron collider experiments to have lower selection efficiency. While traditionally only the few decay modes for which triggering and reconstruction are easiest have been studied in hadron collisions, with current experiments at hadron colliders much more is possible. This is due to triggers based

on the tracking first introduced in CDF and further improved by LHCb. LHCb experiment has also reasonable capability for detection of neutral pions and photons. While both  $e^+e^-$  and hadron colliders have their own strengths and weaknesses, in the domain of decays which involve neutrinos,  $e^+e^-$  experiments are in significant advantage.

In hadron collisions, most production happens as  $b\bar{b}$  pairs, either via  $s$ -channel production or gluon-splitting, with a smaller fraction of single  $b$ -quarks produced by flavor excitation. The total  $b$ -production cross section is an interesting test of our understanding of QCD processes. For many years, experimental measurements have been several times higher than predictions. With improved measurements [25], more accurate input parameters, and more advanced calculations [26], the discrepancy between theory and data diminished and there is now good agreement between measurements and predictions.

Each quark of a  $b\bar{b}$  pair produced in hadron collisions hadronizes separately and incoherently from the other, but it is still possible, although difficult, to obtain a statistical indication of the charge of a produced  $b/\bar{b}$  quark (“flavor tag” or “charge tag”) from the accompanying particles produced in the hadronization process, or from the decay products of the other quark. The momentum spectrum of produced  $b$ -quarks typically peaks near the  $b$ -quark mass, and extends to much higher momenta, dropping by about a decade for every ten GeV. This implies typical decay lengths of the order of a millimeter; the resolution for the decay vertex must be more precise than this to resolve the fast oscillations of  $B_s$  mesons.

In  $e^+e^-$  colliders, since the  $B$  mesons are very slow in the  $\Upsilon(4S)$  rest frame, asymmetric beam energies are used to boost the decay products to improve the precision of time-dependent measurements that are crucial for the study of  $CP$  violation. At KEKB, the boost is  $\beta\gamma = 0.43$ , and the typical  $B$ -meson decay length is dilated from  $\approx 20 \mu\text{m}$  to  $\approx 200 \mu\text{m}$ . PEP-II used a slightly larger boost,  $\beta\gamma = 0.55$ . The two  $B$  mesons produced in  $\Upsilon(4S)$  decay are in a coherent quantum state, which makes it easier than in hadron collisions to infer the charge state of one  $B$  meson from observation of the other; however, the coherence also requires determination of the decay time of both mesons, rather than just one, in order to perform time-dependent  $CP$ -violation measurements. For  $B_s$ , which can be produced at  $\Upsilon(5S)$  the situation is less favourable, as boost is not high enough to provide sufficient time resolution to resolve the fast  $B_s$  oscillations.

For the measurement of branching fractions, the initial composition of the data sample must be known. The  $\Upsilon(4S)$  resonance decays predominantly to  $B^0\bar{B}^0$  and  $B^+B^-$ ; the current experimental upper limit for non- $B\bar{B}$  decays of the  $\Upsilon(4S)$  is less than 4% at the 95% confidence level (CL) [27]. The only known modes of this category are decays to lower  $\Upsilon$  states and a pion pair, observed with branching fractions of order  $10^{-4}$  [28]. The ratio  $f_+/f_0$  of the fractions of charged to neutral  $B$  productions from  $\Upsilon(4S)$  decays has been measured by CLEO, BaBar, and Belle in various ways. They typically

use pairs of isospin-related decays of  $B^+$  and  $B^0$ , such that it can be assumed that  $\Gamma(B^+ \rightarrow x^+) = \Gamma(B^0 \rightarrow x^0)$ . In this way, the ratio of the number of events observed in these modes is proportional to  $(f_+\tau_+)/ (f_0\tau_0)$  [29,30]. BaBar has also performed an independent measurement of  $f_0$  with a different method that does not require isospin symmetry or the value of the lifetime ratio, based on the number of events with one or two reconstructed  $B^0 \rightarrow D^{*-}\ell^+\nu$  decays [31]. The combined result, from the current average of  $\tau_+/\tau_0$ , is  $f_+/f_0 = 1.059 \pm 0.027$  [32]. Though the current  $2.4\sigma$  discrepancy with equal production of  $B^+B^-$  and  $B^0\bar{B}^0$  pairs is somewhat larger than previous averages, we still assume  $f_+/f_0 = 1$  in this mini-review except where explicitly stated otherwise. This assumption is also supported by the near equality of the  $B^+$  and  $B^0$  masses: our fit of CLEO, ARGUS, CDF, and LHCb measurements yields  $m(B^0) = 5279.61 \pm 0.16 \text{ MeV}/c^2$ ,  $m(B^+) = 5279.29 \pm 0.15 \text{ MeV}/c^2$ , and  $m(B^0) - m(B^+) = 0.32 \pm 0.06 \text{ MeV}/c^2$ .

CLEO and Belle have also collected some data at the  $\Upsilon(5S)$  resonance [33,34]. Belle has accumulated more than  $120 \text{ fb}^{-1}$  at this resonance. This resonance does not provide the simple final states like the  $\Upsilon(4S)$ : there are seven possible final states with a pair of non-strange  $B$  mesons and three with a pair of strange  $B$  mesons ( $B_s^*\bar{B}_s^*$ ,  $B_s^*\bar{B}_s$ , and  $B_s\bar{B}_s^*$ ). The fraction of events with a pair of  $B_s$  mesons over the total number of events with a pair of  $b$ -flavored hadrons has been measured to be  $f_s[\Upsilon(5S)] = 0.200^{+0.030}_{-0.031}$ , of which 90% is  $B_s^*\bar{B}_s^*$  events. A few branching fractions of the  $B_s$  have been measured in this way; if the precision of  $f_s$  were improved, they would become the most accurate. Belle has observed a few new  $B_s$  modes that are difficult to reconstruct in hadron colliders and the most precise mass measurement of the  $B_s^*$  meson has been obtained [34]. However, the small boost of  $B_s$  mesons produced in this way prevents resolution of their fast oscillations for time-dependent measurements; these are only accessible in hadron collisions or at the  $Z$  peak.

In high-energy collisions, the produced  $b$  or  $\bar{b}$  quarks can hadronize with different probabilities into the full spectrum of  $b$ -hadrons, either in their ground or excited states. Table 1 shows the measured fractions  $f_d$ ,  $f_u$ ,  $f_s$ , and  $f_{\text{baryon}}$  of  $B^0$ ,  $B^+$ ,  $B_s^0$ , and  $b$  baryons, respectively, in an unbiased sample of weakly decaying  $b$  hadrons produced at the  $Z$  resonance or in  $p\bar{p}$  collisions [32]. The results were obtained from a fit where the sum of the fractions were constrained to equal 1.0, neglecting production of  $B_c$  mesons. The observed yields of  $B_c$  mesons at the Tevatron [19] yields  $f_c = 0.2\%$ , in agreement with expectations [35], and well below the current experimental uncertainties in the other fractions.

For rather long time, the average of fractions in  $p\bar{p}$  collisions and in  $Z$  decay was used as it was assumed that the hadronization is identical in the two environments. It was clear that this assumption does not have to hold in principle, because of the different momentum distributions of the  $b$ -quark in these processes; the sample used in the  $p\bar{p}$  measurements has momenta close to the  $b$  mass, rather than  $m_Z/2$ . But

# Meson Particle Listings

## $b$ -flavored hadrons

**Table 1:** Fragmentation fractions of  $b$  quarks into weakly-decaying  $b$ -hadron species in  $Z \rightarrow b\bar{b}$  decay, in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.

$b$ hadron	Fraction at $Z$ [%]	Fraction at $p\bar{p}$ [%]
$B^+, B^0$	$40.7 \pm 0.7$	$34.4 \pm 2.1$
$B_s$	$10.0 \pm 0.8$	$11.5 \pm 1.3$
$b$ baryons	$8.5 \pm 1.1$	$19.7 \pm 4.6$

in the absence of any significant evidence there was also no strong reason against the average. Some discrepancies were observed, but as picture was also obscured by  $1.8\sigma$  discrepancy in the average time-integrated mixing probability parameter  $\bar{\chi} = f_d\chi_d + f_s\chi_s$  between LEP and Tevatron [8], they were not directly attributed to breakdown of the assumption that hadronization is identical. The first indication that fraction for  $b$ -baryons depends on the momentum and thus environment came from CDF [36], but available precision did not allow for firm conclusion. The final evidence for non-universality of hadronization fractions came from LHCb, where strong dependence on the transverse momentum was observed for the  $\Lambda_b$  fraction [37].

Excited  $B$ -meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the  $B^*-B$  mass difference is  $45.78 \pm 0.35$  MeV/ $c^2$ . Evidence for  $B^{**}$  ( $L=1$ ) production has been initially obtained at LEP [38], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Detailed results from exclusive modes have been obtained at the Tevatron, allowing separation of the narrow states  $B_1$  and  $B_2^*$  and also a measurement of the  $B_2^*$  width [39].

Also the narrow  $B_s^{**}$  states, first sighted by OPAL as a single broad enhancement in the  $B^+K$  mass spectrum [40], have now been clearly observed and separately measured at the hadron colliders [41,42]. The measured masses are  $m(B_{s1}) = 5828.7 \pm 0.4$  MeV/ $c^2$  and  $m(B_{s2}^*) = 5839.96 \pm 0.2$  MeV/ $c^2$ .

Baryon states containing a  $b$  quark are labeled according to the same scheme used for non- $b$  baryons, with the addition of a  $b$  subscript [24]. For many years, the only well-established  $b$  baryon was the  $\Lambda_b^0$  (quark composition  $udb$ ), with only indirect evidence for  $\Xi_b$  ( $dsb$ ) production from LEP [43]. This situation has changed dramatically in the past few years due to the large samples being accumulated at the Tevatron and LHCb. Clear signals of four strongly-decaying baryon states,  $\Sigma_b^+, \Sigma_b^{*+}$  ( $uub$ ),  $\Sigma_b^-, \Sigma_b^{*-}$  ( $ddb$ ) have been obtained by CDF in  $\Lambda_b^0\pi^\pm$  final states [44]. The strange bottom baryon  $\Xi_b^\pm$  was observed in the exclusive mode  $\Xi_b^\pm \rightarrow J/\psi\Xi^\pm$  by D0 [45], and CDF [46]. More recently CDF has also observed the  $\Xi_b$  in the  $\Xi_c\pi$  final state [47]. The relative production of  $\Xi_b$  and  $\Lambda_b$  baryons has been found to be consistent with the  $B_s$  to  $B_d$  production ratio [45]. Observation of the doubly-strange bottom baryon  $\Omega_b^-$  has been published by both D0 [48] and CDF [49]. However the masses

measured by the two experiments show a large discrepancy. The resolution is provided by LHCb which measures the  $\Omega_b^-$  mass consistent with CDF [50]. The CMS experiment added to the list also neutral spin-3/2  $\Xi_b^*$  [51]. The masses of all these new baryons have been measured to a precision of a few MeV/ $c^2$ , and found to be in agreement with predictions from HQET.

While many exotic states were seen in the charm sector, in bottom sector there are fewer seen and none in the direct production. In the recent analysis D0 Collaboration claimed narrow state  $X(5568)$  decaying into  $B_s^0\pi^\pm$  final state [52]. While this would be interesting addition to the observed states as first exotic state with open heavy flavour quantum numbers, preliminary analysis from LHCb yields negative result [53]. While two experiments have different initial state, it would be unusual if  $X(5568)$  can be effectively produced in high energy  $p\bar{p}$  collisions but not in  $pp$  collisions.

**Lifetimes:** Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in  $CP$  violation, such as the determination of  $V_{cb}$  and  $B_s\bar{B}_s$  mixing parameters. In the naive spectator model, the heavy quark can decay only via the external spectator mechanism, and thus, the lifetimes of all mesons and baryons containing  $b$  quarks would be equal. Non-spectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for  $b$ -flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as  $1/m_Q^2$ , where  $m_Q$  is the mass of the heavy quark, the variations in the  $b$  system are expected to be only 10% or less [54]. We expect:

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s) > \tau(\Lambda_b^0) \gg \tau(B_c^+) . \quad (1)$$

For the  $B_c^+$ , both quarks decay weakly, so the lifetime is much shorter.

Measurements of the lifetimes of the different  $b$ -flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the  $b$  sector. Over the past decade, the precision of silicon vertex detectors and the increasing availability of fully-reconstructed samples has resulted in much-reduced statistical and systematic uncertainties ( $\sim 1\%$ ). The averaging of precision results from different experiments is a complex task that requires careful treatment of correlated systematic uncertainties; the world averages given in Table 2 have been determined by the Heavy Flavor Averaging Group (HFAG) [32].

The short  $B_c^+$  lifetime is in good agreement with predictions [55]. With large samples of  $B_c^+$  mesons at the LHCb precision on the lifetimes should significantly improve. The measurement using semileptonic decays gives  $\tau_{B_c^+} = 0.509 \pm 0.008 \pm 0.012$  ps [56] while using decays  $B_c^+ \rightarrow J/\psi\pi^+$  yields  $\tau_{B_c^+} = 0.5134 \pm 0.0110 \pm 0.0057$  ps [57]. Each of these is more precise

**Table 2:** Summary of inclusive and exclusive world-average  $b$ -hadron lifetime measurements. For the two  $B_s$  averages, see text below.

Particle	Lifetime [ps]
$B^+$	$1.638 \pm 0.004$
$B^0$	$1.520 \pm 0.004$
$B_s$ (flavor-specific)	$1.511 \pm 0.014$
$B_s$ ( $1/\Gamma_s$ )	$1.510 \pm 0.005$
$B_c^+$	$0.507 \pm 0.009$
$\Lambda_b^0$	$1.466 \pm 0.010$
$\Xi_b^-$	$1.560 \pm 0.040$
$\Xi_b^0$	$1.464 \pm 0.031$
$\Omega_b^-$	$1.57^{+0.23}_{-0.20}$

than the combination of all previous experiments. For precision comparisons with theory, lifetime ratios are more sensitive. Experimentally we find:

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.076 \pm 0.004, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 0.994 \pm 0.004,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.965 \pm 0.007,$$

while theory makes the following predictions [54,58]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 1.00 \pm 0.01, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.88 \pm 0.05.$$

The ratio of  $B^+$  to  $B^0$  lifetimes has a precision of better than 1%, and is significantly different from 1.0, in agreement with predictions [54]. The ratio of  $B_s$  to  $B^0$  lifetimes is expected to be very close to 1.0. While early measurements were in mild tension with theory, the high precision measurements using fully reconstructed decays and clear definition of lifetime (see below) are in good agreement with theory [59,60,61]. The  $\Lambda_b$  lifetime has a history of discrepancies. Predictions were higher than data before the introduction of higher-order effects lowered them. The first indication that early measurements of the  $\Lambda_b$  are on low side came from the CDF data [62,63]. The recent measurements from LHC experiments [64,65,66,67] significantly improve precision and favour higher lifetime, much closer to the lifetime of  $B^0$  meson. The most precise measurement of the  $\Lambda_b$  lifetime performed by LHCb uses  $\Lambda_b \rightarrow J/\psi p K^-$  decays and finds  $\tau_{\Lambda_b} = 1.479 \pm 0.009 \pm 0.010$  ps [66]. With new results, the discrepancy between theory and experiment on the  $\Lambda_b$  lifetime can be considered resolved.

Neutral  $B$  mesons are two-component systems similar to neutral kaons, with a light (L) and a heavy (H) mass eigenstate, and independent decay widths  $\Gamma_L$  and  $\Gamma_H$ . The SM predicts a non-zero width difference  $\Delta\Gamma = \Gamma_L - \Gamma_H > 0$  for both  $B_s$  and  $B_d$ . For  $B_d$ ,  $\Delta\Gamma_d/\Gamma_d$  is expected to be  $\sim 0.2\%$ . Analysis of BaBar and DELPHI data on  $CP$ -specific modes of the  $B^0$  yield a combined result:  $\Delta\Gamma_d/\Gamma_d = 0.015 \pm 0.018$  [32]. Recently LHCb determined value of  $\Delta\Gamma_d/\Gamma_d = -0.044 \pm 0.025 \pm 0.011$  [67], which is based on the comparison of lifetimes in the  $B^0 \rightarrow J/\psi K^{*0}(892)$  and  $B^0 \rightarrow J/\psi K_S$  decays. Average including all measurements yields  $\Delta\Gamma_d/\Gamma_d = -0.003 \pm 0.015$ . The

issue is much more interesting for the  $B_s$ , since the SM expectation for  $\Delta\Gamma_s/\Gamma_s$  is of order 10%. This potentially non-negligible difference requires care when defining the  $B_s$  lifetime. As indicated in Table 2, two different lifetimes are defined for the  $B_s$  meson: one is defined as  $1/\Gamma_s$ , where  $\Gamma_s$  is the average width of the two mass eigenstates  $(\Gamma_L + \Gamma_H)/2$ ; the other is obtained from “flavor-specific” (*e.g.*, semileptonic) decays and depends both on  $\Gamma_s$  and  $\Delta\Gamma_s$ . Experimentally, the quantity  $\Delta\Gamma_s$  can be accessed by measuring lifetimes in decays into  $CP$  eigenstates, which in the SM are expected to be close approximations to the mass eigenstates. This has been done with the  $J/\psi\phi$  mode, where the two  $CP$  eigenstates are distinguished by angular distributions, and in  $B_s \rightarrow K^+K^-$  or  $B_s \rightarrow J/\psi f_0(980)$  which are  $CP$ -eigenstates. The current experimental information is dominated by measurements on the  $J/\psi\phi$  mode performed by CDF, D0, ATLAS and LHCb experiments. By appropriately combining all published measurements of  $J/\psi\phi$  lifetimes, flavor-specific lifetimes and effective lifetimes in  $CP$  eigenstates, the HFAG group obtains a world-average  $\Delta\Gamma_s/\Gamma_s = 0.124 \pm 0.011$  [32]; the latest theoretical predictions yield  $\Delta\Gamma_s/\Gamma_s = 0.133 \pm 0.032$  [68], in agreement with measurements within the uncertainties. The constraint from measurements of lifetimes in  $CP$  eigenstates is based on the notion of effective lifetime introduced in Ref. [69]. In this class, measurements in decays  $B_s \rightarrow J/\psi f_0(980)$  [70],  $B_s \rightarrow K^+K^-$  [71] decays are used currently. From the theoretical point of view, the best quantity to use is  $\Delta\Gamma_s/\Delta M_s$ , which is much less affected by hadronic uncertainties [68]. Exploiting the accurate measurement of  $\Delta M_s$  available [72], this can be turned into a SM prediction with an uncertainty of only 20%:  $\Delta\Gamma_s/\Gamma_s = 0.137 \pm 0.027$ . This is likely to be of importance in future comparisons, as the experimental precision improves with the growth of LHC samples. Historically, branching fraction of the decay  $B_s \rightarrow D_s^{(*)+} D_s^{(*)-}$  was used to set an bound on  $\Delta\Gamma_s/\Gamma_s$ , but the method is highly model-dependent and with increased precision of direct determinations it stops to be useful.

The width difference  $\Delta\Gamma_s$  is connected to the  $B_s$  mixing phase  $\phi_s$  by  $\Delta\Gamma_s = \Gamma_{12} \cos \phi_s$ , where  $\Gamma_{12}$  is the off-diagonal element of the decay matrix [6,8,68]. The early measurements by CDF [73] and D0 [74] have produced CL contours in the  $(\phi_s, \Delta\Gamma_s)$  plane, and both observed a mild deviation, in the same direction, from the expectation of the SM of the phase  $\phi_s$  near  $\Delta\Gamma_s = 0$ . The possibility of a large value of  $\phi_s$  has attracted significant interest, as it would be very clean evidence for the existence of new sources of  $CP$  violation beyond the SM. However the latest measurements from CDF [59], D0 [75], ATLAS [76], CMS [77] and LHCb [78], which provide significant improvements over initial measurements, show good agreement with the SM. While most experiments use up to now only  $B_s \rightarrow J/\psi\phi$  decay, LHCb also exploits  $B_s \rightarrow J/\psi\pi^+\pi^-$  decays, which are experimentally determined to be pure  $CP$ -odd and therefore in  $B_s \rightarrow J/\psi\pi^+\pi^-$  decays no angular analysis is needed. It should be noted that in pure  $B_s \rightarrow J/\psi\phi$  decay, there is a two-fold ambiguity in the sign of  $\Delta\Gamma_s$  and  $\phi_s$ . This can be

# Meson Particle Listings

## *b*-flavored hadrons

resolved using the interference between the decays to  $J/\psi\phi$  and  $J/\psi K^+K^-$ , where  $K^+K^-$  is in relative S-wave state. This has been used by LHCb experiment to determine the sign of  $\Delta\Gamma_s$  to be positive [79] in accordance with SM. The world average value of the  $CP$  violating phase is  $\phi_s = -0.013 \pm 0.037$  [32] without any tension with the SM.

***B* meson decay properties:** Semileptonic  $B$  decays  $B \rightarrow X_c \ell \nu$  and  $B \rightarrow X_u \ell \nu$  provide an excellent way to measure the magnitude of the CKM elements  $|V_{cb}|$  and  $|V_{ub}|$  respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive and inclusive decays can be used with dominant uncertainties being complementary. For exclusive decay analysis, knowledge of the form factors for the exclusive hadronic system  $X_{c(u)}$  is required. For inclusive analysis, it is usually necessary to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator-product expansion scheme, thus making theoretical calculations unreliable. One of the recent unexpected results was determination of  $|V_{ub}|$  using  $\Lambda_b^0 \rightarrow p\mu^-\bar{\nu}_\mu$  decays by LHCb [80]. A more detailed discussion of  $B$  semileptonic decays and the extraction of  $|V_{cb}|$  and  $|V_{ub}|$  is given elsewhere in this *Review* [9].

On the other hand, hadronic decays of  $B$  are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects. Pure-penguin decays were first established by the observation of  $B \rightarrow K^*\gamma$  [81]. Some observed decay modes such as  $B^0 \rightarrow D_s^- K^+$ , may be interpreted as evidence of a  $W$ -exchange process [82]. The evidence for the decay  $B^+ \rightarrow \tau^+\nu$  from Belle [83] and BaBar [84] is the first sign of a pure annihilation decay. There is growing evidence that penguin annihilation processes may be important in decays with two vector mesons in the final state [85].

***Hadronic decays:*** Most of the hadronic  $B$  decays involve  $b \rightarrow c$  transition at the quark level, resulting in a charmed hadron or charmonium in the final state. Other types of hadronic decays are very rare and will be discussed separately in the next section. The experimental results on hadronic  $B$  decays have steadily improved over the past few years, and the measurements have reached sufficient precision to challenge our understanding of the dynamics of these decays. With the good neutral particle detection and hadron identification capabilities of  $B$ -factory detectors, a substantial fraction of hadronic  $B$  decay events can be fully reconstructed. Because of the kinematic constraint of  $\Upsilon(4S)$ , the energy sum of the final-state particles of a  $B$  meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables,  $\Delta E$  (energy difference) and  $M_B$  ( $B$  candidate mass

with a beam-energy constraint) are very effective for suppressing combinatorial background both from  $\Upsilon(4S)$  and  $e^+e^- \rightarrow q\bar{q}$  continuum events. In particular, the energy-constraint in  $M_B$  improves the signal resolution by almost an order of magnitude.

The kinematically clean environment of  $B$  meson decays provides an excellent opportunity to search for new states. For instance, quark-level  $b \rightarrow c\bar{c}s$  decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BaBar discovered a new narrow charm-strange state  $D_{sJ}^*(2317)$  [86], and CLEO observed a similar state  $D_{sJ}(2460)$  [87]. The properties of these new states were studied in the  $B$  meson decays,  $B \rightarrow DD_{sJ}^*(2317)$  and  $B \rightarrow DD_{sJ}(2460)$  by Belle [88]. Further studies of  $D_{sJ}^{(*)}$  meson production in  $B$  decays have been made by Belle [89] and BaBar [90]. Now these charm-strange meson states are identified as  $D_{s0}^*(2317)$  and  $D_{s1}(2460)$ , respectively.

More recently, Belle observed a new  $D_{sJ}$  meson produced in  $B^+ \rightarrow \bar{D}^0 D_{sJ} \rightarrow \bar{D}^0 D^0 K^+$  [91]. Combined with a subsequent measurement by BaBar [92], the mass and width of this state are determined to be  $2709^{+9}_{-6}$  MeV/ $c^2$  and  $125 \pm 30$  MeV, respectively. An analysis of the helicity angle distribution determines its spin-parity to be  $1^-$ .

A variety of exotic particles have been discovered in  $B$  decays. Belle found the  $X(3872)$  state [93], which is confirmed by CDF [94] and BaBar [95]. Analyzing their full  $\Upsilon(4S)$  data sample, Belle finds a new upper limit on the width of  $X(3872)$  to be  $\Gamma_{X(3872)} < 1.2$  MeV [96], improving on the existing limit by nearly a factor of 2. Radiative decays of  $X(3872)$  can play a crucial role in understanding the nature of the particle. For example, in the molecular model the decay of  $X(3872)$  to  $\psi'\gamma$  is expected to be highly suppressed in comparison to the decay to  $J/\psi\gamma$  [97]. BaBar has seen the evidence for the decay to  $J/\psi\gamma$  [98]. The ratio  $R \equiv \mathcal{B}(X(3872) \rightarrow \psi'\gamma)/\mathcal{B}(X(3872) \rightarrow J/\psi\gamma)$  is measured to be  $3.4 \pm 1.4$  by BaBar [99], while Belle obtains  $R < 2.1$  at 90% CL [100].

Belle has observed a near-threshold enhancement in the  $J/\psi\omega$  invariant mass for  $B \rightarrow J/\psi\omega K$  decays [101]. BaBar has studied  $B \rightarrow J/\psi\pi^+\pi^-K$ , finding an excess of  $J/\psi\pi^+\pi^-$  events with a mass just above 4.2 GeV/ $c^2$ ; this is consistent with the  $Y(4260)$  that was observed by BaBar in ISR (Initial State Radiation) events [102]. A Belle study of  $B \rightarrow \psi'K\pi^\pm$  [103] finds a state called  $X(4430)^\pm$  that decays to  $\psi'\pi^\pm$ . This state was searched for by BaBar with similar sensitivity but was not found [104]. The high statistics study by LHCb experiment confirmed existence of the  $X(4430)^\pm$  in decays  $B \rightarrow \psi'K\pi^\pm$  [105]. Moreover the LHCb experiment demonstrated  $X(4430)^\pm$  resonances character by study of the phase motion and saw evidence for another state. Since it is charged, it could not be a charmonium state. In a Dalitz plot analysis of  $\bar{B}^0 \rightarrow \chi_{c1} K^- \pi^+$ , Belle has observed two resonance-like structures in the  $\chi_{c1}\pi^+$  mass distribution [106], labelled as  $X(4050)^\pm$  and  $X(4250)^\pm$  in this *Review*, while no evidence is found by BaBar in a search with similar sensitivity [107]. Another charge state was seen by Belle in the decay

$B^0 \rightarrow J/\psi K^- \pi^+$  [108]. In the amplitude analysis of the decay  $\Lambda_b^0 \rightarrow J/\psi p K^-$  LHCb experiment also demonstrated that charged states in charmonium region are produced also with non-zero baryon number by observing state decaying to  $J/\psi p$  final state [109].

The hadronic decays  $\bar{B}^0 \rightarrow D^{(*)0} h^0$ , where  $h^0$  stands for light neutral mesons such as  $\pi^0, \eta^{(\prime)}, \rho^0, \omega$ , proceed through color-suppressed diagrams, hence they provide useful tests on the factorization models. Both Belle and BaBar have made comprehensive measurements of such color-suppressed hadronic decays of  $\bar{B}^0$  [110].

Information on  $B_s$  and  $\Lambda_b$  decays is limited, though improving with recent studies of large samples at the Tevatron and LHC experiments. Recent additions are decays of  $B_s \rightarrow J/\psi f_0(980)$  [70,111],  $B_s \rightarrow J/\psi f_2'(1525)$  [112], and  $\Lambda_b \rightarrow \Lambda_c \pi^+ \pi^- \pi^-$  [113]. For the latter, not only the total rate is measured, but also structure involving decays through excited  $\Lambda_c$  and  $\Sigma_c$  baryons.

There have been hundreds of publications on hadronic  $B$  decays to open-charm and charmonium final states mostly from the  $B$ -factory experiments. These results are nicely summarized in a recent report by HFAG [32].

**Rare  $B$  decays:** All  $B$ -meson decays that do not occur through the  $b \rightarrow c$  transition are usually called rare  $B$  decays. These include both semileptonic and hadronic  $b \rightarrow u$  decays that are suppressed at leading order by the small CKM matrix element  $V_{ub}$ , as well as higher-order  $b \rightarrow s(d)$  processes such as electroweak and gluonic penguin decays.

Charmless  $B$  meson decays into two-body hadronic final states such as  $B \rightarrow \pi\pi$  and  $K\pi$  are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct  $CP$  violations. Since the final state particles in these decays tend to have larger momenta than average  $B$  decay products, the event environment is cleaner than for  $b \rightarrow c$  decays. Branching fractions are typically around  $10^{-5}$ . Over the past decade, many such modes have been observed by BaBar, Belle, and CLEO. More recently, comparable samples of the modes with all charged final particles have been reconstructed in  $p\bar{p}$  collisions by CDF and  $pp$  collisions by LHCb by triggering on the impact parameter of the charged tracks. This has also allowed observation of charmless decays of the  $B_s$ , in final states such as  $\phi\phi$  [114],  $K^+ K^-$  [115], and  $K^- \pi^+$  [116], and of charmless decays of the  $\Lambda_b^0$  baryon [116]. Charmless  $B_s$  modes are related to corresponding  $B^0$  modes by U-spin symmetry, and are determined by similar amplitudes. Combining the observables from  $B_s$  and  $B^0$  modes is a further way of eliminating hadronic uncertainties and extracting relevant CKM information [117].

Because of relatively high-momenta for final state particles, the dominant source of background in  $e^+e^-$  collisions is  $q\bar{q}$  continuum events; sophisticated background suppression techniques exploiting event shape variables are essential for these analyses. In hadron collisions, the dominant background comes

from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematic and isolation requirements. The results are in general consistent among the experiments.

BaBar [118] and Belle [119] have observed the decays  $B^+ \rightarrow \bar{K}^0 K^+$  and  $B^0 \rightarrow K^0 \bar{K}^0$ . The world-average branching fractions are  $\mathcal{B}(B^0 \rightarrow K^0 \bar{K}^0) = (0.96^{+0.20}_{-0.18}) \times 10^{-6}$  and  $\mathcal{B}(B^+ \rightarrow \bar{K}^0 K^+) = (1.36 \pm 0.27) \times 10^{-6}$ . These are the first observations of hadronic  $b \rightarrow d$  transitions, with significance  $> 5\sigma$  for all four measurements.  $CP$  asymmetries have even been measured for these modes, though with large errors.

Most rare decay modes including  $B^0 \rightarrow K^+ \pi^-$  have contributions from both  $b \rightarrow u$  tree and  $b \rightarrow sg$  penguin processes. If the size of the two contributions are comparable, the interference between them may result in direct  $CP$  violation, seen experimentally as a charge asymmetry in the decay rate measurement. BaBar [120], Belle [121], and CDF [115] have measured the direct  $CP$  violating asymmetry in  $B^0 \rightarrow K^+ \pi^-$  decays. The BaBar and Belle measurements constitute observation of direct  $CP$  violation with a significance of more than  $5\sigma$ . The world average for this quantity is now rather precise,  $-0.098 \pm 0.013$ . There are sum rules [122] that relate the decay rates and decay-rate asymmetries between the four  $K\pi$  charge states. The experimental measurements of the other three modes are not yet precise enough to test these sum rules.

There is now evidence for direct  $CP$  violation in three other decays:  $B^+ \rightarrow \rho^0 K^+$  [123],  $B^+ \rightarrow \eta K^+$  [124], and  $B^0 \rightarrow \eta K^{*0}$  [125]. The significance is typically  $3\text{--}4\sigma$ , though the significance for the  $B^+ \rightarrow \eta K^+$  decay is now nearly  $5\sigma$  with the recent Belle measurement [124]. In at least the first two cases, a large direct  $CP$  violation might be expected since the penguin amplitude is suppressed so the tree and penguin amplitudes may have comparable magnitudes.

The decay  $B^0 \rightarrow \pi^+ \pi^-$  can be used to extract the CKM angle  $\alpha$ . This is complicated by the presence of significant contributions from penguin diagrams. An isospin analysis [126] can be used to untangle the penguin complications. The decay  $B^0 \rightarrow \pi^0 \pi^0$ , which is now measured by both BaBar and Belle [127], is crucial in this analysis. Unfortunately the amount of penguin pollution in the  $B \rightarrow \pi\pi$  system is rather large. In the past few years, measurements in the  $B^0 \rightarrow \rho\rho$  system have produced more precise values of  $\alpha$ , since penguin amplitudes are generally smaller for decays with vector mesons. An important ingredient in the analysis is the  $B^0 \rightarrow \rho^0 \rho^0$  branching fraction. The average of measurements from BaBar and Belle [128] yields a branching fraction of  $(0.73 \pm 0.28) \times 10^{-6}$ . This is only 3% of the  $\rho^+ \rho^-$  branching fraction, much smaller than the corresponding ratio ( $\sim 10\%$ ) in the  $\pi\pi$  system.

The decay  $B \rightarrow a_1 \pi$  has been seen by BaBar. An analysis of the time evolution of this decay [129] together with measurements of other related decays has been used to measure the CKM angle  $\alpha$  [130] in agreement with the more precise measurements from the  $\rho\rho$  system.

# Meson Particle Listings

## *b*-flavored hadrons

Since  $B \rightarrow \rho\rho$  has two vector mesons in the final state, the  $CP$  eigenvalue of the final state depends on the longitudinal polarization fraction  $f_L$  for the decay. Therefore, a measurement of  $f_L$  is needed to extract the CKM angle  $\alpha$ . Both BaBar and Belle have measured  $f_L$  for the decays  $\rho^+\rho^-$  [131] and  $\rho^+\rho^0$  [132] and in both cases the measurements show  $f_L > 0.9$ , making a complete angular analysis unnecessary.

By analyzing the angular distributions of the  $B$  decays to two vector mesons, we can learn a lot about both weak- and strong-interaction dynamics in  $B$  decays. Decays that are penguin-dominated surprisingly have values of  $f_L$  near 0.5. The list of such decays has now grown to include  $B \rightarrow \phi K^*$ ,  $B \rightarrow \rho K^*$ , and  $B \rightarrow \omega K^*$ . The reasons for this "polarization puzzle" are not fully understood. A detailed description of the angular analysis of  $B$  decays to two vector mesons can be found in a separate mini-review [133] in this *Review*.

There has been substantial progress in measurements of many other rare- $B$  decays. The decay  $B \rightarrow \eta' K$  stood out as the largest rare- $B$  decay for many years. The reasons for the large rate are now largely understood [14,134]. However, there are now measurements of several 3-body or quasi-3-body modes with similarly large branching fractions. States seen so far include  $K\pi\pi$  (three charge states) [135],  $KKK$  (four charge states) [136], and  $K^*\pi\pi$  (two charged states) [137]. Many of these analyses now include Dalitz plot treatments with many intermediate resonances. There has also been an observation of the decay  $B^+ \rightarrow K^+ K^- \pi^+$  by BaBar [138], noteworthy because an even number of kaons is typically indicative of suppressed  $b \rightarrow d$  transitions as discussed above.

Belle [83] and BaBar [84] have found evidence for  $B^+ \rightarrow \tau^+ \nu$ ; the average branching fraction is  $(1.14 \pm 0.27) \times 10^{-4}$ . This is somewhat larger than, though consistent with, the value expected in the SM. This is the first observation of a pure annihilation decay. A substantial region of parameter space of charged Higgs mass vs.  $\tan\beta$  is excluded by the measurements of this mode.

**Electroweak penguin decays:** More than 20 years have passed since the CLEO experiment first observed an exclusive radiative  $b \rightarrow s\gamma$  transition,  $B \rightarrow K^*(892)\gamma$  [81], thus providing the first evidence for the one-loop FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BaBar have updated this analysis [139] with an average branching fraction  $\mathcal{B}(B^0 \rightarrow K^{*0}\gamma) = (43.3 \pm 1.5) \times 10^{-6}$ , and have added several new decay modes such as  $B \rightarrow K_1\gamma$ ,  $K_2^*(1430)\gamma$ , *etc.* [140]. With a sample of 24 fb $^{-1}$  at  $\Upsilon(5S)$ , Belle observed the radiative penguin decay of  $B_s \rightarrow \phi\gamma$  [141]. The decay  $B_s \rightarrow \phi\gamma$  was also seen at LHCb with higher statistics [142]. The two measurements give average branching fraction of  $(36 \pm 4) \times 10^{-6}$ .

Compared to  $b \rightarrow s\gamma$ , the  $b \rightarrow d\gamma$  transitions such as  $B \rightarrow \rho\gamma$ , are suppressed by the small CKM element  $V_{td}$ . Both Belle and BaBar have observed these decays [17,18]. The world average  $\mathcal{B}(B \rightarrow (\rho, \omega)\gamma) = (1.30 \pm 0.23) \times 10^{-6}$ . This can be

used to calculate  $|V_{td}/V_{ts}|$  [143]; the measured values are  $0.233^{+0.033}_{-0.032}$  from BaBar [18] and  $0.195^{+0.025}_{-0.024}$  from Belle [17].

The observed radiative penguin branching fractions can constrain a large class of SM extensions [144]. However, due to the uncertainties in the hadronization, only the inclusive  $b \rightarrow s\gamma$  rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in  $B$  decay. By combining the measurements of  $B \rightarrow X_s\gamma$  from CLEO, BaBar, and Belle experiments [145,146,147], HFAG obtains the new average:  $\mathcal{B}(B \rightarrow X_s\gamma) = (3.43 \pm 0.21 \pm 0.07) \times 10^{-4}$  [32] for  $E_\gamma \geq 1.6$  GeV, which averages over  $B^+$  and  $B^0$ . Consistent but less precise results have been reported by ALEPH for inclusive  $b$ -hadrons produced at the  $Z$ , which includes also small fraction of  $B_s$  and  $\Lambda_b$  hadrons. The measured branching fraction can be compared to theoretical calculations. Recent calculations of  $\mathcal{B}(b \rightarrow s\gamma)$  at NNLO level predict the values of  $(3.15 \pm 0.23) \times 10^{-4}$  [148] and  $(2.98 \pm 0.26) \times 10^{-4}$  [149], where the latter is calculated requiring  $E_\gamma \geq 1.6$  GeV.

The  $CP$  asymmetry in  $b \rightarrow s\gamma$  is extensively studied theoretically both in the SM and beyond [150]. According to the SM, the  $CP$  asymmetry in  $b \rightarrow s\gamma$  is smaller than 1%, but some non-SM models allow significantly larger  $CP$  asymmetry ( $\sim 10\%$ ) without altering the inclusive branching fraction. The current world average is  $A_{CP} = -0.008 \pm 0.029$ , again dominated by BaBar and Belle [151,146]. In addition to the  $CP$  asymmetry, BaBar also measured the isospin asymmetry  $\Delta_{0-} = -0.01 \pm 0.06$  in  $b \rightarrow s\gamma$  measured using sum of exclusive decays [152]. Alternative measurement using full reconstruction of the companion  $B$  in the hadronic decay modes yields consistent, but less precise result [153].

In addition, all three experiments have measured the inclusive photon energy spectrum for  $b \rightarrow s\gamma$ , and by analyzing the shape of the spectrum they obtain the first and second moments for photon energies. Belle has measured these moments covering the widest range in the photon energy ( $1.7 < E_\gamma < 2.8$  GeV) [147]. The measurement by BaBar has slightly smaller range with lower limit at 1.8 GeV [154]. These results can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element  $V_{ub}$ .

Additional information on FCNC processes can be obtained from  $b \rightarrow s\ell^+\ell^-$  decays, which are mediated by electroweak penguin and  $W$ -box diagrams. Measurements at Belle and BaBar suffered from low statistics and therefore they typically provide average between charged and neutral  $B$  mesons as well as between  $e^+e^-$  and  $\mu^+\mu^-$  final states [155,156]. The total branching fraction measured at B-factories for  $B \rightarrow K\ell^+\ell^-$  is  $(0.45 \pm 0.04) \times 10^{-6}$  and for  $B \rightarrow K^*(892)\ell^+\ell^-$  is  $(1.05 \pm 0.10) \times 10^{-6}$ . Measurements at B-factories were complemented by CDF [157], which used only muons in the final state. While precision at CDF was similar to B-factories, it had access also to  $B_s \rightarrow \phi\mu^+\mu^-$  and  $\Lambda_b \rightarrow \Lambda\mu^+\mu^-$  decays, which were observed for the first time [157,158] and confirmed by LHCb [159,160,161].  $B$ -factory experiments also measured

the branching fractions for inclusive  $B \rightarrow X_s \ell^+ \ell^-$  decays [162], with an average of  $(3.66^{+0.76}_{-0.77}) \times 10^{-6}$  [163]. In  $b \rightarrow s \ell^+ \ell^-$  decays, the angular analysis provides several interesting observables, which can be studied as function of dilepton invariant mass squared,  $q^2$ . While first measurements were done by Belle, Babar and CDF, real advance of these measurements came with LHC experiments, where samples available are significantly larger than before. The best known of angular observables is forward-backward asymmetry, which was measured in  $B \rightarrow K^*(892) \ell^+ \ell^-$  by several experiments having access to the decay [155,164,165,166,167,168] with most precise measurement coming from LHCb [169]. Measurements of the  $CP$  asymmetries [156,170,171], the isospin asymmetry [155,156,172] and several other angular observables [167,173] are possible in this class of decays. While most of the measurements agree with the SM, the differential branching fractions, isospin asymmetry in  $B \rightarrow K \mu^+ \mu^-$  and the other angular observable  $P'_5$  [174] measured by the LHCb exhibit small tension with the SM expectation. Although initially the angular analyses were mainly concentrating on the decay  $B \rightarrow K^*(892) \ell^+ \ell^-$ , with large-statistics samples available at LHC, angular analyses of the  $B \rightarrow K \mu^+ \mu^-$  [175],  $B_s \rightarrow \phi \mu^+ \mu^-$  [159] and  $\Lambda_b^0 \rightarrow \Lambda \mu^+ \mu^-$  [161] decays were also performed, with the results being consistent with the SM.

With the data samples available at LHC, lepton universality in  $b \rightarrow s \ell^+ \ell^-$  can be tested. While in the standard model decays to electron-positron and muon pairs are expected to be same up to small corrections due to different masses of leptons, in extensions of the SM this does not have to hold. With this aim the angular analysis of  $B^0 \rightarrow K^{*0} e^+ e^-$  decays was performed by LHCb at low dilepton invariant masses [176]. Most notable result on lepton universality test is the ratio of branching fractions between  $B^+ \rightarrow K^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ e^+ e^-$  at LHCb, which shows  $2.6\sigma$  discrepancy with the SM [177].

Finally the decays  $B_{(s)}^0 \rightarrow e^+ e^-$  and  $\mu^+ \mu^-$  are interesting since they only proceed at second order in weak interactions in the SM, but may have large contributions from supersymmetric loops, proportional to  $(\tan \beta)^6$ . First limits were published 30 years ago and since then experiments at Tevatron,  $B$ -factories and LHC gradually improved those and effectively excluded whole models of new physics and significantly constrained allowed parameter space of others. For the decays to  $\mu^+ \mu^-$ , Tevatron experiments pushed the limits down to roughly factor of 5-10 above the SM expectation [178,179]. The long journey in the search for these decays culminated in 2012, when first evidence for  $B_s \rightarrow \mu^+ \mu^-$  decay was seen [180]. Currently LHCb [181] and CMS [182] observe this decay with significance between 4 and 5 standard deviations. The measured branching fraction is  $(2.9^{+1.1}_{-1.0}) \times 10^{-9}$  at LHCb and  $(3.0^{+1.0}_{-0.9}) \times 10^{-9}$  at CMS, both in agreement with the SM expectation. The combination of the data from CMS and LHCb yields branching fraction  $(2.8^{+0.7}_{-0.6}) \times 10^{-9}$  for  $B_s \rightarrow \mu^+ \mu^-$  decay [183]. The statistical significance of the combined signal is  $6.2\sigma$ . For the  $B^0 \rightarrow \mu^+ \mu^-$  decay, combined analysis of CMS and LHCb

data gives branching fraction  $(3.9^{+1.6}_{-1.4}) \times 10^{-10}$  and statistical significance of  $3.2\sigma$ . The measured branching fraction for  $B_s$  is compatible at  $1.2\sigma$  with the SM. For the  $B^0$ , the measurement is about  $2.2\sigma$  above the SM prediction. Recently ATLAS [184] reported a study of  $B^0 \rightarrow \mu^+ \mu^-$  and  $B_s^0 \rightarrow \mu^+ \mu^-$  decays. For  $B^0$  an upper limit on  $B(B^0 \rightarrow \mu^+ \mu^-) < 4.2 \times 10^{-10}$  is set at 95% C.L. For  $B_s^0$  the result is  $B(B_s^0 \rightarrow \mu^+ \mu^-) = (0.9^{+1.1}_{-0.8}) \times 10^{-9}$ . An upper limit  $B(B_s^0 \rightarrow \mu^+ \mu^-) < 3.0 \times 10^{-9}$  at 95% CL, lower than the SM prediction, and in agreement with the measurement of CMS and LHCb. The limits for the  $e^+ e^-$  modes are:  $< 2.8 \times 10^{-7}$  and  $< 8.3 \times 10^{-8}$ , respectively, for  $B_s$  and  $B^0$  [185]. The searches were also performed for lepton flavour violating decays to two leptons with best limits in  $e^\pm \mu^\mp$  channel, where limits are  $< 3.7 \times 10^{-9}$  for  $B^0$  and  $< 1.4 \times 10^{-8}$  for  $B_s$ , at 95% confidence level [186].

**Summary and Outlook:** The study of  $B$  mesons continues to be one of the most productive fields in particle physics. With the two asymmetric  $B$ -factory experiments Belle and BaBar, we now have a combined data sample of well over  $1 \text{ ab}^{-1}$ .  $CP$  violation has been firmly established in many decays of  $B$  mesons. Evidence for direct  $CP$  violation has been observed. Many rare decays resulting from hadronic  $b \rightarrow u$  transitions and  $b \rightarrow s(d)$  penguin decays have been observed, and the emerging pattern is still full of surprises. Despite the remarkable successes of the  $B$ -factory experiments, many fundamental questions in the flavor sector remain unanswered.

At Fermilab, CDF and D0 each has accumulated about  $10 \text{ fb}^{-1}$ , which is the equivalent of about  $10^{12}$   $b$ -hadrons produced. In spite of the low trigger efficiency of hadronic experiments, a selection of modes have been reconstructed in large quantities, giving a start to a program of studies on  $B_s$  and  $b$ -flavored baryons, in which a first major step has been the determination of the  $B_s$  oscillation frequency.

As Tevatron and  $B$ -factories stop their taking data, the new experiments at the LHC have become very active. The LHC accelerator performed very well in 2011 and 2012. The general purpose experiments ATLAS and CMS collected about  $25 \text{ fb}^{-1}$  while LHCb collected about  $3 \text{ fb}^{-1}$ . After two years of consolidation, the LHC restarted in 2015 and experiments expect to double their  $b$ -hadrons samples during 2016. LHCb, which is almost fully dedicated to the studies of  $b$ - and  $c$ -hadrons, has a data sample that is for many decays larger than the sum of all previous experiments. Of particular note is that after many years of search for the decay  $B_s \rightarrow \mu^+ \mu^-$  the LHCb and CMS experiments finally observed this decay in the combined analysis of their data [183].

In addition, the preparation of the next generation high-luminosity  $B$ -factory at KEK is in its final stages with first physics data taking expected in 2017. The aim to increase sample to  $\sim 50 \text{ ab}^{-1}$  will make it possible to explore the indirect evidence of new physics beyond the SM in the heavy-flavor particles ( $b$ ,  $c$ , and  $\tau$ ), in a way that is complementary to the LHC. In the same time, LHCb Collaboration is working

# Meson Particle Listings

## *b*-flavored hadrons

on the upgrade of its detector, which should be installed in 2018 and 2019. Aim of the upgrade is to increase flexibility of trigger, which will allow to significantly increase instantaneous luminosity and possibly integrate about  $50 \text{ fb}^{-1}$  of data.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and *CP*-violating phenomena.

- A NOTE ON HFAG ACTIVITIES**
- Revised September 2015 by T. Gershon (University of Warwick) and A.J. Schwartz (University of Cincinnati)
- The Heavy Flavor Averaging Group (HFAG) is an international collaboration of physicists from experiments measuring properties of heavy flavored particles. HFAG calculates for the HEP community world average values of quantities such as lifetimes, branching fractions, form factors, mixing parameters, and *CP*-violating asymmetries. Most parameters concern decays of *B* and *D* mesons and  $\tau$  leptons, and many are related to elements of the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix [1,2].
- HFAG was originally formed in 2002 to continue the activities of the LEP Heavy Flavor Steering group. Since its inception a wide range of results have become available from increasingly larger data sets, and consequently HFAG has expanded to include seven subgroups. These are as follows:
- *b*-hadron lifetimes and oscillations, including parameters of *CP* violation in *b* mixing;
  - decay-time-dependent *CP* violation in *B* decays, and angles of the CKM Unitarity Triangle;
  - semileptonic decays of *b*-hadrons ( $B \rightarrow X\ell\nu$ ,  $\ell = e, \mu, \tau$ ), including determinations of the CKM matrix elements  $|V_{cb}|$  and  $|V_{ub}|$ ;
  - *b*-hadron decays to hadronic final states containing *c*-quarks (open charm and charmonium);
  - (rarer) *b*-hadron decays to final states not containing *c*-quarks, including fully hadronic, semileptonic ( $B \rightarrow X\ell\ell, X\nu\bar{\nu}$ ), leptonic, and radiative decays;

# Meson Particle Listings

## $b$ -flavored hadrons, $B^\pm$

- $c$ -hadron physics including branching fractions,  $CP$ - and  $T$ -violating asymmetries,  $D^0$ - $\bar{D}^0$  mixing, semi-leptonic decays, and properties of excited  $D$  states;
- $\tau$ -lepton physics including lepton universality tests, determination of the CKM matrix element  $|V_{us}|$ , and searches for lepton flavor violation.

Each subgroup has one or two conveners and typically a half-dozen members representing experiments currently or recently making measurements in that area. Most groups contain representatives from the Belle, BaBar, and LHCb experiments, while some groups contain representatives or contacts from the BESIII, CLEO(c), CDF and DØ experiments. Members of HFAG are appointed by their respective experimental collaborations. There are two co-leaders of HFAG; these were originally appointed by the managements of the BaBar and Belle collaborations and are now appointed by the managements of Belle/Belle II and LHCb.

The averaging procedures used by HFAG are similar to those of the PDG [3], but there are some differences. When calculating world averages, common input parameters used in the different analyses are adjusted (rescaled) to common values. Close communication between representatives of the experiments and HFAG members performing averaging calculations help ensure that measurement uncertainties, known correlations, and systematic effects are properly accounted for. The confidence level of the fit is provided to indicate the consistency of the measurements included in the average. In the case of obtaining a world average with a small confidence level, *i.e.*, a large  $\chi^2$  per degree of freedom, HFAG does not usually scale the resulting uncertainty as the PDG does. Rather, the systematic uncertainties of each input measurement are reviewed with experts from the experiments to better understand the discrepancy. Unless inconsistencies between the measurements are found, no correction is made to the calculated uncertainty. If special treatment is necessary to calculate an average, or in case an approximation used in an average calculation might not be sufficiently accurate (*e.g.*, assuming Gaussian errors when the likelihood function indicates non-Gaussian behavior), a note is included to describe this treatment.

In general, HFAG uses all publicly available results that have written documentation such as a journal publication, preprint or conference note. These include preliminary results presented at conferences or workshops. However, preliminary results that remain unpublished for an extended period of time, or for which no publication is planned, are not included. A special subset of HFAG world averages are included in the PDG Listings. For these averages, the standard fitting procedures are performed but only input measurements that are published or accepted for publication are used. The averages provided by HFAG are listed by the PDG as “OUR EVALUATION” with a corresponding note.

All HFAG world averages and listings of all input measurements are documented in an approximately biennial preprint

posted to the arXiv preprint server; the most recent version is Ref. 4. The latest results and plots are posted on an extensive set of webpages that are updated several times per year; these are available at

<http://www.slac.stanford.edu/xorg/hfag>.

$B^\pm$

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the  $B^\pm/B^0$  ADMIXTURE and  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

### $B^\pm$ MASS

The fit uses  $m_{B^\pm}$ ,  $(m_{B^0} - m_{B^\pm})$ , and  $m_{B^0}$  to determine  $m_{B^\pm}$ ,  $m_{B^0}$ , and the mass difference.

<sup>1</sup> Uses  $B^+ \rightarrow J/\psi K^+$  fully reconstructed decays.

<sup>2</sup> Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+\mu^-$  decays.

<sup>3</sup> CSORNA 00 uses fully reconstructed 526  $B^+ \rightarrow J/\psi(\Upsilon) K^+$  events and invariant masses without beam constraint.

<sup>4</sup> ALBRECHT 90J assumes 10580 for  $\Upsilon(4S)$  mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.

<sup>5</sup> Found using fully reconstructed decays with  $J/\psi(1S)$ . ALBRECHT 87D assume  $m_{\Upsilon(4S)} = 10577$  MeV.

### $B^\pm$ MEAN LIFE

See  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on  $B$ -hadron mean life averaged over species of bottom particles.

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

<sup>1</sup> Measured mean life using fully reconstructed decays ( $J/\psi K^{(*)}$ ).

<sup>2</sup> Measured using  $B^- \rightarrow D^0 \pi^-$  with  $D^0 \rightarrow K^- \pi^+$  events that were selected using a silicon vertex trigger.

<sup>3</sup> Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.

<sup>4</sup> Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.

<sup>5</sup> Measured mean life using fully reconstructed decays.

<sup>6</sup> Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.

<sup>7</sup> Data analyzed using  $D/D^* \ell X$  event vertices.

<sup>8</sup> Data analyzed using charge of secondary vertex.

<sup>9</sup> ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$ .

<sup>10</sup> Data analyzed using vertex-charge technique to tag  $B$  charge.

<sup>11</sup> Combined result of  $D/D^* \ell X$  analysis and fully reconstructed  $B$  analysis.

<sup>12</sup> Combined ABREU 95Q and ADAM 95 result.

### $\tau_{B^+}/\tau_{B^-}$

VALUE	DOCUMENT ID	TECN	COMMENT

<sup>1</sup> Measured using  $B^\pm \rightarrow J/\psi K^\pm$  decays.

### $B^+$ DECAY MODES

$B^-$  modes are charge conjugates of the modes below. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0 \bar{B}^0$  and 50%  $B^+ B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D, D_s, D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

- [a] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.  
 [b] An  $CP(\pm 1)$  indicates the  $CP=+1$  and  $CP=-1$  eigenstates of the  $D^0$ - $\bar{D}^0$  system.  
 [c]  $D$  denotes  $D^0$  or  $\bar{D}^0$ .  
 [d]  $D_{CP+}^{*0}$  decays into  $D^0 \pi^0$  with the  $D^0$  reconstructed in  $CP$ -even eigenstates  $K^+ K^-$  and  $\pi^+ \pi^-$ .  
 [e]  $\bar{D}^{**}$  represents an excited state with mass  $2.2 < M < 2.8$  GeV/ $c^2$ .  
 [f]  $X(3872)^+$  is a hypothetical charged partner of the  $X(3872)$ .  
 [g]  $\Theta(1710)^{++}$  is a possible narrow pentaquark state and  $G(2220)$  is a possible glueball resonance.  
 [h]  $(\bar{\Lambda}_c^- p)_s$  denotes a low-mass enhancement near 3.35 GeV/ $c^2$ .

## CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 3.7$  for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

10.1 ± 1.8 ± 1.5	ATHANAS	94	CLE2 Sup. by ARTUSO 97

<sup>1</sup> URQUIJO 07 report a measurement of  $(10.34 \pm 0.23 \pm 0.25)\%$  for the partial branching fraction of  $B^+ \rightarrow e^+ \nu_e X_C$  decay with electron energy above 0.6 GeV. We converted the result to  $B^+ \rightarrow e^+ \nu_e X$  branching fraction.

<sup>2</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semi-leptonic decay to electrons with momentum above 0.6 GeV/ $c$  in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .

<sup>3</sup> ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^* \ell \nu_\ell$  and inclusive semileptonic branching ratio from BARISH 96b ( $0.1049 \pm 0.0017 \pm 0.0043$ ).

<sup>4</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semi-leptonic decay to electrons with momentum above 0.6 GeV/ $c$  in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

$\Gamma(e^+ \nu_e X_C) / \Gamma_{\text{total}}$   $\Gamma_2 / \Gamma$

## Meson Particle Listings

 $B^\pm$ 

- <sup>1</sup> Measured using the dependence of  $B^- \rightarrow D^{*0} e^- \bar{\nu}_e$  decay differential rate and the form factor description by CAPRINI 98.
- <sup>2</sup> Simultaneous measurements of both  $B^0 \rightarrow D^*(2010)^- \ell \nu$  and  $B^+ \rightarrow \bar{D}(2007)^0 \ell \nu$ .
- <sup>3</sup> ALBRECHT 92C reports  $0.058 \pm 0.014 \pm 0.013$ . We rescale using the method described in STONE 94 but with the updated PDG 94  $B(D^0 \rightarrow K^- \pi^+)$ . Assumes equal production of  $B^0 \bar{B}^0$  and  $B^+ B^-$  at the  $\Upsilon(4S)$ .
- <sup>4</sup> Uses a fully reconstructed  $B$  meson as a tag on the recoil side.
- <sup>5</sup> The results are based on the same analysis and data sample reported in ADAM 03.
- <sup>6</sup> BARISH 95 use  $B(D^0 \rightarrow K^- \pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$  and  $B(D^{*0} \rightarrow D^0 \pi^0) = (63.6 \pm 2.3 \pm 3.3)\%$ .
- <sup>7</sup> Combining  $\bar{D}^{*0} \ell^+ \nu_\ell$  and  $\bar{D}^{*-} \ell^+ \nu_\ell$  SANGHERA 93 test  $V-A$  structure and fit the decay angular distributions to obtain  $A_{FB} = 3/4 * (\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$ . Assuming a value of  $V_{cb}$ , they measure  $V, A_1$ , and  $A_2$ , the three form factors for the  $D^* \ell \nu_\ell$  decay, where results are slightly dependent on model assumptions.
- <sup>8</sup> Assumes equal production of  $B^0 \bar{B}^0$  and  $B^+ B^-$  at the  $\Upsilon(4S)$ . Uncorrected for  $D$  and  $D^*$  branching ratio assumptions.
- <sup>9</sup> ANTREASYAN 90B is average over  $B$  and  $\bar{D}^*(2010)$  charge states.

1.14 ± 0.16 ± 0.08	<sup>2</sup>	AUBERT	09Q	BABR Repl. by LEES 13A
<2.1	90	<sup>7</sup> BEAN	93B	CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
<sup>1</sup> LEES 13A reports $(1.21 \pm 0.14 \pm 0.08) \times 10^{-4}$ from a measurement of $[\Gamma(B^+ \rightarrow \omega\ell^+\nu_\ell)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow \pi^+\pi^-\pi^0)]$ assuming $B(\omega(782) \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7) \times 10^{-2}$ .				
<sup>2</sup> Uses $B(\Upsilon(4S) \rightarrow B^+B^-) = (51.6 \pm 0.6)\%$ and $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = (48.4 \pm 0.6)\%$ .				
<sup>3</sup> Uses semileptonic tagging. Assumes $B(\omega \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7)\%$ and that the production ratio of $B^+B^-$ to $B^0\bar{B}^0$ from $\Upsilon(4S)$ is $1.056 \pm 0.028$ . The partial branching fractions in three bins of $q^2$ are also reported.				
<sup>4</sup> The signal events are tagged by a second $B$ meson reconstructed in the fully hadronic decays.				
<sup>5</sup> Uses loose neutrino reconstruction technique.				
<sup>6</sup> Assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ .				
<sup>7</sup> BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0\ell^+\nu_\ell)$ and $\Gamma(\rho^-\ell^+\nu_\ell)$ with this result, they obtain a limit $<(1.6\text{--}2.7) \times 10^{-4}$ at 90% CL for $B^+ \rightarrow \omega\ell^+\nu_\ell$ . The range corresponds to the ISGW, WSB, and KS models.				
An upper limit on $ V_{ub}/V_{cb}  < 0.8\text{--}0.13$ at 90% CL is derived as well.

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

<sup>1</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^{(*)0} \ell^- \bar{\nu}_\ell$  in the recoil.

<sup>2</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>3</sup> The authors combine their result with that from HARA 10 obtaining  $B(B^- \rightarrow \tau^- \bar{\nu}_\tau) = (0.96 \pm 0.26) \times 10^{-4}$  and deriving  $f_B |V_{ub}| = (7.4 \pm 0.8 \pm 0.5) \times 10^{-4}$  GeV.

<sup>4</sup> Requires a fully reconstructed hadronic  $B$ -decay in the recoil. Reports that this result combined with AUBERT 10E value gives  $B(B^- \rightarrow \tau^- \bar{\nu}_\tau) = (1.79 \pm 0.48) \times 10^{-4}$ .

<sup>5</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^0 \ell^- \bar{\nu}_\ell X$  in the recoil.

<sup>6</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^{(*)0} \ell^- \bar{\nu}_\ell X$  in the recoil.

<sup>7</sup> The analysis is based on a sample of events with one fully reconstructed tag  $B$  in a hadronic decay mode  $B^- \rightarrow D^{(*)0} X^-$ .

<sup>8</sup> The energy-flow and  $b$ -tagging algorithms were used.

<sup>9</sup> ACCIARRI 97F uses missing-energy technique and  $f(b \rightarrow B^-) = (38.2 \pm 2.5)\%$ .

<sup>10</sup> ALBRECHT 95D uses full reconstruction of one  $B$  decay as tag.

<sup>11</sup> BUSKULIC 95 uses same missing-energy technique as in  $\bar{B} \rightarrow \tau^+ \nu_\tau X$ , but analysis is restricted to endpoint region of missing-energy distribution.

$1.9 \pm 1.0 \pm 0.6$	7	<sup>9</sup> ALBRECHT	88k	ARG $e^+ e^- \rightarrow \Upsilon(4S)$
<sup>1</sup> Assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ .				
<sup>2</sup> ABULENCIA 06j reports $[\Gamma(B^+ \rightarrow \overline{D}^0 \pi^+)/\Gamma_{\text{total}}] / [B(B^0 \rightarrow D^- \pi^+)] = 1.97 \pm 0.10 \pm 0.21$ which we multiply by our best value $B(B^0 \rightarrow D^- \pi^+) = (2.52 \pm 0.13) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.				
<sup>3</sup> Uses a missing-mass method. Does not depend on $D$ branching fractions or $B^+ / B^0$ production rates.				
<sup>4</sup> AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of $B^0$ and $B^+$ , which is not included here.				
<sup>5</sup> Assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ and uses the MarkIII branching fractions for the $D$ .				
<sup>6</sup> BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.				
<sup>7</sup> AUBERT,B 04P reports $[\Gamma(B^+ \rightarrow \overline{D}^0 \pi^+)/\Gamma_{\text{total}}] \times [B(D^0 \rightarrow K^- \pi^+)] = (1.846 \pm 0.032 \pm 0.097) \times 10^{-4}$ which we divide by our best value $B(D^0 \rightarrow K^- \pi^+) = (3.93 \pm 0.04) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.				
<sup>8</sup> ALAM 94 assume equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ and use the CLEOII absolute $B(D^0 \rightarrow K^- \pi^+)$ and the PDG 1992 $B(D^0 \rightarrow K^- \pi^+ \pi^0)/B(D^0 \rightarrow K^- \pi^+)$ and $B(D^0 \rightarrow K^- 2\pi^+ \pi^-)/B(D^0 \rightarrow K^- \pi^+)$ .				
<sup>9</sup> ALBRECHT 88k assumes $B^0 \overline{B}^0 : B^+ B^-$ ratio is 45:55. Superseded by ALBRECHT 90j.

• • • We do not use the following data for averages, fits, limits, etc. • • •

<1.8     90     <sup>5</sup> ALBRECHT     90J     ARG      $e^+e^- \rightarrow \Upsilon(4S)$

- <sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .
- <sup>2</sup> ACOSTA 02F uses as reference of  $B(B \rightarrow J/\psi(1S)K^+) = (10.1 \pm 0.6) \times 10^{-4}$ . The second error includes the systematic error and the uncertainties of the branching ratio.
- <sup>3</sup> BORTOLETTO 92 reports  $(1.2 \pm 0.6 \pm 0.4) \times 10^{-3}$  from a measurement of  $[\Gamma(B^+ \rightarrow J/\psi(1S)K^+\pi^+\pi^-)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .
- <sup>4</sup> ALBRECHT 87D reports  $(1.2 \pm 0.8) \times 10^{-3}$  from a measurement of  $[\Gamma(B^+ \rightarrow J/\psi(1S)K^+\pi^+\pi^-)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$ . Our first error is their experiment's error and our second error is

the systematic error from using our best value. They actually report  $0.0011 \pm 0.0007$  assuming  $B^+B^-/B^0\bar{B}^0$  ratio is 55/45. We rescale to 50/50. Analysis explicitly removes  $B^+ \rightarrow \psi(2S)K^+$ .

- <sup>5</sup> ALBRECHT 90J reports  $< 1.6 \times 10^{-3}$  from a measurement of  $[\Gamma(B^+ \rightarrow J/\psi(1S)K^+\pi^+\pi^-)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = 5.971 \times 10^{-2}$ . Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>2</sup> Measured in the  $B^+ \rightarrow K^+K^-K^+$  decay.

<sup>3</sup> Measured in the  $B^+ \rightarrow K^+K_S^0 K_S^0$  decay.

<sup>4</sup> LEES 11i reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P)K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \pi\pi)] = (1.53 \pm 0.66 \pm 0.27) \times 10^{-6}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow \pi\pi) = (8.33 \pm 0.35) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>5</sup> AUBERT 08Ai reports  $(0.70 \pm 0.10 \pm 0.12 \pm 0.10) \times 10^{-6}$  for  $B(B^+ \rightarrow \chi_{c0}K^+) \times B(\chi_{c0} \rightarrow \pi^+\pi^-)$ . We compute  $B(B^+ \rightarrow \chi_{c0}K^+)$  using the PDG value  $B(\chi_{c0} \rightarrow \pi\pi) = (8.33 \pm 0.35) \times 10^{-3}$  and 2/3 for the  $\pi^+\pi^-$  fraction. Our first error is their experiment's error and the second error is systematic error from using our best value.

<sup>6</sup> AUBERT,BE 06M reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P)K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S))] = (6.1 \pm 2.6 \pm 1.1) \times 10^{-6}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S)) = (1.27 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. The significance of the observed signal is 2.4  $\sigma$ .

<sup>7</sup> AAIJ 13s reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P)K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow p\bar{p})] < 6 \times 10^{-8}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow p\bar{p}) = 2.25 \times 10^{-4}$ .

<sup>8</sup> WICHT 08 reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P)K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \gamma\gamma)] < 0.11 \times 10^{-6}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow \gamma\gamma) = 2.23 \times 10^{-4}$ .

<sup>9</sup> Perform measurements of absolute branching fractions using a missing mass technique.

<sup>10</sup> Measured in the  $B^+ \rightarrow K^+K^-K^+$  decay.

<sup>11</sup> AUBERT,B 05N reports  $(0.66 \pm 0.22 \pm 0.08) \times 10^{-6}$  for  $B(B^+ \rightarrow \chi_{c0}^0 K^+) \times B(\chi_{c0}^0 \rightarrow \pi^+\pi^-)$ . We compute  $B(B^+ \rightarrow \chi_{c0}^0 K^+)$  using the PDG value  $B(\chi_{c0}^0 \rightarrow \pi^+\pi^-) = (7.1 \pm 0.6) \times 10^{-3}$  and 2/3 for the  $\pi^+\pi^-$  fraction.

<sup>12</sup> The measurement performed using decay channels  $\chi_{c0} \rightarrow \pi^+\pi^-$  and  $\chi_{c0} \rightarrow K^+K^-$ . The ratio of the branching ratios for these channels is found to be consistent with world average.

<sup>13</sup> AUBERT 04P reports  $B(B^+ \rightarrow \chi_{c0}K^+) \times B(\chi_{c0} \rightarrow \pi^+\pi^-) = (1.5 \pm 0.4 \pm 0.1) \times 10^{-6}$  and used PDG value of  $B(\chi_{c0} \rightarrow \pi\pi) = (7.4 \pm 0.8) \times 10^{-3}$  and Clebsh-Gordan coefficient to compute  $B(B^\pm \rightarrow \chi_{c0}K^+)$ .

<sup>14</sup> ABE 02B measures the ratio of  $B(B^+ \rightarrow \chi_{c0}K^+)/B(B^+ \rightarrow J/\psi(1S)K^+) = 0.60 \pm 0.21 - 0.18 \pm 0.05 \pm 0.08$ , where the third error is due to the uncertainty in the  $B(\chi_{c0} \rightarrow \pi^+\pi^-)$ , and uses  $B(B^+ \rightarrow J/\psi(1S)K^+) = (10.0 \pm 1.0) \times 10^{-4}$  to obtain the result.

<sup>15</sup> EDWARDS 01 assumes equal production of  $B^0$  and  $B^+$  at the  $\Upsilon(4S)$ . The correlated uncertainties (28.3)% from  $B(J/\psi(1S) \rightarrow \eta\eta_c)$  in those modes have been accounted for.

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>2</sup> AUBERT 08A1 reports  $(1.85 \pm 0.41 \pm^{+0.61}_{-0.29}) \times 10^{-6}$  for  $B(B^+ \rightarrow K_S^*(1430)^0 \pi^+) \times B(K_S^*(1430)^0 \rightarrow K^+ \pi^-)$ . We compute  $B(B^+ \rightarrow K_S^*(1430)^0 \pi^+)$  using the PDG value  $B(K_S^*(1430)^0 \rightarrow K \pi) = (49.9 \pm 1.2) \times 10^{-2}$  and 2/3 for the  $K^+ \pi^-$  fraction. Our first error is their experiment's error and the second error is systematic error from using our best value.

<sup>3</sup> AUBERT,B 05N reports  $7.7 \times 10^{-6}$  at 90% CL for  $B(B^+ \rightarrow K_S^*(1430)^0 \pi^+) \times B(K_S^*(1430)^0 \rightarrow K^+ \pi^-)$ . We rescaled it using the PDG value  $B(K_S^*(1430)^0 \rightarrow K \pi) = 49.9\%$  and 2/3 for the  $K^+ \pi^-$  fraction.

<sup>4</sup> GARMASH 05 reports  $2.3 \times 10^{-6}$  at 90% CL for  $B(B^+ \rightarrow K_S^*(1430)^0 \pi^+) \times B(K_S^*(1430)^0 \rightarrow K^+ \pi^-)$ . We rescaled it using the PDG value  $B(K_S^*(1430)^0 \rightarrow K \pi) = 49.9\%$  and 2/3 for the  $K^+ \pi^-$  mode.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<8$	90	<sup>1,4</sup> GARMASH	05	BELL	$e^+ e^- \rightarrow \Upsilon(4S)$
<sup>1</sup> Assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ .					
<sup>2</sup> Measured in the $B^+ \rightarrow K^+ K^- K^+$ decay.					
<sup>3</sup> Measured in the $B^+ \rightarrow K^+ K_S^0 \bar{K}_S^0$ decay.					
<sup>4</sup> GARMASH 05 reports $B(B^+ \rightarrow f_2'(1525) K^+) \cdot B(f_2'(1525) \rightarrow K^+ K^-) < 4.9 \times 10^{-6}$ at 90% CL. We divide this result by our best value of $B(f_2'(1525) \rightarrow K \bar{K}) = 88.7 \times 10^{-2}$ multiplied by 2/3 to account for the $K^+ K^-$ fraction.

<sup>1</sup> DEL-AMO-SANCHEZ 11k reports $< 8.1 \times 10^{-8}$ from a measurement of $[\Gamma(B^+ \rightarrow \overline{\Lambda}^0 e^+)/\Gamma_{\text{total}}] \times [B(\Lambda \rightarrow p \pi^-)]$ assuming $B(\Lambda \rightarrow p \pi^-) = (63.9 \pm 0.5) \times 10^{-2}$ .					
<sup>2</sup> Uses $B(\Upsilon(4S) \rightarrow B^0 \overline{B}^0) = (51.6 \pm 0.6)\%$ and $B(\Upsilon(4S) \rightarrow B^+ B^-) = (48.4 \pm 0.6)\%$ .					

## POLARIZATION IN $B^+$ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (||) or perpendicular ( $\perp$ ) to each other with the parameters  $\Gamma_L/\Gamma$ ,  $\Gamma_\perp/\Gamma$ , and the relative phases  $\phi_\parallel$  and  $\phi_\perp$ . See the definitions in the note on “Polarization in  $B$  Decays” review in the  $B^0$  Particle Listings.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- <sup>1</sup> Uses binned Dalitz plot analysis of  $B^+ \rightarrow DK^+$  decays, with  $D \rightarrow K_S^0 \pi^+ \pi^-$  and  $D \rightarrow K_S^0 K^+ K^-$ . Strong phase measurements from CLEO-c (LIBBY 10) of the  $D$  decay over the Dalitz plot are used as input.  
<sup>2</sup> Uses  $B^\pm \rightarrow [K^\pm \pi^\mp \pi^+ \pi^-] D h^\pm$  mode.  
<sup>3</sup> Reports combination of published measurements using GGSZ, GLW, and ADS methods.  
<sup>4</sup> Uses Dalitz plot analysis of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays from  $B^+ \rightarrow D^0 K^+$  modes. The corresponding two standard deviation interval is  $0.084 < r_B < 0.239$ .  
<sup>5</sup> AAIJ 14BE uses model-dependent analysis of  $D \rightarrow K_S^0 \pi^+ \pi^-$  amplitudes. The model is the same as in DEL-AMO-SANCHEZ 10F.  
<sup>6</sup> Reports combined statistical and systematic uncertainties.  
<sup>7</sup> Uses binned Dalitz plot of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays from  $B^+ \rightarrow \bar{D}^0 K^+$ . Measurement of strong phases in  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  Dalitz plot from LIBBY 10 is used as input.  
<sup>8</sup> We combined the systematics in quadrature. The authors report separately the contribution to the systematic uncertainty due to the uncertainty on the bin-averaged strong phase difference between  $D^0$  and  $\bar{D}^0$  amplitudes.  
<sup>9</sup> Uses decays of neutral  $D$  to  $K^- \pi^+ \pi^0$ .  
<sup>10</sup> Uses Dalitz plot analysis of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ ,  $K_S^0 K^+ K^-$  decays from  $B^+ \rightarrow D(*) K(*)^+$  modes. The corresponding two standard deviation interval is  $0.037 < r_B < 0.155$ .  
<sup>11</sup> Uses the Cabibbo suppressed decay of  $B^+ \rightarrow \bar{D} K^+$  followed by  $\bar{D} \rightarrow K^- \pi^+$ .  
<sup>12</sup> Uses Dalitz plot analysis of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  and  $\bar{D}^0 \rightarrow K_S^0 K^+ K^-$  decays coming from  $B^\pm \rightarrow D(*) K(*)^\pm$  modes.  
<sup>13</sup> Uses a Dalitz plot analysis of the  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays; Combines the  $DK^+$ ,  $D^* K^+$  and  $DK^{*+}$  modes.  
<sup>14</sup> Uses a Dalitz analysis of neutral  $D$  decays to  $K_S^0 \pi^+ \pi^-$  in the processes  $B^\pm \rightarrow D(*) K^\pm$ ,  $D^* \rightarrow D \pi^0$ ,  $D \gamma$ .

$-0.39 \pm 0.33 \pm 0.12$	AUBERT	03M BABR	Repl. by AUBERT 05G

<sup>1</sup> AAIJ 14B0 reports also  $CP$  asymmetries in restricted regions of phase space.  
<sup>2</sup> AAIJ 14 reports  $A_{CP}(B^+ \rightarrow \pi^+ \pi^- \pi^+) = 0.584 \pm 0.082 \pm 0.027 \pm 0.007$  in the Dalitz plot region of  $m_{\pi^+ \pi^-}^2 > 15 \text{ GeV}^2/c^4$  or  $m_{\pi^+ \pi^-}^2 < 0.4 \text{ GeV}^2/c^4$ . The third uncertainty is due to the  $CP$  asymmetry of the  $B^\pm \rightarrow J/\psi K^\pm$  reference mode uncertainty.

- <sup>1</sup> Uses binned Dalitz plot analysis of  $B^+ \rightarrow DK^+$  decays, with  $D \rightarrow K_S^0 \pi^+ \pi^-$  and  $D \rightarrow K_S^0 K^+ K^-$ . Strong phase measurements from CLEO-c (LIBBY 10) of the  $D$  decay over the Dalitz plot are used as input. Solution that satisfies  $0 < \gamma < 180$  is chosen.
- <sup>2</sup> Reports combination of published measurements using GGSZ, GLW, and ADS methods. Reports also  $2\sigma$  range of  $41\text{--}102^\circ$  and a  $5.9\sigma$  significance for  $\gamma(B^+ \rightarrow D^{(*)0} K^{(*)+}) \neq 0$  hypothesis.
- <sup>3</sup> Uses Dalitz plot analysis of  $\overline{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays from  $B^+ \rightarrow D^{(*)} K^+$  modes. The corresponding two standard deviation interval for  $\gamma$  is  $54.2^\circ < \gamma < 100.5^\circ$ . CP conservation in the combined result is ruled out with a significance of 3.5 standard deviations.
- <sup>4</sup> AAIJ 14BE uses model-dependent analysis of  $D \rightarrow K_S^0 \pi^+ \pi^-$  amplitudes. The model is the same as in DEL-AMO-SANCHEZ 10F.
- <sup>5</sup> Presents a confidence region  $55.4^\circ < \gamma < 82.3^\circ$  at 68% CL with best fit value  $72.6^\circ$  and includes both statistical and systematic uncertainties. The corresponding 95% CL is  $40.2^\circ < \gamma < 92.7^\circ$ . The value is determined from combination of measurements using  $D$  meson decaying to  $K^+ K^-$ ,  $\pi^+ \pi^-$ ,  $K^\pm \pi^\mp$ ,  $K_S^0 \pi^+ \pi^-$ ,  $K_S^0 K^+ K^-$ , and  $K^\pm \pi^\mp \pi^\pm \pi^\mp$ . Combines  $B^\pm \rightarrow DK^\pm$  and  $B^\pm \rightarrow D\pi^\pm$ .
- <sup>6</sup> Reports combined statistical and systematic uncertainties.
- <sup>7</sup> Uses binned Dalitz plot of  $\overline{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays from  $B^+ \rightarrow \overline{D}^0 K^+$ . Measurement of strong phases in  $\overline{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  Dalitz plot from LIBBY 10 is used as input.
- <sup>8</sup> We combined the systematics in quadrature. The authors report separately the contribution to the systematic uncertainty due to the uncertainty on the bin-averaged strong phase difference between  $D^0$  and  $\overline{D}^0$  amplitudes.
- <sup>9</sup> Uses Dalitz plot analysis of  $\overline{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ ,  $K_S^0 K^+ K^-$  decays from  $B^+ \rightarrow D^{(*)} K^+$ ,  $DK^{*+}$  modes. The corresponding two standard deviation interval for  $\gamma$  is  $39^\circ < \gamma < 98^\circ$ . CP conservation in the combined result is ruled out with a significance of 3.5 standard deviations.
- <sup>10</sup> Reports confidence intervals for the CKM angle  $\gamma$  from the measured values of the GLW parameters using  $B^\pm \rightarrow DK^\pm$  decays from  $D$  mesons decaying to non-CP( $K\pi$ ), CP-even ( $K^+ K^-$ ,  $\pi^+ \pi^-$ ), and CP-odd ( $K_S^0 \pi^0$ ,  $K_S^0 \omega$ ) states.
- <sup>11</sup> Uses Dalitz plot analysis of  $\overline{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  and  $\overline{D}^0 \rightarrow K_S^0 K^+ K^-$  decays coming from  $B^\pm \rightarrow D^{(*)} K^{(*)\pm}$  modes. The corresponding two standard deviation interval is  $29^\circ < \gamma < 122^\circ$ .
- <sup>12</sup> Uses a Dalitz plot analysis of the  $\overline{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays; Combines the  $DK^+$ ,  $D^* K^+$  and  $DK^{*+}$  modes. The corresponding two standard deviations interval for gamma is  $8^\circ < \gamma < 111^\circ$ .
- <sup>13</sup> Uses a Dalitz plot analysis of neutral  $D \rightarrow K_S^0 \pi^+ \pi^-$  decays coming from  $B^\pm \rightarrow DK^\pm$  and  $B^\pm \rightarrow D^{*0} K^\pm$  followed by  $D^{*0} \rightarrow D\pi^0$ ,  $D\gamma$ . The corresponding two standard deviations interval for gamma is  $12^\circ < \gamma < 137^\circ$ . AUBERT,B 05Y also reports the amplitude ratios and the strong phases.
- <sup>14</sup> Uses a Dalitz plot analysis of the 3-body  $D \rightarrow K_S^0 \pi^+ \pi^-$  decays coming from  $B^\pm \rightarrow DK^\pm$  and  $B^\pm \rightarrow D^* K^\pm$  followed by  $D^* \rightarrow D\pi^0$ ; here we use  $D$  to denote that the neutral  $D$  meson produced in the decay is an admixture of  $D^0$  and  $\overline{D}^0$ . The corresponding two standard deviations interval for  $\gamma$  is  $26^\circ < \gamma < 126^\circ$ . POLUEKTOV 04 also reports the amplitude ratios and the strong phases.

$\gamma(B^+ \rightarrow DK^+ \pi^- \pi^+, D\pi^+ \pi^- \pi^+)$

### $B^0$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the  $B^\pm/B^0$  ADMIXTURE and  $B^\pm/B^0/B_S^0/b$ -baryon ADMIXTURE sections.

See the Note "Production and Decay of  $b$ -flavored Hadrons" at the beginning of the  $B^\pm$  Particle Listings and the Note on " $B^0$ - $\bar{B}^0$  Mixing" near the end of the  $B^0$  Particle Listings.

### $B^0$ MASS

The fit uses  $m_{B^{+}}$ , ( $m_{B^0} - m_{B^{+}}$ ), and  $m_{B^0}$  to determine  $m_{B^{+}}$ ,  $m_{B^0}$ , and the mass difference.

5280.6 ±0.8 ±2.0		BEBEK	87	CLEO	$e^+e^- \rightarrow \Upsilon(4S)$

- 1 Measured with  $B_D^0 \rightarrow J/\psi(\mu^+\mu^-) K_S^0(\pi^+\pi^-)$  decays.
- 2 Uses  $B^0 \rightarrow J/\psi K^0$  fully reconstructed decays.
- 3 Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+\mu^-$  decays.
- 4 CSORNA 00 uses fully reconstructed 135  $B^0 \rightarrow J/\psi(\ell) K_S^0$  events and invariant masses without beam constraint.
- 5 ALBRECHT 90J assumes 10580 for  $\Upsilon(4S)$  mass. Supersedes ALBRECHT 87c and ALBRECHT 87D.
- 6 Found using fully reconstructed decays with  $J/\psi$ . ALBRECHT 87D assume  $m_{\Upsilon(4S)} = 10577$  MeV.

### $m_{B^0} - m_{B^+}$

−0.4 ±0.6 ±0.5		BORTOLETTO	92 CLEO $e^+e^- \rightarrow \Upsilon(4S)$
−0.9 ±1.2 ±0.5		ALBRECHT	90J ARG $e^+e^- \rightarrow \Upsilon(4S)$
2.0 ±1.1 ±0.3	4	BEBEK	87 CLEO $e^+e^- \rightarrow \Upsilon(4S)$
1 Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+\mu^-$ decay.			
2 Uses the $B$ -momentum distributions in the $e^+e^-$ rest frame.			
3 Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+\mu^-$ decays.			
4 BEBEK 87 actually measure the difference between half of $E_{cm}$ and the $B^\pm$ or $B^0$ mass, so the $m_{B^0} - m_{B^\pm}$ is more accurate. Assume $m_{\Upsilon(4S)} = 10580$ MeV.			

### $m_{B_H^0} - m_{B_L^0}$

See the  $B^0$ - $\bar{B}^0$  MIXING PARAMETERS section near the end of these  $B^0$  Listings.

### $B^0$ MEAN LIFE

See  $B^\pm/B^0/B_S^0/b$ -baryon ADMIXTURE section for data on  $B$ -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- Measured using  $B^0 \rightarrow D^{*-}\mu^+\nu X$  decays.
- Measured mean life using  $B^0 \rightarrow J/\psi K_S^0$  decays.
- Measured using  $B^0 \rightarrow J/\psi K^{*0}$  decays.
- Measured using  $B^0 \rightarrow K^+\pi^-$  decays.
- Measured with  $B_d^0 \rightarrow J/\psi(\mu^+\mu^-) K_S^0(\pi^+\pi^-)$  decays.
- Measured mean life using fully reconstructed decays ( $J/\psi K^{*0}$ ).
- Measured mean life using  $B^0 \rightarrow J/\psi K^{*0}$  decays.
- Measured using a simultaneous fit of the  $B^0$  lifetime and  $\bar{B}^0 B^0$  oscillation frequency  $\Delta m_d$  in the partially reconstructed  $B^0 \rightarrow D^{*-}\ell\nu$  decays.
- Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.
- Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.
- AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed  $B^0 \rightarrow D^*(2010)^-\ell\nu$  and simultaneously measures the lifetime and oscillation frequency.
- Measurement performed with decays  $B^0 \rightarrow D^{*-}\pi^+$  and  $B^0 \rightarrow D^{*-}\rho^+$  using a partial reconstruction technique.
- Measured mean life using fully reconstructed decays.
- Data analyzed using partially reconstructed  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}$  decays.
- Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.
- Data analyzed using  $D/D^*\ell X$  event vertices.
- Data analyzed using charge of secondary vertex.
- Data analyzed using inclusive  $D/D^*\ell X$ .
- Measured mean life using partially reconstructed  $D^{*-}\pi^+ X$  vertices.
- ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-}\ell^+\nu_\ell) = 3.2 \pm 1.7\%$ .
- Data analyzed using vertex-charge technique to tag  $B$  charge.
- AKERS 95T assumes  $B(B^0 \rightarrow D_s^{*0} D^0(*) = 5.0 \pm 0.9\%$  to find  $B^+/B^0$  yield.
- Measured using the time-dependent angular analysis of  $B_d^0 \rightarrow J/\psi K^{*0}$  decays.
- Combined result of  $D/D^*\ell X$  analysis, fully reconstructed  $B$  analysis, and partially reconstructed  $D^{*-}\pi^+ X$  analysis.
- Combined ABREU 95Q and ADAM 95 result.
- WAGNER 90 tagged  $B^0$  mesons by their decays into  $D^{*-}e^+\nu$  and  $D^{*-}\mu^+\nu$  where the  $D^{*-}$  is tagged by its decay into  $\pi^-\bar{D}^0$ .
- AVERILL 89 is an estimate of the  $B^0$  mean lifetime assuming that  $B^0 \rightarrow D^{*+} + X$  always.

 $\tau_{B^0}/\tau_{B^+}$

- Measured using  $B \rightarrow J/\psi K^{(*)}$  decays.

- Measured mean life using fully reconstructed decays ( $J/\psi K^{(*)}$ ).

- Data analyzed using  $D/D^*\mu X$  vertices.

- Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.

- Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.

- Measured using fully reconstructed decays.

- Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.

- Data analyzed using charge of secondary vertex.

- ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-}\ell^+\nu_\ell) = 3.2 \pm 1.7\%$ .

- Data analyzed using vertex-charge technique to tag  $B$  charge.

- AKERS 95T assumes  $B(B^0 \rightarrow D_s^{*0} D^0(*) = 5.0 \pm 0.9\%$  to find  $B^+/B^0$  yield.

- Combined result of  $D/D^*\ell X$  analysis and fully reconstructed  $B$  analysis.

 $\tau_{B^+}/\tau_{B^0}$  (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for  $B^0$  and  $B^+$ . We do not use measurements which assume equal production of  $B^0$  and  $B^+$  because of the large uncertainty in the production ratio.

“OUR EVALUATION” has been obtained by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

- ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^{*}\ell\nu_\ell$  and independent of  $B^0$  and  $B^+$  production fraction.

- Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

- ATHANAS 94 uses events tagged by fully reconstructed  $B^-$  decays and partially or fully reconstructed  $B^0$  decays.

- Assumes equal production of  $B^0$  and  $B^+$ .

- ALBRECHT 92G data analyzed using  $B \rightarrow D_s\bar{D}, D_s\bar{D}^*, D_s^*\bar{D}, D_s^*\bar{D}^*$  events.

- BEAN 87B assume the fraction of  $B^0\bar{B}^0$  events at the  $\Upsilon(4S)$  is 0.41.

 $\text{sgn}(\text{Re}(\lambda_{CP})) \Delta\Gamma_{B_d^0} / \Gamma_{B_d^0}$ 

$\Gamma_{B_d^0}$  and  $\Delta\Gamma_{B_d^0}$  are the decay rate average and difference between two  $B_d^0$   $CP$  eigenstates (light – heavy). The  $\lambda_{CP}$  characterizes  $B^0$  and  $\bar{B}^0$  decays to states of charmonium plus  $K_S^0$ , see the review on “ $CP$  Violation” in the reviews section.

### $B^0$ DECAY MODES

$\bar{B}^0$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0\bar{B}^0$  and 50%  $B^+B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D$ ,  $D_s$ ,  $D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

10.9 ± 0.7 ± 1.1	ATHANAS	94 CLE2	Sup. by ARTUSO 97

<sup>1</sup> URQUIJO 07 report a measurement of  $(9.80 \pm 0.29 \pm 0.21)\%$  for the partial branching fraction of  $B \rightarrow e \nu_e X_c$  decay with electron energy above 0.6 GeV. We converted the result to  $B \rightarrow e \nu_e X$  branching fraction.

<sup>2</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .

<sup>3</sup> ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^* \ell \nu_\ell$  and inclusive semileptonic branching ratio from BARISH 96B ( $0.1049 \pm 0.0017 \pm 0.0043$ ).

<sup>4</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

 $\Gamma(e^+ \nu_e X_c)/\Gamma_{\text{total}}$  $\Gamma_2/\Gamma$ 

VALUE (units $10^{-2}$ )	DOCUMENT ID	TECN	COMMENT
<b>10.08 ± 0.30 ± 0.22</b>	<sup>1</sup> URQUIJO	07 BELL	$e^+ e^- \rightarrow \gamma(4S)$
<sup>1</sup> Measure the independent $B^+$ and $B^0$ partial branching fractions with electron threshold energies of 0.4 GeV.			

 $\Gamma(D^- \ell^+ \nu_\ell)/\Gamma_{\text{total}}$  $\Gamma_4/\Gamma$ 

$\ell$  denotes  $e$  or  $\mu$ , not the sum.

0.070 ± 0.012 ± 0.019	47	<sup>23</sup> ALBRECHT	87J ARG	$e^+ e^- \rightarrow \gamma(4S)$

<sup>1</sup> Uses fully reconstructed  $D^{*-} \ell^+ \nu$  events ( $\ell = e$  or  $\mu$ ).

<sup>2</sup> Uses a fully reconstructed  $B$  meson as a tag on the recoil side.

<sup>3</sup> Measured using fully reconstructed  $D^*$  sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters:  $\rho^2 = 1.191 \pm 0.048 \pm 0.028$ ,  $R_1(1) = 1.429 \pm 0.061 \pm 0.044$ , and  $R_2(1) = 0.827 \pm 0.038 \pm 0.022$ .

<sup>4</sup> Measured using fully reconstructed  $D^*$  sample.

<sup>5</sup> Uses the combined fit of both  $B^0 \rightarrow D^*(2010)^- \ell \nu$  and  $B^+ \rightarrow \bar{D}^*(2010)^0 \ell \nu$  samples.

<sup>6</sup> ABREU 01H measured using about 5000 partial reconstructed  $D^*$  sample.

<sup>7</sup> ABBIENDI 00Q assumes the fraction  $B(b \rightarrow B^0) = (39.7^{+1.8}_{-2.2})\%$ . This result is an average of two methods using exclusive and partial  $D^*$  reconstruction.

<sup>8</sup> BUSKULIC 97 assumes fraction  $(B^+) = \text{fraction}(B^0) = (37.8 \pm 2.2)\%$  and PDG 96 values for  $B$  lifetime and  $D^*$  and  $D$  branching fractions.

<sup>9</sup> Combines with previous partial reconstructed  $D^*$  measurement.

<sup>10</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\gamma(4S)$ .

<sup>11</sup> The results are based on the same analysis and data sample reported in ADAM 03.

<sup>12</sup> ACKERSTAFF 97G assumes fraction  $(B^+) = \text{fraction}(B^0) = (37.8 \pm 2.2)\%$  and PDG 96 values for  $B$  lifetime and branching ratio of  $D^*$  and  $D$  decays.

<sup>13</sup> ABREU 96P result is the average of two methods using exclusive and partial  $D^*$  reconstruction.

<sup>14</sup> BARISH 95 use  $B(D^0 \rightarrow K^- \pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$  and  $B(D^{*+} \rightarrow D^0 \pi^+) = (68.1 \pm 1.0 \pm 1.3)\%$ .

<sup>15</sup> BUSKULIC 95N assumes fraction  $(B^+) = \text{fraction}(B^0) = 38.2 \pm 1.3 \pm 2.2\%$  and  $\tau_{B^0} = 1.58 \pm 0.06$  ps.  $\Gamma(D^{*-} \ell^+ \nu_\ell)/\text{total} = [5.18 - 0.13(\text{fraction}(B^0) - 38.2) - 1.5(\tau_{B^0} - 1.58)]\%$ .

<sup>16</sup> ALBRECHT 94 assumes  $B(D^{*+} \rightarrow D^0 \pi^+) = 68.1 \pm 1.0 \pm 1.3\%$ . Uses partial reconstruction of  $D^{*+}$  and is independent of  $D^0$  branching ratios.

<sup>17</sup> ALBRECHT 93 reports  $0.052 \pm 0.005 \pm 0.006$ . We rescale using the method described in STONE 94 but with the updated PDG 94  $B(D^0 \rightarrow K^- \pi^+)$ . We have taken their average  $e$  and  $\mu$  value. They also obtain  $\alpha = 2s\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$ ,  $A_{AF} = 3/4 * (\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$  and a value of  $|V_{cb}| = 0.036 - 0.045$  depending on model assumptions.

<sup>18</sup> Combining  $\bar{D}^{*0} \ell^+ \nu_\ell$  and  $\bar{D}^{*-} \ell^+ \nu_\ell$  SANGHERA 93 test  $V-A$  structure and fit the decay angular distributions to obtain  $A_{FB} = 3/4 * (\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$ .

# Meson Particle Listings

$B^0$

- Assuming a value of  $V_{cb}$ , they measure  $V$ ,  $A_1$ , and  $A_2$ , the three form factors for the  $D^* \ell \nu_\ell$  decay, where results are slightly dependent on model assumptions.
- <sup>19</sup> ANTREASYAN 90b is average over  $B$  and  $\bar{D}^*$ (2010) charge states.
- <sup>20</sup> The measurement of ALBRECHT 89c suggests a  $D^*$  polarization  $\gamma_L/\gamma_T$  of  $0.85 \pm 0.45$ , or  $\alpha = 0.7 \pm 0.9$ .
- <sup>21</sup> ALBRECHT 89j is ALBRECHT 87j value rescaled using  $B(D^*(2010)^- \rightarrow D^0 \pi^-) = 0.57 \pm 0.04 \pm 0.04$ . Superseded by ALBRECHT 93.
- <sup>22</sup> We have taken average of the the BORTOLETTO 89b values for electrons and muons,  $0.046 \pm 0.005 \pm 0.007$ . We rescale using the method described in STONE 94 but with the updated PDG 94  $B(D^0 \rightarrow K^- \pi^+) = 0.65 \pm 0.66 \pm 0.25$ .
- <sup>23</sup> ALBRECHT 87j assume  $\mu$ -e universality, the  $B(\tau(4S) \rightarrow B^0 \bar{B}^0) = 0.45$ , the  $B(D^0 \rightarrow K^- \pi^+) = (0.042 \pm 0.004 \pm 0.004)$ , and the  $B(D^*(2010)^- \rightarrow D^0 \pi^-) = 0.49 \pm 0.08$ . Superseded by ALBRECHT 89j.

<4.1	<sup>10</sup> BEAN	93B	CLE2	$e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> The signal events are tagged by a second  $B$  meson reconstructed in the fully hadronic decays.<sup>2</sup>  $B^+$  and  $B^0$  decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.<sup>3</sup> The  $B^0$  and  $B^+$  results are combined assuming the isospin,  $B$  lifetimes, and relative charged/neutral  $B$  production at the  $\Upsilon(4S)$ .<sup>4</sup> The signal events are tagged by a second  $B$  meson reconstructed in the semileptonic mode  $B \rightarrow D^{(*)}\ell\nu_\ell$ .<sup>5</sup> Averaging with ALEXANDER 96T results including experimental and theoretical correlations considered, BEHRENS 00 reports systematic errors  $+0.33 \pm 0.41$ , where the second error is theoretical model dependence. We combine these in quadrature.<sup>6</sup> ATHAR 03 reports systematic errors  $+0.47 \pm 0.41 \pm 0.01$ , which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.<sup>7</sup> Uses isospin constraints and extrapolation to all electron energies according to five different form-factor calculations. The second error combines the systematic and theoretical uncertainties in quadrature.<sup>8</sup> BEHRENS 00 reports  $+0.35 \pm 0.40 \pm 0.50$ , where the second error is the theoretical model dependence. We combine these in quadrature.  $B^+$  and  $B^0$  decays combined using isospin symmetry:  $\Gamma(B^0 \rightarrow \rho^-\ell^+\nu) = 2\Gamma(B^+ \rightarrow \rho^0\ell^+\nu) \approx 2\Gamma(B^+ \rightarrow \omega\ell^+\nu)$ . No evidence for  $\omega\ell\nu$  is reported.<sup>9</sup> ALEXANDER 96T reports  $+0.5 \pm 0.5$  where the second error is the theoretical model dependence. We combine these in quadrature.  $B^+$  and  $B^0$  decays combined using isospin symmetry:  $\Gamma(B^0 \rightarrow \rho^-\ell^+\nu) = 2\Gamma(B^+ \rightarrow \rho^0\ell^+\nu) \approx 2\Gamma(B^+ \rightarrow \omega\ell^+\nu)$ . No evidence for  $\omega\ell\nu$  is reported.<sup>10</sup> BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine  $\Gamma(\rho^0\ell^+\nu_\ell)$  and  $\Gamma(\omega\ell^+\nu_\ell)$  with this result, they obtain a limit  $<(1.6-2.7) \times 10^{-4}$  at 90% CL for  $B^+ \rightarrow (\omega \text{ or } \rho^0)\ell^+\nu_\ell$ . The range corresponds to the ISGW, WSB, and KS models. An upper limit on  $|V_{ub}/V_{cb}| < 0.08-0.13$  at 90% CL is derived as well.WEIGHTED AVERAGE  
 $2.45 \pm 0.32$  (Error scaled by 1.6) $\Gamma(\pi^-\ell^+\nu_\ell)/\Gamma_{\text{total}}$  $\Gamma_{19}/\Gamma$

3.1 ± 1.3 ± 1.0	7	<sup>5</sup> ALBRECHT	88k	ARG $e^+ e^- \rightarrow \Upsilon(4S)$
<sup>1</sup> Assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ .				
<sup>2</sup> Uses a missing-mass method. Does not depend on $D$ branching fractions or $B^+ / B^0$ production rates.				
<sup>3</sup> AHMED 02b reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of $B^0$ and $B^+$ , which is not included here.				
<sup>4</sup> BORTOLETTO 92 assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ and uses Mark III branching fractions for the $D$ .				
<sup>5</sup> ALBRECHT 88k assumes $B^0 \overline{B}^0 : B^+ B^-$ production ratio is 45:55. Superseded by AL-BRECHT 90J which assumes 50:50.				
<sup>6</sup> BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.				
<sup>7</sup> AUBERT,B 04o reports $[\Gamma(B^0 \rightarrow D^- \pi^+)/\Gamma_{\text{total}}] \times [B(D^+ \rightarrow K_S^0 \pi^+)] = (42.7 \pm 2.1 \pm 2.2) \times 10^{-6}$ which we divide by our best value $B(D^+ \rightarrow K_S^0 \pi^+) = (1.53 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.				
<sup>8</sup> ALAM 94 reports $[\Gamma(B^0 \rightarrow D^- \pi^+)/\Gamma_{\text{total}}] \times [B(D^+ \rightarrow K^- 2\pi^+)] = (0.265 \pm 0.032 \pm 0.023) \times 10^{-3}$ which we divide by our best value $B(D^+ \rightarrow K^- 2\pi^+) = (9.46 \pm 0.24) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of $B^+$ and $B^0$ at the $\Upsilon(4S)$ .

<sup>1</sup> AUBERT 07AV reports  $[\Gamma(B^0 \rightarrow J/\psi(1S) K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow p\bar{p})] = (2.82^{+0.30+0.36}_{-0.28-0.35}) \times 10^{-6}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow p\bar{p}) = (2.120 \pm 0.029) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>2</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>3</sup> ABE 98o reports  $[B(B^0 \rightarrow J/\psi(1S) K^*(892)^0)]/[B(B^+ \rightarrow J/\psi(1S) K^+)] = 1.76 \pm 0.14 \pm 0.15$ . We multiply by our best value  $B(B^+ \rightarrow J/\psi(1S) K^+) = (9.9 \pm 1.0) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>4</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>5</sup> BORTOLETTO 92 reports  $(1.1 \pm 0.5 \pm 0.3) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow J/\psi(1S) K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>6</sup> ALBRECHT 90J reports  $(1.1 \pm 0.5 \pm 0.2) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow J/\psi(1S) K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>7</sup> BEBEK 87 reports  $(3.5 \pm 1.6 \pm 0.3) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow J/\psi(1S) K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

<sup>8</sup> ABE 96H assumes that  $B(B^+ \rightarrow J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$ .

<sup>9</sup> The neutral and charged  $B$  events together are predominantly longitudinally polarized,  $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$ . This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the  $B \rightarrow \psi K^*$  decay is dominated by the  $CP = -1$   $CP$  eigenstate. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>10</sup> ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal,  $\Gamma_T/\Gamma = 0.03 \pm 0.16 \pm 0.15$  making the neutral decay a  $CP$  eigenstate when the  $K^*$  decays through  $K_S^0 \pi^0$ .

<sup>11</sup> ALBAJAR 91E assumes  $B_D^0$  production fraction of 36%.

<sup>12</sup> ALBRECHT 87D assume  $B^+B^-/B^0\bar{B}^0$  ratio is 55/45. Superseded by ALBRECHT 90J.

<sup>13</sup> ALAM 86 assumes  $B^\pm/B^0$  ratio is 60/40. The observation of the decay  $B^+ \rightarrow J/\psi K^*(892)^+$  (HAAS 85) has been retracted in this paper.

<sup>1</sup> DUH 13 reports also for the same data  $B(B^0 \rightarrow K^+K^-) < 0.20 \times 10^{-6}$  at 90% CL.  
<sup>2</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .  
<sup>3</sup> AAIJ 12AR reports  $[\Gamma(B^0 \rightarrow K^+K^-)/\Gamma_{\text{total}}] / [B(B^0_s \rightarrow K^+K^-)] / [\Gamma(\bar{B} \rightarrow B^0_s)/\Gamma(\bar{B} \rightarrow B^0)] = 0.018^{+0.008}_{-0.007} \pm 0.009$  which we multiply by our best values  $B(B^0_s \rightarrow K^+K^-) = (2.52 \pm 0.17) \times 10^{-5}$ ,  $\Gamma(\bar{B} \rightarrow B^0_s)/\Gamma(\bar{B} \rightarrow B^0) = 0.256 \pm 0.014$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.  
<sup>4</sup> Reported a central value of  $(0.23 \pm 0.10 \pm 0.10) \times 10^{-6}$  using  $B(B^0 \rightarrow K^+\pi^-) = (19.4 \pm 0.6) \times 10^{-6}$ .  
<sup>5</sup> Obtains this result from  $B(K^+K^-)/B(K^+\pi^-) = 0.020 \pm 0.008 \pm 0.006$ , assuming  $B(B^0 \rightarrow K^+\pi^-) = (19.4 \pm 0.6) \times 10^{-6}$ .  
<sup>6</sup> ABULENCIA,A 06D obtains this from  $\Gamma(K^+K^-)/\Gamma(K^+\pi^-) < 0.10$  at 90% CL, assuming  $B(B^0 \rightarrow K^+\pi^-) = (18.9 \pm 0.7) \times 10^{-6}$ .  
<sup>7</sup> ABE 00c assumes  $B(Z \rightarrow b\bar{b}) = (21.7 \pm 0.1)\%$  and the  $B$  fractions  $f_{B^0} = f_{B^+} = (39.7^{+1.8}_{-2.2})\%$  and  $f_{B_s} = (10.5^{+1.8}_{-2.2})\%$ .  
<sup>8</sup> ADAM 96D assumes  $f_{B^0} = f_{B^-} = 0.39$  and  $f_{B_s} = 0.12$ . Contributions from  $B^0$  and  $B_s$  decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral  $B$  mesons.  
<sup>9</sup> BUSKULIC 96v assumes PDG 96 production fractions for  $B^0$ ,  $B^+$ ,  $B_s$ ,  $b$  baryons.  
<sup>10</sup> Assumes a  $B^0$ ,  $B^-$  production fraction of 0.39 and a  $B_s$  production fraction of 0.12. Contributions from  $B^0$  and  $B_s$  decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral  $B$  mesons.

$< 200000$	90	GILES	84 CLEO	Repl. by AVERY 87

<sup>1</sup> Derived from the combined fit to CMS and LHCb data. Uncertainty includes both statistical and systematic component. Also reports  $B(B^0 \rightarrow \mu^+ \mu^-)/B(B_S \rightarrow \mu^+ \mu^-) = 0.14 \pm 0.08$ .

<sup>2</sup> Uses  $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (6.01 \pm 0.21) \times 10^{-5}$  and  $B(B^0 \rightarrow K^+ \pi^-) = (1.94 \pm 0.06) \times 10^{-5}$  for normalization.

<sup>3</sup> Reports also a limit of  $< 7.4 \times 10^{-10}$  at 95% CL. Uses normalization modes  $B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+$  and  $B^0 \rightarrow K^+ \pi^-$ .

<sup>4</sup> Uses normalization mode  $B(B^+ \rightarrow J/\psi K^+) = (10.22 \pm 0.35) \times 10^{-4}$ .

<sup>5</sup> Uses  $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (6.0 \pm 0.2) \times 10^{-5}$  for normalization.

<sup>6</sup> Uses  $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (6.01 \pm 0.21) \times 10^{-5}$ .

<sup>7</sup> Uses  $B$  production ratio  $f(\bar{D} \rightarrow B^+)/f(\bar{D} \rightarrow B_S^0) = 3.71 \pm 0.47$  and three normalization modes.

<sup>8</sup> Uses  $B(B^+ \rightarrow J/\psi K^+) B(J/\psi \rightarrow \mu^+ \mu^-) = (5.94 \pm 0.21) \times 10^{-5}$ .

<sup>9</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>10</sup> Uses  $B(B^+ \rightarrow J/\psi K^+) B(J/\psi \rightarrow \mu^+ \mu^-) = (5.88 \pm 0.26) \times 10^{-5}$ .

<sup>11</sup> Assumes production cross-section  $\sigma(B_S)/\sigma(B^+) = 0.100/0.391$  and the CDF measured value of  $\sigma(B^+) = 3.6 \pm 0.6 \mu\text{b}$ .

<sup>12</sup> ABE 98 assumes production of  $\sigma(B^0) = \sigma(B^+)$  and  $\sigma(B_S)/\sigma(B^0) = 1/3$ . They normalize to their measured  $\sigma(B^0, p_T(B) > 6, |y| < 1.0) = 2.39 \pm 0.32 \pm 0.44 \mu\text{b}$ .

<sup>13</sup> ACCIARRI 97B assume PDG 96 production fractions for  $B^+$ ,  $B^0$ ,  $B_s$ , and  $\Lambda_b$ .

<sup>14</sup> ABE 96i assumes equal  $B^0$  and  $B^+$  production. They normalize to their measured  $\sigma(B^+, p_T(B) > 6 \text{ GeV}/c, |y| < 1) = 2.39 \pm 0.54 \mu\text{b}$ .

<sup>15</sup>  $B^0$  and  $B_S^0$  are not separated.

<sup>16</sup> Obtained from unseparated  $B^0$  and  $B_S^0$  measurement by assuming a  $B^0:B_S^0$  ratio 2:1.

<sup>17</sup> AVERY 89B reports  $< 5 \times 10^{-3}$  assuming the  $\Upsilon(4S)$  decays 43% to  $B^0 \bar{B}^0$ . We rescale to 50%.

<sup>18</sup> ALBRECHT 87D reports  $< 5 \times 10^{-5}$  assuming the  $\Upsilon(4S)$  decays 45% to  $B^0 \bar{B}^0$ . We rescale to 50%.

<sup>19</sup> AVERY 87 reports  $< 9 \times 10^{-5}$  assuming the  $\Upsilon(4S)$  decays 40% to  $B^0 \bar{B}^0$ . We rescale to 50%.

POLARIZATION IN  $B$  DECAYS

Revised August 2015 by A. V. Gritsan (Johns Hopkins University).

We review the notation used in polarization measurements in particle production and decay, with a particular emphasis on the  $B$  decays and the  $CP$ -violating observables in polarization measurements. We look at several examples of vector-vector and vector-tensor  $B$  meson decays, while more details about the theory and experimental results in  $B$  decays can be found in a separate mini-review [1] in this *Review*.

Figure 1 illustrates angular observables in an example of the sequential process  $ab \rightarrow X \rightarrow P_1P_2 \rightarrow (p_{11}p_{12})(p_{21}p_{22})$  [2]. The angular distributions are of particular interest because they are sensitive to spin correlations and reveal properties of particles and their interactions, such as quantum numbers and couplings. In the case of a spin-zero particle  $X$ , such as  $B$  meson or a Higgs boson, there are no spin correlations in the production mechanism and the decay chain is to be analyzed. The angular distribution of decay products can be expressed as a function of three helicity angles which describe the alignment of the particles in the decay chain. The analyzer of the  $B$ -daughter polarization is normally chosen for two-body decays, as the direction of the daughters in the center-of-mass of the parent (*e.g.*,  $\rho \rightarrow 2\pi$ ) [3], and for three-body decays as the normal to the decay plane (*e.g.*,  $\omega \rightarrow 3\pi$ ) [4]. An equivalent set of transversity angles is sometimes used in polarization analyses [5]. The differential decay width depends on complex amplitudes  $A_{\lambda_1\lambda_2}$ , corresponding to the  $X$ -daughter helicity states  $\lambda_i$ .

**Figure 1:** Definition of the production and helicity angles in the sequential process  $ab \rightarrow X \rightarrow P_1P_2 \rightarrow (p_{11}p_{12})(p_{21}p_{22})$ . The three helicity angles include  $\theta_1$  and  $\theta_2$ , defined in the rest frame of the two daughters  $P_1$  and  $P_2$ , and  $\Phi$ , defined in the  $X$  frame as the angle between the two decay planes. The two production angles  $\theta^*$  and  $\Psi$  are defined in the  $X$  frame, where  $\Psi$  is the angle between the production plane and the average of the two decay planes.

In the case of a spin-zero  $B$ -meson decay, its daughter helicities are constrained to  $\lambda_1 = \lambda_2 = \lambda$ . Therefore we simplify amplitude notation as  $A_\lambda$ . Moreover, most  $B$ -decay polarization analyses are limited to the case when the spin of one of the  $B$ -meson daughters is 1. In that case, there are only three independent amplitudes corresponding to  $\lambda = 0$  or  $\pm 1$  [6], where the last two can be expressed in terms of parity-even and parity-odd amplitudes  $A_{\parallel,\perp} = (A_{+1} \pm A_{-1})/\sqrt{2}$ . The overall decay amplitude involves three complex terms proportional to the above amplitudes and the Wigner  $d$  functions of helicity angles. The exact angular dependence would depend on the quantum numbers of the  $B$ -meson daughters and of their decay products, and can be found in the literature [6,7]. The differential decay rate would involve six real quantities  $\alpha_i$ , including interference terms,

$$\frac{d\Gamma}{\Gamma d\cos\theta_1 d\cos\theta_2 d\Phi} = \sum_i \alpha_i f_i(\cos\theta_1, \cos\theta_2, \Phi), \quad (1)$$

where each  $f_i(\cos\theta_1, \cos\theta_2, \Phi)$  has unique angular dependence specific to particle quantum numbers, and the  $\alpha_i$  parameters are defined as:

$$\alpha_1 = \frac{|A_0|^2}{\sum |A_\lambda|^2} = f_L, \quad (2)$$

$$\alpha_2 = \frac{|A_\parallel|^2 + |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L), \quad (3)$$

$$\alpha_3 = \frac{|A_\parallel|^2 - |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L - 2f_\perp), \quad (4)$$

$$\alpha_4 = \frac{\Im m(A_{\perp} A_{\parallel}^*)}{\Sigma |A_{\lambda}|^2} = \sqrt{f_{\perp}(1-f_L-f_{\perp})} \sin(\phi_{\perp}-\phi_{\parallel}), \quad (5)$$

$$\alpha_5 = \frac{\Re e(A_{\parallel} A_0^*)}{\Sigma |A_{\lambda}|^2} = \sqrt{f_L(1-f_L-f_{\perp})} \cos(\phi_{\parallel}), \quad (6)$$

$$\alpha_6 = \frac{\Im m(A_{\perp} A_0^*)}{\Sigma |A_{\lambda}|^2} = \sqrt{f_{\perp} f_L} \sin(\phi_{\perp}), \quad (7)$$

where the amplitudes have been expressed with the help of polarization parameters  $f_L$ ,  $f_{\perp}$ ,  $\phi_{\parallel}$ , and  $\phi_{\perp}$  defined in Table 1. Note that the terms proportional to  $\Re e(A_{\perp} A_{\parallel}^*)$ ,  $\Im m(A_{\parallel} A_0^*)$ , and  $\Re e(A_{\perp} A_0^*)$  are absent in Eqs. (2-7). However, these terms may appear for some three-body decays of a  $B$ -meson daughter, see Ref. 7.

**Table 1:** Rate, polarization, and  $CP$ -asymmetry parameters defined for the  $B$ -meson decays to mesons with non-zero spin. Numerical examples are shown for the average of the  $B^0 \rightarrow \varphi K^*(892)^0$  decay measurements obtained from BABAR [8], Belle [9], and LHCb [10]. The first six parameters are defined under the assumption of no  $CP$  violation in decay, while they are averaged between the  $\bar{B}$  and  $B$  parameters in general. The last six parameters involve differences between the  $\bar{B}$  and  $B$  meson decay parameters. The phase convention  $\delta_0$  is chosen with respect to a single  $A_{00}$  amplitude from a reference  $B$  decay mode, which is  $B^0 \rightarrow \varphi K_0^*(1430)^0$  for numerical results.

parameter	definition	average
$\mathcal{B}$	$\Gamma/\Gamma_{\text{total}}$	$(10.1^{+0.6}_{-0.5}) \times 10^{-6}$
$f_L$	$ A_0 ^2/\Sigma  A_{\lambda} ^2$	$0.497 \pm 0.017$

$\phi_{\perp} - \pi$	$\arg(A_{\perp}/A_0) - \pi$	$-0.615 \pm 0.056$
$\delta_0 - \pi$	$\arg(A_{00}/A_0) - \pi$	$-0.26 \pm 0.10$
$A_{CP}$	$(\bar{\Gamma} - \Gamma)/(\bar{\Gamma} + \Gamma)$	$-0.003 \pm 0.038$
$A_{CP}^0$	$(\bar{f}_L - f_L)/(\bar{f}_L + f_L)$	$-0.007 \pm 0.030$
$A_{CP}^{\perp}$	$(\bar{f}_{\perp} - f_{\perp})/(\bar{f}_{\perp} + f_{\perp})$	$-0.014 \pm 0.057$
$\Delta\phi_{\parallel}$	$(\bar{\phi}_{\parallel} - \phi_{\parallel})/2$	$+0.051 \pm 0.053$
$\Delta\phi_{\perp}$	$(\bar{\phi}_{\perp} - \phi_{\perp} - \pi)/2$	$+0.075 \pm 0.050$
$\Delta\delta_0$	$(\bar{\delta}_0 - \delta_0)/2$	$+0.13 \pm 0.08$

Overall, six real parameters describe three complex amplitudes  $A_0$ ,  $A_{\parallel}$ , and  $A_{\perp}$ . These could be chosen to be the four polarization parameters  $f_L$ ,  $f_{\perp}$ ,  $\phi_{\parallel}$ , and  $\phi_{\perp}$ , one overall size normalization, such as decay rate  $\Gamma$ , or branching fraction  $\mathcal{B}$ , and one overall phase  $\delta_0$ . The phase convention is arbitrary for an isolated  $B$  decay mode. However, for several  $B$  decays, the relative phase could produce meaningful and observable effects through interference with other  $B$  decays with the same final states, such as for  $B \rightarrow VK_J^*$  with  $J = 0, 1, 2, 3, 4, \dots$ . The phase could be referenced to the single  $B \rightarrow VK_0^*$  amplitude  $A_{00}$  in such a case, as shown in Table 1. Here  $V$  stands for any spin-one vector meson.

Moreover,  $CP$  violation can be tested in the angular distribution of the decay as the difference between the  $B$  and  $\bar{B}$ . Each of the six real parameters describing the three complex amplitudes would have a counterpart  $CP$ -asymmetry term, corresponding to three direct- $CP$  asymmetries in three amplitudes, and three  $CP$ -violating phase differences, equivalent to the phase measurements from the mixing-induced  $CP$  asymmetries in the time evolution of  $B$ -decays [1]. In Table 1 and Ref. 11, these are chosen to be the direct- $CP$  asymmetries in the overall decay rate  $\mathcal{A}_{CP}$ , in the  $f_L$  fraction  $\mathcal{A}_{CP}^0$ , and in the  $f_{\perp}$  fraction  $\mathcal{A}_{CP}^{\perp}$ , and three weak phase differences:

$$\Delta\phi_{\parallel} = \frac{1}{2} \arg(\bar{A}_{\parallel} A_0 / A_{\parallel} \bar{A}_0), \quad (8)$$

$$\Delta\phi_{\perp} = \frac{1}{2} \arg(\bar{A}_{\perp} A_0 / A_{\perp} \bar{A}_0) - \frac{\pi}{2}, \quad (9)$$

$$\Delta\delta_0 = \frac{1}{2} \arg(\bar{A}_{00} A_0 / A_{00} \bar{A}_0). \quad (10)$$

The  $\frac{\pi}{2}$  term in Eq. (9) reflects the fact that  $A_{\perp}$  and  $\bar{A}_{\perp}$  differ in phase by  $\pi$  if  $CP$  is conserved. The two parameters  $\Delta\phi_{\parallel}$  and  $\Delta\phi_{\perp}$  are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [12]. The  $CP$ -violating phase difference in the reference decay mode [11] is, in the Wolfenstein CKM quark-mixing phase convention,

$$\Delta\phi_{00} = \frac{1}{2} \arg(A_{00}/\bar{A}_{00}). \quad (11)$$

This can be measured only together with the mixing-induced phase difference for some of the neutral  $B$ -meson decays similar to other mixing-induced  $CP$  asymmetry measurements [1].

It may not always be possible to have a phase-reference decay mode which would define  $\delta_0$  and  $\Delta\delta_0$  parameters. In that case, it may be possible to define the phase difference directly similarly to Eq. (11):

$$\Delta\phi_0 = \frac{1}{2} \arg(A_0/\bar{A}_0). \quad (12)$$

One can measure the angles of the CKM unitarity triangle, assuming Standard Model contributions to the  $\Delta\phi_0$  and  $B$ -mixing phases. Examples include measurements of  $\beta = \phi_1$  with  $B \rightarrow J/\psi K^*$  and  $\alpha = \phi_2$  with  $B \rightarrow \rho\rho$ .

Most of the  $B$  decays that arise from tree-level  $b \rightarrow c$  transitions have the amplitude hierarchy  $|A_0| > |A_{+}| > |A_{-}|$  which is expected from analyses based on quark-helicity conservation [13]. The larger the mass of the vector-meson daughters, the weaker the inequality. The  $B$  meson decays to heavy vector particles with charm, such as  $B \rightarrow J/\psi K^*$ ,  $\psi(2S)K^*$ ,  $\chi_{c1}K^*$ ,  $D^*\rho$ ,  $D^*K^*$ ,  $D^*D^*$ , and  $D^*D_s^*$ , show a substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons ( $A_{\pm 1}$ ), in agreement with the factorization prediction. The detailed amplitude analysis of the  $B \rightarrow J/\psi K^*$  decays has been performed by the BABAR [14], Belle [15], CDF [16], CLEO [17], D0 [18], and LHCb [19] collaborations. Most analyses are performed under the assumption of the absence of direct  $CP$  violation. The parameter values are given in

# Meson Particle Listings

## $B^0$

the particle listing of this *Review*. The difference between the strong phases  $\phi_{\parallel}$  and  $\phi_{\perp}$  deviates significantly from zero. The recent measurements [14,15] of  $CP$ -violating terms similar to those in  $B \rightarrow \varphi K^*$  [11] shown in Table 1 are consistent with zero.

In addition, the mixing-induced  $CP$ -violating asymmetry is measured in the  $B^0 \rightarrow J/\psi K^{*0}$  decay [1,14,15] where angular analysis allows one to separate  $CP$ -eigenstate amplitudes. This allows one to resolve the sign ambiguity of the  $\cos 2\beta$  ( $\cos 2\phi_1$ ) term that appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases  $\phi_{\parallel}$  and  $\phi_{\perp}$ , as discussed below. The BABAR experiment used a method based on the dependence on the  $K\pi$  invariant mass of the interference between the  $S$ - and  $P$ -waves to resolve the discrete ambiguity in the determination of the strong phases ( $\phi_{\parallel}, \phi_{\perp}$ ) in  $B \rightarrow J/\psi K^*$  decays [14]. The result is in agreement with the amplitude hierarchy expectation [13]. The CDF [20], D0 [21], and LHCb [22,23] experiments have studied the  $B_s^0 \rightarrow J/\psi \varphi$ ,  $J/\psi(K^+K^-)$ ,  $J/\psi(\pi^+\pi^-)$  decays and provided the lifetime, polarization, and phase measurements.

The amplitude hierarchy  $|A_0| \gg |A_+| \gg |A_-|$  was expected in  $B$  decays to light vector particles in both penguin transitions [24,25] and tree-level transitions [13]. There is confirmation by the BABAR and Belle experiments of predominantly longitudinal polarization in the tree-level  $b \rightarrow u$  transition, such as  $B^0 \rightarrow \rho^+\rho^-$  [26],  $B^+ \rightarrow \rho^0\rho^+$  [27], and  $B^+ \rightarrow \omega\rho^+$  [28]; this is consistent with the analysis of the quark helicity conservation [13]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current  $B$  samples, and limits on the transverse amplitude fraction are obtained. The small branching fractions of  $B^0 \rightarrow \rho^0\rho^0, \omega\rho^0, \omega\omega$  [30,31,32,28] indicate that  $b \rightarrow d$  penguin pollution is small in the charmless, strangeless vector-vector  $B$  decays. There is a measurement of large longitudinal polarization in  $B^0 \rightarrow \rho^0\rho^0$  [30,31,32] decays. The fraction of transverse polarization is large in decays to heavier mesons such as  $B^0 \rightarrow a_1(1260)^+a_1(1260)^-$  [29].

The interest in the polarization and  $CP$ -asymmetry measurements in penguin transition, such as  $b \rightarrow s$  decays  $B \rightarrow \varphi K^*$ ,  $\rho K^*$ ,  $\omega K^*$ , or  $B_s^0 \rightarrow \varphi\varphi$ ,  $K^*K^*$ , and  $b \rightarrow d$  decay  $B \rightarrow K^*\bar{K}^*$ , is motivated by their potential sensitivity to physics beyond the Standard Model. The decay amplitudes for  $B \rightarrow \varphi K^*$  have been measured by the BABAR, Belle, and LHCb experiments [11,9,33,34,10]. The fractions of longitudinal polarization are  $f_L = 0.50 \pm 0.05$  for the  $B^+ \rightarrow \varphi K^{*+}$  decay and  $f_L = 0.497 \pm 0.017$  for the  $B^0 \rightarrow \varphi K^{*0}$  decay. These indicate significant departure from the naive expectation of predominant longitudinal polarization, suggesting other contributions to the decay amplitude, previously neglected, either within the Standard Model, such as penguin annihilation [35] or QCD rescattering [36], or from physics beyond the Standard Model [37]. The complete set of twelve amplitude parameters measured in the  $B^0 \rightarrow \varphi K^{*0}$  decay is given in Table 1. Several

other parameters could be constructed from the above twelve parameters, as suggested in Ref. 38.

The discrete ambiguity in the phase ( $\phi_{\parallel}, \phi_{\perp}, \Delta\phi_{\parallel}, \Delta\phi_{\perp}$ ) measurements has been resolved by BABAR in favor of  $|A_+| \gg |A_-|$  through interference between the  $S$ - and  $P$ -waves of  $K\pi$ . The search for vector-tensor and vector-axialvector  $B \rightarrow \varphi K_J^{(*)}$  decays with  $J = 1, 2, 3, 4$  revealed a large fraction of longitudinal polarization in the decay  $B \rightarrow \varphi K_2^*(1430)$  with  $f_L = 0.90_{-0.07}^{+0.06}$  [11,39], but large contribution of transverse amplitude in  $B \rightarrow \varphi K_1(1270)$  with  $f_L = 0.46_{-0.15}^{+0.13}$  [40].

Like  $B \rightarrow \varphi K^*$ , the decays  $B \rightarrow \rho K^*$  and  $B \rightarrow \omega K^*$  may be sensitive to New Physics. Measurements of the longitudinal polarization fraction in  $B^+ \rightarrow \rho^0 K^{*0}$ ,  $B^+ \rightarrow \rho^+ K^{*0}$  [41] and in both vector-vector and vector-tensor final states of  $B \rightarrow \omega K_J^*$  [28] reveal a large fraction of transverse polarization, indicating an anomaly similar to  $B \rightarrow \varphi K^*$  except for a different pattern in vector-tensor final states. A large transverse polarization is also observed in the  $B_s^0 \rightarrow \varphi\varphi$  decay by CDF [42] and LHCb [43],  $B_s^0 \rightarrow K^{*0}\bar{K}^{*0}$  decays by LHCb [44], and  $B_s^0 \rightarrow \varphi K^{*0}$  decays by LHCb [45]. At the same time, measurement of the polarization in the  $b \rightarrow d$  penguin decays  $B \rightarrow K^*\bar{K}^*$  indicates a large fraction of longitudinal polarization [46]. The polarization pattern in penguin-dominated  $B$ -meson decays is not fully understood [35,36,37].

The three-body semileptonic  $B$ -meson decays, such as  $B \rightarrow V\ell_1\ell_2$ , share many features with the two-body  $B \rightarrow VV$  decays. Their differential decay width can be parameterized with the two helicity angles defined in the  $V$  and  $(\ell_1\ell_2)$  frames and with the azimuthal angle, as defined in Fig. 1. However, since the  $(\ell_1\ell_2)$  pair does not come from an on-shell particle, the angular distribution is unique to each point in the dilepton mass  $m_{\ell\ell}$  spectrum. The polarization measurements as a function of  $m_{\ell\ell}$  provide complementary information on physics beyond the Standard Model, as discussed for  $B \rightarrow K^*\ell^+\ell^-$  and  $B_s \rightarrow \phi\ell^+\ell^-$  decays in Ref. 47. The current data in these modes have been analyzed by the BABAR, Belle, CDF, LHCb, and CMS experiments [48,49].

The examples of the angular distributions and observables in  $B \rightarrow K^*\ell^+\ell^-$  are discussed in Ref. 47. Typically two angular observables have been measured in this decay in certain ranges of the dilepton mass  $m_{\ell\ell}$  [48]. One parameter is the fraction of longitudinal polarization  $F_L$ , which is determined by the  $K^*$  angular distribution and is similar to  $f_L$  defined for exclusive two-body decays. The other parameter is the forward-backward asymmetry of the lepton pair  $A_{FB}$ , which is the asymmetry of the decay rate with positive and negative values of  $\cos\theta_1$ .

In summary, there has been considerable recent interest in the polarization measurements of  $B$ -meson decays because they reveal both weak- and strong-interaction dynamics [35–37,50]. New measurements will further elucidate the pattern of spin alignment measurements in rare  $B$  decays, and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the  $B$ -decay amplitudes.

## POLARIZATION IN $B^0$ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal ( $L$ ) or both are transverse and parallel ( $\parallel$ ) or perpendicular ( $\perp$ ) to each other with the parameters  $\Gamma_L/\Gamma$ ,  $\Gamma_\parallel/\Gamma$ , and the relative phases  $\phi_\parallel$  and  $\phi_\perp$ . See the definitions in the note on "Polarization in  $B$  Decays" review in the  $B^0$  Particle Listings.

 $B^0$ - $\bar{B}^0$  MIXING

Updated April 2016 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral  $B^0$ - $\bar{B}^0$  meson systems,  $B_d^0$ - $\bar{B}_d^0$  and  $B_s^0$ - $\bar{B}_s^0$  (generically denoted  $B_q^0$ - $\bar{B}_q^0$ ,  $q = s, d$ ), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume  $CPT$  conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{L,H}\rangle = p|B_q^0\rangle \pm q|\bar{B}_q^0\rangle, \quad (1)$$

have a mass difference  $\Delta m_q = m_H - m_L > 0$ , and a total decay width difference  $\Delta\Gamma_q = \Gamma_L - \Gamma_H$ . In the absence of  $CP$  violation in the mixing,  $|q/p| = 1$ , these differences are given by  $\Delta m_q = 2|M_{12}|$  and  $|\Delta\Gamma_q| = 2|\Gamma_{12}|$ , where  $M_{12}$  and  $\Gamma_{12}$  are the off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure  $|B_q^0\rangle$  or  $|\bar{B}_q^0\rangle$  state at  $t = 0$  is given by

$$|B_q^0(t)\rangle = g_+(t)|B_q^0\rangle + \frac{q}{p}g_-(t)|\bar{B}_q^0\rangle, \quad (2)$$

$$|\bar{B}_q^0(t)\rangle = g_+(t)|\bar{B}_q^0\rangle + \frac{p}{q}g_-(t)|B_q^0\rangle, \quad (3)$$

# Meson Particle Listings

## $B^0$

which means that the flavor states remain unchanged (+) or oscillate into each other (−) with time-dependent probabilities proportional to

$$|g_{\pm}(t)|^2 = \frac{e^{-\Gamma_q t}}{2} \left[ \cosh\left(\frac{\Delta\Gamma_q}{2} t\right) \pm \cos(\Delta m_q t) \right], \quad (4)$$

where  $\Gamma_q = (\Gamma_H + \Gamma_L)/2$ . In the absence of  $CP$  violation, the time-integrated mixing probability  $\int |g_{-}(t)|^2 dt / (\int |g_{-}(t)|^2 dt + \int |g_{+}(t)|^2 dt)$  is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2 + 1)}, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}. \quad (5)$$

**Figure 1:** Dominant box diagrams for the  $B_q^0 \rightarrow \bar{B}_q^0$  transitions ( $q = d$  or  $s$ ). Similar diagrams exist where one or both  $t$  quarks are replaced with  $c$  or  $u$  quarks.

### Standard Model predictions and phenomenology

In the Standard Model, the transitions  $B_q^0 \rightarrow \bar{B}_q^0$  and  $\bar{B}_q^0 \rightarrow B_q^0$  are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two  $W$  bosons and two up-type quarks (see Fig. 1), as is the case for  $K^0 - \bar{K}^0$  mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral  $B$  meson systems, because the large  $B$  mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2} S_0(m_t^2/m_W^2) (V_{tq}^* V_{tb})^2, \quad (6)$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta_B' m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[ (V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb} \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2 \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right) \right], \quad (7)$$

where  $G_F$  is the Fermi constant,  $m_W$  the  $W$  boson mass, and  $m_i$  the mass of quark  $i$ ;  $m_{B_q}$ ,  $f_{B_q}$  and  $B_{B_q}$  are the  $B_q^0$  mass, weak decay constant and bag parameter, respectively. The known function  $S_0(x_t)$  can be approximated very well by  $0.784 x_t^{0.76}$  [4], and  $V_{ij}$  are the elements of the CKM matrix [5]. The QCD corrections  $\eta_B$  and  $\eta_B'$  are of order unity. The only non-negligible contributions to  $M_{12}$  are from box diagrams involving two top quarks. The phases of  $M_{12}$  and  $\Gamma_{12}$  satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right), \quad (8)$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the  $K^0 - \bar{K}^0$  system, the heavy state is expected to have a smaller decay width than that of the light state:  $\Gamma_H < \Gamma_L$ . Hence,  $\Delta\Gamma = \Gamma_L - \Gamma_H$  is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left| \frac{\Gamma_{12}}{M_{12}} \right| \simeq \frac{3\pi}{2} \frac{m_b^2}{m_W^2} \frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \quad (9)$$

is small, and a power expansion of  $|q/p|^2$  yields

$$\left| \frac{q}{p} \right|^2 = 1 + \left| \frac{\Gamma_{12}}{M_{12}} \right| \sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left| \frac{\Gamma_{12}}{M_{12}} \right|^2\right). \quad (10)$$

Therefore, considering both Eqs. (8) and (9), the  $CP$ -violating parameter

$$1 - \left| \frac{q}{p} \right|^2 \simeq \text{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \quad (11)$$

is expected to be very small:  $\sim \mathcal{O}(10^{-3})$  for the  $B_d^0 - \bar{B}_d^0$  system and  $\lesssim \mathcal{O}(10^{-4})$  for the  $B_s^0 - \bar{B}_s^0$  system [6].

In the approximation of negligible  $CP$  violation in mixing, the ratio  $\Delta\Gamma_q/\Delta m_q$  is equal to the small quantity  $|\Gamma_{12}/M_{12}|$  of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the  $B_d^0 - \bar{B}_d^0$  and  $B_s^0 - \bar{B}_s^0$  systems. Calculations [7] yield  $\sim 5 \times 10^{-3}$  with a  $\sim 20\%$  uncertainty. Given the published experimental knowledge [8] on the mixing parameter  $x_q$

$$\begin{cases} x_d = 0.775 \pm 0.006 & (B_d^0 - \bar{B}_d^0 \text{ system}) \\ x_s = 26.81 \pm 0.10 & (B_s^0 - \bar{B}_s^0 \text{ system}) \end{cases}, \quad (12)$$

the Standard Model thus predicts that  $\Delta\Gamma_d/\Gamma_d$  is very small (below 1%), but  $\Delta\Gamma_s/\Gamma_s$  considerably larger ( $\sim 10\%$ ). These width differences are caused by the existence of final states to which both the  $B_q^0$  and  $\bar{B}_q^0$  mesons can decay. Such decays involve  $b \rightarrow c\bar{c}q$  quark-level transitions, which are Cabibbo-suppressed if  $q = d$  and Cabibbo-allowed if  $q = s$ .

A complete set of Standard Model predictions for all mixing parameters in both the  $B_d^0 - \bar{B}_d^0$  and  $B_s^0 - \bar{B}_s^0$  systems can be found in Ref. 9.

### Experimental issues and methods for oscillation analyses

Time-integrated measurements of  $B^0 - \bar{B}^0$  mixing were published for the first time in 1987 by UA1 [10] and ARGUS [11], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced  $b\bar{b}$  pairs. Such analyses cannot easily separate the contributions from the different  $b$ -hadron species, therefore, the clean environment of  $\Upsilon(4S)$  machines (where only  $B_d^0$  and charged  $B_u$  mesons are produced) is in principle best suited to measure  $\chi_d$ .

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies  $\Delta m_d$  and  $\Delta m_s$ , from the proper time distributions of

$B_d^0$  or  $B_s^0$  candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the  $B_s^0\text{--}\bar{B}_s^0$  system, where the large value of  $x_s$  implies maximal mixing, *i.e.*,  $\chi_s \simeq 1/2$ . In such analyses, the  $B_d^0$  or  $B_s^0$  mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a  $b \rightarrow \ell^-$  decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron, LHC), the proper time  $t = \frac{m_B}{p}L$  is measured from the distance  $L$  between the production vertex and the  $B$  decay vertex, and from an estimate of the  $B$  momentum  $p$ . At asymmetric  $B$  factories (KEKB, PEP-II), producing  $e^+e^- \rightarrow \Upsilon(4S) \rightarrow B_d^0\bar{B}_d^0$  events with a boost  $\beta\gamma$  ( $= 0.425, 0.55$ ), the proper time difference between the two  $B$  candidates is estimated as  $\Delta t \simeq \frac{\Delta z}{\beta\gamma c}$ , where  $\Delta z$  is the spatial separation between the two  $B$  decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance  $\mathcal{S}$  of a  $B_d^0$  or  $B_s^0$  oscillation signal can be approximated as [12]

$$\mathcal{S} \approx \sqrt{N/2} f_{\text{sig}} (1 - 2\eta) e^{-(\Delta m \sigma_t)^2/2}, \quad (13)$$

where  $N$  is the number of selected and tagged candidates,  $f_{\text{sig}}$  is the fraction of signal in that sample,  $\eta$  is the total mistag probability, and  $\sigma_t$  is the resolution on proper time (or proper time difference). The quantity  $\mathcal{S}$  decreases very quickly as  $\Delta m$  increases; this dependence is controlled by  $\sigma_t$ , which is therefore a critical parameter for  $\Delta m_s$  analyses. At high-energy colliders, the proper time resolution  $\sigma_t \sim \frac{m_B}{\langle p \rangle} \sigma_L \oplus t \frac{\sigma_p}{p}$  includes a constant contribution due to the decay length resolution  $\sigma_L$  (typically 0.04–0.3 ps), and a term due to the relative momentum resolution  $\sigma_p/p$  (typically 10–20% for partially reconstructed decays), which increases with proper time. At  $B$  factories, the boost of the  $B$  mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller  $B$  boost).

In order to tag a  $B$  candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities,  $\eta_i$  and  $\eta_f$ , degrade  $\mathcal{S}$  by a total factor  $(1 - 2\eta) = (1 - 2\eta_i)(1 - 2\eta_f)$ . In lepton-based analyses, the final state is tagged by the charge of the lepton from  $b \rightarrow \ell^-$  decays; the largest contribution to  $\eta_f$  is then due to  $\bar{b} \rightarrow \bar{c} \rightarrow \ell^-$  decays. Alternatively, the charge of a reconstructed charm meson ( $D^{*-}$  from  $B_d^0$  or  $D_s^-$  from  $B_s^0$ ), or that of a kaon hypothesized to come from a  $b \rightarrow c \rightarrow s$  decay [13], can be used. For fully-inclusive analyses based on topological vertexing, final-state tagging techniques include jet-charge [14] and charge-dipole [15,16] methods. At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided into two groups: the ones that tag the initial charge of the  $\bar{b}$  quark contained in the  $B$  candidate itself (same-side tag), and the ones that tag the initial charge of the other  $b$  quark produced in the event

(opposite-side tag). On the same side, the sign of a charged pion, kaon or proton from the primary vertex is correlated with the production state of the  $B_d^0$  or  $B_s^0$  if that particle is a decay product of a  $B^{**}$  state or the first in the fragmentation chain [17,18]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from  $b \rightarrow \ell^-$ , of a kaon from  $b \rightarrow c \rightarrow s$  or of a charm hadron from  $b \rightarrow c$  [19] can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the  $Z \rightarrow b\bar{b}$  decays, and provided another very interesting and effective initial state tag based on the polar angle of the  $B$  candidate [15]. Initial state tags have also been combined to reach  $\eta_i \sim 26\%$  at LEP [18,20], or even 22% at SLD [15] with full efficiency. In the case  $\eta_f = 0$ , this corresponds to an effective tagging efficiency  $Q = \epsilon D^2 = \epsilon(1 - 2\eta)^2$ , where  $\epsilon$  is the tagging efficiency, in the range 23–31%. The equivalent figure achieved by CDF during Tevatron Run I was  $\sim 3.5\%$  [21], reflecting the fact that tagging is more difficult at hadron colliders. The CDF and DØ analyses of Tevatron Run II data reached  $\epsilon D^2 = (1.8 \pm 0.1)\%$  [22] and  $(2.5 \pm 0.2)\%$  [23] for opposite-side tagging, while same-side kaon tagging (for  $B_s^0$  analyses) contributed an additional 3.7–4.8% at CDF [22], and pushed the combined performance to  $(4.7 \pm 0.5)\%$  at DØ [24]. LHCb, operating in the forward region at the LHC where the environment is different in terms of track multiplicity and  $b$ -hadron production kinematics, has reported  $\epsilon D^2 = (2.10 \pm 0.25)\%$  [25] for opposite-side tagging and  $(1.80 \pm 0.26)\%$  [26] for same-side kaon tagging, with a combined figure ranging typically between  $(3.73 \pm 0.15)\%$  [27] and  $(5.33 \pm 0.25)\%$  [28] depending on the mode in which the tagged meson is reconstructed.

At  $B$  factories, the flavor of a  $B_d^0$  meson at production cannot be determined, since the two neutral  $B$  mesons produced in a  $\Upsilon(4S)$  decay evolve in a coherent  $P$ -wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where  $t$  is replaced with  $\Delta t$  (which will take negative values half of the time). Hence, the “initial state” tag of a  $B$  can be taken as the final-state tag of the other  $B$ . Effective tagging efficiencies of 30% are achieved by BaBar and Belle [29], using different techniques including  $b \rightarrow \ell^-$  and  $b \rightarrow c \rightarrow s$  tags. It is worth noting that, in this case, mixing of the other  $B$  (*i.e.*, the coherent mixing occurring before the first  $B$  decay) does not contribute to the mistag probability.

Before the experimental observation of a decay-width difference, oscillation analyses typically neglected  $\Delta\Gamma$  in Eq. (4), and described the physics with the functions  $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$  (high-energy colliders) or  $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$  (asymmetric  $\Upsilon(4S)$  machines). As can be seen from Eq. (4), a non-zero value of  $\Delta\Gamma$  would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements

# Meson Particle Listings

## $B^0$

of  $\Delta m$  are usually extracted from the data using a maximum likelihood fit.

### $\Delta m_d$ and $\Delta \Gamma_d$ measurements

Many  $B_d^0$ - $\bar{B}_d^0$  oscillations analyses have been published [30] by the ALEPH [31], DELPHI [16,32], L3 [33], OPAL [34,35] BaBar [36], Belle [37], CDF [17], DØ [23], and LHCb [38–40] collaborations. Although a variety of different techniques have been used, the individual  $\Delta m_d$  results obtained at LEP and Tevatron have remarkably similar precision. Their average is compatible with the recent and more precise measurements from the asymmetric  $B$  factories and the LHC. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or  $b$ -hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the  $b$ -hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of  $b$  hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published [16,17,23,31–40] or recently submitted [41] measurements and accounting for all identified correlations yields  $\Delta m_d = 0.5065 \pm 0.0016(\text{stat}) \pm 0.0011(\text{syst}) \text{ ps}^{-1}$  [8], a result dominated by the new LHCb measurement with  $B^0 \rightarrow D^{(*)-} \mu^+ \nu_\mu X$  decays [41].

On the other hand, ARGUS and CLEO have published time-integrated measurements [42–44], which average to  $\chi_d = 0.182 \pm 0.015$ . Following Ref. 44, the width difference  $\Delta \Gamma_d$  could in principle be extracted from the measured value of  $\Gamma_d$  and the above averages for  $\Delta m_d$  and  $\chi_d$  (see Eq. (5)), provided that  $\Delta \Gamma_d$  has a negligible impact on the  $\Delta m_d$  measurements. However, direct time-dependent studies published by DELPHI [16], BaBar [45], Belle [46] and LHCb [47] provide stronger constraints, which can be combined to yield [8]

$$\Delta \Gamma_d / \Gamma_d = -0.003 \pm 0.015. \quad (14)$$

Assuming  $\Delta \Gamma_d = 0$  and no  $CP$  violation in mixing, and using the measured  $B_d^0$  lifetime of  $1.520 \pm 0.004 \text{ ps}$ , the  $\Delta m_d$  and  $\chi_d$  results are combined to yield the world average [48]

$$\Delta m_d = 0.5064 \pm 0.0019 \text{ ps}^{-1} \quad (15)$$

or, equivalently,

$$\chi_d = 0.1860 \pm 0.0011. \quad (16)$$

This  $\Delta m_d$  value provides an estimate of  $2|M_{12}|$ , and can be used with Eq. (6) to extract  $|V_{td}|$  within the Standard Model [49]. The main experimental uncertainties on the result come from  $m_t$  and  $\Delta m_d$ , but are completely negligible with respect to the uncertainty due to the hadronic matrix element  $f_{B_d} \sqrt{B_{B_d}} = 216 \pm 15 \text{ MeV}$  [50] obtained from unquenched lattice QCD calculations.

**Figure 2:** Proper time distribution of  $B_s^0 \rightarrow D_s^- \pi^+$  candidates tagged as mixed (red) or unmixed (blue) in the LHCb experiment, displaying  $B_s^0$ - $\bar{B}_s^0$  oscillations (from Ref. [51]).

### $\Delta m_s$ and $\Delta \Gamma_s$ measurements

After many years of intense search at LEP and SLC,  $B_s^0$ - $\bar{B}_s^0$  oscillations were first observed in 2006 by CDF using  $1 \text{ fb}^{-1}$  of Tevatron Run II data [22]. More recently LHCb observed  $B_s^0$ - $\bar{B}_s^0$  oscillations independently with  $B_s^0 \rightarrow D_s^- \pi^+$  [38,51],  $B_s^0 \rightarrow D_s^- \mu^+ \nu X$  [40] and even  $B_s^0 \rightarrow J/\psi K^+ K^-$  [27] decays, using between 1 and  $3 \text{ fb}^{-1}$  of data collected at the LHC until the end of 2012. Taking systematic correlations into account, the average of all published measurements of  $\Delta m_s$  [22,27,38,40,51] is

$$\Delta m_s = 17.757 \pm 0.020(\text{stat}) \pm 0.007(\text{syst}) \text{ ps}^{-1}, \quad (17)$$

dominated by LHCb (see Fig. 2) and still statistically limited.

The information on  $|V_{ts}|$  obtained in the framework of the Standard Model is hampered by the hadronic uncertainty, as in the  $B_d^0$  case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}} \xi^2 \left| \frac{V_{ts}}{V_{td}} \right|^2, \quad (18)$$

where  $\xi = (f_{B_s} \sqrt{B_{B_s}}) / (f_{B_d} \sqrt{B_{B_d}}) = 1.268 \pm 0.063$  is an SU(3) flavor-symmetry breaking factor obtained from unquenched lattice QCD calculations [50]. Using the measurements of Eqs. (15) and (17), one can extract

$$\left| \frac{V_{td}}{V_{ts}} \right| = 0.2159 \pm 0.0004(\text{exp}) \pm 0.0107(\text{lattice}), \quad (19)$$

in good agreement with (but much more precise than) the value obtained from the ratio of the  $b \rightarrow d\gamma$  and  $b \rightarrow s\gamma$  transition rates observed at the  $B$  factories [49].

The CKM matrix can be constrained using experimental results on observables such as  $\Delta m_d$ ,  $\Delta m_s$ ,  $|V_{ub}/V_{cb}|$ ,  $\epsilon_K$ , and  $\sin(2\beta)$  together with theoretical inputs and unitarity conditions [49,52,53]. The constraint from our knowledge on the ratio  $\Delta m_s/\Delta m_d$  is more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the  $\Delta m_d$  measurements alone, due to the reduced hadronic uncertainty in Eq. (18). We also note that the measured value of  $\Delta m_s$  is consistent with the Standard Model prediction obtained

from CKM fits where no experimental information on  $\Delta m_s$  is used, *e.g.*,  $17.5 \pm 1.1 \text{ ps}^{-1}$  [52] or  $16.73^{+0.82}_{-0.57} \text{ ps}^{-1}$  [53].

Information on  $\Delta\Gamma_s$  can be obtained from the study of the proper time distribution of untagged  $B_s^0$  samples [54]. In the case of an inclusive  $B_s^0$  selection [55], or a flavor-specific (semileptonic or hadronic)  $B_s^0$  decay selection [20,56,57], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants  $\Gamma_{L,H} = \Gamma_s \pm \Delta\Gamma_s/2$ . In principle, this provides sensitivity to both  $\Gamma_s$  and  $(\Delta\Gamma_s/\Gamma_s)^2$ . Ignoring  $\Delta\Gamma_s$  and fitting for a single exponential leads to an estimate of  $\Gamma_s$  with a relative bias proportional to  $(\Delta\Gamma_s/\Gamma_s)^2$ . An alternative approach, which is directly sensitive to first order in  $\Delta\Gamma_s/\Gamma_s$ , is to determine the effective lifetime of untagged  $B_s^0$  candidates decaying to pure  $CP$  eigenstates; measurements exist for  $B_s^0 \rightarrow K^+K^-$  [58],  $B_s^0 \rightarrow D_s^+D_s^-$  [57],  $B_s^0 \rightarrow J/\psi f_0(980)$  [59],  $B_s^0 \rightarrow J/\psi\pi^+\pi^-$  [60] and  $B_s^0 \rightarrow J/\psi K_S^0$  [61]. The extraction of  $1/\Gamma_s$  and  $\Delta\Gamma_s$  from such measurements, discussed in detail in Ref. [62], requires additional information in the form of theoretical assumptions or external inputs on weak phases and hadronic parameters. In what follows, the effective lifetimes from the above decays to pure  $CP$  eigenstates will be assumed to be dominated by a single weak phase.

The best sensitivity to  $1/\Gamma_s$  and  $\Delta\Gamma_s$  is achieved by the time-dependent measurements of the  $B_s^0 \rightarrow J/\psi\phi$  (or more generally  $B_s^0 \rightarrow J/\psi K^+K^-$ ) decay rates performed at CDF [63], DØ [64], ATLAS [65,66], CMS [67] and LHCb [27], where the  $CP$ -even and  $CP$ -odd amplitudes are separated statistically through a full angular analysis. The LHCb collaboration analyzes the  $B_s^0 \rightarrow J/\psi K^+K^-$  decay considering that the  $K^+K^-$  system can be in a P-wave or S-wave state, and measures the dependence of the strong phase difference between the P-wave and S-wave amplitudes as a function of the  $K^+K^-$  invariant mass [27,68]; this allows the unambiguous determination of the sign of  $\Delta\Gamma_s$ , which is found to be positive. All these studies use both untagged and tagged  $B_s^0$  candidates and are optimized for the measurement of the  $CP$ -violating phase  $\phi_s$ , defined as the weak phase difference between the  $B_s^0\text{--}\bar{B}_s^0$  mixing amplitude and the  $b \rightarrow c\bar{c}s$  decay amplitude. As reported below in Eq. (28), the current experimental average of  $\phi_s$  is consistent with zero. Assuming no  $CP$  violation (*i.e.*,  $\phi_s = 0$ ) a combination [8] of the published  $B_s^0 \rightarrow J/\psi\phi$ ,  $J/\psi K^+K^-$  analyses [27,63–65] and of the published effective lifetime measurements with flavor-specific [20,56,57] and pure  $CP$  [57–61] final states yields

$$\Delta\Gamma_s = +0.082 \pm 0.007 \text{ ps}^{-1} \quad \text{and} \quad 1/\Gamma_s = 1.510 \pm 0.005 \text{ ps}, \quad (20)$$

or, equivalently,

$$1/\Gamma_L = 1.422 \pm 0.008 \text{ ps} \quad \text{and} \quad 1/\Gamma_H = 1.610 \pm 0.012 \text{ ps}, \quad (21)$$

in good agreement with the Standard Model prediction  $\Delta\Gamma_s = 0.088 \pm 0.020 \text{ ps}^{-1}$  [9].

**Table 1:**  $\bar{\chi}$  and  $b$ -hadron fractions (see text).

	in $Z$ decays [8]	at Tevatron [8]	at LHC [80,82]
$\bar{\chi}$	$0.1259 \pm 0.0042$	$0.147 \pm 0.011$	
$f_u = f_d$	$0.407 \pm 0.007$	$0.344 \pm 0.021$	
$f_s$	$0.100 \pm 0.008$	$0.115 \pm 0.013$	
$f_{\text{baryon}}$	$0.085 \pm 0.011$	$0.197 \pm 0.046$	
$f_s/f_d$	$0.246 \pm 0.023$	$0.334 \pm 0.041$	$0.249 \pm 0.014$

Estimates of  $\Delta\Gamma_s/\Gamma_s$  obtained from measurements of the  $B_s^0 \rightarrow D_s^{(*)+}D_s^{(*)-}$  branching fractions are not included in the average, since they are based on the questionable [7] assumption that these decays account for all  $CP$ -even final states.

#### Average $b$ -hadron mixing probability and $b$ -hadron production fractions at high energy

Mixing measurements can significantly improve our knowledge on the fractions  $f_u$ ,  $f_d$ ,  $f_s$ , and  $f_{\text{baryon}}$ , defined as the fractions of  $B_u$ ,  $B_d$ ,  $B_s^0$ , and  $b$ -baryons in an unbiased sample of weakly decaying  $b$  hadrons produced in high-energy collisions. Indeed, time-integrated mixing analyses using lepton pairs from  $b\bar{b}$  events at high energy measure the quantity

$$\bar{\chi} = f'_d \chi_d + f'_s \chi_s, \quad (22)$$

where  $f'_d$  and  $f'_s$  are the fractions of  $B_d^0$  and  $B_s^0$  hadrons in a sample of semileptonic  $b$ -hadron decays. Assuming that all  $b$  hadrons have the same semileptonic decay width implies  $f'_q = f_q/(\Gamma_q\tau_b)$  ( $q = s, d$ ), where  $\tau_b$  is the average  $b$ -hadron lifetime. Hence  $\bar{\chi}$  measurements performed at LEP [69] and Tevatron [70,71], together with the  $\chi_d$  average of Eq. (16) and the very good approximation  $\chi_s = 1/2$  (in fact  $\chi_s = 0.499308 \pm 0.000005$  from Eqs. (5), (17) and (20)), provide constraints on the fractions  $f_d$  and  $f_s$ .

The LEP experiments have measured  $\mathcal{B}(\bar{b} \rightarrow B_s^0) \times \mathcal{B}(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell X)$  [72],  $\mathcal{B}(b \rightarrow \Lambda_b^0) \times \mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell X)$  [73], and  $\mathcal{B}(b \rightarrow \Xi_b^-) \times \mathcal{B}(\Xi_b^- \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X)$  [74] from partially reconstructed final states including a lepton,  $f_{\text{baryon}}$  from protons identified in  $b$  events [75], and the production rate of charged  $b$  hadrons [76]. The  $b$ -hadron fraction ratios measured at CDF are based on double semileptonic  $K^*\mu\mu$  and  $\phi\mu\mu$  final states [77] and lepton-charm final states [78]; in addition CDF and DØ have both measured strange  $b$ -baryon production [79]. On the other hand, fraction ratios have been studied by LHCb using fully reconstructed hadronic  $B_s^0$  and  $B_d^0$  decays [80], as well as semileptonic decays [81]. ATLAS has measured  $f_s/f_d$  using  $B_s^0 \rightarrow J/\psi\phi$  and  $B^0 \rightarrow J/\psi K^{*0}$  decays [82]. Both CDF and LHCb observe that the ratio  $f_{\Lambda_b^0}/(f_u + f_d)$  decreases with the transverse momentum of the lepton+charm system, indicating that the  $b$ -hadron fractions are not the same in different environments. We therefore provide sets of fractions separately for LEP and Tevatron (and no complete set for LHC, where strange  $b$ -baryon production has not been measured yet). A combination of all the available information under the constraints  $f_u = f_d$ ,  $f_u + f_d + f_s + f_{\text{baryon}} = 1$ , and Eq. (22), yields the averages shown in the first two columns of Table 1.

## $B^0$

### $CP$ -violation studies

Evidence for  $CP$  violation in  $B_q^0\text{--}\bar{B}_q^0$  mixing has been searched for, both with flavor-specific and inclusive  $B_q^0$  decays, in samples where the initial flavor state is tagged, usually with a lepton from the other  $b$ -hadron in the event. In the case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\text{SL}}^q = \frac{N(\bar{B}_q^0(t) \rightarrow \ell^+ \nu_\ell X) - N(B_q^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)}{N(\bar{B}_q^0(t) \rightarrow \ell^+ \nu_\ell X) + N(B_q^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)} \simeq 1 - |q/p|_q^2 \quad (23)$$

has been measured either in time-integrated analyses at CLEO [44,83], BaBar [84], CDF [85], DØ [86–88] and LHCb [89], or in time-dependent analyses at LEP [35,90], BaBar [45,91] and Belle [92]. In the inclusive case, also investigated at LEP [90,93], no final-state tag is used, and the asymmetry [94]

$$\begin{aligned} & \frac{N(\bar{B}_q^0(t) \rightarrow \text{all}) - N(B_q^0(t) \rightarrow \text{all})}{N(\bar{B}_q^0(t) \rightarrow \text{all}) + N(B_q^0(t) \rightarrow \text{all})} \\ & \simeq \mathcal{A}_{\text{SL}}^q \left[ \sin^2 \left( \frac{\Delta m_q t}{2} \right) - \frac{x_q}{2} \sin(\Delta m_q t) \right] \end{aligned} \quad (24)$$

must be measured as a function of the proper time to extract information on  $CP$  violation. In addition LHCb has studied the time dependence of the charge asymmetry of  $B^0 \rightarrow D^{(*)-} \mu^+ \nu_\mu X$  decays without tagging the initial state [95], which would be equal to

$$\frac{N(D^{(*)-} \mu^+ \nu_\mu X) - N(D^{(*)+} \mu^- \bar{\nu}_\mu X)}{N(D^{(*)-} \mu^+ \nu_\mu X) + N(D^{(*)+} \mu^- \bar{\nu}_\mu X)} = \mathcal{A}_{\text{SL}}^d \frac{1 - \cos(\Delta m_d t)}{2} \quad (25)$$

in absence of detection and production asymmetries.

The DØ collaboration measures a like-sign dimuon charge asymmetry in semileptonic  $b$  decays that deviates by  $2.8\sigma$  from the tiny Standard Model prediction and concludes, from a more refined analysis in bins of muon impact parameters, that the overall discrepancy is at the level of  $3.6\sigma$  [86]. In all other cases, asymmetries compatible with zero (and the Standard Model [9]) have been found, with a precision limited by the available statistics. Several of the analyses at high energy don't disentangle the  $B_d^0$  and  $B_s^0$  contributions, and either quote a mean asymmetry or a measurement of  $\mathcal{A}_{\text{SL}}^d$  assuming  $\mathcal{A}_{\text{SL}}^s = 0$ : we no longer include these in the average. An exception is the latest dimuon DØ analysis [86], which separates the two contributions by exploiting their dependence on the muon impact parameter cut. The resulting measurements of  $\mathcal{A}_{\text{SL}}^d$  and  $\mathcal{A}_{\text{SL}}^s$  are then both compatible with the Standard Model. They are also correlated. We therefore perform a two-dimensional average of the measurements of Refs. [44,45,83,84,86–89,91,92,95] and obtain [8]

$$\mathcal{A}_{\text{SL}}^d = -0.0015 \pm 0.0017, \text{ or } |q/p|_d = 1.0007 \pm 0.0009, \quad (26)$$

$$\mathcal{A}_{\text{SL}}^s = -0.0075 \pm 0.0041, \text{ or } |q/p|_s = 1.0038 \pm 0.0021, \quad (27)$$

with a correlation coefficient of  $-0.16$  between  $\mathcal{A}_{\text{SL}}^d$  and  $\mathcal{A}_{\text{SL}}^s$ . These results show no evidence of  $CP$  violation and don't constrain yet the Standard Model.

**Figure 3:** 68% CL contours in the  $(\phi_s, \Delta\Gamma_s)$  plane, showing the measurements from CDF [63], DØ [64], ATLAS [65,66], CMS [67] and LHCb [27,28,96], with their combination [8]. The thin rectangle represents the Standard Model predictions of  $\phi_s$  [53] and  $\Delta\Gamma_s$  [9].

$CP$  violation induced by  $B_s^0\text{--}\bar{B}_s^0$  mixing in  $b \rightarrow c\bar{c}s$  decays has been a field of very active study in the past few years. In addition to the previously mentioned  $B_s^0 \rightarrow J/\psi\phi$  and  $B_s^0 \rightarrow J/\psi K^+ K^-$  studies, the decay modes  $B_s^0 \rightarrow J/\psi\pi^+\pi^-$  (including  $B_s^0 \rightarrow J/\psi f_0(980)$ ) [96] and  $B_s^0 \rightarrow D_s^+ D_s^-$  [28] have also been analyzed by LHCb to measure  $\phi_s$ , without the need for an angular analysis. The  $J/\psi\pi^+\pi^-$  final state has been shown indeed to be (very close to) a pure  $CP$ -odd state [97]. A two-dimensional fit [8] of all these results [27,28,63–67,96] in the  $(\phi_s, \Delta\Gamma_s)$  plane, shown on Fig. 3, yields [48]

$$\phi_s = -0.033 \pm 0.033. \quad (28)$$

This is consistent with the Standard Model prediction for  $\phi_s$ , which is equal to  $-2\beta_s = -2\arg(-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)) = -0.0376^{+0.0008}_{-0.0007}$  [53], assuming negligible Penguin pollution.

### Summary

$B^0\text{--}\bar{B}^0$  mixing has been and still is a field of intense study. The mass differences in the  $B_d^0\text{--}\bar{B}_d^0$  and  $B_s^0\text{--}\bar{B}_s^0$  systems are now known to relative precisions of 0.38% and 0.12%, respectively. The non-zero decay width difference in the  $B_s^0\text{--}\bar{B}_s^0$  system is well established, with a relative difference of  $\Delta\Gamma_s/\Gamma_s = (12.4 \pm 1.1)\%$ , meaning that the heavy state of the  $B_s^0\text{--}\bar{B}_s^0$  system lives  $\sim 13\%$  longer than the light state. In contrast, the relative decay width difference in the  $B_d^0\text{--}\bar{B}_d^0$  system,  $\Delta\Gamma_d/\Gamma_d = (-0.3 \pm 1.5)\%$ , is still consistent with zero.  $CP$  violation in mixing has not been observed yet, with precisions on the semileptonic asymmetries below 0.5%. An impressive progress has been achieved in the measurement of the mixing-induced phase  $\phi_s$  in  $B_s^0$  decays proceeding through the  $b \rightarrow c\bar{c}s$  transition, with an uncertainty of 33 mrad. Despite these significant improvements, all observations remain consistent with the Standard Model expectations.

However, the measurements where New Physics might show up are still statistically limited. More results are awaited from the LHC experiments and Belle II, with promising prospects for the investigation of the  $CP$ -violating phase  $\arg(-M_{12}/\Gamma_{12})$  and an improved determination of  $\phi_s$ .

See key on page 601

Mixing studies have clearly reached the stage of precision measurements, where much effort is needed, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the  $B_d^0$  and  $B_s^0$  mixing amplitudes (magnitudes and phases) with all other measured flavor-physics observables will be possible within the Standard Model, leading to very tight limits on (or otherwise a long-awaited surprise about) New Physics.

### $B^0\text{-}\bar{B}^0$ MIXING PARAMETERS

For a discussion of  $B^0\text{-}\bar{B}^0$  mixing see the note on “ $B^0\text{-}\bar{B}^0$  Mixing” in the  $B^0$  Particle Listings above.

$\chi_d$  is a measure of the time-integrated  $B^0\text{-}\bar{B}^0$  mixing probability that a produced  $B^0(\bar{B}^0)$  decays as a  $\bar{B}^0(B^0)$ . Mixing violates  $\Delta B \neq 2$  rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B_H^0} - m_{B_L^0}) \tau_{B^0},$$

where  $H, L$  stand for heavy and light states of two  $B^0$   $CP$  eigenstates and

$$\tau_{B^0} = \frac{1}{0.5(\Gamma_{B_H^0} + \Gamma_{B_L^0})}.$$

### $\chi_d$

This  $B^0\text{-}\bar{B}^0$  mixing parameter is the probability (integrated over time) that a produced  $B^0$  (or  $\bar{B}^0$ ) decays as a  $\bar{B}^0$  (or  $B^0$ ), e.g. for inclusive lepton decays

$$\chi_d = \frac{\Gamma(B^0 \rightarrow \ell^- X \text{ (via } \bar{B}^0))}{\Gamma(B^0 \rightarrow \ell^\pm X)} = \frac{\Gamma(\bar{B}^0 \rightarrow \ell^+ X \text{ (via } B^0))}{\Gamma(\bar{B}^0 \rightarrow \ell^\pm X)}$$

Where experiments have measured the parameter  $r = \chi/(1-\chi)$ , we have converted to  $\chi$ . Mixing violates the  $\Delta B \neq 2$  rule.

Note that the measurement of  $\chi$  at energies higher than the  $\Upsilon(4S)$  have not separated  $\chi_d$  from  $\chi_s$  where the subscripts indicate  $B^0(\bar{B}^0)$  or  $B_s^0(\bar{B}_s^0)$ . They are listed in the  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section.

The experiments at  $\Upsilon(4S)$  make an assumption about the  $B^0\text{-}\bar{B}^0$  fraction and about the ratio of the  $B^\pm$  and  $B^0$  semileptonic branching ratios (usually that it equals one).

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements, includes  $\chi_d$  calculated from  $\Delta m_{B^0}$  and  $\tau_{B^0}$ .

$<0.27$	90	<sup>10</sup> AVERY	84 CLEO	$e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> BEHRENS 00B uses high-momentum lepton tags and partially reconstructed  $\bar{B}^0 \rightarrow D^{*+}\pi^-, \rho^-$  decays to determine the flavor of the  $B$  meson.

<sup>2</sup> ALBRECHT 94 reports  $r=0.194 \pm 0.062 \pm 0.054$ . We convert to  $\chi$  for comparison. Uses tagged events (lepton + pion from  $D^*$ ).

<sup>3</sup> BARTELT 93 analysis performed using tagged events (lepton+pion from  $D^*$ ). Using dilepton events they obtain  $0.157 \pm 0.016^{+0.033}_{-0.028}$ .

<sup>4</sup> ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of  $r = 20.6 \pm 7.0\%$  is directly measured. The value can be used to measure  $x = \Delta M/\Gamma = 0.72 \pm 0.15$  for the  $B_d^0$  meson. Assumes  $\tau_{B^+}/\tau_{B^0} = 1.0 \pm 0.05$  and uses  $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14)(\tau_{B^\pm}/\tau_{B^0})$ .

<sup>5</sup> Uses  $D^{*+}K^\pm$  correlations.

<sup>6</sup> Uses  $(D^{*+}\ell^-)K^\pm$  correlations.

<sup>7</sup> These experiments see a combination of  $B_s$  and  $B_d$  mesons.

<sup>8</sup> ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged  $B$  decays plus leptons, and one fully reconstructed event. Measures  $r=0.21 \pm 0.08$ . We convert to  $\chi$  for comparison. Superseded by ALBRECHT 92L.

<sup>9</sup> BEAN 87B measured  $r < 0.24$ ; we converted to  $\chi$ .

<sup>10</sup> Same-sign dilepton events. Limit assumes semileptonic BR for  $B^+$  and  $B^0$  equal. If  $B^0/B^\pm$  ratio  $< 0.58$ , no limit exists. The limit was corrected in BEAN 87B from  $r < 0.30$  to  $r < 0.37$ . We converted this limit to  $\chi$ .

$$\Delta m_{B^0} = m_{B_H^0} - m_{B_L^0}$$

$\Delta m_{B^0}$  is a measure of  $2\pi$  times the  $B^0\text{-}\bar{B}^0$  oscillation frequency in time-dependent mixing experiments.

The second “OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first “OUR EVALUATION”, also provided by the HFAG, includes  $\Delta m_d$  calculated from  $\chi_d$  measured at  $\Upsilon(4S)$ .

<sup>1</sup> Measured using  $B^0 \rightarrow D^-\pi^+$  and  $B^0 \rightarrow J/\psi K^*(892)^0$  decays.

<sup>2</sup> Measured using  $B^0 \rightarrow D^-\pi^+$ .

<sup>3</sup> Uses opposite-side flavor-tagging with  $B \rightarrow D^{(*)}\mu^+\mu^-X$  events.

<sup>4</sup> Measured using a simultaneous fit of the  $B^0$  lifetime and  $\bar{B}^0\text{-}B^0$  oscillation frequency  $\Delta m_d$  in the partially reconstructed  $B^0 \rightarrow D^{*-}\ell^+\nu$  decays.

<sup>5</sup> Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.

<sup>6</sup> Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

<sup>7</sup> AUBERT 03C uses a sample of approximately 14,000 exclusively reconstructed  $B^0 \rightarrow D^*(2010)^-\ell^+\nu$  and simultaneously measures the lifetime and oscillation frequency.

# Meson Particle Listings

## $B^0$

- <sup>8</sup> HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports  $f_{+}/f_0 = 1.01 \pm 0.03 \pm 0.09$  and  $CPT$  violation parameters in  $B^0$ - $\bar{B}^0$  mixing.
- <sup>9</sup> ZHENG 03 data analyzed using partially reconstructed  $\bar{B}^0 \rightarrow D^{*-}\pi^+$  decay and a flavor tag based on the charge of the lepton from the accompanying  $B$  decay.
- <sup>10</sup> Uses a tagged sample of fully-reconstructed neutral  $B$  decays at  $\Upsilon(4S)$ .
- <sup>11</sup> Measured based on the time evolution of dilepton events in  $\Upsilon(4S)$  decays.
- <sup>12</sup> Data analyzed using partially reconstructed  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}$  decay and a combination of flavor tags from the rest of the event.
- <sup>13</sup> Uses di-muon events.
- <sup>14</sup> Uses jet-charge and lepton-flavor tagging.
- <sup>15</sup> Uses  $\ell^+D^{*+}\ell^-$  events.
- <sup>16</sup> Uses  $\pi^-B$  in the same side.
- <sup>17</sup> Uses  $\ell\text{-}\ell$ .
- <sup>18</sup> Uses  $\ell\text{-}Q_{\text{hem}}$ .
- <sup>19</sup> Uses  $\ell\text{-}\ell$  with impact parameters.
- <sup>20</sup> Uses  $D^{*\pm}Q_{\text{hem}}$ .
- <sup>21</sup> Uses  $\pi_S^{\pm}\ell\text{-}Q_{\text{hem}}$ .
- <sup>22</sup> Uses  $D^{*\pm}\ell/Q_{\text{hem}}$ .
- <sup>23</sup> Uses  $D^{*\pm}\ell\text{-}Q_{\text{hem}}$ .
- <sup>24</sup> Uses  $D^{*\pm}\ell$ .
- <sup>25</sup> AUBERT 02N result based on the same analysis and data sample reported in AUBERT 02I.
- <sup>26</sup> Uses a tagged sample of  $B^0$  decays reconstructed in the mode  $B^0 \rightarrow D^{*}\ell\nu$ .
- <sup>27</sup> Uses a tagged sample of fully-reconstructed hadronic  $B^0$  decays at  $\Upsilon(4S)$ .
- <sup>28</sup> ACCIARRI 98D combines results from  $\ell\text{-}\ell$ ,  $\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$  with impact parameters.
- <sup>29</sup> ABREU 97N combines results from  $D^{*\pm}Q_{\text{hem}}$ ,  $\ell\text{-}Q_{\text{hem}}$ ,  $\pi_S^{\pm}\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$ .
- <sup>30</sup> ACKERSTAFF 97V combines results from  $\ell\text{-}\ell$ ,  $\ell\text{-}Q_{\text{hem}}$ ,  $D^{*}\ell$ , and  $D^{*\pm}Q_{\text{hem}}$ .
- <sup>31</sup> BUSKULIC 97D combines results from  $D^{*\pm}\ell/Q_{\text{hem}}$ ,  $\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$ .
- <sup>32</sup> ABREU 96Q analysis performed using lepton, kaon, and jet-charge tags.
- <sup>33</sup> ALEXANDER 96V combines results from  $D^{*\pm}\ell$  and  $D^{*\pm}\ell\text{-}Q_{\text{hem}}$ .
- <sup>34</sup> AKERS 95J combines results from charge measurement,  $D^{*\pm}\ell\text{-}Q_{\text{hem}}$  and  $\ell\text{-}\ell$ .

### $\chi_d = \Delta m_{B^0}/\Gamma_{B^0}$

The second “OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first “OUR EVALUATION”, also provided by the HFAG, includes  $\chi_d$  measured at  $\Upsilon(4S)$ .

VALUE	DOCUMENT ID

<sup>1</sup> Measured using  $B^0 \rightarrow J/\psi K_S^0$ ,  $J/\psi K_L^0$ ,  $D^-\pi^+$ ,  $D^{*-}\pi^+$ ,  $D^{*-}\rho^+$ , and  $D^{*-}\ell^+\nu$  decays.

<sup>2</sup> Assuming  $\Delta\Gamma = 0$ , the result becomes  $\text{Im}(z) = -0.0037 \pm 0.0046$ .

<sup>3</sup> Corresponds to 90% confidence range  $[-0.028, 0.104]$ .

<sup>4</sup> Measured using inclusive dilepton events from  $B^0$  decay.

## CP VIOLATION PARAMETERS

### $\text{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$

$CP$  impurity in  $B_d^0$  system. It is obtained from either  $a_{\ell\ell}$ , the charge asymmetry in like-sign dilepton events or  $a_{CP}$ , the time-dependent asymmetry of inclusive  $B^0$  and  $\bar{B}^0$  decays.

The second “OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements. It assumes there is no  $CP$  violation in  $B_s$  mixing.

The first “OUR EVALUATION”, also provided by the HFAG, uses the measurements from  $B$ -factories only.

$< 45$	<sup>16</sup> BARTELT	93	CLE2 $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> AAIJ 15F uses semileptonic  $B^0$  decays in the inclusive final states  $D^-\mu^+$  and  $D^{*-}\mu^+$ , where the  $D^-\mu^+$  meson decays into the  $K^+\pi^-\pi^+$  final state, and the  $D^{*-}$  meson into the  $\bar{D}^0(\rightarrow K^+\pi^-\pi^0)\pi^-$  final state. Reports  $A_{SL}^d = (-0.02 \pm 0.19 \pm 0.30)\%$ , which equals to  $4\text{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$ .

<sup>2</sup> Uses the charge asymmetry in like-sign dilepton events. LEES 15A reports  $A_{SL}^d = (-3.9 \pm 3.5 \pm 1.9) \times 10^{-3}$ .

<sup>3</sup> ABAZOV 14 uses the dimuon charge asymmetry with different impact parameters from which it reports  $A_{SL}^d = (-0.62 \pm 0.42) \times 10^{-2}$ .

<sup>4</sup> Uses  $B^0 \rightarrow D^{*-}X\ell^+\nu_\ell$  and a kaon-tagged sample which yields measurement of  $A_{SL}^d = (0.06 \pm 0.17 \pm 0.38 \pm 0.32)\%$ , corresponding to  $\Delta_{CP} = 1 - |q/p| = (0.29 \pm 0.84 \pm 1.88 \pm 1.61) \times 10^{-3}$ .

<sup>5</sup> ABAZOV 12Ac uses  $B^0 \rightarrow D^-\mu^+X$  and  $B^0 \rightarrow D^*(2010)^-\mu^+X$  decays without initial state flavor tagging which yields measurement of  $A_{SL}^d = (6.8 \pm 4.5 \pm 1.4) \times 10^{-3}$ .

<sup>6</sup> AUBERT 06T reports  $|q/p| - 1 = (-0.8 \pm 2.7 \pm 1.9) \times 10^{-3}$ . We convert to  $(1 - |q/p|^2)/4$ .

<sup>7</sup> Uses the charge asymmetry in like-sign dilepton events and reports  $|q/p| = 1.0005 \pm 0.0040 \pm 0.0043$ .

<sup>8</sup> BARATE 01D measured by investigating time-dependent asymmetries in semileptonic and fully inclusive  $B_d^0$  decays.

<sup>9</sup> JAFFE 01 finds  $a_{\ell\ell} = 0.013 \pm 0.050 \pm 0.005$  and combines with the previous BEHRENS 00B independent measurement.

<sup>10</sup> Data analyzed using the time-dependent asymmetry of inclusive  $B^0$  decay. The production flavor of  $B^0$  mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

<sup>11</sup> ACKERSTAFF 97U assumes  $CPT$  and is based on measuring the charge asymmetry in a sample of  $B^0$  decays defined by lepton and  $Q_{\text{hem}}$  tags. If  $CPT$  is not invoked,  $\text{Re}(\epsilon_B) = -0.006 \pm 0.010 \pm 0.006$  is found. The indirect  $CPT$  violation parameter is determined to  $\text{Im}(\delta B) = -0.020 \pm 0.016 \pm 0.006$ .

<sup>12</sup> ABAZOV 11U uses the dimuon charge asymmetry with different impact parameters from which it reports  $A_{SL}^d = (-1.2 \pm 5.2) \times 10^{-3}$ .

<sup>13</sup> Uses the dimuon charge asymmetry.

<sup>14</sup> AUBERT 04c reports  $|q/p| = 1.029 \pm 0.013 \pm 0.011$  and we converted it to  $(1 - |q/p|^2)/4$ .

<sup>15</sup> BEHRENS 00B uses high-momentum lepton tags and partially reconstructed  $\bar{B}^0 \rightarrow D^{*+}\pi^-$ ,  $\rho^-$  decays to determine the flavor of the  $B$  meson.

<sup>16</sup> BARTELT 93 finds  $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$  which corresponds to  $|a_{\ell\ell}| < 0.18$ , which yields the above  $|\text{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)|$ .

### $A_{T/CP}$

$A_{T/CP}$  is defined as

$$\frac{P(\bar{B}^0 \rightarrow B^0) - P(B^0 \rightarrow \bar{B}^0)}{P(\bar{B}^0 \rightarrow B^0) + P(B^0 \rightarrow \bar{B}^0)},$$

the  $CPT$  invariant asymmetry between the oscillation probabilities  $P(\bar{B}^0 \rightarrow B^0)$  and  $P(B^0 \rightarrow \bar{B}^0)$ .

VALUE	DOCUMENT ID	TECN	COMMENT
<b><math>0.005 \pm 0.012 \pm 0.014</math></b>	<sup>1</sup> AUBERT	02k	BABR $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> AUBERT 02k uses the charge asymmetry in like-sign dilepton events.

See key on page 601

## $C_{\pi\pi}(B^0 \rightarrow \pi^+\pi^-)$

$C_{\pi\pi}$  is defined as  $(1-|\lambda|^2)/(1+|\lambda|^2)$ , where the quantity  $\lambda=q/p \bar{A}_f/A_f$  is a phase convention independent observable quantity for the final state  $f$ . For details, see the review on “CP Violation” in the Reviews section.

- Measurement based on  $B^0 \rightarrow J/\psi K_S^0$ ,  $B^0 \rightarrow \psi(2S) K_S^0$ ,  $B^0 \rightarrow J/\psi K_L^0$ , and  $B^0 \rightarrow \chi_{c1}(1P) K_S^0$  decays.

- SATO 12 uses  $121 \text{ fb}^{-1}$  data collected on  $\Upsilon(5S)$  resonance. Uses the “ $B - \pi$  tagging” where  $B\pi^+$  and  $B\pi^-$  tagged  $J/\psi K_S^0$  events are compared.
- Uses Dalitz plot analysis of  $B^0 \rightarrow K^0 \pi^+ \pi^-$  decays and the first of two equivalent solutions.
- Measurement based on  $B^0 \rightarrow c\bar{c}K^{(*)0}$  decays.
- Measurement in which the  $J/\psi$  decays to hadrons or to muons that do not satisfy the standard identification criteria.
- AFFOLDER 00c uses about  $400 B^0 \rightarrow J/\psi(1S) K_S^0$  events. The production flavor of  $B^0$  was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.
- BARATE 00Q uses 23 candidates for  $B^0 \rightarrow J/\psi(1S) K_S^0$  decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the  $B^0$  production flavor.
- ACKERSTAFF 98z uses 24 candidates for  $B_d^0 \rightarrow J/\psi(1S) K_S^0$  decay. A combination of jet-charge and vertex-charge techniques were used to tag the  $B_d^0$  production flavor.
- Based on  $B^0 \rightarrow \psi(2S) K_S^0$  decays.
- Measurement based on  $152 \times 10^6 B\bar{B}$  pairs.
- Measurement based on  $227 \times 10^6 B\bar{B}$  pairs.
- ABE 02U result is based on the same analysis and data sample reported in ABE 01G.
- ABE 02Z result is based on  $85 \times 10^6 B\bar{B}$  pairs.
- AUBERT 02N result based on the same analysis and data sample reported in AUBERT 01B.
- AUBERT 02P result is based on  $88 \times 10^6 B\bar{B}$  pairs.
- First observation of  $CP$  violation in  $B^0$  meson system.
- ABE 98U uses  $198 \pm 17 B_d^0 \rightarrow J/\psi(1S) K^0$  events. The production flavor of  $B^0$  was determined using the same side tagging technique.

### $C_{J/\psi(nS) K^0} (B^0 \rightarrow J/\psi(nS) K^0)$

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- <sup>1</sup> AAIJ 15N uses 41,560 flavor-tagged  $B_d \rightarrow J/\psi K_S^0$  events from 3 fb<sup>-1</sup> of integrated luminosity. Provides the correlation coefficient  $\rho = 0.483$  between the statistical uncertainties of and measurements.
- <sup>2</sup> Uses  $B^0 \rightarrow J/\psi K_S^0$  decays.
- <sup>3</sup> Based on  $B^0 \rightarrow \psi(2S) K_S^0$  decays.
- <sup>4</sup> Uses  $B^0 \rightarrow J/\psi K_L^0$  decays.
- <sup>5</sup> SATO 12 uses 121 fb<sup>-1</sup> data collected at  $\Upsilon(5S)$  resonance. Uses the " $B - \pi$  tagging" where  $B\pi^+$  and  $B\pi^-$  tagged  $J/\psi K_S^0$  events are compared.
- <sup>6</sup> AFFOLDER 00c uses about 400  $B^0 \rightarrow J/\psi(1S) K_S^0$  events. The production flavor of  $B^0$  was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.
- <sup>7</sup> BARATE 00q uses 23 candidates for  $B^0 \rightarrow J/\psi(1S) K_S^0$  decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the  $B^0$  production flavor.
- <sup>8</sup> ACKERSTAFF 98z uses 24 candidates for  $B_d^0 \rightarrow J/\psi(1S) K_S^0$  decay. A combination of jet-charge and vertex-charge techniques were used to tag the  $B_d^0$  production flavor.
- <sup>9</sup> AAIJ 13K uses 8200 flavor-tagged  $B_d \rightarrow J/\psi K_S^0$  events from 1 fb<sup>-1</sup> of integrated luminosity. Provides the correlation coefficient  $\rho = 0.42$  between the statistical uncertainties of  $S_{J/\psi(nS) K^0}$  ( $B^0 \rightarrow J/\psi(nS) K^0$ ) and  $C_{J/\psi(nS) K^0}$  ( $B^0 \rightarrow J/\psi(nS) K^0$ ) measurements.
- <sup>10</sup> Combined result of CHEN 07 and SAHOO 08.

$-12 \pm 14$			

- <sup>1</sup> Based on an isospin analysis of the  $B \rightarrow \rho\rho$  system.
- <sup>2</sup> Obtained using the time dependent analysis of  $B^0 \rightarrow a_1(1260) \pi^+ \pi^-$  and branching fraction measurements of  $B \rightarrow a_1(1260) K$  and  $B \rightarrow K_1 \pi$ . Uses SU(3) flavor relations.
- <sup>3</sup> The angle  $\alpha_{\text{eff}}$  is obtained using the measured  $CP$  parameters of  $B^0 \rightarrow a_1(1260) \pi^+ \pi^-$  and choosing one of the four solutions that is compatible with the result of SM-based fits.
- <sup>4</sup> Obtained using isospin relation and selecting a solution closest to the CKM best fit average; the 90% CL allowed interval is  $59^\circ < \phi_2 (= \alpha) < 115^\circ$ .
- <sup>5</sup> Obtained using isospin relation and selecting a solution closest to the CKM best fit average; 90% CL allowed interval is  $79^\circ < \alpha < 123^\circ$ .
- <sup>6</sup> Obtained from the measured  $CP$  parameters of the longitudinal polarization by selecting the solution closest to the CKM best fit central value of  $\alpha = 95^\circ - 98^\circ$ .

# Meson Particle Listings

$B^0$

## T and CPT VIOLATION PARAMETERS

Measured values of the  $T$ -,  $CP$ -, and  $CP$ - $T$ -asymmetry parameters, defined as the differences in  $S_{\alpha,\beta}^{\pm}$  and  $C_{\alpha,\beta}^{\pm}$  between symmetry-transformed transitions. The indices  $\alpha = \ell^+, \ell^-$  and  $\beta = K_S^0, K_L^0$  stand for reconstructed the flavor final state and the  $CP$  final states from  $\Upsilon(4S)$  decay. The sign  $\pm$  indicates whether the decay to the flavor final state  $\alpha$  occurs before or after the decay to the  $CP$  final state.

## $B^\pm/B^0$ ADMIXTURE

### B DECAY MODES

The branching fraction measurements are for an admixture of  $B$  mesons that the  $\Upsilon(4S)$ . The values quoted assume that  $\mathcal{B}(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$ .

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{ anything}$ , the treatment of multiple  $D$ 's in the final state must be defined. One possibility would be to count the number of events with one-or-more  $D$ 's and divide by the total number of  $B$ 's. Another possibility would be to count the total number of  $D$ 's and divide by the total number of  $B$ 's, which is the definition of average multiplicity. The two definitions are identical if only one  $D$  is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the  $B$  sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

$\bar{B}$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Semileptonic and leptonic modes</b>		
$\Gamma_1$ $e^+ \nu_e$ anything	[a]	
$\Gamma_2$ $\mu^+ \nu_\mu$ anything	[a]

[a] These values are model dependent.

[b] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.

[c] Here "anything" means at least one particle observed.

[d] This is a  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell)$  value.[e]  $D^{**}$  stands for the sum of the  $D(1^1P_1)$ ,  $D(1^3P_0)$ ,  $D(1^3P_1)$ ,  $D(1^3P_2)$ ,  $D(2^1S_0)$ , and  $D(2^1S_1)$  resonances.

[f] The value is for the sum of the charge states or particle/antiparticle states indicated.

[g]  $D^{(*)}\bar{D}^{(*)}$  stands for the sum of  $D^*\bar{D}^*$ ,  $D^*\bar{D}$ ,  $D\bar{D}^*$ , and  $D\bar{D}$ .[h]  $X(3915)$  denotes a near-threshold enhancement in the  $\omega J/\psi$  mass spectrum.

[i] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

 $B^\pm/B^0$  ADMIXTURE BRANCHING RATIOS $\Gamma(\ell^+ \nu_\ell \text{ anything})/\Gamma_{\text{total}}$  $\Gamma_3/\Gamma$ 

These branching fractions are model dependent.

"OUR EVALUATION" assumes lepton universality and is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

1 URQUIJO 07 report a measurement of  $(10.07 \pm 0.18 \pm 0.21)\%$  for the partial branching fraction of  $B \rightarrow e \nu_e X_c$  decay with electron energy above 0.6 GeV. We converted the result to  $B \rightarrow e \nu_e X$  branching fraction.

2 The measurements are obtained for charged and neutral  $B$  mesons partial rates of semi-leptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .

3 Uses charge and angular correlations in  $\gamma(4S)$  events with a high-momentum lepton and an additional electron.

4 ALBRECHT 93H analysis performed using tagged semileptonic decays of the  $B$ . This technique is almost model independent for the lepton branching ratio.

5 The measurements are obtained for charged and neutral  $B$  mesons partial rates of semi-leptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X)/B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

6 The semileptonic branching ratio,  $|V_{cb}|$  and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

7 Uses the high-momentum lepton tag method and requires the electron energy above 0.6 GeV.

8 Uses the high-momentum lepton tag method. They also report  $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$ .

9 Uses the high-momentum lepton tag method. ABE 02Y also reports  $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$ . The second error is due to uncertainties of theoretical inputs.

10 BARISH 96B analysis performed using tagged semileptonic decays of the  $B$ . This technique is almost model independent for the lepton branching ratio.

11 HENDERSON 92 measurement employs  $e$  and  $\mu$ . The systematic error contains 0.004 in quadrature from model dependence. The authors average a variation of the Isgur, Scora, Grinstein, and Wise model with that of the Altarelli-Cabibbo-Corbo-Maiani-Martinelli model for semileptonic decays to correct the acceptance.

12 YANAGISAWA 91 also measures an average semileptonic branching ratio at the  $\gamma(5S)$  of 9.6–10.5% depending on assumptions about the relative production of different  $B$  meson species.

13 ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta.  $0.099 \pm 0.006$  is obtained using ISGUR 89b.

14 ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta.  $0.097 \pm 0.006$  is obtained using ISGUR 89b.

15 Using data above  $p(e) = 2.4$  GeV, WACHS 89 determine  $\sigma(B \rightarrow e \nu \mu p)/\sigma(B \rightarrow e \nu \text{charm}) < 0.065$  at 90% CL.

16 Ratio  $\sigma(B \rightarrow e \nu \mu p)/\sigma(B \rightarrow e \nu \text{charm}) < 0.055$  at CL = 90%.

- <sup>1</sup> Measures several partial branching fractions in different phase space regions. The most precise result on the full branching fraction is obtained in the region for lepton momentum in  $B$  rest frame  $p_\ell^+ > 1$  GeV/c, where the measured partial branching fraction is  $\Delta B = (1.80 \pm 0.13 \pm 0.15) \times 10^{-3}$ . The acceptance in that region is reported in a private communication by the Authors to be 0.894. The corresponding  $|V_{ub}|$  from the BLNP method is  $(4.28 \pm 0.15 \pm 0.18 \pm 0.19) \times 10^{-3}$ , where the last uncertainty comes from theoretical prediction.
- <sup>2</sup> Obtained from the partial rate  $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$  for the electron momentum interval of 2.0–2.6 GeV/c based on BLNP method.
- <sup>3</sup> Determined from the partial rate  $\Delta B = (4.41 \pm 0.42 \pm 0.42) \times 10^{-4}$  measured for electron energy  $> 2$  GeV and hadronic mass squared  $< 3.5$  GeV<sup>2</sup>, and calculated acceptance 0.174 in that region. The  $V_{ub}$  is measured as  $(4.41 \pm 0.30^{+0.65}_{-0.47} \pm 0.28) \times 10^{-3}$ .
- <sup>4</sup> Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The  $V_{ub}$  is found to be  $(5.08 \pm 0.47^{+0.49}_{-0.48}) \times 10^{-3}$ .
- <sup>5</sup> BORNHEIM 02 uses the observed yield of leptons from semileptonic  $B$  decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on  $B \rightarrow X_S \gamma$ . The  $V_{ub}$  is found to be  $(4.08 \pm 0.34 \pm 0.53) \times 10^{-3}$ .
- <sup>6</sup> Uses a multivariate analysis method and requires lepton momentum in the  $B$  rest frame,  $p_\ell^{*B} > 1.0$  GeV/c.
- <sup>7</sup> Measures several partial branching fractions in different phase space regions. The most precise result is obtained in the region for hadronic mass  $M_X < 1.55$  GeV/c<sup>2</sup>, and is  $\Delta B = (1.18 \pm 0.09 \pm 0.07) \times 10^{-3}$ . The corresponding  $|V_{ub}|$  from the BLNP method is  $(4.27 \pm 0.16 \pm 0.13 \pm 0.30) \times 10^{-3}$ , where the last uncertainty comes from the theoretical prediction of the partial rate in the given phase-space region.
- <sup>8</sup> Used BaBar measurement of Semileptonic branching fraction  $B(B \rightarrow X \ell \nu_\ell) = (10.87 \pm 0.18 \pm 0.30)\%$  to convert the ratio of rates to branching fraction.
- <sup>9</sup> The third error includes the systematics and theoretical errors summed in quadrature.

### $\Gamma(X_u \ell^+ \nu_\ell)/\Gamma(\ell^+ \nu_\ell \text{ anything})$ $\Gamma_{23}/\Gamma_3$

$\ell$  denotes  $e$  or  $\mu$ , not the sum. These experiments measure this ratio in very limited momentum intervals.

- <sup>2</sup> ALBRECHT 94c find  $\Gamma(b \rightarrow c)/\Gamma(b \rightarrow \text{all}) = 0.99 \pm 0.02 \pm 0.04$ .
- <sup>3</sup> BARTELT 93B (CLEO II) measures an excess of  $107 \pm 15 \pm 11$  leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to  $b \rightarrow u \ell \nu_\ell$ . This corresponds to a model-dependent partial branching ratio  $\Delta B_{ub}$  between  $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$ , as evaluated using the KS model (KOERNER 88), and  $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$  using the ACCMM model (ARTUSO 93). The corresponding values of  $|V_{ub}|/|V_{cb}|$  are  $0.056 \pm 0.006$  and  $0.076 \pm 0.008$ , respectively.
- <sup>4</sup> ALBRECHT 91c result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the  $b \rightarrow u$  transition. Using the model of ALTARELLI 82, they obtain  $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$  from 77 leptons in the 2.3–2.6 GeV momentum range.
- <sup>5</sup> ALBRECHT 90 observes 41 ± 10 excess  $e$  and  $\mu$  (lepton) events in the momentum interval  $p = 2.3\text{--}2.6$  GeV signaling the presence of the  $b \rightarrow u$  transition. The events correspond to a model-dependent measurement of  $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$ .
- <sup>6</sup> FULTON 90 observe 76 ± 20 excess  $e$  and  $\mu$  (lepton) events in the momentum interval  $p = 2.4\text{--}2.6$  GeV signaling the presence of the  $b \rightarrow u$  transition. The average branching ratio,  $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$ , corresponds to a model-dependent measurement of approximately  $|V_{ub}/V_{cb}| = 0.1$  using  $B(b \rightarrow c \ell \nu) = 10.2 \pm 0.2 \pm 0.7\%$ .
- <sup>7</sup> The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on  $|V_{ub}|/|V_{cb}| < 0.20$ . While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

<sup>1</sup> GIBBONS 97B reports  $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$  using CLEO measured  $D$  and  $D^*$  branching fractions. We rescale to our PDG 96 values of  $D$  and  $D^*$  branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>2</sup> ALBRECHT 96D reports  $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.196 \pm 0.019$  using CLEO measured  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 0.681 \pm 0.01 \pm 0.013$ ,  $B(D^0 \rightarrow K^- \pi^+) = 0.0401 \pm 0.0014$ ,  $B(D^0 \rightarrow K^- \pi^+ \pi^+ \pi^-) = 0.081 \pm 0.005$ . We rescale to our PDG 96 values of  $D$  and  $D^*$  branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>3</sup> BORTOLETTO 92 reports  $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.25 \pm 0.03 \pm 0.04$  using MARK II  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 0.57 \pm 0.06$  and  $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.008$ . We rescale to our PDG 96 values of  $D$  and  $D^*$  branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>4</sup> ALBRECHT 91H reports  $0.348 \pm 0.060 \pm 0.035$  from a measurement of  $[\Gamma(B \rightarrow D^*(2010)^\pm \text{ anything})/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0 \pi^+)]$  assuming  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 0.55 \pm 0.04$ , which we rescale to our best value  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90  $B(D^0 \rightarrow K^- \pi^+) = 0.0371 \pm 0.0025$ .

<sup>5</sup> BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios  $B(D^0 \rightarrow K^- \pi^+) = 0.056 \pm 0.004 \pm 0.003$  and also assumes  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 0.60 \pm 0.08 \pm 0.15$ . The product branching ratio for  $B(B \rightarrow D^*(2010)^+) B(D^*(2010)^+ \rightarrow D^0 \pi^+)$  is  $0.13 \pm 0.02 \pm 0.012$ . Superseded by BORTOLETTO 92.

<sup>6</sup> V-A momentum spectrum used to extrapolate below  $p = 1$  GeV. We correct the value assuming  $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.006$  and  $B(D^+ \rightarrow D^0 \pi^+) = 0.6 \pm 0.08 \pm 0.15$ . The product branching fraction is  $B(B \rightarrow D^*(2010)^+) B(D^*(2010)^+ \rightarrow D^0 \pi^+) = (68 \pm 15 \pm 9) \times 10^{-4}$ .

<sup>1</sup> Also reports the measurement of  $\psi(2S) \rightarrow \ell^+ \ell^-$  polarization produced directly from B decay.

<sup>2</sup> BALEST 95B assume PDG 1994 values for sub mode branching ratios. They find  $B(B \rightarrow \psi(2S)X, \psi(2S) \rightarrow \ell^+ \ell^-) = 0.30 \pm 0.05 \pm 0.04$  and  $B(B \rightarrow \psi(2S)X, \psi(2S) \rightarrow J/\psi(1S)\pi^+\pi^-) = 0.37 \pm 0.05 \pm 0.05$ . Weighted average is quoted for  $B(B \rightarrow \psi(2S)X)$ .

seen	<sup>3</sup> GIANNINI	82 CUSB	$e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> ALBRECHT 93I value is not independent of the sum of  $B \rightarrow K^+ \text{ anything}$  and  $B \rightarrow K^- \text{ anything}$  ALBRECHT 94C values.

<sup>2</sup> Assuming  $\Upsilon(4S) \rightarrow B\bar{B}$ , a total of  $3.38 \pm 0.34 \pm 0.68$  kaons per  $\Upsilon(4S)$  decay is found (the second error is systematic). In the context of the standard B-decay model, this leads to a value for  $(b\text{-quark} \rightarrow c\text{-quark})/(b\text{-quark} \rightarrow \text{all})$  of  $1.09 \pm 0.33 \pm 0.13$ .

<sup>3</sup> GIANNINI 82 at CESR-CUSB observed  $1.58 \pm 0.35$   $K^0$  per hadronic event much higher than  $0.82 \pm 0.10$  below threshold. Consistent with predominant  $b \rightarrow cX$  decay.

3.36 ± 0.53 ± 0.65 ± 0.68	<sup>13</sup> ABE	01F	BELL Repl. by SAITO 15
2.32 ± 0.57 ± 0.35	ALAM	95	CLE2 Repl. by CHEN 01c

<sup>1</sup> We extrapolate the measured value to  $E_\gamma > 1.6$  GeV using the method of BUCH-MUELLER 06 (average of three theoretical models).

<sup>2</sup> SAITO 15 measured  $(3.51 \pm 0.17 \pm 0.33) \times 10^{-4}$  using a sum-of-exclusive approach in which 38 of the hadronic final states with  $m_{X_c} < 2.8$  GeV/ $c^2$  are reconstructed. The cut of minimum photon energy is  $E_\gamma > 1.9$  GeV.

<sup>3</sup> Reports  $(3.29 \pm 0.19 \pm 0.48) \times 10^{-4}$  for  $E_\gamma > 1.9$  GeV.

<sup>4</sup> Reports  $(3.21 \pm 0.15 \pm 0.29 \pm 0.08) \times 10^{-4}$  for  $1.8 < E_\gamma < 2.8$  GeV, where the last systematic uncertainty is for model dependency. Results with other cutoffs are also reported.

<sup>5</sup> The measurement reported is  $(3.45 \pm 0.15 \pm 0.40) \times 10^{-4}$  for  $E_\gamma > 1.7$  GeV.

<sup>6</sup> Uses a fully reconstructed  $B$  meson as a tag on the recoil side. The measurement reported is  $(3.66 \pm 0.85 \pm 0.60) \times 10^{-4}$  for  $E_\gamma > 1.9$  GeV.

<sup>7</sup> The measurement reported is  $(3.21 \pm 0.43^{+0.32}_{-0.29}) \times 10^{-4}$  for  $E_\gamma > 2.0$  GeV.

<sup>8</sup> Measured using sums of seven exclusive final states  $B \rightarrow X_{d(s)}\gamma$  where  $X_{d(s)}$  is a nonstrange (strange) charmless hadronic system in mass range 0.5–2.0 GeV/ $c^2$ .

<sup>9</sup> Measured using sums of seven exclusive final states  $B \rightarrow X_{d(s)}\gamma$  where  $X_{d(s)}$  is a nonstrange (strange) charmless hadronic system in mass range 0.6–1.8 GeV/ $c^2$ .

<sup>10</sup> The measurement reported is  $(3.67 \pm 0.29 \pm 0.45) \times 10^{-4}$  for  $E_\gamma > 1.9$  GeV.

See key on page 601

$<0.08$	2 <sup>2</sup> ALBRECHT 95D ARG $e^+e^- \rightarrow \Upsilon(4S)$
<sup>1</sup> COAN 98 uses $D$ - $\ell$ correlation.	
<sup>2</sup> ALBRECHT 95D use full reconstruction of one $B$ decay as tag. Two candidate events for charmless $B$ decay can be interpreted as either $b \rightarrow \text{sgluon}$ or $b \rightarrow u$ transition. If interpreted as $b \rightarrow \text{sgluon}$ they find a branching ratio of $\sim 0.026$ or the upper limit quoted above. Result is highly model dependent.

• • • We do not use the following data for averages, fits, limits, etc. • • •	
$6.2 \pm 1.6^{+1.3}_{-2.0}$	<sup>3</sup> BROWDER 98 CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
<sup>1</sup> AUBERT,B 04F reports branching ratio $B \rightarrow \eta' X_S$ for high momentum $\eta'$ between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. $X_S$ represents a recoil system consisting of a kaon and zero to four pions.	
<sup>2</sup> BONVICINI 03 observed a signal of $61.2 \pm 13.9$ events in $B \rightarrow \eta' X_{nc}$ production for high momentum $\eta'$ between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. The $X_{nc}$ denotes “charmless” hadronic states recoiling against $\eta'$ . The second error combines systematic and background subtraction uncertainties in quadrature.	
<sup>3</sup> BROWDER 98 observed a signal of $39.0 \pm 11.6$ events in high momentum $B \rightarrow \eta' X_S$ production between 2.0 and 2.7 GeV/c. The branching fraction is based on the interpretation of $b \rightarrow \text{sg}$ , where the last error includes additional uncertainties due to the color-suppressed $b \rightarrow \text{backgrounds}$ .

1 PROCARIO 94 CLE2 $e^+e^- \rightarrow \Upsilon(4S)$	

<sup>1</sup> PROCARIO 94 reports  $[\Gamma(B \rightarrow \bar{\Sigma}_c^0 \text{ anything})/\Gamma_{\text{total}}] \times [\text{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)] = 0.00023 \pm 0.00008 \pm 0.00007$  which we divide by our best value  $\text{B}(\Lambda_c^+ \rightarrow p K^- \pi^+) = (6.35 \pm 0.33) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

$\Gamma(\bar{\Sigma}_c^0 N(N=p \text{ or } n))/\Gamma_{\text{total}}$	$\Gamma_{107}/\Gamma$
VALUE	CL%
