COURANT 63 and ALFF 65, using  $\Sigma^0 \rightarrow \Lambda e^+ e^-$  decays (Dalitz decays), determined the  $\Sigma^0$  parity to be positive, given that  $J = 1/2$  and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the  $\Sigma^0$  mean life and  $\Sigma^0 \rightarrow \Lambda$  transition magnetic moment come (see below), strongly support  $J = 1/2$ .

## $\Sigma^0$ MASS

The fit uses  $\Sigma^+$ ,  $\Sigma^0$ ,  $\Sigma^-$ , and  $\Lambda$  mass and mass-difference measurements.

## $\Sigma^0$ MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process  $\Lambda \rightarrow \Sigma^0$  in nuclear Coulomb fields. An alternative expression of the same information is the  $\Sigma^0$ - $\Lambda$  transition magnetic moment given in the following section. The relation is  $(\mu_{\Sigma\Lambda}/\mu_N)^2 \tau = 1.92951 \times 10^{-19}$  s (see DEVLIN 86).

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 8.7$  for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_3$	-64		
$x_4$	-77	0	
$x_5$	-5	0	0

#### $\phi$ ANGLE FOR $\Sigma^- \rightarrow n\pi^-$

( $\tan\phi = \beta/\gamma$ )

VALUE (°)	EVTS	DOCUMENT ID	TECN	COMMENT
10±15 OUR AVERAGE				
+ 5±23	1092	6 BERLEY	70B HBC	<i>n</i> rescattering
14±19	1385	BANGERTER	69B HBC	<i>K</i> <sup>-</sup> <i>p</i> 0.4 GeV/ <i>c</i>

<sup>6</sup> BERLEY 70B changed from −5 to +5° to agree with our sign convention.

#### $g_A/g_V$ FOR $\Sigma^- \rightarrow ne^- \bar{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the “Note on Baryon Decay Parameters” in the neutron Listings. What is actually listed is  $|g_1/f_1 - 0.237g_2/f_1|$ . This reduces to  $g_A/g_V \equiv g_1(0)/f_1(0)$  on making the usual assumption that  $g_2 = 0$ . See also the note on HSUEH 88.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.340±0.017 OUR AVERAGE				
+0.327±0.007±0.019	50k	7 HSUEH	88	SPEC $\Sigma^-$ 250 GeV
+0.34 ±0.05	4456	8 BOURQUIN	83c	SPEC SPS hyperon beam
0.385±0.037	3507	9 TANENBAUM	74	ASPK
● ● ● We do not use the following data for averages, fits, limits, etc. ● ● ●				
0.29 ±0.07	25k	HSUEH	85	SPEC See HSUEH 88
0.17 <sup>+0.07</sup> <sub>-0.09</sub>	519	DECAMP	77	ELEC Hyperon beam

<sup>7</sup> The sign is, with our conventions, unambiguously positive. The value assumes, as usual, that  $g_2 = 0$ . If  $g_2$  is included in the fit, than (with our sign convention)  $g_2 = -0.56 \pm 0.37$ , with a corresponding reduction of  $g_A/g_V$  to  $+0.20 \pm 0.08$ .

<sup>8</sup> BOURQUIN 83c favors the positive sign by at least 2.6 standard deviations.

<sup>9</sup> TANENBAUM 74 gives  $0.435 \pm 0.035$ , assuming no  $q^2$  dependence in  $g_A$  and  $g_V$ . The listed result allows  $q^2$  dependence, and is taken from HSUEH 88.

#### $f_2(0)/f_1(0)$ FOR $\Sigma^- \rightarrow ne^- \bar{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the “Note on Baryon Decay Parameters” in the neutron Listings.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT

$\Sigma(1385)$  $\Sigma(1385) \ 3/2^+$ 

$$I(J^P) = 1(\frac{3}{2}^+) \text{ Status: } ****$$

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** S1 (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a  $P$ -wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their  $\Lambda\pi$  spectrum with a  $P$ -wave Breit-Wigner, but includes the partial width for the  $\Sigma\pi$  decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit  $S$ -wave results are given here.

OMITTED FROM SUMMARY TABLE  
These are peaks seen in  $\Lambda\pi$  and  $\Sigma\pi$  spectra in the reaction  $\pi^+ p \rightarrow (\gamma\pi) K^+$  at 1.7 GeV/c. Also, the  $\gamma$  polarization oscillates in the same region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of  $N(1675) \rightarrow \Lambda K$  decay. However, such an explanation for the  $(\Sigma^+\pi^0) K^+$  channel in terms of  $\Delta(1650) \rightarrow \Sigma K$  decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the  $\gamma$  polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in  $K^- p \rightarrow \Lambda\pi^0$ .

ENGELN 80 performs a multichannel analysis of  $K^- p \rightarrow p\bar{K}^0\pi^-$  at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in  $p\bar{K}^0$  which cannot be explained as a reflection of any competing channel.

PRAKHOV 04 sees no evidence for this or other light  $\Sigma$  resonances, aside from the  $\Sigma(1385)$ , in  $K^- p \rightarrow \Lambda\pi^0\pi^0$ .

ZYCHOR 06 finds peaks in  $pp \rightarrow pK^+(\pi^\pm X^\mp)$  at  $p_{\text{beam}} = 3.65$  GeV/c.

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged  $\Lambda/\Sigma\pi$  mass spectra from  $K^-p \rightarrow (\Lambda/\Sigma)\pi K\bar{K}$  at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in  $\Lambda\pi^\pm$  from the reaction  $pp \rightarrow \Lambda\pi^+\pi^-X$ . These enhancements are unlikely to be associated with the  $\Sigma(1580)$  (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1  $\bar{K}N$  total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

$\Sigma(1620)$  Production Experiments

$I(J^P) = 1(?^?)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the previous entry.

The results of CRENNELL 69B at 3.9 GeV/c are not confirmed by SABRE 70 at 3.0 GeV/c. However, at 4.5 GeV/c, AMMANN 70 sees a peak at 1642 MeV which on the basis of branching ratios they do not associate with the  $\Sigma(1670)$ . See MILLER 70 for a review of these conflicts.

## THE $\Sigma(1670)$ REGION

**Production experiments:** The measured  $\Sigma\pi/\Sigma\pi\pi$  branching ratio for the  $\Sigma(1670)$  produced in the reaction  $K^-p \rightarrow \pi^-\Sigma(1670)^+$  is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two  $\Sigma$  resonances with the same mass and quantum numbers: one with a large  $\Sigma\pi\pi$  (mainly  $\Lambda(1405)\pi$ ) branching fraction produced peripherally, and the other with a large  $\Sigma\pi$  branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the  $\Sigma\pi$  and the  $\Lambda(1405)\pi$  states are  $D_{13}$ . There is also possibly a third  $\Sigma$  in this region, the  $\Sigma(1690)$  in the Listings, the main evidence for which is a large  $\Lambda\pi/\Sigma\pi$  branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

**Formation experiments:** Two states are also observed near this mass in formation experiments. One of these, the  $\Sigma(1670)D_{13}$ , has the same quantum numbers as those observed in production and has a large  $\Sigma\pi/\Sigma\pi\pi$  branching ratio; it may well be the  $\Sigma(1670)$  produced at larger angles (see TIMMERMANS 76). The other state, the  $\Sigma(1660)P_{11}$ , has different quantum numbers, its  $\Sigma\pi/\Sigma\pi\pi$  branching ratio is unknown, and its relation to the produced  $\Sigma(1670)$  states is obscure.

## $\Sigma(1670)$ , $\Sigma(1670)$ Bumps

### $\Sigma(1670)$ FOOTNOTES

- <sup>1</sup> The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.  
<sup>2</sup> Results are with and without an  $S_{11}$   $\Sigma(1620)$  in the fit.  
<sup>3</sup> Ratio only for  $\Sigma 2\pi$  system in  $l = 1$ , which cannot be  $\Sigma(1385)$ .  
<sup>4</sup> SIMS 68 uses only cross-section data. Result used as upper limit only.  
<sup>5</sup> Assuming the  $\Lambda(1405)\pi$  cross-section bump is due only to  $3/2^-$  resonance.  
<sup>6</sup> The CAMERON 77 upper limit on  $F$ -wave decay is 0.03.

## $\Sigma(1670)$ Bumps

$$I(J^P) = 1(?)^?$$

### OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the preceding entry.

Probably there are two states at the same mass with the same quantum numbers, one decaying to  $\Sigma\pi$  and  $\Lambda\pi$ , the other to  $\Lambda(1405)\pi$ . See the note in front of the preceding entry.

 $\Sigma(1690)$  FOOTNOTES  
(PRODUCTION EXPERIMENTS)

- <sup>1</sup> From  $\pi^+ p \rightarrow (\Lambda \pi^+) K^+$ .  $J > 1/2$  is not required by the data.  
<sup>2</sup> From  $\pi^+ p \rightarrow (\Lambda \pi^+) (K \pi)^+$ .  $J > 1/2$  is indicated, but large background precludes a definite conclusion.  
<sup>3</sup> See the  $\Sigma(1670)$  Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the  $\Sigma(1690)$ .  
<sup>4</sup> This analysis, which is difficult and requires several assumptions and shows no unambiguous  $\Sigma(1690)$  signal, suggests  $J^P = 5/2^+$ . Such a state would lead all previously known  $Y^*$  trajectories.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to N $\overline{K}$  and Λπ, as well as to Ση whose threshold is at 1746 MeV (JONES 74).

### $\Sigma(1770)$ $1/2^+$

$$I(J^P) = 1(\frac{1}{2}^+) \text{ Status: } *$$

OMITTED FROM SUMMARY TABLE

Evidence for this state now rests solely on solution 1 of BAILLON 75, (see the footnotes) but the  $\Lambda\pi$  partial-wave amplitudes of this solution are in disagreement with amplitudes from most other  $\Lambda\pi$  analyses. ZHANG 13A finds no evidence for this state.

### $\Sigma(1775)$ $5/2^-$

$$I(J^P) = 1(\frac{5}{2}^-) \text{ Status: } ****$$

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the  $\Lambda(1820) F_{05}$  does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

### $\Sigma(1775)$ DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$	$N\bar{K}$
$\Gamma_2$	$\Lambda\pi$
$\Gamma_3$	$\Sigma\pi$
$\Gamma_4$	$\Sigma(1385)\pi$
$\Gamma_5$	$\Sigma(1385)\pi$ , D-wave
$\Gamma_6$	$\Lambda(1520)\pi$ , P-wave
$\Gamma_7$	$\Sigma\pi\pi$
$\Gamma_8$	$\Delta(1232)\bar{K}$ , D-wave
$\Gamma_9$	$N\bar{K}^*(892)$ , S=1/2
$\Gamma_{10}$	$N\bar{K}^*(892)$ , S=3/2, D-wave

The above branching fractions are our estimates, not fits or averages.

### CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 18 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 363.4$  for 14 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	-44			
$x_3$	-23	10		
$x_4$	-23	-32	-4	
$x_6$	-3	1	1	-84
	$x_1$	$x_2$	$x_3$	$x_4$

## Baryon Particle Listings

 $\Sigma(1775)$  $\Sigma(1775)$  BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on  $\Lambda$  and  $\Sigma$  Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too small.

 $\Gamma(N\bar{K})/\Gamma_{\text{total}}$  $\Gamma_1/\Gamma$

## Σ(1775) FOOTNOTES

- <sup>1</sup> The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.  
<sup>2</sup> The CAMERON 78 upper limit on G-wave decay is 0.03.  
<sup>3</sup> This rate combines P-wave- and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are  $-0.303 \pm 0.010$  and  $-0.037 \pm 0.014$ . The published signs have been changed here to be in accord with the baryon-first convention.  
<sup>4</sup> For about 3/4 of this, the  $\Sigma\pi$  system has  $l=0$  and is almost entirely  $\Lambda(1520)$ . For the rest, the  $\Sigma\pi$  has  $l=1$ , which is about what is expected from the known  $\Sigma(1775) \rightarrow \Sigma(1385)\pi$  rate, as seen in  $\Lambda\pi\pi$ .

 $\Sigma(1915), \Sigma(1940)$

$\Sigma(1915) \ 5/2^+$

$I(J^P) = 1(\frac{5}{2}^+)$  Status: \*\*\*\*

Discovered by COOL 66. For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions in this region used to be listed in a separate entry immediately following. They may be found in our 1986 edition Physics Letters **170B** 1 (1986).

$\Sigma(1915)$  FOOTNOTES

- 1 The two entries for CORDEN 77c are from two different acceptable solutions.  
2 Preferred solution 3; see CORDEN 76 for other possibilities.  
3 The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.  
4 The mass and width are fixed to the GOPAL 77 values due to the low elasticity.  
5 The published sign has been changed to be in accord with the baryon-first convention.

$I(J^P) = 1(\frac{1}{2}^-)$  Status: \*

OMITTED FROM SUMMARY TABLE

We list here all reported  $S_{11}$  states lying above the  $\Sigma(1750) S_{11}$ .  
ZHANG 13A finds no evidence for those states.

$\Sigma(2030) 7/2^+$

$I(J^P) = 1(\frac{7}{2}^+)$  Status: \*\*\*

Discovered by COOL 66 and by WOHL 66. For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions around 2030 MeV may be found in our 1984 edition, Reviews of Modern Physics **56** S1 (1984).

$\Sigma(2070) 5/2^+$

$I(J^P) = 1(\frac{5}{2}^+)$  Status: \*

OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 with new  $K^-p$  polarization and  $K^-n$  angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of  $\bar{K}N \rightarrow \Sigma\pi$ .

See key on page 601

$\Sigma(2250)$	$I(J^P) = 1(?^?)$ Status: ***
Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\bar{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\bar{K}N \rightarrow \Lambda\pi$ , $\Sigma\pi$ , and $N\bar{K}$ , respectively, suggest two resonances around this mass.

$I(J^P) = 1(?^?)$  Status: \*

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction  $K^- p \rightarrow Y^{*+} \pi^-$  using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a  $K^- p$  experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 11 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 7.5$  for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

**RADIATIVE HYPERON DECAYS**

Revised July 2011 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons,  $B_i \rightarrow B_f \gamma$ , yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a  $\Delta Q = 0$ ,  $\Delta S = 1$

transition, the angular distribution of the direction  $\hat{\mathbf{p}}$  of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega} = \frac{N}{4\pi} (1 + \alpha_{\gamma} \mathbf{P}_i \cdot \hat{\mathbf{p}}) . \quad (1)$$

Here  $\mathbf{P}_i$  is the polarization of the decaying hyperon, and  $\alpha_{\gamma}$  is the asymmetry parameter. In terms of the form factors  $F_1(q^2)$ ,  $F_2(q^2)$ , and  $G(q^2)$  of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_{\lambda} + iF_2(q^2)\sigma_{\lambda\mu}q^{\mu} + G(q^2)\gamma_{\lambda}\gamma_5 ,$$

$\alpha_{\gamma}$  is

$$\alpha_{\gamma} = \frac{2 \operatorname{Re}[G(0)F_M^*(0)]}{|G(0)|^2 + |F_M(0)|^2} , \quad (2)$$

where  $F_M = (m_i - m_f)[F_2 - F_1/(m_i + m_f)]$ . If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by  $P_f = -\alpha_{\gamma}$  [1].

The angular distribution for the weak hadronic decay,  $B_i \rightarrow B_f \pi$ , has the same form as Eq. (1), but of course with a different asymmetry parameter,  $\alpha_{\pi}$ . Now, however, if the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by  $P_f = +\alpha_{\pi}$  [2,3]. The difference of sign is because the spins of the pion and photon are different.

**$\Xi^0 \rightarrow \Lambda \gamma$  decay**—The radiative decay  $\Xi^0 \rightarrow \Lambda \gamma$  of an unpolarized  $\Xi^0$  uses the hadronic decay  $\Lambda \rightarrow p\pi^-$  as the analyzer. As noted above, the longitudinal polarization of the  $\Lambda$  will be  $P_{\Lambda} = -\alpha_{\Xi\Lambda\gamma}$ . Let  $\alpha_{-}$  be the  $\Lambda \rightarrow p\pi^-$  asymmetry parameter and  $\theta_{\Lambda p}$  be the angle, as seen in the  $\Lambda$  rest frame, between the  $\Lambda$  line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the  $\Lambda \rightarrow p\pi^-$  decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2} (1 - \alpha_{\Xi\Lambda\gamma} \alpha_{-} \cos\theta_{\Lambda p}) \quad (3)$$

for the angular distribution of the proton in the  $\Lambda$  frame. Our current value, from the CERN NA48/1 experiment [4], is  $\alpha_{\Xi\Lambda\gamma} = -0.704 \pm 0.019 \pm 0.064$ .

**$\Xi^0 \rightarrow \Sigma^0 \gamma$  decay**—The asymmetry parameter here,  $\alpha_{\Xi\Sigma\gamma}$ , is measured by following the decay chain  $\Xi^0 \rightarrow \Sigma^0 \gamma$ ,  $\Sigma^0 \rightarrow \Lambda \gamma$ ,  $\Lambda \rightarrow p\pi^-$ . Again, for an unpolarized  $\Xi^0$ , the longitudinal polarization of the  $\Sigma^0$  will be  $P_{\Sigma} = -\alpha_{\Xi\Sigma\gamma}$ . In the  $\Sigma^0 \rightarrow \Lambda \gamma$  decay, a parity-conserving magnetic-dipole transition, the polarization of the  $\Sigma^0$  is transferred to the  $\Lambda$ , as may be seen as follows. Let  $\theta_{\Sigma\Lambda}$  be the angle seen in the  $\Sigma^0$  rest frame between the  $\Sigma^0$  line of flight and the  $\Lambda$  momentum. For  $\Sigma^0$  helicity +1/2, the probability amplitudes for positive and negative spin states of the  $\Sigma^0$  along the  $\Lambda$  momentum are  $\cos(\theta_{\Sigma\Lambda}/2)$  and  $\sin(\theta_{\Sigma\Lambda}/2)$ . Then the amplitude for a negative helicity photon and a negative helicity  $\Lambda$  is  $\cos(\theta_{\Sigma\Lambda}/2)$ , while the amplitude for positive helicities for the photon and  $\Lambda$  is  $\sin(\theta_{\Sigma\Lambda}/2)$ . For  $\Sigma^0$  helicity -1/2, the amplitudes are interchanged. If the  $\Sigma^0$  has longitudinal polarization  $P_{\Sigma}$ , the probabilities for  $\Lambda$  helicities  $\pm 1/2$  are therefore

$$p(\pm 1/2) = \frac{1}{2}(1 \mp P_{\Sigma}) \cos^2(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_{\Sigma}) \sin^2(\theta_{\Sigma\Lambda}/2) , \quad (4)$$

# Baryon Particle Listings

 $\Xi^0, \Xi^-$ 

and the longitudinal polarization of the  $\Lambda$  is

$$P_{\Lambda} = -P_{\Sigma} \cos \theta_{\Sigma\Lambda} = +\alpha_{\Xi\Sigma\gamma} \cos \theta_{\Sigma\Lambda} . \quad (5)$$

Using Eq. (1) for the  $\Lambda \rightarrow p\pi^-$  decay again, we get for the joint angular distribution of the  $\Sigma^0 \rightarrow \Lambda\gamma$ ,  $\Lambda \rightarrow p\pi^-$  chain,

$$\frac{d^2N}{d\cos\theta_{\Sigma\Lambda}d\cos\theta_{\Lambda p}} = \frac{N}{4} (1 + \alpha_{\Xi\Sigma\gamma} \cos\theta_{\Sigma\Lambda} \alpha_- \cos\theta_{\Lambda p}) . \quad (6)$$

Our current average for  $\alpha_{\Xi\Sigma\gamma}$  is  $-0.69 \pm 0.06$  [4,5].

## References

1. R.E. Behrends, Phys. Rev. **111**, 1691 (1958); see Eq. (7) or (8).
2. In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 50 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+) \text{ Status: } ***$$

The parity has not actually been measured, but + is of course expected.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

## $\Xi^-$ MASS

The fit uses the  $\Xi^-$ ,  $\Xi^+$ , and  $\Xi^0$  masses and the  $\Xi^- - \Xi^+$  mass difference. It assumes that the  $\Xi^-$  and  $\Xi^+$  masses are the same.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b><math>1321.71 \pm 0.07</math> OUR FIT</b>				
<b><math>1321.70 \pm 0.08 \pm 0.05</math></b>	2478 $\pm$ 68	ABDALLAH	06E DLPH	from Z decays
• • • We do not use the following data for averages, fits, limits, etc. • • •

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 5 parameters. The overall fit has a χ<sup>2</sup> = 1.0 for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients <δx<sub>i</sub>δx<sub>j</sub>>/(δx<sub>i</sub>δx<sub>j</sub>), in percent, from the fit to the branching fractions, x<sub>i</sub> ≡ Γ<sub>i</sub>/Γ<sub>total</sub>. The fit constrains the x<sub>i</sub> whose labels appear in this array to sum to one.

x <sub>2</sub>	-6			
x <sub>3</sub>	-8	0		
x <sub>4</sub>	-99	0	-1	
x <sub>5</sub>	-5	0	0	0
	x <sub>1</sub>	x <sub>2</sub>	x <sub>3</sub>	x <sub>4</sub>

8 This LUK 00 value is for  $\alpha(\Xi^+)\alpha_+(\bar{\Lambda})$ . We assume  $CP$  conservation here by including it in the average for  $\alpha(\Xi^-)\alpha_-(\Lambda)$ . But see the second data block below for the  $CP$  test.

**α FOR Ξ<sup>-</sup> → Λπ<sup>-</sup>**  
The above average,  $\alpha(\Xi^-)\alpha_-(\Lambda) = -0.294 \pm 0.005$ , where the error includes a scale factor of 1.7, divided by our current average  $\alpha_-(\Lambda) = 0.642 \pm 0.013$ , gives the following value for  $\alpha(\Xi^-)$ .

VALUE	DOCUMENT ID
<b>-0.458 ± 0.012 OUR EVALUATION</b>	Error includes scale factor of 1.8.

**$\frac{[\alpha(\Xi^-)\alpha_-(\Lambda) - \alpha(\Xi^+)\alpha_+(\bar{\Lambda})]}{[\alpha(\Xi^-)\alpha_-(\Lambda) + \alpha(\Xi^+)\alpha_+(\bar{\Lambda})]}$**   
This is zero if  $CP$  is conserved. The  $\alpha$ 's are the decay-asymmetry parameters for  $\Xi^- \rightarrow \Lambda\pi^-$  and  $\Lambda \rightarrow p\pi^-$  and for  $\Xi^+ \rightarrow \bar{\Lambda}\pi^+$  and  $\bar{\Lambda} \rightarrow \bar{p}\pi^+$ .

## $\Xi$ RESONANCES

The accompanying table gives our evaluation of the present status of the  $\Xi$  resonances. Not much is known about  $\Xi$  resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few  $\mu\text{b}$ ), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about  $\Xi$  resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, nothing of significance on  $\Xi$  resonances has been added since our 1988 edition.

For a detailed earlier review, see Meadows [1].

Table 1. The status of the  $\Xi$  resonances. Only those with an overall status of \*\*\* or \*\*\*\* are included in the Baryon Summary Table.

Particle	$J^P$	Overall status	Status as seen in —				
			$\Xi\pi$	$\Lambda K$	$\Sigma K$	$\Xi(1530)\pi$	Other channels
$\Xi(1318)$	$1/2^+$	****					Decays weakly
$\Xi(1530)$	$3/2^+$	****	****				
$\Xi(1620)$		*	*				
$\Xi(1690)$		***		***	**		
$\Xi(1820)$	$3/2^-$	***	**	***	**	**	
$\Xi(1950)$		***	**	**		*	
$\Xi(2030)$		***		**	***		
$\Xi(2120)$		*		*			
$\Xi(2250)$		**					3-body decays
$\Xi(2370)$		**					3-body decays
$\Xi(2500)$		*		*	*		3-body decays
****	Existence is certain, and properties are at least fairly well explored.						
***	Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.						
**	Evidence of existence is only fair.						
*	Evidence of existence is poor.

## $\Xi(1530) 3/2^+$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^+) \text{ Status: } ****$$

This is the only  $\Xi$  resonance whose properties are all reasonably well known. Assuming that the  $\Lambda_c^+$  has  $J^P = 1/2^+$ , AUBERT 08AK, in a study of  $\Lambda_c^+ \rightarrow \Xi^- \pi^+ K^+$ , finds conclusively that the spin of the  $\Xi(1530)^0$  is  $3/2$ . In conjunction with SCHLEIN 63B and BUTTON-SHAFFER 66, this proves also that the parity is +.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

Ξ(1690)

$I(J^P) = \frac{1}{2}(?)^?$  Status: \*\*\*

AUBERT 08AK, in a study of  $\Lambda_c^+ \rightarrow \Xi^- \pi^+ K^+$ , finds some evidence that the Ξ(1690) has  $J^P = 1/2^-$ .

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged  $\Sigma^- \overline{K}$  mass spectra in  $K^-p \rightarrow (\Sigma^- \overline{K}) K \pi$  at 4.2 GeV/c. The data from the  $\Sigma^- \overline{K}$  channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding  $\Lambda^- \overline{K}$  channels, and a coupled-channel analysis yields results consistent with a new Ξ.

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced  $\Lambda K^-$  system. A peak is also observed in the  $\Lambda \overline{K}^0$  mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to  $\Sigma^- \overline{K}^0$ , with the γ from the  $\Sigma^-$  decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of  $\Xi^-$  into  $\Lambda K^-$ . The significance claimed is 6.7 standard deviations.

ADAMOVIICH 98 sees a peak of 1400 ± 300 events in the  $\Xi^- \pi^+$  spectrum produced by 345 GeV/c Σ<sup>-</sup>-nucleus interactions.

## $\Xi(1820) 3/2^-$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-) \text{ Status: } ***$$

The clearest evidence is an 8-standard-deviation peak in  $\Lambda K^-$  seen by GAY 76C. TEODORO 78 favors  $J = 3/2$ , but cannot make a parity discrimination. BIAGI 87C is consistent with  $J = 3/2$  and favors negative parity for this  $J$  value.

### $\Xi(1820)$ MASS

We only average the measurements that appear to us to be most significant and best determined.

## $\Xi(1950)$

$I(J^P) = \frac{1}{2}(?)^?$  Status: \* \* \*

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a  $\Xi$  near 1950 MeV seems strong enough to include a  $\Xi(1950)$  in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one  $\Xi$  near this mass.

 $\Xi(2030)$ 

$$J(P) = \frac{1}{2} (\geq \frac{5}{2}?) \text{ status: } ***$$

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in  $\Sigma \bar{K}$  and a weaker coupling to  $\Lambda \bar{K}$ . ALITTI 68 and HEMINGWAY 77 observe no signals in the  $\Xi \pi \pi$  (or  $\Xi(1530) \pi$ ) channel, in contrast to DIBIANCA 75. The decay  $(\Lambda/\Sigma) \bar{K} \pi$  reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that  $J \geq 5/2$ .

### $\Xi(2120)$ FOOTNOTES

- <sup>1</sup> CHLIAPNIKOV 79 does not uniquely identify the  $K^+$  in the  $(\bar{\Lambda} K^+) X$  final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.  
<sup>2</sup> GAY 76c sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum  $u$ . This suggests an anomalous production mechanism if the  $\Xi(2120)$  is real.

## $\Xi(2250)$

$I(J^P) = \frac{1}{2}(?)^?$  Status: \* \*  
*J, P* need confirmation.

OMITTED FROM SUMMARY TABLE

The evidence for this state is mixed. BARTSCH 69 sees a bump of not much statistical significance in  $\Lambda\bar{K}\pi$ ,  $\Sigma\bar{K}\pi$ , and  $\Xi\pi\pi$  mass spectra. GOLDWASSER 70 sees a narrower bump in  $\Xi\pi\pi$  at a higher mass. Not seen by HASSALL 81 with 45 events/ $\mu\text{b}$  at 6.5 GeV/c. Seen by JENKINS 83. Perhaps seen by BIAGI 87.

$\Omega^- = sss$

$\Omega^-$

$I(J^P) = 0(\frac{3}{2}^+)$  Status: \*\*\*

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out  $J = 1/2$  and find consistency with  $J = 3/2$ . AUBERT, BE 06 finds from the decay angular distributions of  $\Xi_c^0 \rightarrow \Omega^- K^+$  and  $\Omega_c^0 \rightarrow \Omega^- K^+$  that  $J = 3/2$ ; this depends on the spins of the  $\Xi_c^0$  and  $\Omega_c^0$  being  $J = 1/2$ , their supposed values.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

$\Omega^-$  MASS

The fit assumes the  $\Omega^-$  and  $\overline{\Omega}^+$  masses are the same, and averages them together.

- <sup>1</sup>DIBIANCA 75 gives a mass for each event. We quote the average.
- <sup>2</sup>The FRY 55 and FRY 55B events were identified as  $\Omega^-$  by ALVAREZ 73. The masses assume decay to  $\Lambda K^-$  at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the  $K^-$  energy and the resulting  $\Omega^-$  mass by several MeV. This shift is negligible for FRY 55 because the  $\Omega$  decay is approximately perpendicular to its orbital velocity, as is known because the  $\Lambda$  strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.
- <sup>3</sup>Excluded from the average; the  $\Omega^-$  lifetimes measured by the experiments differ significantly from other measurements.
- <sup>4</sup>The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the  $\Omega$  interacted with an Ag nucleus to give  $K^- \Xi \text{Ag}$ .

$\overline{\Omega}^+$  MASS

OMITTED FROM SUMMARY TABLE

A peak in the  $\Omega^-\pi^+\pi^-$  mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

## CHARMED BARYONS ( $C = +1$ )

$$\begin{aligned}\Lambda_c^+ &= udc, & \Sigma_c^{++} &= uuc, & \Sigma_c^+ &= udc, & \Sigma_c^0 &= ddc, \\ \Xi_c^+ &= usc, & \Xi_c^0 &= dsc, & \Omega_c^0 &= ssc\end{aligned}$$

### CHARMED BARYONS

Revised March 2012 by C.G. Wohl (LBNL).

(Note added November 2015.) Since the 2014 *Review*, there have been three papers that improved the values of the masses and/or widths of the  $\Sigma(2455)$ ,  $\Sigma(2520)$ ,  $\Xi_c^+$ ,  $\Xi_c^0$ ,  $\Xi_c(2645)$ ,  $\Xi_c(2970)$ ,  $\Xi_c(3055)$ , and  $\Xi_c(3080)$ . See the Listings for those particles.

There are 18 known charmed baryons, and four other candidates not well enough established to be promoted to the Summary Tables.\* Fig. 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The  $\Lambda_c$  and  $\Sigma_c$  spectra ought to look much like the  $\Lambda$  and  $\Sigma$  spectra, since a  $\Lambda_c$  or a  $\Sigma_c$  differs from a  $\Lambda$  or a  $\Sigma$  only by the replacement of the  $s$  quark with a  $c$  quark. However, a  $\Xi$  or an  $\Omega$  has more than one  $s$  quark, only *one* of which is changed to a  $c$  quark to make a  $\Xi_c$  or an  $\Omega_c$ . Thus the  $\Xi_c$  and  $\Omega_c$  spectra ought to be richer than the  $\Xi$  and  $\Omega$  spectra.\*\*

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells what charmed baryons to expect; this is essential, because few of the spin-parity values given in Fig. 1(a) have been measured.

**Fig. 1.** (a) The known charmed baryons, and (b) the lightest “4-star” strange baryons. Note that there are two  $J^P = 1/2^+$   $\Xi_c$  states, and that the lightest  $\Omega_c$  does not have  $J = 3/2$ . The  $J^P = 1/2^+$  states, all tabbed with a circle, belong to the SU(4) multiplet that includes the nucleon; states with a circle and the same fill belong to the same SU(3) multiplet within that SU(4) multiplet. Similar remarks apply to the other states: same shape of tab, same SU(4) multiplet; same fill of that shape, same SU(3) multiplet. The  $J^P = 1/2^-$  and  $3/2^-$  states tabbed with triangles complete two SU(4) 4 multiplets.

But far and away the most important advance for  $c$ -baryons this edition is the first ever (!) model-independent measurement of a  $\Lambda_c^+$  branching fraction. The anchor for all the other  $\Lambda_c^+$  fractions is the  $pK^-\pi^+$  fraction. Our value for many editions,  $(5.0 \pm 1.3)\%$ , was cobbled together from two ancient model-dependent measurements. Now, thanks to the Belle experiment, it is  $(6.84 \pm 0.24_{\pm 0.27})\%$ . This fraction is 37% larger than the old fraction, and its error is only 27% as large as the old error.

Rather, they have been assigned in accord with expectations of the theory. However, they are all very likely as shown (see below).

**SU(4) multiplets**—Baryons made from  $u$ ,  $d$ ,  $s$ , and  $c$  quarks belong to SU(4) multiplets. The multiplet numerology, analogous to  $3 \times 3 \times 3 = 10 + 8_1 + 8_2 + 1$  for the subset of baryons made from just  $u$ ,  $d$ , and  $s$  quarks, is  $4 \times 4 \times 4 = 20 + 20'_1 + 20'_2 + \bar{4}$ . Figure 2(a) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the  $\Delta(1232)$ .

Figure 2(b) shows the 20'-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon.

## Baryon Particle Listings

### Charmed Baryons

Figure 2(c) shows the  $\bar{4}$  multiplet, an inverted tetrahedron. One level up from the bottom level of each multiplet are the baryons with one  $c$  quark. All the baryons in a given multiplet have the same spin and parity. Each  $N$  or  $\Delta$  or  $SU(3)$ -singlet- $\Lambda$  resonance calls for another  $20'$ - or  $20$ - or  $4$ -plet, respectively.

The flavor symmetries shown in Fig. 2 are of course badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(b), we expect to find, in the same  $J^P = 1/2^+$   $20'$ -plet as the nucleon, a  $\Lambda_c$ , a  $\Sigma_c$ , two  $\Xi_c$ 's, and an  $\Omega_c$ . Note that this  $\Omega_c$  has  $J^P = 1/2^+$  and is not in the same  $SU(4)$  multiplet as the famous  $J^P = 3/2^+$   $\Omega^-$ .

**Figure 2:**  $SU(4)$  multiplets of baryons made of  $u$ ,  $d$ ,  $s$ , and  $c$  quarks. (a) The  $20$ -plet with an  $SU(3)$  decuplet on the lowest level. (b) The  $20'$ -plet with an  $SU(3)$  octet on the lowest level. (c) The  $4$ -plet. Note that here and in Fig. 3, but not in Fig. 1, each charge state is shown separately.

Figure 3 shows in more detail the middle level of the  $20'$ -plet of Fig. 2(b); it splits apart into two  $SU(3)$  multiplets, a  $\bar{3}$  and a  $6$ . The states of the  $\bar{3}$  are antisymmetric under the interchange of the two light quarks (the  $u$ ,  $d$ , and  $s$  quarks), whereas the states of the  $6$  are symmetric under this interchange. We use a prime to distinguish the  $\Xi_c$  in the  $6$  from the one in the  $\bar{3}$ .

**The observed spectra**—(1) The parity of the lightest  $\Lambda_c$  is defined to be positive (as are the parities of the  $p$ ,  $n$ , and  $\Lambda$ ); the limited evidence about its spin is consistent with  $J = 1/2$ . However, few of the  $J^P$  quantum numbers given in Fig. 1(a) have been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the  $J^P$  assignments shown.<sup>†</sup> There are no surprises: the  $J^P = 1/2^+$  states come first, then the  $J^P = 3/2^+$  states...

(2) There is, however, evidence that many of the  $J^P$  assignments in Fig. 1(a) must be correct. As is well known, the successive mass differences between the  $J^P = 3/2^+$  particles, the  $\Delta(1232)^-$ ,  $\Sigma(1385)^-$ ,  $\Xi(1535)^-$ , and  $\Omega^-$ , which lie along the lower left edge of the  $20$ -plet in Fig. 2(a), should according

**Figure 3:** The  $SU(3)$  multiplets on the second level of the  $SU(4)$  multiplet of Fig. 2(b). The  $\Lambda_c$  and  $\Xi_c$  tabbed with open circles in Fig. 1(a) complete a  $J^P = 1/2^+$   $SU(3)$   $\bar{3}$ -plet, as in (a) here. The  $\Sigma_c$ ,  $\Xi_c$ , and  $\Omega_c$  tabbed with closed circles in Fig. 1(a) complete a  $J^P = 1/2^+$   $SU(3)$   $6$ -plet, as in (b) here. Together the nine particles complete the charm = +1 level of a  $J^P = 1/2^+$   $SU(4)$   $20'$ -plet, as in Fig. 2(b).

to  $SU(3)$  be about equal; and indeed experimentally they nearly are. In the same way, the mass differences between the  $J^P = 1/2^+$   $\Sigma_c(2455)^0$ ,  $\Xi_c^0$ , and  $\Omega_c^0$ ,<sup>‡</sup> the particles along the left edge of Fig. 3(b), should be about equal—assuming, of course, that they *do* all have the same  $J^P$ . The measured differences are  $125.0 \pm 2.9$  MeV and  $117.3 \pm 3.4$  MeV—not perfect, but close. Similarly, the mass differences between the presumed  $J^P = 3/2^+$   $\Sigma_c(2520)^0$ ,  $\Xi_c(2645)^0$ , and  $\Omega_c(2770)^0$  are  $127.1 \pm 0.8$  MeV and  $120.0 \pm 2.1$  MeV. In Fig. 1(a), these two sets of charm particles are tabbed with solid circles and solid squares.

(3) Other evidence comes from the decay of the  $\Lambda_c(2593)$ . The only allowed strong decay is  $\Lambda_c(2593)^+ \rightarrow \Lambda_c^+ \pi \pi$ , and this appears to be dominated by the submode  $\Sigma_c(2455)\pi$ , despite little available phase space for the latter (the “ $Q$ ” is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly  $s$ -wave, which, assuming that the  $\Sigma_c(2455)$  does indeed have  $J^P = 1/2^+$ , makes  $J^P = 1/2^-$  for the  $\Lambda_c(2593)$ .

#### Footnotes:

\* The unpromoted states are a  $\Lambda_c(2765)^+$ , a  $\Xi_c(2930)$ , and a  $\Xi_c(3123)$ . There is also very weak evidence for a baryon with *two*  $c$  quarks, a  $\Xi_{cc}^+$  at 3519 MeV. See the Particle Listings.

\*\* For example, there are three  $\Omega_c^0$  states (properly symmetrized states of  $ssc$ ,  $scs$ , and  $css$ ) corresponding to each  $\Omega^-$  ( $sss$ ) state.

† This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.

‡ A reminder about the Particle Data Group naming scheme: A particle has its mass as part of its name if and only if it decays strongly. Thus  $\Sigma(1385)$  and  $\Sigma_c(2455)$  but  $\Omega^-$  and  $\Xi_c'$ .

See key on page 601

## Baryon Particle Listings

 $\Lambda_c^+$ 

$$I(J^P) = 0(\frac{1}{2}^+) \text{ Status: } ****$$

The parity of the  $\Lambda_c^+$  is defined to be positive (as are the parities of the proton, neutron, and  $\Lambda$ ). The quark content is  $udc$ . Results of an analysis of  $pK^-\pi^+$  decays (JEZABEK 92) are consistent with  $J = 1/2$ . Nobody doubts that the spin is indeed  $1/2$ .

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

 $\Lambda_c^+$  MASS

Our value in 2004,  $2284.9 \pm 0.6$  MeV, was the average of the measurements now filed below as "not used." The BABAR measurement is so much better that we use it alone. Note that it is about 2.6 (old) standard deviations above the 2004 value.

The fit also includes  $\Sigma_c^-\Lambda_c^+$  and  $\Lambda_c^{*+}\Lambda_c^+$  mass-difference measurements, but this doesn't affect the  $\Lambda_c^+$  mass. The new (in 2006)  $\Lambda_c^+$  mass simply pushes all those other masses higher.

<sup>1</sup> AUBERT,B 05s uses low-Q  $\Lambda_c^0 K^+$  and  $\Sigma^0 K_S^0 K^+$  decays to minimize systematic errors. The error above includes systematic as well as statistical errors. Many cross checks and adjustments to properties of the BABAR detector, as well as the large number of clean events, make this by far the best measurement of the  $\Lambda_c^+$  mass.

[a] This branching fraction includes all the decay modes of the final-state resonance.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 36 branching ratios uses 57 measurements and one constraint to determine 19 parameters. The overall fit has a  $\chi^2 = 39.9$  for 39 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

-0.96±0.42		ALBRECHT	92
-1.1 ± 0.4	86	AVERY	90B

<sup>1</sup> BISHAI 95 actually gives  $\alpha = -0.94 \pm 0.21 \pm 0.12$ , chopping the errors at the physical limit  $-1.0$ . However, for  $\alpha \approx -1.0$ , some experiments should get unphysical values ( $\alpha < -1.0$ ), and for averaging with other measurements such values (or errors that extend below  $-1.0$ ) should not be chopped.

$\alpha$ FOR $\Lambda_c^+ \rightarrow \Sigma^+ \pi^0$			
VALUE	EVTS	DOCUMENT ID	TECN

$$\Lambda_c(2595)^+$$

$$J(P) = 0(\frac{1}{2}^-) \text{ Status: } ***$$

The  $\Lambda_c^+ \pi^+ \pi^-$  mode is largely, and perhaps entirely,  $\Sigma_c \pi$ , which is just at threshold; since the  $\Sigma_c$  has  $J^P = 1/2^+$ , the  $J^P$  here is almost certainly  $1/2^-$ . This result is in accord with the theoretical expectation that this is the charm counterpart of the strange  $\Lambda(1405)$ .

 $\Lambda_c(2595)^+$  MASS

The mass is obtained from the  $\Lambda_c(2595)^+ - \Lambda_c^+$  mass-difference measurements below.

VALUE (MeV)	DOCUMENT ID
<b>2592.25 ± 0.28 OUR FIT</b>	

 $\Lambda_c(2595)^+ - \Lambda_c^+$  MASS DIFFERENCE

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>305.79 ± 0.24 OUR FIT</b>				
<b>305.79 ± 0.14 ± 0.20</b>	3.5k	AALTONEN	11H CDF	$p\bar{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •				
305.6 ± 0.3		<sup>1</sup> BLECHMAN	03	Threshold shift
309.7 ± 0.9 ± 0.4	19	ALBRECHT	97 ARG	$e^+ e^- \approx 10$ GeV
309.2 ± 0.7 ± 0.3	14 ± 4.5	FRABETTI	96 E687	$\gamma$ Be, $\bar{E}_\gamma \approx 220$ GeV
307.5 ± 0.4 ± 1.0	112 ± 17	EDWARDS	95 CLE2	$e^+ e^- \approx 10.5$ GeV

<sup>1</sup> BLECHMAN 03 finds that a more sophisticated treatment than a simple Breit-Wigner for the proximity of the threshold of the dominant decay,  $\Sigma_c(2455)\pi$ , lowers the  $\Lambda_c(2595)^+ - \Lambda_c^+$  mass difference by 2 or 3 MeV. The analysis of AALTONEN 11H bears this out.

 $\Lambda_c(2595)^+$  WIDTH

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>2.59 ± 0.30 ± 0.47</b>	3.5k	<sup>2</sup> AALTONEN	11H CDF	$p\bar{p}$ at 1.96 TeV

3.9 $\begin{smallmatrix} +1.4 \\ -1.2 \end{smallmatrix}$ $\begin{smallmatrix} +2.0 \\ -1.0 \end{smallmatrix}$	112 ± 17	EDWARDS	95 CLE2	$e^+ e^- \approx 10.5$ GeV

<sup>2</sup> AALTONEN 11H treats the three charged modes  $\Lambda_c(2595)^+ \rightarrow \Sigma_c(2455)^+ \pi^+ \pi^-$ ,  $\Sigma_c(2455)^0 \pi^0$ ,  $\Sigma_c(2455)^0 \pi^+$  separately in terms of a common coupling constant  $h_2$  and obtains  $h_2^2 = 0.36 \pm 0.08$ . From this the width is determined.

 $\Lambda_c(2595)^+$  DECAY MODES

$\Lambda_c^+ \pi \pi$  and its submode  $\Sigma_c(2455)\pi$  — the latter just barely — are the only strong decays allowed to an excited  $\Lambda_c^+$  having this mass; and the submode seems to dominate.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1 \Lambda_c^+ \pi^+ \pi^-$	[a] —
$\Gamma_2 \Sigma_c(2455)^{++} \pi^-$	24 ± 7 %
$\Gamma_3 \Sigma_c(2455)^0 \pi^+$	24 ± 7 %
$\Gamma_4 \Lambda_c^+ \pi^+ \pi^- 3\text{-body}$	18 ± 10 %
$\Gamma_5 \Lambda_c^+ \pi^0$	[b] not seen
$\Gamma_6 \Lambda_c^+ \gamma$	not seen

[a] See AALTONEN 11H, Fig. 8, for the calculated ratio of  $\Lambda_c^+ \pi^0 \pi^0$  and  $\Lambda_c^+ \pi^+ \pi^-$  partial widths as a function of the  $\Lambda_c(2595)^+ - \Lambda_c^+$  mass difference. At our value of the mass difference, the ratio is about 4.

[b] A test that the isospin is indeed 0, so that the particle is indeed a  $\Lambda_c^+$ .

$\Lambda_c(2765)^+$   
or  $\Sigma_c(2765)$

$I(J^P) = ?(??)$  Status: \*

OMITTED FROM SUMMARY TABLE

A broad, statistically significant peak ( $997^{+141}_{-129}$  events) seen in  $\Lambda_c^+ \pi^+ \pi^-$ . However, nothing at all is known about its quantum numbers, including whether it is a  $\Lambda_c^+$  or a  $\Sigma_c$ , or whether the width might be due to overlapping states.

### $\Lambda_c(2765)^+$ MASS

The mass is obtained from the  $\Lambda_c(2765)^+ - \Lambda_c^+$  mass-difference measurement below.

$\Lambda_c(2880)^+$

$I(J^P) = 0(\frac{5}{2}^+)$  Status: \*\*\*

A narrow peak seen in  $\Lambda_c^+ \pi^+ \pi^-$  and in  $pD^0$ . It is not seen in  $pD^+$ , and therefore it is probably a  $\Lambda_c^+$  and not a  $\Sigma_c$ . The evidence for spin 5/2 comes from the  $\Sigma_c(2455)\pi$  decay angular distribution, and the evidence for parity + comes from agreement of the  $\Sigma_c(2520)/\Sigma_c(2455)$  branching ratio with a prediction of heavy quark symmetry (see MIZUK 07).

 $\Sigma_c(2800)$  $I(J^P) = 1(?)^?$  Status: \*\*\*Seen in the  $\Lambda_c^+ \pi^+$ ,  $\Lambda_c^+ \pi^0$ , and  $\Lambda_c^+ \pi^-$  mass spectra. $\Sigma_c(2800)$  MASSES

The charged ++ and + masses are obtained from the mass-difference measurements that follow. The neutral mass is dominated by the mass-difference measurement, but is pulled up somewhat by the less well-determined but considerably higher direct-mass measurement. It is possible, in fact, that AUBERT 08BN is seeing a different  $\Sigma_c$ .

# Baryon Particle Listings

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$  Status: \*\*\*

According to the quark model, the  $\Xi_c^+$  (quark content  $usc$ ) and  $\Xi_c^0$  form an isospin doublet, and the spin-parity ought to be  $J^P = 1/2^+$ . None of  $I$ ,  $J$ , or  $P$  has actually been measured.

## $\Xi_c^+$ MASS

The fit uses the  $\Xi_c^+$  and  $\Xi_c^0$  mass and mass-difference measurements.

2459 $\pm$ 5 $\pm$ 30	56	<sup>2</sup> COTEUS	87 SPEC	$nA \approx 600$ GeV
2460 $\pm$ 25	82	BIAGI	83 SPEC	$\Sigma^-$ Be 135 GeV

<sup>1</sup> The systematic error was (wrongly) given the other way round in LESIAK 05; see the erratum.  
<sup>2</sup> Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (statd significance about 6 standard deviations) in the  $\Lambda K^- \pi^+ \pi^+$  mass spectrum. COTEUS 87 sees *two* peaks in the same spectrum, one at the  $\Xi_c^+$  mass, the other 75 MeV lower. The latter is attributed to  $\Xi_c^+ \rightarrow \Sigma^0 K^- \pi^+ \pi^+ \rightarrow (\Lambda \gamma) K^- \pi^+ \pi^+$ , with the  $\gamma$  unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

## $\Xi_c^+$ DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
------	--------------------------------	------------------

No absolute branching fractions have been measured.  
The following are branching *ratios* relative to  $\Xi^- 2\pi^+$ .

### Cabibbo-favored ( $S = -2$ ) decays — relative to $\Xi^- 2\pi^+$

$\Gamma_1$	$p 2K_S^0$	0.087 $\pm$ 0.021	
$\Gamma_2$	$\Lambda \overline{K}^0 \pi^+$	—	
$\Gamma_3$	$\Sigma(1385)^+ \overline{K}^0$	[a] 1.0 $\pm$ 0.5	
$\Gamma_4$	$\Lambda K^- 2\pi^+$	0.323 $\pm$ 0.033	
$\Gamma_5$	$\Lambda \overline{K}^*(892)^0 \pi^+$	[a] <0.16	90%
$\Gamma_6$	$\Sigma(1385)^+ K^- \pi^+$	[a] <0.23	90%
$\Gamma_7$	$\Sigma^+ K^- \pi^+$	0.94 $\pm$ 0.10	
$\Gamma_8$	$\Sigma^+ \overline{K}^*(892)^0$	[a] 0.81 $\pm$ 0.15	
$\Gamma_9$	$\Sigma^0 K^- 2\pi^+$	0.27 $\pm$ 0.12	
$\Gamma_{10}$	$\Xi^0 \pi^+$	0.55 $\pm$ 0.16	
$\Gamma_{11}$	$\Xi^- 2\pi^+$	DEFINED AS 1	
$\Gamma_{12}$	$\Xi(1530)^0 \pi^+$	[a] <0.10	90%
$\Gamma_{13}$	$\Xi^0 \pi^+ \pi^0$	2.3 $\pm$ 0.7	
$\Gamma_{14}$	$\Xi^0 \pi^- 2\pi^+$	1.7 $\pm$ 0.5	
$\Gamma_{15}$	$\Xi^0 e^+ \nu_e$	2.3 $\pm$ 0.7 -0.8	
$\Gamma_{16}$	$\Omega^- K^+ \pi^+$	0.07 $\pm$ 0.04	

### Cabibbo-suppressed decays — relative to $\Xi^- 2\pi^+$

$\Gamma_{17}$	$p K^- \pi^+$	0.21 $\pm$ 0.04	
$\Gamma_{18}$	$p \overline{K}^*(892)^0$	[a] 0.116 $\pm$ 0.030	
$\Gamma_{19}$	$\Sigma^+ \pi^+ \pi^-$	0.48 $\pm$ 0.20	
$\Gamma_{20}$	$\Sigma^- 2\pi^+$	0.18 $\pm$ 0.09	
$\Gamma_{21}$	$\Sigma^+ K^+ K^-$	0.15 $\pm$ 0.06	
$\Gamma_{22}$	$\Sigma^+ \phi$	[a] <0.11	90%
$\Gamma_{23}$	$\Xi(1690)^0 K^+, \Xi^0 \rightarrow \Sigma^+ K^-$	<0.05	90%

[a] This branching fraction includes all the decay modes of the final-state resonance.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+) \text{ Status: } ** *$$

According to the quark model, the  $\Xi_c^0$  (quark content  $dsc$ ) and  $\Xi_c^+$  form an isospin doublet, and the spin-parity ought to be  $J^P = 1/2^+$ . None of  $I$ ,  $J$ , or  $P$  has actually been measured.

 $\Xi_c^0$  MASSThe fit uses the  $\Xi_c^0$  and  $\Xi_c^+$  mass and mass-difference measurements.

$I(J^P) = \frac{1}{2}(\frac{1}{2}^-)$  Status: \*\*\*

A peak seen in the  $\Xi_c' \pi$  mass spectrum. The simplest assignment, based on the mass, width, and decay mode, is that this belongs in the same SU(4) multiplet as the  $\Lambda(1405)$  and the  $\Lambda_c(2595)^+$ , but the spin and parity have not been measured.

$\Xi_c(2790)$  MASSES

The masses are obtained from the mass-difference measurements that follow.

## $\Omega_c(2770)^0$

$I(J^P) = 0(\frac{3}{2}^+)$  Status: \* \* \*

The natural assignment is that this goes with the  $\Sigma_c(2520)$  and  $\Xi_c(2645)$  to complete the lowest mass  $J^P = \frac{3}{2}^+$  SU(3) sextet, part of the SU(4) 20-plet that includes the  $\Delta(1232)$ . But  $J$  and  $P$  have not been measured.

### $\Omega_c(2770)^0$ MASS

The mass is obtained from the mass-difference measurement that follows.

VALUE (MeV)	DOCUMENT ID
<b>2765.9±2.0 OUR FIT</b>	Error includes scale factor of 1.2.

### $\Omega_c(2770)^0 - \Omega_c^0$ MASS DIFFERENCE

$\Xi_{cc}^{++}$

$I(J^P) = ?(?^?)$  Status: \*

OMITTED FROM SUMMARY TABLE

This would presumably be an isospin-1/2 particle, a  $ccu \Xi_{cc}^{++}$  and a  $ccd \Xi_{cc}^{+}$ . However, opposed to the evidence cited below, the BABAR experiment has found no evidence for a  $\Xi_{cc}^{+}$  in a search in  $\Lambda_c^{+} K^{-} \pi^{+}$  and  $\Xi_c^0 \pi^{+}$  modes, and no evidence of a  $\Xi_{cc}^{++}$  in  $\Lambda_c^{+} K^{-} \pi^{+} \pi^{+}$  and  $\Xi_c^0 \pi^{+} \pi^{+}$  modes (AUBERT,B 06D). Nor have the BELLE (CHISTOV 06, KATO 14) or LHCb (AAIJ 13CD) experiments found any evidence for this state.

### $\Lambda_b^0$ MEAN LIFE

See  $b$ -baryon Admixture section for data on  $b$ -baryon mean life average over species of  $b$ -baryon particles.

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

$\Lambda_b^0$  DECAY MODES

The branching fractions  $B(b\text{-baryon} \rightarrow \Lambda \ell^- \bar{\nu}_\ell \text{anything})$  and  $B(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell \text{anything})$  are not pure measurements because the underlying measured products of these with  $B(b \rightarrow b\text{-baryon})$  were used to determine  $B(b \rightarrow b\text{-baryon})$ , as described in the note "Production and Decay of  $b$ -Flavored Hadrons."

For inclusive branching fractions, e.g.,  $\Lambda_b \rightarrow \bar{\Lambda}_c \text{anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level

$\Gamma_{38}$ $\Lambda^0 \eta'(958)$	$< 3.1 \times 10^{-6}$	CL=90%

[a]  $P_c^+$  is a pentaquark-charmonium state.

[b] Not a pure measurement. See note at head of  $\Lambda_b^0$  Decay Modes.

[c] Here  $h^-$  means  $\pi^-$  or  $K^-$ .

## CONSTRAINED FIT INFORMATION

An overall fit to 10 branching ratios uses 12 measurements and one constraint to determine 7 parameters. The overall fit has a  $\chi^2 = 10.7$  for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$\Gamma(\Lambda_c^+ \ell^- \bar{\nu}_\ell \text{anything})/\Gamma_{\text{total}}$					$\Gamma_{23}/\Gamma$	
The values and averages in this section serve only to show what values result if one assumes our $B(b \rightarrow b\text{-baryon})$ . They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $B(b \rightarrow b\text{-baryon})$ as described in the note on "Production and Decay of $b$ -Flavored Hadrons."

## $\Lambda_b(5912)^0$

$$J^P = \frac{1}{2}^-$$

Status: \*\*\*

Quantum numbers are based on quark model expectations.

## $\Lambda_b(5912)^0$ MASS

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b><math>5912.11 \pm 0.13 \pm 0.23</math></b>	<sup>1,2</sup> AAIJ	12AL LHCb	$pp$ at 7 TeV

<sup>1</sup> Observed in  $\Lambda_b(5912)^0 \rightarrow \Lambda_b^0 \pi^+ \pi^-$  decays with  $17.6 \pm 4.8$  candidates with a significance of 5.2 sigma.

<sup>2</sup> AAIJ 12AL measures  $m(\Lambda_b(5912)^0) - m(\Lambda_b^0) = 292.60 \pm 0.12 \pm 0.04 \text{ MeV}$ . We have adjusted the measurement to our best value of  $m(\Lambda_b^0) = 5619.51 \pm 0.23 \text{ MeV}$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.

**$\Xi_b$  MEAN LIFE**

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

# Baryon Particle Listings

## $b$ -baryon ADMIXTURE ( $\Lambda_b$ , $\Xi_b$ , $\Sigma_b$ , $\Omega_b$ )

### $b$ -baryon ADMIXTURE ( $\Lambda_b$ , $\Xi_b$ , $\Sigma_b$ , $\Omega_b$ )

#### $b$ -baryon ADMIXTURE MEAN LIFE

Each measurement of the  $b$ -baryon mean life is an average over an admixture of various  $b$  baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different  $b$ -baryon mean life. More  $b$ -baryon flavor specific channels are not included in the measurement.

#### $b$ -baryon ADMIXTURE DECAY MODES ( $\Lambda_b$ , $\Xi_b$ , $\Sigma_b$ , $\Omega_b$ )

These branching fractions are actually an average over weakly decaying  $b$ -baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the  $b$ -baryon production fraction  $B(b \rightarrow b\text{-baryon})$ .

The branching fractions  $B(b\text{-baryon} \rightarrow \Lambda\ell^-\bar{\nu}_\ell\text{anything})$  and  $B(\Lambda_b^0 \rightarrow \Lambda_C^+\ell^-\bar{\nu}_\ell\text{anything})$  are not pure measurements because the underlying measured products of these with  $B(b \rightarrow b\text{-baryon})$  were used to determine  $B(b \rightarrow b\text{-baryon})$ , as described in the note "Production and Decay of  $b$ -Flavored Hadrons."

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm\text{anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $p\mu^-\bar{\nu}$ anything	( 5.5 <sup>+2.2</sup> <sub>-1.9</sub> ) %
$\Gamma_2$ $p\ell\bar{\nu}_\ell$ anything	( 5.3 ± 1.2 ) %
$\Gamma_3$ $p$ anything	( 66 ± 21 ) %
$\Gamma_4$ $\Lambda\ell^-\bar{\nu}_\ell$ anything	( 3.6 ± 0.6 ) %
$\Gamma_5$ $\Lambda\ell^+\nu_\ell$ anything	( 3.0 ± 0.8 ) %
$\Gamma_6$ $\Lambda$ anything	( 37 ± 7 ) %
$\Gamma_7$ $\Xi^-\ell^-\bar{\nu}_\ell$ anything	( 6.2 ± 1.6 ) × 10 <sup>-3</sup>

## EXOTIC BARYONS

### PENTAQUARKS

Written March 2016 by M. Karliner (Tel Aviv U.), T. Skwarnicki (Syracuse U.)

Experimental searches for pentaquark hadrons comprised of light flavors have a long and vivid history. No undisputed candidates have been found in 50 years. The first wave of observations of pentaquark candidates containing a strange antiquark occurred in the early seventies, see e.g. a review in the 1976 edition of Particle Data Group listings for  $Z_0(1780)$ ,  $Z_0(1865)$  and  $Z_1(1900)$  [1]. The last mention of these candidates can be found in the 1992 edition [2] with the perhaps prophetic comment “the results permit no definite conclusion - the same story for 20 years. [...] The skepticism about baryons not made of three quarks, and lack of any experimental activity in this area, make it likely that another 20 years will pass before the issue is decided.” A decade later, a second wave of observations occurred, possibly motivated by specific theoretical predictions for their existence [3–5]. The evidence for pentaquarks was based on observations of peaks in the invariant mass distributions of their decay products. More data, or more sensitive experiments did not confirm these claims [6]. In the last mention of the best known candidate from that period,  $\Theta(1540)^+$ , the 2006 Particle Data Group listing [7] included a statement: “The conclusion that pentaquarks in general, and that  $\Theta^+$ , in particular, do not exist, appears compelling.” which well reflected the prevailing mood in the particle physics community until a study of  $\Lambda_b^0 \rightarrow J\psi p K^-$  ( $J\psi \rightarrow \mu^+\mu^-$ ) decays by LHCb [8] (charge conjugate modes are implied). In addition to many excitations of the  $\Lambda$  baryon (hereafter denoted as  $\Lambda^*$  resonances) decaying to  $K^-p$ , these data contain a narrow peak in the  $J\psi p$  mass distribution, which is evident as a horizontal band in the Dalitz plot (Fig. 1).

**Figure 1:** Dalitz plot distributions for  $\Lambda_b^0 \rightarrow J\psi p K^-$  decays as observed by LHCb.

An amplitude analysis was performed to clarify the nature of this band that followed in the footsteps of a similar analysis of  $\bar{B}^0 \rightarrow \psi(2S)\pi^+K^-$  ( $\psi(2S) \rightarrow \mu^+\mu^-$ ) performed by the LHCb a year earlier in which the  $Z(4430)^+$  tetraquark candidate [9] was confirmed and the resonant character of its amplitude was demonstrated by an Argand diagram [10]. The final states are very similar, with  $\pi^+$  being replaced by  $p$ . The signal statistics,  $26\,000 \pm 166$ , and the background level, 5.4%, are also very comparable. The quasi-two-body amplitude model was constructed based on an isobar approximation (*i.e.* summing up Breit-Wigner amplitudes) and helicity formalism to parameterize dynamics of contributing decay processes. The amplitude fit spanned a kinematically complete, six-dimensional space of independent kinematic variables. All six dimensions of  $\Lambda_b$  decay kinematics were used in the amplitude fit, including invariant masses of  $K^-p$  ( $m_{Kp}$ ) and  $J\psi p$ , ( $m_{J\psi p}$ ) helicity angles ( $\theta$ ) of  $\Lambda_b$ ,  $J\psi$ ,  $\Lambda^*$  or pentaquark candidate  $P_c^+ \rightarrow J\psi p$ , and angles between decay planes of the particles. Fourteen reasonably well established  $\Lambda^*$  resonances were considered with masses and widths fixed to the values listed in 2014 PDG edition [11], and varied within their uncertainties when evaluating systematic errors. Their helicity couplings (1-6 complex numbers per resonance) were determined from the fit to the data. It was found that the  $\Lambda^*$  contributions alone failed to describe the data and it was necessary to add two exotic  $P_c^+ \rightarrow J\psi p$  contributions to the matrix element (10 free parameters per resonance), before the narrow structure seen in  $m_{J\psi p}$  could be reasonably well reproduced, as illustrated in Fig. 2.

The lower mass state,  $P_c(4380)^+$ , has a fitted mass of  $4380 \pm 8 \pm 29$  MeV, width of  $205 \pm 18 \pm 86$  MeV, fit fraction of  $8.4 \pm 0.7 \pm 4.2$  % and significance of  $9\sigma$ . The higher mass state,  $P_c(4450)^+$ , has a fitted mass of  $4449.8 \pm 1.7 \pm 2.5$  MeV, narrower width of  $39 \pm 5 \pm 19$  MeV, a fit fraction of  $4.1 \pm 0.5 \pm 1.1$  % and significance of  $12\sigma$ . The need for a second  $P_c^+$  state becomes visually apparent in the  $m_{J\psi p}$  distribution for events with high values of  $m_{Kp}$ , where  $\Lambda^*$  contributions are the smallest (in the inset of Fig. 2). Even though contributions from the two  $P_c^+$  states are most visible in this region, they interfere destructively in this part of the Dalitz plane. The constructive  $P_c^+$  interference makes their combined contribution the largest at the other end of their band on the Dalitz plane, corresponding to the opposite end of the  $\cos\theta_{P_c^+}$  distribution (see Fig. 8b in Ref. 8). This pattern requires them to be of opposite parity. A similar interference pattern is observed in the  $\cos\theta_{\Lambda^*}$  distribution (Fig. 7 in Ref. 8), which is a consequence of parity-doublets in the  $\Lambda^*$  spectrum. Unfortunately, spins of the two  $P_c^+$  states were not uniquely determined. Within the statistical and systematic ambiguities,  $(3/2, 5/2)$  and  $(5/2, 3/2)$  combinations with either  $(-, +)$  or  $(+, -)$  parities, were not well resolved. The other combinations were disfavored. The Argand diagrams for the two  $P_c^+$  states are shown in Fig. 3. They were obtained by replacing the Breit-Wigner amplitude for one of the  $P_c^+$  states at a time by a combination of independent complex amplitudes at six equidistant points in the  $\pm\Gamma_0$  range

# Baryon Particle Listings

## Pentaquarks

**Figure 2:** Projections of the amplitude fits with  $P_c(4380)^+$  and  $P_c(4450)^+$  states to the  $\Lambda_b^0 \rightarrow J\psi p K^-$  data onto the invariant mass distributions of  $m_{Kp}$  (left) and  $m_{J\psi p}$  (right).

(interpolated in mass for continuity) which were fit to the data simultaneously with the other parameters of the full matrix element model. While the narrower  $P_c(4450)^+$  state shows the expected resonant behavior, the diagram for  $P_c(4380)^+$  deviates somewhat from the expectation. The statistical errors are large, especially for the broader  $P_c(4380)^+$  state. Higher statistics data might make these diagrams more conclusive. The addition of further  $\Lambda$  states beyond the well-established ones, of  $\Sigma$  excitations (expected to be suppressed) and of non-resonant contributions with a constant amplitude, did not remove the need for two pentaquark states in the model to describe the data. Yet  $\Lambda^*$  spectroscopy is a complex problem, from both experimental and theoretical points of view. This is illustrated by the recent reanalysis of  $\bar{K}N$  scattering data [12] in which the  $\Lambda(1800)$  state, which was previously considered to be “well established”, is not seen, and where evidence for a few previously unidentified states is included. In fact, all theoretical models of  $\Lambda^*$  baryons [13–18] predict a much larger number of higher mass excitations than is established experimentally. Because of the

high density of predicted states, presumably with large widths, these may be difficult to identify experimentally. Non-resonant contributions with a non-trivial  $K^-p$  mass dependence may also be present. Therefore, LHCb also inspected their data with an approach that is nearly model-independent with respect to  $K^-p$  contributions [19].

**Figure 3:** Fitted values of the real and imaginary parts of the amplitudes of the  $P_c(4450)^+$  (left) and  $P_c(4380)^+$  (right) states for  $\Lambda_b^0 \rightarrow J\psi p K^-$  shown in the Argand diagrams as connected points with the error bars (masses increase counterclockwise). The solid red curves are the predictions from the Breit-Wigner formula, with resonance masses and widths set to the nominal fit results, scaled to the displayed points.

A representation of the Dalitz plane distribution was constructed using the observed  $m_{Kp}$  distribution and Legendre polynomial moments of the cosine of the  $\Lambda^*$  helicity angle determined from the data as a function of  $m_{Kp}$ . The maximal rank of the moments generated by the  $K^-p$  contributions alone cannot be higher than twice the largest total angular momentum. Since high-spin  $\Lambda^*$  states cannot significantly contribute at low  $m_{Kp}$  values, high rank moments were excluded from the representation (see Fig. 1 and 3 in Ref. 19). When projected onto  $m_{J\psi p}$  axis of the Dalitz plane, this representation cannot describe the data as shown in Fig. 4. The disagreement was quantified to be at least  $9\sigma$ , thus the hypothesis that only  $K^-p$  contributions can generate the observed  $m_{J\psi p}$  mass structure could be rejected with very high confidence without any assumptions about number of  $K^-p$  contributions, their resonant or non-resonant character, their mass shapes or their interference patterns. This proved a need for contributions from exotic hadrons or from rescattering effects of conventional ones. However, this approach is not suitable for their characterization.

Many theoretical groups interpreted the  $P_c^+$  states in terms of diquarks and triquarks as building blocks of a compact pentaquark [20–26]. The pair of states of opposite parity with the  $3/2$  spin assignment to  $P_c(4380)^+$  and  $5/2$  to  $P_c(4450)^+$

**Figure 4:** The efficiency-corrected and background-subtracted distribution of  $m_{J/\psi p}$  for the data (black points with error bars), with the reflection of  $K^-p$  mass distribution and of the moments of the  $K^-p$  helicity angle, which can be accommodated by any plausible  $K^-p$  contribution (solid blue line) superimposed. The data and the reflection are inconsistent at  $> 9\sigma$  level.

can be achieved by increasing the angular momentum between the constituents by one unit, which can also make the heavier state narrower. However, their mass splitting is too small to be only due to this mechanism [20] and requires fine-tuning of such models. It is also not clear if centrifugal barrier factor provides enough width suppression via spatial separation of  $c$  and  $\bar{c}$  quarks to explain the width ratio between the two  $P_c^+$  states and the narrowness of  $P_c(4450)^+$  in absolute units as the phase space for  $J/\psi p$  decay is very large (more than 400 MeV).

More effective width suppression mechanism is offered by a loosely bound charmed baryon-anticharmed meson molecular model, in which  $c$  and  $\bar{c}$  can be separated to much larger distances resulting in a smaller probability of them getting close to each other in order to make a  $J/\psi$ . Since molecular binding energy cannot be large, masses of such molecules must be near the sum of the baryon and meson masses. The narrowness of  $P_c(4450)^+$  and its proximity to appropriate baryon-meson mass threshold make the molecular model attractive in spite of its inability to account for other features of the LHCb results (see below).

In order to view the narrow pentaquark in a wider perspective, it is useful to consider it together with several analogous exotic states with hidden charm and bottom in the meson sector. This provides additional significant motivation for the molecular model. At least five exotic mesons are close to thresholds of two heavy-light mesons:  $X(3872)$  [27–30],  $Z_b(10610)$  and  $Z_b(10650)$  in the bottomonium sector [31–35]

and  $Z_c(3900)$  [36–40] and  $Z_c(4020/4025)$  [41–43] in the charmonium sector (see Table II of Ref. 44). They share several important features: a) their masses are near thresholds and their spin and parity correspond to  $S$ -wave combination of the two mesons; b) they are very narrow, despite very large phase space for decay into quarkonium + pion(s); c) the branching fractions for “fall apart” mode into two mesons are much larger than branching fractions for decay into quarkonium and pion(s); d) there are no states at two pseudoscalar thresholds ( $\bar{D}D$  and  $\bar{B}B$ ), where there can be no binding through pseudoscalar exchange.

The above provide a strong hint that these states are deuteron-like loosely bound states of two heavy mesons [45–53]. It is then natural to conjecture that similar bound states might exist of two heavy baryons [54,55], or a meson and a baryon or a baryon and an antibaryon, leading to a rather accurate prediction of the  $P_c(4450)^+$  mass as  $3/2^- \Sigma_c \bar{D}^*$  molecule: 4462.4 MeV [56,44]. It is essential that the two hadrons be heavy, in order to minimize the repulsive kinetic energy [54–57].

One may also consider a wider framework of doubly heavy baryon-meson hadronic molecules, which might include mixtures of various two-hadron states [58,59]. In this context it is important to keep in mind that the molecule’s width cannot be smaller than the sum of its constituents’ widths [60–62].

Following the LHCb discovery, several groups carried out a detailed analysis of the  $P_c^+$  states as hadronic molecules [63–71]. The molecular picture has also been extended to a hadronic molecule built from a colored “baryon” and “meson” [72].

When trying to interpret both  $P_c(4380)^+$  and  $P_c(4380)^+$  as hadronic molecules, it is essential to remember that these two states have opposite parities. Thus one cannot construct both of them as  $S$ -wave bound states of a meson and a baryon with natural parities. Therefore, the interpretation of the  $P_c^+$  states as hadronic molecules has been by no means unanimous. Moreover, the molecular model is not consistent with one of the  $P_c^+$  states having a spin of  $5/2$ , since  $S$ -wave combinations of baryon-meson combination that can produce such spin have thresholds which are too high in mass to be plausible. Therefore, the confirmation or disproof of the presence of this high-spin structure is a critical test of the molecular model. The large  $P_c(4380)^+$  width is also difficult to accommodate in the molecular bound state model, but could have its origin in baryon-meson rescattering effects discussed below.

Shortly after the experimental discovery it has been conjectured that the observed resonances could be kinematic effects due to vicinity of thresholds and so-called triangle singularity [73–76]. While these effects might explain the large  $P_c(4380)^+$  width, since such models involve  $S$ -wave rescattering of virtual baryon-meson pairs, they also cannot be reconciled with one of the  $P_c^+$  peaks having effective spin of  $5/2$ .

In addition to the molecular and diquark approach, the  $P_c^+$  pentaquarks have also been analysed within the soliton

# Baryon Particle Listings

## Pentaquarks

picture of baryons, as a bound state of a soliton and an anti-charmed meson [77]. Quite recently an interesting attempt has been made to explain the narrow width of tetraquarks and pentaquarks by extending to these states the string junction picture of baryons in QCD [78].

More extensive reviews of the theoretical issues can be found in Refs. 79,80.

So far the  $P_c^+$  states have been observed by only one experiment in only one channel. It is essential to explore other possible experimental channels. Proposals have been made for searching for heavy pentaquarks in photoproduction [81–83], (c.f. also related work on computation of  $J/\psi(\eta_c)N$  and  $\Upsilon(\eta_b)N$  cross sections [84]), in heavy ion collisions at LHC [85], in  $pA$  collisions [86], and in pion-induced processes [87,88].

### MAGNETIC MONOPOLES

Updated August 2015 by D. Milstead (Stockholm Univ.) and E.J. Weinberg (Columbia Univ.).

The symmetry between electric and magnetic fields in the sourcefree Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles, even though there is at present no strong theoretical motivation for these.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge  $Q_M$  and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi} \frac{\hat{\mathbf{r}}}{r^2}. \quad (1)$$

Any vector potential  $\mathbf{A}$  whose curl is equal to  $\mathbf{B}$  must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge  $Q_E$  would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of  $2\pi$ . Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges  $Q_E^{\min}$  and  $Q_M^{\min}$  obeying

$$Q_E^{\min} Q_M^{\min} = 2\pi. \quad (2)$$

(For monopoles which also carry an electric charge, called dyons, the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r} \times \mathbf{v} - 4\pi Q_E Q_M \hat{\mathbf{r}} \quad (3)$$

Requiring the radial component of  $\mathbf{L}$  to be quantized in half-integer units yields Eq. (2).

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [2,3]. For example, a monopole could have both a

U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge  $Q_M^D \equiv 2\pi/e$ , the result that would be obtained by substituting the electron charge into Eq. (2). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. (2) and conclude that  $Q_M$  must be a multiple of  $6\pi/e$ .

The prediction of GUT monopoles arises from the work of 't Hooft [4] and Polyakov [5], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field  $\phi$  breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass  $M_V$  to two of the gauge bosons. In order to have finite energy,  $\phi$  must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude  $v$  of  $\langle\phi\rangle$ , but not its orientation in the internal SU(2) space. In the monopole solution, the direction of  $\phi$  in internal space is correlated with the position in physical space; *i.e.*,  $\phi^a \sim v\hat{r}^a$ . The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of  $\phi$  requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge  $Q_M = 4\pi/e$ . Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\text{mon}} \sim \frac{4\pi M_V}{e^2}. \quad (4)$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the electroweak theory, with SU(2) × U(1) broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions.

The second is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. The monopole mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\text{SU}(5) \xrightarrow{M_X} \text{SU}(3) \times \text{SU}(2) \times \text{U}(1) \xrightarrow{M_W} \text{SU}(3) \times \text{U}(1) \quad (5)$$

has a monopole [6] with  $Q_M = 2\pi/e$  and mass

$$M_{\text{mon}} \sim \frac{4\pi M_X}{g^2}, \quad (6)$$

## Searches Particle Listings

### Magnetic Monopole Searches

where  $g$  is the SU(5) gauge coupling. For a unification scale of  $10^{16}$  GeV, these monopoles would have a mass  $M_{\text{mon}} \sim 10^{17} - 10^{18}$  GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$\text{SO}(10) \xrightarrow{M_1} \text{SU}(4) \times \text{SU}(2) \times \text{SU}(2) \xrightarrow{M_2} \text{SU}(3) \times \text{SU}(2) \times \text{U}(1) \quad (7)$$

there is monopole with  $Q_M = 2\pi/e$  and mass  $\sim 4\pi M_1/g^2$  and a much lighter monopole with  $Q_M = 4\pi/e$  and mass  $\sim 4\pi M_2/g^2$  [7].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon-monopole scattering. The surprising feature, pointed out by Callan [8] and Rubakov [9], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as  $p + \text{monopole} \rightarrow e^+ + \pi^0 + \text{monopole}$  are essentially geometric; *i.e.*,  $\sigma_{\Delta B} \sim 10^{-27} \text{ cm}^2$ , where  $\beta = v/c$ . Note, however, that intermediate mass monopoles arising at later stages of symmetry breakings, such as the doubly charged monopoles of the SO(10) theory, do not catalyze baryon number violation.

**Production and Annihilation:** GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early universe as topological defects arising via the Kibble mechanism [10] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [11]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

**Astrophysical and Cosmological Bounds:** If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of  $10^{-3}c$ , comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field  $B \sim 3\mu\text{G}$ .

A monopole with the Dirac charge and mass  $M$  would be accelerated by this field to a velocity

$$v_{\text{mag}} \sim \begin{cases} c, & M \lesssim 10^{11} \text{ GeV} \\ 10^{-3}c \left( \frac{10^{17} \text{ GeV}}{M} \right)^{1/2}, & M \gtrsim 10^{11} \text{ GeV} \end{cases} \quad (8)$$

Accelerating these monopoles drains energy from the magnetic field. Parker [12] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. 13 for details), this Parker bound is

$$F < \begin{cases} 10^{-15} \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}, & M \lesssim 10^{17} \text{ GeV} \\ 10^{-15} \left( \frac{M}{10^{17} \text{ GeV}} \right) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}, & M \gtrsim 10^{17} \text{ GeV} \end{cases} \quad (9)$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [14],

$$F < \left[ \frac{M}{10^{17} \text{ GeV}} + (3 \times 10^{-6}) \right] 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (10)$$

Considering magnetic fields in galactic clusters gives a bound [15] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the universe. If the monopole mass density is a fraction  $\Omega_M$  of the critical density, and the monopoles were uniformly distributed throughout the universe, there would be a monopole flux

$$F_{\text{uniform}} = 1.3 \times 10^{-16} \Omega_M \left( \frac{10^{17} \text{ GeV}}{M} \right) \left( \frac{v}{10^{-3}c} \right) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (11)$$

If we assume that  $\Omega_M \sim 0.1$ , this gives a stronger constraint than the Parker bound for  $M \sim 10^{15}$  GeV. However, monopoles with masses  $\sim 10^{17}$  GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of  $\Omega_M$ , and the mass density bound only becomes stronger than the Parker bound for  $M \sim 10^{18}$  GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [16–20], white dwarfs [21], and Jovian planets [22] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and

on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\left(\frac{\sigma_{\Delta B}\beta}{10^{-27}\text{cm}^2}\right) \sim (10^{-18} - 10^{-29})\text{cm}^{-2}\text{sr}^{-1}\text{sec}^{-1}. \quad (12)$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of Eq. (12).

**Searches for Magnetic Monopoles:** To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be  $Q_e^m < 10^{-24}Q_M^D$  [23] (where  $Q_M^D$  is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass <sup>1</sup> [24]. Nevertheless, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [25]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

**Search Techniques:** Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [26,27].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has

been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

**Searches for Monopoles Bound in Matter:** Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [28]. A stringent upper limit on the monopoles per nucleon ratio of  $\sim 10^{-29}$  has been obtained [28].

**Searches in Cosmic Rays:** Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [29] or assigned a modest value (1mb) [30]. Searches which explicitly exploit the expected catalysed decays are discussed in the next section.

Although early cosmic ray searches using the induction technique [31] and NTDs [32] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of  $\sim 10000\text{m}^2$  for an isotropic flux. As shown in Fig. 1, this experiment has so far provided the most extensive  $\beta$ -dependent flux limits for GUT monopoles with Dirac charge [30]. Also shown are limits from an experiment at the OHYA mine in Japan [29], which used a  $2000\text{m}^2$  array of NTDs.

In Fig. 1, upper flux limits are also shown as a function of mass for monopole speed  $\beta > 0.05$ . In addition to MACRO and OYHA flux limits, results from the SLIM [33] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ( $10^5 \lesssim M \lesssim 10^{12}$  GeV). In addition to the results shown in Fig. 1, limits as low as  $\sim 3 \times 10^{-18} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$  and  $\sim 10^{-17} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$  were obtained for monopoles with  $\beta > 0.8$  and  $\beta > 0.625$  by the IceCube [34] and Antares [35] experiments, respectively. The most stringent constraints on the flux of ultra-relativistic monopoles have been obtained by the RICE [36] and ANITA-II experiments [37] at the South Pole which were sensitive to monopoles with  $\gamma$  values of  $10^7 \lesssim \gamma \lesssim 10^{12}$  and  $10^9 \lesssim \gamma \lesssim 10^{13}$ , respectively, and which produced flux limits as low as  $10^{-19} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ .

**Searches via the Catalysis of Nucleon-Decay:** Searches have been performed for evidence of the catalysed decay of a nucleon by a monopole, as predicted by the Callan-Rubakov mechanism. The searches are thus sensitive to the assumed value of the catalysis decay cross section. Searches have been made with the Soudan [38] and Macro [39] experiments, using tracking detectors. Searches at IMB [40], the underwater Lake Baikal

<sup>1</sup> Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

## Magnetic Monopole Searches

**Figure 1:** Upper flux limits for (a) GUT monopoles as a function of  $\beta$  (b) Monopoles as a function of mass for  $\beta > 0.05$ .

experiment [41] and the The IceCube experiment [42] which exploit the Cerenkov effect have also been made. The resulting  $\beta$ -dependent flux limits from these experiments typically vary between  $\sim 10^{-18}$  and  $\sim 10^{-14} \text{cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$  [25]. A recent search for low energy neutrinos (assumed to be produced from induced proton decay in the sun) was made at Super-Kamiokande [43]. A  $\beta$ -dependent limit of  $6.3 \times 10^{-24} (\frac{\beta}{10^{-3}})^2 \text{cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$  was obtained.

**Searches at Colliders:** Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

**Direct Searches at Colliders:** Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass regions. A conservative approach with as little model-dependence as possible is thus to present the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 2 for recent results from high energy colliders.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made in  $pp$  collisions at the LHC by the ATLAS experiment [44]. In this search, highly ionising particles leaving characteristic energy deposition profiles were sought. Tevatron searches have also been carried out by the CDF [45] and E882 [46] experiments. The CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Earlier searches at the Tevatron, such as [47], used

**Figure 2:** Upper limits on the production cross sections of monopoles from various collider-based experiments.

NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [48] and searches for trapped monopoles [49].

The only LEP-2 search was made by OPAL [50] which quoted cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to  $\sim 45$  GeV. The L6-MODAL experiment [51] gave limits for monopoles with charges in the range  $0.9Q_M^D$  and  $3.6Q_M^D$ , whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as  $0.1Q_M^D$  [52]. The deployment of NTDs around the beam interaction point was also used at earlier  $e^+e^-$  colliders such as KEK [53] and PETRA [54]. Searches at  $e^+e^-$  facilities have also been made for particles following non-helical trajectories [55,56].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beam pipe which had been used by the H1 experiment at HERA [57]. Cross section limits were set for monopoles with charges in the range  $Q_M^D - 6Q_M^D$  for masses up to around 140 GeV.

**Indirect Searches at Colliders:** It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [58,59]. Photon-based searches were made by the D0 [60] and L3 [61] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However,

it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

- <sup>1</sup> AAD 12cs searched for monopoles as highly ionising objects. The cross section limits are based on an assumed Drell Yan-like production process for spin 1/2 monopoles. The limits are mass- and scenario-dependent.
- <sup>2</sup> ABBIENDI 08 assume production of spin 1/2 monopoles with effective charge  $g\beta$  ( $n=1$ ), via  $e^+e^- \rightarrow \gamma^* \rightarrow M\overline{M}$ , so that the cross section is proportional to  $(1 + \cos^2\theta)$ . There is no  $z$  information for such highly saturated tracks, so a parabolic track in the jet chamber is projected onto the  $xy$  plane. Charge per hit in the chamber produces a clean separation of signal and background.
- <sup>3</sup> ABULENCIA 06K searches for high-ionizing signals in CDF central outer tracker and time-of-flight detector. For Drell-Yan  $M\overline{M}$  production, the cross section limit implies  $M > 360$  GeV at 95% CL.
- <sup>4</sup> AKTAS 05A model-dependent limits as a function of monopole mass shown for arbitrary mass of 60 GeV. Based on search for stopped monopoles in the H1 Al beam pipe.
- <sup>5</sup> AKTAS 05A limits with assumed elastic spin 0 monopole pair production.
- <sup>6</sup> AKTAS 05A limits with assumed inelastic spin 1/2 monopole pair production.
- <sup>7</sup> KALBFLEISCH 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Cross section results moderately model dependent; interpretation as a mass lower limit depends on possibly invalid perturbation expansion.
- <sup>8</sup> KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.
- <sup>9</sup> KALBFLEISCH 00 result is for aluminum.
- <sup>10</sup> KALBFLEISCH 00 result is for beryllium.
- <sup>11</sup> HE 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.
- <sup>12</sup> Multiphoton events.
- <sup>13</sup> Cherenkov radiation polarization.
- <sup>14</sup> Re-examines CERN neutrino experiments.

> 510			88-94	$e^+e^-$	<sup>2</sup> ACCIARRI 95c	L3

- <sup>1</sup> ABBOTT 98k search for heavy pointlike Dirac monopoles via central production of a pair of photons with high transverse energies.
- <sup>2</sup> ACCIARRI 95c finds a limit  $B(Z \rightarrow \gamma\gamma\gamma) < 0.8 \times 10^{-5}$  (which is possible via a monopole loop) at 95% CL and sets the mass limit via a cross section model.

### Monopole Flux — Cosmic Ray Searches

“Caty” in the charge column indicates a search for monopole-catalyzed nucleon decay.

- <sup>1</sup> Beyond the monopole speed, the limits of AARTSEN 14 depend on the catalysis cross section ( $\sigma$ ) which corresponds to the monopole radiating  $\tilde{l}$  times the light per track length compared to the Cherenkov light from a single electrically charged, relativistic particle. The values quoted here correspond to  $\sigma = 1$  barn or  $\tilde{l} = 30$ .
- <sup>2</sup> ABBASI 13 and ABBASI 10A were based on a Cherenkov signature in an array of optical modules which were sunk in the Antarctic ice cap. Limits are speed-dependent.
- <sup>3</sup> ADRIAN-MARTINEZ 12A measurements were based on a Cherenkov signature in an underwater telescope in the Western Mediterranean Sea. Limits are speed-dependent.

See key on page 601

Searches Particle Listings  
Magnetic Monopole Searches

- <sup>4</sup> The limits from UENO 12 depend on the monopole speed and are also sensitive to assumed values of monopole mass and the catalysis cross section.
- <sup>5</sup> HOGAN 08 and DETRIXHE 11 limits on relativistic monopoles are based on nonobservation of radio Cherenkov signals at the South Pole. Limits are speed-dependent.
- <sup>6</sup> BALESTRA 08 exposed of nuclear track detector modules totaling 400 m<sup>2</sup> for 4 years at the Chacaltaya Laboratory (5230 m) in search for intermediate-mass monopoles with  $\beta > 0.05$ . The analysis is mainly based on three CR39 modules. For  $M > 5 \times 10^{13}$  GeV there can be upward-going monopoles as well, hence the flux limit is half that obtained for less massive monopoles. Previous experiments (e.g. MACRO and OHYA (ORITO 91)) had set limits only for  $M > 1 \times 10^{19}$  GeV.
- <sup>7</sup> AMBROSIO 02b direct search final result for  $m \geq 10^{17}$  GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from  $\beta=4 \times 10^{-5}$  ( $3.1 \times 10^{-16}$  cm<sup>-2</sup> sr<sup>-1</sup> s<sup>-1</sup>) to  $\beta=1 \times 10^{-4}$  ( $2.1 \times 10^{-16}$  cm<sup>-2</sup> sr<sup>-1</sup> s<sup>-1</sup>). Limit curve in paper is piecewise continuous due to different detection techniques for different  $\beta$  ranges.
- <sup>8</sup> AMBROSIO 02c limit for catalysis of nucleon decay with catalysis cross section of  $\approx 1$  mb. The flux limit increases by  $\sim 3$  at the higher  $\beta$  limit, and increases to  $1 \times 10^{-14}$  cm<sup>-2</sup> sr<sup>-1</sup> s<sup>-1</sup> if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of 4250 m<sup>2</sup> sr.
- <sup>9</sup> AMBROSIO 02d result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of  $\beta$  not given. Included in AMBROSIO 02b.
- <sup>10</sup> AMBROSIO 97 global MACRO 90%CL is  $0.78 \times 10^{-15}$  at  $\beta=1.1 \times 10^{-4}$ , goes through a minimum at  $0.61 \times 10^{-15}$  near  $\beta=(1.1-2.7) \times 10^{-3}$ , then rises to  $0.84 \times 10^{-15}$  at  $\beta=0.1$ . The global limit in this region is below the Parker bound at  $10^{-15}$ . Less stringent limits are established for  $4 \times 10^{-5} < \beta < 1 \times 10^{-4}$ . Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.
- <sup>11</sup> AHLEN 94 limit for dyons extends down to  $\beta=0.9E-4$  and a limit of  $1.3E-4$  extends to  $\beta=0.8E-4$ . Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. See AMBROSIO 97 for additional results.
- <sup>12</sup> Catalysis of nucleon decay; sensitive to assumed catalysis cross section.
- <sup>13</sup> ORITO 91 limits are functions of velocity. Lowest limits are given here.
- <sup>14</sup> Used DKMPR mechanism and Penning effect.
- <sup>15</sup> Assumes monopole attaches fermion nucleus.
- <sup>16</sup> Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.
- <sup>17</sup> Based on lack of high-energy solar neutrinos from catalysis in the sun.
- <sup>18</sup> Anomalous long-range  $\alpha$  (<sup>4</sup>He) tracks.
- <sup>19</sup> CABRERA 82 candidate event has single Dirac charge within  $\pm 5\%$ .
- <sup>20</sup> ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

**I.1. Introduction:** Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory which transforms fermions into bosons and vice versa [1]. The existence of such a non-trivial extension of the Poincaré symmetry of ordinary quantum field theory was initially surprising, and its form is highly constrained by theoretical principles [2]. Supersymmetry also provides a framework for the unification of particle physics and gravity [3–6] at the Planck energy scale,  $M_P \approx 10^{19}$  GeV, where the gravitational interactions become comparable in magnitude to the gauge interactions. Moreover, supersymmetry can provide an explanation of the large hierarchy between the energy scale that characterizes electroweak symmetry breaking (of order 100 GeV) and the Planck scale [7–10]. The stability of this large *gauge hierarchy* with respect to radiative quantum corrections is not possible to maintain in the Standard Model without an *unnatural* fine-tuning of the parameters of the fundamental theory at the Planck scale. In contrast, in a supersymmetric extension of the Standard Model, it is possible to maintain the gauge hierarchy while providing a natural framework for elementary scalar fields.

If supersymmetry were an exact symmetry of nature, then particles and their *superpartners*, which differ in spin by half a unit, would be degenerate in mass. Since superpartners have not (yet) been observed, supersymmetry must be a broken symmetry. Nevertheless, the stability of the gauge hierarchy can still be maintained if the supersymmetry breaking is *soft* [11,12], and the corresponding supersymmetry-breaking mass parameters are no larger than a few TeV. Whether this is still plausible in light of recent supersymmetry searches at the LHC [13] will be discussed in Section I.7.

In particular, soft-supersymmetry-breaking terms of the Lagrangian involve combinations of fields with total mass dimension of three or less, with some restrictions on the dimension-three terms as elucidated in Ref. 11. The impact of the soft terms becomes negligible at energy scales much larger than the

size of the supersymmetry-breaking masses. Thus, a theory of *weak-scale supersymmetry*, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry breaking, provides a *natural* framework for the origin and the stability of the gauge hierarchy [7–10].

At present, there is no unambiguous experimental evidence for the breakdown of the Standard Model at or below the TeV scale. The expectations for new TeV-scale physics beyond the Standard Model are based primarily on three theoretical arguments. First, in a theory with an elementary scalar field of mass  $m$  and interaction strength  $\lambda$  (e.g., a quartic scalar self-coupling, the square of a gauge coupling or the square of a Yukawa coupling), the stability with respect to quantum corrections requires the existence of an energy cutoff roughly of order  $(16\pi^2/\lambda)^{1/2}m$ , beyond which new physics must enter [14]. A significantly larger energy cutoff would require an unnatural fine-tuning of parameters that govern the low-energy theory. Applying this argument to the Standard Model leads to an expectation of new physics at the TeV scale [10].

Second, the unification of the three Standard Model gauge couplings at a very high energy close to the Planck scale is possible if new physics beyond the Standard Model (which modifies the running of the gauge couplings above the electroweak scale) is present. The minimal supersymmetric extension of the Standard Model (MSSM), where superpartner masses lie below a few TeV, provides an example of successful gauge coupling unification [15].

Third, the existence of dark matter, which makes up approximately one quarter of the energy density of the universe, cannot be explained within the Standard Model of particle physics [16]. Remarkably, a stable weakly-interacting massive particle (WIMP) whose mass and interaction rate are governed by new physics associated with the TeV-scale can be consistent with the observed density of dark matter (this is the so-called *WIMP miracle*, which is reviewed in Ref. 17). The lightest supersymmetric particle, if stable, is a promising (although not the unique) candidate for the dark matter [18–22]. Further aspects of dark matter can be found in Ref. 23.

Another phenomenon not explained by the Standard Model is the origin of the matter–antimatter asymmetry of the universe [24,25]. Models of baryogenesis must satisfy the three Sakharov conditions [26]:  $C$  and  $CP$  violation, baryon number violation and a departure from thermal equilibrium. For example, the matter–antimatter asymmetry in the early universe can be generated at the electroweak phase transition if the transition is sufficiently first-order [27]. These conditions are not satisfied in the Standard Model, since the  $CP$  violation is too small and the phase transition is not strongly first-order [24,27]. In contrast, it is possible to satisfy these conditions in supersymmetric extensions of the Standard Model, where new sources of  $CP$ -violation exist and supersymmetric loops provide corrections to the temperature-dependent effective potential that can render the transition sufficiently first-order. The MSSM parameter space in which electroweak baryogenesis

occurs is strongly constrained by LHC data [28]. However, extended supersymmetric models provide new opportunities for successful electroweak baryogenesis [29]. Alternative mechanisms for baryogenesis in supersymmetric models, including the Affleck-Dine mechanism [30,24] (where a baryon asymmetry is generated through coherent scalar fields) and leptogenesis [31] (where the lepton asymmetry is converted into a baryon asymmetry at the electroweak phase transition) have also been considered in the literature.

**I.2. Structure of the MSSM:** The minimal supersymmetric extension of the Standard Model consists of the fields of the two-Higgs-doublet extension of the Standard Model and the corresponding superpartners [32,33]. A particle and its superpartner together form a supermultiplet. The corresponding field content of the supermultiplets of the MSSM and their gauge quantum numbers are shown in Table 1. The electric charge  $Q = T_3 + \frac{1}{2}Y$  is determined in terms of the third component of the weak isospin ( $T_3$ ) and the U(1) weak hypercharge ( $Y$ ).

**Table 1:** The fields of the MSSM and their  $SU(3) \times SU(2) \times U(1)$  quantum numbers are listed. For simplicity, only one generation of quarks and leptons is exhibited. For each lepton, quark, and Higgs super-multiplet, there is a corresponding anti-particle multiplet of charge-conjugated fermions and their associated scalar partners [34].

Field Content of the MSSM						
Super-multiplets	Super-field	Bosonic fields	Fermionic partners	SU(3)	SU(2)	U(1)
gluon/gluino	$\hat{V}_8$	$g$	$\tilde{g}$	8	1	0
gauge/	$\hat{V}$	$W^\pm, W^0$	$\tilde{W}^\pm, \tilde{W}^0$	1	3	0
gaugino	$\hat{V}'$	$B$	$\tilde{B}$	1	1	0
slepton/	$\hat{L}$	$(\tilde{\nu}_L, \tilde{e}_L^-)$	$(\nu, e^-)_L$	1	2	-1
lepton	$\hat{E}^c$	$\tilde{e}_R^+$	$e_L^c$	1	1	2
squark/	$\hat{Q}$	$(\tilde{u}_L, \tilde{d}_L)$	$(u, d)_L$	3	2	1/3
quark	$\hat{U}^c$	$\tilde{u}_R^*$	$u_L^c$	$\bar{3}$	1	-4/3
	$\hat{D}^c$	$\tilde{d}_R^*$	$d_L^c$	$\bar{3}$	1	2/3
Higgs/	$\hat{H}_d$	$(H_d^0, H_d^-)$	$(\tilde{H}_d^0, \tilde{H}_d^-)$	1	2	-1
higgsino	$\hat{H}_u$	$(H_u^+, H_u^0)$	$(\tilde{H}_u^+, \tilde{H}_u^0)$	1	2	1

The gauge supermultiplets consist of the gluons and their *gluino* fermionic superpartners and the  $SU(2) \times U(1)$  gauge bosons and their *gaugino* fermionic superpartners. The matter supermultiplets consist of three generations of left-handed quarks and leptons and their scalar superpartners (*squarks* and *sleptons*, collectively referred to as *sfermions*), and the corresponding antiparticles. The Higgs supermultiplets consist of two complex Higgs doublets, their *higgsino* fermionic superpartners, and the corresponding antiparticles. The enlarged Higgs sector of the MSSM constitutes the minimal structure needed to guarantee the cancellation of anomalies from the introduction of the higgsino superpartners. Moreover, without a second Higgs doublet, one cannot generate mass for both “up”-type and

## Searches Particle Listings

### Supersymmetric Particle Searches

“down”-type quarks (and charged leptons) in a way consistent with the underlying supersymmetry [35–37].

In the most elegant treatment of supersymmetry, spacetime is extended to superspace which consists of the spacetime coordinates and new anticommuting fermionic coordinates  $\theta$  and  $\theta^\dagger$  [38]. Each supermultiplet is represented by a *superfield* that is a function of the superspace coordinates. The fields of a given supermultiplet (which are functions of the spacetime coordinates) are components of the corresponding superfield.

Vector superfields contain the gauge boson fields and their gaugino partners. Chiral superfields contain the spin-0 and spin-1/2 fields of the matter or Higgs supermultiplets. A general supersymmetric Lagrangian is determined by three functions of the chiral superfields [5]: the superpotential, the Kähler potential, and the gauge kinetic function (which can be appropriately generalized to accommodate higher derivative terms [39]). Minimal forms for the Kähler potential and gauge kinetic function, which generate canonical kinetic energy terms for all the fields, are required for *renormalizable* globally supersymmetric theories. A renormalizable superpotential, which is at most cubic in the chiral superfields, yields supersymmetric Yukawa couplings and mass terms. A combination of gauge invariance and supersymmetry produces couplings of gaugino fields to matter (or Higgs) fields and their corresponding superpartners. The (renormalizable) MSSM Lagrangian is then constructed by including all possible supersymmetric interaction terms (of dimension four or less) that satisfy  $SU(3) \times SU(2) \times U(1)$  gauge invariance and  $B-L$  conservation (where  $B$  = baryon number and  $L$  = lepton number). Finally, the most general soft-supersymmetry-breaking terms consistent with these symmetries are added [11,12,40].

Although the MSSM is the focus of much of this review, there is some motivation for considering non-minimal supersymmetric extensions of the Standard Model. For example, extra structure is needed to generate non-zero neutrino masses as discussed in Section I.8. In addition, in order to address some theoretical issues and tensions associated with the MSSM, it has been fruitful to introduce one additional singlet Higgs superfield. The resulting next-to-minimal supersymmetric extension of the Standard Model (NMSSM) [41] is considered further in Sections I.4–I.7 and I.9. Finally, one is always free to add additional fields to the Standard Model along with the corresponding superpartners. However, only certain choices for the new fields (*e.g.*, the addition of complete  $SU(5)$  multiplets) will preserve the successful gauge coupling unification. Some examples will be briefly mentioned in Section I.9.

**I.2.1. R-parity and the lightest supersymmetric particle:** As a consequence of  $B-L$  invariance, the MSSM possesses a multiplicative R-parity invariance, where  $R = (-1)^{3(B-L)+2S}$  for a particle of spin  $S$  [42]. This implies that all the particles of the Standard Model have even R-parity, whereas the corresponding superpartners have odd R-parity. The conservation of R-parity in scattering and decay processes has a critical impact on supersymmetric phenomenology. For example, any

initial state in a scattering experiment will involve ordinary (R-even) particles. Consequently, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. Moreover, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [20]. Consequently, the LSP in an R-parity-conserving theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) energy, due to the escape of the LSP. Moreover, as noted in Section I.1 and reviewed in Refs. [21,22], the stability of the LSP in R-parity-conserving supersymmetry makes it a promising candidate for dark matter.

**I.2.2. The goldstino and gravitino:** In the MSSM, supersymmetry breaking is accomplished by including the most general renormalizable soft-supersymmetry-breaking terms consistent with the  $SU(3) \times SU(2) \times U(1)$  gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the *goldstino* ( $\tilde{G}_{1/2}$ ) must exist. The goldstino would then be the LSP, and could play an important role in supersymmetric phenomenology [43].

However, the goldstino degrees of freedom are physical only in models of spontaneously-broken global supersymmetry. If supersymmetry is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity [44]. In models of spontaneously-broken supergravity, the goldstino is “absorbed” by the *gravitino* ( $\tilde{G}$ ) [often called  $\tilde{g}_{3/2}$  in the older literature], the spin-3/2 superpartner of the graviton, via the super-Higgs mechanism [45]. Consequently, the goldstino is removed from the physical spectrum and the gravitino acquires a mass (denoted by  $m_{3/2}$ ). If  $m_{3/2}$  is smaller than the mass of the lightest superpartner of the Standard Model particles, then the gravitino will be the LSP.

In processes with center-of-mass energy  $E \gg m_{3/2}$ , the goldstino–gravitino equivalence theorem [46] states that the interactions of the helicity  $\pm \frac{1}{2}$  gravitino (whose properties approximate those of the goldstino) dominate those of the helicity  $\pm \frac{3}{2}$  gravitino. The interactions of gravitinos with other light fields can be described by a low-energy effective Lagrangian that is determined by fundamental principles [47].

Theories in which supersymmetry breaking is independently generated by a multiplicity of sources will yield multiple goldstino states, collectively called *goldstini* [48]. One linear combination of the goldstini is identified with the exactly massless goldstino  $\tilde{G}_{1/2}$  of global supersymmetry, which is absorbed by the gravitino in local supersymmetry as described above. The

linear combinations of goldstini orthogonal to  $\tilde{G}_{1/2}$ , sometimes called pseudo-goldstinos in the literature, acquire radiatively generated masses. Theoretical and phenomenological implications of the pseudo-goldstinos are discussed further in Ref. 48.

**I.2.3. Hidden sectors and the structure of supersymmetry breaking:** It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken weak-scale supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. An alternative scheme posits a theory consisting of at least two distinct sectors: a *visible* sector consisting of the particles of the MSSM [40] and a so-called *hidden* sector where supersymmetry breaking is generated. It is often (but not always) assumed that particles of the hidden sector are neutral with respect to the Standard Model gauge group. The effects of the hidden sector supersymmetry breaking are then transmitted to the MSSM by some mechanism (often involving the mediation by particles that comprise an additional *messenger* sector). Two theoretical scenarios that exhibit this structure are gravity-mediated and gauge-mediated supersymmetry breaking.

Supergravity models provide a natural mechanism for transmitting the supersymmetry breaking of the hidden sector to the particle spectrum of the MSSM. In models of *gravity-mediated* supersymmetry breaking, gravity is the messenger of supersymmetry breaking [49–53]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (suppressed by inverse powers of the Planck mass). The soft-supersymmetry-breaking parameters arise as model-dependent multiples of the gravitino mass  $m_{3/2}$ . In this scenario,  $m_{3/2}$  is of order the electroweak-symmetry-breaking scale, while the gravitino couplings are roughly gravitational in strength [3,54]. However, such a gravitino typically plays no direct role in supersymmetric phenomenology at colliders (except perhaps indirectly in the case where the gravitino is the LSP [55]).

Under certain theoretical assumptions on the structure of the Kähler potential (the so-called sequestered form introduced in Ref. 56), supersymmetry breaking is due entirely to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [56]. In particular, gaugino masses are radiatively generated at one-loop, and squark and slepton squared-mass matrices are flavor-diagonal. In sequestered scenarios, sfermion squared-masses arise at two-loops, which implies that gluino and sfermion masses are of the same order or magnitude. This approach is called *anomaly-mediated* supersymmetry breaking (AMSB). Indeed, anomaly mediation is more generic than originally conceived, and provides a ubiquitous source of supersymmetry breaking [57]. However in the simplest formulation of AMSB as applied to the MSSM, the squared-masses of the sleptons are negative (known as the so-called tachyonic slepton problem). It may be possible to cure this fatal flaw in non-minimal extensions of the MSSM [58]. Alternatively, one can assert that anomaly mediation is not the sole source of supersymmetry breaking in the sfermion sectors. In non-sequestered scenarios, sfermion squared-masses can arise

at tree-level, in which case squark masses would be parametrically larger than the loop-suppressed gaugino masses [59].

In *gauge-mediated* supersymmetry breaking (GMSB), gauge forces transmit the supersymmetry breaking to the MSSM. A typical structure of such models involves a hidden sector where supersymmetry is broken, a messenger sector consisting of particles (messengers) with nontrivial  $SU(3) \times SU(2) \times U(1)$  quantum numbers, and the visible sector consisting of the fields of the MSSM [60–62]. The direct coupling of the messengers to the hidden sector generates a supersymmetry-breaking spectrum in the messenger sector. Supersymmetry breaking is then transmitted to the MSSM via the virtual exchange of the messenger fields. In models of *direct gauge mediation*, there is no separate hidden sector. In particular, the sector in which the supersymmetry breaking originates includes fields that carry nontrivial Standard Model quantum numbers, which allows for the direct transmission of supersymmetry breaking to the MSSM [63].

In models of gauge-mediated supersymmetry breaking, the gravitino is the LSP [18], as its mass can range from a few eV (in the case of low supersymmetry breaking scales) up to a few GeV (in the case of high supersymmetry breaking scales). In particular, the gravitino is a potential dark matter candidate (for a review and guide to the literature, see Ref. 22). Big bang nucleosynthesis also provides some interesting constraints on the gravitino and the properties of the next-to-lightest supersymmetric particle that decays into the gravitino LSP [64]. The couplings of the helicity  $\pm\frac{1}{2}$  components of  $\tilde{G}$  to the particles of the MSSM (which approximate those of the goldstino as previously noted in Section I.2.2) are significantly stronger than gravitational strength and amenable to experimental collider analyses.

The concept of a hidden sector is more general than supersymmetry. *Hidden valley* models [65] posit the existence of a hidden sector of new particles and interactions that are very weakly coupled to particles of the Standard Model. The impact of a hidden valley on supersymmetric phenomenology at colliders can be significant if the LSP lies in the hidden sector [66].

#### I.2.4. Supersymmetry and extra dimensions:

Approaches to supersymmetry breaking have also been developed in the context of theories in which the number of space dimensions is greater than three. In particular, a number of supersymmetry-breaking mechanisms have been proposed that are inherently extra-dimensional [67]. The size of the extra dimensions can be significantly larger than  $M_P^{-1}$ ; in some cases of order  $(\text{TeV})^{-1}$  or even larger [68,69].

For example, in one approach the fields of the MSSM live on some brane (a lower-dimensional manifold embedded in a higher-dimensional spacetime), while the sector of the theory that breaks supersymmetry lives on a second spatially-separated brane. Two examples of this approach are anomaly-mediated supersymmetry breaking [56] and gaugino-mediated supersymmetry breaking [70]. In both cases, supersymmetry breaking is transmitted through fields that live in the bulk (the

## Searches Particle Listings

### Supersymmetric Particle Searches

higher-dimensional space between the two branes). This setup has some features in common with both gravity-mediated and gauge-mediated supersymmetry breaking (*e.g.*, a hidden and visible sector and messengers).

Alternatively, one can consider a higher-dimensional theory that is compactified to four spacetime dimensions. In this approach, supersymmetry is broken by boundary conditions on the compactified space that distinguish between fermions and bosons. This is the so-called Scherk-Schwarz mechanism [71]. The phenomenology of such models can be strikingly different from that of the usual MSSM [72].

**I.2.5. Split-supersymmetry:** If supersymmetry is not connected with the origin of the electroweak scale, it may still be possible that some remnant of the superparticle spectrum survives down to the TeV-scale or below. This is the idea of *split-supersymmetry* [73,74], in which scalar superpartners of the quarks and leptons are significantly heavier (perhaps by many orders of magnitude) than 1 TeV, whereas the fermionic superpartners of the gauge and Higgs bosons have masses on the order of 1 TeV or below. With the exception of a single light neutral scalar whose properties are practically indistinguishable from those of the Standard Model Higgs boson, all other Higgs bosons are also assumed to be very heavy. Among the supersymmetric particles, only the fermionic superpartners may be kinematically accessible at the LHC.

In models of split supersymmetry, the top squark masses cannot be arbitrarily heavy, as these parameters enter in the radiative corrections to the observed Higgs mass. In the MSSM, a Higgs boson mass of 125 GeV [75] implies an upper bound on the mass scale that characterizes the top squarks in the range of 10 to  $10^7$  TeV [76,77,78], depending on the value of the ratio of the two neutral Higgs field vacuum expectation values (although the range of upper bounds can be relaxed by further varying other relevant MSSM parameters [78]). In some approaches, gaugino masses are one-loop suppressed relative to the sfermion masses, corresponding to the so-called *mini-split* supersymmetry spectrum [77,79]. The higgsino mass scale may or may not be likewise suppressed depending on the details of the model [80].

The supersymmetry breaking required to produce such a split-supersymmetry spectrum would destabilize the gauge hierarchy, and thus would not yield an explanation for the scale of electroweak symmetry breaking. Nevertheless, models of split-supersymmetry can account for the dark matter (which is assumed to be the LSP gaugino or higgsino) and gauge coupling unification, thereby preserving two of the good features of weak-scale supersymmetry. Finally, as a consequence of the very large squark and slepton masses, the severity of the flavor and CP-violation problems alluded to at the beginning of Section I.6 are sufficiently reduced to be consistent with experimental observations.

**I.3. Parameters of the MSSM:** The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving and the supersymmetry-breaking

sectors. A careful discussion of the conventions used here in defining the tree-level MSSM parameters can be found in Ref. 81. For simplicity, consider first the case of one generation of quarks, leptons, and their scalar superpartners.

#### I.3.1. The supersymmetry-conserving parameters:

The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings,  $g_s$ ,  $g$ , and  $g'$ , corresponding to the Standard Model gauge group  $SU(3) \times SU(2) \times U(1)$  respectively; (ii) a supersymmetry-conserving higgsino mass parameter  $\mu$ ; and (iii) Higgs-fermion Yukawa coupling constants,  $\lambda_u$ ,  $\lambda_d$ , and  $\lambda_e$ , corresponding to the coupling of one generation of left- and right-handed quarks and leptons, and their superpartners to the Higgs bosons and higgsinos. Because there is no right-handed neutrino (and its superpartner) in the MSSM as defined here, a Yukawa coupling  $\lambda_\nu$  is not included. The complex  $\mu$  parameter and Yukawa couplings enter via the most general renormalizable R-parity-conserving superpotential,

$$W = \lambda_d \hat{H}_d \hat{Q} \hat{D}^c - \lambda_u \hat{H}_u \hat{Q} \hat{U}^c + \lambda_e \hat{H}_d \hat{L} \hat{E}^c + \mu \hat{H}_u \hat{H}_d, \quad (1)$$

where the superfields are defined in Table 1 and the gauge group indices are suppressed. The reader is warned that in the literature,  $\mu$  is sometimes defined with the opposite sign to the one given in Eq. (1).

#### I.3.2. The supersymmetry-breaking parameters:

The supersymmetry-breaking sector contains the following sets of parameters: (i) three complex gaugino Majorana mass parameters,  $M_3$ ,  $M_2$ , and  $M_1$ , associated with the  $SU(3)$ ,  $SU(2)$ , and  $U(1)$  subgroups of the Standard Model; (ii) five diagonal sfermion squared-mass parameters,  $M_Q^2$ ,  $M_U^2$ ,  $M_D^2$ ,  $M_L^2$ , and  $M_E^2$ , corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of the left-handed fields  $(u, d)_L$ ,  $u_L^c$ ,  $d_L^c$ ,  $(\nu, e^-)_L$ , and  $e_L^c$ , where the superscript  $c$  indicates a charge-conjugated fermion field [34]; and (iii) three Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with complex coefficients  $\lambda_u A_U$ ,  $\lambda_d A_D$ , and  $\lambda_e A_E$  (which define the so-called “ $A$ -parameters”). The inclusion of the factors of the Yukawa couplings in the definition of the  $A$ -parameters is conventional (originally motivated by a simple class of gravity-mediated supersymmetry-breaking models [3,6]). Thus, if the  $A$ -parameters as defined above are parametrically of the same order (or smaller) relative to other supersymmetry-breaking mass parameters, then only the third generation  $A$ -parameters are phenomenologically relevant. The reader is warned that the convention for the overall sign of the  $A$ -parameters varies in the literature.

Finally, we have (iv) three scalar squared-mass parameters: two of which ( $m_1^2$  and  $m_2^2$ ) are real parameters that contribute to the diagonal Higgs squared-masses, given by  $m_1^2 + |\mu|^2$  and  $m_2^2 + |\mu|^2$ , and a third that contributes to the off-diagonal Higgs squared-mass term,  $m_{12}^2 \equiv \mu B$  (which defines the complex “ $B$ -parameter”). The breaking of the electroweak symmetry  $SU(2) \times U(1)$  to  $U(1)_{EM}$  is only possible after introducing the supersymmetry-breaking Higgs squared-mass parameters.

See key on page 601

## Searches Particle Listings

### Supersymmetric Particle Searches

Minimizing the resulting tree-level Higgs scalar potential, these three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values,  $\langle H_d^0 \rangle \equiv v_d/\sqrt{2}$  and  $\langle H_u^0 \rangle \equiv v_u/\sqrt{2}$  (also called  $v_1$  and  $v_2$ , respectively, in the literature), and the CP-odd Higgs mass  $m_A$  [cf. Eqs. (3) and (4) below].

Note that  $v_d^2 + v_u^2 = 4m_W^2/g^2 \simeq (246 \text{ GeV})^2$  is fixed by the  $W$  mass and the  $SU(2)$  gauge coupling, whereas the ratio

$$\tan \beta = v_u/v_d \quad (2)$$

is a free parameter. It is convenient to choose the phases of the Higgs fields such that  $m_{12}^2$  is real and non-negative. In this case, we can adopt a convention where  $0 \leq \beta \leq \pi/2$ . The tree-level conditions for the scalar potential minimum relate the diagonal and off-diagonal Higgs squared-masses in terms of  $m_Z^2 = \frac{1}{4}(g^2 + g'^2)(v_d^2 + v_u^2)$ , the angle  $\beta$  and the CP-odd Higgs mass  $m_A$ :

$$\sin 2\beta = \frac{2m_{12}^2}{m_1^2 + m_2^2 + 2|\mu|^2} = \frac{2m_{12}^2}{m_A^2}, \quad (3)$$

$$\frac{1}{2}m_Z^2 = -|\mu|^2 + \frac{m_1^2 - m_2^2 \tan^2 \beta}{\tan^2 \beta - 1}. \quad (4)$$

One must also guard against the existence of charge and/or color breaking global minima due to non-zero vacuum expectation values for the squark and charged slepton fields. This possibility can be avoided if the  $A$ -parameters are not unduly large [50,82].

Note that supersymmetry-breaking mass terms for the fermionic superpartners of scalar fields and non-holomorphic trilinear scalar interactions (*i.e.*, interactions that mix scalar fields and their complex conjugates) have not been included above in the soft-supersymmetry-breaking sector. These terms can potentially destabilize the gauge hierarchy [11] in models with gauge-singlet superfields. The latter are not present in the MSSM; hence as noted in Ref. 12, these so-called non-standard soft-supersymmetry-breaking terms are benign. However, the coefficients of these terms (which have dimensions of mass) are expected to be significantly suppressed compared to the TeV-scale in a fundamental theory of supersymmetry-breaking [83]. Consequently, we follow the usual approach and omit these terms from further consideration.

**I.3.3. MSSM-124:** The total number of independent physical parameters that define the MSSM (in its most general form) is quite large, primarily due to the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners,  $M_Q^2$ ,  $M_U^2$ ,  $M_D^2$ ,  $M_L^2$ , and  $M_E^2$  are hermitian  $3 \times 3$  matrices, and  $A_U$ ,  $A_D$ , and  $A_E$  are complex  $3 \times 3$  matrices. In addition,  $M_1$ ,  $M_2$ ,  $M_3$ ,  $B$ , and  $\mu$  are in general complex parameters. Finally, as in the Standard Model, the Higgs-fermion Yukawa couplings,  $\lambda_f$  ( $f = u, d$ , and  $e$ ), are complex  $3 \times 3$  matrices that are related to the quark and lepton mass matrices via:  $M_f = \lambda_f v_f/\sqrt{2}$ , where  $v_e \equiv v_d$  [with  $v_u$  and  $v_d$  as defined above Eq. (2)].

However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. 84 shows that the MSSM possesses 124 independent parameters. Of these, 18 correspond to Standard Model parameters (including the QCD vacuum angle  $\theta_{\text{QCD}}$ ), one corresponds to a Higgs sector parameter (the analogue of the Standard Model Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three  $CP$ -violating phases in the gaugino/higgsino sector, 21 squark and slepton (sfermion) masses, 36 real mixing angles to define the sfermion mass eigenstates, and 40  $CP$ -violating phases that can appear in sfermion interactions. The most general R-parity-conserving minimal supersymmetric extension of the Standard Model (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [85].

**I.4. The supersymmetric-particle spectrum:** The supersymmetric particles (*sparticles*) differ in spin by half a unit from their Standard Model partners. The superpartners of the gauge and Higgs bosons are fermions, whose names are obtained by appending “ino” to the end of the corresponding Standard Model particle name. The gluino is the color-octet Majorana fermion partner of the gluon with mass  $M_{\tilde{g}} = |M_3|$ . The superpartners of the electroweak gauge and Higgs bosons (the gauginos and higgsinos) can mix due to  $SU(2) \times U(1)$  breaking effects. As a result, the physical states of definite mass are model-dependent linear combinations of the charged and neutral gauginos and higgsinos, called *charginos* and *neutralinos*, respectively (sometimes collectively called *electroweakinos*). The neutralinos are Majorana fermions, which can generate some distinctive phenomenological signatures [86,87]. The superpartners of the quarks and leptons are spin-zero bosons: the *squarks*, charged *sleptons*, and *sneutrinos*, respectively. A complete set of Feynman rules for the sparticles of the MSSM can be found in Ref. 88. The MSSM Feynman rules also are implicitly contained in a number of Feynman diagram and amplitude generation software packages (see *e.g.*, Refs. [89–91]).

It should be noted that all mass formulae quoted below in this section are tree-level results. Radiative loop corrections will modify these results and must be included in any precision study of supersymmetric phenomenology [92]. Beyond tree level, the definition of the supersymmetric parameters becomes convention-dependent. For example, one can define physical couplings or running couplings, which differ beyond the tree level. This provides a challenge to any effort that attempts to extract supersymmetric parameters from data. The Supersymmetry Les Houches Accord (SLHA) [93] has been adopted, which establishes a set of conventions for specifying generic file structures for supersymmetric model specifications and input parameters, supersymmetric mass and coupling spectra, and

## Searches Particle Listings

### Supersymmetric Particle Searches

decay tables. These provide a universal interface between spectrum calculation programs, decay packages, and high energy physics event generators.

**I.4.1. The charginos and neutralinos:** The mixing of the charged gauginos ( $\widetilde{W}^\pm$ ) and charged higgsinos ( $H_u^+$  and  $H_d^-$ ) is described (at tree-level) by a  $2 \times 2$  complex mass matrix [94–96]:

$$M_C \equiv \begin{pmatrix} M_2 & \frac{1}{\sqrt{2}} g v_u \\ \frac{1}{\sqrt{2}} g v_d & \mu \end{pmatrix}. \quad (5)$$

To determine the physical chargino states and their masses, one must perform a singular value decomposition [97,98] of the complex matrix  $M_C$ :

$$U^* M_C V^{-1} = \text{diag}(M_{\widetilde{\chi}_1^\pm}, M_{\widetilde{\chi}_2^\pm}), \quad (6)$$

where  $U$  and  $V$  are unitary matrices, and the right-hand side of Eq. (6) is the diagonal matrix of (non-negative) chargino masses. The physical chargino states are denoted by  $\widetilde{\chi}_1^\pm$  and  $\widetilde{\chi}_2^\pm$ . These are linear combinations of the charged gaugino and higgsino states determined by the matrix elements of  $U$  and  $V$  [94–96]. The chargino masses correspond to the *singular values* [97] of  $M_C$ , i.e., the positive square roots of the eigenvalues of  $M_C^\dagger M_C$ :

$$M_{\widetilde{\chi}_1^\pm, \widetilde{\chi}_2^\pm}^2 = \frac{1}{2} \{ |\mu|^2 + |M_2|^2 + 2m_W^2 \mp \sqrt{(|\mu|^2 + |M_2|^2 + 2m_W^2)^2 - 4|\mu M_2 - m_W^2 \sin 2\beta|^2} \}, \quad (7)$$

where the states are ordered such that  $M_{\widetilde{\chi}_1^\pm} \leq M_{\widetilde{\chi}_2^\pm}$ . The relative phase of  $\mu$  and  $M_2$  is physical and potentially observable.

The mixing of the neutral gauginos ( $\widetilde{B}$  and  $\widetilde{W}^0$ ) and neutral higgsinos ( $\widetilde{H}_d^0$  and  $\widetilde{H}_u^0$ ) is described (at tree-level) by a  $4 \times 4$  complex symmetric mass matrix [94,95,99,100]:

$$M_N \equiv \begin{pmatrix} M_1 & 0 & -\frac{1}{2}g'v_d & \frac{1}{2}g'v_u \\ 0 & M_2 & \frac{1}{2}g'v_d & -\frac{1}{2}g'v_u \\ -\frac{1}{2}g'v_d & \frac{1}{2}g'v_d & 0 & -\mu \\ \frac{1}{2}g'v_u & -\frac{1}{2}g'v_u & -\mu & 0 \end{pmatrix}. \quad (8)$$

To determine the physical neutralino states and their masses, one must perform a Takagi-diagonalization [97,98,101,102] of the complex symmetric matrix  $M_N$ :

$$W^T M_N W = \text{diag}(M_{\widetilde{\chi}_1^0}, M_{\widetilde{\chi}_2^0}, M_{\widetilde{\chi}_3^0}, M_{\widetilde{\chi}_4^0}), \quad (9)$$

where  $W$  is a unitary matrix and the right-hand side of Eq. (9) is the diagonal matrix of (non-negative) neutralino masses. The physical neutralino states are denoted by  $\widetilde{\chi}_i^0$  ( $i = 1, \dots, 4$ ), where the states are ordered such that  $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$ . The  $\widetilde{\chi}_i^0$  are the linear combinations of the neutral gaugino and higgsino states determined by the matrix elements of  $W$  (which is denoted by  $N^{-1}$  in Ref. 94). The neutralino masses correspond to the singular values of  $M_N$ , i.e., the positive square roots of the eigenvalues of  $M_N^\dagger M_N$ . Exact formulae for these masses can be found in Refs. [99] and [103]. A

numerical algorithm for determining the mixing matrix  $W$  has been given in Ref. 104.

If a chargino or neutralino state approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if  $|M_1|$  and  $|M_2|$  are small compared to  $m_Z$  and  $|\mu|$ , then the lightest neutralino  $\widetilde{\chi}_1^0$  would be nearly a pure *photino*,  $\widetilde{\gamma}$ , the superpartner of the photon. If  $|M_1|$  and  $m_Z$  are small compared to  $|M_2|$  and  $|\mu|$ , then the lightest neutralino would be nearly a pure *bino*,  $\widetilde{B}$ , the superpartner of the weak hypercharge gauge boson. If  $|M_2|$  and  $m_Z$  are small compared to  $|M_1|$  and  $|\mu|$ , then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure *winos*,  $\widetilde{W}^\pm$ , and  $\widetilde{W}_3^0$ , the superpartners of the weak SU(2) gauge bosons. Finally, if  $|\mu|$  and  $m_Z$  are small compared to  $|M_1|$  and  $|M_2|$ , then the lightest chargino pair and neutralino would be nearly pure *higgsino* states, the superpartners of the Higgs bosons. Each of the above cases leads to a strikingly different phenomenology.

In the NMSSM, an additional Higgs singlet superfield is added to the MSSM. This superfield comprises two real Higgs scalar degrees of freedom and an associated neutral higgsino degree of freedom. Consequently, there are five neutralino mass eigenstates that are obtained by a Takagi-diagonalization of the  $5 \times 5$  neutralino mass matrix. In many cases, the fifth neutralino state is dominated by its SU(2)  $\times$  U(1) singlet component, and thus is very weakly coupled to the Standard Model particles and their superpartners.

**I.4.2. The squarks, sleptons and sneutrinos:** For a given fermion  $f$ , there are two superpartners,  $\widetilde{f}_L$  and  $\widetilde{f}_R$ , where the  $L$  and  $R$  subscripts simply identify the scalar partners that are related by supersymmetry to the left-handed and right-handed fermions,  $f_{L,R} \equiv \frac{1}{2}(1 \mp \gamma_5)f$ , respectively. (There is no  $\widetilde{\nu}_R$  in the MSSM.) However, in general  $\widetilde{f}_L$ – $\widetilde{f}_R$  mixing is possible, in which case  $\widetilde{f}_L$  and  $\widetilde{f}_R$  are not mass eigenstates. For three generations of squarks, one must diagonalize  $6 \times 6$  matrices corresponding to the basis  $(\widetilde{q}_{iL}, \widetilde{q}_{iR})$ , where  $i = 1, 2, 3$  are the generation labels. For simplicity, only the one-generation case is illustrated in detail below. (The effects of second and third generation squark mixing can be significant and is treated in Ref. 105.)

Using the notation of the third family, the one-generation tree-level squark squared-mass matrix is given by [106]

$$\mathcal{M}^2 = \begin{pmatrix} M_Q^2 + m_q^2 + L_q & m_q X_q^* \\ m_q X_q & M_{\widetilde{R}}^2 + m_q^2 + R_q \end{pmatrix}, \quad (10)$$

where

$$X_q \equiv A_q - \mu^* (\cot \beta)^{2T_{3q}}, \quad (11)$$

and  $T_{3q} = \frac{1}{2} [-\frac{1}{2}]$  for  $q = t [b]$ . The diagonal squared-masses are governed by soft-supersymmetry-breaking squared-masses  $M_Q^2$  and  $M_{\widetilde{R}}^2 \equiv M_U^2 [M_D^2]$  for  $q = t [b]$ , the corresponding quark masses  $m_t [m_b]$ , and electroweak correction terms:

$$L_q \equiv (T_{3q} - e_q \sin^2 \theta_W) m_Z^2 \cos 2\beta, \quad R_q \equiv e_q \sin^2 \theta_W m_Z^2 \cos 2\beta, \quad (12)$$

where  $e_q = \frac{2}{3} [-\frac{1}{3}]$  for  $q = t [b]$ . The off-diagonal squark squared-masses are proportional to the corresponding quark masses and depend on  $\tan\beta$ , the soft-supersymmetry-breaking  $A$ -parameters and the higgsino mass parameter  $\mu$ . Assuming that the  $A$ -parameters are parametrically of the same order (or smaller) relative to other supersymmetry-breaking mass parameters, it then follows that  $\tilde{q}_L$ - $\tilde{q}_R$  mixing effects are small, with the possible exception of the third generation, where mixing can be enhanced by factors of  $m_t$  and  $m_b \tan\beta$ .

In the case of third generation  $\tilde{q}_L$ - $\tilde{q}_R$  mixing, the mass eigenstates (usually denoted by  $\tilde{q}_1$  and  $\tilde{q}_2$ , with  $m_{\tilde{q}_1} < m_{\tilde{q}_2}$ ) are determined by diagonalizing the  $2 \times 2$  matrix  $\mathcal{M}^2$  given by Eq. (10). The corresponding squared-masses and mixing angle are given by [106]:

$$m_{\tilde{q}_{1,2}}^2 = \frac{1}{2} \left[ \text{Tr} \mathcal{M}^2 \mp \sqrt{(\text{Tr} \mathcal{M}^2)^2 - 4 \det \mathcal{M}^2} \right],$$

$$\sin 2\theta_{\tilde{q}} = \frac{2m_q |X_q|}{m_{\tilde{q}_2}^2 - m_{\tilde{q}_1}^2}. \quad (13)$$

The one-generation results above also apply to the charged sleptons, with the obvious substitutions:  $q \rightarrow \ell$  with  $T_{3\ell} = -\frac{1}{2}$  and  $e_\ell = -1$ , and the replacement of the supersymmetry-breaking parameters:  $M_Q^2 \rightarrow M_L^2$ ,  $M_D^2 \rightarrow M_E^2$ , and  $A_q \rightarrow A_\tau$ . For the neutral sleptons,  $\tilde{\nu}_R$  does not exist in the MSSM, so  $\tilde{\nu}_L$  is a mass eigenstate.

In the case of three generations, the supersymmetry-breaking scalar-squared masses [ $M_Q^2$ ,  $M_U^2$ ,  $M_D^2$ ,  $M_L^2$ , and  $M_E^2$ ] and the  $A$ -parameters [ $A_U$ ,  $A_D$ , and  $A_E$ ] are now  $3 \times 3$  matrices as noted in Section I.3.3. The diagonalization of the  $6 \times 6$  squark mass matrices yields  $\tilde{f}_{iL}$ - $\tilde{f}_{jR}$  mixing (for  $i \neq j$ ). In practice, since the  $\tilde{f}_L$ - $\tilde{f}_R$  mixing is appreciable only for the third generation, this additional complication can often be neglected (although see Ref. 105 for examples in which the mixing between the second and third generation squarks is relevant).

**I.5. The supersymmetric Higgs sector:** Consider first the MSSM Higgs sector [36,37,107]. Despite the large number of potential  $CP$ -violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs sector is automatically  $CP$ -conserving. This follows from the fact that the only potentially complex parameter ( $m_{12}^2$ ) of the MSSM Higgs potential can be chosen real and positive by rephasing the Higgs fields, in which case  $\tan\beta$  is a real positive parameter. Consequently, the physical neutral Higgs scalars are  $CP$ -eigenstates. The MSSM Higgs sector contains five physical spin-zero particles: a charged Higgs boson pair ( $H^\pm$ ), two  $CP$ -even neutral Higgs bosons (denoted by  $h^0$  and  $H^0$  where  $m_h < m_H$ ), and one  $CP$ -odd neutral Higgs boson ( $A^0$ ). The discovery of a Standard Model-like Higgs boson at the LHC with a mass of 125 GeV [75] strongly suggests that this state should be identified with  $h^0$ , although the possibility that the 125 GeV state should be identified with  $H^0$  cannot be completely ruled out [108].

In the NMSSM [41], the scalar component of the singlet Higgs superfield adds two additional neutral states to the Higgs

sector. In this model, the tree-level Higgs sector can exhibit explicit  $CP$ -violation. If  $CP$  is conserved, then the two extra neutral scalar states are  $CP$ -even and  $CP$ -odd, respectively. These states can potentially mix with the neutral Higgs states of the MSSM. If scalar states exist that are dominantly singlet, then they are weakly coupled to Standard Model gauge bosons and fermions through their small mixing with the MSSM Higgs scalars. Consequently, it is possible that one (or both) of the singlet-dominated states is considerably lighter than the Higgs boson that was observed at the LHC.

**I.5.1 The Tree-level Higgs sector:** The properties of the Higgs sector are determined by the Higgs potential, which is made up of quadratic terms [whose squared-mass coefficients were specified above Eq. (2)] and quartic interaction terms governed by dimensionless couplings. The quartic interaction terms are manifestly supersymmetric at tree level (although these are modified by supersymmetry-breaking effects at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called “ $F$ -terms”), and (ii) interaction terms related by supersymmetry to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called “ $D$ -terms”).

In the MSSM,  $F$ -term contributions to the quartic Higgs self-couplings are absent. As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings. Due to the resulting constraint on the form of the two-Higgs-doublet scalar potential, all the tree-level MSSM Higgs-sector parameters depend only on two quantities:  $\tan\beta$  [defined in Eq. (2)] and one Higgs mass usually taken to be  $m_A$ . From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle  $\alpha$  (which measures the mixture of the original  $Y = \pm 1$  Higgs doublet states in the physical  $CP$ -even neutral scalars), and the Higgs boson self-couplings. Moreover, the tree-level mass of the lighter  $CP$ -even Higgs boson is bounded,  $m_h \leq m_Z |\cos 2\beta| \leq m_Z$  [36,37]. This bound can be substantially modified when radiative corrections are included, as discussed in Section I.5.2.

In the NMSSM, the superpotential contains a trilinear term that couples the two  $Y = \pm 1$  Higgs doublet superfields and the singlet Higgs superfield. The coefficient of this term is denoted by  $\lambda$ . Consequently, the tree-level bound for the mass of the lightest  $CP$ -even MSSM Higgs boson is modified [109],

$$m_h^2 \leq m_Z^2 \cos^2 2\beta + \frac{1}{2} \lambda^2 v^2 \sin^2 2\beta, \quad (14)$$

where  $v \equiv (v_u^2 + v_d^2)^{1/2} = 246$  GeV. If one demands that  $\lambda$  should stay finite after renormalization-group evolution up to the Planck scale, then  $\lambda$  is constrained to lie below about 0.7 at the electroweak scale. However, in light of the observed Higgs mass of 125 GeV, there is some phenomenological motivation for considering larger values of  $\lambda$  [110].

The tree-level Higgs-quark and Higgs-lepton interactions of the MSSM are governed by the Yukawa couplings that were defined by the superpotential given in Eq. (1). In particular,

## Searches Particle Listings

### Supersymmetric Particle Searches

the Higgs sector of the MSSM is a Type-II two-Higgs doublet model [111], in which one Higgs doublet ( $H_d$ ) couples exclusively to the right-handed down-type quark (or lepton) fields and the second Higgs doublet ( $H_u$ ) couples exclusively to the right-handed up-type quark fields. Consequently, the diagonalization of the fermion mass matrices simultaneously diagonalizes the matrix Yukawa couplings, resulting in flavor-diagonal couplings of the neutral Higgs bosons  $h^0$ ,  $H^0$  and  $A^0$  to quark and lepton pairs.

**I.5.2 The radiatively-corrected Higgs sector:** When radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual supersymmetric particles that can appear in loops. The impact of these corrections can be significant [112]. The qualitative behavior of these radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries and the off-diagonal entries of the top-squark squared-mass matrix [Eq. (10)] are small in comparison to the geometric mean of the two top-squark squared-masses,  $M_S^2 \equiv M_{t_1} M_{t_2}$ . In this case (assuming  $m_A > m_Z$ ), the predicted upper bound for  $m_h$  is approximately given by

$$m_h^2 \lesssim m_Z^2 \cos^2 2\beta + \frac{3g^2 m_t^4}{8\pi^2 m_W^2} \left[ \ln \left( \frac{M_S^2}{m_t^2} \right) + \frac{X_t^2}{M_S^2} \left( 1 - \frac{X_t^2}{12M_S^2} \right) \right], \quad (15)$$

where  $X_t \equiv A_t - \mu \cot \beta$  [cf. Eq. (11)] is proportional to the off-diagonal entry of the top-squark squared-mass matrix (where for simplicity,  $A_t$  and  $\mu$  are taken to be real). The Higgs mass upper limit is saturated when  $\tan \beta$  is large (i.e.,  $\cos^2 2\beta \sim 1$ ) and  $X_t = \sqrt{6} M_S$ , which defines the so-called *maximal mixing* scenario.

A more complete treatment of the radiative corrections [113] shows that Eq. (15) somewhat overestimates the true upper bound of  $m_h$ . These more refined computations, which incorporate renormalization group improvement and the leading two-loop contributions, yield  $m_h \lesssim 135$  GeV in the large  $\tan \beta$  regime (with an accuracy of a few GeV) for  $m_t = 175$  GeV and  $M_S \lesssim 2$  TeV [113].

In addition, one-loop radiative corrections can introduce  $CP$ -violating effects in the Higgs sector, which depend on some of the  $CP$ -violating phases among the MSSM-124 parameters [114]. This phenomenon is most easily understood in a scenario where  $m_A \ll M_S$  (i.e., all five physical Higgs states are significantly lighter than the supersymmetry breaking scale). In this case, one can integrate out the heavy superpartners to obtain a low-energy effective theory with two Higgs doublets. The resulting effective two-Higgs doublet model will now contain all possible Higgs self-interaction terms (both  $CP$ -conserving and  $CP$ -violating) and Higgs-fermion interactions (beyond those of Type-II) that are consistent with electroweak gauge invariance [115].

In the NMSSM, the dominant radiative correction to Eq. (14) is the same as the one given in Eq. (15). However, in contrast to the MSSM, one does not need as large a boost from the radiative corrections to achieve a Higgs mass

of 125 GeV in certain regimes of the NMSSM parameter space (e.g.,  $\tan \beta \sim 2$  and  $\lambda \sim 0.7$ ).

**I.6. Restricting the MSSM parameter freedom:** In Sections I.4 and I.5, we surveyed the parameters that comprise the MSSM-124. However, without additional restrictions on the choice of parameters, a generic parameter set within the MSSM-124 framework is not phenomenologically viable. In particular, a generic point of the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers  $L_e$ ,  $L_\mu$ , and  $L_\tau$ ; (ii) unsuppressed flavor-changing neutral currents (FCNCs); and (iii) new sources of  $CP$  violation that are inconsistent with the experimental bounds.

For example, the MSSM contains many new sources of  $CP$  violation [116]. Indeed, some combinations of the complex phases of the gaugino-mass parameters, the  $A$ -parameters, and  $\mu$  must be less than on the order of  $10^{-2}$ – $10^{-3}$  to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [117–119]. The non-observation of FCNCs [120–122] places additional strong constraints on the off-diagonal matrix elements of the squark and slepton soft-supersymmetry-breaking squared-masses and  $A$ -parameters (see Section I.3.3).

The MSSM-124 is also theoretically incomplete as it provides no explanation for the fundamental origin of the supersymmetry-breaking parameters. The successful unification of the Standard Model gauge couplings at very high energies close to the Planck scale [8,74,123,124] suggests that the high-energy structure of the theory may be considerably simpler than its low-energy realization. In a top-down approach, the dynamics that governs the more fundamental theory at high energies is used to derive the effective broken-supersymmetric theory at the TeV scale. A suitable choice for the high energy dynamics is one that yields a TeV-scale theory that satisfies all relevant phenomenological constraints.

In this Section, we examine a number of theoretical frameworks that potentially yield phenomenologically viable regions of the MSSM-124 parameter space. The resulting supersymmetric particle spectrum is then a function of a relatively small number of input parameters. This is accomplished by imposing a simple structure on the soft-supersymmetry-breaking terms at a common high-energy scale  $M_X$  (typically chosen to be the Planck scale,  $M_P$ , the grand unification scale,  $M_{GUT}$ , or the messenger scale,  $M_{\text{mess}}$ ). Using the renormalization group equations, one can then derive the low-energy MSSM parameters relevant for collider physics. The initial conditions (at the appropriate high-energy scale) for the renormalization group equations depend on the mechanism by which supersymmetry breaking is communicated to the effective low energy theory.

Examples of this scenario are provided by models of gravity-mediated, anomaly mediated and gauge-mediated supersymmetry breaking, to be discussed in more detail below. In some of these approaches, one of the diagonal Higgs squared-mass parameters is driven negative by renormalization group evolution [125]. In such models, electroweak symmetry breaking is

generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy supersymmetry breaking.

### I.6.1. Gaugino mass relations

One prediction that arises in many grand unified supergravity models is the unification of the (tree-level) gaugino mass parameters at some high-energy scale  $M_X = M_{\text{GUT}}$  or  $M_{\text{PL}}$ :

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}. \quad (16)$$

Due to renormalization group running, in the one-loop approximation the effective low-energy gaugino mass parameters (at the electroweak scale) are related:

$$M_3 = (g_s^2/g^2)M_2 \simeq 3.5M_2, \quad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2. \quad (17)$$

Eq. (17) can also arise more generally in gauge-mediated supersymmetry-breaking models where the gaugino masses generated at the messenger scale  $M_{\text{mess}}$  (which typically lies significantly below the unification scale where the gauge couplings unify) are proportional to the corresponding squared gauge couplings at that scale.

When Eq. (17) is satisfied, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass,  $\mu$ , and  $\tan\beta$ . It then follows that the lightest neutralino must be heavier than 46 GeV due to the non-observation of charginos at LEP [126]. If in addition  $|\mu| \gg |M_1| \gtrsim m_Z$ , then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders. Although Eq. (17) is often assumed in many phenomenological studies, a truly model-independent approach would take the gaugino mass parameters,  $M_i$ , to be independent parameters to be determined by experiment. Indeed, an approximately massless neutralino *cannot* be ruled out at present by a model-independent analysis [127].

It is possible that the tree-level masses for the gauginos are zero. In this case, the gaugino mass parameters arise at one-loop and do not satisfy Eq. (17). For example, the gaugino masses in AMSB models arise entirely from a model-independent contribution derived from the super-conformal anomaly [56,128]. In this case, Eq. (17) is replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}, \quad (18)$$

where  $m_{3/2}$  is the gravitino mass and the  $b_i$  are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2), and SU(3) gauge groups,  $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$ . Eq. (18) yields  $M_1 \simeq 2.8M_2$  and  $M_3 \simeq -8.3M_2$ , which implies that the lightest chargino pair and neutralino comprise a nearly mass-degenerate triplet of winos,  $\tilde{W}^\pm$ ,  $\tilde{W}^0$  (cf. Table 1), over most of the MSSM parameter space. For example, if  $|\mu| \gg m_Z$ , then Eq. (18) implies that  $M_{\tilde{\chi}_1^\pm} \simeq M_{\tilde{\chi}_1^0} \simeq M_2$  [129]. The corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (17) [130,131].

Finally, it should be noted that the unification of gaugino masses (and scalar masses) can be accidental. In particular, the energy scale where unification takes place may not be directly related to any physical scale. One version of this phenomenon has been called *mirage unification* and can occur in certain theories of fundamental supersymmetry breaking [132].

**I.6.2. The constrained MSSM: mSUGRA, CMSSM, ...** In the *minimal* supergravity (mSUGRA) framework [3–6,49–51], a form of the Kähler potential is employed that yields minimal kinetic energy terms for the MSSM fields [53]. As a result, the soft-supersymmetry-breaking parameters at the high-energy scale  $M_X$  take a particularly simple form in which the scalar squared-masses and the  $A$ -parameters are flavor-diagonal and universal [51]:

$$\begin{aligned} M_Q^2(M_X) &= M_U^2(M_X) = M_D^2(M_X) = m_0^2 \mathbf{1}, \\ M_L^2(M_X) &= M_E^2(M_X) = m_0^2 \mathbf{1}, \\ m_1^2(M_X) &= m_2^2(M_X) = m_0^2, \\ A_U(M_X) &= A_D(M_X) = A_E(M_X) = A_0 \mathbf{1}, \end{aligned} \quad (19)$$

where  $\mathbf{1}$  is a  $3 \times 3$  identity matrix in generation space. As in the Standard Model, this approach exhibits minimal flavor violation [133,134], whose unique source is the nontrivial flavor structure of the Higgs-fermion Yukawa couplings. The gaugino masses are also unified according to Eq. (16).

Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark masses, one must use the *low-energy* values for  $M_Q^2$ ,  $M_U^2$ , and  $M_D^2$  in Eq. (10). Through the renormalization group running with boundary conditions specified in Eqs. (17) and (19), one can show that the low-energy values of  $M_Q^2$ ,  $M_U^2$ , and  $M_D^2$  depend primarily on  $m_0^2$  and  $m_{1/2}^2$ . A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. 135.

In the mSUGRA approach, four flavors of squarks (with two squark eigenstates per flavor) are nearly mass-degenerate. If  $\tan\beta$  is not very large,  $\tilde{b}_R$  is also approximately degenerate in mass with the first two generations of squarks. The  $\tilde{b}_L$  mass and the diagonal  $\tilde{t}_L$  and  $\tilde{t}_R$  masses are typically reduced relative to the common squark mass of the first two generations. In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. As noted below Eq. (10), third-generation squark masses and tau-slepton masses are sensitive to the strength of the respective  $\tilde{f}_L$ – $\tilde{f}_R$  mixing. The LSP is typically the lightest neutralino,  $\tilde{\chi}_1^0$ , which is dominated by its bino component. Regions of the mSUGRA parameter space in which the LSP is electrically charged do exist but are not phenomenologically viable [20].

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 Standard Model

## Searches Particle Listings

### Supersymmetric Particle Searches

parameters (excluding the Higgs mass), one must specify  $m_0$ ,  $m_{1/2}$ ,  $A_0$ , the Planck-scale values for  $\mu$  and  $B$ -parameters (denoted by  $\mu_0$  and  $B_0$ ), and the gravitino mass  $m_{3/2}$ . Without additional model assumptions,  $m_{3/2}$  is independent of the parameters that govern the mass spectrum of the superpartners of the Standard Model [51]. In principle,  $A_0$ ,  $B_0$ ,  $\mu_0$ , and  $m_{3/2}$  can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real.

As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently,  $m_Z$  and  $\tan\beta$ ) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure is to remove  $\mu_0$  and  $B_0$  in favor of  $m_Z$  and  $\tan\beta$  [the sign of  $\mu_0$ , denoted  $\text{sgn}(\mu_0)$  below, is not fixed in this process]. In this case, the MSSM spectrum and its interaction strengths are determined by five parameters:

$$m_0, A_0, m_{1/2}, \tan\beta, \text{ and } \text{sgn}(\mu_0), \quad (20)$$

and an independent gravitino mass  $m_{3/2}$  (in addition to the 18 parameters of the Standard Model). In Ref. 136, this framework was dubbed the *constrained minimal supersymmetric extension of the Standard Model* (CMSSM).

In the early literature, additional conditions were obtained by assuming a simplified form for the hidden sector that provides the fundamental source of supersymmetry breaking. Two additional relations emerged among the mSUGRA parameters [49,53]:  $B_0 = A_0 - m_0$  and  $m_{3/2} = m_0$ . These relations characterize a theory that was called minimal supergravity when first proposed. In the subsequent literature, it has been more common to omit these extra conditions in defining the mSUGRA model (in which case the mSUGRA model and the CMSSM are synonymous). The authors of Ref. 137 advocate restoring the original nomenclature in which the mSUGRA model is defined with the extra conditions as originally proposed. Additional mSUGRA variations can be considered where different relations among the CMSSM parameters are imposed.

One can also relax the universality of scalar masses by decoupling the squared-masses of the Higgs bosons and the squarks/sleptons. This leads to the non-universal Higgs mass models (NUHMs), thereby adding one or two new parameters to the CMSSM depending on whether the diagonal Higgs scalar squared-mass parameters ( $m_1^2$  and  $m_2^2$ ) are set equal (NUHM1) or taken to be independent (NUHM2) at the high energy scale  $M_X^2$ . Clearly, this modification preserves the minimal flavor violation of the mSUGRA approach. Nevertheless, the mSUGRA approach and its NUHM generalizations are probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry-breaking parameters is not generic [138]. In particular, effective operators at the Planck scale exist that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

In the framework of supergravity, if anomaly mediation is the sole source of supersymmetry breaking, then the gaugino mass parameters, diagonal scalar squared-mass parameters, and the supersymmetry-breaking trilinear scalar interaction terms (proportional to  $\lambda_f A_F$ ) are determined in terms of the beta functions of the gauge and Yukawa couplings and the anomalous dimensions of the squark and slepton fields [56,128,131]. As noted in Section I.2.3, this approach yields tachyonic sleptons in the MSSM unless additional sources of supersymmetry breaking are present. In the *minimal* AMSB (mAMSB) scenario, a universal squared-mass parameter,  $m_0^2$ , is added to the AMSB expressions for the diagonal scalar squared-masses [131]. Thus, the mAMSB spectrum and its interaction strengths are determined by four parameters,  $m_0^2$ ,  $m_{3/2}$ ,  $\tan\beta$  and  $\text{sgn}(\mu_0)$ .

The mAMSB scenario appears to be ruled out based on the observed value of the Higgs boson mass, assuming an upper limit on  $M_S$  of a few TeV, since the mAMSB constraint on  $A_F$  implies that the maximal mixing scenario cannot be achieved [cf. Eq. (15)]. Indeed, under the stated assumptions, the mAMSB Higgs mass upper bound lies below the observed Higgs mass value [139]. Thus within the AMSB scenario, either an additional supersymmetry-breaking contribution to  $\lambda_f A_F$  and/or new ingredients beyond the MSSM are required.

**I.6.3. Gauge-mediated supersymmetry breaking:** In contrast to models of gravity-mediated supersymmetry breaking, the universality of the fundamental soft-supersymmetry-breaking squark and slepton squared-mass parameters is guaranteed in gauge-mediated supersymmetry breaking (GMSB) because the supersymmetry breaking is communicated to the sector of MSSM fields via gauge interactions [61,62]. In GMSB models, the mass scale of the messenger sector (or its equivalent) is sufficiently below the Planck scale such that the additional supersymmetry-breaking effects mediated by supergravity can be neglected.

In the minimal GMSB approach, there is one effective mass scale,  $\Lambda$ , that determines all low-energy scalar and gaugino mass parameters through loop effects, while the resulting  $A$ -parameters are suppressed. In order that the resulting superpartner masses be of order 1 TeV or less, one must have  $\Lambda \sim 100$  TeV. The origin of the  $\mu$  and  $B$ -parameters is quite model-dependent, and lies somewhat outside the ansatz of gauge-mediated supersymmetry breaking.

The simplest GMSB models appear to be ruled out based on the observed value of the Higgs boson mass. Due to suppressed  $A$  parameters, it is difficult to boost the contributions of the radiative corrections in Eq. (15) to obtain a Higgs mass as large as 125 GeV. However, this conflict can be alleviated in more complicated GMSB models [140]. To analyze these generalized GMSB models, it has been especially fruitful to develop model-independent techniques that encompass all known GMSB models [141]. These techniques are well-suited for a comprehensive analysis [142] of the phenomenological profile of gauge-mediated supersymmetry breaking.

The gravitino is the LSP in GMSB models, as noted in Section I.2.3. As a result, the next-to-lightest supersymmetric particle (NLSP) now plays a crucial role in the phenomenology of supersymmetric particle production and decays. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are  $\tilde{\chi}_1^0$  and  $\tilde{\tau}_R^\pm$ . The NLSP will decay into its superpartner plus a gravitino (*e.g.*,  $\tilde{\chi}_1^0 \rightarrow \gamma \tilde{G}$ ,  $\tilde{\chi}_1^0 \rightarrow Z \tilde{G}$ ,  $\tilde{\chi}_1^0 \rightarrow h^0 \tilde{G}$  or  $\tilde{\tau}_R^\pm \rightarrow \tau^\pm \tilde{G}$ ), with lifetimes and branching ratios that depend on the model parameters. There are also GMSB scenarios in which there are several nearly degenerate co-NLSP's, any one of which can be produced at the penultimate step of a supersymmetric decay chain [143]. For example, in the slepton co-NLSP case, all three right-handed sleptons are close enough in mass and thus can each play the role of the NLSP.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [62,144]. For example, a long-lived  $\tilde{\chi}_1^0$ -NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the standard phenomenology of the  $\tilde{\chi}_1^0$ -LSP). On the other hand, if  $\tilde{\chi}_1^0 \rightarrow \gamma \tilde{G}$  is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would contain a photon. In contrast, in the case of a  $\tilde{\tau}_R^\pm$ -NLSP, the  $\tilde{\tau}_R^\pm$  would either be long-lived or would decay inside the detector into a  $\tau$ -lepton plus missing energy.

In GMSB models based on the MSSM, the fundamental origins of the  $\mu$  and  $B$ -parameters are not explicitly given, as previously noted. An alternative approach is to consider GMSB models based on the NMSSM [145]. The vacuum expectation value of the additional singlet Higgs superfield can be used to generate effective  $\mu$  and  $B$ -parameters [146]. Such models provide an alternative GMSB framework for achieving a Higgs mass of 125 GeV, while still being consistent with LHC bounds on supersymmetric particle masses [147].

**I.6.4. The phenomenological MSSM:** Of course, any of the theoretical assumptions described in this Section must be tested experimentally and could turn out to be wrong. To facilitate the exploration of MSSM phenomena in a more model-independent way while respecting the constraints noted at the beginning of this Section, the phenomenological MSSM (pMSSM) has been introduced [148].

The pMSSM is governed by 19 independent real supersymmetric parameters: the three gaugino mass parameters  $M_1$ ,  $M_2$  and  $M_3$ , the Higgs sector parameters  $m_A$  and  $\tan\beta$ , the Higgsino mass parameter  $\mu$ , five sfermion squared-mass parameters for the degenerate first and second generations ( $M_{\tilde{Q}}^2$ ,  $M_{\tilde{U}}^2$ ,  $M_{\tilde{D}}^2$ ,  $M_{\tilde{L}}^2$  and  $M_{\tilde{E}}^2$ ), the five corresponding sfermion squared-mass parameters for the third generation, and three third-generation  $A$ -parameters ( $A_t$ ,  $A_b$  and  $A_\tau$ ). As previously noted, the first and second generation  $A$ -parameters can be neglected as their phenomenological consequences are negligible.

A comprehensive study of the 19-parameter pMSSM is computationally expensive. This is somewhat ameliorated in Ref. 149, where the number of pMSSM parameters is reduced to ten by assuming one common squark squared-mass parameter for the first two generations, a second common squark squared-mass parameter for the third generation, a common slepton squared-mass parameter and a common third generation  $A$  parameter. Applications of the pMSSM approach to supersymmetric particle searches, and a discussion of the implications for past and future LHC studies can be found in Refs. [149] and [150].

#### I.6.5. Simplified models:

It is possible to focus on a small subset of the supersymmetric particle spectrum and study its phenomenology with minimal theoretical bias. In this *simplified model* approach [151], one considers the production of a pair of specific superpartners and follows their decay chains under the assumption that a limited number of decay modes dominate. Simplified models depend only on a few relevant quantities (cross sections, branching ratios and masses), and thus provide a framework for studies of supersymmetric phenomena, independently of the precise details of the theory that govern the supersymmetric parameters.

Applications of the simplified models approach to supersymmetric particle searches and a discussion of their limitations can be found in Ref. 13.

#### I.7. Experimental data confronts the MSSM:

At present, there is no evidence for weak-scale supersymmetry from the data analyzed by the LHC experiments. Recent LHC data has been especially effective in ruling out the existence of colored supersymmetric particles (primarily the gluino and the first generation of squarks) with masses below about 1 TeV [13,152]. The precise mass limits are model dependent. For example, higher mass colored superpartners have been ruled out in the context of the CMSSM. In less constrained frameworks of the MSSM, regions of parameter space can be identified in which lighter squarks and gluinos below 1 TeV cannot be definitely ruled out [13]. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of Standard Model processes [120–122].

In light of these negative results, one must confront the tension that exists between the theoretical expectations for the magnitude of the supersymmetry-breaking parameters and the non-observation of supersymmetric phenomena.

##### I.7.1 Naturalness constraints and the little hierarchy:

In Section I, weak-scale supersymmetry was motivated as a natural solution to the hierarchy problem, which could provide an understanding of the origin of the electroweak symmetry-breaking scale without a significant fine-tuning of the fundamental parameters that govern the MSSM. In this context, the soft-supersymmetry-breaking masses must be generally of the order of 1 TeV or below [153]. This requirement is most easily seen in the determination of  $m_Z$  by the scalar potential minimum condition. In light of Eq. (4), to avoid the fine-tuning of

## Searches Particle Listings

### Supersymmetric Particle Searches

MSSM parameters, the soft-supersymmetry-breaking squared-masses  $m_1^2$  and  $m_2^2$  and the higgsino squared-mass  $|\mu|^2$  should all be roughly of  $\mathcal{O}(m_Z^2)$ . Many authors have proposed quantitative measures of fine-tuning [153–155]. One of the simplest measures is the one given by Barbieri and Giudice [153],

$$\Delta_i \equiv \left| \frac{\partial \ln m_Z^2}{\partial \ln p_i} \right|, \quad \Delta \equiv \max_i \Delta_i, \quad (21)$$

where the  $p_i$  are the MSSM parameters at the high-energy scale  $M_X$ , which are set by the fundamental supersymmetry-breaking dynamics. The theory is more fine-tuned as  $\Delta$  becomes larger.

One can apply the fine-tuning measure to any explicit model of supersymmetry breaking. For example, in the approaches discussed in Section I.6, the  $p_i$  are parameters of the model at the energy scale  $M_X$  where the soft-supersymmetry-breaking operators are generated by the dynamics of supersymmetry breaking. Renormalization group evolution then determines the values of the parameters appearing in Eq. (4) at the electroweak scale. In this way,  $\Delta$  is sensitive to all the supersymmetry-breaking parameters of the model (see e.g. Ref. 156).

As anticipated, there is a tension between the present experimental lower limits on the masses of colored supersymmetric particles [157,158] and the expectation that supersymmetry-breaking is associated with the electroweak symmetry-breaking scale. Moreover, this tension is exacerbated by the observed value of the Higgs mass ( $m_h \simeq 125$  GeV), which is not far from the MSSM upper bound ( $m_h \lesssim 135$  GeV) [which depends on the top-squark mass and mixing as noted in Section I.5.2]. If  $M_{\text{SUSY}}$  characterizes the scale of supersymmetric particle masses, then one would crudely expect  $\Delta \sim M_{\text{SUSY}}^2/m_Z^2$ . For example, if  $M_{\text{SUSY}} \sim 1$  TeV then there must be at least a  $\Delta^{-1} \sim 1\%$  fine-tuning of the MSSM parameters to achieve the observed value of  $m_Z$ . This separation of the electroweak symmetry-breaking and supersymmetry-breaking scales is an example of the *little hierarchy problem* [159,160].

However, one must be very cautious when drawing conclusions about the viability of weak-scale supersymmetry to explain the origin of electroweak symmetry breaking [161]. First, one must decide the largest tolerable value of  $\Delta$  within the framework of weak-scale supersymmetry (should it be  $\Delta \sim 10^2$ – $100^3$ ?). Second, the fine-tuning parameter  $\Delta$  depends quite sensitively on the structure of the supersymmetry-breaking dynamics, such as the value of  $M_X$  and relations among supersymmetry-breaking parameters in the fundamental high energy theory [162]. For example, in so-called focus point supersymmetry models [163], all squark masses can be as heavy as 5 TeV *without* significant fine-tuning. This can be attributed to a focusing behavior of the renormalization group evolution where certain relations hold among the high-energy values of the scalar squared-mass supersymmetry-breaking parameters.

Among the colored superpartners, the third generation squarks generically have the most significant impact on the naturalness constraints [164], while their masses are the least constrained by the LHC data. Hence, in the absence of any

relation between third generation squarks and those of the first two generations, the naturalness constraints due to present LHC data can be considerably weaker than those obtained in the CMSSM. Indeed, models with first and second generation squark masses in the multi-TeV range do not generically require significant fine tuning. Such models have the added benefit that undesirable FCNCs mediated by squark exchange are naturally suppressed [165]. Other MSSM mass spectra that are compatible with moderate fine tuning have been considered in Refs. [152,162,166].

The lower bounds on squark and gluino masses may not be as large as suggested by the experimental analyses based on the CMSSM or simplified models. For example, mass bounds for the gluino and the first and second generation squarks based on the CMSSM can often be evaded in alternative or extended MSSM models, *e.g.*, compressed supersymmetry [167] and stealth supersymmetry [168]. Moreover, experimental limits on the masses for the third generation squarks (which enter the fine-tuning considerations more directly) are less constrained than the masses of other colored supersymmetric states.

Among the uncolored superpartners, the higgsinos are the most impacted by the naturalness constraints. In light of Eq. (4), the masses of the two neutral higgsinos and charged higgsino pair (which are governed by  $|\mu|$ ) should not be significantly larger than  $m_Z$  to avoid an unnatural fine-tuning of the supersymmetric parameters. The experimental limits on the masses of such light higgsinos are not well constrained, as they are difficult to detect directly at the LHC due to their soft decay products.

Finally, one can also consider extensions of the MSSM in which the degree of fine-tuning is relaxed. For example, it has already been noted in Section I.5.2 that it is possible to accommodate the observed Higgs mass more easily in the NMSSM due to contributions to  $m_h^2$  proportional to the parameter  $\lambda$ . This means that we do not have to rely on a large contribution from the radiative corrections to boost the Higgs mass sufficiently above its tree-level bound. This allows for smaller top squark masses, which are more consistent with the demands of naturalness. The reduction of the fine-tuning in various NMSSM models was initially advocated in Ref. 169, and more recently has been exhibited in Refs. [110,170]. Naturalness can also be relaxed in extended supersymmetric models with vector-like quarks [171] and in gauge extensions of the MSSM [172].

Thus, it is premature to conclude that weak-scale supersymmetry is on the verge of exclusion. Nevertheless, it is possible to sharpen the upper bounds on superpartner masses based on naturalness arguments, which ultimately will either confirm or refute the weak scale supersymmetry hypothesis [173].

#### I.7.2 Constraints from virtual exchange of supersymmetric particles

There are a number of low-energy measurements that are sensitive to the effects of new physics through indirect searches

via supersymmetric loop effects. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous magnetic moment,  $a_\mu \equiv \frac{1}{2}(g-2)_\mu$ , as reviewed in Ref. 174. The Standard Model prediction for  $a_\mu$  exhibits a deviation at the level of  $3-4\sigma$  from the experimentally observed value [175]. This discrepancy is difficult to accommodate in the constrained supersymmetry models of Section I.6.2 and I.6.3 given the present sparticle mass bounds [158]. Nevertheless, there are regions of the more general pMSSM parameter space that are consistent with the observed value of  $a_\mu$  [176].

The rare inclusive decay  $b \rightarrow s\gamma$  also provides a sensitive probe to the virtual effects of new physics beyond the Standard Model. Recent experimental measurements of  $B \rightarrow X_s + \gamma$  [177] are in very good agreement with the theoretical Standard Model predictions of Ref. 178. Since supersymmetric loop corrections can contribute an observable shift from the Standard Model predictions, the absence of any significant deviations places useful constraints on the MSSM parameter space [179].

The rare decay  $B_s \rightarrow \mu^+\mu^-$  is especially sensitive to supersymmetric loop effects, with some loop contributions scaling as  $\tan^6\beta$  when  $\tan\beta \gg 1$  [180]. The observation of this rare decay mode along with the first observation of  $B_d \rightarrow \mu^+\mu^-$  are compatible with the predicted Standard Model rates at the  $1.2\sigma$  and  $2.2\sigma$  level, respectively [181].

The decays  $B^\pm \rightarrow \tau^\pm\nu_\tau$  and  $B \rightarrow D^{(*)}\tau^-\bar{\nu}_\tau$  are noteworthy, since in models with extended Higgs sectors such as the MSSM, these processes possess *tree-level* charged Higgs exchange contributions that can compete with the dominant  $W$ -exchange. Experimental measurements of  $B^\pm \rightarrow \tau^\pm\nu_\tau$  [182] initially suggested an enhanced rate with respect to the Standard Model, although the latest results of the Belle Collaboration are consistent with Standard Model expectations. The BaBar Collaboration measured values of the rates for  $\bar{B} \rightarrow D\tau^-\bar{\nu}_\tau$  and  $\bar{B} \rightarrow D^*\tau^-\bar{\nu}_\tau$  [183] that showed a combined  $3.4\sigma$  discrepancy from the Standard Model predictions, which was also not compatible with the Type-II Higgs Yukawa couplings employed by the MSSM. Although subsequent measurements of the Belle and LHCb Collaborations [184] are consistent with the BaBar measurements, the most recent Belle measurements are also compatible (at the  $2\sigma$  level) with either the Standard Model or a Type-II two-Higgs doublet model.

In summary, there are a few hints of possible deviations from the Standard Model in rare  $B$  decays, although none of the discrepancies are significant enough to definitively rule out the Standard Model. The absence of a *significant* deviation in these  $B$ -physics observables from their Standard Model predictions also places useful constraints on the MSSM parameter space [122,157,185].

Finally, we note that the constraints from precision electroweak observables [186] are easily accommodated in models of weak-scale supersymmetry [187]. Thus, robust regions of the MSSM parameter space, compatible with the results of direct and indirect searches for supersymmetry, remain unconstrained.

### I.8. Massive neutrinos in weak-scale supersymmetry:

In the minimal Standard Model and its supersymmetric extension, there are no right-handed neutrinos, and Majorana mass terms for the left-handed neutrinos are absent. However, given the overwhelming evidence for neutrino masses and mixing [188,189], any viable model of fundamental particles must provide a mechanism for generating neutrino masses [190]. In extended supersymmetric models, various mechanisms exist for producing massive neutrinos [191]. Although one can devise models for generating massive Dirac neutrinos [192], the most common approaches for incorporating neutrino masses are based on  $L$ -violating supersymmetric extensions of the MSSM, which generate massive Majorana neutrinos. Two classes of  $L$ -violating supersymmetric models will now be considered.

**I.8.1. The supersymmetric seesaw:** Neutrino masses can be incorporated into the Standard Model by introducing  $SU(3) \times SU(2) \times U(1)$  singlet right-handed neutrinos ( $\nu_R$ ) and super-heavy Majorana masses (typically near the grand unification mass scale) for  $\nu_R$ . In addition, one must also include a standard Yukawa couplings between the lepton doublets, the Higgs doublet, and  $\nu_R$ . The Higgs vacuum expectation value then induces an off-diagonal  $\nu_L$ - $\nu_R$  mass on the order of the electroweak scale. Diagonalizing the neutrino mass matrix (in the three-generation model) yields three superheavy neutrino states, and three very light neutrino states that are identified with the light neutrinos observed in nature. This is the seesaw mechanism [193].

It is straightforward to construct a supersymmetric generalization of the seesaw model of neutrino masses [194,195] by promoting the right-handed neutrino field to a superfield  $\tilde{N}^c = (\tilde{\nu}_R; \nu_R)$ . Integrating out the heavy right-handed neutrino supermultiplet yields a new term in the superpotential [cf. Eq. (1)] of the form

$$W_{\text{seesaw}} = \frac{f}{M_R} (\hat{H}_U \hat{L}) (\hat{H}_U \hat{L}), \quad (22)$$

where  $M_R$  is the mass scale of the right-handed neutrino sector and  $f$  is a dimensionless constant. Note that lepton number is broken by two units, which implies that R-parity is conserved. The supersymmetric analogue of the Majorana neutrino mass term in the sneutrino sector leads to sneutrino-antisneutrino mixing phenomena [195,196].

**I.8.2. R-parity-violating supersymmetry:** In order to incorporate massive neutrinos in renormalizable supersymmetric models while retaining the minimal particle content of the MSSM, one must relax the assumption of R-parity invariance. The most general R-parity-violating (RPV) model involving the MSSM spectrum introduces many new parameters to both the supersymmetry-conserving and the supersymmetry-breaking sectors [197]. Each new interaction term violates either  $B$  or  $L$  conservation. For example, starting from the MSSM superpotential given in Eq. (1) [suitably generalized to

## Searches Particle Listings

### Supersymmetric Particle Searches

three generations of quarks, leptons and their superpartners], consider the effect of adding the following new terms:

$$W_{\text{RPV}} = (\lambda_L)_{pmn} \hat{L}_p \hat{L}_m \hat{E}_n^c + (\lambda'_L)_{pmn} \hat{L}_p \hat{Q}_m \hat{D}_n^c + (\lambda_B)_{pmn} \hat{U}_p^c \hat{D}_m^c \hat{D}_n^c + (\mu_L)_p \hat{H}_u \hat{L}_p, \quad (23)$$

where  $p$ ,  $m$ , and  $n$  are generation indices, and gauge group indices are suppressed. Eq. (23) yields new scalar-fermion Yukawa couplings consisting of all possible combinations involving two Standard Model fermions and one scalar superpartner.

Note that the term in Eq. (23) proportional to  $\lambda_B$  violates  $B$ , while the other three terms violate  $L$ . The  $L$ -violating term in Eq. (23) proportional to  $\mu_L$  is the RPV generalization of the  $\mu \hat{H}_u \hat{H}_d$  term of the MSSM superpotential, in which the  $Y = -1$  Higgs/higgsino supermultiplet  $\hat{H}_d$  is replaced by the slepton/lepton supermultiplet  $\hat{L}_p$ .

Phenomenological constraints derived from data on various low-energy  $B$ - and  $L$ -violating processes can be used to establish limits on each of the coefficients  $(\lambda_L)_{pmn}$ ,  $(\lambda'_L)_{pmn}$ , and  $(\lambda_B)_{pmn}$  taken one at a time [197,198]. If more than one coefficient is simultaneously non-zero, then the limits are in general more complicated [199]. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose  $B$  or  $L$  invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which  $B$  is conserved, but  $L$  is violated. It is possible to enforce baryon number conservation (and the stability of the proton), while allowing for lepton-number-violating interactions by imposing a discrete  $\mathbf{Z}_3$  baryon *triality* symmetry on the low-energy theory [200], in place of the standard  $\mathbf{Z}_2$  R-parity. Since the distinction between the Higgs and matter supermultiplets is lost in RPV models where  $L$  is violated, the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos are now possible, leading to more complicated mass matrices and mass eigenstates than in the MSSM. Incorporating neutrino masses and mixing in this framework can be found, *e.g.*, in Ref. 201.

Alternatively, one can consider imposing a lepton parity such that all lepton superfields are odd [202,203]. In this case, only the  $B$ -violating term in Eq. (23) survives, and  $L$  is conserved. Models of this type have been considered in Ref. 204. Since  $L$  is conserved in these models, the mixing of the lepton and Higgs superfields is forbidden. However, one expects that lepton parity cannot be exact due to quantum gravity effects. Remarkably, the standard  $\mathbf{Z}_2$  R-parity and the  $\mathbf{Z}_3$  baryon triality are stable with respect to quantum gravity effects, as they can be identified as residual discrete symmetries that arise from broken non-anomalous gauge symmetries [202].

The supersymmetric phenomenology of the RPV models exhibits features that are distinct from that of the MSSM [197].

The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. Indeed, the sparticle mass bounds obtained in searches for R-parity-conserving supersymmetry can be considerably relaxed in certain RPV models due to the absence of large missing transverse energy signatures [205]. This can alleviate some of the tension with naturalness discussed in Section I.7.1.

Nevertheless, the loss of the missing-energy signature is often compensated by other striking signals (which depend on which R-parity-violating parameters are dominant). For example, supersymmetric particles in RPV models can be singly produced (in contrast to R-parity-conserving models where supersymmetric particles must be produced in pairs). The phenomenology of pair-produced supersymmetric particles is also modified in RPV models due to new decay chains not present in R-parity-conserving supersymmetry models [197].

In RPV models with lepton number violation (these include weak-scale supersymmetry models with baryon triality mentioned above), both  $\Delta L = 1$  and  $\Delta L = 2$  phenomena are allowed, leading to neutrino masses and mixing [206], neutrinoless double-beta decay [207], sneutrino-antisneutrino mixing [208], and resonant  $s$ -channel production of sneutrinos in  $e^+e^-$  collisions [209] and charged sleptons in  $p\bar{p}$  and  $pp$  collisions [210].

**I.9. Extensions beyond the MSSM:** Extensions of the MSSM have been proposed to solve a variety of theoretical problems. One such problem involves the  $\mu$  parameter of the MSSM. Although  $\mu$  is a supersymmetry-preserving parameter, it must be of order the effective supersymmetry-breaking scale of the MSSM to yield a consistent supersymmetric phenomenology [211]. Any natural solution to the so-called  $\mu$ -problem must incorporate a symmetry that enforces  $\mu = 0$  and a small symmetry-breaking parameter that generates a value of  $\mu$  that is not parametrically larger than the effective supersymmetry-breaking scale [212]. A number of proposed mechanisms in the literature (*e.g.*, see Refs. [211–214]) provide concrete examples of a natural solution to the  $\mu$ -problem of the MSSM.

In extensions of the MSSM, new compelling solutions to the  $\mu$ -problem are possible. For example, one can replace  $\mu$  by the vacuum expectation value of a new  $\text{SU}(3) \times \text{SU}(2) \times \text{U}(1)$  singlet scalar field. This is the NMSSM, which yields phenomena that were briefly discussed in Sections I.4–I.7. The NMSSM superpotential consists only of trilinear terms whose coefficients are dimensionless. There are some advantages to extending the NMSSM further to the USSM [102] by adding a new broken  $\text{U}(1)$  gauge symmetry [215], under which the singlet field is charged.

Alternatively, one can consider a generalized version of the NMSSM (called the GNMSSM in Ref. 170), where all possible renormalizable terms in the superpotential are allowed, which yields new supersymmetric mass terms (analogous to the  $\mu$  term of the MSSM). Although the GNMSSM does not solve the  $\mu$ -problem, it does exhibit regions of parameter space in which the degree of fine-tuning is relaxed, as discussed in Section I.7.1.

The generation of the  $\mu$  term may be connected with the solution to the strong CP problem [216]. Models of this type, which include new gauge singlet fields that are charged under the Peccei-Quinn (PQ) symmetry [217], were first proposed in Ref. 211. The breaking of the PQ symmetry is thus intimately tied to supersymmetry breaking, while naturally yielding a value of  $\mu$  that is of order the electroweak symmetry breaking scale [218].

It is also possible to add higher dimensional Higgs multiplets, such as Higgs triplet superfields [219], provided a custodial-symmetric model (in which the  $\rho$ -parameter of precision electroweak physics is close to 1 [186]) can be formulated. Such models can provide a rich phenomenology of new signals for future LHC studies.

All supersymmetric models discussed in this review possess self-conjugate fermions—the Majorana gluinos and neutralinos. However, it is possible to add additional chiral superfields in the adjoint representation. The spin-1/2 components of these new superfields can pair up with the gauginos to form Dirac gauginos [220,221]. Such states appear in models of so-called supersoft supersymmetry breaking [222], in some generalized GMSB models [223] and in R-symmetric supersymmetry [29,224]. Such approaches often lead to improved naturalness and/or significantly relaxed flavor constraints. The implications of models of Dirac gauginos on the observed Higgs boson mass and its properties is addressed in Ref. 225.

For completeness, we briefly note other MSSM extensions considered in the literature. These include an enlarged electroweak gauge group beyond  $SU(2) \times U(1)$  [226]; and/or the addition of new (possibly exotic) matter supermultiplets such as vector-like fermions and their superpartners [171,227].

#### II.1. Introduction

Supersymmetry (SUSY), a transformation relating fermions to bosons and vice versa [1–9], is one of the most compelling possible extensions of the Standard Model of particle physics (SM) that could be discovered at high-energy colliders such as the Large Hadron Collider (LHC) at CERN.

On theoretical grounds SUSY is motivated as a generalization of space-time symmetries. A low-energy realization of SUSY, *i.e.*, SUSY at the TeV scale, is, however, not a necessary consequence. Instead, low-energy SUSY is motivated by the possible cancellation of quadratic divergences in radiative corrections to the Higgs boson mass [10–15]. Furthermore, it is intriguing that a weakly interacting, (meta)stable supersymmetric particle might make up some or all of the dark matter in the universe [16–18]. In addition, SUSY predicts that gauge couplings, as measured experimentally at the electroweak scale, unify at an energy scale  $\mathcal{O}(10^{16})\text{GeV}$  (“GUT scale”) near the Planck scale [19–25].

In the minimal supersymmetric extension to the Standard Model, the so called MSSM [11,26,27], a supersymmetry transformation relates every fermion and gauge boson in the SM to a supersymmetric partner with half a unit of spin difference, but otherwise with the same properties and quantum numbers. These are the “sfermions”: squarks ( $\tilde{q}$ ) and sleptons ( $\tilde{\ell}$ ,  $\tilde{\nu}$ ), and the “gauginos”. The MSSM Higgs sector contains two doublets, for up-type quarks and for down-type quarks and charged leptons respectively. After electroweak symmetry breaking, five Higgs bosons arise, of which two are charged. The supersymmetric partners of the Higgs doublets are known as “higgsinos.” The charged weak gauginos and higgsinos mix to “charginos” ( $\tilde{\chi}^\pm$ ), and the neutral ones mix to “neutralinos” ( $\tilde{\chi}^0$ ). The SUSY partners of the gluons are known as “gluinos” ( $\tilde{g}$ ). The fact that such particles are not yet observed leads to the conclusion that, if supersymmetry is realized, it is a broken symmetry. A description of SUSY in the form of an effective Lagrangian with only “soft” SUSY breaking terms and SUSY masses at the TeV scale maintains cancellation of quadratic divergences in particle physics models.

The phenomenology of SUSY is to a large extent determined by the SUSY breaking mechanism and the SUSY breaking scale. This determines the SUSY particle masses, the mass hierarchy, the field contents of physical particles, and their decay modes. In addition, phenomenology crucially depends on whether the multiplicative quantum number of R-parity [27],  $R = (-1)^{3(B-L)+2S}$ , where  $B$  and  $L$  are baryon and lepton numbers and  $S$  is the spin, is conserved or violated. If R-parity is conserved, SUSY particles (sparticles), which have odd R-parity, are produced in pairs and the decays of each SUSY particle must involve an odd number of lighter SUSY particles. The lightest SUSY particle (LSP) is then stable and often assumed to be a weakly interacting massive particle (WIMP). If R-parity is violated, new terms  $\lambda_{ijk}$ ,  $\lambda'_{ijk}$  and  $\lambda''_{ijk}$  appear in the superpotential, where  $ijk$  are generation indices;  $\lambda$ -type couplings appear between lepton superfields

# Searches Particle Listings

## Supersymmetric Particle Searches

only,  $\lambda''$ -type are between quark superfields only, and  $\lambda'$ -type couplings connect the two. R-parity violation implies lepton and/or baryon number violation. More details of the theoretical framework of SUSY are discussed elsewhere in this volume [28].

Today low-energy data from flavor physics experiments, high-precision electroweak observables as well as astrophysical data impose strong constraints on the allowed SUSY parameter space. Recent examples of such data include measurements of the rare B-meson decay  $B_s \rightarrow \mu^+ \mu^-$  [29] and accurate determinations of the cosmological dark matter relic density constraint [30,31].

These indirect constraints are often more sensitive to higher SUSY mass scales than experiments searching for direct sparticle production at colliders, but the interpretation of these results is often strongly model dependent. In contrast, direct searches for sparticle production at collider experiments are less subject to interpretation ambiguities and therefore they play a crucial role in the search for SUSY.

The discovery of a new scalar boson with a mass around 125 GeV compatible with a Higgs boson imposes constraints on SUSY, which are discussed elsewhere [28,32].

In this review we limit ourselves to direct searches, covering data analyses at LEP, HERA, the Tevatron and the LHC, with emphasis on the latter. For more details on LEP and Tevatron constraints, see earlier PDG reviews [33].

### II.2. Experimental search program

The electron-positron collider LEP was operational at CERN between 1989 and 2000. In the initial phase, center-of-mass energies around the  $Z$ -peak were probed, but after 1995 the LEP experiments collected a significant amount of luminosity at higher center-of-mass energies, some  $235 \text{ pb}^{-1}$  per experiment at  $\sqrt{s} \geq 204 \text{ GeV}$ , with a maximum  $\sqrt{s}$  of 209 GeV.

Searches for new physics at  $e^+e^-$  colliders benefit from the clean experimental environment and the fact that momentum balance can be measured not only in the plane transverse to the beam, but also in the direction along the beam (up to the beam pipe holes), defined as the longitudinal direction. Searches at LEP are dominated by the data samples taken at the highest center-of-mass energies.

Significant constraints on SUSY have been set by the CDF and D0 experiments at the Tevatron, a proton-antiproton collider at a center-of-mass energy of up to 1.96 TeV. CDF and D0 have collected integrated luminosities between 10 and  $11 \text{ fb}^{-1}$  each up to the end of collider operations in 2011.

The electron-proton collider HERA provided collisions to the H1 and ZEUS experiments between 1992 and 2007, at a center-of-mass energy up to 318 GeV. A total integrated luminosity of approximately  $0.5 \text{ fb}^{-1}$  has been collected by each experiment. Since in  $ep$  collisions no annihilation process takes place, SUSY searches at HERA typically look for R-parity violating production of single SUSY particles.

The LHC has started proton-proton operation at a center-of-mass energy of 7 TeV in 2010. By the end of 2011 the experiments ATLAS and CMS had collected about  $5 \text{ fb}^{-1}$  of integrated luminosity each, and the LHCb experiment had collected approximately  $1 \text{ fb}^{-1}$ . In 2012, the LHC operated at a center-of-mass energy of 8 TeV, and ATLAS and CMS collected approximately  $20 \text{ fb}^{-1}$  each, whereas LHCb collected  $2 \text{ fb}^{-1}$ . In 2015, the LHC has started Run 2, with center-of-mass energy of 13 TeV.

Proton-(anti)proton colliders produce interactions at higher center-of-mass energies than those available at LEP, and cross sections of QCD-mediated processes are larger, which is reflected in the higher sensitivity for SUSY particles carrying color charge: squarks and gluinos. Large background contributions from Standard Model processes, however, pose challenges to trigger and analysis. Such backgrounds are dominated by multijet production processes, including, particularly at the LHC, those of top quark production, as well as jet production in association with vector bosons. The proton momentum is shared between its parton constituents, and in each collision only a fraction of the total center-of-mass energy is available in the hard parton-parton scattering. Since the parton momenta in the longitudinal direction are not known on an event-by-event basis, use of momentum conservation constraints in an analysis is restricted to the transverse plane, leading to the definition of transverse variables, such as the missing transverse momentum, and the transverse mass. Proton-proton collisions at the LHC differ from proton-antiproton collisions at the Tevatron in the sense that there are no valence anti-quarks in the proton, and that gluon-initiated processes play a more dominant role. The increased center-of-mass energy of the LHC compared to the Tevatron significantly extends the kinematic reach for SUSY searches. This is reflected foremost in the sensitivity for squarks and gluinos, but also for other SUSY particles.

The main production mechanisms of massive colored sparticles at hadron colliders are squark-squark, squark-gluino and gluino-gluino production; when “squark” is used “antisquark” is also implied. The typical SUSY search signature at hadron colliders contains high- $p_T$  jets, which are produced in the decay chains of heavy squarks and gluinos, and significant missing momentum originating from the two LSPs produced at the end of the decay chain. Assuming R-parity conservation, the LSPs are neutral and weakly interacting massive particles which escape detection. Standard Model backgrounds with missing transverse momentum include leptonic  $W/Z$ -boson decays, heavy-flavor decays to neutrinos, and multijet events that may be affected by instrumental effects such as jet mismeasurement.

Selection variables designed to separate the SUSY signal from the Standard Model backgrounds include  $H_T$ ,  $E_T^{\text{miss}}$ , and  $m_{\text{eff}}$ . The quantities  $H_T$  and  $E_T^{\text{miss}}$  refer to the measured transverse energy and missing transverse momentum in the event, respectively. They are usually defined as the scalar ( $H_T$ ) and negative vector sum ( $E_T^{\text{miss}}$ ) of the transverse jet energies or transverse calorimeter clusters energies measured in

the event. The quantity  $m_{\text{eff}}$  is referred to as the effective mass of the event and is defined as  $m_{\text{eff}} = H_T + |E_T^{\text{miss}}|$ . The peak of the  $m_{\text{eff}}$  distribution for SUSY signal events correlates with the SUSY mass scale, in particular with the mass difference between the primary produced SUSY particle and the LSP [34], whereas the Standard Model backgrounds dominate at low  $m_{\text{eff}}$ . Additional reduction of multijet backgrounds can be achieved by demanding isolated leptons or photons in the final states; in such events the lepton or photon transverse momentum may be added to  $H_T$  or  $m_{\text{eff}}$  for further signal-background separation.

In the past few years alternative approaches have been developed to increase the sensitivity to pair production of heavy sparticles with masses around 1 TeV focusing on the kinematics of their decays, and to further suppress the background from multijet production. Prominent examples of these new approaches are searches using the  $\alpha_T$  [35–39], *razor* [40], *stransverse mass* ( $m_{T2}$ ) [41], and *contransverse mass* ( $m_{CT}$ ) [42] variables.

### II.3. Interpretation of results

Since the mechanism by which SUSY is broken is unknown, a general approach to SUSY via the most general soft SUSY breaking Lagrangian adds a significant number of new free parameters. For the minimal supersymmetric standard model, MSSM, *i.e.*, the model with the minimal particle content, these comprise 105 new parameters. A phenomenological analysis of SUSY searches leaving all these parameters free is not feasible. For the practical interpretation of SUSY searches at colliders several approaches are taken to reduce the number of free parameters.

One approach is to assume a SUSY breaking mechanism and lower the number of free parameters through the assumption of additional constraints. In particular in past years, interpretations of experimental results were predominately performed in constrained models of gravity mediated [43,44], gauge mediated [45,46], and anomaly mediated [47,48] SUSY breaking. Before the start of the LHC and even during its first year of operation, the most popular model for interpretation of collider based SUSY searches was the constrained MSSM (CMSSM) [43,49,50], which in the literature is also referred to as minimal supergravity, or MSUGRA. The CMSSM is described by five parameters: the common sfermion mass  $m_0$ , the common gaugino mass  $m_{1/2}$ , and the common trilinear coupling parameter  $A_0$ , all defined at the GUT scale, the ratio of the vacuum expectation values of the Higgs fields for up-type and down-type fermions  $\tan\beta$ , and the sign of the higgsino mass parameter  $\mu$ , defined at the electroweak scale. In gauge mediation models, the paradigm of general gauge mediation (GGM) [51] is slowly replacing minimal gauge mediation, denoted traditionally as GMSB (gauge mediated SUSY breaking).

These constrained SUSY models are theoretically well motivated and provide a rich spectrum of experimental signatures. Therefore, they represent a useful framework to benchmark performance, compare limits or reaches and assess the expected

sensitivity of different search strategies. However, with universality relations imposed on the soft SUSY breaking parameters, they do not cover all possible kinematic signatures and mass relations of SUSY. In such scenarios the squarks are often nearly degenerate in mass, in particular for the first and second generation. The exclusion of parameter space in the CMSSM and in CMSSM-inspired models is mainly driven by first and second generation squark production together with gluino production.

**Figure 1:** Cross sections for pair production of different sparticles as a function of their mass at the LHC for a center-of-mass energy of 8 TeV [52]. Typically the production cross section of colored squarks and gluinos is several orders of magnitude larger than the one for leptons or charginos. Except for the explicitly shown pair production of stops, production cross sections for squarks assumes mass degeneracy of left- and right-handed  $u$ ,  $d$ ,  $s$ ,  $c$  and  $b$  squarks.

As shown in Fig. 1 [52] these processes possess the largest production cross sections in proton-proton collisions, and thus the LHC searches typically provide the tightest mass limits on these colored sparticles. This, however, implies that the allowed parameter space of constrained SUSY models today has been restrained significantly by searches from ATLAS and CMS. Furthermore, confronting the remaining allowed parameter space with other collider and non-collider measurements, which are directly or indirectly sensitive to contributions from SUSY, the overall compatibility of these models with all data is significantly worse than in the pre-LHC era (see section II.7 for further discussion), indicating that very constrained models like the CMSSM might no longer be good benchmark scenarios to solely characterize the results of SUSY searches at the LHC.

For these reasons, an effort has been made in the past years to complement the traditional constrained models with more flexible approaches.

One answer to study a broader and more comprehensive subset of the MSSM is via the phenomenological-MSSM, or

# Searches Particle Listings

## Supersymmetric Particle Searches

pMSSM [53–55]. It is derived from the MSSM, using experimental data to eliminate parameters that are free in principle but have already been highly constrained by measurements of *e.g.*, flavor mixing and CP-violation. This effective approach reduces the number of free parameters in the MSSM to typically 19, making it a practical compromise between the full MSSM and highly constrained models such as the CMSSM.

Even less dependent on fundamental assumptions are interpretations in terms of so-called simplified models [56–59]. Such models assume a limited set of SUSY particle production and decay modes and leave open the possibility to vary masses and other parameters freely. Therefore, simplified models enable comprehensive studies of individual SUSY topologies, and are useful for optimization of the experimental searches over a wide parameter space. As a consequence, since 2011 ATLAS and CMS have adopted simplified models as the primary framework to provide interpretations of their searches. Today, almost every individual search provides interpretations of their results in one or even several simplified models that are characteristic of SUSY topologies probed by the analysis.

However, while these models are very convenient for the interpretation of individual SUSY production and decay topologies, care must be taken when applying these limits to more complex SUSY spectra. Therefore, in practise, simplified model limits are often used as an approximation of the constraints that can be placed on sparticle masses in more complex SUSY spectra. Yet, depending on the assumed SUSY spectrum, the sparticle of interest, and the considered simplified model limit, this approximation can lead to a significant mistake, typically an overestimation, in the assumed constraint on the sparticle mass (see for example [60]). Only on a case-by-case basis can it be determined whether the limit of a given simplified model represents a good approximation of the true underlying constraint that can be applied on a sparticle mass in a complex SUSY spectrum. In the following, we will always point out explicitly the assumptions that have entered the limits when quoting interpretations from simplified models.

This review covers results up to September 2015 and since none of the searches performed so far have shown significant excess above the SM background prediction, the interpretation of the presented results are exclusion limits on SUSY parameter space.

### II.4. Exclusion limits on gluino and squark masses

Gluinos and squarks are the SUSY partners of gluons and quarks, and thus carry color charge. Limits on squark masses of the order 100 GeV have been set by the LEP experiments [61]. However, due to the colored production of these particles at hadron colliders (see *e.g.* Fig. 1), hadron collider experiments are able to set much tighter mass limits.

Pair production of these massive colored sparticles at hadron colliders generally involve both s-channel and t-channel parton-parton interactions. Since there is a negligible amount of bottom and top quark content in the proton, top- and bottom

squark production proceeds through s-channel diagrams only with smaller cross sections. In the past, experimental analyses of squark and/or gluino production typically assumed the first and second generation squarks to be approximately degenerate in mass. However, in order to have even less model dependent interpretations of the searches, the experiments have started to also provide simplified model limits on individual first or second generation squarks.

Assuming R-parity conservation and assuming gluinos to be heavier than squarks, squarks will predominantly decay to a quark and a neutralino or chargino, if kinematically allowed. The decay may involve the lightest neutralino (typically the LSP) or chargino, but, depending on the masses of the gauginos, may involve heavier neutralinos or charginos. For pair production of first and second generation squarks, the simplest decay modes involve two jets and missing momentum, with potential extra jets stemming from initial state or final state radiation (ISR/FSR) or from decay modes with longer cascades. Similarly, gluino pair production leads to four jets and missing momentum, and possibly additional jets from ISR/FSR or cascades. Associated production of a gluino and a (anti-)squark is also possible, in particular if squarks and gluinos have similar masses, typically leading to three or more jets in the final state. In cascades, isolated photons or leptons may appear from the decays of sparticles such as neutralinos or charginos. Final states are thus characterized by significant missing transverse momentum, and at least two, and possibly many more high  $p_T$  jets, which can be accompanied by one or more isolated objects like photons or leptons, including  $\tau$  leptons, in the final state. Table 1 shows a schematic overview of characteristic final state signatures of gluino and squark production for different mass hierarchy hypotheses and assuming decays involving the lightest neutralino.

The main reference for ATLAS results in this section is the ATLAS Run 1 summary paper on squark and gluino production [62], while for CMS individual results are cited.

**Table 1:** Typical search signatures at hadron colliders for direct gluino and first- and second-generation squark production assuming different mass hierarchies.

Mass Hierarchy	Main Production	Dominant Decay	Typical Signature
$m_{\tilde{q}} \ll m_{\tilde{g}}$	$\tilde{q}\tilde{q}, \tilde{q}\tilde{\bar{q}}$	$\tilde{q} \rightarrow q\tilde{\chi}_1^0$	$\geq 2 \text{ jets} + E_T^{\text{miss}} + X$
$m_{\tilde{q}} \approx m_{\tilde{g}}$	$\tilde{q}\tilde{g}, \tilde{q}\tilde{\bar{g}}$	$\tilde{q} \rightarrow q\tilde{\chi}_1^0$ $\tilde{g} \rightarrow q\tilde{q}\tilde{\chi}_1^0$	$\geq 3 \text{ jets} + E_T^{\text{miss}} + X$
$m_{\tilde{q}} \gg m_{\tilde{g}}$	$\tilde{g}\tilde{g}$	$\tilde{g} \rightarrow q\tilde{q}\tilde{\chi}_1^0$	$\geq 4 \text{ jets} + E_T^{\text{miss}} + X$

#### II.4.1 Exclusion limits on the gluino mass

Limits set by the Tevatron experiments on the gluino mass assume the framework of the CMSSM, with  $\tan\beta = 5$  (CDF) or  $\tan\beta = 3$  (D0),  $A_0 = 0$  and  $\mu < 0$ , and amount to lower limits

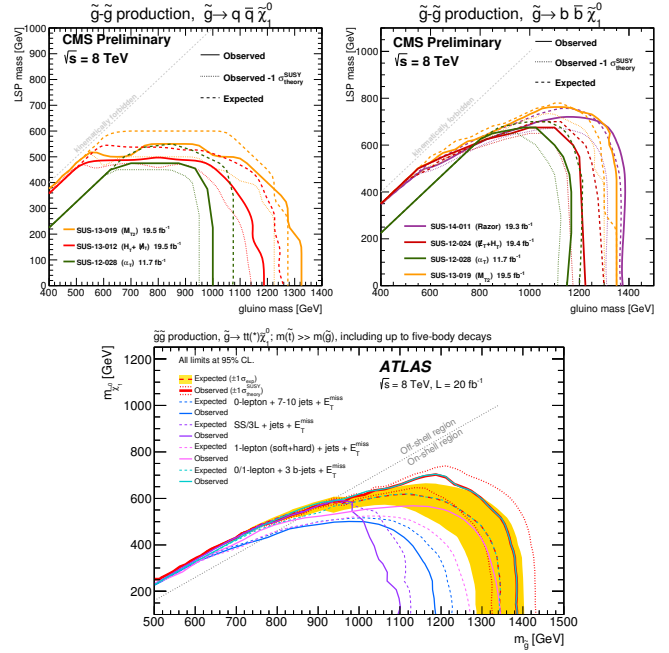

of about 310 GeV for all squark masses, or 390 GeV for the case  $m_{\tilde{q}} = m_{\tilde{g}}$  [63,64]. During the first year of physics operation of the LHC in 2010, these limits have been superseded by those provided by ATLAS and CMS.

Today, limits on the gluino mass have been set using up to approximately  $20 \text{ fb}^{-1}$  of data recorded at a center-of-mass energy of 8 TeV. As shown in Fig. 2, the ATLAS collaboration places limits for several searches in the framework of the CMSSM, assuming  $\tan\beta = 30$ ,  $A_0 = -2m_0$ , and  $\mu > 0$  [62]; these parameter values are chosen since they lead to a mass for the lightest Higgs boson compatible with 125 GeV in a large part of the  $m_0 - m_{1/2}$  plane. For low  $m_0$  the combination of the 0+1 lepton plus jets and missing momentum analyses provides the best sensitivity, while for values of  $m_0$  above  $\approx 1800$  GeV a more dedicated search requiring zero or one isolated lepton accompanied with at least three jets identified to originate from bottom quarks ( $b$ -jets) takes over. The limits at low  $m_0$  are mainly driven by squark-gluino and squark-squark production and at high  $m_0$  gluino pair production dominates. As also indicated in Fig. 1, all other particle production modes do not play a significant role for limits in the CMSSM. In this constrained model gluino masses below around 1300 GeV are excluded by the ATLAS collaboration for all squark masses, while for equal squark and gluino masses, the limit is about 1700 GeV. Further details about the searches that are displayed in Fig. 2 can be obtained from the ATLAS summary paper on squark and gluino production [62].

**Figure 2:** Limits, at 95% C.L., derived from several different ATLAS searches in the CMSSM parameters  $m_0$  and  $m_{1/2}$ , assuming  $\tan\beta = 30$ ,  $A_0 = -2m_0$  and  $\mu > 0$  [62].

Limits on the gluino mass have also been established in the framework of simplified models. Assuming only gluino pair production, in particular three primary decay chains of the gluino have been considered by the LHC experiments for interpretations of their search results. The first decay chain

**Figure 3:** Upper mass limits, at 95% C.L., on gluino pair production for the decay chains  $\tilde{g} \rightarrow q\bar{q}\chi_1^0$  (upper left) [65],  $\tilde{g} \rightarrow b\bar{b}\chi_1^0$  (upper right) [66], and  $\tilde{g} \rightarrow t\bar{t}\chi_1^0$  (lower middle) [62,157]. The limits are defined in the framework of simplified models assuming a single decay chain, (i.e. 100% branching fraction). The upper plots show limits from the CMS collaboration, while the displayed limits for  $\tilde{g} \rightarrow t\bar{t}\chi_1^0$  are obtained from ATLAS searches. It should be noted that the ATLAS results include both on-shell as well as off-shell production of gluino induced stop production (see text for details).

$\tilde{g} \rightarrow q\bar{q}\chi_1^0$  assumes gluino mediated production of first and second generation squarks which leads to four light flavor quarks in the final state. Therefore, inclusive all-hadronic analyses searching for multijet plus  $E_T^{\text{miss}}$  final states are utilized to put limits on this simplified model. These limits are derived as a function of the gluino and neutralino (LSP) mass. As shown in Fig. 3 (upper left), using the cross section from next-to-leading order QCD corrections and the resummation of soft gluon emission at next-to-leading-logarithmic accuracy as reference, the CMS collaboration [65] excludes in this simplified model gluino masses below approximately 1300 GeV (see also [66–68]), for a massless neutralino. In scenarios where neutralinos are not very light, the efficiency of the analyses is reduced by the fact that jets are less energetic, and there is less missing transverse momentum in the event. This leads to weaker limits when the mass difference  $\Delta m = m_{\tilde{g}} - m_{\chi_1^0}$  is reduced. For example, for neutralino masses above about 550 GeV no limit on the gluino mass can be set for this decay chain. Therefore, limits on gluino masses are strongly affected by the assumption of the neutralino mass. Similar results for this simplified model have been obtained by ATLAS [62].

## Searches Particle Listings

### Supersymmetric Particle Searches

The second important decay chain of the gluino considered for interpretation in a simplified model is  $\tilde{g} \rightarrow b\bar{b}\tilde{\chi}_1^0$ . Here the decay is mediated via bottom squarks and thus leads to four jets from  $b$  quarks and  $E_T^{\text{miss}}$  in the final state. Also for this topology inclusive all-hadronic searches provide the highest sensitivity. However, with four  $b$  quarks in the final state, the use of secondary vertex reconstruction for the identification of jets originating from  $b$  quarks provides a powerful handle on the SM background. Therefore, in addition to a multijet plus  $E_T^{\text{miss}}$  signature these searches also require several jets to be tagged as  $b$ -jets. As shown in Fig. 3 (upper right), for this simplified model CMS [66] excludes gluino masses below  $\approx 1350$  GeV for a massless neutralino, while for neutralino masses above  $\approx 750$  GeV no limit on the gluino mass can be set. Comparable limits for this simplified model are provided by searches from ATLAS [62].

Not only first and second generation squarks or bottom squarks may be the product of gluino decays but also, if kinematically allowed, top squarks via the decay  $\tilde{g} \rightarrow \tilde{t}\bar{t}$ . This leads to a “four tops” final state  $ttt\tilde{\chi}_1^0\tilde{\chi}_1^0$  and defines the third important simplified model,  $\tilde{g} \rightarrow \tilde{t}\bar{t}\tilde{\chi}_1^0$ , characterizing gluino pair production. The topology of this decay is very rich in different experimental signatures: as many as four isolated leptons, four  $b$ -jets, several light flavor quark jets, and significant missing momentum from the neutrinos in the  $W$  decay and from the two neutralinos. Therefore, in contrast to the other two simplified models, dedicated searches optimized for this particular final state provide the best mass limit on the gluino for this simplified model. As shown in Fig. 3 (lower middle) [62,157], the ATLAS search requiring significant  $E_T^{\text{miss}}$ , zero or one isolated lepton, and at least three jets identified as  $b$ -jets [69] provides the strongest limit on the gluino mass in the on-shell region ( $m_{\tilde{g}} > 2m_t + m_{\tilde{\chi}_1^0}$ ). At 95% C.L. it rules out a gluino mass below  $\approx 1400$  GeV for  $m_{\tilde{\chi}_1^0} < 300$  GeV. For neutralino masses above  $\approx 700$  GeV, no limit can be placed on the gluino mass for this simplified model. A CMS search [70] also especially optimized for this decay topology by requiring one isolated lepton and high jet multiplicity obtains similar limits.

The ATLAS collaboration also provides limits for the off-shell region ( $m_{\tilde{g}} < 2m_t + m_{\tilde{\chi}_1^0}$ ) of this decay. In the regions of parameter space where the mass difference between the gluino and the lightest neutralino is small, additional sensitivity is obtained from the same-sign search requiring 3 leptons in the final state. To place limits in this off-shell region only four-body ( $\tilde{g} \rightarrow tWb\tilde{\chi}_1^0$ ) and five-body ( $\tilde{g} \rightarrow WbWb\tilde{\chi}_1^0$ ) are considered as for higher multiplicities the gluinos do not decay promptly anymore and thus lead to a different signature topology. With this approach additional parameter space for gluino masses below about 950 GeV can be excluded in the  $m_{\tilde{g}} < 2m_t + m_{\tilde{\chi}_1^0}$  region.

When comparing the limits in Fig. 3 for the three different simplified models it becomes apparent that more parameter space can be excluded when the gluino decay chain is mediated

via third generation squarks. The reason for this is the better control of the SM background by means of identification of  $b$ -jets as well as dedicated topology requirements like high jet multiplicity or isolated leptons for these special signatures. However, this variation in sensitivity of the searches for different gluino decay chains is also a clear indication that care must be taken when limits from these simplified models are applied to SUSY models possessing more complex underlying spectra.

If the gluino decay is suppressed, for example if squark masses are high, gluinos may live longer than typical hadronization times. It is expected that such gluinos will hadronize to semi-stable strongly interacting particles known as R-hadrons. Searches for R-hadrons exploit the typical signature of stable charged massive particles in the detector. As shown in Fig. 4, the CMS experiment excludes semi-stable gluino R-hadrons with masses below approximately 1.3 TeV [71]. The limits depend on the probability for gluinos to form bound states known as gluinoballs, as these are neutral and not observed in the tracking detectors. Similar limits are obtained by the ATLAS experiment [72]. Limits of about 1 TeV are set in the scenario of R-hadron decays inside the detector, for  $c\tau$  ranging from 1 to 1000 mm [73].

Alternatively, since such R-hadrons are strongly interacting, they may be stopped in the calorimeter or in other material, and decay later into energetic jets. These decays are searched for by identifying the jets outside the time window associated with bunch-bunch collisions [74–76]. The latest ATLAS analysis [75] based on the full 2011 and 2012 data set combined (28 fb<sup>-1</sup>) places limits at 95% C.L. on gluino production over almost 16 orders of magnitude in gluino lifetime. For  $m_{\tilde{\chi}_1^0} > 100$  GeV, assuming a 100% branching fraction for gluino decay to gluon (or  $q\bar{q}$ ) + neutralino, gluinos with lifetimes from 10  $\mu$ s to 1000 s and  $m_{\tilde{g}} < 832$  GeV are excluded. When SUSY spectra are compressed, this limit weakens to an exclusion of  $m_{\tilde{g}} < 545$  GeV for  $m_{\tilde{g}} - m_{\tilde{\chi}_1^0} < 100$  GeV.

In summary, for interpretations in the CMSSM, simplified models, and semi-stable R-hadrons, the best limits on the gluino mass range from around 1200 GeV to about 1400 GeV, while for interpretations in the context of stopped R-hadrons the limit on  $m_{\tilde{g}}$  is around 850 GeV. All these limits weaken significantly for compressed SUSY spectra when the mass difference  $m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$  is reduced.

R-parity violating gluino decays are searched for in a number of final states. Searches in multilepton final states set lower mass limits of 1 to 1.4 TeV, depending on neutralino mass and lepton flavor, on decays mediated by  $\lambda$  and  $\lambda'$  couplings [77,78], assuming prompt decays. Searches for displaced vertices are sensitive to non-prompt decays [73]. Multijet final states have been used to search for fully hadronic gluino decays involving  $\lambda''$ , by CDF [79], ATLAS [80] and CMS [81]. Lower mass limits range between 800 and 1000 GeV depending on neutralino mass and flavor content of the final state.

**Figure 4:** Observed 95% C.L. upper limits on the cross section for (semi-)stable top squarks or gluinos [71]. For gluinos, different fractions of gluinoball states produced after hadronization scenarios are indicated. The observed limits are compared with the predicted theoretical cross sections where the bands represent the theoretical uncertainties on the cross section values.

#### II.4.2. Exclusion limits on first and second generation squark masses

Limits on first and second generation squark masses set by the Tevatron experiments assume the CMSSM model, and amount to lower limits of about 380 GeV for all gluino masses, or 390 GeV for the case  $m_{\tilde{q}} = m_{\tilde{g}}$  [63,64].

At the LHC, limits on squark masses have been set using up to approximately  $20 \text{ fb}^{-1}$  of data at 8 TeV. As shown in Fig. 2, the ATLAS collaboration [62] excludes in the framework of the CMSSM squark masses below  $\approx 1600$  GeV for all gluino masses. For equal squark and gluino masses, the limit is about 1700 GeV.

Interpretations in simplified models are typically characterizing squark pair production with only one decay chain of  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ . Here it is assumed that the left and right-handed  $\tilde{u}$ ,  $\tilde{d}$ ,  $\tilde{s}$  and  $\tilde{c}$  squarks are degenerate in mass. Furthermore, it is assumed that the mass of the gluino is very high and thus contributions of the corresponding t-channel diagrams to squark pair production are negligible. Therefore, the total production cross section for this simplified model is eight times

the production cross section of an individual squark (e.g.  $\tilde{u}_L$ ). The CMS collaboration provides interpretations using different all-hadronic searches for this simplified model. As displayed in Fig. 5, best observed exclusion is obtained from the analysis using the  $m_{T2}$  variable [65], which excludes squark masses just below 925 GeV for a light neutralino. The effects of heavy neutralinos on squark limits are similar to those discussed in the gluino case (see section II.4.1) and only for neutralino masses below  $\approx 350$  GeV squark masses can be excluded. Results from the ATLAS collaboration [62] for this simplified model are similar.

For the same analysis ATLAS also provides an interpretation of their search result in a simplified model assuming strong production of first and second generation squarks in association with gluinos. This interpretation excludes squark masses below  $\approx 1400$  GeV for all gluino masses as well as gluino masses below  $\approx 1400$  GeV for all squark masses. For equal squark and gluino masses, the limit is about 1700 GeV and therefore very similar to limits provided in the CMSSM.

If the assumption of mass degenerate first and second generation squarks is dropped and only the production of a single light squark is assumed, the limits weaken significantly. This is shown as the much smaller exclusion region in Fig. 5, which represents the 95% C.L. upper limit of pair production of a single light squark, with the gluino and all other squarks decoupled to very high masses. With a best observed squark mass limit of only  $\approx 575$  GeV for a massless neutralino and a neutralino mass of  $\approx 120$  GeV above which no squark mass limit can be placed, the exclusion reach of the LHC experiments for single light squark is rather weak. It should be noted that this limit is not a result of a simple scaling of the above mentioned mass limits assuming eightfold mass degeneracy but it also takes into account that for an eight times lower production cross section the analyses must probe kinematic regions of phase space that are closer to the ones of SM background production. Since signal acceptance and the ratio of expected signal to SM background events of the analyses are typically worse in this region of phase space not only the  $1/8$  reduction in production cross section but also a worse analysis sensitivity are responsible for the much weaker limit on single squark pair production.

For single light squarks ATLAS also reports results of a dedicated search for pair production of scalar partners of charm quarks [82]. Assuming that the scalar-charm state exclusively decays into a charm quark and a neutralino, scalar-charm masses up to 490 GeV are excluded for neutralino masses below 200 GeV.

R-parity violating production of single squarks via a  $\lambda'$ -type coupling has been studied at HERA. In such models, a lower limit on the squark mass of the order of 275 GeV has been set for electromagnetic-strength-like couplings  $\lambda' = 0.3$  [83]. At the LHC, both prompt [77,78] and non-prompt [73,84] R-parity

**Figure 5:** 95% C.L. exclusion contours in the squark-neutralino mass plane defined in the framework of simplified models assuming a single decay chain of  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  [65]. Two assumptions for the squark pair production cross sections are displayed; a) eightfold degeneracy for the masses of the first and second generation squarks and b) only one light flavor squark.

violating squark decays have been searched for, but no signal was found. Squark mass limits are very model-dependent.

### II.4.3. Exclusion limits on third generation squark masses

SUSY at the TeV-scale is often motivated by naturalness arguments, most notably as a solution to stabilize quadratic divergences in radiative corrections to the Higgs boson mass. In this context, the most relevant terms for SUSY phenomenology arise from the interplay between the masses of the third generation squarks and the Yukawa coupling of the top quark to the Higgs boson. This motivates a potential constraint on the masses of the top squarks and the left-handed bottom squark. Due to the large top quark mass, significant mixing between  $\tilde{t}_L$  and  $\tilde{t}_R$  is expected, leading to a lighter mass state  $\tilde{t}_1$  and a heavier mass state  $\tilde{t}_2$ . In the MSSM, the lightest top squark ( $\tilde{t}_1$ ) can be the lightest squark.

The discovery of a Higgs boson at a mass around 125 GeV has consequences for third generation squarks in the MSSM, which are discussed elsewhere [28]. As a result, and in the absence of a SUSY discovery so far, searches for third generation squark production have become a major focus of the SUSY search program at the LHC. For this reason direct and gluino

mediated top and/or bottom squark production processes, leading to experimental signatures that are rich in jets originating from bottom quarks, are either subject of re-interpretation of inclusive analyses or targets for dedicated searches. The latter ones have become especially important for searches of direct top squark production.

Direct production of top and bottom squark pairs at hadron colliders is suppressed with respect to first generation squarks, due to the absence of  $t$  and  $b$  quarks in the proton (see e.g. the example of direct top squark production in Fig. 1). At the LHC, assuming eightfold mass degeneracy for light flavor squarks as reference, this suppression is at the level of two orders of magnitude for top and bottom squark masses of around 600 GeV. Moreover, at the LHC, there is a very large background of top quark pair production, making especially the experimental analysis of top squark pair production a challenge.

The main reference for ATLAS results in this section is the summary paper for Run1 searches for direct pair production of third-generation squarks [85], while for CMS individual references are cited.

Bottom squarks are expected to decay predominantly to  $b\tilde{\chi}_1^0$  giving rise to the characteristic multi  $b$ -jet and  $E_T^{\text{miss}}$  signature. Direct production of bottom squark pairs has been studied at the Tevatron and at the LHC. Limits from the Tevatron are  $m_{\tilde{b}} > 247$  GeV for a massless neutralino [86,87]. Using the 2011 data the LHC experiments were able to surpass these limits and based on the full 2012 data set, as shown in Fig. 6, using an all-hadronic search requiring significant  $E_T^{\text{miss}}$  and two jets reconstructed as  $b$ -jets in combination with a dedicated mono-jet analysis, ATLAS has set a limit of  $m_{\tilde{b}} \gtrsim 650$  GeV for the same scenario. For  $m_{\tilde{\chi}_1^0} \approx 280$  GeV or higher no limit can be placed on direct bottom squark pair production in this simplified model [85]. The addition of the mono-jet topology increases the sensitivity for compressed spectra allowing for an exclusion of up to  $m_{\tilde{b}} \approx 280$  GeV along the diagonal. The latest CMS results for this simplified model are featured in [65–68,88] and exhibit a similar reach.

Further bottom squark decay modes have also been studied by ATLAS and CMS. For example, in a simplified model for the  $\tilde{b} \rightarrow t\tilde{\chi}_1^\pm$  decay mode, bottom squark quark masses below approximately 450 GeV are excluded [85,88,89].

The top squark decay modes depend on the SUSY mass spectrum, and on the  $\tilde{t}_L$ - $\tilde{t}_R$  mixture of the top squark mass eigenstate. If kinematically allowed, the two-body decays  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  (which requires  $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > m_t$ ) and  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$  (which requires  $m_{\tilde{t}} - m_{\tilde{\chi}_1^\pm} > m_b$ ) are expected to dominate. If not, the top squark decay may proceed either via the two-body decay  $\tilde{t} \rightarrow c\tilde{\chi}_1^0$  or through  $\tilde{t} \rightarrow bf\tilde{\chi}_1^0$  (where  $f$  and  $\bar{f}$  denote a fermion-antifermion pair with appropriate quantum numbers). For  $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > m_b$  the latter decay chain represents a four-body decay with a  $W$  boson, charged Higgs  $H$ , slepton  $\tilde{\ell}$ , or light flavor squark  $\tilde{q}$ , exchange. If the exchanged  $W$  boson and/or sleptons are kinematically allowed to be on-shell (

**Figure 6:** 95% C.L. exclusion contours in the sbottom-neutralino mass plane defined in the framework of a simplified model assuming a single decay chain of  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  [85].

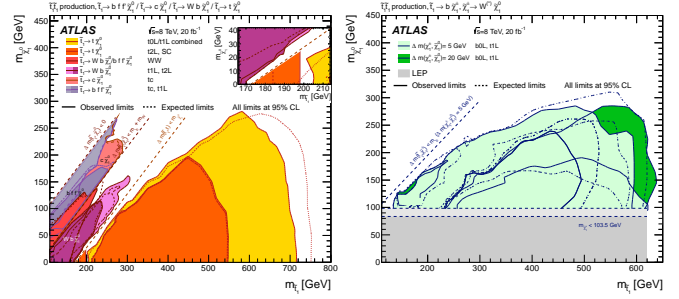

$m_{\tilde{t}} - m_{\tilde{\chi}_1^\pm} > m_b + m_W$  and/or  $m_{\tilde{t}} - m_{\tilde{t}} > m_b$ ), the three-body decays  $\tilde{t} \rightarrow Wb\tilde{\chi}_1^0$  and/or  $\tilde{t} \rightarrow b\tilde{\ell}\tilde{\nu}$  will become dominant. For further discussion on top squark decays see for example Ref. [90].

Limits from LEP on the  $\tilde{t}_1$  mass are  $m_{\tilde{t}} > 96$  GeV in the charm plus neutralino final state, and  $> 93$  GeV in the lepton, b-quark and sneutrino final state [61].

The Tevatron experiments have performed a number of searches for top squarks, often assuming direct pair production. In the  $b\tilde{\ell}\tilde{\nu}$  decay channel, and assuming a 100% branching fraction, limits are set as  $m_{\tilde{t}} > 210$  GeV for  $m_{\tilde{\nu}} < 110$  GeV and  $m_{\tilde{t}} - m_{\tilde{\nu}} > 30$  GeV, or  $m_{\tilde{t}} > 235$  GeV for  $m_{\tilde{\nu}} < 50$  GeV [91,92]. In the  $\tilde{t} \rightarrow c\tilde{\chi}_1^0$  decay mode, a top squark with a mass below 180 GeV is excluded for a neutralino lighter than 95 GeV [93,94]. In both analyses, no limits on the top squark can be set for heavy sneutrinos or neutralinos. In the  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$  decay channel, searches for a relatively light top squark have been performed in the dilepton final state [95,96]. The CDF experiment sets limits in the  $\tilde{t} - \tilde{\chi}_1^0$  mass plane for various branching fractions of the chargino decay to leptons and for two values of  $m_{\tilde{\chi}_1^\pm}$ . For  $m_{\tilde{\chi}_1^\pm} = 105.8$  GeV and  $m_{\tilde{\chi}_1^0} = 47.6$  GeV, top squarks between 128 and 135 GeV are excluded for  $W$ -like leptonic branching fractions of the chargino.

The LHC experiments have improved these limits substantially. As shown in the left plot of Fig. 7, limits on the top squark mass assuming a simplified model with a single decay chain of  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  reach up to about 700 GeV for light neutralinos, while for  $m_{\tilde{\chi}_1^0} > 270$  GeV no limits can be provided. The most important searches for this top squark decay topology are dedicated searches requiring zero or one isolated lepton, modest  $E_T^{\text{miss}}$ , and four or more jets out of which at least one jet must be reconstructed as  $b$ -jet [97,98]. To increase the sensitivity to this decay topology different signal regions are considered in these ATLAS analyses. Searches from the CMS collaboration

requiring one isolated lepton and using a boosted decision tree for a dedicated optimization in the  $m_{\tilde{t}} - m_{\tilde{\chi}_1^0}$  plane [99] or all-hadronic searches [65–68,88] provide comparable limits for this simplified model.

**Figure 7:** 95% C.L. exclusion contours in the  $m_{\tilde{t}} - m_{\tilde{\chi}_1^0}$  plane for different top squark decay chains and different searches from the ATLAS collaboration [85]. The left plot shows simplified model limits for three different decay chains;  $\tilde{t} \rightarrow c\tilde{\chi}_1^0$  ( $W$  and  $t$  forbidden),  $\tilde{t} \rightarrow Wb\tilde{\chi}_1^0$  ( $t$  forbidden), and  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  ( $t$  allowed), which represent three different kinematic regions of the top squark decay. The right plot shows simplified model limits for the top decay chain via a chargino:  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ ,  $\tilde{\chi}_1^\pm \rightarrow W^\pm \tilde{\chi}_1^0$  for different  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$ .

Assuming that the top squark decay exclusively proceeds via the chargino mediated decay chain  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ ,  $\tilde{\chi}_1^\pm \rightarrow W^\pm \tilde{\chi}_1^0$  yields stop mass exclusion limits that vary strongly with the assumptions made on the  $\tilde{t} - \tilde{\chi}_1^\pm - \tilde{\chi}_1^0$  mass hierarchy. As shown in the right plot of Fig. 7, above the universal chargino mass limit of  $m_{\tilde{\chi}_1^\pm} > 103.5$  GeV from LEP (see section II.5.1) the strongest limits are placed for nearly mass degenerate chargino and neutralinos. For  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} > 5$  GeV, a stop mass of  $\approx 650$  GeV for a light  $\tilde{\chi}_1^0$  is excluded, while no limit can be placed for  $m_{\tilde{\chi}_1^0} > 280$  GeV [85]. These limits, however, can weaken significantly when other assumptions about the mass hierarchy are imposed. For example, if the chargino becomes nearly mass degenerate with the top squark the key experimental signature turns from an all-hadronic final state with  $b$ -jets and  $E_T^{\text{miss}}$  into a multi-lepton and  $E_T^{\text{miss}}$  topology yielding significantly weaker limits for this top squark decay. As for the decay with top quarks in the final state, CMS [88,99] also provides comparable limits for this decay chain.

If the decays  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  and  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ ,  $\tilde{\chi}_1^\pm \rightarrow W^\pm \tilde{\chi}_1^0$  are kinematically forbidden, the decay chains  $\tilde{t} \rightarrow Wb\tilde{\chi}_1^0$  and  $\tilde{t} \rightarrow c\tilde{\chi}_1^0$  can become important. As shown in the left plot of Fig. 7, the one-lepton ATLAS search provides for the kinematic region  $m_{\tilde{t}} - m_{\tilde{\chi}_1^\pm} > m_b + m_W$  upper limits on top squark mass of  $\approx 300$  GeV for a neutralino lighter than  $\approx 170$  GeV [85], while the boosted decision tree based CMS analysis pushes this limit to about 320 GeV for neutralino masses below  $\approx 200$  GeV [99]. For the kinematic region in which even the production of

## Searches Particle Listings

### Supersymmetric Particle Searches

real  $W$  bosons is not allowed, ATLAS and CMS improves the Tevatron limit on  $\tilde{t} \rightarrow c\tilde{\chi}^0$  substantially. Based on a combination of a monojet analysis and a dedicated charm quark identification algorithm, away from the kinematic boundary a top squark with a mass below 260 GeV is excluded by the ATLAS analysis for a neutralino lighter than 230 GeV [85]. Along the kinematic boundary for the  $\tilde{t} \rightarrow c\tilde{\chi}^0$  decay the ATLAS monojet results even excludes top squark masses below  $m_{\tilde{\chi}_1^0} \approx 260$  GeV. The corresponding CMS results [88] exhibit similar exclusions. The other decay chain relevant in this phase region is  $\tilde{t} \rightarrow b\tilde{f}\tilde{\chi}^0$ . Here the ATLAS one-lepton search [85] excludes up to  $m_{\tilde{t}} \approx 250$  GeV for  $m_{\tilde{\chi}_1^0}$  below 180 GeV, while the mono-jet excludes at the kinematic boundary top squarks below  $m_{\tilde{\chi}^\pm}$  below 260 GeV. Also for this decay chain CMS [88] provides similar results.

In general, the variety of top squark decay chains in the phase space region where  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  is kinematically forbidden represents a challenge for the experimental search program. As, for example, shown in the inlay of the left plot of Fig. 7 there are still regions in phase space for which the searches do not yet possess enough sensitivity to probe them. Additional data and more refined analyses will be required to also close these gaps.

R-parity violating production of single top squarks has been searched for at LEP, HERA, and the Tevatron. For example, an analysis from the ZEUS collaboration [100] makes an interpretation of its search result assuming top squarks to be produced via a  $\lambda'$  coupling and decay either to  $b\tilde{\chi}_1^\pm$  or R-parity-violating to a lepton and a jet. Limits are set on  $\lambda'_{131}$  as a function of the top squark mass in an MSSM framework with gaugino mass unification at the GUT scale. The search for top squark pair production in the context of R-parity violating supersymmetry has now also become a focus point for searches at the LHC. Recently the CMS collaboration has performed a search for top squarks using a variety of multilepton final states [101]. It provides lower limits on the top squark mass in models with non-zero leptonic R-parity violating couplings  $\lambda_{122}$  and  $\lambda_{233}$ . For a bino mass of 200 GeV, these limits are 1020 GeV and 820 GeV, respectively. The analysis also provides limits in a model with the semileptonic R-parity violating coupling  $\lambda'_{233}$ . The  $\lambda'$ -mediated top squark decay  $\tilde{t} \rightarrow b\ell$  has been studied by ATLAS for prompt decays [102], and by CMS for non-prompt decays [103]. The fully hadronic R-parity violating top squark decay  $\tilde{t} \rightarrow bs$ , involving  $\lambda''$ , has been searched for by ATLAS [104], and a lower top squark mass limit of 310 GeV was set in this decay mode. CMS [105] have searched for a top squark decay to a bottom quark and a light-flavor quark, and excludes top squarks with masses between 200 and 385 GeV in this decay mode.

Top squarks can also be long-lived and hadronize to a R-hadron, for example in the scenario where the top squark is the next-to-lightest SUSY particle (NLSP), with a small mass difference to the LSP. Searches for massive stable charged particles are sensitive to such top squarks. As shown in Fig. 4,

the CMS analysis [71] sets limits  $m_{\tilde{t}} > 800$  GeV in such scenarios, while ATLAS [72] reports limits of  $m_{\tilde{t}} > 900$  GeV. Limits from the Tevatron are about  $m_{\tilde{t}} > 300$  GeV [106,107].

It should be noted that limits discussed in this section belong to different top and bottom squark decay channels, different sparticle mass hierarchies, and different simplified decay scenarios. Therefore, care must be taken when interpreting these limits in the context of more complete SUSY models.

#### II.4.4. Summary of exclusion limits on squarks and gluinos assuming R-Parity conservation

A summary of the most important squark and gluino mass limits for different interpretation approaches assuming R-parity conservation is shown in Table 2.

For gluino masses rather similar limits, ranging from 1.2 TeV to 1.4 TeV, are obtained from different model assumptions indicating that the LHC is indeed probing for a large region in SUSY parameter space direct gluino production at the 1 TeV scale and beyond. However, for neutralino masses above approximately 700 GeV in the best case, ATLAS and CMS searches cannot place any limits on the gluino mass.

Limits on direct squark production, on the other hand, depend strongly on the chosen model. Especially for direct production of top squarks there are still large regions in parameter space where masses below 0.5 TeV cannot be excluded. This is also true for first and second generation squarks when only one single squark is considered. Furthermore, for neutralino masses above  $\approx 300$  GeV no limit on any direct squark production scenario can be placed by the LHC.

#### II.5. Exclusion limits on the masses of charginos and neutralinos

Charginos and neutralinos result from mixing of the charged wino and higgsino states, and the neutral bino, wino and higgsino states, respectively. The mixing is determined by a limited number of parameters. For charginos these are the wino mass parameter  $M_2$ , the higgsino mass parameter  $\mu$ , and  $\tan\beta$ , and for neutralinos these are the same parameters plus the bino mass parameter  $M_1$ . The mass states are four charginos  $\tilde{\chi}_1^\pm$ ,  $\tilde{\chi}_2^\pm$  and  $\tilde{\chi}_2^\pm$ , and four neutralinos  $\tilde{\chi}_1^0$ ,  $\tilde{\chi}_2^0$ ,  $\tilde{\chi}_3^0$  and  $\tilde{\chi}_4^0$ , ordered in increasing mass. The mass states are superpositions of the bino, wino and higgsino states. If any of the parameters  $M_1$ ,  $M_2$  or  $\mu$  happened to be substantially smaller than the others, the chargino and neutralino composition would be dominated by specific states, which are referred to as bino-like ( $M_1 \ll M_2, \mu$ ), wino-like ( $M_2 \ll M_1, \mu$ ), or higgsino-like ( $\mu \ll M_1, M_2$ ). If gaugino mass unification at the GUT scale is assumed, a relation between  $M_1$  and  $M_2$  at the electroweak scale follows:  $M_1 = 5/3 \tan^2 \theta_W M_2 \approx 0.5 M_2$ , with  $\theta_W$  the weak mixing angle. Charginos and neutralinos carry no color charge, and only have electroweak couplings (neglecting gravity).

##### II.5.1. Exclusion limits on chargino masses

If kinematically allowed, two body decay modes such as  $\tilde{\chi}^\pm \rightarrow \tilde{f}\tilde{f}'$  (including  $\ell\bar{\nu}$  and  $\bar{\ell}\nu$ ) are dominant. If not, three

**Table 2:** Summary of squark mass and gluino mass limits using different interpretation approaches assuming R-parity conservation. Masses in this table are provided in GeV. Further details about assumption and analyses from which these limits are obtained are discussed in the corresponding sections of the text.

body decay  $\tilde{\chi}^\pm \rightarrow f\bar{f}'\tilde{\chi}^0$  are mediated through virtual  $W$  bosons or sfermions. If sfermions are heavy, the  $W$  mediation dominates, and  $f\bar{f}'$  are distributed with branching fractions similar to  $W$  decay products (barring phase space effects for small mass gaps between  $\tilde{\chi}^\pm$  and  $\tilde{\chi}^0$ ). If, on the other hand, sleptons are light enough to play a significant role in the decay mediation, leptonic final states will be enhanced.

At LEP, charginos have been searched for in fully-hadronic, semi-leptonic and fully leptonic decay modes [108,109]. A general lower limit on the lightest chargino mass of 103.5 GeV

is derived, except in corners of phase space with low electron sneutrino mass, where destructive interference in chargino production, or two-body decay modes, play a role. The limit is also affected if the mass difference between  $\tilde{\chi}_1^\pm$  and  $\tilde{\chi}_1^0$  is small; dedicated searches for such scenarios set a lower limit of 92 GeV.

At the Tevatron, charginos have been searched for via associated production of  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  [110,111]. Decay modes involving multilepton final states provide the best discrimination against the large multijet background. Analyses have looked for at least three charged isolated leptons, for two leptons with missing transverse momentum, or for two leptons with the same charge. Depending on the  $(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0)$  and/or  $(\tilde{\chi}_2^0 - \tilde{\chi}_1^0)$  mass differences, leptons may be soft.

At the LHC, the search strategy is similar to that at the Tevatron. As shown in Fig. 1, the cross section of pair production of chargino and neutralinos at the LHC, for masses of several hundreds of GeV, is at least two orders of magnitude smaller than for colored SUSY particles (e.g. top squark pair production). For this reason a high statistics data sample is required to improve the sensitivity of LEP and Tevatron searches for direct chargino/neutralino production. With the full LHC Run 1 data, ATLAS and CMS have started to surpass the limits from LEP and Tevatron in regions of SUSY parameter space.

Chargino pair production is searched for in the dilepton plus missing momentum final state. In the simplified model interpretation of the results, assuming mediation of the chargino decay by light sleptons, ATLAS [112] and CMS [113] set limits on the chargino mass up to 540 GeV for massless LSPs, but no limits on the chargino mass can be set for  $\tilde{\chi}_1^0$  heavier than 180 GeV. Limits are fairly robust against variation of the slepton mass, unless the mass gap between chargino and slepton becomes small. First limits are also set on charginos decaying via a  $W$  boson [114]: chargino masses below 180 GeV are excluded for massless LSPs, but no limits are set for LSPs heavier than 25 GeV. The trilepton plus missing momentum final state is used to set limits on  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  production, assuming wino-like  $\tilde{\chi}^\pm$  and  $\tilde{\chi}_2^0$ , bino-like  $\tilde{\chi}_1^0$ , and  $m_{\tilde{\chi}^\pm} = m_{\tilde{\chi}_2^0}$ , leaving  $m_{\tilde{\chi}^\pm}$  and  $m_{\tilde{\chi}_1^0}$  free. Again, the branching fraction of leptonic final states is determined by the slepton masses. If the decay is predominantly mediated by a light  $\tilde{\ell}_L$ , i.e.  $\tilde{\ell}_R$  is assumed to be heavy, the three lepton flavors will be produced in equal amounts. It is assumed that  $\tilde{\ell}_L$  and sneutrino masses are equal, and diagrams with sneutrinos are included. In this scenario, ATLAS [112] and CMS [113] exclude chargino masses below 730 GeV for massless LSPs; no limits are set for LSP masses above 400 GeV. If the decay is dominated by a light  $\tilde{\ell}_R$ , the chargino cannot be a pure wino but needs to have a large higgsino component, preferring the decays to tau leptons. Limits are set in various scenarios. If, like for  $\tilde{\ell}_L$ , a flavor-democratic scenario is assumed, CMS sets limits of 620 GeV on the chargino mass for massless LSPs, but under the assumption that both  $\tilde{\chi}^\pm$  and  $\tilde{\chi}_2^0$  decay leads to tau leptons in the final

## Searches Particle Listings

### Supersymmetric Particle Searches

state, the chargino mass limit deteriorates to 350 GeV for massless LSPs [113]. ATLAS assumes a simplified model in which staus are significantly lighter than the other sleptons in order to search for a similar multi-tau final state, and sets a similar limit on the chargino mass [112].

**Figure 8:** A summary of limits on chargino and neutralino masses in simplified models as obtained by CMS [158].

If sleptons are heavy, the chargino is assumed to decay to a  $W$  boson plus LSP, and the  $\tilde{\chi}_2^0$  into  $Z$  plus LSP or  $H$  plus LSP. In the  $WZ$  channel, ATLAS [112] and CMS [113] limits on the chargino mass reach 420 GeV for massless LSPs, but no limits are set for LSPs heavier than 150 GeV. In the  $WH$  channel, for  $m_H = 125$  GeV and using Higgs decays to  $b\bar{b}$ ,  $\gamma\gamma$  and  $WW$  (ATLAS [115]), or Higgs decays to  $b\bar{b}$ ,  $\gamma\gamma$ ,  $WW$ ,  $ZZ$  and  $\tau^+\tau^-$  (CMS [113,116]), assuming a SM-like branching fraction in these final states, chargino mass limits extend up to 250 GeV for massless LSPs, but vanish for LSPs above 40 GeV.

The CMS results on electroweak gaugino searches interpreted in simplified models are summarized in Fig. 8, the ATLAS results are similar.

In both the wino region (a characteristic of anomaly-mediated SUSY breaking models) and the higgsino region of the MSSM, the mass splitting between  $\tilde{\chi}_1^\pm$  and  $\tilde{\chi}_1^0$  is small. The chargino decay products are very soft and may escape detection. These compressed spectra are very hard to find, and have triggered dedicated search strategies, which, however, still have limited sensitivity. Photons or jets from initial state radiation may be used to tag such decays. An alternative production

mode of electroweak gauginos is provided by vector-boson-fusion, where two additional jets with a large rapidity gap can be used to select events and suppress backgrounds [112,117].

In scenarios with compressed spectra, charginos may be long-lived. Charginos decaying in the detectors away from the primary vertex could lead to signatures such as kinked-tracks, or apparently disappearing tracks, since, for example, the pion in  $\tilde{\chi}_1^\pm \rightarrow \pi^\pm \tilde{\chi}_1^0$  might be too soft to be reconstructed. At the LHC, searches have been performed for such disappearing tracks, and interpreted within anomaly-mediated SUSY breaking models [118,119]. Charginos with lifetimes between 0.1 and 10 ns are excluded for chargino masses up to 500 GeV. Within AMSB models, a lower limit on the chargino mass of 270 GeV is set, for a mass difference with the LSP of 160 MeV and a lifetime of 0.2 ns.

Charginos with a lifetime longer than the time needed to pass through the detector appear as charged stable massive particles. Limits have been derived by the LEP experiments [120], by D0 at the Tevatron [107], and by the LHC experiments [72,121,122]. For lifetimes above 100 ns, charginos below some 800 GeV are excluded.

#### II.5.2. Exclusion limits on neutralino masses

In a considerable part of the MSSM parameter space, and in particular when demanding that the LSP carries no electric or color charge, the lightest neutralino  $\tilde{\chi}_1^0$  is the LSP. If R-parity is conserved, such a  $\tilde{\chi}_1^0$  is stable. Since it is weakly interacting, it will typically escape detectors unseen. Limits on the invisible width of the  $Z$  boson apply to neutralinos with a mass below 45.5 GeV, but depend on the  $Z$ -neutralino coupling. Such a coupling could be small or even absent; in such a scenario there is no general lower limit on the mass of the lightest neutralino [123]. In models with gaugino mass unification and sfermion mass unification at the GUT scale, a lower limit on the neutralino mass is derived from limits from direct searches, notably for charginos and sleptons, and amounts to 47 GeV [124]. Assuming a constraining model like the CMSSM, this limit increases to 50 GeV at LEP; however the strong constraints now set by the LHC increase such CMSSM-derived  $\tilde{\chi}_1^0$  mass limits to well above 200 GeV [125].

In gauge-mediated models, the LSP is typically a gravitino, and the phenomenology is determined by the nature of the next-to-lightest supersymmetric particle (NLSP). A NLSP neutralino will decay to a gravitino and a SM particle whose nature is determined by the neutralino composition. Final states with two high  $p_T$  photons and missing momentum are searched for, and interpreted in gauge mediation models with bino-like neutralinos [126–130].

Assuming the production of at least two neutralinos per event, neutralinos with large non-bino components can also be searched for by their decay in final states with missing momentum plus any two bosons out of the collection  $\gamma, Z, H$ . A number of searches at the LHC have tried to cover the rich phenomenology of the various  $Z$  and  $H$  decay modes [113,116,129–131].

In gauge mediation models, NLSP neutralino decays need not be prompt, and experiments have searched for late decays with photons in the final state. CDF have searched for delayed  $\tilde{\chi}_1^0 \rightarrow \gamma \tilde{G}$  decays using the timing of photon signals in the calorimeter [132]. CMS has used the same technique at the LHC [133]. Results are given as upper limits on the neutralino production cross section as a function of neutralino mass and lifetime. D0 has looked at the direction of showers in the electromagnetic calorimeter with a similar goal [134], and ATLAS has searched for photon candidates that do not point back to the primary vertex, as well as for delayed photons [135].

Heavier neutralinos, in particular  $\tilde{\chi}_2^0$ , have been searched for in their decays to the lightest neutralino plus a  $\gamma$ , a  $Z$  boson or a Higgs boson. Limits on electroweak production of  $\tilde{\chi}_2^0$  plus  $\tilde{\chi}_1^\pm$  from trilepton analyses have been discussed in the section on charginos; the assumption of equal mass of  $\tilde{\chi}_2^0$  and  $\tilde{\chi}_1^\pm$  make the limits on chargino masses apply to  $\tilde{\chi}_2^0$  as well. Multilepton analyses have also been used to set limits on  $\tilde{\chi}_2^0 \tilde{\chi}_3^0$  production; assuming equal mass limits are set up to 680 GeV for massless LSPs [112]. Again, compressed spectra with small mass differences between the heavier neutralinos and the LSP form the most challenging region.

In  $\tilde{\chi}_2^0$  decays to  $\tilde{\chi}_1^0$  and a lepton pair, the lepton pair invariant mass distribution may show a structure that can be used to measure the  $\tilde{\chi}_2^0 - \tilde{\chi}_1^0$  mass difference in case of a signal [34]. This structure, however, can also be used in the search strategy itself, as demonstrated by CMS [136] and ATLAS [131].

In model with R-parity violation, the lightest neutralino can decay even if it is the lightest supersymmetric particle. If the decay involves a non-zero  $\lambda$  coupling, the final state will be a multi-lepton one. Searches for events with four or more isolated charged leptons by ATLAS [77,137] and CMS [78] are interpreted in such models. With very small coupling values, the neutralino would be long-lived, leading to lepton pairs with a displaced vertex, which have also been searched for [73,84]. Searches for events with a displaced hadronic vertex, with or without a matched lepton, are interpreted in a model with R-parity violating neutralino decay involving a non-zero  $\lambda'$  coupling [73,138]. Neutralino decays involving non-zero  $\lambda''$  lead to fully hadronic final states, and searches for jet-pair resonances are used to set limits, typically on the production of colored particles like top squarks or gluinos, which are assumed to be the primary produced sparticles in these interpretations, as discussed earlier.

Interpretations of the search results outside simplified models, such as in the phenomenological MSSM [139–141], show that the simplified model limits must be interpreted with care. Electroweak gauginos in models that are compatible with the relic density of dark matter in the universe, for example, have particularly tuned mixing parameters and mass spectra, which are not always captured by the simplified models used.

**Table 3:** Summary of weak gaugino mass limits in simplified models, assuming R-parity conservation. Masses in the table are provided in GeV. Further details about assumptions and analyses from which these limits are obtained are discussed in the text.

Assumption	$m_\chi$
$\tilde{\chi}_1^\pm$ , all $\Delta m(\tilde{\chi}_1^\pm, \tilde{\chi}_1^0)$	$> 92$
$\tilde{\chi}_1^\pm$ $\Delta m > 5$ , $m_{\tilde{\nu}} > 300$	$> 103.5$
$\tilde{\chi}_1^\pm$ , $m_{(\tilde{\ell}, \tilde{\nu})} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ $m_{\tilde{\chi}_1^0} \approx 0$	$> 540$
$\tilde{\chi}_1^\pm$ , $m_{\tilde{\chi}_1^0} > 180$	no LHC limit
$\tilde{\chi}_1^\pm$ , $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$ $m_{\tilde{\chi}_1^0} \approx 0$	$> 180$

$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$ , $m_{\tilde{\ell}_L} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ $m_{\tilde{\chi}_1^0} \approx 0$	$> 730$
$m_{\tilde{\chi}_1^0} > 400$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$ , $m_{\tilde{\ell}_R} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ $m_{\tilde{\chi}_1^0} \approx 0$	flavor-democratic $> 620$
$m_{\tilde{\chi}_1^0} > 220$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$ , $m_{\tilde{\tau}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ $m_{\tilde{\chi}_1^0} \approx 0$	$\tilde{\tau}$ -dominated $> 350$
$m_{\tilde{\chi}_1^0} > 120$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$ , $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$ , $\text{BF}(WZ) = 1$ $m_{\tilde{\chi}_1^0} \approx 0$	$> 420$
$m_{\tilde{\chi}_1^0} > 150$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$ , $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$ , $\text{BF}(WH) = 1$ $m_{\tilde{\chi}_1^0} \approx 0$	$> 250$
$m_{\tilde{\chi}_1^0} > 40$	no LHC limit

## II.6. Exclusion limits on slepton masses

In models with slepton and gaugino mass unification at the GUT scale, the right-handed slepton,  $\tilde{\ell}_R$ , is expected to be lighter than the left-handed slepton,  $\tilde{\ell}_L$ . For tau sleptons there may be considerable mixing between the L and R states, leading to a significant mass difference between the lighter  $\tilde{\tau}_1$  and the heavier  $\tilde{\tau}_2$ .

### II.6.1. Exclusion limits on the masses of charged sleptons

The most model-independent searches for selectrons, smuons and staus originate from the LEP experiments [142]. Smuon production only takes place via s-channel  $\gamma^*/Z$  exchange. Search results are often quoted for  $\tilde{\mu}_R$ , since it is typically lighter than  $\tilde{\mu}_L$  and has a weaker coupling to the  $Z$  boson; limits are therefore conservative. Decays are expected to be dominated by  $\tilde{\mu}_R \rightarrow \mu \tilde{\chi}_1^0$ , leading to two non-back-to-back muons and missing momentum. Slepton mass limits are calculated in the MSSM under the assumption of gaugino mass unification at the GUT scale, and depend on the mass difference

# Searches Particle Listings

## Supersymmetric Particle Searches

between the smuon and  $\tilde{\chi}_1^0$ . A  $\tilde{\mu}_R$  with a mass below 94 GeV is excluded for  $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10$  GeV. The selectron case is similar to the smuon case, except that an additional production mechanism is provided by t-channel neutralino exchange. The  $\tilde{e}_R$  lower mass limit is 100 GeV for  $m_{\tilde{\chi}_1^0} < 85$  GeV. Due to the t-channel neutralino exchange,  $\tilde{e}_R \tilde{e}_L$  pair production was possible at LEP, and a lower limit of 73 GeV was set on the selectron mass regardless of the neutralino mass by scanning over MSSM parameter space [143]. The potentially large mixing between  $\tilde{\tau}_L$  and  $\tilde{\tau}_R$  not only makes the  $\tilde{\tau}_1$  light, but can also make its coupling to the Z boson small. LEP lower limits on the  $\tilde{\tau}$  mass range between 87 and 93 GeV depending on the  $\tilde{\chi}_1^0$  mass, for  $m_{\tilde{\tau}} - m_{\tilde{\chi}_1^0} > 7$  GeV [142].

As shown in Fig. 1, at the LHC pair production of sleptons is not only heavily suppressed with respect to pair production of colored SUSY particles but the cross section is also almost two orders of magnitude smaller than the one of pair production of chargino and neutralinos. Only with the full Run 1 LHC data set, ATLAS and CMS have started to surpass the sensitivity of the LEP analyses under certain assumptions.

ATLAS and CMS have searched for direct production of selectron pairs and smuon pairs at the LHC, with each slepton decaying to its corresponding SM partner lepton and the  $\tilde{\chi}_1^0$  LSP. ATLAS [114] and CMS [113] set limits in this model of 240 GeV for  $\tilde{\ell}_R$ , and 290 GeV for  $\tilde{\ell}_L$ , for a massless  $\tilde{\chi}_1^0$  and assuming equal selectron and smuon masses, as shown in Fig. 9. The limits deteriorate with increasing  $\tilde{\chi}_1^0$  mass due to decreasing missing momentum and lepton momentum. As a consequence, there is a gap between LEP and LHC limits for  $\tilde{\chi}_1^0$  masses above 20 GeV, and no limits are set for  $\tilde{\chi}_1^0$  masses above 90 GeV ( $\tilde{\ell}_R$ ) or above 150 GeV ( $\tilde{\ell}_L$ ).

**Figure 9:** Exclusion limits on  $\tilde{\ell}_R$  masses (left) and  $\tilde{\ell}_L$  masses (right), assuming equal selectron and smuon masses in both scenarios, and assuming a 100% branching fraction for  $\tilde{\ell} \rightarrow \ell \tilde{\chi}_1^0$  [114].

In gauge-mediated SUSY breaking models, sleptons can be (co-)NLSPs, *i.e.*, the next-to-lightest SUSY particles and almost degenerate in mass, decaying to a lepton and a gravitino. This decay can either be prompt, or the slepton can have a non-zero lifetime. Combining several analyses, lower mass limits on  $\tilde{\mu}_R$  of 96.3 GeV and on  $\tilde{e}_R$  of 66 GeV are set for all

slepton lifetimes at LEP [144]. In a considerable part of parameter space in these models, the  $\tilde{\tau}$  is the NLSP. The LEP experiments have set lower limits on the mass of such a  $\tilde{\tau}$  between 87 and 97 GeV, depending on the  $\tilde{\tau}$  lifetime. ATLAS has searched for final states with  $\tau$ s, jets and missing transverse momentum, and has interpreted the results in GMSB models setting limits on the model parameters [145]. CMS has interpreted a multilepton analysis in terms of limits on gauge mediation models with slepton (co-)NLSP [146]. CDF has put limits on gauge mediation models at high  $\tan\beta$  and slepton (co-)NLSP using an analysis searching for like-charge light leptons and taus [147].

Limits also exist on sleptons in R-parity violating models, both from LEP and the Tevatron experiments. From LEP, lower limits on  $\tilde{\mu}_R$  and  $\tilde{e}_R$  masses in such models are 97 GeV, and the limits on the stau mass are very close: 96 GeV [148].

Charged slepton decays may be kinematically suppressed, for example in the scenario of a NLSP slepton with a very small mass difference to the LSP. Such a slepton may appear to be a stable charged massive particle. Interpretation of searches at LEP for such signatures within GMSB models with stau NLSP or slepton co-NLSP exclude masses up to 99 GeV [120]. Searches of stable charged particles at the Tevatron [106,107] and at the LHC [71,72] are also interpreted in terms of limits on stable charged sleptons. The limits obtained at the LHC exclude stable staus with masses below 339 GeV when produced directly in pairs, and below 500 GeV when staus are produced both directly and indirectly in the decay of other particles in a GMSB model.

**Table 4:** Summary of slepton mass limits from LEP and LHC, assuming R-parity conservation and 100% branching fraction for  $\tilde{\ell} \rightarrow \ell \tilde{\chi}_1^0$ . Masses in this table are provided in GeV.

Assumption	$m_{\tilde{\ell}}$
$\tilde{\mu}_R, \Delta m(\tilde{\mu}_R, \tilde{\chi}_1^0) > 10$	$> 94$
$\tilde{e}_R, \Delta m(\tilde{e}_R, \tilde{\chi}_1^0) > 10$	$> 94$
$\tilde{e}_R$ , any $\Delta m$	$> 73$
$\tilde{\tau}_R, \Delta m((\tilde{\tau}_R, \tilde{\chi}_1^0) > 7$	$> 87$
$\tilde{\nu}_e, \Delta m(\tilde{e}_R, \tilde{\chi}_1^0) > 10$	$> 94$
$m_{\tilde{e}_R} = m_{\tilde{\mu}_R}, m_{\tilde{\chi}_1^0} \approx 0$	$> 240$
$m_{\tilde{\chi}_1^0} > \approx 90$	no LHC limit
$m_{\tilde{e}_L} = m_{\tilde{\mu}_L}, m_{\tilde{\chi}_1^0} \approx 0$	$> 290$
$m_{\tilde{\chi}_1^0} > \approx 150$	no LHC limit

### II.6.2. Exclusion limits on sneutrino masses

The invisible width of the Z boson puts a lower limit on the sneutrino mass of about 45 GeV. Tighter limits are derived from other searches, notably for gauginos and sleptons, under the assumption of gaugino and sfermion mass universality at the GUT scale, and amount to approximately 94 GeV in the MSSM [149]. It is possible that the lightest sneutrino is the

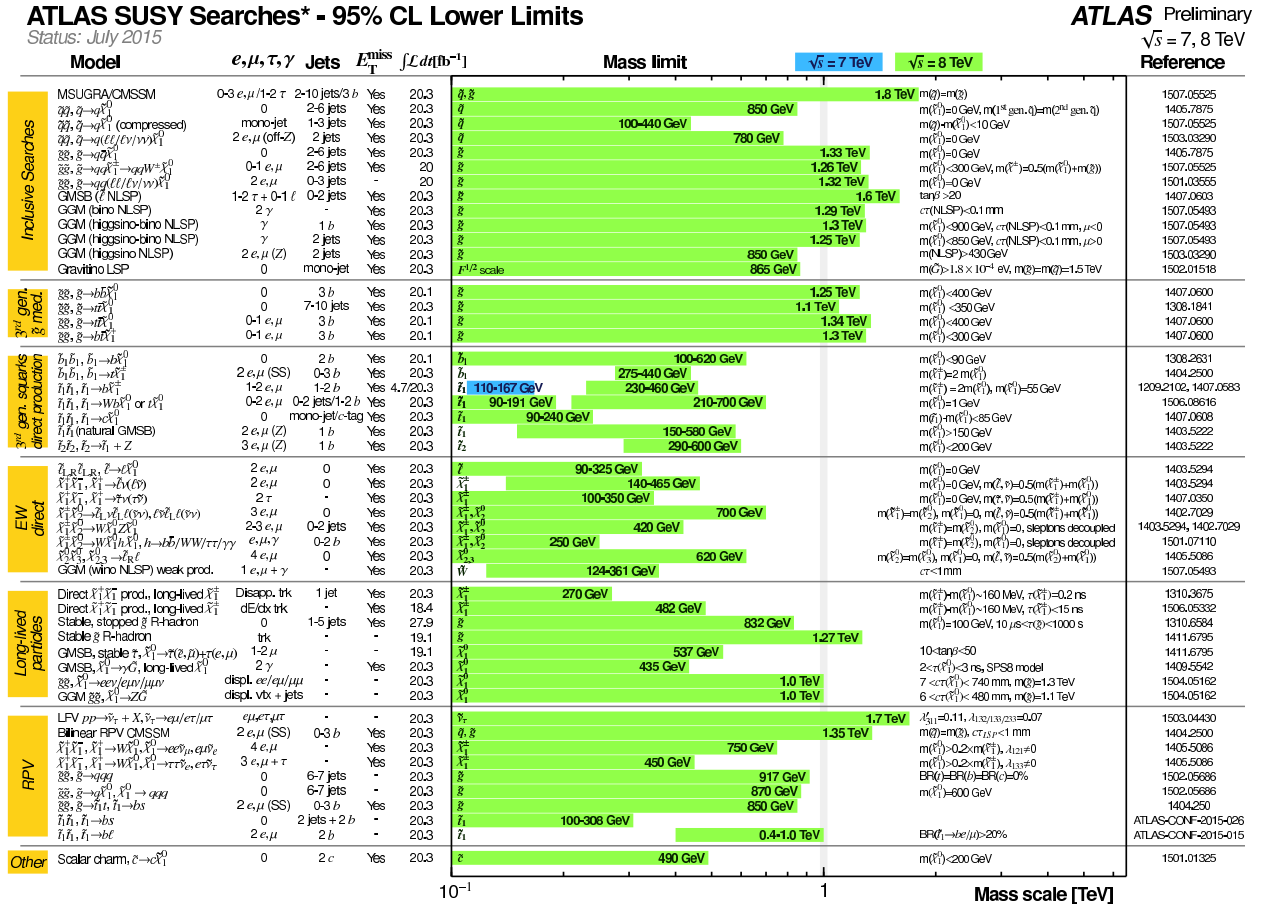

LSP; however, a left-handed sneutrino LSP is ruled out as a cold dark matter candidate [150,151].

Production of pairs of sneutrinos in R-parity violating models has been searched for at LEP [148]. Assuming fully leptonic decays via  $\lambda$ -type couplings, lower mass limits between 85 and 100 GeV are set. At the Tevatron [152,153] and at the LHC [154,155], searches have focused on scenarios with resonant production of a sneutrino, decaying to  $e\mu$ ,  $\mu\tau$  and  $e\tau$  final states. No signal has been seen, and limits have been set on sneutrino masses as a function of the value of relevant RPV couplings. As an example, the LHC experiments exclude a resonant tau sneutrino with a mass below 1500 GeV for  $\lambda_{312} > 0.07$  and  $\lambda'_{311} > 0.01$ .

experiments, flavor physics, high-precision electroweak results, and astrophysical data.

In the pre-LHC era these fits were mainly dominated by indirect constraints. Even for very constrained models like the CMSSM, the allowed parameter space, in terms of squark and gluino masses, ranged from several hundreds of GeV to a few TeV. Furthermore, these global fits indicated that squarks and gluino masses in the range of 500 to 1000 GeV were the preferred region of parameter space, although values as high as few TeV were allowed with lower probabilities [156].

With ATLAS and CMS now probing mass scales around 1 TeV and even beyond, the importance of the direct searches for global analyses of allowed SUSY parameter space has strongly

\*Only a selection of the available mass limits on new states or phenomena is shown. All limits quoted are observed minus  $1\sigma$  theoretical signal cross section uncertainty.

**Figure 10.** Overview of the current landscape of SUSY searches at the LHC. The plot shows exclusion mass limits of ATLAS for different searches and interpretation assumptions [157]. The corresponding results of CMS are comparable.

## II.7. Global interpretations

Apart from the interpretation of direct searches for sparticle production at colliders in terms of limits on masses of individual SUSY particles, model-dependent interpretations of allowed SUSY parameter space are derived from global SUSY fits. Typically these fits combine the results from collider experiments with indirect constraints on SUSY as obtained from low-energy

increased. For example, imposing the new experimental limits on constrained supergravity models pushes the most likely values of first generation squark and gluino masses significantly beyond 1 TeV, typically resulting in overall values of fit quality much worse than those in the pre-LHC era [125]. Although these constrained models are not yet ruled out, the extended

## Supersymmetric Particle Searches

experimental limits impose tight constraints on the allowed parameter space.

For this reason, the emphasis of global SUSY fits has shifted towards less-constrained SUSY models. Especially interpretations in the pMSSM [121,139–141] but also in simplified models have been useful to generalize SUSY searches, for example to redesign experimental analyses in order to increase their sensitivity for compressed spectra, where the mass of the LSP is much closer to squark and gluino masses than predicted, for example, by the CMSSM. As shown in Table 2, for neutralino masses above a few hundred GeV the current set of ATLAS and CMS searches cannot exclude the existence of light squarks and also gluinos above approximately 1 TeV are not yet fully excluded.

Furthermore, the discovery of a Higgs boson with a mass around 125 GeV has triggered many studies regarding the compatibility of SUSY parameter space with this new particle. Much of it is still work in progress and it will be interesting to see how the interplay between the results from direct SUSY searches and more precise measurements of the properties of the Higgs boson will unfold in the forthcoming era of high-energy running of the LHC.

### II.8. Summary and Outlook

Direct searches for SUSY, combined with limits from high-precision experiments that look for new physics in loops, put SUSY under considerable scrutiny. In particular the absence of any observation of new phenomena at the first run of the LHC, at  $\sqrt{s} = 7$  and 8 TeV, place significant constraints on SUSY parameter space. Today, inclusive searches probe production of gluinos in the range of 1.0 – 1.4 TeV, first and second generation squarks to about 1.0 TeV, third generation squarks at scales around 600 GeV, electroweak gauginos at scales around 300 – 500 GeV, and sleptons around 200 GeV. However, depending on the assumptions made of the underlying SUSY spectrum these limits can also weaken considerably. An overview of the current landscape of SUSY searches and corresponding exclusion limits at the LHC is shown in Fig. 10 from the ATLAS experiment [157]. The corresponding results of the CMS experiment are similar [158].

The interpretation of results at the LHC has moved away from constrained models like the CMSSM towards a large set of simplified models, or the pMSSM. On the one hand this move is because the LHC limits have put constrained models like the CMSSM under severe pressure, while on the other hand simplified models leave more freedom to vary parameters and form a better representation of the underlying sensitivity of analyses. However, these interpretations in simplified models do not come without a price: the decomposition of a potentially complicated reality in a limited set of individual decay chains can be significantly incomplete. Therefore, quoted limits in simplified models are only valid under the explicit assumptions made in these models, assumptions that are usually stated on the plots, and in the relevant LHC papers. Interpretations of simplified models in generic cases, ignoring the assumptions made, can

lead to overestimation of limits on SUSY parameter space. The recent addition of more comprehensive interpretations in the pMSSM is expected to overcome some of the limitations arising from the characterisation of searches in simplified model and thus will enable an even more refined understanding of the probed SUSY parameter space. In this context, the limit range of 1.0 – 1.4 TeV on generic colored SUSY particles only holds for light neutralinos, in the R-parity conserving MSSM. Limits on third generation squarks and electroweak gauginos also only hold for light neutralinos, and under specific assumptions for decay modes and slepton masses. In general, SUSY below the 1 TeV scale is not yet ruled out.

The new LHC run at  $\sqrt{s} = 13$  TeV, with significantly larger integrated luminosities, will present again a great opportunity for SUSY searches. The operation at higher energy will increase the production cross section for SUSY particles, shown in Fig. 1, substantially. While typically for masses around 500 GeV the increase is about 3 to 5 times the production cross section at 8 TeV, this becomes an increase of almost two orders of magnitude for a SUSY mass scale of 1.5 to 2 TeV. Apart from pushing the sensitivity of LHC searches to higher mass scales, further LHC data will also help to reduce holes and gaps that are left behind in today's SUSY limits. These could be, for example, due to compressed particle spectra, stealth SUSY, or the violation of R-parity.

### SUPERSYMMETRIC MODEL ASSUMPTIONS

The exclusion of particle masses within a mass range ( $m_1, m_2$ ) will be denoted with the notation “none  $m_1$ – $m_2$ ” in the VALUE column of the following Listings. The latest unpublished results are described in the “Supersymmetry: Experiment” review.

Most of the results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. It is also assumed that  $R$ -parity ( $R$ ) is conserved. Unless otherwise indicated, the results also assume that:

- 1) The  $\tilde{\chi}_1^0$  is the lightest supersymmetric particle (LSP)
- 2)  $m_{\tilde{f}_L} = m_{\tilde{f}_R}$ , where  $\tilde{f}_{L,R}$  refer to the scalar partners of left- and right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with  $R$ -parity violation ( $\tilde{R}$ ) are characterized by a superpotential of the form:  $\lambda_{ijk} L_i L_j e_k^c + \lambda'_{ijk} L_i Q_j d_k^c + \lambda''_{ijk} u_i^c d_j^c d_k^c$ , where  $i, j, k$  are generation indices. The presence of any of these couplings is often identified in the following by the symbols  $LL\tilde{E}$ ,  $LQ\tilde{D}$ , and  $U\tilde{D}\tilde{D}$ . Mass limits in the presence of  $\tilde{R}$  will often refer to “direct” and “indirect” decays. Direct refers to  $\tilde{R}$  decays of the particle in consideration. Indirect refers to cases where  $\tilde{R}$  appears in the decays of the LSP.

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino ( $\tilde{G}$ ) is the LSP. It is usually much lighter than any other massive particle in the spectrum, and  $m_{\tilde{G}}$  is then neglected in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lightest supersymmetric particle (NLSP), and are assumed to decay to their even- $R$  partner plus  $\tilde{G}$ . If the lifetime is short enough for the decay to take place within the detector,  $\tilde{G}$  is assumed to be undetected and to give rise to missing energy ( $\cancel{E}$ ) or missing transverse energy ( $\cancel{E}_T$ ) signatures.

When needed, specific assumptions on the eigenstate content of  $\tilde{\chi}^0$  and  $\tilde{\chi}^\pm$  states are indicated, using the notation  $\tilde{\gamma}$  (photino),  $\tilde{H}$  (higgsino),  $\tilde{W}$  (wino), and  $\tilde{Z}$  (zino) to signal that the limit of pure states was used. The terms gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

### $\tilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

$\tilde{\chi}_1^0$  is often assumed to be the lightest supersymmetric particle (LSP). See also the  $\tilde{\chi}_2^0, \tilde{\chi}_3^0, \tilde{\chi}_4^0$  section below.

We have divided the  $\tilde{\chi}_1^0$  listings below into five sections:

- 1) Accelerator limits for stable  $\tilde{\chi}_1^0$ ,
- 2) Bounds on  $\tilde{\chi}_1^0$  from dark matter searches,
- 3)  $\tilde{\chi}_1^0$ – $p$  elastic cross section (spin-dependent, spin-independent interactions),
- 4) Other bounds on  $\tilde{\chi}_1^0$  from astrophysics and cosmology, and
- 5) Unstable  $\tilde{\chi}_1^0$  (Lightest Neutralino) mass limit.

### Accelerator limits for stable $\tilde{\chi}_1^0$

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of  $\tilde{\chi}_i^0 \tilde{\chi}_j^0$  ( $i \geq 1, j \geq 2$ ),  $\tilde{\chi}_1^\pm \tilde{\chi}_1^\mp$ , and (in the case of hadronic collisions)  $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$  pairs. The mass limits on  $\tilde{\chi}_1^0$  are either direct, or follow indirectly from the constraints set by the non-observation of  $\tilde{\chi}_1^\pm$  and  $\tilde{\chi}_2^0$  states on the gaugino and higgsino MSSM parameters  $M_2$  and  $\mu$ . In some cases, information is used from the nonobservation of slepton decays.

Obsolete limits obtained from  $e^+e^-$  collisions up to  $\sqrt{s}=184$  GeV have been removed from this compilation and can be found in the 2000 Edition (The European Physical Journal **C15** 1 (2000)) of this Review.  $\Delta m = m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$ .

		7 AAD 14K	ATLS	

1 DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless  $\tilde{\chi}_1^0$  is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including  $M_2$ ,  $\mu$  and the slepton and squark masses.

2 ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region  $0 < M_2 < 5000$  GeV,  $-1000 < \mu < 1000$  GeV and  $\tan\beta$  from 1 to 40. This limit supersedes ABBIENDI 00H.

3 HEISTER 04 data collected up to 209 GeV. Updates earlier analysis of selectrons from HEISTER 02c, includes a new analysis of charginos and neutralinos decaying into stau and uses results on charginos with initial state radiation from HEISTER 02j. The limit is based on the direct search for charginos and neutralinos, the constraints from the slepton search and the Higgs mass limits from HEISTER 02 using a top mass of 175 GeV, interpreted in a framework with universal gaugino and sfermion masses. Assuming the mixing in the stau sector to be negligible, the limit improves to 43.1 GeV. Under the assumption of MSUGRA with unification of the Higgs and sfermion masses, the limit improves to 50 GeV, and reaches 53 GeV for  $A_0 = 0$ . These limits include and update the results of BARATE 01.

# Searches Particle Listings

## Supersymmetric Particle Searches

<sup>4</sup> ABDALLAH 03M uses data from  $\sqrt{s}=192\text{--}208$  GeV. A limit on the mass of  $\tilde{\chi}_1^0$  is derived from direct searches for neutralinos combined with the chargino search. Neutralinos are searched in the production of  $\tilde{\chi}_1^{0,0}\tilde{\chi}_2^{0,0}$ ,  $\tilde{\chi}_1^{0,0}\tilde{\chi}_3^{0,0}$ , as well as  $\tilde{\chi}_2^{0,0}\tilde{\chi}_3^{0,0}$  and  $\tilde{\chi}_2^{0,0}\tilde{\chi}_4^{0,0}$  giving rise to cascade decays, and  $\tilde{\chi}_1^{0,0}\tilde{\chi}_2^{0,0}$  and  $\tilde{\chi}_1^{0,0}\tilde{\chi}_3^{0,0}$ , followed by the decay  $\tilde{\chi}_2^0 \rightarrow \tilde{\tau}\tau$ . The results hold for the parameter space defined by values of  $M_2 < 1$  TeV,  $|\mu| \leq 2$  TeV with the  $\tilde{\chi}_1^0$  as LSP. The limit is obtained for  $\tan\beta = 1$  and large  $m_0$ , where  $\tilde{\chi}_2^0\tilde{\chi}_4^0$  and chargino pair production are important. If the constraint from Higgs searches is also imposed, the limit improves to 49.0 GeV in the  $m_h^{\text{max}}$  scenario with  $m_t=174.3$  GeV. These limits update the results of ABREU 00J.

<sup>5</sup> ABDALLAH 03M uses data from  $\sqrt{s}=192\text{--}208$  GeV. An indirect limit on the mass of  $\tilde{\chi}_1^0$  is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays and  $\tilde{\tau}\tau$  final states), for charginos (for all  $\Delta m_+$ ) and for sleptons, stop and sbottom. The results hold for the full parameter space defined by values of  $M_2 < 1$  TeV,  $|\mu| \leq 2$  TeV with the  $\tilde{\chi}_1^0$  as LSP. Constraints from the Higgs search in the  $m_h^{\text{max}}$  scenario assuming  $m_t=174.3$  GeV are included. The limit is obtained for  $\tan\beta \geq 5$  when stau mixing leads to mass degeneracy between  $\tilde{\tau}_1$  and  $\tilde{\chi}_1^0$  and the limit is based on  $\tilde{\chi}_2^0$  production followed by its decay to  $\tilde{\tau}_1\tau$ . In the pathological scenario where  $m_0$  and  $|\mu|$  are large, so that the  $\tilde{\chi}_2^0$  production cross section is negligible, and where there is mixing in the stau sector but not in stop nor sbottom, the limit is based on charginos with soft decay products and an ISR photon. The limit then degrades to 39 GeV. See Figs. 40–42 for the dependence of the limit on  $\tan\beta$  and  $m_{\tilde{\nu}}$ . These limits update the results of ABREU 00W.

<sup>6</sup> ACCIARRI 00D data collected at  $\sqrt{s}=189$  GeV. The results hold over the full parameter space defined by  $0.7 \leq \tan\beta \leq 60$ ,  $0 \leq M_2 \leq 2$  TeV,  $m_0 \leq 500$  GeV,  $|\mu| \leq 2$  TeV. The minimum mass limit is reached for  $\tan\beta=1$  and large  $m_0$ . The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small  $m_0$ . The limit improves to 48 GeV for  $m_0 \gtrsim 200$  GeV and  $\tan\beta \gtrsim 10$ . See their Figs. 6–8 for the  $\tan\beta$  and  $m_0$  dependence of the limits. Updates ACCIARRI 98F.

<sup>7</sup> AAD 14K sets limits on the  $\chi$ -nucleon spin-dependent and spin-independent cross sections out to  $m_\chi = 10$  TeV.

### Bounds on $\tilde{\chi}_1^0$ from dark matter searches

These papers generally exclude regions in the  $M_2-\mu$  parameter plane assuming that  $\tilde{\chi}_1^0$  is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments, telescopes, or by the absence of a signal in underground neutrino detectors. The latter signal is expected if  $\tilde{\chi}_1^0$  accumulates in the Sun or the Earth and annihilates into high-energy  $\nu$ 's.

none 4–15 GeV

<sup>1</sup> AARTSEN 15c is based on 316 live days of running with the IceCube detector. They set a limit of  $1.9 \times 10^{-23} \text{ cm}^3 \text{ s}^{-1}$  on the annihilation cross section to  $\nu\bar{\nu}$  for dark matter with masses between 700–1000 GeV annihilating in the Galactic halo.

<sup>2</sup> AARTSEN 15E is based on 319.7 live days of running with the IceCube 79-string detector. They set a limit of  $4 \times 10^{-24} \text{ cm}^3 \text{ s}^{-1}$  on the annihilation cross section to  $\nu\bar{\nu}$  for dark matter with masses between 30–10000 GeV annihilating in the Galactic center assuming an NFW profile.

<sup>3</sup> ABRAMOWSKI 15 places constraints on the dark matter annihilation cross section for annihilations in the Galactic center for masses between 300 GeV to 10 TeV.

<sup>4</sup> ACKERMANN 15 is based on 5.8 years of data with Fermi-LAT and search for monochromatic gamma-rays in the energy range of 0.2–500 GeV from dark matter annihilations. This updates ACKERMANN 13A.

<sup>5</sup> ACKERMANN 15A is based on 50 months of data with Fermi-LAT and search for dark matter annihilation signals in the isotropic gamma-ray background as well as galactic subhalos in the energy range of a few GeV to a few tens of TeV.

<sup>6</sup> ACKERMANN 15B is based on 6 years of data with Fermi-LAT observations of Milky Way dwarf spheroidal galaxies. Set limits on the annihilation cross section from  $m_\chi = 2$  GeV to 10 TeV. This updates ACKERMANN 14.

<sup>7</sup> ADRIAN-MARTINEZ 15 is based on data from the ANTARES neutrino telescope. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in the galactic center over a background of atmospheric neutrinos and set 90% CL limits on the muon neutrino flux. They also set limits on the annihilation cross section for wimp masses of 25–10000 GeV.

<sup>8</sup> BUCKLEY 15 is based on 5 years of Fermi-LAT data searching for dark matter annihilation signals from Large Magellanic Cloud.

<sup>9</sup> CHOI 15 is based on 3903 days of SuperKamioande data searching for neutrinos produced from dark matter annihilations in the sun. They place constraints on the dark matter-nucleon scattering cross section for dark matter masses between 4–200 GeV.

<sup>10</sup> ALEKSIK 14 is based on almost 160 hours of observations of Segue 1 satellite dwarf galaxy using the MAGIC telescopes between 2011 and 2013. Sets limits on the annihilation cross section out to  $m_\chi = 10$  TeV.

<sup>11</sup> AVRORIN 14 is based on almost 2.76 years with Lake Baikal neutrino telescope. They derive 90% upper limits on the fluxes of muons and muon neutrinos from dark matter annihilations in the Sun.

<sup>12</sup> AARTSEN 13 is based on data collected during 317 effective days with the IceCube 79-string detector including the DeepCore sub-array. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 20–5000 GeV.

<sup>13</sup> AARTSEN 13C is based on data collected during 339.8 effective days with the IceCube 59-string detector. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in nearby galaxies and galaxy clusters. They obtain limits on the neutralino annihilation cross section for neutralino masses in the range 30–100,000 GeV.

<sup>14</sup> ABRAMOWSKI 13 place upper limits on the annihilation cross section with  $\gamma\gamma$  final states in the energy range of 0.5–25 TeV.

<sup>15</sup> ADRIAN-MARTINEZ 13 is based on data from the ANTARES neutrino telescope. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 50–10,000 GeV.

<sup>16</sup> BERGSTROM 13, JIN 13, and KOPP 13 derive limits on the mass and annihilation cross section using AMS-02 data. JIN 13 also sets a limit on the lifetime of the dark matter particle.

<sup>17</sup> BOLIEV 13 is based on data collected during 24.12 years of live time with the Bakson Underground Scintillator Telescope. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 10–1000 GeV.

<sup>18</sup> ABBASI 12 is based on data collected during 812 effective days with AMANDA II and 149 days of the IceCube 40-string detector combined with the data of ABBASI 09B. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. No excess is observed. They also obtain limits on the spin dependent neutralino-proton cross section for neutralino masses in the range 50–5000 GeV.

<sup>19</sup> ABRAMOWSKI 11 place upper limits on the annihilation cross section with  $\gamma\gamma$  final states.

<sup>20</sup> ABDO 10 place upper limits on the annihilation cross section with  $\gamma\gamma$  or  $\mu^+\mu^-$  final states.

<sup>21</sup> ACKERMANN 10 place upper limits on the annihilation cross section with  $b\bar{b}$  or  $\mu^+\mu^-$  final states.

<sup>22</sup> ABBASI 09B is based on data collected during 104.3 effective days with the IceCube 22-string detector. They looked for interactions of  $\nu_\mu$ 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent neutralino-proton cross section for neutralino masses in the range 250–5000 GeV.

<sup>23</sup> ACHTERBERG 06 is based on data collected during 421.9 effective days with the AMANDA detector. They looked for interactions of  $\nu_\mu$ 's from the centre of the Earth over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into  $W^+W^-$  and  $b\bar{b}$  at the centre of the Earth for MSSM parameters compatible with the relic dark matter density, see their Fig. 7.

<sup>24</sup> ACKERMANN 06 is based on data collected during 143.7 days with the AMANDA-II detector. They looked for interactions of  $\nu_\mu$ 's from the Sun over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into  $W^+W^-$  in the Sun for SUSY model parameters compatible with the relic dark matter density, see their Fig. 3.

<sup>25</sup> DEBOER 06 interpret an excess of diffuse Galactic gamma rays observed with the EGRET satellite as originating from  $\pi^0$  decays from the annihilation of neutralinos into quark jets. They analyze the corresponding parameter space in a supergravity inspired MSSM model with radiative electroweak symmetry breaking, see their Fig. 3 for the preferred region in the  $(m_0, m_{1/2})$  plane of a scenario with large  $\tan\beta$ .

<sup>26</sup> AMBROSIO 99 and DESAI 04 set new neutrino flux limits which can be used to limit the parameter space in supersymmetric models based on neutralino annihilation in the Sun and the Earth.

<sup>27</sup> LOSECCO 95 reanalyzed the IMB data and places lower limit on  $m_{\tilde{\chi}_1^0}$  of 18 GeV if the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-energy neutrinos and the limits on neutrino fluxes from the IMB detector.

<sup>28</sup> MORI 93 excludes some region in  $M_2-\mu$  parameter space depending on  $\tan\beta$  and lightest scalar Higgs mass for neutralino dark matter  $m_{\tilde{\chi}_0} > m_W$ , using limits on upgoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.

- <sup>29</sup> BOTTINO 92 excludes some region  $M_2-\mu$  parameter space assuming that the lightest neutralino is the dark matter, using ongoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.
- <sup>30</sup> BOTTINO 91 excluded a region in  $M_2-\mu$  plane using ongoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy.
- <sup>31</sup> GELMINI 91 exclude a region in  $M_2-\mu$  plane using dark matter searches.
- <sup>32</sup> KAMIONKOWSKI 91 excludes a region in the  $M_2-\mu$  plane using 1MB limit on ongoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that  $m_{H_1^0} \lesssim 50$  GeV. See Fig. 8 in the paper.
- <sup>33</sup> MORI 91B exclude a part of the region in the  $M_2-\mu$  plane with  $m_{\tilde{\chi}_1^0} \lesssim 80$  GeV using a limit on ongoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that  $m_{H_1^0} \lesssim 80$  GeV.
- <sup>34</sup> OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

### $\tilde{\chi}_1^0-p$ elastic cross section

Experimental results on the  $\tilde{\chi}_1^0-p$  elastic cross section are evaluated at  $m_{\tilde{\chi}_1^0}=100$  GeV. The experimental results on the cross section are often mass dependent. Therefore, the mass and cross section results are also given where the limit is strongest, when appropriate. Results are quoted separately for spin-dependent interactions (based on an effective 4-Fermi Lagrangian of the form  $\tilde{\chi}\gamma^\mu\gamma^5\chi\bar{q}\gamma_\mu\gamma^5q$ ) and spin-independent interactions ( $\tilde{\chi}\chi\bar{q}q$ ). For calculational details see GRIEST 88b, ELLIS 88b, BARBIERI 89c, DREES 93b, ARNOWITT 96, BERGSTROM 96, and BAER 97 in addition to the theory papers listed in the Tables. For a description of the theoretical assumptions and experimental techniques underlying most of the listed papers, see the review on "Dark matter" in this "Review of Particle Physics," and references therein. Most of the following papers use galactic halo and nuclear interaction assumptions from (LEWIN 96).

- <sup>1</sup> The strongest limit is 0.001 pb and occurs at  $m_{\tilde{\chi}} = 40$  GeV.
- <sup>2</sup> The strongest limit is 0.0043 pb and occurs at  $m_{\tilde{\chi}} = 35$  GeV. FELIZARDO 14 also presents limits for the scattering on neutrons. At  $m_{\tilde{\chi}} = 100$  GeV, the upper limit is 0.13 pb and the strongest limit is 0.066 pb at  $m_{\tilde{\chi}} = 35$  GeV.
- <sup>3</sup> The strongest limit is 0.006 pb and occurs at  $m_{\tilde{\chi}} = 60$  GeV. APRILE 13 also presents limits for the scattering on neutrons. At 100 GeV, the upper limit is  $4 \times 10^{-4}$  pb and the strongest limit is  $3.5 \times 10^{-4}$  pb at 45 GeV.
- <sup>4</sup> This result updates LEBEDENKO 09A. The strongest limit is  $8 \times 10^{-3}$  pb at  $m_{\tilde{\chi}} = 50$  GeV. Limit applies to the neutralino neutron elastic cross section.
- <sup>5</sup> This result updates ARCHAMBAULT 09. The strongest limit is 0.032 pb at  $m_{\tilde{\chi}} = 20$  GeV.
- <sup>6</sup> The strongest limit is  $6 \times 10^{-3}$  at  $m_{\tilde{\chi}} = 60$  GeV.
- <sup>7</sup> The strongest limit is 1.8 pb and occurs at  $m_{\tilde{\chi}} = 100$  GeV.
- <sup>8</sup> The strongest limit is  $5.7 \times 10^{-3}$  at  $m_{\tilde{\chi}} = 35$  GeV.
- <sup>9</sup> This result updates LEE 07A. The strongest limit is at  $m_{\tilde{\chi}} = 80$  GeV.

- <sup>10</sup> Predictions for the spin-dependent elastic cross section based on a frequentist approach to electroweak observables in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.
- <sup>11</sup> The strongest limit is 0.6 pb and occurs at  $m_{\tilde{\chi}} = 30$  GeV. The limit for scattering on neutrons is 0.01 pb at  $m_{\tilde{\chi}} = 100$  GeV, and the strongest limit is 0.0045 pb at  $m_{\tilde{\chi}} = 30$  GeV.
- <sup>12</sup> Limit applies to neutron elastic cross section.
- <sup>13</sup> The strongest upper limit is 0.25 pb and occurs at  $m_{\tilde{\chi}} \simeq 40$  GeV.
- <sup>14</sup> The strongest upper limit is 4 pb and occurs at  $m_{\tilde{\chi}} \simeq 60$  GeV. The limit on the neutron spin-dependent elastic cross section is 0.07 pb. This latter limit is improved in AHMED 09, where a limit of 0.02 pb is obtained at  $m_{\tilde{\chi}} = 100$  GeV. The strongest limit in AHMED 09 is 0.018 pb and occurs at  $m_{\tilde{\chi}} = 60$  GeV.
- <sup>15</sup> The strongest upper limit is 1.2 pb and occurs at  $m_{\tilde{\chi}} \simeq 40$  GeV. The limit on the neutron spin-dependent cross section is 35 pb.
- <sup>16</sup> The strongest upper limit is 0.35 pb and occurs at  $m_{\tilde{\chi}} \simeq 60$  GeV.
- <sup>17</sup> The strongest upper limit is 1.2 pb and occurs  $m_{\tilde{\chi}} \simeq 30$  GeV.
- <sup>18</sup> ELLIS 04 calculates the  $\chi p$  elastic scattering cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses. In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes  $2 \times 10^{-4}$ , see ELLIS 03c.
- <sup>19</sup> The strongest upper limit is 0.75 pb and occurs at  $m_{\tilde{\chi}} \approx 70$  GeV.
- <sup>20</sup> The strongest upper limit is 30 pb and occurs at  $m_{\tilde{\chi}} \approx 20$  GeV.
- <sup>21</sup> The strongest upper limit is 8 pb and occurs at  $m_{\tilde{\chi}} \approx 30$  GeV.
- <sup>22</sup> ELLIS 01c calculates the  $\chi-p$  elastic scattering cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry. In models with nonuniversal Higgs masses, the upper limit to the cross section is  $6 \times 10^{-4}$ .
- <sup>23</sup> The strongest upper limit is 3 pb and occurs at  $m_{\tilde{\chi}} \simeq 60$  GeV. The limits are for inelastic scattering  $\chi^0 + {}^{129}\text{Xe} \rightarrow \chi^0 + {}^{129}\text{Xe}^* (39.58 \text{ keV})$ .
- <sup>24</sup> The strongest upper limit is 4.4 pb and occurs at  $m_{\tilde{\chi}} \simeq 60$  GeV.
- <sup>25</sup> The strongest upper limit is about 35 pb and occurs at  $m_{\tilde{\chi}} \simeq 15$  GeV.

1 AGNESE 15A presents 90% CL limits on the elastic cross section for masses in the range 5–20 GeV, from a likelihood analysis of CDMS II data. The limit at 10 GeV is  $2.5 \times 10^{-6}$  pb.  
2 AGNESE 15B result updates AHMED 10 and AHMED 09. The strongest limit is  $1.8 \times 10^{-8}$  pb and occurs at  $m_\chi = 60$  GeV.  
3 AMOLE 15 presents 90% CL limits on the elastic cross section for masses in the range 3–25 GeV. The strongest limit is  $2 \times 10^{-6}$  pb and occurs at  $m_\chi = 25$  GeV.  
4 XIAO 15 presents 90% CL limits on the elastic cross section for masses in the range 3–100 GeV. The strongest limit is  $1 \times 10^{-8}$  pb and occurs at  $m_\chi = 45$  GeV, using the PANDA 54 kg liquid Xenon detector over 80.1 days.  
5 AGNESE 14 presents 90% CL limits on the elastic cross section for masses in the range 3–30 GeV from 577 kg days at SuperCDMS. The strongest limit is  $1 \times 10^{-7}$  pb and occurs at  $m_\chi = 20$  GeV.  
6 The strongest upper limit is  $7.6 \times 10^{-10}$  at  $m_\chi = 33$  GeV.  
7 Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using the 20 fb $^{-1}$  8 TeV and the 5 fb $^{-1}$  7 TeV LHC data and the LUX data.  
8 The strongest limit is  $3.6 \times 10^{-6}$  pb and occurs at  $m_\chi = 35$  GeV.  
9 Predictions for the spin-independent elastic cross section based on a Bayesian approach to electroweak observables in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using the 20 fb $^{-1}$  LHC data and LUX.  
10 AALSETH 13 presents 90% CL limits on the elastic cross section for masses in the range 4–25 GeV in addition to a region of interest at about 8 GeV. The strongest upper limit is  $2 \times 10^{-5}$  pb at  $m_\chi = 14$  GeV.  
11 AGNESE 13 presents 90% CL limits on the elastic cross section for masses in the range 7–100 GeV using the Si based detector. The strongest upper limit is  $1.8 \times 10^{-6}$  pb at  $m_\chi = 50$  GeV. This limit is improved to  $7 \times 10^{-7}$  pb in AGNESE 13A.  
12 LI 13B presents 90% CL limits on the elastic cross section for masses in the range 4–40 GeV. The strongest upper limit is  $4 \times 10^{-5}$  pb at  $m_\chi = 14$  GeV.  
13 This result updates LEBEDENKO 09. The strongest limit is  $3.9 \times 10^{-8}$  pb at  $m_\chi = 52$  GeV.  
14 ANGLÖHER 12 presents results of 730 kg days from the CRESST-II dark matter detector. They find two maxima in the likelihood function corresponding to best fit WIMP masses of 25.3 and 11.6 GeV with elastic cross sections of  $1.6 \times 10^{-6}$  and  $3.7 \times 10^{-5}$  pb respectively, see their Table 4. The statistical significance is more than 4 $\sigma$ .  
15 APRILE 12 updates the result of APRILE 11B. The strongest upper limit is <  $2.0 \times 10^{-9}$  pb and occurs at  $m_\chi \simeq 50$  GeV.  
16 The strongest limit is  $6.1 \times 10^{-5}$  pb at  $m_\chi = 20$  GeV.  
17 Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using the 5 fb $^{-1}$  LHC data and XENON100.  
18 The strongest limit is  $1.4 \times 10^{-7}$  at  $m_\chi = 60$  GeV.  
19 The strongest limit is  $4.7 \times 10^{-6}$  at  $m_\chi = 35$  GeV.  
20 This result updates LEE 07A. The strongest limit is  $2.1 \times 10^{-7}$  at  $m_\chi = 70$  GeV.  
21 AHMED 11A gives combined results from CDMS and EDELWEISS. The strongest limit is at  $m_\chi = 90$  GeV.  
22 ARMENGAUD 11 updates result of ARMENGAUD 10. Strongest limit at  $m_\chi = 85$  GeV.  
23 The strongest upper limit is  $4.8 \times 10^{-7}$  pb and occurs at  $m_\chi = 50$  GeV.  
24 The strongest upper limit is  $5.1 \times 10^{-8}$  pb and occurs at  $m_\chi \simeq 30$  GeV. The values quoted here are based on the analysis performed in ANGLE 08 with the update from SORENSEN 09.  
25 The strongest upper limit is  $6.6 \times 10^{-7}$  pb and occurs at  $m_\chi \simeq 65$  GeV.  
26 AKERIB 06A updates the results of AKERIB 05. The strongest upper limit is  $1.6 \times 10^{-7}$  pb and occurs at  $m_\chi \simeq 60$  GeV.  
27 The strongest upper limit is also close to  $1.0 \times 10^{-6}$  pb and occurs at  $m_\chi \simeq 70$  GeV. BENOIT 06 claim that the discrimination power of ZEPLIN-I measurement (ALNER 05A) is not reliable enough to obtain a limit better than  $1 \times 10^{-3}$  pb. However, SMITH 06 do not agree with the criticisms of BENOIT 06.  
28 The strongest upper limit is also close to  $1.4 \times 10^{-6}$  pb and occurs at  $m_\chi \simeq 70$  GeV.  
29 AKERIB 04 is incompatible with BERNABEI 00 most likely value, under the assumption of standard WIMP-halo interactions. The strongest upper limit is  $4 \times 10^{-7}$  pb and occurs at  $m_\chi \simeq 60$  GeV.  
30 Predictions for the spin-independent elastic cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.  
31 KIM 02 and ELLIS 04 calculate the  $\chi p$  elastic scattering cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses.  
32 In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes  $2 \times 10^{-6}$  ( $2 \times 10^{-11}$  when constraint from the BNL  $g-2$  experiment are included), see ELLIS 03e. ELLIS 05 display the sensitivity of the elastic scattering cross section to the  $\pi$ -Nucleon  $\Sigma$  term.

33 PIERCE 04A calculates the  $\chi p$  elastic scattering cross section in the framework of models with very heavy scalar masses. See Fig. 2 of the paper.  
34 The strongest upper limit is  $1.8 \times 10^{-5}$  pb and occurs at  $m_\chi \simeq 80$  GeV.  
35 Under the assumption of standard WIMP-halo interactions, Akerib 03 is incompatible with BERNABEI 00 most likely value at the 99.98% CL. See Fig. 4.  
36 BAER 03A calculates the  $\chi p$  elastic scattering cross section in several models including the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.  
37 The strongest upper limit is  $7 \times 10^{-6}$  pb and occurs at  $m_\chi \simeq 30$  GeV.  
38 ABRAMS 02 is incompatible with the DAMA most likely value at the 99.9% CL. The strongest upper limit is  $3 \times 10^{-6}$  pb and occurs at  $m_\chi \simeq 30$  GeV.  
39 BENOIT 02 excludes the central result of DAMA at the 99.8% CL.  
40 The strongest upper limit is  $2 \times 10^{-5}$  pb and occurs at  $m_\chi \simeq 40$  GeV.  
41 The strongest upper limit is  $7 \times 10^{-6}$  pb and occurs at  $m_\chi \simeq 46$  GeV.  
42 The strongest upper limit is  $1.8 \times 10^{-5}$  pb and occurs at  $m_\chi \simeq 32$  GeV  
43 BOTTINO 01 calculates the  $\chi$ - $p$  elastic scattering cross section in the framework of the following supersymmetric models:  $N=1$  supergravity with the radiative breaking of the electroweak gauge symmetry,  $N=1$  supergravity with nonuniversal scalar masses and an effective MSSM model at the electroweak scale.  
44 Calculates the  $\chi$ - $p$  elastic scattering cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.  
45 ELLIS 01c calculates the  $\chi$ - $p$  elastic scattering cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry. ELLIS 02B find a range  $2 \times 10^{-8}$ – $1.5 \times 10^{-7}$  at  $\tan\beta=50$ . In models with nonuniversal Higgs masses, the upper limit to the cross section is  $4 \times 10^{-7}$ .  
46 ACCOMANDO 00 calculate the  $\chi$ - $p$  elastic scattering cross section in the framework of minimal  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry. The limit is relaxed by at least an order of magnitude when models with nonuniversal scalar masses are considered. A subset of the authors in ARNOWITT 02 updated the limit to <  $9 \times 10^{-8}$  ( $\tan\beta < 55$ ).  
47 BERNABEI 00 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 4 $\sigma$  and are consistent, for a particular model framework quoted there, with  $m_{\chi^0}=44^{+12}_{-9}$  GeV and a spin-independent  $\chi^0$ -proton cross section of  $(5.4 \pm 1.0) \times 10^{-6}$  pb. See also BERNABEI 01 and BERNABEI 00c.  
48 FENG 00 calculate the  $\chi$ - $p$  elastic scattering cross section in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry with a particular emphasis on focus point models. At  $\tan\beta=50$ , the range is  $8 \times 10^{-8}$ – $4 \times 10^{-7}$ .

### Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the  $M_2 - \mu$  parameter plane by requiring that the  $\tilde{\chi}_1^0$  contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

<sup>1</sup> ELLIS 00 updates ELLIS 98. Uses LEP  $e^+e^-$  data at  $\sqrt{s}=202$  and 204 GeV to improve bound on neutralino mass to 51 GeV when scalar mass universality is assumed and 46 GeV when Higgs mass universality is relaxed. Limits on  $\tan\beta$  improve to  $> 2.7$  ( $\mu > 0$ ),  $> 2.2$  ( $\mu < 0$ ) when scalar mass universality is assumed and  $> 1.9$  (both signs of  $\mu$ ) when Higgs mass universality is relaxed.

<sup>2</sup> Implications of the LHC result on the Higgs mass and on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.

<sup>3</sup> BUCHMUELLER 14A places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches using the 20  $\text{fb}^{-1}$  8 TeV and the 5  $\text{fb}^{-1}$  7 TeV LHC and the LUX data.

<sup>4</sup> ROSZKOWSKI 14 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using Bayesian statistics and indirect experimental searches using the 20  $\text{fb}^{-1}$  LHC and the LUX data.

<sup>5</sup> CABRERA 13 and STREGE 13 place constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry with and without non-universal Higgs masses using the 5.8  $\text{fb}^{-1}$ ,  $\sqrt{s}=7$  TeV ATLAS supersymmetry searches and XENON100 results.

<sup>6</sup> ELLIS 13B place constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry with and without Higgs mass universality. Models with universality below the GUT scale are also considered.

<sup>7</sup> BALAZS 12 and STREGE 12 place constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using the 1  $\text{fb}^{-1}$  LHC supersymmetry searches, the 5  $\text{fb}^{-1}$  Higgs mass constraints, both with  $\sqrt{s}=7$  TeV, and XENON100 results.

<sup>8</sup> BECHTLE 12 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, using the 5  $\text{fb}^{-1}$  LHC and XENON100 data.

<sup>9</sup> BESKIDT 12 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, the 5  $\text{fb}^{-1}$  LHC and the XENON100 data.

<sup>10</sup> BELANGER 04 and BOTTINO 12 (see also BOTTINO 03, BOTTINO 03A and BOTTINO 04) do not assume gaugino or scalar mass unification.

<sup>11</sup> FENG 12B places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry and large sfermion masses using the 1  $\text{fb}^{-1}$  LHC supersymmetry searches, the 5  $\text{fb}^{-1}$  LHC Higgs mass constraints both with  $\sqrt{s}=7$  TeV, and XENON100 results.

<sup>12</sup> BUCHMUELLER 11 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches and including supersymmetry breaking relations between A and B parameters.

<sup>13</sup> Places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal Higgs masses.

<sup>14</sup> ELLIS 10 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale.

<sup>15</sup> BUCHMUELLER 09 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

<sup>16</sup> DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless  $\tilde{\chi}_1^0$  is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including  $M_2$ ,  $\mu$  and the slepton and squark masses.

<sup>17</sup> BUCHMUELLER 08 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

<sup>18</sup> CALIBBI 07 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale including the effects of right-handed neutrinos.

<sup>19</sup> ELLIS 07 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry with universality below the GUT scale.

<sup>20</sup> ALLANACH 06 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.

<sup>21</sup> DE-AUSTRI 06 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.

<sup>22</sup> BALTZ 04 places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.

<sup>23</sup> Limit assumes a pseudo scalar mass  $< 200$  GeV. For larger pseudo scalar masses,  $m_{\tilde{\chi}} > 18(29)$  GeV for  $\tan\beta = 50(10)$ . Bounds from WMAP,  $(g-2)_\mu$ ,  $b \rightarrow s\gamma$ , LEP.

<sup>24</sup> ELLIS 04B places constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry including supersymmetry breaking relations between A and B parameters. See also ELLIS 03D.

<sup>25</sup> PIERCE 04A places constraints on the SUSY parameter space in the framework of models with very heavy scalar masses.

<sup>26</sup> BAER 03, CHATTOPADHYAY 03, ELLIS 03C and LAHANAS 03 place constraints on the SUSY parameter space in the framework of  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry based on WMAP results for the cold dark matter density.

<sup>27</sup> BOEHM 00B and ELLIS 03 place constraints on the SUSY parameter space in the framework of minimal  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry. Includes the effect of  $\tilde{\chi}-\tilde{t}$  co-annihilations.

<sup>28</sup> LAHANAS 02 places constraints on the SUSY parameter space in the framework of minimal  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on the role of pseudo-scalar Higgs exchange.

<sup>29</sup> BARGER 01C use the cosmic relic density inferred from recent CMB measurements to constrain the parameter space in the framework of minimal  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.

<sup>30</sup> ELLIS 01B places constraints on the SUSY parameter space in the framework of minimal  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on models with large  $\tan\beta$ .

<sup>31</sup> FENG 00 explores cosmologically allowed regions of MSSM parameter space with multi-TeV masses.

<sup>32</sup> ELLIS 98B assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increased due to the inclusion of  $\tilde{\chi}-\tilde{t}_R$  coannihilations.

<sup>33</sup> EDSJO 97 included all coannihilation processes between neutralinos and charginos for any neutralino mass and composition.

<sup>34</sup> Notes the location of the neutralino Z resonance and h resonance annihilation corridors in minimal supergravity models with radiative electroweak breaking.

<sup>35</sup> Mass of the bino (=LSP) is limited to  $m_{\tilde{B}} \lesssim 350$  GeV for  $m_t = 174$  GeV.

<sup>36</sup> DREES 93, KELLEY 93 compute the cosmic relic density of the LSP in the framework of minimal  $N=1$  supergravity models with radiative breaking of the electroweak gauge symmetry.

<sup>37</sup> FALK 93 relax the upper limit to the LSP mass by considering sfermion mixing in the MSSM.

<sup>38</sup> MIZUTA 93 include coannihilations to compute the relic density of Higgsino dark matter.

<sup>39</sup> LOPEZ 92 calculate the relic LSP density in a minimal SUSY GUT model.

<sup>40</sup> MCDONALD 92 calculate the relic LSP density in the MSSM including exact tree-level annihilation cross sections for all two-body final states.

<sup>41</sup> GRIEST 91 improve relic density calculations to account for coannihilations, pole effects, and threshold effects.

<sup>42</sup> NOJIRI 91 uses minimal supergravity mass relations between squarks and sleptons to narrow cosmologically allowed parameter space.

<sup>43</sup> Mass of the bino (=LSP) is limited to  $m_{\tilde{B}} \lesssim 350$  GeV for  $m_t \leq 200$  GeV. Mass of the higgsino (=LSP) is limited to  $m_{\tilde{H}} \lesssim 1$  TeV for  $m_t \leq 200$  GeV.

<sup>44</sup> ROSZKOWSKI 91 calculates LSP relic density in mixed gaugino/higgsino region.

<sup>45</sup> Mass of the bino (=LSP) is limited to  $m_{\tilde{B}} \lesssim 550$  GeV. Mass of the higgsino (=LSP) is limited to  $m_{\tilde{H}} \lesssim 3.2$  TeV.

<sup>46</sup> KRAUSS 83 finds  $m_{\tilde{\gamma}}$  not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region  $m_{\tilde{\gamma}} = 4-20$  MeV exists if  $m_{\text{gravitino}} < 40$  TeV. See figure 2.

### Unstable $\tilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass  $m_{\tilde{G}}$  is assumed to be negligible relative to all other masses. In the following,  $\tilde{G}$  is assumed to be undetected and to give rise to a missing energy ( $\cancel{E}$ ) signature.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

<sup>1</sup> KHACHATRYAN 14L searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for evidence of direct pair production of neutralinos with Higgs or  $Z$ -bosons in the decay chain, leading to  $HH, HZ$  and  $ZZ$  final states with missing transverse energy. The decays of 16–20, a Higgs boson to a  $b$ -quark pair, to a photon pair, and to final states with leptons are considered in conjunction with hadronic and leptonic decay modes of the  $Z$  and  $W$  bosons. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of GMSB simplified models where the decays  $\tilde{\chi}_1^0 \rightarrow H\tilde{G}$  or  $\tilde{\chi}_1^0 \rightarrow Z\tilde{G}$  take place either 100% or 50% of the time, see Figs. 16–20.

<sup>2</sup> AAD 14BH searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing non-pointing photons in a diphoton plus missing transverse energy final state. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. exclusion limits in the context of gauge-mediated supersymmetric breaking models, with the lightest neutralino being the next-to-lightest supersymmetric particle and decaying with a lifetime in the range from 0.25 ns to about 100 ns into a photon and a gravitino. For limits on the NLSF lifetime versus  $\Lambda$  plane, for the SPS8 model, see their Fig. 7.

<sup>3</sup> AAD 13AP searched in 4.8 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing non-pointing photons in a diphoton plus missing transverse energy final state. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. exclusion limits in the context of gauge-mediated supersymmetric breaking models, with the lightest neutralino being the next-to-lightest supersymmetric particle and decaying with a lifetime in excess of 0.25 ns into a photon and a gravitino. For limits in the NLSF lifetime versus  $\Lambda$  plane, for the SPS8 model, see their Fig. 8.

<sup>4</sup> AAD 13Q searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing a high- $p_T$  isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSF, see their Fig. 4. Intermediate neutralino masses between 220 and 380 GeV are excluded at 95% C.L., regardless of the squark and gluino masses, purely on the basis of the expected weak production.

<sup>5</sup> AAD 13R looked in 4.4 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing new, heavy particles that decay at a significant distance from their production point into a final state containing a high-momentum muon and charged hadrons. No excess over the expected background is observed and limits are placed on the production cross-section of neutralinos via squarks for various  $m_{\tilde{q}}, m_{\tilde{\chi}_1^0}$  in an  $R$ -parity violating scenario with

$\lambda'_{211} \neq 0$ , as a function of the neutralino lifetime, see their Fig. 6.

<sup>6</sup> AALTONEN 13i searched in 6.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for events containing  $\cancel{E}_T$  and a delayed photon that arrives late in the detector relative to the time expected from prompt production. No evidence of delayed photon production is observed.

<sup>7</sup> CHATRCHYAN 13AH searched in 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing  $\cancel{E}_T$  and a delayed photon that arrives late in the detector relative to the time expected from prompt production. No significant excess above the expected background was found and limits were set on the pair production of  $\tilde{\chi}_1^0$  depending on the neutralino proper decay length, see Fig. 8. Supersedes CHATRCHYAN 12BK.

<sup>8</sup> AAD 12CP searched in 4.8 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with two photons and large  $\cancel{E}_T$  due to  $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$  decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSF, see Figs. 6 and 7. The other sparticle masses were decoupled,  $\tan\beta = 2$  and  $c\tau_{NLSF} < 0.1$  mm. Also, in the framework of the SPS8 model, limits are presented in Fig. 8.

<sup>9</sup> AAD 12CT searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing four or more leptons (electrons or muons) and either moderate values of missing transverse momentum or large effective mass. No significant excess is found in the data. Limits are presented in a simplified model of  $R$ -parity violating supersymmetry in which charginos are pair-produced and then decay into a  $W$ -boson and a  $\tilde{\chi}_1^0$ , which in turn decays through an RPV coupling into two charged leptons ( $e^\pm e^\mp$  or  $\mu^\pm \mu^\mp$ ) and a neutrino. In this model, limits are set on the neutralino mass as a function of the chargino mass, see Fig. 3a. Limits are also set in an  $R$ -parity violating mSUGRA model, see Fig. 3b.

<sup>10</sup> AAD 12R looked in 33 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing new, heavy particles that decay at a significant distance from their production point into a final state containing a high-momentum muon and charged hadrons. No excess over the expected background is observed and limits are placed on the production cross-section

of neutralinos via squarks for various  $(m_{\tilde{q}}, m_{\tilde{\chi}_1^0})$  in an  $R$ -parity violating scenario with

$\lambda'_{211} \neq 0$ , as a function of the neutralino lifetime, see their Fig. 8. Superseded by AAD 13R.

<sup>11</sup> ABAZOV 12AD looked in 6.2 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 1.96$  TeV for events with a photon, a  $Z$ -boson, and large  $\cancel{E}_T$  in the final state. This topology corresponds to a GMSB model where pairs of neutralino NLSPs are either pair produced promptly or from decays of other supersymmetric particles and then decay to either  $Z\tilde{G}$  or  $\gamma\tilde{G}$ . No significant excess over the SM expectation is observed and a limit at 95% C.L. on the cross section is derived as a function of the effective SUSY breaking scale  $\Lambda$ , see Fig. 3. Assuming  $N_{mes} = 2$ ,  $M_{mes} = 3\Lambda$ ,  $\tan\beta = 3$ ,  $\mu = 0.75 M_1$ , and  $C_{grav} = 1$ , the model is excluded at 95% C.L. for values of  $\Lambda < 87$  TeV.

<sup>12</sup> CHATRCHYAN 12BK searched in 2.23 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with two photons and large  $\cancel{E}_T$  due to  $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$  decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the pair production of  $\tilde{\chi}_1^0$  depending on the neutralino lifetime, see Fig. 6.

<sup>13</sup> CHATRCHYAN 11B looked in 35 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with an isolated lepton ( $e$  or  $\mu$ ), a photon and  $\cancel{E}_T$  which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.

<sup>14</sup> AALTONEN 10 searched in 2.6 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for diphoton events with large  $\cancel{E}_T$ . They may originate from the production of  $\tilde{\chi}^\pm$  in pairs or associated to a  $\tilde{\chi}_1^0$ , decaying into  $\tilde{\chi}_1^0$  which itself decays in GMSB to  $\gamma\tilde{G}$ . There is no excess of events beyond expectation. An upper limit on the cross section is calculated in the GMSB model as a function of the  $\tilde{\chi}_1^0$  mass and lifetime, see their Fig. 2. A limit is derived on the  $\tilde{\chi}_1^0$  mass of 149 GeV for  $\tau_{\tilde{\chi}_1^0} \ll 1$  ns, which improves the results of previous searches.

<sup>15</sup> ABAZOV 10P looked in 6.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for events with at least two isolated  $\gamma$ s and large  $\cancel{E}_T$ . These could be the signature of  $\tilde{\chi}_2^0$  and  $\tilde{\chi}_1^\pm$  production, decaying to  $\tilde{\chi}_1^0$  and finally  $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$  in a GMSB framework. No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section is derived for  $N_{mes} = 1$ ,  $\tan\beta = 15$  and  $\mu > 0$ , see their Fig. 2. This allows them to set a limit on the effective SUSY breaking scale  $\Lambda > 124$  TeV, from which the excluded  $\tilde{\chi}_1^0$  mass range is obtained.

<sup>16</sup> ABAZOV 08F looked in 1.1 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for diphoton events with large  $\cancel{E}_T$ . They may originate from the production of  $\tilde{\chi}^\pm$  in pairs or associated to a  $\tilde{\chi}_1^0$ , decaying to a  $\tilde{\chi}_1^0$  which itself decays promptly in GMSB to  $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ . No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for  $M = 2\Lambda$ ,  $N = 1$ ,  $\tan\beta = 15$  and  $\mu > 0$ , see Figure 2. It also excludes  $\Lambda < 91.5$  TeV. Supersedes the results of ABAZOV 05A. Superseded by ABAZOV 10P.

<sup>17</sup> ABULENCIA 07H searched in 346 pb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for events with at least three leptons ( $e$  or  $\mu$ ) from the decay of  $\tilde{\chi}_1^0$  via  $L\bar{L}\bar{E}$  couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of  $\tilde{\chi}_1^0$  and  $\tilde{\chi}_1^\pm$ , see e.g. their Fig. 3 and Tab. II.

<sup>18</sup> ABBIENDI 06B use 600 pb<sup>-1</sup> of data from  $\sqrt{s} = 189$ –209 GeV. They look for events with diphotons +  $\cancel{E}$  final states originating from prompt decays of pair-produced neutralinos in a GMSB scenario with  $\tilde{\chi}_1^0$  NLSP. Limits on the cross-section are computed as a function of  $m(\tilde{\chi}_1^0)$ , see their Fig. 14. The limit on the  $\tilde{\chi}_1^0$  mass is for a pure Bino state assuming a prompt decay, with lifetimes up to  $10^{-9}$ s. Supersedes the results of ABBIENDI 04N.

<sup>19</sup> ABDALLAH 05B use data from  $\sqrt{s} = 180$ –209 GeV. They look for events with single photons +  $\cancel{E}$  final states. Limits are computed in the plane  $(m(\tilde{G}), m(\tilde{\chi}_1^0))$ , shown in their Fig. 9b for a pure Bino state in the GMSB framework and in Fig. 9c for a no-scale supergravity model. Supersedes the results of ABREU 00Z.

<sup>20</sup> ABDALLAH 05B use data from  $\sqrt{s} = 130$ –209 GeV. They look for events with diphotons +  $\cancel{E}$  final states and single photons not pointing to the vertex, expected in GMSB when the  $\tilde{\chi}_1^0$  is the NLSP. Limits are computed in the plane  $(m(\tilde{G}), m(\tilde{\chi}_1^0))$ , see their Fig. 10.

The lower limit is derived on the  $\tilde{\chi}_1^0$  mass for a pure Bino state assuming a prompt decay and  $m_{\tilde{e}R} = m_{\tilde{e}L} = 2 m_{\tilde{\chi}_1^0}$ . It improves to 100 GeV for  $m_{\tilde{e}R} = m_{\tilde{e}L} = 1.1 m_{\tilde{\chi}_1^0}$  and

the limit in the plane  $(m(\tilde{\chi}_1^0), m(\tilde{e}R))$  is shown in Fig. 10b. For long-lived neutralinos, cross-section limits are displayed in their Fig. 11. Supersedes the results of ABREU 00Z.

## $\tilde{\chi}_2^0, \tilde{\chi}_3^0, \tilde{\chi}_4^0$ (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos,  $z$ -inos, and neutral higgsinos (the supersymmetric partners of photons and of  $Z$  and Higgs bosons). The limits here apply only to  $\tilde{\chi}_2^0, \tilde{\chi}_3^0$ , and  $\tilde{\chi}_4^0$ .  $\tilde{\chi}_1^0$  is the lightest supersymmetric particle (LSP); see  $\tilde{\chi}_1^0$  Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various  $\tilde{\chi}^0$  decay modes, on the masses of decay products ( $\tilde{e}, \tilde{\gamma}, \tilde{q}, \tilde{g}$ ), and on the  $\tilde{e}$  mass exchanged in  $e^+e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0$ . Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters  $M_2$  and  $\mu$  through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the  $m_{\tilde{\chi}^0} - m_{\tilde{g}}$  plane vs other parameters. When specific assumptions are made, e.g. the neutralino is a pure photino ( $\tilde{\gamma}$ ), pure  $z$ -ino ( $\tilde{Z}$ ), or pure neutral higgsino ( $\tilde{H}^0$ ), the neutralinos will be labelled as such.

Limits obtained from  $e^+e^-$  collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. Some later papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, et al. (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

1 AAD 15BA searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of charginos and neutralinos decaying to a final state containing a  $W$  boson and a 125 GeV Higgs boson, plus missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with the decays  $\tilde{\chi}_1^\pm \rightarrow W^\pm \tilde{\chi}_1^0$  and  $\tilde{\chi}_2^0 \rightarrow H \tilde{\chi}_1^0$  having 100% branching fraction, see Fig. 8. A combination of the multiple final states for the Higgs decay yields the best limits (Fig. 8d).

2 AAD 14H searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of charginos and neutralinos decaying to a final state with three leptons and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via either all three generations of leptons, staus only, gauge bosons, or Higgs bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 8.

3 AAD 14x searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the chargino mass in an R-parity conserving simplified model where the decay  $\tilde{\chi}_{2,3}^0 \rightarrow \ell^\pm \ell^\mp \tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 10.

4 AAD 13 searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for charginos and neutralinos decaying to a final state with three leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 and 3, and in simplified models, see Fig. 4. For the simplified models with intermediate slepton decays, degenerate  $\tilde{\chi}_1^\pm$  and  $\tilde{\chi}_2^0$  masses up to 500 GeV are excluded at 95% C.L. for very large mass differences with the  $\tilde{\chi}_1^0$ . Supersedes AAD 12As.

5 CHATRCHYAN 12BJ searched in 4.98 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for direct electroweak production of charginos and neutralinos in events with at least two leptons, jets and missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of  $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$  pair production were set in a number of simplified models, see Figs. 7 to 12. Most limits are for exactly 3 jets.

6 AAD 14G searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of chargino-neutralino pairs, decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via gauge bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 10.

7 KHACHATRYAN 14I searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of charginos and neutralinos decaying to a final state with three leptons ( $e$  or  $\mu$ ) and missing transverse momentum, or with a  $Z$ -boson, dijets and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Figs. 12–16.

8 AAD 12As searched in 2.06 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for charginos and neutralinos decaying to a final state with three leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 (top), and in simplified models, see Fig. 2 (bottom).

9 AAD 12T looked in 1 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for the production of supersymmetric particles decaying into final states with missing transverse momentum and exactly two isolated leptons ( $e$  or  $\mu$ ). Same-sign dilepton events were separately studied. Additionally, in opposite-sign events, a search was made for an excess of same-flavor over different-flavor lepton pairs. No excess over the expected background is observed and limits are placed on the effective production cross section of opposite-sign dilepton events with  $\cancel{E}_T > 250$  GeV and on same-sign dilepton events with  $\cancel{E}_T > 100$  GeV. The latter limit is interpreted in a simplified electroweak gaugino production model.

### $\tilde{\chi}_1^\pm, \tilde{\chi}_2^0$ (Charginos) MASS LIMITS

Charginos are unknown mixtures of  $w$ -inos and charged higgsinos (the supersymmetric partners of  $W$  and Higgs bosons). A lower mass limit for the lightest chargino ( $\tilde{\chi}_1^\pm$ ) of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the  $Z$  width and decays. These results, as well as other now superseded limits from  $e^+e^-$  collisions at energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and stfermion mass unification at the GUT scale. These papers generally study production of  $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$ ,  $\tilde{\chi}_1^\pm \tilde{\chi}_1^\mp$  and (in the case of hadronic collisions)  $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$  pairs, including the effects of cascade decays. The mass limits on  $\tilde{\chi}_1^\pm$  are either direct, or follow indirectly from the constraints set by the non-observation of  $\tilde{\chi}_2^0$  states on the gaugino and higgsino MSSM parameters  $M_2$  and  $\mu$ . For generic values of the MSSM parameters, limits from high-energy  $e^+e^-$  collisions coincide with the highest value of the mass allowed by phase-space, namely  $m_{\tilde{\chi}_1^\pm} \lesssim \sqrt{s}/2$ . The still unpublished combination of the results of

the four LEP collaborations from the 2000 run of LEP2 at  $\sqrt{s}$  up to  $\approx 209$  GeV yields a lower mass limit of 103.5 GeV valid for general MSSM models. The limits become however weaker in certain regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen when: (i) the mass differences  $\Delta m_+ = m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$  or  $\Delta m_- = m_{\tilde{\chi}_1^\pm} - m_{\tilde{\nu}}$  are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the  $\tilde{\chi}_1^\pm$  production rate is suppressed due to a destructive interference between  $s$  and  $t$  channel exchange diagrams. The regions of MSSM parameter space where the following limits are valid are indicated in the comment lines or in the footnotes.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

- 1 AAD 15BA searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of charginos and neutralinos decaying to a final state containing a  $W$  boson and a 125 GeV Higgs boson, plus missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with the decays  $\tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$  and  $\tilde{\chi}_2^0 \rightarrow H\tilde{\chi}_1^0$  having 100% branching fraction, see Fig. 8. A combination of the multiple final states for the Higgs decay yields the best limits (Fig. 8d).
- 2 AAD 15CA searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with one or more photons and  $\cancel{E}_T$ , with or without leptons ( $e, \mu$ ). No significant excess above the Standard Model expectation is observed. Limits are set on wino masses in the general gauge-mediated SUSY breaking model (GGM), for wino-like NLSP, see Fig. 9, 12.
- 3 AAD 14H searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of charginos and neutralinos decaying to a final state with three leptons and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of direct chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via either all three generations of leptons, staus only, gauge bosons, or Higgs bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 8.
- 4 AAD 14X searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectation is observed. Limits are set on the wino-like chargino mass in an  $R$ -parity violating simplified model where the decay  $\tilde{\chi}_1^\pm \rightarrow W^{(*)}\pm\tilde{\chi}_1^0$ , with  $\tilde{\chi}_1^0 \rightarrow \ell^\pm\ell^\mp\nu$ , takes place with a branching ratio of 100%, see Fig. 8.
- 5 KHACHATRYAN 14L searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for evidence of chargino-neutralino  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  pair production with Higgs or  $W$ -bosons in the decay chain, leading to  $HW$  final states with missing transverse energy. The decays of a Higgs boson to a photon pair are considered in conjunction with hadronic and leptonic decay modes of the  $W$  bosons. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of simplified models where the decays  $\tilde{\chi}_2^0 \rightarrow H\tilde{\chi}_1^0$  and  $\tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$  take place 100% of the time, see Figs. 22-23.
- 6 AAD 13 searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for charginos and neutralinos decaying to a final state with three leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 and 3, and in simplified models, see Fig. 4. For the simplified models with intermediate slepton decays, degenerate  $\tilde{\chi}_1^\pm$  and  $\tilde{\chi}_2^0$  masses up to 500 GeV are excluded at 95% C.L. for very large mass differences with the  $\tilde{\chi}_1^0$ . Supersedes AAD 12As.
- 7 AAD 13B searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for gauginos decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of wino-like chargino pair production, where the chargino always decays to the lightest neutralino via an intermediate on-shell charged slepton, see Fig. 2(b). Chargino masses between 110 and 340 GeV are excluded at 95% C.L. for  $m_{\tilde{\chi}_1^0} = 10$  GeV. Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.
- 8 AAD 12CT searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing four or more leptons (electrons or muons) and either moderate values of missing transverse momentum or large effective mass. No significant excess is found in the data. Limits are presented in a simplified model of  $R$ -parity violating supersymmetry in which charginos are pair-produced and then decay into a  $W$ -boson and a  $\tilde{\chi}_1^0$ , which in turn decays through an RPV coupling into two charged leptons ( $e^\pm e^\mp$  or  $e^\pm\mu^\mp$ ) and a neutrino. In this model, chargino masses up to 540 GeV are excluded at 95% C.L. for  $m_{\tilde{\chi}_1^0}$  above 300 GeV, see Fig. 3a. The limit deteriorates for lighter  $\tilde{\chi}_1^0$ . Limits are also set in an  $R$ -parity violating mSUGRA model, see Fig. 3b.
- 9 CHATRCHYAN 12BJ searched in 4.98 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for direct electroweak production of charginos and neutralinos in events with at least two leptons, jets and missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  pair production were set in a number of simplified models, see Figs. 7 to 12.
- 10 ABDALLAH 03M uses data from  $\sqrt{s} = 192$ -208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass of charginos is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays), for charginos and for sleptons. These limits are valid for values of  $M_2 < 1$  TeV,  $|\mu| \leq 2$  TeV with the  $\tilde{\chi}_1^0$  as LSP. Constraints from the Higgs search in the  $m_h^{\max}$  scenario assuming  $m_t = 174.3$  GeV are included. The quoted limit applies if there is no mixing in the third family or when  $m_{\tilde{t}_1} - m_{\tilde{\chi}_1^0} > 6$  GeV. If mixing is included the limit degrades to 90 GeV. See Fig. 43 for the mass limits as a function of  $\tan\beta$ . These limits update the results of ABREU 00W.

- 11 AAD 14AV searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for the direct production of charginos, neutralinos and staus in events containing at last two hadronically decaying  $\tau$ -leptons, large missing transverse momentum and low jet activity. The quoted limit was derived for direct  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  and  $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$  production with  $\tilde{\chi}_2^0 \rightarrow \tau\tau \rightarrow \tau\tau\tilde{\chi}_1^0$  and  $\tilde{\chi}_1^\pm \rightarrow \tau\nu(\bar{\nu}\tau) \rightarrow \tau\nu\tilde{\chi}_1^0, m_{\tilde{\chi}_2^0} = m_{\tilde{\chi}_1^\pm}, m_{\tilde{\tau}} = 0.5(m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0}), m_{\tilde{\chi}_1^0} = 0$  GeV. No excess over the expected SM background is observed. Exclusion limits are set in simplified models of  $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$  and  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  pair production, see their Figure 7. Upper limits on the cross section and signal strength for direct di-stau production are derived, see Figures 8 and 9. Also, limits are derived in a pMSSM model where the only light slepton is the  $\tilde{\tau}_R$ , see Figure 10.
- 12 AAD 14AV searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for the direct production of charginos, neutralinos and staus in events containing at last two hadronically decaying  $\tau$ -leptons, large missing transverse momentum and low jet activity. The quoted limit was derived for direct  $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$  production with  $\tilde{\chi}_1^\pm \rightarrow \tau\nu(\bar{\nu}\tau) \rightarrow \tau\nu\tilde{\chi}_1^0, m_{\tilde{\tau}} = 0.5(m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0}), m_{\tilde{\chi}_1^0} = 0$  GeV. No excess over the expected SM background is observed. Exclusion limits are set in simplified models of  $\tilde{\chi}_1^\pm\tilde{\chi}_1^\mp$  and  $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$  pair production, see their Figure 7. Upper limits on the cross section and signal strength for direct di-stau production are derived, see Figures 8 and 9. Also, limits are derived in a pMSSM model where the only light slepton is the  $\tilde{\tau}_R$ , see Figure 10.
- 13 AAD 14G searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of chargino pairs, or chargino-neutralino pairs, decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of chargino pair production, with chargino decays to the lightest neutralino via either sleptons or gauge bosons, see Fig. 5.; or in simplified models of chargino and next-to-lightest neutralino production, with decays to the lightest neutralino via gauge bosons, see Fig. 7. An interpretation in the pMSSM is also given, see Fig. 10.
- 14 AALTONEN 14 searched in 5.8 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for evidence of chargino and next-to-lightest neutralino associated production in final states consisting of three leptons (electrons, muons or taus) and large missing transverse momentum. The results are consistent with the Standard Model predictions within 1.85  $\sigma$ . Limits on the chargino mass are derived in an mSUGRA model with  $m_0 = 60$  GeV,  $\tan\beta = 3$ ,  $A_0 = 0$  and  $\mu > 0$ , see their Fig. 2.
- 15 KHACHATRYAN 14l searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of chargino pairs decaying to a final state with opposite-sign lepton pairs ( $e$  or  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Fig. 18.
- 16 AALTONEN 13Q searched in 6.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for evidence of chargino-neutralino associated production in like-sign dilepton final states. One lepton is identified as the hadronic decay of a tau lepton, while the other is an electron or muon. Good agreement with the Standard Model predictions is observed and limits are set on the chargino-neutralino cross section for simplified gravity- and gauge-mediated models, see their Figs. 2 and 3.
- 17 AAD 12AS searched in 2.06 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for charginos and neutralinos decaying to a final state with three leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 (top), and in simplified models, see Fig. 2 (bottom).
- 18 AAD 12T looked in 1 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for the production of supersymmetric particles decaying into final states with missing transverse momentum and exactly two isolated leptons ( $e$  or  $\mu$ ). Opposite-sign and same-sign dilepton events were separately studied. Additionally, in opposite-sign events, a search was made for an excess of same-flavor over different-flavor lepton pairs. No excess over the expected background is observed and limits are placed on the effective production cross section of opposite-sign dilepton events with  $\cancel{E}_T > 250$  GeV and on same-sign dilepton events with  $\cancel{E}_T > 100$  GeV. The latter limit is interpreted in a simplified electroweak gaugino production model as a lower chargino mass limit.
- 19 CHATRCHYAN 11B looked in 35 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=7$  TeV for events with an isolated lepton ( $e$  or  $\mu$ ), a photon and  $\cancel{E}_T$  which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.
- 20 CHATRCHYAN 11V looked in 35 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with  $\geq 3$  isolated leptons ( $e, \mu$  or  $\tau$ ), with or without jets and  $\cancel{E}_T$ . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM ( $m_0, m_{1/2}$ ) plane for  $\tan\beta = 3$  (see Fig. 5).

### Long-lived $\tilde{\chi}^\pm$ (Chargino) MASS LIMITS

<sup>1</sup> AAD 15AE searched in  $19.1\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ALTA5 muon system. In the absence of an excess of events above the expected backgrounds, limits are set on stable charginos, see Fig. 10.

<sup>2</sup> AAD 15BM searched in  $18.4\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for stable and metastable non-relativistic charged particles through their anomalous specific ionization energy loss in the ATLAS pixel detector. In absence of an excess of events above the expected backgrounds, limits are set on stable charginos (see Table 5) and on metastable charginos decaying to  $\tilde{\chi}_1^0 \pi^\pm$ , see Fig. 11.

<sup>3</sup> AAD 13H searched in  $4.7\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7\text{ TeV}$  for direct electroweak production of long-lived charginos in the context of AMSB scenarios. The search is based on the signature of a high-momentum isolated track with few associated hits in the outer part of the tracking system, arising from a chargino decay into a neutralino and a low-momentum pion. The  $p_T$  spectrum of the tracks was found to be consistent with the SM expectations. Constraints on the lifetime and the production cross section were obtained, see Fig. 6. In the minimal AMSB framework with  $\tan\beta = 5$ , and  $\mu > 0$ , a chargino having a mass below  $103\text{ (85) GeV}$  for a chargino-neutralino mass splitting  $\Delta m_{\tilde{\chi}_1^\pm}$  of  $160\text{ (170) MeV}$  is excluded at the 95% C.L. See Fig. 7 for more precise bounds.

<sup>4</sup> AAD 12BJ looked in  $1.02\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7\text{ TeV}$  for signatures of decaying charginos resulting in isolated tracks with few associated hits in the outer region of the tracking system. The  $p_T$  spectrum of the tracks was found to be consistent with the SM expectations. Constraints on the lifetime and the production cross section were obtained. In the minimal AMSB framework with  $m_{3/2} < 32\text{ TeV}$ ,  $m_0 < 1.5\text{ TeV}$ ,  $\tan\beta = 5$ , and  $\mu > 0$ , a chargino having a mass below  $92\text{ GeV}$  and a lifetime between  $0.5\text{ ns}$  and  $2\text{ ns}$  is excluded at the 95% C.L. See their Fig. 8 for more precise bounds.

<sup>5</sup> ABAZOV 09M searched in  $1.1\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96\text{ TeV}$  for events with direct production of a pair of charged massive stable particles identified by their TOF. The number of the observed events is consistent with the predicted background. The data are used to constrain the production cross section as a function of the  $\tilde{\chi}_1^\pm$  mass, see their Fig. 2. The quoted limit improves to  $206\text{ GeV}$  for gaugino-like charginos.

<sup>6</sup> ABBENDI 03L used  $e^+e^-$  data at  $\sqrt{s} = 130\text{--}209\text{ GeV}$  to select events with two high momentum tracks with anomalous  $dE/dx$ . The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The bounds are valid for colorless fermions with lifetime longer than  $10^{-6}\text{ s}$ . Supersedes the results from ACKERSTAFF 98P.

<sup>7</sup> ABREU 00T searches for the production of heavy stable charged particles, identified by their ionization or Cherenkov radiation, using data from  $\sqrt{s} = 130\text{ to }189\text{ GeV}$ . These limits include and update the results of ABREU 98P.

<sup>8</sup> KHACHATRYAN 15AB searched in  $19.5\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for events containing tracks with little or no associated calorimeter energy deposits and with missing hits in the outer layers of the tracking system (disappearing-track signature). Such disappearing tracks can result from the decay of charginos that are nearly mass degenerate with the lightest neutralino. The number of observed events is in agreement with the background expectation. Limits are set on the cross section of electroweak chargino production in terms of the chargino mass and mean proper lifetime, see Fig. 4. In the minimal AMSB model, a chargino mass below  $260\text{ GeV}$  is excluded at 95% C.L., see their Fig. 5.

<sup>9</sup> KHACHATRYAN 15O searched in  $18.8\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for evidence of long-lived charginos in the context of AMSB and pMSSM scenarios. The results are based on a previously published search for heavy stable charged particles at  $7\text{ and }8\text{ TeV}$ . In the minimal AMSB framework with  $\tan\beta = 5$  and  $\mu \geq 0$ , constraints on the chargino mass and lifetime were placed, see Fig. 5. Charginos with a mass below  $800\text{ (100) GeV}$  are excluded at the 95% C.L. for lifetimes above  $100\text{ ns}$  ( $3\text{ ns}$ ). Constraints are also placed on the pMSSM parameter space, see Fig. 3.

<sup>10</sup> KHACHATRYAN 15W searched in up to  $20.5\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for evidence of long-lived neutralinos produced through  $\tilde{q}\text{-}\bar{q}$  pair production, with  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  and  $\tilde{\chi}_1^0 \rightarrow \ell^+ \ell^- \nu$  ( $R: \lambda_{121}, \lambda_{122} \neq 0$ ). 95% C.L. exclusion limits on cross section times branching ratio are set as a function of mean proper decay length of the neutralino, see Figs. 6 and 9.

<sup>11</sup> AAD 13BD searched in  $20.3\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for events containing tracks with no associated hits in the outer region of the tracking system resulting from the decay of charginos that are nearly mass degenerate with the lightest neutralino, as is often the case in AMSB scenarios. No significant excess above the background expectation is observed for candidate tracks with large transverse momentum. Constraints on chargino properties are obtained and in the minimal AMSB model, a chargino mass below  $270\text{ GeV}$  is excluded at 95% C.L., see their Fig. 7.

<sup>12</sup> ABAZOV 13B looked in  $6.3\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96\text{ TeV}$  for charged massive long-lived particles in events with muon-like particles that have both speed and ionization energy loss inconsistent with muons produced in beam collisions. In the absence of an excess, limits are set at 95% C.L. on gaugino- and higgsino-like charginos, see their Table 20 and Fig. 23.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

<sup>1</sup> AAD 14X searched in  $20.3\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the sneutrino mass in an R-parity violating simplified model where the decay  $\tilde{\nu} \rightarrow \nu\tilde{\chi}_1^0$ , with  $\tilde{\chi}_1^0 \rightarrow \ell^\pm \ell^\mp \nu$ , takes place with a branching ratio of 100%, see Fig. 9.

<sup>2</sup> AAD 11Z looked in  $1.07\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7\text{ TeV}$  for events with one electron and one muon of opposite charge from the production of  $\tilde{\nu}_\tau$  via an  $R \lambda'_{311}$  coupling and followed by a decay via  $\lambda_{312}$  into  $e + \mu$ . No evidence for an  $(e, \mu)$  resonance over the SM expectation is observed, and a limit is derived in the plane of  $\lambda'_{311}$  versus  $m_{\tilde{\nu}}$  for three values of  $\lambda_{312}$ , see their Fig. 2. Masses  $m_{\tilde{\nu}} < 1.32\text{ (1.45) TeV}$  are excluded for  $\lambda'_{311} = 0.10$  and  $\lambda_{312} = 0.05$  ( $\lambda'_{311} = 0.11$  and  $\lambda_{312} = 0.07$ ).

<sup>3</sup> ABDALLAH 03M uses data from  $\sqrt{s} = 192\text{--}208\text{ GeV}$  to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of  $M_2 < 1\text{ TeV}$ ,  $|\mu| \leq 1\text{ TeV}$  with the  $\tilde{\chi}_1^0$  as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of  $\tan\beta$ . These limits update the results of ABREU 00W.

<sup>4</sup> HEISTER 02N derives a bound on  $m_{\tilde{\nu}_e}$  by exploiting the mass relation between the  $\tilde{\nu}_e$  and  $\tilde{e}$ , based on the assumption of universal GUT scale gaugino and scalar masses  $m_{1/2}$  and  $m_0$  and the search described in the  $\tilde{e}$  section. In the MSUGRA framework with radiative electroweak symmetry breaking, the limit improves to  $m_{\tilde{\nu}_e} > 130\text{ GeV}$ , assuming a trilinear coupling  $A_0=0$  at the GUT scale. See Figs. 5 and 7 for the dependence of the limits on  $\tan\beta$ .

<sup>5</sup> DECAMP 92 limit is from  $\Gamma(\text{invisible})/\Gamma(\ell\ell) = 5.91 \pm 0.15$  ( $N_\nu = 2.97 \pm 0.07$ ).

<sup>6</sup> AAD 15O searched in  $20.3\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$  for evidence of heavy particles decaying into  $e\mu, e\tau$  or  $\mu\tau$  final states. No significant excess above the Standard Model expectation is observed, and 95% C.L. exclusions are placed on the cross section times branching ratio for the production of an R-parity-violating supersymmetric tau sneutrino, applicable to any sneutrino flavour, see their Fig. 2.

<sup>7</sup> AAD 13AI searched in  $4.6\text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7\text{ TeV}$  for evidence of heavy particles decaying into  $e\mu, e\tau$  or  $\mu\tau$  final states. No significant excess above the Standard Model expectation is observed, and 95% C.L. exclusions are placed on the cross section times branching ratio for the production of an R-parity-violating supersymmetric tau sneutrino, see their Fig. 2. For couplings  $\lambda'_{311} = 0.10$  and  $\lambda_{33k} = 0.05$ , the lower limits on the  $\tilde{\nu}_\tau$  mass are  $1610, 1110, 1100\text{ GeV}$  in the  $e\mu, e\tau$ , and  $\mu\tau$  channels, respectively.

<sup>8</sup> AAD 11H looked in  $35\text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7\text{ TeV}$  for events with one electron and one muon of opposite charge from the production of  $\tilde{\nu}_\tau$  via an  $R \lambda'_{311}$  coupling and followed by a decay via  $\lambda_{312}$  into  $e + \mu$ . No evidence for an excess over the SM expectation is observed, and a limit is derived in the plane of  $\lambda'_{311}$  versus  $m_{\tilde{\nu}}$  for several values of  $\lambda_{312}$ , see their Fig. 2. Superseded by AAD 11Z.

<sup>9</sup> AALTONEN 10Z searched in  $1\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96\text{ TeV}$  for events from the production  $d\bar{d} \rightarrow \tilde{\nu}_\tau$  with the subsequent decays  $\tilde{\nu}_\tau \rightarrow e\mu, \mu\tau, e\tau$  in the MSSM framework with  $R$ . Two isolated leptons of different flavor and opposite charges are required, with  $\tau$ s identified by their hadronic decay. No statistically significant excesses are observed over the SM background. Upper limits on  $\lambda'_{311}$  times the branching ratio are listed in their Table III for various  $\tilde{\nu}_\tau$  masses. Limits on the cross section times branching ratio for  $\lambda'_{311} = 0.10$  and  $\lambda_{33k} = 0.05$ , displayed in Fig. 2, are used to set limits on the  $\tilde{\nu}_\tau$  mass of  $558\text{ GeV}$  for the  $e\mu, 441\text{ GeV}$  for the  $\mu\tau$  and  $442\text{ GeV}$  for the  $e\tau$  channels.

<sup>10</sup> ABAZOV 10M looked in  $5.3\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96\text{ TeV}$  for events with exactly one pair of high  $p_T$  isolated  $e\mu$  and a veto against hard jets. No evidence for an excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Fig. 3. These limits are translated into limits on couplings as a function of  $m_{\tilde{\nu}_\tau}$  as shown in their Fig. 4. As an example, for  $m_{\tilde{\nu}_\tau} = 100\text{ GeV}$  and  $\lambda_{312} \leq 0.07$ , couplings  $\lambda'_{311} > 7.7 \times 10^{-4}$  are excluded.

<sup>11</sup> ABDALLAH 04N uses data from LEP 1 and  $\sqrt{s} = 192\text{--}208\text{ GeV}$ . They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region  $1 < m_{3/2} < 50\text{ TeV}$ ,  $0 < m_0 < 1000\text{ GeV}$ ,  $1.5 < \tan\beta < 35$ , both signs of  $\mu$ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z

### $\tilde{\nu}$ (Sneutrino) MASS LIMIT

The limits may depend on the number,  $N(\tilde{\nu})$ , of sneutrinos assumed to be degenerate in mass. Only  $\tilde{\nu}_L$  (not  $\tilde{\nu}_R$ ) is assumed to exist. It is possible that  $\tilde{\nu}$  could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from the fit of the final results obtained by the LEP Collaborations on the invisible width of the Z boson ( $\Delta\Gamma_{\text{inv}} < 2.0\text{ MeV}$ , LEP-SLC 06):  $m_{\tilde{\nu}} > 43.7\text{ GeV}$  ( $N(\tilde{\nu})=1$ ) and  $m_{\tilde{\nu}} > 44.7\text{ GeV}$  ( $N(\tilde{\nu})=3$ ).

# Searches Particle Listings

## Supersymmetric Particle Searches

width of 3.2 MeV. The limit is for  $m_t = 174.3$  GeV (see Table 2 for other  $m_t$  values). The limit improves to 114 GeV for  $\mu < 0$ .

<sup>12</sup> ADRIANI 93M limit from  $\Delta\Gamma(Z)(\text{invisible}) < 16.2$  MeV.

<sup>13</sup> ALEXANDER 91F limit is for one species of  $\tilde{\nu}$  and is derived from  $\Gamma(\text{invisible, new})/\Gamma(\ell\ell) < 0.38$ .

### CHARGED SLEPTONS

This section contains limits on charged scalar leptons ( $\tilde{\ell}$ , with  $\ell=e, \mu, \tau$ ). Studies of width and decays of the Z boson (use is made here of  $\Delta\Gamma_{\text{inv}} < 2.0$  MeV, LEP 00) conclusively rule out  $m_{\tilde{\ell}_R} < 40$  GeV (41 GeV for  $\tilde{\ell}_L$ ), independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for  $\tilde{\ell}_L$ ) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting  $\Delta m = m_{\tilde{\ell}} - m_{\tilde{\chi}_1^0}$ . The mass and composition

of  $\tilde{\chi}_1^0$  may affect the selection production rate in  $e^+e^-$  collisions through  $t$ -channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate  $\tilde{\ell}_1 = \tilde{\ell}_R \sin\theta_{\tilde{\ell}} + \tilde{\ell}_L \cos\theta_{\tilde{\ell}}$ . It is generally assumed that only  $\tilde{\tau}$  may have significant mixing. The coupling to the Z vanishes for  $\theta_{\tilde{\ell}}=0.82$ . In the high-energy limit of  $e^+e^-$  collisions the interference between  $\gamma$  and Z exchange leads to a minimal cross section for  $\theta_{\tilde{\ell}}=0.91$ , a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on  $m_{\tilde{\ell}_R}$  are quoted, it is understood that limits on  $m_{\tilde{\ell}_L}$  are usually at least as strong.

Possibly open decays involving gauginos other than  $\tilde{\chi}_1^0$  will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of  $\tilde{\ell}^+\tilde{\ell}^-$  production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of  $e^+e^-$  collisions at high energies can be found in previous Editions of this Review.

For decays with final state gravitinos ( $\tilde{G}$ ),  $m_{\tilde{G}}$  is assumed to be negligible relative to all other masses.

### $\tilde{e}$ (Selectron) MASS LIMIT

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

<sup>1</sup> AAD 14x searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in an R-parity violating simplified model where the decay  $\tilde{\ell} \rightarrow \ell\tilde{\chi}_1^0$ , with  $\tilde{\chi}_1^0 \rightarrow \ell^\pm \ell^\mp \nu$ , takes place with a branching ratio of 100%, see Fig. 9.

<sup>2</sup> CHATRCHYAN 14R searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in a stau (N)NLSP simplified model (GMSB) where the decay  $\tilde{\ell} \rightarrow \ell^\pm \tau^\mp \tau^\mp \tilde{G}$  takes place with a branching ratio of 100%, see Fig. 8.

<sup>3</sup> AAD 13b searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for sleptons decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of direct left-handed slepton pair production, where left-handed slepton masses between 85 and 195 GeV are excluded at 95% C.L. for  $m_{\tilde{\chi}_1^0} = 20$  GeV. See also Fig. 2(a). Exclusion

limits are also derived in the phenomenological MSSM, see Fig. 3.

<sup>4</sup> ABBIENDI 04 search for  $\tilde{e}_R \tilde{e}_R$  production in acoplanar di-electron final states in the 183–208 GeV data. See Fig. 13 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$  and for the limit at  $\tan\beta=35$ . This limit supersedes ABBIENDI 00c.

<sup>5</sup> ACHARD 04 search for  $\tilde{e}_R \tilde{e}_L$  and  $\tilde{e}_R \tilde{e}_R$  production in single- and acoplanar di-electron final states in the 192–209 GeV data. Absolute limits on  $m_{\tilde{e}_R}$  are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses

$m_{1/2}$  and  $m_0$ ,  $1 \leq \tan\beta \leq 60$  and  $-2 \leq \mu \leq 2$  TeV. See Fig. 4 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$ . This limit supersedes ACCIARRI 99w.

<sup>6</sup> ABDALLAH 03M looked for acoplanar dielectron +  $\tilde{Z}$  final states at  $\sqrt{s} = 189$ –208 GeV. The limit assumes  $\mu = -200$  GeV and  $\tan\beta=1.5$  in the calculation of the production cross section and  $B(\tilde{e} \rightarrow e\tilde{\chi}_1^0)$ . See Fig. 15 for limits in the  $(m_{\tilde{e}_R}, m_{\tilde{\chi}_1^0})$  plane. These limits

include and update the results of ABREU 01

<sup>7</sup> ABDALLAH 03M uses data from  $\sqrt{s} = 192$ –208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of  $M_2 < 1$  TeV,  $|\mu| \leq 1$  TeV with the  $\tilde{\chi}_1^0$  as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of  $\tan\beta$ . These limits update the results of ABREU 00w.

<sup>8</sup> HEISTER 02E looked for acoplanar dielectron +  $\tilde{Z}$  final states from  $e^+e^-$  interactions between 183 and 209 GeV. The mass limit assumes  $\mu < -200$  GeV and  $\tan\beta=2$  for the production cross section and  $B(\tilde{e} \rightarrow e\tilde{\chi}_1^0)=1$ . See their Fig. 4 for the dependence of the limit on  $\Delta m$ . These limits include and update the results of BARATE 01.

<sup>9</sup> HEISTER 02N search for  $\tilde{e}_R \tilde{e}_L$  and  $\tilde{e}_R \tilde{e}_R$  production in single- and acoplanar di-electron final states in the 183–208 GeV data. Absolute limits on  $m_{\tilde{e}_R}$  are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses  $m_{1/2}$  and  $m_0$ ,  $1 \leq \tan\beta \leq 50$  and  $-10 \leq \mu \leq 10$  TeV. The region of small  $|\mu|$ , where cascade decays are important, is covered by a search for  $\tilde{\chi}_1^0 \tilde{\chi}_3^0$  in final states with leptons and possibly photons. Limits on  $m_{\tilde{e}_L}$  are derived by exploiting the mass relation between the  $\tilde{e}_L$  and  $\tilde{e}_R$ , based on universal  $m_0$  and  $m_{1/2}$ . When the constraint from the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve to  $m_{\tilde{e}_R} > 77(75)$  GeV and  $m_{\tilde{e}_L} > 115(115)$  GeV for a top mass of 175(180) GeV. In the MSUGRA framework with radiative electroweak symmetry breaking, the limits improve further to  $m_{\tilde{e}_R} > 95$  GeV and  $m_{\tilde{e}_L} > 152$  GeV, assuming a trilinear coupling  $A_0=0$  at the GUT scale. See Figs. 4, 5, 7 for the dependence of the limits on  $\tan\beta$ .

<sup>10</sup> AAD 14G searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of slepton pairs, decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of slepton pair production, see Fig. 8. An interpretation in the pMSSM is also given, see Fig. 10.

<sup>11</sup> KHACHATRYAN 14I searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for electroweak production of slepton pairs decaying to a final state with opposite-sign lepton pairs ( $e$  or  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Fig. 18.

<sup>12</sup> ABBIENDI 04F use data from  $\sqrt{s} = 189$ –209 GeV. They derive limits on sparticle masses under the assumption of  $R$  with  $LL\tilde{E}$  or  $LQ\tilde{D}$  couplings. The results are valid for  $\tan\beta = 1.5$ ,  $\mu = -200$  GeV, with, in addition,  $\Delta m > 5$  GeV for indirect decays via  $LQ\tilde{D}$ . The limit quoted applies to direct decays via  $LL\tilde{E}$  or  $LQ\tilde{D}$  couplings. For indirect decays, the limits on the  $\tilde{e}_R$  mass are respectively 99 and 92 GeV for  $LL\tilde{E}$  and  $LQ\tilde{D}$  couplings and  $m_{\tilde{\chi}_1^0} = 10$  GeV and degrade slightly for larger  $\tilde{\chi}_1^0$  mass. Supersedes the results of ABBIENDI 00.

<sup>13</sup> ABDALLAH 04M use data from  $\sqrt{s} = 192$ –208 GeV to derive limits on sparticle masses under the assumption of  $R$  with  $LL\tilde{E}$  or  $UD\tilde{D}$  couplings. The results are valid for  $\mu = -200$  GeV,  $\tan\beta = 1.5$ ,  $\Delta m > 5$  GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect  $UD\tilde{D}$  decays using the neutralino constraint of 39.5 GeV for  $LL\tilde{E}$  and of 38.0 GeV for  $UD\tilde{D}$  couplings, also derived in ABDALLAH 04M. For indirect decays via  $LL\tilde{E}$  the limit improves to 95 GeV if the constraint from the neutralino is used and to 94 GeV if it is not used. For indirect decays via  $UD\tilde{D}$  couplings it remains unchanged when the neutralino constraint is not used. Supersedes the result of ABREU 00u.

## Searches Particle Listings

### Supersymmetric Particle Searches

- <sup>2</sup> CHATRCHYAN 14R searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the slepton mass in a stau (N)NLSP simplified model (GMSB) where the decay  $\tilde{\ell} \rightarrow \ell^\pm \tau^\pm \tilde{\tau}^\mp \tilde{G}$  takes place with a branching ratio of 100%, see Fig. 8.
- <sup>3</sup> AAD 13b searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for sleptons decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of direct left-handed slepton pair production, where left-handed slepton masses between 85 and 195 GeV are excluded at 95% C.L. for  $m_{\tilde{\chi}_1^0} = 20 \text{ GeV}$ . See also Fig. 2(a). Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.
- <sup>4</sup> ABBIENDI 04 search for  $\tilde{\mu}_R \tilde{\mu}_R$  production in acoplanar di-muon final states in the 183–208 GeV data. See Fig. 14 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$  and for the limit at  $\tan\beta=35$ . Under the assumption of 100% branching ratio for  $\tilde{\mu}_R \rightarrow \mu \tilde{\chi}_1^0$ , the limit improves to 94.0 GeV for  $\Delta m > 4 \text{ GeV}$ . See Fig. 11 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$  at several values of the branching ratio. This limit supersedes ABBIENDI 00g.
- <sup>5</sup> ACHARD 04 search for  $\tilde{\mu}_R \tilde{\mu}_R$  production in acoplanar di-muon final states in the 192–209 GeV data. Limits on  $m_{\tilde{\mu}_R}$  are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses  $m_{1/2}$  and  $m_0$ ,  $1 \leq \tan\beta \leq 60$  and  $-2 \leq \mu \leq 2 \text{ TeV}$ . See Fig. 4 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$ . This limit supersedes ACCIARRI 99w.
- <sup>6</sup> ABDALLAH 03M looked for acoplanar dimuon +  $\cancel{E}_T$  final states at  $\sqrt{s} = 189\text{--}208 \text{ GeV}$ . The limit assumes  $B(\tilde{\mu} \rightarrow \mu \tilde{\chi}_1^0) = 100\%$ . See Fig. 16 for limits on the  $(m_{\tilde{\mu}_R}, m_{\tilde{\chi}_1^0})$  plane. These limits include and update the results of ABREU 01.
- <sup>7</sup> ABDALLAH 03M uses data from  $\sqrt{s} = 192\text{--}208 \text{ GeV}$  to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of  $M_2 < 1 \text{ TeV}$ ,  $|\mu| \leq 1 \text{ TeV}$  with the  $\tilde{\chi}_1^0$  as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of  $\tan\beta$ . These limits update the results of ABREU 00w.
- <sup>8</sup> HEISTER 02E looked for acoplanar dimuon +  $\cancel{E}_T$  final states from  $e^+e^-$  interactions between 183 and 209 GeV. The mass limit assumes  $B(\tilde{\mu} \rightarrow \mu \tilde{\chi}_1^0) = 1$ . See their Fig. 4 for the dependence of the limit on  $\Delta m$ . These limits include and update the results of BARATE 01.
- <sup>9</sup> AAD 14g searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for electroweak production of slepton pairs, decaying to a final state with two leptons ( $e$  and  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models of slepton pair production, see Fig. 8. An interpretation in the pMSSM is also given, see Fig. 10.
- <sup>10</sup> KHACHATRYAN 14i searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for electroweak production of slepton pairs decaying to a final state with opposite-sign lepton pairs ( $e$  or  $\mu$ ) and missing transverse momentum. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models, see Fig. 18.
- <sup>11</sup> ABDALLAH 04M use data from  $\sqrt{s} = 192\text{--}208 \text{ GeV}$  to derive limits on sparticle masses under the assumption of  $R$  with  $L\tilde{L}\tilde{E}$  or  $U\tilde{D}\tilde{D}$  couplings. The results are valid for  $\mu = -200 \text{ GeV}$ ,  $\tan\beta = 1.5$ ,  $\Delta m > 5 \text{ GeV}$  and assuming a BR of 1 for the given decay. The limit quoted is for indirect  $U\tilde{D}\tilde{D}$  decays using the neutralino constraint of 39.5 GeV for  $L\tilde{L}\tilde{E}$  and of 38.0 GeV for  $U\tilde{D}\tilde{D}$  couplings, also derived in ABDALLAH 04M. For indirect decays via  $L\tilde{L}\tilde{E}$  the limit improves to 90 GeV if the constraint from the neutralino is used and remains at 87 GeV if it is not used. For indirect decays via  $U\tilde{D}\tilde{D}$  couplings it degrades to 85 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 00u.
- <sup>12</sup> HEISTER 03G searches for the production of smuons in the case of  $R$  prompt decays with  $L\tilde{L}\tilde{E}$ ,  $L\tilde{Q}\tilde{D}$  or  $U\tilde{D}\tilde{D}$  couplings at  $\sqrt{s} = 189\text{--}209 \text{ GeV}$ . The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays mediated by  $R$   $L\tilde{Q}\tilde{D}$  couplings and improves to 90 GeV for indirect decays (for  $\Delta m > 10 \text{ GeV}$ ). Limits are also given for  $L\tilde{L}\tilde{E}$  direct ( $m_{\tilde{\mu}_R} > 87 \text{ GeV}$ ) and indirect decays ( $m_{\tilde{\mu}_R} > 96 \text{ GeV}$  for  $m(\tilde{\chi}_1^0) > 23 \text{ GeV}$  from BARATE 98s) and for  $U\tilde{D}\tilde{D}$  indirect decays ( $m_{\tilde{\mu}_R} > 85 \text{ GeV}$  for  $\Delta m > 10 \text{ GeV}$ ). Supersedes the results from BARATE 01b.
- <sup>13</sup> ABREU 00v use data from  $\sqrt{s} = 130\text{--}189 \text{ GeV}$  to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of  $m_{\tilde{\tau}_1}$ , after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. For limits at different  $m_{\tilde{G}}$ , see their Fig. 12.

#### $\tilde{\tau}$ (Stau) MASS LIMIT

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, et al. (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

- <sup>1</sup> ABBIENDI 04 search for  $\tilde{\tau}\tilde{\tau}$  production in acoplanar di-tau final states in the 183–208 GeV data. See Fig. 15 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$  and for the limit at  $\tan\beta=35$ . Under the assumption of 100% branching ratio for  $\tilde{\tau}_R \rightarrow \tau \tilde{\chi}_1^0$ , the limit improves to 89.8 GeV for  $\Delta m > 8 \text{ GeV}$ . See Fig. 12 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$  at several values of the branching ratio and for their dependence on  $\theta_\tau$ . This limit supersedes ABBIENDI 00g.
- <sup>2</sup> ACHARD 04 search for  $\tilde{\tau}\tilde{\tau}$  production in acoplanar di-tau final states in the 192–209 GeV data. Limits on  $m_{\tilde{\tau}_R}$  are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses  $m_{1/2}$  and  $m_0$ ,  $1 \leq \tan\beta \leq 60$  and  $-2 \leq \mu \leq 2 \text{ TeV}$ . See Fig. 4 for the dependence of the limits on  $m_{\tilde{\chi}_1^0}$ .
- <sup>3</sup> ABDALLAH 03M looked for acoplanar ditau +  $\cancel{E}$  final states at  $\sqrt{s} = 130\text{--}208 \text{ GeV}$ . A dedicated search was made for low mass  $\tilde{\tau}$ s decoupling from the  $Z^0$ . The limit assumes  $B(\tilde{\tau} \rightarrow \tau \tilde{\chi}_1^0) = 100\%$ . See Fig. 20 for limits on the  $(m_{\tilde{\tau}}, m_{\tilde{\chi}_1^0})$  plane and as function of the  $\tilde{\chi}_1^0$  mass and of the branching ratio. The limit in the low-mass region improves to 29.6 and 31.1 GeV for  $\tilde{\tau}_R$  and  $\tilde{\tau}_L$ , respectively, at  $\Delta m > m_{\tilde{\tau}}$ . The limit in the high-mass region improves to 84.7 GeV for  $\tilde{\tau}_R$  and  $\Delta m > 15 \text{ GeV}$ . These limits include and update the results of ABREU 01.
- <sup>4</sup> HEISTER 02E looked for acoplanar ditau +  $\cancel{E}_T$  final states from  $e^+e^-$  interactions between 183 and 209 GeV. The mass limit assumes  $B(\tilde{\tau} \rightarrow \tau \tilde{\chi}_1^0) = 1$ . See their Fig. 4 for the dependence of the limit on  $\Delta m$ . These limits include and update the results of BARATE 01.
- <sup>5</sup> AAD 12AF searched in  $2 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with two tau leptons, jets and large  $\cancel{E}_T$  in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C.L. lower limit of 32 TeV on the mGMSB breaking scale  $\Lambda$  is set for  $M_{\text{mess}} = 250 \text{ TeV}$ ,  $N_S = 3$ ,  $\mu > 0$  and  $C_{\text{grav}} = 1$ , independent of  $\tan\beta$ .
- <sup>6</sup> AAD 12AG searched in  $2.05 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with at least one hadronically decaying tau lepton, jets, and large  $\cancel{E}_T$  in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C.L. lower limit of 30 TeV on the mGMSB breaking scale  $\Lambda$  is set for  $M_{\text{mess}} = 250 \text{ TeV}$ ,  $N_S = 3$ ,  $\mu > 0$  and  $C_{\text{grav}} = 1$ , independent of  $\tan\beta$ . For large values of  $\tan\beta$ , the limit on  $\Lambda$  increases to 43 TeV.
- <sup>7</sup> AAD 12CM searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with at least one tau lepton, zero or one additional light lepton ( $e/\mu$ ) jets, and large  $\cancel{E}_T$  in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C. L. lower limit of 54 TeV on the mGMSB breaking scale  $\Lambda$  is set for  $M_{\text{mess}} = 250 \text{ TeV}$ ,  $N_S = 3$ ,  $\mu > 0$  and  $C_{\text{grav}} = 1$ , for  $\tan\beta > 20$ . Here the  $\tilde{\tau}_1$  is the NLSP.
- <sup>8</sup> ABBIENDI 06B use 600 pb $^{-1}$  of data from  $\sqrt{s} = 189\text{--}209 \text{ GeV}$ . They look for events from pair-produced staus in a GMSB scenario with  $\tilde{\tau}$  NLSP including prompt  $\tilde{\tau}$  decays to ditau +  $\cancel{E}$  final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of  $m(\tilde{\tau})$  and the lifetime, see their Fig. 7. The limit is compared to the  $\sigma \cdot BR^2$  from a scan over the GMSB parameter space.
- <sup>9</sup> ABBIENDI 04F use data from  $\sqrt{s} = 189\text{--}209 \text{ GeV}$ . They derive limits on sparticle masses under the assumption of  $R$  with  $L\tilde{L}\tilde{E}$  or  $L\tilde{Q}\tilde{D}$  couplings. The results are valid for  $\tan\beta = 1.5$ ,  $\mu = -200 \text{ GeV}$ , with, in addition,  $\Delta m > 5 \text{ GeV}$  for indirect decays via  $L\tilde{Q}\tilde{D}$ . The limit quoted applies to direct decays with  $L\tilde{L}\tilde{E}$  couplings and improves to 75 GeV for  $L\tilde{Q}\tilde{D}$  couplings. The limit on the  $\tilde{\tau}_R$  mass for indirect decays is 92 GeV for  $L\tilde{L}\tilde{E}$  couplings at  $m_{\tilde{\chi}_1^0} = 10 \text{ GeV}$  and no exclusion is obtained for  $L\tilde{Q}\tilde{D}$  couplings. Supersedes the results of ABBIENDI 00.
- <sup>10</sup> ABDALLAH 04H use data from LEP 1 and  $\sqrt{s} = 192\text{--}208 \text{ GeV}$ . They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region  $1 < m_{3/2} < 50 \text{ TeV}$ ,  $0 < m_0 < 1000 \text{ GeV}$ ,  $1.5 < \tan\beta < 35$ , both signs of  $\mu$ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM  $Z$  width of 3.2 MeV. The limit is for  $m_{\tilde{t}} = 174.3 \text{ GeV}$  (see Table 2 for other  $m_{\tilde{t}}$  values). The limit improves to 75 GeV for  $\mu < 0$ .
- <sup>11</sup> ABDALLAH 04M use data from  $\sqrt{s} = 192\text{--}208 \text{ GeV}$  to derive limits on sparticle masses under the assumption of  $R$  with  $L\tilde{L}\tilde{E}$  couplings. The results are valid for  $\mu = -200 \text{ GeV}$ ,  $\tan\beta = 1.5$ ,  $\Delta m > 5 \text{ GeV}$  and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays via  $L\tilde{L}\tilde{E}$  the limit decreases to 86 GeV if the constraint from the neutralino is not used. Supersedes the result of ABREU 00u.

#### Degenerate Charged Sleptons

Unless stated otherwise in the comment lines or in the footnotes, the following limits assume 3 families of degenerate charged sleptons.

# Searches Particle Listings

## Supersymmetric Particle Searches

- <sup>1</sup> BARATE 01 looked for acoplanar dilepton +  $\cancel{E}_T$  and single electron (for  $\tilde{e}\tilde{e}_L$ ) final states at 189 to 202 GeV. The limit assumes  $\mu=200$  GeV and  $\tan\beta=2$  for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than  $\tilde{e} \rightarrow \ell\tilde{\chi}_1^0$ . The slepton masses are determined from the GUT relations without stau mixing. See their Fig. 1 for the dependence of the limit on  $\Delta m$ .
- <sup>2</sup> ABBIENDI 06b use 600 pb<sup>-1</sup> of data from  $\sqrt{s}=189\text{--}209$  GeV. They look for events from pair-produced staus in a GMSB scenario with  $\tilde{t}$  co-NLSP including prompt  $\tilde{t}$  decays to dileptons +  $\cancel{E}$  final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of  $m(\tilde{t})$  and the lifetime, see their Fig. 7. The limit is compared to the  $\sigma \cdot BR^2$  from a scan over the GMSB parameter space. The highest mass limit is reached for  $\tilde{\mu}_R$ , from which the quoted mass limit is derived by subtracting  $m_{\tilde{\tau}}$ .
- <sup>3</sup> ABDALLAH 03D use data from  $\sqrt{s}=130\text{--}208$  GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of  $m(\tilde{G})$ , after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays. The above limit is reached for prompt decays and assumes the degeneracy of the sleptons. For limits at different  $m(\tilde{G})$ , see their Fig. 9. Supersedes the results of ABREU 01G.
- <sup>4</sup> ACHARD 02 searches for the production of sparticles in the case of  $\tilde{R}$  prompt decays with  $L\tilde{L}\tilde{E}$  or  $U\tilde{D}\tilde{D}$  couplings at  $\sqrt{s}=189\text{--}208$  GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale and no mixing in the slepton sector, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for  $L\tilde{L}\tilde{E}$  couplings and increases to 88.7 GeV for  $U\tilde{D}\tilde{D}$  couplings. For L3 limits from  $L\tilde{Q}\tilde{D}$  couplings, see ACCIARRI 01.
- <sup>5</sup> ABBIENDI 01 looked for final states with  $\gamma\gamma\tilde{E}$ ,  $\ell\ell\tilde{E}$ , with possibly additional activity and four leptons +  $\cancel{E}$  to search for prompt decays of  $\tilde{\chi}_1^0$  or  $\tilde{\ell}_1$  in GMSB. They derive limits in the plane  $(m_{\tilde{\chi}_1^0}, m_{\tilde{\ell}_1})$ , see Fig. 6, allowing either the  $\tilde{\chi}_1^0$  or a  $\tilde{\ell}_1$  to be the NLSP. Two scenarios are considered:  $\tan\beta=2$  with the 3 sleptons degenerate in mass and  $\tan\beta=20$  where the  $\tilde{\tau}_1$  is lighter than the other sleptons. Data taken at  $\sqrt{s}=189$  GeV. For  $\tan\beta=20$ , the obtained limits are  $m_{\tilde{\tau}_1} > 69$  GeV and  $m_{\tilde{e}_1, \tilde{\mu}_1} > 88$  GeV.
- <sup>6</sup> ABREU 01 looked for acoplanar dilepton + diphoton +  $\cancel{E}$  final states from  $\tilde{e}$  cascade decays at  $\sqrt{s}=130\text{--}189$  GeV. See Fig. 9 for limits on the  $(\mu, M_2)$  plane for  $m_{\tilde{e}}=80$  GeV,  $\tan\beta=1.0$ , and assuming degeneracy of  $\tilde{\mu}$  and  $\tilde{e}$ .
- <sup>7</sup> ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from  $\tilde{R}$  prompt decays with  $L\tilde{L}\tilde{E}$ ,  $L\tilde{Q}\tilde{D}$ , or  $U\tilde{D}\tilde{D}$  couplings at  $\sqrt{s}=189$  GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the  $\tilde{\chi}_1^0$  or a  $\tilde{\ell}$  as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the  $Z^0$  width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99i.
- <sup>8</sup> ABREU 00v use data from  $\sqrt{s}=130\text{--}189$  GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of  $m_{\tilde{\tau}}$ , after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. For limits at different  $m_{\tilde{G}}$ , see their Fig. 12. The above limit assumes the degeneracy of stau and smuon.

### Long-lived $\tilde{\tau}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum  $e^+e^-$  annihilation are also independent of flavor for smuons and staus. Selection limits from  $e^+e^-$  collisions in the continuum depend on MSSM parameters because of the additional neutralino exchange contribution.

>136	95	<sup>13</sup> AAD	11P ATLS	stable $\tilde{\tau}$ , GMSB scenario, $\tan\beta=5$

- <sup>1</sup> AAD 15AE searched in 19.1 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=8$  TeV for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ALTA muon system. In the absence of an excess of events above the expected backgrounds, limits are set on stable  $\tilde{\tau}$  sleptons in various scenarios, see Figs. 5–7.
- <sup>2</sup> AAIJ 15BD searched in 3.0 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=7$  and 8 TeV for evidence of Drell-Yan pair production of long-lived  $\tilde{\tau}$  particles. No evidence for such particles is observed and 95% C.L. upper limits on the cross section of  $\tilde{\tau}$  pair production are derived, see Fig. 7. In the mGMSB, assuming the SPS7 benchmark scenario  $\tilde{\tau}$  masses between 124 and 309 GeV are excluded at 95% C.L.

- <sup>3</sup> ABBIENDI 03L used  $e^+e^-$  data at  $\sqrt{s}=130\text{--}209$  GeV to select events with two high momentum tracks with anomalous  $dE/dx$ . The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The limit improves to 98.5 GeV for  $\tilde{\mu}_L$  and  $\tilde{\tau}_L$ . The bounds are valid for colorless spin 0 particles with lifetimes longer than  $10^{-6}$  s. Supersedes the results from ACKERSTAFF 98P.
- <sup>4</sup> ABREU 00q searches for the production of pairs of heavy, charged stable particles in  $e^+e^-$  annihilation at  $\sqrt{s}=130\text{--}189$  GeV. The upper bound improves to 88 GeV for  $\tilde{\mu}_L, \tilde{\tau}_L$ . These limits include and update the results of ABREU 98P.
- <sup>5</sup> ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at  $\sqrt{s}=130\text{--}183$  GeV. The upper bound improves to 82.2 GeV for  $\tilde{\mu}_L, \tilde{\tau}_L$ .
- <sup>6</sup> The BARATE 98K mass limit improves to 82 GeV for  $\tilde{\mu}_L, \tilde{\tau}_L$ . Data collected at  $\sqrt{s}=161\text{--}184$  GeV.
- <sup>7</sup> AAD 13AA searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=7$  TeV for events containing long-lived massive particles in a GMSB framework. No significant excess above the expected background was found. A 95% C.L. lower limit of 300 GeV is placed on long-lived  $\tilde{\tau}$ 's in the GMSB model with  $M_{mess}=250$  TeV,  $N_5=3$ ,  $\mu > 0$ , for  $\tan\beta=5\text{--}20$ . The lower limit on the GMSB breaking scale  $\Lambda$  was found to be 99–110 TeV, for  $\tan\beta$  values between 5 and 40, see Fig. 4 (top). Also, directly produced long-lived sleptons, or sleptons decaying to long-lived ones, are excluded at 95% C.L. up to a  $\tilde{\tau}$  mass of 278 GeV for models with slepton splittings smaller than 50 GeV.
- <sup>8</sup> ABZOV 13b looked in 6.3 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV for charged massive long-lived particles in events with muon-like particles that have both speed and ionization energy loss inconsistent with muons produced in beam collisions. In the absence of an excess, limits are set at 95% C.L. on the production cross section of stau leptons in the mass range 100–300 GeV, see their Table 20 and Fig. 23.
- <sup>9</sup> CHATRCHYAN 13AB looked in 5.0 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=7$  TeV and in 18.8 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=8$  TeV for events with heavy stable particles, identified by their anomalous  $dE/dx$  in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of  $\tilde{\tau}_1$ 's. No evidence for an excess over the expected background is observed. Supersedes CHATRCHYAN 12L.
- <sup>10</sup> CHATRCHYAN 13AB limits are derived for pair production of  $\tilde{\tau}_1$  as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 8 and Table 7). The limit given here is valid for direct pair  $\tilde{\tau}_1$  production.
- <sup>11</sup> CHATRCHYAN 13AB limits are derived for the production of  $\tilde{\tau}_1$  as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 8 and Table 7). The limit given here is valid for the production of  $\tilde{\tau}_1$  from both direct pair production and from the decay of heavier supersymmetric particles.
- <sup>12</sup> CHATRCHYAN 12L looked in 5.0 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=7$  TeV for events with heavy stable particles, identified by their anomalous  $dE/dx$  in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of  $\tilde{\tau}_1$ 's. No evidence for an excess over the expected background is observed. Limits are derived for the production of  $\tilde{\tau}_1$  as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 3). The limit given here is valid for the production of  $\tilde{\tau}_1$  in the decay of heavier supersymmetric particles.
- <sup>13</sup> AAD 11P looked in 37 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s}=8$  TeV for events with two heavy stable particles, reconstructed in the Inner tracker and the Muon System and identified by their time of flight in the Muon System. No evidence for an excess over the SM expectation is observed. Limits on the mass are derived, see Fig. 3, for  $\tilde{\tau}$  in a GMSB scenario and for sleptons produced by electroweak processes only, in which case the limit degrades to 110 GeV.

### $\tilde{q}$ (Squark) MASS LIMIT

For  $m_{\tilde{q}} > 60\text{--}70$  GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from  $e^+e^-$  collisions depend on the mixing angle of the lightest mass eigenstate  $\tilde{q}_1 = \tilde{q}_R \sin\theta_q + \tilde{q}_L \cos\theta_q$ . It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  decays if  $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}_1^0} \gtrsim 5$  GeV. For smaller values of  $\Delta m$ , current constraints on the invisible width of the Z ( $\Delta\Gamma_{inv} < 2.0$  MeV, LEP 00) exclude  $m_{\tilde{\mu}_L, R} < 44$  GeV,  $m_{\tilde{d}_R} < 33$  GeV,  $m_{\tilde{d}_L} < 44$  GeV and, assuming all squarks degenerate,  $m_{\tilde{q}} < 45$  GeV.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

- <sup>1</sup> AAD 15BV summarized and extended ATLAS searches for gluinos and first- and second-generation squarks in final states containing jets and missing transverse momentum, with or without leptons or  $b$ -jets in the  $\sqrt{s} = 8$  TeV data set collected in 2012. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on the squark mass in several  $R$ -parity conserving models. See their Figs. 9, 11, 18, 22, 24, 27, 28.
- <sup>2</sup> AAD 15CS searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for evidence of pair production of squarks, decaying into a quark and a neutralino, where a photon was radiated either from an initial-state quark, from an intermediate squark, or from a final-state quark. No evidence was found for an excess above the expected level of Standard Model background and a 95% C.L. exclusion limit was set on the squark mass as a function of the squark-neutralino mass difference, see Fig. 19.
- <sup>3</sup> AAD 15K searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing at least two jets, where the two leading jets are each identified as originating from  $c$ -quarks, and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the mass of superpartners of charm quarks ( $\tilde{c}$ ). Assuming that the decay  $\tilde{c} \rightarrow c\tilde{\chi}_1^0$  takes place 100% of the time, a scalar charm mass below 490 GeV is excluded for  $m_{\tilde{\chi}_1^0} < 200$  GeV. For more details, see their Fig. 2.
- <sup>4</sup> KHACHATRYAN 15AF searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least two energetic jets and significant  $\cancel{E}_T$ , using the transverse mass variable  $M_{T2}$  to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the squark mass in simplified models where the decay  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, both for the case of a single light squark or 8 degenerate squarks, see Fig. 12. See also Table 5. Exclusions in the CMSSM, assuming  $\tan\beta = 30$ ,  $A_0 = -2 \max(m_0, m_{1/2})$  and  $\mu > 0$ , are also presented, see Fig. 15.
- <sup>5</sup> AAD 14AE searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for strongly produced supersymmetric particles in events containing jets and large missing transverse momentum, and no electrons or muons. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing squarks that decay via  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ , where either a single light state or two degenerate generations of squarks are assumed, see Fig. 10.
- <sup>6</sup> CHATRCHYAN 14AH searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with at least two energetic jets and significant  $\cancel{E}_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 28. Exclusions in the CMSSM, assuming  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , are also presented, see Fig. 26.
- <sup>7</sup> CHATRCHYAN 14I searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing multijets and large  $\cancel{E}_T$ . No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing squarks that decay via  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ , where either a single light state or two degenerate generations of squarks are assumed, see Fig. 7a.
- <sup>8</sup> AAD 13L searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no high- $p_T$  electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , squarks and gluinos of equal mass are excluded for masses below 1360 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, squark masses below 1320 GeV are excluded at 95% C.L. for gluino masses below 2 TeV. See Figures 10–15 for more precise bounds.
- <sup>9</sup> AAD 13Q searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events containing a high- $p_T$  isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the squark mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSP, see their Fig. 4. For neutralino masses greater than 220 GeV, squark masses below 1020 GeV are excluded at 95% C.L.
- <sup>10</sup> CHATRCHYAN 13 looked in 4.98 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with two opposite-sign leptons ( $e, \mu, \tau$ ), jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the mSUGRA/CMSSM model with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , see Fig. 6.
- <sup>11</sup> CHATRCHYAN 13G searched in 4.98 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for the production of squarks and gluinos in events containing 0,1,2,  $\geq 3$   $b$ -jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with  $\tan\beta = 10$ ,  $A_0 = 0$ , and  $\mu > 0$ , squarks and gluinos of equal mass are excluded for masses below 1250 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 7.
- <sup>12</sup> CHATRCHYAN 13H searched in 4.96 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with two photons,  $\geq 4$  jets and low  $\cancel{E}_T$  due to  $\tilde{q} \rightarrow \gamma\tilde{\chi}_1^0$  decays in a stealth SUSY framework, where the  $\tilde{\chi}_1^0$  decays through a singlino ( $\tilde{S}$ ) intermediate state to  $\gamma S \tilde{G}$ , with the singlet state  $S$  decaying to two jets. No significant excess above the expected background was found and limits were set in a particular  $R$ -parity conserving stealth SUSY model. The model assumes  $m_{\tilde{\chi}_1^0} = 0.5 m_{\tilde{q}}$ ,  $m_{\tilde{S}} = 100$  GeV and  $m_S = 90$  GeV. Under these assumptions, squark masses less than 1430 GeV were excluded at the 95% C.L.
- <sup>13</sup> CHATRCHYAN 13T searched in 11.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least two energetic jets and significant  $\cancel{E}_T$ , using the  $\alpha_T$  variable to discriminate between processes with genuine and misreconstructed  $\cancel{E}_T$ . No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in simplified models where the decay  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, assuming an eightfold degeneracy of the masses of the first two generation squarks, see Fig. 8 and Table 9. Also limits in the case of a single light squark are given.
- <sup>14</sup> AAD 12AX searched in 1.04 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for supersymmetry in events containing jets, missing transverse momentum and one isolated electron or muon. No excess over the expected SM background is observed and model-independent limits are set on the cross section of new physics contributions to the signal regions. In mSUGRA/CMSSM models with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , squarks and gluinos of

# Searches Particle Listings

## Supersymmetric Particle Searches

- equal mass are excluded for masses below 820 GeV at 95% C.L. Limits are also set on simplified models for squark production and decay via an intermediate chargino and on supersymmetric models with bilinear  $R$ -parity violation. Supersedes AAD 11c.
- 15 AAD 12CJ searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events containing one or more isolated leptons (electrons or muons), jets and  $E_{T\text{miss}}$ . The observations are in good agreement with the SM expectations and exclusion limits have been set in number of SUSY models. In the mSUGRA/CMSSM model with  $\tan\beta = 10$ ,  $A_0 = 0$ , and  $\mu > 0$ , 95% C.L. exclusion limits have been derived for  $m_{\tilde{q}} < 1200 \text{ GeV}$ , assuming equal squark and gluino masses. In minimal GMSB, values of the effective SUSY breaking scale  $\Lambda < 50 \text{ TeV}$  are excluded at 95% C.L. for  $\tan\beta < 45$ . Also exclusion limits in a number of simplified models have been presented, see Figs. 10 and 12.
- 16 AAD 12CP searched in  $4.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with two photons and large  $E_{T\text{miss}}$  due to  $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$  decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the squark mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP. The other sparticle masses were decoupled,  $\tan\beta = 2$  and  $\tau_{\text{NLSP}} < 0.1 \text{ mm}$ . Also, in the framework of the SP58 model, a 95% C.L. lower limit was set on the breaking scale  $\Lambda$  of 196 TeV.
- 17 AAD 12W searched in  $1.04 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , squarks and gluinos of equal mass are excluded for masses below 950 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, squark masses below 875 GeV are excluded at 95% C.L.
- 18 CHATRCHYAN 12 looked in  $35 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with  $e$  and/or  $\mu$  and/or jets, a large total transverse energy, and  $E_{T\text{miss}}$ . The event selection is based on the dimensionless razor variable  $R$ , related to the  $E_{T\text{miss}}$  and  $M_{\text{RP}}$ , an indicator of the heavy particle mass scale. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM ( $m_0, m_{1/2}$ ) plane for  $\tan\beta = 3, 10$  and 50 (see Fig. 7 and 8). Limits are also obtained for Simplified Model Spectra.
- 19 CHATRCHYAN 12AE searched in  $4.98 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with at least three jets and large missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of squarks in a scenario where  $\tilde{q} \rightarrow q\tilde{\chi}_1^0$  with a 100% branching ratio, see Fig. 3. For  $m_{\tilde{\chi}_1^0} < 200 \text{ GeV}$ , values of  $m_{\tilde{q}}$  below 760 GeV are excluded at 95% C.L. Also limits in the CMSSM are presented, see Fig. 2.
- 20 CHATRCHYAN 12AL looked in  $4.98 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for anomalous production of events with three or more isolated leptons. Limits on squark and gluino masses are set in  $R$  SUSY models with leptonic  $LL\tilde{E}$  couplings,  $\lambda_{123} > 0.05$ , and hadronic  $U\tilde{D}\tilde{D}$  couplings,  $\lambda_{112}'' > 0.05$ , see their Fig. 5. In the  $U\tilde{D}\tilde{D}$  case the leptons arise from supersymmetric cascade decays. A very specific supersymmetric spectrum is assumed. All decays are prompt.
- 21 CHATRCHYAN 12AT searched in  $4.73 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , squarks with masses below 1110 GeV are excluded at 95% C.L. Squarks and gluinos of equal mass are excluded for masses below 1180 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 6.
- 22 AAD 15AI searched in  $20 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events containing at least one isolated lepton (electron or muon), jets, and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the squark masses in the CMSSM/mSUGRA, see Fig. 15, in the NUHMG, see Fig. 16, and in various simplified models, see Figs. 19–21.
- 23 AAD 15CB searched for events containing at least one long-lived particle that decays at a significant distance from its production point (displaced vertex, DV) into two leptons or into five or more charged particles in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$ . The dilepton signature is characterised by DV formed from at least two lepton candidates. Four different final states were considered for the multitrack signature, in which the DV must be accompanied by a high-transverse momentum muon or electron candidate that originates from the DV, jets or missing transverse momentum. No events were observed in any of the signal regions. Results were interpreted in SUSY scenarios involving  $R$ -parity violation, split supersymmetry, and gauge mediation. See their Fig. 14–20.
- 24 KHACHATRYAN 15AR searched in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events containing jets, either a charged lepton or a photon, and low missing transverse momentum. No significant excess above the Standard Model expectations is observed. Limits are set on the squark mass in a stealth SUSY model where the decays  $\tilde{q} \rightarrow q\tilde{\chi}_1^\pm$ ,  $\tilde{\chi}_1^\pm \rightarrow \tilde{S}W^\pm$ ,  $\tilde{S} \rightarrow S\tilde{G}$  and  $S \rightarrow g\tilde{g}$ , with  $m_{\tilde{S}} = 100 \text{ GeV}$  and  $m_{\tilde{S}} = 90 \text{ GeV}$ , take place with a branching ratio of 100%. See Fig. 6 for  $\gamma$  or Fig. 7 for  $e^\pm$  analyses.
- 25 KHACHATRYAN 15AZ searched in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with either at least one photon, hadronic jets and  $E_{T\text{miss}}$  (single photon channel) or with at least two photons and at least one jet and using the razor variables. No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for both a bino-like and wino-like neutralino NLSP scenario, see Fig. 8 and 9.
- 26 AAD 14E searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from  $b$ -quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figs. 5 and 6. In the  $\tilde{q} \rightarrow q'\tilde{\chi}_1^\pm$ ,  $\tilde{\chi}_1^\pm \rightarrow W(*)\tilde{\chi}_2^0$ ,  $\tilde{\chi}_2^0 \rightarrow Z(*)\tilde{\chi}_1^0$  simplified model, the following assumptions have been made:  $m_{\tilde{\chi}_1^\pm} = 0.5 m_{\tilde{\chi}_1^0} + m_{\tilde{g}}$ ,  $m_{\tilde{\chi}_2^0} = 0.5 (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_1^\pm})$ . In the  $\tilde{q} \rightarrow q'\tilde{\chi}_1^\pm$  or  $\tilde{q} \rightarrow q'\tilde{\chi}_2^0$ ,  $\tilde{\chi}_1^\pm \rightarrow e^\pm\nu\tilde{\chi}_1^0$  or  $\tilde{\chi}_2^0 \rightarrow e^\pm e^\mp(\nu\nu)\tilde{\chi}_1^0$  simplified model, the following assumptions have been made:  $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0} = 0.5 (m_{\tilde{\chi}_1^0} + m_{\tilde{q}})$ ,  $m_{\tilde{\chi}_1^0} < 460 \text{ GeV}$ . Limits are also derived in the mSUGRA/CMSSM, BRPV and GMSB models, see their Fig. 8.
- 27 CHATRCHYAN 2013AO searched in  $4.98 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with two opposite-sign isolated leptons accompanied by hadronic jets and  $E_{T\text{miss}}$ . No significant excesses over the expected SM backgrounds are observed and 95% C.L.

exclusion limits are derived in the mSUGRA/CMSSM model with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , see Fig. 8.

- 28 CHATRCHYAN 13AV searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for new heavy particle pairs decaying into jets (possibly  $b$ -tagged), leptons and  $E_{T\text{miss}}$  using the Razor variables. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , see Fig. 3. The results are also interpreted in various simplified models, see Fig. 4.
- 29 CHATRCHYAN 13W searched in  $4.93 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with one or more photons, hadronic jets and  $E_{T\text{miss}}$ . No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in the general gauge-mediated SUSY breaking model (GGM), for both a wino-like and bino-like neutralino NLSP scenario, see Fig. 5.
- 30 DREINER 12A reassesses constraints from CMS (at  $7 \text{ TeV}$ ,  $\sim 4.4 \text{ fb}^{-1}$ ) under the assumption that the first and second generation squarks and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).
- 31 DREINER 12A reassesses constraints from CMS (at  $7 \text{ TeV}$ ,  $\sim 4.4 \text{ fb}^{-1}$ ) under the assumption that the first and second generation squarks, the gluino, and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

### Long-lived $\tilde{q}$ (Squark) MASS LIMIT

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates:  $\tilde{q}_1 = \tilde{q}_L \cos\theta_q + \tilde{q}_R \sin\theta_q$ .

The coupling to the  $Z^0$  boson vanishes for up-type squarks when  $\theta_q = 0.98$ , and for down type squarks when  $\theta_q = 1.17$ .

- 1 AAD 15AE searched in  $19.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ATLAS muon system. In the absence of an excess of events above the expected backgrounds, limits are set on R-hadrons in various scenarios, see Fig. 11. Limits are also set in LeptoSUSY models where the gluino decays to stable 300 GeV leptons, see Fig. 9.
- 2 AAD 15BM searched in  $18.4 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for stable and metastable non-relativistic charged particles through their anomalous specific ionization energy loss in the ATLAS pixel detector. In absence of an excess of events above the expected backgrounds, limits are set on stable bottom and top squark R-hadrons, see Table 5.
- 3 KHACHATRYAN 15AK looked in a data set corresponding to  $\text{fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$ , and a search interval corresponding to 281 h of trigger lifetime, for long-lived particles that have stopped in the CMS detector. No evidence for an excess over the expected background in a cloud interaction model is observed. Assuming the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  and lifetimes between  $1 \mu\text{s}$  and  $1000 \text{ s}$ , limits are derived on  $\tilde{t}$  production as a function of  $m_{\tilde{\chi}_1^0}$ , see Figs. 4 and 7. The exclusions require that  $m_{\tilde{\chi}_1^0}$  is kinematically consistent with the minimum values of the jet energy thresholds used.
- 4 AAD 13AA searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a  $\tilde{t}$  are excluded for masses up to 683 GeV at 95% C.L. in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.
- 5 AAD 13AA searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a  $\tilde{b}$  are excluded for masses up to 612 GeV at 95% C.L. in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.
- 6 AAD 13BC searched in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  and in  $22.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on sbottom masses for the decay  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$ , for different lifetimes, and for a neutralino mass of 100 GeV, see their Table 6 and Fig 10.
- 7 AAD 13BC searched in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  and in  $22.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on stop masses for the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$ , for different lifetimes, and for a neutralino mass of 100 GeV, see their Table 6 and Fig 10.

## Searches Particle Listings Supersymmetric Particle Searches

<sup>8</sup> CHATRCHYAN 13AB looked in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  and in  $18.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with heavy stable particles, identified by their anomalous  $dE/dx$  in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of  $\tilde{t}_1$ 's. No evidence for an excess over the expected background is observed. Limits are derived for pair production of stops as a function of mass in the cloud interaction model (see Fig. 8 and Table 6). In the charge-suppressed model, the limit decreases to 818 GeV.

### $\tilde{b}$ (Sbottom) MASS LIMIT

Limits in  $e^+e^-$  depend on the mixing angle of the mass eigenstate  $\tilde{b}_1 = \tilde{b}_L \cos\theta_b + \tilde{b}_R \sin\theta_b$ . Coupling to the  $Z$  vanishes for  $\theta_b \sim 1.17$ . As a consequence, no absolute constraint in the mass region  $\lesssim 40 \text{ GeV}$  is available in the literature at this time from  $e^+e^-$  collisions. In the Listings below, we use  $\Delta m = m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0}$ .

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

- <sup>1</sup> AAD 15CJ searched in  $20 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for evidence of third generation squarks by combining a large number of searches covering various final states. Limits on the sbottom mass are shown, either assuming the  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  decay, see Fig. 11, or assuming the  $\tilde{b} \rightarrow t\tilde{\chi}_1^\pm$  decay, with  $\tilde{\chi}_1^\pm \rightarrow W^{(*)}\tilde{\chi}_1^0$ , see Fig. 12a, or assuming the  $\tilde{b} \rightarrow b\tilde{\chi}_2^0$  decay, with  $\tilde{\chi}_2^0 \rightarrow h\tilde{\chi}_1^0$ , see Fig. 12b. Interpretations in the pMSSM are also discussed, see Figures 13–15.
- <sup>2</sup> KHACHATRYAN 15AF searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with at least two energetic jets and significant  $\cancel{E}_T$ , using the transverse mass variable  $M_{T2}$  to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in simplified models where the decay  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 12. See also Table 5. Exclusions in the CMSSM, assuming  $\tan\beta = 30$ ,  $A_0 = -2 \max(m_0, m_{1/2})$  and  $\mu > 0$ , are also presented, see Fig. 15.
- <sup>3</sup> KHACHATRYAN 15AH searched in  $19.4$  or  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events containing either a fully reconstructed top quark, or events containing dijets requiring one or both jets to originate from  $b$ -quarks, or events containing a mono-jet. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in simplified models where the decay  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 12. Limits are also set in a simplified model where the decay  $\tilde{b} \rightarrow c\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 12.
- <sup>4</sup> KHACHATRYAN 15I searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events in which  $b$ -jets and four  $W$ -bosons are produced. Five individual search channels are combined (fully hadronic, single lepton, same-sign dilepton, opposite-sign dilepton, multi-lepton). No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in a simplified model where the decay  $\tilde{b} \rightarrow t\tilde{\chi}_1^\pm$ , with  $\tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$ , takes place with a branching ratio of 100%, see Fig. 7.
- <sup>5</sup> AAD 14T searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for monojet-like events. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which assume that the decay  $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$  takes place 100% of the time, see Fig. 12.
- <sup>6</sup> CHATRCHYAN 14AH searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with at least two energetic jets and significant  $\cancel{E}_T$ , using the razor variables ( $M_R$  and  $R_2$ ) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a  $b$ -quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , are also presented, see Fig. 26.
- <sup>7</sup> CHATRCHYAN 14R searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a simplified model where the decay  $\tilde{b} \rightarrow t\tilde{\chi}_1^\pm$ , with  $\tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$ , takes place with a branching ratio of 100%, see Fig. 11.
- <sup>8</sup> KHACHATRYAN 15AD searched in  $19.4 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two opposite-sign same flavor isolated leptons featuring either a kinematic edge, or a peak at the  $Z$ -boson mass, in the invariant mass spectrum. No evidence for a statistically significant excess over the expected SM backgrounds is observed and 95% C.L. exclusion limits are derived in a simplified model of sbottom pair production where the sbottom decays into a  $b$ -quark, two opposite-sign dileptons and a neutralino LSP, through an intermediate state containing either an off-shell  $Z$ -boson or a slepton, see Fig. 8.
- <sup>9</sup> AAD 14AX searched in  $20.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for the strong production of supersymmetric particles in events containing either zero or at least one high- $p_T$  lepton, large missing transverse momentum, high jet multiplicity and at least three jets identified as originating from  $b$ -quarks. No excess over the expected SM background is observed. Limits are derived in mSUGRA/CMSSM models with  $\tan\beta = 30$ ,  $A_0 = -2 m_0$  and  $\mu > 0$ , see their Fig. 14. Also, exclusion limits are set in simplified models containing scalar bottom quarks, where the decay  $\tilde{b} \rightarrow b\tilde{\chi}_2^0$  and  $\tilde{\chi}_2^0 \rightarrow h\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see their Figures 11.
- <sup>10</sup> AAD 14E searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from  $b$ -quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing bottom, see Fig. 7. Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.
- <sup>11</sup> CHATRCHYAN 14H searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the sbottom mass in a simplified models where the decay  $\tilde{b} \rightarrow t\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, with varying mass of the  $\tilde{\chi}_1^\pm$ , for  $m_{\tilde{\chi}_1^0} = 50 \text{ GeV}$ , see Fig. 6.
- <sup>12</sup> AAD 13AU searched in  $20.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events containing two jets identified as originating from  $b$ -quarks and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks. Assuming that the decay  $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$  takes place 100% of the time, a  $\tilde{b}_1$  mass below 620 GeV is excluded for  $m_{\tilde{\chi}_1^0} < 120 \text{ GeV}$ . For more details, see their Fig. 5.
- <sup>13</sup> CHATRCHYAN 13AT provides interpretations of various searches for supersymmetry by the CMS experiment based on  $4.73\text{--}4.98 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  in the framework of simplified models. Limits are set on the sbottom mass in a simplified models where sbottom quarks are pair-produced and the decay  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 4.
- <sup>14</sup> CHATRCHYAN 13T searched in  $11.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with at least two energetic jets and significant  $\cancel{E}_T$ , using the  $\alpha_T$  variable to discriminate between processes with genuine and misreconstructed  $\cancel{E}_T$ . No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\tilde{b} \rightarrow b\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 8 and Table 9.

## Supersymmetric Particle Searches

- <sup>15</sup> CHATRCHYAN 13v searched in  $10.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two isolated same-sign dileptons and at least two  $b$ -jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the bottom mass in a simplified models where the decay  $\tilde{b} \rightarrow t\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow W^\pm \tilde{\chi}_1^0$  takes place with a branching ratio of 100%, with varying mass of the  $\tilde{\chi}_1^\pm$ , for  $m_{\tilde{\chi}_1^0} = 50 \text{ GeV}$ , see Fig. 4.
- <sup>16</sup> AAD 12AN searched in  $2.05 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for scalar bottom quarks in events with large missing transverse momentum and two  $b$ -jets in the final state. The data are found to be consistent with the Standard Model expectations. Limits are set in an  $R$ -parity conserving minimal supersymmetric scenario, assuming  $B(\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0) = 100\%$ , see their Fig. 2.
- <sup>17</sup> CHATRCHYAN 12Ai looked in  $4.98 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with two same-sign leptons ( $e, \mu$ ), but not necessarily same flavor, at least 2  $b$ -jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in a simplified model for sbottom pair production, where the sbottom decays through  $\tilde{b}_1 \rightarrow t\tilde{\chi}_1 W$ , see Fig. 8.
- <sup>18</sup> CHATRCHYAN 12Bo searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for scalar bottom quarks in events with large missing transverse momentum and two  $b$ -jets in the final state. The data are found to be consistent with the Standard Model expectations. Limits are set in an  $R$ -parity conserving minimal supersymmetric scenario, assuming  $B(\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0) = 100\%$ , see their Fig. 2.
- <sup>19</sup> AAD 11K looked in  $34 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with heavy stable particles, identified by their anomalous  $dE/dx$  in the tracker or time of flight in the tile calorimeter, from pair production of  $\tilde{b}$ . No evidence for an excess over the SM expectation is observed and limits on the mass are derived for pair production of sbottom, see Fig. 4.
- <sup>20</sup> AAD 11o looked in  $35 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with jets, of which at least one is a  $b$ -jet, and  $\cancel{E}_T$ . No excess above the Standard Model was found. Limits are derived in the  $(m_{\tilde{g}}, m_{\tilde{b}_1})$  plane (see Fig. 2) under the assumption of 100% branching ratios and  $\tilde{b}_1$  being the lightest squark. The quoted limit is valid for  $m_{\tilde{b}_1} < 500 \text{ GeV}$ . A similar approach for  $\tilde{t}_1$  as the lightest squark with  $\tilde{g} \rightarrow \tilde{t}_1 t$  and  $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$  with 100% branching ratios leads to a gluino mass limit of  $520 \text{ GeV}$  for  $130 < m_{\tilde{t}_1} < 300 \text{ GeV}$ . Limits are also derived in the CMSSM  $(m_0, m_{1/2})$  plane for  $\tan\beta = 40$ , see Fig. 4, and in scenarios based on the gauge group  $SO(10)$ .
- <sup>21</sup> CHATRCHYAN 11D looked in  $35 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with  $\geq 2$  jets, at least one of which is  $b$ -tagged, and  $\cancel{E}_T$ , where the  $b$ -jets are decay products of  $\tilde{t}$  or  $\tilde{b}$ . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM  $(m_0, m_{1/2})$  plane for  $\tan\beta = 50$  (see Fig. 2).
- <sup>22</sup> AALTONEN 10R searched in  $2.65 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$  for events with  $\cancel{E}_T$  and exactly two jets, at least one of which is  $b$ -tagged. The results are in agreement with the SM prediction, and a limit on the cross section of  $0.1 \text{ pb}$  is obtained for the range of masses  $80 < m_{\tilde{b}_1} < 280 \text{ GeV}$  assuming that the sbottom decays exclusively to  $b\tilde{\chi}_1^0$ . The excluded mass region in the framework of conserved  $R_p$  is shown in a plane of  $(m_{\tilde{b}_1}, m_{\tilde{\chi}_1^0})$ , see their Fig. 2.
- <sup>23</sup> ABZOV 10L looked in  $5.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$  for events with at least 2  $b$ -jets and  $\cancel{E}_T$  from the production of  $\tilde{b}_1 \tilde{b}_1$ . No evidence for an excess over the SM expectation is observed, and a limit on the cross section is derived under the assumption of 100% branching ratio. The excluded mass region in the framework of conserved  $R_p$  is shown in a plane of  $(m_{\tilde{b}_1}, m_{\tilde{\chi}_1^0})$ , see their Fig. 3b. The exclusion also extends to  $m_{\tilde{\chi}_1^0} = 110 \text{ GeV}$  for  $160 < m_{\tilde{b}_1} < 200 \text{ GeV}$ .

### $\tilde{t}$ (Stop) MASS LIMIT

Limits depend on the decay mode. In  $e^+e^-$  collisions they also depend on the mixing angle of the mass eigenstate  $\tilde{t}_1 = \tilde{t}_L \cos\theta_t + \tilde{t}_R \sin\theta_t$ . The coupling to the  $Z$  vanishes when  $\theta_t = 0.98$ . In the Listings below, we use  $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\chi}_1^0}$  or  $\Delta m \equiv m_{\tilde{t}_1} - m_{\tilde{\nu}}$ , depending on relevant decay mode. See also bounds in “ $\tilde{a}$  (Squark) MASS LIMIT.”

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

- <sup>1</sup> AAD 15CJ searched in  $20 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for evidence of third generation squarks by combining a large number of searches covering various final states. Stop decays with and without charginos in the decay chain are considered and summaries of all ATLAS Run 1 searches for direct stop production can be found in Fig. 4 (no intermediate charginos) and Fig. 7 (intermediate charginos). Limits are set on stop masses in compressed mass regions regions, with  $B(\tilde{t} \rightarrow c\tilde{\chi}_1^0) + B(\tilde{t} \rightarrow bff'\tilde{\chi}_1^0) = 1$ , see Fig. 5. Limits are also set on stop masses assuming that both the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  and  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$  are possible, with both their branching ratios summing up to 1, assuming  $\tilde{\chi}_1^\pm \rightarrow W^{(*)}\tilde{\chi}_1^0$  and  $m_{\tilde{\chi}_1^\pm} = 2m_{\tilde{\chi}_1^0}$ , see Fig. 6. Limits on the mass of the next-to-lightest stop  $\tilde{t}_2$ , decaying either to  $Z\tilde{t}_1, h\tilde{t}_1$  or  $t\tilde{\chi}_1^0$ , are also presented, see Figs. 9 and 10. Interpretations in the pMSSM are also discussed, see Figs 13–15.
- <sup>2</sup> AAD 15J interpreted the measurement of spin correlations in  $t\bar{t}$  production using  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  in exclusion limits on the pair production of light  $\tilde{t}_1$  squarks with masses similar to the top quark mass. The  $\tilde{t}_1$  is assumed to decay through  $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$  with predominantly right-handed top and a 100% branching ratio. The data are found to be consistent with the Standard Model expectations and masses between the top quark mass and 191 GeV are excluded, see their Fig. 2.

- <sup>3</sup> KHACHATRYAN 15AF searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least two energetic jets and significant  $E_T$ , using the transverse mass variable  $M_{T2}$  to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 12. See also Table 5. Exclusions in the CMSSM, assuming  $\tan\beta = 30$ ,  $A_0 = -2 \max(m_0, m_{1/2})$  and  $\mu > 0$ , are also presented, see Fig. 15.
- <sup>4</sup> KHACHATRYAN 15AH searched in 19.4 or 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing either a fully reconstructed top quark, or events containing dijets requiring one or both jets to originate from  $b$ -quarks, or events containing a mono-jet. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 9. Limits are also set in simplified models where the decays  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  and  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ , with  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$  GeV, each take place with a branching ratio of 50%, see Fig. 10, or with other fractions, see Fig. 11. Finally, limits are set in a simplified model where the decay  $\tilde{t} \rightarrow c\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Figs. 9, 10 and 11.
- <sup>5</sup> KHACHATRYAN 15AH searched in 19.4 or 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing either a fully reconstructed top quark, or events containing dijets requiring one or both jets to originate from  $b$ -quarks, or events containing a mono-jet. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 9. Limits are also set in simplified models where the decays  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  and  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ , with  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$  GeV, each take place with a branching ratio of 50%, see Fig. 10, or with other fractions, see Fig. 11. Finally, limits are set in a simplified model where the decay  $\tilde{t} \rightarrow c\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Figs. 9, 10, and 11.
- <sup>6</sup> KHACHATRYAN 15L searched in 19.4 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for pair production of heavy resonances decaying to pairs of jets in four jet events. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in  $R$ -parity-violating supersymmetry models where  $\tilde{t} \rightarrow q\bar{q}$  ( $\lambda_{312} \neq 0$ ), see Fig. 6 (top) and  $\tilde{t} \rightarrow q\bar{b}$  ( $\lambda_{323} \neq 0$ ), see Fig. 6 (bottom).
- <sup>7</sup> KHACHATRYAN 15x searched in 19.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least two energetic jets, at least one of which is required to originate from a  $b$  quark, possibly a lepton, and significant  $E_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in simplified models where the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  and the decay  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ , with  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} = 5$  GeV, take place with branching ratios varying between 0 and 100%, see Figs. 15, 16 and 17.
- <sup>8</sup> AAD 14AJ searched in 20.1 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing four or more jets and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which either assume that the decay  $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$  takes place 100% of the time, see Fig. 8, or that this decay takes place 50% of the time, while the decay  $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$  takes place the other 50% of the time, see Fig. 9.
- <sup>9</sup> AAD 14BD searched in 20 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing one isolated lepton, jets and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which either assume that the decay  $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$  takes place 100% of the time, see Fig. 15, or the decay  $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$  takes place 100% of the time, see Fig. 16–22. For the mixed decay scenario, see Fig. 23.
- <sup>10</sup> AAD 14F searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing two leptons ( $e$  or  $\mu$ ), and possibly jets and missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which either assume that the decay  $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$  takes place 100% of the time, see Figs. 14–17 and 20, or that the decay  $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$  takes place 100% of the time, see Figs. 18 and 19.
- <sup>11</sup> AAD 14T searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for monojet-like and  $c$ -tagged events. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks in simplified models which assume that the decay  $\tilde{t}_1 \rightarrow c\tilde{\chi}_1^0$  takes place 100% of the time, see Fig. 9 and 10. The results of the monojet-like analysis are also interpreted in terms of stop pair production in the four-body decay  $\tilde{t}_1 \rightarrow b\bar{t}\bar{t}'\tilde{\chi}_1^0$ , see Fig. 11.
- <sup>12</sup> CHATRCHYAN 14AH searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with at least two energetic jets and significant  $E_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a  $b$ -quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\tilde{t} \rightarrow t\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , are also presented, see Fig. 26.
- <sup>13</sup> CHATRCHYAN 14R searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the stop mass in a natural higgsino NLSP simplified model (GMSB) where the decay  $\tilde{t} \rightarrow b\tilde{\chi}_1^\pm$ , with  $\tilde{\chi}_1^\pm \rightarrow (qq'/\ell\nu)H$ ,  $Z\bar{G}$ , takes place with a branching ratio of 100% (the particles between brackets have a soft  $p_T$  spectrum), see Figs. 4–6.

- <sup>14</sup> KHACHATRYAN 14T searched in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with  $\tau$ -leptons and  $b$ -quark jets, possibly with extra light-flavour jets. No excess above the Standard Model expectations is observed. Limits are set on stop masses in  $R$  SUSY models with  $L\bar{Q}\bar{D}$  couplings, in two simplified models. In the first model, the decay  $\tilde{t} \rightarrow \tau b$  is considered, with  $\lambda_{333} \neq 0$ , see Fig. 3. In the second model, the decay  $\tilde{t} \rightarrow \tilde{\chi}^\pm b$ , with the subsequent decay  $\tilde{\chi}^\pm \rightarrow qq\tau^\pm$  is considered, with  $\lambda'_{3jk} \neq 0$  and the mass splitting between the top squark and the charging chosen to be 100 GeV, see Fig. 4.
- <sup>15</sup> KHACHATRYAN 15E searched for long-lived particles decaying to leptons in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV. Events were selected with an electron and muon with opposite charges and each with transverse impact parameter values between 0.02 and 2 cm. Limits are set on SUSY benchmark models with pair production of top squarks decaying into an  $e\mu$  final state via RPV interactions. See their Fig. 2.
- <sup>16</sup> AAD 14B searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing a  $Z$  boson, with or without additional leptons, plus jets originating from  $b$ -quarks and significant missing transverse momentum. No excess over the expected SM background is observed. Limits are derived in simplified models featuring  $\tilde{t}_2$  production, with  $\tilde{t}_2 \rightarrow Z\tilde{t}_1$ ,  $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$  with a 100% branching ratio, see Fig. 4, and in the framework of natural GMSB, see Fig. 6.
- <sup>17</sup> CHATRCHYAN 14U searched in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for evidence of direct pair production of top squarks, with Higgs bosons in the decay chain. The search is performed using a selection of events containing two Higgs bosons, each decaying to a photon pair, missing transverse energy and possibly  $b$ -quark jets. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of a “natural SUSY” simplified model where the decays  $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$ , with  $\tilde{\chi}_1^\pm \rightarrow f\bar{f}'\tilde{\chi}_1^0$ , and  $\tilde{\chi}_1^0 \rightarrow H\bar{G}$ , all happen with 100% branching ratio, see Fig. 4.
- <sup>18</sup> KHACHATRYAN 14C searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for evidence of direct pair production of top squarks, with Higgs or  $Z$ -bosons in the decay chain. The search is performed using a selection of events containing leptons and  $b$ -quark jets. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in the context of a simplified model with pair production of a heavier top-squark mass eigenstate  $\tilde{t}_2$  decaying to a lighter top-squark eigenstate  $\tilde{t}_1$  via either  $\tilde{t}_2 \rightarrow H\tilde{t}_1$  or  $\tilde{t}_2 \rightarrow Z\tilde{t}_1$ , followed in both cases by  $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$ . The interpretation is performed in the region where the mass difference between the  $\tilde{t}_1$  and  $\tilde{\chi}_1^0$  is approximately equal to the top-quark mass, which is not probed by searches for direct  $\tilde{t}_1$  pair production, see Figs. 5 and 6. The analysis excludes top squarks with masses  $m_{\tilde{t}_2} < 575$  GeV and  $m_{\tilde{t}_1} < 400$  GeV at 95% C.L.

Heavy  $\tilde{g}$  (Gluino) MASS LIMIT

For  $m_{\tilde{g}} > 60$ –70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, et al. (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

- <sup>1</sup> AAD 15BG searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with jets, missing  $E_T$ , and two opposite-sign same flavor isolated leptons featuring either a kinematic edge, or a peak at the Z-boson mass, in the invariant mass spectrum. No evidence for a statistically significant excess over the expected SM backgrounds is observed and 95% C.L. exclusion limits are derived in a GGM simplified model of gluino pair production where the gluino decays into quarks, a Z-boson, and a massless gravitino LSP, see Fig. 12. Also, limits are set in simplified models with slepton/sneutrino intermediate states, see Fig. 13.
- <sup>2</sup> AAD 15bv summarized and extended ATLAS searches for gluinos and first- and second-generation squarks in final states containing jets and missing transverse momentum, with or without leptons or  $b$ -jets in the  $\sqrt{s} = 8$  TeV data set collected in 2012. The paper reports the results of new interpretations and statistical combinations of previously published analyses, as well as new analyses. Exclusion limits at 95% C.L. are set on the gluino mass in several R-parity conserving models, leading to a generalized constraint on gluino masses exceeding 1150 GeV for lightest supersymmetric particle masses below 100 GeV. See their Figs. 10, 19, 20, 21, 23, 25, 26, 29–37.
- <sup>3</sup> AAD 15bx interpreted the results of a wide range of ATLAS direct searches for supersymmetry, during the first run of the LHC using the  $\sqrt{s} = 7$  TeV and  $\sqrt{s} = 8$  TeV data set collected in 2012, within the wider framework of the phenomenological MSSM (pMSSM). The integrated luminosity was up to 20.3 fb<sup>-1</sup>. From an initial random sampling of 500 million pMSSM points, generated from the 19-parameter pMSSM, a total of 310,327 model points with  $\bar{\chi}_1^0$  LSP were selected each of which satisfies constraints from previous collider searches, precision measurements, cold dark matter energy density measurements and direct dark matter searches. The impact of the ATLAS Run 1 searches on this space was presented, considering the fraction of model points surviving, after projection into two-dimensional spaces of sparticle masses. Good complementarity is observed between different ATLAS analyses, with almost all showing regions of unique sensitivity. ATLAS searches have good sensitivity at LSP mass below 800 GeV.
- <sup>4</sup> AAD 15CA searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with one or more photons, hadronic jets or  $b$ -jets and  $E_T$ . No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for bino-like or higgsino-bino admixtures NLSP, see Fig. 8, 10, 11.
- <sup>5</sup> KHACHATRYAN 15AF searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least two energetic jets and significant  $E_T$ , using the transverse mass variable  $M_{T2}$  to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay  $\bar{g} \rightarrow q\bar{q}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 13(a), or where the decay  $\bar{g} \rightarrow b\bar{b}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 13(b), or where the decay  $\bar{g} \rightarrow t\bar{t}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 13(c). See also Table 5. Exclusions in the CMSSM, assuming  $\tan\beta = 30$ ,  $A_0 = -2 \max(m_0, m_{1/2})$  and  $\mu > 0$ , are also presented, see Fig. 15.
- <sup>6</sup> KHACHATRYAN 15i searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events in which  $b$ -jets and four  $W$ -bosons are produced. Five individual search channels are combined (fully hadronic, single lepton, same-sign dilepton, opposite-sign dilepton, multi-lepton). No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a simplified model where the decay  $\bar{g} \rightarrow t\bar{t}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 5. Also a simplified model with gluinos decaying into on-shell top squarks is considered, see Fig. 6.
- <sup>7</sup> KHACHATRYAN 15x searched in 19.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least two energetic jets, at least one of which is required to originate from a  $b$  quark, and significant  $E_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay  $\bar{g} \rightarrow b\bar{b}\bar{\chi}_1^0$  and the decay  $\bar{g} \rightarrow t\bar{t}\bar{\chi}_1^0$  take place with branching ratios varying between 0, 50 and 100%, see Figs. 13 and 14.
- <sup>8</sup> AAD 14AE searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for strongly produced supersymmetric particles in events containing jets and large missing transverse momentum, and no electrons or muons. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figures 5, 6 and 7. Limits are also derived in the mSUGRA/CMSSM with parameters  $\tan\beta = 30$ ,  $A_0 = -2 m_0$  and  $\mu > 0$ , see their Fig. 8.
- <sup>9</sup> AAD 14AG searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing one hadronically decaying  $\tau$ -lepton, zero or one additional light leptons (electrons or muons), jets and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set in several SUSY scenarios. For an interpretation in the minimal GMSB model, see their Fig. 8. For an interpretation in the mSUGRA/CMSSM with parameters  $\tan\beta = 30$ ,  $A_0 = -2 m_0$  and  $\mu > 0$ , see their Fig. 9. For an interpretation in the framework of natural Gauge Mediation, see Fig. 10. For an interpretation in the bRPV scenario, see their Fig. 11.
- <sup>10</sup> AAD 14x searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in an R-parity violating simplified model where the decay  $\bar{g} \rightarrow q\bar{q}\bar{\chi}_1^0$ , with  $\bar{\chi}_1^0 \rightarrow e^\pm e^\mp \nu$ , takes place with a branching ratio of 100%, see Fig. 8.
- <sup>11</sup> AAD 14x searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least four leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a general gauge-mediation model (GGM) where the decay  $\bar{g} \rightarrow q\bar{q}\bar{\chi}_1^0$ , with  $\bar{\chi}_1^0 \rightarrow e^\pm e^\mp \bar{G}$ , takes place with a branching ratio of 100%, for two choices of  $\tan\beta = 1.5$  and 30, see Fig. 11. Also some constraints on the higgsino mass parameter  $\mu$  are discussed.

- <sup>12</sup> CHATRCHYAN 14AH searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with at least two energetic jets and significant  $E_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\bar{g} \rightarrow q\bar{q}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 28. Exclusions in the CMSSM, assuming  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , are also presented, see Fig. 26.
- <sup>13</sup> CHATRCHYAN 14AH searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with at least two energetic jets and significant  $E_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a  $b$ -quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\bar{g} \rightarrow b\bar{b}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , are also presented, see Fig. 26.
- <sup>14</sup> CHATRCHYAN 14AH searched in 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with at least two energetic jets and significant  $E_T$ , using the razor variables ( $M_R$  and  $R^2$ ) to discriminate between signal and background processes. A second analysis requires at least one of the jets to be originating from a  $b$ -quark. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay  $\bar{g} \rightarrow t\bar{t}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Figs. 28 and 29. Exclusions in the CMSSM, assuming  $\tan\beta = 10$ ,  $A_0 = 0$  and  $\mu > 0$ , are also presented, see Fig. 26.
- <sup>15</sup> CHATRCHYAN 14i searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing multijets and large  $E_T$ . No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos that decay via  $\bar{g} \rightarrow q\bar{q}\bar{\chi}_1^0$  with a 100% branching ratio, see Fig. 7b, or via  $\bar{g} \rightarrow t\bar{t}\bar{\chi}_1^0$  with a 100% branching ratio, see Fig. 7c, or via  $\bar{g} \rightarrow q\bar{q}W/Z\bar{\chi}_1^0$ , see Fig. 7d.
- <sup>16</sup> CHATRCHYAN 14N searched in 19.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing a single isolated electron or muon and multiple jets, at least two of which are identified as originating from a  $b$ -quark. No significant excesses over the expected SM backgrounds are observed. The results are interpreted in three simplified models of gluino pair production with subsequent decay into virtual or on-shell top squarks, where each of the top squarks decays in turn into a top quark and a  $\bar{\chi}_1^0$ , see Fig. 4. The models differ in which masses are allowed to vary.
- <sup>17</sup> CHATRCHYAN 14P searched in 19.4 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for three-jet resonances produced in the decay of a gluino in R-parity violating supersymmetric models. No excess over the expected SM background is observed. Assuming a 100% branching ratio for the gluino decay into three light-flavour jets, limits are set on the cross section of gluino pair production, see Fig. 7, and gluino masses below 650 GeV are excluded at 95% C.L. Assuming a 100% branching ratio for the gluino decaying to one  $b$ -quark jet and two light-flavour jets, gluino masses between 200 GeV and 835 GeV are excluded at 95% C.L.
- <sup>18</sup> CHATRCHYAN 14R searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a slepton co-NLSP simplified model (GMSB) where the decay  $\bar{g} \rightarrow q\bar{q}e^\pm e^\mp \bar{G}$  takes place with a branching ratio of 100%, see Fig. 8.
- <sup>19</sup> CHATRCHYAN 14R searched in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with at least three leptons (electrons, muons, taus) in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in a simplified model where the decay  $\bar{g} \rightarrow t\bar{t}\bar{\chi}_1^0$  takes place with a branching ratio of 100%, see Fig. 11.
- <sup>20</sup> AAD 15AB searched for the decay of neutral, weakly interacting, long-lived particles in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV. Signal events require at least two reconstructed vertices possibly originating from long-lived particles decaying to jets in the inner tracking detector and muon spectrometer. No significant excess of events over the expected background was found. Results were interpreted in Stealth SUSY benchmark models where a pair of gluinos decay to long-lived singlinos,  $\tilde{S}$ , which in turn each decay to a low-mass gravitino and a pair of jets. The 95% confidence-level limits are set on the cross section  $\times$  branching ratio for the decay  $\bar{g} \rightarrow \tilde{S}g$ , as a function of the singlino proper lifetime ( $c\tau$ ). See their Fig. 10(f).
- <sup>21</sup> AAD 15Ai searched in 20 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing at least one isolated lepton (electron or muon), jets, and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the gluino mass in the CMSSM/mSUGRA, see Fig. 15, in the NUHM2, see Fig. 16, and in various simplified models, see Figs. 18–22.
- <sup>22</sup> AAD 15CB searched for events containing at least one long-lived particle that decays at a significant distance from its production point (displaced vertex, DV) into two leptons or into five or more charged particles in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The dilepton signature is characterised by DV formed from at least two lepton candidates. Four different final states were considered for the multitrack signature, in which the DV must be accompanied by a high-transverse momentum muon or electron candidate that originates from the DV, jets or missing transverse momentum. No events were observed in any of the signal regions. Results were interpreted in SUSY scenarios involving R-parity violation, split supersymmetry, and gauge mediation. See their Fig. 12–20.
- <sup>23</sup> AAD 15x searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events containing large number of jets, no requirements on missing transverse momentum and no isolated electrons or muons. The sensitivity of the search is enhanced by considering the number of  $b$ -tagged jets and the scalar sum of masses of large-radius jets in an event. No evidence was found for excesses above the expected level of Standard Model background. Exclusion limits at 95% C.L. are set on the gluino mass assuming the gluino decays to various quark flavors, and for various neutralino masses. See their Fig. 11–16.
- <sup>24</sup> KHACHATRYAN 15AD searched in 19.4 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for events with two opposite-sign same flavor isolated leptons featuring either a kinematic edge, or a peak at the Z-boson mass, in the invariant mass spectrum. No evidence for a statistically significant excess over the expected SM backgrounds is observed and 95% C.L. exclusion limits are derived in a simplified model of gluino pair production where the gluino decays into quarks, a Z-boson, and a massless gravitino LSP, see Fig. 9.

# Searches Particle Listings

## Supersymmetric Particle Searches

- <sup>25</sup> KHACHATRYAN 15AZ searched in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with either at least one photon, hadronic jets and  $E_T$  (single photon channel) or with at least two photons and at least one jet and using the razor variables. No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for both a bino-like and wino-like neutralino NLSP scenario, see Fig. 8 and 9.
- <sup>26</sup> AAD 14AX searched in  $20.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for the strong production of supersymmetric particles in events containing either zero or at least one high- $p_T$  lepton, large missing transverse momentum, high jet multiplicity and at least three jets identified as originating from  $b$ -quarks. No excess over the expected SM background is observed. Limits are derived in mSUGRA/CMSSM models with  $\tan\beta = 30$ ,  $A_0 = -2m_0$  and  $\mu > 0$ , see their Fig. 14. Also, exclusion limits in simplified models containing gluinos and scalar top and bottom quarks are set, see their Figures 12, 13.
- <sup>27</sup> AAD 14E searched in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for strongly produced supersymmetric particles in events containing jets and two same-sign leptons or three leptons. The search also utilises jets originating from  $b$ -quarks, missing transverse momentum and other variables. No excess over the expected SM background is observed. Exclusion limits are derived in simplified models containing gluinos and squarks, see Figures 5 and 6. In the  $\tilde{g} \rightarrow qq'\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow W^{(*)}\pm\tilde{\chi}_2^0, \tilde{\chi}_2^0 \rightarrow Z^{(*)}\tilde{\chi}_1^0$  simplified model, the following assumptions have been made:  $m_{\tilde{\chi}_1^\pm} = 0.5 m_{\tilde{\chi}_1^0} + m_{\tilde{g}}, m_{\tilde{\chi}_2^0} = 0.5 (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_1^\pm}), m_{\tilde{\chi}_1^0} < 520 \text{ GeV}$ . In the  $\tilde{g} \rightarrow qq'\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow t\bar{t}\nu\tilde{\chi}_1^0$  or  $\tilde{g} \rightarrow qq'\tilde{\chi}_2^0, \tilde{\chi}_2^0 \rightarrow t\bar{t}\ell^+\ell^-(\nu\nu)\tilde{\chi}_1^0$  simplified model, the following assumptions have been made:  $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0} = 0.5 (m_{\tilde{\chi}_1^0} + m_{\tilde{g}}), m_{\tilde{\chi}_1^0} < 660 \text{ GeV}$ . Limits are also derived in the mSUGRA/CMSSM, bRPV and GMSB models, see their Fig. 8.
- <sup>28</sup> CHATRCHYAN 14H searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay  $\tilde{g} \rightarrow t\bar{t}\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, or where the decay  $\tilde{g} \rightarrow \tilde{t}\bar{t}, \tilde{t} \rightarrow t\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, with varying mass of the  $\tilde{\chi}_1^0$ , or where the decay  $\tilde{g} \rightarrow b\bar{b}, \tilde{b} \rightarrow t\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, with varying mass of the  $\tilde{\chi}_1^\pm$ , see Fig. 5.
- <sup>29</sup> CHATRCHYAN 14H searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay  $\tilde{g} \rightarrow qq'\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, with varying mass of the  $\tilde{\chi}_1^\pm$  and  $\tilde{\chi}_1^0$ , see Fig. 7.
- <sup>30</sup> CHATRCHYAN 14H searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay  $\tilde{g} \rightarrow b\bar{t}\tilde{\chi}_1^\pm, \tilde{\chi}_1^\pm \rightarrow W^\pm\tilde{\chi}_1^0$  takes place with a branching ratio of 100%, for two choices of  $m_{\tilde{\chi}_1^\pm}$  and fixed  $m_{\tilde{\chi}_1^0}$ , see Fig. 6.
- <sup>31</sup> CHATRCHYAN 14H searched in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with two isolated same-sign dileptons and jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the R-parity violating decay  $\tilde{g} \rightarrow tbs$  takes place with a branching ratio of 100%, see Fig. 8.

### Long-lived/light $\tilde{g}$ (Gluino) MASS LIMIT

Limits on light gluinos ( $m_{\tilde{g}} < 5 \text{ GeV}$ ), or gluinos which leave the detector before decaying.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, *et al.* (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

<sup>1</sup> AAD 15AE searched in  $19.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for heavy long-lived charged particles, measured through their specific ionization energy loss in the ATLAS pixel detector or their time-of-flight in the ATLAS muon system. In the absence of an excess of events above the expected backgrounds, limits are set R-hadrons in various scenarios, see Fig. 11. Limits are also set in LeptoSUSY models where the gluino decays to stable 300 GeV leptons, see Fig. 9.

<sup>2</sup> AAD 15BM searched in  $18.4 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for stable and metastable non-relativistic charged particles through their anomalous specific ionization energy loss in the ATLAS pixel detector. In absence of an excess of events above the expected backgrounds, limits are set within a generic R-hadron model, on stable gluino R-hadrons (see Table 5) and on metastable gluino R-hadrons decaying to  $(g/q\bar{q})$  plus a light  $\tilde{\chi}_1^0$  (see Fig. 7) and decaying to  $t\bar{t}$  plus a light  $\tilde{\chi}_1^0$  (see Fig. 9).

<sup>3</sup> KHACHATRYAN 15AK looked in a data set corresponding to  $18.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$ , and a search interval corresponding to 281 h of trigger lifetime, for long-lived particles that have stopped in the CMS detector. No evidence for an excess over the expected background in a cloud interaction model is observed. Assuming the decay  $\tilde{g} \rightarrow g\tilde{\chi}_1^0$  and lifetimes between 1  $\mu\text{s}$  and 1000 s, limits are derived on  $\tilde{g}$  production as a function of  $m_{\tilde{\chi}_1^0}$ , see Figs. 4 and 6. The exclusions require that  $m_{\tilde{\chi}_1^0}$  is kinematically consistent with the minimum values of the jet energy thresholds used.

<sup>4</sup> AAD 13AA searched in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a  $\tilde{g}$  are excluded for masses up to 985 GeV at 95% C.L. in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

<sup>5</sup> AAD 13BC searched in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  and in  $22.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on gluino masses for different decays, lifetimes, and neutralino masses, see their Table 6 and Fig. 10.

<sup>6</sup> CHATRCHYAN 13AB looked in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  and in  $18.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of  $\tilde{g}$ 's. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 8 and Table 5), depending on the fraction,  $f$ , of formation of  $\tilde{g}$ - $\tilde{g}$  (R-gluonball) states. The quoted limit is for  $f = 0.1$ , while for  $f = 0.5$  it degrades to 1276 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 928 GeV for  $f = 0.1$ .

<sup>7</sup> AAD 12P looked in  $31 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via  $\tilde{g} \rightarrow g\tilde{\chi}_1^0$  during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of  $m_{\tilde{g}}$  is derived for  $m_{\tilde{\chi}_1^0} = 100 \text{ GeV}$ , see Fig. 4. The limit is valid for lifetimes between  $10^{-5}$  and  $10^3$  seconds and assumes the Generic matter interaction model for the production cross section.

<sup>8</sup> CHATRCHYAN 12AN looked in  $4.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via  $\tilde{g} \rightarrow g\tilde{\chi}_1^0$  during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of  $m_{\tilde{g}}$  is derived, see Fig. 3. The mass limit is valid for lifetimes between  $10^{-5}$  and  $10^3$  seconds, for what they call "the daughter gluon energy  $E_g > 100 \text{ GeV}$  and assuming the cloud interaction model for R-hadrons. Supersedes KHACHATRYAN 11.

<sup>9</sup> CHATRCHYAN 12L looked in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of  $\tilde{g}$ 's. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction,  $f$ , of formation of  $\tilde{g}$ - $\tilde{g}$  (R-gluonball) states. The quoted limit is for  $f = 0.1$ , while for  $f = 0.5$  it degrades to 1046 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 928 GeV for  $f = 0.1$ . Supersedes KHACHATRYAN 11C.

<sup>10</sup> AAD 11K looked in  $34 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of  $\tilde{g}$ . No evidence for an excess over the SM expectation is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 4), for a fraction,  $f = 10\%$ , of formation of  $\tilde{g}$ - $\tilde{g}$  (R-gluonball). If instead of a phase space driven approach for the hadronic scattering of the R-hadrons,

a triple-Regge model or a bag-model is used, the limit degrades to 566 and 562 GeV, respectively.

- <sup>11</sup> AAD 11P looked in 37 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with heavy stable particles, reconstructed and identified by their time of flight in the Muon System. There is no requirement on their observation in the tracker to increase the sensitivity to cases where gluinos have a large fraction,  $f$ , of formation of neutral  $\tilde{g} - g$  (R-gluonball). No evidence for an excess over the SM expectation is observed. Limits are derived as a function of mass (see Fig. 4), for  $f=0.1$ . For fractions  $f = 0.5$  and 1.0 the limit degrades to 537 and 530 GeV, respectively.

- <sup>12</sup> KHACHATRYAN 11 looked in 10 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via  $\tilde{g} \rightarrow g \chi_1^0$  during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section times branching ratio is derived for  $m_{\tilde{g}} - m_{\chi_1^0} > 100$  GeV, see their Fig. 2. Assuming 100% branching

ratio, lifetimes between 75 ns and  $3 \times 10^5$  s are excluded for  $m_{\tilde{g}} = 300$  GeV. The  $\tilde{g}$  mass exclusion is obtained with the same assumptions for lifetimes between 10  $\mu$ s and 1000 s, but shows some dependence on the model for R-hadron interactions with matter, illustrated in Fig. 3. From a time-profile analysis, the mass exclusion is 382 GeV for a lifetime of 10  $\mu$ s under the same assumptions as above.

- <sup>13</sup> KHACHATRYAN 11C looked in 3.1 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of  $\tilde{g}$ . No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction,  $f$ , of formation of  $\tilde{g} - g$  (R-gluonball). The quoted limit is for  $f=0.1$ , while for  $f=0.5$  it degrades to 357 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 311 GeV for  $f=0.1$ .

### LIGHT $\tilde{G}$ (Gravitino) MASS LIMITS FROM COLLIDER EXPERIMENTS

The following are bounds on light ( $< 1$  eV) gravitino indirectly inferred from its coupling to matter suppressed by the gravitino decay constant.

Unless otherwise stated, all limits assume that other supersymmetric particles besides the gravitino are too heavy to be produced. The gravitino is assumed to be undetected and to give rise to a missing energy ( $\cancel{E}$ ) signature.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, et al. (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

$> 1.3 \times 10^{-5}$		<sup>4</sup> HEISTER	03C ALEP	$e^+e^- \rightarrow \tilde{G} \tilde{G} \gamma$
$> 11.7 \times 10^{-6}$	95	<sup>5</sup> ACOSTA	02H CDF	$p\bar{p} \rightarrow \tilde{G} \tilde{G} \gamma$
$> 8.7 \times 10^{-6}$	95	<sup>6</sup> ABBIENDI,G	00D OPAL	$e^+e^- \rightarrow \tilde{G} \tilde{G} \gamma$

- <sup>1</sup> AAD 15BH searched in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 8$  TeV for associated production of a light gravitino and a squark or gluino. The squark (gluino) is assumed to decay exclusively to a quark (gluon) and a gravitino. No evidence was found for an excess above the expected level of Standard Model background and 95% C.L. lower limits were set on the gravitino mass as a function of the squark/gluino mass, both in the case of degenerate and non-degenerate squark/gluino masses, see Figs. 14 and 15.

- <sup>2</sup> ABDALLAH 05B use data from  $\sqrt{s} = 180$ –208 GeV. They look for events with a single photon +  $\cancel{E}$  final states from which a cross section limit of  $\sigma < 0.18$  pb at 208 GeV is obtained, allowing a limit on the mass to be set. Supersedes the results of ABREU 00Z.

- <sup>3</sup> ACHARD 04E use data from  $\sqrt{s} = 189$ –209 GeV. They look for events with a single photon +  $\cancel{E}$  final states from which a limit on the Gravitino mass is set corresponding to  $\sqrt{\mathcal{F}} > 238$  GeV. Supersedes the results of ACCIARRI 99R.

- <sup>4</sup> HEISTER 03C use the data from  $\sqrt{s} = 189$ –209 GeV to search for  $\gamma \cancel{E}_T$  final states.

- <sup>5</sup> ACOSTA 02H looked in 87 pb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV for events with a high- $E_T$  photon and  $\cancel{E}_T$ . They compared the data with a GMSB model where the final state could arise from  $q\bar{q} \rightarrow \tilde{G} \tilde{G} \gamma$ . Since the cross section for this process scales as  $1/|F|^4$ , a limit at 95% CL is derived on  $|F|^{1/2} > 221$  GeV. A model independent limit for the above topology is also given in the paper.

- <sup>6</sup> ABBIENDI,G 00D searches for  $\gamma \cancel{E}$  final states from  $\sqrt{s}=189$  GeV.

### Supersymmetry Miscellaneous Results

Results that do not appear under other headings or that make nonminimal assumptions.

Some earlier papers are now obsolete and have been omitted. They were last listed in our PDG 14 edition: K. Olive, et al. (Particle Data Group), Chinese Physics C **38** 070001 (2014) (<http://pdg.lbl.gov>).

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
		<sup>1</sup> AAD	13P ATLS	dark $\gamma$ , hidden valley
		<sup>2</sup> AALTONEN	12AB CDF	hidden-valley Higgs
none 100–185	95	<sup>3</sup> AAD	11AA ATLS	scalar gluons
		<sup>4</sup> CHATRCHYAN 11E	CMS	$\mu\mu$ resonances
		<sup>5</sup> ABAZOV	10N D0	$\gamma_D$ , hidden valley

- <sup>1</sup> AAD 13P searched in 5 fb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for single lepton-jets with at least four muons; pairs of lepton-jets, each with two or more muons; and pairs of lepton-jets with two or more electrons. All of these could be signatures of Hidden Valley supersymmetric models. No statistically significant deviations from the Standard Model expectations are found. 95% C.L. limits are placed on the production cross section times branching ratio of dark photons for several parameter sets of a Hidden Valley model.

- <sup>2</sup> AALTONEN 12AB looked in 5.1 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for anomalous production of multiple low-energy leptons in association with a  $W$  or  $Z$  boson. Such events may occur in hidden valley models in which a supersymmetric Higgs boson is produced in association with a  $W$  or  $Z$  boson, with  $H \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0$  pair and with the  $\tilde{\chi}_1^0$  further decaying into a dark photon ( $\gamma_D$ ) and the unobservable lightest SUSY particle of the hidden sector. As the  $\gamma_D$  is expected to be light, it may decay into a lepton pair. No significant excess over the SM expectation is observed and a limit at 95% C.L. is set on the cross section for a benchmark model of supersymmetric hidden-valley Higgs production.

- <sup>3</sup> AAD 11AA looked in 34 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with  $\geq 4$  jets originating from pair production of scalar gluons, each decaying to two gluons. No two-jet resonances are observed over the SM background. Limits are derived on the cross section times branching ratio (see Fig. 3). Assuming 100% branching ratio for the decay to two gluons, the quoted exclusion range is obtained, except for a 5 GeV mass window around 140 GeV.

- <sup>4</sup> CHATRCHYAN 11E looked in 35 pb<sup>-1</sup> of  $pp$  collisions at  $\sqrt{s} = 7$  TeV for events with collimated  $\mu$  pairs (leptonic jets) from the decay of hidden sector states. No evidence for new resonance production is found. Limits are derived and compared to various SUSY models (see Fig. 4) where the LSP, either the  $\tilde{\chi}_1^0$  or a  $\tilde{q}$ , decays to dark sector particles.

- <sup>5</sup> ABAZOV 10N looked in 5.8 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV for events from hidden valley models in which a  $\tilde{\chi}_1^0$  decays into a dark photon,  $\gamma_D$ , and the unobservable lightest SUSY particle of the hidden sector. As the  $\gamma_D$  is expected to be light, it may decay into a tightly collimated lepton pair, called lepton jet. They searched for events with  $\cancel{E}_T$  and two isolated lepton jets observable by an opposite charged lepton pair  $e e$ ,  $e \mu$  or  $\mu \mu$ . No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Table I. They also examined the invariant mass of the lepton jets for a narrow resonance, see their Fig. 4, but found no evidence for a signal.

**Technicolor****DYNAMICAL ELECTROWEAK SYMMETRY BREAKING: IMPLICATIONS OF THE  $H^0$** 

Updated October 2015 by R.S. Chivukula (Michigan State University), M. Narain (Brown University), and J. Womersley (STFC, Rutherford Appleton Laboratory).

**1. Introduction and Phenomenology**

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a composite operator, typically a fermion bilinear. In these theories, the longitudinal components of the massive weak bosons are identified with composite Nambu-Goldstone bosons arising from dynamical symmetry breaking in a strongly-coupled extension of the standard model. Viable theories of dynamical electroweak symmetry breaking must also explain (or at least accommodate) the presence of an additional composite scalar state to be identified with the  $H^0$  scalar boson [1,2] – a state unlike any other observed to date.

Theories of dynamical electroweak symmetry breaking can be classified by the nature of the composite singlet state to be associated with the  $H^0$ , and the corresponding dimensional scales  $f$ , the analog of the pion decay-constant in QCD, and  $\Lambda$ , the scale of the underlying strong dynamics.<sup>1</sup> Of particular importance is the ratio  $v/f$ , where  $v^2 = 1/(\sqrt{2}G_F) \approx (246 \text{ GeV})^2$ , since this ratio measures the expected size of the deviations of the couplings of a composite Higgs boson from those expected in the standard model. The basic possibilities, and the additional states that they predict, are described below.

**1.1 Technicolor,  $v/f \simeq 1$ ,  $\Lambda \simeq 1 \text{ TeV}$ :**

Technicolor models [8–10] incorporate a new asymptotically free gauge theory (“technicolor”) and additional massless fermions (“technifermions”) transforming under a vectorial representation of the gauge group). The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral symmetry in QCD is broken down to isospin by the formation of a quark condensate. The  $SU(2)_W \times U(1)_Y$  interactions are embedded in the global technifermion chiral symmetries in such a way that the only unbroken gauge symmetry after chiral symmetry breaking is  $U(1)_{em}$ .<sup>2</sup> These theories naturally provide the Nambu-Goldstone bosons “eaten” by the  $W$  and  $Z$  boson. There would also typically be additional heavy states (e.g. vector mesons, analogous to the  $\rho$  and  $\omega$  mesons in QCD) with TeV masses [14,15], and the  $WW$  and  $ZZ$  scattering amplitudes would be expected to be strong at energies of order 1 TeV.

<sup>1</sup> In a strongly interacting theory “Naive Dimensional Analysis” [3,4] implies that, in the absence of fine-tuning,  $\Lambda \simeq g^* f$  where  $g^* \simeq 4\pi$  is the typical size of a strong coupling in the low-energy theory [5,6]. This estimate is modified in the presence of multiple flavors or colors [7].

<sup>2</sup> For a review of technicolor models, see [11–13].

## Technicolor

There are various possibilities for the scalar  $H^0$  in technicolor models, as described below.<sup>3</sup> In all of these cases, however, to the extent that the  $H^0$  has couplings consistent with those of the standard model, these theories are very highly constrained.

- a)  **$H^0$  as a singlet scalar resonance:** The strongly-interacting fermions which make up the Nambu-Goldstone bosons eaten by the weak bosons would naturally be expected to also form an isoscalar neutral bound state, analogous to the  $\sigma$  particle expected in pion-scattering in QCD [16]. However, in this case, there is no symmetry protecting the mass of such a particle – which would therefore generically be of order the energy scale of the underlying strong dynamics  $\Lambda$ . In the simplest theories of this kind – those with a global  $SU(2)_L \times SU(2)_R$  chiral symmetry which is spontaneously broken to  $SU(2)_V$  – the natural dynamical scale  $\Lambda$  would be of order a TeV, resulting in a particle too heavy and broad to be identified with the  $H^0$ . The scale of the underlying interactions could naturally be smaller than 1 TeV if the global symmetries of the theory are larger than  $SU(2)_L \times SU(2)_R$ , but in this case there would be additional (pseudo-)Nambu-Goldstone bosons (more on this below). A theory of this kind would only be viable, therefore, if some choice of the parameters of the high energy theory could give rise to sufficiently light state without the appearance of additional particles that should have already been observed. Furthermore, while a particle with these quantum numbers could have Higgs-like couplings to any electrically neutral spin-zero state made of quarks, leptons, or gauge-bosons, there is no symmetry insuring that the coupling strengths of such a composite singlet scalar state would be precisely the same as those of the standard model Higgs [17].
- b)  **$H^0$  as a dilaton:** It is possible that the underlying strong dynamics is approximately scale-invariant, as inspired by theories of “walking technicolor” [18–22], and that both the scale and electroweak symmetries are spontaneously broken at the TeV energy scale [23]. In this case, due to the spontaneous breaking of approximate scale invariance, one might expect a corresponding (pseudo-) Nambu-Goldstone boson [19] with a mass less than a TeV, the dilaton.<sup>4</sup> A dilaton couples to the trace of the energy momentum tensor, which leads to a similar pattern of two-body couplings as the couplings of the standard model Higgs boson [28–30]. Scale-invariance is a space-time symmetry, however, and is unrelated to the global symmetries that we can identify with the electroweak group. Therefore the

<sup>3</sup> In these models, the self-coupling of the  $H^0$  scalar is not related to its mass, as it is in the SM – though there are currently no experimental constraints on this coupling.

<sup>4</sup> Even in this case, however, a dilaton associated with electroweak symmetry breaking will likely not *generically* be as light as the  $H^0$  [24–27].

decay-constants associated with the breaking of the scale and electroweak symmetries will not, in general, be the same.<sup>5</sup> In other words, if there are no large anomalous dimensions associated with the  $W$ - and  $Z$ -bosons or the top- or bottom-quarks, the ratios of the couplings of the dilaton to these particles would be the same as the ratios of the same couplings for the standard model Higgs boson, but the overall strength of the dilaton couplings would be expected to be different [31,32]. Furthermore, the couplings of the dilaton to gluon- and photon-pairs can be related to the beta functions of the corresponding gauge interactions in the underlying high-energy theory, and will not in general yield couplings with the exactly the same strengths as the standard model [33,34].

- c)  **$H^0$  as a singlet Pseudo-Nambu-Goldstone Boson:** If the global symmetries of the technicolor theory are larger than  $SU(2)_L \times SU(2)_R$ , there can be extra singlet (pseudo-) Nambu-Goldstone bosons which could be identified with the  $H^0$ . In this case, however, the coupling strength of the singlet state to  $WW$  and  $ZZ$  pairs would be comparable to the couplings to gluon and photon pairs, and these would all arise from loop-level couplings in the underlying technicolor theory [35]. This pattern of couplings is not supported by the data.

### 1.2 The Higgs doublet as a pseudo-Nambu-Goldstone Boson, $v/f < 1$ , $\Lambda > 1$ TeV:

In technicolor models, the symmetry-breaking properties of the underlying strong dynamics necessarily breaks the electroweak gauge symmetries. An alternative possibility is that the underlying strong dynamics itself does not break the electroweak interactions, and that the entire quartet of bosons in the Higgs doublet (including the state associated with the  $H^0$ ) are composite (pseudo-) Nambu-Goldstone particles [36,37]. In this case, the underlying dynamics can occur at energies larger than 1 TeV and additional interactions with the top-quark mass generating sector (and possibly with additional weakly-coupled gauge bosons) cause the vacuum energy to be minimized when the composite Higgs doublet gains a vacuum expectation value [38,39]. In these theories, the couplings of the remaining singlet scalar state would naturally be equal to that of the standard model Higgs boson up to corrections of order  $(v/f)^2$  and, therefore, constraints on the size of deviations of the  $H^0$  couplings from that of the standard model Higgs give rise to lower bounds on the scales  $f$  and  $\Lambda$ .<sup>6</sup>

<sup>5</sup> If both the electroweak symmetry and the approximate scale symmetry are broken only by electroweak doublet condensate(s), then the decay-constants for scale and electroweak symmetry breaking may be approximately equal – differing only by terms formally proportional to the amount of explicit scale-symmetry breaking.

<sup>6</sup> In these models  $v/f$  is an adjustable parameter, and in the limit  $v/f \rightarrow 1$  they reduce, essentially, to the technicolor models discussed in the previous subsection. Our discussion here is

See key on page 601

The electroweak gauge interactions, as well as the interactions responsible for the top-quark mass, explicitly break the chiral symmetries of the composite Higgs model, and lead generically to sizable corrections to the mass-squared of the Higgs-doublet – the so-called “Little Hierarchy Problem” [40]. “Little Higgs” theories [41–44] are examples of composite Higgs models in which the (collective) symmetry-breaking structure is selected so as to suppress these contributions to the Higgs mass-squared.

Composite Higgs models typically require a larger global symmetry of the underlying theory, and hence additional relatively light (compared to  $\Lambda$ ) scalar particles, extra electroweak vector bosons (e.g. an additional  $SU(2) \times U(1)$  gauge group), and vector-like partners of the top-quark of charge  $+2/3$  and possibly also  $+5/3$  [45]. Finally, in addition to these states, one would expect the underlying dynamics to yield additional scalar and vector resonances with masses of order  $\Lambda$ . If the theory respects a custodial symmetry [46], the couplings of these additional states to the electroweak and Higgs boson will be related – and, for example, one might expect a charged vector resonance to have similar branching ratios to  $WZ$  and  $WH$ . Different composite Higgs models utilize different mechanisms for arranging for the hierarchy of scales  $v < f$  and arranging for a scalar Higgs self-coupling small enough to produce an  $H^0$  of mass of order 125 GeV, for a review see [48].

### 1.3 Top-Condensate, Top-Color, Top-Seesaw and related theories, $v/f < 1$ , $\Lambda > 1$ TeV:

A final alternative is to consider a strongly interacting theory with a high (compared to a TeV) underlying dynamical scale that *would* naturally break the electroweak interactions, but whose strength is adjusted (“fine-tuned”) to produce electroweak symmetry breaking at 1 TeV. This alternative is possible if the electroweak (quantum) phase transition is continuous (second order) in the strength of the strong dynamics [47]. If the fine tuning can be achieved, the underlying strong interactions will produce a light composite Higgs bound state with couplings equal to that of the standard model Higgs boson up to corrections of order  $(1 \text{ TeV}/\Lambda)^2$ . As in theories in which electroweak symmetry breaking occurs through vacuum alignment, therefore, constraints on the size of deviations of the  $H^0$  couplings from that of the standard model Higgs give rise to lower bounds on the scale  $\Lambda$ . Formally, in the limit  $\Lambda \rightarrow \infty$  (a limit which requires arbitrarily fine adjustment of the strength of the high-energy interactions), these theories are equivalent to a theory with a fundamental Higgs boson – and the fine adjustment of the coupling strength is a manifestation of the hierarchy problem of theories with a fundamental scalar particle.

In many of these theories the top-quark itself interacts strongly (at high energies), potentially through an extended consistent with that given there, since we expect corrections to the SM Higgs couplings to be large for  $v/f \simeq 1$ .

color gauge sector [49–53]. In these theories, top-quark condensation (or the condensation of an admixture of the top with additional vector-like quarks) is responsible for electroweak symmetry breaking, and the  $H^0$  is identified with a bound state involving the third generation of quarks. These theories typically include an extra set of massive color-octet vector bosons (top-gluons), and an extra  $U(1)$  interaction (giving rise to a top-color  $Z'$ ) which couple preferentially to the third generation and whose masses define the scale  $\Lambda$  of the underlying physics.

### 1.4 Flavor

In addition to the electroweak symmetry breaking dynamics described above, which gives rise to the masses of the  $W$  and  $Z$  particles, additional interactions must be introduced to produce the masses of the standard model fermions. Two general avenues have been suggested for these new interactions. In one case, e.g. “extended technicolor” (ETC) theories [54,55], the gauge interactions in the underlying strongly interacting theory are extended to incorporate flavor. This extended gauge symmetry is broken down (possibly sequentially, at several different mass scales) to the residual strongly-interacting interaction responsible for electroweak symmetry breaking. The massive gauge-bosons corresponding to the broken symmetries then mediate interactions between mass operators for the quarks/leptons and the corresponding bilinears of the strongly-interacting fermions, giving rise to the masses of the ordinary fermions after electroweak symmetry breaking. An alternative proposal, “partial compositeness” [56], the additional interactions giving rise to mixing between the ordinary quarks and leptons and massive composite fermions in the strongly-interacting underlying theory. Theories incorporating partial compositeness include additional vector-like partners of the ordinary quarks and leptons, typically with masses of order a TeV or less.

In both cases, the effects of these flavor interactions on the electroweak properties of the ordinary quarks and leptons are likely to be most pronounced in the third generation of fermions.<sup>7</sup> The additional particles present, especially the additional scalars, often couple more strongly to heavier fermions.

Moreover, since the flavor interactions must give rise to quark mixing, we expect that a generic theory of this kind could give rise to large flavor-changing neutral-currents [55]. In ETC theories, these constraints are typically somewhat relaxed if the theory incorporates approximate generational flavor symmetries [57], the theory “walks” [18–22], or if  $\Lambda > 1$  TeV [58]. In theories of partial compositeness, the masses of the ordinary fermions depend on the scaling-dimension of the operators corresponding to the composite fermions with which they mix. This leads to a new mechanism for generating the

<sup>7</sup> Indeed, from this point of view, the vector-like partners of the top-quark in top-seesaw and little Higgs models can be viewed as incorporating partial compositeness to explain the origin of the top quark’s large mass.

## Technicolor

mass-hierarchy of the observed quarks and leptons that, potentially, ameliorates flavor-changing neutral current problems and can provide new contributions to the composite Higgs potential which allows for  $v/f < 1$  [59–63].

Alternatively, one can assume that the underlying flavor dynamics respects flavor symmetries (“minimal” [64,65] or “next-to-minimal” [66] flavor violation) which suppress flavor-changing neutral currents in the two light generations. Additional considerations apply when extending these considerations to potential explanation of neutrino masses (see, for example, [67,68]).

Since the underlying high-energy dynamics in these theories are strongly coupled, there are no reliable calculation techniques that can be applied to analyze their properties. Instead, most phenomenological studies depend on the construction of a “low-energy” effective theory describing additional scalar, fermion, or vector boson degrees of freedom, which incorporates the relevant symmetries and, when available, dynamical principles. In some cases, motivated by the AdS/CFT correspondence [69], the strongly-interacting theories described above have been investigated by analyzing a dual compactified five-dimensional gauge theory. In these cases, the AdS/CFT “dictionary” is used to map the features of the underlying strongly coupled high-energy dynamics onto the low-energy weakly coupled dual theory [70].

More recently, progress has been made in investigating strongly-coupled models using lattice gauge theory [71–73]. These calculations offer the prospect of establishing which strongly coupled theories of electroweak symmetry breaking have a particle with properties consistent with those observed for the  $H^0$  – and for establishing concrete predictions for these theories at the LHC [74].

## 2. Experimental Searches

As discussed above, the extent to which the couplings of the  $H^0$  conform to the expectations for a standard model Higgs boson constrains the viability of each of these models. Measurements of the  $H^0$  couplings, and their interpretation in terms of effective field theory, are summarized in the  $H^0$  review in this volume. In what follows, we will focus on searches for the additional particles that might be expected to accompany the singlet scalar: extra scalars, fermions, and vector bosons. In some cases, detailed model-specific searches have been made for the particles described above (though generally not yet taking account of the demonstrated existence of the  $H^0$  boson).

In most cases, however, generic searches (e.g. for extra  $W'$  or  $Z'$  particles, extra scalars in the context of multi-Higgs models, or for fourth-generation quarks) are quoted that can be used – when appropriately translated – to derive bounds on a specific model of interest.

The mass scale of the new particles implied by the interpretations of the low mass of  $H^0$  discussed above, and existing studies from the Tevatron and lower-energy colliders, suggests that only the Large Hadron Collider has any real sensitivity.

A number of analyses already carried out by ATLAS and CMS use relevant final states and might have been expected to observe a deviation from standard model expectations – in no case so far has any such deviation been reported. The detailed implications of these searches in various model frameworks are described below.

Except where otherwise noted, all limits in this section are quoted at a confidence level of 95%. The ATLAS searches have analyzed  $20.3 \text{ fb}^{-1}$  of data recorded at the LHC with  $\sqrt{s}=8 \text{ TeV}$ , and the CMS analyses are based on the data collected at  $\sqrt{s} = 8 \text{ TeV}$  in 2012 with an integrated luminosity of  $19.7 \text{ fb}^{-1}$ .

### 2.1 Searches for $Z'$ or $W'$ Bosons

Massive vector bosons or particles with similar decay channels would be expected to arise in Little Higgs theories, in theories of Technicolor, or models involving a dilaton, adjusted to produce a light Higgs boson, consistent with the observed  $H^0$ . These particles would be expected to decay to pairs of vector bosons, to third generation quarks, or to leptons. The generic searches for  $W'$  and  $Z'$  vector bosons listed below can, therefore, be used to constrain models incorporating a composite Higgs-like boson.

#### $Z' \rightarrow \ell\ell$ :

ATLAS [76] and CMS [77] have both searched for  $Z'$  production with  $Z' \rightarrow ee$  or  $\mu\mu$ . The main backgrounds to these analyses arise from Drell-Yan,  $t\bar{t}$ , and diboson production and are estimated using Monte Carlo simulation, with the cross sections scaled by next-to-next-to-leading-order  $k$ -factors. Instrumental backgrounds from QCD multijet and  $W$ +jet events are estimated using control data samples. No deviation from the standard model prediction is seen in the dielectron and dimuon invariant mass spectra, by either the ATLAS or the CMS analysis, and lower limits on possible  $Z'$  boson masses are set. The dielectron channel has higher sensitivity due to the superior mass resolution compared to the dimuon channel. A  $Z'_{\text{SSM}}$  with couplings equal to the standard model  $Z$  (a “sequential standard model”  $Z'$ ) and a mass below 2.79 TeV is excluded by ATLAS, while CMS sets a lower mass limit of 2.90 TeV. The ATLAS analysis rules out various  $E6$ -motivated bosons ( $Z'_\psi, Z'_\chi$ ) and  $Z^*$  with masses lower than 2.51, 2.62 and 2.85 TeV, while a  $Z'_\psi$  with a mass below 2.57 TeV is excluded by CMS. The experiments also place limits on the parameters of extra dimension models and in the case of ATLAS on the parameters of a minimal walking technicolor model [18–22], consistent with a 125 GeV Higgs boson.

In addition, both experiments have also searched for  $Z'$  decaying to a ditau final state [78,79]. While less sensitive than dielectron or dimuon final states, an excess in  $\tau^+\tau^-$  could have interesting implications for models in which lepton universality is not a necessary requirement and enhanced couplings to the third generation are allowed. This analysis leads to lower limits on the mass of a  $Z'_{\text{SSM}}$  of 2.0 and 1.3 TeV from ATLAS and CMS respectively.

$Z' \rightarrow q\bar{q}$ :

The ability to relatively cleanly select  $t\bar{t}$  pairs at the LHC together with the existence of enhanced couplings to the third generation in many models makes it worthwhile to search for new particles decaying in this channel. Both ATLAS [80] and CMS [81] have carried out searches for new particles decaying into  $t\bar{t}$ . ATLAS focuses on the lepton plus jets final state, where the top quark pair decays as  $t\bar{t} \rightarrow WbWb$  with one  $W$  boson decaying leptonically and the other hadronically; CMS uses final states where both, one or neither  $W$  decays leptonically and then combines the results. The  $t\bar{t}$  invariant mass spectrum is analyzed for any excess, and no evidence for any resonance is seen. ATLAS excludes a narrow ( $\Gamma/m = 1.2\%$ ) leptophobic top-color  $Z'$  boson with a mass below 1.8 TeV; upper limits are set on the cross section times branching ratio for a broad color octet resonance with  $\Gamma/m = 15\%$  decaying to  $t\bar{t}$  which range from 4.8 pb for  $m = 0.4$  TeV to 0.09 pb for  $m = 3.0$  TeV. CMS sets limits on a narrow ( $\Gamma/m = 1.2\%$ )  $Z'$  boson decaying to  $t\bar{t}$  of 2.4 TeV and on a wide resonance (10% width) of 2.8 TeV. In the Randall-Sundrum model, KK gravitons ( $g_{KK}$ ) with masses below 2.2 TeV are excluded by ATLAS and (for a different set of model parameters) below 2.7 TeV by CMS.

Both ATLAS [82] and CMS [83] have also searched for resonances decaying into  $q\bar{q}$ ,  $qg$  or  $gg$  using the dijet invariant mass spectrum. Model-independent upper limits on cross sections are set; ATLAS excludes color-octet scalars below 2.72 TeV,  $W'$  bosons below 2.45 TeV and chiral  $W^*$  bosons below 1.75 TeV. CMS is able to exclude  $W'$  bosons below 1.9 TeV or between 2.0 and 2.2 TeV;  $Z'$  bosons below 1.7 TeV; and  $g_{KK}$  gravitons below 1.6 TeV. Searches are also carried out for wide resonances, assuming  $\Gamma/m$  up to 30%, and exclude axigluons and colorons with mass below 3.6 TeV, and color-octet scalars with mass below 2.5 TeV.

 $W' \rightarrow \ell\nu$ :

Both LHC experiments have also searched for massive charged vector bosons. ATLAS [85] searched for a heavy  $W'$  decaying to  $e\nu$  or  $\mu\nu$  and find no excess over the standard model expectation. A sequential standard model  $W'$  (assuming zero branching ratio to  $WZ$ ) with mass less than 3.24 TeV is excluded, and excited chiral bosons  $W^*$  excluded up to 3.21 TeV.

CMS [86] has carried out a complementary search in the  $\tau\nu$  final state. As noted above, such searches place interesting limits on models with enhanced couplings to the third generation. No excess is observed and limits between 2.0 and 2.7 TeV are set on the mass of a  $W'$  decaying preferentially to the third generation; a  $W'$  with universal fermion couplings is also excluded for masses less than 2.7 TeV.

 $W' \rightarrow t\bar{b}$ :

Heavy new gauge bosons can couple to left-handed fermions like the  $W$  boson or to right-handed fermions.  $W'$  bosons that couple only to right-handed fermions may not have leptonic decay modes, depending on the mass of the right-handed

neutrino. For these  $W'$  bosons, the  $t\bar{b}$  decay mode is especially important because it is the hadronic decay mode with the best signal-to-background.

ATLAS has searched for  $W'$  bosons in the  $t\bar{b}$  final state both for leptonic [87] and hadronic [88] decays of the top. No significant deviations from the standard model are seen in either analysis and limits are set on the  $W' \rightarrow t\bar{b}$  cross section times branching ratio and on the  $W'$  effective couplings.  $W'$  bosons with purely left-handed (right-handed) couplings to fermions are excluded for masses below 1.70 (1.92) TeV.

**2.2 Searches for Resonances decaying to Vector Bosons and/or Higgs Bosons** $X \rightarrow WW, WZ, ZZ$ :

Both experiments have used the data collected at  $\sqrt{s} = 8$  TeV to search for resonances decaying to pairs of bosons.

ATLAS [89] and CMS [90] have both looked for a resonant state (such as a  $W'$ ) decaying to  $WZ$  in the fully-leptonic channel,  $\ell\nu\ell'\ell'$  (where  $\ell, \ell' = e, \mu$ ). The  $WZ$  invariant mass distribution reconstructed from the observed lepton momenta missing transverse energy. The backgrounds arise mainly from standard model  $WZ$ ,  $ZZ$  and  $t\bar{t} + W/Z$  production. No significant deviation from the standard model prediction is observed by either experiment. A  $W'$  with mass less than 1.55 (1.52) TeV is excluded by CMS (ATLAS); ATLAS also sets limits on the production cross section for heavy vector triplet particles, and CMS sets limits on the production of low-scale technimesons  $\rho_{TC}$  from the reconstructed  $WZ$  mass spectrum and cross section.

ATLAS [91,92] and CMS [93] have also searched for narrow resonances decaying to  $WW$ ,  $WZ$  or  $ZZ$  in  $\ell\nu jj$  and  $\ell\ell jj$  final states (where one boson decays leptonically and the other to jets). No deviation from the standard model is seen by either experiment; resonance masses below 1.59 TeV for an extended gauge model  $W'$  are excluded by ATLAS. CMS interprets their results in terms of Randall-Sundrum  $g_{KK}$  production but also presents model-independent cross section limits that can be used to constrain other models.

Searches have also been conducted in fully hadronic final states. ATLAS [94] and CMS [95] have searched for massive resonance in dijet systems with one or both jets identified as a  $W$  or a  $Z$  boson using jet-substructure techniques. ATLAS observes a small excess (less than three standard deviations) around 2 TeV in the  $WZ$  channel but otherwise no deviations from the standard model are seen. Limits are set by both experiments on the production cross section times branching ratio for new heavy  $W'$  decaying to  $WZ$  and for  $g_{KK}$  gravitons decaying to  $WW$  or  $ZZ$ . CMS also sets limits on the production of particles decaying to  $qW$  and  $qZ$ .

 $X \rightarrow W/Z + H^0$  and  $X \rightarrow H^0 H^0$ :

With the existence and decay properties of the Higgs boson established, and the significant datasets now available, it is

## Searches Particle Listings

### Technicolor

possible to use searches for anomalous production of the Higgs as a potential signature for new physics. ATLAS [96] and CMS [97,98] have both searched in the data collected at  $\sqrt{s} = 8$  TeV for new particles decaying to a vector boson plus a Higgs boson, where the vector boson decays leptonically (ATLAS) or hadronically (CMS) and the Higgs boson to  $b\bar{b}$  (both experiments),  $WW$  or  $\tau^+\tau^-$  (CMS). No deviation from the standard model is seen in any of these final states and limits can be placed on the allowed production cross section times branching ratio for resonances between 0.8 and 2.5 TeV, on the parameters of a Minimal Walking Technicolor Model and on a heavy vector triplet model.

Both experiments [99,100] have also searched for resonant production of Higgs boson pairs  $X \rightarrow H^0 H^0$  with  $H^0 \rightarrow b\bar{b}$ . No signal is observed and limits are placed on the possible production cross section for any new resonance.

#### $Y \rightarrow W/Z + X$ with $X \rightarrow jj$ :

ATLAS has searched for a dijet resonance [101] with an invariant mass in the range 130 – 300 GeV, produced in association with a  $W$  or a  $Z$  boson. The analysis used  $20.3 \text{ fb}^{-1}$  of data recorded at  $\sqrt{s} = 8$  TeV. The  $W$  or  $Z$  boson is required to decay leptonically ( $\ell = e, \mu$ ). No significant deviation from the standard model prediction is observed and limits are set on the production cross section times branching ratio for a hypothetical technipion produced in association with a  $W$  or  $Z$  boson from the decay of a technirho particle in the context of Low Scale Technicolor models.

### 2.3 Vector-like third generation quarks

Vector-like quarks (VLQ) have non-chiral couplings to  $W$  bosons, i.e. their left- and right-handed components couple in the same way. They therefore have vectorial couplings to  $W$  bosons. Vector-like quarks arise in Little Higgs theories, top-coloron-models, and theories of a composite Higgs boson with partial compositeness. At the LHC, VLQs can be pair produced, via the dominant gluon-gluon fusion. VLQs can also be produced singly by their electroweak effective couplings to a weak boson and a standard model quark. In the following the notation  $T$  quark refers to a vector-like quark with charge  $2/3$  and the notation  $B$  quark refers to a vector-like quark with charge  $-1/3$ .  $T$  quarks can decay to  $bW$ ,  $tZ$ , or  $tH^0$ . Weak isospin singlets are expected to decay to all three final states with (asymptotic) branching fractions of 50%, 25%, 25%, respectively. Weak isospin doublets are expected to decay exclusively to  $tZ$  and to  $tH^0$  [102]. Analogously,  $B$  quarks can decay to  $tW$ ,  $bZ$ , or  $bH^0$ .

### Searches for $T$ quarks that decay to $W$ , $Z$ and $H^0$ bosons

#### $T \rightarrow bW$ :

CMS has searched for pair production of heavy  $T$  quarks that decay exclusively to  $bW$  [103]. The analysis selects events with exactly one charged lepton, assuming that the  $W$  boson from the second  $T$  quark decays hadronically. Under

this hypothesis, a 2-constraint kinematic fit can be performed to reconstruct the mass of the  $T$  quark. The two-dimensional distribution of reconstructed mass vs  $S_T$  is used to test for the signal.  $S_T$  is the scalar sum of the missing  $p_T$  and the transverse momenta of the lepton and the leading four jets. At times the hadronically-decaying  $W$  boson is produced with a large Lorentz boost, leading to the  $W$  decay products merged into a wide single jet also known as a fat jet. Algorithms such as jet pruning [104] are used to resolve the substructure of the fat jets from the decays of the heavy particles. If the mass of the boosted jet is compatible with the  $W$ -boson mass, then this  $W$  boson candidate jet used in the kinematic reconstruction of the  $T$  quark. No excess over standard model backgrounds is observed. This analysis, when combined with the search in the fully hadronic final state [105] excludes new quarks that decay 100% to  $bW$  for masses below 890 GeV [106].

An analogous search has been carried out by ATLAS [109]. It uses the lepton+jets final state with an isolated electron or muon and at least four jets, at least one of which must be tagged as a b-jet. The selection is optimized for  $T$  quark masses above about 400 GeV and requires reconstruction of hadronically decaying  $W$  boson, including those with a high boost leading to merged decay products, and large angular separation between the  $W$  bosons and the b-jets originating from the decay of the heavy  $T$  quark. The analysis focuses on the reconstructed heavy  $T$  quark mass from the hadronic  $W$  candidate and a b-jet. No significant excess of events above standard model expectation is observed. For  $BR(T \rightarrow bW) = 1$ ,  $T$  quark masses lower than 765 GeV are excluded.

#### $T \rightarrow tH^0$ :

ATLAS has performed a search for  $T\bar{T}$  production with  $T \rightarrow tH^0$  [109]. Given the dominant decay mode  $H^0 \rightarrow b\bar{b}$ , these events are characterized by a large number of jets, many of which are b-jets. Thus the event selection requires one isolated electron or muon and at least five jets, two of which must be tagged as b-jets. The data are classified according to their jet-multiplicity (five and six-or-more), b-jet multiplicity (2, 3, and  $\geq 4$ ) and the invariant mass of the two b-tagged jets with lowest  $\Delta R$  between the two b-tagged jets (for  $\geq$  six jet events). The distribution of  $H_T$ , the scalar sum of the lepton and jet  $p_T$ s and the missing  $E_T$ , for each category is used as the discriminant for the final signal and background separation. No excess of events is found. Weak isospin doublet  $T$  quarks are excluded below 855 GeV for  $BR(T \rightarrow tH^0) = 1$ . The CMS search for  $T\bar{T}$  production, with  $T \rightarrow tH^0$  decays have been performed in both lepton+jets, multilepton and all hadronic final states. The lepton+jets analysis [110] emphasizes the presence of large number of b-tagged jets, and combines with other kinematic variables in a Boosted Decision Tree (BDT) for enhancing signal to background discrimination. The multilepton analysis [110] optimized for the presence of b-jets and the large hadronic activity. For  $BR(T \rightarrow Wb) = 1$ , the combined lepton+jets and multilepton analyses lead to a lower limit on  $T$  quark

masses of 706 GeV. A search for  $T \rightarrow tH^0$  in all hadronic decays [111], optimized for a high mass  $T$  quark, and based on identifying boosted top quark jets has been carried out by CMS. This search aims to resolve sub-jets within the fat jet arising from boosted top quark decays, including b-tagging of the sub-jets. A likelihood discriminator is defined based on the distributions of  $H_T$ , and the invariant mass of the two b-jets in the events for signal and background. No excess above background expectations is observed. Assuming 100% BR for  $T \rightarrow tH^0$ , this analysis leads to a lower limit of 745 GeV on the mass of the  $T$  quark.

A CMS search for  $T \rightarrow tH^0$  with  $H^0 \rightarrow \gamma\gamma$  decays has been performed [112]. To identify the Higgs boson produced in the decay of the heavy  $T$  quark, and the subsequent  $H^0 \rightarrow \gamma\gamma$  decay, the analysis focuses on identification of two photons in events with one or more high  $p_T$  lepton+jets or events with no leptons and large hadronic activity. A search for a resonance in the invariant mass distribution of the two photons in events with large hadronic activity defined by the  $H_T$  variable shows no excess above the prediction from standard model processes. The analysis results in exclusion of  $T$  quark masses below 540 GeV.

#### $T \rightarrow tZ$ :

A targeted search by CMS for  $T$  quarks that decay exclusively to  $tZ$  based on an integrated luminosity of  $1.1 \text{ fb}^{-1}$  from pp collisions at  $\sqrt{s} = 7 \text{ TeV}$  [107]. Selected events must have three isolated charged leptons, two of which must be consistent with a leptonic  $Z$ -boson decay. No significant excess was observed.  $T$  quark masses below 485 GeV are excluded. The CMS analysis [110] with combined searches in lepton+jets, dilepton and multilepton final states yields a lower limit on the mass of the  $T$  of 782 GeV. A complementary search has been carried out by ATLAS for new heavy quarks decaying into a  $Z$  boson and a third generation quark [113], with  $T \rightarrow tZ$ . Selected events contain a high transverse momentum  $Z$  boson that decays leptonically, together with two b-jets, which is modified to require at least one b-tagged jet, for events with additional leptons. No significant excess of events above the standard model expectation is observed. For the weak-isospin singlet scenario, a  $T$  quark with mass lower than 655 GeV is excluded, while for a particular weak-isospin doublet scenario, a  $T$  quark with mass lower than 735 GeV is excluded.

The ATLAS experiment has studied the electroweak production of single  $T$  quarks, which is accompanied by a b-jet and a light jet [113]. The initial event selection for this search is very similar to that of  $T\bar{T}$  production with  $T \rightarrow tZ$  decays, and for both the dilepton and trilepton signatures, it requires the presence of an additional energetic jet in the forward region ( $2.5 < |\eta| < 4.5$ ), a characteristic signature of single heavy quark production. An upper limit of 190 fb is obtained for the process  $\sigma(pp \rightarrow T\bar{t}q) \times B(T \rightarrow tZ)$  with a heavy  $T$  quark mass at 700 GeV. For a specific composite Higgs model [114], the  $WTb$  vertex is parameterized by  $\lambda_T$ , which is associated with

the Yukawa coupling in the composite sector and the degree of compositeness of the quarks in the 3<sup>rd</sup> generation. With the current dataset unfortunately the search is not sensitive to  $\lambda_T < 1.5$  nor to any values of  $V_{Tb} < 1$ .

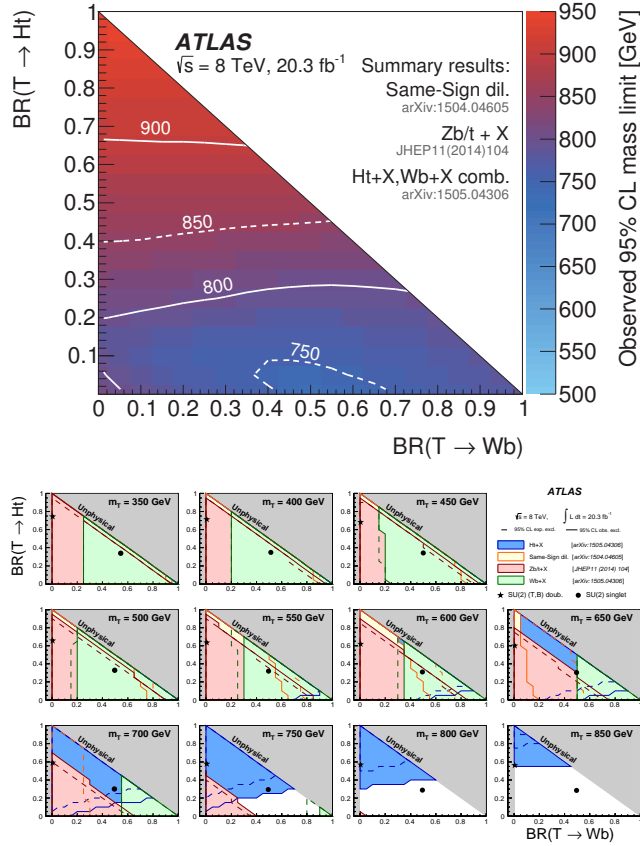

#### Same-Sign dilepton analyses:

Pair-production of  $T$  or  $B$  quarks with their antiparticles can result in events with like-sign leptons, for example if the decay  $T \rightarrow tH \rightarrow bWW^+W^-$  is present, followed by leptonic decays of two same-sign  $W$  bosons. ATLAS and CMS have searched for this final state. The ATLAS search [121] requires two leptons with the same electric charge, at least two jets of which at least one must be tagged as a b-jet, and missing  $p_T$ . ATLAS quotes exclusions of some possible branching fraction combinations depending on the mass of the new quarks.  $T$  quarks that are electroweak singlets are excluded below 590 GeV (assuming branching fractions to the  $W$ ,  $Z$ , and  $H^0$  decay modes arising from a singlet model). For the same-sign lepton signature, the sensitivity is largest for  $T$  quarks that decay exclusively to  $tH^0$ .

#### Combination $T \rightarrow bW/tZ/tH^0$ :

The limits set by ATLAS searches in lepton+jets, dileptons with same-sign charge, and final states with  $Z$  boson have been combined and the results obtained for various combinations of branching fractions for  $T$  quark decays to  $bW$ ,  $tH^0$  and  $tZ$  are shown in Fig. 1. The combined analysis excludes  $T$  quarks that exclusively decay to  $bW/tH^0$  with masses below 765/950 GeV [109], and sets lower  $T$  quarks mass limits that range from 715 to 950 GeV for all possible values of the branching fractions to the three decay modes.

An inclusive search by CMS targeted at heavy  $T$  quarks decaying to any combination of  $bW$ ,  $tZ$ , or  $tH^0$  is described in Ref. [110]. Selected events have at least one isolated charged lepton. Events are categorized according to number and flavour of the leptons, the number of jets, and the presence of hadronic vector boson and top quark decays that are merged into a single jet. The use of jet substructure to identify hadronic decays significantly increases the acceptance for high  $T$  quark masses. No excess above standard model backgrounds is observed. Limits on the pair production cross section of the new quarks are set, combining all event categories, for all combinations of branching fractions into the three final states. For  $T$  quarks that exclusively decay to  $bW/tZ/tH^0$ , masses below 700/782/706 GeV are excluded. Electroweak singlet vector-like  $T$  quarks which decay 50% to  $bW$ , 25% to  $tZ$ , and 25% to  $tH^0$  are excluded for masses below 696 GeV (Fig. 2 top panel). This analysis was the first from CMS to obtain limits on the mass of the  $T$  quark for all possible values of the branching fractions into the three different final states  $bW$ ,  $tZ$  and  $tH$  [110]. A combination [106] of the leptonic inclusive analysis with the targeted  $T \rightarrow tH^0$  decays to all-hadronic final state, and  $T \rightarrow Wb$  decays with all-hadronic and single-lepton final states with emphasis on  $bW$  mass reconstruction, leads to a combined exclusion of  $T$  quarks between 790 and 890 GeV and is shown

**Figure 1:** Observed limits on the mass of the  $T$  quark in the plane of  $BR(T \rightarrow tH^0)$  versus  $BR(T \rightarrow bW)$  from all ATLAS searches for  $TT$  production [109]. Top panel: summary of the most restrictive observed limit on the mass. Contour lines are provided to guide the eye. Bottom panel: Exclusion limits are drawn sequentially for each of the analyses and overlaid (rather than combined). The circle and star symbols denote the default branching ratios for the weak-isospin singlet and doublet cases.

in Fig. 2 (bottom panel). From the combination analyses, any  $T$  quark that exclusively decays to  $bW/tZ/tH$  is required to have masses above 890/830/840 GeV [106].

#### Searches $B$ quarks that decay to $W$ , $Z$ and $H^0$ bosons

ATLAS and CMS have performed searches for pair production of heavy  $B$  quarks which subsequently decay to  $Wt$ ,  $bZ$  or  $bH^0$ . The searches have been carried out in final states with single leptons, di-leptons (with same charge or opposite charge), multileptons, as well as in fully hadronic final states.

##### $B \rightarrow WtX$ :

Search for  $B \rightarrow tW$  has been performed by the ATLAS experiment [116] using lepton+jets events. This analysis relies on a discriminant obtained via the BDT technique. The BDT uses kinematic and topological variables such as the jet and  $b$ -jet multiplicity,  $H_T$ , the angular separation between the lepton and the leading  $b$ -tagged jet or between lepton and hadronic  $W/Z$

**Figure 2:** Top panel: upper limit on the  $T$  quark production cross section for branching fractions into  $bW$ ,  $tH^0$ ,  $tZ$  of 50%, 25%, 25% obtained from the leptonic inclusive analysis [110]. Bottom panel: Branching fraction triangle with observed limits for the  $T$  quark mass from the CMS combination analysis [106].

candidates, the transverse mass of the leptonically decaying  $W$  boson candidate,  $p_T$  of various objects including the leptonically decaying  $W$  boson, the number of hadronic  $W/Z$  candidates, etc. For  $BR(B \rightarrow tW) = 1$ , the lower limit on the mass of the  $B$  quark is obtained to be 810 GeV. For the weak-isospin singlet scenario, a  $B$  quark with mass lower than 640 GeV is excluded. A similar search by CMS [117] selects events with one lepton and four or more jets, with at least one  $b$ -tagged jet, significant missing  $p_T$ , and further categorizes them based on the number of jets tagged as arising from the decay of boosted  $W$ ,  $Z$  or  $H^0$  bosons. The  $S_T$  distributions of the events in different categories show no excess of events above the expected

background and yield a lower limit on the  $B$  quark mass of 732 GeV for  $BR(B \rightarrow Wt) = 1$ .

#### $B \rightarrow bZX$ :

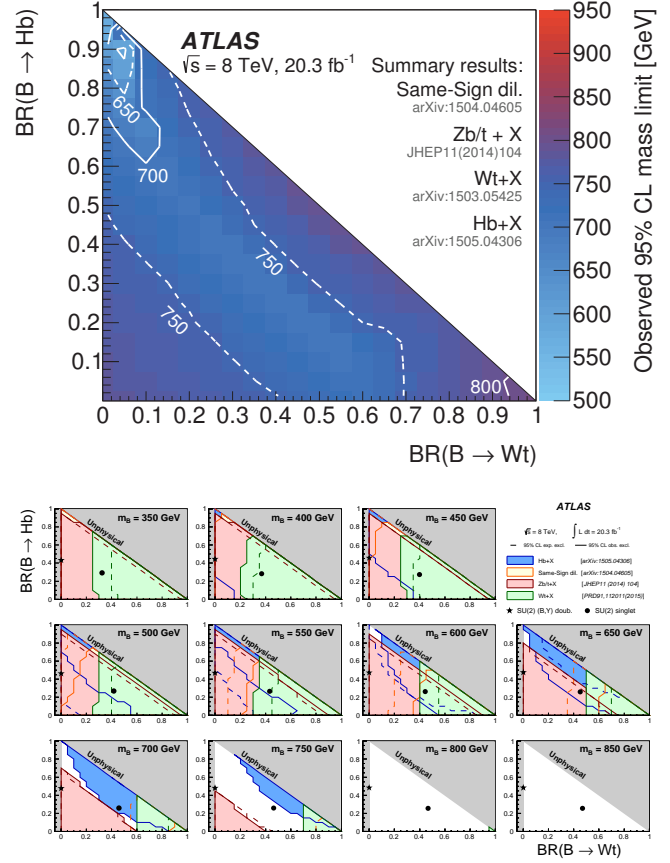

A search by CMS [115] for the pair-production of a heavy  $B$  quark and its antiparticle, one of which decays to  $bZ$  selects events with a  $Z$ -boson decay to  $e^+e^-$  or  $\mu^+\mu^-$  and a jet identified as originating from a  $b$  quark. The signal from  $B \rightarrow bZ$  decays would appear as a local enhancement in the  $bZ$  mass distribution. No such enhancement is found and  $B$  quarks that decay 100% into  $bZ$  are excluded below 700 GeV. This analysis also sets upper limits on the branching fraction for  $B \rightarrow bZ$  decays of 30-100% in the  $B$  quark mass range 450-700 GeV. A complementary search has been carried out by ATLAS for new heavy quarks decaying into a  $Z$  boson and a  $b$ -quark [113]. Selected dilepton events contain a high transverse momentum  $Z$  boson that decays leptonically, together with two  $b$ -jets. If the dilepton events have an extra lepton in addition to those from the  $Z$  boson, then only one  $b$ -jet is required. No significant excess of events above the standard model expectation is observed, and mass limits are set depending on the assumed branching ratios, see Fig. 3. In a weak-isospin singlet scenario, a  $B$  quark with mass lower than 645 GeV is excluded, while for a particular weak-isospin doublet scenario, a  $B$  quark with mass lower than 725 GeV is excluded.

ATLAS has searched for the electroweak production of single  $B$  quarks, which is accompanied by a  $b$ -jet and a light jet [113]. The dilepton selection for double  $B$  production is modified for the single  $B$  production study by requesting the presence of an additional energetic jet in the forward region. An upper limit of 200 fb is obtained for the process  $\sigma(pp \rightarrow B\bar{b}q) \times B(B \rightarrow Zb)$  with a heavy  $B$  quark mass at 700 GeV. This search indicates that the electroweak mixing parameter  $X_{Bb}$  below 0.5 is neither expected or observed to be excluded for any values of  $B$  quark mass.

#### Combination $B \rightarrow tW/bZ/bH^0$ :

The ATLAS experiment has combined the various analyses targeted for specific decay modes to obtain the most sensitive limits on the pair production of  $B$  quarks [109]. The analyses using single lepton events, same sign charge dilepton events, events with opposite sign dilepton events, and multilepton events are combined to obtain lower limits on the mass of the  $B$  quark in the plane of  $BR(B \rightarrow Wt)$  vs  $BR(B \rightarrow bH)$ . The searches are optimized for 100% branching fractions and hence are most sensitive at large  $BR(B \rightarrow Wt)$ , and also at large  $BR(B \rightarrow bH^0)$ . For all possible values of branching ratios in the three decay modes  $tW$ ,  $bZ$ , or  $bH^0$ , the lower limits on the  $B$  quark mass is found to be between 575 GeV and 813 GeV and as shown in Fig. 3.

A similar combination of CMS analyses [115] in the final states with single leptons, di-leptons (with same charge or opposite charge), multileptons, as well as fully hadronic decays

**Figure 3:** Observed limits on the mass of the  $T$  quark in the plane of  $BR(B \rightarrow bH^0)$  versus  $BR(B \rightarrow tW)$  from all ATLAS searches for  $BB$  production [109]. Top panel: summary of the most restrictive observed limit on the mass. Contour lines are provided to guide the eye. Bottom panel: Exclusion limits are drawn sequentially for each of the analyses and overlaid (rather than combined).

lead to results shown in Fig. 4. The discriminating variables used in these analyses are  $S_T$ ,  $H_T$  and the invariant mass of the dileptons and the  $b$ -jets. As different topologies target multiple decay modes, with various degree of sensitivity to the  $B$  quark mass, the best results for the  $Wt$  decays is obtained from the combination of lepton+jets, same-sign dilepton and multilepton events, while for the  $bZ$  mode a combination of opposite-sign dilepton and multilepton events leads to the best sensitivity for the mass limits. For the  $bH^0$  decays, the all-hadronic events give the dominant contribution to the mass limit. For  $B$  quarks that decay exclusively into  $tW$  masses below 880 GeV are excluded, while for 100% decay branching fraction of  $B$  to  $bH^0$ ,  $B$  quarks up to 900 GeV are excluded. The exclusion limits for all combinations of branching fractions lie between 740 GeV to 900 GeV, and are shown in Fig. 4, together with the cross section limit plotted for  $B$  quark decays to the  $bH^0$  mode.

**Figure 4:** Top panel: observed limits on the  $B$  quark mass for each combination of branching fractions to  $tW$ ,  $bZ$ , and  $bH^0$  obtained by the combination of channels. The color scale represents the mass exclusion limit obtained at each point [115]. Bottom panel: Observed and expected cross section limit results as a function of  $B$  mass, for the combination of all channels and for exclusive branching fraction of  $B$  to  $bH$  [115].

#### 2.4 A charge +5/3 top-partner quark

In models of dynamical electroweak symmetry breaking, the same interactions which give rise to the mass of the top-quark can give unacceptably large corrections to the branching ratio of the  $Z$  boson to  $b\bar{b}$  [75]. These corrections can be substantially reduced, however, in theories with an extended “custodial symmetry” [45]. This symmetry requires the existence of a charge +5/3 vector-like partner of the top quark.

Both experiments have performed a search for a heavy top vector-like quark  $T_{5/3}$ , with exotic charge 5/3, such as that proposed in Refs. [118,119]. The analyses assume pair-production of  $T_{5/3}$  with  $T_{5/3}$  decaying with 100% branching fraction to  $tW$ . The analysis is based on searching for same-sign leptons, from the two  $W$  bosons from one of the

$T_{5/3}$ . Requiring same-sign leptons eliminates most of the standard model background processes, leaving those with smaller cross sections:  $t\bar{t}$ ,  $W$ ,  $t\bar{t}Z$ ,  $WWW$ , and same-sign  $WW$ . In addition backgrounds from instrumental effects due to charge misidentification are considered. The CMS search also utilizes jet substructure techniques to identify boosted  $T_{5/3}$  topologies. These searches restrict the  $T_{5/3}$  mass to be higher than 800 GeV [120]. The pair-production limits obtained by ATLAS correspond to a lower mass limit on  $T_{5/3}$  of 840 GeV [116].

The single  $T_{5/3}$  production cross section depends on the coupling constant  $\lambda$  of the  $tWT_{5/3}$  vertex. ATLAS has performed an analysis of same-sign dileptons which includes both the single and pair production. This analysis leads to a lower limit on the mass of the  $T_{5/3}$  of 750 GeV for both values of  $\lambda = 0.5$  and  $1.0$  [121].

#### 2.5 Colorons and Colored Scalars

These particles are associated with top-condensate and top-seesaw models, which involve an enlarged color gauge group. The new particles decay to dijets,  $t\bar{t}$ , and  $b\bar{b}$ .

Direct searches for colorons, color-octet scalars and other heavy objects decaying to  $q\bar{q}$ ,  $qg$ ,  $q\bar{q}$ , or  $g\bar{g}$  has been performed using LHC data from pp collisions at  $\sqrt{s} = 7$  and 8 TeV. Based on the analysis of dijet events from a data sample corresponding to a luminosity of  $19.6 \text{ fb}^{-1}$ , the CMS experiment excludes pair production of colorons with mass between  $1.20 - 3.60$  and  $3.90 - 4.08$  TeV at 95% C.L. as shown in Fig. 5 [83]. A search for pair-produced colorons based on an integrated luminosity of  $5.0 \text{ fb}^{-1}$  at  $\sqrt{s} = 7$  TeV by CMS excludes colorons with masses between 250 GeV and 740 GeV, assuming colorons decay 100% into  $q\bar{q}$  [122]. This analysis is based on events with at least four jets and two dijet combinations with similar dijet mass. Color-octet scalars (s8) with masses between  $1.20 - 2.79$  TeV are excluded by CMS (Fig. 5 [83]), and below 2.7 TeV by ATLAS [82].

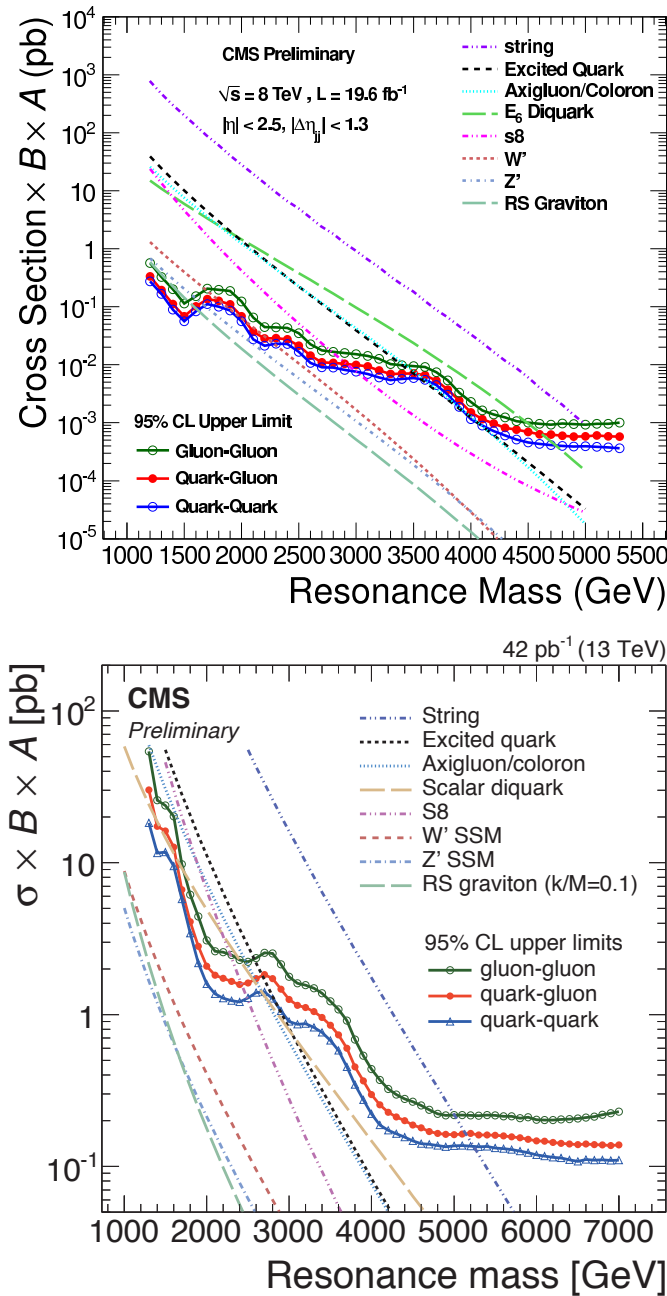

These studies have now been extended to take advantage of the increased center-of-mass energy during Run 2 of the LHC. Using the  $40 \text{ pb}^{-1}$  of data collected at  $\sqrt{s} = 13$  TeV, searches for narrow resonances have been performed by CMS. An analysis of the dijet invariant mass spectrum formed using wide jets [123], separated by  $\Delta\eta_{jj} \leq 1.3$ , leads to limits on new particles decaying to parton pairs ( $q\bar{q}$ ,  $qg$ ,  $g\bar{g}$ ). Specific exclusions on the masses of colorons and color-octet scalars are obtained and shown in Fig. 5.

#### 3. Conclusions

As the above analyses have demonstrated, there is already substantial sensitivity to possible new particles predicted to accompany the  $H^0$  in dynamical frameworks of electroweak symmetry breaking. No hints of any deviations from the standard model have been observed, and limits typically at the scale of a few hundred GeV to 1 TeV are set.

Given the need to better understand the  $H^0$  and to determine in detail how it behaves, we expect that such analyses will be a major theme of Run 2 the LHC, and we look forward to

**Figure 5:** Observed 95% C.L. limits on  $\sigma \times B \times A$  for string resonances, excited quarks, axigluons, colorons, E6 diquarks, s8 resonances,  $W'$  and  $Z'$  bosons, and Randall-Sundrum gravitons  $g_{KK}$ . Top panel: results from Ref. [83] from Run 1. Bottom panel: results from Ref. [123] from Run 2.

increased sensitivity as a result of the higher luminosity at the increased centre of mass energy of collisions.

- 1 KHACHATRYAN 16E search for top-color  $Z'$  decaying to  $t\bar{t}$ . The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ . Also exclude  $m_{Z'} < 2.9$  TeV for wider topcolor  $Z'$  with  $\Gamma_{Z'}/m_{Z'} = 0.1$ .
- 2 AAD 15AB search for long-lived hidden valley  $\pi_V$  particles which are produced in pairs by the decay of a scalar boson.  $\pi_V$  is assumed to decay into dijets. See their Fig. 10 for the limit on  $\sigma B$ .
- 3 AAD 15AO search for top-color  $Z'$  decaying to  $t\bar{t}$ . The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 4 AAD 15BB search for minimal walking technicolor (MWT) isotriplet vector and axial-vector resonances decaying to  $Wh$  or  $Zh$ . See their Fig. 3 for the exclusion limit in the MWT parameter space.
- 5 AAD 15Q search for long-lived hidden valley  $\pi_V$  particles which are produced in pairs by the decay of scalar boson.  $\pi_V$  is assumed to decay into dijets. See their Fig. 5 and Fig. 6 for the limit on  $\sigma B$ .
- 6 AAIJ 15AN search for long-lived hidden valley  $\pi_V$  particles which are produced in pairs by the decay of scalar boson with a mass of 120 GeV.  $\pi_V$  is assumed to decay into dijets. See their Fig. 4 for the limit on  $\sigma B$ .
- 7 KHACHATRYAN 15C search for a vector techni-resonance decaying to  $WZ$ . The limit assumes  $M_{\pi_T} = (3/4) M_{\rho_T} = 25$  GeV. See their Fig. 3 for the limit in  $M_{\pi_T} - M_{\rho_T}$  plane of the low scale technicolor model.
- 8 KHACHATRYAN 15W search for long-lived hidden valley  $\pi_V$  particles which are produced in pairs in the decay of heavy higgs boson  $H$ .  $\pi_V$  is assumed to decay into  $\ell^+\ell^-$ . See their Fig. 7 and Fig. 8 for the limits on  $\sigma B$ .
- 9 AAD 14AT search for techni- $\omega$  and techni- $a$  resonances decaying to  $V\gamma$  with  $V = W(\rightarrow \ell\nu)$  or  $Z(\rightarrow \ell^+\ell^-)$ .
- 10 AAD 14V search for vector techni-resonances decaying into electron or muon pairs in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See their table IX for exclusion limits with various assumptions.
- 11 AAD 13AN search for vector techni-resonance  $a_T$  decaying into  $W\gamma$ .
- 12 AAD 13AN search for vector techni-resonance  $\omega_T$  decaying into  $Z\gamma$ .
- 13 Search for top-color  $Z'$  decaying to  $t\bar{t}$ . The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 14 CHATRCHYAN 13AP search for top-color leptophobic  $Z'$  decaying to  $t\bar{t}$ . The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 15 BAAK 12 give electroweak oblique parameter constraints on the QCD-like technicolor models. See their Fig. 28.
- 16 CHATRCHYAN 12AF search for a vector techni-resonance decaying to  $WZ$ . The limit assumes  $M_{\pi_T} = (3/4) M_{\rho_T} = 25$  GeV. See their Fig. 3 for the limit in  $M_{\pi_T} - M_{\rho_T}$  plane of the low scale technicolor model.

- 17 Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11 obtain a limit on the top-Higgs mass  $> 300$  GeV at 95% CL assuming 150 GeV top-pion mass.
- 18 Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11A obtain a limit on the technipion mass ruling out the region  $110 \text{ GeV} < m_P < 2m_t$ . Existence of color techni-fermions, top-color mechanism, and  $N_{TC} \geq 3$  are assumed.
- 19 AALTONEN 10I search for the vector techni-resonances ( $\rho_T, \omega_T$ ) decaying into  $W\pi_T$  with  $W \rightarrow \ell\nu$  and  $\pi_T \rightarrow b\bar{b}, b\bar{c},$  or  $b\bar{u}$ . See their Fig. 3 for the exclusion plot in  $M_{\pi_T} - M_{\rho_T}$  plane.
- 20 ABAZOV 10A search for a vector techni-resonance decaying into  $WZ$ . The limit assumes  $M_{\rho_T} < M_{\pi_T} + M_W$ .
- 21 ABAZOV 07I search for the vector techni-resonances ( $\rho_T, \omega_T$ ) decaying into  $W\pi_T$  with  $W \rightarrow e\nu$  and  $\pi_T \rightarrow b\bar{b}$  or  $b\bar{c}$ . See their Fig. 2 for the exclusion plot in  $M_{\pi_T} - M_{\rho_T}$  plane.
- 22 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions. at  $\sqrt{s} = 1.96$  TeV. The limit assumes Technicolor-scale mass parameters  $M_V = M_A = 500$  GeV.
- 23 CHEKANOV 02B search for color octet techni- $\pi$   $P$  decaying into dijets in  $ep$  collisions. See their Fig. 5 for the limit on  $\sigma(ep \rightarrow ePX) \cdot B(P \rightarrow 2j)$ .
- 24 ABAZOV 01B searches for vector techni-resonances ( $\rho_T, \omega_T$ ) decaying to  $e^+e^-$ . The limit assumes  $M_{\rho_T} = M_{\omega_T} < M_{\pi_T} + M_W$ .
- 25 The limit is independent of the  $\pi_T$  mass. See their Fig. 9 and Fig. 10 for the exclusion plot in the  $M_{\rho_T} - M_{\pi_T}$  plane. ABDALLAH 01 limit on the technipion mass is  $M_{\pi_T} > 79.8$  GeV for  $N_D = 2$ , assuming its point-like coupling to gauge bosons.
- 26 AFFOLDER 00F search for  $\rho_T$  decaying into  $W\pi_T$  or  $\pi_T\pi_T$  with  $W \rightarrow \ell\nu$  and  $\pi_T \rightarrow b\bar{b}, b\bar{c}$ . See Fig. 1 in the above Note on “Dynamical Electroweak Symmetry Breaking” for the exclusion plot in the  $M_{\rho_T} - M_{\pi_T}$  plane.
- 27 AFFOLDER 00K search for the  $\rho_{T8}$  decaying into  $\pi_{LQ}\pi_{LQ}$  with  $\pi_{LQ} \rightarrow b\nu$ . For  $\pi_{LQ} \rightarrow c\nu$ , the limit is  $M_{\rho_{T8}} > 510$  GeV. See their Fig. 2 and Fig. 3 for the exclusion plot in the  $M_{\rho_{T8}} - M_{\pi_{LQ}}$  plane.
- 28 ABE 99F search for a new particle  $X$  decaying into  $b\bar{b}$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. See Fig. 7 in the above Note on “Dynamical Electroweak Symmetry Breaking” for the upper limit on  $\sigma(p\bar{p} \rightarrow X) \times B(X \rightarrow b\bar{b})$ . ABE 99F also exclude top gluons of width  $\Gamma = 0.3M$  in the mass interval  $280 < M < 670$  GeV, of width  $\Gamma = 0.5M$  in the mass interval  $340 < M < 640$  GeV, and of width  $\Gamma = 0.7M$  in the mass interval  $375 < M < 560$  GeV.
- 29 ABE 99N search for the techni- $\omega$  decaying into  $\gamma\pi_T$ . The technipion is assumed to decay  $\pi_T \rightarrow b\bar{b}$ . See Fig. 2 in the above Note on “Dynamical Electroweak Symmetry Breaking” for the exclusion plot in the  $M_{\omega_T} - M_{\pi_T}$  plane.
- 30 ABE 97G search for a new particle  $X$  decaying into dijets in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. See Fig. 5 in the above Note on “Dynamical Electroweak Symmetry Breaking” for the upper limit on  $\sigma(p\bar{p} \rightarrow X) \times B(X \rightarrow 2j)$ .

## Quark and Lepton Compositeness

### Quark and Lepton Compositeness, Searches for

The latest unpublished results are described in the “Quark and Lepton Compositeness” review.

#### SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

Revised 2015 by K. Hikasa (Tohoku University), M. Tanabashi (Nagoya University), K. Terashi (University of Tokyo), and N. Varelas (University of Illinois at Chicago)

#### Limits on contact interactions

If quarks and leptons are made of constituents, then at the scale of constituent binding energies there should appear new interactions among them. At energies much below the compositeness scale ( $\Lambda$ ), these interactions are suppressed by inverse powers of  $\Lambda$ . The dominant effect of the compositeness of fermion  $\psi$  should come from the lowest dimensional interactions with four fermions (contact terms), whose most general flavor-diagonal color-singlet chirally invariant form reads [1,2]

$$\mathcal{L} = \frac{g_{\text{contact}}^2}{2\Lambda^2} \sum_{i,j} \left[ \eta_{LL}^{ij} (\bar{\psi}_L^i \gamma_\mu \psi_L^i) (\bar{\psi}_L^j \gamma^\mu \psi_L^j) + \eta_{RR}^{ij} (\bar{\psi}_R^i \gamma_\mu \psi_R^i) (\bar{\psi}_R^j \gamma^\mu \psi_R^j) + \eta_{LR}^{ij} (\bar{\psi}_L^i \gamma_\mu \psi_L^i) (\bar{\psi}_R^j \gamma^\mu \psi_R^j) + \eta_{RL}^{ij} (\bar{\psi}_R^i \gamma_\mu \psi_R^i) (\bar{\psi}_L^j \gamma^\mu \psi_L^j) \right], \quad (1)$$

with  $i, j$  being the indices of fermion species. Color and other indices are suppressed in Eq. (1). Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size  $\Lambda$ . Note  $\eta_{\alpha\beta}^{ij} = \eta_{\beta\alpha}^{ji}$ , therefore, in order to specify the contact interaction among the same fermion species  $i = j$ , it is enough to use  $\eta_{LL}$ ,  $\eta_{RR}$  and  $\eta_{LR}$ . We will suppress the indices of fermion species hereafter. We may determine the scale  $\Lambda$  unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting  $g_{\text{contact}}^2/4\pi = g_{\text{contact}}^2(\Lambda)/4\pi = 1$  for the new strong interaction coupling and by setting the largest magnitude of the coefficients  $\eta_{\alpha\beta}$  to be unity. In the following, we denote

$$\begin{aligned} \Lambda &= \Lambda_{LL}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, 0, 0), \\ \Lambda &= \Lambda_{RR}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm 1, 0), \\ \Lambda &= \Lambda_{VV}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \pm 1), \\ \Lambda &= \Lambda_{AA}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \mp 1), \\ \Lambda &= \Lambda_{V-A}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, 0, \pm 1). \end{aligned} \quad (2)$$

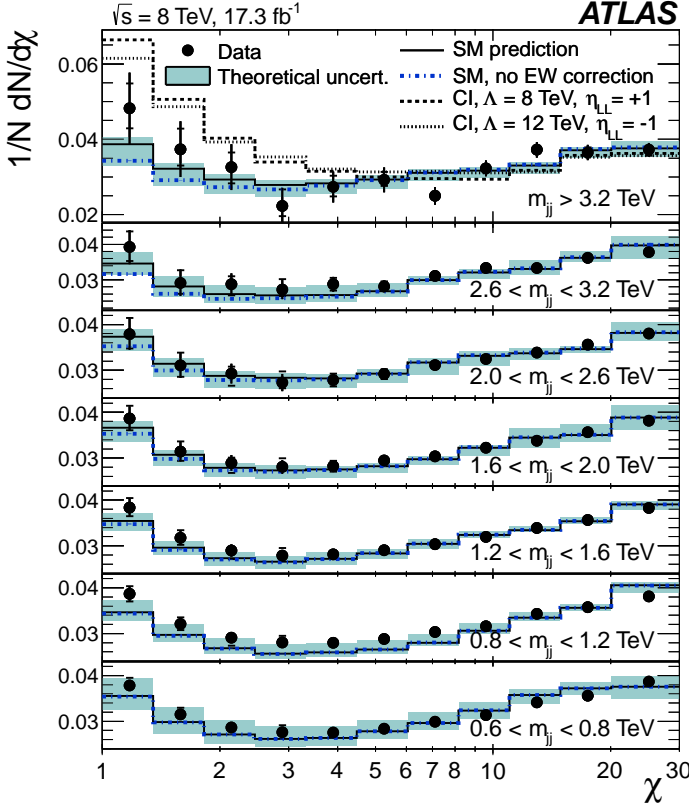

Such interactions can arise by interchanging constituents (when the fermions have common constituents), and/or by exchanging the binding quanta (whenever binding quanta couple to constituents of both particles).

Fermion scattering amplitude induced from the contact interaction in Eq. (1) interferes with the Standard Model (SM)

amplitude destructively or constructively. The sign of interference depends on the sign of  $\eta_{\alpha\beta}$ . For instance, in the parton level  $qq \rightarrow qq$  scattering cross section in the  $\Lambda_{LL}^\pm$  model, the contact interaction amplitude and the SM gluon exchange amplitude interfere destructively for  $\eta_{LL} = +1$ , while they interfere constructively for  $\eta_{LL} = -1$ . In models of quark compositeness, the quark scattering cross sections induced from the contact interactions receive sizable QCD radiative corrections. Ref. 3 provides the exact next-to-leading order (NLO) QCD corrections to the contact interaction induced quark scattering cross sections.

Over the last three decades experiments at the CERN SpS [4,5], the Fermilab Tevatron [6,7], and the CERN LHC [8–12] have searched for quark contact interactions, characterized by the four-fermion effective Lagrangian in Eq. (1), using jet final states. These searches have been performed primarily by studying the angular distribution of the two highest transverse momentum,  $p_T$ , jets (dijets), and the inclusive jet  $p_T$  spectrum. The variable  $\chi = \exp(|(y_1 - y_2)|)$  is used to measure the dijet angular distribution, where  $y_1$  and  $y_2$  are the rapidities of the two jets with the highest transverse momenta. For collinear massless parton scattering,  $\chi$  is related to the polar scattering angle  $\theta^*$  in the partonic center-of-mass frame by  $\chi = (1 + |\cos \theta^*|)/(1 - |\cos \theta^*|)$ . The choice of  $\chi$  is motivated by the fact that the angular distribution for Rutherford scattering, which is proportional to  $1/(1 - \cos \theta^*)^2$ , is independent of  $\chi$ . In perturbative QCD the  $\chi$  distributions are relatively flat and only mildly modified by higher-order QCD or electroweak corrections. Signatures of quark contact interactions exhibit more isotropic angular distribution than QCD and they can be identified as an excess at low values of  $\chi$ . In the inclusive jet cross section measurement, quark contact interaction effects are searched as deviations from the predictions of perturbative QCD in the tails of the high- $p_T$  jet spectrum.

Recent results from the LHC, using data collected at proton-proton center-of-mass energies of  $\sqrt{s} = 7$  and 8 TeV, extend previous Tevatron limits on quark contact interactions. Figure 1 shows the normalized dijet angular distributions for several dijet mass ranges measured in ATLAS [9] at  $\sqrt{s} = 8$  TeV. The data distributions are compared with SM predictions, estimated using PYTHIA8 [13] with GEANT4-based [14] ATLAS detector simulation and corrected to NLO QCD calculation provided by NLO Jet++ [15] including electroweak corrections [16], and with predictions including a contact interaction term in which only left-handed quarks participate at compositeness scale  $\Lambda_{LL}^+ = 8$  TeV ( $\Lambda_{LL}^- = 12$  TeV) with destructive (constructive) interference. Over a wide range of  $\chi$  and dijet mass the data are well described by the SM predictions. Using the dijet angular distributions measured at high dijet masses and  $\sqrt{s} = 8$  TeV, the ATLAS [9] and CMS [12] Collaborations have set 95% confidence level (C.L.) lower limits on the contact interaction scale  $\Lambda$ , ranging from 8.1 to 15.2 TeV for different quark contact interaction models that correspond to various combinations of  $(\eta_{LL}, \eta_{RR}, \eta_{LR})$ , as summarized in Figure 2.

**Figure 1:** Normalized dijet angular distributions in several dijet mass ( $m_{jj}$ ) ranges. The data distributions are compared to the SM predictions (solid line) and with the predictions including a contact interaction (CI) term in which only left-handed quarks participate of compositeness scale  $\Lambda_{LL}^+ = 8$  TeV (dashed line) and  $\Lambda_{LL}^- = 12$  TeV (dotted line). The SM prediction without the electroweak (EW) corrections is also shown (blue dashed dotted line). The error bars on the data points represent statistical and experimental uncertainties combined in quadrature. The ticks on the error bars represent experimental uncertainties only. The shaded band displayed around the SM prediction shows the theoretical uncertainties. Figure adopted from Ref. 9.

The contact interaction scale limits extracted using the dijet angular distributions include the exact NLO QCD corrections to dijet production induced by contact interactions [3]. In proton-proton collisions, the  $\Lambda_{LL}^\pm$  and  $\Lambda_{RR}^\pm$  contact interaction models result in identical tree-level cross sections and NLO QCD corrections and yield the same exclusion limits. For  $\Lambda_{VV}^\pm$  and  $\Lambda_{AA}^\pm$ , the contact interaction predictions are identical at tree level, but exhibit different NLO QCD corrections and yield different exclusion limits. Figure 2 also shows lower limits for two benchmark contact interaction models in which only left-handed quarks participate with destructive ( $\eta_{LL} = +1$ ) and constructive ( $\eta_{LL} = -1$ ) interference, using the inclusive jet  $p_T$  spectrum measured in CMS at  $\sqrt{s} = 7$  TeV [11].

If leptons ( $l$ ) and quarks ( $q$ ) are composite with common constituents, the interaction of these constituents will manifest itself in the form of a  $llqq$ -type four-fermion contact interaction Lagrangian at energies below the compositeness scale  $\Lambda$ . The  $llqq$  terms in the contact interaction Lagrangian can be expressed as

**Figure 2:** Observed (solid lines) and expected (dashed lines) 95% C.L. lower limits on the contact interaction scale  $\Lambda$  for different contact interaction models from ATLAS [9] and CMS [11,12] using the dijet angular distributions and the inclusive jet  $p_T$  spectrum. The contact interaction models used for the dijet angular distributions include the exact NLO QCD corrections to dijet production. All limits are extracted using the  $CL_s$  technique [17,18].

$$\mathcal{L} = \frac{g_{\text{contact}}^2}{\Lambda^2} [\eta_{LL}(\bar{q}_L \gamma_\mu q_L)(\bar{l}_L \gamma^\mu l_L) + \eta_{RR}(\bar{q}_R \gamma_\mu q_R)(\bar{l}_R \gamma^\mu l_R) + \eta_{LR}(\bar{q}_L \gamma_\mu q_L)(\bar{l}_R \gamma^\mu l_R) + \eta_{RL}(\bar{q}_R \gamma_\mu q_R)(\bar{l}_L \gamma^\mu l_L)]. \quad (3)$$

Searches on quark-lepton compositeness have been reported from experiments at LEP [19–23], HERA [24,25], the Tevatron [26–30], and recently from the ATLAS [31–34] and CMS [35] experiments at the LHC. The most stringent searches for  $llqq$  contact interactions are performed by the LHC experiments using high-mass oppositely-charged lepton pairs produced through the  $q\bar{q} \rightarrow l^+l^-$  Drell-Yan process. The contact interaction amplitude of the  $u\bar{u} \rightarrow l^+l^-$  process interferes with the corresponding SM amplitude constructively (destructively) for  $\eta_{\alpha\beta} = -1$  ( $\eta_{\alpha\beta} = +1$ ). The ATLAS Collaboration has extracted limits on the  $llqq$  contact interaction for the right-right ( $\eta_{RR} = \pm 1$ ,  $\eta_{LL} = \eta_{LR} = \eta_{RL} = 0$ ), left-left ( $\eta_{LL} = \pm 1$ ,  $\eta_{RR} = \eta_{LR} = \eta_{RL} = 0$ ), and left-right ( $\eta_{LR} = \eta_{RL} = \pm 1$ ,  $\eta_{RR} = \eta_{LL} = 0$ ) models [34]. With the ATLAS full dataset at  $\sqrt{s} = 8$  TeV and combining the dielectron and dimuon channels, the 95% C.L. lower limits on the  $llqq$  contact interaction scale  $\Lambda$  are 21.1 TeV (17.5 TeV) for the right-right model, 21.6 TeV (17.2 TeV) for the left-left model, and 26.3

# Searches Particle Listings

## Quark and Lepton Compositeness

TeV (19.0 TeV) for the left-right model, each with constructive (destructive) interference [34]. The limits are extracted using a Bayesian approach with a prior probability flat in  $1/\Lambda^2$ . Using the dimuon channel from the 7-TeV run, the CMS Collaboration, using the  $CL_s$  technique, has set a 95% C.L. lower limit on the scale  $\Lambda$  of 13.1 TeV (9.5 TeV) for the benchmark left-left  $llqq$  contact interaction model with constructive (destructive) interference [35].

Note that the contact interactions arising from the compositeness of quarks and leptons Eq. (1) can also be regarded as a part of more general dimension six operators in the context of low energy standard model effective theory. For a complete list of these dimension six operators see Refs. 36,37.

Interactions of hypothetical dark matter candidate particles with SM can also be described as contact interactions at low energy. See “*Searches for WIMPs and Other Particles*” in this volume for limits on the interactions involving dark matter candidate particles.

### Limits on excited fermions

Another typical consequence of compositeness is the appearance of excited leptons and quarks ( $l^*$  and  $q^*$ ). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares a leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron  $e^*$  is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for  $g - 2$  suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton [38–40].

Excited leptons may be classified by  $SU(2) \times U(1)$  quantum numbers. Typical examples are:

1. Sequential type  

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \quad [\nu_R^*], \quad l_R^*.$$

$\nu_R^*$  is necessary unless  $\nu^*$  has a Majorana mass.

2. Mirror type  

$$[\nu_L^*], \quad l_L^*, \quad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

3. Homodoublet type  

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \quad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their minimal gauge couplings. The couplings of excited leptons with  $Z$  are given by

$$\begin{aligned} & \frac{e}{2 \sin \theta_W \cos \theta_W} (-1 + 2 \sin^2 \theta_W) \bar{l}^* \gamma^\mu l^* Z_\mu \\ & + \frac{e}{2 \sin \theta_W \cos \theta_W} \bar{\nu}^* \gamma^\mu \nu^* Z_\mu \end{aligned}$$

in the homodoublet model. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at  $q^2 \neq 0$ , they are usually neglected.

Excited fermions may also be produced via the contact interactions with ordinary quarks and leptons [41]

$$\begin{aligned} \mathcal{L} = & \frac{g_{\text{contact}}^2}{\Lambda^2} [\eta'_{LL} (\bar{\psi}_L \gamma_\mu \psi_L) (\bar{\psi}_L^* \gamma^\mu \psi_L^*) \\ & + (\eta''_{LL} (\bar{\psi}_L \gamma_\mu \psi_L) (\bar{\psi}_L^* \gamma^\mu \psi_L) + \text{h.c.}) + \dots] \end{aligned} \quad (4)$$

Again, the coefficient is conventionally taken  $g_{\text{contact}}^2 = 4\pi$ . It is widely assumed  $\eta'_{LL} = \eta''_{LL} = 1$ ,  $\eta'_{LR} = \eta''_{LR} = \eta'_{RL} = \eta''_{RL} = \eta'_{RR} = \eta''_{RR} = 0$  in experimental analyses for simplicity.

In addition, transition-magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned} \mathcal{L} = & \frac{\lambda_\gamma^{(\psi^*)} e}{2m_{\psi^*}} \bar{\psi}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \psi F_{\mu\nu} \\ & + \frac{\lambda_Z^{(\psi^*)} e}{2m_{\psi^*}} \bar{\psi}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \psi Z_{\mu\nu} \\ & + \frac{\lambda_W^{(l^*)} g}{2m_{l^*}} \bar{l}^* \sigma^{\mu\nu} \frac{1-\gamma_5}{2} \nu W_{\mu\nu} \\ & + \frac{\lambda_W^{(\nu^*)} g}{2m_{\nu^*}} \bar{\nu}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) l W_{\mu\nu}^\dagger \\ & + \text{h.c.}, \end{aligned} \quad (5)$$

where  $g = e/\sin \theta_W$ ,  $\psi = \nu$  or  $l$ ,  $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$  is the photon field strength,  $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$ , *etc.*. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L \eta_R = 0. \quad (6)$$

These couplings in Eq. (5) can arise from  $SU(2) \times U(1)$ -invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type  $l^*$  with the Lagrangian (see Refs. 42,43)

$$\mathcal{L} = \frac{1}{2\Lambda} \bar{L}^* \sigma^{\mu\nu} (g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \frac{1-\gamma_5}{2} L + \text{h.c.}, \quad (7)$$

where  $L$  denotes the lepton doublet  $(\nu, l)$ ,  $\Lambda$  is the compositeness scale,  $g, g'$  are  $SU(2)$  and  $U(1)_Y$  gauge couplings, and  $W_{\mu\nu}^a$  and  $B_{\mu\nu}$  are the field strengths for  $SU(2)$  and  $U(1)_Y$  gauge fields. These couplings satisfy the relation

$$\lambda_W = -\sqrt{2} \sin^2 \theta_W (\lambda_Z \cot \theta_W + \lambda_\gamma), \quad (8)$$

with  $\lambda_{W,Z,\gamma}$  being defined in Eq. (5) with  $\lambda_{W,Z,\gamma} = \lambda_{W,Z,\gamma}^{(\ell^*)}$  or  $\lambda_{W,Z,\gamma} = \lambda_{W,Z,\gamma}^{(\nu^*)}$ . Here  $(\eta_L, \eta_R) = (1, 0)$  is assumed. It should be noted that the electromagnetic radiative decay of  $l^*$  ( $\nu^*$ ) is forbidden if  $f = -f'$  ( $f = f'$ ).

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned} \mathcal{L} = & \frac{1}{2\Lambda} \bar{Q}^* \sigma^{\mu\nu} \left( g_s f_s \frac{\lambda^a}{2} G_{\mu\nu}^a + g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu} \right) \\ & \times \frac{1-\gamma_5}{2} Q + \text{h.c.}, \end{aligned} \quad (9)$$

where  $Q$  denotes a quark doublet,  $g_s$  is the QCD gauge coupling, and  $G_{\mu\nu}^a$  the gluon field strength.

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons ( $l_8$ ) and the ordinary lepton ( $l$ ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_l \{ \bar{l}_8^\alpha g_S F_{\mu\nu}^{\alpha} \sigma^{\mu\nu} (\eta_L l_L + \eta_R l_R) + \text{h.c.} \} \quad (10)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies  $\eta_L \eta_R = 0$  as before.

Searches for excited quarks and leptons have been performed over the last decades in experiments at the LEP [44–52], HERA [53–56], Tevatron [57–62], and LHC [63–80]. Most stringent constraints from these experiments described below are all given at 95% confidence level.

The signature of excited quarks  $q^*$  at hadron colliders is characterized by a narrow resonant peak in the reconstructed invariant mass distribution of  $q^*$  decay products. The decays via the transition-magnetic type operator in Eq. (9) are considered for excited quarks in LHC searches, and the final states to search for are dijet ( $qg$ ) [63–65, 71–74] or a jet in association with a photon ( $q\gamma$ ) [66, 67, 75] or a weak gauge boson ( $qW, qZ$ ) [76–78]. All analyses consider only spin-1/2 excited states of first generation quarks ( $u^*, d^*$ ) with degenerate masses, expected to be predominantly produced in proton-proton collisions, except for Ref. 74 where excited  $b$  quarks are also considered. Only the minimal gauge interactions and the transition-magnetic couplings with the form given in Eq. (9) are considered in the production process, and hence the contact interactions in Eq. (4) are not considered. The compositeness scale  $\Lambda$  is taken to be the same as the excited quark mass  $m_{q^*}$ . The transition-magnetic coupling coefficients  $f_s, f$  and  $f'$  are assumed to be equal (denoted by  $f$ ) and around order 1.

With the full proton-proton collision data recorded at  $\sqrt{s} = 8$  TeV at LHC, the excited quark masses are excluded in dijet resonance searches up to 4.06 TeV in ATLAS [65] and 3.5 TeV in CMS [74]. Figure 3 shows the dijet mass distribution measured in CMS by using the two highest  $p_T$  jets reconstructed with the anti- $k_T$  algorithm [81] of a distance parameter of 0.5, and by combining nearby jets within  $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$  around the leading two jets. The measured dijet mass spectrum is compared to a fit with smoothly falling background shape (solid curve) to look for a narrow resonance (3.6 TeV excited quark signal shown as one of two benchmark signals) and predictions from multi-jet events (dashed curve labeled as QCD MC) generated using PYTHIA 6.426 [82] with GEANT4-based [14] CMS detector simulation. The photon + jet resonance searches have excluded excited quarks with mass up to 3.5 TeV in both ATLAS [67] and CMS [75]. All these mass exclusions are obtained for  $f = 1$ . The  $W/Z$  boson + jet final states are examined to look for  $q^* \rightarrow q + W$  and  $q + Z$  signal in CMS [78], exploiting jet substructure technique designed to provide sensitivity for highly-boosted hadronically decaying  $W$

**Figure 3:** Dijet mass distribution measured by CMS using wide jets reconstructed from two highest transverse momentum jets by adding nearby jets within  $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$ . The data distribution is compared to a fit representing a smooth background spectrum (solid curve) and to the normalized prediction of multi-jet background simulated by PYTHIA (labeled as QCD MC). Excited quark signal with mass of 3.6 TeV is also shown for comparison. Shown at the bottom panel is the bin-by-bin fit residuals normalized by the statistical uncertainty of the data. Figure adopted from Ref. 74.

and  $Z$  bosons. The  $q^*$  mass exclusion of 3.2 (2.9) TeV is obtained from the  $W + \text{jet}$  ( $Z + \text{jet}$ ) search.

Searches for excited leptons  $l^*$  are also performed at the LHC using proton-proton collision data recorded at  $\sqrt{s} = 7$  and 8 TeV [68–70, 79, 80]. Considering the single  $l^*$  production Eq. (4) and electromagnetic radiative decay to a SM lepton ( $l$ ) and a photon ( $\gamma$ ), both the excited electron and excited muon masses below 2.2 TeV are excluded for  $\Lambda = m_{l^*}$  at  $\sqrt{s} = 8$  TeV in ATLAS [69]. With the full data at  $\sqrt{s} = 8$  TeV, the inclusive search on multi-lepton signatures with 3 or more charged leptons in ATLAS [70] further constrains the excited charged leptons and neutrinos. Considering both the transition-magnetic Eq. (7) and contact interaction Eq. (4) processes, the lower mass limits for the  $e^*, \mu^*, \tau^*$  and  $\nu^*$  (for every excited neutrino flavor) are obtained to be 3.0, 3.0, 2.5 and 1.6 TeV, respectively, for  $\Lambda = m_{e^*}, m_{\mu^*}, m_{\tau^*}$  and  $m_{\nu^*}$ . The rate of pair-produced excited leptons is independent of  $\Lambda$  for the minimal gauge interaction processes, and it allows to improve the search sensitivity with multi-lepton signatures at high  $\Lambda$ , especially for excited neutrinos because the predominant  $\nu_l^* \rightarrow l + W$  decays

## Quark and Lepton Compositeness

**Figure 4:** 95% C.L. lower mass limits for the excited quarks and leptons at ATLAS [65,67,69,70] and CMS [74,75,78,80] experiments. Shown are the most stringent limits for each excited fermion from both experiments. Only first generation quarks ( $u, d$ ) with transition-magnetic type interactions with  $f_s = f = f' = 1$  are considered for excited quarks, and the limits are shown for different final states denoted in parentheses. Excited lepton limits are given for contact interactions with  $\Lambda = m_{l^*}$ . The observed limit from  $q^* \rightarrow q + \gamma$  is 3.5 TeV for both ATLAS and CMS. For the excited leptons the observed and expected limits are same in both ATLAS and CMS.

result in a higher acceptance for  $\geq 3$  charged lepton final states. A similar search for excited leptons with  $l^* \rightarrow l + \gamma$  decays ( $l = e, \mu$ ) produced in contact interactions is performed by the CMS Collaboration at  $\sqrt{s} = 7$  TeV [80], resulting in a mass exclusion of 1.9 TeV for  $\Lambda = m_{l^*}$ . Figure 4 summarizes the most stringent 95% C.L. lower mass limits for the excited quarks and leptons obtained from the LHC experiments.

- <sup>1</sup> AAD 14BE limits are from  $pp$  collisions at  $\sqrt{s} = 8\text{ TeV}$ . The quoted limit uses a uniform positive prior in  $1/\Lambda^2$ .  
<sup>2</sup> ABDALLAH 09 and SCHAEEL 07A limits are from  $R_b$ ,  $A_{FB}^b$ .  
<sup>3</sup> SCHAEEL 07A limits are from  $R_C$ ,  $Q_{FB}^{\text{depl}}$ , and hadronic cross section measurements.  
<sup>4</sup> CHEUNG 01B is an update of BARGER 98E.  
<sup>5</sup> KHACHATRYAN 15AE limit is from  $e^{+}e^{-}$  mass distribution in  $pp$  collisions at  $E_{\text{cm}} = 8\text{ TeV}$ .  
<sup>6</sup> AAD 13E limits are from  $e^{+}e^{-}$  mass distribution in  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ .  
<sup>7</sup> AAD 12AB limits are from  $e^{+}e^{-}$  mass distribution in  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ .  
<sup>8</sup> AARON 11C limits are from  $Q^2$  spectrum measurements of  $e^{\pm}p \rightarrow e^{\pm}X$ .  
<sup>9</sup> ABDALLAH 11 limit is from  $e^{+}e^{-} \rightarrow t\bar{c}$  cross section.  $\Lambda_{LL} = \Lambda_{LR} = \Lambda_{RL} = \Lambda_{RR}$  is assumed.  
<sup>10</sup> SCHAEEL 07A limit assumes quark flavor universality of the contact interactions.  
<sup>11</sup> ABULENCIA 06L limits are from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96\text{ TeV}$ .

<b>&gt;5.0</b>	<b>&gt;5.4</b>	95	<sup>1</sup> MCFARLAND 98	CCFR	$\nu N$ scattering

<sup>1</sup> MCFARLAND 98 assumed a flavor universal interaction. Neutrinos were mostly of muon type.

#### MASS LIMITS for Excited $e$ ( $e^*$ )

Most  $e^+e^-$  experiments assume one-photon or  $Z$  exchange. The limits from some  $e^+e^-$  experiments which depend on  $\lambda$  have assumed transition couplings which are chirality violating ( $\eta_L = \eta_R$ ). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value  $\lambda$  by  $\sqrt{2}$ ; see Note.

Excited leptons have the same quantum numbers as other ortho-leptons. See also the searches for ortho-leptons in the "Searches for Heavy Leptons" section.

#### Limits for Excited $e$ ( $e^*$ ) from Pair Production

These limits are obtained from  $e^+e^- \rightarrow e^{*+}e^{*-}$  and thus rely only on the (electroweak) charge of  $e^*$ . Form factor effects are ignored unless noted. For the case of limits from  $Z$  decay, the  $e^*$  coupling is assumed to be of sequential type. Possible  $t$ -channel contribution from transition magnetic coupling is neglected. All limits assume a dominant  $e^* \rightarrow e\gamma$  decay except the limits from  $\Gamma(Z)$ .

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

<sup>1</sup> DORENBOS... 89	CHRM	$\overline{\nu}_\mu e \rightarrow \overline{\nu}_\mu e, \nu_\mu e \rightarrow \nu_\mu e$	
<sup>2</sup> GRIFOLS 86	THEO	$\nu_\mu e \rightarrow \nu_\mu e$	
<sup>3</sup> RENARD 82	THEO	$g-2$ of electron	

<sup>1</sup> DORENBOSCH 89 obtain the limit  $\lambda_\gamma^2 \Lambda_{\text{cut}}^2 / m_{e^*}^2 < 2.6$  (95% CL), where  $\Lambda_{\text{cut}}$  is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that  $\Lambda_{\text{cut}} = 1$  TeV and  $\lambda_\gamma = 1$ , one obtains  $m_{e^*} > 620$  GeV. However, one generally expects  $\lambda_\gamma \approx m_{e^*} / \Lambda_{\text{cut}}$  in composite models.

<sup>2</sup> GRIFOLS 86 uses  $\nu_\mu e \rightarrow \nu_\mu e$  and  $\overline{\nu}_\mu e \rightarrow \overline{\nu}_\mu e$  data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

<sup>3</sup> RENARD 82 derived from  $g-2$  data limits on mass and couplings of  $e^*$  and  $\mu^*$ . See figures 2 and 3 of the paper.

Extra Dimensions

For explanation of terms used and discussion of significant model dependence of following limits, see the "Extra Dimensions" review. Footnotes describe originally quoted limit.  $\delta$  indicates the number of extra dimensions.

Limits not encoded here are summarized in the "Extra Dimensions" review, where the latest unpublished results are also described.

EXTRA DIMENSIONS

Updated September 2015 by John Parsons (Columbia University) and Alex Pomarol (Universitat Autònoma de Barcelona)

I Introduction

Proposals for a spacetime with more than three spatial dimensions date back to the 1920's, mainly through the work of Kaluza and Klein, in an attempt to unify the forces of nature [1]. Although their initial idea failed, the formalism that they and others developed is still useful nowadays. Around 1980, string theory proposed again to enlarge the number of space dimensions, this time as a requirement for describing a consistent theory of quantum gravity. The extra dimensions were supposed to be compactified at a scale close to the Planck scale, and thus not testable experimentally in the near future.

A different approach was given by Arkani-Hamed, Dimopoulos and Dvali (ADD) in their seminal paper in 1998 [2], where they showed that the weakness of gravity could be explained by postulating two or more extra dimensions in which only gravity could propagate. The size of these extra dimensions should range between roughly a millimeter and  $\sim 1/\text{TeV}$ , leading to possible observable consequences in current and future experiments. A year later, Randall and Sundrum (RS) [3] found a new possibility using a warped geometry, postulating a five-dimensional Anti-de Sitter (AdS) spacetime with a compactification scale of order TeV. The origin of the smallness of the electroweak scale versus the Planck scale was explained by the gravitational redshift factor present in the warped AdS metric. As in the ADD model, originally only gravity was assumed to propagate in the extra dimensions, although it was soon clear that this was not necessary in warped extra-dimensions and also the SM gauge fields [4] and SM fermions [5,6] could propagate in the five-dimensional space.

# Searches Particle Listings

## Extra Dimensions

The physics of warped extra-dimensional models has an alternative interpretation by means of the AdS/CFT correspondence [7]. Models with warped extra dimensions are related to four-dimensional strongly-interacting theories, allowing an understanding of the properties of five-dimensional fields as those of four-dimensional composite states [8]. This approach has opened new directions for tackling outstanding questions in particle physics, such as the flavor problem, grand unification, and the origin of electroweak symmetry breaking or supersymmetry breaking.

### Experimental

**Constraints:** Constraints on extra-dimensional models arise from astrophysical and cosmological considerations. In addition, as we will show below, tabletop experiments exploring gravity at sub-mm distances restrict certain models. Collider limits on extra-dimensional models are dominated by Run 1 LHC results. This review includes the most recent limits, most of which are published results based on LHC data collected in 2012 at a center-of-mass energy of 8 TeV. In addition, there are a few preliminary 8 TeV results, which can be found on the WWW pages of public ATLAS [9] and CMS [10]. Unless otherwise stated, all LHC results use the full  $\sim 20 \text{ fb}^{-1}$  samples of 8 TeV collisions recorded in 2012. Run 2 LHC results, with operations at 13 TeV, will greatly extend the sensitivity of the collider searches for evidence of extra dimensions, particularly once comparable integrated luminosities (and eventually much more) have been accumulated. For some models, much smaller data samples already suffice; indeed a few preliminary 13 TeV analyses focusing on strong gravity signatures have been presented at the LHCP Conference in early September 2015, and are included here since they already surpass the sensitivity of the 8 TeV results, despite using very early Run 2 data samples of less than  $0.1 \text{ fb}^{-1}$ .

**Kaluza-Klein Theories:** Field theories with compact extra dimensions can be written as theories in ordinary four dimensions (4D) by performing a Kaluza-Klein (KK) reduction. As an illustration, consider a simple example, namely a field theory of a complex scalar in flat five-dimensional (5D) spacetime. The action will be given by <sup>†</sup>

$$S_5 = - \int d^4x dy M_5 \left[ |\partial_\mu \phi|^2 + |\partial_y \phi|^2 + \lambda_5 |\phi|^4 \right], \quad (1)$$

where  $y$  refers to the extra (fifth) dimension. A universal scale  $M_5$  has been extracted in front of the action in order to keep the 5D field with the same mass-dimension as in 4D. This theory is perturbative for energies  $E \lesssim \ell_5 M_5 / \lambda_5$  where  $\ell_5 = 24\pi^3$  [11].

Let us now consider that the fifth dimension is compact with the topology of a circle  $S^1$  of radius  $R$ , which corresponds to the identification of  $y$  with  $y + 2\pi R$ . In such a case, the 5D complex scalar field can be expanded in a Fourier series:

$$\phi(x, y) = \frac{1}{\sqrt{2\pi R M_5}} \sum_{n=-\infty}^{\infty} e^{iny/R} \phi^{(n)}(x),$$

<sup>†</sup> Our convention for the metric is  $\eta_{MN} = \text{Diag}(-1, 1, 1, 1, 1)$ .

that, inserted in Eq. (1) and integrating over  $y$ , gives

$$S_5 = S_4^{(0)} + S_4^{(n)},$$

where

$$S_4^{(0)} = - \int d^4x \left[ |\partial_\mu \phi^{(0)}|^2 + \lambda_4 |\phi^{(0)}|^4 \right], \text{ and} \quad (2)$$

$$S_4^{(n)} = - \int d^4x \sum_{n \neq 0} \left[ |\partial_\mu \phi^{(n)}|^2 + \left(\frac{n}{R}\right)^2 |\phi^{(n)}|^2 \right] + \text{quartic int.}$$

The  $n = 0$  mode self-coupling is given by

$$\lambda_4 = \frac{\lambda_5}{2\pi R M_5}. \quad (3)$$

The above action corresponds to a 4D theory with a massless scalar  $\phi^{(0)}$ , referred to as the zero-mode, and an infinite tower of massive modes  $\phi^{(n)}$ , known as KK modes. The KK reduction thus allows a treatment of 5D theories as 4D field theories with an infinite number of fields. At energies smaller than  $1/R$ , the KK modes can be neglected, leaving the zero-mode action of Eq. (2). The strength of the interaction of the zero-mode, given by Eq. (3), decreases as  $R$  increases. Thus, for a large extra dimension  $R \gg 1/M_5$ , the massless scalar is weakly coupled.

## II Large Extra Dimensions for Gravity

### II.1 The ADD Scenario

The ADD scenario [2,12,13] assumes a  $D = 4 + \delta$  dimensional spacetime, with  $\delta$  compactified spatial dimensions. The weakness of gravity arises since it propagates in the higher-dimensional space. The SM is assumed to be localized in a 4D subspace, a 3-brane, as can be found in certain string constructions [14]. Gravity is described by the Einstein-Hilbert action in  $D = 4 + \delta$  spacetime dimensions

$$S_D = - \frac{\bar{M}_D^{2+\delta}}{2} \int d^4x d^\delta y \sqrt{-g} \mathcal{R} + \int d^4x \sqrt{-g_{\text{ind}}} \mathcal{L}_{\text{SM}}, \quad (4)$$

where  $x$  labels the ordinary four coordinates,  $y$  the  $\delta$  extra coordinates,  $g$  refers to the determinant of the  $D$ -dimensional metric whose Ricci scalar is defined by  $\mathcal{R}$ , and  $\bar{M}_D$  is the reduced Planck scale of the  $D$ -dimensional theory. In the second term of Eq. (4), which gives the gravitational interactions of SM fields, the  $D$ -dimensional metric reduces to the induced metric on the 3-brane where the SM fields propagate. The extra dimensions are assumed to be flat and compactified in a volume  $V_\delta$ . As an example, consider a toroidal compactification of equal radii  $R$  and volume  $V_\delta = (2\pi R)^\delta$ . After a KK reduction, one finds that the fields that couple to the SM are the spin-2 gravitational field  $G_{\mu\nu}(x, y)$  and a tower of spin-1 KK graviscalars [15]. The graviscalars, however, only couple to SM fields through the trace of the energy-momentum tensor, resulting in weaker couplings to the SM fields. The Fourier expansion of the spin-2 field is given by

$$G_{\mu\nu}(x, y) = G_{\mu\nu}^{(0)}(x) + \frac{1}{\sqrt{V_\delta}} \sum_{\vec{n} \neq 0} e^{i\vec{n} \cdot \vec{y}/R} G_{\mu\nu}^{(\vec{n})}(x), \quad (5)$$

where  $\vec{y} = (y_1, y_2, \dots, y_\delta)$  are the extra-dimensional coordinates and  $\vec{n} = (n_1, n_2, \dots, n_\delta)$ . Eq. (5) contains a massless state, the 4D graviton, and its KK tower with masses  $m_n^2 = |\vec{n}|^2/R^2$ . At energies below  $1/R$  the action is that of the zero-mode

$$S_4^{(0)} = -\frac{\bar{M}_D^{2+\delta}}{2} \int d^4x V_\delta \sqrt{-g^{(0)}} \mathcal{R}^{(0)} + \int d^4x \sqrt{-g_{\text{ind}}^{(0)}} \mathcal{L}_{\text{SM}},$$

where we can identify the 4D reduced Planck mass,  $M_P \equiv G_N/\sqrt{8\pi} \simeq 2.4 \times 10^{18}$  GeV, as a function of the  $D$ -dimensional parameters:

$$M_P^2 = V^\delta \bar{M}_D^{2+\delta} \equiv R^\delta M_D^{2+\delta}. \quad (6)$$

Fixing  $M_D$  at around the electroweak scale  $M_D \sim \text{TeV}$  to avoid introducing a new mass-scale in the model, Eq. (6) gives a prediction for  $R$ :

$$\delta = 1, 2, \dots, 6 \rightarrow R \sim 10^9 \text{ km}, 0.5 \text{ mm}, \dots, 0.1 \text{ MeV}^{-1}. \quad (7)$$

The option  $\delta = 1$  is clearly ruled out, as it leads to modifications of Newton's law at solar system distances. However this is not the case for  $\delta \geq 2$ , and possible observable consequences can be sought in present and future experiments.

Consistency of the model requires a stabilization mechanism for the radii of the extra dimensions, to the values shown in Eq. (7). The fact that we need  $R \gg 1/M_D$  leads to a new hierarchy problem, the solution of which might require imposing supersymmetry in the extra-dimensional bulk [16].

## II.2 Tests of the Gravitational Force Law at Sub-mm Distances

The KK modes of the graviton give rise to deviations from Newton's law of gravitation for distances  $\lesssim R$ . Such deviations are usually parametrized by a modified Newtonian potential of the form

$$V(r) = -G_N \frac{m_1 m_2}{r} \left[ 1 + \alpha e^{-r/\lambda} \right]. \quad (8)$$

For a 2-torus compactification,  $\alpha = 16/3$  and  $\lambda = R$ . Searches for deviations from Newton's law of gravitation have been performed in several experiments. Ref. [17] gives the present constraints:  $R < 37 \mu\text{m}$  at 95% CL for  $\delta = 2$ , corresponding to  $M_D > 3.6 \text{ TeV}$ .

## II.3 Astrophysical and Cosmological Constraints

The light KK gravitons could be copiously produced in stars, carrying away energy. Ensuring that the graviton luminosity is low enough to preserve the agreement of stellar models with observations provides powerful bounds on the scale  $M_D$ . The most stringent arises from supernova SN1987A, giving  $M_D > 27$  (2.4) TeV for  $\delta = 2$  (3) [18]. After a supernova explosion, most of the KK gravitons stay gravitationally trapped in the remnant neutron star. The requirement that neutron stars are not excessively heated by KK decays into photons leads to  $M_D > 1700$  (76) TeV for  $\delta = 2$  (3) [19].

Cosmological constraints are also quite stringent [20]. To avoid overclosure of the universe by relic gravitons one needs  $M_D > 7 \text{ TeV}$  for  $\delta = 2$ . Relic KK gravitons decaying into photons contribute to the cosmic diffuse gamma radiation, from which one can derive the bound  $M_D > 100 \text{ TeV}$  for  $\delta = 2$ .

We must mention however that bounds coming from the decays of KK gravitons into photons can be reduced if we assume that KK gravitons decay mainly into other non-SM states. This could happen, for example, if there were other 3-branes with hidden sectors residing on them [12].

## II.4 Collider Signals

### II.4a Graviton and Other Particle Production

Although each KK graviton has a purely gravitational coupling, suppressed by  $1/M_P$ , inclusive processes in which one sums over the almost continuous spectrum of available gravitons have cross sections suppressed only by powers of  $M_D$ . Processes involving gravitons are therefore detectable in collider experiments if  $M_D \sim \text{TeV}$ . A number of experimental searches for evidence of large extra dimensions have been performed at colliders, and interpreted in the context of the ADD model.

One signature arises from direct graviton emission. By making a derivative expansion of Einstein gravity, one can construct an effective theory, valid for energies much lower than  $M_D$ , and use it to make predictions for graviton-emission processes at colliders [15,21,22]. Gravitons produced in the final state would escape detection, giving rise to missing transverse energy ( $\cancel{E}_T$ ). The results quoted below are 95% CL lower limits on  $M_D$  for a range of values of  $\delta$  between 2 and 6, with more stringent limits corresponding to lower  $\delta$  values.

At hadron colliders, experimentally sensitive channels include the jet ( $j$ ) +  $\cancel{E}_T$  and  $\gamma$  +  $\cancel{E}_T$  final states. The CMS analysis of the  $j$  +  $\cancel{E}_T$  final state assumes k-factors varying between 1.4 for  $\delta = 2, 3$  and down to 1.2 for  $\delta = 6$  to account for next-to-leading order (NLO) contributions to the signal cross sections, and sets limits of  $M_D > 3.53 - 6.09 \text{ TeV}$  [23]. ATLAS  $j$  +  $\cancel{E}_T$  results provide limits of  $M_D > 3.06 - 5.25 \text{ TeV}$  [24], assuming leading order (LO) cross sections. For these analyses, the LHC experiments handle somewhat differently the issue that the effective theory is only valid for energies much less than  $M_D$ : the ATLAS results are quoted for the full space, and include the information that suppressing the graviton cross section by a factor  $M_D^4/\hat{s}^2$  for  $\sqrt{\hat{s}} > M_D$ , where  $\sqrt{\hat{s}}$  is the parton-level center-of-mass energy of the hard collision, weakens the limits on  $M_D$  by a negligible amount ( $\sim 3\%$ ) for  $\delta = 2$  ( $\delta = 6$ ). CMS considers the impact of simply truncating the differential cross section to remove the contribution from events where  $\sqrt{\hat{s}} > M_D$ , and shows that the effect of the truncation changes the cross section by a maximum of 11%. Less stringent limits are obtained by both ATLAS [25] and CMS [26] from analyses of the  $\gamma$  +  $\cancel{E}_T$  final state.

In models in which the ADD scenario is embedded in a string theory at the TeV scale [14], we expect the string scale  $M_s$  to be smaller than  $M_D$ , and therefore expect production of string resonances at the LHC [27]. A preliminary CMS Run 2 result from analysing the dijet invariant mass distribution for  $42 \text{ pb}^{-1}$  of 13 TeV data excludes string resonances that decay predominantly to  $q+g$  with masses below 5.1 TeV [28], already slightly extending their lower limit [29] of 5.0 TeV obtained

### Extra Dimensions

using their complete 20 fb<sup>-1</sup> sample of 8 TeV collisions. ATLAS dijet analyses include a published result using their full 8 TeV dataset [30] and a preliminary Run 2 result using 80 pb<sup>-1</sup> of 13 TeV data [31], and provide their results in the context of model-independent limits on the cross section times acceptance for generic resonances of a variety of possible widths.

#### II.4b Virtual graviton effects

One can also search for virtual graviton effects, the calculation of which however depends on the ultraviolet cut-off of the theory and is therefore very model dependent. In the literature, several different formulations exist [15,22,32] for the dimension-eight operator for gravity exchange at tree level:

$$\mathcal{L}_8 = \pm \frac{4}{M_{TT}^4} \left( T_{\mu\nu} T^{\mu\nu} - \frac{1}{\delta + 2} T_\mu^\mu T_\nu^\nu \right), \quad (9)$$

where  $T_{\mu\nu}$  is the energy-momentum tensor and  $M_{TT}$  is related to  $M_D$  by some model-dependent coefficient [33]. The relations with the parametrizations of Refs. [32] and [15] are, respectively,  $M_{TT} = M_S$  and  $M_{TT} = (2/\pi)^{1/4} \Lambda_T$ . The experimental results below are given as 95% CL lower limits on  $M_{TT}$ , including in some cases the possibility of both constructive or destructive interference, depending on the sign chosen in Eq. (9).

The most stringent limits arise from LHC analyses of the dijet angular distribution. Using their full 8 TeV dataset, CMS [34] obtains results that correspond to an approximate limit of  $M_{TT} > 6.3$  TeV. An ATLAS analysis [35] of 17 fb<sup>-1</sup> of 8 TeV collisions would provide similar sensitivity, but quotes the results only in the context of limits on contact interactions. The next most restrictive results are obtained by LHC analyses combining the dielectron and dimuon final states, with both experiments providing similar limits of approximately  $M_{TT} > 3.7$  TeV. The ATLAS [36] (CMS [37]) dilepton results assume LO (NLO) signal cross section values.

At the one-loop level, gravitons can also generate dimension-six operators with coefficients that are also model dependent. Experimental bounds on these operators can also give stringent constraints on  $M_D$  [33].

#### II.4c Black Hole Production

The physics at energies  $\sqrt{s} \sim M_D$  is sensitive to the details of the unknown quantum theory of gravity. Nevertheless, in the transplanckian regime,  $\sqrt{s} \gg M_D$ , one can rely on a semiclassical description of gravity to obtain predictions. An interesting feature of transplanckian physics is the creation of black holes [38]. A black hole is expected to be formed in a collision in which the impact parameter is smaller than the Schwarzschild radius [39]:

$$R_S = \frac{1}{M_D} \left[ \frac{2^\delta \pi^{\delta-3/2}}{\delta + 2} \Gamma\left(\frac{\delta + 3}{2}\right) \frac{M_{BH}}{M_D} \right]^{1/(\delta+1)}, \quad (10)$$

where  $M_{BH}$  is the mass of the black hole, which would roughly correspond to the total energy in the collision. The cross section for black hole production can be estimated to be of the same order as the geometric area  $\sigma \sim \pi R_S^2$ . For  $M_D \sim \text{TeV}$ , this gives

a production of  $\sim 10^7$  black holes at the  $\sqrt{s} = 14$  TeV LHC with an integrated luminosity of 30 fb<sup>-1</sup> [38]. A black hole would provide a striking experimental signature since it is expected to thermally radiate with a Hawking temperature  $T_H = (\delta + 1)/(4\pi R_S)$ , and therefore would evaporate democratically into all SM states. Nevertheless, given the present constraints on  $M_D$ , the LHC will not be able to reach energies much above  $M_D$ . This implies that predictions based on the semiclassical approximation could receive sizable modifications from model-dependent quantum-gravity effects.

The most stringent limits on microscopic black holes arise from LHC searches which observed no excesses above the SM background in high-multiplicity final states. The results are usually quoted as model-independent limits on the cross section for new physics in the final state and kinematic region analyzed. These results can then be used to provide constraints of models of low-scale gravity and weakly-coupled string theory. In addition, limits are sometimes quoted on particular implementations of models, which are used as benchmarks to illustrate the sensitivity. A preliminary Run 2 ATLAS search [40] for an excess of events with multiple high transverse momentum objects, including charged leptons and jets, using 80 pb<sup>-1</sup> of 13 TeV data, excludes semiclassical black holes below masses of  $\sim 7.3$  TeV for  $M_D = 2$  TeV and  $\delta = 6$ , extending by almost 1.5 TeV the limit of the corresponding analysis [41] applied to the full 20 fb<sup>-1</sup> 8 TeV dataset. Another preliminary Run 2 ATLAS analysis [42], again using 80 pb<sup>-1</sup> of 13 TeV data, looks at very high transverse energy multijet events and excludes black hole masses in the range 7.5 – 8.5 TeV, depending on  $M_D$ , for  $\delta = 6$ , again extending the limits of the corresponding 8 TeV analysis [43] by 0.5-1.5 TeV. The 8 TeV ATLAS analysis [44] of the track multiplicity in same-sign dimuon events provides lower mass limits of 5.1 - 5.7 TeV for  $M_D = 1.5$  TeV, with the range of limits depending on details of the model and also the number of extra dimensions. A CMS analysis [45] of multi-object final states using 12 fb<sup>-1</sup> of 8 TeV data provides similar limits, extending out to values of  $M_D \sim 5$  TeV.

For black hole masses near  $M_D$ , the semi-classical approximation is not valid, and one instead expects quantum black holes (QBH) that decay primarily into two-body final states [46]. LHC Run 1 results at 8 TeV provide lower limits on quantum black hole masses of order 4.6 - 6.3 TeV, depending on the details of the model. Searches that consider interpretations in terms of QBH limits include the CMS multi-object [45] analysis, as well as their dijet analysis [29]. ATLAS results include, in addition to their dijet analysis [30], searches in the photon+jet [47] and lepton+jet [48] final states. The preliminary Run 2 ATLAS dijet analysis [31] using 80 pb<sup>-1</sup> of 13 TeV collisions extends the exclusions to 6.5 – 6.8 TeV, depending on the model details.

In weakly-coupled string models the semiclassical description of gravity fails in the energy range between  $M_s$  and  $M_s/g_s^2$  where stringy effects are important. In this regime one expects, instead of black holes, the formation of string balls, made of

highly excited long strings, that could be copiously produced at the LHC for  $M_s \sim \text{TeV}$  [49], and would evaporate thermally at the Hagedorn temperature giving rise to high-multiplicity events. The same analyses used to search for black holes can be interpreted in the context of string balls. For example, for the case of  $\delta = 6$  and with model parameters fixed to values of  $g_s = 0.4$ ,  $M_D = 1.5 \text{ TeV}$ , and  $M_s = M_D/1.26 = 1.2 \text{ TeV}$ , the ATLAS same-sign dimuon [44] (multiple high transverse momentum object [41]) analysis excludes string balls with minimal masses below 5.3 (5.7) TeV. The CMS multi-object [45] analysis excludes the production of string balls with a minimum mass below  $\sim 5.5 \text{ TeV}$  for  $g_s = 0.4$ ,  $M_D$  in the range of 1.4–2.1 TeV, and  $M_s = M_D/1.25$ .

### III TeV-Scale Extra Dimensions

#### III.1 Warped Extra Dimensions

The RS model [3] is the most attractive setup of warped extra dimensions at the TeV scale, since it provides an alternative solution to the hierarchy problem. The RS model is based on a 5D theory with the extra dimension compactified in an orbifold,  $S^1/Z_2$ , a circle  $S^1$  with the extra identification of  $y$  with  $-y$ . This corresponds to the segment  $y \in [0, \pi R]$ , a manifold with boundaries at  $y = 0$  and  $y = \pi R$ . Let us now assume that this 5D theory has a cosmological constant in the bulk  $\Lambda$ , and on the two boundaries  $\Lambda_0$  and  $\Lambda_{\pi R}$ :

$$S_5 = - \int d^4x dy \left\{ \sqrt{-g} \left[ \frac{1}{2} M_5^3 \mathcal{R} + \Lambda \right] + \sqrt{-g_0} \delta(y) \Lambda_0 + \sqrt{-g_{\pi R}} \delta(y - \pi R) \Lambda_{\pi R} \right\}, \quad (11)$$

where  $g_0$  and  $g_{\pi R}$  are the values of the determinant of the induced metric on the two respective boundaries. Einstein's equations can be solved, giving in this case the metric

$$ds^2 = a(y)^2 dx^\mu dx^\nu \eta_{\mu\nu} + dy^2, \quad a(y) = e^{-ky}, \quad (12)$$

where  $k = \sqrt{-\Lambda/6M_5^3}$ . Consistency of the solution requires  $\Lambda_0 = -\Lambda_{\pi R} = -\Lambda/k$ . The metric in Eq. (12) corresponds to a 5D AdS space. The factor  $a(y)$  is called the “warp” factor and determines how 4D scales change as a function of the position in the extra dimension. In particular, this implies that energy scales for 4D fields localized at the boundary at  $y = \pi R$  are red-shifted by a factor  $e^{-k\pi R}$  with respect to those localized at  $y = 0$ . For this reason, the boundaries at  $y = 0$  and  $y = \pi R$  are usually referred to as the ultraviolet (UV) and infrared (IR) boundaries, respectively.

As in the ADD case, we can perform a KK reduction and obtain the low-energy effective theory of the 4D massless graviton. In this case we obtain

$$M_P^2 = \int_0^{\pi R} dy e^{-2ky} M_5^3 = \frac{M_5^3}{2k} (1 - e^{-2k\pi R}). \quad (13)$$

Taking  $M_5 \sim k \sim M_P$ , we can generate an IR-boundary scale of order  $ke^{-k\pi R} \sim \text{TeV}$  for an extra dimension of radius  $R \simeq 11/k$ . Mechanisms to stabilize  $R$  to this value have been proposed [50]

that, contrary to the ADD case, do not require introducing any new small or large parameter. Therefore a natural solution to the hierarchy problem can be achieved in this framework if the Higgs field, whose vacuum expectation value (VEV) is responsible for electroweak symmetry breaking, is localized at the IR-boundary where the effective mass scales are of order TeV. The radion field is generically heavy in models with a stabilized  $R$ . Nevertheless, it has been recently discussed that under some conditions a naturally light radion can arise [51]. In these cases the radion is identified with the dilaton, the Goldstone boson associated to the spontaneous breaking of scale invariance, and its mass can be naturally below  $ke^{-k\pi R} \sim \text{TeV}$ .

In the RS model [3], all the SM fields were assumed to be localized on the IR-boundary. Nevertheless, for the hierarchy problem, only the Higgs field has to be localized there. SM gauge bosons and fermions can propagate in the 5D bulk [4,5,6,52]. By performing a KK reduction from the 5D action of a gauge boson, we find [4]

$$\frac{1}{g_4^2} = \int_0^{\pi R} dy \frac{1}{g_5^2} = \frac{\pi R}{g_5^2},$$

where  $g_D$  ( $D = 4, 5$ ) is the gauge coupling in  $D$ -dimensions. Therefore the 4D gauge couplings can be of order one, as is the case of the SM, if one demands  $g_5^2 \sim \pi R$ . Using  $kR \sim 10$  and  $g_4 \sim 0.5$ , one obtains the 5D gauge coupling

$$g_5 \sim 4/\sqrt{k}. \quad (14)$$

Boundary kinetic terms for the gauge bosons can modify this relation, allowing for larger values of  $g_5\sqrt{k}$ .

Fermions propagating in a warped extra dimension have 4D massless zero-modes with wavefunctions which vary as  $f_0 \sim \exp[(1/2 - c_f)ky]$ , where  $c_fk$  is their 5D mass [53,6]. Depending on the free parameter  $c_fk$ , fermions can be localized either towards the UV-boundary ( $c_f > 1/2$ ) or IR-boundary ( $c_f < 1/2$ ). Since the Higgs boson is localized on the IR-boundary, one can generate exponentially suppressed Yukawa couplings by having the fermion zero-modes localized towards the UV-boundary, generating naturally the light SM fermion spectrum [6]. A large overlap with the wavefunction of the Higgs is needed for the top quark, in order to generate its large mass, thus requiring it to be localized towards the IR-boundary. In conclusion, the large mass hierarchies present in the SM fermion spectrum can be easily obtained in warped models via suitable choices of the order-one parameters  $c_f$  [54]. In these scenarios, deviations in flavor physics from the SM predictions are expected to arise from flavor-changing KK gluon couplings [55], putting certain constraints on the parameters of the models and predicting new physics effects to be observed in  $B$ -physics processes [56].

The masses of the KK states can also be calculated. One finds [6]

$$m_n \simeq \left( n + \frac{\alpha}{2} - \frac{1}{4} \right) \pi k e^{-\pi k R}, \quad (15)$$

# Searches Particle Listings

## Extra Dimensions

where  $n = 1, 2, \dots$  and  $\alpha = \{|c_f - 1/2|, 0, 1\}$  for KK fermions, KK gauge bosons and KK gravitons, respectively. Their masses are of order  $ke^{-\pi kR} \sim \text{TeV}$ ; the first KK state of the gauge bosons would be the lightest, while gravitons are expected to be the heaviest.

### III.1a Models of Electroweak Symmetry Breaking

Theories in warped extra dimensions can be used to implement symmetry breaking at low energies by boundary conditions [57]. For example, for a  $U(1)$  gauge symmetry in the 5D bulk, this can be easily achieved by imposing a Dirichlet boundary condition on the IR-boundary for the gauge-boson field,  $A_\mu|_{y=\pi R} = 0$ . This makes the zero-mode gauge boson get a mass, given by  $m_A = g_4 \sqrt{2k/g_5^2} e^{-\pi kR}$ . A very different situation occurs if the Dirichlet boundary condition is imposed on the UV-boundary,  $A_\mu|_{y=0} = 0$ . In this case the zero-mode gauge boson disappears from the spectrum. Finally, if a Dirichlet boundary condition is imposed on the two boundaries, one obtains a massless 4D scalar corresponding to the fifth component of the 5D gauge boson,  $A_5$ . Thus, different scenarios can be implemented by appropriately choosing the 5D bulk gauge symmetry,  $\mathcal{G}_5$ , and the symmetries to which it reduces on the UV and IR-boundary,  $\mathcal{H}_{UV}$  and  $\mathcal{H}_{IR}$ , respectively. In all cases the KK spectrum comes in representations of the group  $\mathcal{G}_5$ .

The recent discovery of a light Higgs boson with  $m_H \sim 125 \text{ GeV}$  [58] rules out Higgsless 5D models for electroweak symmetry breaking [59]. This discovery, however, is consistent with 5D composite Higgs models where a light Higgs boson is present in the spectrum.

**Composite Higgs models:** Warped extra dimensions can give rise to scenarios, often called gauge-Higgs unified models, where the Higgs boson appears as the fifth component of a 5D gauge boson,  $A_5$ . The Higgs mass is protected by the 5D gauge invariance and can only get a nonzero value from non-local one-loop effects [60]. To guarantee the relation  $M_W^2 \simeq M_Z^2 \cos^2 \theta_W$ , a custodial  $SU(2)_V$  symmetry is needed in the bulk and IR-boundary [61]. The simplest realization [62] has

$$\begin{aligned}\mathcal{G}_5 &= SU(3)_c \times SO(5) \times U(1)_X, \\ \mathcal{H}_{IR} &= SU(3)_c \times SO(4) \times U(1)_X, \\ \mathcal{H}_{UV} &= G_{SM}.\end{aligned}$$

The Higgs boson gets a potential at the one-loop level that triggers a VEV, breaking the electroweak symmetry. In these models there is a light Higgs boson whose mass can be around 125 GeV, as required by the recently discovered Higgs boson [58]. This state, as will be explained in Sec. III.2, behaves as a composite pseudo-Goldstone boson with couplings that deviate from the SM Higgs [63]. The present experimental determination of the Higgs couplings at the LHC, that agrees with the SM predictions, put important constraints on these scenarios [58]. The lightest KK modes of the model are color fermions with charges  $Q = -1/3, 2/3$  and  $5/3$  [64].

### III.1b Constraints from Electroweak Precision Tests

Models in which the SM gauge bosons propagate in 1/TeV-sized extra dimensions give generically large corrections to electroweak observables. When the SM fermions are confined on a boundary these corrections are universal and can be parametrized by four quantities:  $\hat{S}$ ,  $\hat{T}$ ,  $W$  and  $Y$ , as defined in Ref. [65]. For warped models, where the 5D gauge coupling of Eq. (14) is large, the most relevant parameter is  $\hat{T}$ , which gives the bound  $m_{KK} \gtrsim 10 \text{ TeV}$  [52]. When a custodial symmetry is imposed [61], the main constraint comes from the  $\hat{S}$  parameter, requiring  $m_{KK} \gtrsim 3 \text{ TeV}$ , independent of the value of  $g_5$ . Corrections to the  $Zb_L\bar{b}_L$  coupling can also be important [52], especially in warped models for electroweak symmetry breaking as the ones described above.

### III.1c Kaluza-Klein Searches

The main prediction of 1/TeV-sized extra dimensions is the presence of a discretized KK spectrum, with masses around the TeV scale, associated with the SM fields that propagate in the extra dimension.

In the RS model [3], only gravity propagates in the 5D bulk. Experimental searches have been performed for the lightest KK graviton through its decay to a variety of SM particle-antiparticle pairs. The results are usually interpreted in the plane of the dimensionless coupling  $k/M_P$  versus  $m_1$ , where  $M_P$  is the reduced Planck mass defined previously and  $m_1$  is the mass of the lightest KK excitation of the graviton. Since the AdS curvature  $\sim k$  cannot exceed the cut-off scale of the model, which is estimated to be  $\ell_5^{1/3} M_5$  [33], one must demand  $k \ll \sqrt{2\ell_5} M_P$ . The results quoted below are 95% CL lower limits on the KK graviton mass for a coupling  $k/M_P = 0.1$ .

The most stringent limits currently arise from LHC searches for resonances in the dilepton and diphoton final states, using the full samples of 8 TeV collisions. The CMS [66] and ATLAS [67] dilepton analyses, combining results from the  $ee$  and  $\mu\mu$  channels, exclude gravitons with masses below 2.73 TeV and 2.68 TeV, respectively. Similar results are obtained in the  $\gamma\gamma$  final state, which is quite powerful since it has a branching fraction twice that of any individual lepton flavor. The ATLAS  $\gamma\gamma$  analysis [68] provides a lower limit on the graviton mass of 2.66 TeV, while a preliminary CMS result [69] excludes gravitons below 2.78 TeV. Less stringent limits on the KK graviton mass come from 8 TeV analyses of the dijet [29],  $HH$  [70] and  $VV$  [71] final states, where  $V$  can represent either a  $W$  or  $Z$  boson. Experimental searches for the radion [70], through its production via gluon fusion and decaying to  $HH$ , exclude masses from 300 to 1100 GeV for a decay constant of 1 TeV.

In warped extra-dimensional models in which the SM fields propagate in the 5D bulk, the couplings of the KK graviton to  $ee/\mu\mu/\gamma\gamma$  are suppressed [72], and the above bounds do not apply. Furthermore, the KK graviton is the heaviest KK state (see Eq. (15)), and therefore experimental searches for KK gauge bosons and fermions are more appropriate discovery channels in these scenarios. For the scenarios discussed above in which only the Higgs boson and the top quark are localized

close to the IR-boundary, the KK gauge bosons mainly decay into top quarks, longitudinal  $W/Z$  bosons, and Higgs bosons. Couplings to light SM fermions are suppressed by a factor  $g/\sqrt{g_5^2 k} \sim 0.2$  [6] for the value of Eq. (14) that is considered from now on. Searches have been made for evidence of the lightest KK excitation of the gluon, through its decay to  $t\bar{t}$  pairs. The searches take into account the natural KK gluon width, which is typically  $\sim 15\%$  of its mass. The decay of a heavy particle to  $t\bar{t}$  would tend to produce highly boosted top (anti-)quarks in the final state. Products of the subsequent top decays would therefore tend to be close to each other in the detector. In the case of  $t \rightarrow Wb \rightarrow jjb$  decays, the three jets could overlap one another and not be individually reconstructed with the standard jet algorithms, while  $t \rightarrow Wb \rightarrow \ell\nu b$  decays could result in the lepton failing standard isolation requirements due to its proximity to the  $b$ -jet; in both cases, the efficiency for properly reconstructing the final state would fall as the mass of the original particle increases. To avoid the loss in sensitivity which would result, a number of techniques, known generally as “top quark tagging”, have been developed to reconstruct and identify highly boosted top quarks, for example by using a single “wide” jet to contain all the decay products of a hadronic top decay. The large backgrounds from QCD jets can then be reduced by requiring the “jet mass” be consistent with that of a top quark, and also by examining the substructure of the wide jet for indication that it resulted from the hadronic decay of a top quark. These techniques are key to extending to very high masses the range of accessible resonances decaying to  $t\bar{t}$  pairs. The CMS analysis [73] combines results from the dilepton, lepton-plus-jets and fully hadronic final states and excludes KK gluons with masses below 2.8 TeV. An ATLAS analysis [74] of the lepton-plus-jets final state excludes KK gluon masses below 2.2 TeV. The results are not directly comparable between the two LHC experiments, since they employ in their respective analyses different implementations of the theoretical model.

A gauge boson KK excitation could be also sought through its decay to longitudinal  $W/Z$  bosons. While searches for  $WZ$  resonances have been used to set limits on sequential SM  $W'$  bosons [75] or other models, as yet no  $WZ$  experimental results have been interpreted in the context of warped extra dimensions. The decay to a pair of intermediate vector bosons has, however, been exploited to search for KK gravitons in models in which the SM fields propagate in the 5D bulk. The analyses typically reconstruct hadronic  $W/Z$  decays using variants of the boosted techniques mentioned previously. A combination of ATLAS analyses [76] searching in the dilepton, single-lepton-plus-jets, and fully hadronic final states for  $G^* \rightarrow VV$ , where  $V$  can represent either a  $W$  or  $Z$  boson, exclude gravitons with masses below 0.81 TeV, for a value of  $k/M_P = 1$ . CMS  $VV$  analyses with one boson decaying leptonically and the other hadronically [77] or both decaying hadronically [71] also provide cross section limits in the context of bulk gravitons; however, a maximum value of  $k/M_P = 0.5$  is presented, for which no mass

exclusion is possible using the full 8 TeV sample. Less restrictive limits in these models result from searching for  $G^* \rightarrow HH$  [78].

The lightest KK states are, in certain models, the partners of the top quark. For example, in 5D composite Higgs models these are colored states with charges  $Q = -1/3, 2/3$  and  $5/3$ , and masses expected to be below the TeV [64]. They can be either singly or pair-produced, and mainly decay into a combination of  $W/Z$  with top/bottom quarks [79]. Of particular note, the  $Q = 5/3$  state decays mainly into  $W^+t \rightarrow W^+W^+b$ , giving a pair of same-sign leptons in the final state. An analysis by ATLAS [81] searching in the lepton-plus-jets final state for evidence of pair production of the  $Q = 5/3$  state provides a lower mass limit of 840 GeV. Their analysis requiring in addition to a pair of same-sign leptons at least one  $b$ -tagged jet in the event [82] provides less stringent limits from pair production, and also from single production, the cross section for which is model-dependent [80]. A CMS same-sign dilepton analysis [83] searching for pair production of the  $Q = 5/3$  state excludes masses below 800 GeV. Both LHC experiments have searched for pair production of vector-like quarks  $T$  and  $B$  of charges  $Q = 2/3$  and  $-1/3$  respectively, assuming the allowable decays are  $T \rightarrow Wb/Zt/Ht$  and  $B \rightarrow Wt/Zb/Hb$ . In each case, it is assumed the branching fractions of the three decay modes sum to unity, but the individual branching fractions, which are model-dependent, are allowed to vary within this constraint. Depending on the values of the individual branching fractions, CMS obtains lower limits on the mass of the  $T$  [84] ( $B$  [85]) vector-like quark in the range of 720–920 GeV (740–900 GeV), while a summary [86] of the ATLAS searches provides lower limits on the  $T$  ( $B$ ) mass in the range of 715–950 GeV (575–813 GeV).

### III.2 Connection with Strongly-Coupled Models via the AdS/CFT Correspondence

The AdS/CFT correspondence [7] provides a connection between warped extra-dimensional models and strongly-coupled theories in ordinary 4D. Although the exact connection is only known for certain cases, the AdS/CFT techniques have been very useful to obtain, at the qualitative level, a 4D holographic description of the various phenomena in warped extra-dimensional models [8].

The connection goes as follows. The physics of the bulk AdS<sub>5</sub> models can be interpreted as that of a 4D conformal field theory (CFT) which is strongly coupled. The extra-dimensional coordinate  $y$  plays the role of the renormalization scale  $\mu$  of the CFT by means of the identification  $\mu \equiv ke^{-ky}$ . Therefore the UV-boundary corresponds in the CFT to a UV cut-off scale at  $\Lambda_{UV} = k \sim M_P$ , breaking explicitly conformal invariance, while the IR-boundary can be interpreted as a spontaneous breaking of the conformal symmetry at energies  $ke^{-k\pi R} \sim \text{TeV}$ . Fields localized on the UV-boundary are elementary fields external to the CFT, while fields localized on the IR-boundary and KK states corresponds to composite resonances of the CFT. Furthermore, local gauge symmetries in the 5D models,  $G_5$ ,

## Searches Particle Listings

### Extra Dimensions

correspond to global symmetries of the CFT, while the UV-boundary symmetry can be interpreted as a gauging of the subgroup  $\mathcal{H}_{UV}$  of  $\mathcal{G}_5$  in the CFT. Breaking gauge symmetries by IR-boundary conditions corresponds to the spontaneous breaking  $\mathcal{G}_5 \rightarrow \mathcal{H}_{IR}$  in the CFT at energies  $\sim ke^{-k\pi R}$ . Using this correspondence one can easily derive the 4D massless spectrum of the compactified AdS<sub>5</sub> models. One also has the identification  $k^3/M_5^3 \approx 16\pi^2/N^2$  and  $g_5^2 k \approx 16\pi^2/N^r$  ( $r = 1$  or  $2$  for CFT fields in the fundamental or adjoint representation of the gauge group), where  $N$  plays the role of the number of colors of the CFT. Therefore the weak-coupling limit in AdS<sub>5</sub> corresponds to a large- $N$  expansion in the CFT.

Following the above AdS/CFT dictionary one can understand the RS solution to the hierarchy problem from a 4D viewpoint. The equivalent 4D model is a CFT with a TeV mass-gap and a Higgs emerging as a composite state. In the particular case where the Higgs is the fifth-component of the gauge-boson,  $A_5$  [87], this corresponds to models, similar to those proposed in Ref. [88], where the Higgs is a composite pseudo-Goldstone boson arising from the spontaneous breaking  $\mathcal{G}_5 \rightarrow \mathcal{H}_{IR}$  in the CFT. The AdS/CFT dictionary tells us that KK states must behave as composite resonances. For example, if the SM gauge bosons propagate in the 5D bulk, the lowest KK  $SU(2)_L$ -gauge boson must have properties similar to those of the Techni-rho  $\rho_T$  [89] with a coupling to longitudinal  $W/Z$  bosons given by  $g_5\sqrt{k} \approx g_{\rho T}$ , while the coupling to elementary fermions is  $g^2/\sqrt{g_5^2 k} \approx g^2 F_{\rho T}/M_{\rho T}$ .

Fermions in compactified AdS<sub>5</sub> also have a simple 4D holographic interpretation. The 4D massless mode described in Sec. III.1 corresponds to an external fermion  $\psi_i$  linearly coupled to a fermionic CFT operator  $\mathcal{O}_i$ :  $\mathcal{L}_{\text{int}} = \lambda_i \bar{\psi}_i \mathcal{O}_i + h.c.$ . The dimension of the operator  $\mathcal{O}_i$  is related to the 5D fermion mass according to  $\text{Dim}[\mathcal{O}_i] = |c_f + 1/2| - 1$ . Therefore, by varying  $c_f$  one varies  $\text{Dim}[\mathcal{O}_i]$ , making the coupling  $\lambda_i$  irrelevant ( $c_f > 1/2$ ), marginal ( $c_f = 1/2$ ) or relevant ( $c_f < 1/2$ ). When irrelevant, the coupling is exponentially suppressed at low energies, and then the coupling of  $\psi_i$  to the CFT (and eventually to the composite Higgs) is very small. When relevant, the coupling grows in the IR and become as large as  $g_5$  (in units of  $k$ ), meaning that the fermion is as strongly coupled as the CFT states [62]. In this latter case  $\psi_i$  behaves as a composite fermion.

### III.3 Flat Extra Dimensions

Models with quantum-gravity at the TeV scale, as in the ADD scenario, can have extra (flat) dimensions of  $1/\text{TeV}$  size, as happens in string scenarios [90]. All SM fields may propagate in these extra dimensions, leading to the possibility of observing their corresponding KK states.

A simple example is to assume that the SM gauge bosons propagate in a flat five-dimensional orbifold  $S^1/Z_2$  of radius  $R$ , with the fermions localized on a 4D boundary. The KK gauge bosons behave as sequential SM gauge bosons with a coupling to fermions enhanced by a factor  $\sqrt{2}$  [90]. The

experimental limits on such sequential gauge bosons could therefore be recast as limits on KK gauge bosons. Such an interpretation of the ATLAS 7 TeV dilepton analysis [91] yielded the bound  $1/R > 4.16$  TeV, while a CMS 8 TeV search with a lepton and missing transverse energy in the final state [92] give  $1/R > 3.4$  TeV. Indirect bounds from LEP2 require however  $1/R \gtrsim 6$  TeV [93,65].

An alternative scenario, known as Universal Extra Dimensions (UED) [94], assumes that all SM fields propagate universally in a flat orbifold  $S^1/Z_2$  with an extra  $Z_2$  parity, called KK-parity, that interchanges the two boundaries. In this case, the lowest KK state is stable and is a Dark Matter candidate. At colliders, the KK particles would have to be created in pairs, and would then cascade decay to the lightest KK particle (LKP), which would be stable and escape detection. Experimental signatures, such as jets or leptons and  $\cancel{E}_T$ , would be similar to those of typical  $R$ -parity conserving SUSY searches. Theoretical studies of the trilepton final state [95] suggest a potential bound from the LHC at 8 TeV with  $20 \text{ fb}^{-1}$  of  $1/R \gtrsim 1.3$  TeV for  $\Lambda R = 10$ , where  $\Lambda$  is the cut-off scale of the model. The experimental searches have not yet been interpreted in the general UED scenario; for example, the ATLAS trilepton analysis [96] of their full 8 TeV dataset provides upper limits on the visible cross section for new physics that could be utilized to determine UED limits.

Experimental limits have been provided on two specific UED models which include KK parity violation. In one case, KK parity is violated by gravitational interactions [97], and the LKP can decay via  $\gamma^* \rightarrow \gamma + G$ . Beginning with strong production of a pair of KK quarks and/or gluons [98,99], the final state would be  $\gamma\gamma + \cancel{E}_T + X$ . Using their full 7 TeV datasets, ATLAS [100] and CMS [101] each determine a limit of  $1/R \gtrsim 1.4$  TeV for  $\Lambda R = 20$ . In a second model, that involves two UEDs, the breaking of the KK parity allows the decay of the KK photon to  $t\bar{t}$  [102]. The ATLAS vector-like quark search [86] (same-sign dilepton plus b-jet analysis [82]), applied to search for a  $t\bar{t}t\bar{t}$  final state for evidence of pair-produced KK photons, excludes KK masses below 1.12 TeV (0.96 TeV) in this model.

Finally, realistic models of electroweak symmetry breaking can also be constructed with flat extra spatial dimensions, similarly to those in the warped case, requiring, however, the presence of sizeable boundary kinetic terms [103]. There is also the possibility of breaking supersymmetry by boundary conditions [104]. Models of this type could explain naturally the presence of a Higgs boson lighter than  $M_D \sim \text{TeV}$  [105].

### Limits on $R$ from Deviations in Gravitational Force Law

This section includes limits on the size of extra dimensions from deviations in the Newtonian ( $1/r^2$ ) gravitational force law at short distances. Deviations are parametrized by a gravitational potential of the form  $V = -(G m m'/r) [1 + \alpha \exp(-r/R)]$ . For  $\delta$  toroidal extra dimensions of equal size,  $\alpha = 8\delta/3$ . Quoted bounds are for  $\delta = 2$  unless otherwise noted.

- 1 KAPNER 07 search for new forces, probing a range of  $\alpha \simeq 10^{-3}$ – $10^5$  and length scales  $R \simeq 10$ – $1000 \mu\text{m}$ . For  $\delta = 1$  the bound on  $R$  is  $44 \mu\text{m}$ . For  $\delta = 2$ , the bound is expressed in terms of  $M_*$ , here translated to a bound on the radius. See their Fig. 6 for details on the bound.
- 2 XU 13 obtain constraints on non-Newtonian forces with strengths  $|\alpha| \simeq 10^{34}$ – $10^{36}$  and length scales  $R \simeq 1$ – $10 \text{ fm}$ . See their Fig. 4 for more details. These constraints do not place limits on the size of extra flat dimensions.
- 3 BEZERRA 11 obtain constraints on non-Newtonian forces with strengths  $10^{11} \lesssim |\alpha| \lesssim 10^{18}$  and length scales  $R = 30$ – $1260 \text{ nm}$ . See their Fig. 2 for more details. These constraints do not place limits on the size of extra flat dimensions.
- 4 SUSHKOV 11 obtain improved limits on non-Newtonian forces with strengths  $10^7 \lesssim |\alpha| \lesssim 10^{11}$  and length scales  $0.4 \mu\text{m} < R < 4 \mu\text{m}$  (95% CL). See their Fig. 2. These bounds do not place limits on the size of extra flat dimensions. However, a model dependent bound of  $M_* > 70 \text{ TeV}$  is obtained assuming gauge bosons that couple to baryon number also propagate in  $(4 + \delta)$  dimensions.
- 5 BEZERRA 10 obtain improved constraints on non-Newtonian forces with strengths  $10^{19} \lesssim |\alpha| \lesssim 10^{29}$  and length scales  $R = 1.6$ – $14 \text{ nm}$  (95% CL). See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.
- 6 MASUDA 09 obtain improved constraints on non-Newtonian forces with strengths  $10^9 \lesssim |\alpha| \lesssim 10^{11}$  and length scales  $R = 1.0$ – $2.9 \mu\text{m}$  (95% CL). See their Fig. 3. This bound does not place limits on the size of extra flat dimensions.
- 7 GERACI 08 obtain improved constraints on non-Newtonian forces with strengths  $|\alpha| > 14,000$  and length scales  $R = 5$ – $15 \mu\text{m}$ . See their Fig. 9. This bound does not place limits on the size of extra flat dimensions.
- 8 TRENKEL 08 uses two independent measurements of Newton's constant  $G$  to constrain new forces with strength  $|\alpha| \simeq 10^{-4}$  and length scales  $R = 0.02$ – $1 \text{ m}$ . See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.
- 9 DECCA 07A search for new forces and obtain bounds in the region with strengths  $|\alpha| \simeq 10^{13}$ – $10^{18}$  and length scales  $R = 20$ – $86 \text{ nm}$ . See their Fig. 6. This bound does not place limits on the size of extra flat dimensions.
- 10 TU 07 search for new forces probing a range of  $|\alpha| \simeq 10^{-1}$ – $10^5$  and length scales  $R \simeq 20$ – $1000 \mu\text{m}$ . For  $\delta = 1$  the bound on  $R$  is  $53 \mu\text{m}$ . See their Fig. 3 for details on the bound.
- 11 SMULLIN 05 search for new forces, and obtain bounds in the region with strengths  $\alpha \simeq 10^3$ – $10^8$  and length scales  $R = 6$ – $20 \mu\text{m}$ . See their Figs. 1 and 16 for details on the bound. This work does not place limits on the size of extra flat dimensions.
- 12 HOYLE 04 search for new forces, probing  $\alpha$  down to  $10^{-2}$  and distances down to  $10 \mu\text{m}$ . Quoted bound on  $R$  is for  $\delta = 2$ . For  $\delta = 1$ , bound goes to  $160 \mu\text{m}$ . See their Fig. 34 for details on the bound.
- 13 CHIAVERINI 03 search for new forces, probing  $\alpha$  above  $10^4$  and  $\lambda$  down to  $3 \mu\text{m}$ , finding no signal. See their Fig. 4 for details on the bound. This bound does not place limits on the size of extra flat dimensions.
- 14 LONG 03 search for new forces, probing  $\alpha$  down to 3, and distances down to about  $10 \mu\text{m}$ . See their Fig. 4 for details on the bound.
- 15 HOYLE 01 search for new forces, probing  $\alpha$  down to  $10^{-2}$  and distances down to  $20 \mu\text{m}$ . See their Fig. 4 for details on the bound. The quoted bound is for  $\alpha \geq 3$ .
- 16 HOSKINS 85 search for new forces, probing distances down to  $4 \text{ mm}$ . See their Fig. 13 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

### Limits on $R$ from On-Shell Production of Gravitons: $\delta = 2$

This section includes limits on on-shell production of gravitons in collider and astrophysical processes. Bounds quoted are on  $R$ , the assumed common radius of the flat extra dimensions, for  $\delta = 2$  extra dimensions. Studies often quote bounds in terms of derived parameter; experiments are actually sensitive to the masses of the KK gravitons:  $m_{\vec{n}} = |\vec{n}|/R$ . See the Review on “Extra Dimensions” for details. Bounds are given in  $\mu\text{m}$  for  $\delta = 2$ .

- 1 KHACHATRYAN 15AL search for  $pp \rightarrow jG$ , using  $19.7 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 8 \text{ TeV}$  to place bounds on  $M_D$  for two to six extra dimensions, from which this bound on  $R$  is derived. See their Table 7 for bounds on all  $\delta \leq 6$ .
- 2 HANNESTAD 03 obtain a limit on  $R$  from the heating of old neutron stars by the surrounding cloud of trapped KK gravitons. Limits for all  $\delta \leq 7$  are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.
- 3 AAD 15Cs search for  $pp \rightarrow \gamma G$ , using  $20.3 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 8 \text{ TeV}$  to place lower limits on  $M_D$  for two to six extra dimensions (see their Fig. 18).
- 4 AAD 13AD search for  $pp \rightarrow jG$ , using  $4.7 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$  to place bounds on  $M_D$  for two to six extra dimensions, from which this bound on  $R$  is derived. See their Table 8 for bounds on all  $\delta \leq 6$ .
- 5 AAD 13c search for  $pp \rightarrow \gamma G$ , using  $4.6 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$  to place bounds on  $M_D$  for two to six extra dimensions, from which this bound on  $R$  is derived.
- 6 AAD 13b search for the dijet decay of quantum black holes in  $4.8 \text{ fb}^{-1}$  of data produced in  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  to place bounds on  $M_D$  for two to seven extra dimensions, from which these bounds on  $R$  are derived. Limits on  $M_D$  for all  $\delta \leq 7$  are given in their Table 3.
- 7 AJELLO 12 obtain a limit on  $R$  from the gamma-ray emission of point  $\gamma$  sources that arise from the photon decay of KK gravitons which are gravitationally bound around neutron stars. Limits for all  $\delta \leq 7$  are given in their Table 7.
- 8 CHATRCHYAN 12AP search for  $pp \rightarrow jG$ , using  $5.0 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$  to place bounds on  $M_D$  for two to six extra dimensions, from which this bound on  $R$  is derived. See their Table 7 for bounds on all  $\delta \leq 6$ .
- 9 AAD 11s search for  $pp \rightarrow jG$ , using  $33 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$ , to place bounds on  $M_D$  for two to four extra dimensions, from which these bounds on  $R$  are derived. See their Table 3 for bounds on all  $\delta \leq 4$ .
- 10 CHATRCHYAN 11u search for  $pp \rightarrow jG$ , using  $36 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$ , to place bounds on  $M_D$  for two to six extra dimensions, from which these bounds on  $R$  are derived. See their Table 3 for bounds on all  $\delta \leq 6$ .
- 11 AALTONEN 08AC search for  $p\bar{p} \rightarrow \gamma G$  and  $p\bar{p} \rightarrow jG$  at  $\sqrt{s} = 1.96 \text{ TeV}$  with  $2.0 \text{ fb}^{-1}$  and  $1.1 \text{ fb}^{-1}$  respectively, in order to place bounds on the fundamental scale and size of the extra dimensions. See their Table III for limits on all  $\delta \leq 6$ .
- 12 ABAZOV 08s search for  $p\bar{p} \rightarrow \gamma G$ , using  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$  to place bounds on  $M_D$  for two to eight extra dimensions, from which these bounds on  $R$  are derived. See their paper for intermediate values of  $\delta$ .
- 13 DAS 08 obtain a limit on  $R$  from Kaluza-Klein graviton cooling of SN1987A due to plasmon-plasmon annihilation.
- 14 ABULENCIA 06 search for  $p\bar{p} \rightarrow jG$  using  $368 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . See their Table II for bounds for all  $\delta \leq 6$ .
- 15 ABDALLAH 05B search for  $e^+e^- \rightarrow \gamma G$  at  $\sqrt{s} = 180\text{--}209 \text{ GeV}$  to place bounds on the size of extra dimensions and the fundamental scale. Limits for all  $\delta \leq 6$  are given in their Table 6. These limits supersede those in ABREU 002.
- 16 ACHARD 04E search for  $e^+e^- \rightarrow \gamma G$  at  $\sqrt{s} = 189\text{--}209 \text{ GeV}$  to place bounds on the size of extra dimensions and the fundamental scale. See their Table 8 for limits with  $\delta \leq 8$ . These limits supersede those in ACCIARRI 99R.
- 17 ACOSTA 04C search for  $p\bar{p} \rightarrow jG$  at  $\sqrt{s} = 1.8 \text{ TeV}$  to place bounds on the size of extra dimensions and the fundamental scale. See their paper for bounds on  $\delta = 4, 6$ .
- 18 CASSE 04 obtain a limit on  $R$  from the gamma-ray emission of point  $\gamma$  sources that arises from the photon decay of gravitons around newly born neutron stars, applying the technique of HANNESTAD 03 to neutron stars in the galactic bulge. Limits for all  $\delta \leq 7$  are given in their Table I.
- 19 ABAZOV 03 search for  $p\bar{p} \rightarrow jG$  at  $\sqrt{s} = 1.8 \text{ TeV}$  to place bounds on  $M_D$  for 2 to 7 extra dimensions, from which these bounds on  $R$  are derived. See their paper for bounds on intermediate values of  $\delta$ . We quote results without the approximate NLO scaling introduced in the paper.
- 20 HANNESTAD 03 obtain a limit on  $R$  from graviton cooling of supernova SN1987A. Limits for all  $\delta \leq 7$  are given in their Tables V and VI.
- 21 HANNESTAD 03 obtain a limit on  $R$  from gravitons emitted in supernovae and which subsequently decay, contaminating the diffuse cosmic  $\gamma$  background. Limits for all  $\delta \leq 7$  are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.
- 22 HANNESTAD 03 obtain a limit on  $R$  from gravitons emitted in two recent supernovae and which subsequently decay, creating point  $\gamma$  sources. Limits for all  $\delta \leq 7$  are given in their Tables V and VI. These limits are corrected in the published erratum.
- 23 HEISTER 03c use the process  $e^+e^- \rightarrow \gamma G$  at  $\sqrt{s} = 189\text{--}209 \text{ GeV}$  to place bounds on the size of extra dimensions and the scale of gravity. See their Table 4 for limits with  $\delta \leq 6$  for derived limits on  $M_D$ .
- 24 FAIRBAIRN 01 obtains bounds on  $R$  from over production of KK gravitons in the early universe. Bounds are quoted in paper in terms of fundamental scale of gravity. Bounds depend strongly on temperature of QCD phase transition and range from  $R < 0.13 \mu\text{m}$  to  $0.001 \mu\text{m}$  for  $\delta=2$ ; bounds for  $\delta=3,4$  can be derived from Table I in the paper.
- 25 HANHART 01 obtain bounds on  $R$  from limits on graviton cooling of supernova SN1987a using numerical simulations of proto-neutron star neutrino emission.
- 26 CASSISI 00 obtain rough bounds on  $M_D$  (and thus  $R$ ) from red giant cooling for  $\delta=2,3$ . See their paper for details.
- 27 ACCIARRI 99s search for  $e^+e^- \rightarrow ZG$  at  $\sqrt{s}=189 \text{ GeV}$ . Limits on the gravity scale are found in their Table 2, for  $\delta \leq 4$ .

### Mass Limits on $M_{TT}$

This section includes limits on the cut-off mass scale,  $M_{TT}$ , of dimension-8 operators from KK graviton exchange in models of large extra dimensions. Ambiguities in the UV-divergent summation are absorbed into the parameter  $\lambda$ , which is taken to be  $\lambda = \pm 1$  in the following analyses. Bounds for  $\lambda = -1$  are shown in parenthesis after the bound for  $\lambda = +1$ , if appropriate. Different papers use slightly different definitions of the mass scale. The definition used here is related to another popular convention by  $M_{TT}^4 = (2/\pi) \Lambda_4^4$ , as discussed in the above Review on "Extra Dimensions."

- 1 KHACHATRYAN 15J use dijet angular distributions in  $19.7 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  to place a lower bound on  $\Lambda_T$ , here converted to  $M_{TT}$ .
- 2 GIUDICE 03 place bounds on  $\Lambda_6$ , the coefficient of the gravitationally-induced dimension-6 operator  $(2\pi\lambda/\Lambda_6^2)(\sum \bar{\psi}\gamma^\mu\psi)(\sum \bar{\psi}\gamma_\mu\psi)$ , using data from a variety of experiments. Results are quoted for  $\lambda=\pm 1$  and are independent of  $\delta$ .
- 3 KHACHATRYAN 15AE use  $20.6 (19.7) \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  in the dimuon (dielectron) channel to place a lower limit on  $\Lambda_T$ , here converted to  $M_{TT}$ .
- 4 AAD 14BE use  $20 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8 \text{ TeV}$  in the dilepton channel to place lower limits on  $M_{TT}$  (equivalent to their  $M_S$ ).
- 5 AAD 13AS use  $4.9 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  to place lower limits on  $M_{TT}$  (equivalent to their  $M_S$ ).
- 6 AAD 13E use  $4.9$  and  $5.0 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  in the dielectron and dimuon channels, respectively, to place lower limits on  $M_{TT}$  (equivalent to their  $M_S$ ). The dielectron and dimuon channels are combined with previous results in the diphoton channel to set the best limit. Bounds on individual channels and different priors can be found in their Table VII.
- 7 AAD 12Y use  $2.12 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  to place lower limits on  $M_{TT}$  (equivalent to their  $M_S$ ).
- 8 BAAK 12 use electroweak precision observables to place bounds on the ratio  $\Lambda_T/M_D$  as a function of  $M_D$ . See their Fig. 22 for constraints with a Higgs mass of  $120 \text{ GeV}$ .
- 9 CHATRCHYAN 12J use approximately  $2 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  in the dielectron and dimuon channels to place lower limits on  $\Lambda_T$ , here converted to  $M_{TT}$ .
- 10 CHATRCHYAN 12R use  $2.2 \text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  to place lower limits on  $M_{TT}$  (equivalent to their  $M_S$ ).
- 11 AARON 11c search for deviations in the differential cross section of  $e^\pm p \rightarrow e^\pm X$  in  $446 \text{ pb}^{-1}$  of data taken at  $\sqrt{s} = 301$  and  $319 \text{ GeV}$  to place a bound on  $M_{TT}$ .
- 12 CHATRCHYAN 11A use  $36 \text{ pb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  to place lower limits on  $\Lambda_T$ , here converted to  $M_{TT}$ .
- 13 ABAZOV 09AE use dijet angular distributions in  $0.7 \text{ fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$  to place lower bounds on  $\Lambda_T$  (equivalent to their  $M_S$ ), here converted to  $M_{TT}$ .
- 14 ABAZOV 09D use  $1.05 \text{ fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$  to place lower bounds on  $\Lambda_T$  (equivalent to their  $M_S$ ), here converted to  $M_{TT}$ .
- 15 SCHAEEL 07A use  $e^+e^-$  collisions at  $\sqrt{s} = 189\text{--}209 \text{ GeV}$  to place lower limits on  $\Lambda_T$ , here converted to limits on  $M_{TT}$ .
- 16 ABDALLAH 06C use  $e^+e^-$  collisions at  $\sqrt{s} \sim 130\text{--}207 \text{ GeV}$  to place lower limits on  $M_{TT}$ , which is equivalent to their definition of  $M_S$ . Bound shown includes all possible final state leptons,  $\ell = e, \mu, \tau$ . Bounds on individual leptonic final states can be found in their Table 31.
- 17 GERDES 06 use  $100$  to  $110 \text{ pb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.8 \text{ TeV}$ , as recorded by the CDF Collaboration during Run I of the Tevatron. Bound shown includes a  $K$ -factor of  $1.3$ . Bounds on individual  $e^+e^-$  and  $\gamma\gamma$  final states are found in their Table I.
- 18 ABAZOV 05v use  $246 \text{ pb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$  to search for deviations in the differential cross section to  $\mu^+\mu^-$  from graviton exchange.

- <sup>19</sup> CHEKANOV 04B search for deviations in the differential cross section of  $e^{\pm}p \rightarrow e^{\pm}X$  with  $130\text{ pb}^{-1}$  of combined data and  $Q^2$  values up to  $40,000\text{ GeV}^2$  to place a bound on  $M_{TT}$ .
- <sup>20</sup> ABBIENDI 03D use  $e^+e^-$  collisions at  $\sqrt{s}=181\text{--}209\text{ GeV}$  to place bounds on the ultraviolet scale  $M_{TT}$ , which is equivalent to their definition of  $M_S$ .
- <sup>21</sup> ACHARD 03D look for deviations in the cross section for  $e^+e^- \rightarrow ZZ$  from  $\sqrt{s}=200\text{--}209\text{ GeV}$  to place a bound on  $M_{TT}$ .
- <sup>22</sup> ADLOFF 03 search for deviations in the differential cross section of  $e^{\pm}p \rightarrow e^{\pm}X$  at  $\sqrt{s}=301$  and  $319\text{ GeV}$  to place bounds on  $M_{TT}$ .
- <sup>23</sup> GIUDICE 03 review existing experimental bounds on  $M_{TT}$  and derive a combined limit.
- <sup>24</sup> HEISTER 03C use  $e^+e^-$  collisions at  $\sqrt{s}=189\text{--}209\text{ GeV}$  to place bounds on the scale of dim-8 gravitational interactions. Their  $M_S^{\pm}$  is equivalent to our  $M_{TT}$  with  $\lambda=\pm 1$ .
- <sup>25</sup> ACHARD 02 search for s-channel graviton exchange effects in  $e^+e^- \rightarrow \gamma\gamma$  at  $E_{\text{cm}}=192\text{--}209\text{ GeV}$ .
- <sup>26</sup> ABBOTT 01 search for variations in differential cross sections to  $e^+e^-$  and  $\gamma\gamma$  final states at the Tevatron.
- <sup>27</sup> ABBIENDI 00R uses  $e^+e^-$  collisions at  $\sqrt{s}=189\text{ GeV}$ .
- <sup>28</sup> ABREU 00A search for s-channel graviton exchange effects in  $e^+e^- \rightarrow \gamma\gamma$  at  $E_{\text{cm}}=189\text{--}202\text{ GeV}$ .
- <sup>29</sup> ABREU 00s uses  $e^+e^-$  collisions at  $\sqrt{s}=183$  and  $189\text{ GeV}$ . Bounds on  $\mu$  and  $\tau$  individual final states given in paper.
- <sup>30</sup> CHANG 00B derive  $3\sigma$  limit on  $M_{TT}$  of  $(28,19,15)\text{ TeV}$  for  $\delta=(2,4,6)$  respectively assuming the presence of a torsional coupling in the gravitational action. Highly model dependent.
- <sup>31</sup> CHEUNG 00 obtains limits from anomalous diphoton production at OPAL due to graviton exchange. Original limit for  $\delta=4$ . However, unknown  $UV$  theory renders  $\delta$  dependence unreliable. Original paper works in HLZ convention.
- <sup>32</sup> GRAESSER 00 obtains a bound from graviton contributions to  $g\text{--}2$  of the muon through loops of  $0.29\text{ TeV}$  for  $\delta=2$  and  $0.38\text{ TeV}$  for  $\delta=4,6$ . Limits scale as  $\lambda^{1/2}$ . However calculational scheme not well-defined without specification of high-scale theory. See the "Extra Dimensions Review."
- <sup>33</sup> HAN 00 calculates corrections to gauge boson self-energies from KK graviton loops and constrain them using  $S$  and  $T$ . Bounds on  $M_{TT}$  range from  $0.5\text{ TeV}$  ( $\delta=6$ ) to  $1.1\text{ TeV}$  ( $\delta=2$ ); see text. Limits have strong dependence,  $\lambda^{\delta+2}$ , on unknown  $\lambda$  coefficient.
- <sup>34</sup> MATHEWS 00 search for evidence of graviton exchange in CDF and DØ dijet production data. See their Table 2 for slightly stronger  $\delta$ -dependent bounds. Limits expressed in terms of  $\tilde{M}_S^4 = M_{TT}^4/8$ .
- <sup>35</sup> MELE 00 obtains bound from KK graviton contributions to  $e^+e^- \rightarrow VV$  ( $V=\gamma, W, Z$ ) at LEP. Authors use Hewett conventions.
- <sup>36</sup> ABBIENDI 99P search for s-channel graviton exchange effects in  $e^+e^- \rightarrow \gamma\gamma$  at  $E_{\text{cm}}=189\text{ GeV}$ . The limits  $G_{\pm} > 660\text{ GeV}$  and  $G_{\pm} > 634\text{ GeV}$  are obtained from combined  $E_{\text{cm}}=183$  and  $189\text{ GeV}$  data, where  $G_{\pm}$  is a scale related to the fundamental gravity scale.
- <sup>37</sup> ACCIARRI 99M search for the reaction  $e^+e^- \rightarrow \gamma G$  and s-channel graviton exchange effects in  $e^+e^- \rightarrow \gamma\gamma, W^+W^-, ZZ, e^+e^-, \mu^+\mu^-, \tau^+\tau^-, q\bar{q}$  at  $E_{\text{cm}}=183\text{ GeV}$ . Limits on the gravity scale are listed in their Tables 1 and 2.
- <sup>38</sup> ACCIARRI 99s search for the reaction  $e^+e^- \rightarrow ZG$  and s-channel graviton exchange effects in  $e^+e^- \rightarrow \gamma\gamma, W^+W^-, ZZ, e^+e^-, \mu^+\mu^-, \tau^+\tau^-, q\bar{q}$  at  $E_{\text{cm}}=189\text{ GeV}$ . Limits on the gravity scale are listed in their Tables 1 and 2.
- <sup>39</sup> BOURILKOV 99 performs global analysis of LEP data on  $e^+e^-$  collisions at  $\sqrt{s}=183$  and  $189\text{ GeV}$ . Bound is on  $\Lambda_T$ .

### Limits on $1/R = M_c$

This section includes limits on  $1/R = M_c$ , the compactification scale in models with one TeV-sized extra dimension, due to exchange of Standard Model KK excitations. Bounds assume fermions are not in the bulk, unless stated otherwise. See the "Extra Dimensions" review for discussion of model dependence.

- <sup>1</sup> AAD 12CC use  $4.9$  and  $5.0\text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest KK  $Z/\gamma$  boson (equivalent to  $1/R = M_c$ ). The limit quoted here assumes a flat prior corresponding to when the pure  $Z/\gamma$  KK cross section term dominates. See their Section 15 for more details.
- <sup>2</sup> BARBIERI 04 use electroweak precision observables to place a lower bound on the compactification scale  $1/R$ . Both the gauge bosons and the Higgs boson are assumed to propagate in the bulk.
- <sup>3</sup> ACCOMANDO 15 use electroweak precision observables to place a lower bound on the compactification scale  $1/R$ . See their Fig. 2 for the bound as a function of  $\sin\beta$ , which parametrizes the VEV contribution from brane and bulk Higgs fields. The quoted value is for the minimum bound which occurs at  $\sin\beta = 0.45$ .
- <sup>4</sup> KHACHATRYAN 15T use  $19.7\text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s}=8\text{ TeV}$  to place a lower bound on the compactification scale  $1/R$ .
- <sup>5</sup> CHATRCHYAN 13AQ use  $5.0\text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  and a further  $3.7\text{ fb}^{-1}$  of data at  $\sqrt{s}=8\text{ TeV}$  to place a lower bound on the compactification scale  $1/R$ , in models with universal extra dimensions and Standard Model fields propagating in the bulk. See their Fig. 5 for the bound as a function of the universal bulk fermion mass parameter  $\mu$ .
- <sup>6</sup> CHATRCHYAN 13W use diphoton events with large missing transverse momentum in  $4.93\text{ fb}^{-1}$  of data produced from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c = 20$ . The model parameters are chosen such that the decay  $\gamma^* \rightarrow G\gamma$  occurs with an appreciable branching fraction.
- <sup>7</sup> EDELHAUSER 13 use  $19.6$  and  $20.6\text{ fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s}=8\text{ TeV}$  analyzed by the CMS Collaboration in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the second lightest Kaluza-Klein  $Z/\gamma$  boson (converted to a limit on  $1/R = M_c$ ). The bound assumes Standard Model fields propagating in the bulk and that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c = 20$ .
- <sup>8</sup> AAD 12CP use diphoton events with large missing transverse momentum in  $4.8\text{ fb}^{-1}$  of data produced from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c = 20$ . The model parameters are chosen such that the decay  $\gamma^* \rightarrow G\gamma$  occurs with an appreciable branching fraction.
- <sup>9</sup> AAD 12X use diphoton events with large missing transverse momentum in  $1.07\text{ fb}^{-1}$  of data produced from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c = 20$ . The model parameters are chosen such that the decay  $\gamma^* \rightarrow G\gamma$  occurs with an appreciable branching fraction.
- <sup>10</sup> ABAZOV 12M use same-sign dimuon events in  $7.3\text{ fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s}=1.96\text{ TeV}$  to place a lower bound on the compactification scale  $1/R$ , in models with universal extra dimensions where all Standard Model fields propagate in the bulk.
- <sup>11</sup> BAAK 12 use electroweak precision observables to place a lower bound on the compactification scale  $1/R$ , in models with universal extra dimensions and Standard Model fields propagating in the bulk. Bound assumes a  $125\text{ GeV}$  Higgs mass. See their Fig. 25 for the bound as a function of the Higgs mass.
- <sup>12</sup> FLACKE 12 use electroweak precision observables to place a lower bound on the compactification scale  $1/R$ , in models with universal extra dimensions and Standard Model fields propagating in the bulk. See their Fig. 1 for the bound as a function of the universal bulk fermion mass parameter  $\mu$ .
- <sup>13</sup> NISHIWAKI 12 use up to  $2\text{ fb}^{-1}$  of data from the ATLAS and CMS experiments that constrains the production cross section of a Higgs-like particle to place a lower bound on the compactification scale  $1/R$  in universal extra dimension models. The quoted bound assumes Standard Model fields propagating in the bulk and a  $125\text{ GeV}$  Higgs mass. See their Fig. 1 for the bound as a function of the Higgs mass.
- <sup>14</sup> AAD 11F use diphoton events with large missing transverse energy in  $3.1\text{ pb}^{-1}$  of data produced from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c = 20$ . The model parameters are chosen such that the decay  $\gamma^* \rightarrow G\gamma$  occurs with an appreciable branching fraction.
- <sup>15</sup> AAD 11X use diphoton events with large missing transverse energy in  $36\text{ pb}^{-1}$  of data produced from  $pp$  collisions at  $\sqrt{s}=7\text{ TeV}$  to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c = 20$ . The model parameters are chosen such that the decay  $\gamma^* \rightarrow G\gamma$  occurs with an appreciable branching fraction.
- <sup>16</sup> ABAZOV 10P use diphoton events with large missing transverse energy in  $6.3\text{ fb}^{-1}$  of data produced from  $p\bar{p}$  collisions at  $\sqrt{s}=1.96\text{ TeV}$  to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale  $\Lambda$ , for the radiative corrections to the Kaluza-Klein masses, satisfies  $\Lambda/M_c=20$ . The model parameters are chosen such that the decay  $\gamma^* \rightarrow G\gamma$  occurs with an appreciable branching fraction.
- <sup>17</sup> ABAZOV 09AE use dijet angular distributions in  $0.7\text{ fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s}=1.96\text{ TeV}$  to place a lower bound on the compactification scale.
- <sup>18</sup> HAISCH 07 use inclusive  $\bar{B}$ -meson decays to place a Higgs mass independent bound on the compactification scale  $1/R$  in the minimal universal extra dimension model.
- <sup>19</sup> GOGOLADZE 06 use electroweak precision observables to place a lower bound on the compactification scale in models with universal extra dimensions. Bound assumes a  $115\text{ GeV}$  Higgs mass. See their Fig. 3 for the bound as a function of the Higgs mass.
- <sup>20</sup> CORNET 00 translates a bound on the coefficient of the 4-fermion operator  $(\bar{\ell}\gamma_{\mu}\tau^a\ell)(\bar{\ell}\gamma^{\mu}\tau^a\ell)$  derived by Hagiwara and Matsumoto into a limit on the mass scale of KK  $W$  bosons.
- <sup>21</sup> RIZZO 00 obtains limits from global electroweak fits in models with a Higgs in the bulk ( $3.8\text{ TeV}$ ) or on the standard brane ( $3.3\text{ TeV}$ ).

### Limits on Kaluza-Klein Gravitons in Warped Extra Dimensions

This section places limits on the mass of the first Kaluza-Klein (KK) excitation of the graviton in the warped extra dimension model of Randall and Sundrum. Bounds in parenthesis assume Standard Model fields propagate in the bulk. Experimental bounds

depend strongly on the warp parameter,  $k$ . See the “Extra Dimensions” review for a full discussion.

Here we list limits for the value of the warp parameter  $k/\overline{M}_P = 0.1$ .

- <sup>1</sup> KHACHATRYAN 15AE use 20.6 (19.7)  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV in the dimuon (dielectron) channel to place a lower bound on the mass of the lightest KK graviton.
- <sup>2</sup> AAD 15AD use 20.3  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV in the diphoton channel to place a lower limit on the mass of the lightest KK graviton. See their Table IV for limits with warp parameter values  $k/\overline{M}_P$  between 0.01 and 0.1.
- <sup>3</sup> AAD 15BK use 19.5  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV to search for Higgs boson pair production in the  $b\bar{b}b\bar{b}$  final state, and exclude masses of the lightest KK graviton. See their Table 9 for the excluded mass ranges with warp parameter values  $k/\overline{M}_P = 1.0, 1.5$ , and 2.0.
- <sup>4</sup> KHACHATRYAN 15R use 17.9  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV to search for Higgs boson pair production in the  $b\bar{b}b\bar{b}$  final state, and exclude a KK graviton with mass from 380 to 830 GeV.
- <sup>5</sup> AAD 14V use 20  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV in the dielectron and dimuon channels to place a lower bound on the mass of the lightest KK graviton.
- <sup>6</sup> KHACHATRYAN 14A use 19.7  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV to search for KK gravitons in a warped extra dimension decaying to dibosons. See their Figure 9 for limits on the cross section times branching fraction as a function of the KK graviton mass.
- <sup>7</sup> AAD 13A use 4.7  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV to place a lower bound on the mass of the lightest KK graviton.
- <sup>8</sup> AAD 13AS use 4.9  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. The diphoton channel is combined with previous results in the dielectron and dimuon channels to set the best limit. See their Table 2 for warp parameter values  $k/\overline{M}_P$  between 0.01 and 0.1.
- <sup>9</sup> CHATRCHYAN 13AF use 5.3 and 4.1  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV and 8 TeV, respectively, in the dielectron and dimuon channels, to place a lower bound on the mass of the lightest KK graviton.
- <sup>10</sup> CHATRCHYAN 13U use 5  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV to search for KK gravitons in a warped extra dimension decaying to  $ZZ$  dibosons. See their Figure 5 for limits on the lightest KK graviton mass as a function of  $k/\overline{M}_P$ .
- <sup>11</sup> AAD 12AD use 1.02  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV to search for KK gravitons in a warped extra dimension decaying to  $ZZ$  dibosons in the  $lljj$  and  $llll$  channels ( $\ell = e, \mu$ ). The limit is quoted for the combined  $lljj + llll$  channels. See their Figure 5 for limits on the cross section  $\sigma(G \rightarrow ZZ)$  as a function of the graviton mass.
- <sup>12</sup> AAD 12CC use 4.9 and 5.0  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest KK graviton. See their Figure 5 for limits on the lightest KK graviton mass as a function of  $k/\overline{M}_P$ .
- <sup>13</sup> AAD 12Y use 2.12  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. The diphoton channel is combined with previous results in the dielectron and dimuon channels to set the best limit. See their Table 3 for warp parameter values  $k/\overline{M}_P$  between 0.01 and 0.1.
- <sup>14</sup> AALTONEN 12V use 6  $\text{fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in a warped extra dimension decaying to  $ZZ$  dibosons in the  $lljj$  and  $llll$  channels ( $\ell = e, \mu$ ). It provides improved limits over the previous analysis in AALTONEN 11G. See their Figure 16 for limits from all channels combined on the cross section times branching ratio  $\sigma(p\bar{p} \rightarrow G^* \rightarrow ZZ)$  as a function of the graviton mass.
- <sup>15</sup> BAAK 12 use electroweak precision observables to place a lower bound on the compactification scale  $k e^{-\pi k R}$ , assuming Standard Model fields propagate in the bulk and the Higgs is confined to the IR brane. See their Fig. 27 for more details.
- <sup>16</sup> CHATRCHYAN 12R use 2.2  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. See their Table III for warp parameter values  $k/\overline{M}_P$  between 0.01 and 0.1.

- <sup>17</sup> AAD 11AD use 1.08 and 1.21  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest graviton. For warp parameter values  $k/\overline{M}_P$  between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 0.71 and 1.63 TeV. See their Table IV for more details.
- <sup>18</sup> AALTONEN 11G use 2.5–2.9  $\text{fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in a warped extra dimension decaying to  $ZZ$  dibosons via the  $eee, ee\mu\mu, \mu\mu\mu\mu, eejj$ , and  $\mu\mu jj$  channels. See their Fig. 20 for limits on the cross section  $\sigma(G \rightarrow ZZ)$  as a function of the graviton mass.
- <sup>19</sup> AALTONEN 11R uses 5.7  $\text{fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV in the dielectron channel to place a lower bound on the mass of the lightest graviton. It provides combined limits with the diphoton channel analysis of AALTONEN 11U. For warp parameter values  $k/\overline{M}_P$  between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 612 and 1058 GeV. See their Table I for more details.
- <sup>20</sup> ABAZOV 11H use 5.4  $\text{fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to place a lower bound on the mass of the lightest graviton. Their 95% C.L. exclusion limit does not include masses less than 300 GeV.
- <sup>21</sup> CHATRCHYAN 11 use 35 and 40  $\text{pb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest graviton. For a warp parameter value  $k/\overline{M}_P = 0.05$ , the lower limit on the mass of the lightest graviton is 0.855 TeV.
- <sup>22</sup> AALTONEN 10N use 2.9  $\text{fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to place a lower bound on the mass of the lightest graviton.
- <sup>23</sup> ABAZOV 10F use 5.4  $\text{fb}^{-1}$  of data from  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to place a lower bound on the mass of the lightest graviton. For warp parameter values of  $k/\overline{M}_P$  between 0.01 and 0.1 the lower limit on the mass of the lightest graviton is between 560 and 1050 GeV. See their Fig. 3 for more details.
- <sup>24</sup> AALTONEN 08S use  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to four electrons via two  $Z$  bosons using 1.1  $\text{fb}^{-1}$  of data. See their Fig. 8 for limits on  $\sigma \cdot \text{B}(G \rightarrow ZZ)$  versus the graviton mass.
- <sup>25</sup> ABAZOV 08J use  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons and photons using 1  $\text{fb}^{-1}$  of data. For warp parameter values of  $k/\overline{M}_P$  between 0.01 and 0.1 the lower limit on the mass of the lightest excitation is between 300 and 900 GeV. See their Fig. 4 for more details.
- <sup>26</sup> AALTONEN 07G use  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to photons using 1.2  $\text{fb}^{-1}$  of data. For warp parameter values of  $k/\overline{M}_P = 0.1, 0.05$ , and 0.01 the bounds on the graviton mass are 850, 694, and 230 GeV, respectively. See their Fig. 3 for more details. See also AALTONEN 07H.
- <sup>27</sup> AALTONEN 07H use  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons using 1.3  $\text{fb}^{-1}$  of data. For a warp parameter value of  $k/\overline{M}_P = 0.1$  the bound on the graviton mass is 807 GeV. See their Fig. 4 for more details. A combined analysis with the diphoton data of AALTONEN 07G yields for  $k/\overline{M}_P = 0.1$  a graviton mass lower bound of 889 GeV.
- <sup>28</sup> ABAZOV 05N use  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons, electrons or photons, using 260  $\text{pb}^{-1}$  of data. For warp parameter values of  $k/\overline{M}_P = 0.1, 0.05$ , and 0.01, the bounds on the graviton mass are 785, 650 and 250 GeV respectively. See their Fig. 3 for more details.
- <sup>29</sup> ABULENCIA 05A use  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons or electrons, using 200  $\text{pb}^{-1}$  of data. For warp parameter values of  $k/\overline{M}_P = 0.1, 0.05$ , and 0.01, the bounds on the graviton mass are 710, 510 and 170 GeV respectively.

### Limits on Kaluza-Klein Gluons in Warped Extra Dimensions

This section places limits on the mass of the first Kaluza-Klein (KK) excitation of the gluon in warped extra dimension models with Standard Model fields propagating in the bulk. Bounds are given for a specific benchmark model with  $\Gamma/m = 15.3\%$  where  $\Gamma$  is the width and  $m$  the mass of the KK gluon. See the “Extra Dimensions” review for more discussion.

VALUE (TeV)	CL%	DOCUMENT ID	TECN	COMMENT
<b>&gt;2.5</b>	95	<sup>1</sup> CHATRCHYAN13BM CMS	$g_{KK} \rightarrow t\bar{t}$	• • • We do not use the following data for averages, fits, limits, etc. • • •

	95	<sup>3</sup> CHEN 13A	$\bar{B} \rightarrow X_s \gamma$	
>1.5	95	<sup>4</sup> AAD 12BV ATLS	$g_{KK} \rightarrow t\bar{t} \rightarrow \ell j$	

<sup>1</sup> CHATRCHYAN 13BM use 19.7  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 8$  TeV. Bound is for a width of approximately 15–20% of the KK gluon mass.

<sup>2</sup> AAD 13AQ use 4.7  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV.

<sup>3</sup> CHEN 13A place limits on the KK mass scale for a specific warped model with custodial symmetry and bulk fermions. See their Figures 4 and 5.

<sup>4</sup> AAD 12BV use 2.05  $\text{fb}^{-1}$  of data from  $pp$  collisions at  $\sqrt{s} = 7$  TeV.

## WIMPs and Other Particles Searches for

### OMITTED FROM SUMMARY TABLE WIMPS AND OTHER PARTICLE SEARCHES

Revised August 2013 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

1. Galactic WIMP (weakly-interacting massive particle) searches
2. Concentration of stable particles in matter
3. General new physics searches
4. Limits on jet-jet resonance in hadron collisions
5. Limits on neutral particle production at accelerators
6. Limits on charged particles in  $e^+e^-$  collisions
7. Limits on charged particles in hadron reactions
8. Limits on charged particles in cosmic rays
9. Searches for quantum black hole production

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including  $W_R$ ,  $W'$ ,  $Z'$ , leptoquarks, axiglons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, *etc.*

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

### GALACTIC WIMP SEARCHES

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of  $0.3 \text{ GeV}/\text{cm}^3$  is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the  $X^0$  mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

### Limits for Spin-Independent Cross Section of Dark Matter Particle ( $X^0$ ) on Nucleon

Isoscalar coupling is assumed to extract the limits from those on  $X^0$ -nuclei cross section.

### For $m_{X^0} = 20 \text{ GeV}$

For limits from  $X^0$  annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

- 1 AGNESE 15A reanalyse AHMED 11B low threshold data. See their Fig. 12 (left) for improved limits extending down to 5 GeV.
- 2 AGNESE 15B reanalyse AHMED 10 data.
- 3 See their Fig. 7 for limits extending down to 4 GeV.
- 4 See their Fig. 13 for limits extending down to 5 GeV.
- 5 This limit value is provided by the authors. See their Fig. 4 for limits extending down to  $m_{\chi^0} = 3.5$  GeV.
- 6 This limit value is provided by the authors. AGNESE 14A result is from CDMSlite mode operation with enhanced sensitivity to low mass  $m_{\chi^0}$ . See their Fig. 3 for limits extending down to  $m_{\chi^0} = 3.5$  GeV (see also Fig. 4 in AGNESE 14).
- 7 See their Fig. 5 for limits extending down to  $m_{\chi^0} = 5.5$  GeV.
- 8 See their Fig. 5 for limits extending down to  $m_{\chi^0} = 1$  GeV.
- 9 See their Fig. 5 for limits extending down to  $m_{\chi^0} = 5$  GeV.
- 10 LIU 14A result is based on prototype CDEX-0 detector. See their Fig. 13 for limits extending down to  $m_{\chi^0} = 2$  GeV.
- 11 See their Fig. 4 for limits extending down to  $m_{\chi^0} = 4.5$  GeV.
- 12 AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the sun in data taken between June 2010 and May 2011.
- 13 See their Fig. 8 for limits extending down to  $m_{\chi^0} = 7$  GeV.
- 14 This limit value is provided by the authors. AGNESE 13 use data taken between Oct. 2006 and July 2007. See their Fig. 4 for limits extending down to  $m_{\chi^0} = 7$  GeV.
- 15 This limit value is provided by the authors. AGNESE 13A use data taken between July 2007 and Sep. 2008. Three candidate events are seen. Assuming these events are real, the best fit parameters are  $m_{\chi^0} = 8.6$  GeV and  $\sigma = 1.9 \times 10^{-5}$  pb.
- 16 This limit value is provided by the authors. Limit from combined data of AGNESE 13 and AGNESE 13A. See their Fig. 4 for limits extending down to  $m_{\chi^0} = 5.5$  GeV.
- 17 See their Fig. 4 for limits extending down to  $m_{\chi^0} = 4$  GeV.
- 18 See their Fig. 5 for limits for  $m_{\chi^0} = 4$ –12 GeV.
- 19 ANGLOHER 12 observe excess events above the expected background which are consistent with  $X^0$  with mass  $\sim 25$  GeV (or 12 GeV) and spin-independent  $X^0$ -nucleon cross section of  $2 \times 10^{-6}$  pb (or  $4 \times 10^{-5}$  pb).
- 20 Reanalysis of ANGLOHER 09 data with all three nuclides. See also BROWN 12.
- 21 See also APRILE 14A.
- 22 See their Fig. 7 for cross section limits for  $m_{\chi^0}$  between 4 and 12 GeV.
- 23 See their Fig. 4 for limits extending down to  $m_{\chi^0} = 7$  GeV.
- 24 See their Fig. 13 for cross section limits for  $m_{\chi^0}$  between 1.2 and 10 GeV.
- 25 See also DAHL 12 for a criticism.
- 26 See their Fig. 4 for limits extending to  $m_{\chi^0} = 3.5$  GeV.
- 27 AALSETH 11A find indications of annual modulation of the data, the energy spectrum being compatible with  $X^0$  mass around 8 GeV. See also AALSETH 13.
- 28 AHMED 11 search for  $X^0$  inelastic scattering. See their Fig. 8–10 for limits. The inelastic cross section reduces to the elastic cross section at the limit of zero mass splitting (Fig. 8, left).
- 29 AHMED 11A combine CDMS II and EDELWEISS data.
- 30 AHMED 11B give limits on spin-independent  $X^0$ -nucleon cross section for  $m_{\chi^0} = 4$ –12 GeV in the range  $10^{-3}$ – $10^{-5}$  pb. See their Fig. 3.
- 31 See their Fig. 3 for limits down to  $m_{\chi^0} = 4$  GeV.

- 32 APRILE 11 reanalyze APRILE 10 data.
- 33 APRILE 11A search for  $X^0$  inelastic scattering. See their Fig. 2 and 3 for limits. See also APRILE 14A.
- 34 HORN 11 perform detector calibration by neutrons. Earlier results are only marginally affected.
- 35 See their Fig. 10 and 12 for limits extending to  $X^0$  mass of 1 GeV.
- 36 Superseded by AHMED 10.
- 37 See their Fig. 6(a) for cross section limits for  $m_{\chi^0}$  extending down to 2 GeV.
- 38 See their Fig. 2 for cross section limits for  $m_{\chi^0}$  between 4 and 10 GeV.

### For $m_{\chi^0} = 100$ GeV

For limits from  $X^0$  annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

# Searches Particle Listings

## WIMPs and Other Particle Searches

<sup>1</sup> Use a direction-sensitive detector.

<sup>2</sup> AVORIN 14 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the Sun in data taken between 1998 and 2003. See their Table 1 for limits assuming annihilation into neutrino pairs.

<sup>3</sup> AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the sun in data taken between June 2010 and May 2011.

<sup>4</sup> ADRIAN-MARTINEZ 13 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the sun in data taken between Jan. 2007 and Dec. 2008.

<sup>5</sup> The value has been provided by the authors. APRILE 13 note that the proton limits on Xe are highly sensitive to the theoretical model used. See also APRILE 14A.

<sup>6</sup> BOLIEV 13 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the sun in data taken from 1978 to 2009. See also SUVOROVA 13 for an older analysis of the same data.

<sup>7</sup> ABBASI 12 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the Sun. The amount of  $X^0$  depends on the  $X^0$ -proton cross section.

<sup>8</sup> TANAKA 11 search for neutrinos from the Sun arising from the pair annihilation of  $X^0$  trapped by the Sun. The amount of  $X^0$  depends on the  $X^0$ -proton cross section.

<sup>9</sup> See their Fig. 3 for limits on spin-dependent proton couplings for  $X^0$  mass of 50 GeV.

<sup>10</sup> See also AKERIB 05.

<sup>11</sup> GIULIANI 05A analyze available data and give combined limits.

<sup>12</sup> GIULIANI 04 reanalyze COLLAR 00 data and give limits for spin-dependent  $X^0$ -proton coupling.

<sup>13</sup> GIULIANI 04A give limits for spin-dependent  $X^0$ -proton couplings from existing data.

### For $m_{X^0} = 1 \text{ TeV}$

For limits from  $X^0$  annihilation in the Sun, the assumed annihilation final state is shown in parenthesis in the comment.

< 0.12	90	12 REUSSER	91	CNTR Natural Ge
< 0.06	95	CALDWELL	88	CNTR Natural Ge

<sup>1</sup> UCHIDA 14 limit is for inelastic scattering  $\chi^0 + ^{129}\text{Xe}^* \rightarrow \chi^0 + ^{129}\text{Xe}^*$  (39.58 keV).

<sup>2</sup> ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.

<sup>3</sup> BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.

<sup>4</sup> KLIMENKO 98 limit is for inelastic scattering  $\chi^0 \text{ } ^{73}\text{Ge} \rightarrow \chi^0 \text{ } ^{73}\text{Ge}^*$  (13.26 keV).

<sup>5</sup> BELLI 96 limit for inelastic scattering  $\chi^0 \text{ } ^{129}\text{Xe} \rightarrow \chi^0 \text{ } ^{129}\text{Xe}^*$  (39.58 keV).

<sup>6</sup> BELLI 96c use background subtraction and obtain  $\sigma < 150 \text{ pb}$  ( $< 1.5 \text{ fb}$ ) (90% CL) for spin-dependent (independent)  $\chi^0$ -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.

<sup>7</sup> BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.

<sup>8</sup> SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.

<sup>9</sup> SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of  $0.4 \text{ GeV cm}^{-3}$  is assumed.

<sup>10</sup> GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.

<sup>11</sup> SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for <sup>27</sup>Al and <sup>28</sup>Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.

<sup>12</sup> REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For  $m_{\chi^0} = 100 \text{ GeV}$

<sup>1</sup> UCHIDA 14 limit is for inelastic scattering  $\chi^0 + ^{129}\text{Xe}^* \rightarrow \chi^0 + ^{129}\text{Xe}^*$  (39.58 keV).

<sup>2</sup> ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.

<sup>3</sup> BELLI 02 discuss dependence of the extracted WIMP cross section on the assumptions of the galactic halo structure.

<sup>4</sup> BERNABEI 02c analyze the DAMA data in the scenario in which  $\chi^0$  scatters into a slightly heavier state as discussed by SMITH 01.

<sup>5</sup> GREEN 02 discusses dependence of extracted WIMP cross section limits on the assumptions of the galactic halo structure.

<sup>6</sup> ULLIO 01 disfavor the possibility that the BERNABEI 99 signal is due to spin-dependent WIMP coupling.

<sup>7</sup> BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.

<sup>8</sup> BERNABEI 00d limit is for inelastic scattering  $\chi^0 \text{ } ^{129}\text{Xe} \rightarrow \chi^0 \text{ } ^{129}\text{Xe}^*$  (39.58 keV).

<sup>9</sup> AMBROSIO 99 search for upgoing muon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.

<sup>10</sup> BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.

<sup>11</sup> KLIMENKO 98 limit is for inelastic scattering  $\chi^0 \text{ } ^{73}\text{Ge} \rightarrow \chi^0 \text{ } ^{73}\text{Ge}^*$  (13.26 keV).

<sup>12</sup> KLIMENKO 98 limit is for inelastic scattering  $\chi^0 \text{ } ^{73}\text{Ge} \rightarrow \chi^0 \text{ } ^{73}\text{Ge}^*$  (66.73 keV).

<sup>13</sup> BELLI 96 limit for inelastic scattering  $\chi^0 \text{ } ^{129}\text{Xe} \rightarrow \chi^0 \text{ } ^{129}\text{Xe}^*$  (39.58 keV).

<sup>14</sup> BELLI 96c use background subtraction and obtain  $\sigma < 0.35 \text{ pb}$  ( $< 0.15 \text{ fb}$ ) (90% CL) for spin-dependent (independent)  $\chi^0$ -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.

<sup>15</sup> BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.

<sup>16</sup> SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.

<sup>17</sup> SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of  $0.4 \text{ GeV cm}^{-3}$  is assumed.

<sup>18</sup> GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.

<sup>19</sup> SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for <sup>27</sup>Al and <sup>28</sup>Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.

<sup>20</sup> BECK 94 uses enriched <sup>76</sup>Ge (86% purity).

<sup>21</sup> REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For  $m_{\chi^0} = 1 \text{ TeV}$

## Searches Particle Listings

### WIMPs and Other Particle Searches

- <sup>1</sup> UCHIDA 14 limit is for inelastic scattering  $X^0 + {}^{129}\text{Xe}^* \rightarrow X^0 + {}^{129}\text{Xe}^*$  (39.58 keV).
- <sup>2</sup> ANGLÖHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- <sup>3</sup> BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay Nal experiments.
- <sup>4</sup> BERNABEI 99d search for SIMPs (Strongly Interacting Massive Particles) in the mass range  $10^3\text{--}10^{16}$  GeV. See their Fig. 3 for cross-section limits.
- <sup>5</sup> DERBIN 99 search for SIMPs (Strongly Interacting Massive Particles) in the mass range  $10^2\text{--}10^{14}$  GeV. See their Fig. 3 for cross-section limits.
- <sup>6</sup> KLIMENKO 98 limit is for inelastic scattering  $X^0 {}^{73}\text{Ge} \rightarrow X^0 {}^{73}\text{Ge}^*$  (13.26 keV).
- <sup>7</sup> KLIMENKO 98 limit is for inelastic scattering  $X^0 {}^{73}\text{Ge} \rightarrow X^0 {}^{73}\text{Ge}^*$  (66.73 keV).
- <sup>8</sup> BELL 96 limit for inelastic scattering  $X^0 {}^{129}\text{Xe} \rightarrow X^0 {}^{129}\text{Xe}^*$  (39.58 keV).
- <sup>9</sup> BELL 96 limit for inelastic scattering  $X^0 {}^{129}\text{Xe} \rightarrow X^0 {}^{129}\text{Xe}^*$  (236.14 keV).
- <sup>10</sup> BELL 96c use background subtraction and obtain  $\sigma < 0.7$  pb ( $< 0.7$  fb) (90% CL) for spin-dependent (independent)  $X^0$ -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- <sup>11</sup> BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
- <sup>12</sup> SARSA 96 search for annual modulation of WIMP. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
- <sup>13</sup> SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of  $0.4 \text{ GeV cm}^{-3}$  is assumed.
- <sup>14</sup> GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
- <sup>15</sup> SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for  ${}^{27}\text{Al}$  and  ${}^{28}\text{Si}$ . See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
- <sup>16</sup> BECK 94 uses enriched  ${}^{76}\text{Ge}$  (86% purity).
- <sup>17</sup> REUSSER 91 limit here is changed from published (5) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

- <sup>1</sup> AARTSEN 15c search for neutrinos from  $X^0$  annihilation in the Galactic halo. See their Figs. 16 and 17, and Table 5 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 100 GeV and 100 TeV.
- <sup>2</sup> AARTSEN 15E search for neutrinos from  $X^0$  annihilation in the Galactic center. See their Figs. 7 and 9, and Table 3 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 30 GeV and 10 TeV.
- <sup>3</sup> ABRAMOWSKI 15 search for  $\gamma$  from  $X^0$  annihilation in the Galactic center. See their Fig. 4 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 250 GeV and 10 TeV.
- <sup>4</sup> ACKERMANN 15 search for monochromatic  $\gamma$  from  $X^0$  annihilation in the Galactic halo. See their Fig. 8 and Tables 2-4 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 0.2 GeV and 500 GeV.
- <sup>5</sup> ACKERMANN 15A search for  $\gamma$  from  $X^0$  annihilation (both Galactic and extragalactic) in the isotropic  $\gamma$  background. See their Fig. 7 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 10 GeV and 30 TeV.
- <sup>6</sup> ACKERMANN 15B search for  $\gamma$  from  $X^0$  annihilation in 15 dwarf spheroidal satellite galaxies of the Milky Way. See their Figs. 1 and 2 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 2 GeV and 10 TeV.

- <sup>7</sup> ADRIAN-MARTINEZ 15 search for neutrinos from  $X^0$  annihilation in the Galactic center. See their Figs. 10 and 11 and Tables 1 and 2 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 25 GeV and 10 TeV.
- <sup>8</sup> ACKERMANN 14 search for  $\gamma$  from  $X^0$  annihilation in 25 dwarf spheroidal satellite galaxies of the Milky Way. See their Tables II-VII for limits assuming annihilation into  $e^+e^-$ ,  $\mu^+\mu^-$ ,  $\tau^+\tau^-$ ,  $u\bar{u}$ ,  $b\bar{b}$ , and  $W^+W^-$ , for  $X^0$  mass ranging from 2 GeV to 10 TeV.
- <sup>9</sup> Limit assuming  $X^0$  pair annihilation into  $b\bar{b}$ .
- <sup>10</sup> Limit assuming  $X^0$  pair annihilation into  $W^+W^-$ .
- <sup>11</sup> ALEKSIC 14 search for  $\gamma$  from  $X^0$  annihilation in the dwarf spheroidal galaxy Segue 1. The listed limit assumes annihilation into  $W^+W^-$ . See their Figs. 6, 7, and 16 for limits on  $\sigma \cdot v$  for annihilation channels  $\mu^+\mu^-$ ,  $\tau^+\tau^-$ ,  $b\bar{b}$ ,  $t\bar{t}$ ,  $\gamma\gamma$ ,  $\gamma Z$ ,  $W^+W^-$ ,  $ZZ$  for  $X^0$  mass between  $10^2$  and  $10^4$  GeV.
- <sup>12</sup> AARTSEN 13c search for neutrinos from  $X^0$  annihilation in nearby galaxies and galaxy clusters. See their Figs. 5-7 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 300 GeV and 100 TeV.
- <sup>13</sup> ABRAMOWSKI 13 search for monochromatic  $\gamma$  from  $X^0$  annihilation in the Milky Way halo in the central region. Limit on  $\sigma \cdot v$  between  $10^{-28}$  and  $10^{-25} \text{ cm}^3\text{s}^{-1}$  (95% CL) is obtained for  $X^0$  mass between 500 GeV and 20 TeV for  $X^0 \rightarrow \gamma\gamma$ .  $X^0$  density distribution in the Galaxy by Einasto is assumed. See their Fig. 4.
- <sup>14</sup> ACKERMANN 13A search for monochromatic  $\gamma$  from  $X^0$  annihilation in the Milky Way. Limit on  $\sigma \cdot v$  for the process  $X^0 X^0 \rightarrow \gamma\gamma$  in the range  $10^{-29}\text{--}10^{-27} \text{ cm}^3\text{s}^{-1}$  (95% CL) is obtained for  $X^0$  mass between 5 and 300 GeV. The limit depends slightly on the assumed density profile of  $X^0$  in the Galaxy. See their Tables VII-X and Fig.10. Supersedes ACKERMANN 12.
- <sup>15</sup> ABRAMOWSKI 12 search for  $\gamma$ 's from  $X^0$  annihilation in the Fornax galaxy cluster. See their Fig. 7 for limits on  $\sigma \cdot v$  for  $X^0$  mass between 0.1 and 100 TeV for the annihilation channels  $\tau^+\tau^-$ ,  $b\bar{b}$ , and  $W^+W^-$ .
- <sup>16</sup> ACKERMANN 12 search for monochromatic  $\gamma$  from  $X^0$  annihilation in the Milky Way. Limit on  $\sigma \cdot v$  in the range  $10^{-28}\text{--}10^{-26} \text{ cm}^3\text{s}^{-1}$  (95% CL) is obtained for  $X^0$  mass between 7 and 200 GeV if  $X^0$  annihilates into  $\gamma\gamma$ . The limit depends slightly on the assumed density profile of  $X^0$  in the Galaxy. See their Table III and Fig. 15.
- <sup>17</sup> ACKERMANN 12 search for  $\gamma$  from  $X^0$  annihilation in the Milky Way in the diffuse  $\gamma$  background. Limit on  $\sigma \cdot v$  of  $10^{-24} \text{ cm}^3\text{s}^{-1}$  or larger is obtained for  $X^0$  mass between 5 GeV and 10 TeV for various annihilation channels including  $W^+W^-$ ,  $b\bar{b}$ ,  $g g$ ,  $e^+e^-$ ,  $\mu^+\mu^-$ ,  $\tau^+\tau^-$ . The limit depends slightly on the assumed density profile of  $X^0$  in the Galaxy. See their Figs. 17-20.
- <sup>18</sup> ALIU 12 search for  $\gamma$ 's from  $X^0$  annihilation in the dwarf spheroidal galaxy Segue 1. Limit on  $\sigma \cdot v$  in the range  $10^{-24}\text{--}10^{-20} \text{ cm}^3\text{s}^{-1}$  (95% CL) is obtained for  $X^0$  mass between 10 GeV and 2 TeV for annihilation channels  $e^+e^-$ ,  $\mu^+\mu^-$ ,  $\tau^+\tau^-$ ,  $b\bar{b}$ , and  $W^+W^-$ . See their Fig. 3.
- <sup>19</sup> ABBASI 11c search for  $\nu_\mu$  from  $X^0$  annihilation in the outer halo of the Milky Way. The limit assumes annihilation into  $\nu\nu$ . See their Fig. 9 for limits with other annihilation channels.
- <sup>20</sup> ABRAMOWSKI 11 search for  $\gamma$  from  $X^0$  annihilation near the Galactic center. The limit assumes Einasto DM density profile.
- <sup>21</sup> ACKERMANN 11 search for  $\gamma$  from  $X^0$  annihilation in ten dwarf spheroidal satellite galaxies of the Milky Way. The limit for  $m = 10$  GeV assumes annihilation into  $b\bar{b}$ , the others  $W^+W^-$ . See their Fig. 2 for limits with other final states. See also GERINGER-SAMETH 11 for a different analysis of the same data.

#### Dark Matter Particle ( $X^0$ ) Production in Hadron Collisions

Searches for  $X^0$  production in association with observable particles ( $\gamma$ , jets, ...) in high energy hadron collisions. If a specific form of effective interaction Lagrangian is assumed, the limits may be translated into limits on  $X^0$ -nucleon scattering cross section.

<sup>4</sup> Bound valid up to $m_{X^-} \sim 100$ TeV.				

### GENERAL NEW PHYSICS SEARCHES

This subsection lists some of the search experiments which look for general signatures characteristic of new physics, independent of the framework of a specific model.

The observed events are compatible with Standard Model expectation, unless noted otherwise.

<sup>1</sup> AAD 15AT search for events with a top quark and mssing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV with  $L = 20.3 \text{ fb}^{-1}$ .

<sup>2</sup> KHACHATRYAN 15F search for events with a top quark and mssing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV with  $L = 19.7 \text{ fb}^{-1}$ .

<sup>3</sup> AALTONEN 14J examine events with a  $W$  and two jets in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 8.9 \text{ fb}^{-1}$ . Invariant mass distributions of the two jets are consistent with the Standard Model expectation.

<sup>4</sup> AAD 13A search for resonant  $WW$  production in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.7 \text{ fb}^{-1}$ .

<sup>5</sup> AAD 13C search for events with a photon and missing  $\cancel{E}_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.6 \text{ fb}^{-1}$ .

<sup>6</sup> AALTONEN 13I search for events with a photon and missing  $E_T$ , where the photon is detected after the expected timing, in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 6.3 \text{ fb}^{-1}$ . The data are consistent with the Standard Model expectation.

<sup>7</sup> CHATRCHYAN 13 search for events with an opposite-sign lepton pair, jets, and missing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.98 \text{ fb}^{-1}$ .

<sup>8</sup> AAD 12C search for events with a  $t\bar{t}$  pair and missing  $\cancel{E}_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 1.04 \text{ fb}^{-1}$ .

<sup>9</sup> AALTONEN 12M search for events with a jet and missing  $E_T$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 6.7 \text{ fb}^{-1}$ .

<sup>10</sup> CHATRCHYAN 12AP search for events with a jet and missing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 5.0 \text{ fb}^{-1}$ .

<sup>11</sup> CHATRCHYAN 12Q search for events with a  $Z$ , jets, and missing  $\cancel{E}_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.98 \text{ fb}^{-1}$ .

<sup>12</sup> CHATRCHYAN 12T search for events with a photon and missing  $\cancel{E}_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 5.0 \text{ fb}^{-1}$ .

<sup>13</sup> AAD 11S search for events with one jet and missing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 33 \text{ pb}^{-1}$ .

<sup>14</sup> AALTONEN 11AF search for high- $p_T$  like-sign dileptons in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 6.1 \text{ fb}^{-1}$ .

<sup>15</sup> CHATRCHYAN 11C search for events with an opposite-sign lepton pair, jets, and missing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 34 \text{ pb}^{-1}$ .

<sup>16</sup> CHATRCHYAN 11U search for events with one jet and missing  $E_T$  in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 36 \text{ pb}^{-1}$ .

<sup>17</sup> AALTONEN 10AF search for  $\gamma\gamma$  events with  $e, \mu, \tau$ , or missing  $E_T$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 1.1\text{--}2.0 \text{ fb}^{-1}$ .

<sup>18</sup> AALTONEN 09AF search for  $\ell\gamma b$  events with missing  $E_T$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 1.9 \text{ fb}^{-1}$ . The observed events are compatible with Standard Model expectation including  $t\bar{t}\gamma$  production.

<sup>19</sup> AALTONEN 09G search for  $\mu\mu\mu$  and  $\mu\mu e$  events with missing  $E_T$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 976 \text{ pb}^{-1}$ .

## LIMITS ON JET-JET RESONANCES

## Heavy Particle Production Cross Section

- 1 AAD 13D search for dijet resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.8$  fb $^{-1}$ . The observed events are compatible with Standard Model expectation. See their Fig. 6 and Table 2 for limits on resonance cross section in the range  $m = 1.0$ –4.0 TeV.
- 2 AALTONEN 13R search for production of a pair of jet-jet resonances in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 6.6$  fb $^{-1}$ . See their Fig. 5 and Tables I, II for cross section limits.
- 3 CHATRCHYAN 13A search for  $qq$ ,  $qg$ , and  $gg$  resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.8$  fb $^{-1}$ . See their Fig. 3 and Table 1 for limits on resonance cross section in the range  $m = 1.0$ –4.3 TeV.
- 4 CHATRCHYAN 13A search for  $b\bar{b}$  resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.8$  fb $^{-1}$ . See their Fig. 8 and Table 4 for limits on resonance cross section in the range  $m = 1.0$ –4.0 TeV.
- 5 AAD 12S search for dijet resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 1.0$  fb $^{-1}$ . See their Fig. 3 and Table 2 for limits on resonance cross section in the range  $m = 0.9$ –4.0 TeV.
- 6 CHATRCHYAN 12BL search for  $t\bar{t}$  resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 4.4$  fb $^{-1}$ . See their Fig. 4 for limits on resonance cross section in the range  $m = 0.5$ –3.0 TeV.
- 7 AAD 11AG search for dijet resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 36$  pb $^{-1}$ . Limits on number of events for  $m = 0.6$ –4 TeV are given in their Table 3.
- 8 AALTONEN 11M find a peak in two jet invariant mass distribution around 140 GeV in  $W + 2$  jet events in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 4.3$  fb $^{-1}$ .
- 9 ABABOV 11I search for two-jet resonances in  $W + 2$  jet events in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV with  $L = 4.3$  fb $^{-1}$  and give limits  $\sigma < (2.6$ –1.3) pb (95% CL) for  $m = 110$ –170 GeV. The result is incompatible with AALTONEN 11M.
- 10 AAD 10 search for narrow dijet resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 315$  nb $^{-1}$ . Limits on the cross section in the range  $10$ – $10^3$  pb is given for  $m = 0.3$ –1.7 TeV.
- 11 KHACHATRYAN 10 search for narrow dijet resonances in  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV with  $L = 2.9$  pb $^{-1}$ . Limits on the cross section in the range  $1$ –300 pb is given for  $m = 0.5$ –2.6 TeV separately in the final states  $qq$ ,  $qg$ , and  $gg$ .
- 12 ABE 99F search for narrow  $b\bar{b}$  resonances in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8$  TeV. Limits on  $\sigma(p\bar{p} \rightarrow X + \text{anything}) \times B(X \rightarrow b\bar{b})$  in the range  $3$ – $10^3$  pb (95%CL) are given for  $m_X = 200$ –750 GeV. See their Table I.
- 13 ABE 97G search for narrow dijet resonances in  $p\bar{p}$  collisions with  $106$  pb $^{-1}$  of data at  $E_{\text{cm}} = 1.8$  TeV. Limits on  $\sigma(p\bar{p} \rightarrow X + \text{anything}) \times B(X \rightarrow jj)$  in the range  $10^4$ – $10^{-1}$  pb (95%CL) are given for dijet mass  $m = 200$ –1150 GeV with both jets having  $|\eta| < 2.0$  and the dijet system having  $|\cos\theta^*| < 0.67$ . See their Table I for the list of limits. Supersedes ABE 93G.
- 14 ABE 93G give cross section times branching ratio into light ( $d, u, s, c, b$ ) quarks for  $\Gamma = 0.02 M$ . Their Table II gives limits for  $M = 200$ –900 GeV and  $\Gamma = (0.02$ – $0.2) M$ .

## LIMITS ON NEUTRAL PARTICLE PRODUCTION

## Heavy Particle Production Cross Section

VALUE (cm $^2$ /N)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
		1 LEES 15E	BABR	$e^+e^-$ collisions
		2 ADAMS 97B	KTEV	$m = 1.2$ –5 GeV
		3 GALLAS 95	TOF	$m = 0.5$ –20 GeV
		4 AKESSON 91	CNTR	$m = 0$ –5 GeV
		5 BADIER 86	BDMP	$\tau = (0.05$ – $1.) \times 10^{-8}$ s
		6 GUSTAFSON 76	CNTR	$\tau > 10^{-7}$ s

- 1 LEES 15E search for long-lived neutral particles produced in  $e^+e^-$  collisions in the Upsilon region, which decays into  $e^+e^-$ ,  $\mu^+\mu^-$ ,  $e^+\mu^\mp$ ,  $\pi^+\pi^-$ ,  $K^+K^-$ , or  $\pi^\pm K^\mp$ . See their Fig. 2 for cross section limits.
- 2 ADAMS 97B search for a hadron-like neutral particle produced in  $pN$  interactions, which decays into a  $\rho^0$  and a weakly interacting massive particle. Upper limits are given for the ratio to  $K_L$  production for the mass range 1.2–5 GeV and lifetime  $10^{-9}$ – $10^{-4}$  s. See also our Light Gluino Section.
- 3 GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c  $pN$  interactions decaying with a lifetime of  $10^{-4}$ – $10^{-8}$  s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section  $10^{-29}$ – $10^{-33}$  cm $^2$ . See Fig. 10.
- 4 AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in  $pN$  reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for  $\tau > 10^{-7}$  s. For  $\tau > 10^{-9}$  s,  $\sigma < 10^{-30}$  cm $^2$ /nucleon is obtained.
- 5 BADIER 86 looked for long-lived particles at 300 GeV  $\pi^-$  beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass  $> 2$  GeV. The limit applies for particle modes,  $\mu^+\pi^-$ ,  $\mu^+\mu^-$ ,  $\pi^+\pi^-X$ ,  $\pi^+\pi^-\pi^\pm$  etc. See their figure 5 for the contours of limits in the mass- $\tau$  plane for each mode.
- 6 GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy ( $m > 2$  GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for  $m = 3$  GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

Production of New Penetrating Non- $\nu$  Like States in Beam Dump

		9 BARTEL 80	JADE	$Q=(3,4,5)/3$ 2–12 GeV

- 1 ACKERSTAFF 98P search for pair production of long-lived charged particles at  $E_{\text{cm}}$  between 130 and 183 GeV and give limits  $\sigma < (0.05$ – $0.2)$  pb (95%CL) for spin-0 and spin-1/2 particles with  $m=45$ –89.5 GeV, charge 1 and 2/3. The limit is translated to the cross section at  $E_{\text{cm}}=183$  GeV with the  $s$  dependence described in the paper. See their Figs. 2–4.
- 2 ABREU 97D search for pair production of long-lived particles and give limits  $\sigma < (0.4$ – $2.3)$  pb (95%CL) for various center-of-mass energies  $E_{\text{cm}}=130$ –136, 161, and 172 GeV, assuming an almost flat production distribution in  $\cos\theta$ .
- 3 BARATE 97K search for pair production of long-lived charged particles at  $E_{\text{cm}} = 130$ , 136, 161, and 172 GeV and give limits  $\sigma < (0.2$ – $0.4)$  pb (95%CL) for spin-0 and spin-1/2 particles with  $m=45$ –85 GeV. The limit is translated to the cross section at  $E_{\text{cm}}=172$  GeV with the  $E_{\text{cm}}$  dependence described in the paper. See their Figs. 2 and 3 for limits on  $J = 1/2$  and  $J = 0$  cases.
- 4 AKERS 95R is a CERN-LEP experiment with  $W_{\text{cm}} \sim m_Z$ . The limit is for the production of a stable particle in multihadron events normalized to  $\sigma(e^+e^- \rightarrow \text{hadrons})$ . Constant phase space distribution is assumed. See their Fig. 3 for bounds for  $Q = \pm 2/3$ ,  $\pm 4/3$ .
- 5 BUSKULIC 93C is a CERN-LEP experiment with  $W_{\text{cm}} = m_Z$ . The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.
- 6 ADACHI 90C is a KEK-TRISTAN experiment with  $W_{\text{cm}} = 52$ –60 GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.
- 7 ADACHI 90E is KEK-TRISTAN experiment with  $W_{\text{cm}} = 52$ –61.4 GeV. The above limit is for inclusive production cross section normalized to  $\sigma(e^+e^- \rightarrow \mu^+\mu^-) \times \beta(3 - \beta^2)/2$ , where  $\beta = (1 - 4m^2/W_{\text{cm}}^2)^{1/2}$ . See the paper for the assumption about the production mechanism.
- 8 KINOSHITA 82 is SLAC PEP experiment at  $W_{\text{cm}} = 29$  GeV using lexan and  $^{39}\text{Cr}$  plastic sheets sensitive to highly ionizing particles.
- 9 BARTEL 80 is DESY-PETRA experiment with  $W_{\text{cm}} = 27$ –35 GeV. Above limit is for inclusive pair production and ranges between  $1. \times 10^{-1}$  and  $1. \times 10^{-2}$  depending on mass and production momentum distributions. (See their figures 9, 10, 11).

### Branching Fraction of $Z^0$ to a Pair of Stable Charged Heavy Fermions

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$<5 \times 10^{-6}$	95	<sup>1</sup> AKERS	95R OPAL	$m = 40.4\text{--}45.6$ GeV
$<1 \times 10^{-3}$	95	AKRAWY	90O OPAL	$m = 29\text{--}40$ GeV
<sup>1</sup> AKERS 95R give the 95% CL limit $\sigma(X\bar{X})/\sigma(\mu\mu) < 1.8 \times 10^{-4}$ for the pair production of singly- or doubly-charged stable particles. The limit applies for the mass range 40.4–45.6 GeV for $X^\pm$ and $< 45.6$ GeV for $X^{\pm\pm}$ . See the paper for bounds for $Q = \pm 2/3, \pm 4/3$ .				

### LIMITS ON CHARGED PARTICLES IN HADRONIC REACTIONS

#### MASS LIMITS for Long-Lived Charged Heavy Fermions

Limits are for spin 1/2 particles with no color and  $SU(2)_L$  charge. The electric charge  $Q$  of the particle (in the unit of  $e$ ) is therefore equal to its weak hypercharge. Pair production by Drell-Yan like  $\gamma$  and  $Z$  exchange is assumed to derive the limits.

- 1 See AGNESE 15 Fig. 6 for limits extending down to Q = 1/200.
- 2 SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.
- 3 MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake effect.
- 4 SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10<sup>17</sup> eV may indicate production of very heavy parent at top of atmosphere.
- 5 BHAT 82 observed 12 events with delay > 2. × 10<sup>-8</sup> s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.
- 6 MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
- 7 YOCK 81 saw another 3 events with Q = ±1 and m about 4.5 m<sub>p</sub> as well as 2 events with m > 5.3 m<sub>p</sub>, Q = ±0.75 ± 0.05 and m > 2.8 m<sub>p</sub>, Q = ±0.70 ± 0.05 and 1 event with m = (9.3 ± 3.) m<sub>p</sub>, Q = ±0.89 ± 0.06 as possible heavy candidates.
- 8 YOCK 80 events are with charge exactly or approximately equal to unity.
- 9 BHAT 78 is at Kolar gold fields. Limit is for τ > 10<sup>-6</sup> s.
- 10 YOCK 74 events could be tritons.

- 1 ADRIANI 15 search for relatively light quark matter with charge Z = 1–8. See their Figs. 2 and 3 for flux upper limits.
- 2 AMBROSIO 00B searched for quark matter (“nuclearites”) in the velocity range (10<sup>-5</sup>–1) c. The listed limit is for 2 × 10<sup>-3</sup> c.
- 3 ASTONE 93 searched for quark matter (“nuclearites”) in the velocity range (10<sup>-3</sup>–1) c. Their Table 1 gives a compilation of searches for nuclearites.
- 4 AHLEN 92 searched for quark matter (“nuclearites”). The bound applies to velocity < 2.5 × 10<sup>-3</sup> c. See their Fig. 3 for other velocity/c and heavier mass range.
- 5 NAKAMURA 91 searched for quark matter in the velocity range (4 × 10<sup>-5</sup>–1) c.
- 6 ORITO 91 searched for quark matter. The limit is for the velocity range (10<sup>-4</sup>–10<sup>-3</sup>) c.
- 7 LIU 88 searched for quark matter (“nuclearites”) in the velocity range (2.5 × 10<sup>-3</sup>–1) c. A less stringent limit of 5.8 × 10<sup>-11</sup> applies for (1–2.5) × 10<sup>-3</sup> c.
- 8 BARISH 87 searched for quark matter (“nuclearites”) in the velocity range (2.7 × 10<sup>-4</sup>–5 × 10<sup>-3</sup>) c.
- 9 NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity of (10<sup>-4</sup>–10<sup>-3</sup>) c.
- 10 ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.

Time-projection chambers (TPC) (non-accelerator) . . . . .	501	Universe (cont.)	
Top-changing neutral currents, tests for . . . . .	105	matter-dominated . . . . .	361
Top quark ( $t$ ) . . . . .	<b>36</b> , 807	phase transitions . . . . .	360
Top quark, note on . . . . .	807	radiation content at early times . . . . .	359
Top quark mass from electroweak analyses . . . . .	161	thermodynamic equilibrium . . . . .	359
Toroidal collider detector magnets . . . . .	487	thermal history of . . . . .	358
Total cross sections, table of fit parameters . . . . .	590	$\Upsilon$ states, width determinations of, note on . . . . .	1460
Total cross sections, summary plot . . . . .	593	$\Upsilon(1S)$ . . . . .	<b>80</b> , 1462
Total energy density of Universe, $\Omega_{tot}$ . . . . .	391	$\Upsilon(2S)$ . . . . .	<b>81</b> , 1472
Total lepton number conservation . . . . .	105	$\Upsilon(3S)$ . . . . .	<b>82</b> , 1482
TPC, Time-projection chambers . . . . .	470	$\Upsilon(4S)$ . . . . .	<b>83</b> , 1486
TPC, Time-projection chambers (non-accelerator) . . . . .	501	$\Upsilon(10860)$ . . . . .	<b>83</b> , 1490
Tracking Cherenkov detectors . . . . .	463	$\Upsilon(11020)$ . . . . .	<b>83</b> , 1492
Transformation of electromagnetic fields, relativistic . . . . .	128	$V_{cb}$ and $V_{ub}$ CKM Matrix Elements . . . . .	1313
Transition radiation . . . . .	452	$V_{cb}$ and $V_{ub}$ determination of, note on . . . . .	1313
Transition radiation detectors (TRD) . . . . .	472	$V_{ud}$ , $V_{us}$ determination of, note on . . . . .	1011
Triangles, unitarity, note on . . . . .	224	$V_{ud}$ , $V_{us}$ , $V_{ub}$ , $V_{cd}$ , $V_{cs}$ , $V_{cb}$ , $V_{td}$ , $V_{ts}$ , $V_{tb}$ . . . . .	224
Triple gauge couplings, note on the extraction of . . . . .	618	Vacuum energy parameter, $\Omega_v$ . . . . .	356
Tropical year . . . . .	120	Variance, definition . . . . .	517
Two-body decay kinematics . . . . .	560	Vector meson candidates . . . . .	974

- $W$  (gauge boson) . . . . . **29**, 614  
 $W$ -boson mass, note on . . . . . 614  
 $W$  boson, mass, width, branching ratios,  
and coupling to fermions . . . . . **29**, 119, 153, 161, 162  
 $W^\pm$ : Triple gauge couplings, note on the extraction of . . . . . 618  
 $W$  and  $Z$  differential cross section . . . . . 584  
 $w$ , dark energy equation of state parameter . . . . . 356  
 $W'$  searches, note on . . . . . 665  
WMAP, NASA's Wilkinson Microwave Anisotropy Probe . . . . . 389  
Weak boson searches . . . . . **30**, 665  
Weak neutral currents, tests for  
( $\Delta B = 1, \Delta C = 1, \Delta S = 1, \Delta T = 1$ ) . . . . . 105  
Weinberg angle ( $\sin^2 \theta_W$ ) . . . . . 119, 151  
Width determinations of  $\Upsilon$  states, note on . . . . . 1460  
Width of  $W$  and  $Z$  bosons . . . . . 161  
Wien displacement law constant . . . . . 119  
WIMPs (also see dark matter limits) . . . . . 395  
WIMPs and other particle searches, note on . . . . . 1778  
Wire chambers . . . . . 465  
 $xF_3$  structure function, plots of . . . . . 333  
 $x$  variable (of Feynman's) . . . . . 562  
 $X$  mesons  
 $X(1840)$  . . . . . 956  
 $X(1850)$  [*now called*  $\phi_3(1850)$ ] . . . . . **42**, 957  
 $X(3823)$  [*now called*  $\psi(3823)$ ] . . . . . **77**, 1439  
 $X(3872)$  . . . . . **77**, 1440  
 $X(3900)$  . . . . . **77**, 1442  
 $X(3940)$  . . . . . 1444  
 $X(4020)$  . . . . . **78**, 1445  
 $X(3915)$  . . . . . **77**, 1443  
 $X(4050)^\pm$  . . . . . 1447  
 $X(4055)^\pm$  . . . . . 1448  
 $X(4140)$  . . . . . **78**, 1448  
 $\psi(4160)$  . . . . . **78**, 1449  
 $X(4160)$  . . . . . 1451  
 $X(4200)^\pm$  . . . . . 1451  
 $X(4230)$  . . . . . 1451  
 $X(4240)^\pm$  . . . . . 1452  
 $X(4250)^\pm$  . . . . . 1452  
 $X(4260)$  . . . . . **78**, 1452  
 $X(4350)$  . . . . . 1455  
 $X(4360)$  . . . . . **79**, 1455  
 $X(4430)^\pm$  . . . . . **79**, 1457  
 $X(4660)$  . . . . . **79**, 1458  
 $X(10610)^\pm$  . . . . . **83**, 1488  
 $X(10610)^0$  . . . . . **83**, 1489  
 $X(10650)^\pm$  . . . . . 1489  
 $\Xi$  baryons . . . . . **95**, 1620  
 $\Xi$  resonances, note on . . . . . 1625  
 $\Xi^0$  . . . . . **95**, 1620  
 $\Xi^-$  . . . . . **95**, 1622  
 $\Xi_b^0, \Xi_b^-$  . . . . . 1662  
 $\Xi_c^+$  . . . . . **98**, 1648  
 $\Xi_c^0$  . . . . . **98**, 1649  
 $\Xi_c'^+$  . . . . . **99**, 1650  
 $\Xi_c'^0$  . . . . . **99**, 1651  
 $\Xi_c(2645)$  . . . . . **99**, 1651  
 $\Xi_c(2790)$  . . . . . **99**, 1651  
 $\Xi_c(2815)$  . . . . . **99**, 1651  
 $\xi(2220)$  [*now called*  $f_J(2220)$ ] . . . . . 968  
Year, sidereal . . . . . 120  
Year, tropical . . . . . 120  
Young diagrams (tableaux) . . . . . 559  
Young's modulus of solid elements, table . . . . . 127  
Yukawa coupling unification . . . . . 290  
 $Z$ : Anomalous  $ZZ\gamma$ ,  $Z\gamma\gamma$ , and  $ZZV$  couplings . . . . . 644  
 $Z$  (gauge boson) . . . . . **29**, 624  
 $Z$  boson, note on . . . . . 624  
 $Z$  boson, mass, width, branching ratios,  
and coupling to fermions . . . . . **29**, 119, 153, 161, 162, 670  
 $Z$  decay to heavy flavors . . . . . 628  
 $Z$  width, plot . . . . . 589  
 $Z'$  searches, note on . . . . . 670
