Fully exclusive predictions via Monte Carlo generators for the  $t\bar{t}$  and single top production processes at NLO accuracy in QCD, including top-quark decays, are available [16,17] through the MC@NLO [18] and POWHEG [19] methods.

Besides fully inclusive QCD or EW top-quark production, more exclusive final states can be accessed at hadron colliders, whose cross sections are typically much smaller, yet can provide key information on the properties of the top quark. For all relevant final states (*e.g.*,  $t\bar{t}V$ ,  $t\bar{t}VV$  with  $V = \gamma, W, Z$ ,  $t\bar{t}H$ ,  $t\bar{t}$ +jets,  $t\bar{t}b\bar{b}$ ,  $t\bar{t}t\bar{t}$ ) automatic or semi-automatic predictions

at NLO accuracy in QCD also in the form of event generators, *i.e.*, interfaced to parton-shower programs, are available (see the review “Monte Carlo event generators” for more information).

### C. Top-quark measurements

Since the discovery of the top quark, direct measurements of  $t\bar{t}$  production have been made at five center-of-mass energies, providing stringent tests of QCD. The first measurements were made in Run I at the Tevatron at  $\sqrt{s} = 1.8$  TeV. In Run II at the Tevatron relatively precise measurements were made at  $\sqrt{s} = 1.96$  TeV. Finally, beginning in 2010, measurements have been made at the LHC at  $\sqrt{s} = 7$  TeV and  $\sqrt{s} = 8$  TeV, and very recently at  $\sqrt{s} = 13$  TeV.

Production of single top quarks through electroweak interactions has now been measured with good precision at the Tevatron at  $\sqrt{s} = 1.96$  TeV, and at the LHC at  $\sqrt{s} = 7$  TeV and  $\sqrt{s} = 8$  TeV, and now also at  $\sqrt{s} = 13$  TeV. Recent measurements at the Tevatron have managed to separate the *s*- and *t*-channel production cross sections, and at the LHC, the *Wt* mechanism as well, though the *t*-channel is measured with best precision to date. The measurements allow an extraction of the CKM matrix element  $V_{tb}$ .

With approximately  $10 \text{ fb}^{-1}$  of Tevatron data analyzed as of this writing, and almost  $5 \text{ fb}^{-1}$  at 7 TeV,  $20 \text{ fb}^{-1}$  at 8 TeV and the first  $78 \text{ pb}^{-1}$  at 13 TeV at the LHC, many properties of the top quark have been measured with precision. These include properties related to the production mechanism, such as  $t\bar{t}$  spin correlations, forward-backward or charge asymmetries, and differential production cross sections, as well as properties related to the  $tWb$  decay vertex, such as the helicity of the *W*-bosons from the top-quark decay. Recently, also studies of the  $t\bar{t}\gamma$  and the  $t\bar{t}Z$  interactions have been made. In addition, many searches for physics beyond the Standard Model are being performed with increasing reach in both production and decay channels.

In the following sections we review the current status of measurements of the characteristics of the top quark.

### C.1 Top-quark production

**C.1.1  $t\bar{t}$  production:** Fig. 1 summarizes the  $t\bar{t}$  production cross-section measurements from both the Tevatron and LHC. The most recent measurement from DØ [20], combining the measurements from the dilepton and lepton plus jets final states in  $9.7 \text{ fb}^{-1}$ , is  $7.73 \pm 0.13 \pm 0.55 \text{ pb}$ .

From CDF the most precise measurement made recently [21] is in  $8.8 \text{ fb}^{-1}$  in the dilepton channel requiring at least one *b*-tag, yielding  $7.09 \pm 0.84 \text{ pb}$ . Both of these measurements assume a top-quark mass of  $172.5 \text{ GeV}/c^2$ . The dependence of the cross section measurements on the value chosen for the mass is less than that of the theory calculations because it only affects the determination of the acceptance. In some analyses also the shape of topological variables might be modified.

The resulting combined  $t\bar{t}$  cross-section is  $\sigma_{t\bar{t}} = 7.63 \pm 0.50 \text{ pb}$  (6.6%) for CDF,  $\sigma_{t\bar{t}} = 7.56 \pm 0.59 \text{ pb}$  (7.8%) for DØ and

$\sigma_{t\bar{t}} = 7.60 \pm 0.41 \text{ pb}$  (5.4%) for the Tevatron combination [22] in good agreement with the SM expectation of  $7.35^{+0.28}_{-0.33} \text{ pb}$  at NNLO+NNLL in perturbative QCD [1] for a top mass of  $172.5 \text{ GeV}$ . The contributions to the uncertainty are  $0.20 \text{ pb}$  from statistical sources,  $0.29 \text{ pb}$  from systematic sources, and  $0.21 \text{ pb}$  from the uncertainty on the integrated luminosity.

CDF has measured the  $t\bar{t}$  production cross section in the dilepton channel with one hadronically decaying tau in  $9.0 \text{ fb}^{-1}$ , yielding  $\sigma_{t\bar{t}} = 8.1 \pm 2.1 \text{ pb}$ . By separately identifying the single-tau and the ditau components, they measure the branching fraction of the top quark into the tau lepton, tau neutrino, and bottom quark to be  $(9.6 \pm 2.8)\%$  [23]. CDF also performs measurements of the  $t\bar{t}$  production cross section normalized to the *Z* production cross section in order to reduce the impact of the luminosity uncertainty.

The LHC experiments ATLAS and CMS use similar techniques to measure the  $t\bar{t}$  cross-section in *pp* collisions. The most precise measurements come from the dilepton channel, and in particular the  $e\mu$  channel. At  $\sqrt{s} = 7$  TeV, ATLAS uses  $4.6 \text{ fb}^{-1}$  of  $e\mu$  events in which they select an extremely clean sample and determine the  $t\bar{t}$  cross-section simultaneously with the efficiency to reconstruct and tag *b*-jets, yielding  $\sigma_{t\bar{t}} = 182.9 \pm 7.1 \text{ pb}$ , corresponding to 3.9% precision [24]. Other measurements by ATLAS at  $\sqrt{s} = 7$  TeV, include a measurement in  $0.7 \text{ fb}^{-1}$  in the lepton+jets channel [25], in the dilepton channel [26], and in  $1.02 \text{ fb}^{-1}$  in the all-hadronic channel [27], which together yield a combined value of  $\sigma_{t\bar{t}} = 177 \pm 3(\text{stat.})^{+8}_{-7}(\text{syst.}) \pm 7(\text{lumi.}) \text{ pb}$  (6.2%) assuming  $m_t = 172.5 \text{ GeV}/c^2$  [28]. In  $4.7 \text{ fb}^{-1}$  of all-jets events, they obtain  $\sigma_{t\bar{t}} = 168 \pm 62 \text{ pb}$  [29]. Further analyses in the hadronic  $\tau$  plus jets channel in  $1.67 \text{ fb}^{-1}$  [30] and the hadronic  $\tau + \text{lepton}$  channel in  $2.05 \text{ fb}^{-1}$  [31], yield consistent albeit less precise results. The most precise measurement from CMS is also obtained in the dilepton channel, where they measure  $\sigma_{t\bar{t}} = 162 \pm 2(\text{stat.}) \pm 5(\text{syst.}) \pm 4(\text{lumi.}) \text{ pb}$ , corresponding to a 4.2% precision [32]. Other measurements at  $\sqrt{s} = 7$  TeV from CMS include measurements with  $2.3 \text{ fb}^{-1}$  in the  $e/\mu$ +jets channel [33], with  $3.5 \text{ fb}^{-1}$  in the all-hadronic channel [34], with  $2.2 \text{ fb}^{-1}$  in the lepton+ $\tau$  channel [35], and with  $3.9 \text{ fb}^{-1}$  in the  $\tau$ +jets channel [36]. ATLAS and CMS also provide a combined cross section of  $173.3 \pm 2.3(\text{stat.}) \pm 7.6(\text{syst.}) \pm 6.3(\text{lump.}) \text{ pb}$  using slightly older results based on  $0.7 - 1.1 \text{ fb}^{-1}$  [37].

At  $\sqrt{s} = 8$  TeV, ATLAS measures the  $t\bar{t}$  cross-section with  $20.3 \text{ fb}^{-1}$  using  $e\mu$  dilepton events, with a simultaneous measurement of the *b*-tagging efficiency, yielding  $\sigma_{t\bar{t}} = 242.4 \pm 1.7(\text{stat.}) \pm 5.5(\text{syst.}) \pm 7.5(\text{lumi.}) \pm 4.2(\text{beam energy}) \text{ pb}$  [24] assuming  $m_t = 172.5 \text{ GeV}/c^2$ , which corresponds to a 4.7% precision. In the lepton+jets channel, they measure  $\sigma_{t\bar{t}} = 260 \pm 1(\text{stat.})^{+20}_{-23}(\text{syst.}) \pm 8(\text{lumi.}) \pm 4(\text{beam energy}) \text{ pb}$  [38] in  $20.3 \text{ fb}^{-1}$  using a likelihood discriminant fit and *b*-jet identification.

CMS performs a template fit to the  $M_{b\bar{b}}$  mass distribution using  $2.8 \text{ fb}^{-1}$  in the lepton+jets channel yielding

# Quark Particle Listings

*t*

$\sigma_{t\bar{t}} = 228 \pm 9(\text{stat.})^{+29}_{-26}(\text{syst.}) \pm 10(\text{lumi.})$  pb [39]. In the dilepton channel, the cross sections are extracted using a binned likelihood fit to multi-differential final state distributions related to identified  $b$  quark and other jets in the event. Using the full data samples collected in 2011 and 2012 they obtain  $\sigma_{t\bar{t}} = 245.6 \pm 1.3(\text{stat.}) \pm 6.0(\text{syst.}) \pm 6.5(\text{lumi.})$  pb [40]. The cross section is also measured in the all-jets final state giving  $\sigma_{t\bar{t}} = 275.6 \pm 6.1(\text{stat.}) \pm 37.8(\text{syst.}) \pm 7.2(\text{lumi.})$  pb [41]. In combination of the most precise  $e\mu$  measurements in  $5.3 - 20.3 \text{ fb}^{-1}$ , ATLAS and CMS together yield  $\sigma_{t\bar{t}} = 241.5 \pm 1.4(\text{stat.}) \pm 5.7(\text{syst.}) \pm 6.2(\text{lumi.})$  pb [42], which corresponds to a 3.5% precision, challenging the precision of the corresponding theoretical predictions.

**Figure 1:** Measured and predicted  $t\bar{t}$  production cross sections from Tevatron energies in  $p\bar{p}$  collisions to LHC energies in  $pp$  collisions. Tevatron data points at  $\sqrt{s} = 1.8$  TeV are from Refs. [49,50]. Those at  $\sqrt{s} = 1.96$  TeV are from Refs. [20–22]. The ATLAS, CMS, and LHCb data points are from Refs. [28–29,38], and [33–34], and [43], respectively. Theory curves and uncertainties are generated using [1] for  $m_t = 172.5 \text{ GeV}/c^2$ , the  $m_t$  value assumed in the cross section measurements. Figure adapted from Ref. [46].

Recently, the LHCb collaboration presented the first observation of top-quark production in the forward region in  $pp$ -collisions. The  $W + b$  final state with  $W \rightarrow \mu\nu$  is reconstructed using muons with a transverse momentum,  $p_T$ , larger than 25 GeV in the pseudorapidity range  $2.0 < \eta < 4.5$ . The  $b$ -jets are required to have  $50 \text{ GeV} < p_T < 100 \text{ GeV}$  and  $2.2 < \eta < 4.2$ , while the transverse component of the sum of the muon and  $b$ -jet momenta must satisfy  $p_T > 20 \text{ GeV}$ . The results are based on data corresponding to integrated luminosities of 1.0 and  $2.0 \text{ fb}^{-1}$  collected at center-of-mass energies of 7 and 8 TeV by LHCb. The inclusive top quark production cross-sections in the fiducial region are  $\sigma_{t\bar{t}} = 239 \pm 53(\text{stat.}) \pm 38(\text{syst.})$  pb at 7 TeV, and  $\sigma_{t\bar{t}} = 289 \pm 43(\text{stat.}) \pm 46(\text{syst.})$  pb at 8 TeV [43].

Very recently, ATLAS and CMS have also measured the  $t\bar{t}$  production cross section with early Run-II data at  $\sqrt{s} = 13 \text{ TeV}$  in  $e\mu$  events with at least one  $b$ -tag. ATLAS uses  $78 \text{ pb}^{-1}$

and obtains  $\sigma_{t\bar{t}} = 825 \pm 114$  pb [44]. CMS uses  $42 \text{ pb}^{-1}$  and measures  $\sigma_{t\bar{t}} = 836 \pm 27(\text{stat.}) \pm 88(\text{syst.}) \pm 100(\text{lumi.})$  pb [45].

These experimental results should be compared to the theoretical calculations at NNLO+NNLL that yield  $7.16^{+0.20}_{-0.23}$  pb for top-quark mass of  $173.3 \text{ GeV}/c^2$  [1] at  $\sqrt{s} = 1.96 \text{ TeV}$ , and for top-quark mass of  $173.2 \text{ GeV}/c^2$   $\sigma_{t\bar{t}} = 173.6^{+4.5+8.9}_{-5.9-8.9}$  pb at  $\sqrt{s} = 7 \text{ TeV}$ ,  $\sigma_{t\bar{t}} = 247.7^{+6.3+11.5}_{-8.5-11.5}$  pb at  $\sqrt{s} = 8 \text{ TeV}$ , and  $\sigma_{t\bar{t}} = 816.0^{+19.4+34.4}_{-28.6-34.4}$  pb at  $\sqrt{s} = 13 \text{ TeV}$ , at the LHC [1].

In Fig. 1, one sees the importance of  $p\bar{p}$  at Tevatron energies where the valence antiquarks in the antiprotons contribute to the dominant  $q\bar{q}$  production mechanism. At LHC energies, the dominant production mode is gluon-gluon fusion and the  $pp$ - $p\bar{p}$  difference nearly disappears. The excellent agreement of these measurements with the theory calculations is a strong validation of QCD and the soft-gluon resummation techniques employed in the calculations. The measurements reach high precision and provide stringent tests of pQCD calculations at NNLO+NNLL level including their respective PDF uncertainties.

Most of these measurements assume a  $t \rightarrow Wb$  branching ratio of 100%. CDF and DØ have made direct measurements of the  $t \rightarrow Wb$  branching ratio [47]. Comparing the number of events with 0, 1 and 2 tagged  $b$  jets in the lepton+jets channel, and also in the dilepton channel, using the known  $b$ -tagging efficiency, the ratio  $R = B(t \rightarrow Wb) / \sum_{q=d,s,b} B(t \rightarrow Wq)$  can be extracted. In  $5.4 \text{ fb}^{-1}$  of data, DØ measures  $R = 0.90 \pm 0.04$ ,  $2.5\sigma$  from unity. The currently most precise measurement was made by CMS in  $19.7 \text{ fb}^{-1}$  at  $\sqrt{s} = 8 \text{ TeV}$ . They find  $R = 1.014 \pm 0.003(\text{stat.}) \pm 0.032(\text{syst.})$  and  $R > 0.955$  at 95% C.L. [48]. A significant deviation of  $R$  from unity would imply either non-SM top-quark decay (for example a flavor-changing neutral-current decay), or a fourth generation of quarks.

Thanks to the large available event samples, the Tevatron and the LHC experiments also performed differential cross-section measurements in  $t\bar{t}$  production. Such measurements are crucial, as they allow even more stringent tests of perturbative QCD as description of the production mechanism, allow the extraction or the use of PDF fits, and enhance the sensitivity to possible new physics contributions, especially now that NNLO predictions for the main differential observables in  $t\bar{t}$  prediction have become available [51]. Furthermore, such measurements reduce the uncertainty in the description of  $t\bar{t}$  production as background in Higgs physics and searches for rare processes or beyond Standard Model physics. Differential cross-sections are typically measured by a selection of candidate events, their kinematic reconstruction and subsequent unfolding of the obtained event counts in bins of kinematic distributions in order to correct for detector resolution effects, acceptance and migration effects. In some cases a bin-by-bin unfolding is used, while other analyses use a more sophisticated techniques.

Experiments at Tevatron and LHC measure the differential cross-section with respect to the  $t\bar{t}$  invariant mass,  $d\sigma/dM_{t\bar{t}}$ . The spectra are fully corrected for detector efficiency and resolution effects and are compared to several Monte Carlo

simulations as well as selected theoretical calculations. Using  $2.7 \text{ fb}^{-1}$ , CDF measured  $d\sigma/dM_{t\bar{t}}$  in the lepton+jets channel providing sensitivity to a variety of exotic particles decaying into  $t\bar{t}$  pairs [52]. In  $9.7 \text{ fb}^{-1}$  of lepton+jets data, DØ measured the differential  $t\bar{t}$  production cross-section with respect to the transverse momentum and absolute rapidity of the top quarks as well as of the invariant mass of the  $t\bar{t}$  pair [53], which are all found to be in good agreement with the SM predictions. Also ATLAS measured the differential  $t\bar{t}$  production cross-section with respect to the top-quark transverse momentum, and of the mass, transverse momentum and rapidity of the top-quark, the antitop-quark as well as the  $t\bar{t}$  system in  $4.6 \text{ fb}^{-1}$  at  $\sqrt{s} = 7 \text{ TeV}$  in the lepton+jets channel [54–56]. The results show sensitivity to these predictions and to different sets of parton distribution functions. It is found that data is softer than all predictions for higher values of the mass of the  $t\bar{t}$  system as well as in the tail of the top-quark  $p_T$  spectrum beginning at 200 GeV, particularly in the case of the **Alpgen+Herwig** generator. The  $M_{t\bar{t}}$  spectrum is not well described by NLO+NNLL calculations and there are also disagreements between the measured  $y_{t\bar{t}}$  spectrum and the **MC@NLO+Herwig** and **POWHEG+Herwig** generators, both evaluated with the CT10 PDF set. All distributions show a preference for HERAPDF1.5 when used for the NLO QCD predictions. Recently, using  $20.3 \text{ fb}^{-1}$  of 8 TeV data, ATLAS performed a dedicated differential  $t\bar{t}$  cross section measurement of highly boosted top quarks, where the hadronically decaying top quark has a transverse momentum above 300 GeV [57]. Jet substructure techniques are employed to identify top quarks, which are reconstructed with an anti- $k_t$  jet with a radius parameters  $R = 1.0$ . The predictions of next-to-leading-order and leading-order matrix element plus parton shower Monte Carlo generators are found to generally overestimate the measured cross sections. A corresponding analysis at high transverse momentum regime for the top quarks, is performed by the CMS collaboration in  $19.7 \text{ fb}^{-1}$  at  $\sqrt{s} = 8 \text{ TeV}$  [58]. The measurement is performed for events in electron/muon plus jets final states where the hadronically decaying top quark is reconstructed as a single large-radius jet and identified as a top candidate using jet substructure techniques. The integrated cross section is measured at particle-level within a fiducial region resembling the detector-level selection as well as at parton-level. At particle-level, the cross section is measured to be  $\sigma_{t\bar{t}} = 1.28 \pm 0.09(\text{stat.} + \text{syst.}) \pm 0.10(\text{pdf}) \pm 0.09(\text{scales}) \pm 0.03(\text{lumi.})$  pb for  $p_T > 400 \text{ GeV}$ . At parton-level, it translates to  $\sigma_{t\bar{t}} = 1.44 \pm 0.10(\text{stat.} + \text{syst.}) \pm 0.13(\text{pdf}) \pm 0.15(\text{scales}) \pm 0.04(\text{lumi.})$  pb, 14% lower than the SM prediction of **POWHEG+Pythia6**. In  $5.0 \text{ fb}^{-1}$  of  $\sqrt{s} = 7 \text{ TeV}$  data in the lepton+jets and the dilepton channels, CMS measured normalised differential  $t\bar{t}$  cross-sections with respect to kinematic properties of the final-state charged leptons and jets associated to  $b$ -quarks, as well as those of the top quarks and the  $t\bar{t}$  system. The data are compared with several predictions from perturbative QCD calculations and found to be consistent [59]. Recently, in  $19.7 \text{ fb}^{-1}$

at  $\sqrt{s} = 8 \text{ TeV}$ , CMS repeated those measurements in the lepton+jets and in the dilepton channels [60]. While the overall precision is improved, no significant deviations from the Standard Model are found, yet a softer spectrum for the top quark at high  $p_T$  with respect to theoretical available predictions has been observed. This behaviour has been also observed in the all-jets final state [41].

Very recently, they also performed differential cross-section measurements in  $42 \text{ pb}^{-1}$  of single-lepton data at 13 TeV with respect to kinematic properties of the top quarks and the  $t\bar{t}$  system, as well as of the jet multiplicity in the event. The results are confronted with several predictions from pQCD and found to be consistent [61].

Further cross-section measurements are performed for  $t\bar{t}$ +heavy flavour [62] and  $t\bar{t}$ +jets production as well as the differential measurement of the jet multiplicity in  $t\bar{t}$  events [63,64]. Here, **MC@NLO+Herwig** MC is found to predict too few events at higher jet multiplicities. In addition, CMS measured the cross section ratio  $\sigma_{t\bar{t}b\bar{b}}/\sigma_{t\bar{t}jj}$  using  $19.6 \text{ fb}^{-1}$  of 8 TeV data [65]. This is of high relevance for top quark production as background to searches, for example for the ongoing search for  $t\bar{t}h$  production. Very recently, ATLAS also measured the  $t\bar{t}$  production cross section along with as the branching ratios into channels with leptons and quarks using  $4.6 \text{ fb}^{-1}$  of 7 TeV data [66]. They find agreement with the standard model at the level of a few percent.

**C.1.2 Single-top production:** Single-top quark production was first observed in 2009 by DØ [67] and CDF [68,69] at the Tevatron. The production cross section at the Tevatron is roughly half that of the  $t\bar{t}$  cross section, but the final state with a single  $W$ -boson and typically two jets is less distinct than that for  $t\bar{t}$  and much more difficult to distinguish from the background of  $W$ +jets and other sources. A comprehensive review of the first observation and the techniques used to extract the signal from the backgrounds can be found in [70].

The dominant production at the Tevatron is through  $s$ -channel and  $t$ -channel  $W$ -boson exchange. Associated production with a  $W$ -boson ( $Wt$  production) has a cross section that is too small to observe at the Tevatron. The  $t$ -channel process is  $qb \rightarrow q't$ , while the  $s$ -channel process is  $q\bar{q}' \rightarrow t\bar{b}$ . The  $s$ - and  $t$ -channel productions can be separated kinematically. This is of particular interest because potential physics beyond the Standard Model, such as fourth-generation quarks, heavy  $W$  and  $Z$  bosons, flavor-changing-neutral-currents [10], or a charged Higgs boson, would affect the  $s$ - and  $t$ -channels differently. However, the separation is difficult and initial observations and measurements at the Tevatron by both experiments were of combined  $s + t$ -channel production. The two experiments combined their measurements for maximum precision with a resulting  $s + t$ -channel production cross section of  $2.76^{+0.58}_{-0.47} \text{ pb}$  [71]. The measured value assumes a top-quark mass of  $170 \text{ GeV}/c^2$ . The mass dependence of the result comes both from the acceptance dependence and from the  $t\bar{t}$  background evaluation. Also the

# Quark Particle Listings

*t*

shape of discriminating topological variables is sensitive to  $m_t$ . It is therefore not necessarily a simple linear dependence but amounts to only a few tenths of picobarns over the range 170 – 175 GeV/ $c^2$ . The measured value agrees well with the theoretical calculation at  $m_t = 173$  GeV/ $c^2$  of  $\sigma_{s+t} = 3.12$  pb (including both top and anti-top production) [6,8].

Using the full Run-II data set of up to 9.7 fb $^{-1}$ , CDF and DØ have measured the  $t$ -channel single-top quark production to be  $\sigma_t = 2.25^{+0.29}_{-0.31}$  pb [72]. In the same publication, they also present the simultaneously measured  $s$ - and  $t$ -channel cross sections and the  $s+t$  combined cross section measurement resulting in  $\sigma_{s+t} = 3.30^{+0.52}_{-0.40}$  pb, without assuming the SM ratio of  $\sigma_s/\sigma_t$ . The modulus of the CKM matrix element obtained from the  $s+t$ -channel measurement is  $|V_{tb}| = 1.02^{+0.06}_{-0.05}$  and its value is used to set a lower limit of  $|V_{tb}| > 0.92$  at 95% C.L. Those results are in good agreement with the theoretical value at the mass 172.5 GeV/ $c^2$  of  $\sigma_t = 2.08 \pm 0.13$  pb [6]. It should be noted that the theory citations here list cross sections for  $t$  or  $\bar{t}$  alone, whereas the experiments measure the sum. At the Tevatron, these cross sections are equal. The theory values quoted here already include this factor of two.

Using datasets of 9.7 fb $^{-1}$  each, CDF and DØ combine their analyses and report the first observation of single-top-quark production in the  $s$ -channel, yielding  $\sigma_s = 1.29^{+0.26}_{-0.24}$  pb [73]. The probability of observing a statistical fluctuation of the background of the given size is  $1.8 \times 10^{-10}$ , corresponding to a significance of 6.3 standard deviations.

At the LHC, the  $t$ -channel cross section is expected to be more than three times as large as  $s$ -channel and  $Wt$  production, combined. Both ATLAS and CMS have measured single top production cross sections at  $\sqrt{s} = 7$  TeV in  $pp$  collisions (assuming  $m_t = 172.5$  GeV/ $c^2$  unless noted otherwise).

Using 4.59 fb $^{-1}$  of data, ATLAS measures the  $t$ -channel single-top quark cross section in the lepton plus 2 or 3 jets channel with one  $b$ -tag by fitting the distribution of a multivariate discriminant constructed with a neural network, yielding  $\sigma_t = 46 \pm 6$  pb,  $\sigma_{\bar{t}} = 23 \pm 4$  pb with a ratio  $R_t = \sigma_t/\sigma_{\bar{t}} = 2.04 \pm 0.18$  and  $\sigma_{t+\bar{t}} = 68 \pm 8$  pb, consistent with SM expectations [74]. CMS follows two approaches in 1.6 fb $^{-1}$  of lepton plus jets events. The first approach exploits the distributions of the pseudorapidity of the recoil jet and reconstructed top-quark mass using background estimates determined from control samples in data. The second approach is based on multivariate analysis techniques that probe the compatibility of the candidate events with the signal. They find  $\sigma_t = 67.2 \pm 6.1$  pb, and  $|V_{tb}| = 1.020 \pm 0.046(\text{exp.}) \pm 0.017(\text{th.})$  [76].

At  $\sqrt{s} = 8$  TeV, both experiments repeat and refine their measurements. ATLAS uses 20.3 fb $^{-1}$  by performing a combined binned maximum likelihood fit to the neural network output distribution. The measured  $t$ -channel cross-section is  $\sigma_t = 82.6 \pm 1.2(\text{stat.}) \pm 11.4(\text{syst.}) \pm 3.1(\text{pdf}) \pm 2.3(\text{lumi.})$  pb with  $|V_{tb}| = 0.97^{+0.09}_{-0.10}$  and  $|V_{tb}| > 0.78$  at 95% C.L. [77].

CMS uses 19.7 fb $^{-1}$  in the electron or muon plus jets channel, exploiting the pseudorapidity distribution of the recoil jet. They find  $\sigma_t = 53.8 \pm 1.5(\text{stat.}) \pm 4.4(\text{syst.})$  pb and  $\sigma_{\bar{t}} = 27.6 \pm 1.3(\text{stat.}) \pm 3.7(\text{syst.})$  pb, resulting in an inclusive  $t$ -channel cross section of  $\sigma_{t+\bar{t}} = 83.6 \pm 2.3(\text{stat.}) \pm 7.4(\text{syst.})$  [78]. They measure a cross section ratio of  $R_t = \sigma_t/\sigma_{\bar{t}} = 1.95 \pm 0.10(\text{stat.}) \pm 0.19(\text{syst.})$ , in agreement with the SM. The CKM matrix element  $V_{tb}$  is extracted to be  $|V_{tb}| = 0.998 \pm 0.038(\text{exp.}) \pm 0.016(\text{th.})$ .

More recently, CMS has also provided a fiducial cross section measurement for  $t$ -channel single top at  $\sqrt{s} = 8$  TeV with 19.7 fb $^{-1}$  of data in signal events with exactly one muon or electron and two jets, one of which is associated with a  $b$ -hadron. The definition of the fiducial phase space follows closely the constraints imposed by event-selection criteria and detector acceptance. The total fiducial cross section is measured using different generators at next-to-leading order plus parton-shower accuracy. Using as reference the aMC@NLO MC predictions in the four-flavour scheme a  $\sigma_t^{\text{fid}} = 3.38 \pm 0.25(\text{exp.}) \pm 0.20(\text{th.})$  pb is obtained, in good agreement with the theory predictions.

A measurement of the  $t$ -channel single top-quark cross section is also available at 13 TeV with the CMS detector, corresponding to an integrated luminosity of 42 pb $^{-1}$ . The measured cross-section is  $\sigma_t = 274 \pm 98(\text{stat.}) \pm 52(\text{syst.}) \pm 33(\text{lumi.})$  pb [79].

The  $s$ -channel production cross section is expected to be only  $4.6 \pm 0.3$  pb for  $m_t = 173$  GeV/ $c^2$  at  $\sqrt{s} = 7$  TeV [8]. The  $Wt$  process has a theoretical cross section of  $15.6 \pm 1.2$  pb [9]. This is of interest because it probes the  $Wtb$  vertex in a different kinematic region than  $s$ - and  $t$ -channel production, and because of its similarity to the associated production of a charged-Higgs boson and a top quark. The signal is difficult to extract because of its similarity to the  $t\bar{t}$  signature. Furthermore, it is difficult to uniquely define because at NLO a subset of diagrams have the same final state as  $t\bar{t}$  and the two interfere [80]. The cross section is calculated using the *diagram removal* technique [81] to define the signal process. In the diagram removal technique the interfering diagrams are removed, at the amplitude level, from the signal definition (an alternative technique, *diagram subtraction* removes these diagrams at the cross-section level and yields similar results [81]). These techniques work provided the selection cuts are defined such that the interference effects are small, which is usually the case.

Both, ATLAS and CMS, also provide evidence for the associate  $Wt$  production at  $\sqrt{s} = 7$  TeV [82,83]. ATLAS uses 2.05 fb $^{-1}$  in the dilepton plus missing  $E_T$  plus jets channel, where a template fit to the final classifier distributions resulting from boosted decision trees as signal to background separation is performed. The result is incompatible with the background-only hypothesis at the  $3.3\sigma$  ( $3.4\sigma$  expected) level, yielding  $\sigma_{Wt} = 16.8 \pm 2.9(\text{stat.}) \pm 4.9(\text{syst.})$  pb and  $|V_{tb}| = 1.03^{+0.16}_{-0.19}$  [82]. CMS uses 4.9 fb $^{-1}$  in the dilepton plus jets channel with at least one  $b$ -tag. A multivariate analysis based on kinematic properties is utilized to separate the  $t\bar{t}$  background from the signal. The

observed signal has a significance of  $4.0\sigma$  and corresponds to a cross section of  $\sigma_{Wt} = 16^{+5}_{-4}$  pb [83]. Both experiments repeated their analyses at  $\sqrt{s} = 8$  TeV. ATLAS uses  $20.3 \text{ fb}^{-1}$  to select events with one electron and one oppositely-charged muon, significant missing transverse momentum and at least one  $b$ -tagged central jet. They perform a template fit to a boosted decision tree classifier distribution and obtain  $\sigma_{Wt} = 27.2 \pm 5.8$  pb and  $|V_{tb}| = 1.10 \pm 0.12(\text{exp.}) \pm 0.03(\text{th.})$  [84], which corresponds to a  $4.2\sigma$  significance. Assuming  $|V_{tb}| \gg |V_{ts}|, |V_{td}|$  they derive  $|V_{tb}| > 0.72$  at 95% C.L. CMS uses  $12.2 \text{ fb}^{-1}$  in events with two leptons and a jet originated from a  $b$ -quark. A multivariate analysis based on kinematic properties is utilized to separate the signal and background. The  $Wt$  associate production signal is observed at the level of  $6.1\sigma$ , yielding  $\sigma_{Wt} = 23.4 \pm 5.4$  pb and  $|V_{tb}| = 1.03 \pm 0.12(\text{exp.}) \pm 0.04(\text{th.})$  [85]. They also combine their measurements and obtain  $\sigma_{Wt} = 25.0 \pm 1.4(\text{stat.}) \pm 4.4(\text{syst.}) \pm 0.7(\text{lumi.}) \text{ pb} = 25.0 \pm 4.7$  pb [86], in agreement with the NLO+NNLL expectation. They extract a 95% C.L. lower limit on the CKM matrix element of  $|V_{tb}| > 0.79$ .

At ATLAS, a search for  $s$ -channel single top quark production is performed in  $0.7 \text{ fb}^{-1}$  at 7 TeV using events containing one lepton, missing transverse energy and two  $b$ -jets. Using a cut-based analysis, an observed (expected) upper limit at 95% C.L. on the  $s$ -channel cross-section of  $\sigma_s < 26.5(20.5)$  pb is obtained [87]. In 8 TeV data, both ATLAS and CMS search for  $s$ -channel production. ATLAS uses  $20.3 \text{ fb}^{-1}$  of data with one lepton, large missing transverse momentum and exactly two  $b$ -tagged jets. They perform a maximum-likelihood fit of a discriminant based on a Matrix Element Method and optimized in order to separate single top-quark  $s$ -channel events from the main background contributions which are top-quark pair production and  $W$  boson production in association with heavy flavour jets. They find  $\sigma_s = 4.8 \pm 1.1$  pb with a signal significance of 3.2 standard deviations [88]. CMS uses  $19.3 \text{ fb}^{-1}$  and analyses leptonic decay modes by performing a likelihood fit to a multivariate discriminant as form by a Boosted Decision Tree, yielding an upper limit of  $\sigma_s < 11.5$  pb at 95% C.L. [89].

Fig. 2 provides a summary of all single top cross-section measurements at the Tevatron and the LHC as a function of the center-of-mass energy. All cross-section measurements are very well described by the theory calculation within their uncertainty.

Thanks to the large statistics now available at the LHC, both CMS and ATLAS experiments also performed differential cross-section measurements in single-top  $t$ -channel production [74], [98]. Such measurements are extremely useful as they test our understanding of both QCD and EW top-quark interactions.

The CMS collaboration has measured differential single top quark  $t$ -channel production cross sections as functions of the transverse momentum and the absolute value of the rapidity of the top quark. The analysis is performed in the leptonic decay channels of the top quark, with either a muon or an electron in the final state, using data collected with the CMS

**Figure 2:** Measured and predicted single top production cross sections from Tevatron energies in  $p\bar{p}$  collisions to LHC energies in  $pp$  collisions. Tevatron data points at  $\sqrt{s} = 1.96$  TeV are from Refs. [90,91] and [92]. The ATLAS and CMS data points at  $\sqrt{s} = 7$  TeV are from Refs. [75,82,87,93] and [76,83,94], respectively. The ones at  $\sqrt{s} = 8$  TeV are from Refs. [84,96] and [95,96,97]. Theory curves are generated using [6,8,9].

experiment at the LHC at  $\sqrt{s} = 8$  TeV and corresponding to an integrated luminosity of  $19.7 \text{ fb}^{-1}$ . Artificial neural networks are used to discriminate the signal process from the various background contributions. The results are found to agree with predictions from Monte Carlo generators [98]. Using the same data set and under the assumption that the spin analyzing power of a charged lepton is 100% as predicted in the SM, they are also able to measure the polarization of the top quark  $P_t = 0.82 \pm 0.12(\text{stat.}) \pm 0.32(\text{syst.})$  [99].

**C.1.3 Top-Quark Forward-Backward & Charge Asymmetry:** A forward-backward asymmetry in  $t\bar{t}$  production arises starting at order  $\alpha_S^3$  in QCD from the interference between the Born amplitude  $q\bar{q} \rightarrow t\bar{t}$  with 1-loop box production diagrams and between diagrams with initial- and final-state gluon radiation. The asymmetry,  $A_{FB}$ , is defined by

$$A_{FB} = \frac{N(\Delta y > 0) - N(\Delta y < 0)}{N(\Delta y > 0) + N(\Delta y < 0)} \quad (2)$$

where  $\Delta y = y_t - y_{\bar{t}}$  is the rapidity difference between the top- and the anti-top quark. Calculations at  $\alpha_S^3$  predict a small  $A_{FB}$  at the Tevatron. The most recent calculations up to order  $\alpha_S^4$ , including electromagnetic and electroweak corrections, yield a predicted asymmetry of  $(\approx 9.5 \pm 0.7)\%$  [100]. This is about 10% higher than the previous calculation at NLO [101,102], and improves the agreement with experiment.

Both, CDF and DØ, measured asymmetry values in excess of the SM prediction, fueling speculation about exotic production mechanisms (see, for example, [103] and references therein). The first measurement of this asymmetry by DØ in  $0.9 \text{ fb}^{-1}$  [104] found an asymmetry at the detector level of  $(12 \pm 8)\%$ . The first CDF measurement in  $1.9 \text{ fb}^{-1}$  [105] yielded  $(24 \pm 14)\%$  at parton level. Both values were higher, though

# Quark Particle Listings

*t*

statistically consistent with the SM expectation. With the addition of more data, the uncertainties have been reduced, and the central values, if somewhat smaller, have remained consistent with the first measurements. At the same time, the improved calculations from theory have increased the predicted asymmetry values to the point where the discrepancy is no longer statistically significant. The most recent measurement from  $D\bar{O}$  using the full Tevatron dataset of  $9.7 \text{ fb}^{-1}$  finds an asymmetry in lepton+jet events, corrected for detector acceptance and resolution, of  $(10.6 \pm 3.0)\%$  [106] in good agreement with the prediction. Using the same dataset, the  $D\bar{O}$  measurement in dilepton events and assuming SM top polarization is  $17.5 \pm 5.6(\text{stat.}) \pm 3.1(\text{syst.})\%$  [107]. Combining the lepton+jets with the dilepton gives  $11.8 \pm 2.5(\text{stat.}) \pm 1.3(\text{syst.})\%$ .

From CDF, the most recent measurement in lepton+jets uses  $9.4 \text{ fb}^{-1}$ , and finds  $(16.4 \pm 4.7)\%$  [108]. This measurement has now been combined with an asymmetry measured in dilepton events using  $9.1 \text{ fb}^{-1}$  [109]. The asymmetry reported for dilepton events is  $(12 \pm 13)\%$ , and the combined asymmetry is  $(16.0 \pm 4.5)\%$ , which is about  $1.5\sigma$  above the NNLO prediction.

Both experiments have measured  $A_{FB}$  as a function of  $M_{t\bar{t}}$ , the  $t\bar{t}$  invariant mass and in bins of  $|\Delta y|$  [108,106]. The experiments see, and theory predicts, a positive slope in  $A_{FB}$  with increasing  $M_{t\bar{t}}$  and  $|\Delta y|$ . The slopes seen in the CDF data remain larger than the theoretical expectation, while the  $D\bar{O}$  data are in good agreement with the latest theoretical calculation [100].

At the LHC, where the dominant  $t\bar{t}$  production mechanism is the charge-symmetric gluon-gluon fusion, the measurement is more difficult. For the sub-dominant  $q\bar{q}$  production mechanism, the symmetric  $pp$  collision does not define a forward and backward direction. Instead, the charge asymmetry,  $A_C$ , is defined in terms of a positive versus a negative  $t - \bar{t}$  rapidity difference

$$A_C = \frac{N(\Delta y > 0) - N(\Delta y < 0)}{N(\Delta y > 0) + N(\Delta y < 0)} \quad (3)$$

Both CMS and ATLAS have measured  $A_C$  in the LHC dataset. Using lepton+jets events in  $4.7 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$ , ATLAS measures  $A_C = (0.6 \pm 1.0)\%$  [110]. More recently, ATLAS has reported on the same measurement performed at  $\sqrt{s} = 8 \text{ TeV}$  with at  $20.3 \text{ fb}^{-1}$  of data. The result is  $A_C = (0.009 \pm 0.005)$  [111]. CMS, in  $5.0(19.7) \text{ fb}^{-1}$  of  $\sqrt{s} = 7(8) \text{ TeV}$  data uses lepton+jets events to measure  $A_C = (0.4 \pm 1.5)\%$  ( $A_C = (0.33 \pm 0.26(\text{stat.}) \pm 0.33(\text{syst.}))\%$ ) [112,113]. Both measurements are consistent with the SM expectations of  $A_C = 1.23 \pm 0.05\%$  at  $\sqrt{s} = 7 \text{ TeV}$  and  $1.11 \pm 0.04\%$  at  $\sqrt{s} = 8 \text{ TeV}$  [102], although the uncertainties are still too large for a precision test. In their 7 and 8 TeV analyses ATLAS and CMS also provide differential measurements as a function of  $M_{t\bar{t}}$  and the transverse momentum  $p_T$  and rapidity  $y$  of the  $t\bar{t}$  system. In a recent work [114] the CMS collaboration has provided the result of  $A_C = -0.0035 \pm 0.0072(\text{stat.}) \pm 0.0031(\text{syst.})$  obtained in the fiducial phase space of top quark pair production.

Another avenue for measuring the forward-backward and charge asymmetries that has recently been exploited by the experiments is given by the measurement of the pseudorapidity distributions of the charged leptons resulting from  $t\bar{t}$  decay. Although the expected asymmetry is smaller, this technique does not require the reconstruction of the top-quark direction. Single-lepton asymmetries,  $A_{FB}^\ell$ , are defined by  $q \times \eta$ , and dilepton asymmetries,  $A^{\ell\ell}$ , by the sign of  $\Delta\eta$ , where  $q$  and  $\eta$  are the charge and pseudorapidity of the lepton and  $\Delta\eta = \eta_{\ell^+} - \eta_{\ell^-}$ .  $D\bar{O}$  has measured  $A_{FB}^\ell$  in  $9.7 \text{ fb}^{-1}$  of lepton+jets events, and finds a value of  $(4.2 \pm 2.3^{+1.7}_{-2.0})\%$  [115], consistent with an expectation of  $(3.8 \pm 0.6)\%$  [102]. A measurement by  $D\bar{O}$  using dilepton events in the same dataset [116] yields  $A^{\ell\ell} = (12.3 \pm 5.4 \pm 1.5)\%$ , compared to the expectation of  $(4.8 \pm 0.4)\%$  [102], and  $A_{FB}^\ell = 4.4 \pm 3.7 \pm 1.1$ . The combination of the results for  $A_{FB}^\ell$  in the single lepton and dilepton channels by  $D\bar{O}$  yields  $(4.2 \pm 2.0 \pm 1.4)\%$ . CDF, in  $9.4 \text{ fb}^{-1}$  of Tevatron data measures [117]  $A_{FB}^\ell = (9.4^{+3.2}_{-2.9})\%$ . As in the  $D\bar{O}$  case, this is larger than the SM expectation, but less than two standard deviations away.

At the LHC, both ATLAS and CMS have now measured leptonic asymmetries. ATLAS, in  $4.6 \text{ fb}^{-1}$  of  $\sqrt{s} = 7 \text{ TeV}$  data, has measured  $A^{\ell\ell} = (2.4 \pm 1.5 \pm 0.9)\%$  in dilepton events [118]. Using a neutrino weighting technique in the same dataset to reconstruct the top quarks, ATLAS measures  $A_C = (2.1 \pm 2.5 \pm 1.7)\%$ . CMS, in  $5.0 \text{ fb}^{-1}$  of  $\sqrt{s} = 7 \text{ TeV}$  data, uses dilepton events to measure  $A_C = (1.0 \pm 1.5 \pm 0.6)\%$ , where a matrix weighting technique is used to reconstruct the top quarks, and  $A^{\ell\ell} = (0.9 \pm 1.0 \pm 0.6)\%$  [119]. An earlier result using lepton+jets events from the same CMS dataset found  $A_C = (0.4 \pm 1.0 \pm 1.1)\%$  [112]. These results are all consistent, within their large uncertainties, with the SM expectations of  $A^{\ell\ell} = (0.70 \pm 0.03)\%$  and  $A_C = (1.23 \pm 0.05)\%$  [102].

A model-independent comparison of the Tevatron and LHC results is made difficult by the differing  $t\bar{t}$  production mechanisms at work at the two accelerators and by the symmetric nature of the  $pp$  collisions at the LHC. Given a particular model of BSM physics, a comparison can be obtained through the resulting asymmetry predicted by the model at the two machines, see for example [120].

## C.2 Top-Quark Properties

**C.2.1 Top-Quark Mass Measurements:** The most precisely studied property of the top quark is its mass. The top-quark mass has been measured in the lepton+jets, the dilepton, and the all-jets channel by all four Tevatron and LHC experiments. The latest and/or most precise results are summarized in Table 1. The lepton+jets channel yields the most precise single measurements because of good signal to background ratio (in particular after  $b$ -tagging) and the presence of only a single neutrino in the final state. The momentum of a single neutrino can be reconstructed (up to a quadratic ambiguity) via the missing  $E_T$  measurement and the constraint that the

lepton and neutrino momenta reconstruct to the known  $W$  boson mass. In the large data samples available at the LHC, measurements in the dilepton channel can be competitive and certainly complementary to those in the lepton+jets final state.

A large number of techniques have now been applied to measuring the top-quark mass. The original ‘template method’ [121], in which Monte Carlo templates of reconstructed mass distributions are fit to data, has evolved into a precision tool in the lepton+jets channel, where the systematic uncertainty due to the jet energy scale (JES) uncertainty is controlled by a simultaneous, *in situ* fit to the  $W \rightarrow jj$  hypothesis [122]. All the latest measurements in the lepton+jets and the all-jets channels use this technique in one way or another. In  $4.6 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 7 \text{ TeV}$  in the lepton+jets channel, ATLAS achieves a total uncertainty of 0.73% with a statistical component of 0.44% [123]. The measurement is based on a 3-dimensional template fit, determining the top-quark mass, the global jet energy scale and a  $b$ -to-light jet energy scale factor. In  $19.7 \text{ fb}^{-1}$  of  $\sqrt{s} = 8 \text{ TeV}$  data, CMS achieves a total uncertainty of 0.45% with a statistical component of 0.11% [124].

The template method is complemented by the ‘matrix element’ method. This method was first applied by the DØ Collaboration [125], and is similar to a technique originally suggested by Kondo *et al.* [126] and Dalitz and Goldstein [127]. In the matrix element method a probability for each event is calculated as a function of the top-quark mass, using a LO matrix element for the production and decay of  $t\bar{t}$  pairs. The *in situ* calibration of dijet pairs to the  $W \rightarrow jj$  hypothesis is now also used with the matrix element technique to constrain the jet energy scale uncertainty. The latest measurement with this technique from DØ in the lepton+jets channel uses the full Tevatron dataset of  $9.7 \text{ fb}^{-1}$  and yields an uncertainty of about 0.43% [128].

In the dilepton channel, the signal to background is typically very good, but reconstruction of the mass is non-trivial because there are two neutrinos in the final state, yielding a kinematically unconstrained system. A variety of techniques have been developed to handle this. An analytic solution to the problem has been proposed [129], but this has not yet been used in the mass measurement. One of the most precise measurements in the dilepton channel comes from using the invariant mass of the charged lepton and  $b$ -quark system ( $M_{\ell b}$ ), which is sensitive to the top-quark mass and avoids the kinematic difficulties of the two-neutrino final state. In  $4.6 \text{ fb}^{-1}$  of  $\sqrt{s} = 7 \text{ TeV}$  data, ATLAS has measured the top-quark mass in the dilepton channel to a precision of 0.81% using a template fit to the  $M_{\ell b}$  distribution [123]. A similar measurement has been also provided by CMS [130], giving a precision of 0.75%. The other dilepton-channel measurement of similar precision comes from  $19.7 \text{ fb}^{-1}$  of CMS data at  $\sqrt{s} = 8 \text{ TeV}$  [131] using a so-called analytical matrix weighting technique (AMWT) in which each event is fit many times to a range of top-quark masses and each fit is assigned a weight, from the PDFs, given by the inferred kinematics of the initial state partons, and from

the probability of the observed charged lepton energies for the top-quark mass in question.

Several other techniques can also yield precise measurements in the dilepton channel. In the neutrino weighting technique, similar to AMWT above, a weight is assigned by assuming a top-quark mass value and applying energy-momentum conservation to the top-quark decay, resulting in up to four possible pairs of solutions for the neutrino and anti-neutrino momenta. The missing  $E_T$  calculated in this way is then compared to the observed missing  $E_T$  to assign a weight [132]. A recent CDF result, using the full  $9.1 \text{ fb}^{-1}$  dataset achieves a precision of 1.8% using a combination of neutrino weighting and an “alternative mass”, which is insensitive to the jet energy scale [133]. The alternative mass depends on the angles between the leptons and the leading jets and the lepton four-momenta.

In the all-jets channel there is no ambiguity due to neutrino momenta, but the signal to background is significantly poorer due to the severe QCD multijets background. The emphasis therefore has been on background modeling, and reduction through event selection. The most recent measurement in the all-jets channel, by CMS in  $18.2 \text{ fb}^{-1}$  of  $\sqrt{s} = 8 \text{ TeV}$  data [134], uses an ideogram and a 2-dimensional simultaneous fit for  $m_t$  and the jet energy scale to extract the top-quark mass and achieves a precision of 0.53%. A recent measurement from ATLAS [135] uses the template method in the all-hadronic channel, also with an *in situ* fit to the  $W \rightarrow jj$  hypothesis, yielding a measurement with 1.9% precision in  $4.6 \text{ fb}^{-1}$  of data. A measurement from CDF in  $9.3 \text{ fb}^{-1}$  uses similar two-dimensional template fit and achieves a precision of 1.1% [136].

A dominant systematic uncertainty in these methods is the understanding of the jet energy scale, and so several techniques have been developed that have little sensitivity to the jet energy scale uncertainty. In addition to Reference [133] mentioned above, these include the measurement of the top-quark mass using the following techniques: Fitting of the lepton  $p_T$  spectrum of candidate events [137]; fitting of the transverse decay length of the  $b$ -jet ( $L_{xy}$ ) [138]; fitting the invariant mass of a lepton from the  $W$ -decay and a muon from the semileptonic  $b$  decay [139].

Several measurements have now been made in which the top-quark mass is extracted from the measured cross section using the theoretical relationship between the mass and the production cross section. These determinations make use of predictions calculated at higher orders, where the top mass enters as an input parameter defined in a given scheme. At variance with the usual methods, which involve the kinematic properties of the final states and therefore the pole mass, this approach allows to directly determine a short-distance mass, such as the  $\overline{\text{MS}}$  mass [140]. With an alternative method ATLAS recently extracted the top-quark pole mass using  $t\bar{t}$  events with at least one additional jet, basing the measurement on the relationship between the differential rate of gluon radiation and the mass of the quark [141].

# Quark Particle Listings

*t*

Each of the experiments has produced a measurement combining its various results. The combined measurement from CMS with up to  $19.7 \text{ fb}^{-1}$  of data achieves statistical and systematic uncertainties of 0.06% and 0.38%, respectively [142]. The combined measurement from ATLAS, with  $4.6 \text{ fb}^{-1}$  yields statistical and systematic uncertainties of 0.28% and 0.45%, respectively [123]. CDF has combined measurements with up to  $9.3 \text{ fb}^{-1}$  [143] and achieves a statistical precision of 0.33% and a systematic uncertainty of 0.43%. DØ achieves a 0.33% statistical+JES and a 0.28% systematic uncertainty by combining results in  $9.7 \text{ fb}^{-1}$  [144].

Combined measurements from the Tevatron experiments and from the LHC experiments take into account the correlations between different measurements from a single experiment and between measurements from different experiments. The Tevatron average [145], using up to  $9.7 \text{ fb}^{-1}$  of data, now has a precision of 0.37%. The LHC combination, using up to  $4.9 \text{ fb}^{-1}$  of data, has a precision of 0.56% [146], where more work on systematic uncertainties is required. The first Tevatron-LHC combination has now been released, combining the results of all four experiments, using the full Tevatron dataset and the  $\sqrt{s} = 7 \text{ TeV}$  LHC data, with a resulting precision of 0.44% [3]

The direct measurements of the top-quark mass, such as those shown in Table 1, strictly speaking, is the corresponding parameter used in the Monte Carlo generators. The relation between the parameter in the Monte Carlo generator and the pole mass is affected by non-perturbative contributions, which could be order  $1 \text{ GeV}/c^2$  [147], i.e., comparable to the measurement uncertainty.

With the discovery of a Higgs boson at the LHC with a mass of about  $126 \text{ GeV}/c^2$  [148,149], the precision measurement of the top-quark mass takes a central role in the question of the stability of the electroweak vacuum because top-quark radiative corrections tend to drive the Higgs quartic coupling,  $\lambda$ , negative, potentially leading to an unstable vacuum. A recent calculation at NNLO [150] leads to the conclusion of vacuum stability for a Higgs mass satisfying  $M_H \geq 129.4 \pm 5.6 \text{ GeV}/c^2$  [151]. Given the uncertainty, a Higgs mass of  $126 \text{ GeV}/c^2$  satisfies the limit, but the central values of the Higgs and top-quark masses put the electroweak vacuum squarely in the metastable region. The uncertainty is dominated by the precision of the top-quark mass measurement and its interpretation as the pole mass. For more details, see the Higgs boson review in this volume.

As a test of the CPT-symmetry, the mass difference of top- and antitop-quarks  $\Delta m_t = m_t - m_{\bar{t}}$ , which is expected to be zero, can be measured. CDF measures the mass difference in  $8.7 \text{ fb}^{-1}$  of 1.96 TeV data in the lepton+jets channel using a template method to find  $\Delta m_t = -1.95 \pm 1.11(\text{stat.}) \pm 0.59(\text{syst.}) \text{ GeV}/c^2$  [152] while DØ uses  $3.6 \text{ fb}^{-1}$  of lepton+jets events and the matrix element method with at least one *b*-tag. They find  $\Delta m_t = 0.8 \pm 1.8(\text{stat.}) \pm 0.5(\text{syst.}) \text{ GeV}/c^2$  [153]. In  $4.7 \text{ fb}^{-1}$  of 7 TeV data, ATLAS measures the mass difference in lepton+jets events with a double *b*-tag requirement and hence very low background to find  $\Delta m_t = 0.67 \pm 0.61(\text{stat.}) \pm$

**Table 1:** Measurements of top-quark mass from Tevatron and LHC.  $\int \mathcal{L} dt$  is given in  $\text{fb}^{-1}$ . The results shown are mostly preliminary (not yet submitted for publication as of August 2015); for a complete set of published results see the Listings. Statistical uncertainties are listed first, followed by systematic uncertainties.

$m_t \text{ (GeV}/c^2\text{)}$	Source	$\int \mathcal{L} dt$	Ref.	Channel
$172.99 \pm 0.48 \pm 0.78$	ATLAS	4.6	[123]	$\ell$ +jets+ $\ell\ell$
$172.04 \pm 0.19 \pm 0.75$	CMS	19.7	[124]	$\ell$ +jets
$172.47 \pm 0.17 \pm 1.40$	CMS	19.7	[131]	$\ell\ell$
$172.32 \pm 0.25 \pm 0.59$	CMS	19.7	[134]	All jets
$174.34 \pm 0.37 \pm 0.52$	CDF,DØ (I+II)	$\leq 9.7$	[145]	publ. or prelim.
$173.34 \pm 0.27 \pm 0.71$	Tevatron+LHC	$\leq 8.7 + \leq 4.9$	[3]	publ. or prelim.

$0.41(\text{syst.}) \text{ GeV}/c^2$  [154]. CMS measures the top-quark mass difference in  $5 \text{ fb}^{-1}$  of 7 TeV data in the lepton+jets channel and finds  $\Delta m_t = -0.44 \pm 0.46(\text{stat.}) \pm 0.27(\text{syst.}) \text{ GeV}/c^2$  [155]. They repeat this measurement with  $18.9 \text{ fb}^{-1}$  of 8 TeV data to find  $\Delta m_t = -0.27 \pm 0.20(\text{stat.}) \pm 0.12(\text{syst.}) \text{ GeV}/c^2$  [156]. All measurements are consistent with the SM expectation.

## C.2.2 Top-Quark Spin Correlations, Polarization, and Width:

One of the unique features of the top quark is that it decays before its spin can be flipped by the strong interaction. Thus the top-quark polarization is directly observable via the angular distribution of its decay products. Hence, it is possible to define and measure observables sensitive to the top-quark spin and its production mechanism. Although the top- and antitop-quarks produced by strong interactions in hadron collisions are essentially unpolarized, the spins of *t* and  $\bar{t}$  are correlated. For QCD production at threshold, the  $t\bar{t}$  system is produced in a  $^3S_1$  state with parallel spins for  $q\bar{q}$  annihilation or in a  $^1S_0$  state with antiparallel spins for gluon-gluon fusion. Hence, the situations at the Tevatron and at the LHC are somewhat complementary. However, at the LHC production of  $t\bar{t}$  pairs at large invariant mass occurs primarily via fusion of gluons with opposite helicities, and the  $t\bar{t}$  pairs so produced have parallel spins as in production at the Tevatron via  $q\bar{q}$  annihilation. The direction of the top-quark spin is 100% correlated to the angular distributions of the down-type fermion (charged leptons or *d*-type quarks) in the decay. The joint angular distribution [157–159]

$$\frac{1}{\sigma} \frac{d^2\sigma}{d(\cos\theta_+)d(\cos\theta_-)} = \frac{1 + \kappa \cdot \cos\theta_+ \cdot \cos\theta_-}{4}, \quad (4)$$

where  $\theta_+$  and  $\theta_-$  are the angles of the daughters in the top-quark rest frame with respect to a particular spin quantization axis, is a very sensitive observable. The maximum value for  $\kappa$ , 0.782 at NLO at the Tevatron [160], is found in the off-diagonal basis [157], while at the LHC the value at NLO is 0.326 in the helicity basis [160]. In place of  $\kappa$ ,  $A\alpha_+\alpha_-$  is often used, where

$\alpha_i$  is the spin analyzing power, and  $A$  is the spin correlation coefficient, defined as

$$A = \frac{N(\uparrow\uparrow) + N(\downarrow\downarrow) - N(\uparrow\downarrow) - N(\downarrow\uparrow)}{N(\uparrow\uparrow) + N(\downarrow\downarrow) + N(\uparrow\downarrow) + N(\downarrow\uparrow)}, \quad (5)$$

where the first arrow represents the direction of the top-quark spin along a chosen quantization axis, and the second arrow represents the same for the antitop-quark. The spin analyzing power  $\alpha_i$  is +0.998 for positively charged leptons, -0.966 for down-type quarks from  $W$  decays, and -0.393 for bottom quarks [161]. The sign of  $\alpha$  flips for the respective antiparticles. The spin correlation could be modified by a new  $t\bar{t}$  production mechanism such as through a  $Z'$  boson, Kaluza-Klein gluons, or a Higgs boson.

CDF used  $5.1 \text{ fb}^{-1}$  in the dilepton channel to measure the correlation coefficient in the beam axis [162]. The measurement was made using the expected distributions of  $(\cos\theta_+, \cos\theta_-)$  and  $(\cos\theta_b, \cos\theta_{\bar{b}})$  of the charged leptons or the  $b$ -quarks in the  $t\bar{t}$  signal and background templates to calculate a likelihood of observed reconstructed distributions as a function of assumed  $\kappa$ . They determined the 68% confidence interval for the correlation coefficient  $\kappa$  as  $-0.52 < \kappa < 0.61$  or  $\kappa = 0.04 \pm 0.56$  assuming  $m_t = 172.5 \text{ GeV}/c^2$ .

CDF also analyzed lepton+jets events in  $5.3 \text{ fb}^{-1}$  [163] assuming  $m_t = 172.5 \text{ GeV}/c^2$ . They form three separate templates - the same-spin template, the opposite-spin template, and the background template for the 2-dimensional distributions in  $\cos(\theta_l)\cos(\theta_d)$  vs.  $\cos(\theta_l)\cos(\theta_b)$ . The fit to the data in the helicity basis returns an opposite helicity fraction of  $F_{OH} = 0.74 \pm 0.24(\text{stat.}) \pm 0.11(\text{syst.})$ . Converting this to the spin correlation coefficient yields  $\kappa_{\text{helicity}} = 0.48 \pm 0.48(\text{stat.}) \pm 0.22(\text{syst.})$ . In the beamline basis, they find an opposite spin fraction of  $F_{OS} = 0.86 \pm 0.32(\text{stat.}) \pm 0.13(\text{syst.})$  which can be converted into a correlation coefficient of  $\kappa_{\text{beam}} = 0.72 \pm 0.64(\text{stat.}) \pm 0.26(\text{syst.})$ .

DØ performed a measurement of the ratio  $f$  of events with correlated  $t$  and  $\bar{t}$  spins to the total number of  $t\bar{t}$  events in  $5.3 \text{ fb}^{-1}$  in the lepton+jets channel using a matrix element technique [164]. The SM expectation is  $f = 1$ . From 729 events, they obtain  $f_{\text{exp.}} = 1.15^{+0.42}_{-0.43}(\text{stat.} + \text{syst.})$  and can exclude values of  $f < 0.420$  at the 95% C.L. In the dilepton channel [165], they also use a matrix element method and can exclude at the 97.7% C.L. the hypothesis that the spins of the  $t$  and  $\bar{t}$  are uncorrelated. The combination [164] yields  $f_{\text{exp.}} = 0.85 \pm 0.29(\text{stat.} + \text{syst.})$  and a  $t\bar{t}$  production cross section which is in good agreement with the SM prediction and previous measurements. For an expected fraction of  $f = 1$ , they can exclude  $f < 0.481$  at the 95% C.L. For the observed value of  $f_{\text{exp.}} = 0.85$ , they can exclude  $f < 0.344(0.052)$  at the 95(99.7)% C.L. The observed fraction  $f_{\text{exp.}}$  translates to a measured asymmetry value of  $A_{\text{exp.}} = 0.66 \pm 0.23(\text{stat.} + \text{syst.})$ . They therefore obtained the first evidence of SM spin correlation at 3.1 standard deviations.

Using  $5.4 \text{ fb}^{-1}$  of data, DØ measures the correlation in the dilepton channel also from the angles of the two leptons in the  $t$  and  $\bar{t}$  rest frames, yielding a correlation strength  $C = 0.10 \pm 0.45$  [166] ( $C$  is equivalent to negative  $\kappa$  in Eq. 4), in agreement with the NLO QCD prediction, but also in agreement with the no correlation hypothesis.

Spin correlations have now been conclusively measured at the LHC by both the ATLAS and CMS collaborations. In the dominant gluon fusion production mode for  $t\bar{t}$  pairs at the LHC, the angular distribution between the two leptons in  $t\bar{t}$  decays to dileptons is sensitive to the degree of spin correlation [167].

The ATLAS collaboration has measured spin correlations in  $t\bar{t}$  production at  $\sqrt{s} = 7 \text{ TeV}$  using  $4.6 \text{ fb}^{-1}$  of data. Candidate events are selected in the dilepton and lepton plus jets topologies. Four observables are used to extract the spin correlation: The difference,  $\Delta\phi$  in azimuthal angle between the two charged leptons in dilepton events or the lepton and down-quark or bottom-quark candidate from the hadronic  $W$ -decay; An observable based on the ratio matrix elements with and without spin correlation; The double differential distribution of Eq. 4 in two different bases. The most sensitive measurement comes from using  $\Delta\phi$  in dilepton events and results in  $f_{\text{SM}} = 1.19 \pm 0.09 \pm 0.18$ . Using the helicity basis as the quantization axis, the strength of the spin correlation between the top- and antitop-quark is measured to be  $A_{\text{helicity}}^{\text{exp.}} = 0.37 \pm 0.03 \pm 0.06$  [168], which is in agreement with the NLO prediction of about 0.31 [169]. Using the same events but converting  $f_{\text{exp.}}$  into  $A_{\text{maximal}}^{\text{exp.}}$  yields  $A_{\text{maximal}}^{\text{exp.}} = 0.52 \pm 0.04 \pm 0.08$ , to be compared to the NLO prediction of 0.44. In a similar analysis using  $20.3 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 8 \text{ TeV}$ , ATLAS measures  $f_{\text{SM}} = 1.20 \pm 0.05(\text{stat.}) \pm 0.13(\text{syst.})$ , corresponding to  $A_{\text{helicity}}^{\text{exp.}} = 0.38 \pm 0.04$  [170], which compares well to the SM expectation of  $A_{\text{helicity}}^{\text{SM}} = 0.318 \pm 0.005$  [169].

The CMS collaboration uses angular asymmetry variables in dilepton events, unfolded to the parton level. The most sensitive measurement is made using

$$A_{\Delta\phi} = \frac{N(\Delta\phi_{\ell+\ell-} > \pi/2) - N(\Delta\phi_{\ell+\ell-} < \pi/2)}{N(\Delta\phi_{\ell+\ell-} > \pi/2) + N(\Delta\phi_{\ell+\ell-} < \pi/2)}, \quad (6)$$

In  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$ , CMS measures  $A_{\Delta\phi} = 0.113 \pm 0.010 \pm 0.006 \pm 0.012$  [171], where the uncertainties are statistical, systematic, and due to the reweighting of the top  $p_T$  in the Monte Carlo to match data. A recent CMS result in  $\mu$  plus jets events in  $19.7 \text{ fb}^{-1}$  of  $\sqrt{s} = 8 \text{ TeV}$  data uses a matrix-element technique to extract  $f_{\text{exp.}} = 0.72 \pm 0.09^{+0.15}_{-0.13}$ , corresponding to  $A_{\text{helicity}}^{\text{exp.}} = 0.22 \pm 0.03^{+0.05}_{-0.04}$  [172]. Corresponding results obtained by studying the dilepton final state, also show consistency with the SM expectations [173].

Measurements of the polarization of top quarks in  $t\bar{t}$  production at  $\sqrt{s} = 7 \text{ TeV}$  have been made by both ATLAS and CMS. In  $4.7 \text{ fb}^{-1}$  of data, ATLAS measures the product of the leptonic spin-analyzing power ( $\alpha_\ell$ ) and the top quark polarization. The measurement is made in one or two lepton final states, assuming that the polarization is introduced

# Quark Particle Listings

*t*

by a CP-conserving (CPC) or maximally CP-violating (CPV) process. The results are  $\alpha_\ell P_{CPC} = -0.035 \pm 0.014 \pm 0.037$  and  $\alpha_\ell P_{CPV} = 0.020 \pm 0.016^{+0.013}_{-0.017}$  [174], where the uncertainties are statistical and systematic, respectively. The CMS measurement is made with  $5.0 \text{ fb}^{-1}$  of dilepton events. The polarization is extracted through an asymmetry,  $A_P$ , in the angular distribution of the two leptons,  $A_P$ , defined as

$$A_P = \frac{N(\cos \theta_\ell^* > 0) - N(\cos \theta_\ell^* < 0)}{N(\cos \theta_\ell^* > 0) + N(\cos \theta_\ell^* < 0)}, \quad (7)$$

where  $\theta^*$  is the angle of the charged lepton in the rest frame of its parent top quark or antiquark. The polarization,  $P$  in the helicity basis is given by  $P = 2A_P$ . After unfolding to the parton level, the measurement yields  $A_P = 0.005 \pm 0.013 \pm 0.014 \pm 0.008$  [171], where the uncertainties are, respectively, statistical, systematic, and from top-quark  $p_T$  reweighting. Both the ATLAS and CMS results are consistent with the SM expectation of negligible polarization.

Observation of top-quark spin correlations requires a top-quark lifetime less than the spin decorrelation timescale [175]. The top-quark width, inversely proportional to its lifetime, is expected to be of order  $1 \text{ GeV}/c^2$  (Eq. 1). The sensitivity of current experiments does not approach this level in direct measurements. Nevertheless, several measurements have been made.

CDF presents a direct measurement of the top-quark width in the lepton+jets decay channel of  $t\bar{t}$  events from a data sample corresponding to  $8.7 \text{ fb}^{-1}$  of integrated luminosity. The top-quark mass and the mass of the hadronically decaying  $W$  boson that comes from the top-quark decay are reconstructed for each event and compared with templates of different top-quark widths ( $\Gamma_t$ ) and deviations from nominal jet energy scale ( $\Delta JES$ ) to perform a simultaneous fit for both parameters, where  $\Delta JES$  is used for the *in situ* calibration of the jet energy scale. By applying a Feldman-Cousins approach, they establish an upper limit at 95% C.L. of  $\Gamma_t < 6.38 \text{ GeV}$  and a two-sided 68% C.L. interval of  $1.10 \text{ GeV} < \Gamma_t < 4.05 \text{ GeV}$ , corresponding to a lifetime interval of  $1.6 \times 10^{-15} < \tau_{top} < 6.0 \times 10^{-25}$  [176], consistent with the SM prediction. For comparison, a typical hadronization timescale is an order of magnitude larger than these limits.

The total width of the top-quark can also be determined from the partial decay width  $\Gamma(t \rightarrow Wb)$  and the branching fraction  $B(t \rightarrow Wb)$ . DØ obtains  $\Gamma(t \rightarrow Wb)$  from the measured  $t$ -channel cross section for single top-quark production in  $5.4 \text{ fb}^{-1}$ , and  $B(t \rightarrow Wb)$  is extracted from a measurement of the ratio  $R = B(t \rightarrow Wb)/B(t \rightarrow Wq)$  in  $t\bar{t}$  events in lepton+jets channels with 0, 1 and 2 b-tags. Assuming  $B(t \rightarrow Wq) = 1$ , where  $q$  includes any kinematically accessible quark, the result is:  $\Gamma_t = 2.00^{+0.47}_{-0.43} \text{ GeV}$  which translates to a top-quark lifetime of  $\tau_t = (3.29^{+0.90}_{-0.63}) \times 10^{-25} \text{ s}$ . Assuming a high mass fourth generation  $b'$  quark and unitarity of the four-generation quark-mixing matrix, they set the first upper limit on  $|V_{tb'}| < 0.59$  at 95% C.L. [177]. A similar analysis has performed by CMS in

$19.7 \text{ fb}^{-1}$  of  $\sqrt{s} = 8 \text{ TeV}$  data. It provides a better determination of the total width with respect to the measurement by DØ giving  $\Gamma_t = 1.36 \pm 0.02(\text{stat.})^{+0.14}_{-0.11}(\text{syst.}) \text{ GeV}$  [178].

**C.2.3 W-Boson Helicity in Top-Quark Decay:** The Standard Model dictates that the top quark has the same vector-minus-axial-vector ( $V - A$ ) charged-current weak interactions  $\left(-i\frac{g}{\sqrt{2}}V_{tb}\gamma^\mu\frac{1}{2}(1-\gamma_5)\right)$  as all the other fermions. In the SM, the fraction of top-quark decays to longitudinally polarized  $W$  bosons is similar to its Yukawa coupling and hence enhanced with respect to the weak coupling. It is expected to be [179]  $\mathcal{F}_0^{\text{SM}} \approx x/(1+x)$ ,  $x = m_t^2/2M_W^2$  ( $\mathcal{F}_0^{\text{SM}} \sim 70\%$  for  $m_t = 175 \text{ GeV}/c^2$ ). Fractions of left-handed, right-handed, or longitudinal  $W$  bosons are denoted as  $\mathcal{F}_-$ ,  $\mathcal{F}_+$ , and  $\mathcal{F}_0$  respectively. In the SM,  $\mathcal{F}_-$  is expected to be  $\approx 30\%$  and  $\mathcal{F}_+ \approx 0\%$ . Predictions for the  $W$  polarization fractions at NNLO in QCD are available [180].

The Tevatron and the LHC experiments use various techniques to measure the helicity of the  $W$  boson in top-quark decays, in both the lepton+jets and in dilepton channels in  $t\bar{t}$  production.

The first method uses a kinematic fit, similar to that used in the lepton+jets mass analyses, but with the top-quark mass constrained to a fixed value, to improve the reconstruction of final-state observables, and render the under-constrained dilepton channel solvable. Alternatively, in the dilepton channel the final-state momenta can also be obtained through an algebraic solution of the kinematics. The distribution of the helicity angle ( $\cos \theta^*$ ) between the lepton and the  $b$  quark in the  $W$  rest frame provides the most direct measure of the  $W$  helicity. In a simplified version of this approach, the  $\cos \theta^*$  distribution is reduced to a forward-backward asymmetry.

The second method ( $p_T^\ell$ ) uses the different lepton  $p_T$  spectra from longitudinally or transversely polarized  $W$ -decays to determine the relative contributions.

A third method uses the invariant mass of the lepton and the  $b$ -quark in top-quark decays ( $M_{\ell b}^2$ ) as an observable, which is directly related to  $\cos \theta^*$ .

At the LHC, top-quark pairs in the dilepton channels are reconstructed by solving a set of six independent kinematic equations on the missing transverse energy in  $x$ - and in  $y$ -direction, two  $W$ -masses, and the two top/antitop-quark masses. In addition, the two jets with the largest  $p_T$  in the event are interpreted as  $b$ -jets. The pairing of the jets to the charged leptons is based on the minimization of the sum of invariant masses  $M_{min}$ . Simulations show that this criterion gives the correct pairing in 68% of the events.

Finally, the Matrix Element method (ME) has also been used, in which a likelihood is formed from a product of event probabilities calculated from the ME for a given set of measured kinematic variables and assumed  $W$ -helicity fractions. The results of recent CDF, DØ, ATLAS, and CMS analyses are summarized in Table 2.

**Table 2:** Measurement and 95% C.L. upper limits of the  $W$  helicity in top-quark decays. The table includes both preliminary, as of August 2015, and published results. A full set of published results is given in the Listings.

$W$ Helicity	Source	$\int \mathcal{L} dt$ (fb $^{-1}$ )	Ref.	Method
$\mathcal{F}_0 = 0.722 \pm 0.081$	CDF+DØ Run II	2.7-5.4	[181]	$\cos \theta^*$ 2-par.
$\mathcal{F}_0 = 0.682 \pm 0.057$	CDF+DØ Run II	2.7-5.4	[181]	$\cos \theta^*$ 1-par.
$\mathcal{F}_0 = 0.726 \pm 0.094$	CDF Run II	8.7	[182]	ME 2-param

$\mathcal{F}_0 = 0.626 \pm 0.059$	ATLAS+CMS (7 TeV)	2.2	[185]	$\cos \theta^*$ 3-par.
$\mathcal{F}_0 = 0.659 \pm 0.027$	CMS (8 TeV)	19.6	[186]	$\cos \theta^*$ 3-par.
$\mathcal{F}_0 = 0.720 \pm 0.054$	CMS (8 TeV)	19.7	[187]	$\cos \theta^*$ 3-par.
$\mathcal{F}_0 = 0.653 \pm 0.029$	CMS (8 TeV)	19.7	[188]	$\cos \theta^*$ 3-par.
$\mathcal{F}_+ = -0.033 \pm 0.046$	CDF+DØ Run II	2.7-5.4	[181]	$\cos \theta^*$ 2-par.
$\mathcal{F}_+ = -0.015 \pm 0.035$	CDF+DØ Run II	2.7-5.4	[181]	$\cos \theta^*$ 1-par.
$\mathcal{F}_+ = -0.045 \pm 0.073$	CDF Run II	8.7	[182]	ME 2-par.
$\mathcal{F}_+ = 0.01 \pm 0.05$	ATLAS (7 TeV)	1.0	[183]	$\cos \theta^*$ 3-par.
$\mathcal{F}_+ = 0.008 \pm 0.018$	CMS (7 TeV)	5.0	[184]	$\cos \theta^*$ 3-par.
$\mathcal{F}_+ = 0.015 \pm 0.034$	ATLAS+CMS (7 TeV)	2.2	[185]	$\cos \theta^*$ 3-par.
$\mathcal{F}_+ = -0.009 \pm 0.021$	CMS (8 TeV)	19.6	[186]	$\cos \theta^*$ 3-par.
$\mathcal{F}_+ = -0.018 \pm 0.022$	CMS (8 TeV)	19.7	[187]	$\cos \theta^*$ 3-par.
$\mathcal{F}_+ = 0.018 \pm 0.027$	CMS (8 TeV)	19.7	[188]	$\cos \theta^*$ 3-par.

The datasets are now large enough to allow for a simultaneous fit of  $\mathcal{F}_0$ ,  $\mathcal{F}_-$  and  $\mathcal{F}_+$ , which we denote by ‘3-param’ or  $\mathcal{F}_0$  and  $\mathcal{F}_+$ , which we denote by ‘2-param’ in the table. Results with either  $\mathcal{F}_0$  or  $\mathcal{F}_+$  fixed at its SM value are denoted ‘1-param’. For the simultaneous fits, the correlation coefficient between the two values is about  $-0.8$ . A complete set of published results can be found in the Listings. All results are in agreement with the SM expectation.

CDF and DØ combined their results based on  $2.7 - 5.4$  fb $^{-1}$  [181] for a top-quark mass of  $172.5$  GeV/ $c^2$ . ATLAS presents results from  $1.04$  fb $^{-1}$  of  $\sqrt{s} = 7$  TeV data using a template method for the  $\cos \theta^*$  distribution and angular asymmetries from the unfolded  $\cos \theta^*$  distribution in the lepton+jets and the dilepton channel [183]. CMS performs a similar measurement based on template fits to the  $\cos \theta^*$  distribution with  $5.0$  fb $^{-1}$  of  $7$  TeV data in the lepton+jets final state [184]. As the polarization of the  $W$  bosons in top-quark decays is sensitive to the  $Wtb$  vertex Lorentz structure and anomalous couplings, both experiments also derive limits on anomalous contributions to the  $Wtb$  couplings. Recently, both experiments also combined their results from  $7$  TeV data to obtain values on the helicity fractions as well as limits on anomalous couplings [185].

CMS came out with a measurement of the  $W$ -helicity fractions in  $19.6$  fb $^{-1}$  of muon+jets events recorded at  $8$  TeV [186]. Also, using the same dataset a first measurement of the  $W$ -boson helicity in top-quark decays was made in electroweak single top production [187], yielding similarly precise and consistent results.

**C.2.4 Top-Quark Electroweak Charges:** The top quark is the only quark whose electric charge has not been measured

through production at threshold in  $e^+e^-$  collisions. Furthermore, it is the only quark whose electromagnetic coupling has not been observed and studied until recently. Since the CDF and DØ analyses on top-quark production did not associate the  $b$ ,  $\bar{b}$ , and  $W^\pm$  uniquely to the top or antitop, decays such as  $t \rightarrow W^+\bar{b}, \bar{t} \rightarrow W^-b$  were not excluded. A charge  $4/3$  quark of this kind is consistent with current electroweak precision data. The  $Z \rightarrow \ell^+\ell^-$  and  $Z \rightarrow b\bar{b}$  data, in particular the discrepancy between  $A_{LR}$  from SLC at SLAC and  $A_{FB}^{0,b}$  of  $b$ -quarks and  $A_{FB}^{0,\ell}$  of leptons from LEP at CERN, can be fitted with a top quark of mass  $m_t = 270$  GeV/ $c^2$ , provided that the right-handed  $b$  quark mixes with the isospin  $+1/2$  component of an exotic doublet of charge  $-1/3$  and  $-4/3$  quarks,  $(Q_1, Q_4)_R$  [189,190].

DØ studies the top-quark charge in double-tagged lepton+jets events, CDF does it in single tagged lepton+jets and dilepton events. Assuming the top- and antitop-quarks have equal but opposite electric charge, then reconstructing the charge of the  $b$ -quark through jet charge discrimination techniques, the  $|Q_{top}| = 4/3$  and  $|Q_{top}| = 2/3$  scenarios can be differentiated. For the exotic model of Chang *et al.* [190] with a top-quark charge  $|Q_{top}| = 4/3$ , DØ excludes the exotic model at 91.2% C.L. [191] using  $370$  pb $^{-1}$ , while CDF excludes the model at 99% C.L. [192] in  $5.6$  fb $^{-1}$ . Recently, DØ excluded the model at a significance greater than 5 standard deviations using  $5.3$  fb $^{-1}$  and set an upper limit of  $0.46$  on the fraction of such quarks in the selected sample [193]. All those results indicate that the observed particle is indeed consistent with being a SM  $|Q_{top}| = 2/3$  quark.

In  $2.05$  fb $^{-1}$  at  $\sqrt{s} = 7$  TeV, ATLAS performed a similar analysis, reconstructing the  $b$ -quark charge either via a jet-charge technique or via the lepton charge in soft muon decays in combination with a kinematic likelihood fit. They measure the top-quark charge to be  $0.64 \pm 0.02(stat.) \pm 0.08(syst.)e$  from the charges of the top-quark decay products in single lepton  $t\bar{t}$  events, and hence exclude the exotic scenario with charge  $-4/3$  at more than  $8\sigma$  [194].

In  $4.6$  fb $^{-1}$  at  $\sqrt{s} = 7$  TeV, CMS discriminates between the Standard Model and the exotic top-quark charge scenario in the muon+jets final states in  $t\bar{t}$  events. They exploit the charge correlation between high- $p_t$  muons from  $W$ -boson decays and soft muons from  $B$ -hadron decays in  $b$ -jets. Using an asymmetry technique, where  $A = -1$  represent the exotic  $q = -4/3$  scenario and  $A = +1$  the Standard Model  $q = +2/3$  scenario, they find  $A_{meas} = 0.97 \pm 0.12(stat.) \pm 0.31(sys.)$ , which agrees with the Standard Model expectation and excludes the exotic scenario at 99.9% C.L. [195].

The electromagnetic or the weak coupling of the top quark can be probed directly by investigating  $t\bar{t}$  events with an additional gauge boson, like  $t\bar{t}\gamma$  and  $t\bar{t}Z$  events.

CDF performs a search for events containing a lepton, a photon, significant missing transverse momentum, and a jet identified as containing a  $b$ -quark and at least three jets and large total transverse energy in  $6.0$  fb $^{-1}$ . They reported evidence for the observation of  $t\bar{t}\gamma$  production with a cross

# Quark Particle Listings

*t*

section  $\sigma_{t\bar{t}\gamma} = 0.18 \pm 0.08$  pb and a ratio of  $\sigma_{t\bar{t}\gamma}/\sigma_{t\bar{t}} = 0.024 \pm 0.009$  [196].

ATLAS performed a first measurement of the  $t\bar{t}\gamma$  cross section in pp collisions at  $\sqrt{s} = 7$  TeV using  $4.6 \text{ fb}^{-1}$  of data. Events are selected that contain a large transverse momentum electron or muon and a large transverse momentum photon, yielding 140 and 222 events in the electron and muon samples, respectively. The production of  $t\bar{t}\gamma$  events is observed with a significance of 5.3% standard deviations. The resulting cross section times branching ratio into the single lepton channel for  $t\bar{t}\gamma$  production with a photon with transverse momentum above 20 GeV is  $\sigma^{\text{fid.}}(t\bar{t}\gamma) \times Br = 63 \pm 8(\text{stat.})_{-13}^{+17}(\text{syst.}) \pm 1(\text{lumi.})$  pb per lepton flavour [198], which is consistent with leading-order theoretical calculations. Using  $19.7 \text{ fb}^{-1}$  of data at 8 TeV, CMS performs a similar measurement of the  $t\bar{t}\gamma$  production cross section in the muon+jets decay mode with a photon transverse momentum above 20 GeV and a separation  $\Delta R(\gamma, b/\bar{b}) > 0.1$ . They obtain a normalized cross section  $R = \sigma_{t\bar{t}+\gamma}/\sigma_{t\bar{t}} = (1.07 \pm 0.07(\text{stat.}) \pm 0.27(\text{syst.})) \times 10^{-2}$  and a cross section  $\sigma_{t\bar{t}+\gamma} = 2.4 \pm 0.2(\text{stat.}) \pm 0.6(\text{syst.})$  pb [199], consistent with the Standard Model expectations. A real test, however, of the vector and axial vector couplings in  $t\bar{t}\gamma$  events or searches for possible tensor couplings of top-quarks to photons will only be feasible with an integrated luminosity of several hundred  $\text{fb}^{-1}$  in the future.

ATLAS and CMS also studied the associate production of top-antitop quark pairs along with an electroweak gauge boson, where in the Standard Model the  $W$ -boson is expected to be produced via initial state radiation, while the  $Z$ -boson can also be radiated from a final-state top-quark and hence provides sensitivity to the top-quark neutral current weak gauge coupling, which implies a sensitivity to the third component of the top-quark's weak isospin.

CMS performed measurements of the  $t\bar{t}W$  and  $t\bar{t}Z$  production cross section at  $\sqrt{s} = 7$  TeV with  $5 \text{ fb}^{-1}$ , yielding results at about 3 standard deviations significance [200]. ATLAS performed a similar analysis with  $4.7 \text{ fb}^{-1}$  in the three-lepton channel and set an upper limit of 0.71 pb at 95% C.L. [201].

Using  $20.3 \text{ fb}^{-1}$  of 8 TeV data, ATLAS performs a simultaneous measurement of the  $t\bar{t}W$  and  $t\bar{t}Z$  cross section. They observe the  $t\bar{t}W$  and  $t\bar{t}Z$  production at the  $5.0\sigma$  and  $4.2\sigma$  level, respectively, yielding  $\sigma_{t\bar{t}W} = 369_{-91}^{+100}$  fb and  $\sigma_{t\bar{t}Z} = 176_{-52}^{+58}$  fb [202]. CMS performs an analysis where signal events are identified by matching reconstructed objects in the detector to specific final state particles from  $t\bar{t}W$  and  $t\bar{t}Z$  decays. using  $19.5 \text{ fb}^{-1}$  of 8 TeV data. They obtain  $\sigma_{t\bar{t}W} = 382_{-102}^{+117}$  fb and  $\sigma_{t\bar{t}Z} = 242_{-55}^{+65}$  fb, yielding a significance of 4.8 and 6.4 standard, respectively [203]. These measurements are used to set bounds on five anomalous dimension-six operators that would affect the  $t\bar{t}W$  and  $t\bar{t}Z$  cross sections.

## C.3 Searches for Physics Beyond the Standard Model

The top quark plays a special role in the SM. Being the only quark with a coupling to the Higgs boson of order one,

it provides the most important contributions to the quadratic radiative corrections to the Higgs mass raising the question of the naturalness of the SM. It is therefore very common for models where the naturalness problem is addressed to have new physics associated with the top quark. In SUSY, for instance, naturalness predicts the scalar top partners to be the lightest among the squarks and to be accessible at the LHC energies (see the review "Supersymmetry: Theory"). In models where the Higgs is a pseudo-Goldstone boson, such as Little Higgs models, naturalness predicts the existence of partners of the top quarks with the same spin and color, but with different electroweak couplings, the so-called vectorial  $t'$ . Stops and  $t'$ 's are expected to have sizable branching ratios to top quarks. Another intriguing prediction of SUSY models with universal couplings at the unification scale is that for a top-quark mass close to the measured value, the running of the Yukawa coupling down to 1 TeV naturally leads to the radiative breaking of the electroweak symmetry [204]. In fact, the top quark plays a role in the dynamics of electroweak symmetry breaking in many models. One example is topcolor [205], where a large top-quark mass can be generated through the formation of a dynamic  $t\bar{t}$  condensate,  $X$ , which is formed by a new strong gauge force coupling preferentially to the third generation. Another example is topcolor-assisted technicolor [206], predicting the existence of a heavy  $Z'$  boson that couples preferentially to the third generation of quarks. If light enough such a state might be directly accessible at the present hadron collider energies, or if too heavy, lead to four-top interactions possibly visible in the  $t\bar{t}t\bar{t}$  final state, for which limits on production cross sections at the LHC  $\sqrt{s} = 8$  TeV exist [207,208].

Current strategies to search for new physics in top-quark events at hadron colliders are either tailored to the discovery of specific models or model independent. They can be broadly divided in two classes. In the first class new resonant states are looked for through decay processes involving the top quarks. Current searches for bosonic resonances in  $t\bar{t}$  final states, or for direct stop and  $t'$  production, or for a charged Higgs in  $H^+ \rightarrow t\bar{b}$  fall in the category. On the other hand, if new states are too heavy to be directly produced, they might still give rise to deviations from the SM predictions for the strength and Lorentz form of the top-quark couplings to other SM particles. Accurate predictions and measurements are therefore needed and the results be efficiently systematized in the framework of an effective field theory [210,211]. For instance, the on-going efforts to constrain the structure of the top couplings to vector bosons ( $g, \gamma, Z, W$ ) and to the Higgs boson, including flavor-changing neutral currents involving the top quark [212], fall in this second category.

**C.3.1 New Physics in Top-Quark Production:** Theoretical [213–215] and experimental efforts have been devoted to the searches of  $t\bar{t}$  resonances.

At the Tevatron, both the CDF and DØ collaborations have searched for resonant production of  $t\bar{t}$  pairs in the lepton+jets

channel [216,217]. In both analyses, the data indicate no evidence of resonant production of  $t\bar{t}$  pairs. They place upper limits on the production cross section times branching fraction to  $t\bar{t}$  in comparison to the prediction for a narrow ( $\Gamma_{Z'} = 0.012M_{Z'}$ ) leptophobic topcolor  $Z'$  boson. Within this model, they exclude  $Z'$  bosons with masses below 915 (CDF-full data set) and 835 ( $D\bar{O}$ ,  $5\text{ fb}^{-1}$ )  $\text{GeV}/c^2$  at the 95% C.L. These limits turn out to be independent of couplings of the  $t\bar{t}$  resonance (pure vector, pure axial-vector, or SM-like  $Z'$ ). A similar analysis has been performed by CDF in the all-jets channel using  $2.8\text{ fb}^{-1}$  of data [218].

At the LHC, both the CMS and ATLAS collaborations have searched for resonant production of  $t\bar{t}$  pairs, employing different techniques and final-state signatures (all-jets, lepton+jets, dilepton) at  $\sqrt{s} = 7$  and 8 TeV. In the low mass range, from the  $t\bar{t}$  threshold to about one TeV, standard techniques based on the reconstruction of each of the decay objects (lepton, jets and  $b$ -jets, missing  $E_T$ ) are used to identify the top quarks, while at higher invariant mass, the top quarks are boosted and the decay products more collimated and can appear as large-radius jets with substructure. Dedicated reconstruction techniques have been developed in recent years for boosted top quarks [219] that are currently employed at the LHC. Most of the analyses are model-independent (i.e., no assumption on the quantum numbers of the resonance is made) yet they assume a small width and no signal-background interference.

Using dilepton and lepton+jets signatures in a data set corresponding to an integrated luminosity of  $5.0\text{ fb}^{-1}$ , the CMS collaboration finds no significant deviations from the SM background. In the dilepton analysis, upper limits are presented for the production cross section times branching fraction of top quark-antiquark resonances for masses from 750 to 3000  $\text{GeV}/c^2$ . In particular, the existence of a leptophobic topcolor particle  $Z'$  is excluded at the 95% confidence level for resonance masses  $M_{Z'} < 1.3$  (1.9)  $\text{TeV}/c^2$  for  $\Gamma_{Z'} = 0.012(0.1)M_{Z'}$  [220]. Using a lepton+jets sample, results are obtained from the combination of two dedicated searches optimized for boosted production and production at threshold. In this case, topcolor  $Z'$  bosons with narrow (wide) width are excluded at 95% confidence level for masses below 1.49 (2.04)  $\text{TeV}/c^2$  and an upper limit of 0.3 (1.3) pb or lower is set on the production cross section times branching fraction for resonance masses above 1  $\text{TeV}/c^2$ . Kaluza-Klein excitations of a gluon with masses below 1.82  $\text{TeV}/c^2$  (at 95% confidence level) in the Randall-Sundrum model are also excluded, and an upper limit of 0.7 pb or lower is set on the production cross section times branching fraction for resonance masses above 1  $\text{TeV}/c^2$  [221]. In  $19.7\text{ fb}^{-1}$  of 8 TeV data, CMS recently updated their measurement in the lepton+jets and the all-jets channel to obtain an exclusion of  $M_{Z'} < 2.1(2.7)\text{ TeV}/c^2$  for  $\Gamma_{Z'} = 0.013(0.1)M_{Z'}$  and gluon masses below 2.5  $\text{TeV}/c^2$  in Randall-Sundrum models at 95% C.L. [222]. These limits have been improved in a recent analysis which uses events with three different final states, defined by the number of leptons and optimized for reconstruction

of top quarks with high Lorentz boosts [223]. For example, in this analysis a narrow leptophobic topcolor  $Z'$  resonance with a mass below 2.4 TeV is excluded at 95% confidence level.

The ATLAS collaboration has performed a search for resonant  $t\bar{t}$  production in the lepton+jets channel using  $4.7\text{ fb}^{-1}$  ( $19.7\text{ fb}^{-1}$ ) of proton-proton (pp) collision data collected at a center-of-mass energy  $\sqrt{s} = 7(8)\text{ TeV}$  [224,225]. The  $t\bar{t}$  system is reconstructed using both small-radius and large-radius jets, the latter being supplemented by a jet substructure analysis. A search for local excesses in the number of data events compared to the Standard Model expectation in the  $t\bar{t}$  invariant mass spectrum is performed. No evidence for a  $t\bar{t}$  resonance is found and 95% confidence-level limits on the production rate are determined for massive states predicted in two benchmark models. The most stringent limits come from the sample collected at 8 TeV. The upper limits on the cross section times branching ratio of a narrow  $Z'$  boson decaying to top-quark pairs range from 4.2 pb for a resonance mass of 0.4  $\text{TeV}/c^2$  to 0.03 pb for a mass of 3  $\text{TeV}/c^2$ . A narrow leptophobic topcolor  $Z'$  boson with a mass below 1.8  $\text{TeV}/c^2$  is excluded. Upper limits are set on the cross section times branching ratio for a broad color-octet resonance with  $\Gamma/m = 15\%$  decaying to  $t\bar{t}$ . These range from 2.5 pb for a mass of 0.4  $\text{TeV}/c^2$  to 0.03 pb for a mass of 3  $\text{TeV}/c^2$ . A Kaluza-Klein excitation of the gluon in a Randall-Sundrum model (a slightly different model is used compared to CMS) is excluded for masses below 2.2  $\text{TeV}/c^2$ .

ATLAS has also conducted a search in the all-jet final state at 7 TeV corresponding to an integrated luminosity of  $4.7\text{ fb}^{-1}$  [226]. The  $t\bar{t}$  events are reconstructed by selecting two top quarks in their fully hadronic decay modes which are reconstructed using the Cambridge/Aachen jet finder algorithm with a radius parameter of 1.5. The substructure of the jets is analysed using the HEPTopTagger algorithm [227] to separate top-quark jets from those originating from gluons and lighter quark jets. The invariant mass spectrum of the data is compared to the SM prediction, and no evidence for resonant production of top-quark pairs is found. The data are used to set upper limits on the cross section times branching ratio for resonant  $t\bar{t}$  production in two models at 95% confidence level. Leptophobic  $Z'$  bosons with masses between 700 and 1000  $\text{GeV}/c^2$  as well as 1280 – 1320  $\text{GeV}/c^2$  and Kaluza-Klein-Gluons with masses between 700 and 1620  $\text{GeV}/c^2$  are excluded at the 95% confidence level.

Heavy charged bosons, such as  $W'$  or  $H^+$ , can also be searched for in  $t\bar{b}$  final states (for more information see the review "W'-boson searches" and "Higgs Bosons: theory and searches"). Other resonances are searched for in final states such as  $tZ, t\bar{j}, tH, tW, bW$ .

For instance, ATLAS has performed a search for  $t$ -jet resonances in the lepton+jets channel of  $t\bar{t}$ +jets events in  $4.7\text{ fb}^{-1}$  at  $\sqrt{s} = 7\text{ TeV}$  [228]. A heavy new particle, assumed to be produced singly in association with a  $t(\bar{t})$  quark, decays to a  $t(\bar{t})$  quark and a light flavor quark, leading to a color singlet (triplet) resonance in the  $t(\bar{t})$ +jet system. The full 2011 ATLAS

# Quark Particle Listings

## *t*

$pp$  collision dataset from the LHC ( $4.7 \text{ fb}^{-1}$ ) is used to select  $t\bar{t}$  events. The data are consistent with the SM expectation and a new particle with mass below 350 (430)  $\text{GeV}/c^2$  for  $W$  (color triplet) models is excluded with a 95% confidence level, assuming unit right-handed coupling. ATLAS has conducted a search for the single and pair production of a new charge  $+2/3$  quark ( $T$ ) decaying via  $T \rightarrow Zt$  (and also  $-1/3$  quark ( $B$ ) decaying via  $B \rightarrow Zb$ ) in a dataset corresponding to  $20.3 \text{ fb}^{-1}$  luminosity at  $\sqrt{s} = 8 \text{ TeV}$  [229]. Selected events contain a high transverse momentum  $Z$ -boson candidate reconstructed from a pair of oppositely charged electrons or muons. Additionally, the presence of at least two jets possessing properties consistent with the decay of a  $b$ -hadron is required, as well as large total transverse momentum of all central jets in the event. No significant excess of events above the SM expectation is observed, and upper limits are derived for vector-like quarks of various masses in a two-dimensional plane of branching ratios. Under branching ratio assumptions corresponding to a weak-isospin singlet scenario, a  $T$  quark with mass lower than  $655 \text{ GeV}/c^2$  is excluded at the 95% confidence level. Under branching ratio assumptions corresponding to a particular weak-isospin doublet scenario, a  $T$  quark with mass lower than  $735 \text{ GeV}/c^2$  is excluded at the 95% confidence level.

A complementary search [208] in the lepton+jets final state of the same dataset, characterized by an isolated electron or muon with moderately high transverse momentum, significant missing transverse momentum, and multiple jets is performed to look for  $T(B) \rightarrow Wb, Zt, Ht(Wt, Zb, Hb)$ , decays. No significant excess of events above the SM expectation is observed, and upper limits are derived for vector-like quarks of various masses under several branching ratio hypotheses. The 95% C.L. observed lower limits on the  $T$  quark mass range between 715  $\text{GeV}$  and 950  $\text{GeV}$  for all possible values of the branching ratios into the three decay modes. In addition this study provides limits on four top-quark production and production of two positively-charged top quarks. No significant excess of events over the background expectation is observed. The four top-quark production cross section must be less than 23  $\text{fb}$  in the SM and less than 12  $\text{fb}$  for production via a contact interaction; in the case of sgluon pair production decaying to  $t\bar{t}$ , where a sgluon is a scalar partner of the gluino [209], the mass of a sgluon must be greater than  $1.06 \text{ TeV}/c^2$ . Finally, limits in the context of models featuring two extra dimensions are also set.

In many models top-quark partners preferably decay to top quarks and weakly interacting neutral stable particles, i.e., possibly dark matter candidates, that are not detected. An observable especially sensitive to new physics effects in  $t\bar{t}$  production is therefore the missing momentum.

CMS has presented a differential cross section measurement of top-quark pair production with missing transverse energy using  $20 \text{ fb}^{-1}$  at 8  $\text{TeV}$  [230]. The results are consistent with the predictions of the SM. More recently, CMS has presented a search for particle dark matter produced in association with a pair of top quarks in  $19.7 \text{ fb}^{-1}$  of data at 8  $\text{TeV}$  [231].

This search requires the presence of one lepton, multiple jets, and large missing transverse energy. No excess of events is found above the SM expectation, and upper limits are derived on the production cross section. Cross sections larger than 20 to 55  $\text{fb}$  are excluded at 90% C.L. for dark matter particles with the masses ranging from 1 to 1000  $\text{GeV}$ . Interpreting the findings in the context of a scalar contact interaction between fermionic dark matter particles and top quarks, lower limits on the interaction scale are set. Assuming a dark matter particle with a mass of 100  $\text{GeV}$ , values of the interaction scale below 118  $\text{GeV}$  are excluded at 90% C.L. An analogous search, at a center-of-mass energy of 7  $\text{TeV}$  in  $1.04 \text{ fb}^{-1}$  of data has been performed by ATLAS [232]. The search is carried out in the lepton+jets channel. The results are interpreted in terms of a model where new top-quark partners are pair-produced and each decay to an on-shell top (or antitop) quark and a long-lived undetected neutral particle. The data are found to be consistent with SM expectations. A limit at 95% C.L. is set excluding a cross-section times branching ratio of 1.1  $\text{pb}$  for a top-partner mass of  $420 \text{ GeV}/c^2$  and a neutral particle mass less than 10  $\text{GeV}/c^2$ . In a model of exotic fourth generation quarks, top-partner masses are excluded up to  $420 \text{ GeV}/c^2$  and neutral particle masses up to  $140 \text{ GeV}/c^2$ .

Flavor-changing-neutral-currents (FCNC) are hugely suppressed in the SM, and non zero only due to the large mass hierarchy between the top quark and the other quarks. Several observables are accessible at colliders to test and constrain such couplings.

CMS has performed several studies on the search for FCNC in top-quark production. They have considered single top quark production in the  $t$ -channel in  $5 \text{ fb}^{-1}$  integrated luminosity at 7  $\text{TeV}$  [233]. Events with the top quark decaying into a muon, neutrino and  $b$ -quark are selected. The upper limits on effective coupling strength can be translated to the 95% upper limits on the corresponding branching ratios  $B(t \rightarrow gu) \leq 3.55 \cdot 10^{-4}$ ,  $B(t \rightarrow gc) \leq 3.44 \cdot 10^{-3}$ . They have performed a search for a single top quark produced in association with a photon in  $19.1 \text{ fb}^{-1}$  integrated luminosity at 8  $\text{TeV}$  [234]. The event selection requires the presence of one isolated muon and jets in the final state. The upper limits on effective coupling strength can be translated to the 95% upper limits on the corresponding branching ratios  $B(t \rightarrow \gamma u) \leq 0.0161\%$ ,  $B(t \rightarrow \gamma c) \leq 0.182\%$ .

ATLAS has presented results on the search for single top-quark production via FCNC's in strong interactions using data collected at  $\sqrt{s}=8 \text{ TeV}$  and corresponding to an integrated luminosity of  $20.3 \text{ fb}^{-1}$ . Flavor-changing-neutral-current events are searched for in which a light quark ( $u$  or  $c$ ) interacts with a gluon to produce a single top quark, either with or without the associated production of another light quark or gluon. Candidate events of top quarks decaying into leptons and jets are selected and classified into signal- and background-like events using a neural network. The observed 95% C.L. limit is  $\sigma_{qq \rightarrow t} \times B(t \rightarrow Wb) < 3.4 \text{ pb}$  that can be interpreted as limits on the branching ratios,  $B(t \rightarrow ug) < 4 \cdot 10^{-5}$  and  $B(t \rightarrow cg) <$

$1.7 \cdot 10^{-4}$  [235]. This result supersedes the corresponding 7 TeV analysis in  $2 \text{ fb}^{-1}$  [236].

Constraints on FCNC couplings of the top quark can also be obtained from searches for anomalous single top-quark production in  $e^+e^-$  collisions, via the process  $e^+e^- \rightarrow \gamma, Z^* \rightarrow t\bar{q}$  and its charge-conjugate ( $q = u, c$ ), or in  $e^\pm p$  collisions, via the process  $e^\pm u \rightarrow e^\pm t$ . For a leptonic  $W$  decay, the topology is at least a high- $p_T$  lepton, a high- $p_T$  jet and missing  $E_T$ , while for a hadronic  $W$ -decay, the topology is three high- $p_T$  jets. Limits on the cross section for this reaction have been obtained by the LEP collaborations [237] in  $e^+e^-$  collisions, and by H1 [238] and ZEUS [239] in  $e^\pm p$  collisions. When interpreted in terms of branching ratios in top decay [240,241], the LEP limits lead to typical 95% C.L. upper bounds of  $B(t \rightarrow qZ) < 0.137$ . Assuming no coupling to the  $Z$  boson, the 95% C.L. limits on the anomalous FCNC coupling  $\kappa_\gamma < 0.13$  and  $< 0.27$  by ZEUS and H1, respectively, are stronger than the CDF limit of  $\kappa_\gamma < 0.42$ , and improve over LEP sensitivity in that domain. The H1 limit is slightly weaker than the ZEUS limit due to an observed excess of five-candidate events over an expected background of  $3.2 \pm 0.4$ . If this excess is attributed to FCNC top-quark production, this leads to a total cross section of  $\sigma(ep \rightarrow e + t + X, \sqrt{s} = 319 \text{ GeV}) < 0.25 \text{ pb}$  [238,242].

**C.3.2 New Physics in Top-Quark decays:** The large sample of top quarks produced at the Tevatron and the LHC allows to measure or set stringent limits on the branching ratios of rare top-quark decays. For example, the existence of a light  $H^+$  can be constrained by looking for  $t \rightarrow H^+ b$  decay, in particular with tau-leptons in the final state (for more information see the review "Higgs Bosons: theory and searches").

A first class of searches for new physics focuses on the structure of the  $Wtb$  vertex. Using up to  $2.7 \text{ fb}^{-1}$  of data, DØ has measured the  $Wtb$  coupling form factors by combining information from the  $W$ -boson helicity in top-quark decays in  $t\bar{t}$  events and single top-quark production, allowing to place limits on the left-handed and right-handed vector and tensor couplings [243–245].

ATLAS has published the results of a search for  $CP$  violation in the decay of single top quarks produced in the  $t$ -channel where the top quarks are predicted to be highly polarized, using the lepton+jets final state [246]. The data analyzed are from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  and correspond to an integrated luminosity of  $4.7 \text{ fb}^{-1}$ . In the Standard Model, the couplings at the  $Wtb$  vertex are left-handed, right-handed couplings being absent. A forward-backward asymmetry with respect to the normal to the plane defined by the  $W$ -momentum and the top-quark polarization has been used to probe the complex phase of a possibly non-zero value of the right-handed coupling, signaling a source of  $CP$ -violation beyond the SM. The measured value of the asymmetry is  $0.031 \pm 0.065(stat.)^{+0.029}_{-0.031}(syst.)$  in good agreement with the Standard Model.

A second class of searches focuses on FCNC's in the top-quark decays. Both, CDF and DØ, have provided the first

limits for FCNC's in Run I and II. The most recent results from CDF give  $B(t \rightarrow qZ) < 3.7\%$  and  $B(t \rightarrow q\gamma) < 3.2\%$  at the 95% C.L. [247] while DØ [248,249] sets  $B(t \rightarrow qZ)(q = u, c \text{ quarks}) < 3.2\%$  at 95% C.L.,  $B(t \rightarrow gu) < 2.0 \cdot 10^{-4}$ , and  $B(t \rightarrow gc) < 3.9 \cdot 10^{-3}$  at the 95% C.L.

At the LHC, CMS has used a sample at a center-of-mass energy of 8 TeV corresponding to  $19.7 \text{ fb}^{-1}$  of integrated luminosity to perform a search for flavor changing neutral current top-quark decay  $t \rightarrow Zq$ . Events with a topology compatible with the decay chain  $t\bar{t} \rightarrow Wb + Zq \rightarrow \ell\nu b + \ell\ell q$  are searched for. There is no excess seen in the observed number of events relative to the SM prediction; thus no evidence for flavor changing neutral current in top-quark decays is found. A combination with a previous search at 7 TeV excludes a  $t \rightarrow Zq$  branching fraction greater than 0.05% at the 95% confidence level [250]. The ATLAS collaboration has also searched for FCNC processes in  $20.3 \text{ fb}^{-1}$  of  $t\bar{t}$  events with one top quark decaying through FCNC ( $t \rightarrow qZ$ ) and the other through the SM dominant mode ( $t \rightarrow bW$ ). Only the decays of the  $Z$  boson to charged leptons and leptonic  $W$  boson decays were considered as signal, leading to a final state topology characterized by the presence of three isolated leptons, at least two jets and missing transverse energy from the undetected neutrino. No evidence for an FCNC signal was found. An upper limit on the  $t \rightarrow qZ$  branching ratio of  $B(t \rightarrow qZ) < 7 \times 10^{-4}$  is set at the 95% confidence level [251], which supersedes previous results [252].

Another search for FCNCs is in the decay of a top-quark to a Higgs boson plus a light parton,  $t \rightarrow qH$ ,  $q = u, c$ . The CMS collaboration has performed two searches using a sample at a center-of-mass energy of 8 TeV corresponding to  $19.7 \text{ fb}^{-1}$  of integrated luminosity, one in a multi-lepton final state [253] and the other with the Higgs boson decaying to  $\gamma\gamma$  [254]. The first analysis sets an upper limit on the  $t \rightarrow cH$  branching ratio of  $B(t \rightarrow cH) < 0.93\%$  at 95% confidence level, while the second sets an upper limit on the  $t \rightarrow c(u)H$  branching ratios of  $B(t \rightarrow c(u)H) < 0.71(0.65)\%$  at 95% confidence level. The ATLAS collaboration considers  $t \rightarrow qH$ ,  $q = u, c$  with  $4.7 \text{ fb}^{-1}$  of  $t\bar{t}$  events at  $\sqrt{s} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  of  $t\bar{t}$  events at  $\sqrt{s} = 8 \text{ TeV}$ . A combined measurement including  $H \rightarrow \gamma\gamma$  and  $H \rightarrow WW^*, \tau\tau$  modes yields a 95% C.L. upper limit of 0.46% and 0.45% on the branching ratios of  $B(t \rightarrow cH)$  and  $B(t \rightarrow uH)$ , respectively [255].

## D. Outlook

Top-quark physics at hadron colliders has developed into precision physics. Various properties of the top quark have been measured with high precision, where the LHC is about to or has already reached the precision of the Tevatron. Several  $\sqrt{s}$ -dependent physics quantities, such as the production cross-section, have been measured at several energies at the Tevatron and the LHC. Up to now, all measurements are consistent with the SM predictions and allow stringent tests of the underlying production mechanisms by strong and weak interactions. Given the very large event samples available at

# Quark Particle Listings

*t*

the LHC, top-quark properties will be further determined in  $t\bar{t}$  as well as in electroweak single top-quark production. At the Tevatron, the  $t$ – and  $s$ –channels for electroweak single top-quark production have been measured separately. At the LHC, significant progress has been achieved and all the three relevant channels are expected to be independently accessible in the near future. Furthermore,  $t\bar{t}\gamma$ ,  $t\bar{t}Z$ , and  $t\bar{t}W$  together with  $t\bar{t}H$  associated production will provide further information on the top-quark electroweak couplings. At the same time various models of physics beyond the SM involving top-quark production are being constrained. With the first results from LHC Run-II at a higher center-of-mass energy and much higher luminosity starting to be released, top-quark physics has the potential to shed light on open questions and new aspects of physics at the TeV scale.

## *t*-QUARK MASS

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured  $t\bar{t}$  cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

OUR EVALUATION of  $173.21 \pm 0.51 \pm 0.71$  GeV is an average of published top mass measurements from Tevatron Runs. The first combination of the top-quark mass measurements, including some unpublished data, has been performed by the CDF and DØ experiments at the Tevatron and ATLAS and CMS experiments at the LHC. The resulting combined top-quark mass is  $173.34 \pm 0.27 \pm 0.71$  GeV, consistent with Tevatron average. The latest Tevatron average,  $174.34 \pm 0.37 \pm 0.52$  GeV, was provided by the Tevatron Electroweak Working Group (TEVEWWG). It takes correlated uncertainties into account and has a  $\chi^2$  of 10.8 for 11 degrees of freedom.

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

## *t*-Quark Mass (Direct Measurements)

The following measurements extract a *t*-quark mass from the kinematics of  $t\bar{t}$  events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information.

<sup>1</sup> ABAZOV 16 based on  $9.7 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Employs improved fit to minimize statistical errors and improved jet energy calibration, using lepton + jets mode, which reduces error of jet energy scale. Based on previous determination in ABAZOV 12AB with increased integrated luminosity and improved fit and calibrations.

<sup>2</sup> AAD 15AW based on  $4.6 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . Uses template fits to the ratio of the masses of three-jets (from *t* candidate) and dijets (from *W* candidate). Large background from multijet production is modeled with data-driven methods.

<sup>3</sup> AAD 15BF based on  $4.6 \text{ fb}^{-1}$  in  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$ . Using a three-dimensional template likelihood technique the lepton plus jets ( $\geq 1b$ -tagged) channel gives  $172.33 \pm 0.75 \pm 1.02 \text{ GeV}$ , while exploiting a one dimensional template method using  $m_{\ell\ell}$  the dilepton channel (1 or 2*b*-tags) gives  $173.79 \pm 0.54 \pm 1.30 \text{ GeV}$ . The results are combined.

<sup>4</sup> AALTONEN 15D based on  $9.1 \text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Uses a template technique to fit a distribution of a variable defined by a linear combination of variables sensitive and insensitive to jet energy scale to optimize reduction of systematic errors. *b*-tagged and non-*b*-tagged events are separately analyzed and combined.

<sup>5</sup> Based on  $9.3 \text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Multivariate algorithm is used to discriminate signal from backgrounds, and templates are used to measure  $m_t$ .

<sup>6</sup> Based on  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 1.96 \text{ TeV}$ . A matrix element method is used to calculate the probability of an event to be signal or background, and the overall jet energy scale is constrained *in situ* by  $m_{W\ell}$ . See ABAZOV 15G for further details.

- <sup>7</sup> Based on  $3.54 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . The mass is reconstructed for each event employing a kinematic fit of the jets to a  $t\bar{t}$  hypothesis. The combination with the previous CMS measurements in the dilepton and the lepton+jets channels gives  $173.54 \pm 0.33 \pm 0.96 \text{ GeV}$ .
- <sup>8</sup> Based on  $8.7 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with an identified charged lepton or small  $E_T$  are rejected from the event sample, so that the measurement is statistically independent from those in the  $\ell + \text{jets}$  and all hadronic channels while being sensitive to those events with a  $\tau$  lepton in the final state.
- <sup>9</sup> Based on  $5.0 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . CHATRCHYAN 13s studied events with di-lepton +  $E_T + \geq 2 \text{ b-jets}$ , and looked for kinematical endpoints of MT2, MT2T, and subsystem variables.
- <sup>10</sup> Based on  $8.7 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ . The JES is calibrated by using the dijet mass from the  $W$  boson decay.
- <sup>11</sup> Use the ME method based on  $2.2 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ .
- <sup>12</sup> Combination with the result in  $1 \text{ fb}^{-1}$  of preceding data reported in ABAZOV 09AH as well as the MWT result of ABAZOV 11R with a statistical correlation of 60%.
- <sup>13</sup> Based on  $5.0 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . Uses an analytical matrix weighting technique (AMWT) and full kinematic analysis (KIN).
- <sup>14</sup> Based on  $5.0 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . The first error is statistical and JES combined, and the second is systematic. Ideogram method is used to obtain 2D likelihood for the kinematical fit with two parameters  $m_{\text{top}}$  and JES.
- <sup>15</sup> Based on  $5.6 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The likelihood calculated using a matrix element method gives  $m_t = 173.0 \pm 0.7(\text{stat}) \pm 0.6(\text{JES}) \pm 0.9(\text{syst}) \text{ GeV}$ , for a total uncertainty of  $1.2 \text{ GeV}$ .
- <sup>16</sup> Based on  $1.9 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The result is from the measurement using the transverse decay length of  $b$ -hadrons and that using the transverse momentum of the  $W$  decay muons, which are both insensitive to the JES (jet energy scale) uncertainty. OUR EVALUATION uses only the measurement exploiting the decay length significance which yields  $166.9^{+9.5}_{-8.5}(\text{stat}) \pm 2.9(\text{syst}) \text{ GeV}$ . The measurement that uses the lepton transverse momentum is excluded from the average because of a statistical correlation with other samples.
- <sup>17</sup> Obtained by re-analysis of the lepton + jets candidate events that led to ABBOTT 98f. It is based upon the maximum likelihood method which makes use of the leading order matrix elements.
- <sup>18</sup> Based on  $125 \pm 7 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- <sup>19</sup> Based on  $\sim 106 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- <sup>20</sup> Based on  $109 \pm 7 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- <sup>21</sup> See AFFOLDER 01 for details of systematic error re-evaluation.
- <sup>22</sup> Based on the first observation of all hadronic decays of  $t\bar{t}$  pairs. Single  $b$ -quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.
- <sup>23</sup> AAD 12i based on  $1.04 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . Uses 2d-template analysis (MT) with  $m_t$  and jet energy scale factor (JSF) from  $m_W$  mass fit.
- <sup>24</sup> Combination based on up to  $5.8 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ .
- <sup>25</sup> Based on  $5.8 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ . The quoted systematic error is the sum of JES( $\pm 1.0$ ) and systematic( $\pm 1.1$ ) uncertainties. The measurement is performed with a likelihood fit technique which simultaneously determines  $m_t$  and JES.
- <sup>26</sup> Based on  $4.3 \text{ fb}^{-1}$  of data in  $p$ - $\bar{p}$  collisions at  $1.96 \text{ TeV}$ . The measurement reduces the JES uncertainty by using the single lepton channel study of ABAZOV 11P.
- <sup>27</sup> Based on  $3.2 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and JES combined, and the latter is from the other systematic uncertainties. The result is obtained using an unbinned maximum likelihood method where the top quark mass and the JES are measured simultaneously, with  $\Delta_{JES} = 0.3 \pm 0.3(\text{stat})$ .
- <sup>28</sup> Based on  $5.7 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with an identified charged lepton or small  $E_T$  are rejected from the event sample, so that the measurement is statistically independent from those in the  $\ell + \text{jets}$  and all hadronic channels while being sensitive to those events with a  $\tau$  lepton in the final state. Supersedes AALTONEN 07B.
- <sup>29</sup> AALTONEN 11E based on  $5.6 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Employs a multi-dimensional template likelihood technique where the lepton plus jets (one or two  $b$ -tags) channel gives  $172.2 \pm 1.2 \pm 0.9 \text{ GeV}$  while the dilepton channel yields  $170.3 \pm 2.0 \pm 3.1 \text{ GeV}$ . The results are combined. OUR EVALUATION includes the measurement in the dilepton channel only.
- <sup>30</sup> Uses a likelihood fit of the lepton  $p_T$  distribution based on  $2.7 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- <sup>31</sup> Based on  $3.6 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . ABAZOV 11P reports  $174.94 \pm 0.83 \pm 0.78 \pm 0.96 \text{ GeV}$ , where the first uncertainty is from statistics, the second from JES, and the last from other systematic uncertainties. We combine the JES and systematic uncertainties. A matrix-element method is used where the JES uncertainty is constrained by the  $W$  mass. ABAZOV 11P describes a measurement based on  $2.6 \text{ fb}^{-1}$  that is combined with ABAZOV 08AH, which employs an independent  $1 \text{ fb}^{-1}$  of data.
- <sup>32</sup> Based on a matrix-element method which employs  $5.4 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Superseded by ABAZOV 12AB.
- <sup>33</sup> Based on  $36 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$ . A Kinematic Method using  $b$ -tagging and an analytical Matrix Weighting Technique give consistent results and are combined. Superseded by CHATRCHYAN 12BA.
- <sup>34</sup> Based on  $3.4 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The result is obtained by combining the MT2 variable method and the NVA (Neutrino Weighting Algorithm). The MT2 method alone gives  $m_t = 168.0^{+4.8}_{-4.0}(\text{stat}) \pm 2.9(\text{syst}) \text{ GeV}$  with smaller systematic error due to small JES uncertainty.
- <sup>35</sup> Based on  $2.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and JES uncertainty, and the latter is from the other systematics. Neural-network-based kinematical selection of 6 highest  $E_T$  jets with a vtx  $b$ -tag is used to distinguish signal from background. Superseded by AALTONEN 12G.
- <sup>36</sup> Based on  $2 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The top mass is obtained from the measurement of the invariant mass of the lepton ( $e$  or  $\mu$ ) from  $W$  decays and the soft  $\mu$  in  $b$ -jet. The result is insensitive to jet energy scaling.
- <sup>37</sup> Based on  $1.9 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators.
- <sup>38</sup> Based on  $943 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09k selected 6 jet events with one or more vertex  $b$ -tags and used the tree-level matrix element to construct template models of signal and background.

- <sup>39</sup> Based on  $1.9 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain  $m_t$  and JES. Lepton + jets data only give  $m_t = 171.8 \pm 2.2 \text{ GeV}$ , and dilepton data only give  $m_t = 171.2^{+5.3}_{-5.1} \text{ GeV}$ .
- <sup>40</sup> Based on  $2 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Matrix Element method. Optimal selection criteria for candidate events with two high  $p_T$  leptons, high  $E_T$ , and two or more jets with and without  $b$ -tag are obtained by neural network with neuroevolution technique to minimize the statistical error of  $m_t$ .
- <sup>41</sup> Based on  $2.9 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Mass  $m_t$  is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two neutrino momenta.
- <sup>42</sup> Based on  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with two identified leptons, and those with one lepton plus one isolated track and a  $b$ -tag were used to constrain  $m_t$ . The result is a combination of the  $\nu$ WT ( $\nu$  Weighting Technique) result of  $176.2 \pm 4.8 \pm 2.1 \text{ GeV}$  and the MWT (Matrix-element Weighting Technique) result of  $173.2 \pm 4.9 \pm 2.0 \text{ GeV}$ .
- <sup>43</sup> Reports measurement of  $170.7^{+4.2}_{-3.9} \pm 2.6 \pm 2.4 \text{ GeV}$  based on  $1.2 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The last error is due to the theoretical uncertainty on  $\sigma_{t\bar{t}}$ . Without the cross-section constraint a top mass of  $169.7^{+5.2}_{-4.9} \pm 3.1 \text{ GeV}$  is obtained.
- <sup>44</sup> Template method.
- <sup>45</sup> Result is based on  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.
- <sup>46</sup> Based on  $310 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- <sup>47</sup> Ideogram method.
- <sup>48</sup> Based on  $311 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with 4 or more jets with  $E_T > 15 \text{ GeV}$ , significant missing  $E_T$ , and secondary vertex  $b$ -tag are used in the fit. About 44% of the signal acceptance is from  $\tau\nu + 4 \text{ jets}$ . Events with identified  $e$  or  $\mu$  are vetoed to provide a statistically independent measurement.
- <sup>49</sup> Based on  $1.02 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Superseded by AALTONEN 12G.
- <sup>50</sup> Based on  $955 \text{ pb}^{-1}$  of data  $\sqrt{s} = 1.96 \text{ TeV}$ .  $m_t$  and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of  $1.5 \text{ GeV}$ .
- <sup>51</sup> Matrix element method.
- <sup>52</sup> Based on  $425 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is a combination of statistics and JES (Jet Energy Scale) uncertainty, which has been measured simultaneously to give  $JES = 0.989 \pm 0.029(\text{stat})$ .
- <sup>53</sup> Based on  $370 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Combined result of MWT (Matrix-element Weighting Technique) and  $\nu$ WT ( $\nu$  Weighting Technique) analyses is  $178.1 \pm 6.7 \pm 4.8 \text{ GeV}$ .
- <sup>54</sup> Based on  $1.0 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation.
- <sup>55</sup> Based on  $695 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The transverse decay length of the  $b$  hadron is used to determine  $m_t$ , and the result is free from the JES (jet energy scale) uncertainty.
- <sup>56</sup> Based on  $\sim 400 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the  $b$ -tagging information. The result without  $b$ -tagging is  $169.2^{+5.0}_{-7.4} \pm 1.5 \pm 1.4 \text{ GeV}$ . Superseded by ABAZOV 08AH.
- <sup>57</sup> Based on  $318 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- <sup>58</sup> Dynamical likelihood method.
- <sup>59</sup> Based on  $340 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- <sup>60</sup> Based on  $360 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- <sup>61</sup> Based on  $110.2 \pm 5.8 \text{ pb}^{-1}$  at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- <sup>62</sup> Based on the all hadronic decays of  $t\bar{t}$  pairs. Single  $b$ -quark tagging via the decay chain  $b \rightarrow c \rightarrow \mu$  was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.
- <sup>63</sup> Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97R, ABE 99B], and dilepton [ABE 99B] decay topologies.
- <sup>64</sup> Obtained by combining the D0 result  $m_t(\text{GeV}) = 168.4 \pm 12.3 \pm 3.6$  from 6 di-lepton events (see also ABBOTT 98d) and  $m_t(\text{GeV}) = 173.3 \pm 5.6 \pm 5.5$  from lepton+jets events (ABBOTT 98f).
- <sup>65</sup> Obtained by combining the CDF results of  $m_t(\text{GeV}) = 167.4 \pm 10.3 \pm 4.8$  from 8 dilepton events,  $m_t(\text{GeV}) = 175.9 \pm 4.8 \pm 5.3$  from lepton+jets events (ABE 98E), and  $m_t(\text{GeV}) = 186.0 \pm 10.0 \pm 5.7$  from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.
- <sup>66</sup> See ABAZOV 04G.
- <sup>67</sup> The updated systematic error is listed. See AFFOLDER 01, appendix C.
- <sup>68</sup> Obtained by combining the D0 results of  $m_t(\text{GeV}) = 168.4 \pm 12.3 \pm 3.6$  from 6 dilepton events and  $m_t(\text{GeV}) = 173.3 \pm 5.6 \pm 5.5$  from 77 lepton+jets events.
- <sup>69</sup> Obtained by combining the D0 results from dilepton and lepton+jets events, and the CDF results (ABE 99B) from dilepton, lepton+jets events, and all-jet events.

### t-Quark $\overline{MS}$ Mass from Cross-Section Measurements

The top quark  $\overline{MS}$  or pole mass can be extracted from a measurement of  $\sigma(t\bar{t})$  by using theory calculations. We quote below the  $\overline{MS}$  mass. See the review "The Top Quark" and references therein for more information.

*t*

- <sup>1</sup> Based on 5.3 fb<sup>-1</sup> in *p* $\bar{p}$  collisions at  $\sqrt{s}$  = 1.96 TeV. ABAZOV 11s uses the measured *t* $\bar{t}$  production cross section of 8.13<sup>+1.02</sup><sub>-0.90</sub> pb [ABAZOV 11E] in the lepton plus jets channel to obtain the top quark  $\overline{MS}$  mass by using an approximate NNLO computation (MOCH 08, LANGENFELD 09). The corresponding top quark pole mass is 167.5<sup>+5.4</sup><sub>-4.9</sub> GeV. A different theory calculation (AHRENS 10, AHRENS 10A) is also used and yields  $m_t^{\overline{MS}} = 154.5^{+5.0}_{-4.3}$  GeV.
- <sup>2</sup> Based on 1 fb<sup>-1</sup> of data at  $\sqrt{s}$  = 1.96 TeV. Uses the  $\ell$  + jets,  $\ell\ell$ , and  $\ell\tau$  + jets channels. ABAZOV 09AG extract the pole mass of the top quark using two different calculations that yield 169.1<sup>+5.9</sup><sub>-5.2</sub> GeV (MOCH 08, LANGENFELD 09) and 168.2<sup>+5.9</sup><sub>-5.4</sub> GeV (KIDONAKIS 08).
- <sup>3</sup> Based on 1 fb<sup>-1</sup> of data at  $\sqrt{s}$  = 1.96 TeV. Uses the  $\ell\ell$  and  $\ell\tau$  + jets channels. ABAZOV 09R extract the pole mass of the top quark using two different calculations that yield 173.3<sup>+9.8</sup><sub>-8.6</sub> GeV (MOCH 08, LANGENFELD 09) and 171.5<sup>+9.9</sup><sub>-8.8</sub> GeV (CACCIARI 08).

## t-Quark Pole Mass from Cross-Section Measurements

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
<b>174.2<math>\pm</math>1.4 OUR AVERAGE</b>			
173.7 <sup>+2.3</sup> <sub>-2.1</sub>	<sup>1</sup> AAD	15BWATLS	$\ell$ + $\cancel{E}_T$ + $\geq$ 5j (2b-tag)
172.9 <sup>+2.5</sup> <sub>-2.6</sub>	<sup>2</sup> AAD	14AY ATLS	$pp$ at $\sqrt{s}$ = 7, 8 TeV
176.7 <sup>+3.0</sup> <sub>-2.8</sub>	<sup>3</sup> CHATRCHYAN 14	CMS	$pp$ at $\sqrt{s}$ = 7 TeV

- <sup>1</sup> AAD 15BW based on 4.6 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}$  = 7 TeV. Uses normalized differential cross section for *t* $\bar{t}$  + 1 jet as a function of the inverse of the invariant mass of the *t* $\bar{t}$  + 1 jet system. The measured cross section is corrected to the parton level. Then a fit to the data using NLO + parton shower prediction is performed.
- <sup>2</sup> Used  $\sigma(t\bar{t})$  for  $e\mu$  events. The result is a combination of the measurements  $m_t = 171.4 \pm 2.6$  GeV based on 4.6 fb<sup>-1</sup> of data at 7 TeV and  $m_t = 174.1 \pm 2.6$  GeV based on 20.3 fb<sup>-1</sup> of data at 8 TeV.
- <sup>3</sup> Used  $\sigma(t\bar{t})$  from  $pp$  collisions at  $\sqrt{s}$  = 7 TeV measured in CHATRCHYAN 12AX to obtain  $m_t(\text{pole})$  for  $\alpha_s(m_Z) = 0.1184 \pm 0.0007$ . The errors have been corrected in KHACHATRYAN 14K.

$$m_t - m_{\bar{t}}$$

Test of *CPT* conservation. OUR AVERAGE assumes that the systematic uncertainties are uncorrelated.

<13.1	95	<sup>6</sup> AALTONEN	09M CDF	$m_t(\text{rec})$ distribution

- <sup>1</sup> Based on 19.7 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}$  = 8 TeV. The result is obtained by combining the measurement of  $R = \Gamma(t \rightarrow Wb)/\Gamma(t \rightarrow Wq (q=b,s,d))$  and a previous CMS measurement of the *t*-channel single top production cross section of CHATRCHYAN 12Bq, by using the theoretical calculation of  $\Gamma(t \rightarrow Wb)$  for  $m_t = 172.5$  GeV.
- <sup>2</sup> Based on 5.4 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV.  $\Gamma(t \rightarrow bW) = 1.87^{+0.44}_{-0.40}$  GeV is obtained from the observed *t*-channel single top quark production cross section, whereas  $\Gamma(t \rightarrow bW) = 0.90 \pm 0.04$  is used assuming  $\sum_q \Gamma(t \rightarrow qW) = 1$ . The result is valid for  $m_t = 172.5$  GeV. See the paper for the values for  $m_t = 170$  or 175 GeV.
- <sup>3</sup> Based on 8.7 fb<sup>-1</sup> of data. The two sided 68% CL interval is 1.10 GeV <  $\Gamma_t$  < 4.05 GeV for  $m_t = 172.5$  GeV.

- <sup>4</sup> Based on 2.3 fb<sup>-1</sup> in  $p\bar{p}$  collisions at  $\sqrt{s}$  = 1.96 TeV. ABAZOV 11B extracted  $\Gamma_t$  from the partial width  $\Gamma(t \rightarrow Wb) = 1.92^{+0.58}_{-0.51}$  GeV measured using the *t*-channel single top production cross section, and the branching fraction  $\text{br}(t \rightarrow Wb) = 0.962^{+0.068}_{-0.066}(\text{stat})^{+0.064}_{-0.052}(\text{syst})$ . The  $\Gamma(t \rightarrow Wb)$  measurement gives the 95% CL lowerbound of  $\Gamma(t \rightarrow Wb)$  and hence that of  $\Gamma_t$ .
- <sup>5</sup> Results are based on 4.3 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}$  = 1.96 TeV. The top quark mass and the hadronically decaying *W* boson mass are reconstructed for each candidate events and compared with templates of different top quark width. The two sided 68% CL interval is 0.3 GeV <  $\Gamma_t$  < 4.4 GeV for  $m_t = 172.5$  GeV.
- <sup>6</sup> Based on 955 pb<sup>-1</sup> of  $p\bar{p}$  collision data at  $\sqrt{s}$  = 1.96 TeV. AALTONEN 09M selected *t* $\bar{t}$  candidate events for the  $\ell$  +  $\cancel{E}_T$  + jets channel with one or two *b*-tags, and examine the decay width dependence of the reconstructed  $m_t$  distribution. The result is for  $m_t = 175$  GeV, whereas the upper limit is lower for smaller  $m_t$ .

## t DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $t \rightarrow W q (q = b, s, d)$		
$\Gamma_2$ $t \rightarrow W b$		
$\Gamma_3$ $t \rightarrow \ell \nu_\ell$ anything	[a,b] ( 9.4 $\pm$ 2.4) %	
$\Gamma_4$ $t \rightarrow e \nu_e b$	(13.3 $\pm$ 0.6) %	
$\Gamma_5$ $t \rightarrow \mu \nu_\mu b$	(13.4 $\pm$ 0.6) %	
$\Gamma_6$ $t \rightarrow \tau \nu_\tau b$		
$\Gamma_7$ $t \rightarrow q \bar{q} b$	(66.5 $\pm$ 1.4) %	
$\Gamma_8$ $t \rightarrow \gamma q (q=u,c)$	[c] < 5.9 $\times 10^{-3}$	95%
<b><math>\Delta T = 1</math> weak neutral current (<i>T</i><sub>1</sub>) modes</b>		
$\Gamma_9$ $t \rightarrow Z q (q=u,c)$	$\pi_1$ [d] < 5 $\times 10^{-4}$	95%
$\Gamma_{10}$ $t \rightarrow H q$		
$\Gamma_{11}$ $t \rightarrow \ell^+ \bar{q} \bar{q}' (q=d,s,b; q'=u,c)$	< 1.6 $\times 10^{-3}$	95%

- [a]  $\ell$  means *e* or  $\mu$  decay mode, not the sum over them.
- [b] Assumes lepton universality and *W*-decay acceptance.
- [c] This limit is for  $\Gamma(t \rightarrow \gamma q)/\Gamma(t \rightarrow Wb)$ .
- [d] This limit is for  $\Gamma(t \rightarrow Z q)/\Gamma(t \rightarrow Wb)$ .

0.94 $\pm$ 0.26 $\pm$ 0.17 $\pm$ 0.21 $\pm$ 0.12	<sup>8</sup> AFFOLDER	01c CDF	

- <sup>1</sup> Based on 8.7 fb<sup>-1</sup> of data. This measurement gives  $|V_{tb}| = 0.93 \pm 0.04$  and  $|V_{tb}| > 0.85$  (95% CL) in the SM.
- <sup>2</sup> Based on 19.7 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}$  = 8 TeV. The result is obtained by counting the number of *b* jets per *t* $\bar{t}$  signal events in the dilepton channel. The *t* $\bar{t}$  production cross section is measured to be  $\sigma(t\bar{t}) = 238 \pm 1 \pm 15$  pb, in good agreement with the SM prediction and the latest CMS measurement of CHATRCHYAN 14F. The measurement gives  $R > 0.995$  (95% CL), or  $|V_{tb}| > 0.975$  (95% CL) in the SM, requiring  $R \leq 1$ .
- <sup>3</sup> Based on 8.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s}$  = 1.96 TeV. Measure the fraction of  $t \rightarrow Wb$  decays simultaneously with the *t* $\bar{t}$  cross section. The correlation coefficient between those two measurements is -0.434. Assume unitarity of the 3x3 CKM matrix and set  $|V_{tb}| > 0.89$  at 95% CL.
- <sup>4</sup> Based on 5.4 fb<sup>-1</sup> of data. The error is statistical and systematic combined. The result is a combination of 0.95  $\pm$  0.07 from  $\ell$  + jets channel and 0.86  $\pm$  0.05 from  $\ell\ell$  channel.  $|V_{tb}| = 0.95 \pm 0.02$  follows from the result by assuming unitarity of the 3x3 CKM matrix.
- <sup>5</sup> Result is based on 0.9 fb<sup>-1</sup> of data. The 95% CL lower bound  $R > 0.79$  gives  $|V_{tb}| > 0.89$  (95% CL).
- <sup>6</sup> ABAZOV 06K result is from the analysis of *t* $\bar{t}$   $\rightarrow \ell\nu + \geq 3$  jets with 230 pb<sup>-1</sup> of data at  $\sqrt{s}$  = 1.96 TeV. It gives  $R > 0.61$  and  $|V_{tb}| > 0.78$  at 95% CL. Superseded by ABAZOV 08M.
- <sup>7</sup> ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of *t* $\bar{t}$  candidate events with  $\sim 162$  pb<sup>-1</sup> of data at  $\sqrt{s}$  = 1.96 TeV. The first error is statistical and the second systematic. It gives  $R > 0.61$ , or  $|V_{tb}| > 0.78$  at 95% CL.
- <sup>8</sup> AFFOLDER 01c measures the top-quark decay width ratio  $R = \Gamma(Wb)/\Gamma(Wq)$ , where *q* is a *d*, *s*, or *b* quark, by using the number of events with multiple *b*tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives  $R > 0.61$  (0.56) at 90% (95%) CL. By assuming three generation unitarity,  $|V_{tb}| = 0.97^{+0.16}_{-0.12}$  or  $|V_{tb}| > 0.78$  (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb<sup>-1</sup> of data at  $\sqrt{s}$  = 1.8 TeV.

	3 ABULENCIA	06R CDF	$\ell\tau$ + jets
	4 ABE	97v CDF	$\ell\tau$ + jets

<sup>1</sup> AAD 15cc based on 4.6 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. It is assumed that the top branching ratios to leptons and jets add up to one and that only SM processes contribute to the background. The event selection criteria are optimized for the  $\ell\tau_h$  + jets channel.

<sup>2</sup> Based on 9 fb<sup>-1</sup> of data. The measurement is in the channel  $t\bar{t} \rightarrow (b\ell\nu)(\tau\nu)$ , where  $\tau$  decays into hadrons ( $\tau_h$ ), and  $\ell$  ( $e$  or  $\mu$ ) include  $\ell$  from  $\tau$  decays ( $\tau_\ell$ ). The result is consistent with lepton universality.

<sup>3</sup> ABULENCIA 06R looked for  $t\bar{t} \rightarrow (\ell\nu_\ell)(\tau\nu_\tau)b\bar{b}$  events in 194 pb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. 2 events are found where 1.00 ± 0.17 signal and 1.29 ± 0.25 background events are expected, giving a 95% CL upper bound for the partial width ratio  $\Gamma(t \rightarrow \tau\nu)/\Gamma_{SM}(t \rightarrow \tau\nu) < 5.2$ .

<sup>4</sup> ABE 97v searched for  $t\bar{t} \rightarrow (\ell\nu_\ell)(\tau\nu_\tau)b\bar{b}$  events in 109 pb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.8$  TeV. They observed 4 candidate events where one expects  $\sim 1$  signal and  $\sim 2$  background events. Three of the four observed events have jets identified as  $b$  candidates.

<b>&lt; 0.0059</b>	95	1 CHEKANOV 03	ZEUS	$B(t \rightarrow \gamma u)$	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
< 0.0064	95	2 AARON	09A	$t \rightarrow \gamma u$	
< 0.0465	95	3 ABDALLAH	04C	DLPH $B(\gamma c \text{ or } \gamma u)$	
< 0.0132	95	4 AKTAS	04	H1 $B(t \rightarrow \gamma u)$	
< 0.041	95	5 ACHARD	02J	L3 $B(t \rightarrow \gamma c \text{ or } \gamma u)$	
< 0.032	95	6 ABE	98G	CDF $t\bar{t} \rightarrow (Wb)(\gamma c \text{ or } \gamma u)$	

<sup>1</sup> CHEKANOV 03 looked for single top production via FCNC in the reaction  $e^\pm p \rightarrow e^\pm (t \text{ or } \bar{t}) X$  in 130.1 pb<sup>-1</sup> of data at  $\sqrt{s}=300\text{--}318$  GeV. No evidence for top production and its decay into  $bW$  was found. The result is obtained for  $m_t=175$  GeV when  $B(\gamma c)=B(Zq)=0$ , where  $q$  is a  $u$  or  $c$  quark. Bounds on the effective  $t$ - $u$ - $\gamma$  and  $t$ - $u$ - $Z$  couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.

<sup>2</sup> AARON 09A looked for single top production via FCNC in  $e^\pm p$  collisions at HERA with 474 pb<sup>-1</sup>. The upper bound of the cross section gives the bound on the FCNC coupling  $\kappa_{t u \gamma}/\Lambda < 1.03$  TeV<sup>-1</sup>, which corresponds to the result for  $m_t = 175$  GeV.

<sup>3</sup> ABDALLAH 04c looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 541 pb<sup>-1</sup> of data at  $\sqrt{s}=189\text{--}208$  GeV. No deviation from the SM is found, which leads to the bound on  $B(t \rightarrow \gamma q)$ , where  $q$  is a  $u$  or a  $c$  quark, for  $m_t = 175$  GeV when  $B(t \rightarrow Zq)=0$  is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective  $t$ - $q$ - $\gamma$  and  $t$ - $q$ - $Z$  couplings are given in their Fig. 7 and Table 4, for  $m_t = 170\text{--}180$  GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual  $\gamma$  and  $Z$  exchange amplitudes.

<sup>4</sup> AKTAS 04 looked for single top production via FCNC in  $e^\pm$  collisions at HERA with 118.3 pb<sup>-1</sup>, and found 5 events in the  $e$  or  $\mu$  channels. By assuming that they are due to statistical fluctuation, the upper bound on the  $t u \gamma$  coupling  $\kappa_{t u \gamma} < 0.27$  (95% CL) is obtained. The conversion to the partial width limit, when  $B(\gamma c) = B(Zu) = B(Zc) = 0$ , is from private communication, E. Perez, May 2005.

<sup>5</sup> ACHARD 02J looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 634 pb<sup>-1</sup> of data at  $\sqrt{s}=189\text{--}209$  GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction  $B(\gamma q)$ , where  $q$  is a  $u$  or  $c$  quark. The bound assumes  $B(Zq)=0$  and is for  $m_t = 175$  GeV; bounds for  $m_t=170$  GeV and 180 GeV and  $B(Zq) \neq 0$  are given in Fig. 5 and Table 7.

<sup>6</sup> ABE 98G looked for  $t\bar{t}$  events where one  $t$  decays into  $q\gamma$  while the other decays into  $bW$ . The quoted bound is for  $\Gamma(\gamma q)/\Gamma(Wb)$ .

<sup>1</sup> AAD 16D based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. The FCNC decay is searched for in  $t\bar{t}$  events in the final state  $(bW)(qZ)$  when both  $W$  and  $Z$  decay leptonically, giving 3 charged leptons.

<sup>2</sup> CHATRCHYAN 14s combined search limit from this and CHATRCHYAN 13F data.

<sup>3</sup> Based on 19.7 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. The flavor changing decay is searched for in  $t\bar{t}$  events in the final state  $(bW)(qZ)$  when both  $W$  and  $Z$  decay leptonically, giving 3 charged leptons.

<sup>4</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. Search for FCNC decays of the top quark in  $t\bar{t} \rightarrow \ell^+ \ell^- \ell^\pm \nu$  + jets ( $\ell, \ell' = e, \mu$ ) final states found no excess of signal events.

<sup>5</sup> Based on 2.1 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV.

<sup>6</sup> Based on 4.1 fb<sup>-1</sup> of data. ABAZOV 11M searched for FCNC decays of the top quark in  $t\bar{t} \rightarrow \ell^+ \ell^- \ell^\pm \nu$  + jets ( $\ell, \ell' = e, \mu$ ) final states, and absence of the signal gives the bound.

<sup>7</sup> Based on  $p\bar{p}$  data of 1.52 fb<sup>-1</sup>. AALTONEN 09AL compared  $t\bar{t} \rightarrow WbWb \rightarrow \ell\nu b j j b$  and  $t\bar{t} \rightarrow ZcWb \rightarrow \ell\ell c j j b$  decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized  $Z$  boson and the theoretical  $t\bar{t}$  production cross section. The results for different  $Z$  polarizations and those without the cross section assumption are given in their Table XII.

<sup>8</sup> Result is based on 1.9 fb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV.  $t\bar{t} \rightarrow WbZq$  or  $ZqZq$  processes have been looked for in  $Z + \geq 4$  jet events with and without  $b$ -tag. No signal leads to the bound  $B(t \rightarrow Zq) < 0.037$  (0.041) for  $m_t = 175$  (170) GeV.

<sup>9</sup> ABDALLAH 04c looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 541 pb<sup>-1</sup> of data at  $\sqrt{s}=189\text{--}208$  GeV. No deviation from the SM is found, which leads to the bound on  $B(t \rightarrow \gamma q)$ , where  $q$  is a  $u$  or a  $c$  quark, for  $m_t = 175$  GeV when  $B(t \rightarrow Zq)=0$  is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective  $t$ - $q$ - $\gamma$  and  $t$ - $q$ - $Z$  couplings are given in their Fig. 7 and Table 4, for  $m_t = 170\text{--}180$  GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual  $\gamma$  and  $Z$  exchange amplitudes.

<sup>10</sup> ACHARD 02J looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 634 pb<sup>-1</sup> of data at  $\sqrt{s}=189\text{--}209$  GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction  $B(Zq)$ , where  $q$  is a  $u$  or  $c$  quark. The bound assumes  $B(\gamma q)=0$  and is for  $m_t = 175$  GeV; bounds for  $m_t=170$  GeV and 180 GeV and  $B(\gamma q) \neq 0$  are given in Fig. 5 and Table 7. Table 6 gives constraints on  $t$ - $c$ - $e$ - $e$  four-fermi contact interactions.

<sup>11</sup> HEISTER 02Q looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 214 pb<sup>-1</sup> of data at  $\sqrt{s}=204\text{--}209$  GeV. No deviation from the SM is found, which leads to a bound on the branching fraction  $B(Zq)$ , where  $q$  is a  $u$  or  $c$  quark. The bound assumes  $B(\gamma q)=0$  and is for  $m_t = 174$  GeV. Bounds on the effective  $t$ - $(c \text{ or } u)$ - $\gamma$  and  $t$ - $(c \text{ or } u)$ - $Z$  couplings are given in their Fig. 2.

<sup>12</sup> ABBIENDI 01T looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 600 pb<sup>-1</sup> of data at  $\sqrt{s}=189\text{--}209$  GeV. No deviation from the SM is found, which leads to bounds on the branching fractions  $B(Zq)$  and  $B(\gamma q)$ , where  $q$  is a  $u$

# Quark Particle Listings

*t*

or *c* quark. The result is obtained for  $m_t = 174$  GeV. The upper bound becomes 9.7% (20.6%) for  $m_t = 169$  (179) GeV. Bounds on the effective  $t$ -(*c* or *u*)- $\gamma$  and  $t$ -(*c* or *u*)- $Z$  couplings are given in their Fig. 4.

- <sup>13</sup> BARATE 00s looked for single top production via FCNC in the reaction  $e^+e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 411 pb<sup>-1</sup> of data at c.m. energies between 189 and 202 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction. The bound assumes  $B(\gamma q)=0$ . Bounds on the effective  $t$ -(*c* or *u*)- $\gamma$  and  $t$ -(*c* or *u*)- $Z$  couplings are given in their Fig. 4.

- <sup>14</sup> ABE 98G looked for  $t\bar{t}$  events where one *t* decays into three jets and the other decays into  $qZ$  with  $Z \rightarrow \ell\ell$ . The quoted bound is for  $\Gamma(Zq)/\Gamma(Wb)$ .

- <sup>1</sup> Based on 8.7 fb<sup>-1</sup> of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV using  $t\bar{t}$  events with  $\ell + \cancel{E}_T + \geq 4$  jets ( $\geq 1b$ ), and under the constraint  $F_0 + F_+ + F_- = 1$ . The statistical errors of  $F_0$  and  $F_+$  are correlated with correlation coefficient  $\rho(F_0, F_+) = -0.69$ .

- <sup>2</sup> Based on 5.0 fb<sup>-1</sup> of *pp* data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 13BH studied *tt* events with large  $\cancel{E}_T$  and  $\ell + \geq 4$  jets using a constrained kinematic fit.

- <sup>3</sup> Based on 1.04 fb<sup>-1</sup> of *pp* data at  $\sqrt{s} = 7$  TeV. AAD 12Bg studied *tt* events with large  $\cancel{E}_T$  and either  $\ell + \geq 4j$  or  $\ell\ell + \geq 2j$ . The uncertainties are not independent,  $\rho(F_0, F_-) = -0.96$ .

- <sup>4</sup> Based on 2.7 and 5.1 fb<sup>-1</sup> of CDF data in  $\ell$  + jets and dilepton channels, and 5.4 fb<sup>-1</sup> of D0 data in  $\ell$  + jets and dilepton channels.  $F_0 = 0.682 \pm 0.035 \pm 0.046$  if  $F_+ = 0.0017(1)$ , while  $F_+ = -0.015 \pm 0.018 \pm 0.030$  if  $F_0 = 0.688(4)$ , where the assumed fixed values are the SM prediction for  $m_t = 173.3 \pm 1.1$  GeV and  $m_W = 80.399 \pm 0.023$  GeV.

- <sup>5</sup> Results are based on 5.4 fb<sup>-1</sup> of data in *p* $\bar{p}$  collisions at 1.96 TeV, including those of ABZOV 08B. Under the SM constraint of  $f_0 = 0.698$  (for  $m_t = 173.3$  GeV,  $m_W = 80.399$  GeV),  $f_+ = 0.010 \pm 0.022 \pm 0.030$  is obtained.

- <sup>6</sup> AFFOLDER 00B studied the angular distribution of leptonic decays of *W* bosons in  $t \rightarrow Wb$  events. The ratio  $F_0$  is the fraction of the helicity zero (longitudinal) *W* bosons in the decaying top quark rest frame.  $B(t \rightarrow W_+b)$  is the fraction of positive helicity (right-handed) positive charge *W* bosons in the top quark decays. It is obtained by assuming the Standard Model value of  $F_0$ .

- <sup>7</sup> Results are based on 2.7 fb<sup>-1</sup> of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.  $F_0$  result is obtained by assuming  $F_+ = 0$ , while  $F_+$  result is obtained for  $F_0 = 0.70$ , the SM value. Model independent fits for the two fractions give  $F_0 = 0.88 \pm 0.11 \pm 0.06$  and  $F_+ = -0.15 \pm 0.07 \pm 0.06$  with correlation coefficient of  $-0.59$ . The results are for  $m_t = 175$  GeV.

- <sup>8</sup> Results are based on 1.9 fb<sup>-1</sup> of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.  $F_0$  result is obtained assuming  $F_+ = 0$ , while  $F_+$  result is obtained for  $F_0 = 0.70$ , the SM values. Model independent fits for the two fractions give  $F_0 = 0.66 \pm 0.16 \pm 0.05$  and  $F_+ = -0.03 \pm 0.06 \pm 0.03$ .

- <sup>9</sup> Based on 1 fb<sup>-1</sup> at  $\sqrt{s} = 1.96$  TeV.

- <sup>10</sup> Based on 318 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV.

- <sup>11</sup> Based on 200 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV.  $t \rightarrow Wb \rightarrow \ell\nu b$  ( $\ell = e$  or  $\mu$ ). The errors are stat + syst.

- <sup>12</sup> ABZOV 05G studied the angular distribution of leptonic decays of *W* bosons in  $t\bar{t}$  candidate events with lepton + jets final states, and obtained the fraction of longitudinally polarized *W* under the constraint of no right-handed current,  $F_+ = 0$ . Based on 125 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.8$  TeV.

**Spin Correlation in  $t\bar{t}$  Production in  $p\bar{p}$  Collisions**

$C$  is the correlation strength parameter,  $f$  is the ratio of events with correlated  $t$  and  $\bar{t}$  spins (SM prediction:  $f = 1$ ), and  $\kappa$  is the spin correlation coefficient. See "The Top Quark" review for more information.

$0.10 \pm 0.45$	<sup>5</sup> ABAZOV	11AF D0	$C(\ell\ell + E_T + \geq 2 \text{ jets})$

- <sup>1</sup> This is a combination of the lepton + jets analysis presented in ABAZOV 12B and the dilepton measurement of ABAZOV 11AE. It provides a  $3.1 \sigma$  evidence for the  $t\bar{t}$  spin correlation.
- <sup>2</sup> Based on  $5.3 \text{ fb}^{-1}$  of data. The error is statistical and systematic combined. A matrix element method is used.
- <sup>3</sup> Based on  $4.3 \text{ fb}^{-1}$  of data. The measurement is based on the angular study of the top quark decay products in the helicity basis. The theory prediction is  $\kappa \approx 0.40$ .
- <sup>4</sup> Based on  $5.4 \text{ fb}^{-1}$  of data using a matrix element method. The error is statistical and systematic combined. The no-correlation hypothesis is excluded at the 97.7% CL.
- <sup>5</sup> Based on  $5.4 \text{ fb}^{-1}$  of data. The error is statistical and systematic combined. The NLO QCD prediction is  $C = 0.78 \pm 0.03$ . The neutrino weighting method is used for reconstruction of kinematics.

**Spin Correlation in  $t\bar{t}$  Production in  $pp$  Collisions**

Spin correlation,  $f_{SM}$ , measures the strength of the correlation between the spins of the pair produced  $t\bar{t}$ .  $f_{SM} = 1$  for the SM, while  $f_{SM} = 0$  for no spin correlation.

*t*

- <sup>1</sup> Based on 2.05 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. The results are obtained from the 95% CL upper limit on the single top-quark production  $\sigma(qg \rightarrow t)\text{-}B(t \rightarrow bW) < 3.9$  pb, for  $q=u$  or  $q=c$ ,  $B(t \rightarrow ug) < 5.7 \times 10^{-5}$  and  $B(t \rightarrow ug) < 2.7 \times 10^{-4}$ .
- <sup>2</sup> Based on 2.3 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Upper limit of single top quark production cross section 0.20 pb and 0.27 pb via FCNC  $t$ - $u$ - $g$  and  $t$ - $c$ - $g$  couplings, respectively, lead to the bounds without assuming the absence of the other coupling.  $B(t \rightarrow u + g) < 2.0 \times 10^{-4}$  and  $B(t \rightarrow c + g) < 3.9 \times 10^{-3}$  follow.
- <sup>3</sup> Based on 2.2 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Upper limit of single top quark production cross section  $\sigma(u(c) + g \rightarrow t) < 1.8$  pb (95% CL) via FCNC  $t$ - $u$ - $g$  and  $t$ - $c$ - $g$  couplings lead to the bounds.  $B(t \rightarrow u + g) < 3.9 \times 10^{-4}$  and  $B(t \rightarrow c + g) < 5.7 \times 10^{-3}$  follow.
- <sup>4</sup> Result is based on 230 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV. Absence of single top quark production events via FCNC  $t$ - $u$ - $g$  and  $t$ - $c$ - $g$  couplings lead to the upper bounds on the dimensioned couplings,  $\kappa_t^{u\bar{t}g}/\Lambda$  and  $\kappa_t^{c\bar{t}g}/\Lambda$ , respectively.

- <sup>1</sup> AALTONEN 15H based on 9.7 fb<sup>-1</sup> of data per experiment. The result is for  $m_t = 172.5$  GeV, and is a combination of the CDF measurements (AALTONEN 16) and the D0 measurements (ABAZOV 13o) on the  $t$ -channel single  $t$ -quark production cross section. The result is consistent with the NLO+NNLL SM prediction and gives  $|V_{tb}| = 1.02^{+0.06}_{-0.05}$  and  $|V_{tb}| > 0.92$  (95% CL).

- <sup>2</sup> AALTONEN 15H is a combined measurement of  $s$ -channel single top cross section by CDF + D0. AALTONEN 14M is not included.

- <sup>3</sup> Based on 9.45 fb<sup>-1</sup> of data, using neural networks to separate signal from backgrounds. The result is for  $m_t = 172.5$  GeV. Combination of this result with the CDF measurement in the 1 lepton channel AALTONEN 14L gives  $1.36^{+0.37}_{-0.32}$  pb, consistent with the SM prediction, and is 4.2 sigma away from the background only hypothesis.

- <sup>4</sup> Based on 9.4 fb<sup>-1</sup> of data, using neural networks to separate signal from backgrounds. The result is for  $m_t = 172.5$  GeV. The result is 3.8 sigma away from the background only hypothesis.

- <sup>5</sup> Based on 9.7 fb<sup>-1</sup> of data per experiment. The result is for  $m_t = 172.5$  GeV, and is a combination of the CDF measurements AALTONEN 14L, AALTONEN 14K and the D0 measurement ABAZOV 13o on the  $s$ -channel single  $t$ -quark production cross section. The result is consistent with the SM prediction of  $1.05 \pm 0.06$  pb and the significance of the observation is of 6.3 standard deviations.

- <sup>6</sup> Based on 7.5 fb<sup>-1</sup> of data. Neural network is used to discriminate signals ( $s$ -,  $t$ - and  $Wt$ -channel single top production) from backgrounds. The result is consistent with the SM prediction, and gives  $|V_{tb}| = 0.95 \pm 0.09$  (stat + syst)  $\pm 0.05$  (theory) and  $|V_{tb}| > 0.78$  (95% CL). The result is for  $m_t = 172.5$  GeV.

- <sup>7</sup> Based on 9.7 fb<sup>-1</sup> of data. Events with  $\ell + \cancel{E}_T + 2$  or 3 jets (1 or 2  $b$ -tag) are analysed, assuming  $m_t = 172.5$  GeV. The combined  $s$ - +  $t$ -channel cross section gives  $|V_{tb}| \frac{f_L^1}{f_L^1} = 1.12^{+0.09}_{-0.08}$ , or  $|V_{tb}| > 0.92$  at 95% CL for  $f_L^1 = 1$  and a flat prior within  $0 \leq |V_{tb}|^2 \leq 1$ .

- <sup>8</sup> Based on 5.4 fb<sup>-1</sup> of data. The error is statistical + systematic combined. The results are for  $m_t = 172.5$  GeV. Results for other  $m_t$  values are given in Table 2 of ABAZOV 11AA.

- <sup>9</sup> Based on 5.4 fb<sup>-1</sup> of data and for  $m_t = 172.5$  GeV. The error is statistical + systematic combined. Results for other  $m_t$  values are given in Table III of ABAZOV 11AD. The result is obtained by assuming the SM ratio between  $t\bar{b}$  ( $s$ -channel) and  $tqb$  ( $t$ -channel) productions, and gives  $|V_{tb}| \frac{f_L^1}{f_L^1} = 1.02^{+0.10}_{-0.11}$ , or  $|V_{tb}| > 0.79$  at 95% CL for a flat prior within  $0 < |V_{tb}|^2 < 1$ .

- <sup>10</sup> Based on 3.2 fb<sup>-1</sup> of data. For combined  $s$ - +  $t$ -channel result see AALTONEN 09AT.

- <sup>11</sup> Result is based on 2.1 fb<sup>-1</sup> of data. Events with large missing  $E_T$  and jets with at least one  $b$ -jet without identified electron or muon are selected. Result is obtained when observed  $2.1 \sigma$  excess over the background originates from the signal for  $m_t = 175$  GeV, giving  $|V_{tb}| = 1.24^{+0.34}_{-0.29} \pm 0.07$  (theory).

- <sup>12</sup> Result is based on 2.3 fb<sup>-1</sup> of data. Events with isolated  $\ell + \cancel{E}_T + 2, 3, 4$  jets with one or two  $b$ -tags are selected. The analysis assumes  $m_t = 170$  GeV.

- <sup>13</sup> Result is based on 4.8 fb<sup>-1</sup> of data. Events with an isolated reconstructed tau lepton, missing  $E_T + 2, 3$  jets with one or two  $b$ -tags are selected. When combined with ABAZOV 09Z result for  $e + \mu$  channels, the  $s$ - and  $t$ -channels combined cross section is  $3.84^{+0.69}_{-0.83}$  pb.

- <sup>14</sup> Based on 3.2 fb<sup>-1</sup> of data. Events with isolated  $\ell + \cancel{E}_T$  + jets with at least one  $b$ -tag are analyzed and  $s$ - and  $t$ -channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for  $s$ -channel process, and neural-networked based analysis of events with  $\cancel{E}_T$  that has sensitivity for  $W \rightarrow \tau\nu$  decays. The result is for  $m_t = 175$  GeV, and the mean value decreases by 0.02 pb/GeV for smaller  $m_t$ . The signal has 5.0 sigma significance. The result gives  $|V_{tb}| = 0.91 \pm 0.11$  (stat+syst)  $\pm 0.07$  (theory), or  $|V_{tb}| > 0.71$  at 95% CL.

- <sup>15</sup> Based on 2.3 fb<sup>-1</sup> of data. Events with isolated  $\ell + \cancel{E}_T + \geq 2$  jets with 1 or 2  $b$ -tags are analyzed and  $s$ - and  $t$ -channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives  $|V_{tb}| = 1.07 \pm 0.12$ , or  $|V_{tb}| > 0.78$  at 95% CL. The analysis assumes  $m_t = 170$  GeV.

- <sup>16</sup> Result is based on 2.2 fb<sup>-1</sup> of data. Events with isolated  $\ell + \cancel{E}_T + 2, 3$  jets with at least one  $b$ -tag are selected, and  $s$ - and  $t$ -channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as  $|V_{tb}| = 0.88^{+0.13}_{-0.12}$  (stat + syst)  $\pm 0.07$  (theory), and  $|V_{tb}| > 0.66$  (95% CL) under the  $|V_{tb}| < 1$  constraint.

- <sup>17</sup> Result is based on 0.9 fb<sup>-1</sup> of data. Events with isolated  $\ell + \cancel{E}_T + 2, 3, 4$  jets with one or two  $b$ -vertex-tag are selected, and contributions from  $W$  + jets,  $t\bar{t}$ ,  $s$ - and  $t$ -channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element  $|V_{tb}| = 1.31^{+0.25}_{-0.21}$ , or  $|V_{tb}| > 0.68$  (95% CL) under the  $|V_{tb}| < 1$  constraint.

- <sup>18</sup> Result is based on 0.9 fb<sup>-1</sup> of data. This result constrains  $V_{tb}$  to  $0.68 < |V_{tb}| \leq 1$  at 95% CL.

- <sup>19</sup> ABAZOV 05P bounds single top-quark production from either the  $s$ -channel  $W$ -exchange process,  $q'\bar{q} \rightarrow t\bar{b}$ , or the  $t$ -channel  $W$ -exchange process,  $q'g \rightarrow q\bar{t}\bar{b}$ , based on  $\sim 230$  pb<sup>-1</sup> of data.

- <sup>20</sup> ACOSTA 05N bounds single top-quark production from the  $t$ -channel  $W$ -exchange process ( $q'g \rightarrow q\bar{t}\bar{b}$ ), the  $s$ -channel  $W$ -exchange process ( $q'\bar{q} \rightarrow t\bar{b}$ ), and from the combined cross section of  $t$ - and  $s$ -channel. Based on  $\sim 162$  pb<sup>-1</sup> of data.

## $t$ -channel Single $t$ Production Cross Section in $pp$ Collisions at $\sqrt{s} = 7$ TeV

Direct probe of the  $t\bar{b}W$  coupling and possible new physics at  $\sqrt{s} = 7$  TeV.

67.2 ± 6.1	<sup>3</sup> CHATRCHYAN12BQ	CMS	$t$ -channel $\ell + \cancel{E}_T + \geq 2j$ (1b)
83.6 ± 29.8 ± 3.3	<sup>4</sup> CHATRCHYAN11R	CMS	$t$ -channel

<sup>1</sup> Based on  $4.59 \text{ fb}^{-1}$  of data, using neural networks for signal and background separation.  $\sigma(tq) = 46 \pm 1 \pm 6 \text{ pb}$  and  $\sigma(\bar{t}q) = 23 \pm 1 \pm 3 \text{ pb}$  are separately measured, as well as their ratio  $R = \sigma(tq)/\sigma(\bar{t}q) = 2.04 \pm 0.13 \pm 0.12$ . The results are for  $m_t = 172.5 \text{ GeV}$ , and those for other  $m_t$  values are given by eq.(4) and Table IV. The measurements give  $|V_{tb}| = 1.02 \pm 0.07$  or  $|V_{tb}| > 0.88$  (95% CL).

<sup>2</sup> Based on  $1.04 \text{ fb}^{-1}$  of data. The result gives  $|V_{tb}| = 1.13^{+0.14}_{-0.13}$  from the ratio  $\sigma(\text{exp})/\sigma(\text{th})$ , where  $\sigma(\text{th})$  is the SM prediction for  $|V_{tb}| = 1$ . The 95% CL lower bound of  $|V_{tb}| > 0.75$  is found if  $|V_{tb}| < 1$  is assumed.  $\sigma(t) = 59^{+18}_{-16} \text{ pb}$  and  $\sigma(\bar{t}) = 33^{+13}_{-12} \text{ pb}$  are found for the separate single  $t$  and  $\bar{t}$  production cross sections, respectively. The results assume  $m_t = 172.5 \text{ GeV}$  for the acceptance.

<sup>3</sup> Based on  $1.17 \text{ fb}^{-1}$  of data for  $\ell = \mu$ ,  $1.56 \text{ fb}^{-1}$  of data for  $\ell = e$  at  $7 \text{ TeV}$  collected during 2011. The result gives  $|V_{tb}| = 1.020 \pm 0.046(\text{meas}) \pm 0.017(\text{th})$ . The 95% CL lower bound of  $|V_{tb}| > 0.92$  is found if  $|V_{tb}| < 1$  is assumed. The results assume  $m_t = 172.5 \text{ GeV}$  for the acceptance.

<sup>4</sup> Based on  $36 \text{ pb}^{-1}$  of data. The first error is statistical + systematic combined, the second is luminosity. The result gives  $|V_{tb}| = 1.114 \pm 0.22(\text{exp}) \pm 0.02(\text{th})$  from the ratio  $\sigma(\text{exp})/\sigma(\text{th})$ , where  $\sigma(\text{th})$  is the SM prediction for  $|V_{tb}| = 1$ . The 95% CL lower bound of  $|V_{tb}| > 0.62$  (0.68) is found from the 2D (BDT) analysis under the constraint  $0 < |V_{tb}|^2 < 1$ .

$23.0 \pm 1.3^{+3.2}_{-3.5} \pm 1.1$	<sup>1</sup> AAD	16B ATLS	$2\ell + \cancel{E}_T + 1b$
$23.4 \pm 5.4$	<sup>2</sup> CHATRCHYAN14AC	CMS	$t + W$ channel, $2\ell + \cancel{E}_T + 1b$

<sup>1</sup> AAD 16B based on  $20.3 \text{ fb}^{-1}$  of data. The result gives  $|V_{tb}| = 1.01 \pm 0.10$  and  $|V_{tb}| > 0.80$  (95% CL) without assuming unitarity of the CKM matrix. The results assume  $m_t = 172.5 \text{ GeV}$  for the acceptance.

<sup>2</sup> Based on  $12.2 \text{ fb}^{-1}$  of data. Events with two oppositely charged leptons, large  $\cancel{E}_T$  and a  $b$ -tagged jet are selected, and a multivariate analysis is used to separate the signal from the backgrounds. The result is consistent with the SM prediction of  $22.2 \pm 0.6(\text{scale}) \pm 1.4(\text{PDF}) \text{ pb}$  at approximate NNLO.

### Single t-Quark Production Cross Section in ep Collisions

VALUE (pb)	CL%	DOCUMENT ID	TECN	COMMENT
------------	-----	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$< 0.25$	95	<sup>1</sup> AARON	09A H1	$e^\pm p \rightarrow e^\pm t X$
$< 0.55$	95	<sup>2</sup> AKTAS	04 H1	$e^\pm p \rightarrow e^\pm t X$
$< 0.225$	95	<sup>3</sup> CHEKANOV	03 ZEUS	$e^\pm p \rightarrow e^\pm t X$

<sup>1</sup> AARON 09A looked for single top production via FCNC in  $e^\pm p$  collisions at HERA with  $474 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 301\text{--}319 \text{ GeV}$ . The result supersedes that of AKTAS 04.

<sup>2</sup> AKTAS 04 looked for single top production via FCNC in  $e^\pm$  collisions at HERA with  $118.3 \text{ pb}^{-1}$ , and found 5 events in the  $e$  or  $\mu$  channels while  $1.31 \pm 0.22$  events are expected from the Standard Model background. No excess was found for the hadronic channel. The observed cross section of  $\sigma(ep \rightarrow etX) = 0.29^{+0.15}_{-0.14} \text{ pb}$  at  $\sqrt{s} = 319 \text{ GeV}$  gives the quoted upper bound if the observed events are due to statistical fluctuation.

<sup>3</sup> CHEKANOV 03 looked in  $130.1 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 301$  and  $318 \text{ GeV}$ . The limit is for  $\sqrt{s} = 318 \text{ GeV}$  and assumes  $m_t = 175 \text{ GeV}$ .

### t $\bar{t}$ Production Cross Section in p $\bar{p}$ Collisions at $\sqrt{s} = 1.8 \text{ TeV}$

Only the final combined  $t\bar{t}$  production cross sections obtained from Tevatron Run I by the CDF and D0 experiments are quoted below.

<sup>1</sup> Based on  $9 \text{ fb}^{-1}$  of data. The measurement is in the channel  $t\bar{t} \rightarrow (b\ell\nu)(b\tau\nu)$ , where  $\tau$  decays into hadrons ( $\tau_h$ ), and  $\ell$  ( $e$  or  $\mu$ ) include  $\ell$  from  $\tau$  decays ( $\tau_\ell$ ). The result is for  $m_t = 173 \text{ GeV}$ .

<sup>2</sup> Based on  $8.8 \text{ fb}^{-1}$  of data. Combination of CDF and D0 measurements given, respectively, by  $\sigma(t\bar{t}; \text{CDF}) = 7.63 \pm 0.31 \pm 0.36 \pm 0.16 \text{ pb}$ ,  $\sigma(t\bar{t}; \text{D0}) = 7.56 \pm 0.20 \pm 0.32 \pm 0.46 \text{ pb}$ . All the results are for  $m_t = 172.5 \text{ GeV}$ . The  $m_t$  dependence of the mean value is parametrized in eq. (1) and shown in Fig. 2.

<sup>3</sup> Based on  $9.7 \text{ fb}^{-1}$  of data. Differential cross sections with respect to  $m_{t\bar{t}}$ ,  $|y(\text{top})|$ ,  $E_T(\text{top})$  are shown in Figs. 9, 10, 11, respectively, and are compared to the predictions of MC models.

<sup>4</sup> Based on  $8.8 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .

<sup>5</sup> Based on  $8.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Measure the  $t\bar{t}$  cross section simultaneously with the fraction of  $t \rightarrow Wb$  decays. The correlation coefficient between

# Quark Particle Listings

*t*

- those two measurements is  $-0.434$ . Assume unitarity of the  $3 \times 3$  CKM matrix and set  $|V_{tb}| > 0.89$  at 95% CL.
- <sup>6</sup> Based on  $2.2 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at 1.96 TeV. The result assumes the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>7</sup> Based on  $1.12 \text{ fb}^{-1}$  and assumes  $m_t = 175 \text{ GeV}$ , where the cross section changes by  $\pm 0.1 \text{ pb}$  for every  $\mp 1 \text{ GeV}$  shift in  $m_t$ . AALTONEN 11D fits simultaneously a jet production cross section and the  $b$ -tagging efficiency and find improvements in both measurements.
- <sup>8</sup> Based on  $2.7 \text{ fb}^{-1}$ . The first error is from statistics and systematics, the second is from luminosity. The result is for  $m_t = 175 \text{ GeV}$ . AALTONEN 11W fits simultaneously a jet flavor discriminator between  $b$ -,  $c$ -, and light-quarks, and find significant reduction in the systematic error.
- <sup>9</sup> Based on  $2.2 \text{ fb}^{-1}$ . The result is for  $m_t = 172.5 \text{ GeV}$ . AALTONEN 11Y selects multi-jet events with large  $E_T$ , and vetoes identified electrons and muons.
- <sup>10</sup> Based on  $5.3 \text{ fb}^{-1}$ . The error is statistical + systematic + luminosity combined. The result is for  $m_t = 172.5 \text{ GeV}$ . The results for other  $m_t$  values are given in Table XII and eq.(10) of ABAZOV 11E.
- <sup>11</sup> Combination of a dilepton measurement presented in ABAZOV 11Z (based on  $5.4 \text{ fb}^{-1}$ ), which yields  $7.36^{+0.90}_{-0.79} \text{ (stat+syst) pb}$ , and the lepton + jets measurement of ABAZOV 11E. The result is for  $m_t = 172.5 \text{ GeV}$ . The results for other  $m_t$  values is given by eq.(5) of ABAZOV 11A.
- <sup>12</sup> Based on  $2.8 \text{ fb}^{-1}$ . The result is for  $m_t = 175 \text{ GeV}$ .
- <sup>13</sup> Based on  $2.9 \text{ fb}^{-1}$ . Result is obtained from the fraction of signal events in the top quark mass measurement in the all hadronic decay channel.
- <sup>14</sup> Based on  $1.7 \text{ fb}^{-1}$ . The result is for  $m_t = 175 \text{ GeV}$ . AALTONEN 10V uses soft electrons from  $b$ -hadron decays to suppress  $W$ +jets background events.
- <sup>15</sup> Based on  $4.6 \text{ fb}^{-1}$ . The result is for  $m_t = 172.5 \text{ GeV}$ . The ratio  $\sigma(t\bar{t} \rightarrow \ell\text{+jets}) / \sigma(Z/\gamma^* \rightarrow \ell\bar{\ell})$  is measured and then multiplied by the theoretical  $Z/\gamma^* \rightarrow \ell\bar{\ell}$  cross section of  $\sigma(Z/\gamma^* \rightarrow \ell\bar{\ell}) = 251.3 \pm 5.0 \text{ pb}$ , which is free from the luminosity error.
- <sup>16</sup> Based on  $1 \text{ fb}^{-1}$ . The result is for  $m_t = 175 \text{ GeV}$ .  $7.9 \pm 2.3 \text{ pb}$  is found for  $m_t = 170 \text{ GeV}$ . ABAZOV 10I uses a likelihood discriminant to separate signal from background, where the background model was created from lower jet-multiplicity data.
- <sup>17</sup> Based on  $1 \text{ fb}^{-1}$ . The result is for  $m_t = 170 \text{ GeV}$ . For  $m_t = 175 \text{ GeV}$ , the result is  $6.3^{+1.2}_{-1.1} \text{ (stat)} \pm 0.7 \text{ (syst)} \pm 0.4 \text{ (lumi) pb}$ . Cross section of  $t\bar{t}$  production has been measured in the  $t\bar{t} \rightarrow \tau_h + \text{jets}$  topology, where  $\tau_h$  denotes hadronically decaying  $\tau$  leptons. The result for the cross section times the branching ratio is  $\sigma(t\bar{t}) \cdot B(t\bar{t} \rightarrow \tau_h + \text{jets}) = 0.60^{+0.23+0.15}_{-0.22-0.14} \pm 0.04 \text{ pb}$  for  $m_t = 170 \text{ GeV}$ .
- <sup>18</sup> Based on  $1.1 \text{ fb}^{-1}$ . The result is for  $B(W \rightarrow \ell\nu) = 10.8\%$  and  $m_t = 175 \text{ GeV}$ ; the mean value is  $9.8$  for  $m_t = 172.5 \text{ GeV}$  and  $10.1$  for  $m_t = 170 \text{ GeV}$ . AALTONEN 09AD used high  $p_T$   $e$  or  $\mu$  with an isolated track to select  $t\bar{t}$  decays into dileptons including  $\ell = \tau$ . The result is based on the candidate event samples with and without vertex  $b$ -tag.
- <sup>19</sup> Based on  $2 \text{ fb}^{-1}$ . The result is for  $m_t = 175 \text{ GeV}$ ; the mean value is 3% higher for  $m_t = 170 \text{ GeV}$  and 4% lower for  $m_t = 180 \text{ GeV}$ .
- <sup>20</sup> Result is based on  $1 \text{ fb}^{-1}$  of data. The result is for  $m_t = 170 \text{ GeV}$ , and the mean value decreases with increasing  $m_t$ ; see their Fig. 2. The result is obtained after combining  $\ell + \text{jets}$ ,  $\ell\bar{\ell}$ , and  $\ell\tau$  final states, and the ratios of the extracted cross sections are  $R^{\ell\bar{\ell}}/\ell j = 0.86^{+0.19}_{-0.17}$  and  $R^{\ell\tau}/\ell\bar{\ell} - \ell j = 0.97^{+0.32}_{-0.29}$ , consistent with the SM expectation of  $R = 1$ . This leads to the upper bound of  $B(t \rightarrow bH^+) \text{ as a function of } m_{H^+}$ . Results are shown in their Fig. 1 for  $B(H^+ \rightarrow \tau\nu) = 1$  and  $B(H^+ \rightarrow c\bar{s}) = 1$  cases. Comparison of the  $m_t$  dependence of the extracted cross section and a partial NNLO prediction gives  $m_t = 169.1^{+5.9}_{-5.2} \text{ GeV}$ .
- <sup>21</sup> Result is based on  $1 \text{ fb}^{-1}$  of data. The result is for  $m_t = 170 \text{ GeV}$ , and the mean value changes by  $-0.07 [m_t(\text{GeV}) - 170] \text{ pb}$  near the reference  $m_t$  value. Comparison of the  $m_t$  dependence of the extracted cross section and a partial NNLO QCD prediction gives  $m_t = 171.5^{+9.9}_{-8.8} \text{ GeV}$ . The  $\ell\tau$  channel alone gives  $7.6^{+4.9+3.5+1.4}_{-4.3-3.4-0.9} \text{ pb}$  and the  $\ell\bar{\ell}$  channel gives  $7.5^{+1.2+0.7+0.7}_{-1.1-0.6-0.5} \text{ pb}$ .
- <sup>22</sup> Result is based on  $0.9 \text{ fb}^{-1}$  of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for  $m_t = 175 \text{ GeV}$ , and the mean value changes by  $-0.09 \text{ pb} [m_t(\text{GeV}) - 175]$ .
- <sup>23</sup> Result is based on  $0.9 \text{ fb}^{-1}$  of data. The cross section is obtained from the  $\ell + \geq 3$  jet event rates with 1 or 2  $b$ -tag, and also from the kinematical likelihood analysis of the  $\ell + 3, 4$  jet events. The result is for  $m_t = 172.6 \text{ GeV}$ , and its  $m_t$  dependence shown in Fig. 3 leads to the constraint  $m_t = 170 \pm 7 \text{ GeV}$  when compared to the SM prediction.
- <sup>24</sup> Result is based on  $360 \text{ pb}^{-1}$  of data. Events with high  $p_T$  oppositely charged dileptons  $\ell^+\ell^-$  ( $\ell = e, \mu$ ) are used to obtain cross sections for  $t\bar{t}$ ,  $W^+W^-$ , and  $Z \rightarrow \tau^+\tau^-$  production processes simultaneously. The other cross sections are given in Table IV.
- <sup>25</sup> Based on  $1.02 \text{ fb}^{-1}$  of data. Result is for  $m_t = 175 \text{ GeV}$ . Secondary vertex  $b$ -tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.
- <sup>26</sup> Based on  $425 \text{ pb}^{-1}$  of data. Result is for  $m_t = 175 \text{ GeV}$ . For  $m_t = 170.9 \text{ GeV}$ ,  $7.8 \pm 1.8 \text{ (stat + syst) pb}$  is obtained.
- <sup>27</sup> Based on  $405 \pm 25 \text{ pb}^{-1}$  of data. Result is for  $m_t = 175 \text{ GeV}$ . The last error is for luminosity. Secondary vertex  $b$ -tag and neural network are used to separate the signal events from the background.
- <sup>28</sup> Based on  $425 \text{ pb}^{-1}$  of data. Assumes  $m_t = 175 \text{ GeV}$ .
- <sup>29</sup> Based on  $\sim 425 \text{ pb}^{-1}$ . Assuming  $m_t = 175 \text{ GeV}$ . The first error is combined statistical and systematic, the second one is luminosity.
- <sup>30</sup> Based on  $\sim 318 \text{ pb}^{-1}$ . Assuming  $m_t = 178 \text{ GeV}$ . The cross section changes by  $\pm 0.08 \text{ pb}$  for each  $\mp 1 \text{ GeV}$  change in the assumed  $m_t$ . Result is for at least one  $b$ -tag. For at least two  $b$ -tagged jets,  $t\bar{t}$  signal of significance greater than  $5\sigma$  is found, and the cross section is  $10.1^{+1.6+2.0}_{-1.4-1.3} \text{ pb}$  for  $m_t = 178 \text{ GeV}$ .
- <sup>31</sup> Based on  $\sim 311 \text{ pb}^{-1}$ . Assuming  $m_t = 178 \text{ GeV}$ . For  $m_t = 175 \text{ GeV}$ , the result is  $6.0 \pm 1.2^{+0.9}_{-0.7}$ . This is the first CDF measurement without lepton identification, and hence it has sensitivity to the  $W \rightarrow \tau\nu$  mode.
- <sup>32</sup> ABULENCIA, A 06E measures the  $t\bar{t}$  production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one  $b$ -jet.  $S/B = 1/5$  has been achieved. Based on  $311 \text{ pb}^{-1}$ . Assuming  $m_t = 178 \text{ GeV}$ .

- <sup>33</sup> Based on  $\sim 318 \text{ pb}^{-1}$ . Assuming  $m_t = 178 \text{ GeV}$ . Result is for at least one  $b$ -tag. For at least two  $b$ -tagged jets, the cross section is  $11.1^{+2.3+2.5}_{-1.9-1.9} \text{ pb}$ .
- <sup>34</sup> ABAZOV 05Q measures the top-quark pair production cross section with  $\sim 230 \text{ pb}^{-1}$  of data, based on the analysis of  $W$  plus  $n$ -jet events where  $W$  decays into  $e$  or  $\mu$  plus neutrino, and at least one of the jets is  $b$ -jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes  $m_t = 175 \text{ GeV}$ ; the mean value changes by  $(175 - m_t(\text{GeV})) \times 0.06 \text{ pb}$  in the mass range 160 to 190 GeV.
- <sup>35</sup> ABAZOV 05R measures the top-quark pair production cross section with  $224\text{--}243 \text{ pb}^{-1}$  of data, based on the analysis of events with two charged leptons in the final state. The result assumes  $m_t = 175 \text{ GeV}$ ; the mean value changes by  $(175 - m_t(\text{GeV})) \times 0.08 \text{ pb}$  in the mass range 160 to 190 GeV.
- <sup>36</sup> Based on  $230 \text{ pb}^{-1}$ . Assuming  $m_t = 175 \text{ GeV}$ .
- <sup>37</sup> Based on  $194 \text{ pb}^{-1}$ . Assuming  $m_t = 175 \text{ GeV}$ .
- <sup>38</sup> Based on  $194 \pm 11 \text{ pb}^{-1}$ . Assuming  $m_t = 175 \text{ GeV}$ .
- <sup>39</sup> Based on  $162 \pm 10 \text{ pb}^{-1}$ . Assuming  $m_t = 175 \text{ GeV}$ .
- <sup>40</sup> ACOSTA 05V measures the top-quark pair production cross section with  $\sim 162 \text{ pb}^{-1}$  of data, based on the analysis of  $W$  plus  $n$ -jet events where  $W$  decays into  $e$  or  $\mu$  plus neutrino, and at least one of the jets is  $b$ -jet like. Assumes  $m_t = 175 \text{ GeV}$ .
- <sup>41</sup> ACOSTA 04I measures the top-quark pair production cross section with  $197 \pm 12 \text{ pb}^{-1}$  of data, based on the analysis of events with two charged leptons in the final state. Assumes  $m_t = 175 \text{ GeV}$ .

## Ratio of the Production Cross Sections of $t\bar{t}\gamma$ to $t\bar{t}$ at $\sqrt{s} = 1.96 \text{ TeV}$

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
$0.024 \pm 0.009$	<sup>1</sup> AALTONEN 11Z	CDF	$E_T(\gamma) > 10 \text{ GeV}$ , $ \eta(\gamma)  < 1.0$
<sup>1</sup> Based on $6.0 \text{ fb}^{-1}$ of data. The error is statistical and systematic combined. Events with lepton + $E_T + \geq 3$ jets ( $\geq 1b$ ) with and without central, high $E_T$ photon are measured. The result is consistent with the SM prediction of $0.024 \pm 0.005$ . The absolute production cross section is measured to be $0.18 \pm 0.08 \text{ fb}$ . The statistical significance is 3.0 standard deviations.			

## $t\bar{t}$ Production Cross Section in $pp$ Collisions at $\sqrt{s} = 7 \text{ TeV}$

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

- <sup>1</sup> Based on  $4.6 \text{ fb}^{-1}$  of data. Uses a template fit to distributions of  $E_T$  and jet multiplicities to measure simultaneously  $t\bar{t}$ ,  $WW$ , and  $Z/\gamma^* \rightarrow \tau\tau$  cross sections, assuming  $m_t = 172.5 \text{ GeV}$ .
- <sup>2</sup> AAD 15CC based on  $4.6 \text{ fb}^{-1}$  of data. The event selection criteria are optimized for the  $\ell\tau_h + \text{jets}$  channel. Using only this channel  $183 \pm 9 \pm 23 \pm 3 \text{ pb}$  is derived for the cross section.
- <sup>3</sup> AAIJ 15R, based on  $1.0 \text{ fb}^{-1}$  of data, reports  $0.239 \pm 0.053 \pm 0.033 \pm 0.024 \text{ pb}$  cross section for the forward fiducial region  $p_T(\mu) > 25 \text{ GeV}$ ,  $2.0 < \eta(\mu) < 4.5$ ,  $50 \text{ GeV} < p_T(b) < 100 \text{ GeV}$ ,  $2.2 < \eta(b) < 4.2$ ,  $\Delta R(\mu, b) > 0.5$ , and  $p_T(\mu+b) > 20 \text{ GeV}$ . The three errors are from statistics, systematics, and theory. The result agrees with the SM NLO prediction.
- <sup>4</sup> AAD 14AY reports  $182.9 \pm 3.1 \pm 4.2 \pm 3.6 \pm 3.3 \text{ pb}$  value based on  $4.6 \text{ fb}^{-1}$  of data. The four errors are from statistics, systematic, luminosity, and the 0.66% beam energy uncertainty. We have combined the systematic uncertainties in quadrature. The result is for  $m_t = 172.5 \text{ GeV}$ ; for other  $m_t$ ,  $\sigma(m_t) = \sigma(172.5 \text{ GeV}) \times [1 - 0.0028 \times (m_t - 172.5 \text{ GeV})]$ . The result is consistent with the SM prediction at NNLO.
- <sup>5</sup> Based on  $1.67 \text{ fb}^{-1}$  of data. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>6</sup> Based on  $3.54 \text{ fb}^{-1}$  of data.
- <sup>7</sup> Based on  $2.3 \text{ fb}^{-1}$  of data.
- <sup>8</sup> Based on  $3.9 \text{ fb}^{-1}$  of data.
- <sup>9</sup> Based on  $35 \text{ pb}^{-1}$  of data for an assumed top quark mass of  $m_t = 172.5 \text{ GeV}$ .
- <sup>10</sup> Based on  $0.70 \text{ fb}^{-1}$  of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>11</sup> Based on  $35 \text{ pb}^{-1}$  of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$  and  $173 \pm 17^{+18}_{-16} \pm 6 \text{ pb}$  is found without the  $b$ -tag.

<sup>12</sup>Based on 2.05 fb<sup>-1</sup> of data. The hadronic  $\tau$  candidates are selected using a BDT technique. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5$  GeV.

<sup>13</sup>Based on 2.0 fb<sup>-1</sup> and 2.2 fb<sup>-1</sup> of data for  $\ell = e$  and  $\ell = \mu$ , respectively. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5$  GeV.

<sup>14</sup>Based on 2.3 fb<sup>-1</sup> of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the profile likelihood-ratio (PLB) method and an assumed  $m_t$  of 172.5 GeV.

<sup>15</sup>Based on 2.9 pb<sup>-1</sup> of data. The result for single lepton channels is  $142 \pm 34^{+50}_{-31}$  pb, while for the dilepton channels is  $151^{+78+37}_{-62-24}$  pb.

<sup>16</sup>Result is based on 36 pb<sup>-1</sup> of data. The first uncertainty corresponds to the statistical and systematic uncertainties, and the second corresponds to the luminosity.

<sup>17</sup>Based on 36 pb<sup>-1</sup> of data. The ratio of  $t\bar{t}$  and  $Z/\gamma^*$  cross sections is measured as  $\sigma(pp \rightarrow t\bar{t})/\sigma(pp \rightarrow Z/\gamma^* \rightarrow e^+e^-/\mu^+\mu^-) = 0.175 \pm 0.018(\text{stat}) \pm 0.015(\text{syst})$  for  $60 < m_{\ell\ell} < 120$  GeV, for which they use an NNLO prediction for the denominator cross section of 972  $\pm$  42 pb.

<sup>18</sup>Result is based on 36 pb<sup>-1</sup> of data. The first error is from statistical and systematic uncertainties, and the second from luminosity. This is a combination of a measurement in the dilepton channel (CHATRCHYAN 11f) and the measurement in the  $\ell$  + jets channel (CHATRCHYAN 11z) which yields  $150 \pm 9 \pm 17 \pm 6$  pb.

<sup>19</sup>Result is based on  $3.1 \pm 0.3$  pb<sup>-1</sup> of data.

### $t\bar{t}$ Production Cross Section in $pp$ Collisions at $\sqrt{s} = 8$ TeV

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

<sup>1</sup>AAD 15BP based on 20.3 fb<sup>-1</sup> of data. The result is for  $m_t = 172.5$  GeV and in agreement with the SM prediction  $253^{+13}_{-15}$  pb at NNLO+NNLL.

<sup>2</sup>AAIJ 15R, based on 2.0 fb<sup>-1</sup> of data, reports  $0.289 \pm 0.043 \pm 0.040 \pm 0.029$  pb cross section for the forward fiducial region  $p_T(\mu) > 25$  GeV,  $2.0 < \eta(\mu) < 4.5$ ,  $50 \text{ GeV} < p_T(b) < 100$  GeV,  $2.2 < \eta(b) < 4.2$ ,  $\Delta R(\mu, b) > 0.5$ , and  $p_T(\mu + b) > 20$  GeV. The three errors are from statistics, systematics, and theory. The result agrees with the SM NLO prediction.

<sup>3</sup>AAD 14AY reports  $242.4 \pm 1.7 \pm 5.5 \pm 7.5 \pm 4.2$  pb value based on 20.3 fb<sup>-1</sup> of data. The four errors are from statistics, systematic, luminosity, and the 0.66% beam energy uncertainty. We have combined the systematic uncertainties in quadrature. The result is for  $m_t = 172.5$  GeV; for other  $m_t$ ,  $\sigma(m_t) = \sigma(172.5 \text{ GeV}) \times [1 - 0.0028 \times (m_t - 172.5 \text{ GeV})]$ . Also measured is the ratio  $\sigma(t\bar{t}; 8 \text{ TeV})/\sigma(t\bar{t}; 7 \text{ TeV}) = 1.326 \pm 0.024 \pm 0.015 \pm 0.049 \pm 0.001$ . The results are consistent with the SM predictions at NNLO.

<sup>4</sup>Based on 5.3 fb<sup>-1</sup> of data. The result is for  $m_t = 172.5$  GeV, and a parametrization is given in eq.(6.1) for the mean value at other  $m_t$  values. The result is in agreement with the SM prediction  $252.9^{+6.4}_{-8.6}$  pb at NNLO.

<sup>5</sup>Based on 19.6 fb<sup>-1</sup> of data. The measurement is in the channel  $t\bar{t} \rightarrow (b\ell\nu)(b\tau\nu)$ , where  $\tau$  decays into hadrons ( $\tau_h$ ). The result is for  $m_t = 172.5$  GeV. For  $m_t = 173.3$  GeV, the cross section is lower by 3.1 pb.

### Fraction of $t\bar{t}$ + multi-jet Events in $pp$ Collisions at $\sqrt{s} = 7$ TeV

VALUE	DOCUMENT ID	TECN	COMMENT
• • •	We do not use the following data for averages, fits, limits, etc. • • •		
	<sup>1</sup> AAD	15D ATLS	$\ell + \cancel{E}_T + n_j$ ( $n=3$ to 8)
0.332 $\pm 0.090$	<sup>2</sup> CHATRCHYAN14AE	CMS	$t\bar{t}(\ell\ell) + 0 \text{ jet}$ ( $E_T > 30 \text{ GeV}$ )
0.436 $\pm 0.098$	<sup>2</sup> CHATRCHYAN14AE	CMS	$t\bar{t}(\ell\ell) + 1 \text{ jet}$ ( $E_T > 30 \text{ GeV}$ )
0.232 $\pm 0.125$	<sup>2</sup> CHATRCHYAN14AE	CMS	$t\bar{t}(\ell\ell) + \geq 2 \text{ jet}$ ( $E_T > 30 \text{ GeV}$ )

<sup>1</sup>Based on 4.6 fb<sup>-1</sup> of data. Fiducial  $t\bar{t}$  production cross section is presented as a function of the jet multiplicity for up to eight jets with the jet  $p_T$  threshold of 25, 40, 60, and 80 GeV, and as a function of jet  $p_T$  up to the 5th jet. MC models can be discriminated by using data for high jet multiplicity and by  $p_T$  distributions of the leading and 5th jet.

<sup>2</sup>Based on 5.0 fb<sup>-1</sup> of data. Events with two oppositely charged leptons, large  $\cancel{E}_T$  and jets with at least 1  $b$ -tag are used to measure the fraction of  $t\bar{t}$  plus additional jets. The gap fraction ( $n=0$  jet rate) as a function of the jet  $p_T$  and that of  $H_T$ , the scalar sum of the  $p_T$ 's of additional jets, is shown in Fig. 8.

### $t\bar{t}$ Charge Asymmetry ( $A_C$ ) in $pp$ Collisions at $\sqrt{s} = 7$ TeV

$A_C = (N(\Delta|y| > 0) - N(\Delta|y| < 0)) / (N(\Delta|y| > 0) + N(\Delta|y| < 0))$  where  $\Delta|y| = |y_t| - |y_{\bar{t}}|$  is the difference between the absolute values of the top and antitop rapidities and  $N$  is the number of events with  $\Delta|y|$  positive or negative.

<sup>1</sup>AAD 15AJ based on 4.6 fb<sup>-1</sup> of data. After kinematic reconstruction the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. The lepton charge asymmetry is measured as  $A_C^\ell = 0.024 \pm 0.015 \pm 0.009$ . All the measurements are consistent with the SM predictions.

<sup>2</sup>Based on 4.7 fb<sup>-1</sup> of data. The result is consistent with the SM prediction of  $A_C = 0.0123 \pm 0.0005$ . The asymmetry is  $0.011 \pm 0.018$  if restricted to those events where  $\beta_Z(t\bar{t}) > 0.6$ , which is also consistent with the SM prediction of  $0.020^{+0.006}_{-0.007}$ .

<sup>3</sup>Based on 5.0 fb<sup>-1</sup> of data. The lepton charge asymmetry is measured as  $A_C^\ell = 0.009 \pm 0.0010 \pm 0.006$ .  $A_C^\ell$  dependences on  $m_{t\bar{t}}$ ,  $|y(t\bar{t})|$ , and  $p_T(t\bar{t})$  are given in Fig. 5. All measurements are consistent with the SM predictions.

<sup>4</sup>Based on 1.04 fb<sup>-1</sup> of data. The result is consistent with  $A_C = 0.006 \pm 0.002$  (MC at NLO). No significant dependence of  $A_C$  on  $m_{t\bar{t}}$  is observed.

<sup>5</sup>Based on 5.0 fb<sup>-1</sup> of data at 7 TeV.

<sup>6</sup>Based on 1.09 fb<sup>-1</sup> of data. The result is consistent with the SM predictions.

### $t$ -quark Polarization in $t\bar{t}$ Events in $p\bar{p}$ Collisions at $\sqrt{s} = 1.96$ TeV

<sup>1</sup>ABAZOV 15K based on 9.7 fb<sup>-1</sup> of data. The value is top quark polarization times spin analyzing power in the beam basis. The result is consistent with the SM prediction of  $-0.0019 \pm 0.0005$ .

# Quark Particle Listings

*t*

## *t*-quark Polarization in *t* $\bar{t}$ Events in *p**p* Collisions at $\sqrt{s} = 7$ TeV

The double differential distribution in polar angles,  $\theta_1$  ( $\theta_2$ ) of the decay particle of the top (anti-top) decay products, is parametrized as  $(1/\sigma)d\sigma/(d\cos\theta_1 d\cos\theta_2) = (1/4) (1 + A_+ \cos\theta_1 + A_- \cos\theta_2 - C \cos\theta_1 \cos\theta_2)$ . The charged lepton is used to tag *t* or  $\bar{t}$ . The coefficient  $A_+$  and  $A_-$  measure the average helicity of *t* and  $\bar{t}$ , respectively.  $A_{CPC}$  assumes *CP* conservation, whereas  $A_{CPV}$  corresponds to maximal *CP* violation.

$19.6 \pm 6.5$	<sup>10</sup> ABAZOV	11AH D0	$\ell + \cancel{E}_T + \geq 4$ jets ( $\geq 1b$ -tag)
$17 \pm 8$	<sup>11</sup> AALTONEN	08AB CDF	<i>p</i> $\bar{p}$ frame
$24 \pm 14$	<sup>11</sup> AALTONEN	08AB CDF	<i>t</i> $\bar{t}$ frame
$12 \pm 8 \pm 1$	<sup>12</sup> ABAZOV	08L D0	$\ell + \cancel{E}_T + \geq 4$ jets

<sup>1</sup> ABAZOV 15K based on 9.7 fb<sup>-1</sup> of data. The result is consistent with the SM predictions. By combining with the previous D0 measurement in the  $\ell$  + jet channel ABAZOV 14H,  $A_{FB}^{\ell} = 0.118 \pm 0.025 \pm 0.013$  is obtained.

<sup>2</sup> Based on 9.1 fb<sup>-1</sup> of data. Both results are consistent with the SM predictions. By combining with the previous CDF measurement in the  $\ell$  + jet channel AALTONEN 13X,  $A_{FB}^{\ell} = 0.090^{+0.028}_{-0.026}$  is obtained. The combined result is about two sigma larger than the SM prediction of  $A_{FB}^{\ell} = 0.038 \pm 0.003$ .

<sup>3</sup> Based on 9.7 fb<sup>-1</sup> of *p* $\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV. The asymmetry is corrected for the production level for events with  $|y_{\ell}| < 1.5$ . Asymmetry as functions of  $E_T(\ell)$  and  $|y_{\ell}|$  are given in Figs. 7 and 8, respectively. Combination with the asymmetry measured in the dilepton channel [ABAZOV 13P] gives  $A_{FB}^{\ell} = 4.2 \pm 2.0 \pm 1.4$  %, in agreement with the SM prediction of 2.0%.

<sup>4</sup> Based on 9.7 fb<sup>-1</sup> of data of *p* $\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV. The measured asymmetry is in agreement with the SM predictions of  $8.8 \pm 0.9$  % [BERNREUTHER 12], which includes the EW effects. The dependences of the asymmetry on  $|y(t) - y(\bar{t})|$  and  $m_{t\bar{t}}$  are shown in Figs. 9 and 10, respectively.

<sup>5</sup> Based on 9.4 fb<sup>-1</sup> of data. Reported  $A_{FB}^{\ell}$  values come from the determination of  $a_i$  coefficients of  $d\sigma/d(\cos\theta_{\ell}) = \sum_i a_i P_i(\cos\theta_{\ell})$  measurement. The result of  $a_1/a_0 = (40 \pm 12)\%$  seems higher than the NLO SM prediction of  $(15^{+7}_{-3})\%$ .

<sup>6</sup> Based on 9.4 fb<sup>-1</sup> of data. The quoted result is the asymmetry at the parton level.

<sup>7</sup> Based on 9.4 fb<sup>-1</sup> of data. The observed asymmetry is to be compared with the SM prediction of  $A_{FB}^{\ell} = 0.038 \pm 0.003$ .

<sup>8</sup> Based on 5.4 fb<sup>-1</sup> of data. ABAZOV 13A studied the dilepton channel of the *t* $\bar{t}$  events and measured the leptonic forward-backward asymmetry to be  $A_{FB}^{\ell} = 5.8 \pm 5.1 \pm 1.3\%$ , which is consistent with the SM (QCD+EW) prediction of  $4.7 \pm 0.1\%$ . The result is obtained after combining the measurement  $(15.2 \pm 4.0\%)$  in the  $\ell$  + jets channel ABAZOV 11AH. The top quark helicity is measured by using the neutrino weighting method to be consistent with zero in both dilepton and  $\ell$  + jets channels.

<sup>9</sup> Based on 5.3 fb<sup>-1</sup> of data. The error is statistical and systematic combined. Events with lepton +  $E_T + \geq 4$  jets ( $\geq 1b$ ) are used. AALTONEN 11F also measures the asymmetry as a function of the rapidity difference  $|y_{\ell} - y_{\bar{\ell}}|$ . The NLO QCD predictions [MCFM] are  $(4.0 \pm 0.6)\%$  and  $(8.8 \pm 1.3)\%$  for  $m_{t\bar{t}} < 450$  and  $> 450$  GeV, respectively.

<sup>10</sup> Based on 5.4 fb<sup>-1</sup> of data. The error is statistical and systematic combined. The quoted asymmetry is obtained after unfolding to be compared with the MC@NLO prediction of  $(5.0 \pm 0.1)\%$ . No significant difference between the  $m_{t\bar{t}} < 450$  and  $> 450$  GeV data samples is found. A corrected asymmetry based on the lepton from a top quark decay of  $(15.2 \pm 4.0)\%$  is measured to be compared to the MC@NLO prediction of  $(2.1 \pm 0.1)\%$ .

<sup>11</sup> Result is based on 1.9 fb<sup>-1</sup> of data. The *FB* asymmetry in the *t* $\bar{t}$  events has been measured in the  $\ell$  + jets mode, where the lepton charge is used as the flavor tag. The asymmetry in the *p* $\bar{p}$  frame is defined in terms of  $\cos(\theta)$  of hadronically decaying *t*-quark momentum, whereas that in the *t* $\bar{t}$  frame is defined in terms of the *t* and  $\bar{t}$  rapidity difference. The results are consistent ( $\leq 2\sigma$ ) with the SM predictions.

<sup>12</sup> Result is based on 0.9 fb<sup>-1</sup> of data. The asymmetry in the number of *t* $\bar{t}$  events with  $y_t > y_{\bar{t}}$  and those with  $y_t < y_{\bar{t}}$  has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of 0.8% by MC@NLO, and an upper bound on the  $Z' \rightarrow t\bar{t}$  contribution for the SM Z-like couplings is given in Fig. 2 for  $350 \text{ GeV} < m_{Z'} < 1 \text{ TeV}$ .

## *t*-Quark Electric Charge

VALUE	DOCUMENT ID	TECN	COMMENT
<b><math>0.64 \pm 0.02 \pm 0.08</math></b>	<sup>1</sup> AAD	13AY ATLS	$\ell + \cancel{E}_T + \geq 4$ jets ( $\geq 1$ <i>b</i> )
• • • We do not use the following data for averages, fits, limits, etc. • • •			
	<sup>2</sup> ABAZOV	14D D0	$\ell + \cancel{E}_T + \geq 4$ jets ( $\geq 2$ <i>b</i> )
	<sup>3</sup> AALTONEN	13J CDF	<i>p</i> $\bar{p}$ at 1.96 TeV
	<sup>4</sup> AALTONEN	10S CDF	Repl. by AALTONEN 13J
	<sup>5</sup> ABAZOV	07c D0	fraction of $ q  = 4e/3$ pair

<sup>1</sup> AAD 13AY result is based on 2.05 fb<sup>-1</sup> of *p**p* data at  $\sqrt{s} = 7$  TeV, the result is obtained by reconstructing *t* $\bar{t}$  events in the lepton + jets final state, where *b*-jet charges are tagged by the jet-charge algorithm. This measurement excludes the charge  $-4/3$  assignment to the top quark at more than 8 standard deviations.

<sup>2</sup> ABAZOV 14D result is based on 5.3 fb<sup>-1</sup> of *p* $\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV. The electric charge of *b* + *W* system in *t* $\bar{t}$  candidate events is measured from the charges of the leptons from *W* decay and in *b* jets. Under the assumption that the *b* + *W* system consists of the sum of the top quark and the charge  $-4/3$  quark  $b'(-4/3)$  of the same mass, the top quark fraction is found to be  $f = 0.88 \pm 0.13$  (stat)  $\pm 0.11$  (syst), or the upper bound for the  $b'(-4/3)$  contamination of  $1 - f < 0.46$  (95% CL).

<sup>3</sup> AALTONEN 13J excludes the charge  $-4/3$  assignment to the top quark at 99% CL, using 5.6 fb<sup>-1</sup> of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Result is obtained by reconstructing *t* $\bar{t}$  events in the lepton + jets final state, where *b*-jet charges are tagged by the jet-charge algorithm.

<sup>4</sup> AALTONEN 10S excludes the charge  $-4/3$  assignment for the top quark [CHANG 99] at 95% CL, using 2.7 fb<sup>-1</sup> of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Result is obtained by reconstructing *t* $\bar{t}$  events in the lepton + jets final state, where *b*-jet charges are tagged by the SLT (soft lepton tag) algorithm.

<sup>5</sup> ABAZOV 07c reports an upper limit  $\rho < 0.80$  (90% CL) on the fraction  $\rho$  of exotic quark pairs  $Q\bar{Q}$  with electric charge  $|q| = 4e/3$  in *t* $\bar{t}$  candidate events with high  $p_T$  lepton, missing  $E_T$  and  $\geq 4$  jets. The result is obtained by measuring the fraction of events in which the quark pair decays into  $W^- + b$  and  $W^+ + \bar{b}$ , where *b* and  $\bar{b}$  jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on 370 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV.

1 AAD 15BY based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Limit on pair-produced vector-like  $b'$  assuming the branching fractions to  $W$ ,  $Z$ , and  $h$  modes of the singlet model. Used events containing  $\geq 2\ell + \cancel{E}_T + \geq 2j$  ( $\geq 1b$ ) and including a same-sign lepton pair.

2 AAD 15BY based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Limit on pair-produced chiral  $b'$ -quark. Used events containing  $\geq 2\ell + \cancel{E}_T + \geq 2j$  ( $\geq 1b$ ) and including a same-sign lepton pair.

3 AAD 15Z based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Used events with  $\ell + \cancel{E}_T + \geq 6j$  ( $\geq 1b$ ) and at least one pair of jets from weak boson decay, primarily designed to select the signature  $b'\bar{b}' \rightarrow WWt\bar{t} \rightarrow WWWWb\bar{b}$ . This is a limit on pair-produced vector-like  $b'$ . The lower mass limit is 640 GeV for a vector-like singlet  $b'$ .

4 Based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. No significant excess over SM expectation is found in the search for pair production or single production of  $b'$  in the events with dilepton from a high  $p_T$   $Z$  and additional jets ( $\geq 1b$ -tag). If instead of  $B(b' \rightarrow Wt) = 1$  an electroweak singlet with  $B(b' \rightarrow Wt) \sim 0.45$  is assumed, the limit reduces to 685 GeV.

5 Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 13i looked for events with one isolated electron or muon, large  $\cancel{E}_T$ , and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

6 Result is based on 1.1 fb<sup>-1</sup> of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for  $2 < c\tau < 7000$  mm; see Fig. 3. 95% CL excluded region of  $b'$  lifetime and mass is shown in Fig. 4.

7 ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of 90 pb<sup>-1</sup> of  $\sqrt{s}=1.8$  TeV  $p\bar{p}$  collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge (2/3) $e$  quark ( $t'$ ) is 220 GeV. The  $t'$  bound is higher than the  $b'$  bound because  $t'$  is more likely to produce charged hadrons than  $b'$ . The 95% CL upper bounds for the production cross sections are given in their Fig. 3.

8 AAD 15AR based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Used lepton-plus-jets final state. See Fig. 24 for mass limits in the plane of  $B(b' \rightarrow Wt)$  vs.  $B(b' \rightarrow Hb)$  from  $b'\bar{b}' \rightarrow Hb + X$  searches.

9 AAD 15CN based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Limit on pair-production of chiral  $b'$ -quark. Used events with  $\ell + \cancel{E}_T + \geq 4j$  (non- $b$ -tagged). Limits on a heavy vector-like quark, which decays into  $Wq$ ,  $Zq$ ,  $hq$ , are presented in the plane  $B(Q \rightarrow Wq)$  vs.  $B(Q \rightarrow hq)$  in Fig. 12.

10 Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. No signal is found for the search of heavy quark pair production that decay into  $W$  and a  $t$  quark in the events with a high  $p_T$  isolated lepton, large  $\cancel{E}_T$ , and at least 6 jets in which one, two or more dijets are from  $W$ .

11 Based on 2.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. No  $b' \rightarrow Zb$  invariant mass peak is found in the search of heavy quark pair production that decay into  $Z$  and a  $b$  quark in events with  $Z \rightarrow e^+e^-$  and at least one  $b$ -jet. The lower mass limit is 358 GeV for a vector-like singlet  $b'$  mixing solely with the third SM generation.

12 Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. No signal is found for the search of heavy quark pair production that decay into  $W$  and a quark in the events with dileptons, large  $\cancel{E}_T$ , and  $\geq 2$  jets.

13 Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. AAD 12bE looked for events with two isolated like-sign leptons and at least 2 jets, large  $\cancel{E}_T$  and  $H_T > 350$  GeV.

14 Based on 5 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 12bH searched for QCD and EW production of single and pair of degenerate 4<sup>th</sup> generation quarks that decay to  $bW$  or  $tW$ . Absence of signal in events with one lepton, same-sign dileptons or tripletons gives the bound. With a mass difference of 25 GeV/ $c^2$  between  $m_{t'}$  and  $m_{b'}$ , the corresponding limit shifts by about  $\pm 20$  GeV/ $c^2$ .

15 Based on 4.9 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 12x looked for events with tripletons or same-sign dileptons and at least one  $b$  jet.

16 Based on 4.8 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. AALTONEN 11j looked for events with  $\ell + \cancel{E}_T + \geq 5j$  ( $\geq 1b$  or  $c$ ). No signal is observed and the bound  $\sigma(b'\bar{b}')$  < 30 fb for  $m_{b'} > 375$  GeV is found for  $B(b' \rightarrow Wt) = 1$ .

17 Based on 34 pb<sup>-1</sup> of data in  $pp$  collisions at 7 TeV. CHATRCHYAN 11L looked for multi-jet events with tripletons or same-sign dileptons. No excess above the SM background excludes  $m_{b'}$  between 255 and 361 GeV at 95% CL for  $B(b' \rightarrow Wt) = 1$ .

18 Based on 2.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. AALTONEN 10H looked for pair production of heavy quarks which decay into  $tW^-$  or  $tW^+$ , in events with same sign dileptons ( $e$  or  $\mu$ ), several jets and large missing  $E_T$ . The result is obtained for  $b'$  which decays into  $tW^-$ . For the charge 5/3 quark ( $T_{5/3}$ ) which decays into  $tW^+$ ,  $m_{T_{5/3}} > 365$  GeV (95% CL) is found when it has the charge  $-1/3$  partner  $B$  of the same mass.

19 FLACCO 10 result is obtained from AALTONEN 10H result of  $m_{b'} > 338$  GeV, by relaxing the condition  $B(b' \rightarrow Wt) = 100\%$  when  $m_{b'} > m_{t'}$ .

20 Result is based on 1.06 fb<sup>-1</sup> of data. No excess from the SM  $Z$ +jet events is found when  $Z$  decays into  $ee$  or  $\mu\mu$ . The  $m_{b'}$  bound is found by comparing the resulting upper bound on  $\sigma(b'\bar{b}')$  [ $1-(1-B(b' \rightarrow Zb))$ ] and the LO estimate of the  $b'$  pair production cross section shown in Fig. 38 of the article.

21 HUANG 08 reexamined the  $b'$  mass lower bound of 268 GeV obtained in AALTONEN 07c that assumes  $B(b' \rightarrow Zb) = 1$ , which does not hold for  $m_{b'} > 255$  GeV. The lower mass bound is given in the plane of  $\sin^2(\theta_{b'})$  and  $m_{b'}$ .

22 AFFOLDER 00 looked for  $b'$  that decays in to  $b+Z$ . The signal searched for is  $bbZZ$  events where one  $Z$  decays into  $e^+e^-$  or  $\mu^+\mu^-$  and the other  $Z$  decays hadronically. The bound assumes  $B(b' \rightarrow Zb) = 100\%$ . Between 100 GeV and 199 GeV, the 95%CL upper bound on  $\sigma(b' \rightarrow \bar{b}') \times B^2(b' \rightarrow Zb)$  is also given (see their Fig. 2).

23 ABE 98N looked for  $Z \rightarrow e^+e^-$  decays with displaced vertices. Quoted limit assumes  $B(b' \rightarrow Zb) = 1$  and  $c\tau_{b'} = 1$  cm. The limit is lower than  $m_Z + m_b$  ( $\sim 96$  GeV) if  $c\tau > 22$  cm or  $c\tau < 0.009$  cm. See their Fig. 4.

24 ABACHI 97D searched for  $b'$  that decays mainly via FCNC. They obtained 95%CL upper bounds on  $B(b'\bar{b}' \rightarrow \gamma + 3 \text{ jets})$  and  $B(b'\bar{b}' \rightarrow 2\gamma + 2 \text{ jets})$ , which can be interpreted as the lower mass bound  $m_{b'} > m_Z + m_b$ .

25 ABACHI 95F bound on the top-quark also applies to  $b'$  and  $t'$  quarks that decay predominantly into  $W$ . See FROGGATT 97.

26 MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes  $B(b' \rightarrow b\ell^+\ell^-) = 1\%$ . For an exotic quark decaying only via virtual  $Z$  [ $B(b\ell^+\ell^-) = 3\%$ ], the limit is 85 GeV.

27 ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to  $b'$  quarks, as discussed in ABE 90B.

28 ABE 90B exclude the region 28–72 GeV.

29 AKESSON 90 searched for events having an electron with  $p_T > 12$  GeV, missing momentum > 15 GeV, and a jet with  $E_T > 10$  GeV,  $|\eta| < 2.2$ , and excluded  $m_{b'}$  between 30 and 69 GeV.

30 For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

31 ALBAJAR 88 study events at  $E_{cm} = 546$  and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the  $b'\bar{b}'$  production cross section and by assuming that it cannot be produced in  $W$  decays. The value quoted here is revised using the full  $O(\alpha_s^3)$  cross section of ALTARELLI 88.

#### $b'(-1/3)$ mass limits from single production in $p\bar{p}$ and $pp$ collisions

1 Based on 19.7 fb<sup>-1</sup> of data in  $pp$  collisions at 8 TeV. Limit on left-handed  $b'$  assuming 100% decay to  $tW$  and using all-hadronic, lepton + jets, and dilepton final states.

2 Based on 19.7 fb<sup>-1</sup> of data in  $pp$  collisions at 8 TeV. Limit on right-handed  $b'$  assuming 100% decay to  $tW$  and using all-hadronic, lepton + jets, and dilepton final states.

3 Based on 19.7 fb<sup>-1</sup> of data in  $pp$  collisions at 8 TeV. Limit on vector-like  $b'$  assuming 100% decay to  $tW$  and using all-hadronic, lepton+ jets, and dilepton final states.

4 Based on 5.4 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. ABAZOV 11F looked for single production of  $b'$  via the  $W$  or  $Z$  coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes  $p\bar{p} \rightarrow b'q \rightarrow Wuq$ , and  $p\bar{p} \rightarrow b'q \rightarrow Zdq$  are given in Figs. 3 and 4,

See key on page 601

## Quark Particle Listings

 $b'$  (Fourth Generation) Quark,  $t'$  (Fourth Generation) Quark

respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

MASS LIMITS for  $b'$  (4<sup>th</sup> Generation) Quark or Hadron in  $e^+e^-$  Collisions

Search for hadrons containing a fourth-generation  $-1/3$  quark denoted  $b'$ .

The last column specifies the assumption for the decay mode ( $CC$  denotes the conventional charged-current decay) and the event signature which is looked for.

<sup>1</sup> DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes  $b' \rightarrow bg$  for  $B(b' \rightarrow bg) > 65\%$   $b' \rightarrow b\gamma$  for  $B(b' \rightarrow b\gamma) > 5\%$  are excluded. Charged Higgs decay were not discussed.

<sup>2</sup> ABDALLAH 07 searched for  $b'$  pair production at  $E_{\text{cm}}=196\text{--}209$  GeV, with  $420\text{ pb}^{-1}$ . No signal leads to the 95% CL upper limits on  $B(b' \rightarrow bZ)$  and  $B(b' \rightarrow cW)$  for  $m_{b'} = 96$  to  $103$  GeV.

<sup>3</sup> ADRIANI 93G search for vector quarkonium states near  $Z$  and give limit on quarkonium- $Z$  mixing parameter  $\delta m^2 < (10\text{--}30)$  GeV<sup>2</sup> (95%CL) for the mass  $88\text{--}94.5$  GeV. Using Richardson potential, a  $1S$  ( $b'\bar{b}'$ ) state is excluded for the mass range  $87.7\text{--}94.7$  GeV. This range depends on the potential choice.

<sup>4</sup> ABREU 90D assumed  $m_{H^-} < m_{b'} - 3$  GeV.

<sup>5</sup> Superseded by ABREU 91F.

<sup>6</sup> AKRAWY 90B search was restricted to data near the  $Z$  peak at  $E_{\text{cm}} = 91.26$  GeV at LEP. The excluded region is between  $23.6$  and  $41.4$  GeV if no  $H^+$  decays exist. For charged Higgs decays the excluded regions are between  $(m_{H^+} + 1.5 \text{ GeV})$  and  $45.5$  GeV.

<sup>7</sup> AKRAWY 90J search for isolated photons in hadronic  $Z$  decay and derive  $B(Z \rightarrow b'\bar{b}')B(b' \rightarrow \gamma X)/B(Z \rightarrow \text{hadrons}) < 2.2 \times 10^{-3}$ . Mass limit assumes  $B(b' \rightarrow \gamma X) > 10\%$ .

<sup>8</sup> ABE 89E search at  $E_{\text{cm}} = 56\text{--}57$  GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.

<sup>9</sup> ABE 89G search was at  $E_{\text{cm}} = 55\text{--}60.8$  GeV at TRISTAN.

<sup>10</sup> If the photonic decay mode is large ( $B(b' \rightarrow b\gamma) > 25\%$ ), the ABRAMS 89C limit is  $45.4$  GeV. The limit for Higgs decay ( $b' \rightarrow cH^-, H^- \rightarrow \bar{\nu}_s$ ) is  $45.2$  GeV.

<sup>11</sup> ADACHI 89C search was at  $E_{\text{cm}} = 56.5\text{--}60.8$  GeV at TRISTAN using multi-hadron events accompanying muons.

<sup>12</sup> ADACHI 89C also gives limits for any mixture of  $CC$  and  $bg$  decays.

<sup>13</sup> ENO 89 search at  $E_{\text{cm}} = 50\text{--}60.8$  at TRISTAN.

<sup>14</sup> ENO 89 considers arbitrary mixture of the charged current,  $bg$ , and  $b\gamma$  decays.

<sup>15</sup> IGARASHI 88 searches for leptons in low-thrust events and gives  $\Delta R(b') < 0.26$  (95% CL) assuming charged current decay, which translates to  $m_{b'} > 24.4$  GeV.

<sup>16</sup> SAGAWA 88 set limit  $\sigma(\text{top}) < 6.1$  pb at CL=95% for top-flavored hadron production from event shape analyses at  $E_{\text{cm}} = 52$  GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of  $23.8$  GeV for charge  $-1/3$  quarks.

<sup>17</sup> ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section,  $\Delta R$ , as a function of the minimum c.m. energy (see their figure 3). Production of a pair of  $1/3$  charge quarks is excluded up to  $E_{\text{cm}} = 45.4$  GeV.

<sup>18</sup> ALTHOFF 84C narrow state search sets limit  $\Gamma(e^+e^-)B(\text{hadrons}) < 2.4$  keV CL = 95% and heavy charge  $1/3$  quark pair production  $m > 21$  GeV, CL = 95%.

<sup>19</sup> ALTHOFF 84I exclude heavy quark pair production for  $7 < m < 19$  GeV ( $1/3$  charge) using aplanarity distributions (CL = 95%).

<sup>1</sup> AAD 15AR based on  $20.3\text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 8$  TeV. Used lepton-plus-jets final state. See Fig. 20 for mass limits in the plane of  $B(t' \rightarrow Ht)$  vs.  $B(t' \rightarrow Wb)$  from a combination of  $t'\bar{t}' \rightarrow Wb + X$  and  $t'\bar{t}' \rightarrow Ht + X$  searches. Any branching ratio scenario is excluded for mass below  $715$  GeV.

<sup>2</sup> AAD 15BY based on  $20.3\text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 8$  TeV. Limit on pair-produced vector-like  $t'$  assuming the branching fractions to  $W, Z$ , and  $h$  modes of the singlet lepton pair. Used events containing  $\geq 2\ell + \cancel{E}_T + \geq 2j$  ( $\geq 1b$ ) and including a same-sign lepton pair.

<sup>3</sup> KHACHATRYAN 15AI based on  $19.7\text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 8$  TeV. The search exploits all-hadronic final states by tagging boosted Higgs boson using jet substructure and  $b$ -tagging.

# Quark Particle Listings

## $t'$ (Fourth Generation) Quark, Free Quark Searches

- <sup>4</sup> Based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. No significant excess over SM expectation is found in the search for pair production or single production of  $t'$  in the events with dilepton from a high  $p_T$   $Z$  and additional jets ( $\geq 1$   $b$ -tag). If instead of  $B(b' \rightarrow Wt) = 1$  an electroweak singlet with  $B(b' \rightarrow Wt) \sim 0.45$  is assumed, the limit reduces to 685 GeV.
- <sup>5</sup> Based on 19.5 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. The  $t'$  quark is pair produced and is assumed to decay into three different final states of  $bW$ ,  $tZ$ , and  $th$ . The search is carried out using events with at least one isolated lepton.
- <sup>6</sup> Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. No signal is found for the search of heavy quark pair production that decay into  $W$  and a quark in the events with dileptons, large  $E_T$ , and  $\geq 2$  jets.
- <sup>7</sup> Based on 1.04 fb<sup>-1</sup> of data in  $pp$  collisions at 7 TeV. AAD 12c looked for  $t'\bar{t}'$  production followed by  $t'$  decaying into a top quark and  $X$ , an invisible particle, in a final state with an isolated high- $p_T$  lepton, four or more jets, and a large missing transverse energy. No excess over the SM  $t\bar{t}$  production gives the upper limit on  $t'\bar{t}'$  production cross section as a function of  $m_{t'}$  and  $m_X$ . The result is obtained for  $B(t' \rightarrow Wt) = 1$ .
- <sup>8</sup> Based on 5 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4<sup>th</sup> generation quarks that decay to  $Wb$  or  $Wt$ . Absence of signal in events with one lepton, same-sign dileptons or tripletons gives the bound. With a mass difference of 25 GeV/c<sup>2</sup> between  $m_{t'}$  and  $m_{b'}$ , the corresponding limit shifts by about  $\pm 20$  GeV/c<sup>2</sup>.
- <sup>9</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 12P looked for  $t'\bar{t}'$  production events with two isolated high  $p_T$  leptons, large  $E_T$ , and 2 high  $p_T$  jets with  $b$ -tag. The absence of signal above the SM background gives the limit for  $B(t' \rightarrow Wb) = 1$ .
- <sup>10</sup> Based on 4.7 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. No signal is found for the search of heavy quark pair production that decay into  $W$  and a  $b$  quark in the events with a high  $p_T$  isolated lepton, large  $E_T$  and at least 3 jets ( $\geq 1$   $b$ -tag). Vector-like quark of charge 2/3 with  $400 < m_{t'} < 550$  GeV and  $B(t' \rightarrow Wb) > 0.63$  is excluded at 95% CL.
- <sup>11</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 13I looked for events with one isolated electron or muon, large  $E_T$ , and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.
- <sup>12</sup> Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. No signal is found in the search for pair produced heavy quarks that decay into  $W$  boson and a  $b$  quark in the events with a high  $p_T$  isolated lepton, large  $E_T$  and at least 3 jets ( $\geq 1$   $b$ -tag).
- <sup>13</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 12Bc looked for  $t'\bar{t}'$  production events with a single isolated high  $p_T$  lepton, large  $E_T$  and at least 4 high  $p_T$  jets with a  $b$ -tag. The absence of signal above the SM background gives the limit for  $B(t' \rightarrow Wb) = 1$ .
- <sup>14</sup> Based on 5.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. AALTONEN 11AH looked for  $t'\bar{t}'$  production followed by  $t'$  decaying into a top quark and  $X$ , an invisible particle, in the all hadronic decay mode of  $t\bar{t}$ . No excess over the SM  $t\bar{t}$  production gives the upper limit on  $t'\bar{t}'$  production cross section as a function of  $m_{t'}$  and  $m_X$ . The result is obtained for  $B(t' \rightarrow Xt) = 1$ .
- <sup>15</sup> Based on 5.6 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. AALTONEN 11AL looked for  $\ell + \geq 4j$  events and set upper limits on  $\sigma(t'\bar{t}')$  as functions of  $m_{t'}$ .
- <sup>16</sup> Based on 4.8 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. AALTONEN 11I looked for  $t'\bar{t}'$  production signal when  $t'$  decays into a top quark and  $X$ , an invisible particle, in  $\ell + E_T + \text{jets}$  channel. No excess over the SM  $t\bar{t}$  production gives the upper limit on  $t'\bar{t}'$  production cross section as a function of  $m_{t'}$  and  $m_X$ . The result is obtained for  $B(t' \rightarrow Xt) = 1$ .
- <sup>17</sup> Based on 5.3 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. ABZOV 11Q looked for  $\ell + E_T + \geq 4j$  events and set upper limits on  $\sigma(t'\bar{t}')$  as functions of  $m_{t'}$ .
- <sup>18</sup> Searches for pair production of a new heavy top-like quark  $t'$  decaying to a  $W$  boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed  $t'$  mass in the lepton + jets events.
- <sup>19</sup> HUANG 08 reexamined the  $t'$  mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes  $B(b' \rightarrow qZ) = 1$  for  $q = u, c$  which does not hold when  $m_{b'} < m_{t'} - m_W$  or the mixing  $\sin^2(\theta_{bt'})$  is so tiny that the decay occurs outside of the vertex detector. Fig. 1 gives that lower bound on  $m_{t'}$  in the plane of  $\sin^2(\theta_{bt'})$  and  $m_{b'}$ .

### $t'(5/3)$ -quark/hadron mass limits in $p\bar{p}$ and $pp$ collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>750	95	<sup>1</sup> AAD 15BY ATLS	$t'(5/3) \rightarrow tW^+$	
>840	95	<sup>2</sup> AAD 15Z ATLS	$t'(5/3) \rightarrow tW^+$	
>800	95	<sup>3</sup> CHATRCHYAN 14T	CMS $t'(5/3) \rightarrow tW^+$	

<sup>1</sup> AAD 15BY based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Limit on  $t'(5/3)$  in pair and single production assuming its coupling to  $Wt$  is equal to one. Used events containing  $\geq 2\ell + E_T + \geq 2j$  ( $\geq 1$   $b$ ) and including a same-sign lepton pair.

<sup>2</sup> AAD 15Z based on 20.3 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Used events with  $\ell + E_T + \geq 6j$  ( $\geq 1$   $b$ ) and at least one pair of jets from weak boson decay, sensitive to the final state  $b\bar{b}W^+W^-W^+W^-$ .

<sup>3</sup> Based on 19.5 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 8$  TeV. Non-observation of anomaly in  $H_T$  distribution in the same sign dilepton events leads to the limit when pair produced  $t'(5/3)$  quark decays exclusively into  $t$  and  $W^+$ , resulting in the final state with  $b\bar{b}W^+W^-W^+W^-$ .

### $t'(2/3)$ mass limits from single production in $p\bar{p}$ and $pp$ collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>403	95	<sup>1</sup> ABZOV	11F D0	$q\bar{d} \rightarrow q't' \rightarrow q'(Wd)$ $\bar{\kappa}_{d't'}=1, B(t' \rightarrow Wd)=1$
>551	95	<sup>1</sup> ABZOV	11F D0	$qu \rightarrow q't' \rightarrow q(Zu)$ $\bar{\kappa}_{u't'}=\sqrt{2}, B(t' \rightarrow Zu)=1$

<sup>1</sup> Based on 5.4 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. ABZOV 11F looked for single production of  $t'$  via the  $Z$  or  $E$  coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes  $p\bar{p} \rightarrow t'q \rightarrow (Wd)q$ , and  $p\bar{p} \rightarrow t'q \rightarrow (Zd)q$  are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

## Free Quark Searches

### FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to “unglue” quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–4.

- 1 See AGNESE 15 Fig.6 for limits on vertical density as function of charge extending to  $|q|/e < 1/10$ .
- 2 AMBROSIO 00C limit is below  $11 \times 10^{-15}$  for  $0.25 < q/e < 0.5$ , and is changing rapidly near  $q/e=2/3$ , where it is  $2 \times 10^{-14}$ .
- 3 Distribution in celestial sphere was described as anisotropic.
- 4 With telescope axis at zenith angle  $40^\circ$  to the south.
- 5 Leptonik quarks.
- 6 Lifetime  $> 10^{-8}$  s; charge  $\pm 0.70, 0.68, 0.42$ ; and mass  $> 4.4, 4.8$ , and  $20$  GeV, respectively.
- 7 Time delayed air shower search.
- 8 Prompt air shower search.
- 9 Also  $e/4$  and  $e/6$  charges.
- 10 No events in subsequent experiments.

- 1 95% CL limit for fractional charge particles with  $0.18e \leq |Q_{residual}| \leq 0.82e$  in total of 70.1 mg of silicone oil.
- 2 95% CL limit for particles with fractional charge  $|Q_{residual}| > 0.16e$  in total of 17.4 mg of silicone oil.
- 3 Also set limits for  $Q = \pm e/6$ .
- 4 Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.
- 5 Limit inferred by JONES 77B.

# LIGHT UNFLAVORED MESONS ( $S = C = B = 0$ )

For  $I = 1$  ( $\pi, b, \rho, a$ ):  $u\bar{d}, (u\bar{u}-d\bar{d})/\sqrt{2}, d\bar{u}$ ;  
for  $I = 0$  ( $\eta, \eta', h, h', \omega, \phi, f, f'$ ):  $c_1(u\bar{u}+d\bar{d}) + c_2(s\bar{s})$

 $\pi^\pm$ 

$$I^G(J^P) = 1^-(0^-)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

## $\pi^\pm$ MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in  $\pi^-$ -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with pi-mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of  $> 0.005$  MeV have been omitted from this Listing.

139.5686 ±0.0020	CARTER	76	CNTR	—	Mesonic atoms
139.5660 ±0.0024	<sup>7,8</sup> MARUSHEN... 76	CNTR	—	Mesonic atoms	

<sup>1</sup> LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.

<sup>2</sup> JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive  $m_{\nu_\mu}^2$ .

<sup>3</sup> ASSAMAGAN 96 measures the  $\mu^+$  momentum  $p_\mu$  in  $\pi^+ \rightarrow \mu^+ \nu_\mu$  decay at rest to be  $29.79200 \pm 0.00011$  MeV/c. Combined with the  $\mu^+$  mass and the assumption  $m_{\nu_\mu} = 0$ , this gives the  $\pi^+$  mass above; if  $m_{\nu_\mu} > 0$ ,  $m_{\pi^+}$  given above is a lower limit.

Combined instead with  $m_\mu$  and (assuming  $CPT$ ) the  $\pi^-$  mass of JECKELMANN 94,  $p_\mu$  gives an upper limit on  $m_{\nu_\mu}$  (see the  $\nu_\mu$ ).

<sup>4</sup> JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative  $m_{\nu_\mu}^2$ . It is accordingly not used in our fits.

<sup>5</sup> The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the  $\mu^+$  momentum for  $\pi^+$  decay at rest,  $p_\mu = 29.79179 \pm 0.00053$  MeV, uses  $m_\mu = 105.658389 \pm 0.000034$  MeV, and assumes that  $m_{\nu_\mu} = 0$ . The last assumption means that in fact the value is a lower limit.

<sup>6</sup> JECKELMANN 86b gives  $m_{\pi^+}/m_e = 273.12677(71)$ . We use  $m_e = 0.51099906(15)$  MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible  $\pi^\pm$  masses.

<sup>7</sup> These values are scaled with a new wavelength-energy conversion factor  $V\lambda = 1.23984244(37) \times 10^{-6}$  eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

<sup>8</sup> This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration  $\gamma$  energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

$$m_{\pi^+} - m_{\mu^+}$$

## Lepton Family number (LF) or Lepton number (L) violating modes

$\Gamma_8$ $\mu^+ \bar{\nu}_e$	L	[c] < 1.5	× $10^{-3}$ 90%
$\Gamma_9$ $\mu^+ \nu_e$	LF	[c] < 8.0	× $10^{-3}$ 90%
$\Gamma_{10}$ $\mu^- e^+ e^+ \nu$	LF	< 1.6	× $10^{-6}$ 90%

[a] Measurements of  $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$  always include decays with  $\gamma$ 's, and measurements of  $\Gamma(e^+ \nu_e \gamma)$  and  $\Gamma(\mu^+ \nu_\mu \gamma)$  never include low-energy  $\gamma$ 's. Therefore, since no clean separation is possible, we consider the modes with  $\gamma$ 's to be subreactions of the modes without them, and let  $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$ .

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy  $\gamma$ 's are not included.

## FORM FACTORS FOR RADIATIVE PION AND KAON DECAYS

Updated August 2015 by M. Bychkov (University of Virginia) and G. D’Ambrosio (INFN Sezione di Napoli)

The radiative decays,  $\pi^\pm \rightarrow l^\pm \nu \gamma$  and  $K^\pm \rightarrow l^\pm \nu \gamma$ , with  $l$  standing for an  $e$  or a  $\mu$ , and  $\gamma$  for a real or virtual photon ( $e^+e^-$  pair), provide a powerful tool to investigate the hadronic structure of pions and kaons. The structure-dependent part  $SD_i$  of the amplitude describes the emission of photons from virtual hadronic states, and is parametrized in terms of form factors  $V, A$ , (vector, axial vector), in the standard description [1,2,3,4]. Note that in the Listings below and some literature, equivalent nomenclature  $F_V$  and  $F_A$  for the vector and axial form factors is often used. Exotic, non-standard contributions like  $i = T, S$  (tensor, scalar) have also been considered. Apart from the SD terms, there is also the Inner Bremsstrahlung amplitude, IB, corresponding to photon radiation from external charged particles and described by Low theorem in terms of the physical decay  $\pi^\pm(K^\pm) \rightarrow l^\pm \nu$ . Experiments try to optimize their kinematics so as to minimize the IB part of the amplitude.

The SD amplitude in its standard form is given as

$$M(SD_V) = \frac{-eG_F U_{qq'}}{\sqrt{2}m_P} \epsilon^\mu l^\nu V^P \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau \quad (1)$$

$$M(SD_A) = \frac{-ieG_F U_{qq'}}{\sqrt{2}m_P} \epsilon^\mu l^\nu \{A^P[(qk - k^2)g_{\mu\nu} - q_\mu k_\nu] + R^P k^2 g_{\mu\nu}\}, \quad (2)$$

which contains an additional axial form factor  $R^P$  which only can be accessed if the photon remains virtual.  $U_{qq'}$  is the Cabibbo-Kobayashi-Maskawa mixing-matrix element;  $\epsilon^\mu$  is the polarization vector of the photon (or the effective vertex,  $\epsilon^\mu = (e/k^2)\bar{u}(p_-)\gamma^\mu v(p_+)$ , of the  $e^+e^-$  pair);  $\ell^\nu = \bar{u}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_\ell)$  is the lepton-neutrino current;  $q$  and  $k$  are the meson and photon four-momenta ( $k = p_+ + p_-$  for virtual photons); and  $P$  stands for  $\pi$  or  $K$ .

The pion vector form factor,  $V^\pi$ , is related via CVC (Conserved Vector Current) to the  $\pi^0 \rightarrow \gamma\gamma$  decay width. The constant term is given by  $|V^\pi(0)| = (1/\alpha)\sqrt{2\Gamma_{\pi^0 \rightarrow \gamma\gamma}/\pi m_{\pi^0}}$  [3]. The resulting value,  $V^\pi(0) = 0.0259(9)$ , has been confirmed by calculations based on chiral perturbation theory ( $\chi PT$ ) [4], and by two experiments given in the Listings below. A recent experiment by the PIBETA collaboration [5] obtained a  $V^\pi(0)$  that is in excellent agreement with the CVC hypothesis. It also measured the slope parameter  $a$  in  $V^\pi(s) = V^\pi(0)(1 + a \cdot s)$ , where  $s = (1 - 2E_\gamma/m_\pi)$ , and  $E_\gamma$  is the gamma energy in the pion rest frame:  $a = 0.095 \pm 0.058$ . A functional dependence on  $s$  is expected for all form factors. It becomes non-negligible in the case of  $V^\pi(s)$  when a wide range of photon momenta is recorded; proper treatment in the analysis of  $K$  decays is mandatory.

The form factor,  $R^P$ , can be related to the electromagnetic radius,  $r_P$ , of the meson [2]:  $R^P = \frac{1}{3}m_P f_P \langle r_P^2 \rangle$  using PCAC (Partial Conserved Axial vector Current;  $f_P$  is the meson decay constant). In lowest order  $\chi PT$ , the ratio  $A^\pi/V^\pi$  is related to the pion electric polarizability  $\alpha_E = [\alpha/(8\pi^2 m_\pi f_\pi^2)] \times A^\pi/V^\pi$  [6]. The experimental and theoretical status of the pion polarizability is currently an area under discussion and will be addressed in a future edition of this article. The first non-trivial  $\chi PT$  contributions to  $A^K$  and  $V^K$  appear at  $\mathcal{O}(p^4)$  [4], respectively from Gasser-Leutwyler coefficients,  $L_i$ 's, and the anomalous lagrangian:

$$A^K = \frac{4\sqrt{2}M_K}{F_\pi}(L_9^r + L_{10}^r) = 0.042, \quad V^K = \frac{\sqrt{2}M_K}{8\pi^2 F_\pi} = 0.096. \quad (3)$$

$\mathcal{O}(p^6)$  contributions to  $A^K$  can be predicted accurately: they are flat in the momentum dependence and shift the  $\mathcal{O}(p^4)$  value to 0.034.  $\mathcal{O}(p^6)$  contributions to  $V^K$  are model dependent and can be approximated by a form factor linearly dependent on momentum. For example, when looking at the spread of results obtained within two different models, the constant piece of this linear form factor is shifted to  $0.078 \pm 0.005$  [1,2,4].

For decay processes where the photon is real, the partial decay width can be written in analytical form as a sum of IB, SD, and IB/SD interference terms INT [1,4]:

$$\begin{aligned} \frac{d^2\Gamma_{P \rightarrow \ell\nu\gamma}}{dxdy} &= \frac{d^2(\Gamma_{IB} + \Gamma_{SD} + \Gamma_{INT})}{dxdy} \\ &= \frac{\alpha}{2\pi}\Gamma_{P \rightarrow \ell\nu} \frac{1}{(1-r)^2} \left\{ \text{IB}(x, y) \right. \end{aligned}$$

**Figure 1:** Components of the structure dependent terms of the decay width. Left:  $SD^+$ , right:  $SD^-$

$$\begin{aligned} &+ \frac{1}{r} \left( \frac{m_P}{2f_P} \right)^2 \left[ (V+A)^2 SD^+(x, y) + (V-A)^2 SD^-(x, y) \right] \\ &+ \frac{m_P}{f_P} \left[ (V+A) S_{INT}^+(x, y) + (V-A) S_{INT}^-(x, y) \right] \}. \quad (4) \end{aligned}$$

Here

$$\begin{aligned} \text{IB}(x, y) &= \left[ \frac{1-y+r}{x^2(x+y-1-r)} \right] \\ &\quad \left[ x^2 + 2(1-x)(1-r) - \frac{2xr(1-r)}{x+y-1-r} \right] \\ SD^+(x, y) &= (x+y-1-r) \left[ (x+y-1)(1-x) - r \right] \\ SD^-(x, y) &= (1-y+r) \left[ (1-x)(1-y) + r \right] \\ S_{INT}^+(x, y) &= \left[ \frac{1-y+r}{x(x+y-1-r)} \right] \left[ (1-x)(1-x-y) + r \right] \\ S_{INT}^-(x, y) &= \left[ \frac{1-y+r}{x(x+y-1-r)} \right] \left[ x^2 - (1-x)(1-x-y) - r \right] \end{aligned} \quad (5)$$

where  $x = 2E_\gamma/m_P$ ,  $y = 2E_\ell/m_P$ , and  $r = (m_\ell/m_P)^2$ . The structure dependent terms  $SD^+$  and  $SD^-$  are shown in Fig. 1. The  $SD^-$  term is maximized in the same kinematic region where overwhelming IB term dominates (along  $x+y=1$  diagonal). Thus experimental yields with less background are dominated by  $SD^+$  contribution and proportional to  $A^P + V^P$  making simultaneous precise determination of the form factors difficult.

Recently, formulas (4) and (5) have been extended to describe polarized distributions in radiative meson and muon decays [7].

The ‘‘helicity’’ factor  $r$  is responsible for the enhancement of the SD over the IB amplitude in the decays  $\pi^\pm \rightarrow e^\pm \nu \gamma$ , while  $\pi^\pm \rightarrow \mu^\pm \nu \gamma$  is dominated by IB. Interference terms are important for the decay  $K^\pm \rightarrow \mu^\pm \nu \gamma$  [8], but contribute only a few percent correction to pion decays. However, they provide the basis for determining the signs of  $V$  and  $A$ . Radiative corrections to the decay  $\pi^+ \rightarrow e^+ \nu \gamma$  have to be taken into account in the analysis of the precision experiments. They

# Meson Particle Listings

$\pi^\pm$

make up to 4% corrections in the total decay rate [9]. In  $\pi^\pm \rightarrow e^\pm \nu e^\pm e^-$  and  $K^\pm \rightarrow \ell^\pm \nu e^\pm e^-$  decays, all three form factors,  $V^P$ ,  $A^P$ , and  $R^P$ , can be determined [10,11].

We give the experimental  $\pi^\pm$  form factors  $F_T^\pi$ ,  $A_T^\pi$ , and  $R^\pi$  in the Listings below. In the  $K^\pm$  Listings, we give the extracted sum  $A^K + V^K$  and difference  $A^K - V^K$ , as well as  $V^K$ ,  $A^K$  and  $R^K$ . In particular KLOE has measured for the constant piece of the form factor  $A^K + V^K = 0.125 \pm 0.007 \pm 0.001$  [13] while Istra+,  $V^K - A^K = 0.21 \pm 0.04 \pm 0.04$  [14].

Several searches for the exotic form factors  $F_T^K$ ,  $F_T^K$  (tensor), and  $F_S^K$  (scalar) have been pursued in the past. In particular,  $F_T^\pi$  has been brought into focus by experimental as well as theoretical work [12]. New high-statistics data from the PIBETA collaboration have been re-analyzed together with an additional data set optimized for low backgrounds in the radiative pion decay. In particular, lower beam rates have been used in order to reduce the accidental background, thereby making the treatment of systematic uncertainties easier and more reliable. The PIBETA analysis now restricts  $F_T^\pi$  to the range  $-5.2 \times 10^{-4} < F_T^\pi < 4.0 \times 10^{-4}$  at a 90% confidence limit [5]. This result is in excellent agreement with the most recent theoretical work [4].

Precision measurements of radiative pion and kaon decays are effective tools to study QCD in the non-perturbative region and are of interest beyond the scope of radiative decays. Meanwhile other processes such as  $\pi^+ \rightarrow e^+ \nu$  that seem to be better suited to search for new physics at the precision frontier are currently studied. The advantages of such process are the very accurate and reliable theoretical predictions and the more straightforward experimental analysis.

## $\pi^\pm$ FORM FACTORS

### $F_V$ , VECTOR FORM FACTOR

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
<b>0.0254 ± 0.0017 OUR AVERAGE</b>				
0.0258 ± 0.0017	65k	<sup>1</sup> BYCHKOV	09	PIBE $e^+ \nu \gamma$ at rest
0.014 ± 0.009		<sup>2</sup> BOLOTOV	90B	SPEC 17 GeV $\pi^- \rightarrow e^- \bar{\nu}_e \gamma$
0.023 <sup>+0.015</sup> <sub>-0.013</sub>	98	EGLI	89	SPEC $\pi^+ \rightarrow e^+ \nu_e e^+ e^-$

<sup>1</sup> The BYCHKOV 09  $F_A$  and  $F_V$  results are highly (anti-)correlated:  $F_A + 1.0286 F_V = 0.03853 \pm 0.00014$ .  
<sup>2</sup> BOLOTOV 90B only determines the absolute value.

### $F_A$ , AXIAL-VECTOR FORM FACTOR

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
<b>0.0119 ± 0.0001</b>	65k	<sup>1,2</sup> BYCHKOV	09	PIBE $e^+ \nu \gamma$ at rest
• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.0115 ± 0.0004	41k	<sup>1,3</sup> FRLEZ	04	PIBE $\pi^+ \rightarrow e^+ \nu \gamma$ at rest
0.0106 ± 0.0060		<sup>1,4</sup> BOLOTOV	90B	SPEC 17 GeV $\pi^- \rightarrow e^- \bar{\nu}_e \gamma$
0.021 <sup>+0.011</sup> <sub>-0.013</sub>	98	EGLI	89	SPEC $\pi^+ \rightarrow e^+ \nu_e e^+ e^-$
0.0135 ± 0.0016		<sup>1,4</sup> BAY	86	SPEC $\pi^+ \rightarrow e^+ \nu \gamma$
0.006 ± 0.003		<sup>1,4</sup> PIILONEN	86	SPEC $\pi^+ \rightarrow e^+ \nu \gamma$
0.011 ± 0.003		<sup>1,4,5</sup> STETZ	78	SPEC $\pi^+ \rightarrow e^+ \nu \gamma$

<sup>1</sup> These values come from fixing the vector form factor at the CVC prediction,  $F_V = 0.0259 \pm 0.0005$ .  
<sup>2</sup> When  $F_V$  is released, the BYCHKOV 09  $F_A$  is  $0.0117 \pm 0.0017$ , and  $F_A$  and  $F_V$  results are highly (anti-)correlated:  $F_A + 1.0286 F_V = 0.03853 \pm 0.00014$ .

<sup>3</sup> The sign of  $\gamma = F_A / F_V$  is determined to be positive.  
<sup>4</sup> Only the absolute value of  $F_A$  is determined.

<sup>5</sup> The result of STETZ 78 has a two-fold ambiguity. We take the solution compatible with later determinations.

### VECTOR FORM FACTOR SLOPE PARAMETER $a$

 $\pi^0$  MEAN LIFE

Most experiments measure the  $\pi^0$  width which we convert to a lifetime. ATHERTON 85 is the only direct measurement of the  $\pi^0$  lifetime. Our average based only on indirect measurement yields  $(8.30 \pm 0.19) \times 10^{-17}$  s. The two Primakoff measurements from 1970 have been excluded from our average because they suffered model-related systematics unknown at the time. More information on the  $\pi^0$  lifetime can be found in BERNSTEIN 13.

VALUE ( $10^{-17}$ s)	EVTS	DOCUMENT ID	TECN	COMMENT

7.3 ±1.1		BELLETTINI	65B	CNTR Primakoff effect

- <sup>1</sup> LARIN 11 reported  $\Gamma(\pi^0 \rightarrow \gamma\gamma) = 7.82 \pm 0.14 \pm 0.17$  eV which we converted to mean life  $\tau = \hbar/\Gamma(\text{total})$ .
- <sup>2</sup> BYCHKOV 09 obtains this using the conserved-vector-current relation between the vector form factor  $F_V$  and the  $\pi^0$  lifetime.
- <sup>3</sup> WILLIAMS 88 gives  $\Gamma(\gamma\gamma) = 7.7 \pm 0.5 \pm 0.5$  eV. We give here  $\tau = \hbar/\Gamma(\text{total})$ .
- <sup>4</sup> BROWMAN 74 gives a  $\pi^0$  width  $\Gamma = 8.02 \pm 0.42$  eV. The mean life is  $\hbar/\Gamma$ .

 $\pi^0$  DECAY MODES

For decay limits to particles which are not established, see the appropriate Search sections ( $A^0$  (axion) and Other Light Boson ( $X^0$ ) Searches, etc.).

[a] Astrophysical and cosmological arguments give limits of order  $10^{-13}$ ; see the Particle Listings below.

## CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 4.6$  for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

 $\pi^0$  ELECTROMAGNETIC FORM FACTOR

The amplitude for the process  $\pi^0 \rightarrow e^+ e^- \gamma$  contains a form factor  $F(x)$  at the  $\pi^0 \gamma \gamma$  vertex, where  $x = [m_{e^+ e^-}/m_{\pi^0}]^2$ . The parameter  $a$  in the linear expansion  $F(x) = 1 + ax$  is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

LINEAR COEFFICIENT OF  $\pi^0$  ELECTROMAGNETIC FORM FACTOR

20 BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of  $a$  is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

21 TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

22 The FISCHER 78 error is statistical only. The result without radiation corrections is  $+0.05 \pm 0.03$ .

 $\eta$ 

$$I^G(J^{PC}) = 0^+(0^-+)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

 $\eta$  MASS

Recent measurements resolve the obvious inconsistency in previous  $\eta$  mass measurements in favor of the higher value first reported by NA48 (LA1 02). We use only precise measurements consistent with this higher mass value for our  $\eta$  mass average.

$\Gamma_{22}$	$\pi^+ \pi^- \pi^0 \gamma$	< 5 × 10 <sup>−4</sup>	CL=90%
$\Gamma_{23}$	$\pi^0 \mu^+ \mu^- \gamma$	< 3 × 10 <sup>−6</sup>	CL=90%

### Charge conjugation (C), Parity (P), Charge conjugation × Parity (CP), or Lepton Family number (LF) violating modes

$\Gamma_{24}$	$\pi^0 \gamma$	C	< 9 × 10 <sup>−5</sup>	CL=90%
$\Gamma_{25}$	$\pi^+ \pi^-$	P,CP	< 1.3 × 10 <sup>−5</sup>	CL=90%
$\Gamma_{26}$	$2\pi^0$	P,CP	< 3.5 × 10 <sup>−4</sup>	CL=90%
$\Gamma_{27}$	$2\pi^0 \gamma$	C	< 5 × 10 <sup>−4</sup>	CL=90%
$\Gamma_{28}$	$3\pi^0 \gamma$	C	< 6 × 10 <sup>−5</sup>	CL=90%
$\Gamma_{29}$	$3\gamma$	C	< 1.6 × 10 <sup>−5</sup>	CL=90%
$\Gamma_{30}$	$4\pi^0$	P,CP	< 6.9 × 10 <sup>−7</sup>	CL=90%
$\Gamma_{31}$	$\pi^0 e^+ e^-$	C	[a] < 4 × 10 <sup>−5</sup>	CL=90%
$\Gamma_{32}$	$\pi^0 \mu^+ \mu^-$	C	[a] < 5 × 10 <sup>−6</sup>	CL=90%
$\Gamma_{33}$	$\mu^+ e^- + \mu^- e^+$	LF	< 6 × 10 <sup>−6</sup>	CL=90%

[a] C parity forbids this to occur as a single-photon process.

### CONSTRAINED FIT INFORMATION

An overall fit to 2 decay rate and 19 branching ratios uses 50 measurements and one constraint to determine 9 parameters. The overall fit has a  $\chi^2 = 43.8$  for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_3$	24							
$x_4$	4	1						
$x_9$	−73	−80	−4					
$x_{10}$	−56	−60	−3	61				
$x_{11}$	−5	−5	0	−6	−4			
$x_{12}$	−1	0	0	−1	0	0		
$x_{16}$	0	0	0	0	0	0	0	
$\Gamma$	−14	−3	−32	11	8	1	0	0
	$x_2$	$x_3$	$x_4$	$x_9$	$x_{10}$	$x_{11}$	$x_{12}$	$x_{16}$

Mode	Rate (keV)	Scale factor
$\Gamma_2$ $2\gamma$	0.515 ± 0.018	
$\Gamma_3$ $3\pi^0$	0.427 ± 0.015	
$\Gamma_4$ $\pi^0 2\gamma$	(3.34 ± 0.28 ) × 10 <sup>−4</sup>	
$\Gamma_9$ $\pi^+ \pi^- \pi^0$	0.299 ± 0.011	
$\Gamma_{10}$ $\pi^+ \pi^- \gamma$	0.0551 ± 0.0022	
$\Gamma_{11}$ $e^+ e^- \gamma$	0.0090 ± 0.0006	1.2
$\Gamma_{12}$ $\mu^+ \mu^- \gamma$	(4.1 ± 0.5 ) × 10 <sup>−4</sup>	
$\Gamma_{16}$ $\pi^+ \pi^- e^+ e^- (\gamma)$	(3.50 ± 0.19 ) × 10 <sup>−4</sup>	

### $\eta$ DECAY RATES

#### $\Gamma(2\gamma)$

#### $\Gamma_2$

See the table immediately above giving the fitted decay rates. Following the advice of NEFKENS 02, we have removed the Primakoff-effect measurement from the average. See also the “Note on the Decay Width  $\Gamma(\eta \rightarrow \gamma\gamma)$ ,” in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1451, for a discussion of the various measurements.

0.324±0.046		BROWMAN	74B	CNTR Primakoff effect
1.00 ± 0.22		<sup>2</sup> BEMPORAD	67	CNTR Primakoff effect

• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the  $\eta$  photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of  $\Gamma(\eta \rightarrow 2\gamma)$  in line with direct measurements of the width. The error here is only statistical.

<sup>2</sup> BEMPORAD 67 gives  $\Gamma(2\gamma) = 1.21 \pm 0.26$  keV assuming  $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$ . Bemporad private communication gives  $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$ . We evaluate this using  $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$ . Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

### $\pi^+\pi^-\pi^0$ QUADRANT ASYMMETRY PARAMETER

VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN
<b><math>-0.09 \pm 0.09</math></b>	<b>OUR AVERAGE</b>		
$-0.05 \pm 0.10$	$+0.03$	1.34M	AMBROSINO 08D KLOE
$-0.30 \pm 0.25$	165k	JANE 74	OSPK
$-0.07 \pm 0.22$	220k	LAYER 72	ASPK

**$\pi^+\pi^-\gamma$  LEFT-RIGHT ASYMMETRY PARAMETER**  
Measurements with an error  $> 2.0 \times 10^{-2}$  have been omitted.

VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN
<b><math>0.9 \pm 0.4</math></b>	<b>OUR AVERAGE</b>		
$1.2 \pm 0.6$	35k	JANE 74B	OSPK
$0.5 \pm 0.6$	36k	THALER 72	ASPK
$1.22 \pm 1.56$	7257	GORMLEY 70	ASPK

### $\pi^+\pi^-\gamma$ PARAMETER $\beta$ ( $D$ -wave)

Sensitive to a  $D$ -wave contribution:  $dN/d\cos\theta = \sin^2\theta (1 + \beta \cos^2\theta)$ .

VALUE	EVTS	DOCUMENT ID	TECN
<b><math>-0.02 \pm 0.07</math></b>	<b>OUR AVERAGE</b>		
$0.11 \pm 0.11$	35k	JANE 74B	OSPK
$-0.060 \pm 0.065$	7250	GORMLEY 70	WIRE
• • • We do not use the following data for averages, fits, limits, etc. • • •			
$0.12 \pm 0.06$		<sup>1</sup> THALER 72	ASPK

<sup>1</sup>The authors don't believe this indicates  $D$ -wave because the dependence of  $\beta$  on the  $\gamma$  energy is inconsistent with the theoretical prediction. A  $\cos^2\theta$  dependence can also come from  $P$ - and  $F$ -wave interference.

### $\eta$ CP-NONCONSERVING DECAY PARAMETER

#### $\pi^+\pi^-e^+e^-$ DECAY-PLANE ASYMMETRY PARAMETER $A_\phi$

In the  $\eta$  rest frame, the total momentum of the  $e^+e^-$  pair is equal and opposite to that of the  $\pi^+\pi^-$  pair. Let  $\hat{z}$  be the unit vector along the momentum of the  $e^+e^-$  pair; let  $\hat{n}_{ee}$  and  $\hat{n}_{\pi\pi}$  be the unit vectors normal to the  $e^+e^-$  and  $\pi^+\pi^-$  planes; and let  $\phi$  be the angle between the two normals. Then

$$\sin\phi \cos\phi = [(\hat{n}_{ee} \times \hat{n}_{\pi\pi}) \cdot \hat{z}] (\hat{n}_{ee} \cdot \hat{n}_{\pi\pi}),$$

and

$$A_\phi \equiv \frac{N_{\sin\phi \cos\phi > 0} - N_{\sin\phi \cos\phi < 0}}{N_{\sin\phi \cos\phi > 0} + N_{\sin\phi \cos\phi < 0}}.$$

## NOTE ON SCALAR MESONS BELOW 2 GEV

Revised November 2015 by C. Amsler (Univ. of Bern), S. Eidelman (Budker Institute of Nuclear Physics, Novosibirsk), T. Gutsche (University of Tübingen), C. Hanhart (Forschungszentrum Jülich), S. Spanier (University of Tennessee), and N.A. Törnqvist (University of Helsinki)

**I. Introduction:** In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. Scalar resonances are difficult to resolve because some of them have large decay widths which cause a strong overlap between resonances and background. In addition, several decay channels sometimes open up within a short mass interval (*e.g.* at the  $K\bar{K}$  and  $\eta\eta$  thresholds), producing cusps in the line shapes of the near-by resonances. Furthermore, one expects non- $q\bar{q}$  scalar objects, such as glueballs and multi-quark states in the mass range below 2 GeV (for reviews see, *e.g.*, Refs. [1–5] and the mini-review on *non- $q\bar{q}$  states* in this Review of Particle Physics (RPP)).

Light scalars are produced, for example, in  $\pi N$  scattering on polarized/unpolarized targets,  $p\bar{p}$  annihilation, central hadronic production,  $J/\Psi$ ,  $B^-$ ,  $D^-$  and  $K$ -meson decays,  $\gamma\gamma$  formation, and  $\phi$  radiative decays. Especially for the lightest scalar mesons simple parameterizations fail and more advanced theory tools are necessary to extract the resonance parameters from data. In the analyses available in the literature fundamental properties of the amplitudes such as unitarity, analyticity, Lorentz invariance, chiral and flavor symmetry are implemented at different levels of rigor. Especially, chiral symmetry implies the appearance of zeros close to the threshold in elastic  $S$ -wave scattering amplitudes involving soft pions [6,7], which may be shifted or removed in associated production processes [8]. The methods employed are the  $K$ -matrix formalism, the  $N/D$ -method, the Dalitz–Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories and the linear sigma model, *etc.* Dynamics near the lowest two-body thresholds in some analyses are described by crossed channel ( $t$ ,  $u$ ) meson exchange or with an effective range parameterization instead of, or in addition to, resonant features in the  $s$ -channel. Dispersion theoretical approaches are applied to pin down the location of resonance poles for the low-lying states [9–12].

The mass and width of a resonance are found from the position of the nearest pole in the process amplitude ( $T$ -matrix or  $S$ -matrix) at an unphysical sheet of the complex energy plane, traditionally labeled as

$$\sqrt{s_{\text{Pole}}} = M - i\Gamma/2.$$

It is important to note that the pole of a Breit-Wigner parameterization agrees with this pole position only for narrow

and well-separated resonances, far away from the opening of decay channels. For a detailed discussion of this issue we refer to the review on *Resonances* in this RPP.

In this note, we discuss the light scalars below 2 GeV organized in the listings under the entries ( $I = 1/2$ )  $K_0^*(800)$  (or  $\kappa$ , currently omitted from the summary table),  $K_0^*(1430)$ , ( $I = 1$ )  $a_0(980)$ ,  $a_0(1450)$ , and ( $I = 0$ )  $f_0(500)$  (or  $\sigma$ ),  $f_0(980)$ ,  $f_0(1370)$ ,  $f_0(1500)$ , and  $f_0(1710)$ . This list is minimal and does not necessarily exhaust the list of actual resonances. The ( $I = 2$ )  $\pi\pi$  and ( $I = 3/2$ )  $K\pi$  phase shifts do not exhibit any resonant behavior.

**II. The  $I = 1/2$  States:** The  $K_0^*(1430)$  [13] is perhaps the least controversial of the light scalar mesons. The  $K\pi$   $S$ -wave scattering has two possible isospin channels,  $I = 1/2$  and  $I = 3/2$ . The  $I = 3/2$  wave is elastic and repulsive up to 1.7 GeV [14] and contains no known resonances. The  $I = 1/2$   $K\pi$  phase shift, measured from about 100 MeV above threshold in  $Kp$  production, rises smoothly, passes  $90^\circ$  at 1350 MeV, and continues to rise to about  $170^\circ$  at 1600 MeV. The first important inelastic threshold is  $K\eta'(958)$ . In the inelastic region the continuation of the amplitude is uncertain since the partial-wave decomposition has several solutions. The data are extrapolated towards the  $K\pi$  threshold using effective range type formulas [13,15] or chiral perturbation predictions [16,17]. From analyses using unitarized amplitudes there is agreement on the presence of a resonance pole around 1410 MeV having a width of about 300 MeV. With reduced model dependence, Ref. [18] finds a larger width of 500 MeV.

Similar to the situation for the  $f_0(500)$ , discussed in the next section, the presence and properties of the light  $K_0^*(800)$  (or  $\kappa$ ) meson in the 700–900 MeV region are difficult to establish since it appears to have a very large width ( $\Gamma \approx 500$  MeV) and resides close to the  $K\pi$  threshold. Hadronic  $D$ - and  $B$ -meson decays provide additional data points in the vicinity of the  $K\pi$  threshold and are discussed in detail in the *Review on Multibody Charm Analyses* in this RPP. Precision information from semileptonic  $D$  decays avoiding theoretically ambiguous three-body final state interactions is not available. BES II [19] (re-analyzed in [20]) finds a  $K_0^*(800)$ -like structure in  $J/\psi$  decays to  $\bar{K}^{*0}(892)K^+\pi^-$  where  $K_0^*(800)$  recoils against the  $K^*(892)$ . Also clean with respect to final state interaction is the decay  $\tau^- \rightarrow K_S^0\pi^-\nu_\tau$  studied by Belle [21], with  $K_0^*(800)$  parameters fixed to those of Ref. [19].

Some authors find a  $K_0^*(800)$  pole in their phenomenological analysis (see, *e.g.*, [22–33]), while others do not need to include it in their fits (see, *e.g.*, [17,34–37]). Similarly to the case of the  $f_0(500)$  discussed below, all works including constraints from chiral symmetry at low energies naturally seem to find a light  $K_0^*(800)$  below 800 MeV, see, *e.g.*, [38–42]. In these works the  $K_0^*(800)$ ,  $f_0(500)$ ,  $f_0(980)$  and  $a_0(980)$  appear to form a nonet [39,40]. Additional evidence for this assignment is presented in Ref. [12], where the couplings of the nine states to  $q\bar{q}$  sources were compared. The same low-lying scalar nonet was

# Meson Particle Listings

## $f_0(500)$

also found earlier in the unitarized quark model of Ref. [41]. The analysis of Ref. [43] is based on the Roy-Steiner equations, which include analyticity and crossing symmetry. It establishes the existence of a light  $K_0^*(800)$  pole in the  $K\pi \rightarrow K\pi$  amplitude on the second sheet. In Ref. [44] a first lattice study for the  $K\pi$  S-wave system is presented, however, with a pion mass of 400 MeV it can not be compared to data yet.

**III. The  $I = 1$  States:** Two isovector scalar states are known below 2 GeV, the  $a_0(980)$  and the  $a_0(1450)$ . Independent of any model, the  $K\bar{K}$  component in the  $a_0(980)$  wave function must be large: it lies just below the opening of the  $K\bar{K}$  channel to which it strongly couples [15,45]. This generates an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled-channel model with energy-dependent widths and mass shift contributions is necessary. All listed  $a_0(980)$  measurements agree on a mass position value near 980 MeV, but the width takes values between 50 and 100 MeV, mostly due to the different models. For example, the analysis of the  $p\bar{p}$ -annihilation data [15] using a unitary  $K$ -matrix description finds a width as determined from the  $T$ -matrix pole of  $92 \pm 8$  MeV, while the observed width of the peak in the  $\pi\eta$  mass spectrum is about 45 MeV.

The relative coupling  $K\bar{K}/\pi\eta$  is determined indirectly from  $f_1(1285)$  [46–48] or  $\eta(1410)$  decays [49–51], from the line shape observed in the  $\pi\eta$  decay mode [52–55], or from the coupled-channel analysis of the  $\pi\pi\eta$  and  $K\bar{K}\pi$  final states of  $p\bar{p}$  annihilation at rest [15].

The  $a_0(1450)$  is seen in  $p\bar{p}$  annihilation experiments with stopped and higher momenta antiprotons, with a mass of about 1450 MeV or close to the  $a_2(1320)$  meson which is typically a dominant feature. A contribution from  $a_0(1450)$  is also found in the analysis of the  $D^\pm \rightarrow K^+ K^- \pi^\pm$  decay [56]. The broad structure at about 1300 MeV observed in  $\pi N \rightarrow K\bar{K}N$  reactions [57] needs still further confirmation in its existence and isospin assignment.

**IV. The  $I = 0$  States:** The  $I = 0$ ,  $J^{PC} = 0^{++}$  sector is the most complex one, both experimentally and theoretically. The data have been obtained from the  $\pi\pi$ ,  $K\bar{K}$ ,  $\eta\eta$ ,  $4\pi$ , and  $\eta\eta'(958)$  systems produced in  $S$ -wave. Analyses based on several different production processes conclude that probably four poles are needed in the mass range from  $\pi\pi$  threshold to about 1600 MeV. The claimed isoscalar resonances are found under separate entries  $f_0(500)$  (or  $\sigma$ ),  $f_0(980)$ ,  $f_0(1370)$ , and  $f_0(1500)$ .

For discussions of the  $\pi\pi$   $S$  wave below the  $K\bar{K}$  threshold and on the long history of the  $f_0(500)$ , which was suggested in linear sigma models more than 50 years ago, see our reviews in previous editions and the recent review [5].

Information on the  $\pi\pi$   $S$ -wave phase shift  $\delta_f^I = \delta_0^0$  was already extracted many years ago from  $\pi N$  scattering [58–60],

and near threshold from the  $K_{e4}$ -decay [61]. The kaon decays were later revisited leading to consistent data, however, with very much improved statistics [62,63]. The reported  $\pi\pi \rightarrow K\bar{K}$  cross sections [64–67] have large uncertainties. The  $\pi N$  data have been analyzed in combination with high-statistics data (see entries labeled as RVUE for re-analyses of the data). The  $2\pi^0$  invariant mass spectra of the  $p\bar{p}$  annihilation at rest [68–70] and the central collision [71] do not show a distinct resonance structure below 900 MeV, but these data are consistently described with the standard solution for  $\pi N$  data [59,72], which allows for the existence of the broad  $f_0(500)$ . An enhancement is observed in the  $\pi^+\pi^-$  invariant mass near threshold in the decays  $D^+ \rightarrow \pi^+\pi^-\pi^+$  [73–101] and  $J/\psi \rightarrow \omega\pi^+\pi^-$  [76,98], and in  $\psi(2S) \rightarrow J/\psi\pi^+\pi^-$  with very limited phase space [78,79].

The precise  $f_0(500)$  (or  $\sigma$ ) pole is difficult to establish because of its large width, and because it can certainly not be modeled by a naive Breit-Wigner resonance. For the same reason a splitting in background and resonance contributions is not possible in a model-independent way. The  $\pi\pi$  scattering amplitude shows an unusual energy dependence due to the presence of a zero in the unphysical regime close to the threshold [6–7], required by chiral symmetry, and possibly due to crossed channel exchanges, the  $f_0(1370)$ , and other dynamical features. However, most of the analyses listed under  $f_0(500)$  agree on a pole position near  $(500 - i250)$  MeV. In particular, analyses of  $\pi\pi$  data that include unitarity,  $\pi\pi$  threshold behavior, strongly constrained by the  $K_{e4}$  data, and the chiral symmetry constraints from Adler zeroes and/or scattering lengths find a light  $f_0(500)$ , see, *e.g.*, [80,81].

Precise pole positions with an uncertainty of less than 20 MeV (see our table for the  $T$ -matrix pole) were extracted by use of Roy equations, which are twice subtracted dispersion relations derived from crossing symmetry and analyticity. In Ref. [10] the subtraction constants were fixed to the  $S$ -wave scattering lengths  $a_0^0$  and  $a_2^0$  derived from matching Roy equations and two-loop chiral perturbation theory [9]. The only additional relevant input to fix the  $f_0(500)$  pole turned out to be the  $\pi\pi$ -wave phase shifts at 800 MeV. The analysis was improved further in Ref. [12]. Alternatively, in Ref. [11] only data were used as input inside Roy equations. In that reference also once-subtracted Roy-like equations, called GKPY equations, were used, since the extrapolation into the complex plane based on the twice subtracted equations leads to larger uncertainties mainly due to the limited experimental information on the isospin-2  $\pi\pi$  scattering length. All these extractions find consistent results. Using analyticity and unitarity only to describe data from  $K_{2\pi}$  and  $K_{e4}$  decays, Ref. [82] finds consistent values for the pole position and the scattering length  $a_0^0$ . The importance of the  $\pi\pi$  scattering data for fixing the  $f_0(500)$  pole is nicely illustrated by comparing analyses of  $p\bar{p} \rightarrow 3\pi^0$  omitting [68,83] or including [69,84] information on  $\pi\pi$  scattering: while the former analyses find an extremely broad structure above 1 GeV, the latter find  $f_0(500)$  masses of the order of 400 MeV.

**Figure 1:** Location of the  $f_0(500)$  (or  $\sigma$ ) poles in the complex energy plane. Circles denote the recent analyses based on Roy(-like) dispersion relations [9–12], while all other analyses are denoted by triangles. The corresponding references are given in the listing.

As a result of the sensitivity of the extracted  $f_0(500)$  pole position on the high accuracy low energy  $\pi\pi$  scattering data [62,63], the currently quoted range of pole positions for the  $f_0(500)$ , namely

$$\sqrt{s_{\text{Pole}}} = (400 - 550) - i(200 - 350) \text{ MeV},$$

in the listing was fixed including only those analyses consistent with these data, Refs. [26,29,39,41,42,54,69,78–82,85–101] as well as the advanced dispersion analyses [9–12]. The pole positions from those references are compared to the range of pole positions quoted above in Fig. 1. Note that this range is labeled as 'our estimate' — it is not an average over the quoted analyses but is chosen to include the bulk of the analyses consistent with the mentioned criteria. An averaging procedure is not justified, since the analyses use overlapping or identical data sets.

One might also take the more radical point of view and just average the most advanced dispersive analyses, Refs. [9–12], shown as solid dots in Fig. 1, for they provide a determination of the pole positions with minimal bias. This procedure leads to the much more restricted range of  $f_0(500)$  parameters

$$\sqrt{s_{\text{Pole}}} = (446 \pm 6) - i(276 \pm 5) \text{ MeV}.$$

Due to the large strong width of the  $f_0(500)$  an extraction of its two-photon width directly from data is not possible. Thus, the values for  $\Gamma(\gamma\gamma)$  quoted in the literature as well as the listing are based on the expression in the narrow width approximation [102]  $\Gamma(\gamma\gamma) \simeq \alpha^2 |g_\gamma|^2 / (4\text{Re}(\sqrt{s_{\text{Pole}}}))$  where  $g_\gamma$  is derived from the residue at the  $f_0(500)$  pole to two photons and  $\alpha$  denotes the electromagnetic fine structure constant.

**Figure 2:** Values of the  $f_0(980)$  masses as they appear in the listing compared to the currently quoted mass estimate. The newest references appear at the bottom, the oldest on the top. The corresponding references are given in the listing.

The explicit form of the expression may vary between different authors due to different definitions of the coupling constant, however, the expression given for  $\Gamma(\gamma\gamma)$  is free of ambiguities. According to Refs. [103,104], the data for  $f_0(500) \rightarrow \gamma\gamma$  are consistent with what is expected for a two-step process of  $\gamma\gamma \rightarrow \pi^+\pi^-$  via pion exchange in the  $t$ - and  $u$ -channel, followed by a final state interaction  $\pi^+\pi^- \rightarrow \pi^0\pi^0$ . The same conclusion is drawn in Ref. [105] where the bulk part of the  $f_0(500) \rightarrow \gamma\gamma$  decay width is dominated by re-scattering. Therefore, it might be difficult to learn anything new about the nature of the  $f_0(500)$  from its  $\gamma\gamma$  coupling. For the most recent work on  $\gamma\gamma \rightarrow \pi\pi$ , see [106–108]. There are theoretical indications (*e.g.*, [109–112]) that the  $f_0(500)$  pole behaves differently from a  $q\bar{q}$ -state – see next section and the mini-review on *non  $q\bar{q}$ -states* in this RPP for details.

The  **$f_0(980)$**  overlaps strongly with the background represented mainly by the  $f_0(500)$  and the  $f_0(1370)$ . This can lead to a dip in the  $\pi\pi$  spectrum at the  $K\bar{K}$  threshold. It changes from a dip into a peak structure in the  $\pi^0\pi^0$  invariant mass spectrum of the reaction  $\pi^-p \rightarrow \pi^0\pi^0n$  [113], with increasing four-momentum transfer to the  $\pi^0\pi^0$  system, which means increasing the  $a_1$ -exchange contribution in the amplitude, while the  $\pi$ -exchange decreases. The  $f_0(500)$  and the  $f_0(980)$  are also observed in data for radiative decays ( $\phi \rightarrow f_0\gamma$ ) from SND [114,115], CMD2 [116], and KLOE [117,118]. A dispersive analysis was used to simultaneously pin down the pole parameters of both the  $f_0(500)$  and the  $f_0(980)$  [11]; the uncertainty in the pole position quoted for the latter state is

# Meson Particle Listings

## $f_0(500)$

of the order of 10 MeV, only (see the lowest point in Fig. 2). Compared to the 2010 issue of the *Review of Particle Physics*, in this issue we extended the allowed range of the  $f_0(980)$  masses to include the mass value derived in Ref. [11]. We now quote for the mass

$$M_{f_0(980)} = 990 \pm 20 \text{ MeV}.$$

As in case of the  $f_0(500)$  (or  $\sigma$ ), this range is not an average, but is labeled as 'our estimate'. A comparison of the mass values in the listing and the allocated range is shown in Fig. 2.

Analyses of  $\gamma\gamma \rightarrow \pi\pi$  data [119–121] underline the importance of the  $K\bar{K}$  coupling of  $f_0(980)$ , while the resulting two-photon width of the  $f_0(980)$  cannot be determined precisely [122]. The prominent appearance of the  $f_0(980)$  in the semileptonic  $D_s$  decays and decays of  $B$  and  $B_s$ -mesons implies a dominant ( $\bar{s}s$ ) component: those decays occur via weak transitions that alternatively result in  $\phi(1020)$  production. Ratios of decay rates of  $B$  and/or  $B_s$  mesons into  $J/\psi$  plus  $f_0(980)$  or  $f_0(500)$  were proposed to allow for an extraction of the flavor mixing angle and to probe the tetraquark nature of those mesons within a certain model [123,124]. The phenomenological fits of the LHCb collaboration using the isobar model do neither allow for a contribution of the  $f_0(980)$  in the  $B \rightarrow J/\psi\pi\pi$  [125] nor for an  $f_0(500)$  in  $B_s \rightarrow J/\psi\pi\pi$  decays [126]. From the former analysis the authors conclude that their data is incompatible with a model where  $f_0(500)$  and  $f_0(980)$  are formed from two quarks and two antiquarks (tetraquarks) at the eight standard deviation level. In addition, they extract an upper limit for the mixing angle of  $17^\circ$  at 90% C.L. between the  $f_0(980)$  and the  $f_0(500)$  that would correspond to a substantial ( $\bar{s}s$ ) content in  $f_0(980)$  [125]. However, in a dispersive analysis of the same data that allows for a model-independent inclusion of the hadronic final state interactions in Ref. [127] a substantial  $f_0(980)$  contribution is also found in the  $B$ -decays putting into question the conclusions of Ref. [125].

**The  $f_0$ 's above 1 GeV.** A meson resonance that is very well studied experimentally, is the  **$f_0(1500)$**  seen by the Crystal Barrel experiment in five decay modes:  $\pi\pi$ ,  $K\bar{K}$ ,  $\eta\eta$ ,  $\eta\eta'(958)$ , and  $4\pi$  [15,69,70]. Due to its interference with the  $f_0(1370)$  (and  **$f_0(1710)$** ), the peak attributed to the  $f_0(1500)$  can appear shifted in invariant mass spectra. Therefore, the application of simple Breit-Wigner forms arrives at slightly different resonance masses for  $f_0(1500)$ . Analyses of central-production data of the likewise five decay modes Refs. [128,129] agree on the description of the  $S$ -wave with the one above. The  $p\bar{p}$ ,  $p\bar{n}/n\bar{p}$  measurements [70,130–132] show a single enhancement at 1400 MeV in the invariant  $4\pi$  mass spectra, which is resolved into  $f_0(1370)$  and  $f_0(1500)$  [133,134]. The data on  $4\pi$  from central production [135] require both resonances, too, but disagree on the relative content of  $\rho\rho$  and  $f_0(500)f_0(500)$  in  $4\pi$ . All investigations agree that the  $4\pi$  decay mode represents about half of the  $f_0(1500)$  decay width and is dominant for  $f_0(1370)$ .

The determination of the  $\pi\pi$  coupling of  **$f_0(1370)$**  is aggravated by the strong overlap with the broad  $f_0(500)$  and  $f_0(1500)$ . Since it does not show up prominently in the  $2\pi$  spectra, its mass and width are difficult to determine. Multi-channel analyses of hadronically produced two- and three-body final states agree on a mass between 1300 MeV and 1400 MeV and a narrow  $f_0(1500)$ , but arrive at a somewhat smaller width for  $f_0(1370)$ .

**V. Interpretation of the scalars below 1 GeV:** In the literature, many suggestions are discussed, such as conventional  $q\bar{q}$  mesons,  $q\bar{q}q\bar{q}$  or meson-meson bound states. In addition, one expects a scalar glueball in this mass range. In reality, there can be superpositions of these components, and one often depends on models to determine the dominant one. Although we have seen progress in recent years, this question remains open. Here, we mention some of the present conclusions.

The  $f_0(980)$  and  $a_0(980)$  are often interpreted as multiquark states [136–140] or  $K\bar{K}$  bound states [141]. The insight into their internal structure using two-photon widths [115,142–148] is not conclusive. The  $f_0(980)$  appears as a peak structure in  $J/\psi \rightarrow \phi\pi^+\pi^-$  and in  $D_s$  decays without  $f_0(500)$  background, while being nearly invisible in  $J/\psi \rightarrow \omega\pi^+\pi^-$ . Based on that observation it is suggested that  $f_0(980)$  has a large  $s\bar{s}$  component, which according to Ref. [149] is surrounded by a virtual  $K\bar{K}$  cloud (see also Ref. [150]). Data on radiative decays ( $\phi \rightarrow f_0\gamma$  and  $\phi \rightarrow a_0\gamma$ ) from SND, CMD2, and KLOE (see above) are consistent with a prominent role of kaon loops. This observation is interpreted as evidence for a compact four-quark [151] or a molecular [152,153] nature of these states. Details of this controversy are given in the comments [154,155]; see also Ref. [156]. It remains quite possible that the states  $f_0(980)$  and  $a_0(980)$ , together with the  $f_0(500)$  and the  $K_0^*(800)$ , form a new low-mass state nonet of predominantly four-quark states, where at larger distances the quarks recombine into a pair of pseudoscalar mesons creating a meson cloud (see, *e.g.*, Ref. [157]). Different QCD sum rule studies [158–162] do not agree on a tetraquark configuration for the same particle group.

Models that start directly from chiral Lagrangians, either in non-linear [42,25,80,152] or in linear [163–169] realization, predict the existence of the  $f_0(500)$  meson near 500 MeV. Here the  $f_0(500)$ ,  $a_0(980)$ ,  $f_0(980)$ , and  $K_0^*(800)$  (in some models the  $K_0^*(1430)$ ) would form a nonet (not necessarily  $q\bar{q}$ ). In the linear sigma models the lightest pseudoscalars appear as their chiral partners. In these models the light  $f_0(500)$  is often referred to as the "Higgs boson of strong interactions", since here the  $f_0(500)$  plays a role similar to the Higgs particle in electro-weak symmetry breaking: within the linear sigma models it is important for the mechanism of chiral symmetry breaking, which generates most of the proton mass, and what is referred to as the constituent quark mass.

In the non-linear approaches of [25,80] the above resonances together with the low lying vector states are generated starting from chiral perturbation theory predictions near the first open

channel, and then by extending the predictions to the resonance regions using unitarity and analyticity.

Ref. [163] uses a framework with explicit resonances that are unitarized and coupled to the light pseudoscalars in a chirally invariant way. Evidence for a non- $\bar{q}q$  nature of the lightest scalar resonances is derived from their mixing scheme. In Ref. [164] the scheme is extended and applied to the decay  $\eta' \rightarrow \eta\pi\pi$ , which lead to the same conclusions. To identify the nature of the resonances generated from scattering equations, in Ref. [170] the large  $N_c$  behavior of the poles was studied, with the conclusion that, while the light vector states behave consistent with what is predicted for  $\bar{q}q$  states, the light scalars behave very differently. This finding provides strong support for a non- $\bar{q}q$  nature of the light scalar resonances. Note, the more refined study of Ref. [109] found, in case of the  $f_0(500)$ , in addition to a dominant non- $\bar{q}q$  nature, indications for a subdominant  $\bar{q}q$  component located around 1 GeV. Additional support for the non- $\bar{q}q$  nature of the  $f_0(500)$  is given in Ref. [171], where the connection between the pole of resonances and their Regge trajectories is analyzed.

A model-independent method to identify hadronic molecules goes back to a proposal by Weinberg [172], shown to be equivalent to the pole counting arguments of [173–175] in Ref. [176]. The formalism allows one to extract the amount of molecular component in the wave function from the effective coupling constant of a physical state to a nearby continuum channel. It can be applied to near threshold states only and provided strong evidence that the  $f_0(980)$  is a  $\bar{K}K$  molecule, while the situation turned out to be less clear for the  $a_0(980)$  (see also Refs. [148,146]). Further insights into  $a_0(980)$  and  $f_0(980)$  are expected from their mixing [177]. The corresponding signal predicted in Refs. [178,179] was recently observed at BES III [180]. It turned out that in order to get a quantitative understanding of those data in addition to the mixing mechanism itself, some detailed understanding of the production mechanism seems necessary [181].

In the unitarized quark model with coupled  $q\bar{q}$  and meson-meson channels, the light scalars can be understood as additional manifestations of bare  $q\bar{q}$  confinement states, strongly mass shifted from the 1.3 - 1.5 GeV region and very distorted due to the strong  $^3P_0$  coupling to  $S$ -wave two-meson decay channels [182] vanbeveren01b. Thus, in these models the light scalar nonet comprising the  $f_0(500)$ ,  $f_0(980)$ ,  $K_0^*(800)$ , and  $a_0(980)$ , as well as the nonet consisting of the  $f_0(1370)$ ,  $f_0(1500)$  (or  $f_0(1710)$ ),  $K_0^*(1430)$ , and  $a_0(1450)$ , respectively, are two manifestations of the same bare input states (see also Ref. [184]).

Other models with different groupings of the observed resonances exist and may, *e.g.*, be found in earlier versions of this review.

**VI. Interpretation of the  $f_0$ 's above 1 GeV:** The  $f_0(1370)$  and  $f_0(1500)$  decay mostly into pions ( $2\pi$  and  $4\pi$ ) while the  $f_0(1710)$  decays mainly into the  $K\bar{K}$  final states. The  $K\bar{K}$  decay branching ratio of the  $f_0(1500)$  is small [128,185].

If one uses the naive quark model, it is natural to assume that the  $f_0(1370)$ ,  $a_0(1450)$ , and the  $K_0^*(1430)$  are in the same SU(3) flavor nonet, being the  $(u\bar{u} + d\bar{d})$ ,  $u\bar{d}$  and  $u\bar{s}$  states, probably mixing with the light scalars [186], while the  $f_0(1710)$  is the  $s\bar{s}$  state. Indeed, the production of  $f_0(1710)$  (and  $f_2'(1525)$ ) is observed in  $p\bar{p}$  annihilation [187] but the rate is suppressed compared to  $f_0(1500)$  (respectively,  $f_2(1270)$ ), as would be expected from the OZI rule for  $s\bar{s}$  states. The  $f_0(1500)$  would also qualify as a  $(u\bar{u} + d\bar{d})$  state, although it is very narrow compared to the other states and too light to be the first radial excitation.

However, in  $\gamma\gamma$  collisions leading to  $K_S^0 K_S^0$  [188] a spin-0 signal is observed at the  $f_0(1710)$  mass (together with a dominant spin-2 component), while the  $f_0(1500)$  is not observed in  $\gamma\gamma \rightarrow K\bar{K}$  nor  $\pi^+\pi^-$  [189]. In  $\gamma\gamma$  collisions leading to  $\pi^0\pi^0$  Ref. [190] reports the observation of a scalar around 1470 MeV albeit with large uncertainties on the mass and  $\gamma\gamma$  couplings. This state could be the  $f_0(1370)$  or the  $f_0(1500)$ . The upper limit from  $\pi^+\pi^-$  [189] excludes a large  $n\bar{n}$  (here  $n$  stands for the two lightest quarks) content for the  $f_0(1500)$  and hence points to a mainly  $s\bar{s}$  state [191]. This appears to contradict the small  $K\bar{K}$  decay branching ratio of the  $f_0(1500)$  and makes a  $q\bar{q}$  assignment difficult for this state. Hence the  $f_0(1500)$  could be mainly glue due the absence of a  $2\gamma$ -coupling, while the  $f_0(1710)$  coupling to  $2\gamma$  would be compatible with an  $s\bar{s}$  state. This is in accord with the recent high-statistics Belle data in  $\gamma\gamma \rightarrow K_S^0 K_S^0$  [192] in which the  $f_0(1500)$  is absent, while a prominent peak at 1710 MeV is observed with quantum numbers  $0^{++}$ , compatible with the formation of an  $s\bar{s}$  state. However, the  $2\gamma$ -couplings are sensitive to glue mixing with  $q\bar{q}$  [193].

Note that an isovector scalar, possibly the  $a_0(1450)$  (albeit at a lower mass of 1317 MeV) is observed in  $\gamma\gamma$  collisions leading to  $\eta\pi^0$  [194]. The state interferes destructively with the non-resonant background, but its  $\gamma\gamma$  coupling is comparable to that of the  $a_2(1320)$ , in accord with simple predictions (see, *e.g.*, Ref. [191]).

The small width of  $f_0(1500)$ , and its enhanced production at low transverse momentum transfer in central collisions [195–197] also favor  $f_0(1500)$  to be non- $q\bar{q}$ . In the mixing scheme of Ref. [193], which uses central production data from WA102 and the recent hadronic  $J/\psi$  decay data from BES [198,199], glue is shared between  $f_0(1370)$ ,  $f_0(1500)$  and  $f_0(1710)$ . The  $f_0(1370)$  is mainly  $n\bar{n}$ , the  $f_0(1500)$  mainly glue and the  $f_0(1710)$  dominantly  $s\bar{s}$ . This agrees with previous analyses [200,201]. In Ref. [202]  $f_0(1710)$  qualifies as a glueball candidate based on an analysis of decay data in an extended linear sigma model with a dilaton field.

However, alternative schemes have been proposed (*e.g.*, in [203–204]; for a review see, *e.g.*, Ref. [1]) . In particular, for a scalar glueball, the two-gluon coupling to  $n\bar{n}$  appears to be suppressed by chiral symmetry [205] and therefore the  $K\bar{K}$  decay could be enhanced. This mechanism would imply that the  $f_0(1710)$  can possibly be interpreted as an unmixed

# Meson Particle Listings

## $f_0(500)$

glueball [206]. In Ref. [207], a large  $K^+K^-$  scalar signal reported by Belle in  $B$  decays into  $KK\bar{K}$  [208], compatible with the  $f_0(1500)$ , is explained as due to constructive interference with a broad glueball background. However, the Belle data are inconsistent with the BaBar measurements which show instead a broad scalar at this mass for  $B$  decays into both  $K^\pm K^\pm K^\mp$  [209] and  $K^+K^-\pi^0$  [210].

Whether the  $f_0(1500)$  is observed in 'gluon rich' radiative  $J/\psi$  decays is debatable [211] because of the limited amount of data - more data for this and the  $\gamma\gamma$  mode are needed.

In Ref. [212], further refined in Ref. [213],  $f_0(1370)$  and  $f_0(1710)$  (together with  $f_2(1270)$  and  $f_2'(1525)$ ) were interpreted as bound systems of two vector mesons. This picture could be tested in radiative  $J/\psi$  decays [214] as well as radiative decays of the states themselves [215]. The vector-vector component of the  $f_0(1710)$  might also be the origin of the enhancement seen in  $J/\psi \rightarrow \gamma\phi\omega$  near threshold [216] observed at BES [217].

<sup>1</sup> Applying the chiral unitary approach at NLO to the  $K_{e4}$  data of BATLEY 10 and  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

<sup>2</sup> Uses the  $K_{e4}$  data of BATLEY 10c and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

<sup>3</sup> Analytic continuation using Roy equations.

<sup>4</sup> Analytic continuation using GKPY equations.

<sup>5</sup> Using Roy equations.

<sup>6</sup> Average of three variants of the analytic K-matrix model. Uses the  $K_{e4}$  data of BATLEY 08A and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73 and GRAYER 74.

<sup>7</sup> Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.

<sup>8</sup> From the  $K_{e4}$  data of BATLEY 08A and  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73.

<sup>9</sup> From the  $K_{e4}$  data of BATLEY 08A and  $\pi N \rightarrow \pi\pi N$  data of PROTOPODESCU 73, GRAYER 74, and ESTABROOKS 74.

<sup>10</sup> From a mean of three different  $f_0(500)$  parametrizations. Uses 40k events.

<sup>11</sup> From an isobar model using 2.6k events.

<sup>12</sup> Reanalysis of ABLIKIM 04A, PISLAK 01, and HYAMS 73 data.

<sup>13</sup> Using the N/D method.

<sup>14</sup> From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPODESCU 73 data.

See key on page 601

## Meson Particle Listings

 $f_0(500)$ 

- 15 Reanalysis of the data from PROTOPODESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.  
 16 From a mean of six different analyses and  $f_0(500)$  parameterizations.  
 17 Using data on  $\psi(2S) \rightarrow J/\psi \pi \pi$  from BAI 00E and on  $\Upsilon(nS) \rightarrow \Upsilon(mS) \pi \pi$  from BUTLER 94B and ALEXANDER 98.  
 18 Reanalysis of data from PROTOPODESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.  
 19 From a combined analysis of HYAMS 73, AUGUSTIN 89, AITALA 01B, and PISLAK 01.  
 20 A similar analysis (KOMADA 01) finds  $(580^{+79}_{-30}) - i(190^{+107}_{-49})$  MeV.  
 21 Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82B using the uniformizing variable.  
 22 Using the inverse amplitude method and data of ESTABROOKS 73, GRAYER 74, and PROTOPODESCU 73.  
 23 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.  
 24 Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.  
 25 Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.  
 26 Demonstrates explicitly that  $f_0(500)$  and  $f_0(1370)$  are two different poles.  
 27 Analysis of data from FALVARD 88.  
 28 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.  
 29 Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.  
 30 Coupled-channel analysis using data from PROTOPODESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEN 79, BISWAS 81.  
 31 Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.  
 32 Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72, PROTOPODESCU 73, and WALKER 67.

- 55 Using dispersive analysis with phases from GARCIA-MARTIN 11A and BUETTAKER 04 as input.  
 56 Using Roy-Steiner equations with  $\pi \pi$  phase shifts from an update of COLANGELO 01 and from GARCIA-MARTIN 11A.  
 57 Using an analytic K-matrix model.  
 58 Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.  
 59 Used dispersion theory. The value quoted used the  $f_0(500)$  pole position of  $457 - i276$  MeV.  
 60 Using  $p, n$  polarizabilities from PDG 06 and fitting to  $\pi \pi$  phase motion from GARCIA-MARTIN 07 and  $\sigma$ -poles from GARCIA-MARTIN 07 and CAPRINI 06.  
 61 Using twice-subtracted dispersion integrals.  
 62 Supersedes OLLER 08.  
 63 Solution A (preferred solution based on  $\chi^2$ -analysis).  
 64 Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.  
 65 Solution B (worse than solution A; still acceptable when systematic uncertainties are included).  
 66 Using unitarity and the  $\sigma$  pole position from CAPRINI 06.  
 67 This width could equally well be assigned to the  $f_0(1370)$ . The authors analyse data from BOYER 90 and MARSISKE 90 and report strong correlation with  $\gamma \gamma$  width of  $f_2(1270)$ .  
 68 Supersedes MORGAN 90.

## THE $\rho(770)$

Updated May 2012 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

The determination of the parameters of the  $\rho(770)$  is beset with many difficulties because of its large width. In physical region fits, the line shape does not correspond to a relativistic Breit-Wigner function with a  $P$ -wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the  $\rho(770)$  line shape, particularly in multiparticle final state systems [2].

The same model-dependence afflicts any other source of resonance parameters, such as the energy-dependence of the phase shift  $\delta_1^+$ , or the pole position. It is, therefore, not surprising that a study of  $\rho(770)$  dominance in the decays of the  $\eta$  and  $\eta'$  reveals the need for specific dynamical effects, in addition to the  $\rho(770)$  pole [3,4].

The cleanest determination of the  $\rho(770)$  mass and width comes from  $e^+e^-$  annihilation and  $\tau$ -lepton decays. Analysis of ALEPH [5] showed that the charged  $\rho(770)$  parameters measured from  $\tau$ -lepton decays are consistent with those of the neutral one determined from  $e^+e^-$  data [6]. This conclusion is qualitatively supported by the later studies of CLEO [7] and Belle [8]. However, model-independent comparison of the two-pion mass spectrum in  $\tau$  decays, and the  $e^+e^- \rightarrow \pi^+\pi^-$  cross section, gave indications of discrepancies between the overall normalization:  $\tau$  data are about 3% higher than  $e^+e^-$  data [7,9]. A detailed analysis using such two-pion mass spectra from  $\tau$  decays measured by OPAL [10], CLEO [7], and ALEPH [11,12], as well as recent pion form factor measurements in  $e^+e^-$  annihilation by CMD-2 [13,14], showed that the discrepancy can be as high as 10% above the  $\rho$  meson [15,16]. This discrepancy remains after recent measurements of the two-pion cross section in  $e^+e^-$  annihilation at KLOE [17,18] and SND [19,20]. This effect is not accounted for by isospin breaking [21–24], but the accuracy of its calculation may be overestimated [25,26].

This problem seems to be solved after a recent analysis in [27] which showed that after correcting the  $\tau$  data for the missing  $\rho - \gamma$  mixing contribution, besides the other known isospin symmetry violating corrections, the  $\pi\pi$  I=1 part of the hadronic vacuum polarization contribution to the muon  $g - 2$  is fully compatible between  $\tau$  based and  $e^+e^-$  based evaluations including more recent BaBar [28] and KLOE [29] data. Further proof of the consistency of the data on  $\tau$  decays to two pions and  $e^+e^-$  annihilation is given by the global fit of the whole set of the  $\rho$ ,  $\omega$ , and  $\phi$  decays, taking into account mixing effects in the hidden local symmetry model [30].

# Meson Particle Listings

## $\rho(770)$

- <sup>1</sup> Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho$ - $\omega$  interference and leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.
- <sup>2</sup> A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.
- <sup>3</sup> Supersedes ACHASOV 05A.
- <sup>4</sup> A fit of the SND data from 400 to 1000 MeV using parameters of the  $\rho(1450)$  and  $\rho(1700)$  from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.
- <sup>5</sup> Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho$ - $\omega$  interference.
- <sup>6</sup> Update of AKHMETSHIN 02.
- <sup>7</sup> Assuming  $m_{\rho^+} = m_{\rho^-}$ ,  $\Gamma_{\rho^+} = \Gamma_{\rho^-}$ .
- <sup>8</sup> From the GOUNARIS 68 parametrization of the pion form factor.
- <sup>9</sup> Assuming  $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$ ,  $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$ .
- <sup>10</sup> Without limitations on masses and widths.
- <sup>11</sup> Assuming  $m_{\rho^0} = m_{\rho^\pm}$ ,  $g_{\rho^0\pi\pi} = g_{\rho^\pm\pi\pi}$ .
- <sup>12</sup> Using the data of BARKOV 85 in the hidden local symmetry model.
- <sup>13</sup> From the fit to  $e^+e^- \rightarrow \pi^+\pi^-$  data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.
- <sup>14</sup> A fit of BARKOV 85 data assuming the direct  $\omega\pi\pi$  coupling.
- <sup>15</sup> Applying the S-matrix formalism to the BARKOV 85 data.
- <sup>16</sup> Includes BARKOV 85 data. Model-dependent width definition.
- <sup>17</sup>  $|F_\pi(0)|^2$  fixed to 1.
- <sup>18</sup> From the GOUNARIS 68 parametrization of the pion form factor.
- <sup>19</sup> The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.
- <sup>20</sup>  $\rho(1700)$  mass and width fixed at 1700 MeV and 235 MeV respectively.
- <sup>21</sup> From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.
- <sup>22</sup> Using the data of BARATE 97M and the effective chiral Lagrangian.
- <sup>23</sup> From a fit of the model-independent parametrization of the pion form factor to the data of BARATE 97M.
- <sup>24</sup> Assuming the equality of  $\rho^+$  and  $\rho^-$  masses and widths.
- <sup>25</sup> Mass errors enlarged by us to  $\Gamma/\sqrt{N}$ ; see the note with the  $K^*(892)$  mass.
- <sup>26</sup> Phase shift analysis. Systematic errors added corresponding to spread of different fits.
- <sup>27</sup> From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.
- <sup>28</sup> Using the KUHN 90 parametrization of the pion form factor, neglecting  $\rho$ - $\omega$  interference.
- <sup>29</sup> From the parametrization according to SOEDING 66.
- <sup>30</sup> From the parametrization according to ROSS 66.
- <sup>31</sup> HEYN 81 includes all spacelike and timelike  $F_\pi$  values until 1978.
- <sup>32</sup> From pole extrapolation.
- <sup>33</sup> From phase shift analysis of GRAYER 74 data.
- <sup>34</sup> Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDHABER 64, ABOLINS 63.
- <sup>35</sup> Breit-Wigner mass from a phase-shift analysis of HYAMS 73 and PROTOPOPESCU 73 data.
- <sup>36</sup> Using relativistic Breit-Wigner and taking into account  $\rho$ - $\omega$  interference.
- <sup>37</sup> Systematic errors not evaluated.
- <sup>38</sup> Systematic effects not studied.
- <sup>39</sup> From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity. CHABAUD 83 includes data of GRAYER 74.

$\rho(770)$ RANGE PARAMETER					
The range parameter $R$ enters an energy-dependent correction to the width, of the form $(1 + q^2 R^2) / (1 + q^2 R^2)$ , where $q$ is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$ .

45 Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho$ - $\omega$  interference and leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.

46 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.

47 Supersedes ACHASOV 05A.

48 A fit of the SND data from 400 to 1000 MeV using parameters of the  $\rho(1450)$  and  $\rho(1700)$  from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.

49 Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho$ - $\omega$  interference.

50 From a fit in the energy range 0.61 to 0.96 GeV. Update of AKHMETSHIN 02.

51 Assuming  $m_{\rho^+} = m_{\rho^-}$ ,  $\Gamma_{\rho^+} = \Gamma_{\rho^-}$ .

52 From the GOUNARIS 68 parametrization of the pion form factor.

53 Assuming  $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$ ,  $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$ .

54 Without limitations on masses and widths.

55 Assuming  $m_{\rho^0} = m_{\rho^\pm}$ ,  $g_{\rho^0 \pi \pi} = g_{\rho^\pm \pi \pi}$ .

56 Using the data of BARKOV 85 in the hidden local symmetry model.

57 From the fit to  $e^+ e^- \rightarrow \pi^+ \pi^-$  data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.

58 A fit of BARKOV 85 data assuming the direct  $\omega \pi \pi$  coupling.

59 Applying the S-matrix formalism to the BARKOV 85 data.

60 Includes BARKOV 85 data. Model-dependent width definition.

61  $|F_\pi(0)|^2$  fixed to 1.

62 From the GOUNARIS 68 parametrization of the pion form factor.

63 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.

64  $\rho(1700)$  mass and width fixed at 1700 MeV and 235 MeV respectively.

65 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.

66 Using the data of BARATE 97M and the effective chiral Lagrangian.

67 Assuming the equality of  $\rho^+$  and  $\rho^-$  masses and widths.

68 Width errors enlarged by us to  $4\Gamma/\sqrt{N}$ ; see the note with the  $K^*(892)$  mass.

69 Phase shift analysis. Systematic errors added corresponding to spread of different fits.

70 From fit of 3-parameter relativistic  $P$ -wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.

71 Using the KUHN 90 parametrization of the pion form factor, neglecting  $\rho$ - $\omega$  interference.

72 From the parametrization according to SOEDING 66.

73 From the parametrization according to ROSS 66.

74 From pole extrapolation.

75 From phase shift analysis of GRAYER 74 data.

76 Using relativistic Breit-Wigner and taking into account  $\rho$ - $\omega$  interference.

77 Systematic errors not evaluated.

78 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of  $P$ -wave intensity. CHABAUD 83 includes data of GRAYER 74.

79 HEYN 81 includes all spacelike and timelike  $F_\pi$  values until 1978.

80 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDBABER 64, ABOLINS 63.

## Meson Particle Listings

 $\rho(770)$  $\rho(770)^0$  decays

	$\sim 100$	%
$\Gamma_6 \pi^+ \pi^-$	( 9.9 $\pm$ 1.6 )	$\times 10^{-3}$
$\Gamma_7 \pi^+ \pi^- \gamma$	( 6.0 $\pm$ 0.8 )	$\times 10^{-4}$
$\Gamma_8 \pi^0 \gamma$	( 3.00 $\pm$ 0.20 )	$\times 10^{-4}$
$\Gamma_9 \eta \gamma$	( 4.5 $\pm$ 0.8 )	$\times 10^{-5}$
$\Gamma_{10} \pi^0 \pi^0 \gamma$	( 4.55 $\pm$ 0.28 )	$\times 10^{-5}$
$\Gamma_{11} \mu^+ \mu^-$	[a] ( 4.72 $\pm$ 0.05 )	$\times 10^{-5}$
$\Gamma_{12} e^+ e^-$	( 1.01 $\pm$ 0.54 $\pm$ 0.34 )	$\times 10^{-4}$
$\Gamma_{13} \pi^+ \pi^- \pi^0$	( 1.8 $\pm$ 0.9 )	$\times 10^{-5}$
$\Gamma_{14} \pi^+ \pi^- \pi^+ \pi^-$	( 1.6 $\pm$ 0.8 )	$\times 10^{-5}$
$\Gamma_{15} \pi^+ \pi^- \pi^0 \pi^0$	< 1.2	$\times 10^{-5}$
$\Gamma_{16} \pi^0 e^+ e^-$		
$\Gamma_{17} \eta e^+ e^-$		

[a] The  $\omega\rho$  interference is then due to  $\omega\rho$  mixing only, and is expected to be small. If  $e\mu$  universality holds,  $\Gamma(\rho^0 \rightarrow \mu^+ \mu^-) = \Gamma(\rho^0 \rightarrow e^+ e^-) \times 0.99785$ .

## CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 10.7$  for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_3$	-100

## CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 51 measurements and one constraint to determine 10 parameters. The overall fit has a  $\chi^2 = 51.8$  for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	22

### PARAMETER $\Lambda$ IN $\omega \rightarrow \pi^0\mu^+\mu^-$ DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass  $M$  is given by the expression:  
 $|F|^2 = (1 - M^2/\Lambda^2)^{-2}$ ,  
where for the parameter  $\Lambda$  vector dominance predicts  $\Lambda = M_\rho \approx 0.770$  GeV. The ARNALDI 09 measurement is in obvious conflict with this expectation. Note that for  $\eta \rightarrow \mu^+\mu^-\gamma$  decay ARNALDI 09 and DZHELYADIN 80 obtain the value of  $\Lambda$  consistent with vector dominance.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 16 branching ratios uses 46 measurements and one constraint to determine 9 parameters. The overall fit has a  $\chi^2 = 52.8$  for 38 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

### $\eta'(958) \Gamma(i) \Gamma(\gamma\gamma) / \Gamma(\text{total})$

This combination of a partial width with the partial width into  $\gamma\gamma$  and with the total width is obtained from the integrated cross section into channel(i) in the  $\gamma\gamma$  annihilation.

$\Gamma(\gamma\gamma) \times \Gamma(\rho^0 \gamma \text{ (including non-resonant } \pi^+ \pi^- \gamma)) / \Gamma_{\text{total}}$				$\Gamma_6 \Gamma_2 / \Gamma$

### $\eta'(958) \rightarrow \eta\pi\pi$ DECAY PARAMETERS

$$|\text{MATRIX ELEMENT}|^2 = |1 + \alpha Y|^2 + CX + DX^2$$

$X$  and  $Y$  are Dalitz variables;  $\alpha$  is complex and  $C$ , and  $D$  are real-valued. Parameters  $C$  and  $D$  are not necessarily equal to  $c$  and  $d$ , respectively, in the generalized parameterization following this one. May be different for  $\eta'(958) \rightarrow \eta\pi^+\pi^-$  and  $\eta'(958) \rightarrow \eta\pi^0\pi^0$  decays. Because of different initial assumptions and strong correlations of the parameters we do not average the parameters in the section below.

54 ± 16		<sup>36</sup> PROTOPOP...	73 HBC	7 $\pi^+ p \rightarrow \pi^+ \pi^+ \pi^-$

<sup>1</sup> Analytic continuation using Roy equations. Uses the  $K_{e4}$  data of BATLEY 10C and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

<sup>2</sup> Quoted number refers to twice imaginary part of pole position.

<sup>3</sup> Analytic continuation using GKPY equations. Uses the  $K_{e4}$  data of BATLEY 10C and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

<sup>4</sup> Pole position. Used Roy equations.

<sup>5</sup> Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.

<sup>6</sup> On sheet II in a 2-pole solution. The other pole is found on sheet III at (850–100i) MeV

<sup>7</sup> Using a relativistic Breit-Wigner function and taking into account the finite  $D_S$  mass.

<sup>8</sup> Breit-Wigner  $\pi\pi$  width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0} K K / g_{f_0} \pi\pi = 0$ .

<sup>9</sup> Systematic errors not estimated.

<sup>10</sup> Breit-Wigner  $\pi\pi$  width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0} K K / g_{f_0} \pi\pi = 4.21 \pm 0.25 \pm 0.21$  from ABLIKIM 05.

<sup>11</sup> Breit-Wigner, solution 1, PWA ambiguous.

<sup>12</sup> K-matrix pole from combined analysis of  $\pi^- p \rightarrow \pi^0 \pi^0 n$ ,  $\pi^- p \rightarrow \pi^+ \pi^- n$ ,  $\pi^+ \pi^- \rightarrow \pi^0 \pi^0 \pi^0$ ,  $\pi^0 \eta \eta$ ,  $\pi^0 \pi^0 \eta$ ,  $\pi^+ \pi^- \pi^0$ ,  $K^+ K^- \pi^0$ ,  $K_S^0 K_S^0 \pi^0$ ,  $K^+ K_S^0 \pi^-$  at rest,  $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$ ,  $K_S^0 K^- \pi^0$ ,  $K_S^0 K_S^0 \pi^-$  at rest.

<sup>13</sup> Using the data of AKHMETSHIN 99C, ACHASOV 00H, and ALOISIO 02D.

<sup>14</sup> Breit-Wigner width.

<sup>15</sup> Supersedes ACHASOV 98i. Using the model of ACHASOV 89.

<sup>16</sup> Supersedes ACHASOV 98i.

<sup>17</sup> In the “narrow resonance” approximation.

<sup>18</sup> From the combined fit of the photon spectra in the reactions  $e^+ e^- \rightarrow \pi^+ \pi^- \gamma$ ,  $\pi^0 \pi^0 \gamma$ .

<sup>19</sup> Supersedes BARBERIS 99 and BARBERIS 99B

<sup>20</sup> T-matrix pole.

<sup>21</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039–93i) MeV.

<sup>22</sup> From invariant mass fit.

<sup>23</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at (963–29i) MeV.

<sup>24</sup> Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.

<sup>25</sup> At high  $|t|$ .

<sup>26</sup> At low  $|t|$ .

<sup>27</sup> On sheet II in a 4-pole solution, the other poles are found on sheet III at (953–55i) MeV and on sheet IV at (938–35i) MeV.

<sup>28</sup> Combined fit of ALDE 95B, ANISOVICH 94,

<sup>29</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at (996–103i) MeV.

<sup>30</sup> From sheet II pole position.

<sup>31</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185i) MeV and can be interpreted as a shadow pole.

<sup>32</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at (978–28i) MeV.

<sup>33</sup> From coupled channel analysis.

<sup>34</sup> Coupled channel analysis with finite width corrections.

<sup>35</sup> From coupled channel fit to the HYAMS 73 and PROTOPODESCU 73 data. With a simultaneous fit to the  $\pi\pi$  phase-shifts, inelasticity and to the  $K_S^0 K_S^0$  invariant mass.

<sup>36</sup> Included in AGUILAR-BENITEZ 78 fit.

<sup>1</sup> Using dispersive analysis with phases from GARCIA-MARTIN 11A and BUETTIKER 04 as input.

<sup>2</sup> Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0} K K / g_{f_0} \pi\pi = 0$ .

<sup>3</sup> Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0} K K / g_{f_0} \pi\pi = 4.21 \pm 0.25 \pm 0.21$  from ABLIKIM 05.

<sup>4</sup> OEST 90 quote systematic errors<sup>+0.08</sup><sub>-0.18</sub>. We use ±0.18. Observed 60 events.

<sup>5</sup> Uses an analytic K-matrix model. Compilation.

<sup>6</sup> Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.

<sup>7</sup> Solution A (preferred solution based on  $\chi^2$ -analysis).

<sup>8</sup> Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.

<sup>9</sup> Solution B (worse than solution A; still acceptable when systematic uncertainties are included).

<sup>10</sup> Supersedes MORGAN 90.

<sup>11</sup> From analysis allowing arbitrary background unconstrained by unitarity.

<sup>12</sup> Data included in MORGAN 90, BOGLIONE 99 analyses.

<sup>13</sup> From amplitude analysis of BOYER 90 and MARSISKE 90, data corresponds to resonance parameters  $m = 989$  MeV,  $\Gamma = 61$  MeV.

<sup>1</sup> Using the model of ACHASOV 89 and ACHASOV 03b.

<sup>2</sup> From a fit with the S-wave amplitude including two interfering Breit-Wigners plus a background term.

<sup>3</sup> Parameterizes couplings to  $\bar{K}K, \pi\eta$ , and  $\pi\eta'$ .

<sup>4</sup> Using AMSLER 94d and ABELE 98.

<sup>5</sup> From the T-matrix pole on sheet II.

<sup>6</sup> Using the model of ACHASOV 89. Supersedes ACHASOV 98b.

<sup>7</sup> Using the model of JAFFE 77. Supersedes ACHASOV 98b.

<sup>8</sup> T-matrix pole.

<sup>9</sup> Breit-Wigner fit, average between  $a_0^{\pm}$  and  $a_0^0$ . The fit favors a slightly heavier  $a_0^{\pm}$ .

<sup>10</sup> From a single Breit-Wigner fit.

<sup>11</sup> From  $f_1(1285)$  decay.

<b>0.6340±0.0070±0.0039</b>	<sup>1</sup> LEES	13Q BABR	$e^+e^- \rightarrow K^+K^-\gamma$

<sup>1</sup> Using a phenomenological model based on KUNN 90 with a sum of Breit-Wigner resonances for  $\rho(770)$ ,  $\omega(782)$ ,  $\phi(1020)$  and their higher mass excitations. The first error combines statistical and systematic uncertainties. The second one is due to the parametrization of the charged kaon form factor and mass calibration.

2 Update of AKHMETSHIN 99D  
3 Recalculated by us from the cross section in the peak.4 From a combined fit of  $\sigma(e^+e^- \rightarrow \eta\gamma)$  with  $\eta \rightarrow 3\pi^0$  and  $\eta \rightarrow \pi^+\pi^-\pi^0$ , and fixing  $B(\eta \rightarrow 3\pi^0) / B(\eta \rightarrow \pi^+\pi^-\pi^0) = 1.44 \pm 0.04$ . Recalculated by us from the cross section at the peak. Supersedes ACHASOV 00D and ACHASOV 06A.5 From the  $\eta \rightarrow 2\gamma$  decay and using  $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$ .  
6 From the  $\eta \rightarrow 3\pi^0$  decay and using  $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$ .7 The combined fit from 600 to 1380 MeV taking into account  $\rho(770)$ ,  $\omega(782)$ ,  $\phi(1020)$ , and  $\rho(1450)$  (mass and width fixed at 1450 MeV and 310 MeV respectively).  
8 From the  $\eta \rightarrow 2\gamma$  decay and using  $B(\eta \rightarrow 2\gamma) = (39.21 \pm 0.34) \times 10^{-2}$ .

9 Recalculated by the authors from the cross section in the peak.

10 From the  $\eta \rightarrow \pi^+\pi^-\pi^0$  decay and using  $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.1 \pm 0.5) \times 10^{-2}$ .11 A simultaneous fit of  $e^+e^- \rightarrow \pi^+\pi^-$ ,  $\pi^+\pi^-\pi^0$ ,  $\pi^0\gamma$ ,  $\eta\gamma$  data.12 From the  $\pi^0 \rightarrow 2\gamma$  decay and using  $B(\pi^0 \rightarrow 2\gamma) = (98.798 \pm 0.032) \times 10^{-2}$ .13 A simultaneous fit to  $e^+e^- \rightarrow \pi^+\pi^-$ ,  $\pi^+\pi^-\pi^0$ ,  $\pi^0\gamma$ ,  $\eta\gamma$ ,  $K\bar{K}$ , and  $\tau^- \rightarrow \pi^-\pi^0\nu_\tau$  data.

14 Recalculated by the authors from the cross section at the peak.

15 AMBROSINO 08G reports  $[\Gamma(\phi(1020) \rightarrow \omega\pi^0)/\Gamma_{\text{total}} \times \Gamma(\phi(1020) \rightarrow e^+e^-)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow \pi^+\pi^-\pi^0)] = (1.22 \pm 0.13 \pm 0.08) \times 10^{-8}$  which we divide by our best value  $B(\omega(782) \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

16 Calculated by the authors from the cross section at the peak.

<b>&lt;1 <math>\times 10^{-6}</math></b>	90	78 BABUSCI	13B KLOE	1.02 $e^+e^- \rightarrow \eta e^+e^-$	

- <sup>1</sup> Combined analysis of the CMD-2 data on  $\phi \rightarrow K^+K^-, K_S^0 K_L^0, \pi^+\pi^-\pi^0, \eta\gamma$  assuming that the sum of their branching fractions is 0.99741  $\pm$  0.00007.
- <sup>2</sup> Using  $B(\phi \rightarrow e^+e^-) = (2.93 \pm 0.14) \times 10^{-4}$ .
- <sup>3</sup> Theoretical analysis of BRAMON 00 taking into account phase-space difference, electromagnetic radiative corrections, as well as isospin breaking, predicts 0.62. FLOREZ-BAEZ 08 predicts 0.63 considering also structure-dependent radiative corrections. FISCHBACH 02 calculates additional corrections caused by the close threshold and predicts 0.68. See also BENAYOUN 01 and DUBYNISKIY 07. BENAYOUN 12 obtains  $0.71 \pm 0.01$  in the HLS model.
- <sup>4</sup> Using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .
- <sup>5</sup> Using  $\Gamma(\phi) = 4.1$  MeV. If interference between the  $\rho\pi$  and  $3\pi$  modes is neglected, the fraction of the  $\rho\pi$  is more than 80% at the 90% confidence level.
- <sup>6</sup> From a fit without limitations on charged and neutral  $\rho$  masses and widths.
- <sup>7</sup> Adding the direct and  $\omega\pi$  contributions and considering the interference between the  $\rho\pi$  and  $\pi^+\pi^-\pi^0$ .
- <sup>8</sup> Neglecting the interference between the  $\rho\pi$  and  $\pi^+\pi^-\pi^0$ .
- <sup>9</sup> Using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$  and  $B(\eta \rightarrow 3\pi^0) = (32.2 \pm 0.4) \times 10^{-2}$ .
- <sup>10</sup> From  $\pi^+\pi^-\pi^0$  decay mode of  $\eta$ .
- <sup>11</sup> From  $2\gamma$  decay mode of  $\eta$ .
- <sup>12</sup> From  $3\pi^0$  decay mode of  $\eta$ .
- <sup>13</sup> ACHASOV 07b reports  $[\Gamma(\phi(1020) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [B(\phi(1020) \rightarrow e^+e^-)] = (4.050 \pm 0.067 \pm 0.118) \times 10^{-6}$  which we divide by our best value  $B(\phi(1020) \rightarrow e^+e^-) = (2.954 \pm 0.030) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00b and ACHASOV 06a.
- <sup>14</sup> Using  $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$  and  $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$ .
- <sup>15</sup> Not independent of the corresponding  $\Gamma(e^+e^-) \times \Gamma(\pi^0\gamma)/\Gamma_{\text{total}}^2$ .
- <sup>16</sup> Using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$  and  $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$ .
- <sup>17</sup> The combined fit from 600 to 1380 MeV taking into account  $\rho(770), \omega(782), \phi(1020)$ , and  $\rho(1450)$  (mass and width fixed at 1450 MeV and 310 MeV respectively).
- <sup>18</sup> From the  $\eta \rightarrow 2\gamma$  decay and using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .
- <sup>19</sup> From  $\pi^+\pi^-\pi^0$  decay mode of  $\eta$  and using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .
- <sup>20</sup> Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.

### PARAMETER $\beta$ IN $\phi \rightarrow \eta e^+e^-$ DECAY

In the one-pole approximation the electromagnetic transition form factor for  $\phi \rightarrow \eta e^+e^-$  is given as a function of the  $e^+e^-$  invariant mass squared,  $q^2$ , by the expression:

$$|F(q^2)|^2 = (1 - q^2/\Lambda^2)^{-2},$$

where vector meson dominance predicts parameter  $\Lambda \approx 0.770$  GeV ( $\Lambda^{-2} \approx 1.687$  GeV $^{-2}$ ). The slope of this form factor,  $\beta = dF/dq^2(q^2=0)$ , equals  $\Lambda^{-2}$  in this approximation.

The measurements below obtain  $\beta$  in the one-pole approximation.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 45 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 83.0$  for 38 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

• • • We do not use the following data for averages, fits, limits, etc. • • •						
<1.7	90	VOROBYEV	88	ND	$e^+e^- \rightarrow \pi^0\pi^0$	

- From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
- From analysis of L3 data at 91 and 183–209 GeV and using SU(3) relations.
- Based on a K-matrix analysis of BELLE data from MORI 07, UEHARA 08A, UEHARA 09 and UEHARA 13. The width is derived for the pole on the third sheet which is closest to the physical axis. Supersedes PENNINGTON 08.
- Solution A (preferred solution based on  $\chi^2$ -analysis).
- Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
- Solution B (worse than solution A; still acceptable when systematic uncertainties are included).
- With a narrow scalar state around 1220 MeV.
- Using a unitarized model with a 300–500 keV wide scalar at 1100 MeV.
- Using the unitarized model of LYTH 85.
- Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with  $\gamma\gamma$  width of  $f_0(1370)$ :  $\Gamma(f_2) + 1/4 \Gamma(f^0) = 3.6 \pm 0.3$  KeV.
- Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes  $2.66 \pm 0.21$  in the calculation of LANDRO 86.
- Using the MENNESSIER 83 model.
- Superseded by BOYER 90.
- If helicity = 2 assumption is not made.
- Using mass, width and  $B(f_2(1270) \rightarrow 2\pi)$  from PDG 78.

- <sup>1</sup> Using the  $2\pi+2\pi^-$  and  $\pi^+\pi^-\eta$  modes of  $f_1(1285)$  decay.  
<sup>2</sup> The selected process is  $J/\psi \rightarrow \omega a_0(980)\pi$ .  
<sup>3</sup> Supersedes ABATZIS 94, ARMSTRONG 89E.  
<sup>4</sup> From partial wave analysis of  $K^+ \bar{K}^0 \pi^-$  system.  
<sup>5</sup> No systematic error given.  
<sup>6</sup> From a unitarized quark-model calculation.  
<sup>7</sup> From phase shift analysis of  $\eta\pi^+\pi^-$  system.  
<sup>8</sup> Seen in the missing mass spectrum.

$f_1(1285)$  WIDTH

Only experiments giving width error less than 20 MeV are kept for averaging.

## CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 24.7$  for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_9$	-17			
$x_{10}$	-8	-95		
$x_{11}$	46	-9	-4

## CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 9.3$  for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_5$	10		
$x_6$	-89	-46	
$x_7$	-1	-2	-24

**THE PSEUDOSCALAR AND PSEUDOVECTOR MESONS IN THE 1400 MEV REGION**

Revised July 2015 by C. Amsler (University of Bern) and A. Masoni (INFN Cagliari).

This minireview deals with some of the  $0^{-+}$  and  $1^{++}$  mesons reported in the 1200–1500 MeV region, namely the  $\eta(1405)$ ,  $\eta(1475)$ ,  $f_1(1285)$ ,  $f_1(1420)$ ,  $a_1(1420)$  and  $f_1(1510)$ . The first observation of a pseudoscalar resonance around 1400 MeV – the  $\eta(1440)$  – was made in  $p\bar{p}$  annihilation at rest into  $\eta(1440)\pi^+\pi^-$ ,  $\eta(1440) \rightarrow K\bar{K}\pi$  [1]. This state was reported to decay into  $a_0(980)\pi$  and  $K^*(892)\bar{K}$  with roughly equal contributions. The  $\eta(1440)$  was also observed in radiative  $J/\psi(1S)$  decay into  $K\bar{K}\pi$  [2–4] and  $\gamma\rho$  [5]. However, two pseudoscalars are now reported in this mass region, the  $\eta(1405)$  and  $\eta(1475)$ . The former decays mainly through  $a_0(980)\pi$  (or direct  $K\bar{K}\pi$ ) and the latter mainly to  $K^*(892)\bar{K}$ .

The simultaneous observation of two pseudoscalars is reported in three production mechanisms:  $\pi^-p$  [6,7]; radiative  $J/\psi(1S)$  decay [8,9]; and  $\bar{p}p$  annihilation at rest [10–13]. All of them give values for the masses, widths, and decay modes that are in reasonable agreement. However, Ref. [9] favors a state decaying into  $K^*(892)\bar{K}$  at a lower mass than the state decaying into  $a_0(980)\pi$ . In  $J/\psi(1S)$  radiative decay, the  $\eta(1405)$  decays into  $K\bar{K}\pi$  through  $a_0(980)\pi$ , and hence a signal is also expected in the  $\eta\pi\pi$  mass spectrum. This was indeed observed by MARK III in  $\eta\pi^+\pi^-$  [14], which reported a mass of 1400 MeV, in line with the existence of the  $\eta(1405)$  decaying into  $a_0(980)\pi$ .

BESII [15] observes an enhancement in  $K^+K^-\pi^0$  around 1.44 GeV in  $J/\psi(1S)$  decay, recoiling against an  $\omega$  (but not a  $\phi$ ) without resolving the presence of two states nor performing a spin-parity analysis, due to low statistics. This state could also be the  $f_1(1420)$  (see below). On the other hand, BESII observes  $\eta(1405) \rightarrow \eta\pi\pi$  in  $J/\psi(1S)$  decay, recoiling against an  $\omega$  [16]. A single unresolved broad peak is also observed by

BESIII in the decay  $\psi(2S) \rightarrow \omega K^* K$  which could be due to  $\eta(1405)$ ,  $\eta(1475)$  and  $f_1(1420)$  [17].

The  $\eta(1405)$  is also observed in  $\bar{p}p$  annihilation at rest into  $\eta\pi^+\pi^-\pi^0\pi^0$ , where it decays into  $\eta\pi\pi$  [18]. The intermediate  $a_0(980)\pi$  accounts for roughly half of the  $\eta\pi\pi$  signal, in agreement with MARK III [14] and DM2 [4].

However, the issue remains controversial as to whether two pseudoscalar mesons really exist. According to Ref. [19] the splitting of a single state could be due to nodes in the decay amplitudes which differ in  $\eta\pi\pi$  and  $K^*(892)\bar{K}$ . Based on the isospin violating decay  $J/\psi(1S) \rightarrow \gamma 3\pi$  observed by BESIII [20] the splitting could also be due to a triangular singularity mixing  $\eta\pi\pi$  and  $K^*(892)\bar{K}$  [21–22]. However, in a further paper [23], using the approach of [21], the authors concluded that the BESIII results can be reproduced either with the  $\eta(1405)$  or the  $\eta(1475)$ , or by a mixture of these two states.

The  $\eta(1295)$  has been observed by four  $\pi^-p$  experiments [7,24–26], and evidence is reported in  $\bar{p}p$  annihilation [27–29]. In  $J/\psi(1S)$  radiative decay, the  $\eta(1295)$  signal is evident in the  $0^{-+}$   $\eta\pi\pi$  wave of the DM2 data [9]. Also BaBar [30] reports evidence for a signal around 1295 MeV in  $B$  decays into  $\eta\pi\pi K$ . Nonetheless, the existence of the  $\eta(1295)$  is questioned in Refs. [19] and [31] in which the authors claim the existence of a single pseudoscalar meson at 1440 MeV, the first radial excitation of the  $\eta$ . This conclusion is mainly based on the analysis of the annihilation  $\bar{p}p \rightarrow 4\pi\eta$  with Crystal Barrel data [32].

Considering that the  $\eta(1295)$  has been reported by several experiments, using different production mechanisms, we shall assume that this state is established. The  $\eta(1475)$  could then be the first radial excitation of the  $\eta'$ , with the  $\eta(1295)$  being the first radial excitation of the  $\eta$ . Ideal mixing, suggested by the  $\eta(1295)$  and  $\pi(1300)$  mass degeneracy, would then imply that the second isoscalar in the nonet is mainly  $s\bar{s}$ , and hence couples to  $K^*\bar{K}$ , in agreement with properties of the  $\eta(1475)$ . Also, its width matches the expected width for the radially excited  $s\bar{s}$  state [33,34]. A study of radial excitations of pseudoscalar mesons [35] favors the  $s\bar{s}$  interpretation of the  $\eta(1475)$ . However, due to the strong kinematical suppression the data are not sufficient to exclude a sizeable  $s\bar{s}$  admixture also in the  $\eta(1405)$ .

The  $K\bar{K}\pi$  and  $\eta\pi\pi$  channels were studied in  $\gamma\gamma$  collisions by L3 [36]. The analysis led to a clear  $\eta(1475)$  signal in  $K\bar{K}\pi$ , decaying into  $K^*\bar{K}$ , very well identified in the untagged data sample, where contamination from spin 1 resonances is not allowed. At the same time, L3 [36] did not observe the  $\eta(1405)$ , neither in  $K\bar{K}\pi$  nor in  $\eta\pi\pi$ . The observation of the  $\eta(1475)$ , combined with the absence of an  $\eta(1405)$  signal, strengthens the two-resonances hypothesis. Since gluonium production is presumably suppressed in  $\gamma\gamma$  collisions, the L3 results [36] suggest that  $\eta(1405)$  has a large gluonic content (see also Refs. [37] and [38]).

The L3 result is somewhat in disagreement with that of CLEO-II, which did not observe any pseudoscalar signal in  $\gamma\gamma \rightarrow \eta(1475) \rightarrow K_S^0 K^\pm \pi^\mp$  [39]. However, more data are

# Meson Particle Listings

## $\eta(1405)$

required. Moreover, after the CLEO-II result, L3 performed a further analysis with full statistics [40], confirming their previous evidence for the  $\eta(1475)$ . The CLEO upper limit [39] for  $\Gamma_{\gamma\gamma}(\eta(1475))$ , and the L3 results [40], are consistent with the world average for the  $\eta(1475)$  width.

BaBar [30] also reports the  $\eta(1475)$  in  $B$  decays into  $K\bar{K}^*$  recoiling against a  $K$ , but upper limits only are given for the  $\eta(1405)$ . As mentioned above, in  $B$  decays into  $\eta\pi\pi K$  the  $\eta(1295) \rightarrow \eta\pi\pi$  is observed while only upper limits are given for the  $\eta(1405)$ . The  $f_1(1420)$  (and  $f_1(1285)$ ) are not seen.

The gluonium interpretation for the  $\eta(1405)$  is not favored by lattice gauge theories which predict the  $0^{-+}$  state above 2 GeV [41,42] (see also the article on the “Quark model” in this issue of the Review). However, the  $\eta(1405)$  is an excellent candidate for the  $0^{-+}$  glueball in the fluxtube model [43]. In this model, the  $0^{++}$   $f_0(1500)$  glueball is also naturally related to a  $0^{-+}$  glueball with mass degeneracy broken in QCD. Also, Ref. [44] shows that the pseudoscalar glueball could lie at a lower mass than predicted from lattice calculation. In this model the  $\eta(1405)$  appears as the natural glueball candidate, see also Refs. [45–47]. A detailed review of the experimental situation is available in Ref. [48].

Let us now deal with the  $1^{++}$  mesons. The pseudovector nonet is believed to consist of the isovector  $a_1(1260)$ , the isoscalars  $f_1(1285)$  and  $f_1(1420)$ , and the  $K_{1A}$ , which is a mixture of about 50%  $K_1(1270)$  and 50%  $K_1(1400)$ . (This last property prevents a straightforward calculation of the nonet mixing angle via the mass formulae.) The  $f_1(1285)$  could also be a  $K^*\bar{K}$  molecule [49] or as a tetraquark state [50] and the  $f_1(1420)$  a  $K^*\bar{K}$  molecule, due to the proximity of the  $K^*\bar{K}$  threshold [51]. LHCb has analyzed the decays  $\bar{B}^0$  and  $\bar{B}_s^0 \rightarrow J/\psi(1S)f_1(1285)$  and determined the nonet mixing angle to be consistent with a mostly  $u\bar{u} + d\bar{d}$  structure [52] without specifying the identity of its isoscalar partner. This is consistent with earlier determinations assuming the  $f_1(1420)$  as the isoscalar partner [53] and the ratio of  $\bar{B}^0/\bar{B}_s^0$  decay rates excludes the tetraquark interpretation of this state [52].

The  $f_1(1420)$ , decaying into  $K^*\bar{K}$ , was first reported in  $\pi^-p$  reactions at 4 GeV/c [54]. However, later analyses found that the 1400–1500 MeV region was far more complex [55–57]. A reanalysis of the MARK III data in radiative  $J/\psi(1S)$  decay into  $K\bar{K}\pi$  [8] shows the  $f_1(1420)$  decaying into  $K^*\bar{K}$ . A  $C=+1$  state is also seen in tagged  $\gamma\gamma$  collisions (*e.g.*, Ref. [58]).

In  $\pi^-p \rightarrow \eta\pi\pi n$  charge-exchange reactions at 8–9 GeV/c the  $\eta\pi\pi$  mass spectrum is dominated by the  $\eta(1440)$  and  $\eta(1295)$  [24,59], and at 100 GeV/c Ref. [25] reports the  $\eta(1295)$  and  $\eta(1440)$  decaying into  $\eta\pi^0\pi^0$  with a weak  $f_1(1285)$  signal, and no evidence for the  $f_1(1420)$ .

Axial ( $1^{++}$ ) mesons are not observed in  $\bar{p}p$  annihilation at rest in liquid hydrogen, which proceeds dominantly through  $S$ -wave annihilation. However, in gaseous hydrogen,  $P$ -wave annihilation is enhanced and, indeed, Ref. [11] reports  $f_1(1420)$  decaying into  $K^*\bar{K}$ . The  $f_1(1420)$ , decaying into  $K\bar{K}\pi$ , is also seen in  $pp$  central production, together with the  $f_1(1285)$ . The

latter decays via  $a_0(980)\pi$ , and the former only via  $K^*\bar{K}$ , while the  $\eta(1440)$  is absent [60,61]. The  $K_S^0 K_S^0 \pi^0$  decay mode of the  $f_1(1420)$  establishes unambiguously  $C=+1$ . On the other hand, there is no evidence for any state decaying into  $\eta\pi\pi$  around 1400 MeV, and hence the  $\eta\pi\pi$  mode of the  $f_1(1420)$  must be suppressed [62].

The COMPASS Collaboration has recently reported an isovector state at 1414 MeV, the  $a_1(1420)$  [63]. This relatively narrow state ( $\simeq 150$  MeV) is produced by diffractive dissociation with 190 GeV pions in  $\pi N \rightarrow 3\pi N$ , decays into  $f_0(980)\pi \rightarrow 3\pi$  (P-wave) and has therefore the quantum numbers  $(I^G)J^{PC} = (1^-)1^{++}$ . The pseudovector nonet already contains the established  $a_1(1260)$  as the  $I = 1$  state. As mentioned above, the  $f_1(1420)$  has been interpreted as a  $K^*\bar{K}$  molecule [51]. The new  $a_1(1420)$  could be its isovector partner. Arguments favoring the  $f_1(1420)$  being a hybrid  $q\bar{q}g$  meson [64] or a four-quark state [65] were also put forward. The  $q\bar{q}$  state would then remain to be identified, with the  $f_1(1510)$  (see below) as a candidate. However, an alternative explanation is suggested in Ref. [66] in which the authors claim a single  $1^{++}$  isovector around 1400 MeV, leading to two peaks in the  $3\pi$  mass spectrum, depending on the production mechanism,  $\rho\pi$  for the  $a_1(1260)$  and  $f_0(980)\pi$  for the  $a_1(1420)$ .

We now turn to the experimental evidence for the  $f_1(1510)$ . The  $f_1(1510)$  was seen in  $K^-p \rightarrow \Lambda K\bar{K}\pi$  at 4 GeV/c [67], and at 11 GeV/c [68]. Evidence is also reported in  $\pi^-p$  at 8 GeV/c, based on the phase motion of the  $1^{++}$   $K^*\bar{K}$  wave [57]. A somewhat broader  $1^{++}$  signal is also observed in  $J/\psi(1S) \rightarrow \gamma\eta\pi^+\pi^-$  [69] as well as a small signal in  $J/\psi(1S) \rightarrow \gamma\eta'\pi^+\pi^-$ , attributed to the  $f_1(1510)$  [70].

The absence of  $f_1(1420)$  in  $K^-p$  [68] argues against the  $f_1(1420)$  being the  $s\bar{s}$  member of the  $1^{++}$  nonet. However, the  $f_1(1420)$  was reported in  $K^-p$  but not in  $\pi^-p$  [71], while two experiments do not observe the  $f_1(1510)$  in  $K^-p$  [71,72]. The latter is also not seen in central collisions [61], nor  $\gamma\gamma$  collisions [73], although, surprisingly for an  $s\bar{s}$  state, a signal is reported in  $4\pi$  decays [74]. These facts led to the conclusion that  $f_1(1510)$  was not well established [75].

Summarizing, there is evidence for two isovector  $1^{++}$  states in the 1400 MeV region, the  $a_1(1260)$  and  $a_1(1420)$ , which cannot be both  $q\bar{q}$  states. These two states could stem from the same pole, or the latter be exotic (tetraquark or hybrid) or a molecular state. The  $f_1(1285)$  and the  $f_1(1420)$  are well known but their nature ( $q\bar{q}$ , tetraquark or molecular) remains to be established. In the  $0^{-+}$  sector there is evidence for two pseudoscalars in the 1400 MeV region, the  $\eta(1405)$  and  $\eta(1475)$ , decaying into  $a_0(980)\pi$  and  $K^*\bar{K}$ , respectively. Alternatively, these two structures could originate from a single pole. Doubts have been expressed on the existence of the  $\eta(1295)$ . The  $f_1(1510)$  remains to be firmly established.

- The selected process is  $J/\psi \rightarrow \omega a_0(980) \pi$ .
- From fit to the  $a_0(980) \pi$   $0^-+$  partial wave.
- Best fit with a single Breit Wigner.
- Decaying dominantly directly to  $K^+ K^- \pi^0$ .
- Decaying into  $(K\bar{K})_S \pi$ ,  $(K\pi)_S \bar{K}$ , and  $a_0(980) \pi$ .
- From fit to the  $a_0(980) \pi$   $0^-+$  partial wave. Cannot rule out a  $a_0(980) \pi$   $1^-+$  partial wave.
- Excluded from averaging because averaging would be meaningless.
- Best fit with a single Breit Wigner.
- This peak in the  $\gamma \rho$  channel may not be related to the  $\eta(1405)$ .

<sup>10</sup> Estimated by us from various fits.

<sup>11</sup> These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to  $\eta(1475)$ .

<sup>12</sup> Systematic uncertainty not evaluated.

<sup>13</sup> From best fit of  $0^-+$  partial wave, 50%  $K^*(892) K$ , 50%  $a_0(980) \pi$ .

80±10	800	22,24 BAILLON	67 HBC	0.0 $\bar{p} p \rightarrow K\bar{K}\pi\pi\pi$

14 The selected process is  $J/\psi \rightarrow \omega a_0(980)\pi$ .15 From fit to the  $a_0(980)\pi 0^-+$  partial wave.16 From  $\eta\pi^+\pi^-$  mass distribution - mainly  $a_0(980)\pi$  - no spin-parity determination available.17 Decaying dominantly directly to  $K^+ K^- \pi^0$ .18 Decaying into  $(K\bar{K})_S \pi$ ,  $(K\pi)_S \bar{K}$ , and  $a_0(980)\pi$ .19 From fit to the  $a_0(980)\pi 0^-+$  partial wave, but  $a_0(980)\pi 1^++$  cannot be excluded.20 This peak in the  $\gamma\rho$  channel may not be related to the  $\eta(1405)$ .

21 Estimated by us from various fits.

22 These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to  $\eta(1475)$ .

23 Systematic uncertainty not evaluated.

24 From best fit to  $0^-+$  partial wave, 50%  $K^*(892)K$ , 50%  $a_0(980)\pi$ . $\eta(1405)$  DECAY MODES

## CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 11.4$  for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_4$	-83			
$x_{11}$	11	-52

$\Gamma_6$ $\pi\pi\eta$	
$\Gamma_7$ $\pi^+\pi^+\pi^-\pi^-$	
$\Gamma_8$ $\gamma\gamma$	( 1.10 ±0.14 ) × 10 <sup>−6</sup>

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 17 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 14.3$  for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	−100

## CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 1.9$  for 3 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

## $\rho_3(1690)$

### CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 14.7$  for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

 $\rho(1700)$ 

$$J^G(J^{PC}) = 1^+(1^{--})$$

THE  $\rho(1450)$  AND THE  $\rho(1700)$ 

Updated November 2015 by S. Eidelman (Novosibirsk), C. Hanhart (Juelich) and G. Venanzoni (Frascati).

In our 1988 edition, we replaced the  $\rho(1600)$  entry with two new ones, the  $\rho(1450)$  and the  $\rho(1700)$ , because there was emerging evidence that the 1600-MeV region actually contains two  $\rho$ -like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of  $2\pi$  and  $4\pi$  electromagnetic form factors and the  $\pi\pi$  scattering length. Donnachie [2], with a full analysis of data on the  $2\pi$  and  $4\pi$  final states in  $e^+e^-$  annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of  $\rho(1450)$  was supported by the analysis of  $\eta\rho^0$  mass spectra obtained in photoproduction and  $e^+e^-$  annihilation [3], as well as that of  $e^+e^- \rightarrow \omega\pi$  [4].

The analysis of [2] was further extended by [5,6] to include new data on  $4\pi$ -systems produced in  $e^+e^-$  annihilation, and in  $\tau$ -decays ( $\tau$  decays to  $4\pi$ , and  $e^+e^-$  annihilation to  $4\pi$  can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two  $\rho$ -like states, and from the tail of the  $\rho(770)$  decaying into two-body states. While specific conclusions on  $\rho(1450) \rightarrow 4\pi$  were obtained, little could be said about the  $\rho(1700)$ .

Independent evidence for two  $1^-$  states is provided by [7] in  $4\pi$  electroproduction at  $\langle Q^2 \rangle = 1$  (GeV/c)<sup>2</sup>, and by [8] in a high-statistics sample of the  $\eta\pi\pi$  system in  $\pi^-p$  charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of  $\rho$ -like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the  $e^+e^- \rightarrow \eta\pi^+\pi^-$  cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the  $\rho(1450)$ .

Decisive evidence for the  $\pi\pi$  decay mode of both  $\rho(1450)$  and  $\rho(1700)$  comes from  $\bar{p}p$  annihilation at rest [11]. It has been shown that these resonances also possess a  $K\bar{K}$  decay mode [12–14]. High-statistics studies of the decays  $\tau \rightarrow \pi\pi\nu_\tau$  [15,16], and  $\tau \rightarrow 4\pi\nu_\tau$  [17] also require the  $\rho(1450)$ , but are not sensitive to the  $\rho(1700)$ , because it is too close to the  $\tau$  mass. A recent very-high-statistics study of the  $\tau \rightarrow \pi\pi\nu_\tau$  decay performed at Belle [18] reports the first observation of both  $\rho(1450)$  and  $\rho(1700)$  in  $\tau$  decays. A clear picture of the two  $\pi^+\pi^-$  resonances interfering with the  $\rho(770)$  was also reported by BaBar using the ISR method [19].

The structure of these  $\rho$  states is not yet completely clear. Barnes [20] and Close [21] claim that  $\rho(1450)$  has a mass consistent with radial  $2S$ , but its decays show characteristics of hybrids, and suggest that this state may be a  $2S$ -hybrid mixture. Donnachie [22] argues that hybrid states could have a  $4\pi$  decay mode dominated by the  $a_1\pi$ . Such behavior has been observed by [23] in  $e^+e^- \rightarrow 4\pi$  in the energy range 1.05–1.38 GeV, and by [17] in  $\tau \rightarrow 4\pi$  decays. CLEO [24] and Belle [25] observe the  $\rho(1450) \rightarrow \omega\pi$  decay mode in  $B$ -meson decays, however, do not find  $\rho(1700) \rightarrow \omega\pi^0$ . A similar conclusion is made by [26], who studied the process  $e^+e^- \rightarrow \omega\pi^0$ . Various decay modes of the  $\rho(1450)$  and  $\rho(1700)$  are observed in  $\bar{p}n$  and  $\bar{p}p$  annihilation [27,28], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the  $\rho$  states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the  $\rho(1570)$ , the  $\phi\pi$  state with  $J^{PC} = 1^{--}$  earlier observed by [29] (referred to as  $C(1480)$ ) and recently confirmed by [30]. While [31] shows that it may be a threshold effect, [5] and [32] suggest two independent vector states with this decay mode. The  $C(1480)$  has not been seen in the  $\bar{p}p$  [33] and  $e^+e^-$  [34,35] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [30]. Note that [30] can not exclude that their observation is due to an OZI-suppressed decay mode of the  $\rho(1700)$ .

Several observations on the  $\omega\pi$  system in the 1200-MeV region [36–42] may be interpreted in terms of either  $J^P = 1^-$   $\rho(770) \rightarrow \omega\pi$  production [43], or  $J^P = 1^+$   $b_1(1235)$  production [41,42]. We argue that no special entry for a  $\rho(1250)$  is needed. The LASS amplitude analysis [44] showing

# Meson Particle Listings

## $\rho(1700)$

evidence for  $\rho(1270)$  is preliminary and needs confirmation. For completeness, the relevant observations are listed under the  $\rho(1450)$ .

Recently [45] reported a very broad  $1^{--}$  resonance-like  $K^+K^-$  state in  $J/\psi \rightarrow K^+K^-\pi^0$  decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [46–48] suggest its exotic structure (molecular or multiquark), while [49] and [50] explain it by the interference between the  $\rho(1450)$  and  $\rho(1700)$ . We quote [45] as  $X(1575)$  in the section “Further States.”

Evidence for  $\rho$ -like mesons decaying into  $6\pi$  states was first noted by [51] in the analysis of  $6\pi$  mass spectra from  $e^+e^-$  annihilation [52,53] and diffractive photoproduction [54]. Clegg [51] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the  $\rho(2150)$ , the latter could be a manifestation of the  $\rho(1700)$  distorted by threshold effects. BaBar reported observations of the new decay modes of the  $\rho(2150)$  in the channels  $\eta'(958)\pi^+\pi^-$  and  $f_1(1285)\pi^+\pi^-$  [55]. The relativistic quark model [56] predicts the  $2^3D_1$  state with  $J^{PC} = 1^{--}$  at 2.15 GeV which can be identified with the  $\rho(2150)$ .

We no longer list under a separate particle  $\rho(1900)$  various observations of irregular behavior of the cross sections near the  $N\bar{N}$  threshold. Dips of various width around 1.9 GeV were reported by the E687 Collaboration (a narrow one in the  $3\pi^+3\pi^-$  diffractive photoproduction [57,58]), by the FENICE experiment (a narrow structure in the  $R$  value [59]), by BaBar in ISR (a narrow structure in  $e^+e^- \rightarrow \phi\pi$  final state [60], but much broader in  $e^+e^- \rightarrow 3\pi^+3\pi^-$  and  $e^+e^- \rightarrow 2(\pi^+\pi^-\pi^0)$  [61]), by CMD-3 (also a rather broad dip in  $e^+e^- \rightarrow 3\pi^+3\pi^-$  [62]). Most probably, these structures emerge as a threshold effect due to the opening of the  $N\bar{N}$  channel [63,64].

1 From partial wave analysis including all possible combinations of  $0^{++}$ ,  $2^{++}$ , and  $4^{++}$  resonances.

2 In the SU(3) based model with a specific interference pattern of the  $f_2(1270)$ ,  $a_2^0(1320)$ ,

and  $f_2'(1525)$  mesons incoherently added to the  $f_0(1710)$  and non-resonant background. This state may be different from  $f_0(1710)$ , see CLOSE 05.

3  $J^P = 0^+$ .

4 T-matrix pole.

5 Supersedes BARBERIS 99 and BARBERIS 99B.

6  $J^P = 0^+$ , supersedes by ARMSTRONG 89D.

7  $N_B J^{PC}$  determination.

8  $J^P = 2^+$ .

9 Using CLEO-c data but not authored by the CLEO Collaboration.

10 From a fit to a Breit-Wigner line shape with fixed  $\Gamma = 135$  MeV.

11 Breit-Wigner mass.

12 Systematic errors not estimated.

13 K-matrix pole, assuming  $J^P = 0^+$ , from combined analysis of  $\pi^- p \rightarrow \pi^0\pi^0 n$ ,  $\pi^- p \rightarrow K\bar{K}n$ ,  $\pi^+\pi^- \rightarrow \pi^+\pi^-$ ,  $\bar{p}p \rightarrow \pi^0\pi^0\pi^0$ ,  $\pi^0\eta\eta$ ,  $\pi^0\pi^0\eta$ ,  $\pi^+\pi^-\pi^0$ ,  $K^+K^-\pi^0$ ,  $K_S^0 K_S^0\pi^0$ ,  $K^+K_S^0\pi^-$  at rest,  $\bar{p}n \rightarrow \pi^-\pi^-\pi^+$ ,  $K_S^0 K^-\pi^0$ ,  $K_S^0 K_S^0\pi^-$  at rest.

14 Decaying to  $f_0(1370)\pi\pi$ .

15  $J^P = 0^+$ .

16 Not seen by AMSLER 02.

17 T-matrix pole, assuming  $J^P = 0^+$ .

18 No  $J^{PC}$  determination.

19 No  $J^{PC}$  determination, width not determined.

20 From a fit to the  $0^+$  partial wave.

21 ALDE 92D combines all the GAMS-2000 data.

22  $J^P = 2^+$ , superseded by FRENCH 99.

23 From an analysis ignoring interference with  $f_2'(1525)$ .

24 From an analysis including interference with  $f_2'(1525)$ .

25 Superseded by ALDE 92D.

26 Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.

27  $J^P = 2^+$  preferred.

28 From fit neglecting nearby  $f_2'(1525)$ . Replaced by BLOOM 83.

29 Superseded by LONGACRE 86.

1 From partial wave analysis including all possible combinations of  $0^{++}$ ,  $2^{++}$ , and  $4^{++}$  resonances.

2 In the SU(3) based model with a specific interference pattern of the  $f_2(1270)$ ,  $a_2^0(1320)$ , and  $f_2'(1525)$  mesons incoherently added to the  $f_0(1710)$  and non-resonant background.

3 Breit-Wigner width.

4  $J^P = 0^+$ .

5 T-matrix pole.

6 Supersedes BARBERIS 99 and BARBERIS 99B.

7  $J^P = 0^+$ , supersedes by ARMSTRONG 89D.

8  $N_B J^{PC}$  determination.

9  $J^P = 2^+$ .

10 No  $J^{PC}$  determination.

11 Systematic errors not estimated.

12 This state may be different from  $f_0(1710)$ , see CLOSE 05.

13 (Solution I)

14 K-matrix pole, assuming  $J^P = 0^+$ , from combined analysis of  $\pi^- p \rightarrow \pi^0\pi^0 n$ ,  $\pi^- p \rightarrow K\bar{K}n$ ,  $\pi^+\pi^- \rightarrow \pi^+\pi^-$ ,  $\bar{p}p \rightarrow \pi^0\pi^0\pi^0$ ,  $\pi^0\eta\eta$ ,  $\pi^0\pi^0\eta$ ,  $\pi^+\pi^-\pi^0$ ,  $K^+K^-\pi^0$ ,  $K_S^0 K_S^0\pi^0$ ,  $K^+K_S^0\pi^-$  at rest,  $\bar{p}n \rightarrow \pi^-\pi^-\pi^+$ ,  $K_S^0 K^-\pi^0$ ,  $K_S^0 K_S^0\pi^-$  at rest.

# Meson Particle Listings

## $f_0(1710)$

- 15 (Solution I)
- 16 Decaying to  $f_0(1370)\pi\pi$ .
- 17  $J^P = 0^+$ .
- 18 Not seen by AMSLER 02.
- 19 T-matrix pole, assuming  $J^P = 0^+$
- 20 No  $J^{PC}$  determination.
- 21 From a fit to the  $0^+$  partial wave.
- 22 ALDE 92d combines all the GAMS-2000 data.
- 23  $J^P = 2^+$ , ( $0^+$  excluded).
- 24 From an analysis ignoring interference with  $f_2'(1525)$ .
- 25 From an analysis including interference with  $f_2'(1525)$ .
- 26 Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
- 27  $J^P = 2^+$  preferred.
- 28 From fit neglecting nearby  $f_2'(1525)$ . Replaced by BLOOM 83.
- 29 From an amplitude analysis of the  $K_S^0 K_S^0$  system, superseded by LONGACRE 86.

### $X(1835)$

$$I^G(J^{PC}) = ?^?(0^-+)$$

### OMITTED FROM SUMMARY TABLE

Could be a superposition of two states, one with small width appearing as threshold enhancement in  $p\bar{p}$ , the other one with a larger width, decaying into  $\pi^+\pi^-\eta'$  and  $K_S^0 K_S^0 \eta$ . For the former ABLIKIM 12D determine  $J^{PC} = 0^-+$ .

- <sup>3</sup> The selected process is  $J/\psi \rightarrow \omega \eta(980) \pi$ . This state may be due also to  $\eta_2(1870)$  or to a combination of  $X(1835)$  and  $\eta_2(1870)$ .
- <sup>4</sup> From a fit of the  $p\overline{p}$  mass distribution to a combination of  $\gamma X(1835)$ ,  $\gamma R$  with  $M(R) = 2100$  MeV and  $\Gamma(R) = 160$  MeV, and  $\gamma p\overline{p}$  phase space, for  $M(p\overline{p}) < 2.85$  GeV.
- <sup>5</sup> Evidence for a threshold enhancement in the  $p\overline{p}$  mass spectrum was also reported by ABE 02K, AUBERT,B 05L, and WANG 05A in  $B^+ \rightarrow p\overline{p} K^+$ , WANG 05A in  $B^0 \rightarrow p\overline{p} K_S^0$ , ABE 02W in  $\overline{B}^0 \rightarrow p\overline{p} D^0$ , DEL-AMO-SANCHEZ 12 in  $B \rightarrow D(D^*) p\overline{p}(\pi)$ , and WEI 08 in  $B^+ \rightarrow p\overline{p} \pi^+$  decays. Not seen by ATHAR 06 in  $\Upsilon(1S) \rightarrow p\overline{p} \gamma$ .
- <sup>6</sup> From the fit including final state interaction effects in isospin 0  $S$ -wave according to SIBIRTSEV 05A. Systematic errors not estimated.

OMITTED FROM SUMMARY TABLE  
We list here three different peaks with close masses and widths seen in the mass distributions of  $\omega\omega$ ,  $\eta\eta'$ , and  $K^+ K^-$  final states. ALDE 91B argues that they are of different nature.

$f_2(1910)$ MASS					

$f_2(1910) \omega\omega$ MODE

## Meson Particle Listings

 $\rho(2150), \phi(2170)$  $\pi^- p \rightarrow \omega \pi^0 n$ 

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b>2155±21 OUR AVERAGE</b>			
2140±30	ALDE	95	GAM2 38 $\pi^- p \rightarrow \omega \pi^0 n$
2170±30	ALDE	92c	GAM4 100 $\pi^- p \rightarrow \omega \pi^0 n$

<sup>1</sup> Using the GOUNARIS 68 parametrization of the pion form factor leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.

<sup>2</sup> Includes ATKINSON 85.

<sup>3</sup> See however KLOET 96 who fit  $\pi^+ \pi^-$  only and find waves only up to  $J = 3$  to be important but not significantly resonant.

<sup>4</sup>  $I(J^P) = 1(1^-)$  from simultaneous analysis of  $p\bar{p} \rightarrow \pi^- \pi^+$  and  $\pi^0 \pi^0$ .

<sup>5</sup> From the combined analysis of ANISOVICH 00J, ANISOVICH 01D, ANISOVICH 01E, and ANISOVICH 02.

<sup>6</sup> Isospins 0 and 1 not separated.

<sup>7</sup> From a fit to the total elastic cross section.

<sup>8</sup> Referred to as  $T$  or  $T$  region by ALSPECTOR 73.

<sup>9</sup> Seen as bump in  $l = 1$  state. See also COOPER 68. PEASLEE 75 confirm  $\bar{p}p$  results of ABRAMS 70, no narrow structure.

**STRANGE MESONS**

$$(S = \pm 1, C = B = 0)$$

$$K^+ = u\bar{s}, K^0 = d\bar{s}, \bar{K}^0 = \bar{d}s, K^- = \bar{u}s, \text{ similarly for } K^{*'}s$$

 $K^\pm$ 

$$I(J^P) = \frac{1}{2}(0^-)$$

**THE CHARGED KAON MASS**

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV } (S = 2.4), \quad (1)$$

where the error has been increased by the scale factor  $S$ . The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV},$$

$$\chi^2 = 22.9 \text{ for 5 D.F., Prob.} = 0.04\%, \quad (2)$$

where the high  $\chi^2$  and correspondingly low  $\chi^2$  probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \quad \text{DENISOV 91}$$

$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV } (S = 1.5) \quad \text{GALL 88}$$

$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$

$$\chi^2 = 21.2 \text{ for 1 D.F., Prob.} = 0.0004\%, \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high  $\chi^2$ .

The GALL 88 measurement was made using four different kaonic atom transitions,  $K^- \text{ Pb } (9 \rightarrow 8)$ ,  $K^- \text{ Pb } (11 \rightarrow 10)$ ,  $K^- \text{ W } (9 \rightarrow 8)$ , and  $K^- \text{ W } (11 \rightarrow 10)$ . The  $m_{K^\pm}$  values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their  $K^- \text{ Pb } (9 \rightarrow 8)$   $m_{K^\pm}$  is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007,$$

$$\chi^2 = 7.0 \text{ for 3 D.F., Prob.} = 7.2\%. \quad (4)$$

This is a low but acceptable  $\chi^2$  probability so, to be conservative, GALL 88 scaled up the error on their average by  $S=1.5$  to obtain their published error  $\pm 0.011$  shown in Eq. (3) above and used in the Particle Listings average.

**Figure 1:** Ideogram of  $m_{K^\pm}$  mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88  $K^- \text{ Pb } (9 \rightarrow 8)$  measurement yield two well-separated peaks. One might suspect the GALL 88  $K^- \text{ Pb } (9 \rightarrow 8)$  measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

**Table 1:**  $m_{K^\pm}$  averages for some combinations of Fig. 1 data.

$m_{K^\pm}$ (MeV)	$\chi^2$	D.F.	Prob. (%)	Measurements used
$493.664 \pm 0.004$	52.6	12	0.00005	all 13 measurements
$493.690 \pm 0.006$	10.1	10	43	no $K^- \text{ Pb } (9 \rightarrow 8)$
$493.687 \pm 0.006$	14.6	11	20	no GALL 88 $K^- \text{ Pb } (9 \rightarrow 8)$
$493.642 \pm 0.006$	17.8	11	8.6	no DENISOV 91

To see if the disagreement could result from a systematic problem with the  $K^- \text{ Pb } (9 \rightarrow 8)$  transition, we have separated the CHENG 75 data, which also used  $K^- \text{ Pb}$ , into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88  $K^- \text{ Pb } (9 \rightarrow 8)$  values are consistent, suggesting the possibility of a common effect such as contaminant nuclear  $\gamma$  rays near the  $K^- \text{ Pb } (9 \rightarrow 8)$  transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a  $\chi^2$  of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable  $\chi^2$  probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the  $K^- \text{ Pb } (9 \rightarrow 8)$  transition and yields a  $\chi^2$  probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88  $K^- \text{ Pb } (9 \rightarrow 8)$  [DENISOV 91] measurement and yields a

# Meson Particle Listings

$K^\pm$

$\chi^2$  probability of 20% [8.6%]. Table 1 shows that removing both measurements of the  $K^-$  Pb ( $9 \rightarrow 8$ ) transition produces the most consistent set of data, but that excluding only the GALL 88  $K^-$  Pb ( $9 \rightarrow 8$ ) transition or DENISOV 91 also produces acceptable probabilities.

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved  $^{192}\text{Ir}$  and  $^{198}\text{Au}$  calibration  $\gamma$ -ray energies. He estimates that CHENG 75 and BACKENSTOSS 73  $m_{K^\pm}$  values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88  $K^-$  Pb ( $9 \rightarrow 8$ ) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88  $K^-$  Pb ( $9 \rightarrow 8$ ) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

**Table 2:**  $m_{K^\pm}$  averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

$m_{K^\pm}$ (MeV)	$\chi^2$	D.F.	Prob. (%)	Measurements used
$493.666 \pm 0.004$	53.9	12	0.00003	all 13 measurements
$493.693 \pm 0.006$	9.0	10	53	no $K^-$ Pb( $9 \rightarrow 8$ )
$493.690 \pm 0.006$	11.5	11	40	no GALL 88 $K^-$ Pb( $9 \rightarrow 8$ )
$493.645 \pm 0.006$	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear  $\gamma$  rays. Studies of  $\gamma$  rays following stopped  $\pi^-$  and  $\Sigma^-$  absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in  $K^-$   $^{12}\text{C}$ . The high resolution and the light nucleus reduce the probability for overlap by contaminant  $\gamma$  rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in  $\pi^-$   $^{12}\text{C}$ , which is good agreement with the calculated energy.

While we suspect that the GALL 88  $K^-$  Pb ( $9 \rightarrow 8$ ) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

## RARE KAON DECAYS

Revised September 2015 by L. Littenberg (BNL) and G. Valencia (Monash University).

**A. Introduction:** There are several useful reviews on rare kaon decays and related topics [1–17]. Activity in rare kaon decays can be divided roughly into four categories:

1. Searches for explicit violations of the Standard Model
2. Measurements of Standard Model parameters
3. Searches for direct *CP* violation
4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay  $K_L \rightarrow \mu e$ . Category 2 includes processes such as  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ , which is sensitive to CKM parameters. Much of the interest in Category 3 is focused on the decays  $K_L \rightarrow \pi^0 \ell \ell$ , where  $\ell \equiv e, \mu, \nu$ . Category 4 includes reactions like  $K^+ \rightarrow \pi^+ \ell^+ \ell^-$  which constitute a testing ground for the ideas of chiral perturbation theory. Category 4 also includes  $K_L \rightarrow \pi^0 \gamma \gamma$  and  $K_L \rightarrow \ell^+ \ell^- \gamma$ . The former is important in understanding a *CP*-conserving contribution to  $K_L \rightarrow \pi^0 \ell^+ \ell^-$ , whereas the latter could shed light on long distance contributions to  $K_L \rightarrow \mu^+ \mu^-$ .

The interplay between Categories 2–4 can be illustrated in Fig. 1. The modes  $K \rightarrow \pi \nu \bar{\nu}$  are the cleanest ones theoretically. They can provide accurate determinations of certain CKM parameters (shown in the figure). In combination with alternate determinations of these parameters, they also constrain new interactions. The modes  $K_L \rightarrow \pi^0 e^+ e^-$ ,  $K_L \rightarrow \pi^0 \mu^+ \mu^-$  and  $K_L \rightarrow \mu^+ \mu^-$  are also sensitive to CKM parameters. However, they suffer from a number of hadronic uncertainties that can be addressed, at least in part, through a systematic study of the additional modes indicated in the figure.

**B. Explicit violations of the Standard Model:** Much activity has focussed on searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass  $M_X$  that couples to left-handed fermions with electroweak strength and without mixing angles yields  $B(K_L \rightarrow \mu e) = 4.7 \times 10^{-12} (148 \text{ TeV}/M_X)^4$  [4]. This simple dimensional analysis may be used to read from Table 1 that the reaction  $K_L \rightarrow \mu e$  is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis-à-vis LFV. The decays  $K_L \rightarrow \mu^\pm e^\mp$  and  $K^+ \rightarrow \pi^+ e^\mp \mu^\pm$  (or  $K_L \rightarrow \pi^0 e^\mp \mu^\pm$ ) provide complementary information on potential family number violating interactions, since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Limits on certain lepton-number violating kaon decays also exist, some recent ones being those of Refs. [18,19,20]. Related searches in  $\mu$  and  $\tau$  processes are discussed in our section “Tests of Conservation Laws.”

**Table 1:** Searches for lepton flavor violation in *K* decay

Mode	90% CL upper limit	Exp’t	Yr./Ref.
$K^+ \rightarrow \pi^+ e^- \mu^+$	$1.2 \times 10^{-11}$	BNL-865	2005/Ref. 21
$K^+ \rightarrow \pi^+ e^+ \mu^-$	$5.2 \times 10^{-10}$	BNL-865	2000/Ref. 18
$K_L \rightarrow \mu e$	$4.7 \times 10^{-12}$	BNL-871	1998/Ref. 22
$K_L \rightarrow \pi^0 e \mu$	$7.6 \times 10^{-11}$	KTeV	2008/Ref. 23
$K_L \rightarrow \pi^0 \pi^0 e \mu$	$1.7 \times 10^{-10}$	KTeV	2008/Ref. 23

Physics beyond the SM is also pursued through the search for  $K^+ \rightarrow \pi^+ X^0$ , where  $X^0$  is a new light particle. The searches cover both long-lived particles (*e.g.*, hyperphoton, axion, familon, *etc.*), and short lived ones that decay to muon, electron or photon pairs. The 90% CL upper limit on  $K^+ \rightarrow \pi^+ X^0$  is  $7.3 \times 10^{-11}$  [24] for the case of massless  $X^0$ ; additional results as a function of the  $X^0$  mass can be found in [37].

# Meson Particle Listings

$K^\pm$

Recently these limits have been reinterpreted in connection with a dark photon [25] or dark Z [26]. Such vectors have also been sought in their  $e^+e^-$  decay mode by NA48 [27]. Additional bounds for a short lived pseudoscalar  $X^0$  decaying to muons or photons are  $B(K_L \rightarrow \pi^0 \pi^0 \mu^+ \mu^-) < 1 \times 10^{-10}$  [28] and  $B(K_L \rightarrow \pi^0 \pi^0 \gamma \gamma) < 2.4 \times 10^{-7}$  [29].

## C. Measurements of Standard Model parameters:

In the SM, the decay  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$  is dominated by one-loop diagrams with top-quark intermediate states and long-distance contributions are known to be quite small [2,30]. This permits a precise calculation of this rate in terms of SM parameters. Studies of this process are thus motivated by the possibility of detecting non-SM physics when comparing with the results of global fits [31,32].

BNL-787 observed two candidate events [33,34] in the clean high  $\pi^+$  momentum and one event [35] in the low-momentum region. The successor experiment BNL-949 observed one more in the high-momentum region [24] and three more in the low-momentum region [36] yielding a branching ratio of  $(1.73^{+1.15}_{-1.05}) \times 10^{-10}$  [37]. A subsequent experiment, NA62, with a sensitivity goal of  $\sim 10^{-12}$ /event was proposed [38] at CERN in 2005. It was approved and ran with a partial detector in autumn 2012, followed by a successful commissioning run in the fall of 2014. The first physics run started in the summer of 2015. The NA62 experiment will be the first one performed with kaon decays in flight. In the future, this mode may provide grounds for precision tests of flavor dynamics [40].

The branching ratio can be written in a compact form that exhibits the different ingredients that go into the calculation [41],

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}(\gamma)) = \kappa_+(1 + \Delta_{\text{EM}}) \left[ \left( \frac{\text{Im}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 + \left( \frac{\text{Re}(V_{cs}^* V_{cd})}{\lambda} (P_c + \delta P_{c,u}) + \frac{\text{Re}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 \right]. \quad (1)$$

The parameters in Eq. (1) incorporate the *a priori* unknown hadronic matrix element in terms of the very well-measured  $K_{\ell 3}$  rate [2] in  $\kappa_+$ ; long distance QED corrections in  $\Delta_{\text{EM}}$  [43]; the Inami-Lim function for the short distance top-quark contribution [44] including NLO QCD corrections [45] and the two-loop electroweak correction [41], all in  $X_t$ ; and the charm-quark contributions due to short distance effects including NNLO QCD corrections [46] and NLO electroweak corrections via  $P_c$  [47], as well as certain long distance effects via  $\delta P_{c,u}$  [48]. An interesting approximate way to cast this result in terms of the CKM parameters  $\lambda$ ,  $V_{cb}$ ,  $\bar{\rho}$  and  $\bar{\eta}$  (see our Section on “The Cabibbo-Kobayashi-Maskawa mixing matrix”) [11] is:

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \bar{\eta}^2 + (\rho_c - \bar{\rho})^2], \quad (2)$$

where  $\rho_c \approx 1.45$  and  $\sigma \equiv 1/(1 - \frac{1}{2}\lambda^2)^2$ . Thus,  $B(K^+ \rightarrow \pi^+ \nu \bar{\nu})$  determines an ellipse in the  $\bar{\rho}$ ,  $\bar{\eta}$  plane with center  $(\rho_c, 0)$  and semiaxes  $\approx \frac{1}{|V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$  and  $\frac{1}{\sigma |V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$ . A recent numerical study leads to a predicted branching ratio

$(7.81^{+0.80}_{-0.71} \pm 0.29) \times 10^{-11}$  [41], near the lower end of the measurement of BNL-787 and 949. However, parametric uncertainty in the CKM angles can result in numbers that differ from this one by up to 10% [42].

Modes with an extra pion,  $K \rightarrow \pi \pi \nu \bar{\nu}$ , could also be used in the extraction of CKM parameters as they are also dominated by short distance contributions [49]. However, they occur at much lower rates with branching ratios of order  $10^{-13}$ , and the current best bound from KEK-391a is  $B(K_L \rightarrow \pi^0 \pi^0 \nu \bar{\nu}) < 8.1 \times 10^{-7}$  at 90% CL [50]. There is also an older bound of  $B(K^+ \rightarrow \pi^+ \pi^0 \nu \bar{\nu}) < 4.3 \times 10^{-5}$  at 90% CL [51] from BNL-787.

The decay  $K_L \rightarrow \mu^+ \mu^-$  also has a short distance contribution sensitive to the CKM parameter  $\bar{\rho}$ , given by [11]:

$$B_{\text{SD}}(K_L \rightarrow \mu^+ \mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho'_c - \bar{\rho})^2 \quad (3)$$

where  $\rho'_c$  depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for  $K_L \rightarrow \gamma \gamma$  to be  $B_{\text{abs}}(K_L \rightarrow \mu^+ \mu^-) = (6.64 \pm 0.07) \times 10^{-9}$ ; and it almost completely saturates the observed rate  $B(K_L \rightarrow \mu^+ \mu^-) = (6.84 \pm 0.11) \times 10^{-9}$  [52]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. The latter cannot be derived directly from experiment [53], but can be estimated with certain assumptions [54,55].

The decay  $K_L \rightarrow e^+ e^-$  is completely dominated by long distance physics and is easier to estimate. The result,  $B(K_L \rightarrow e^+ e^-) \sim 9 \times 10^{-12}$  [53,56], is in good agreement with the BNL-871 measurement,  $(8.7^{+5.7}_{-4.1}) \times 10^{-12}$  [57].

The mode  $K_S \rightarrow \mu^+ \mu^-$  also has a short distance contribution proportional to the square of the CKM parameter  $\bar{\eta}$  entering at the  $10^{-13}$  level [15] as well as long distance contributions which arise in this case from a two photon intermediate state and result in a rate  $B(K_S \rightarrow \mu^+ \mu^-)_{\text{LD}} = 5.1 \times 10^{-12}$  [15]. A 95% (90%) c.l. limit  $B(K_S \rightarrow \mu^+ \mu^-) < 11(9) \times 10^{-9}$  was obtained by LHCb [58].

**D. Searches for direct CP violation:** The mode  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  is dominantly CP-violating and free of hadronic uncertainties [2,59,60]. In the Standard Model, this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ . The branching ratio is given by Ref. 11:

$$B(K_L \rightarrow \pi^0 \nu \bar{\nu}) = \kappa_L \left( \frac{\text{Im}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 \approx 7.6 \times 10^{-5} |V_{cb}|^4 \bar{\eta}^2. \quad (4)$$

The hadronic matrix element can be related to that measured in  $K_{\ell 3}$  decay and is parameterized in  $\kappa_L$ . A recent numerical evaluation leads to a predicted branching ratio  $(2.43^{+0.40}_{-0.37} \pm$

$0.06) \times 10^{-11}$  [41]. As noted for the charged kaon mode, parametric uncertainty in the CKM angles can result in a central value that differs from this one by up to almost 20% [42]. The 90% CL bound on  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$  provides a nearly model-independent bound  $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 1.46 \times 10^{-9}$  [61]. KEK-391a, which took data in 2004 and 2005, has published a 90% CL upper bound of  $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \leq 2.6 \times 10^{-8}$  [62]. The KOTO experiment at J-PARC [63], whose initial goal is to observe it, had a short physics run in the spring of 2013, reaching a single event sensitivity of  $1.29 \times 10^{-8}$  [65], and resuming the data taking in May 2015. It was pointed out in a recent paper that the above Grossman-Nir bound [61] on the three body decay  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  doesn't necessarily apply to two body decays such as  $K_L \rightarrow \pi^0 X^0$ , so that KOTO may be interesting for new physics searches at the current sensitivity level [64].

There has been much theoretical work on possible contributions to rare  $K$  decays beyond the SM. A comprehensive discussion of these can be found in Refs. [14] and [66].

The decay  $K_L \rightarrow \pi^0 e^+ e^-$  also has sensitivity to the CKM parameter  $\eta$  through its  $CP$ -violating component. There are both direct and indirect  $CP$ -violating amplitudes that can interfere. The direct  $CP$ -violating amplitude is short distance dominated and has been calculated in detail within the SM [8]. The indirect  $CP$ -violating amplitude can be inferred from a measurement of  $K_S \rightarrow \pi^0 e^+ e^-$ . The complete  $CP$ -violating contribution to the rate can be written as [67,68]:

$$B_{CPV} \approx 10^{-12} \left[ 15.7 |a_S|^2 \pm 1.4 \left( \frac{|V_{cb}|^2 \eta}{10^{-4}} \right) |a_S| + 0.12 \left( \frac{|V_{cb}|^2 \eta}{10^{-4}} \right)^2 \right] \quad (5)$$

where the three terms correspond to the indirect  $CP$  violation, the interference, and the direct  $CP$  violation respectively. The parameter  $a_S$  has been extracted by NA48 from a measurement of the decay  $K_S \rightarrow \pi^0 e^+ e^-$  with the result  $|a_S| = 1.06_{-0.21}^{+0.26} \pm 0.07$  [69], as well as from a measurement of the decay  $K_S \rightarrow \pi^0 \mu^+ \mu^-$  with the result  $|a_S| = 1.54_{-0.32}^{+0.40} \pm 0.06$  [70]. With current constraints on the CKM parameters, and assuming a positive sign for the interference term [68,71], this implies that  $B_{CPV}(K_L \rightarrow \pi^0 e^+ e^-) \approx (3.1 \pm 0.9) \times 10^{-11}$ , and that the indirect  $CP$  violation is larger than the direct  $CP$  violation. The complete  $CP$  violating amplitude for the related mode  $K_L \rightarrow \pi^0 \mu^+ \mu^-$  is predicted to be  $B_{CPV}(K_L \rightarrow \pi^0 \mu^+ \mu^-) \approx (1.4 \pm 0.5) \times 10^{-11}$  [72,15].

$K_L \rightarrow \pi^0 e^+ e^-$  also has a  $CP$ -conserving component dominated by a two-photon intermediate state. This component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low  $m_{\gamma\gamma}$  region of the  $K_L \rightarrow \pi^0 \gamma \gamma$  spectrum. The rate and the shape of the distribution  $d\Gamma/dm_{\gamma\gamma}$  in  $K_L \rightarrow \pi^0 \gamma \gamma$  are well described in chiral perturbation theory in terms of three (*a priori*) unknown parameters [73,74].

Both KTeV and NA48 have studied the mode  $K_L \rightarrow \pi^0 \gamma \gamma$ , reporting similar results. KTeV finds  $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.29 \pm 0.03_{\text{stat}} \pm 0.05_{\text{sys}}) \times 10^{-6}$  [75], while NA48 finds  $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.36 \pm 0.03_{\text{stat}} \pm 0.03_{\text{sys}} \pm 0.03_{\text{norm}}) \times 10^{-6}$  [76]. Both experiments are consistent with a negligible rate in the low  $m_{\gamma\gamma}$  region, suggesting a very small  $CP$ -conserving component  $B_{CP}(K_L \rightarrow \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$  [68,74,76]. There remains some model dependence in the estimate of the dispersive part of the  $CP$ -conserving  $K_L \rightarrow \pi^0 e^+ e^-$  [68].

The related process,  $K_L \rightarrow \pi^0 \gamma e^+ e^-$ , is potentially an additional background in some region of phase space [77]. This process has been observed with a branching ratio of  $(1.62 \pm 0.14_{\text{stat}} \pm 0.09_{\text{sys}}) \times 10^{-8}$  [78].

The decay  $K_L \rightarrow \gamma \gamma e^+ e^-$  constitutes the dominant background to  $K_L \rightarrow \pi^0 e^+ e^-$ . It was first observed by BNL-845 [79], and subsequently confirmed with a much larger sample by KTeV [80]. It has been estimated that this background will enter at about the  $10^{-10}$  level [81,82], comparable to or larger than the signal level. Because of this, the observation of  $K_L \rightarrow \pi^0 e^+ e^-$  at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 68 and references cited therein.

The 90% CL upper bound for the process  $K_L \rightarrow \pi^0 e^+ e^-$  is  $2.8 \times 10^{-10}$  [82]. For the closely related muonic process, the published upper bound is  $B(K_L \rightarrow \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$  [83], compared with the SM prediction of  $(1.5 \pm 0.3) \times 10^{-11}$  [72] (assuming positive interference between the direct- and indirect- $CP$  violating components).

A study of  $K_L \rightarrow \pi^0 \mu^+ \mu^-$  has indicated that it might be possible to extract the direct  $CP$ -violating contribution by a joint study of the Dalitz plot variables and the components of the  $\mu^+$  polarization [84]. The latter tends to be quite substantial so that large statistics may not be necessary.

Combined information from the two  $K_L \rightarrow \pi^0 \ell^+ \ell^-$  modes complements the  $K \rightarrow \pi \nu \bar{\nu}$  measurements in constraining physics beyond the SM [85].

#### E. Other long distance dominated modes:

The decays  $K^+ \rightarrow \pi^+ \ell^+ \ell^-$  ( $\ell = e$  or  $\mu$ ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [86,87,20].

The measurements have been used to exclude new physics such as a dark photon [25]. Ref. 67 has proposed a parametrization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections. NA62 has now also observed the mode  $K^+ \rightarrow \pi^+ \pi^0 e^+ e^-$  [88] studied in [89].

The decay  $K^+ \rightarrow \pi^+ \gamma \gamma$  can be predicted in terms of one unknown parameter to leading order in  $\chi$ PT resulting in a correlation between the rate and the diphoton mass spectrum [90]. Certain important corrections at the next order are also known [91]. The rate was first measured by E787 [92], more recently NA48/2 [93] has obtained a more precise result with 6% error along with the corresponding spectrum fits. The most recent, and precise, result is from NA62 based on a sample

# Meson Particle Listings

$K^\pm$

of 232 events [94] and is still insufficient to distinguish between the leading order and next order  $\chi$ PT parametrizations.

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes  $K_L \rightarrow \ell^+ \ell^- \gamma$  [95,96], and  $K_L \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$  for  $\ell, \ell' = e$  or  $\mu$  [19,97–99]. All these results are used to test hadronic models and could further our understanding of the long distance component in  $K_L \rightarrow \mu^+ \mu^-$ .

- [a] See the Particle Listings below for the energy limits used in this measurement.
- [b] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.
- [c] Structure-dependent part.
- [d] See the "Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors" in the  $\pi^\pm$  Particle Listings for definitions and details.
- [e] Direct-emission branching fraction.
- [f] Derived from an analysis of neutrino-oscillation experiments.
- [g] Violates angular-momentum conservation.

## CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 15 branching ratios uses 35 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 53.4$  for 28 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

2.37 ±0.17	534	HEARD	75B	SPEC +
2.42 ±0.42	112	CLARK	72	OSP K +

- 1 LAZZERONI 13 uses full data sample collected from 2007 to 2008. This ratio is defined to be fully inclusive, including internal-bremsstrahlung.
- 2 The ratio is defined to include internal-bremsstrahlung, ignoring direct-emission contributions. AMBROSINO 09E determined the ratio from the measurement of  $\Gamma(K \rightarrow e \nu(\gamma))$ ,  $E_\gamma < 10 \text{ MeV}$  /  $\Gamma(K \rightarrow \mu \nu(\gamma))$ . 89.8% of  $K \rightarrow e \nu(\gamma)$  events had  $E_\gamma < 10 \text{ MeV}$ .
- 3 This ratio is defined to be fully inclusive, including internal-bremsstrahlung.

<sup>1</sup>BATLEY 12 uses data collected in 2003–2004. The result is inclusive of  $K^\pm \rightarrow \pi^+ \pi^- e^\pm \nu_\gamma$  decays. Using PDG 12 value for  $\Gamma(\pi^+ \pi^- \pi^+)/\Gamma = (5.59 \pm 0.04) \times 10^{-2}$ . BATLEY 12 obtains  $B(\pi^+ \pi^- e \nu) = (4.257 \pm 0.004 \pm 0.035) \times 10^{-5}$  where the syst. error is dominated by the error on the normalization mode.

<sup>2</sup>PISLAK 01 reports  $\Gamma(\pi^+ \pi^- e^+ \nu_e)/\Gamma_{\text{total}} = (4.109 \pm 0.008 \pm 0.110) \times 10^{-5}$  using the PDG 00 value  $\Gamma(\pi^+ \pi^+ \pi^-)/\Gamma_{\text{total}} = (5.59 \pm 0.05) \times 10^{-2}$ . We divide by the PDG value and unfold its error from the systematic error. PISLAK 03 and PISLAK 10A give additional details on the branching ratio measurement and give improved errors on the S-wave  $\pi$ - $\pi$  scattering length:  $a_0^0 = 0.235 \pm 0.013$  and  $a_0^0 = -0.0410 \pm 0.0027$ .

## Hadronic modes with photons

 $\Gamma(\pi^+ \pi^0 \gamma(\text{INT}))/\Gamma_{\text{total}}$  $\Gamma_{21}/\Gamma$ 

The  $K^+ \rightarrow \pi^+ \pi^0 \gamma$  differential decay rate can be described in terms of  $T_{\pi^+}$ , the charged pion kinetic energy, and  $W^2 = (P_{K^+} \cdot P_\gamma) (P_{\pi^+} \cdot P_\gamma) / (m_K m_{\pi^+})^2$ ; then we can write  $d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma) / (dT_{\pi^+} dW^2) = d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} / (dT_{\pi^+} dW^2) [1 + 2 \cos(\pm\phi + \delta_1^+ - \delta_0^0) m_\pi^2 m_K^2 W^2 X_E + m_\pi^4 m_K^4 (X_E^2 + X_M^2) W^4]$ . The IB differential and total branching ratios are expressed in terms of the non-radiative experimental width  $\Gamma(K^+ \rightarrow \pi^+ \pi^0)$  by Low's theorem. Using PDG 10  $B(K^+ \rightarrow \pi^+ \pi^0) = 0.2066 \pm 0.0008$ , one obtains respectively  $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB}$  (55 <  $T_{\pi^+}$  < 90 MeV) =  $2.55 \times 10^{-4}$  and  $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB}$  (0 <  $T_{\pi^+}$  < 80 MeV) =  $1.80 \times 10^{-4}$ . Fitting respectively the piece proportional to  $W^2$  and the piece proportional to  $W^4$ , the interference contribution (INT), proportional to  $X_E$ , and the direct contribution (DE) proportional to  $X_E^2 + X_M^2$  are extracted.

<sup>1</sup> LAZZERONI 14 combines NA62 and NA48/2 results. The result for the full kinematic range is extrapolated from the model-independent branching fraction  $(9.65 \pm 0.61 \pm 0.14) \times 10^{-7}$  for  $(m_{\gamma\gamma}/m_K)^2 > 0.2$ . The measured ChPT parameter  $\hat{c} = 1.86 \pm 0.25$ .

<sup>2</sup> KITCHING 97 is extrapolated from their model-independent branching fraction  $(6.0 \pm 1.5 \pm 0.7) \times 10^{-7}$  for 100 MeV/c <  $P_\pi$  < 180 MeV/c using Chiral Perturbation Theory.

<sup>3</sup> BATLEY 14 uses data collected in 2003 and 2004. Branching ratio is obtained by determining the parameter  $\hat{c} = 1.41 \pm 0.38 \pm 0.11$  and integrating the  $\mathcal{O}(p^6)$  chiral spectrum. A model independent value for the branching ratio is also obtained  $(8.77 \pm 0.87 \pm 0.17) \times 10^{-7}$  for kinematic range  $(m_{\gamma\gamma}/m_K)^2 > 0.2$ .

<sup>4</sup> ARTAMONOV 05 limit assumes ChPT with  $\hat{c} = 1.8$  with unitarity corrections. With  $\hat{c} = 1.6$  and no unitarity corrections they obtain  $< 2.3 \times 10^{-8}$  at 90% CL. This partial branching ratio is predicted to be  $6.10 \times 10^{-9}$  and  $0.49 \times 10^{-9}$  for the cases with and without unitarity correction.

 $\Gamma(\pi^+ 3\gamma)/\Gamma_{\text{total}}$  $\Gamma_{26}/\Gamma$

<b>1.19 ± 0.12 ± 0.04</b>	113	<sup>1</sup> BATLEY	08	NA48 $m_{ee\gamma} > 260$ MeV

<sup>1</sup> BATLEY 08 also reports the Chiral Perturbation Theory parameter  $\hat{c} = 0.9 \pm 0.45$  obtained using the shape of the  $e^+ e^- \gamma$  invariant mass spectrum. By extrapolating the theoretical amplitude to  $m_{ee\gamma} < 260$  MeV, it obtains the inclusive  $B(K^+ \rightarrow \pi^+ e^+ e^- \gamma) = (1.29 \pm 0.13 \pm 0.03) \times 10^{-8}$ , where the first error is the combined statistical and systematic errors and the second error is from the uncertainty in  $\hat{c}$ .

$10.0 \pm 1.9 \pm 0.7$		35	PARK	02	HYCP	-
<23		90	ATIYA	89	B787	+

<sup>1</sup> BATLEY 11A also studies the form factor  $f(z)$  dependence of the decay, described via single photon exchange: i) assuming a linear form factor,  $f(z) = f_0(1 + \delta z)$ ,  $z = (M_{\mu\mu}/m_K)^2$ , finding  $f_0 = 0.470 \pm 0.040$  and  $\delta = 3.11 \pm 0.57$  and ii) assuming a linear form factor including  $\pi$ - $\pi$  rescattering,  $W_{\pi\pi}$ , as in DAMBROSIO 98a, finding  $f(z) = G_F m_K^2 (a_+ + b_+ z) + W_{\pi\pi}(z)$ ,  $a_+ = -0.575 \pm 0.039$ ,  $b_+ = -0.813 \pm 0.145$ .

<sup>2</sup> PARK 02 “ $\pm$ ” result comes from combining  $K^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $K^- \rightarrow \pi^- \mu^+ \mu^-$ , assuming  $CP$  is conserved.

<sup>3</sup> MA 00 establishes vector nature of this decay and determines form factor  $f(z) = f_0(1 + \delta z)$ ,  $z = (M_{\mu\mu}/m_K)^2$ ,  $\delta = 2.45 \pm 1.30 - 0.95$ .

<sup>4</sup> ADLER 97c gives systematic error  $0.7 \times 10^{-8}$  and theoretical uncertainty  $0.6 \times 10^{-8}$ , which we combine in quadrature to obtain our second error.

$\Gamma(\pi^+\nu\bar{\nu})/\Gamma_{\text{total}}$	$\Gamma_{38}/\Gamma$
Test for $\Delta S = 1$ weak neutral current. Allowed by higher-order electroweak interactions. Branching ratio values are extrapolated from the momentum or energy regions shown in the comments assuming Standard Model phase space except for those labeled “Scalar” or “Tensor” to indicate the assumed non-Standard-Model interaction.

## DALITZ PLOT PARAMETERS FOR $K \rightarrow 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for  $K^\pm \rightarrow \pi^\pm \pi^\pm \pi^\mp$ ,  $K^\pm \rightarrow \pi^0 \pi^0 \pi^\pm$ , and  $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$  can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\begin{aligned} |M|^2 &\propto 1 + g \frac{(s_3 - s_0)}{m_{\pi^+}^2} + h \left[ \frac{s_3 - s_0}{m_{\pi^+}^2} \right]^2 \\ &+ j \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k \left[ \frac{s_2 - s_1}{m_{\pi^+}^2} \right]^2 \\ &+ f \frac{(s_2 - s_1)(s_3 - s_0)}{m_{\pi^+}^2 m_{\pi^+}^2} + \dots, \end{aligned} \quad (1)$$

where  $m_{\pi^+}^2$  has been introduced to make the coefficients  $g$ ,  $h$ ,  $j$ , and  $k$  dimensionless, and

$$\begin{aligned} s_i &= (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i, \quad i = 1, 2, 3, \\ s_0 &= \frac{1}{3} \sum_i s_i = \frac{1}{3} (m_K^2 + m_1^2 + m_2^2 + m_3^2). \end{aligned}$$

Here the  $P_i$  are four-vectors,  $m_i$  and  $T_i$  are the mass and kinetic energy of the  $i^{\text{th}}$  pion, and the index 3 is used for the odd pion.

The coefficient  $g$  is a measure of the slope in the variable  $s_3$  (or  $T_3$ ) of the Dalitz plot, while  $h$  and  $k$  measure the quadratic dependence on  $s_3$  and  $(s_2 - s_1)$ , respectively. The coefficient  $j$  is related to the asymmetry of the plot and must be zero if  $CP$  invariance holds. Note also that if  $CP$  is good,  $g$ ,  $h$ , and  $k$  must be the same for  $K^+ \rightarrow \pi^+ \pi^+ \pi^-$  as for  $K^- \rightarrow \pi^- \pi^- \pi^+$ .

Since different experiments use different forms for  $|M|^2$ , in order to compare the experiments we have converted to  $g$ ,  $h$ ,  $j$ , and  $k$  whatever coefficients have been measured. Where such conversions have been done, the measured coefficient  $a_y$ ,  $a_t$ ,  $a_u$ , or  $a_v$  is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

## ENERGY DEPENDENCE OF $K^\pm$ DALITZ PLOT

$$\begin{aligned} |\text{matrix element}|^2 &= 1 + gu + hu^2 + kv^2 \\ \text{where } u &= (s_3 - s_0) / m_\pi^2 \text{ and } v = (s_2 - s_1) / m_\pi^2 \end{aligned}$$

## LINEAR COEFFICIENT $g$ FOR $K^\pm \rightarrow \pi^\pm \pi^+ \pi^-$

Some experiments use Dalitz variables  $x$  and  $y$ . In the comments we give  $a_y$  = coefficient of  $y$  term. See note above on "Dalitz Plot Parameters for  $K \rightarrow 3\pi$  Decays." For discussion of the conversion of  $a_y$  to  $g$ , see the earlier version of the same note in the Review published in Physics Letters **111B** 70 (1982).

<sup>1</sup> BATLEY 07E includes data from BATLEY 06. Uses quadratic parametrization and value  $g_+ + g_- = 2g$  from BATLEY 07B. This measurement neglects any possible charge asymmetries in higher order slope parameters  $h$  or  $k$ .

<sup>2</sup> This measurement neglects any possible charge asymmetries in higher order slope parameters  $h$  or  $k$ .

## LINEAR COEFFICIENT $g$ FOR $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$

Unless otherwise stated, all experiments include terms quadratic in  $(s_3 - s_0) / m_\pi^2$ . See note above on "Dalitz Plot Parameters for  $K \rightarrow 3\pi$  Decays."

See BATUSOV 98 for a discussion of the discrepancy between their result and others, especially BOLOTOV 86. At this time we have no way to resolve the discrepancy so we depend on the large scale factor as a warning.

<sup>1</sup> BATLEY 07e includes data from BATLEY 06a. Uses quadratic parametrization and PDG 06 value  $g = 0.626 \pm 0.007$  to obtain  $g_+ - g_- = (2.2 \pm 2.1 \pm 0.7) \times 10^{-4}$ . Neglects any possible charge asymmetries in higher order slope parameters  $h$  or  $k$ .

<sup>2</sup> Asymmetry obtained assuming that  $g_+ + g_- = 2 \times 0.652$  (PDG 02) and that asymmetries in  $h$  and  $k$  are zero.

<sup>3</sup> Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters  $h$  or  $k$  are neglected.

**ALTERNATIVE PARAMETRIZATIONS OF  $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$  DALITZ PLOT**

The following functional form for the matrix element suggested by  $\pi\pi$  rescattering in  $K^+ \rightarrow \pi^+ \pi^+ \pi^- \pi^0 \rightarrow \pi^+ \pi^0 \pi^0$  is used for this fit (CABIBBO 04a, CABIBBO 05): Matrix element =  $M_0 + M_1$  where  $M_0 = 1 + (1/2)g_0 u + (1/2)h' u^2 + (1/2)k_0 v^2$  with  $u = (s_3 - s_0)/(m_{\pi^+})^2$ ,  $v = (s_2 - s_1)/(m_{\pi^+})^2$  and where  $M_1$  takes into account the non-analytic piece due to  $\pi\pi$  rescattering amplitudes  $a_0$  and  $a_2$ ; The parameters  $g_0$  and  $h'$  are related to the parameters  $g$  and  $h$  of the matrix element squared given in the previous section by the approximations  $g_0 \sim g^{PDG}$  and  $h' \sim h^{PDG} - (g/2)^2$  and  $k_0 \sim k^{PDG}$ .

In addition, we also consider the effective field theory framework of COLANGELO 06a and BISSEGGER 09 to extract  $g_{BB}$  and  $h'_{BB}$ .

 **$K_{\ell 3}^\pm$  AND  $K_{\ell 3}^0$  FORM FACTORS**

Updated September 2013 by T.G. Trippe (LBNL) and C.-J. Lin (LBNL).

Assuming that only the vector current contributes to  $K \rightarrow \pi \ell \nu$  decays, we write the matrix element as

$$M \propto f_+(t) [(P_K + P_\pi)_\mu \bar{\ell} \gamma_\mu (1 + \gamma_5) \nu] + f_-(t) [m_\ell \bar{\ell} (1 + \gamma_5) \nu], \quad (1)$$

where  $P_K$  and  $P_\pi$  are the four-momenta of the  $K$  and  $\pi$  mesons,  $m_\ell$  is the lepton mass, and  $f_+$  and  $f_-$  are dimensionless form factors which can depend only on  $t = (P_K - P_\pi)^2$ , the square of the four-momentum transfer to the leptons. If time-reversal invariance holds,  $f_+$  and  $f_-$  are relatively real.  $K_{\mu 3}$  experiments, discussed immediately below, measure  $f_+$  and  $f_-$ , while  $K_{e 3}$  experiments, discussed further below, are sensitive only to  $f_+$  because the small electron mass makes the  $f_-$  term negligible.

**$K_{\mu 3}$  Experiments.** Analyses of  $K_{\mu 3}$  data frequently assume a linear dependence of  $f_+$  and  $f_-$  on  $t$ , i.e.,

$$f_\pm(t) = f_\pm(0) [1 + \lambda_\pm(t/m_{\pi^+}^2)]. \quad (2)$$

Most  $K_{\mu 3}$  data are adequately described by Eq. (2) for  $f_+$  and a constant  $f_-$  (i.e.,  $\lambda_- = 0$ ).

There are two equivalent parametrizations commonly used in these analyses:

**(1)  $\lambda_+, \xi(0)$  parametrization.** Older analyses of  $K_{\mu 3}$  data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t). \quad (3)$$

The  $K_{\mu 3}$  decay distribution is then described by the two parameters  $\lambda_+$  and  $\xi(0)$  (assuming time reversal invariance and  $\lambda_- = 0$ ).

**(2)  $\lambda_+, \lambda_0$  parametrization.** More recent  $K_{\mu 3}$  analyses have parametrized in terms of the form factors  $f_+$  and  $f_0$ , which are associated with vector and scalar exchange, respectively, to the lepton pair.  $f_0$  is related to  $f_+$  and  $f_-$  by

$$f_0(t) = f_+(t) + [t/(m_K^2 - m_\pi^2)] f_-(t). \quad (4)$$

# Meson Particle Listings

$K^\pm$

Here  $f_0(0)$  must equal  $f_+(0)$  unless  $f_-(t)$  diverges at  $t = 0$ . The earlier assumption that  $f_+$  is linear in  $t$  and  $f_-$  is constant leads to  $f_0$  linear in  $t$ :

$$f_0(t) = f_0(0) [1 + \lambda_0(t/m_{\pi^+}^2)] . \quad (5)$$

With the assumption that  $f_0(0) = f_+(0)$ , the two parametrizations,  $(\lambda_+, \xi(0))$  and  $(\lambda_+, \lambda_0)$  are equivalent as long as correlation information is retained.  $(\lambda_+, \lambda_0)$  correlations tend to be less strong than  $(\lambda_+, \xi(0))$  correlations.

Since the 2006 edition of the *Review* [4], we no longer quote results in the  $(\lambda_+, \xi(0))$  parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the  $K_{\mu 3}^0$  parameters, correlations, and conversion between parametrizations.

**Quadratic Parametrization.** More recent high-statistics experiments have included a quadratic term in the expansion of  $f_+(t)$ ,

$$f_+(t) = f_+(0) \left[ 1 + \lambda'_+(t/m_{\pi^+}^2) + \frac{\lambda''_+}{2}(t/m_{\pi^+}^2)^2 \right] . \quad (6)$$

If there is a non-vanishing quadratic term, then  $\lambda_+$  of Eq. (2) represents the average slope, which is then different from  $\lambda'_+$ . Our convention is to include the factor  $\frac{1}{2}$  in the quadratic term, and to use  $m_{\pi^+}$  even for  $K_{e3}^+$  and  $K_{\mu 3}^+$  decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the “ $K_{e3}^\pm$  and  $K_{\mu 3}^0$  Form Factors” sections of the Listings.

**Pole Parametrization:** The pole model describes the  $t$ -dependence of  $f_+(t)$  and  $f_0(t)$  in terms of the exchange of the lightest vector and scalar  $K^*$  mesons with masses  $M_v$  and  $M_s$ , respectively:

$$f_+(t) = f_+(0) \left[ \frac{M_v^2}{M_v^2 - t} \right] , \quad f_0(t) = f_0(0) \left[ \frac{M_s^2}{M_s^2 - t} \right] . \quad (7)$$

**Dispersive Parametrization** [7,8]. This approach uses dispersive techniques and the known low-energy  $K$ - $\pi$  phases to parametrize the vector and scalar form factors:

$$f_+(t) = f_+(0) \exp \left[ \frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right] ; \quad (8)$$

$$f_0(t) = f_0(0) \exp \left[ \frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t)) \right] , \quad (9)$$

where  $\Lambda_+$  is the slope of the vector form factor, and  $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$  is the logarithm of the scalar form factor at the Callan-Treiman point. The functions  $H(t)$  and  $G(t)$  are dispersive integrals.

**$K_{e3}$  Experiments:** Analysis of  $K_{e3}$  data is simpler than that of  $K_{\mu 3}$  because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here  $f_+$  can be assumed to be linear in  $t$ , in which case the linear coefficient  $\lambda_+$  of Eq. (2) is determined, or quadratic, in which case the linear coefficient  $\lambda'_+$  and quadratic coefficient  $\lambda''_+$  of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1 + \gamma_5)\nu \\ + (2f_T/m_K)(P_K)_\lambda (P_\pi)_\mu \bar{\ell} \sigma_{\lambda\mu} (1 + \gamma_5)\nu , \quad (10)$$

where  $f_S$  is the scalar form factor, and  $f_T$  is the tensor form factor. In the case of the  $K_{e3}$  decays where the  $f_-$  term can be neglected, experiments have yielded limits on  $|f_S/f_+|$  and  $|f_T/f_+|$ .

**Fits for  $K_{e3}$  Form Factors.** For  $K_{e3}$  data, we determine best values for the three parametrizations: linear  $(\lambda_+)$ , quadratic  $(\lambda'_+, \lambda''_+)$  and pole  $(M_v)$ . For  $K_{\mu 3}$  data, we determine best values for the three parametrizations: linear  $(\lambda_+, \lambda_0)$ , quadratic  $(\lambda'_+, \lambda''_+, \lambda_0)$  and pole  $(M_v, M_s)$ . We then assume  $\mu - e$  universality so that we can combine  $K_{e3}$  and  $K_{\mu 3}$  data, and again determine best values for the three parametrizations: linear  $(\lambda_+, \lambda_0)$ , quadratic  $(\lambda'_+, \lambda''_+, \lambda_0)$ , and pole  $(M_v, M_s)$ . When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two  $K_{e3}$  cases where there is only one parameter: linear  $(\lambda_+)$  and pole  $(M_v)$ .

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter  $\lambda''_+$  is highly correlated with the linear parameter  $\lambda'_+$ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The “Kaon Particle Listings” show the results with and without assuming  $\mu - e$  universality. The “Meson Summary Tables” show all of the results assuming  $\mu - e$  universality, but most results not assuming  $\mu - e$  universality are given only in the Listings.

**$K_{e3}^\pm$  FORM FACTORS**

In the form factor comments, the following symbols are used.

$f_+$  and  $f_-$  are form factors for the vector matrix element.

$f_S$  and  $f_T$  refer to the scalar and tensor term.

$f_0 = f_+ + f_- t/(m_{K^+}^2 - m_{\pi^0}^2)$ .

$t$  = momentum transfer to the  $\pi$ .

$\lambda_+$  and  $\lambda_0$  are the linear expansion coefficients of  $f_+$  and  $f_0$ :

$f_+(t) = f_+(0) (1 + \lambda_+ t/m_{\pi^+}^2)$

For quadratic expansion

$f_+(t) = f_+(0) (1 + \lambda'_+ t/m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2/m_{\pi^+}^4)$

as used by KTeV. If there is a non-vanishing quadratic term, then  $\lambda_+$  represents an average slope, which is then different from  $\lambda'_+$ .

NA48 and ISTRA quadratic expansion coefficients are converted with  $\lambda'^+_{PDG} = \lambda_{NA48}$  and  $\lambda''_{PDG} = 2 \lambda'_{NA48}$

$\lambda'^+_{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+ ISTRA$  and

$\lambda''_{PDG} = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda'_+ ISTRA$

ISTRA linear expansion coefficients are converted with

$\lambda^+_{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+ ISTRA$  and  $\lambda_0_{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0 ISTRA$

The pole parametrization is

$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$

$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$

where  $M_V$  and  $M_S$  are the vector and scalar pole masses.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI =  $\pi$  spectrum analysis.

MU =  $\mu$  spectrum analysis.

POL =  $\mu$  polarization analysis.

BR =  $K_{\mu 3}^\pm/K_{e 3}^\pm$  branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

 **$\lambda_+$  (LINEAR ENERGY DEPENDENCE OF  $f_+$  IN  $K_{e3}^\pm$  DECAY)**

These results are for a linear expansion only. See the next section for fits including a quadratic term. For radiative correction of the  $K_{e3}^\pm$  Dalitz plot, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review " $K_{e3}^\pm$  and  $K_{\mu 3}^0$  Form Factors" above. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

### $K_{\ell 4}^\pm$ FORM FACTORS

Based on the parametrizations of AMOROS 99, the  $K_{\ell 4}^\pm$  form factors can be expressed as

$$F_s = f_s + f'_s q^2 + f''_s q^4 + f'_e S_e / 4m_\pi^2$$
$$F_p = f_p$$
$$G_p = g_p + g'_p q^2$$
$$H_p = h_p$$

where  $q^2 = (S_\pi / 4m_\pi^2) - 1$ ,  $S_\pi$  is the invariant mass squared of the dipion, and  $S_e$  is the invariant mass squared of the dilepton.

### DECAY FORM FACTOR FOR $K^\pm \rightarrow \pi^0 \pi^0 e^\pm \nu$

Given in BOLOTOV 86b, BARMIN 88b, and SHIMIZU 04.

### $K^\pm \rightarrow \ell^\pm \nu \gamma$ FORM FACTORS

For definitions of the axial-vector  $F_A$  and vector  $F_V$  form factor, see the “Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors” in the  $\pi^\pm$  section. In the kaon literature, often different definitions  $a_K = F_A/m_K$  and  $v_K = F_V/m_K$  are used.

### $F_A + F_V$ , SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \rightarrow e \nu_e \gamma$

## Meson Particle Listings

 $K^\pm$ 

<sup>1</sup> Vector form factor fitted with a linear function,  $V(x) = F_V (1 + \lambda(1-x))$ ,  $x = 2E_\gamma/m_K$ . The fitted value of  $\lambda = 0.38 \pm 0.20 \pm 0.02$  with a correlation of  $-0.93$  between  $(F_V + F_A)$  and  $\lambda$ .

<sup>2</sup> HEINTZE 79 quotes absolute value of  $|F_A + F_V| \sin\theta_C$ . We use  $\sin\theta_C = V_{us} = 0.2205$ .

<sup>3</sup> HEARD 75 quotes absolute value of  $|F_A + F_V| \sin\theta_C$ . We use  $\sin\theta_C = V_{us} = 0.2205$ .

--------------------------	------	-------------	-------

**$6.6 \pm 1.3 \pm 1.0$**  640k 1 ANGELOPO... 98E CPLR

<sup>1</sup> ANGELOPOULOS 98E measures the asymmetry  $A_T = [\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) - \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})] / [\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) + \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})]$  as a function of the neutral-kaon eigentime  $\tau$ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions  $p\bar{p} \rightarrow K^- \pi^+ K^0$  and  $p\bar{p} \rightarrow K^+ \pi^- \bar{K}^0$ . The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of  $A_T$  over the interval  $1\tau_S < \tau < 20\tau_S$ . From this value of  $A_T$  ANGELOPOULOS 01B, assuming  $CPT$  invariance in the  $e\pi\nu$  decay amplitude, determine the  $T$ -violating as  $\Delta S = \Delta S$  conserving parameter (for its definition, see Review below)  $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$ .

 **$CPT$  INVARIANCE TESTS IN NEUTRAL KAON DECAY**

Updated October 2013 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

$CPT$  theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in  $K^0 - \bar{K}^0$  system, described by the equation

$$i \frac{d}{dt} \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix} = [M - i\Gamma/2] \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix},$$

where  $M$  and  $\Gamma$  are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [5] for notations and previous literature), allows a very accurate test of  $CPT$  symmetry; indeed since  $CPT$  requires  $M_{11} = M_{22}$  and  $\Gamma_{11} = \Gamma_{22}$ , the mass and width eigenstates,  $K_{S,L}$ , have a  $CPT$ -violating piece,  $\delta$ , in addition to the usual  $CPT$ -conserving parameter  $\epsilon$ :

$$K_{S,L} = \frac{1}{\sqrt{2(1 + |\epsilon_{S,L}|^2)}} \left[ (1 + \epsilon_{S,L}) K^0 \pm (1 - \epsilon_{S,L}) \bar{K}^0 \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[ M_{11} - M_{22} - \frac{i}{2}(\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta. \quad (1)$$

Using the phase convention  $\Im(\Gamma_{12}) = 0$ , we determine the phase of  $\epsilon$  to be  $\varphi_{SW} \equiv \arctan \frac{2(m_L - m_S)}{\Gamma_S - \Gamma_L}$ . Imposing unitarity to an arbitrary combination of  $K^0$  and  $\bar{K}^0$  wave functions, we obtain the Bell-Steinberger relation [4] connecting  $CP$  and  $CPT$  violation in the mass matrix to  $CP$  and  $CPT$  violation in the decay; in fact, neglecting  $\mathcal{O}(\epsilon)$  corrections to the coefficient of the  $CPT$ -violating parameter,  $\delta$ , we can write [5]

$$\left[ \frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{SW} \right] \left[ \frac{\Re(\epsilon)}{1 + |\epsilon|^2} - i\Im(\delta) \right] =$$

$$\frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f), \quad (2)$$

**Table 1:** Values, errors, and correlation coefficients for  $\Re(\delta)$ ,  $\Im(\delta)$ ,  $\Re(x_-)$ ,  $\Im(x_+)$ , and  $A_S + A_L$  obtained from a combined fit, including KLOE [5] and CPLEAR [14].

	value	Correlations coefficients			
$\Re(\delta)$	$(3.0 \pm 2.3) \times 10^{-4}$	1			
$\Im(\delta)$	$(-0.66 \pm 0.65) \times 10^{-2}$	-0.21	1		
$\Re(x_-)$	$(-0.30 \pm 0.21) \times 10^{-2}$	-0.21	-0.60	1	
$\Im(x_+)$	$(0.02 \pm 0.22) \times 10^{-2}$	-0.38	-0.14	0.47	1
$A_S + A_L$	$(-0.40 \pm 0.83) \times 10^{-2}$	-0.10	-0.63	0.99	0.43 1

where  $A_{L,S}(f) \equiv A(K_{L,S} \rightarrow f)$ . We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle \mathcal{A}_L(i) \mathcal{A}_S^*(i) \rangle = \eta_i \mathcal{B}(K_S \rightarrow i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^- (\gamma), 3\pi^0, \pi^0 \pi^+ \pi^- (\gamma), \quad (3)$$

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 5 has been updated by using the recent measurements of  $K_L$  branching ratios from KTeV [6,7], NA48 [8,9], and the results described in the  $CP$  violation in  $K_L$  decays minireview, and the recent KLOE result [10])

$$\alpha_{\pi^+ \pi^-} = ((1.112 \pm 0.010) + i(1.061 \pm 0.010)) \times 10^{-3},$$

$$\alpha_{\pi^0 \pi^0} = ((0.493 \pm 0.005) + i(0.471 \pm 0.005)) \times 10^{-3},$$

$$\alpha_{\pi^+ \pi^- \pi^0} = ((0 \pm 2) + i(0 \pm 2)) \times 10^{-6},$$

$$|\alpha_{\pi^0 \pi^0 \pi^0}| < 1.5 \times 10^{-6} \quad \text{at } 95\% \text{ CL}. \quad (4)$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y),$$

$$\mathcal{A}(K^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*)(x_+ - x_-)^*,$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*),$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y)(x_+ + x_-), \quad (5)$$

where  $x_+$  ( $x_-$ ) describes the violation of the  $\Delta S = \Delta Q$  rule in  $CPT$ -conserving (violating) decay amplitudes, and  $y$  parametrizes  $CPT$  violation for  $\Delta S = \Delta Q$  transitions. Taking advantage of their tagged  $K^0(\bar{K}^0)$  beams, CPLEAR has measured  $\Im(x_+)$ ,  $\Re(x_-)$ ,  $\Im(\delta)$ , and  $\Re(\delta)$  [11]. These determinations have been improved in Ref. 5 by including the information  $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$ , where  $A_{L,S}$  are the  $K_L$  and  $K_S$  semileptonic charge asymmetries, respectively, from the PDG [12] and KLOE [13]. Here we are also including the  $T$ -violating asymmetry measurement from CPLEAR [14].

# Meson Particle Listings

$K^0$

The value  $A_S + A_L$  in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\begin{aligned} \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle \\ = 2\Gamma(K_L \rightarrow \pi\ell\nu) (\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta))) \\ = 2\Gamma(K_L \rightarrow \pi\ell\nu) ((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))) . \end{aligned} \quad (6)$$

Defining

$$\alpha_{\pi\ell\nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle + 2i \frac{\tau_{KS}}{\tau_{KL}} \mathcal{B}(K_L \rightarrow \pi\ell\nu) \Im(\delta) , \quad (7)$$

we find:

$$\alpha_{\pi\ell\nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5} .$$

Inserting the values of the  $\alpha$  parameters into Eq. (2), we find

$$\begin{aligned} \Re(\epsilon) &= (161.1 \pm 0.5) \times 10^{-5} , \\ \Im(\delta) &= (-0.7 \pm 1.4) \times 10^{-5} . \end{aligned} \quad (8)$$

The complete information on Eq. (8) is given in Table 2.

**Table 2:** Summary of results: values, errors, and correlation coefficients for  $\Re(\epsilon)$ ,  $\Im(\delta)$ ,  $\Re(\delta)$ , and  $\Re(x_-)$ .

	value	Correlations coefficients			
$\Re(\epsilon)$	$(161.1 \pm 0.5) \times 10^{-5}$	+1			
$\Im(\delta)$	$(-0.7 \pm 1.4) \times 10^{-5}$	+0.09	1		
$\Re(\delta)$	$(2.4 \pm 2.3) \times 10^{-4}$	+0.08	-0.12	1	
$\Re(x_-)$	$(-4.1 \pm 1.7) \times 10^{-3}$	+0.14	0.22	-0.43	1

Now the agreement with  $CPT$  conservation,  $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$ , is at 18% C.L.

The allowed region in the  $\Re(\epsilon) - \Im(\delta)$  plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

The process giving the largest contribution to the size of the allowed region is  $K_L \rightarrow \pi^+\pi^-$ , through the uncertainty on  $\phi_{+-}$ .

The limits on  $\Im(\delta)$  and  $\Re(\delta)$  can be used to constrain the  $K^0 - \bar{K}^0$  mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\bar{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\bar{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)] .$$

The allowed region in the  $\Delta M = (m_{K^0} - m_{\bar{K}^0})$ ,  $\Delta\Gamma = (\Gamma_{K^0} - \Gamma_{\bar{K}^0})$  plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 12) and in the limit  $\Gamma_{K^0} - \Gamma_{\bar{K}^0} = 0$  we obtain

$$\begin{aligned} -4.0 \times 10^{-19} \text{ GeV} &< m_{K^0} - m_{\bar{K}^0} \\ &< 4.0 \times 10^{-19} \text{ GeV} \quad \text{at } 95 \% \text{ C.L.} \end{aligned}$$

**Figure 1:** Top: allowed region at 68% and 95% C.L. in the  $\Re(\epsilon)$ ,  $\Im(\delta)$  plane. Bottom: allowed region at 68% and 95% C.L. in the  $\Delta M$ ,  $\Delta\Gamma$  plane.

**CPT-VIOLATION PARAMETERS**

In  $K^0$ - $\bar{K}^0$  mixing, if CP-violating interactions include a  $T$  conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle] / \sqrt{1 + |\epsilon + \delta|^2}$$

$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle] / \sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\bar{K}^0\rangle] / \sqrt{2}$$

$$|K_2\rangle = [|K^0\rangle - |\bar{K}^0\rangle] / \sqrt{2}$$

and

$$|\bar{K}^0\rangle = CP|K^0\rangle.$$

The parameter  $\delta$  specifies the CPT-violating part.

Estimates of  $\delta$  are given below assuming the validity of the  $\Delta S = \Delta Q$  rule. See also THOMSON 95 for a test of CPT-symmetry conservation in  $K^0$  decays using the Bell-Steinberger relation.

**REAL PART OF  $\delta$** 

A nonzero value violates CPT invariance.

$(-3 \pm 4) \times 10^{-18}$		<sup>1</sup> ANGELOPO... 99B RVUE	

<sup>1</sup> ANGELOPOULOS 99B assumes only unitarity and combines CPLEAR and other results.

$$(\Gamma_{K^0} - \Gamma_{\bar{K}^0}) / m_{\text{average}}$$

A test of CPT invariance.

VALUE	DOCUMENT ID	TECN
<b><math>(7.8 \pm 8.4) \times 10^{-18}</math></b>	<sup>1</sup> ANGELOPO... 99B RVUE	

<sup>1</sup> ANGELOPOULOS 99B assumes only unitarity and combines CPLEAR with other results. Correlated with  $(m_{K^0} - m_{\bar{K}^0}) / m_{\text{average}}$  with a correlation coefficient of  $-0.95$ .

**TESTS OF  $\Delta S = \Delta Q$  RULE****Re( $x_+$ )**

A non-zero value would violate the  $\Delta S = \Delta Q$  rule in CPT conserving transitions.  $x_+$  is defined above in the Re( $x_-$ ) section.

VALUE (units $10^{-3}$ )	EVTS	DOCUMENT ID	TECN
<b><math>-0.9 \pm 3.0</math> OUR AVERAGE</b>			
-2 $\pm$ 10		<sup>1</sup> BATLEY 07D NA48	
-0.5 $\pm$ 3.6	13k	<sup>2</sup> AMBROSINO 06E KLOE	
-1.8 $\pm$ 6.1		<sup>3</sup> ANGELOPO... 98D CPLR	

<sup>1</sup> Result obtained from the measurement  $\Gamma(K_S^0 \rightarrow \pi \nu) / \Gamma(K_L^0 \rightarrow \pi \nu) = 0.993 \pm 0.34$ , neglecting possible CPT non-invariance and using PDG 06 values of  $B(K_L^0 \rightarrow \pi \nu) = 0.4053 \pm 0.0015$ ,  $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$  s and  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.

<sup>2</sup> Re( $x_+$ ) can be shown to be equal to the following combination of rates:

$$\text{Re}(x_+) = \frac{1}{2} \frac{\Gamma(K_S^0 \rightarrow \pi \nu) - \Gamma(K_L^0 \rightarrow \pi \nu)}{\Gamma(K_S^0 \rightarrow \pi \nu) + \Gamma(K_L^0 \rightarrow \pi \nu)}$$

which is valid up to first order in terms violating CPT and/or the  $\Delta S = \Delta Q$  rule.

<sup>3</sup> Obtained neglecting CPT violating amplitudes.

### $K_S^0$ MEAN LIFE

For earlier measurements, beginning with BOLDT 58B, see our 1986 edition, Physics Letters **170B** 130 (1986).

OUR FIT is described in the note on “ $CP$  violation in  $K_L^0$  decays” in the  $K^0$  Particle Listings. The result labeled “OUR FIT Assuming  $CPT$ ” [“OUR FIT Not assuming  $CPT$ ”] includes all measurements except those with the comment “Not assuming  $CPT$ ” [“Assuming  $CPT$ ”]. Measurements with neither comment do not assume  $CPT$  and enter both fits.

0.872 ± 0.009	20000	9,10 HILL	68	DBC

<sup>1</sup> The two ABOUZAID 11 values use the same full KTeV dataset from 1996, 1997, and 1999. The first enters the “assuming  $CPT$ ” fit and the second enters the “not assuming  $CPT$ ” fit.

<sup>2</sup> ABOUZAID 11 fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_e$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  as free parameters. See  $\text{Im}(\epsilon'/\epsilon)$  in the “ $K_L^0$   $CP$  violation” section for correlation information.

<sup>3</sup> ABOUZAID 11 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_e$  to the Superweak value, i.e. assumes  $CPT$ . This  $\tau_S$  value is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  measurement in the  $K_L^0$  listings. The correlation coefficient  $\rho(\tau_S, \Delta m) = -0.670$ .

<sup>4</sup> Fit to the proper time distribution.

<sup>5</sup> This ALAVI-HARATI 03 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_{+-}$  to the Superweak value, i.e. assumes  $CPT$ . This  $\tau_S$  value is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  measurement in the  $K_L^0$  listings. The correlation coefficient  $\rho(\tau_S, \Delta m) = -0.396$ . Superseded by ABOUZAID 11.

<sup>6</sup> This ALAVI-HARATI 03 fit has  $\Delta m$ ,  $\phi_{+-}$ , and  $\tau_{K_S}$  free. See  $\phi_{+-}$  in the “ $K_L$   $CP$  violation” section for correlation information. Superseded by ABOUZAID 11.

<sup>7</sup> ARONSON 82 find that  $K_S^0$  mean life may depend on the kaon energy.

<sup>8</sup> CARITHERS 75 measures the  $\Delta m$  dependence of the total decay rate (inverse mean life) to be  $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m]10^{10}/\text{s}$ , or, in terms of mean life, CARITHERS 75 measures  $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348] (10^{-10} \text{ s})$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \hbar \text{ s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>9</sup> HILL 68 has been changed by the authors from the published value ( $0.865 \pm 0.009$ ) because of a correction in the shift due to  $\eta_{+-}$ . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

<sup>10</sup> Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

### $K_S^0$ DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Hadronic modes</b>		
$\Gamma_1$ $\pi^0 \pi^0$	(30.69 ± 0.05) %	
$\Gamma_2$ $\pi^+ \pi^-$	(69.20 ± 0.05) %	
$\Gamma_3$ $\pi^+ \pi^- \pi^0$	( 3.5 $^{+1.1}_{-0.9}$ ) × 10 <sup>-7</sup>	
<b>Modes with photons or <math>\ell\bar{\ell}</math> pairs</b>		
$\Gamma_4$ $\pi^+ \pi^- \gamma$	[a,b] ( 1.79 ± 0.05) × 10 <sup>-3</sup>	
$\Gamma_5$ $\pi^+ \pi^- e^+ e^-$	( 4.79 ± 0.15) × 10 <sup>-5</sup>	
$\Gamma_6$ $\pi^0 \gamma \gamma$	[a] ( 4.9 ± 1.8 ) × 10 <sup>-8</sup>	
$\Gamma_7$ $\gamma \gamma$	( 2.63 ± 0.17) × 10 <sup>-6</sup>	S=3.0
<b>Semileptonic modes</b>		
$\Gamma_8$ $\pi^\pm e^\mp \nu_e$	[c] ( 7.04 ± 0.08) × 10 <sup>-4</sup>	
$\Gamma_9$ $\pi^\pm \mu^\mp \nu_\mu$	[c,d] ( 4.69 ± 0.05) × 10 <sup>-4</sup>	

### $CP$ violating ( $CP$ ) and $\Delta S = 1$ weak neutral current ( $S1$ ) modes

$\Gamma_{10}$ $3\pi^0$	$CP$	< 2.6	× 10 <sup>-8</sup>	CL=90%
$\Gamma_{11}$ $\mu^+ \mu^-$	$S1$	< 9	× 10 <sup>-9</sup>	CL=90%
$\Gamma_{12}$ $e^+ e^-$	$S1$	< 9	× 10 <sup>-9</sup>	CL=90%
$\Gamma_{13}$ $\pi^0 e^+ e^-$	$S1$	[a] ( 3.0 $^{+1.5}_{-1.2}$ )	× 10 <sup>-9</sup>	
$\Gamma_{14}$ $\pi^0 \mu^+ \mu^-$	$S1$	( 2.9 $^{+1.5}_{-1.2}$ )	× 10 <sup>-9</sup>	

[a] See the Particle Listings below for the energy limits used in this measurement.

[b] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Not a measurement. Calculated as  $0.666 \cdot B(\pi^\pm e^\mp \nu_e)$ .

### CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.1$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	-100		
$x_8$	-6	3	
$x_9$	-6	3	100
	$x_1$	$x_2$	$x_8$

3.9 + 5.4 - 1.8 - 0.7	<sup>5</sup> THOMSON 94 E621 Sup. by ZOU 96

<sup>1</sup> BATLEY 05 is obtained by measuring the interference parameters in  $K_S, K_L \rightarrow \pi^+ \pi^- \pi^0$ .  $\text{Re}(\lambda) = 0.038 \pm 0.008 \pm 0.006$  and  $\text{Im}(\lambda) = -0.013 \pm 0.005 \pm 0.004$ ; the correlation coeff. between  $\text{Re}(\lambda)$  and  $\text{Im}(\lambda)$  is 0.66 (statistical only).

<sup>2</sup> ADLER 97b find the  $CP$ -conserving parameters  $\text{Re}(\lambda) = (28 \pm 7 \pm 3) \times 10^{-3}$ ,  $\text{Im}(\lambda) = (-10 \pm 8 \pm 2) \times 10^{-3}$ . They estimate  $B(K_S^0 \rightarrow \pi^+ \pi^- \pi^0)$  from  $\text{Re}(\lambda)$  and the  $K_L^0$  decay parameters. See also ANGELOPOULOS 98c.

<sup>3</sup> ZOU 96 is from the the measured quantities  $|\rho_{+-0}| = 0.039 \pm 0.009 \pm 0.005$  and  $\phi_p = (-9 \pm 18)^\circ$ .

<sup>4</sup> ADLER 96e is from the measured quantities  $\text{Re}(\lambda) = 0.036 \pm 0.010 \pm 0.002 \pm 0.003$  and  $\text{Im}(\lambda)$  consistent with zero. Note that the quantity  $\lambda$  is the same as  $\rho_{+-0}$  used in other footnotes.

<sup>5</sup> THOMSON 94 calculates this branching ratio from their measurements  $|\rho_{+-0}| = 0.035 \pm 0.019 \pm 0.011 \pm 0.004$  and  $\phi_p = (-59 \pm 48)^\circ$  where  $|\rho_{+-0}| e^{i\phi_p} = A(K_S^0 \rightarrow \pi^+ \pi^- \pi^0, I = 2)/A(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)$ .

## $K_S^0$

- <sup>1</sup> Reconstructed from  $K^0(\overline{K}^0)(t) \rightarrow \pi e \nu$  distributions using PDG values of  $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$ ,  $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$  s and  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.
- <sup>2</sup> Uses the PDG 00 value for  $B(K_S^0 \rightarrow \pi^+ \pi^-)$ .
- <sup>3</sup> Obtained by imposing  $\Sigma_i B(K_S^0 \rightarrow i) = 1$ , where  $i$  runs over all the four branching ratios  $\pi^+ \pi^-$ ,  $\pi^0 \pi^0$ ,  $\pi e \nu$ , and  $\pi \mu \nu$ . Input value of  $B(K_S^0 \rightarrow \pi^+ \pi^-) / B(K_S^0 \rightarrow \pi^0 \pi^0)$  from AMBROSINO 06c is used. To derive  $\Gamma(K_S^0 \rightarrow \pi^+ \mu \nu) / \Gamma(K_S^0 \rightarrow \pi^+ e \nu)$ , lepton universality is assumed, radiative corrections from ANDRE 07 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their  $\Gamma(\pi^\pm e^\mp \nu_e) / \Gamma(\pi^+ \pi^-)$  branching ratio measurement.

## $\Gamma(\pi^\pm \mu^\mp \nu_\mu) / \Gamma_{\text{total}}$ $\Gamma_9 / \Gamma$

The PDG 06 value below has not been measured but is computed to be 0.666 times the  $K_S \rightarrow \pi^\pm e^\mp \nu_e$  branching fraction. It is included in the fit that constrains the four branching ratios  $\pi^+ \pi^-$ ,  $\pi^0 \pi^0$ ,  $\pi e \nu$ , and  $\pi \mu \nu$  to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the  $\pi^+ \pi^-$  and  $\pi^0 \pi^0$  modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 07, and phase space integrals from KTeV, ALEXOPOULOS 04A.

### $K_S^0$ FORM FACTORS

For discussion, see note on  $K_{f3}$  form factors in the  $K^\pm$  section of the Particle Listings above. Because the semileptonic branching fraction is smaller in  $K_S^0$  than  $K_L^0$  by the ratio of the mean lives, the  $K_S^0$  semileptonic form factor has so far been measured only in the  $K_{e3}$  mode using the linear expansion  $f_+(t) = f_+(0) (1 + \lambda_+ t / m_\pi^2)$ , which gives the vector form factor  $f_+(t)$  relative to its value at  $t = 0$ .

### CP VIOLATION IN $K_S \rightarrow 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay  $K^0 \rightarrow \pi^+ \pi^- \pi^0$  have isospin  $I = 0, 1, 2$ , and 3. The  $I = 0$  and  $I = 2$  states have  $CP = +1$  and  $K_S$  can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The  $I = 1$  and  $I = 3$  states, which have no centrifugal barrier, have  $CP = -1$  so that the  $K_S$  decay to these requires CP violation.

In order to see CP violation in  $K_S \rightarrow \pi^+ \pi^- \pi^0$ , it is necessary to observe the interference between  $K_S$  and  $K_L$  decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \rightarrow \pi^+ \pi^- \pi^0)}{A(K_L \rightarrow \pi^+ \pi^- \pi^0)}. \quad (1)$$

If  $\eta_{+-0}$  is obtained from an integration over the whole Dalitz plot, there is no contribution from the  $I = 0$  and  $I = 2$  final states and a nonzero value of  $\eta_{+-0}$  is entirely due to CP violation.

Only  $I = 1$  and  $I = 3$  states, which are  $CP = -1$ , are allowed for  $K^0 \rightarrow \pi^0 \pi^0 \pi^0$  decays and the decay of  $K_S$  into  $3\pi^0$  is an unambiguous sign of CP violation. Similarly to  $\eta_{+-0}$ ,  $\eta_{000}$  is defined as

$$\eta_{000} = \frac{A(K_S \rightarrow \pi^0 \pi^0 \pi^0)}{A(K_L \rightarrow \pi^0 \pi^0 \pi^0)}. \quad (2)$$

If one assumes that CPT invariance holds and that there are no transitions to  $I = 3$  (or to nonsymmetric  $I = 1$  states), it can be shown that

$$\begin{aligned} \eta_{+-0} &= \eta_{000} \\ &= \epsilon + i \frac{\text{Im } a_1}{\text{Re } a_1}. \end{aligned} \quad (3)$$

<sup>1</sup> The two ABOUZAID 11 values use the same data. The first enters the “assuming *CPT*” fit and the second enters the “not assuming *CPT*” fit.

<sup>2</sup> ABOUZAID 11 fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_e$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  as free parameters. See  $\text{Im}(\epsilon'/\epsilon)$  in the “ $K_L^0$  *CP* violation” section for correlation information.

<sup>3</sup> ABOUZAID 11 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_e$  to the Superweak value, i.e. assumes *CPT*. See “ $K_S^0$  Mean Life” section for correlation information.

<sup>4</sup> Fits  $\Delta m$  and  $\phi_{+-}$  simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20–160 GeV *K* beams.

<sup>5</sup> GIBBONS 93 value assume  $\phi_{+-} = \phi_{00} = \phi_{\text{SW}} = (43.7 \pm 0.2)^\circ$ , i.e. assumes *CPT*. 20–160 GeV *K* beams.

<sup>6</sup> These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.

<sup>7</sup> GJESDAL 74 uses charge asymmetry in  $K_{L3}^0$  decays.

<sup>8</sup> ALAVI-HARATI 03 fit  $\Delta m$  and  $\tau_{K_S^0}$  simultaneously.  $\phi_{+-}$  is constrained to the Superweak value, i.e. *CPT* is assumed. See “ $K_S^0$  Mean Life” section for correlation information. Superseded by ABOUZAID 11.

<sup>9</sup> ALAVI-HARATI 03 fit  $\Delta m$ ,  $\phi_{+-}$ , and  $\tau_{K_S}$  simultaneously. See  $\phi_{+-}$  in the “ $K_L$  *CP* violation” section for correlation information. Superseded by ABOUZAID 11.

<sup>10</sup> ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.

<sup>11</sup> Uses  $\bar{K}_{e3}^0$  and  $K_{e3}^0$  strangeness tagging at production and decay. Assumes *CPT* conservation on  $\Delta S = -\Delta Q$  transitions.

<sup>12</sup> ADLER 96C is the result of a fit which includes nearly the same data as entered into the “OUR FIT” value above.

<sup>13</sup> ARONSON 82 find that  $\Delta m$  may depend on the kaon energy.

<sup>14</sup> ARONSON 70 and CARNEGIE 71 use  $K_S^0$  mean life =  $(0.862 \pm 0.006) \times 10^{-10}$  s. We have not attempted to adjust these values for the subsequent change in the  $K_S^0$  mean life or in  $\eta_{+-}$ .

## $K_L^0$ MEAN LIFE

VALUE ( $10^{-8}$ s)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>5.116 ± 0.021 OUR FIT</b>	Error includes scale factor of 1.1.			
<b>5.099 ± 0.021 OUR AVERAGE</b>				
5.072 ± 0.011 ± 0.035	13M	<sup>1</sup> AMBROSINO 06	KLOE	$\sum_i B_i = 1$
5.092 ± 0.017 ± 0.025	15M	AMBROSINO 05c	KLOE	
5.154 ± 0.044	0.4M	VOSBURGH 72	CNTR	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
5.15 ± 0.14		DEVLIN 67	CNTR	

<sup>1</sup> AMBROSINO 06 uses  $\phi \rightarrow K_L K_S$  with  $K_L$  tagged by  $K_S \rightarrow \pi^+\pi^-$ . The four major  $K_L$  BR’s are measured, the small remainder ( $\pi^+\pi^-, \pi^0\pi^0, \gamma\gamma$ ) is taken from PDG 04. This KLOE  $K_L$  lifetime is obtained by imposing  $\sum_i B_i = 1$ . The correlation matrix among the four measured  $K_L$  BR’s and this  $K_L$  lifetime is

	$K_{e3}$	$K_{\mu 3}$	$3\pi^0$	$\pi^+\pi^-\pi^0$	$\tau_{K_L}$
$K_{e3}$	1	−0.25	−0.56	−0.07	0.25
$K_{\mu 3}$		1	−0.43	−0.20	0.33
$3\pi^0$			1	−0.39	−0.21
$\pi^+\pi^-\pi^0$				1	−0.39
$\tau_{K_L}$					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05c is  $(5.084 \pm 0.023) \times 10^{-8}$  s.

 $V_{ud}, V_{us}$ , THE CABIBBO ANGLE, AND CKM UNITARITY

Updated May 2016 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters  $(\lambda, A, \rho, \eta)$  [3] nicely illustrates the orthonormality constraint of unitarity and central role played by  $\lambda$ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle,  $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$ . Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Until about 11 years ago, the precise value of  $\lambda$  was somewhat controversial, with kaon decays suggesting [4]  $\lambda \simeq 0.220$ , while indirect determinations via nuclear  $\beta$ -decays implied a somewhat larger  $\lambda \simeq 0.225 - 0.230$ . This difference resulted in a 2 – 2.5 sigma deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1, \quad (2)$$

a potential signal [5] for new physics effects. Below, we discuss the current status of  $V_{ud}$ ,  $V_{us}$ , and their associated unitarity test in Eq. (2). (Since  $|V_{ub}|^2 \simeq 1 \times 10^{-5}$  is negligibly small,

# Meson Particle Listings

$K_L^0$

it is ignored in this discussion.) Eq. (2) is currently the most stringent test of unitarity in the CKM matrix.

## $V_{ud}$

The value of  $V_{ud}$  has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of  $V_{ud}$  comes from a set of superallowed nuclear beta-decays [5] ( $0^+ \rightarrow 0^+$  transitions). Measuring their half-lives,  $t$ , and  $Q$  values that give the decay rate factor,  $f$ , leads to a precise determination of  $V_{ud}$  via the master formula [6–10]

$$|V_{ud}|^2 = \frac{2984.48(5) \text{ sec}}{ft(1 + \Delta)}, \quad (3)$$

where  $\Delta$  denotes the entire effect of electroweak radiative corrections (RC), nuclear structure, and isospin violating nuclear effects.  $\Delta$  is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays.

The most recent analysis of 14 precisely measured superallowed transitions by Hardy and Towner [11] gives a weighted average of

$$V_{ud} = 0.97417(5)_{\text{exp.}}(9)_{\text{nucl.dep.}}(18)_{\text{RC}} \text{ (superallowed)}, \quad (4)$$

which, assuming unitarity, corresponds to  $\lambda = 0.2258(9)$ . This recent determination of  $V_{ud}$  has shifted downward compared to the 2014 value of 0.97425(22) primarily from improvements in the nuclear isospin breaking corrections [11]. It is now closer to the central value quoted in 2007.

Combined measurements of the neutron lifetime,  $\tau_n$ , and the ratio of axial-vector/vector couplings,  $g_A \equiv G_A/G_V$ , via neutron decay asymmetries can also be used to determine  $V_{ud}$ :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n(1 + 3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [7] due to hadronic loop effects. Those effects were updated and their error was reduced by about a factor of 2 [8], leading to a  $\pm 0.0002$  theoretical uncertainty in  $V_{ud}$  (common to all  $V_{ud}$  extractions). Using the world averages from this *Review*

$$\begin{aligned} \tau_n^{\text{ave}} &= 880.3(1.1) \text{ sec} \quad (\times 1.9 \text{ PDG scale factor}) \\ g_A^{\text{ave}} &= 1.2723(23) \quad (\times 2.2 \text{ PDG scale factor}) \end{aligned} \quad (6)$$

leads to

$$V_{ud} = 0.9758(6)_{\tau_n}(15)_{g_A}(2)_{\text{RC}}, \quad (7)$$

with the error dominated by  $g_A$  uncertainties. We note that the larger  $g_A$  now adopted in Eq. (6) leads to a value of  $V_{ud}$  that is still somewhat high, but in accord with the superallowed nuclear beta decay result in Eq. (4). Future neutron studies [12] are expected to resolve any current inconsistencies and significantly

reduce the uncertainties in  $g_A$  and  $\tau_n$ , potentially making them a competitive way to determine  $V_{ud}$  without nuclear physics uncertainties.

The PIBETA experiment at PSI measured the very small ( $\mathcal{O}(10^{-8})$ ) branching ratio for  $\pi^+ \rightarrow \pi^0 e^+ \nu_e$  with about  $\pm 1/2\%$  precision. Their result gives [13]

$$V_{ud} = 0.9749(26) \left[ \frac{BR(\pi^+ \rightarrow e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for  $BR(\pi^+ \rightarrow e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$  [6], rather than the experimental branching ratio from this *Review* of  $1.230(4) \times 10^{-4}$  which would lower the value to  $V_{ud} = 0.9728(30)$ . Theoretical uncertainties in the pion  $\beta$ -decay determination are very small; however, much higher statistics would be required to make this approach competitive with others.

## $V_{us}$

$|V_{us}|$  may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used  $K\ell 3$  decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW}(1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here,  $\ell$  refers to either  $e$  or  $\mu$ ,  $G_F$  is the Fermi constant,  $M_K$  is the kaon mass,  $S_{EW}$  is the short-distance radiative correction,  $\delta_K^\ell$  is the mode-dependent long-distance radiative correction,  $f_+(0)$  is the calculated form factor at zero momentum transfer for the  $\ell\nu$  system, and  $I_K^\ell$  is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays,  $\delta_{SU2}$  is the deviation from one of the ratio of  $f_+(0)$  for the charged to neutral kaon decay; it is zero for the neutral kaon.  $C^2$  is 1 (1/2) for neutral (charged) kaon decays. Most early determinations of  $|V_{us}|$  were based solely on  $K \rightarrow \pi e \nu$  decays;  $K \rightarrow \pi \mu \nu$  decays were not used because of large uncertainties in  $I_K^\mu$ . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for  $S_{EW}$ ,  $\delta_K^\ell$ ,  $\delta_{SU2}$ , and  $f_+(0)$ .

Many measurements during the last decade have resulted in a significant shift in  $V_{us}$ . Most importantly, recent measurements of the  $K \rightarrow \pi e \nu$  branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [14] in the charged kaon system and then by KTeV [15,16] in the neutral kaon system; subsequent measurements were made by KLOE [17–20], NA48 [21–23], and ISTRA+ [24]. Current averages (*e.g.*, by the PDG [25] or Flavianet [26]) of the semileptonic branching fractions are based only on recent, high-statistics experiments

where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [27] and form factors [28–32], have resulted in improved precision for all of the experimental inputs to  $V_{us}$ . Precise measurements of form factors for  $K_{\mu 3}$  decay make it possible to use both semileptonic decay modes to extract  $V_{us}$ .

Following the analysis of Moulson [33] and the Flavianet group [26], one finds, after including the isospin violating up-down mass difference effect, the values of  $|V_{us}|f_+(0)$  in Table 1. The average of these measurements gives

$$f_+(0)|V_{us}| = 0.2165(4). \quad (10)$$

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [34], as well as  $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$ , the expectation for  $f_+(0)|V_{us}|$  assuming unitarity, based on  $|V_{ud}| = 0.97417 \pm 0.00021$ , and  $|V_{ub}| = (4.1 \pm 0.4) \times 10^{-3}$  [35].

Lattice calculations of  $f_+(0)$  have been carried out for 2, 2+1, and 2+1+1 quark flavors and range from about 0.96 to 0.97. Here, we use  $f_+(0) = 0.9677(37)$ , the 2015 preliminary (2+1)-flavor FLAG average reported by Rosner, Stone, and Van de Water in footnote 10 of their PDG review of pseudoscalar decay constants [35], in Eq. (10), and find

$$|V_{us}| = \lambda = 0.2237(4)_{\text{exp+RC}}(9)_{\text{lattice}} (K_{\ell 3} \text{ Decays}). \quad (11)$$

**Table 1:**  $|V_{us}|f_+(0)$  from  $K_{\ell 3}$ .

Decay Mode	$ V_{us} f_+(0)$
$K^\pm e 3$	$0.2172 \pm 0.0008$
$K^\pm \mu 3$	$0.2170 \pm 0.0011$
$K_L e 3$	$0.2163 \pm 0.0006$
$K_L \mu 3$	$0.2166 \pm 0.0006$
$K_S e 3$	$0.2155 \pm 0.0013$
Average	$0.2165 \pm 0.0004$

A value of  $V_{us}$  can also be obtained from a comparison of the radiative inclusive decay rates for  $K \rightarrow \mu\nu(\gamma)$  and  $\pi \rightarrow \mu\nu(\gamma)$  combined with a lattice gauge theory calculation of  $f_{K^+}/f_{\pi^+}$  via [42]

$$\frac{|V_{us}|f_{K^+}}{|V_{ud}|f_{\pi^+}} = 0.23871(20) \left[ \frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} \right]^{\frac{1}{2}} \quad (12)$$

with the small error coming from electroweak radiative corrections and isospin breaking effects. Employing

$$\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} = 1.3367(29), \quad (13)$$

which includes the recent update  $\Gamma(K \rightarrow \mu\nu(\gamma)) = 5.134(11) \times 10^7 \text{s}^{-1}$  [33,43] and [35]

$$f_{K^+}/f_{\pi^+} = 1.1928(26) \quad (14)$$

**Figure 1:** Comparison of determinations of  $|V_{us}|f_+(0)$  from this review (labeled 2016), from the PDG 2002, and with the prediction from unitarity using  $|V_{ud}|$  and the lattice calculation of  $f_+(0) = 0.9677(37)$  [35]. For  $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$ , the inner error bars are from the quoted uncertainty in  $f_+(0)$ ; the total uncertainties include the  $|V_{ud}|$  and  $|V_{ub}|$  errors.

along with the value of  $V_{ud}$  in Eq. (4) leads to

$$|V_{us}| = 0.22540(53)_{\text{exp}}(19)_{\text{RC}}(49)_{\text{lattice}} (K_{\mu 2} \text{ Decays}). \quad (15)$$

Together, a weighted average of the  $K_{\ell 3}$  (Eq. (11)) and  $K_{\mu 2}$  (Eq. (15)) results gives

$$|V_{us}| = 0.2248(6). \quad (16)$$

It should be mentioned that hyperon decay fits suggest [45]

$$|V_{us}| = 0.2250(27) \text{ (Hyperon Decays)} \quad (17)$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a representative effort [46] that incorporates SU(3) breaking found  $V_{us} = 0.226(5)$ . Strangeness changing tau decays, averaging both inclusive and exclusive measurements, currently give [47]

$$|V_{us}| = 0.2202(15) \text{ (Tau Decays)}, \quad (18)$$

which differs by about 3 sigma from the kaon determination discussed above, and would, if combined with  $V_{ud}$  from super-allowed beta decays, lead to a 2.6 sigma deviation from unitarity. This discrepancy results mainly from the inclusive tau decay results that rely on Finite Energy Sum Rule techniques and assumptions. Further investigation of that approach seems to be warranted.

Employing the values of  $V_{ud}$  and  $V_{us}$  from Eq. (4) and Eq. (16), respectively, leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9995(4)(3). \quad (19)$$

where the first error is the uncertainty from  $|V_{ud}|^2$  and the second error is the uncertainty from  $|V_{us}|^2$ .

## CKM Unitarity Constraints

The current good experimental agreement with unitarity,  $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9995(5)$ , provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on “New Physics” effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays,  $K$  decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant,  $G_\mu = 1.1663787(6) \times 10^{-5} \text{GeV}^{-2}$ .

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50] (beyond ordinary muon decay  $\mu^+ \rightarrow e^+ \nu_e \bar{\nu}_\mu$ ) and (2) new heavy quark mixing  $V_{uD}$  [51]. Other examples in the literature [52,53] include  $Z_\chi$  boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

## Exotic Muon Decays

If additional lepton flavor violating decays such as  $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$  (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays  $\Gamma(\text{exotic } \mu \text{ decays})$ , they should be subtracted before the extraction of  $G_\mu$  and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \geq 0.9987 \quad (20)$$

or

$$BR(\text{exotic } \mu \text{ decays}) \leq 0.0013. \quad (21)$$

This bound is a factor of 10 better than the direct experimental bound on  $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$ .

## New Heavy Quark Mixing

Heavy  $D$  quarks naturally occur in fourth quark generation models and some heavy quark “new physics” scenarios such as  $E_6$  grand unification. Their mixing with ordinary quarks gives rise to  $V_{uD}$  which is constrained by unitarity (one sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - |V_{uD}|^2 \geq 0.9987 \\ |V_{uD}| \leq 0.04. \quad (22)$$

A similar constraint applies to heavy neutrino mixing and the couplings  $V_{\mu N}$  and  $V_{eN}$ .

- <sup>1</sup> Result obtained using C13pi model of CABIBBO 05 to include  $\pi\pi$  rescattering effects. The systematic error includes an external error of  $1.06 \times 10^{-3}$  from the parametrization input of  $(a_0 - a_2) m_{\pi^+} = 0.268 \pm 0.017$  from BATLEY 06B.
- <sup>2</sup> LAI 01B and SOMALWAR 92 results do not include  $\pi\pi$  final state rescattering effects.
- <sup>3</sup> SOMALWAR 92 chose  $m_{\pi^+}$  as normalization to make it compatible with the Particle Data Group  $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$  definitions.

# Meson Particle Listings

$K_L^0$

## $K_L^0$ FORM FACTORS

For discussion, see note on form factors in the  $K^\pm$  section of the Particle Listings above.

In the form factor comments, the following symbols are used.

- $f_+$  and  $f_-$  are form factors for the vector matrix element.
- $f_S$  and  $f_T$  refer to the scalar and tensor terms.
- $f_0(t) = f_+(t) + f_-(t) t/(m_{K^0}^2 - m_{\pi^+}^2)$ .
- $t$  = momentum transfer to the  $\pi$ .
- $\lambda_+$  and  $\lambda_0$  are the linear expansion coefficients of  $f_+$  and  $f_0$ :
- $f_+(t) = f_+(0) (1 + \lambda_+ t/m_{\pi^+}^2)$
- For quadratic expansion
- $f_+(t) = f_+(0) (1 + \lambda'_+ t/m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2/m_{\pi^+}^4)$
- as used by KTeV. If there is a non-vanishing quadratic term, then  $\lambda_+$  represents an average slope, which is then different from  $\lambda'_+$ .
- NA48 ( $K_{e3}$ ) and ISTRA quadratic expansion coefficients are converted with  $\lambda'_+{}^{PDG} = \lambda_+{}^{NA48}$  and  $\lambda''_+{}^{PDG} = 2 \lambda'_+{}^{NA48}$
- $\lambda'_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA}$  and
- $\lambda''_+{}^{PDG} = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda'_+{}^{ISTRA}$
- ISTRA linear expansion coefficients are converted with  $\lambda_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA}$  and  $\lambda_0{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0{}^{ISTRA}$

The pole parametrization is

$$f_+(t) = f_+(0) \left( \frac{M_V^2}{M_V^2 - t} \right)$$

$$f_0(t) = f_0(0) \left( \frac{M_S^2}{M_S^2 - t} \right)$$

where  $M_V$  and  $M_S$  are the vector and scalar pole masses.

The dispersive parametrization is

$$f_+(t) = f_+(0) \exp \left[ \frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right];$$

$$f_0(t) = f_+(0) \exp \left[ \frac{t}{m_K^2 - m_\pi^2} (\ln[C] - G(t)) \right],$$

where  $\Lambda_+$  is the slope parameter and  $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$  is the logarithm of the scalar form factor at the Callan-Treiman point.

$H(t)$  and  $G(t)$  are dispersive integrals.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI =  $\pi$  spectrum analysis.

MU =  $\mu$  spectrum analysis.

POL =  $\mu$  polarization analysis.

BR =  $K_{\mu 3}^0/K_{e 3}^0$  branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

## $\lambda_+$ (LINEAR ENERGY DEPENDENCE OF $f_+$ IN $K_{e 3}^0$ DECAY)

For radiative correction of  $K_{e 3}^0$  DP, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review “ $K_{e 3}^\pm$  and  $K_{\mu 3}^0$  Form Factors” in the  $K^\pm$  Listings. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

## $\alpha_{K^*}^{\text{eff}}$ DECAY FORM FACTOR FOR $K_L \rightarrow e^+ e^- e^+ e^-$

$\alpha_{K^*}^{\text{eff}}$  is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two  $e^+ e^-$  pairs here compared with one in  $e^+ e^- \gamma$  decays, a factorized expression is used for the  $e^+ e^- e^+ e^-$  decay form factor.

<sup>1</sup> Using KTeV dataset collected in 1996, 1997, and 1999.<sup>2</sup> Superseded by ABOUZAID 08. **$CP$  VIOLATION IN  $K_L$  DECAYS**

Updated April 2016 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL), and T.G. Trippe (LBNL).

The symmetries  $C$  (particle-antiparticle interchange) and  $P$  (space inversion) hold for strong and electromagnetic interactions. After the discovery of large  $C$  and  $P$  violation in the weak interactions, it appeared that the product  $CP$  was a good symmetry. In 1964  $CP$  violation was observed in  $K^0$  decays at a level given by the parameter  $\epsilon \approx 2.3 \times 10^{-3}$ .

A unified treatment of  $CP$  violation in  $K$ ,  $D$ ,  $B$ , and  $B_s$  mesons is given in “ $CP$  Violation in Meson Decays” by D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine  $CP$  violation parameters is given in a book

by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of  $CP$  violation in  $K_L$  decays, and a description of our fits for the best values of these parameters.

**1. Formalism for  $CP$  violation in Kaon decay:**

$CP$  violation has been observed in the semi-leptonic decays  $K_L^0 \rightarrow \pi^\mp \ell^\pm \nu$ , and in the nonleptonic decay  $K_L^0 \rightarrow 2\pi$ . The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-) = |\eta_{+-}| e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0) = |\eta_{00}| e^{i\phi_{00}} \quad (1c)$$

$CP$  violation can occur either in the  $K^0 - \bar{K}^0$  mixing or in the decay amplitudes. Assuming  $CPT$  invariance, the mass eigenstates of the  $K^0 - \bar{K}^0$  system can be written

$$|K_S\rangle = p|K^0\rangle + q|\bar{K}^0\rangle, \quad |K_L\rangle = p|K^0\rangle - q|\bar{K}^0\rangle \quad (2)$$

If  $CP$  invariance held, we would have  $q = p$  so that  $K_S$  would be  $CP$ -even and  $K_L$   $CP$ -odd. (We define  $|\bar{K}^0\rangle$  as  $CP$   $|K^0\rangle$ ).  $CP$  violation in  $K^0 - \bar{K}^0$  mixing is then given by the parameter  $\tilde{\epsilon}$  where

$$\frac{p}{q} = \frac{(1 + \tilde{\epsilon})}{(1 - \tilde{\epsilon})} \quad (3)$$

$CP$  violation can also occur in the decay amplitudes

$$A(K^0 \rightarrow \pi\pi(I)) = A_I e^{i\delta_I}, \quad A(\bar{K}^0 \rightarrow \pi\pi(I)) = A_I^* e^{i\delta_I} \quad (4)$$

where  $I$  is the isospin of  $\pi\pi$ ,  $\delta_I$  is the final-state phase shift, and  $A_I$  would be real if  $CP$  invariance held. The  $CP$ -violating observables are usually expressed in terms of  $\epsilon$  and  $\epsilon'$  defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon' \quad (5a)$$

One can then show [2]

$$\epsilon = \tilde{\epsilon} + i (\text{Im } A_0 / \text{Re } A_0), \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\text{Re } A_2 / \text{Re } A_0) (\text{Im } A_2 / \text{Re } A_2 - \text{Im } A_0 / \text{Re } A_0), \quad (5c)$$

$$A_L = 2\text{Re } \epsilon / (1 + |\epsilon|^2) \approx 2\text{Re } \epsilon \quad (5d)$$

In Eqs. (5a), small corrections [3] of order  $\epsilon' \times \text{Re } (A_2/A_0)$  are neglected, and Eq. (5d) assumes the  $\Delta S = \Delta Q$  rule.

The quantities  $\text{Im } A_0$ ,  $\text{Im } A_2$ , and  $\text{Im } \tilde{\epsilon}$  depend on the choice of phase convention, since one can change the phases of  $K^0$  and  $\bar{K}^0$  by a transformation of the strange quark state  $|s\rangle \rightarrow |s\rangle e^{i\alpha}$ ; of course, observables are unchanged. It is possible by a choice of phase convention to set  $\text{Im } A_0$  or  $\text{Im } A_2$  or  $\text{Im } \tilde{\epsilon}$  to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice  $\text{Im } A_0 = 0$  is called the Wu-Yang phase convention [4], in which case  $\epsilon = \tilde{\epsilon}$ . The value of  $\epsilon'$  is independent of phase convention, and a nonzero value demonstrates  $CP$  violation in the decay amplitudes, referred to

# Meson Particle Listings

$K_L^0$

as direct  $CP$  violation. The possibility that direct  $CP$  violation is essentially zero, and that  $CP$  violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying  $CPT$  invariance and unitarity the phase of  $\epsilon$  is given approximately by

$$\phi_\epsilon \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.52 \pm 0.05^\circ, \quad (6a)$$

while Eq. (5c) gives the phase of  $\epsilon'$  to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ, \quad (6b)$$

where the numerical value is based on an analysis of  $\pi\pi$  scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct  $CP$  violation is very small in all  $K^0$  decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of  $\epsilon'$  and of  $\eta_{+-0}$  and  $\eta_{000}$ , the  $CP$ -violation parameters in the decays  $K_S \rightarrow \pi^+\pi^-\pi^0$  [7], and  $K_S \rightarrow \pi^0\pi^0\pi^0$  [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase  $\phi_{SW}$ . An important point for the analysis is that  $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$ . The consequence is that only two real quantities need be measured, the magnitude of  $\epsilon$  and the value of  $(\epsilon'/\epsilon)$ , including its sign. The measured quantity  $|\eta_{00}/\eta_{+-}|^2$  is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}(\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon, \quad (7a)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|). \quad (7b)$$

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}, \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.5)^\circ, \quad (8b)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.23) \times 10^{-3}, \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.5)^\circ, \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.34 \pm 0.32)^\circ, \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3}. \quad (8f)$$

Direct  $CP$  violation, as indicated by  $\epsilon'/\epsilon$ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of  $A_L$  agrees with Eq. (5d). The values of  $\phi_{+-}$  and  $\phi_{00} - \phi_{+-}$  are used to set limits on  $CPT$  violation [see “Tests of Conservation Laws”].

## 2. Fits for $K_L^0$ $CP$ -violation parameters:

In recent years,  $K_L^0$   $CP$ -violation experiments have improved our knowledge of  $CP$ -violation parameters, and their consistency with the expectations of  $CPT$  invariance and unitarity. To determine the best values of the  $CP$ -violation parameters in  $K_L^0 \rightarrow \pi^+\pi^-$  and  $\pi^0\pi^0$  decay, we make two types of fits, one for the phases  $\phi_{+-}$  and  $\phi_{00}$  jointly with  $\Delta m$  and  $\tau_S$ , and the other for the amplitudes  $|\eta_{+-}|$  and  $|\eta_{00}|$  jointly with the  $K_L^0 \rightarrow \pi\pi$  branching fractions.

**Figure 1:**  $\phi_{+-}$  vs  $\Delta m$  for experiments which do not assume  $CPT$  invariance.  $\Delta m$  measurements appear as vertical bands spanning  $\Delta m \pm 1\sigma$ , cut near the top and bottom to aid the eye. Most  $\phi_{+-}$  measurements appear as diagonal bands spanning  $\phi_{+-} \pm \sigma_\phi$ . Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows  $\phi_{SW}$ . The ellipse “a” shows the  $\chi^2 = 1$  contour of the fit result.

**Table 1:** References, Document ID’s, and sources corresponding to the letter labels in the figures. The data are given in the  $\phi_{+-}$  and  $\Delta m$  sections of the  $K_L$  Listings, and the  $\tau_S$  section of the  $K_S$  Listings.

**Fits to  $\phi_{+-}$ ,  $\phi_{00}$ ,  $\Delta\phi$ ,  $\Delta m$ , and  $\tau_S$  data:** These are joint fits to the data on  $\phi_{+-}$ ,  $\phi_{00}$ , the phase difference  $\Delta\phi = \phi_{00} - \phi_{+-}$ , the  $K_L^0 - K_S^0$  mass difference  $\Delta m$ , and the  $K_S^0$  mean life  $\tau_S$ , including the effects of correlations.

Measurements of  $\phi_{+-}$  and  $\phi_{00}$  are highly correlated with  $\Delta m$  and  $\tau_S$ . Some measurements of  $\tau_S$  are correlated with  $\Delta m$ . The correlations are given in the footnotes of the  $\phi_{+-}$  and  $\phi_{00}$  sections of the  $K_L^0$  Listings, and the  $\tau_S$  section of the  $K_S^0$  Listings.

In most cases, the correlations are quoted as 100%, *i.e.*, with the value and error of  $\phi_{+-}$  or  $\phi_{00}$  given at a fixed value of  $\Delta m$  and  $\tau_S$ , with additional terms specifying the dependence of the value on  $\Delta m$  and  $\tau_S$ . These cases lead to diagonal bands in Figs. 1 and 2. The KTeV experiment [10] quotes its results as values of  $\Delta m$ ,  $\tau_S$ ,  $\phi_\epsilon$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  with correlations, leading to the ellipses labeled “b.” The correlations for the KTeV measurements are given in the  $\text{Im}(\epsilon'/\epsilon)$  section of the  $K_L^0$  Listings. For small  $|\epsilon'/\epsilon|$ ,  $\phi_{+-} \approx \phi_\epsilon + \text{Im}(\epsilon'/\epsilon)$ .

The data on  $\tau_S$ ,  $\Delta m$ , and  $\phi_{+-}$  shown in Figs. 1 and 2 are combined with data on  $\phi_{00}$  and  $\phi_{00} - \phi_{+-}$  in two fits, one without assuming *CPT*, and the other with this assumption. The results without assuming *CPT* are shown as ellipses labeled “a.” These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{\text{SW}} = \tan^{-1} \left( \frac{2\Delta m}{\Delta \Gamma} \right) = \tan^{-1} \left( \frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)} \right). \quad (9)$$

In Figs. 1 and 2,  $\phi_{\text{SW}}$  is shown as narrow bands labeled “j.”

Table 2 column 2, “Fit w/o *CPT*,” gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled “a” in Fig. 1 and Fig. 2 are the  $\chi^2 = 1$  contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the  $\phi_{\text{SW}}$  bands.

If *CPT* invariance and unitarity are assumed, then by Eq. (6a), the phase of  $\epsilon$  is constrained to be approximately equal to

$$\begin{aligned} \phi_{\text{SW}} &= (43.50258 \pm 0.00021)^\circ + 54.1(\Delta m - 0.5289)^\circ \\ &\quad + 32.0(\tau_S - 0.89564) \end{aligned} \quad (10)$$

where we have linearized the  $\Delta m$  and  $\tau_S$  dependence of Eq. (9). The error  $\pm 0.00021$  is due to the uncertainty in  $\tau_L$ . Here  $\Delta m$  has units  $10^{10} \hbar s^{-1}$  and  $\tau_S$  has units  $10^{-10} s$ .

If in addition we use the observation that  $\text{Re}(\epsilon'/\epsilon) \ll 1$  and  $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$ , as well as the numerical value of  $\phi_{\epsilon'}$  given in Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3 \text{Im} \left( \frac{\epsilon'}{\epsilon} \right) \\ &\approx -3 \text{Re} \left( \frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx 0.006^\circ \pm 0.008^\circ, \end{aligned} \quad (11)$$

so that  $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{\text{SW}}$ .

**Figure 2:**  $\phi_{+-}$  vs  $\tau_S$ .  $\tau_S$  measurements appear as vertical bands spanning  $\tau_S \pm 1\sigma$ , some of which are cut near the top and bottom to aid the eye. Most  $\phi_{+-}$  measurements appear as diagonal or horizontal bands spanning  $\phi_{+-} \pm \sigma_\phi$ . Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows  $\phi_{\text{SW}}$ . The ellipse “a” shows the fit result’s  $\chi^2 = 1$  contour.

**Table 2:** Fit results for  $\phi_{+-}$ ,  $\Delta m$ ,  $\tau_S$ ,  $\phi_{00}$ ,  $\Delta\phi = \phi_{00} - \phi_{+-}$ , and  $\phi_\epsilon$  without and with the *CPT* assumption.

In the fit assuming *CPT*, we constrain  $\phi_\epsilon = \phi_{\text{SW}}$  using the linear expression in Eq. (10), and constrain  $\phi_{00} - \phi_{+-}$  using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 16. Some additional data for which the authors assumed *CPT* are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

**Figure 3:** Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, “Fit w/*CPT*,” and the correlation matrix is shown in Table 4. The  $\Delta m$  precision is improved by the *CPT* assumption.

**Table 3:** Correlation matrix for the results of the fit without the *CPT* assumption

#### Fits for $\epsilon'/\epsilon$ , $|\eta_{+-}|$ , $|\eta_{00}|$ , and $B(K_L \rightarrow \pi\pi)$

We list measurements of  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\epsilon'/\epsilon$ . Independent information on  $|\eta_{+-}|$  and  $|\eta_{00}|$  can be obtained from measurements of the  $K_L^0$  and  $K_S^0$  lifetimes ( $\tau_L$ ,  $\tau_S$ ), and branching ratios ( $B$ ) to  $\pi\pi$ , using the relations

$$|\eta_{+-}| = \left[ \frac{B(K_L^0 \rightarrow \pi^+\pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^+\pi^-)} \right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[ \frac{B(K_L^0 \rightarrow \pi^0\pi^0)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^0\pi^0)} \right]^{1/2}. \quad (12b)$$

For historical reasons, the branching ratio fits and the *CP*-violation fits are done separately, but we want to include the influence of  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\epsilon'/\epsilon$  measurements on  $B(K_L^0 \rightarrow \pi^+\pi^-)$  and  $B(K_L^0 \rightarrow \pi^0\pi^0)$  and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the  $K_L^0$  branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{+-}/\eta_{00}|$ , and  $\epsilon'/\epsilon$  measurements. The results from fit 1, along with the  $K_S^0$  values from this edition, are used to compute values of  $|\eta_{+-}|$  and  $|\eta_{00}|$ , which are included as measurements in the  $|\eta_{00}|$  and  $|\eta_{+-}|$  sections with a document ID of BRFIT 16. Thus, the fit values of  $|\eta_{+-}|$  and  $|\eta_{00}|$  given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct  $|\eta|$  measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 16 values) are used along with the  $K_L^0$  and  $K_S^0$  mean lives and the  $K_S^0 \rightarrow \pi\pi$  branching fractions to compute the  $K_L^0$  branching ratio  $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$ . This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 16. Thus, the  $K_L^0$  branching ratio fit values in this edition include the results of the direct measurement of  $|\eta_{00}/\eta_{+-}|$  and  $\epsilon'/\epsilon$ . Most individual measurements of  $|\eta_{+-}|$  and  $|\eta_{00}|$  enter our fits directly via the corresponding measurements of  $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(\text{total})$  and  $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(\text{total})$ , and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

### CP-VIOLATION PARAMETERS IN $K_L^0$ DECAYS

#### CHARGE ASYMMETRY IN $K_S^0$ DECAYS

Such asymmetry violates *CP*. It is related to  $\text{Re}(\epsilon)$ .

#### $A_L$ = weighted average of $A_L(\mu)$ and $A_L(e)$

In previous editions and in the literature the symbol used for this asymmetry was  $\delta_L^{\pm}$  or  $\delta$ . We use  $A_L$  for consistency with  $B^0$  asymmetry notation and with recent  $K_S^0$  notation.

### PARAMETERS FOR $K_L^0 \rightarrow 2\pi$ DECAY

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0)$$

The fitted values of  $|\eta_{+-}|$  and  $|\eta_{00}|$  given below are the results of a fit to  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\text{Re}(\epsilon'/\epsilon)$ . Independent information on  $|\eta_{+-}|$  and  $|\eta_{00}|$  can be obtained from the fitted values of the  $K_L^0 \rightarrow \pi\pi$  and  $K_S^0 \rightarrow \pi\pi$  branching ratios and the  $K_L^0$  and  $K_S^0$  lifetimes. This information is included as data in the  $|\eta_{+-}|$  and  $|\eta_{00}|$  sections with a Document ID "BRFIT." See the note "CP violation in  $K_L^0$  decays" above for details.

$$|\eta_{00}| = |A(K_L^0 \rightarrow 2\pi^0) / A(K_S^0 \rightarrow 2\pi^0)|$$

2.95 ±0.63	<sup>2</sup> CHOLLET	70	OSPK Cu reg., $4\gamma$ 's

<sup>1</sup> Error is statistical only.

<sup>2</sup> CHOLLET 70 gives  $|\eta_{00}| = (1.23 \pm 0.24) \times (\text{regeneration amplitude, 2 GeV/c Cu})/10000\text{mb}$ . WOLFF 71 gives  $|\eta_{00}| = (1.13 \pm 0.12) \times (\text{regeneration amplitude, 2 GeV/c Cu})/10000\text{mb}$ . We compute both  $|\eta_{00}|$  values for (regeneration amplitude, 2 GeV/c Cu) =  $24 \pm 2\text{mb}$ . This regeneration amplitude results from averaging over FAISSNER 69, extrapolated using optical-model calculations of Bohm *et al.*, Physics Letters **27B** 594 (1968) and the data of BALATS 71. (From H. Faissner, private communication).

$$|\eta_{+-}| = |A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)|$$

<sup>1</sup> Value obtained from the NA48 measurements of  $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)/\Gamma(K_L^0 \rightarrow \pi e \nu_e)$  and  $\tau_{K_S^0}$  and KLOE measurements of  $B(K_S^0 \rightarrow \pi^+ \pi^-)$  and  $\tau_{K_L^0}$ .  $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)$  is defined to include the inner bremsstrahlung component  $\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \gamma(\text{IB}))$  but

exclude the direct emission component  $B(K_S^0 \rightarrow \pi^+ \pi^- (\text{DE}))$ . Their  $|\eta_{+-}|$  value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

<sup>2</sup> AMBROSINO 06F uses KLOE branching ratios and  $\tau_L$  together with  $\tau_S$  from PDG 04. Their  $|\eta_{+-}|$  value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

<sup>3</sup> ALEXOPOULOS 04  $|\eta_{+-}|$  uses their  $K_L^0 \rightarrow \pi\pi$  branching fractions,  $\tau_S = (0.8963 \pm 0.0005) \times 10^{-10}\text{s}$  from the average of KTeV and NA48  $\tau_S$  measurements, and assumes that  $\Gamma(K_L^0 \rightarrow \pi e \nu_e) = \Gamma(K_L^0 \rightarrow \pi \ell \nu_\ell)$  giving  $B(K_S^0 \rightarrow \pi \ell \nu_\ell) = 0.118\%$ . Their  $\eta_{+-}$  is not directly used in our fit, but enters our fit via their branching ratio measurements.

<sup>4</sup> APOSTOLAKIS 99C report  $(2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934]) \times 10^{-3}$ . We evaluate for our 2006 best value  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}\text{s}$ .

<sup>5</sup> ADLER 95B report  $(2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926]) \times 10^{-3}$ . We evaluate for our 1996 best values  $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10}\text{fs}^{-1}$  and  $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}\text{s}$ . Superseded by APOSTOLAKIS 99C.

$$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$$

This expression is a very good approximation, good to about one part in  $10^{-4}$  because of the small measured value of  $\phi_{00} - \phi_{+-}$  and small theoretical ambiguities.

<sup>1</sup> The two ABOUZAID 11 values use the same data. The fits are performed with and without *CPT* invariance requirement.

<sup>2</sup> These values are derived from  $|\eta_{00}/\eta_{+-}|$  measurements. They enter the average in this section but enter the fit via the  $|\eta_{00}/\eta_{+-}|$  only.

<sup>3</sup> This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

<sup>4</sup> We use ABOUZAID 11  $\text{Re}(\epsilon'/\epsilon)$  value with *CPT* assumption in our fits for  $|\eta_{+-}|$ ,  $|\eta_{00}|$ , and  $\text{Re}(\epsilon'/\epsilon)$ .

<sup>5</sup> These values are derived from  $|\eta_{00}/\eta_{+-}|$  measurements.

WEIGHTED AVERAGE  
1.68 ± 0.20 (Error scaled by 1.4)

## $\phi_{+-}$ , PHASE of $\eta_{+-}$

The dependence of the phase on  $\Delta m$  and  $\tau_S$  is given for each experiment in the comments below, where  $\Delta m$  is the  $K_L^0 - K_S^0$  mass difference in units  $10^{10} \text{ h s}^{-1}$  and  $\tau_S$  is the  $K_S$  mean life in units  $10^{-10} \text{ s}$ . We also give the regeneration phase  $\phi_f$  in the comments below.

OUR FIT is described in the note on “*CP* violation in  $K_L$  decays” in the  $K_L^0$  Particle Listings. Most experiments in this section are included in both the “Not Assuming *CPT*” and “Assuming *CPT*” fits. In the latter fit, they have little direct influence on  $\phi_{+-}$  because their errors are large compared to that assuming *CPT*, but they influence  $\Delta m$  and  $\tau_S$  through their dependencies on these parameters, which are given in the footnotes.

44.3 ± 2.8 ± 0.2		<sup>14</sup> CARITHERS 75	SPEC	C regenerator

<sup>1</sup> APOSTOLAKIS 99c measures  $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300 [\Delta m - 0.5301] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>2</sup> SCHWINGENHEUER 95 measures  $\phi_{+-} = (43.53 \pm 0.76) + 173 [\Delta m - 0.5282] - 275 [\tau_S - 0.8926] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>3</sup> These experiments measure  $\phi_{+-} - \phi_f$  and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of  $0.35^\circ$  [0.5°] for uncertainties in their modeling of the regeneration amplitude.

<sup>4</sup> GIBBONS 93 measures  $\phi_{+-} = (42.21 \pm 0.9) + 189 [\Delta m - 0.5257] - 460 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports  $\phi_{+-} = (42.2 \pm 1.4)^\circ$ . They measure  $\phi_{+-} - \phi_f$  and calculate the regeneration phase  $\phi_f$  from the power law momentum dependence of the regeneration amplitude using analyticity. An error of  $0.6^\circ$  is included for possible uncertainties in the regeneration phase.

<sup>5</sup> CAROSI 90 measures  $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579 [\Delta m - 0.5351] + 303 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>6</sup> GEWENIGER 74B measures  $\phi_{+-} = (49.4 \pm 1.0) + 565 [\Delta m - 0.540] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>7</sup> Not independent of other phase parameters reported in ABOUZAID 11.

<sup>8</sup> ALAVI-HARATI 03  $\phi_{+-}$  is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  and  $\tau_{K_S}$  measurements in the  $K_L^0$  and  $K_S^0$  sections respectively. The correlation coefficients are  $\rho(\phi_{+-}, \Delta m) = +0.955$ ,  $\rho(\phi_{+-}, \tau_S) = -0.871$ , and  $\rho(\tau_S, \Delta m) = -0.840$ . *CPT* is not assumed. Uses scintillator Pb regenerator. Superseded by ABOUZAID 11.

<sup>9</sup> ADLER 96C measures  $\phi_{+-} = (43.82 \pm 0.41) + 339 [\Delta m - 0.5307] - 252 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>10</sup> ADLER 96C is the result of a fit which includes nearly the same data as entered into the “OUR FIT” value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).

<sup>11</sup> ADLER 95B measures  $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316 [\Delta m - 0.5274] + 30 [\tau_S - 0.8926] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>12</sup> ADLER 92B quote separately two systematic errors:  $\pm 0.4$  from their experiment and  $\pm 1.0$  degrees due to the uncertainty in the value of  $\Delta m$ .

<sup>13</sup> KARLSSON 90 systematic error does not include regeneration phase uncertainty.

<sup>14</sup> CARITHERS 75 measures  $\phi_{+-} = (45.5 \pm 2.8) + 224 [\Delta m - 0.5348] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.  $\phi_f = -40.9 \pm 2.6^\circ$ .

## $\phi_{00}$ , PHASE of $\eta_{00}$

See comment in  $\phi_{+-}$  header above for treatment of  $\Delta m$  and  $\tau_S$  dependence, as well as for the inclusion of data in both the “Assuming *CPT*” and “Not Assuming *CPT*” fits.

OUR FIT is described in the note on “*CP* violation in  $K_L$  decays” in the  $K_L^0$  Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
<b>43.52 ± 0.05 OUR FIT</b>			Error includes scale factor of 1.3. Assuming <i>CPT</i>
<b>43.7 ± 0.6 OUR FIT</b>			Error includes scale factor of 1.2. Not assuming <i>CPT</i>
44.5 ± 2.3 ± 0.5	<sup>1</sup> CAROSI 90	NA31	
• • • We do not use the following data for averages, fits, limits, etc. • • •			
44.06 ± 0.68	<sup>2</sup> ABOUZAID 11	KTEV	Not assuming <i>CPT</i>
41.7 ± 5.9 ± 0.2	<sup>3</sup> ANGELOPOULOS... 98	CPLR	
50.8 ± 7.1 ± 1.7	<sup>4</sup> ADLER 96B	CPLR	Sup. by ANGELOPOULOS 98
47.4 ± 1.4 ± 0.9	<sup>5</sup> KARLSSON 90	E731	

<sup>1</sup> CAROSI 90 measures  $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579 [\Delta m - 0.5351] + 252 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>2</sup> Not independent of other phase parameters reported in ABOUZAID 11.

<sup>3</sup> ANGELOPOULOS 98 measures  $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240 [\Delta m - 0.5307] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values. The  $\tau_S$  dependence is negligible.

<sup>4</sup> ADLER 96B identified initial neutral kaon individually as being a  $K^0$  or a  $\bar{K}^0$ . The systematic uncertainty is  $\pm 1.5^\circ$  combined in quadrature with  $\pm 0.8^\circ$  due to  $\Delta m$ .

<sup>5</sup> KARLSSON 90 systematic error does not include regeneration phase uncertainty.

## $\phi_e = (2\phi_{+-} + \phi_{00})/3$

This expression is a very good approximation, good to about  $10^{-3}$  degrees because of the small measured values of  $\phi_{00} - \phi_{+-}$  and  $\text{Re } \epsilon'/\epsilon$ , and small theoretical ambiguities.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
<b>43.52 ± 0.05 OUR FIT</b>			Error includes scale factor of 1.2. Assuming <i>CPT</i>
<b>43.5 ± 0.5 OUR FIT</b>			Error includes scale factor of 1.3. Not assuming <i>CPT</i>
43.5164 ± 0.0002 ± 0.0518	<sup>1</sup> SUPERWEAK 16		Assuming <i>CPT</i>
43.86 ± 0.63	<sup>2</sup> ABOUZAID 11	KTEV	Not assuming <i>CPT</i>

<sup>1</sup> SUPERWEAK 16 is a fake measurement used to impose the *CPT* or Superweak constraint  $\phi_{+-} = \phi_{SW} = \tan^{-1}[2 \frac{\Delta m}{h} (\frac{\tau_S \tau_L}{\tau_L - \tau_S})]$ . This “measurement” is linearized using values near the PDG 04 edition values of  $\Delta m$ ,  $\tau_S$  and  $\tau_L$ , and then adjusted to our current values as described in the following “measurement”. SUPERWEAK 16 measures  $\phi_e = (43.50258 \pm 0.00021) + 54.1 [\Delta m - 0.5289] + 32.0 [\tau_S - 0.89564] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>2</sup> ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. See  $\text{Im}(\epsilon'/\epsilon)$  section for correlation information.

See key on page 601

# Meson Particle Listings

$K_L^0$

$$\text{Im}(\epsilon'/\epsilon) = -(\phi_{00} - \phi_{+-})/3$$

For small  $|\epsilon'/\epsilon|$ ,  $\text{Im}(\epsilon'/\epsilon)$  is related to the phases of  $\eta_{00}$  and  $\eta_{+-}$  by the above expression.

<sup>1</sup> ABOUZAIID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. The fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_\epsilon$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  as free parameters. The reported value of  $\text{Im}(\epsilon'/\epsilon) = (-17.20 \pm 20.20) \times 10^{-4}$  rad. The correlation coefficients are  $\rho(\phi_\epsilon, \Delta m) = 0.828$ ,  $\rho(\phi_\epsilon, \tau_S) = -0.765$ ,  $\rho(\Delta m, \tau_S) = -0.858$ ,  $\rho(\text{Im}(\epsilon'/\epsilon), \phi_\epsilon) = -0.041$ ,  $\rho(\text{Im}(\epsilon'/\epsilon), \Delta m) = 0.026$ ,  $\rho(\text{Im}(\epsilon'/\epsilon), \tau_S) = -0.010$ .

## DECAY-PLANE ASYMMETRY IN $\pi^+\pi^-e^+e^-$ DECAYS

This is the *CP*-violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where  $\phi$  is the angle between the  $e^+e^-$  and  $\pi^+\pi^-$  planes in the  $K_L^0$  rest frame.

## CP ASYMMETRY $A$ in $K_L^0 \rightarrow \pi^+\pi^-e^+e^-$

## CPT-INVARIANCE TESTS IN $K_L^0$ DECAYS

### PHASE DIFFERENCE $\phi_{00} - \phi_{+-}$

Test of *CPT*.

OUR FIT is described in the note on "*CP* violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
<b>0.006 ± 0.014 OUR FIT</b>			Error includes scale factor of 1.7. Assuming <i>CPT</i>
<b>0.34 ± 0.32 OUR FIT</b>			Not assuming <i>CPT</i>
0.006 ± 0.008	<sup>1</sup> SUPERWEAK	16	Assuming <i>CPT</i>
-0.30 ± 0.88	<sup>2</sup> SCHWINGEN...	95	Combined E731, E773
• • • We do not use the following data for averages, fits, limits, etc. • • •			
0.30 ± 0.35	<sup>3</sup> ABOUZAIID	11	KTEV Not assuming <i>CPT</i>
0.39 ± 0.22 ± 0.45	<sup>4</sup> ALAVI-HARATI03		KTEV
0.62 ± 0.71 ± 0.75	SCHWINGEN...	95	E773
-1.6 ± 1.2	<sup>5</sup> GIBBONS	93	E731
0.2 ± 2.6 ± 1.2	<sup>6</sup> CAROSI	90	NA31
-0.3 ± 2.4 ± 1.2	KARLSSON	90	E731

<sup>1</sup> SUPERWEAK 16 is a fake experiment to constrain  $\phi_{00} - \phi_{+-}$  to a small value as described in the note "*CP* violation in  $K_L$  decays."

<sup>2</sup> This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

<sup>3</sup> Not independent of other phase parameters reported in ABOUZAIID 11.

<sup>4</sup> ALAVI-HARATI 03 fit  $\text{Re}(\epsilon'/\epsilon)$ ,  $\text{Im}(\epsilon'/\epsilon)$ ,  $\Delta m$ ,  $\tau_S$ , and  $\phi_{+-}$  simultaneously, not assuming *CPT*. Phase difference is obtained from  $\phi_{00} - \phi_{+-} \approx -3\text{Im}(\epsilon'/\epsilon)$  for small  $|\epsilon'/\epsilon|$ . Superseded by ABOUZAIID 11.

<sup>5</sup> GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the  $K_S^0$  mean life) and mass difference (see the section on  $m_{K_0^0} - m_{K_S^0}$ ).

<sup>6</sup> CAROSI 90 is excluded from the fit because it it is not independent of  $\phi_{+-}$  and  $\phi_{00}$  values.

### PHASE DIFFERENCE $\phi_{+-} - \phi_{SW}$

Test of *CPT*. The Superweak phase  $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$  where  $\Delta m = m_{K_L^0} - m_{K_S^0}$  and  $\Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L\tau_S)$ .

VALUE (°)	DOCUMENT ID	TECN
<b>0.61 ± 0.62 ± 1.01</b>	<sup>1</sup> ALAVI-HARATI03	KTEV

<sup>1</sup> ALAVI-HARATI 03 fit is the same as their  $\phi_{+-}$ ,  $\tau_{K_S}$ ,  $\Delta m$  fit, except that the parameter  $\phi_{+-} - \phi_{SW}$  is used in place of  $\phi$ .

$$\text{Re}(\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}) - \frac{A_f}{A_\pi}$$

Test of *CPT*

VALUE (units $10^{-6}$ )	DOCUMENT ID	TECN	COMMENT
<b>-3 ± 35</b>	<sup>1</sup> ALAVI-HARATI02	E799	Uses $A_L$ from $K_{e3}$ decays

<sup>1</sup> ALAVI-HARATI 02 uses PDG 00 values of  $\eta_{+-}$  and  $\eta_{00}$ .

Meson Particle Listings

$K_L^0$

$\Delta S = \Delta Q$  IN  $K^0$  DECAYS

The relative amount of  $\Delta S \neq \Delta Q$  component present is measured by the parameter  $x$ , defined as

$$x = A(\overline{K}^0 \rightarrow \pi^- \ell^+ \nu) / A(K^0 \rightarrow \pi^- \ell^+ \nu) .$$

We list  $\text{Re}\{x\}$  and  $\text{Im}\{x\}$  for  $K_{e3}$  and  $K_{\mu 3}$  combined.

$$x = A(\overline{K}^0 \rightarrow \pi^- \ell^+ \nu) / A(K^0 \rightarrow \pi^- \ell^+ \nu) = A(\Delta S = -\Delta Q) / A(\Delta S = \Delta Q)$$

722 ± 60			<sup>16</sup> BUGG	03 RVUE $11 K^- \rho \rightarrow K^- \pi^+ n$
905 ± 65 ± 30			<sup>17</sup> ISHIDA	97B RVUE $11 K^- \rho \rightarrow K^- \pi^+ n$

<sup>1</sup> The Breit-Wigner parameters from a fit with seven intermediate resonances. The S-matrix pole position is  $(764 \pm 63^{+71}_{-54}) - i(306 \pm 149^{+143}_{-85})$  MeV.

<sup>2</sup> From a fit including ten additional resonances and energy-independent Breit-Wigner width.

<sup>3</sup> S-matrix pole.

<sup>4</sup> S-matrix pole. GUO 06 in a chiral unitary approach report a mass of  $757 \pm 33$  MeV and a width of  $558 \pm 82$  MeV.

<sup>5</sup> A fit in the  $K_0^*(800) + K^*(892) + K^*(1410)$  model with mass and width of the  $K_0^*(800)$  from ABLIKIM 06c well describes the left slope of the  $K_S^0 \pi^-$  invariant mass spectrum in  $\tau^- \rightarrow K_S^0 \pi^- \nu_\tau$  decay studied by EPIFANOV 07.

<sup>6</sup> S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.

<sup>7</sup> Not seen by KOPP 01 using 7070 events of  $D^0 \rightarrow K^- \pi^+ \pi^0$ . LINK 02e and LINK 05i show clear evidence for a constant non-resonant scalar amplitude rather than  $K_0^*(800)$  in their high statistics analysis of  $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$ .

<sup>8</sup> AUBERT 07t does not find evidence for the charged  $K_0^*(800)$  using 11k events of  $D^0 \rightarrow K^- K^+ \pi^0$ .

<sup>9</sup> S-Matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.

<sup>10</sup> T-matrix pole.

<sup>11</sup> A Breit-Wigner mass and width.

<sup>12</sup> S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the  $\kappa$  an s-dependent width with an Adler zero near threshold.

<sup>13</sup> Breit-Wigner parameters. A significant S-wave can be also modeled as a non-resonant contribution.

<sup>14</sup> Using ASTON 88.

<sup>15</sup> T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.

<sup>16</sup> T-matrix pole. Reanalysis of ASTON 88 data.

<sup>17</sup> Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

WEIGHTED AVERAGE  
895.81 ± 0.19 (Error scaled by 1.4)

- Inclusive reaction. Complicated background and phase-space effects.
- Mass errors enlarged by us to  $\Gamma/\sqrt{N}$ . See note.
- Number of events in peak reevaluated by us.
- K-matrix pole.
- From a partial wave amplitude analysis.
- From a fit in the  $K_0^*(800) + K^*(892) + K^*(1410)$  model.
- From the pole position of the  $K\pi$  vector form factor using EPIFANOV 07 and constraints from  $K_{J3}$  decays in ANTONELLI 10.
- Systematic uncertainties not estimated.
- From the pole position of the  $K\pi$  vector form factor in the complex s-plane and using EPIFANOV 07 data.
- Reanalysis of EPIFANOV 07 using resonance chiral theory.
- Calculated by us from the shift by  $4.7 \pm 0.9$  MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.
- With mass and width of the  $K^*(1410)$  fixed at 1412 MeV and 227 MeV, respectively.
- Taking into account the  $K^*(892)^0$ , S-wave and P-wave ( $K^*(1410)^0$ ).
- From the isobar model with a complex pole for the  $\kappa$ .
- Fit to  $K\pi$  mass spectrum includes a non-resonant scalar component.
- From pole extrapolation.
- This value comes from a fit with  $\chi^2$  of 178/117.

 $K^*(892)$  MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple “realistic” tests for the minimum errors on the determination of a mass and width from a sample of  $N$  events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4 \frac{\Gamma}{\sqrt{N}}. \quad (1)$$

# Meson Particle Listings

## $K^*(892)$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

$K^*(892), K_1(1270)$

CONSTRAINED FIT INFORMATION		
An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.		
The following <i>off-diagonal</i> array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters $p_i$ , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the $x_i$ whose labels appear in this array to sum to one.		
$x_5$	$\begin{array}{ c } \hline -100 \\ \hline \end{array}$

- Using both  $\eta \rightarrow \gamma\gamma$  and  $\eta \rightarrow \pi^+ \pi^- \pi^0$ . From a likelihood scan in the presence of several interfering scalar-meson resonances with fixed width  $\Gamma(K_0^*(1430)) = 210$  MeV.
- S-Matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an  $s$ -dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.
- From the isobar model with a complex pole for the  $\kappa$ .
- From a non-parametric analysis.
- A Breit-Wigner mass and width.
- S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the  $\kappa$  with an  $s$ -dependent width and an Adler zero near threshold.
- S-matrix pole. Using ASTON 88 and assuming  $K_0^*(800)$ ,  $K_0^*(1950)$ .
- Using ASTON 88 and assuming  $K_0^*(800)$ .
- T-matrix pole. Reanalysis of ASTON 88 data.
- Breit-Wigner fit. Using ASTON 88.
- Assuming a low-mass scalar  $K\pi$  resonance,  $\kappa(800)$ .
- T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.
- $J^P$  not determined, could be  $K_2^*(1430)$ .
- T-matrix pole.
- Uses a model for the background, without this background they get a mass 1340 MeV, where the phase shift passes 90°.
- Mass defined by pole position. From elastic  $K\pi$  partial-wave analysis.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 20.2$  for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

14 From phase shift analysis.  
15 ASTON 88b quote < 0.0092 at CL=95%. We convert this to a central value and 1 sigma error in order to be able to use it in our constrained fit.  
16 Restated by us.  
17 Assuming  $\pi\pi$  system has isospin 1, which is supported by the data.

$I^G(J^{PC}) = ?^?(?^{??})$

OMITTED FROM SUMMARY TABLE

Narrow peak observed in several ( $\Lambda \bar{p}$  + pions) and ( $\bar{\Lambda} p$  + pions) states in  $\Sigma^-$  Be reactions by BOURQUIN 86 and in  $n p$  and  $n A$  reactions by ALEEV 93. Not seen by BOEHNLEIN 91. If due to strong decays, this state has exotic quantum numbers ( $B=0, Q=+1, S=-1$  for  $\Lambda \bar{p} \pi^+ \pi^+$  and  $I \geq 3/2$  for  $\Lambda \bar{p} \pi^-$ ). Needs confirmation.

$D^+$  DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Inclusive modes</b>		
$\Gamma_1$ $e^+$ semileptonic	(16.07 ± 0.30) %	
$\Gamma_2$ $\mu^+$ anything	(17.6 ± 3.2) %	
$\Gamma_3$ $K^-$ anything	(25.7 ± 1.4) %	
$\Gamma_4$ $\bar{K}^0$ anything + $K^0$ anything	(61 ± 5) %	
$\Gamma_5$ $K^+$ anything	( 5.9 ± 0.8) %	
$\Gamma_6$ $K^*(892)^-$ anything	( 6 ± 5) %	
$\Gamma_7$ $\bar{K}^*(892)^0$ anything	(23 ± 5) %

$\Gamma_{141}$	Unaccounted decay modes		$(50.2 \pm 0.9) \%$	S=1.1
----------------	-------------------------	--	---------------------	-------

[a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[b] These subfractions of the  $K^- 2\pi^+$  mode are uncertain: see the Particle Listings.

[c] Submodes of the  $D^+ \rightarrow K^- 2\pi^+ \pi^0$  and  $K_S^0 2\pi^+ \pi^-$  modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

[d] The unseen decay modes of the resonances are included.

[e] This is *not* a test for the  $\Delta C=1$  weak neutral current, but leads to the  $\pi^+ \ell^+ \ell^-$  final state.

[f] This mode is not a useful test for a  $\Delta C=1$  weak neutral current because both quarks must change flavor in this decay.

## CONSTRAINED FIT INFORMATION

An overall fit to 23 branching ratios uses 31 measurements and one constraint to determine 15 parameters. The overall fit has a  $\chi^2 = 33.4$  for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

<sup>1</sup> ABLIKIM 14F obtain  $|V_{cd}| \cdot f_{D^+} = (45.75 \pm 1.20 \pm 0.39)$  MeV, and using  $|V_{cd}| = 0.22520 \pm 0.00065$  gets  $f_{D^+} = (203.2 \pm 5.3 \pm 1.8)$  MeV.

<sup>2</sup> EISENSTEIN 08, using the  $D^+$  lifetime and assuming  $|V_{cd}| = |V_{us}|$ , gets  $f_{D^+} = (205.8 \pm 8.5 \pm 2.5)$  MeV from this measurement.

<sup>3</sup> ABLIKIM 05D finds a background-subtracted  $2.67 \pm 1.74$   $D^+ \rightarrow \mu^+ \nu_\mu$  events, and from this obtains  $f_{D^+} = 371 \pm^{+129}_{-119} \pm 25$  MeV.

<sup>4</sup> ARTUSO 05A obtains  $f_{D^+} = 222.6 \pm 16.7 \pm^{+2.8}_{-3.4}$  MeV from this measurement.

<sup>5</sup> BONVICINI 04A finds eight events with an estimated background of one, and from the branching fraction obtains  $f_{D^+} = 202 \pm 41 \pm 17$  MeV.

<sup>6</sup> BAI 98B obtains  $f_{D^+} = (300 \pm^{+180}_{-150} \pm^{+80}_{-40})$  MeV from this measurement.

<sup>1</sup> DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.  
<sup>2</sup> BALEST 94 measures the ratio of  $D^+ \rightarrow K^- \pi^+ \pi^+$  and  $D^0 \rightarrow K^- \pi^+$  branching fractions to be  $2.35 \pm 0.16 \pm 0.16$  and uses their absolute measurement of the  $D^0 \rightarrow K^- \pi^+$  fraction (AKERIB 93).  
<sup>3</sup> BARLAG 92c computes the branching fraction by topological normalization.  
<sup>4</sup> SCHINDLER 81 (MARK-2) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.38 \pm 0.05$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 4.2 \pm 0.6 \pm 0.3$  nb.

## REVIEW OF MULTIBODY CHARM ANALYSES

Revised 2015 by D. M. Asner (Pacific Northwest National Laboratory) and J. Rademacker (University of Bristol)

**Kinematics & Models** The differential decay rate to a point  $s = (s_1, \dots, s_n)$  in  $n$  dimensional phase space can be expressed as

$$d\Gamma = |\mathcal{M}(s)|^2 \left| \frac{\partial^n \phi}{\partial(s_1 \dots s_n)} \right| d^n s \tag{1}$$

where  $|\frac{\partial^n \phi}{\partial(s_1 \dots s_n)}|$  represents the density of states at  $s$ , and  $\mathcal{M}$  the matrix element for the decay at that point in phase space. For two-body decays,  $|\frac{\partial^n \phi}{\partial(s_1 \dots s_n)}|$  is a  $\delta$  function, while for  $D^0$  decays to 3,4,5, . . . pseudoscalars, phase space is 2,5,8, . . . dimensional, leading to a rich phenomenology. Additional parameters are required to fully describe decays with vector particles in the initial or final state.

For the important case of a pseudoscalar decaying to 3 pseudoscalars, the decay kinematics can be described in a two dimensional Dalitz plot [1]. The Dalitz plot of  $D \rightarrow abc$  is usually parametrized in terms of invariant-mass-squared variables  $s_1 = (p_a + p_b)^2$  and  $s_2 = (p_b + p_c)^2$ , where  $p_a, p_b, p_c$  are the four-momenta of particles  $a, b, c$ . In terms of these variables, phase-space density is constant across the kinematically allowed region, so that any structure seen in the Dalitz plot is a direct consequence of the dynamics encoded in  $|\mathcal{M}|^2$ .

An important difference between decays to two or three pseudoscalars compared to decays to four or more particles is the behavior under parity. In the former case, the operation of parity can also be expressed as a rotation, so no parity violating observables can be defined (unless they also violate rotational invariance). This is not the case for decays to four or more particles. This leads to the interesting possibility of using parity-odd observables in four body decays for  $CP$  violation searches, as discussed below. Another consequence of these considerations is that four-body-decay kinematics cannot be described unambiguously in terms of invariant-mass-squared variables, as these are all parity even.

The matrix element  $\mathcal{M}$  is usually modeled as a sum of interfering decay amplitudes, each proceeding through resonant two-body decays [2]. See Refs [2–4] for a review of resonance phenomenology. In most analyses, each resonance is described by a Breit–Wigner or Flatté lineshape, and the model includes a non-resonant term with a constant phase and magnitude across the Dalitz plot. This approach has well-known theoretical limitations, such as the violation of unitarity and analyticity, which tend to be particularly problematic for broad, overlapping resonances. This motivates the use of more sophisticated descriptions, especially for the broad, overlapping resonances that occur typically in the S-wave components. In charm analyses, these have included the K-matrix approach [5,6,7] which respects unitarity; the use of LASS scattering data [8]; dispersive methods [9,10]; methods based on chiral symmetry [11,12]; and quasi model-independent parametrizations [13,14]. An important example first analyzed by CLEO [15,16,17] is  $D^0 \rightarrow K_S \pi^+ \pi^-$ , which is a key channel in  $CP$  violation and charm mixing analyses. Belle models this final state as a superposition of 18 resonances (including 4 significant doubly Cabibbo suppressed amplitudes) described by Breit–Wigner or Flatté lineshapes, plus a non-resonant component [18]. CDF’s analysis follows a similar approach [19]. BaBar’s model for the same decay replaces the broad  $\pi\pi$  and  $K\pi$  S-wave resonances and the non-resonant component with a K-matrix description [20]. Belle’s and BaBar’s data have been re-analyzed by [21] in a QCD factorization framework, using line-shape parametrizations for the S [11,12] and P wave [10] contributions (with input from  $\tau^- \rightarrow K_S \pi^- \nu_\tau$  data [22] for the latter) that preserve 2-body unitarity and analyticity. The measurements give compatible results for the components they share. All three approaches remain within the confines of the “isobar” framework which treats the decay as a series of independent two-body processes, ignoring long-range hadronic effects. Dispersive techniques that account for these hadronic effects and respect full 3 body unitarity and analyticity have been applied to regions of the  $D^- \rightarrow K^- \pi^+ \pi^+$  Dalitz plot below the  $\eta'K$  threshold [23].

Limitations in the theoretical description of interfering resonances are the leading source of systematic uncertainty in many analyses. This is set to become increasingly problematic given the statistical precision achievable with the vast charm samples

available at the B factories, LHCb, and their upgrades. Already now, clean data samples with millions of charm events are available even in suppressed decay modes, e.g. 2.4M  $D^0 \rightarrow \pi^- \pi^+ \pi^0$  events at LHCb [24]. In some cases, the model uncertainty can be removed through model-independent amplitude methods, often relying on input from the charm threshold, as discussed below. At the same time, increasingly sophisticated models are being developed, and applied to data.

**Applications of multibody charm analyses** The interference between the decay paths via which multibody decays proceed provides sensitivity to both relative magnitudes and phases of the contributing decay amplitudes. It is especially this sensitivity to phases that makes amplitude analyses such a uniquely powerful tool for studying a wide range of phenomena. Here we concentrate on their use for  $CP$  violation measurements and mixing in charm, and charm inputs to  $CP$  violation analyses in  $B$  meson decays. The properties of light-meson resonances determined in  $D$ -meson amplitude analyses are reported in the light-unflavored-meson section of this *Review*.

#### **Time-integrated searches for $CP$ violation in charm**

Comparing the results of amplitude fits for  $CP$ -conjugate decay modes provides a measure of  $CP$  violation. The advantage of this approach over the model-independent searches discussed in the next paragraph is the physical interpretation of any  $CP$  violation observation that such a fit result would allow. The disadvantage lies in the theoretical uncertainty intrinsic to such analyses due to the amplitude-model dependence. Recent  $CP$  violation searches using this method include CLEO’s amplitude analysis of  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  [25] and CDF’s analysis of  $\sim 350,000$   $D^0 \rightarrow K_S \pi^+ \pi^-$  events [19].

The most common model-independent approach for searching for local  $CP$  violation across a Dalitz plot is based on performing a  $\chi^2$  comparison of the number of events in the bins of  $CP$ -conjugate Dalitz plots. This method was pioneered by BaBar [26] and developed further in [27,28], with recent results in  $D^\pm \rightarrow K^+ K^- \pi^\pm$  [29,30,31],  $D^0 \rightarrow K_S \pi^+ \pi^-$  [19], and  $D^+ \rightarrow \pi^- \pi^+ \pi^+$  [32]. These techniques have been generalized to four-body decays, and applied to  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  and  $D^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^-$  [33]. Un-binned methods can increase the sensitivity [34]; two different unbinned methods have been applied by LHCb to  $D^+ \rightarrow \pi^- \pi^+ \pi^+$  [32] and  $D^0 \rightarrow \pi^+ \pi^- \pi^0$  [24]. None of these analyses have shown evidence of  $CP$  violation.

Another model-independent approach, providing complementary information, is based on constructing observables in four body decays that are odd under motion reversal (“naïve T”) [35–43], which is equivalent to  $P$  for scalar particles [43]. One such observable is  $C_T = \vec{p}_{K^+} \cdot (\vec{p}_{\pi^+} \times \vec{p}_{\pi^-})$  in  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ . The rate asymmetry of positive and negative  $C_T$ ,  $A_T \equiv \frac{\Gamma(C_T > 0) - \Gamma(C_T < 0)}{\Gamma(C_T > 0) + \Gamma(C_T < 0)}$ , is a  $P$  violating parameter. Comparing  $A_T$  with the  $C$ -conjugate asymmetry in  $\overline{D}^0$  decays,  $\overline{A}_T$ , provides sensitivity to  $CP$  violation. Searches for  $CP$  violation in this manner have been carried out by FOCUS in  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  [44], BaBar in  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ ,

# Meson Particle Listings

$D^\pm$

$D^+ \rightarrow K^+ K_S \pi^+ \pi^-$ , and  $D_s^+ \rightarrow K^+ K_S \pi^+ \pi^-$  [45,46], and LHCb in  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  [47]. In addition to a phase-space integrated result, LHCb's analysis is also carried out locally in sub-regions of phase space to enhance the sensitivity of the method. All results so far have been consistent with  $CP$  conservation.

**$D$  mixing and  $CP$  violation** Time-dependent amplitude analyses in decays to final states that are accessible to both  $D^0$  and  $\bar{D}^0$  have unique sensitivity to mixing parameters. A Dalitz plot analysis of a self-conjugate final state, such as  $K_S \pi^+ \pi^-$  and  $K_S K^+ K^-$ , allows the measurement of the phase difference between the relevant  $D^0$  and  $\bar{D}^0$  decay amplitudes, and thus a direct measurement of the mixing parameters  $x, y$  (rather than the decay-specific parameters  $x'^2, y'$  measured for example in  $D^0 \rightarrow K\pi$ ) [17]. These analyses are also sensitive to  $CP$  violation in mixing and in the interference between mixing and decay. These results are summarized in Ref. [48]. The important role from charm threshold data as input to such measurements is discussed below.

**Charm amplitude analyses for measuring  $\gamma/\phi_3$**  Neutral  $D$  mesons originating from  $B^- \rightarrow DK^-$  (which we denote with  $D_{B^-}$ ) are a superposition of  $D^0$  and  $\bar{D}^0$  with a relative phase that depends on  $\gamma/\phi_3$ :

$$D_{B^-} \propto D^0 + r_B e^{i(\delta_B - \gamma)} \bar{D}^0,$$

where  $\delta_B$  is a  $CP$  conserving strong phase, and  $r_B \sim 0.1$ . In the corresponding  $CP$ -conjugate expression,  $\gamma/\phi_3$  changes sign. An amplitude analysis of the subsequent decay of the  $D_{B^\pm}$  allows an extraction of  $\gamma/\phi_3$  [49–54]. The method generalizes to similar  $B$  hadron decays, such as  $B^0 \rightarrow DK^{*0}$ . Measurements based on this technique have been reported by BaBar, Belle and LHCb using both model-dependent approaches and model-independent ones based on CLEO-c input [18,55–61,65–67]. The most precise individual results come from the study of the  $D_{B^-} \rightarrow K_S \pi^+ \pi^-$  and  $D_{B^-} \rightarrow K_S K^+ K^-$  with an uncertainty of approximately  $15^\circ$  [18,55,59,67].

## Model independent methods for $\gamma/\phi_3$ and charm mixing

The theoretical uncertainty on amplitude models of multibody  $D^0$  decays potentially limits the precision of measurements of  $\gamma/\phi_3$  in  $B^\pm \rightarrow DK^\pm$  and related decay modes. Model-independent methods to measure  $\gamma/\phi_3$  require input related to the relative phases of the  $D^0$  and  $\bar{D}^0$  decay amplitudes across the phase-space distribution. The same considerations apply to measurements of  $D^0$  mixing and  $CP$  violation parameters in time-dependent Dalitz plot analyses. The required phase information is accessible at the charm threshold, where CLEO-c and BES III operate [48,52,68–74]. There,  $D$  mesons originate from the decay  $\psi(3770) \rightarrow D\bar{D}$ . The two  $D$  mesons are quantum-correlated which can be used to identify decays of well-defined  $D^0 - \bar{D}^0$  superpositions to the final state of interest. The resulting interference of  $D^0$  and  $\bar{D}^0$  amplitudes provides the desired model-independent phase information. For decays to non-self-conjugate decays such as  $D^0 \rightarrow K^+ \pi^- \pi^+ \pi^-$ , analysing  $D^0 - \bar{D}^0$

superpositions provides the only way of measuring the relative phase between the  $D^0$  and  $\bar{D}^0$  amplitudes.

These analyses can be performed in sub-regions/bins of phase space, or integrated across phase space. The relevant result can be expressed in terms of one complex parameter  $\mathcal{Z} = R e^{-i\delta}$  per pair of  $CP$ -conjugate phase space bins, with magnitude  $R \leq 1$ . The larger  $R$ , the higher the sensitivity to interference effects, and thus to  $\gamma/\phi_3$ . The sensitivity of the binned analyses can be optimized by using amplitude model-dependent information to maximize  $R$  in each bin, without introducing a model-dependent bias in the result. CLEO-c data have been analyzed in this way to provide binned results for the self-conjugate decays  $D^0 \rightarrow K_S \pi\pi$  and  $D^0 \rightarrow K_S K K$  [75,76]. The phase-space integrated analyses for  $D^0, \bar{D}^0 \rightarrow K_S K^+ \pi^-$ ,  $K^- \pi^+ \pi^0$ , and  $K^- \pi^+ \pi^- \pi^+$  have yielded  $\mathcal{Z}_{K_S K \pi} = (0.73 \pm 0.8) e^{-i(8.3^\circ \pm 15.2^\circ)}$ ,  $\mathcal{Z}_{K \pi \pi^0} = (0.82 \pm 0.07) e^{-i(164^\circ \pm 20^\circ)}$ ,  $\mathcal{Z}_{K 3\pi} = (0.32_{-0.28}^{+0.20}) e^{-i(225^\circ \pm 21^\circ)}$ , respectively [77,78,79]. These results follow the usual convention for  $\gamma/\phi_3$ -related studies where  $CP|D^0\rangle = +|\bar{D}^0\rangle$ , while in charm mixing measurements, one usually takes  $CP|D^0\rangle = -|\bar{D}^0\rangle$ , leading to a phase-shift in  $\delta$  of  $\pi$ . Restricting the analysis to a bin around the  $K^* K$  resonance in the  $K_S K \pi$  Dalitz plot, [77] find  $R = 1.00 \pm 0.16$ , illustrating the benefit in dividing phase space into bins.

The corresponding phase space-integrated input for self-conjugate decays such as  $D^0 \rightarrow \pi^+ \pi^- \pi^0$  takes the form of a single real parameter, the  $CP$ -even fraction  $F_+$ , defined such that a  $CP$  even eigenstate has  $F_+ = 1$ , while a  $CP$ -odd eigenstate has  $F_+ = 0$  [72]. A recent analysis of CLEO-c data revealed that  $D^0 \rightarrow \pi^+ \pi^- \pi^0$  is compatible with being completely  $CP$ -even with  $F_+ = 1.014 \pm 0.045 \pm 0.022$ , while  $D^0 \rightarrow K^+ K^- \pi^0$  has  $F_+ = 0.734 \pm 0.106 \pm 0.054$  and  $D^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^-$  has  $F_+ = 0.737 \pm 0.028$  [73].

The charm system itself provides, through mixing, a well-defined, time-dependent superposition of  $D^0$  and  $\bar{D}^0$ . Using mixing parameters measured independently as input, this can be used to obtain the relevant information for  $\gamma/\phi_3$  measurements. This method is expected to be particularly powerful in doubly Cabibbo-suppressed decays such as  $D^0 \rightarrow K^+ \pi^- \pi^+ \pi^-$ , and when used in conjunction with information from charm threshold [80,81].

**Summary** Multibody charm decays offer a rich phenomenology, including unique sensitivity to  $CP$  violation and charm mixing. This is a highly dynamic field with many new results (some of which we presented here) and rapidly increasing, high quality datasets. These datasets constitute a huge opportunity, but also a challenge to improve the theoretical descriptions of soft hadronic effects in multibody decays. For some measurements, model-independent methods, many relying on input from the charm threshold, provide a way of removing model-induced uncertainties. At the same time, work is ongoing to improve the theoretical description of multibody decays.

0.8323 ± 0.0150 ± 0.0008	<sup>3</sup> LINK	07B	FOCS See LINK 09

<sup>1</sup> This LINK 09 model-independent partial-wave analysis of the  $K^-\pi^+$  S-wave slices the  $K^-\pi^+$  mass range into 39 bins.

<sup>2</sup> The BONVICINI 08A QMIPWA (quasi-model-independent partial-wave analysis) of the  $K^-\pi^+$  S-wave amplitude slices the  $K^-\pi^+$  mass range into 26 bins but keeps the Breit-Wigner  $\bar{K}_0^*(1430)^0$ .

<sup>3</sup> This LINK 07B fit uses a K matrix. The  $K^-\pi^+$  S-wave fit fraction given above breaks down into  $(207.3 \pm 25.5 \pm 12.4)\%$  isospin-1/2 and  $(40.5 \pm 9.6 \pm 3.2)\%$  isospin-3/2 — with large interference between the two. The isospin-1/2 component includes the  $\kappa$  (or  $\bar{K}_0^*(800)^0$ ) and  $\bar{K}_0^*(1430)^0$ .

 $\Gamma(\bar{K}_0^*(800)^0\pi^+, \bar{K}_0^*(800) \rightarrow K^-\pi^+)/\Gamma(K^-2\pi^+)$   $\Gamma_{42}/\Gamma_{40}$ 

This is the “fit fraction” from the Dalitz-plot analysis.

 $D^\pm$ WEIGHTED AVERAGE  
3.48±0.19 (Error scaled by 1.4) $\Gamma(\rho^0 \pi^+)/\Gamma(2\pi^+ \pi^-)$  $\Gamma_{73}/\Gamma_{72}$ 

This is the “fit fraction” from the Dalitz-plot analysis.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.25 ± 0.04 OUR AVERAGE</b>			Error includes scale factor of 2.4. See the ideogram below.
0.200 ± 0.023 ± 0.009	BONVICINI 07	CLEO	Dalitz fit, $\approx 2240$ evts
0.3082 ± 0.0314 ± 0.0230	LINK 04	FOCS	Dalitz fit, 1527 ± 51 evts
0.336 ± 0.032 ± 0.022	AITALA 01B	E791	Dalitz fit, 1172 evts

WEIGHTED AVERAGE  
0.25±0.04 (Error scaled by 2.4) $\Gamma(\pi^+ (\pi^+ \pi^-)_{S\text{-wave}})/\Gamma(2\pi^+ \pi^-)$  $\Gamma_{74}/\Gamma_{72}$ 

This is the “fit fraction” from the Dalitz-plot analysis. See also the next three data blocks.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.5600 ± 0.0324 ± 0.0214</b>	<sup>1</sup> LINK 04	FOCS	Dalitz fit, 1527 ± 51 evts

<sup>1</sup> LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full  $\pi\pi$ -S-wave isoscalar scattering amplitude to describe the  $\pi^+\pi^-$  S-wave component of the  $\pi^+\pi^+\pi^-$  state. The fit fraction given above is a sum over five  $f_0$  mesons, the  $f_0(980)$ ,  $f_0(1300)$ ,  $f_0(1200\text{--}1600)$ ,  $f_0(1500)$ , and  $f_0(1750)$ . See LINK 04 for details and discussion.

 $\Gamma(\sigma \pi^+, \sigma \rightarrow \pi^+ \pi^-)/\Gamma(2\pi^+ \pi^-)$  $\Gamma_{75}/\Gamma_{72}$ 

This is the “fit fraction” from the Dalitz-plot analysis.

$D^\pm$   $\chi^2$  TESTS OF  $CP$ -VIOLATION ( $CPV$ )

We list model-independent searches for local  $CP$  violation in phase-space distributions of multi-body decays.

Most of these searches divide phase space (Dalitz plot for 3-body decays, five-dimensional equivalent for 4-body decays) into bins, and perform a  $\chi^2$  test comparing normalised yields  $N_i$ ,  $\bar{N}_i$  in  $CP$ -conjugate bin pairs  $i$ :  $\chi^2 = \sum_i (N_i - \alpha \bar{N}_i) / \sigma(N_i - \alpha \bar{N}_i)$ . The factor  $\alpha = (\sum_i N_i) / (\sum_i \bar{N}_i)$  removes the dependence on phase-space-integrated rate asymmetries. The result is used to obtain the probability (p-value) to obtain the measured  $\chi^2$  or larger under the assumption of  $CP$  conservation [AUBERT 08AO, BEDIAGA 09]. Alternative methods obtain p-values from other test variables based on unbinned analyses [WILLIAMS 11, AAIJ 14c]. Results can be combined using Fisher's method [MOSTELLER 48].

Local  $CPV$  in  $D^\pm \rightarrow \pi^+ \pi^- \pi^\pm$

31	OUR EVALUATION			
72	224k	LEES	13f BABR	$\chi^2$
12.7	370k	<sup>1</sup> AAIJ	11g LHCb	$\chi^2$

<sup>1</sup> AAIJ 11g publishes results for several binning schemes. We picked the first value in their table of results.

 $CP$  VIOLATING ASYMMETRIES OF  $P$ -ODD ( $T$ -ODD) MOMENTS $A_{T\text{viol}}(K_S^0 K^\pm \pi^+ \pi^-)$  in  $D^\pm \rightarrow K_S^0 K^\pm \pi^+ \pi^-$ 

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a parity-odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta for the  $D^+$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $D^-$ . Then

$A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ , and  
 $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ , and

$A_{T\text{viol}} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ .  $C_T$  and  $\bar{C}_T$  are commonly referred to as  $T$ -odd moments, because they are odd under  $T$  reversal. However, the  $T$ -conjugate process  $K_S^0 K^\pm \pi^+ \pi^- \rightarrow D^\pm$  is not accessible, while the  $P$ -conjugate process is.

$2.0 \pm 0.6 \pm 0.3$	183	ANJOS	90E E691	$\bar{K}^*(892)^0 e^+ \nu_e$

<sup>1</sup> DEL-AMO-SANCHEZ 11i finds the pole mass  $m_A = (2.63 \pm 0.10 \pm 0.13)$  GeV ( $m_V$  is fixed at 2 GeV).

<sup>2</sup> LINK 02L includes the effects of interference with an  $S$ -wave background. This much improves the goodness of fit, but does not much shift the values of the form factors.

<sup>3</sup> This is slightly different from the AITALA 98B value: see ref. [5] in AITALA 98F.

 $D^0 - \bar{D}^0$  MIXING

Revised August 2015 by D. M. Asner (Pacific Northwest National Laboratory)

The detailed formalism for  $D^0 - \bar{D}^0$  mixing is presented in the note on “ $CP$  Violation in Meson Decays” in this *Review*. For completeness, we present an overview here. The time evolution of the  $D^0 - \bar{D}^0$  system is described by the Schrödinger equation

$$i \frac{\partial}{\partial t} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix} = \left( \mathbf{M} - \frac{i}{2} \mathbf{\Gamma} \right) \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix}, \quad (1)$$

where the  $\mathbf{M}$  and  $\mathbf{\Gamma}$  matrices are Hermitian, and  $CPT$  invariance requires that  $M_{11} = M_{22} \equiv M$  and  $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$ . The

off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because  $CP$  violation is expected to be quite small here, it is convenient to label the mass eigenstates by the  $CP$  quantum number in the limit of  $CP$  conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\bar{D}^0\rangle, \quad (2)$$

where

$$\left( \frac{q}{p} \right)^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}. \quad (3)$$

The normalization condition is  $|p|^2 + |q|^2 = 1$ . Our phase convention is  $CP|D^0\rangle = +|\bar{D}^0\rangle$ , and the sign is chosen so that  $D_1$  has  $CP$  even, or nearly so.

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2}\Gamma_{1,2} = \left( M - \frac{i}{2}\Gamma \right) \pm \frac{q}{p} \left( M_{12} - \frac{i}{2}\Gamma_{12} \right), \quad (4)$$

where  $m_{1,2}$  and  $\Gamma_{1,2}$  are the masses and widths of the  $D_{1,2}$ .

We define dimensionless mixing parameters  $x$  and  $y$  by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \quad (6)$$

where  $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$ . If  $CP$  is conserved, then  $M_{12}$  and  $\Gamma_{12}$  are real,  $\Delta m = 2M_{12}$ ,  $\Delta\Gamma = 2\Gamma_{12}$ , and  $p = q = 1/\sqrt{2}$ . The signs of  $\Delta m$  and  $\Delta\Gamma$  are to be determined experimentally.

The parameters  $x$  and  $y$  are measured in several ways. The most precise values are obtained using the time dependence of  $D$  decays. Since  $D^0 - \bar{D}^0$  mixing is a small effect, the identifying tag of the initial particle as a  $D^0$  or a  $\bar{D}^0$  must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence  $D^{*+} \rightarrow D^0 \pi^+$  or  $D^{*-} \rightarrow \bar{D}^0 \pi^-$ . In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the  $B$ -factories allow the production flavor to also be determined by fully reconstructing charm on the “other side” of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the  $D$ ’s produced from  $\psi(3770) \rightarrow D^0 \bar{D}^0$  decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the  $D^0$  and  $\bar{D}^0$  do not travel far enough), the quantum-coherent  $C = -1$   $\psi(3770) \rightarrow D^0 \bar{D}^0$  state provides time-integrated sensitivity [2,3].

**Time-Dependent Analyses:** We extend the formalism of this *Review*’s note on “ $CP$  Violation in Meson Decays.” In addition to the “right-sign” instantaneous decay amplitudes  $\bar{A}_f \equiv \langle f|H|\bar{D}^0\rangle$  and  $A_{\bar{f}} \equiv \langle \bar{f}|H|D^0\rangle$  for final states  $f = K^+ \pi^-, \dots$  and their  $CP$  conjugate  $\bar{f} = K^- \pi^+, \dots$ , we include “wrong-sign” amplitudes  $\bar{A}_{\bar{f}} \equiv \langle \bar{f}|H|\bar{D}^0\rangle$  and  $A_f \equiv \langle f|H|D^0\rangle$ .

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral  $D$ -meson mean lifetime,  $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$ . Starting from a pure  $|D^0\rangle$  or  $|\bar{D}^0\rangle$  state at  $t = 0$ , the time-dependent rates of decay

# Meson Particle Listings

## $D^0$

to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{|\langle f | H | D^0(t) \rangle|^2}{|\bar{A}_f|^2} = \left| \frac{q}{p} \right|^2 \left| g_+(t) \lambda_f^{-1} + g_-(t) \right|^2, \quad (7)$$

and

$$\bar{r}(t) \equiv \frac{|\langle \bar{f} | H | \bar{D}^0(t) \rangle|^2}{|A_{\bar{f}}|^2} = \left| \frac{p}{q} \right|^2 \left| g_+(t) \lambda_{\bar{f}} + g_-(t) \right|^2. \quad (8)$$

where

$$\lambda_f \equiv q\bar{A}_f/pA_f, \quad \lambda_{\bar{f}} \equiv q\bar{A}_{\bar{f}}/pA_{\bar{f}}, \quad (9)$$

and

$$g_{\pm}(t) = \frac{1}{2} (e^{-iz_1 t} \pm e^{-iz_2 t}), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}. \quad (10)$$

Note that a change in the convention for the relative phase of  $D^0$  and  $\bar{D}^0$  would cancel between  $q/p$  and  $\bar{A}_f/A_f$  and leave  $\lambda_f$  unchanged. We expand  $r(t)$  and  $\bar{r}(t)$  to second order in  $x$  and  $y$  for modes in which the ratio of decay amplitudes,  $R_D = |A_f/\bar{A}_f|^2$ , is very small.

**Semileptonic decays:** Consider the final state  $f = K^+ \ell^- \bar{\nu}_\ell$ , where  $A_f = \bar{A}_{\bar{f}} = 0$  in the Standard Model. The final state  $\bar{f}$  is only accessible through mixing and  $r(t)$  is

$$r(t) = |g_-(t)|^2 \left| \frac{q}{p} \right|^2 \approx \frac{e^{-t}}{4} (x^2 + y^2) t^2 \left| \frac{q}{p} \right|^2. \quad (11)$$

For  $\bar{r}(t)$   $q/p$  is replaced by  $p/q$ . In the Standard Model,  $CP$  violation in charm mixing is small and  $|q/p| \approx 1$ . In the limit of  $CP$  conservation,  $r(t) = \bar{r}(t)$ , and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t) dt = \left| \frac{q}{p} \right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} \approx \frac{1}{2} (x^2 + y^2). \quad (12)$$

**Table 1:** Results for  $R_M$  in  $D^0$  semileptonic decays.

Year	Exper.	Final stat.	$R_M (\times 10^{-3})$	90% C.L.
2008	Belle [4]	$K^{(*)+} e^- \bar{\nu}_e$	$0.13 \pm 0.22 \pm 0.20$	$< 0.61 \times 10^{-3}$
2007	BaBar [1]	$K^{(*)+} e^- \bar{\nu}_e$	$0.04^{+0.70}_{-0.60}$	$(-1.3, 1.2) \times 10^{-3}$
2005*	Belle [5]	$K^{(*)+} e^- \bar{\nu}_e$	$0.02 \pm 0.47 \pm 0.14$	$< 1.0 \times 10^{-3}$
2005	CLEO [6]	$K^{(*)+} e^- \bar{\nu}_e$	$1.6 \pm 2.9 \pm 2.9$	$< 7.8 \times 10^{-3}$
2004*	BaBar [7]	$K^{(*)+} e^- \bar{\nu}_e$	$2.3 \pm 1.2 \pm 0.4$	$< 4.2 \times 10^{-3}$
2002*	FOCUS [8]	$K^+ \mu^- \bar{\nu}_\mu$	$-0.76^{+0.99}_{-0.93}$	$< 1.01 \times 10^{-3}$
1996	E791 [9]	$K^+ \ell^- \bar{\nu}_\ell$	$(1.1^{+3.0}_{-2.7}) \times 10^{-3}$	$< 5.0 \times 10^{-3}$
HFAG [10]			$0.13 \pm 0.27$	

\*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the statistical correlation of the BaBar result with Ref. 1 has not been established, and the Belle result is superseded by Ref. 4. The HFAG average assumes reported statistical and systematic uncertainties are uncorrelated.

Table 1 summarizes results for  $R_M$  from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is  $R_M = (1.30 \pm 2.69) \times 10^{-4}$ .

**Wrong-sign decays to hadronic non- $CP$  eigenstates:** Consider the final state  $f = K^+ \pi^-$ , where  $A_f$  is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\bar{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left| \frac{A_f}{\bar{A}_f} \right| \sim O(\tan^2 \theta_c), \quad (13)$$

where  $R_D$  is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate,  $\delta_f$  is the strong phase difference between DCS and CF processes, and  $\theta_c$  is the Cabibbo angle. The minus sign originates from the sign of  $V_{us}$  relative to  $V_{cd}$ .

We characterize the violation of  $CP$  with the real-valued parameters  $A_M$ ,  $A_D$ , and  $\phi$ . We adopt the parametrization (see Refs. 11 and 12)

$$\left| \frac{q}{p} \right|^2 = \sqrt{\frac{1+A_M}{1-A_M}}, \quad (14)$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\bar{A}_f} = -\sqrt{R_D} \left( \frac{(1+A_D)(1-A_M)}{(1-A_D)(1+A_M)} \right)^{1/4} e^{-i(\delta_f+\phi)}, \quad (15)$$

$$\lambda_{\bar{f}} \equiv \frac{q\bar{A}_{\bar{f}}}{pA_{\bar{f}}} = -\sqrt{R_D} \left( \frac{(1-A_D)(1+A_M)}{(1+A_D)(1-A_M)} \right)^{1/4} e^{-i(\delta_f-\phi)}, \quad (16)$$

and  $A_D$  is a measure of direct  $CP$  violation, while  $A_M$  is a measure of  $CP$  violation in mixing. From these relations, we obtain

$$\sqrt{\frac{1+A_D}{1-A_D}} = \frac{|A_f/\bar{A}_f|}{|\bar{A}_{\bar{f}}/A_{\bar{f}}|}, \quad (17)$$

The angle  $\phi$  measures  $CP$  violation in interference between mixing and decay. While  $A_M$  is independent of the decay process,  $A_D$  and  $\phi$ , in general, depend on  $f$ .

In general,  $\lambda_{\bar{f}}$  and  $\lambda_f^{-1}$  are independent complex numbers. More detail on  $CP$  violation in meson decays can be found in Ref. 13. To leading order, for  $A_D$  and  $A_M \ll 1$ ,

$$r(t) = e^{-t} \left[ R_D(1+A_D) + \sqrt{R_D(1+A_M)(1+A_D)} y'_- t + \frac{1}{2} (1+A_M) R_M t^2 \right] \quad (18)$$

and

$$\bar{r}(t) = e^{-t} \left[ R_D(1-A_D) + \sqrt{R_D(1-A_M)(1-A_D)} y'_+ t + \frac{1}{2} (1-A_M) R_M t^2 \right] \quad (19)$$

Here

$$\begin{aligned} y'_\pm &\equiv y' \cos \phi \pm x' \sin \phi \\ &= y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi), \end{aligned} \quad (20)$$

where

$$\begin{aligned} x' &\equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi}, \\ y' &\equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi}, \end{aligned} \quad (21)$$

and  $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$  is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of  $CP$  violation. In the limit of  $CP$  conservation,  $A_M$ ,  $A_D$ , and  $\phi$  are all zero. Then

$$r(t) = \bar{r}(t) = e^{-t} \left( R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right), \quad (22)$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) dt = R_D + \sqrt{R_D} y' + R_M. \quad (23)$$

The ratio  $R$  is the most readily accessible experimental quantity. In Table 2 are reported the measurements of  $R$ ,  $R_D$  and  $A_D$  in  $D^0 \rightarrow K^+ \pi^-$ , and their HFAG average [24] from a general fit; that allows for both mixing and  $CP$  violation. Typically, the fit parameters are  $R_D$ ,  $x'^2$ , and  $y'$ . Table 3 summarizes the results for  $x'^2$  and  $y'$ . Allowing for  $CP$  violation, the separate contributions to  $R$  can be extracted by fitting the  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^- \pi^+$  decay rates.

**Table 2:** Results for  $R$ ,  $R_D$ , and  $A_D$  in  $D^0 \rightarrow K^+ \pi^-$ .

\*These measurements are excluded from the HFAG average of  $R_D$ . The CDF result is superseded by Ref. 16 and the LHCb is superseded by Ref. 15. The LHCb result is included in the average of  $R$ . The Belle result for  $R$  and  $R_D$  is superseded by Ref. 14.

†These measurements are excluded from the HFAG average due to poor precision.

Extraction of the mixing parameters  $x$  and  $y$  from the results in Table 3 requires knowledge of the relative strong phase  $\delta_{K\pi}$ . An interference effect that provides useful sensitivity to  $\delta_{K\pi}$  arises in the decay chain  $\psi(3770) \rightarrow D^0 \bar{D}^0 \rightarrow (f_{CP})(K^+ \pi^-)$ , where  $f_{CP}$  denotes a  $CP$ -even or -odd eigenstate from  $D^0$  decay, such as  $K^+ K^-$  or  $K_S^0 \pi^0$ , respectively [26]. Here, the amplitude relation

**Table 3:** Results on the time-dependence of  $r(t)$  in  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^- \pi^+$  decays. The Belle 2014, LHCb and CDF results assume no  $CP$  violation. The FOCUS, CLEO, and Belle 2006 results restrict  $x'^2$  to the physical region. The confidence intervals from FOCUS, CLEO, and BaBar are obtained from the fit, whereas Belle uses a Feldman-Cousins method, and CDF uses a Bayesian method.

† This Belle result allows for  $CP$  violation. HFAG uses this result for the  $CP$ -violation allowed fit. This result is not superseded by Ref. 14.

\*† This Belle result does not allow for  $CP$  violation. HFAG uses this result for the  $CP$ -conserving fit. This result does not supersede Ref. 20.

$$\sqrt{2} A(D_\pm \rightarrow K^- \pi^+) = A(D^0 \rightarrow K^- \pi^+) \pm A(\bar{D}^0 \rightarrow K^- \pi^+). \quad (24)$$

where  $D_\pm$  denotes a  $CP$ -even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \rightarrow K^- \pi^+)|^2 - |A(D_- \rightarrow K^- \pi^+)|^2}{2\sqrt{R_D} |A(D^0 \rightarrow K^- \pi^+)|^2}. \quad (25)$$

This neglects  $CP$  violation and uses  $\sqrt{R_D} \ll 1$ .

The asymmetry of  $CP$ -tagged  $D$  decays rates to  $K^- \pi^+$  is denoted as

$$A_{K\pi}^{CP} \equiv \frac{|A(D_- \rightarrow K^- \pi^+)|^2 - |A(D_+ \rightarrow K^- \pi^+)|^2}{|A(D_- \rightarrow K^- \pi^+)|^2 + |A(D_+ \rightarrow K^- \pi^+)|^2}. \quad (26)$$

To lowest order in the mixing parameters [2,3]

$$2\sqrt{R_D} \cos \delta_{K\pi} + y = (1 + R) \dot{A}_{K\pi}^{CP} \quad (27)$$

where  $R$  is the time-integrated wrong-sign rate relative to the integrated right-sign rate from Eq. (23).

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although  $x$  and  $y$  do not vary across the space, knowledge of the resonant substructure is needed to extrapolate the strong phase difference  $\delta$  from point to point to determine  $x$  and  $y$ . Model-independent methods to measure  $D$  mixing parameters require input related to the relative phases of the  $D^0$  and  $\bar{D}^0$  decay amplitudes across the

# Meson Particle Listings

## $D^0$

phase-space distribution [25]. The required phase information is accessible at the charm threshold, where CLEO-c and BESIII operate [26,27].

A time-dependent analysis of the process  $D^0 \rightarrow K^+\pi^-\pi^0$  from BaBar [28,29] determines the *relative* strong phase variation across the Dalitz plot and reports  $x'' = (2.61^{+0.57}_{-0.68} \pm 0.39)\%$ , and  $y'' = (-0.06^{+0.55}_{-0.64} \pm 0.34)\%$ , where  $x''$  and  $y''$  are defined as

$$\begin{aligned} x'' &\equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0}, \\ y'' &\equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0}, \end{aligned} \quad (28)$$

in parallel to  $x'$ ,  $y'$ , and  $\delta_{K\pi}$  of Eq. (21). Here  $\delta_{K\pi\pi^0}$  is the remaining strong phase difference between the DCS  $D^0 \rightarrow K^+\rho^-$  and the CF  $\overline{D}^0 \rightarrow K^+\rho^-$  amplitudes and does not vary across the Dalitz plot. Both strong phases,  $\delta_{K\pi}$  and  $\delta_{K\pi\pi^0}$ , can be determined from time-integrated  $CP$  asymmetries in correlated  $D^0\overline{D}^0$  produced at the  $\psi(3770)$  [26,27].

Both the sign and magnitude of  $x$  and  $y$  without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody  $D^0$  decays [30,31]. In  $D^0 \rightarrow K_S^0\pi^+\pi^-$ , the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phases. CLEO [32], Belle [31,34], and BaBar [33] have measured the relative phase between  $D^0 \rightarrow K^*(892)^-\pi^+$  and  $D^0 \rightarrow K^*(892)^+\pi^-$  to be  $(189 \pm 10 \pm 3^{+15}_{-5})^\circ$ ,  $(173.9 \pm 0.7 \text{ (stat. only)})^\circ$ , and  $(177.6 \pm 1.1 \text{ (stat. only)})^\circ$ , respectively. These results are close to the  $180^\circ$  expected from Cabibbo factors and a small strong phase. Table 4 summarizes the results of a time-dependent Dalitz-plot analyses.

**Table 4:** Results from time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0\pi^+\pi^-$  (CLEO and Belle) and  $D^0 \rightarrow K_S^0\pi^+\pi^-, K_S^0K^+K^-$  (BaBar). The errors are statistical, experimental systematic, and decay-model systematic, respectively.

In addition, Belle [31,34] has results for both the relative phase (statistical errors only) and ratio  $R$  (central values only) of the DCS fit fraction relative to the CF fit fractions for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ ,  $K_2^*(1430)^+\pi^-$ ,  $K^*(1410)^+\pi^-$ , and  $K^*(1680)^+\pi^-$ . Similarly, BaBar [33,35,36] has reported central values for  $R$  for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ , and

$K_2^*(1430)^+\pi^-$ . The systematic uncertainties on  $R$  must be evaluated. The large differences in  $R$  among these final states could point to an interesting role for hadronic effects.

**Decays to  $CP$  Eigenstates:** When the final state  $f$  is a  $CP$  eigenstate, there is no distinction between  $f$  and  $\overline{f}$ , and  $A_f = A_{\overline{f}}$  and  $\overline{A}_{\overline{f}} = \overline{A}_f$ . We denote final states with  $CP$  eigenvalues  $\pm 1$  by  $f_\pm$  and write  $\lambda_\pm$  for  $\lambda_{f_\pm}$ .

The quantity  $y$  may be measured by comparing the rate for  $D^0$  decays to non- $CP$  eigenstates such as  $K^-\pi^+$  with decays to  $CP$  eigenstates such as  $K^+K^-$  [12]. If decays to  $K^+K^-$  have a shorter effective lifetime than those to  $K^-\pi^+$ ,  $y$  is positive.

In the limit of slow mixing ( $x, y \ll 1$ ) and the absence of direct  $CP$  violation ( $A_D = 0$ ), but allowing for small indirect  $CP$  violation ( $|A_M|, |\phi| \ll 1$ ), we can write

$$\lambda_\pm = \left| \frac{q}{p} \right| e^{\pm i\phi}. \quad (29)$$

In this scenario, to a good approximation, the decay rates for states that are initially  $D^0$  and  $\overline{D}^0$  to a  $CP$  eigenstate have exponential time dependence:

$$r_\pm(t) \propto \exp(-t/\tau_\pm), \quad (30)$$

$$\overline{r}_\pm(t) \propto \exp(-t/\overline{\tau}_\pm), \quad (31)$$

where  $\tau$  is measured in units of  $1/\Gamma$ .

The effective lifetimes are given by

$$1/\tau_\pm = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi), \quad (32)$$

$$1/\overline{\tau}_\pm = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi). \quad (33)$$

The effective decay rate to a  $CP$  eigenstate combining both  $D^0$  and  $\overline{D}^0$  decays is

$$r_\pm(t) + \overline{r}_\pm(t) \propto e^{-(1 \pm y_{CP})t}. \quad (34)$$

Here

$$y_{CP} = \frac{1}{2} \left( \left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left( \left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (35)$$

$$\approx y \cos \phi - A_M x \sin \phi. \quad (36)$$

If  $CP$  is conserved,  $y_{CP} = y$ .

All measurements of  $y_{CP}$  are relative to the  $D^0 \rightarrow K^-\pi^+$  decay rate. Table 5 summarizes the current status of measurements. Belle [41], BaBar [42], LHCb [43], CDF [39] have reported  $y_{CP}$  and the decay-rate asymmetry for  $CP$  even final states (assuming  $A_D = 0$ )

$$A_\Gamma = \frac{\overline{\tau}_+ - \tau_+}{\overline{\tau}_+ + \tau_+} = \frac{(1/\tau_+) - (1/\overline{\tau}_+)}{(1/\tau_+) + (1/\overline{\tau}_+)} \quad (37)$$

$$= \frac{1}{2} \left( \left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left( \left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) x \sin \phi \quad (38)$$

$$\approx A_M y \cos \phi - x \sin \phi. \quad (39)$$

2013	LHCb [55]	$-3.4 \pm 1.5 \pm 1.0$
2013	CDF [56]	$-6.2 \pm 2.1 \pm 1.0$
2012	Belle [14]	$-8.7 \pm 4.1 \pm 0.6$
2008	BaBar [57]	$2.4 \pm 6.2 \pm 2.6$
HFAG [24]		$-2.53 \pm 1.04$

Belle [45] has also reported  $y_{CP}$  for the final state  $K_S^0K^+K^-$  which is dominated by the  $CP$  odd final state  $K_S^0\phi$ . If  $CP$  is conserved,  $A_\Gamma = 0$ .

Substantial work on the time-integrated  $CP$  asymmetries in decays to  $CP$  eigenstates are summarized in this *Review* [53]. Table 6 summarizes the current status of measurements of the difference in time-integrated  $CP$  asymmetry,  $\Delta A_{CP} = A_K - A_\pi$ , between  $D^0 \rightarrow K^+K^-$  and  $D^0 \rightarrow \pi^+\pi^-$ . The HFAG fit is marginally consistent with no  $CP$  violation at the 5.1% Confidence Level [24].

**Coherent  $D^0\bar{D}^0$  Analyses:** Measurements of  $R_D$ ,  $\cos\delta_{K\pi}$ ,  $\sin\delta_{K\pi}$ ,  $x$ , and  $y$  can be determined simultaneously from a combined fit to the time-integrated single-tag (ST) and double-tag (DT) yields in correlated  $D^0\bar{D}^0$  produced at the  $\psi(3770)$  [26,27].

Due to quantum correlations in the  $C = -1$  and  $C = +1$   $D^0\bar{D}^0$  pairs produced in the reactions  $e^+e^- \rightarrow D^0\bar{D}^0(\pi^0)$  and  $e^+e^- \rightarrow D^0\bar{D}^0\gamma(\pi^0)$ , respectively, the time-integrated  $D^0\bar{D}^0$

decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from  $D^0\bar{D}^0$  mixing.

The following categories of final states are considered:

**$f$  or  $\bar{f}$ :** Hadronic states accessed from either  $D^0$  or  $\bar{D}^0$  decay but that are not  $CP$  eigenstates. An example is  $K^-\pi^+$ , which results from Cabibbo-favored  $D^0$  transitions or DCS  $\bar{D}^0$  transitions.

**$\ell^+$  or  $\ell^-$ :** Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent  $D^0$ .

**$f_+$  or  $f_-$ :**  $CP$ -even and  $CP$ -odd eigenstates, respectively.

The decay rates for  $D^0\bar{D}^0$  pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both  $C = -1$  and  $C = +1$ , reproducing the work of Ref. 3. Such  $D^0\bar{D}^0$  combinations, where both  $D$  final states are specified, are double tags. In addition, the rates for single tags, where either the  $D^0$  or  $\bar{D}^0$  is identified and the other neutral  $D$  decays generically are given in Ref. 2.

BESIII has reported results using  $2.92 \text{ pb}^{-1}$  of  $e^+e^- \rightarrow \psi(3770)$  data where the quantum-coherent  $D^0\bar{D}^0$  pairs are in the  $C = -1$  state. The values of  $y_{CP} = (-2.0 \pm 1.3 \pm 0.7)\%$  [38] and  $A_{K\pi}^{CP} = (12.7 \pm 1.3 \pm 0.7)\%$  [61] are determined from DT yields including a  $CP$  eigenstate vs semileptonic and vs  $K\pi$ , respectively. For  $y_{CP}$ , the  $CP$  eigenstates included are  $K^-K^+$  ( $f_+$ ),  $\pi^+\pi^-$  ( $f_+$ ),  $K_S^0\pi^0\pi^0$  ( $f_+$ ),  $K_S^0\pi^0$  ( $f_-$ ),  $K_S^0\eta$  ( $f_-$ ), and  $K_S^0\omega$  ( $f_-$ ). For  $A_{K\pi}^{CP}$ , the additional  $CP$  eigenstates included are  $\pi^0\pi^0$  ( $f_+$ ) and  $\rho^0\pi^0$  ( $f_+$ ). Using the external inputs from  $R_D$  and  $y$  from HFAG [62] and  $R$  from PDG [63]—see Eq. (27), they obtain  $\cos\delta_{K\pi} = 1.02 \pm 0.11 \pm 0.06 \pm 0.01$  [61] where the third uncertainty is due to the external inputs.

CLEO-c has reported results using  $818 \text{ pb}^{-1}$  of  $e^+e^- \rightarrow \psi(3770)$  data [58–60]. The values of  $y$ ,  $R_M$ ,  $\cos\delta_{K\pi}$ , and  $\sin\delta_{K\pi}$  are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are  $K^-\pi^+$  ( $f$ ),  $K^+\pi^-$  ( $\bar{f}$ ),  $K^-K^+$  ( $f_+$ ),  $\pi^+\pi^-$  ( $f_+$ ),  $K_S^0\pi^0\pi^0$  ( $f_+$ ),  $K_L^0\pi^0$  ( $f_+$ ),  $K_L^0\eta$  ( $f_+$ ),  $K_L^0\omega$  ( $f_+$ ),  $K_S^0\pi^0$  ( $f_-$ ),  $K_S^0\eta$  ( $f_-$ ),  $K_S^0\omega$  ( $f_-$ ), and  $K_L^0\pi^0\pi^0$  ( $f_-$ ), and  $K_S^0\pi^+\pi^-$  (mixture of  $f, \bar{f}, f_+$ , and  $f_-$ ). The two flavored final states,  $K^-\pi^+$  and  $K^+\pi^-$ , can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one  $D$  is fully reconstructed in one of the hadronic modes listed above, and the other  $D$  is partially reconstructed in either  $D \rightarrow K\ell\nu$  or  $D \rightarrow K\mu\nu$ . When the lepton is accompanied by a flavor tag ( $D \rightarrow K^-\pi^+$  or  $K^+\pi^-$ ), both the “right-sign” and “wrong-sign” DT samples are used, where the electron and kaon charges are the same and opposite, respectively.

The main results of the CLEO-c analysis are the determination of  $\cos\delta_{K\pi} = 0.81^{+0.22+0.07}_{-0.18-0.05}$ ,  $\sin\delta_{K\pi} = -0.01 \pm 0.49 \pm 0.04$ , and World Averages for the mixing parameters from an “extended” fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [60]. These fits allow  $\cos\delta_{K\pi}$ ,  $\sin\delta_{K\pi}$  and  $x^2$  to be unphysical. Constraining

## $D^0$

$\cos \delta_{K\pi}$  and  $\sin \delta_{K\pi}$  to  $[-1, +1]$ —that is interpreting  $\delta_{K\pi}$  as an angle—yields  $\delta_{K\pi} = (18^{+11}_{-17} \pm 7)^\circ$ . Note that measurements of  $y$  (Table 4 and Table 5) and  $y'$  (Table 3) contribute to the determination of  $\delta_{K\pi}$ .

**Summary of Experimental Results:** Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For  $D^0 \rightarrow K^+\pi^-$ , LHCb [15,17], CDF [16], and Belle [14] each exclude the no-mixing hypothesis by more than 5 standard deviations.

For  $y_{CP}$  in  $D^0 \rightarrow K^+K^-$  and  $\pi^+\pi^-$ , Belle [41] and BaBar [42] find  $4.5\sigma$  and  $3.3\sigma$  effects. The most sensitive measurement of  $x$  and  $y$  is in  $D^0 \rightarrow K_S^0\pi^+\pi^-$  from Belle [34] and the no mixing solution is only excluded at  $2.5\sigma$ . In a similar analysis using  $D^0 \rightarrow K_S^0\pi^+\pi^-$  and  $D^0 \rightarrow K_S^0K^+K^-$  BaBar [33] also finds the no mixing solution excluded at  $1.9\sigma$ .

The current situation would benefit from better knowledge of the strong phase difference  $\delta_{K\pi}$  than provided by the current CLEO-c [60] and BESIII [61] results. This would allow one to unfold  $x$  and  $y$  from the  $D^0 \rightarrow K^+\pi^-$  measurements of  $x'^2$  and  $y'$ , and directly compare them to the  $D^0 \rightarrow K_S^0\pi^+\pi^-$  results.

The experimental data consistently indicate that the  $D^0$  and  $\bar{D}^0$  do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to non-Standard Model processes, significant constraints on a variety of new physics models are obtained [64]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. The evidence for time integrated  $CP$ -violation,  $\Delta A_{CP} \neq 0$  is intriguing. This result is marginally consistent with Standard Model expectation [65–67].

### HFAG Averaging of Charm Mixing Results:

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of  $x$ ,  $y$ ,  $\delta_{K\pi}$ ,  $\delta_{K\pi\pi^0}$ ,  $R_D$ ,  $A_D \equiv (R_D^+ - R_D^-)/(R_D^+ + R_D^-)$ ,  $|q/p|$ ,  $\text{Arg}(q/p) \equiv \phi$ , and the time-integrated  $CP$  asymmetries  $A_K$  and  $A_\pi$ . Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of  $D^0 \rightarrow K^{(*)}\ell^-\bar{\nu}$ ,  $K^+K^-$ ,  $\pi^+\pi^-$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ ,  $K_S^0\pi^+\pi^-$ , and  $K_S^0K^+K^-$  decays, as well as CLEO-c and BESIII results for double-tagged branching fractions measured at the  $\psi(3770)$  are used.

For the global fit, confidence contours in the two dimensions  $(x, y)$  and  $(|q/p|, \phi)$  are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to-5  $\sigma$  contours. The fits exclude the no-mixing point ( $x = y = 0$ ) at more than  $11.5\sigma$ , when  $CP$  violation is allowed. The fits are consistent with no  $CP$  violation at the 27% Confidence Level. The parameters  $x$  and  $y$  differ from zero by  $2.1\sigma$  and  $6.8\sigma$ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The

**Figure 1:** Two-dimensional  $1\sigma$ - $5\sigma$  contours for  $(x, y)$  from measurements of  $D^0 \rightarrow K^{(*)}\ell\nu$ ,  $h^+h^-$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ ,  $K_S^0\pi^+\pi^-$ , and  $K_S^0K^+K^-$  decays, and double-tagged branching fractions measured at the  $\psi(3770)$  resonance (from HFAG [24]).

**Table 7:** HFAG Charm Mixing Averages [24].

Parameter	No $CP$ Violation	$CP$ Violation Allowed	95% C.L. Interval
$x(\%)$	$0.49^{+0.14}_{-0.15}$	$0.37 \pm 0.16$	$[0.06, 0.67]$
$y(\%)$	$0.61 \pm 0.08$	$0.66^{+0.07}_{-0.10}$	$[0.46, 0.79]$
$R_D(\%)$	$0.349 \pm 0.004$	$0.349 \pm 0.004$	$[0.342, 0.357]$
$\delta_{K\pi}(\circ)$	$6.9^{+9.7}_{-11.2}$	$11.8^{+9.5}_{-14.7}$	$[-21.1, 29.3]$
$\delta_{K\pi\pi^0}(\circ)$	$18.1^{+23.2}_{-23.8}$	$27.3^{+24.4}_{-25.4}$	$[-23.3, 74.8]$
$A_D(\%)$	—	$-0.39^{+1.01}_{-1.05}$	$[-2.4, 1.5]$
$ q/p $	—	$0.91^{+0.12}_{-0.08}$	$[0.77, 1.14]$
$\phi(\circ)$	—	$-9.4^{+11.9}_{-9.8}$	$[-28.3, 12.9]$
$A_K$	—	$-0.15 \pm 0.14$	$[-0.42, 0.12]$
$A_\pi$	—	$0.10 \pm 0.15$	$[-0.19, 0.38]$

resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 7. The  $\chi^2$  for the HFAG fit is 69 for 45 degrees of freedom indicating some disagreement among the measurements included in the combination.

From the results of the HFAG averaging, the following can be concluded: (1) Since  $CP$  violation is small and  $y_{CP}$  is positive, the  $CP$ -even state is shorter-lived, as in the  $K^0\bar{K}^0$  system; (2) However, since  $x$  appears to be positive, the  $CP$ -even state is heavier, unlike in the  $K^0\bar{K}^0$  system; (3) The strong phase difference  $\delta_{K\pi}$  is consistent with the SU(3) expectation of zero but large values are not excluded; (4) There is no evidence yet for  $CP$ -violation in  $D^0\bar{D}^0$  mixing. Observing  $CP$ -violation in mixing ( $|q/p| \neq 1$ ) at the current level of sensitivity would indicate new physics.

**Figure 2:** Two-dimensional  $1\sigma$ - $5\sigma$  contours for  $(|q/p|, \text{Arg}(q/p))$  from measurements of  $D^0 \rightarrow K^{(*)+} \ell \nu, h^+ h^-, K^+ \pi^-, K^+ \pi^- \pi^0, K^+ \pi^- \pi^+ \pi^-, K_S^0 \pi^+ \pi^-,$  and  $K_S^0 K^+ K^-$  decays, and double-tagged branching fractions measured at the  $\psi(3770)$  resonance (from HFAG [24]).

The author would like to acknowledge helpful input from Bostjan Golob, Marco Gersabeck, and especially Alan Schwartz of the Heavy Flavor Averaging Group.

$$|m_{D_1^0} - m_{D_2^0}| = x \Gamma$$

The  $D_1^0$  and  $D_2^0$  are the mass eigenstates of the  $D^0$  meson, as described in the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above. The experiments usually present  $x \equiv \Delta m/\Gamma$ . Then  $\Delta m = x \Gamma = x \hbar/\tau$ .

“OUR EVALUATION” comes from CPV allowing averages provided by the Heavy Flavor Averaging Group, see the note on “ $D^0$ - $\bar{D}^0$  Mixing.”

<sup>1</sup> Based on  $976 \text{ fb}^{-1}$  of data collected at  $Y(nS)$  resonances. Assumes no  $CP$  violation. Reported  $x'^2 = (0.09 \pm 0.22) \times 10^{-3}$  and  $y' = (4.6 \pm 3.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$ .

<sup>2</sup> The time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$  is employed. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\bar{D}^0 \rightarrow K^{*+} \pi^-$ . This value allows  $CP$  violation and is sensitive to the sign of  $\Delta m$ .

<sup>3</sup> Based on  $3 \text{ fb}^{-1}$  of data collected at  $\sqrt{s} = 7, 8 \text{ TeV}$ . Assumes no  $CP$  violation. Reported  $x'^2 = (5.5 \pm 4.9) \times 10^{-4}$  and  $y' = (4.8 \pm 1.0) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$ .

<sup>4</sup> Based on  $9.6 \text{ fb}^{-1}$  of data collected at the Tevatron. Assumes no  $CP$  violation. Reported  $x'^2 = (0.08 \pm 0.18) \times 10^{-3}$  and  $y' = (4.3 \pm 4.3) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$ .

<sup>5</sup> DEL-AMO-SANCHEZ 10D uses  $540,800 \pm 800 K_S^0 \pi^+ \pi^-$  and  $79,900 \pm 300 K_S^0 K^+ K^-$  events in a time-dependent amplitude analysis of the  $D^0$  and  $\bar{D}^0$  Dalitz plots. No evidence was found for  $CP$  violation, and the values here assume no such violation.

<sup>6</sup> Based on  $1 \text{ fb}^{-1}$  of data collected at  $\sqrt{s} = 7 \text{ TeV}$  in 2011. Assumes no  $CP$  violation. Reported  $x'^2 = (-0.9 \pm 1.3) \times 10^{-4}$  and  $y' = (7.2 \pm 2.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$ .

<sup>7</sup> The AUBERT 09AN values are inferred from the branching ratio  $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0)/\Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$  given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between  $D^0 \rightarrow K^+ \pi^- \pi^0$  and  $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$  is assumed to be small. The width difference here is  $y''$ , which is not the same as  $y_{CP}$  in the note on  $D^0$ - $\bar{D}^0$  mixing.

<sup>8</sup> LOWREY 09 uses quantum correlations in  $e^+ e^- \rightarrow D^0 \bar{D}^0$  at the  $\psi(3770)$ . See below for coherence factors and average relative strong phases for both  $D^0 \rightarrow K^- \pi^+ \pi^0$  and  $D^0 \rightarrow K^- \pi^- \pi^+$ . A fit that includes external measurements of charm mixing parameters gets  $\Delta m = (2.34 \pm 0.61) \times 10^{10} \hbar s^{-1}$ .
