Information on  $\Delta\Gamma_s$  can be obtained from the study of the proper time distribution of untagged  $B_s^0$  samples [49]. In the case of an inclusive  $B_s^0$  selection [50], or a semileptonic (or flavor-specific)  $B_s^0$  decay selection [18,51], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants  $\Gamma_{L,H} = \Gamma_s \pm \Delta\Gamma_s/2$ . In principle, this provides sensitivity to both  $\Gamma_s$  and  $(\Delta\Gamma_s/\Gamma_s)^2$ . Ignoring  $\Delta\Gamma_s$  and fitting for a single exponential leads to an estimate of  $\Gamma_s$  with a relative bias proportional to  $(\Delta\Gamma_s/\Gamma_s)^2$ . An alternative approach, which is directly sensitive to first order in  $\Delta\Gamma_s/\Gamma_s$ , is to determine the effective lifetime of untagged  $B_s^0$  candidates decaying to (fairly pure)  $CP$  eigenstates; measurements exist for  $B_s^0 \rightarrow D_s^{(*)+} D_s^{(*)-}$  [52],  $B_s^0 \rightarrow K^+ K^-$  [53], and  $B_s^0 \rightarrow J/\psi f_0(980)$  [54]. The extraction of  $1/\Gamma_s$  and  $\Delta\Gamma_s$  from such measurements, discussed in detail in Ref. [55], requires additional information in the form of theoretical assumptions

or external inputs on weak phases and hadronic parameters. In what follows, only the effective lifetimes from the decays to the pure  $CP$  eigenstates  $K^+ K^-$  and  $J/\psi f_0(980)$  will be used, under the assumption that these decays are dominated by a single weak phase.

The best sensitivity to  $1/\Gamma_s$  and  $\Delta\Gamma_s$  is achieved by the recent time-dependent measurements of the  $B_s^0 \rightarrow J/\psi\phi$  decay rates performed at CDF [56,57], DØ [58] and LHCb [59,60], where the  $CP$ -even and  $CP$ -odd amplitudes are separated statistically through a full angular analysis. In particular LHCb obtained the first observation of a non-zero value of  $\Delta\Gamma_s$  [60]. These studies use both untagged and tagged  $B_s^0$  candidates and are optimized for the measurement of the  $CP$ -violating phase  $\phi_s$ , defined as the weak phase difference between the  $B_s^0\text{-}\bar{B}_s^0$  mixing amplitude and the  $b \rightarrow c\bar{c}s$  decay amplitude. The Standard Model prediction for  $\phi_s$ , if Penguin pollution is neglected, is equal to  $-2\beta_s = -2 \arg(-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)) = -0.0363^{+0.0016}_{-0.0015}$  [48]. With a Gaussian constraint on  $\phi_s$  to this Standard Model expectation, a combination [8] of the published  $B_s^0 \rightarrow J/\psi\phi$  analyses [56,58,59] and of the lifetime measurements with flavor-specific [18,51] and pure  $CP$  [53,54] final states yields

$$\Delta\Gamma_s = +0.100 \pm 0.013 \text{ ps}^{-1} \quad \text{and} \quad 1/\Gamma_s = 1.497 \pm 0.015 \text{ ps}, \quad (20)$$

or, equivalently,

$$1/\Gamma_L = 1.393 \pm 0.019 \text{ ps} \quad \text{and} \quad 1/\Gamma_H = 1.618 \pm 0.024 \text{ ps}, \quad (21)$$

in good agreement with the Standard Model prediction  $\Delta\Gamma_s = 0.087 \pm 0.021 \text{ ps}^{-1}$  [7].

The positive sign of  $\Delta\Gamma_s$  is due to the constraint applied on  $\phi_s$ . In absence of such constraint, there would be two mirror solutions related by the transformation  $(\Delta\Gamma_s, \phi_s) \rightarrow (-\Delta\Gamma_s, \pi - \phi_s)$ . Recently the LHCb collaboration analyzed the  $B_s^0 \rightarrow J/\psi K^+ K^-$  decay, considering that the  $K^+ K^-$  system can be in a P-wave or S-wave state, and measured the dependence of the strong phase difference between the P-wave and S-wave amplitudes as a function of the  $K^+ K^-$  invariant mass [61]. This allowed, for the first time, the unambiguous determination of the sign of  $\Delta\Gamma_s$ , which was found to be positive at the  $4.7\sigma$  level.

Independent estimates of  $\Delta\Gamma_s/\Gamma_s$  obtained from measurements of the  $B_s^0 \rightarrow D_s^{(*)+} D_s^{(*)-}$  branching fractions [52,62] are no longer included in the average, since they are based on the questionable [7] assumption that these decays account for all  $CP$ -even final states.

#### Average $b$ -hadron mixing probability and $b$ -hadron production fractions at high energy

Mixing measurements can significantly improve our knowledge on the fractions  $f_u$ ,  $f_d$ ,  $f_s$ , and  $f_{\text{baryon}}$ , defined as the fractions of  $B_u$ ,  $B_d^0$ ,  $B_s^0$ , and  $b$ -baryons in an unbiased sample of weakly decaying  $b$  hadrons produced in high-energy collisions.

# Meson Particle Listings

## $B^0$

Indeed, time-integrated mixing analyses using lepton pairs from  $b\bar{b}$  events at high energy measure the quantity

$$\bar{\chi} = f'_d \chi_d + f'_s \chi_s, \quad (22)$$

where  $f'_d$  and  $f'_s$  are the fractions of  $B_d^0$  and  $B_s^0$  hadrons in a sample of semileptonic  $b$ -hadron decays. Assuming that all  $b$  hadrons have the same semileptonic decay width implies  $f'_q = f_q/(\Gamma_q \tau_b)$  ( $q = s, d$ ), where  $\tau_b$  is the average  $b$ -hadron lifetime. Hence  $\bar{\chi}$  measurements performed at LEP [63] and Tevatron [64,65,66], together with the  $\chi_d$  average of Eq. (15) and the very good approximation  $\chi_s = 1/2$  (in fact  $\chi_s = 0.499292 \pm 0.000016$  from Eqs. (5), (16) and (20)), provide constraints on the fractions  $f_d$  and  $f_s$ . In what follows, we use the preliminary  $\bar{\chi}$  result from CDF [65] instead of the published one [64]. Averages based on published data only can be found in the full listings of this *Review*.

The LEP experiments have measured  $\mathcal{B}(\bar{b} \rightarrow B_s^0) \times \mathcal{B}(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell X)$  [67],  $\mathcal{B}(b \rightarrow \Lambda_b^0) \times \mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell X)$  [68], and  $\mathcal{B}(b \rightarrow \Xi_b^-) \times \mathcal{B}(\Xi_b^- \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X)$  [69] from partially reconstructed final states including a lepton,  $f_{\text{baryon}}$  from protons identified in  $b$  events [70], and the production rate of charged  $b$  hadrons [71]. The  $b$ -hadron fraction ratios measured at CDF are based on double semileptonic  $K^* \mu \mu$  and  $\phi \mu \mu$  final states [72] and lepton-charm final states [73]; in addition CDF and DØ have both measured strange  $b$ -baryon production [74]. On the other hand, fraction ratios have been studied by LHCb using fully reconstructed hadronic  $B_s^0$  and  $B_d^0$  decays [75], as well as semileptonic decays [76]. Both CDF and LHCb observe that the ratio  $f_{\Lambda_b^0}/(f_u + f_d)$  decreases with the transverse momentum of the lepton+charm system, indicating that the  $b$ -hadron fractions are not the same in different environments. We therefore provide sets of fractions separately for LEP and Tevatron (and no complete set for LHCb, where strange  $b$ -baryon production has not been measured yet). A combination of all the available information under the constraints  $f_u = f_d$ ,  $f_u + f_d + f_s + f_{\text{baryon}} = 1$ , and Eq. (22), yields the averages shown in Table 1.

**Table 1:**  $\bar{\chi}$  and  $b$ -hadron fractions (see text).

	in $Z$ decays [8]	at Tevatron [8]	at LHCb [76]
$\bar{\chi}$	$0.1259 \pm 0.0042$	$0.127 \pm 0.008$	
$f_u = f_d$	$0.403 \pm 0.009$	$0.330 \pm 0.030$	
$f_s$	$0.103 \pm 0.009$	$0.103 \pm 0.012$	
$f_{\text{baryon}}$	$0.090 \pm 0.015$	$0.236 \pm 0.067$	
$f_s/f_d$	$0.256 \pm 0.025$	$0.311 \pm 0.037$	$0.267^{+0.021}_{-0.020}$

### $CP$ -violation studies

Evidence for  $CP$  violation in  $B_q^0-\bar{B}_q^0$  mixing has been searched for, both with flavor-specific and inclusive  $B_q^0$  decays, in samples where the initial flavor state is tagged, usually with a lepton from the other  $b$ -hadron in the event. In the

case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\text{SL}}^q = \frac{N(\bar{B}_q^0(t) \rightarrow \ell^+ \nu_\ell X) - N(B_q^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)}{N(\bar{B}_q^0(t) \rightarrow \ell^+ \nu_\ell X) + N(B_q^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)} \simeq 1 - |q/p|_q^2 \quad (23)$$

has been measured either in time-integrated analyses at CLEO [37,77], CDF [78] and DØ [79], or in time-dependent analyses at LEP [31,80], BaBar [38,81], Belle [82] and DØ [83]. In the inclusive case, also investigated at LEP [80,84], no final-state tag is used, and the asymmetry [85]

$$\frac{N(B_q^0(t) \rightarrow \text{all}) - N(\bar{B}_q^0(t) \rightarrow \text{all})}{N(B_q^0(t) \rightarrow \text{all}) + N(\bar{B}_q^0(t) \rightarrow \text{all})} \simeq \mathcal{A}_{\text{SL}}^q \left[ \frac{x_q}{2} \sin(\Delta m_q t) - \sin^2 \left( \frac{\Delta m_q t}{2} \right) \right] \quad (24)$$

must be measured as a function of the proper time to extract information on  $CP$  violation.

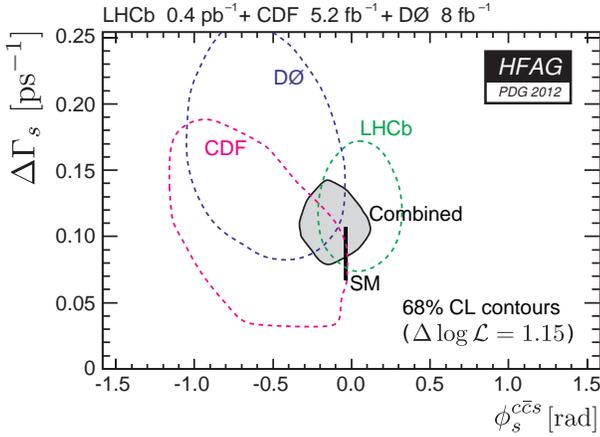

The DØ collaboration measures a like-sign dimuon charge asymmetry in semileptonic  $b$  decays that deviates by  $3.9\sigma$  from the Standard Model prediction [79]. In all other cases, asymmetries compatible with zero (and the Standard Model) have been found, with a precision limited by the available statistics. Most of the analyses at high energy don't disentangle the  $B_d^0$  and  $B_s^0$  contributions, and either quote a mean asymmetry or a measurement of  $\mathcal{A}_{\text{SL}}^d$  assuming  $\mathcal{A}_{\text{SL}}^s = 0$ : we no longer include these in the average. An exception is the latest dimuon DØ analysis [79], which separates the two contributions by exploiting their dependence on the muon impact parameter cut. The resulting measurements of  $\mathcal{A}_{\text{SL}}^d$  and  $\mathcal{A}_{\text{SL}}^s$  are then both compatible with the Standard Model. They are also correlated. We therefore perform a two-dimensional average of all published measurements [37,38,77,79,81–83] and obtain [8]

$$\mathcal{A}_{\text{SL}}^d = -0.0033 \pm 0.0033, \quad \text{or } |q/p|_d = 1.0017 \pm 0.0017, \quad (25)$$

$$\mathcal{A}_{\text{SL}}^s = -0.0105 \pm 0.0064, \quad \text{or } |q/p|_s = 1.0052 \pm 0.0032, \quad (26)$$

with a correlation coefficient of  $-0.57$  between  $\mathcal{A}_{\text{SL}}^d$  and  $\mathcal{A}_{\text{SL}}^s$ . These results show no evidence of  $CP$  violation and don't constrain yet the Standard Model.

$CP$  violation induced by  $B_s^0-\bar{B}_s^0$  mixing in  $b \rightarrow c\bar{c}s$  decays has been a field of very active study in the past couple of years. In addition to the previously mentioned  $B_s^0 \rightarrow J/\psi \phi$  studies, the recently observed  $CP$ -odd decay mode  $B_s^0 \rightarrow J/\psi \phi(980)$ ,  $f_0(980) \rightarrow \pi^+ \pi^-$  has also been analyzed by LHCb to measure  $\phi_s$ , without the need for an angular analysis [86]. A two-dimensional fit [8] of all published analyses [56,58,59,86] in the  $(\phi_s, \Delta\Gamma_s)$  plane, shown on Fig. 2, yields  $\phi_s = -0.14^{+0.16}_{-0.11}$ . This is consistent with the Standard Model expectation, although with a large uncertainty. The fit is then repeated, but using the external constraint provided by the measured semileptonic asymmetry of Eq. (26), which depends on  $\Delta\Gamma_s$  and on the mixing phase difference  $\phi_M - \phi_\Gamma - \pi = \arg(-M_{12}/\Gamma_{12})$  of Eq. (8). Since New Physics is expected to affect  $\arg(-M_{12}/\Gamma_{12})$

**Figure 2:** 68% CL contours in the  $(\phi_s, \Delta\Gamma_s)$  plane, showing the measurements from CDF [56], DØ [58] and LHCb [59,86], with their combination [8]. The unphysical mirror solution with  $\Delta\Gamma_s < 0$  [61] is not shown. The thin rectangle represents the Standard Model predictions of  $\phi_s$  [48] and  $\Delta\Gamma_s$  [7].

and  $\phi_s$  in the same way, the constraint is implemented under the assumption that a new phase in  $B_s^0$  mixing would not change the difference  $\arg(-M_{12}/\Gamma_{12}) - \phi_s$  from its Standard Model value [7]. The result is [8]

$$\phi_s = -0.17^{+0.14}_{-0.11}, \quad (27)$$

still not showing any sign of  $CP$  violation or New Physics. The precision on this average will soon improve significantly. Indeed it does not include yet the preliminary updates of CDF [57] and LHCb [60], nor a new preliminary LHCb measurement using  $B_s^0 \rightarrow J/\psi\pi^+\pi^-$  decays [87]. The LHCb preliminary combined value is  $\phi_s = -0.002 \pm 0.083(\text{stat}) \pm 0.027(\text{syst})$  [60].

### Summary

$B^0-\bar{B}^0$  mixing has been and still is a field of intense study. While relatively little experimental progress was achieved in the  $B_d^0$  sector during the past years, impressive new  $B_s^0$  results became available from CDF, DØ and LHCb. The mass difference in the  $B_s^0-\bar{B}_s^0$  system is now known to a relative precision which is significantly better than that in the  $B_d^0-\bar{B}_d^0$  system. The non-zero decay width difference in the  $B_s^0-\bar{B}_s^0$  system is now firmly established, with a relative difference of  $(15 \pm 2)\%$ . Its sign has been determined: the heavy state of the  $B_s^0-\bar{B}_s^0$  system lives longer than the light state. In contrast, the relative decay width difference in the  $B_d^0-\bar{B}_d^0$  system,  $(1.5 \pm 1.8)\%$ , is still consistent with zero.  $CP$  violation in mixing has not been observed yet, with precisions on the semileptonic asymmetries below 1%. A quantum step has been achieved in the measurement of the mixing-induced phase  $\phi_s$  in  $B_s^0$  decays proceeding through the  $b \rightarrow c\bar{c}s$  transition, with a Gaussian uncertainty reaching the 0.1 radian level. Despite these significant improvements, all observations remain consistent with the Standard Model expectations.

However, the measurements where New Physics might show up are still statistically limited. More results are expected in the future, especially from LHCb in the  $B_s^0$  sector, with promising prospects for the investigation of the  $CP$ -violating phase  $\arg(-M_{12}/\Gamma_{12})$  and an expected uncertainty on  $\phi_s$  of  $\sim 0.05$  radian by the time of the next edition of this *Review*.

Mixing studies have clearly reached the stage of precision measurements, where much effort is needed, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the  $B_d^0$  and  $B_s^0$  mixing amplitudes (magnitudes and phases) with all other measured flavor-physics observables will be possible within the Standard Model, leading to very tight limits on (or otherwise a long-awaited surprise about) New Physics.

**$B^0-\bar{B}^0$  MIXING PARAMETERS**

For a discussion of  $B^0-\bar{B}^0$  mixing see the note on “ $B^0-\bar{B}^0$  Mixing” in the  $B^0$  Particle Listings above.

$\chi_d$  is a measure of the time-integrated  $B^0-\bar{B}^0$  mixing probability that a produced  $B^0(\bar{B}^0)$  decays as a  $\bar{B}^0(B^0)$ . Mixing violates  $\Delta B \neq 2$  rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B_H^0} - m_{B_L^0}) \tau_{B^0}$$

where  $H, L$  stand for heavy and light states of two  $B^0$  CP eigenstates and  $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B_H^0} + \Gamma_{B_L^0})}$ .

**$\chi_d$**

This  $B^0-\bar{B}^0$  mixing parameter is the probability (integrated over time) that a produced  $B^0$  (or  $\bar{B}^0$ ) decays as a  $\bar{B}^0$  (or  $B^0$ ), e.g. for inclusive lepton decays

$$\chi_d = \frac{\Gamma(B^0 \rightarrow \ell^- X \text{ (via } \bar{B}^0)) / \Gamma(B^0 \rightarrow \ell^\pm X)}{\Gamma(\bar{B}^0 \rightarrow \ell^+ X \text{ (via } B^0)) / \Gamma(\bar{B}^0 \rightarrow \ell^\pm X)}$$

Where experiments have measured the parameter  $r = \chi/(1-\chi)$ , we have converted to  $\chi$ . Mixing violates the  $\Delta B \neq 2$  rule.

Note that the measurement of  $\chi$  at energies higher than the  $\Upsilon(4S)$  have not separated  $\chi_d$  from  $\chi_s$  where the subscripts indicate  $B^0(\bar{D}^0)$  or  $B_s^0(\bar{B}_s^0)$ . They are listed in the  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section.

The experiments at  $\Upsilon(4S)$  make an assumption about the  $B^0\bar{B}^0$  fraction and about the ratio of the  $B^\pm$  and  $B^0$  semileptonic branching ratios (usually that it equals one).

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements, includes  $\chi_d$  calculated from  $\Delta m_{B^0}$  and  $\tau_{B^0}$ .

- <sup>1</sup> BEHRENS 00B uses high-momentum lepton tags and partially reconstructed  $\bar{B}^0 \rightarrow D^{*+} \pi^-, \rho^-$  decays to determine the flavor of the B meson.
- <sup>2</sup> ALBRECHT 94 reports  $r=0.194 \pm 0.062 \pm 0.054$ . We convert to  $\chi$  for comparison. Uses tagged events (lepton + pion from  $D^*$ ).
- <sup>3</sup> BARTELT 93 analysis performed using tagged events (lepton+pion from  $D^*$ ). Using dilepton events they obtain  $0.157 \pm 0.016 \pm_{-0.028}^{+0.033}$ .
- <sup>4</sup> ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of  $r = 20.6 \pm 7.0\%$  is directly measured. The value can be used to measure  $x = \Delta M/\Gamma = 0.72 \pm 0.15$  for the  $B_d$  meson. Assumes  $f_{+,-}/f_0 = 1.0 \pm 0.05$  and uses  $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14) (f_{+,-}/f_0)$ .
- <sup>5</sup> Uses  $D^{*+} K^\pm$  correlations.
- <sup>6</sup> Uses  $(D^{*+} \ell^-) K^\pm$  correlations.
- <sup>7</sup> These experiments see a combination of  $B_s$  and  $B_d$  mesons.
- <sup>8</sup> ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures  $r=0.21 \pm 0.08$ . We convert to  $\chi$  for comparison. Superseded by ALBRECHT 92L.
- <sup>9</sup> BEAN 87B measured  $r < 0.24$ ; we converted to  $\chi$ .
- <sup>10</sup> Same-sign dilepton events. Limit assumes semileptonic BR for  $B^+$  and  $B^0$  equal. If  $B^0/B^\pm$  ratio  $< 0.58$ , no limit exists. The limit was corrected in BEAN 87B from  $r < 0.30$  to  $r < 0.37$ . We converted this limit to  $\chi$ .

**$\Delta m_{B^0} = m_{B_H^0} - m_{B_L^0}$**

$\Delta m_{B^0}$  is a measure of  $2\pi$  times the  $B^0-\bar{B}^0$  oscillation frequency in time-dependent mixing experiments.

The second “OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first “OUR EVALUATION”, also provided by the HFAG, includes  $\Delta m_d$  calculated from  $\chi_d$  measured at  $\Upsilon(4S)$ .

1 Measured using  $B^0 \rightarrow D^-\pi^+$ .2 Uses opposite-side flavor-tagging with  $B \rightarrow D^{(*)}\mu\nu\mu X$  events.3 Measured using a simultaneous fit of the  $B^0$  lifetime and  $\bar{B}^0$  oscillation frequency  $\Delta m_d$  in the partially reconstructed  $B^0 \rightarrow D^{*+}\ell\nu$  decays.4 Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.

5 Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

6 HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports  $f_+/f_0 = 1.01 \pm 0.03 \pm 0.09$  and  $CPT$  violation parameters in  $B^0\text{-}\bar{B}^0$  mixing.7 ZHENG 03 data analyzed using partially reconstructed  $\bar{B}^0 \rightarrow D^{*+}\pi^+$  decay and a flavor tag based on the charge of the lepton from the accompanying  $B$  decay.8 Uses a tagged sample of fully-reconstructed neutral  $B$  decays at  $\Upsilon(4S)$ .9 Measured based on the time evolution of dilepton events in  $\Upsilon(4S)$  decays.10 Data analyzed using partially reconstructed  $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}$  decay and a combination of flavor tags from the rest of the event.

11 Uses di-muon events.

12 Uses jet-charge and lepton-flavor tagging.

13 Uses  $\ell^-D^{*+}\ell$  events.14 Uses  $\pi-B$  in the same side.15 Uses  $\ell\text{-}\ell$ .16 Uses  $\ell\text{-}Q_{\text{hem}}$ .17 Uses  $\ell\text{-}\ell$  with impact parameters.18 Uses  $D^{*+}\text{-}Q_{\text{hem}}$ .19 Uses  $\pi_s^{\pm}\text{-}\ell\text{-}Q_{\text{hem}}$ .20 Uses  $D^{*+}\text{-}\ell/Q_{\text{hem}}$ .21 Uses  $D^{*+}\text{-}\ell\text{-}Q_{\text{hem}}$ .22 Uses  $D^{*+}\text{-}\ell$ .23 AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed  $B^0 \rightarrow D^{*+}(2010)^-\ell\nu$  and simultaneously measures the lifetime and oscillation frequency.

24 AUBERT 02n result based on the same analysis and data sample reported in AUBERT 02i.

25 Uses a tagged sample of  $B^0$  decays reconstructed in the mode  $B^0 \rightarrow D^{*+}\ell\nu$ .26 Uses a tagged sample of fully-reconstructed hadronic  $B^0$  decays at  $\Upsilon(4S)$ .27 ACCIARRI 98D combines results from  $\ell\text{-}\ell$ ,  $\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$  with impact parameters.28 ABREU 97N combines results from  $D^{*+}\text{-}Q_{\text{hem}}$ ,  $\ell\text{-}Q_{\text{hem}}$ ,  $\pi_s^{\pm}\text{-}\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$ .29 ACKERSTAFF 97v combines results from  $\ell\text{-}\ell$ ,  $\ell\text{-}Q_{\text{hem}}$ ,  $D^{*+}\text{-}\ell$ , and  $D^{*+}\text{-}Q_{\text{hem}}$ .30 BUSKULIC 97D combines results from  $D^{*+}\text{-}\ell/Q_{\text{hem}}$ ,  $\ell\text{-}Q_{\text{hem}}$ , and  $\ell\text{-}\ell$ .

31 ABREU 96Q analysis performed using lepton, kaon, and jet-charge tags.

32 ALEXANDER 96v combines results from  $D^{*+}\text{-}\ell$  and  $D^{*+}\text{-}\ell\text{-}Q_{\text{hem}}$ .33 AKERS 95j combines results from charge measurement,  $D^{*+}\text{-}\ell\text{-}Q_{\text{hem}}$  and  $\ell\text{-}\ell$ . $\chi_d = \Delta m_{B^0}/\Gamma_{B^0}$ 

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes  $\chi_d$  measured at  $\Upsilon(4S)$ .

3.8 ±2.9 ±2.5 3 AUBERT,B 04c BABR Repl. by AUBERT 06T

-3 ±1 ±3 4 HASTINGS 03 BELL Repl. by HIGUCHI 12

1 Measured using  $B^0 \rightarrow J/\psi K_S^0$ ,  $J/\psi K_L^0$ ,  $D^-\pi^+$ ,  $D^{*+}\pi^+$ ,  $D^{*+}\rho^+$ , and  $D^{*+}\ell^+\nu$  decays.2 Assuming  $\Delta\Gamma = 0$ , the result becomes  $\text{Im}(z) = -0.0037 \pm 0.0046$ .3 Corresponds to 90% confidence range  $[-0.028, 0.104]$ .4 Measured using inclusive dilepton events from  $B^0$  decay.

## CP VIOLATION PARAMETERS

 $\text{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$ 

$CP$  impurity in  $B^0$  system. It is obtained from either  $a_{\ell\ell}$ , the charge asymmetry in like-sign dilepton events or  $a_{CP}$ , the time-dependent asymmetry of inclusive  $B^0$  and  $\bar{B}^0$  decays.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements. It assumes there is no  $CP$  violation in  $B_s$  mixing.

The first "OUR EVALUATION", also provided by the HFAG, uses the measurements from  $B$ -factories only.

See key on page 457

$< 45$	12 BARTELT	93 CLE2	$e^+e^- \rightarrow \Upsilon(4S)$

- 1 Uses the dimuon charge asymmetry with different impact parameters from which it reports  $A_{SL}^d = (-1.2 \pm 5.2) \times 10^{-3}$ .
- 2 AUBERT 06T reports  $|q/p| - 1 = (-0.8 \pm 2.7 \pm 1.9) \times 10^{-3}$ . We convert to  $(1 - |q/p|^2)/4$ .
- 3 Uses the charge asymmetry in like-sign dilepton events and reports  $|q/p| = 1.0005 \pm 0.0040 \pm 0.0043$ .
- 4 AUBERT 02k uses the charge asymmetry in like-sign dilepton events.
- 5 BARATE 01D measured by investigating time-dependent asymmetries in semileptonic and fully inclusive  $B^0$  decays.
- 6 JAFFE 01 finds  $a_{\ell\ell} = 0.013 \pm 0.050 \pm 0.005$  and combines with the previous BEHRENS 00b independent measurement.
- 7 Data analyzed using the time-dependent asymmetry of inclusive  $B^0$  decay. The production flavor of  $B^0$  mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.
- 8 ACKERSTAFF 97u assumes  $CP$  and is based on measuring the charge asymmetry in a sample of  $B^0$  decays defined by lepton and  $Q_{\text{hem}}$  tags. If  $CP$  is not invoked,  $\text{Re}(\epsilon_B) = -0.006 \pm 0.010 \pm 0.006$  is found. The indirect  $CP$  violation parameter is determined to  $\text{Im}(\delta B) = -0.020 \pm 0.016 \pm 0.006$ .
- 9 Uses the dimuon charge asymmetry.
- 10 AUBERT 04c reports  $|q/p| = 1.029 \pm 0.013 \pm 0.011$  and we converted it to  $(1 - |q/p|^2)/4$ .
- 11 BEHRENS 00b uses high-momentum lepton tags and partially reconstructed  $\bar{B}^0 \rightarrow D^{*+} \pi^-, \rho^-$  decays to determine the flavor of the  $B$  meson.
- 12 BARTELT 93 finds  $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$  which corresponds to  $|a_{\ell\ell}| < 0.18$ , which yields the above  $|\text{Re}(\epsilon_{B^0})/(1 + |\epsilon_{B^0}|^2)|$ .

 $A_{T/CP}$  $A_{T/CP}$  is defined as

$$\frac{P(\bar{B}^0 \rightarrow B^0) - P(B^0 \rightarrow \bar{B}^0)}{P(\bar{B}^0 \rightarrow B^0) + P(B^0 \rightarrow \bar{B}^0)}$$

the  $CP$ -invariant asymmetry between the oscillation probabilities  $P(\bar{B}^0 \rightarrow B^0)$  and  $P(B^0 \rightarrow \bar{B}^0)$ .

<sup>1</sup> Uses Dalitz plot analysis of  $B^0 \rightarrow K^0 \pi^+ \pi^-$  decays and the first of two equivalent solutions.

<sup>2</sup> Measurement based on  $B^0 \rightarrow c\bar{c}K^{(*)0}$  decays.

<sup>3</sup> Based on  $B^0 \rightarrow \psi(2S)K_S^0$  decays.

<sup>4</sup> Measurement in which the  $J/\psi$  decays to hadrons or to muons that do not satisfy the standard identification criteria.

<sup>5</sup> AFFOLDER 00C uses about 400  $B^0 \rightarrow J/\psi(1S)K_S^0$  events. The production flavor of  $B^0$  was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.

<sup>6</sup> BARATE 00Q uses 23 candidates for  $B^0 \rightarrow J/\psi(1S)K_S^0$  decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the  $B^0$  production flavor.

<sup>7</sup> ACKERSTAFF 98Z uses 24 candidates for  $B_d^0 \rightarrow J/\psi(1S)K_S^0$  decay. A combination of jet-charge and vertex-charge techniques were used to tag the  $B_d^0$  production flavor.

<sup>8</sup> Measurement based on  $152 \times 10^6 B\bar{B}$  pairs.

<sup>9</sup> Measurement based on  $227 \times 10^6 B\bar{B}$  pairs.

<sup>10</sup> ABE 02U result is based on the same analysis and data sample reported in ABE 01G.

<sup>11</sup> ABE 02Z result is based on  $85 \times 10^6 B\bar{B}$  pairs.

<sup>12</sup> AUBERT 02N result based on the same analysis and data sample reported in AUBERT 01B.

<sup>13</sup> AUBERT 02P result is based on  $88 \times 10^6 B\bar{B}$  pairs.

<sup>14</sup> First observation of CP violation in  $B^0$  meson system.

<sup>15</sup> ABE 98U uses  $198 \pm 17 B_d^0 \rightarrow J/\psi(1S)K_S^0$  events. The production flavor of  $B^0$  was determined using the same side tagging technique.

### $C_{J/\psi(nS)K^0}(B^0 \rightarrow J/\psi(nS)K^0)$

"OUR EVALUATION" is an average using rescaled values of the data listed below.

The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

<sup>1</sup> Uses fully reconstructed  $B^0 \rightarrow D^{(*)\pm} \pi^\mp$  and  $D^\pm \rho^\mp$  decays and some theoretical assumptions.

<sup>2</sup> Combines the results from fully reconstructed and partially reconstructed  $D^{(*)} \pi$  events by taking weighted averages. Assumes that systematic errors from physics parameters and fit biases in the two measurements are 100% correlated.

<sup>3</sup> Uses partially reconstructed  $B^0 \rightarrow D^{*\pm} \pi^\mp$  decays and some theoretical assumptions.

<sup>4</sup> Uses fully reconstructed  $B^0 \rightarrow D^{(*)\pm} \pi^\mp$  decays and some theoretical assumptions, such as the SU(3) symmetry relation.

<sup>5</sup> Combining this measurement with the results from AUBERT 04V for fully reconstructed  $B^0 \rightarrow D^{(*)\pm} \pi^\mp$  and some theoretical assumptions, such as the SU(3) symmetry relation.

 $2\beta + \gamma$ 

VALUE (°)	DOCUMENT ID	TECN	COMMENT
<b>83 ± 53 ± 20</b>	1 AUBERT	08AC BABR	$e^+ e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Used a time-dependent Dalitz-plot analysis of  $B^0 \rightarrow D^\mp K^0 \pi^\pm$  assuming the ratio of the  $b \rightarrow u$  and  $b \rightarrow c$  decay amplitudes to be 0.3.

 $\gamma(B^0 \rightarrow D^0 K^{*0})$ 

VALUE (°)	DOCUMENT ID	TECN	COMMENT
<b>162 ± 56</b>	1 AUBERT	09R BABR	$e^+ e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Uses Dalitz plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays coming from  $B^0 \rightarrow D^0 K^{*0}$  modes. The corresponding 95% CL interval is  $77^\circ < \gamma < 247^\circ$ . A 180 degree ambiguity is implied.

 $\alpha$ 

For angle  $\alpha$  ( $\phi_2$ ) of the CKM unitarity triangle, see the review on "CP violation" in the reviews section.

102 <sup>+16</sup> <sub>-12</sub> ± 14	6 AUBERT,B	04R BABR	Repl. by AUBERT,B 05C

<sup>1</sup> Obtained using the time dependent analysis of  $B^0 \rightarrow a_1(1260)^\pm \pi^\mp$  and branching fraction measurements of  $B \rightarrow a_1(1260) K$  and  $B \rightarrow K_1 \pi$ .

<sup>2</sup> Based on the favored  $B \rightarrow \rho \rho$  isospin method.

<sup>3</sup> Obtained using isospin relation and selecting a solution closest to the CKM best fit average; the 90% CL allowed interval is  $59^\circ < \phi_2 (\equiv \alpha) < 115^\circ$ .

<sup>4</sup> The angle  $\alpha_{\text{eff}}$  is obtained using the measured CP parameters of  $B^0 \rightarrow a_1(1260)^\pm \pi^\mp$  and choosing one of the four solutions that is compatible with the result of SM-based fits.

<sup>5</sup> Obtained using isospin relation and selecting a solution closest to the CKM best fit average; 90% CL allowed interval is  $79^\circ < \alpha < 123^\circ$ .

<sup>6</sup> Obtained from the measured CP parameters of the longitudinal polarization by selecting the solution closest to the CKM best fit central value of  $\alpha = 95^\circ - 98^\circ$ .

## $B^\pm/B^0$ ADMIXTURE

### B DECAY MODES

The branching fraction measurements are for an admixture of  $B$  mesons at the  $\Upsilon(4S)$ . The values quoted assume that  $B(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$ .

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the treatment of multiple  $D$ 's in the final state must be defined. One possibility would be to count the number of events with one-or-more  $D$ 's and divide by the total number of  $B$ 's. Another possibility would be to count the total number of  $D$ 's and divide by the total number of  $B$ 's, which is the definition of average multiplicity. The two definitions are identical if only one  $D$  is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the  $B$  sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

$\bar{B}$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

## Meson Particle Listings

 $B^\pm/B^0$  ADMIXTURE

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level	
<b>Semileptonic and leptonic modes</b>			
$\Gamma_1$	$e^+ \nu_e$ anything	[a] ( 10.72 $\pm$ 0.13 ) %	
$\Gamma_2$	$\bar{p} e^+ \nu_e$ anything	< 5.9 $\times 10^{-4}$ CL=90%	
$\Gamma_3$	$\mu^+ \nu_\mu$ anything	[a] ( 10.72 $\pm$ 0.13 ) %

$\Gamma_{125}$	$K^*(892)\ell^+\ell^-$	B1	( 1.08 ± 0.11 ) × 10 <sup>-6</sup>	
$\Gamma_{126}$	$K\nu\bar{\nu}$	B1	< 1.4	× 10 <sup>-5</sup> CL=90%
$\Gamma_{127}$	$K^*\nu\bar{\nu}$	B1	< 8	× 10 <sup>-5</sup> CL=90%
$\Gamma_{128}$	$s e^\pm \mu^\mp$	LF	[e] < 2.2	× 10 <sup>-5</sup> CL=90%
$\Gamma_{129}$	$\pi e^\pm \mu^\mp$	LF	< 9.2	× 10 <sup>-8</sup> CL=90%
$\Gamma_{130}$	$\rho e^\pm \mu^\mp$	LF	< 3.2	× 10 <sup>-6</sup> CL=90%
$\Gamma_{131}$	$K e^\pm \mu^\mp$	LF	< 3.8	× 10 <sup>-8</sup> CL=90%
$\Gamma_{132}$	$K^*(892)e^\pm \mu^\mp$	LF	< 5.1	× 10 <sup>-7</sup> CL=90%

[a] These values are model dependent.

[b] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.

[c] Here "anything" means at least one particle observed.

[d]  $D^{**}$  stands for the sum of the  $D(1^1P_1)$ ,  $D(1^3P_0)$ ,  $D(1^3P_1)$ ,  $D(1^3P_2)$ ,  $D(2^1S_0)$ , and  $D(2^1S_1)$  resonances.

[e] The value is for the sum of the charge states or particle/antiparticle states indicated.

[f]  $D^*(\bar{D}^*)$  stands for the sum of  $D^*\bar{D}^*$ ,  $D^*\bar{D}$ ,  $D\bar{D}^*$ , and  $D\bar{D}$ .[g]  $X(3915)$  denotes a near-threshold enhancement in the  $\omega J/\psi$  mass spectrum.

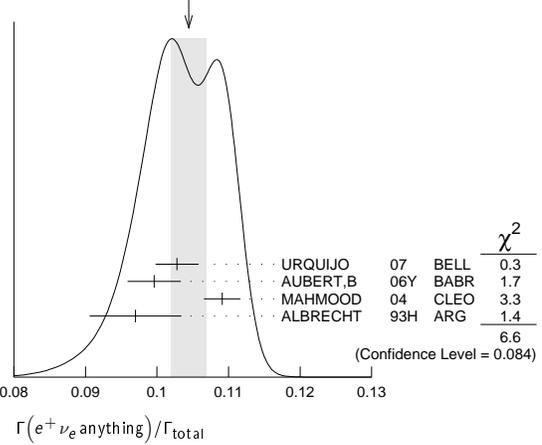

[h] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

<sup>11</sup> YANAGISAWA 91 also measures an average semileptonic branching ratio at the  $\Upsilon(5S)$  of 9.6–10.5% depending on assumptions about the relative production of different  $B$  meson species.

<sup>12</sup> ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

<sup>13</sup> Using data above  $p(e) = 2.4$  GeV, WACHS 89 determine  $\sigma(B \rightarrow e\nu\mu)/\sigma(B \rightarrow e\nu\text{charm}) < 0.065$  at 90% CL.

<sup>14</sup> Ratio  $\sigma(b \rightarrow e\nu\mu)/\sigma(b \rightarrow e\nu\text{charm}) < 0.055$  at CL = 90%.

<sup>1</sup> URQUIJO 07 report a measurement of  $(10.07 \pm 0.18 \pm 0.21)\%$  for the partial branching fraction of  $B \rightarrow e\nu_e X_c$  decay with electron energy above 0.6 GeV. We converted the result to  $B \rightarrow e\nu_e X$  branching fraction.

<sup>2</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .

<sup>3</sup> Uses charge and angular correlations in  $\Upsilon(4S)$  events with a high-momentum lepton and an additional electron.

<sup>4</sup> ALBRECHT 93H analysis performed using tagged semileptonic decays of the  $B$ . This technique is almost model independent for the lepton branching ratio.

<sup>5</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X)/B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

<sup>6</sup> The semileptonic branching ratio,  $|V_{cb}|$  and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

<sup>7</sup> Uses the high-momentum lepton tag method and requires the electron energy above 0.6 GeV.

<sup>8</sup> Uses the high-momentum lepton tag method. They also report  $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$ .

<sup>9</sup> Uses the high-momentum lepton tag method. ABE 02y also reports  $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$ . The second error is due to uncertainties of theoretical inputs.

<sup>10</sup> BARISH 96B analysis performed using tagged semileptonic decays of the  $B$ . This technique is almost model independent for the lepton branching ratio.

- Obtained from a combined fit to the moments of observed spectra in inclusive  $B \rightarrow X_c \ell^+ \nu_\ell$  decay.
- Measured the independent  $B^+$  and  $B^0$  partial branching fractions with electron energy above 0.4 GeV.
- The semileptonic branching ratio,  $|V_{cb}|$  and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

### $\Gamma(X_{cb} \ell^+ \nu_\ell)/\Gamma_{\text{total}}$ $\Gamma_{23}/\Gamma$

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- Obtained from the partial rate  $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$  for the electron momentum interval of 2.0–2.6 GeV/c based on BLNP method.
- Determined from the partial rate  $\Delta B = (4.41 \pm 0.42 \pm 0.42) \times 10^{-4}$  measured for electron energy > 2 GeV and hadronic mass squared < 3.5 GeV<sup>2</sup>, and calculated acceptance 0.174 in that region. The  $V_{ub}$  is measured as  $(4.41 \pm 0.30^{+0.65}_{-0.47} \pm 0.28) \times 10^{-3}$ .
- Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The  $V_{ub}$  is found to be  $(5.08 \pm 0.47^{+0.49}_{-0.48}) \times 10^{-3}$ .
- BORNHEIM 02 uses the observed yield of leptons from semileptonic  $B$  decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on  $B \rightarrow X_S \gamma$ . The  $V_{ub}$  is found to be  $(4.08 \pm 0.34 \pm 0.53) \times 10^{-3}$ .
- Uses a multivariate analysis method and requires lepton momentum in the  $B$  rest frame,  $p_T^{*B} > 1.0$  GeV/c.
- Measures several partial branching fractions in different phase space regions. The most precise result is obtained in the region for hadronic mass  $M_X < 1.55$  GeV/c<sup>2</sup>, and is  $\Delta B = (1.18 \pm 0.09 \pm 0.07) \times 10^{-3}$ . The corresponding  $|V_{ub}|$  from the BLNP method is  $(4.27 \pm 0.16 \pm 0.13 \pm 0.30) \times 10^{-3}$ , where the last uncertainty comes from the theoretical prediction of the partial rate in the given phase-space region.
- Used BaBar measurement of Semileptonic branching fraction  $B(B \rightarrow X \ell \nu_\ell) = (10.87 \pm 0.18 \pm 0.30)\%$  to convert the ratio of rates to branching fraction.
- The third error includes the systematics and theoretical errors summed in quadrature.

### $\Gamma(X_{cb} \ell^+ \nu_\ell)/\Gamma(\ell^+ \nu_\ell \text{ anything})$ $\Gamma_{23}/\Gamma_4$

$\ell$  denotes  $e$  or  $\mu$ , not the sum. These experiments measure this ratio in very limited momentum intervals.

<b>2.06 ± 0.25 ± 0.42</b>			<sup>1</sup> AUBERT	04i BABR	$e^+ e^- \rightarrow \Upsilon(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
			<sup>2</sup> ALBRECHT	94c ARG	$e^+ e^- \rightarrow \Upsilon(4S)$
	107		<sup>3</sup> BARTELT	93B CLE2	$e^+ e^- \rightarrow \Upsilon(4S)$
	77		<sup>4</sup> ALBRECHT	91c ARG	$e^+ e^- \rightarrow \Upsilon(4S)$
	41		<sup>5</sup> ALBRECHT	90 ARG	$e^+ e^- \rightarrow \Upsilon(4S)$
	76		<sup>6</sup> FULTON	90 CLEO	$e^+ e^- \rightarrow \Upsilon(4S)$
<4.0	90		<sup>7</sup> BEHRENDIS	87 CLEO	$e^+ e^- \rightarrow \Upsilon(4S)$
<4.0	90		CHEN	84 CLEO	Direct $e$ at $\Upsilon(4S)$
<5.5	90		KLOPFEN...	83B CUSB	Direct $e$ at $\Upsilon(4S)$

- The third error includes the systematics and theoretical errors summed in quadrature.
- ALBRECHT 94c find  $\Gamma(b \rightarrow c)/\Gamma(b \rightarrow \text{all}) = 0.99 \pm 0.02 \pm 0.04$ .
- BARTELT 93B (CLEO II) measures an excess of  $107 \pm 15 \pm 11$  leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to  $b \rightarrow u \ell \nu_\ell$ . This corresponds to a model-dependent partial branching ratio  $\Delta B_{ub}$  between  $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$ , as evaluated using the KS model (KOERNER 88), and  $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$  using the ACCMM model (ARTUSO 93). The corresponding values of  $|V_{ub}|/|V_{cb}|$  are  $0.056 \pm 0.006$  and  $0.076 \pm 0.008$ , respectively.
- ALBRECHT 91c result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the  $b \rightarrow u$  transition. Using the model of ALTARELLI 82, they obtain  $|V_{ub}|/|V_{cb}| = 0.11 \pm 0.012$  from 77 leptons in the 2.3–2.6 GeV momentum range.

<sup>5</sup> ALBRECHT 90 observes  $41 \pm 10$  excess  $e$  and  $\mu$  (lepton) events in the momentum interval  $p = 2.3\text{--}2.6$  GeV signaling the presence of the  $b \rightarrow u$  transition. The events correspond to a model-dependent measurement of  $|V_{ub}|/|V_{cb}| = 0.10 \pm 0.01$ .

<sup>6</sup> FULTON 90 observe  $76 \pm 20$  excess  $e$  and  $\mu$  (lepton) events in the momentum interval  $p = 2.4\text{--}2.6$  GeV signaling the presence of the  $b \rightarrow u$  transition. The average branching ratio,  $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$ , corresponds to a model-dependent measurement of approximately  $|V_{ub}|/|V_{cb}| = 0.1$  using  $B(b \rightarrow c \ell \nu) = 10.2 \pm 0.2 \pm 0.7\%$ .

<sup>7</sup> The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on  $|V_{ub}|/|V_{cb}| < 0.20$ . While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

### $\Gamma(K^+ \ell^+ \nu_\ell \text{ anything})/\Gamma(\ell^+ \nu_\ell \text{ anything})$ $\Gamma_{24}/\Gamma_4$

<sup>1</sup> GIBBONS 97B reports  $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$  using CLEO measured  $D$  and  $D^*$  branching fractions. We rescale to our PDG 96 values of  $D$  and  $D^*$  branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>2</sup> ALBRECHT 96D reports  $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.196 \pm 0.019$  using CLEO measured  $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.681 \pm 0.01 \pm 0.013$ ,  $B(D^0 \rightarrow K^- \pi^+) = 0.0401 \pm 0.0014$ ,  $B(D^0 \rightarrow K^- \pi^+ \pi^+ \pi^-) = 0.081 \pm 0.005$ . We rescale to our PDG 96 values of  $D$  and  $D^*$  branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>3</sup> BORTOLETTO 92 reports  $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.25 \pm 0.03 \pm 0.04$  using MARK II  $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.57 \pm 0.06$  and  $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.008$ . We rescale to our PDG 96 values of  $D$  and  $D^*$  branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>4</sup> ALBRECHT 91H reports  $0.348 \pm 0.060 \pm 0.035$  from a measurement of  $[\Gamma(B \rightarrow D^*(2010)^\pm \text{ anything})/\Gamma_{\text{total}}] \times [B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm)]$  assuming  $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.55 \pm 0.04$ , which we rescale to our best value  $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90  $B(D^0 \rightarrow K^- \pi^+) = 0.0371 \pm 0.0025$ .

<sup>5</sup> BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios  $B(D^0 \rightarrow K^- \pi^+) = 0.056 \pm 0.004 \pm 0.003$  and also assumes  $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.60 \pm 0.08$ . The product branching ratio for  $B(B \rightarrow D^*(2010)^\pm) B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm)$  is  $0.13 \pm 0.02 \pm 0.012$ . Superseded by BORTOLETTO 92.

<sup>6</sup>  $V-A$  momentum spectrum used to extrapolate below  $p = 1$  GeV. We correct the value assuming  $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.006$  and  $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.6 \pm 0.08$ . The product branching fraction is  $B(B \rightarrow D^*(2010)^\pm) B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = (68 \pm 15 \pm 9) \times 10^{-4}$ .

• • • We do not use the following data for averages, fits, limits, etc. • • •

0.0080 ± 0.0008 <sup>3</sup> BALEST 95B CLE2  $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> AUBERT 03F also reports the helicity of  $J/\psi \rightarrow \ell^+\ell^-$  produced directly in  $B$  decay.

<sup>2</sup> Also reports the measurement of  $J/\psi \rightarrow \ell^+\ell^-$  polarization produced directly from  $B$  decay.

<sup>3</sup> BALEST 95B assume PDG 1994 values for sub mode branching ratios.  $J/\psi(1S)$  mesons are reconstructed in  $J/\psi(1S) \rightarrow e^+e^-$  and  $J/\psi(1S) \rightarrow \mu^+\mu^-$ . The  $B \rightarrow J/\psi(1S)X$  branching ratio contains  $J/\psi(1S)$  mesons directly from  $B$  decays and also from feeddown through  $\psi(2S) \rightarrow J/\psi(1S)$ ,  $\chi_{c1}(1P) \rightarrow J/\psi(1S)$ , or  $\chi_{c2}(1P) \rightarrow J/\psi(1S)$ . Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the  $B \rightarrow J/\psi(1S) \text{ (direct) } X$  branching ratio.

<sup>1</sup> ABE 02L uses PDG 01 values for  $B(J/\psi(1S) \rightarrow \ell^+\ell^-)$  and  $B(\chi_{c1,c2} \rightarrow J/\psi(1S)\gamma)$ .

<sup>2</sup> CHEN 01 reports  $0.00383 \pm 0.00031 \pm 0.00040$  from a measurement of  $[\Gamma(B \rightarrow \chi_{c1}(1P)(\text{direct anything})/\Gamma_{\text{total}}) \times [B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S))] \text{ assuming } B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S)) = 0.273 \pm 0.016, \text{ which we rescale to our best value } B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S)) = (34.4 \pm 1.5) \times 10^{-2}.$  Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>3</sup> BALEST 95B assume PDG 1994 values.  $J/\psi(1S)$  mesons are reconstructed in the  $e^+e^-$  and  $\mu^+\mu^-$  modes. The  $B \rightarrow \chi_{c1}(1P)X$  branching ratio contains  $\chi_{c1}(1P)$  mesons directly from  $B$  decays and also from feeddown through  $\psi(2S) \rightarrow \chi_{c1}(1P)\gamma$ . Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the  $B \rightarrow \chi_{c1}(1P)(\text{direct})X$  branching ratio.

seen <sup>2</sup> BRODY 82 CLEO  $e^+e^- \rightarrow \Upsilon(4S)$

seen <sup>3</sup> GIANNINI 82 CUSB  $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> ALBRECHT 93I value is not independent of the sum of  $B \rightarrow K^+$  anything and  $B \rightarrow K^-$  anything ALBRECHT 94C values.

<sup>2</sup> Assuming  $\Upsilon(4S) \rightarrow B\bar{B}$ , a total of  $3.38 \pm 0.34 \pm 0.68$  kaons per  $\Upsilon(4S)$  decay is found (the second error is systematic). In the context of the standard  $B$ -decay model, this leads to a value for  $(b\text{-quark} \rightarrow c\text{-quark})/(b\text{-quark} \rightarrow \text{all})$  of  $1.09 \pm 0.33 \pm 0.13$ .

<sup>3</sup> GIANNINI 82 at CESR-CUSB observed  $1.58 \pm 0.35$   $K^0$  per hadronic event much higher than  $0.82 \pm 0.10$  below threshold. Consistent with predominant  $b \rightarrow cX$  decay.

$<0.068$	90		<sup>1</sup> COAN 98	CLE2	$e^+e^- \rightarrow \Upsilon(4S)$
$<0.08$			<sup>2</sup> ALBRECHT 95D	ARG	$e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> COAN 98 uses  $D$ - $\ell$  correlation.  
<sup>2</sup> ALBRECHT 95D use full reconstruction of one  $B$  decay as tag. Two candidate events for charmless  $B$  decay can be interpreted as either  $b \rightarrow s\text{gluon}$  or  $b \rightarrow u$  transition. If interpreted as  $b \rightarrow s\text{gluon}$  they find a branching ratio of  $\sim 0.026$  or the upper limit quoted above. Result is highly model dependent.

4.6 ± 1.1 ± 0.6	<sup>2</sup> BONVICINI	03	CLE2 $e^+e^- \rightarrow \Upsilon(4S)$

• • • We do not use the following data for averages, fits, limits, etc. • • •

6.2 ± 1.6 <sup>+1.3</sup> <sub>-2.0</sub>	<sup>3</sup> BROWDER	98	CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
---	----------------------	----	--

<sup>1</sup> AUBERT,B 04F reports branching ratio  $B \rightarrow \eta' X_S$  for high momentum  $\eta'$  between 2.0 and 2.7 GeV/c in the  $\Upsilon(4S)$  center-of-mass frame.  $X_S$  represents a recoil system consisting of a kaon and zero to four pions.

<sup>2</sup> BONVICINI 03 observed a signal of  $61.2 \pm 13.9$  events in  $B \rightarrow \eta' X_{nc}$  production for high momentum  $\eta'$  between 2.0 and 2.7 GeV/c in the  $\Upsilon(4S)$  center-of-mass frame. The  $X_{nc}$  denotes "charmless" hadronic states recoiling against  $\eta'$ . The second error combines systematic and background subtraction uncertainties in quadrature.

<sup>3</sup> BROWDER 98 observed a signal of  $39.0 \pm 11.6$  events in high momentum  $B \rightarrow \eta' X_S$  production between 2.0 and 2.7 GeV/c. The branching fraction is based on the interpretation of  $b \rightarrow sg$ , where the last error includes additional uncertainties due to the color-suppressed  $b \rightarrow$  backgrounds.

0.076 ± 0.014	<sup>2</sup> ALBRECHT 89k	ARG	$e^+e^- \rightarrow \Upsilon(4S)$
---------------	---------------------------	-----	-----------------------------------

<sup>1</sup> ALBRECHT 92o result is from simultaneous analysis of  $p$  and  $\Lambda$  yields,  $p\bar{p}$  and  $\Lambda\bar{\Lambda}$  correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89k.

<sup>2</sup> ALBRECHT 89k obtain this result by adding their measurements (5.5 ± 1.6)% for direct protons and (4.2 ± 0.5 ± 0.6)% for inclusive  $\Lambda$  production. They then assume (5.5 ± 1.6)% for neutron production and add it in also. Since each  $B$  decay has two baryons, they divide by 2 to obtain (7.6 ± 1.4)%.

### CP VIOLATION

$A_{CP}$  is defined as

$$\frac{B(\bar{B} \rightarrow \bar{f}) - B(B \rightarrow f)}{B(\bar{B} \rightarrow \bar{f}) + B(B \rightarrow f)},$$

the CP-violation charge asymmetry of inclusive  $B^\pm$  and  $B^0$  decay.

### $A_{CP}(B \rightarrow K^*(892)\gamma)$

$-0.13 \pm 0.04^{+0.02}_{-0.03}$	<sup>1</sup> NISHIMURA	10 BELL	$e^+e^- \rightarrow \Upsilon(4S)$

- Uses  $B \rightarrow \eta X_S$  with  $0.4 < m_{X_S} < 2.6$  GeV/ $c^2$ .

### POLARIZATION IN B DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal ( $L$ ) or both are transverse and parallel ( $\parallel$ ) or perpendicular ( $\perp$ ) to each other with the parameters  $\Gamma_L/\Gamma$ ,  $\Gamma_\perp/\Gamma$ , and the relative phases  $\phi_\parallel$  and  $\phi_\perp$ . See the definitions in the note on "Polarization in B Decays" review in the  $B^0$  Particle Listings.

### LEPTON FORWARD-BACKWARD ASYMMETRY IN $B \rightarrow K^{(*)}\ell^+\ell^-$ DECAY

The forward-backward angular asymmetry of the lepton pair in  $B \rightarrow K^{(*)}\ell^+\ell^-$  decay is defined as

$$A_{FB}(s) = \frac{N(\cos\theta > 0) - N(\cos\theta < 0)}{N(\cos\theta > 0) + N(\cos\theta < 0)},$$

where  $s = q^2/m_B^2$ , and  $\theta$  is the angle of the lepton with respect to the flight direction of the  $B$  meson, measured in the dilepton rest frame. In addition, the fraction of longitudinal polarization  $F_L$  of the  $K^*$  and  $F_{S_1}$ , the relative contribution from scalar and pseudoscalar penguin amplitudes in  $B \rightarrow K\ell^+\ell^-$ , can be measured from the angular distribution of its decay products.

1 The leptons are required to have  $E_l > 1.5 \text{ GeV}$  in the B rest frame. The result with  $E_l > 0.6 \text{ GeV}$  is also given.

$\langle E_\gamma \rangle$

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
<b>2.306 ± 0.014 OUR AVERAGE</b>			
2.311 ± 0.009 ± 0.015	1 LIMOSANI	09	BELL $e^+e^- \rightarrow \Upsilon(4S)$
2.289 ± 0.058 ± 0.027	1,2 AUBERT	08o	BABR $e^+e^- \rightarrow \Upsilon(4S)$
2.309 ± 0.023 ± 0.023	1,3 SCHWANDA	08	BELL $e^+e^- \rightarrow \Upsilon(4S)$
2.288 ± 0.025 ± 0.023	1 AUBERT.BE	06b	BABR $e^+e^- \rightarrow \Upsilon(4S)$

1 The result is for  $E_\gamma > 1.9 \text{ GeV}$ .  
 2 Uses a fully reconstructed B meson as a tag on the recoil side.  
 3 Results for different  $E_\gamma$  threshold values are also measured.

$\langle E_\gamma^2 \rangle - \langle E_\gamma \rangle^2$

VALUE ( $10^{-2} \text{ GeV}^2$ )	DOCUMENT ID	TECN	COMMENT
<b>2.99 ± 0.28 OUR AVERAGE</b>			
3.02 ± 0.19 ± 0.30	1 LIMOSANI	09	BELL $e^+e^- \rightarrow \Upsilon(4S)$

0.98 ± 0.12 ± 0.13	ONG	89	MRK2	$E_{cm}^{90} = 29$ GeV
1.17 $^{+0.27}_{-0.22}$ $^{+0.17}_{-0.16}$	KLEM	88	DLCO	$E_{cm}^{90} = 29$ GeV
1.29 ± 0.20 ± 0.21	25 ASH	87	MAC	$E_{cm}^{90} = 29$ GeV
1.02 $^{+0.42}_{-0.39}$	301 26 BROM	87	HRS	$E_{cm}^{90} = 29$ GeV

- Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.
- Measured using inclusive  $J/\psi(1S) \rightarrow \mu^+ \mu^-$  vertex.
- ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.
- ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.
- BUSKULIC 96F analyzed using 3D impact parameter.
- ABE,K 95b uses an inclusive topological technique.
- ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.
- ACTON 93L and ADRIANI 93K analyzed using lepton ( $e$  and  $\mu$ ) impact parameter at Z.
- BUSKULIC 93o analyzed using dipole method.
- Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.
- From proper time distribution of  $b \rightarrow J/\psi(1S)$  anything.
- ABE 93i analyzed using  $J/\psi(1S) \rightarrow \mu\mu$  vertices.
- ABREU 93d data analyzed using  $D/D^* \ell$  anything event vertices.
- ABREU 93c data analyzed using charged and neutral vertices.
- ACTON 93c analyzed using  $D/D^* \ell$  anything event vertices.
- ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave  $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$  s for an admixture of  $B$  species weighted by production fraction and mean charge multiplicity, while muon tracks gave  $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$  s for an admixture weighted by production fraction and semileptonic branching fraction.
- ACTON 92 is combined result of muon and electron impact parameter analyses.
- BUSKULIC 92f uses the lepton impact parameter distribution for data from the 1991 run.
- BUSKULIC 92g use  $J/\psi(1S)$  tags to measure the average  $b$  lifetime. This is comparable to other methods only if the  $J/\psi(1S)$  branching fractions of the different  $b$ -flavored hadrons are in the same ratio.
- Using  $Z \rightarrow e^+ X$  or  $\mu^+ X$ , ADEVA 91H determined the average lifetime for an admixture of  $B$  hadrons from the impact parameter distribution of the lepton.
- Using  $Z \rightarrow J/\psi(1S) X$ ,  $J/\psi(1S) \rightarrow \ell^+ \ell^-$ , ALEXANDER 91G determined the average lifetime for an admixture of  $B$  hadrons from the decay point of the  $J/\psi(1S)$ .
- Using  $Z \rightarrow e X$  or  $\mu X$ , DECAAMP 91C determines the average lifetime for an admixture of  $B$  hadrons from the signed impact parameter distribution of the lepton.
- HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
- LYONS 90 combine the results of the  $B$  lifetime measurements of ONG 89, BRAUN-SCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
- We have combined an overall scale error of 15% in quadrature with the systematic error of  $\pm 0.7$  to obtain  $\pm 2.1$  systematic error.
- Statistical and systematic errors were combined by BROM 87.

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE MEAN LIFE

Each measurement of the  $B$  mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different  $B$  mean life.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

## $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

### $\bar{b}$ PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of  $B$  mesons and baryons at energies above the  $\Upsilon(4S)$ . Only the highest energy results (LHC, LEP, Tevatron,  $Sp\bar{p}S$ ) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a  $\bar{b}$  initial state.  $b$  modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
------	--------------------------------	-----------------------------------

### PRODUCTION FRACTIONS

The production fractions for weakly decaying  $b$ -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note " $B^0$ - $\bar{B}^0$  Mixing" in the  $B^0$  Particle Listings. The production fractions in  $b$ -hadronic  $Z$  decay or  $p\bar{p}$  collisions at the Tevatron are also listed at the end of the section. Values assume

$$B(\bar{b} \rightarrow B^+) = B(\bar{b} \rightarrow B^0)$$

$$B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\%.$$

The correlation coefficients between production fractions are also reported:

$$\text{cor}(B_s^0, b\text{-baryon}) = -0.277$$

$$\text{cor}(B_s^0, B^\pm=B^0) = -0.119$$

$$\text{cor}(b\text{-baryon}, B^\pm=B^0) = -0.921.$$

The notation for production fractions varies in the literature ( $f_d, d_{B^0}, f(b \rightarrow \bar{B}^0), \text{Br}(b \rightarrow \bar{B}^0)$ ). We use our own branching fraction notation here,  $B(\bar{b} \rightarrow B^0)$ .

Note these production fractions are  $b$ -hadronization fractions, not the conventional branching fractions of  $b$ -quark to a  $B$ -hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

0.114 ± 0.003 ± 0.004	50 BUSKULIC	94G	ALEP $e^+e^- \rightarrow Z$
0.100 ± 0.007 ± 0.007	51 ABREU	93c	DLPH $e^+e^- \rightarrow Z$
0.105 ± 0.006 ± 0.005	52 AKERS	93B	OPAL Repl. by ABBI-ENDI 00E

<sup>43</sup> Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

<sup>44</sup> The experimental systematic and model uncertainties are combined in quadrature.

<sup>45</sup> ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged  $Z \rightarrow b\bar{b}$  sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

<sup>46</sup> ACCIARRI 00 result obtained from a combined fit of  $R_B = \Gamma(Z \rightarrow b\bar{b})/\Gamma(Z \rightarrow \text{hadrons})$  and  $B(b \rightarrow \ell\nu X)$ , using double-tagging method.

<sup>47</sup> ACCIARRI 96c result obtained by a fit to the single lepton spectrum.

<sup>48</sup> Assumes Standard Model value for  $R_B$ .

<sup>49</sup> ABREU 95D give systematic errors  $\pm 0.0019$  (model) and 0.0012 ( $R_c$ ). We combine these in quadrature.

<sup>50</sup> BUSKULIC 94G uses  $e$  and  $\mu$  events. This value is from a global fit to the lepton  $p$  and  $p_T$  (relative to jet) spectra which also determines the  $b$  and  $c$  production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high  $p_T$ , but the lower  $p_T$  portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is  $\pm 0.0026$  and is included in the systematic error.

<sup>51</sup> ABREU 93c event count includes  $ee$  events. Combining  $ee$ ,  $\mu\mu$ , and  $e\mu$  events, they obtain  $0.100 \pm 0.007 \pm 0.007$ .

<sup>52</sup> AKERS 93B analysis performed using single and dilepton events.

$\Gamma(e^+ \nu_e \text{ anything})/\Gamma_{\text{total}}$   $\Gamma_7/\Gamma$

## $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

<sup>60</sup> ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged  $Z \rightarrow b\bar{b}$  sample using artificial neural network techniques. The first error is statistical; the second error is the total systematic error.

<sup>61</sup> ACCIARRI 96c result obtained by a fit to the single lepton spectrum.

<sup>62</sup> Assumes Standard Model value for  $R_B$ .

<sup>63</sup> ABREU 93c event count includes  $\mu\mu$  events. Combining  $e e$ ,  $\mu\mu$ , and  $e\mu$  events, they obtain  $0.100 \pm 0.007 \pm 0.007$ .

<sup>64</sup> ADEVA 91c measure the average  $B(b \rightarrow eX)$  branching ratio using single and double tagged  $b$  enhanced  $Z$  events. Combining  $e$  and  $\mu$  results, they obtain  $0.113 \pm 0.010 \pm 0.006$ . Constraining the initial number of  $b$  quarks by the Standard Model prediction ( $378 \pm 3$  MeV) for the decay of the  $Z$  into  $b\bar{b}$ , the muon result gives  $0.123 \pm 0.003 \pm 0.006$ . They obtain  $0.119 \pm 0.003 \pm 0.006$  when  $e$  and  $\mu$  results are combined. Used to measure the  $b\bar{b}$  width itself, this muon result gives  $394 \pm 9 \pm 22$  MeV and combined with the electron result gives  $385 \pm 7 \pm 22$  MeV.

<sup>65</sup> AKERS 93B analysis performed using single and dilepton events.

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

<sup>84</sup> Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

<sup>85</sup> The experimental systematic and model uncertainties are combined in quadrature.

<sup>86</sup> ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged  $Z \rightarrow b\bar{b}$  sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

<sup>87</sup> ABREU 95D give systematic errors  $\pm 0.0033$  (model) and  $0.0032$  ( $R_c$ ). We combine these in quadrature. This result is from the same global fit as their  $\Gamma(\bar{b} \rightarrow \ell^+ \nu_\ell X)$  data.

<sup>88</sup> BUSKULIC 94G uses  $e$  and  $\mu$  events. This value is from the same global fit as their  $\Gamma(\bar{b} \rightarrow \ell^+ \nu_\ell \text{anything})/\Gamma_{\text{total}}$  data.

<sup>89</sup> AKERS 93B analysis performed using single and dilepton events.

## $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

- <sup>111</sup> Measurement performed using an inclusive identification of  $B$  mesons and the  $D$  candidates.  
<sup>112</sup> Evaluated via summation of exclusive and inclusive channels.  
<sup>113</sup> ABREU 98b results are extracted from a fit to the  $b$ -tagging probability distribution based on the impact parameter.  
<sup>114</sup> BUSKULIC 96 $\nu$  assumes PDG 96 production fractions for  $B^0, B^+, B_s, b$  baryons, and PDG 96 branching ratios for charm decays. This is sum of their inclusive  $\overline{D}^0, D^-, \overline{D}_s,$  and  $\Lambda_c$  branching ratios, corrected to include inclusive  $\Xi_c$  and charmonium.

<sup>133</sup> GROSSMAN 96 limit is derived from the ALEPH BUSKULIC 95 limit  $B(B^+ \rightarrow \tau^+\nu_\tau) < 1.8 \times 10^{-3}$  at CL=90% using conservative simplifying assumptions.

### $\chi_b$ AT HIGH ENERGY

For a discussion of  $B\text{-}\overline{B}$  mixing, see the note on " $B^0\text{-}\overline{B}^0$  Mixing" in the  $B^0$  Particle Listings.

$\chi_b$  is the average  $B\text{-}\overline{B}$  mixing parameter at high-energy  $\chi_b = f_d' \chi_d + f_s' \chi_s$  where  $f_d'$  and  $f_s'$  are the fractions of  $B^0$  and  $B_s^0$  hadrons in an unbiased sample of semileptonic  $b$ -hadron decays.

## Meson Particle Listings

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- 134 Uses the dimuon charge asymmetry. Averaged over the mix of  $b$ -flavored hadrons.
- 135 Measurement performed using events containing a dimuon or an  $e/\mu$  pair.
- 136 The average  $B$  mixing parameter is determined simultaneously with  $b$  and  $c$  forward-backward asymmetries in the fit.
- 137 The experimental systematic and model uncertainties are combined in quadrature.
- 138 ACCIARRI 99d uses maximum-likelihood fits to extract  $\chi_b$  as well as the  $A_{FB}^b$  in  $Z \rightarrow b\bar{b}$  events containing prompt leptons.
- 139 This ABREU 94J result is from 5182  $\ell\ell$  and 279  $A\ell$  events. The systematic error includes 0.004 for model dependence.
- 140 BUSKULIC 94G data analyzed using  $ee$ ,  $e\mu$ , and  $\mu\mu$  events.
- 141 BUSKULIC 92b uses a jet charge technique combined with electrons and muons.
- 142 ABE 91G measurement of  $\chi$  is done with  $e\mu$  and  $ee$  events.
- 143 ALBAJAR 91D measurement of  $\chi$  is done with dimuons.
- 144 Uses di-muon events.
- 145 ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract  $\chi$  as well as the forward-backward asymmetries in  $e^+e^- \rightarrow Z \rightarrow b\bar{b}$  and  $cc$ .
- 146 UENO 96 extracted  $\chi$  from the energy dependence of the forward-backward asymmetry.
- 147 ABREU 94F uses the average electric charge sum of the jets recoiling against a  $b$ -quark jet tagged by a high  $p_T$  muon. The result is for  $\bar{\chi} = f_d\chi_d + 0.9f_s\chi_s$ .
- 148 This ABREU 94J result combines  $\ell\ell$ ,  $A\ell$ , and jet-charge  $\ell$  (ABREU 94F) analyses. It is for  $\bar{\chi} = f_d\chi_d + 0.96f_s\chi_s$ .
- 149 ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.
- 150 ABREU 93c data analyzed using  $ee$ ,  $e\mu$ , and  $\mu\mu$  events.
- 151 AKERS 93b analysis performed using dilepton events.
- 152 ACTON 92c uses electrons and muons. Superseded by AKERS 93b.
- 153 ADEVA 92c uses electrons and muons.
- 154 DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92b.
- 155 ADEVA 90P measurement uses  $ee$ ,  $e\mu$ , and  $\mu\mu$  events from 118k events at the Z. Superseded by ADEVA 92c.
- 156 These experiments are not in the average because the combination of  $B_s$  and  $B_d$  mesons which they see could differ from those at higher energy.
- 157 The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.
- 158 ALBAJAR 87c measured  $\chi = (\bar{B}^0 \rightarrow B^0 \rightarrow \mu^+X)$  divided by the average production weighted semileptonic branching fraction for  $B$  hadrons at 546 and 630 GeV.
- 159 Limit is average probability for hadron containing  $B$  quark to produce a positive lepton.

CP VIOLATION PARAMETERS IN SEMILEPTONIC  $b$ -HADRON DECAYS. $\text{Re}(\epsilon_b) / (1 + |\epsilon_b|^2)$ 

CP impurity in semileptonic  $b$ -hadron decays.

VALUE (units $10^{-3}$ )	DOCUMENT ID	TECN	COMMENT
<b>-1.97 ± 0.43 ± 0.23</b>	160 ABAZOV	11U D0	$p\bar{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •			
-2.39 ± 0.63 ± 0.37	161 ABAZOV	10H D0	Repl. by ABAZOV 11U
160 ABAZOV 11U reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-7.87 \pm 1.72 \pm 0.93) \times 10^{-3}$ in semileptonic $b$ -hadron decays.			
161 ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-9.57 \pm 2.51 \pm 1.46) \times 10^{-3}$ in semileptonic $b$ -hadron decays. Using the measured production ratio of $B_d^0$ and $B_s^0$ , and the asymmetry of $B_d^0 A_{SL}^d = (-4.7 \pm 4.6) \times 10^{-3}$ measured from $B$ -factories, they obtain the asymmetry for $B_s^0$ as $A_{SL}^s = (-14.6 \pm 7.5) \times 10^{-3}$ .			

## B-HADRON PRODUCTION FRACTIONS IN HADRONIC Z DECAY

The production fractions of  $b$ -hadrons in hadronic Z decays have been calculated using the best values of mean lives, mixing parameters and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see <http://www.slac.stanford.edu/xorg/hfag/>).

The values reported below assume:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0)$$

$$f(\bar{b} \rightarrow B^+) + f(\bar{b} \rightarrow B^0) + f(\bar{b} \rightarrow B_s^0) + f(b \rightarrow b\text{-baryon}) = 1$$

The values are:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0) = 0.403 \pm 0.009$$

$$f(\bar{b} \rightarrow B_s^0) = 0.103 \pm 0.009$$

$$f(b \rightarrow b\text{-baryon}) = 0.090 \pm 0.015$$

and their correlation coefficients are:

$$\text{cor}(B_s^0, b\text{-baryon}) = +0.036$$

$$\text{cor}(B_s^0, B^+ = B^0) = -0.522$$

$$\text{cor}(b\text{-baryon}, B^+ = B^0) = -0.871$$

as obtained using a time-integrated mixing parameter  $\bar{\chi} = 0.1259 \pm 0.0042$  given by a fit to heavy quark quantities with asymmetries removed (see the note "The Z boson").

B-HADRON PRODUCTION FRACTIONS IN  $p\bar{p}$  COLLISIONS AT Tevatron

The production fractions for  $b$ -hadrons in  $p\bar{p}$  collisions at the Tevatron have been calculated from the best values of mean lifetimes, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see <http://www.slac.stanford.edu/xorg/hfag/>).

The values reported below assume:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0)$$

$$f(\bar{b} \rightarrow B^+) + f(\bar{b} \rightarrow B^0) + f(\bar{b} \rightarrow B_s^0) + f(b \rightarrow b\text{-baryon}) = 1$$

The values are:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0) = 0.339 \pm 0.031$$

$$f(\bar{b} \rightarrow B_s^0) = 0.111 \pm 0.014$$

$$f(b \rightarrow b\text{-baryon}) = 0.212 \pm 0.069$$

and their correlation coefficients are:

$$\text{cor}(B_s^0, b\text{-baryon}) = -0.581$$

$$\text{cor}(B_s^0, B^+ = B^0) = +0.425$$

$$\text{cor}(b\text{-baryon}, B^+ = B^0) = -0.984$$

as obtained with the Tevatron average of time-integrated mixing parameter  $\bar{\chi} = 0.147 \pm 0.011$ .

 $V_{cb}$  and  $V_{ub}$  CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

DETERMINATION OF  $V_{cb}$  AND  $V_{ub}$ 

Updated February 2012 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

## INTRODUCTION

Precision determinations of  $|V_{ub}|$  and  $|V_{cb}|$  are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in  $B$  decays. The length of the side of the unitarity triangle opposite the well-measured angle  $\beta$  is proportional to the ratio  $|V_{ub}|/|V_{cb}|$ , making its determination a high priority of the heavy-flavor physics program.

The semileptonic transitions  $b \rightarrow c\ell\bar{\nu}_\ell$  and  $b \rightarrow u\ell\bar{\nu}_\ell$  provide two avenues for determining these CKM matrix elements, namely through inclusive and exclusive final states. The experimental and theoretical techniques underlying these two avenues are independent, providing a crucial cross-check on our understanding. Recent measurements and calculations are reflected in the values quoted in this article, which is an update on the previous review [1]. The leptonic decay  $B^- \rightarrow \tau\bar{\nu}$  can also be used to extract  $|V_{ub}|$ , but we do not use this information at present since none of the current experimental measurements have a significance above 3.6 $\sigma$ .

The theory underlying the determination of  $|V_{qb}|$  is mature, in particular for  $|V_{cb}|$ . Most of the theoretical approaches use the fact that the mass  $m_b$  of the  $b$  quark is large compared to the scale  $\Lambda_{\text{QCD}}$  that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of  $\Lambda/m_b$ , where  $\Lambda \sim 500 - 700$  MeV is a hadronic scale of the order of  $\Lambda_{\text{QCD}}$ , using effective-field-theory methods to separate non-perturbative from perturbative contributions. The expansion in  $\Lambda/m_b$  and  $\alpha_s$  works well enough to enable a precision determination of  $|V_{cb}|$  and  $|V_{ub}|$  in semileptonic decays.

The large data samples available at the  $B$  factories enable analyses where one  $B$  meson from an  $\Upsilon(4S)$  decay is fully reconstructed, allowing a recoiling semileptonic  $B$  decay to be studied with high purity. Improved knowledge of  $\bar{B} \rightarrow X_c\ell\bar{\nu}_\ell$  decays allows partial rates for  $\bar{B} \rightarrow X_u\ell\bar{\nu}_\ell$  transitions to be measured in regions previously considered inaccessible, increasing the acceptance for  $\bar{B} \rightarrow X_u\ell\bar{\nu}_\ell$  transitions and reducing theoretical uncertainties.

Experimental measurements of the exclusive  $\bar{B} \rightarrow \pi\ell\bar{\nu}_\ell$  decay are quite precise, and recent improvements in the theoretical calculation of the form factor normalization have enabled a determination of  $|V_{ub}|$  from this decay with an uncertainty below 10%.

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [2].

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

### DETERMINATION OF $|V_{cb}|$

*Summary:* The determination of  $|V_{cb}|$  from  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$  decays is currently at a relative precision of about 2%. The main limitation is the knowledge of the form factor near the maximum momentum transfer to the leptons. For the  $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$  channel experimental measurements have recently been substantially improved, allowing this channel to provide a meaningful cross-check on  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$ .

Determinations of  $|V_{cb}|$  from inclusive decays are currently below 2% relative uncertainty. The limitations arise mainly from our ignorance of higher-order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are marginally consistent with each other:

$$|V_{cb}| = (41.9 \pm 0.7) \times 10^{-3} \quad (\text{inclusive}) \quad (1)$$

$$|V_{cb}| = (39.6 \pm 0.9) \times 10^{-3} \quad (\text{exclusive}). \quad (2)$$

An average of the above gives  $|V_{cb}| = (40.9 \pm 0.6) \times 10^{-3}$ , with  $p(\chi^2) = 0.04$ . Scaling the error by  $\sqrt{\chi^2/1} = 2.0$  we quote

$$|V_{cb}| = (40.9 \pm 1.1) \times 10^{-3}. \quad (3)$$

### $|V_{cb}|$ from exclusive decays

Exclusive determinations of  $|V_{cb}|$  are based on a study of semileptonic  $B$  decays into the ground state charmed mesons  $D$  and  $D^*$ . The main uncertainties in this approach stem from our ignorance of the form factors describing the  $B \rightarrow D$  and  $B \rightarrow D^*$  transitions. However, in the limit of infinite bottom and charm quark masses only a single form factor appears, the Isgur-Wise function [3], which depends on the product of the four-velocities  $v$  and  $v'$  of the initial and final-state hadrons.

The extraction of  $|V_{cb}|$  is based on the distribution of the variable  $w \equiv v \cdot v'$ , which corresponds to the energy of the final state  $D^{(*)}$  meson in the rest frame of the decay. Heavy Quark Symmetry (HQS) [3,4] predicts the normalization of the rate at  $w = 1$ , the point of maximum momentum transfer to the leptons, and  $|V_{cb}|$  is obtained from an extrapolation of the measured spectrum to  $w = 1$ . This extrapolation relies on a parametrization of the form factor, as explained below.

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the slope of the form factors near the point  $w = 1$ , since the phase space vanishes there. The corrections to the HQS prediction due to finite quark masses are given in terms of the symmetry-breaking parameter

$$\frac{1}{\mu} = \frac{1}{m_c} - \frac{1}{m_b},$$

which is essentially  $1/m_c$  for realistic quark masses. HQS ensures that those matrix elements that correspond to the currents that generate the HQS are normalized at  $w = 1$ ; as a result, some of the form factors either vanish or are normalized to unity at  $w = 1$ . Due to Luke's Theorem [5] (which is an application of the Ademollo-Gatto theorem [6] to heavy

quarks), the leading correction to those form factors normalized due to HQS is quadratic in  $1/\mu$ , while for the form factors that vanish in the infinite mass limit the corrections are in general linear in  $1/m_c$  and  $1/m_b$ . Thus we have, using the definitions as in Eq. (2.84) of Ref. [7]

$$\begin{aligned} h_i(1) &= 1 + \mathcal{O}(1/\mu^2) & \text{for } i = +, V, A_1, A_3, \\ h_i(1) &= \mathcal{O}(1/m_c, 1/m_b) & \text{for } i = -, A_2. \end{aligned} \quad (4)$$

In addition to these corrections, there are perturbatively calculable radiative corrections from QCD and QED, which will be discussed in the relevant sections. Both - radiative corrections as well as  $1/m_{b,c}$  corrections - are considered in the framework of Heavy Quark Effective Theory (HQET) [8], which provides for a systematic expansion.

### $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$

The decay rate for  $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$  is given by

$$\frac{d\Gamma}{dw}(\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 m_{D^*}^3 (w^2 - 1)^{1/2} P(w) (\eta_{\text{em}} \mathcal{F}(w))^2, \quad (5)$$

where  $P(w)$  is a phase space factor with  $P(1) = 12(m_B - m_{D^*})^2$  and  $\mathcal{F}(w)$  is dominated by the axial vector form factor  $h_{A_1}$  as  $w \rightarrow 1$ . Furthermore,  $\eta_{\text{em}} = 1.007$  accounts for the electroweak corrections to the four-fermion operator mediating the semileptonic decay [11]. In the infinite-mass limit, the HQS normalization gives  $\mathcal{F}(1) = 1$ .

The form factor  $\mathcal{F}(w)$  must be parametrized to perform an extrapolation to the zero-recoil point. A frequently used one-parameter form motivated by analyticity and unitarity is [9,10]

$$\begin{aligned} \mathcal{F}(w) &= \eta_A \left[ 1 + \delta_{1/m^2} + \dots \right] \\ &= [1 - 8\rho_{A_1}^2 z + (53\rho_{A_1}^2 - 15)z^2 - (231\rho_{A_1}^2 - 91)z^3] \end{aligned} \quad (6)$$

with  $z = (\sqrt{w+1} - \sqrt{2})/(\sqrt{w+1} + \sqrt{2})$  originating from a conformal transformation. The parameter  $\rho_{A_1}^2$  is the slope of the form factor at  $w = 1$ . The factor  $\eta_A$  is the QCD short-distance radiative correction [12] to the form factor

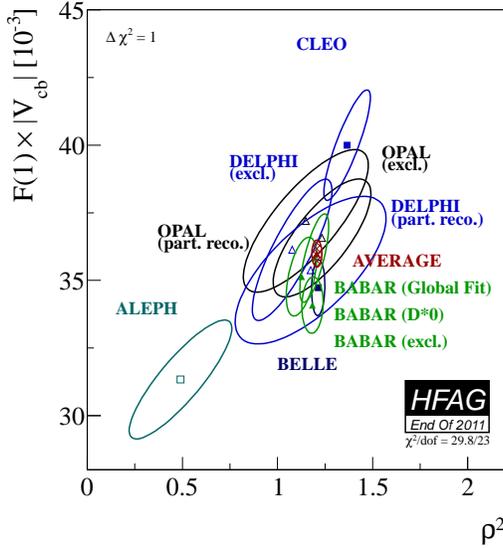

$$\eta_A = 0.960 \pm 0.007, \quad (7)$$

and  $\delta_{1/m^2}$  comes from non-perturbative  $1/m^2$  corrections.

Improved lattice simulations that include effects from finite quark masses are used to calculate the deviation of  $\mathcal{F}(1)$  from unity. A recent calculation gives

$$\mathcal{F}(1) = 0.902 \pm 0.017, \quad (8)$$

where the factor  $\eta_{\text{em}}$  has been divided out from the value quoted in Ref. [13] and the errors have been added in quadrature. The leading uncertainties are due to heavy-quark discretization and chiral extrapolation errors.

**Figure 1:** Measurements of  $|V_{cb}|\mathcal{F}(1)$  vs.  $\rho_{A_1}^2$  are shown as  $\Delta\chi^2 = 1$  ellipses.

Non-lattice estimates based on sum rules for the form factor tend to yield lower values for  $\mathcal{F}(1)$  [14,15,16]. Omitting the contributions from excited states, the sum rules indicate that  $\mathcal{F}(1) < 0.93$ . Including an estimate for the contribution of the excited states yields  $\mathcal{F}(1) = 0.86 \pm 0.01 \pm 0.02$  [16], where the second uncertainty originates from the estimate for the excited states.

Many experiments [17–25] have measured the differential rate as a function of  $w$ . Fig. 1 shows corresponding values of  $\mathcal{F}(1)|V_{cb}|$  and  $\rho_{A_1}^2$  (as defined in Ref. [10]). These measurements are input to a four-dimensional fit [26] for  $\mathcal{F}(1)|V_{cb}|$ ,  $\rho_{A_1}^2$  and the form factor ratios  $R_1 \propto A_2/A_1$  and  $R_2 \propto V/A_1$ . The leading sources of uncertainty on  $\mathcal{F}(1)|V_{cb}|$  are due to detection efficiencies and  $D^{(*)}$  decay branching fractions, while for  $\rho_{A_1}^2$  the uncertainties in  $R_1$  and  $R_2$  still dominate. Recent BABAR measurements, one using  $\overline{B}^0 \rightarrow D^{*0}\ell\overline{\nu}_\ell$  decays [23] and the other using a global fit to  $\overline{B} \rightarrow D\ell\overline{\nu}_\ell X$  decays [24] are completely insensitive to uncertainties related to the reconstruction of the charged pion from  $D^* \rightarrow D\pi$  decays; both measurements agree with the average given below.

The fit gives  $\mathcal{F}(1)|V_{cb}| = (36.0 \pm 0.5) \times 10^{-3}$  with a  $p$ -value of 0.15. Along with the lattice value given above for  $\mathcal{F}(1)$  this yields

$$|V_{cb}| = (39.6 \pm 0.6_{\text{exp}} \pm 0.8_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell, \text{LQCD}). \quad (9)$$

The value of  $\mathcal{F}(1)$  obtained from QCD sum rules results in a larger value for  $|V_{cb}|$ :

$$|V_{cb}| = (41.6 \pm 0.6_{\text{exp}} \pm 1.9_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell, \text{SR}). \quad (10)$$

### $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$

The differential rate for  $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$  is given by

$$\frac{d\Gamma}{dw}(\overline{B} \rightarrow D\ell\overline{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 (m_B + m_D)^2 m_D^3 (w^2 - 1)^{3/2} (\eta_{\text{em}} \mathcal{G}(w))^2. \quad (11)$$

The form factor is

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D} h_-(w), \quad (12)$$

where  $h_+$  is normalized to unity in the infinite-mass limit due to HQS and  $h_-$  vanishes in the heavy-mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D} \frac{1}{m_c}\right) \quad (13)$$

and the corrections to the HQET predictions are parametrically larger than was the case for  $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$ .

In order to get a more precise prediction for the form factor  $\mathcal{G}(1)$  the heavy-quark expansion can be supplemented by additional assumptions. It has been argued in Ref. [27] that in a limit in which the kinetic energy  $\mu_\pi^2$  is equal to the chromomagnetic moment  $\mu_G^2$  (these quantities are discussed below in more detail) one may obtain the value

$$\mathcal{G}(1) = 1.04 \pm 0.01_{\text{power}} \pm 0.01_{\text{pert}}. \quad (14)$$

Lattice calculations including effects beyond the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case  $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$  is irrelevant. These unquenched calculations quote a value (preliminary, from 2005) [28]

$$\mathcal{G}(1) = 1.074 \pm 0.018 \pm 0.016. \quad (15)$$

The measurements of  $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$  have improved substantially in the last few years. The new measurements [24,29] are consistent with previous measurements [17,30,31] but significantly more precise. The average of these inputs [26] gives  $\mathcal{G}(1)|V_{cb}| = (42.6 \pm 0.7 \pm 1.4) \times 10^{-3}$ . Using the value given in Eq. (15) for  $\mathcal{G}(1)$ , accounting for the electroweak correction and conservatively adding the theory uncertainties linearly results in

$$|V_{cb}| = (39.4 \pm 1.4 \pm 1.3) \times 10^{-3} \quad (\overline{B} \rightarrow D\ell\overline{\nu}_\ell, \text{LQCD}), \quad (16)$$

where the first uncertainty is from experiment and the second from theory.

Using the non-lattice estimate from Eq. (14) one finds  $|V_{cb}| = (40.7 \pm 1.5 \pm 0.8) \times 10^{-3}$ .

Measuring the differential rate at  $w = 1$  is more difficult in  $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$  decays than in  $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$  decays, since the rate is smaller and the background from misreconstructed  $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$  decays is significant; this is reflected in the larger experimental uncertainty. The  $B$  factories address these limitations by studying decays recoiling against fully reconstructed  $B$  mesons or doing a global fit to  $\overline{B} \rightarrow X_c\ell\overline{\nu}_\ell$  decays. Theoretical input

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

on the shape of the  $w$  spectrum in  $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$  is valuable, as precise measurements of the total rate are easier; recent measurements [24,29] of  $\mathcal{B}(\bar{B} \rightarrow D\ell\bar{\nu}_\ell)$  have uncertainties of  $\sim 5\%$ .

The determinations from  $\bar{B} \rightarrow D^*\ell\bar{\nu}_\ell$  and  $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$  decays are consistent, and their uncertainties are largely uncorrelated. Averaging these two lattice-based results gives

$$|V_{cb}| = (39.6 \pm 0.9) \times 10^{-3} \quad (\text{exclusive}). \quad (17)$$

### Prospects for Lattice determinations of the $B \rightarrow D^{(*)}$ form factors

Lattice determinations of the  $B \rightarrow D^{(*)}$  form factors naturally build in heavy-quark symmetries, so all uncertainties scale with the deviation of the form factor from unity [32,33]. In combination with unquenched calculations, i.e. calculations with realistic sea quarks, one obtains quite precise calculations of the form factors, now at the 2% level. The dominant uncertainties are due to the chiral extrapolation from the light quark masses used in the numerical lattice computation to realistic up and down quark masses, and to discretization errors. These sources of uncertainty will be reduced with larger lattice sizes and smaller lattice spacings.

A further ongoing development is the extension of these calculations to nonzero recoil. Such calculations are especially helpful for avoiding the  $w \rightarrow 1$  extrapolation in  $B \rightarrow D$ .

### Decays to Excited $D$ Meson States

Above the ground state  $D$  and  $D^*$  mesons lie four positive-parity states with one unit of orbital angular momentum, generically denoted as  $D^{**}$ . In the heavy mass limit they form two spin symmetry doublets with  $j_\ell = 1/2$  and  $j_\ell = 3/2$ , where  $j_\ell$  is the total angular momentum of the light degrees of freedom. The doublet with  $j_\ell = 3/2$  is expected to be narrow while the states with  $j_\ell = 1/2$  should be broad, consistent with experimental measurements. Furthermore, one expects that in the heavy mass limit  $\Gamma(B \rightarrow D^{**}(j_\ell = 3/2)\ell\bar{\nu}) \gg \Gamma(B \rightarrow D^{**}(j_\ell = 1/2)\ell\bar{\nu})$  [34,35,36]. Measurements indicate that this expectation may be violated, although the experimental situation is not clear. BELLE [37] and BABAR [38] report different results for the broad states and the experiments do not have the sensitivity to identify the spin-parity of these states. It has been suggested that decays to radially excited charm mesons may play a role in this puzzle [39]. If a violation is confirmed, it may indicate substantial mixing between the two spin symmetry doublets, which can occur due to terms of order  $1/m_c$ . However, the impact on the exclusive  $|V_{cb}|$  determination is expected to be small, since the zero-recoil point is protected against corrections of order  $1/m_c$  by Luke's theorem.

### $|V_{cb}|$ from inclusive decays

At present the most precise determinations of  $|V_{cb}|$  come from inclusive decays. The method is based on a measurement of the total semileptonic decay rate, together with the leptonic energy and the hadronic invariant mass spectra of inclusive

semileptonic decays. The total decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the spectra.

### Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE), a systematic expansion in inverse powers of the  $b$ -quark mass [40,41]. The validity of the OPE is proven in the deep Euclidean region for the momenta (which is satisfied, *e.g.*, in deep inelastic scattering), but its application to heavy-quark decays requires a continuation to time-like momenta  $p_B^2 = M_B^2$ , where possible contributions which are exponentially damped in the Euclidean region could become oscillatory. The validity of the OPE for inclusive decays is equivalent to the assumption of parton-hadron duality, hereafter referred to simply as duality, and possible oscillatory contributions would be an indication of duality violation.

Duality-violating effects are hard to quantify. In practice, they would appear as unnaturally large coefficients of higher order terms in the  $1/m$  expansion [42]. The description of  $\sim 60$  measurements in terms of  $\sim 6$  free parameters in global fits to  $\bar{B} \rightarrow X_c\ell\bar{\nu}_\ell$  decays provides a non-trivial testing ground for the HQE predictions. Present fits include terms up to order  $1/m_b^3$ , the coefficients of which have sizes as expected a priori by theory and are in quantitative agreement with extractions from other observables. The consistency of the data with these OPE fits will be discussed later; no indication is found that terms of order  $1/m_b^4$  or higher are large, and there is no evidence for duality violations in the data. Thus duality or, likewise, the validity of the OPE, is assumed in the analysis, and no further uncertainty is assigned to potential duality violations.

The OPE result for the total rate can be written schematically (the details of the expression can be found, *e.g.*, in Ref. [43]) as

$$\begin{aligned} \Gamma = & |V_{cb}|^2 \hat{\Gamma}_0 m_b^5(\mu) (1 + A_{\text{ew}}) \times \\ & \left[ z_0^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_0^{(1)}(r) + \left( \frac{\alpha_s(\mu)}{\pi} \right)^2 z_0^{(2)}(r) + \dots \right. \\ & + \frac{\mu_\pi^2}{m_b^2} \left( z_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_2^{(1)}(r) + \dots \right) \\ & + \frac{\mu_G^2}{m_b^2} \left( y_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_2^{(1)}(r) + \dots \right) \\ & + \frac{\rho_D^3}{m_b^3} \left( z_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_3^{(1)}(r) + \dots \right) \\ & + \frac{\rho_{\text{LS}}^3}{m_b^3} \left( y_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_3^{(1)}(r) + \dots \right) \\ & \left. + z_4 \left( r, \frac{s_i}{m_b^4}, \frac{\alpha_s(\mu)}{\pi} \right) + \dots \right] \quad (18) \end{aligned}$$

where  $A_{\text{ew}}$  denotes the electroweak corrections,  $r$  is the ratio  $m_c/m_b$  and the  $y_i$  and  $z_i$  are known functions which appear in the perturbative expansion of the different orders of the heavy mass expansion. A similar expansion can be set up for

moments of the distributions of charged-lepton energy, hadronic invariant mass and hadronic energy.

This expression is known up to order  $1/m_b^5$ , where the terms of order  $1/m_b^n$  with  $n > 2$  have been computed only at tree level [44,45,46,47]. The leading term is the parton model, which is known completely to order  $\alpha_s$  and  $\alpha_s^2$  [48–50], and the terms of order  $\alpha_s^{n+1}\beta_0^n$  (where  $\beta_0$  is the first coefficient of the QCD  $\beta$  function,  $\beta_0 = (33 - 2n_f)/3$ ) have been included by the usual BLM procedure [43,51,52]. Furthermore, the corrections of order  $\alpha_s\mu_\pi^2/m_b^2$  have been computed [53].

Starting at order  $1/m_b^3$  contributions with an infrared sensitivity to the charm mass  $m_c$  appear [46,54,112]. At order  $1/m_b^3$  this “intrinsic charm” contribution is a  $\log(m_c)$  in the coefficient of the Darwin term  $\rho_D^3$ . At higher orders, terms such as  $1/m_b^3 \times 1/m_c^2$  and  $\alpha_s(m_c)1/m_b^3 \times 1/m_c$  appear, which are comparable in size to the contributions of order  $1/m_b^4$ .

The HQE parameters are given in terms of forward matrix elements; the parameters entering the expansion for orders up to  $1/m_b^3$  are

$$\begin{aligned}\bar{\Lambda} &= M_B - m_b, \\ \mu_\pi^2 &= -\langle B|\bar{b}(iD_\perp)^2b|B\rangle, \\ \mu_G^2 &= \langle B|\bar{b}(iD_\perp^\mu)(iD_\perp^\nu)\sigma_{\mu\nu}b|B\rangle, \\ \rho_D^3 &= \langle B|\bar{b}(iD_{\perp\mu})(ivD)(iD_\perp^\nu)b|B\rangle, \\ \rho_{LS}^3 &= \langle B|\bar{b}(iD_\perp^\mu)(ivD)(iD_\perp^\nu)\sigma_{\mu\nu}b|B\rangle.\end{aligned}\quad (19)$$

The hadronic parameters of the orders  $1/m_b^4$  and  $1/m_b^5$  can be found in Ref. [47] while the five hadronic parameters  $s_i$  of the order  $1/m_b^4$  can be found in Ref. [45]; these have not yet been included in the fits. The non-perturbative matrix elements depend on the renormalization scale  $\mu$ , on the chosen renormalization scheme and on the quark mass  $m_b$ , and may eventually be calculated in Lattice QCD. The rates and the spectra depend strongly on  $m_b$  (or equivalently on  $\bar{\Lambda}$ ), which makes the discussion of renormalization issues mandatory.

Using the pole mass definition for the heavy quark masses, it is well known that the corresponding perturbative series of decay rates does not converge very well, making a precision determination of  $|V_{cb}|$  in such a scheme impossible. The solution to this problem is to choose an appropriate “short-distance” mass definition. Frequently used mass definitions are the kinetic scheme [14], or the 1S scheme [56]. Both of these schemes have been applied to semileptonic  $b \rightarrow c$  transitions, yielding comparable results and uncertainties.

The 1S scheme eliminates the  $b$  quark pole mass by relating it to the perturbative expression for the mass of the 1S state of the  $\Upsilon$  system. The physical mass of the  $\Upsilon(1S)$  contains non-perturbative contributions, which have been estimated in Ref. [57]. These non-perturbative contributions are small; nevertheless, the best determination of the  $b$  quark mass in the 1S scheme is obtained from sum rules for  $e^+e^- \rightarrow b\bar{b}$  [58].

Alternatively one may use a short-distance mass definition such as the  $\overline{\text{MS}}$  mass  $m_b^{\overline{\text{MS}}}(m_b)$ . However, it has been argued that the scale  $m_b$  is unnaturally high for  $B$  decays, while

for smaller scales  $\mu \sim 1\text{ GeV}$   $m_b^{\overline{\text{MS}}}(\mu)$  is under poor control. For this reason the so-called “kinetic mass”  $m_b^{\text{kin}}(\mu)$ , has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy-quark sum rules [14].

The HQE parameters also depend on the renormalization scale and scheme. The matrix elements given in Eq. (19) are defined with the full QCD fields and states, which is the definition frequently used in the kinetic scheme. Sometimes slightly different parameters  $\lambda_1$  and  $\lambda_2$  are used, which are defined in the infinite mass limit. The relation between these parameters is

$$\begin{aligned}\bar{\Lambda}_{\text{HQET}} &= \lim_{m_b \rightarrow \infty} \bar{\Lambda}, \quad -\lambda_1 = \lim_{m_b \rightarrow \infty} \mu_\pi^2, \\ \lambda_2 &= \lim_{m_b \rightarrow \infty} \mu_G^2, \quad \rho_1 = \lim_{m_b \rightarrow \infty} \rho_D^3, \\ \rho_2 &= \lim_{m_b \rightarrow \infty} \rho_{LS}^3.\end{aligned}\quad (20)$$

Defining the kinetic energy and the chromomagnetic moment in the infinite-mass limit (as, *e.g.*, in the 1S scheme) requires that  $1/m_b$  corrections to the matrix elements defined in Eq. (19) be taken into account once one goes beyond order  $1/m_b^2$ . As a result, additional quantities  $\mathcal{T}_1 \cdots \mathcal{T}_4$  appear at order  $1/m_b^3$ . However, these quantities are correlated such that the total number of non-perturbative parameters to order  $1/m_b^3$  is the same as in the scheme where  $m_b$  is kept finite in the matrix elements which define the non-perturbative parameters. A detailed discussion of these issues can be found in Ref. [59].

In order to define the HQE parameters properly one must adopt a renormalization scheme, as was done for the heavy quark mass. Since all these parameters can again be determined by heavy-quark sum rules, one may adopt a scheme similar to the kinetic scheme for the quark mass. The HQE parameters in the kinetic scheme depend on powers of the renormalization scale  $\mu$ , and the above relations are valid in the limit  $\mu \rightarrow 0$ , leaving only logarithms of  $\mu$ .

Some of these parameters also appear in the relation for the heavy hadron masses. The quantity  $\bar{\Lambda}$  is determined once a definition is specified for the quark mass. The parameter  $\mu_G^2$  can be extracted from the mass splitting in the lowest spin-symmetry doublet of heavy mesons [60]

$$\mu_G^2(\mu) = \frac{3}{4}C_G(\mu, m_b)(M_{B^*}^2 - M_B^2), \quad (21)$$

where  $C_G(\mu, m_b)$  is a perturbatively-computable coefficient which depends on the scheme. In the kinetic scheme we have

$$\mu_G^2(1\text{ GeV}) = 0.35_{-0.02}^{+0.03}\text{ GeV}^2. \quad (22)$$

#### Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays [61–69] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum (0<sup>th</sup>–3<sup>rd</sup>) and of the squared hadronic mass spectrum (0<sup>th</sup>–2<sup>nd</sup>) have statistical uncertainties that are roughly equal

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

to their systematic uncertainties. They can be improved with more data and significant effort. The sets of moments measured by each experiment have strong correlations; the full statistical and systematic correlation matrices are required to allow these to be used in a global fit. Measurements of photon energy moments (0<sup>th</sup>-2<sup>nd</sup>) in  $B \rightarrow X_s \gamma$  decays [70–74] as a function of the minimum accepted photon energy are still primarily statistics limited.

Global fits to the full set of moments [69,71,75–78] have been performed in the 1S and kinetic schemes. The semileptonic moments alone determine a linear combination of  $m_b$  and  $m_c$  very accurately but leave the orthogonal combination poorly determined [79]; additional input is required to allow a precise determination of  $m_b$ . This additional information can come from the radiative  $B \rightarrow X_s \gamma$  moments, which provide complementary information on  $m_b$  and  $\mu_\pi^2$ , or from precise determinations of the charm quark mass [80,81]. The values obtained in the kinetic scheme fits [77] with these two constraints are consistent. Based on the charm quark mass constraint [80],  $m_c^{\overline{\text{MS}}}(3 \text{ GeV}) = 0.998 \pm 0.029 \text{ GeV}$ ,

$$|V_{cb}| = (41.88 \pm 0.44 \pm 0.59) \times 10^{-3} \quad (23)$$

$$m_b^{\text{kin}} = 4.560 \pm 0.023 \text{ GeV} \quad (24)$$

$$\mu_\pi^2(\text{kin}) = 0.453 \pm 0.036 \text{ GeV}^2, \quad (25)$$

where the first error on  $|V_{cb}|$  includes experimental and theoretical uncertainties and the second error is from the estimated accuracy of the HQE for the total semileptonic rate.

Theoretical uncertainties are estimated and included in performing the fits. The  $\chi^2/\text{dof}$  is substantially below unity in all fits, suggesting that the theoretical uncertainties may be overestimated. In any case, the low  $\chi^2$  shows no evidence for duality violations at a significant level. Similar values for the parameters are obtained when only experimental uncertainties are used in the fits. If the photon energy spectrum moments from  $\overline{B} \rightarrow X_s \gamma$  are used in place of the constraint on the charm quark mass, the results change by only small amounts, e.g.,  $m_b^{\text{kin}}$  increases to  $4.574 \pm 0.032 \text{ GeV}$ . The mass in the  $\overline{\text{MS}}$  scheme corresponding to Eq. (24) is  $m_b^{\overline{\text{MS}}} = 4.19 \pm 0.04 \text{ GeV}$ , which can be compared with a recent value obtained using relativistic sum rules [82],  $m_b^{\overline{\text{MS}}} = 4.163 \pm 0.016 \text{ GeV}$ , and provides a non-trivial cross-check.

A fit to the same moments in the 1S scheme gives [78]

$$|V_{cb}| = (41.96 \pm 0.45 \pm 0.07) \times 10^{-3} \quad (26)$$

$$m_b^{1\text{S}} = 4.691 \pm 0.037 \text{ GeV} \quad (27)$$

$$\lambda_1(1\text{S}) = -0.362 \pm 0.067 \text{ GeV}^2, \quad (28)$$

where the last error on  $|V_{cb}|$  is due to the uncertainties in the B meson lifetimes. This fit uses semileptonic and radiative moments and constrains the chromomagnetic operator using the mass difference between the  $D$  and  $D^*$  mesons. This independent fit gives consistent results for  $|V_{cb}|$  and, after translation to a common renormalization scheme, for  $m_b$  and  $\mu_\pi^2$ .

The precision of the global fit results can be further improved. Some of the measurements, in particular of the  $\overline{B} \rightarrow X_s \gamma$  photon energy spectrum, can be improved by using the full B-factory data sets. Improvements can be made in the theory by calculating higher order perturbative corrections to the coefficients of the HQE parameters, in particular the still missing  $\alpha_s \mu_G^2$  corrections, which are presently only known for  $B \rightarrow X_s \gamma$  [84]. The inclusion of still higher order moments may improve the sensitivity of the fits to higher order terms in the HQE.

### Determination of $|V_{ub}|$

*Summary:* The determination of  $|V_{ub}|$  is the focus of significant experimental and theoretical work. The determinations based on inclusive semileptonic decays using different calculational ansätze are consistent. The largest parametric uncertainty comes from the error on  $m_b$ . Significant progress has been made in determinations of  $|V_{ub}|$  from  $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$  decays by using combined fits to theory and experimental data as a function of  $q^2$ . Further improvements in the form factor normalization are needed to improve the precision.

The values obtained from inclusive and exclusive determinations are

$$|V_{ub}| = (4.41 \pm 0.15 \pm_{0.17}^{0.15}) \times 10^{-3} \quad (\text{inclusive}), \quad (29)$$

$$|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3} \quad (\text{exclusive}). \quad (30)$$

The two determinations are independent, and the dominant uncertainties are on multiplicative factors. The inclusive and exclusive values are weighted by their relative errors and the uncertainties are treated as normally distributed. The resulting average has  $p(\chi^2) = 0.01$ , so we scale the error by  $\sqrt{\chi^2/1} = 2.6$  to find

$$|V_{ub}| = (4.15 \pm 0.49) \times 10^{-3}. \quad (31)$$

Given the poor consistency between the two determinations, this average should be treated with caution.

### $|V_{ub}|$ from inclusive decays

The theoretical description of inclusive  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays is based on the Heavy Quark Expansion, as for  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  decays, and leads to a predicted total decay rate with uncertainties below 5% [85,86]. Unfortunately, the total decay rate is hard to measure due to the large background from CKM-favored  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  transitions. Technically, the calculation of the partial decay rate in regions of phase space where  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  decays are suppressed is different from what has been described above, since it requires the introduction of a non-perturbative distribution function, the “shape function” (SF) [87,88]. Due to this, the theoretical input for the extraction on  $V_{ub}$  from inclusive decays is more challenging. The shape function becomes important when the light-cone momentum component  $P_+ \equiv E_X - |P_X|$  is not large compared to  $\Lambda_{QCD}$ . This additional difficulty can be addressed in two complementary ways. The leading shape function can either be measured in the radiative decay  $\overline{B} \rightarrow X_s \gamma$ , or be modeled with

constraints on the 0<sup>th</sup>-2<sup>nd</sup> moments, and the results applied to the calculation of the  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  partial decay rate [89–91]; in such an approach the largest challenges are for the theory. Alternatively, measurements of  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  partial decay rates can be extended further into the  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ -allowed region, enabling a simplified theoretical (pure HQE) treatment [92] but requiring precise experimental knowledge of the  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  background.

The shape function is a universal property of  $B$  mesons at leading order. It has been recognized for many years [87,88] that the leading SF can be measured in  $\overline{B} \rightarrow X_s \gamma$  decays. However, sub-leading shape functions [93–98] arise at each order in  $1/m_b$ , and differ in semileptonic and radiative  $B$  decays. The form of the SFs cannot be calculated from first principles. Prescriptions that relate directly the partial rates for  $\overline{B} \rightarrow X_s \gamma$  and  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays and thereby avoid any parameterization of the leading SF are available [99–102]; uncertainties due to sub-leading SFs remain in these approaches. Existing measurements have tended to use parameterizations of the leading SF that respect constraints on the zeroth, first and second moments. At leading order the first and second moments are equal to  $\overline{\Lambda} = M_B - m_b$  and  $\mu_\pi^2$ , respectively. The relations between SF moments and the non-perturbative parameters of the HQE are known to second order in  $\alpha_s$  [103]. As a result, measurements of HQE parameters from global fits to  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  and  $\overline{B} \rightarrow X_s \gamma$  moments can be used to constrain the SF moments, as well as provide accurate values of  $m_b$  and other parameters for use in determining  $|V_{ub}|$ . The possibility of measuring these HQE parameters directly from moments in  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays has been explored [104], but the experimental precision achievable there is not competitive with other approaches.

A recent development is to use appropriate basis functions to approximate the shape function, thereby also including the known short-distance contributions as well as the renormalization properties of the SF [105], in order to allow a global fit of all inclusive  $B$  meson decay data.

The calculations that are used for the fits performed by HFAG are documented in Refs. [89] (BLNP), [106] (GGOU), [107] (DGE) and [92] (BLL).

The calculations start from the triple differential rate using the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (32)$$

for which the differential rate becomes

$$\frac{d^3\Gamma}{dP_+ dP_- dP_l} = \frac{G_F^2 |V_{ub}|^2}{16\pi^2} (M_B - P_+) \quad (33)$$

$$\left\{ (P_- - P_l)(M_B - P_- + P_l - P_+) \mathcal{F}_1 \right. \\ \left. + (M_B - P_-)(P_- - P_+) \mathcal{F}_2 + (P_- - P_l)(P_l - P_+) \mathcal{F}_3 \right\}.$$

The “structure functions”  $\mathcal{F}_i$  can be calculated using factorization theorems that have been proven to subleading order in the  $1/m_b$  expansion.

The BLNP [89] calculation uses these factorization theorems to write the  $\mathcal{F}_i$  in terms of perturbatively calculable hard coefficients  $H$  and jet functions  $J$ , which are convolved with the (soft) light-cone distribution functions  $S$ , the shape functions of the  $B$  meson. The BLNP calculation has been updated to include the full  $\mathcal{O}(\alpha_s^2)$  contributions [108].

The leading order term in the  $1/m_b$  expansion of the  $\mathcal{F}_i$  contains a single non-perturbative function and is calculated to subleading order in  $\alpha_s$ , while at subleading order in the  $1/m_b$  expansion there are several independent non-perturbative functions which have been calculated only at tree level in the  $\alpha_s$  expansion.

To extract the non-perturbative input one can study the photon energy spectrum in  $B \rightarrow X_s \gamma$  [91]. This spectrum is known at a similar accuracy as the  $P_+$  spectrum in  $B \rightarrow X_u \ell \overline{\nu}_\ell$ . Going to subleading order in the  $1/m_b$  expansion requires the modeling of subleading SFs, a large variety of which were studied in Ref. [89].

A distinct approach (GGOU) [106] uses a hard, Wilsonian cut-off that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite  $m_b$  and depend on the light-cone component  $k_+$  of the  $b$  quark momentum and on the momentum transfer  $q^2$  to the leptons. These functions include sub-leading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (33). Their  $k_+$  moments can be computed in the OPE and related to observables and to the shape functions defined in Ref. [89].

Going to subleading order in  $\alpha_s$  requires the definition of a renormalization scheme for the HQE parameters and for the SF. It has been noted that the relation between the moments of the SF and the forward matrix elements of local operators is plagued by ultraviolet problems which require additional renormalization. A possible scheme for improving this behavior has been suggested in Refs. [89,91], which introduce a particular definition of the quark mass (the so-called shape function scheme) based on the first moment of the measured spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

One can also attempt to calculate the SF by using additional assumptions. One possible approach (DGE) is the so-called “dressed gluon exponentiation” [107], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large  $\beta_0$  limit, where  $\beta_0$  has been defined following Eq. (18).

While attempts to quantify the SF are important, the impact of uncertainties in the SF is significantly reduced in some recent measurements that cover a larger portion of the  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  phase space. Several measurements using a combination of cuts on the leptonic momentum transfer  $q^2$  and the hadronic invariant mass  $m_X$  as suggested in Ref. [109] have been made. Measurements of the electron spectrum in

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

$\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays have been made down to momenta of 1.9 GeV or even lower, where SF uncertainties are not dominant. Of course, determining  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  partial rates in charm-dominated regions can bring in a strong dependence on the modeling of the  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  spectrum, which is problematic. The measurements quoted below have used a variety of functional forms to parameterize the leading SF; in no case does this lead to more than a 2% uncertainty on  $|V_{ub}|$ .

Weak Annihilation [110,111,106] (WA) can in principle contribute significantly in the restricted region (at high  $q^2$ ) accepted by measurements of  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays. An estimate [92] based on leptonic  $D_s$  decays [111,112] leads to a  $\sim 2\%$  uncertainty on the total  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  rate from the  $\Upsilon(4S)$ . The differential spectrum from WA decays is not well known, but they are expected to contribute predominantly at high  $q^2$ . More recent investigations of WA [112,113,114] confirm that WA is a small effect, but may become a significant source of uncertainty for  $|V_{ub}|$  measurements that only accept a small fraction,  $f_u$ , of the full  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  phase space. Model-dependent limits on WA were determined in Ref. [115], where the CLEO data were fitted to combinations of WA models and a spectator  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  component and background. More direct experimental constraints [116] on WA have recently been made by comparing the  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decay rates of charged and neutral  $B$  mesons. However, these constraints are not sensitive to the isoscalar contribution to WA. The sensitivity of  $|V_{ub}|$  determinations to WA can also be reduced by removing the region at high  $q^2$  in those measurements where  $q^2$  is determined.

### Measurements

We summarize the measurements used in the determination of  $|V_{ub}|$  below. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [117–120] will not be further considered in this review.

Inclusive electron momentum measurements [121–123] reconstruct a single charged electron to determine a partial decay rate for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  near the kinematic endpoint. This results in a high  $\mathcal{O}(50\%)$  selection efficiency and only modest sensitivity to the modeling of detector response. The decay rate can be cleanly extracted for  $E_e > 2.3$  GeV, but this is deep in the SF region, where theoretical uncertainties are large. Measurements down to 2.0 or 1.9 GeV exist, but have low ( $< 1/10$ ) signal-to-background (S/B) ratio, making the control of the  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  background a crucial point. In these analyses the inclusive electron momentum spectrum from  $B\bar{B}$  events is determined by subtracting the  $e^+e^- \rightarrow q\bar{q}$  continuum background using data samples collected just below  $B\bar{B}$  threshold. The continuum-subtracted spectrum is fitted to a combination of a model  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  spectrum and several components ( $D\ell\bar{\nu}_\ell$ ,  $D^*\ell\bar{\nu}_\ell$ , ...) of the  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  background. The resulting  $|V_{ub}|$  values for various  $E_e$  cuts are given in Table 1. The leading uncertainty at the lower lepton momentum cuts comes from the  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  background. Prospects for

reducing further the lepton momentum cut are improving in light of better knowledge of the semileptonic decays to higher mass  $X_c \ell \bar{\nu}$  states [124,37]. The determination of  $|V_{ub}|$  from these measurements is discussed below.

An untagged “neutrino reconstruction” measurement [125] from BABAR uses a combination [126] of a high-energy electron with a measurement of the missing momentum vector. This allows a much higher S/B  $\sim 0.7$  at the same  $E_e$  cut and a  $\mathcal{O}(5\%)$  selection efficiency, but at the cost of a smaller accepted phase space for  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays and uncertainties associated with the determination of the missing momentum. A control sample of  $\Upsilon(4S) \rightarrow B\bar{B}$  decays where one  $B$  is reconstructed as  $\bar{B} \rightarrow D^0(X)e\bar{\nu}$  with  $D^0 \rightarrow K^-\pi^+$  is used to reduce uncertainties from detector and background modeling. The corresponding values for  $|V_{ub}|$  are given in Table 1.

The large samples accumulated at the  $B$  factories allow studies in which one  $B$  meson is fully reconstructed and the recoiling  $B$  decays semileptonically [127–130]. The experiments can fully reconstruct a “tag”  $B$  candidate in about 0.5% (0.3%) of  $B^+B^-$  ( $B^0\bar{B}^0$ ) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag  $B$  and the remaining particles are assigned to the  $X_u$  system. The full set of kinematic properties ( $E_\ell$ ,  $m_X$ ,  $q^2$ , etc.) are available for studying the semileptonically decaying  $B$ , making possible selections that accept up to 70% of the full  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  rate. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with additional missing particles, undetected or mis-measured particles from  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decay (e.g.,  $K_L^0$  and additional neutrinos) remain an important source of uncertainty. Measurements with the largest kinematic acceptance (i.e.  $E_\ell > 1$  GeV) lead to the smallest theoretical and overall uncertainties on  $|V_{ub}|$ .

BABAR [127] and BELLE [128,129] have measured partial rates with cuts on  $m_X$ ,  $m_X$  and  $q^2$ , and  $P_+$  based on large samples of  $B\bar{B}$  events. Correlations amongst these related partial rates are taken into account in the average given in Table 1. In each case the experimental systematics have significant contributions from the modeling of  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  and  $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$  decays and from the detector response to charged particles, photons and neutral hadrons.

### Determination of $|V_{ub}|$

The determination of  $|V_{ub}|$  from the measured partial rates requires input from theory. The BLNP, GGOU and DGE calculations described previously are used to determine  $|V_{ub}|$  from all measured partial  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  rates; the values [26] are given in Table 1. The  $m_b$  input values used are derived from the fitted value in equation Eq. (24):  $m_b^{SF} = 4.588 \pm 0.025$  GeV for BLNP,  $m_b^{\text{kin}} = 4.560 \pm 0.023$  GeV for GGOU, and  $m_b^{\overline{MS}} = 4.194 \pm 0.043$  GeV for DGE. The larger uncertainties on  $m_b^{SF}$  and  $m_b^{\overline{MS}}$  reflect the effect of scheme translations, which are done at fixed-order in  $\alpha_s$ .

As an illustration of the relative sizes of the uncertainties entering  $|V_{ub}|$  we give the error breakdown for the GGOU average: statistical—2.0%; experimental—1.7%;  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  modeling—1.3%;  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  modeling—1.9%; HQE parameters—1.9%; higher-order corrections—1.4%;  $q^2$  modeling—1.3%; Weak Annihilation— $^{+0}_{-1.9}\%$ ; SF form—0.2%. The uncertainty on  $m_b$  dominates the uncertainty on  $|V_{ub}|$  from HQE parameters, but no longer dominates the overall uncertainty.

The correlations amongst the multiple BABAR recoil-based measurements [127] are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments.

**Table 1:**  $|V_{ub}|$  (in units of  $10^{-5}$ ) from inclusive  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  measurements. The first uncertainty on  $|V_{ub}|$  is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are listed in order of increasing  $f_u$  (0.19 to 0.90); those below the horizontal bar are based on recoil methods.

The theoretical calculations produce very similar results for  $|V_{ub}|$ ; the standard deviation of the theory predictions for the endpoint rate is 4.6%, for the  $m_X - q^2$  rate is 2.2%, and for the  $E_e > 1$  GeV rate is 0.8%. The  $|V_{ub}|$  values do not show a marked trend versus the kinematic acceptance,  $f_u$ , for  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays. The  $p$ -values of the averages are in the range 30-50%, indicating that the ratios of calculated partial widths in the different phase space regions are in good agreement with ratios of measured partial branching fractions.

A recent calculation [108] at NNLO accuracy of the leading term in the partial rate for kinematically restrictive cuts (e.g. near the electron endpoint energy) shows a surprisingly large change from the NLO calculation used in the BLNP method, increasing  $|V_{ub}|$  by up to  $\sim 8\%$  for some measurements. These updated calculations are not reflected in the BLNP values shown in Table 1. In the GGOU and the DGE approaches the inclusion of the dominant  $\alpha_s^2 \beta_0$  contributions do not suggest large  $\alpha_s^2$  corrections in these methods.

All calculations yield compatible  $|V_{ub}|$  values and similar error estimates. We take the arithmetic mean of the values and errors to find

$$|V_{ub}| = (4.41 \pm 0.15_{\text{exp}} \begin{smallmatrix} +0.15 \\ -0.17 \end{smallmatrix} \text{ th}) \times 10^{-3} \quad (\text{inclusive}). \quad (34)$$

As was the case with  $|V_{cb}|$ , it is hard to assign an uncertainty to  $|V_{ub}|$  for possible duality violations. However, theoretical arguments suggest that duality should hold even better in  $b \rightarrow u \ell \overline{\nu}_\ell$  than in  $b \rightarrow c \ell \overline{\nu}_\ell$  [42]. In any case, unless duality violations are much larger in  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays than in  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  decays, the precision of the  $|V_{ub}|$  determination is not yet at the level where duality violations are likely to be significant.

Hadronization uncertainties also impact the  $|V_{ub}|$  determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (e.g.  $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ ); this must be added “by hand” to the simulated  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables averaged over the sample. The resulting uncertainties have been estimated to be  $\sim 1$ -2% on  $|V_{ub}|$ .

A separate class of analyses follows the strategy discussed in Refs. [99–102], where integrals of differential distributions in  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays are compared with corresponding integrals in  $\overline{B} \rightarrow X_s \gamma$  decays to extract  $|V_{ub}|$ , thereby eliminating the need to model the leading shape function. A study [132] using the measured BABAR electron spectrum in  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays provides  $|V_{ub}|$  determinations using all available “SF-free” calculations; the resulting  $|V_{ub}|$  values have total uncertainties of  $\sim 12\%$  and are compatible with the average quoted above.

The BLL [109] calculation can be used for measurements [128,130,131] with cuts on  $m_X$  and  $q^2$ . Using the same HQE parameter input as above yields a  $|V_{ub}|$  value of  $(4.62 \pm 0.20 \pm 0.29) \times 10^{-3}$ , which is about 7% higher than the values obtained from the calculations used in Table 1 for these measurements.

### Status and outlook

At present, as indicated by the average given above, the uncertainty on  $|V_{ub}|$  from inclusive decays is at the 5% level. Are these uncertainties justified? The uncertainty on  $m_b$  was discussed in detail above. The uncertainties quoted in the calculations due to matching scales, higher order corrections, etc., are at the few percent level on  $|V_{ub}|$ . While these uncertainties are inherently difficult to quantify, the calculations take different approaches yet produce similar estimates. Experimental uncertainties have been assessed independently by BaBar and Belle. An important common source of uncertainty comes from modelling the  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays. Better measurements of these exclusive decays would be helpful in this regard, as would improved knowledge of the main  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  decays.

### $|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining  $|V_{ub}|$ . For the experiments, the specification of the final state provides better background rejection, but the lower branching fraction reflects itself in lower yields compared with inclusive decays. For theory, the calculation of the form factors for  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on  $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ , as it is the most promising mode for both experiment and theory, and recent improvements have been made in both areas. Measurements of other exclusive states can be found in Refs. [135–140,154].

**$\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$  form factor calculations** The relevant form factors for the decay  $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$  are usually defined as

$$\begin{aligned} \langle \pi(p_\pi) | V^\mu | B(p_B) \rangle = & \quad (35) \\ f_+(q^2) \left[ p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \right] + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \end{aligned}$$

in terms of which the rate becomes (in the limit  $m_\ell \rightarrow 0$ )

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_\pi|^3 |f_+(q^2)|^2, \quad (36)$$

where  $p_\pi$  is the momentum of pion in the  $B$  meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD (LQCD) and light-cone sum rules (LCSR). The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer  $q^2$  to the leptons, to avoid large discretization errors, while light-cone sum rules provide information near  $q^2 = 0$ . Interpolations between these two regions can be constrained by unitarity and analyticity.

Unquenched simulations, for which quark loop effects in the QCD vacuum are fully incorporated, have become quite common, and the first results based on these simulations for the  $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$  form factors have been obtained by the Fermilab/MILC collaboration [141] and the HPQCD collaboration [142]. The two calculations differ in the way the  $b$  quark is simulated, with HPQCD using nonrelativistic QCD and Fermilab/MILC the so-called Fermilab heavy-quark method; they agree within the quoted errors.

In order to obtain the partially-integrated differential rate, the BK parameterization [143]

$$f_+(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \tilde{q}^2)(1 - \alpha_B \tilde{q}^2)}, \quad (37)$$

$$f_0(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \tilde{q}^2/\beta_B)}, \quad (38)$$

with  $\tilde{q}^2 \equiv q^2/m_{B^*}^2$  has been used frequently to extrapolate to small values of  $q^2$ . It includes the leading pole contribution from  $B^*$ , and higher poles are modeled by a single pole. The heavy-quark scaling is satisfied if the parameters  $c_B$ ,  $\alpha_B$  and  $\beta_B$  scale appropriately. However, the BK parameterization should

be used with some caution, since it is not consistent with SCET [144]. More recently, analyticity and unitarity bounds have been employed to constrain the form factors. Making use of the heavy-quark limit, stringent constraints on the shape of the form factor can be derived [144], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in this variable. The use of lattice data in combination with a data point at small  $q^2$  from SCET or sum rules provides a stringent constraint on the shape of the form factor [145]. The form factor parametrization given in Ref. [145] has been applied to the extraction of  $|V_{ub}|$  from  $B \rightarrow \pi \ell \overline{\nu}_\ell$  using lattice data in Ref. [141].

Much work remains to be done, since the current combined statistical plus systematic errors in the lattice results are still at the  $\sim 10\%$  level on  $|V_{ub}|$  and need to be reduced. Reduction of errors to the  $\sim 5\text{--}6\%$  level for  $|V_{ub}|$  will be feasible within the next few years, with the inclusion of numerical data at lighter pion masses and finer lattice spacings, as well as possibly two-loop or nonperturbative matching between lattice and continuum heavy-to-light current operators.

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR), where the heavy mass limit has been discussed from the point of view of SCET in Ref. [147]. The sum-rule approach provides an approximation for the product  $f_B f_+(q^2)$ , valid in the region  $0 < q^2 < \sim 12 \text{ GeV}^2$ . The determination of  $f_+(q^2)$  itself requires knowledge of the decay constant  $f_B$ , which usually is obtained by replacing  $f_B$  by its two-point QCD (SVZ) sum rule [148] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio  $(f_B f_+)/f_B$ . The LCSR for  $f_B f_+$  is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite  $b$ -quark mass. The resulting expressions actually comprise a triple expansion: in the twist  $t$  of the operators near the light-cone, in  $\alpha_s$ , and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry.

There are multiple sources of uncertainties in the LCSR calculation, which are discussed in Refs. [149,150]. Currently, a total uncertainty slightly larger than  $10\%$  on  $|V_{ub}|$  is extracted from a LCSR calculation of

$$\begin{aligned} \Delta\zeta(0, q_{max}^2) &= \frac{G_F^2}{24\pi^3} \int_0^{q_{max}^2} dq^2 p_\pi^3 |f_+(q^2)|^2 \\ &= \frac{1}{|V_{ub}|^2 \tau_{B_0}} \int_0^{q_{max}^2} dq^2 \frac{d\mathcal{B}(B \rightarrow \pi \ell \nu)}{dq^2} \end{aligned} \quad (39)$$

which turn out to be [151]

$$\Delta\zeta(0, 12 \text{ GeV}^2) = 4.59_{-0.85}^{+1.00} \text{ ps}^{-1}. \quad (40)$$

It is interesting to note that the results from the LQCD and LCSR are consistent with each other when either the

See key on page 457

## Meson Particle Listings

### $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

BK parameterization or parametrizations based on conformal mappings [145,146] are used to relate them. This increases confidence in the theoretical predictions for the rate of  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ . This is complementary to the lattice results at large values of  $q^2$ , and the results from LCSR smoothly extrapolate the lattice data to small values of  $q^2$ .

An alternative determination of  $|V_{ub}|$  has been proposed by several authors [152,153] based on a model-independent relation between rare decays such as  $\bar{B} \rightarrow K^* \ell^+ \ell^-$  and  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$ . However, it requires a precise measurement of the  $\bar{B} \rightarrow K^* \ell^+ \ell^-$  decay, which is a task for ultra-high-rate experiments.

#### $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ measurements

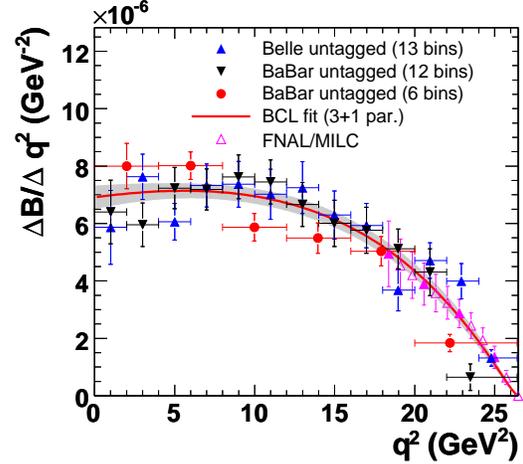

The  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second  $B$  meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance, S/B as high as 10, but low statistics. The untagged measurements have somewhat higher background levels (S/B < 1) and make slightly more restrictive kinematic cuts, but have adequate statistics to measure the  $q^2$  dependence of the form factor.

**Table 2:** Total and partial branching fractions for  $\bar{B}^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$ , scaled to a common set of external inputs. The uncertainties are from statistics and systematics. Measurements of  $\mathcal{B}(B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell)$  have been multiplied by a factor  $2\tau_{B^0}/\tau_{B^+}$  to obtain the values below.

	$\mathcal{B} \times 10^4$	$\mathcal{B}(q^2 > 16) \times 10^4$

Average	$1.42 \pm 0.03 \pm 0.04$	$0.37 \pm 0.01 \pm 0.02$

CLEO has analyzed  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  and  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$  using an untagged analysis [139]. Similar analyses have been done at BABAR [140,154] and BELLE [155]. The leading systematic uncertainties in the untagged  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  analyses are associated with modeling the missing momentum reconstruction, with backgrounds from  $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$  decays and  $e^+ e^- \rightarrow q \bar{q}$  continuum events, and with varying the form factor for the  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$  decay. The values obtained for the full and partial

branching fractions [26] are listed in Table 2 above the horizontal line. These BABAR and BELLE measurements provide the differential  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  rate versus  $q^2$ , shown in Fig. 2, which is used in the determination of  $|V_{ub}|$  discussed below.

**Figure 2:** The untagged measurements of the differential  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  branching fraction versus  $q^2$  that are used together with lattice calculations in the determination of  $|V_{ub}|$ .

Analyses [156,158] based on reconstructing a  $B$  in the  $\bar{D}^{(*)} \ell^+ \nu_\ell$  decay mode and looking for a  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  or  $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$  decay amongst the remaining particles in the event make use of the fact that the  $B$  and  $\bar{B}$  are back-to-back in the  $\Upsilon(4S)$  frame to construct a discriminant variable that provides a signal-to-noise ratio above unity for all  $q^2$  bins. A related technique was discussed in Ref. [161]. BABAR [158] and BELLE [157] have also used their samples of  $B$  mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays giving very clean but low-yield samples. The resulting full and partial branching fractions are given in Table 2. The averages take account of correlations and common systematic uncertainties, and have  $p(\chi^2) > 0.5$  in each case.

$|V_{ub}|$  can be obtained from the average  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  branching fraction and the measured  $q^2$  spectrum. Using the average [26] of partial branching fractions in the  $q^2 < 12 \text{ GeV}^2$  region,  $(0.81 \pm 0.02 \pm 0.03) \times 10^{-4}$ , along with an LCSR calculation of the theoretical rate [151] gives

$$|V_{ub}| = (3.40 \pm 0.07_{\text{exp}}^{+0.37}_{-0.32} \text{theo}) \times 10^{-3} \quad (\text{LCSR}, q^2 < 12 \text{ GeV}^2). \quad (41)$$

Fits to the measured  $q^2$  spectrum using a theoretically motivated parameterization (e.g. "BCL" from Ref. [146]) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum. Recent determinations [26,141] of  $|V_{ub}|$  from  $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$  decays have used simultaneous fits (see

# Meson Particle Listings

## $V_{cb}$ and $V_{ub}$ CKM Matrix Elements

also Refs. [162]) to the experimental partial rate and lattice points versus  $q^2$ . A fit [26] to the untagged measurements incorporates the full statistical and systematic uncertainties in the measured spectrum and uses four lattice points in the region  $q^2 > 16 \text{ GeV}^2$ , taking into account their correlations. The fit, shown in Fig. 2, has  $p(\chi^2) = 2.2\%$ . If the tagged measurements, which are less consistent in the  $q^2 < 8 \text{ GeV}^2$  region, are included, the fit gives  $p(\chi^2) < 0.01\%$ . We quote the result from the untagged measurements and add the difference ( $0.09 \times 10^{-3}$ ) between the  $|V_{ub}|$  values from the two fits as an additional uncertainty to find

$$|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3} \quad (\text{exclusive}). \quad (42)$$

The largest contributions to the uncertainty come from lattice systematic and statistical errors, which will be further improved in the future.

### Conclusion

The study of semileptonic  $B$  meson decays continues to be an active area for both theory and experiment. Substantial progress has been made in the application of HQE calculations to inclusive decays, where fits to moments of  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  decays provide precise values for  $|V_{cb}|$  and, in conjunction with  $B \rightarrow X_s \gamma$  decays or input on  $m_c$ , provide precise and consistent values for  $m_b$ . The values from the inclusive and exclusive  $|V_{cb}|$  determinations are in reasonable agreement.

Continued improvements in measurements of inclusive  $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$  decays, along with additional theoretical studies of higher order contributions and improved knowledge of  $m_b$ , have strengthened our determination of  $|V_{ub}|$ . Further progress in this area is possible, but will require better theoretical control over higher order terms, and improved experimental knowledge of the  $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$  background.

Progress in both  $b \rightarrow u$  and  $b \rightarrow c$  exclusive channels depends crucially on progress in lattice calculations. Here the prospects are good, since unquenched calculations are now available for the semileptonic form factors discussed here, as well as for other hadronic weak matrix elements needed to obtain the elements and phase of the CKM matrix [163,164]. Projections for future uncertainties from lattice calculations can be found in Ref. [165].

The measurements of the  $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$  branching fraction have uncertainties below 4%, and the measured  $q^2$  dependence is reasonably precise. Reducing the theoretical uncertainties to a comparable level will require significant effort, but is clearly vital.

The difference between the values for  $|V_{ub}|$  obtained from inclusive and exclusive decays has persisted for many years, despite significant improvements in both theory and experiment for both methods. How to reconcile these results remains an intriguing puzzle.

Both  $|V_{cb}|$  and  $|V_{ub}|$  are indispensable inputs into unitarity triangle fits. In particular, knowing  $|V_{ub}|$  with good precision allows a test of CKM unitarity in the most direct way, by

comparing the length of the  $|V_{ub}|$  side of the unitarity triangle with the measurement of  $\sin(2\beta)$ . This comparison of a “tree” process ( $b \rightarrow u$ ) with a “loop-induced” process ( $B^0 - \overline{B}^0$  mixing) provides sensitivity to possible contributions from new physics. While the effort required to further improve our knowledge of these CKM matrix elements is large, it is well motivated.

The authors would like to acknowledge helpful input from C. Bozzi, J. Dingfelder, P. Gambino, A. Kronfeld, V. Luth, F. Muheim, C. Schwanda, P. Urquijo and R. Van de Water.

### $V_{cb}$ MEASUREMENTS

For the discussion of  $V_{cb}$  measurements, which is not repeated here, see the review on "Determination of  $|V_{cb}|$  and  $|V_{ub}|$ ."

The CKM matrix element  $|V_{cb}|$  can be determined by studying the rate of the semileptonic decay  $B \rightarrow D^{(*)} \ell \nu$  as a function of the recoil kinematics of  $D^{(*)}$  mesons. Taking advantage of theoretical constraints on the normalization and a linear  $\omega$  dependence of the form factors ( $F(\omega)$ ,  $G(\omega)$ ) provided by Heavy Quark Effective Theory (HQET), the  $|V_{cb}| \times F(\omega)$  and  $\rho^2$  ( $a^2$ ) can be simultaneously extracted from data, where  $\omega$  is the scalar product of the two-meson four velocities,  $F(1)$  is the form factor at zero recoil ( $\omega=1$ ) and  $\rho^2$  is the slope, sometimes denoted as  $a^2$ . Using the theoretical input of  $F(1)$ , a value of  $|V_{cb}|$  can be obtained.

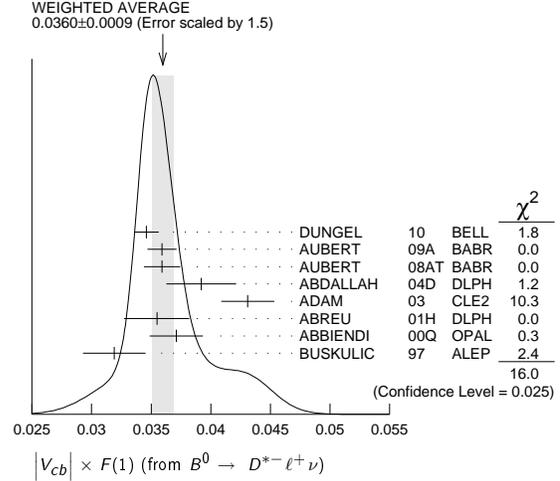

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

### $|V_{cb}| \times F(1)$ (from $B^0 \rightarrow D^{*-} \ell^+ \nu$ )

- 1 Uses fully reconstructed  $D^{*-} \ell^+ \nu$  events ( $\ell = e$  or  $\mu$ ).
- 2 Obtained from a global fit to  $B \rightarrow D^{(*)} \ell \nu$  events, with reconstructed  $D^0 \ell$  and  $D^+ \ell$  final states and  $\rho^2 = 1.22 \pm 0.02 \pm 0.07$ .
- 3 Measured using the dependence of  $B^- \rightarrow D^{*0} e^- \bar{\nu}_e$  decay differential rate and the form factor description by CAPRINI 98 with  $\rho^2 = 1.16 \pm 0.06 \pm 0.08$ .
- 4 Measurement using fully reconstructed  $D^*$  sample with a  $\rho^2 = 1.32 \pm 0.15 \pm 0.33$ .
- 5 Average of the  $B^0 \rightarrow D^*(2010)^- \ell^+ \nu$  and  $B^+ \rightarrow \bar{D}^*(2007)^+ \ell^+ \nu$  modes with  $\rho^2 = 1.61 \pm 0.09 \pm 0.21$  and  $f_{\pm} = 0.521 \pm 0.012$ .
- 6 ABREU 01H measured using about 5000 partial reconstructed  $D^*$  sample with a  $\rho^2 = 1.34 \pm 0.14 \pm 0.24$ .
- 7 ABBIENDI 00Q: measured using both inclusively and exclusively reconstructed  $D^{*\pm}$  samples with a  $\rho^2 = 1.21 \pm 0.12 \pm 0.20$ . The statistical and systematic correlations between  $|V_{cb}| \times F(1)$  and  $\rho^2$  are 0.90 and 0.54 respectively.
- 8 BUSKULIC 97: measured using exclusively reconstructed  $D^{*\pm}$  with a  $a^2 = 0.31 \pm 0.17 \pm 0.08$ . The statistical correlation is 0.92.
- 9 Measured using fully reconstructed  $D^*$  sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters:  $\rho^2 = 1.191 \pm 0.048 \pm 0.028$ ,  $R_1(1) = 1.429 \pm 0.061 \pm 0.044$ , and  $R_2(1) = 0.827 \pm 0.038 \pm 0.022$ .
- 10 Measurement using fully reconstructed  $D^*$  sample with a  $\rho^2 = 1.29 \pm 0.03 \pm 0.27$ .
- 11 Combines with previous partial reconstructed  $D^*$  measurement with a  $\rho^2 = 1.39 \pm 0.10 \pm 0.33$ .
- 12 Measured using exclusive  $B^0 \rightarrow D^*(892)^- e^+ \nu$  decays with  $\rho^2 = 1.35 \pm 0.17 \pm 0.19$  and a correlation of 0.91.
- 13 BRIERE 02 result is based on the same analysis and data sample reported in ADAM 03.
- 14 ABREU 96P: measured using both inclusively and exclusively reconstructed  $D^{*\pm}$  samples.

- 15 BARISH 95: measured using both exclusive reconstructed  $B^0 \rightarrow D^{*-} \ell^+ \nu$  and  $B^+ \rightarrow D^{*0} \ell^+ \nu$  samples. They report their experiment's uncertainties  $\pm 0.0019 \pm 0.0018 \pm 0.0008$ , where the first error is statistical, the second is systematic, and the third is the uncertainty in the lifetimes. We combine the last two in quadrature.

### $|V_{cb}| \times G(1)$ (from $B \rightarrow D^- \ell^+ \nu$ )

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.04264 ± 0.00153 OUR EVALUATION</b>	with $\rho^2=1.186 \pm 0.054$ and a correlation 0.83. The fitted $\chi^2$ is 0.5 for 8 degrees of freedom.

- 16 Obtained from a fit to the combined  $B \rightarrow \bar{D} \ell^+ \nu \ell$  sample in which a hadronic decay of the second  $B$  meson is fully reconstructed and  $\rho^2 = 1.20 \pm 0.09 \pm 0.04$ .
- 17 Obtained from a global fit to  $B \rightarrow D^{(*)} \ell \nu$  events, with reconstructed  $D^0 \ell$  and  $D^+ \ell$  final states and  $\rho^2 = 1.20 \pm 0.04 \pm 0.07$ .
- 18 Using the missing energy and momentum to extract kinematic information about the undetected neutrino in the  $B^0 \rightarrow D^- \ell^+ \nu$  decay.
- 19 BARTELT 99: measured using both exclusive reconstructed  $B^0 \rightarrow D^- \ell^+ \nu$  and  $B^+ \rightarrow D^0 \ell^+ \nu$  samples.
- 20 BUSKULIC 97: measured using exclusively reconstructed  $D^{*\pm}$  with a  $a^2 = -0.05 \pm 0.53 \pm 0.38$ . The statistical correlation is 0.99.
- 21 ATHANAS 97: measured using both exclusive reconstructed  $B^0 \rightarrow D^- \ell^+ \nu$  and  $B^+ \rightarrow D^0 \ell^+ \nu$  samples with a  $\rho^2 = 0.59 \pm 0.22 \pm 0.12 \pm 0.59$ . They report their experiment's uncertainties  $\pm 0.0044 \pm 0.0048 \pm 0.0053$ , where the first error is statistical, the second is systematic, and the third is the uncertainty due to the form factor model variations. We combine the last two in quadrature.

### $V_{ub}$ MEASUREMENTS

For the discussion of  $V_{ub}$  measurements, which is not repeated here, see the review on "Determination of  $|V_{cb}|$  and  $|V_{ub}|$ ."

The CKM matrix element  $|V_{ub}|$  can be determined by studying the rate of the charmless semileptonic decay  $b \rightarrow u \ell \nu$ . The relevant branching ratio measurements based on exclusive and inclusive decays can be found in the  $B$  Listings, and are not repeated here.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
5713 ± 2		<sup>4</sup> ACCIARRI 99N	L3	$e^+e^- \rightarrow Z$

<sup>1</sup> AFFOLDER 01F uses the reconstructed  $B$  meson through semileptonic decay channels. The fraction of light  $B$  mesons that are produced at  $L=1$   $B^{**}$  states is measured to be  $0.28 \pm 0.06 \pm 0.03$ .

<sup>2</sup> BARATE 98L uses fully reconstructed  $B$  mesons to search for  $B^{**}$  production in the  $B\pi^\pm$  system. In the framework of heavy quark symmetry (HQS), they also measured the mass of  $B_2^*$  to be  $5739^{+8+6}_{-11-4}$  MeV/ $c^2$  and the relative production rate of  $B(b \rightarrow B_2^* \rightarrow B^{(*)}\pi)/B(b \rightarrow B_{u,d}) = (31 \pm 9^{+6}_{-5})\%$ .

<sup>3</sup> Using  $m_{B\pi} - m_B = 424 \pm 4 \pm 10$  MeV.

<sup>4</sup> ACCIARRI 99N uses inclusive reconstructed  $B$  mesons to search for  $B^{**}$  production in the  $B^{(*)}\pi^\pm$  system. In the framework of HQET, they measured the mass of  $B_1^*$  and  $B_2^*$  to be  $5670 \pm 10 \pm 13$  MeV and  $5768 \pm 5 \pm 6$  with the  $B(b \rightarrow B^{**}) = (32 \pm 3 \pm 6) \times 10^{-2}$ . They also reported the evidence for the existence of an excited  $B$ -meson state or mixture of states in the region 5.9–6.0 GeV.

<sup>1</sup> Uses  $B_s^0 \rightarrow J/\psi\phi$  fully reconstructed decays.

<sup>2</sup> Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+\mu^-$  decays.

<sup>3</sup> From the decay  $B_s \rightarrow J/\psi(1S)\phi$ .

<sup>4</sup> From the decay  $B_s \rightarrow D_s^-\pi^+$ .

$$m_{B_s^0} - m_B$$

$m_B$  is the average of our  $B$  masses ( $m_{B^\pm} + m_{B^0}$ )/2.

80 to 130	68	LEE-FRANZINI	90	CSB2 $e^+e^- \rightarrow \Upsilon(5S)$

<sup>1</sup> The reported result is  $m_{B_s^0} - m_{B^+} = 87.52 \pm 0.30 \pm 0.12$  MeV. We convert it to the mass difference with respect to the average of ( $m_{B^\pm} + m_{B^0}$ )/2.

<sup>2</sup> The reported result is  $m_{B_s^0} - m_{B^0} = 86.38 \pm 0.90 \pm 0.06$  MeV. We convert it to the mass difference with respect to the average of ( $m_{B^\pm} + m_{B^0}$ )/2.

$$m_{B_{SH}^0} - m_{B_{SL}^0}$$

See the  $B_s^0 - \bar{B}_s^0$  MIXING section near the end of these  $B_s^0$  Listings.

### $B_s^0$ MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

The

First "OUR EVALUATION" is an average of  $1 / [\Gamma_{B_s^0} + \Gamma_{B_s^{*L}}]$ .

The Second "OUR EVALUATION" is the average of  $B_s \rightarrow D_s X$  data listed below.

<sup>1</sup> AALTONEN 11AP combines the fully reconstructed  $B_s^0 \rightarrow D_s^-\pi^+$  decays and partially reconstructed  $B_s^0 \rightarrow D_s X$  decays.

<sup>2</sup> Measured using  $D_s \mu^+$  vertices.

<sup>3</sup> Uses  $D_s^- \ell^+$ , and  $\phi \ell^+$  vertices.

<sup>4</sup> Measured using  $D_s$  hadron vertices.

<sup>5</sup> Measured using  $D_s^- \ell^+$  vertices.

<sup>6</sup> ACKERSTAFF 98F use fully reconstructed  $D_s^- \rightarrow \phi\pi^-$  and  $D_s^- \rightarrow K^{*0}K^-$  in the inclusive  $B_s^0$  decay.

<sup>7</sup> Combined results from  $D_s^- \ell^+$  and  $D_s$  hadron.

<sup>8</sup> Measured using  $\phi \ell$  vertices.

<sup>9</sup> Measured using inclusive  $D_s$  vertices.

<sup>10</sup> Combined result for the four ABREU 96F methods.

<sup>11</sup> Exclusive reconstruction of  $B_s \rightarrow \psi\phi$ .

<sup>12</sup> ABREU 94E uses the flight-distance distribution of  $D_s$  vertices,  $\phi$ -lepton vertices, and  $D_s \mu$  vertices.

## $B_s^0$

- <sup>1</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays.
- <sup>2</sup> Uses the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays and assuming  $CP$ -violating angle  $\beta_s(B^0 \rightarrow J/\psi\phi) = 0.02$ .
- <sup>3</sup> The error includes both statistical and systematic uncertainties.
- <sup>4</sup> Measured using fully reconstructed  $B_s \rightarrow J/\psi\phi$  decays.
- <sup>5</sup> Measured the angular and lifetime parameters for the time-dependent angular untagged decays  $B_d^0 \rightarrow J/\psi K^{*0}$  and  $B_s^0 \rightarrow J/\psi\phi$ .
- <sup>6</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays and assuming  $CP$ -violating phase  $\phi_s = 0$ .
- <sup>7</sup> Obtains 90% CL interval  $-0.06 < \Delta\Gamma_s < 0.30$ .
- <sup>8</sup> ABAZOV 07 reports  $0.17 \pm 0.09 \pm 0.02$  with  $CP$ -violating phase  $\phi_s$  as a free parameter.
- <sup>9</sup> Combines  $D^0$  measurements of time-dependent angular distributions in  $B_s^0 \rightarrow J/\psi\phi$  and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

### $\Delta\Gamma_s^{CP} / \Gamma_s$

$\Gamma_s$  and  $\Delta\Gamma_s^{CP}$  are the decay rate average and difference between even,  $\Gamma_s^{CP-even}$ , and odd,  $\Gamma_s^{CP-odd}$ ,  $CP$  eigenstates.

- <sup>1</sup> AAIJ 12d reports average decay width of  $B_s^0$ ,  $\Gamma_{B_s^0} = 0.657 \pm 0.009 \pm 0.008 \text{ ps}^{-1}$  that we converted to  $1/\Gamma_{B_s^0}$ .
- <sup>2</sup> Measured using the time-dependent angular analysis of  $B_s^0 \rightarrow J/\psi\phi$  decays.
- <sup>3</sup> The error includes both statistical and systematic uncertainties.

## $B_s^0$ DECAY MODES

These branching fractions all scale with  $B(\bar{b} \rightarrow B_s^0)$ .

The branching fraction  $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$  is not a pure measurement since the measured product branching fraction  $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$  was used to determine  $B(\bar{b} \rightarrow B_s^0)$ , as described in the note on " $B^0$ - $\bar{B}^0$  Mixing"

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{ anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction ( $\Gamma_i / \Gamma$ )	Confidence level
$\Gamma_1 D_s^- \text{ anything}$	$(93 \pm 25) \%$	
$\Gamma_2 \ell \nu_\ell X$	$(9.5 \pm 2.7) \%$

## Meson Particle Listings

 $B_s^0$ [a] Not a pure measurement. See note at head of  $B_s^0$  Decay Modes.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

## CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 11 measurements and one constraint to determine 6 parameters. The overall fit has a  $\chi^2 = 1.5$  for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
<b>0.93 ± 0.25 OUR AVERAGE</b>				
0.91 ± 0.18 ± 0.41		<sup>1</sup> DRUTSKOY 07	BELL	$e^+ e^- \rightarrow \Upsilon(4S)$
0.81 ± 0.24 ± 0.22	90	<sup>2</sup> BUSKULIC 96E	ALEP	$e^+ e^- \rightarrow Z$
1.56 ± 0.58 ± 0.44	147	<sup>3</sup> ACTON 92N	OPAL	$e^+ e^- \rightarrow Z$

<sup>1</sup> The extraction of this result takes into account the correlation between the measurements of  $B(\Upsilon(5S) \rightarrow D_s X)$  and  $B(\Upsilon(5S) \rightarrow D^0 X)$ .

<sup>2</sup> BUSKULIC 96E separate  $c\bar{c}$  and  $b\bar{b}$  sources of  $D_s^+$  mesons using a lifetime tag, subtract generic  $\bar{b} \rightarrow W^+ \rightarrow D_s^+$  events, and obtain  $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \text{ anything}) = 0.088 \pm 0.020 \pm 0.020$  assuming  $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$  and PDG 1994 values for the relative partial widths to other  $D_s$  channels. We evaluate using our current values  $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{b} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .

<sup>3</sup> ACTON 92N assume that excess of 147 ± 48  $D_s^0$  events over that expected from  $B^0$ ,  $B^+$ , and  $c\bar{c}$  is all from  $B_s^0$  decay. The product branching fraction is measured to be  $B(\bar{b} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1) \times 10^{-3}$ . We evaluate using our current values  $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{b} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .

 $\Gamma(\ell\nu_\ell X) / \Gamma_{\text{total}}$   $\Gamma_2 / \Gamma$ 

VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN	COMMENT
<b>9.5 ± 2.5 ± 1.1</b>		<sup>1</sup> LEES	12A	BABR $e^+ e^-$
<b>-2.0 - 1.9</b>				

<sup>1</sup> The measurement corresponds to a branching fraction where the lepton originates from bottom decay and is the average between the electron and muon branching fractions. LEES 12A uses the correlation of the production of  $\phi$  mesons in association with a lepton in  $e^+ e^-$  data taken at center-of-mass energies between 10.54 and 11.2 GeV.

 $\Gamma(D_s^- \ell^+ \nu_\ell \text{ anything}) / \Gamma_{\text{total}}$   $\Gamma_3 / \Gamma$ 

The values and averages in this section serve only to show what values result if one assumes our  $B(\bar{b} \rightarrow B_s^0)$ . They cannot be thought of as measurements since the underlying product branching fractions were also used to determine  $B(\bar{b} \rightarrow B_s^0)$  as described in the note on "Production and Decay of  $b$ -Flavored Hadrons."

0.13 ± 0.04 ± 0.04	27	<sup>4</sup> BUSKULIC 92E	ALEP	$e^+ e^- \rightarrow Z$

<sup>1</sup> BUSKULIC 95o use  $D_s \ell$  correlations. The measured product branching ratio is  $B(\bar{b} \rightarrow B_s) \times B(B_s \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = (0.82 \pm 0.09_{-0.14}^{+0.13})\%$  assuming  $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$  and PDG 1994 values for the relative partial widths to the six other  $D_s$  channels used in this analysis. Combined with results from  $\Upsilon(4S)$  experiments this can be used to extract  $B(\bar{b} \rightarrow B_s) = (11.0 \pm 1.2_{-2.6}^{+2.5})\%$ . We evaluate using our current values  $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{b} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .

<sup>2</sup> ABREU 92M measured muons only and obtained product branching ratio  $B(Z \rightarrow b\bar{b}) \times B(\bar{b} \rightarrow B_s) \times B(B_s \rightarrow D_s \mu^+ \nu_\mu \text{ anything}) \times B(D_s \rightarrow \phi\pi) = (18 \pm 8) \times 10^{-5}$ . We evaluate using our current values  $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due

to  $B(\bar{b} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ . We use  $B(Z \rightarrow b\bar{b}) = 2B(Z \rightarrow b\bar{b}) = 2 \times (0.2212 \pm 0.0019)$ .

<sup>3</sup> ACTON 92N is measured using  $D_s \rightarrow \phi\pi^+$  and  $K^*(892)^0 K^+$  events. The product branching fraction measured is measured to be  $B(\bar{b} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$ . We evaluate using our current values  $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{b} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ .

<sup>4</sup> BUSKULIC 92E is measured using  $D_s \rightarrow \phi\pi^+$  and  $K^*(892)^0 K^+$  events. They use  $2.7 \pm 0.7\%$  for the  $\phi\pi^+$  branching fraction. The average product branching fraction is measured to be  $B(\bar{b} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = 0.020 \pm 0.0055_{-0.006}^{+0.005}$ .

We evaluate using our current values  $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$  and  $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$ . Our first error is their experiment's and our second error is that due to  $B(\bar{b} \rightarrow B_s^0)$  and  $B(D_s \rightarrow \phi\pi)$ . Superseded by BUSKULIC 95o.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

### $B_s^0\bar{B}_s^0$ MIXING

For a discussion of  $B_s^0\bar{B}_s^0$  mixing see the note on " $B^0\bar{B}^0$  Mixing" in the  $B^0$  Particle Listings above.

$\chi_s$  is a measure of the time-integrated  $B_s^0\bar{B}_s^0$  mixing probability that produced  $B_s^0(\bar{B}_s^0)$  decays as a  $\bar{B}_s^0(B_s^0)$ . Mixing violates  $\Delta B \neq 2$  rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$\chi_s = \frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = (m_{B_{sH}^0} - m_{B_{sL}^0}) \tau_{B_s^0}$$

where  $H, L$  stand for heavy and light states of two  $B_s^0$   $CP$  eigenstates and

$$\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_{sH}^0} + \Gamma_{B_{sL}^0})}$$

#### $\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$

$\Delta m_{B_s^0}$  is a measure of  $2\pi$  times the  $B_s^0\bar{B}_s^0$  oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is provided by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

- Measured using  $B_S^0 \rightarrow D_S^- \pi^+$  and  $D_S^- \pi^+ \pi^- \pi^+$  decays.
- Significance of oscillation signal is  $5.4 \sigma$ . Also reports  $|V_{td} / V_{ts}| = 0.2060 \pm 0.0007^{+0.0081}_{-0.0060}$ .
- A likelihood scan over the oscillation frequency,  $\Delta m_s$ , gives a most probable value of  $19 \text{ ps}^{-1}$  and a range of  $17 < \Delta m_s < 21 (\text{ps}^{-1})$  at 90% C.L. assuming Gaussian uncertainties. Also excludes  $\Delta m_s < 14.8 \text{ ps}^{-1}$  at 95% C.L.
- Significance of oscillation signal is 0.2%. Also reported the value  $|V_{td} / V_{ts}| = 0.208^{+0.001+0.008}_{-0.002-0.006}$ .
- Uses leptons emitted with large momentum transverse to a jet and improved techniques for vertexing and flavor-tagging.
- Updates of  $D_S$ -lepton analysis.
- Combined results from all Delphi analyses.
- Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.
- ABE 03 uses the novel "charge dipole" technique to reconstruct separate secondary and tertiary vertices originating from the  $B \rightarrow D$  decay chain. The analysis excludes  $\Delta m_s < 4.9 \text{ ps}^{-1}$  and  $7.9 < \Delta m_s < 10.3 \text{ ps}^{-1}$ .
- Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with  $D_S$  exclusively reconstructed; (3) inclusive semileptonic decays.
- ABE 02V uses exclusively reconstructed  $D_S^-$  mesons and excludes  $\Delta m_s < 1.4 \text{ ps}^{-1}$  and  $2.4 < \Delta m_s < 5.3 \text{ ps}^{-1}$  at 95% CL.
- Uses fully or partially reconstructed  $D_S \ell$  vertices and a mixing tag as a flavor tagging.
- Replaced by ABDALLAH 04A. Uses  $D_S^- \ell^+$ , and  $\phi \ell^+$  vertices, and a multi-variable discriminant as a flavor tagging.
- Uses inclusive  $D_S$  vertices and fully reconstructed  $B_S$  decays and a multi-variable discriminant as a flavor tagging.
- Uses  $\ell$ - $Q_{\text{hem}}$  and  $\ell$ - $\ell$ .
- ABE 99D assumes  $\tau_{B_S^0} = 1.55 \pm 0.05 \text{ ps}$  and  $\Delta\Gamma/\Delta m = (5.6 \pm 2.6) \times 10^{-3}$ .
- ABE 99J uses  $\phi$   $\ell$ - $\ell$  correlation.
- BARATE 99J uses combination of an inclusive lepton and  $D_S^-$ -based analyses.
- BARATE 98C combines results from  $D_S h\ell/Q_{\text{hem}}$ ,  $D_S hK$  in the same side,  $D_S \ell/Q_{\text{hem}}$  and  $D_S \ell K$  in the same side.
- Uses  $\ell$ - $Q_{\text{hem}}$ .
- Uses  $\ell$ - $\ell$ .
- ADAM 97 combines results from  $D_S \ell$ - $Q_{\text{hem}}$ ,  $\ell$ - $Q_{\text{hem}}$ , and  $\ell$ - $\ell$ .
- BUSKULIC 96M uses  $D_S$  lepton correlations and lepton, kaon, and jet charge tags.
- BUSKULIC 95J uses  $\ell$ - $Q_{\text{hem}}$ . They find  $\Delta m_s > 5.6 [ > 6.1 ]$  for  $f_S = 10\% [12\%]$ . We interpolate to our central value  $f_S = 10.5\%$ .

$$x_s = \Delta m_{B_S^0} / \Gamma_{B_S^0}$$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on  $\Delta m_{B_S^0}$  and "OUR EVALUATION" of the  $B_S^0$  mean lifetime.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 Uses the dimuon charge asymmetry with different impact parameters from which it reports  $A_{SL}^{\mu\mu} = (-18.1 \pm 10.6) \times 10^{-3}$ .
- 2 ABAZOV 10E reports a measurement of flavor-specific asymmetry in  $B_S^0 \rightarrow \mu^+ D_{(s)}^{*-} X$  decays with a decay-time analysis including initial-state flavor tagging,  $A_{SL}^{\mu\mu} = (-1.7 \pm 9.1^{+1.4}_{-1.5}) \times 10^{-3}$  which is approximately equal to  $4 \times \text{Re}(\epsilon_{B_S^0}) / (1 + |\epsilon_{B_S^0}|^2)$ .
- 3 ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of  $A_{SL}^{\mu\mu} = (-9.57 \pm 2.51 \pm 1.46) \times 10^{-3}$  in semileptonic  $b$ -hadron decays. Using the measured production ratio of  $B_d^0$  and  $B_s^0$ , and the asymmetry of  $B_d^0 A_{SL}^{\mu\mu} = (-4.7 \pm 4.6) \times 10^{-3}$  measured from  $B$ -factories, they obtain the asymmetry for  $B_S^0$ .
- 4 The first direct measurement of the time integrated flavor untagged charge asymmetry in semileptonic  $B_S^0$  decays is reported as  $2x A_{SL}^{\mu\mu}(\text{untagged}) = A_{SL}^{\mu\mu} = (2.45 \pm 1.93 \pm 0.35) \times 10^{-2}$ .

CP Violation phase  $\beta_s$ 

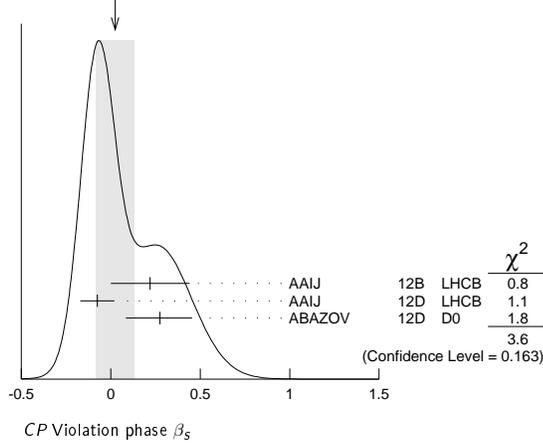

$-2\beta_s$  is the weak phase difference between  $B_S^0$  mixing amplitude and the  $B_S^0 \rightarrow J/\psi \phi$  decay amplitude. The Standard Model value of  $\beta_s$  is  $\arg(-\frac{V_{ts}V_{cb}^*}{V_{cs}V_{cb}^*})$ .

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/scaling procedure takes into account correlation between the measurements.

6.32 ± 0.06	<sup>3</sup> ACKERSTAFF 98o	OPAL	$e^+e^- \rightarrow Z$

- <sup>1</sup> Measured using a fully reconstructed decay mode of  $B_c \rightarrow J/\psi\pi$ .
- <sup>2</sup> ABE 98M observed  $20.4^{+6.2}_{-5.5}$  events in the  $B_c^+ \rightarrow J/\psi(1S)\ell\nu_\ell$  with a significance of  $> 4.8$  standard deviations. The mass value is estimated from  $m(J/\psi(1S)\ell)$ .
- <sup>3</sup> ACKERSTAFF 98o observed 2 candidate events in the  $B_c \rightarrow J/\psi(1S)\pi^+$  channel with an estimated background of 0.63 ± 0.20 events.

### $B_c^\pm$ MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

VALUE ( $10^{-12}$ s)	DOCUMENT ID	TECN	COMMENT
<b>0.453 ± 0.041 OUR EVALUATION</b>			
<b>0.45 ± 0.04 OUR AVERAGE</b>			
$0.448^{+0.038}_{-0.036} \pm 0.032$	<sup>4</sup> ABAZOV 09H	D0	$p\bar{p}$ at 1.96 TeV

### DEVELOPMENTS IN HEAVY QUARKONIUM SPECTROSCOPY

Written May 2012 by S. Eidelman (Budker Inst. and Novosibirsk State Univ.), B.K. Heltsley (Cornell Univ.), J.J. Hernandez-Rey (Univ. Valencia-CSIC), S. Navas (Univ. Granada), and C. Patrignani (Univ. Genova, INFN).

A golden age for heavy quarkonium physics dawned a decade ago, initiated by the confluence of exciting advances in quantum chromodynamics (QCD) and an explosion of related experimental activity. The subsequent broad spectrum of breakthroughs, surprises, and continuing puzzles had not been anticipated. In that period, the BESII program concluded only

## Heavy Quarkonium Spectroscopy

to give birth to BESIII; the  $B$ -factories and CLEO-c flourished; quarkonium production and polarization measurements at HERA and the Tevatron matured; and heavy-ion collisions at RHIC opened a window on the deconfinement regime. For an extensive presentation of the status of heavy quarkonium physics, the reader is referred to several reviews [1–7], the last of which covers developments through the middle of 2010, and which supplies some tabular information and phrasing reproduced here (with kind permission, copyright 2011, Springer). This note focuses solely on experimental developments in heavy quarkonium spectroscopy, and in particular on those too recent to have been included in Ref. 7.

Table 1 lists properties of newly observed conventional heavy quarkonium states, where “newly” is interpreted to mean within the past decade. The  $h_c$  is the  $^1P_1$  state of charmonium, singlet partner of the long-known  $\chi_{cJ}$  triplet  $^3P_J$ . The  $\eta_c(2S)$  is the first excited state of the pseudoscalar ground state  $\eta_c(1S)$ , lying just below the mass of its vector counterpart,  $\psi(2S)$ . The state originally dubbed  $Z(3930)$  is now regarded by many as the first observed  $2P$  state of  $\chi_{cJ}$ , the  $\chi_{c2}(2P)$ . The first  $B$ -meson seen that contains charm is the  $B_c^+$ . The ground state of bottomonium is the  $\eta_b(1S)$ , recently confirmed with a second observation of more than  $5\sigma$  significance. The  $\Upsilon(1D)$  is the lowest-lying  $D$ -wave triplet of the  $b\bar{b}$  system.

**Table 1:** New *conventional* states in the  $c\bar{c}$ ,  $b\bar{c}$ , and  $b\bar{b}$  regions, ordered by mass. Masses  $m$  and widths  $\Gamma$  represent the weighted averages from the listed sources. Quoted uncertainties reflect quadrature summation from individual experiments. In the Process column, the decay mode of the new state claimed is indicated in parentheses. Ellipses (...) indicate inclusively selected event topologies; *i.e.*, additional particles not required by the Experiments to be present. A question mark (?) indicates an unmeasured value. For each Experiment a citation is given, as well as the statistical significance in number of standard deviations ( $\#\sigma$ ), or “(np)” for “not provided”. The Year column gives the date of first measurement cited. The Status column indicates that the state has been observed by at most one (NC!-needs confirmation) or at least two independent experiments with significance of  $>5\sigma$  (OK). The state labelled  $\chi_{c2}(2P)$  has previously been called  $Z(3930)$ . See also the reviews in [1–7]. Adapted from [7] with kind permission, copyright (2011), Springer.

Both the  $h_b(1P)$ , the bottomonium counterpart of  $h_c(1P)$ , and the next excited state,  $h_b(2P)$ , were very recently observed by Belle [31], as described further below, in dipion transitions from either the  $\Upsilon(5S)$  or  $Y_b(10888)$ . All fit into their respective spectroscopies roughly where expected. Their exact masses, production mechanisms, and decay modes provide guidance to their descriptions within QCD. The  $h_b(nP)$  states still need experimental confirmation at the  $5\sigma$  level, as does the  $\chi_{bJ}(3P)$  triplet.

Correspondingly, the menagerie of new, heavy-quarkonium-like *unanticipated* states\* is shown in Table 2; notice that just a handful have been experimentally confirmed. None can unambiguously be assigned a place in the hierarchy of charmonia or bottomonia; neither do any have a universally accepted unconventional origin. The  $X(3872)$  occupies a unique niche among the unexplained states as both the first and the most intriguing. It is, by now, widely studied, yet its interpretation demands much more experimental attention. The  $Y(4260)$  and  $Y(4360)$  are vector states decaying to  $\pi^+\pi^-J/\psi$  and  $\pi^+\pi^-\psi(2S)$ , respectively, yet, unlike most conventional vector charmonia, do not correspond to enhancements in the  $e^+e^-$  hadronic cross section. The three  $Z_c^+$  and two  $Z_b^+$  states, each decaying to a charged pion and conventional heavy quarkonium state, would be manifestly exotic, but remain unconfirmed. Final states of the type  $\Upsilon(nS)\pi^+\pi^-$  from  $e^+e^-$  collisions acquired near the  $\Upsilon(5S)$  have a lineshape differing somewhat from that of multi-hadronic events, which suggested a new state  $Y_b(10888)$ , distinct from  $\Upsilon(5S)$ , which could be analogous to  $Y(4260)$ . The nature of  $Y_b(10888)$ , if it does mimic the behavior of the charmonium-region  $Y$ 's, could help to explain the observed (and otherwise unexpected) high rate of dipion transitions to  $\Upsilon(nS)$  and  $h_b(nP)$  seen in the  $e^+e^-$  collisions near the  $\Upsilon(5S)$ . It could also provide insight into the  $Z_b^+$  states, which appear to be intermediate resonances in the dipion transitions.

BABAR [71,59] has searched for the three  $Z_c^\pm$  states in the charmonium mass region seen by Belle, and failed to observe any significant signals. The approach taken in searching for  $B \rightarrow Z^\pm K \rightarrow (c\bar{c})K\pi$ , where  $(c\bar{c})$  is  $\psi(2S)$  or  $\chi_{c1}$ , is to first fit the data for all reasonable  $K\pi$  mass or angular structure, having demonstrated that the presence of one or more  $Z$ 's cannot be accommodated by this procedure. After doing so, the finding is that some of what might be the Belle excess of events above Belle background gets absorbed into the  $K\pi$  structure of the BABAR background. As shown in Table 2, where Belle observes signals of significances  $5.0\sigma$ ,  $5.0\sigma$ , and  $6.4\sigma$  for  $Z_1(4050)^+$ ,  $Z_2(4250)^+$ , and  $Z(4430)^+$ , respectively, BABAR reports  $1.1\sigma$ ,  $2.0\sigma$ , and  $2.4\sigma$  effects, setting upper limits on product branching fractions that are not inconsistent with Belle's measured rates, leaving the situation unresolved.

\* For consistency with the literature, we preserve the use of  $X$ ,  $Y$ ,  $Z$ , and  $G$ , contrary to the practice of the PDG, which exclusively uses  $X$  for unidentified states.

**Figure 1:** From Belle [31], the mass recoiling against  $\pi^+\pi^-$  pairs,  $M_{\text{miss}}$ , in  $e^+e^-$  collision data taken near the peak of the  $\Upsilon(5S)$  (points with error bars). The smooth combinatoric and  $K_S^0 \rightarrow \pi^+\pi^-$  background contributions have already been subtracted. The fit to the various labeled signal contributions overlaid (curve). Adapted from [31] with kind permission, copyright (2011) The American Physical Society.

Although  $\eta_c(2S)$  measurements began to converge on a mass and width nearly a decade ago, refinements are still in progress. In particular, Belle [14] has revisited its analysis of  $B \rightarrow K\eta_c(2S)$ ,  $\eta_c(2S) \rightarrow KK\pi$  decays with more data and methods that account for interference between the above decay chain, an equivalent one with the  $\eta_c(1S)$  instead, and one with no intermediate resonance. The net effect of this interference is far from trivial; it shifts the apparent mass by  $\sim +10$  MeV and blows up the apparent width by a factor of six. The updated  $\eta_c(2S)$  mass and width are in better accordance with other measurements than the previous treatment [13] not including interference. Complementing this measurement in  $B$ -decay, BABAR [15] updated their previous [16]  $\eta_c(2S)$  mass and width measurements in two-photon production, where interference effects, judging from studies of  $\eta_c(1S)$ , appear to be small. In combination, precision on the  $\eta_c(2S)$  mass has improved dramatically.

New results on  $\eta_b$ ,  $h_b$ , and  $Z_b^+$  mostly come from Belle, all from analyses of  $121.4 \text{ fb}^{-1}$  of  $e^+e^-$  collision data collected near the peak of the  $\Upsilon(5S)$  resonance. They also appear in the same types of decay chains:  $\Upsilon(5S) \rightarrow \pi^- Z_b^+ \rightarrow \pi^+(b\bar{b})$ , and, when the  $b\bar{b}$  forms an  $h_b(1P)$ , frequently  $h_b(1P) \rightarrow \gamma\eta_b$ .

Previous unsuccessful searches for  $h_b$  focused on what was considered the most easily detected production mechanism,  $\Upsilon(3S) \rightarrow \pi^0 h_b(1P)$ . In early 2011 BABAR presented marginal evidence for this transition at the  $3\sigma$  level, at a mass near that expected for zero hyperfine splitting.

## Heavy Quarkonium Spectroscopy

**Table 2:** As in Table 1, but for new *unconventional* states in the  $c\bar{c}$  and  $b\bar{b}$  regions, ordered by mass. For  $X(3872)$ , the values given are based only upon decays to  $\pi^+\pi^-J/\psi$ .  $X(3945)$  and  $Y(3940)$  have been subsumed under  $X(3915)$  due to compatible properties. The state known as  $Z(3930)$  appears as the  $\chi_{c2}(2P)$  in Table 1. In some cases experiment still allows two  $J^{PC}$  values, in which case both appear. See also the reviews in [1–7]. Adapted from [7] with kind permission, copyright (2011), Springer.

The Belle  $h_b$  discovery analysis [31] selects hadronic events and looks for peaks in the mass recoiling against  $\pi^+\pi^-$  pairs, the spectrum for which, after subtraction of smooth combinatoric and  $K_S^0 \rightarrow \pi^+\pi^-$  backgrounds, appears in Fig. 1. Prominent and unmistakable  $h_b(1P)$  and  $h_b(2P)$  peaks are present. This search was directly inspired by a new CLEO result [77], which found the surprisingly copious transitions  $\psi(4160) \rightarrow \pi^+\pi^-h_c(1P)$  and an indication that  $Y(4260) \rightarrow \pi^+\pi^-h_c(1P)$  occurs at a comparable rate as the signature mode,  $Y(4260) \rightarrow \pi^+\pi^-J/\psi$ . The presence of  $\Upsilon(nS)$  peaks in Fig. 1 at rates two orders of magnitude larger than expected for transitions requiring a heavy-quark spin-flip, along with separate studies with exclusive decays  $\Upsilon(nS) \rightarrow \mu^+\mu^-$ , allow precise calibration of the  $\pi^+\pi^-$  recoil mass spectrum and very accurate measurements of  $h_b(1P)$  and  $h_b(2P)$  masses. Both corresponding hyperfine splittings are consistent with zero

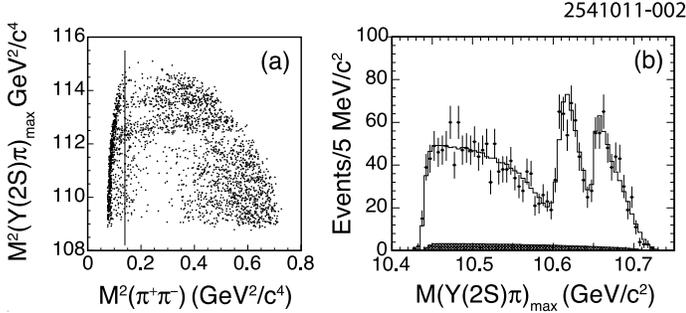

within an uncertainty of about 1.5 MeV (lowered to  $\pm 1.1$  MeV for  $h_b(1P)$  in Ref. 30). Belle soon noticed that, for events in the peaks of Fig. 1, there seemed to be two intermediate charged states nearby. For example, Fig. 2 shows a Dalitz plot for events restricted to the  $\Upsilon(2S)$  region of  $\pi^+\pi^-$  recoil mass. The two bands observed in the maximum of the two  $M[\pi^\pm\Upsilon(2S)]^2$  values also appear for  $\Upsilon(1S)$ ,  $\Upsilon(3S)$ ,  $h_b(1P)$ , and  $h_b(2P)$  samples, but do not appear in the respective  $[b\bar{b}]$  sidebands. Belle fits all subsamples to resonant plus non-resonant amplitudes, allowing for interference (notably, between  $\pi^-Z_b^+$  and  $\pi^+Z_b^-$ ), and finds consistent pairs of  $Z_b^+$  masses for all bottomonium transitions, and comparable strengths of the two states. Angular analysis favors a  $J^P = 1^+$  assignment for both  $Z_b^+$  states, which must also have negative  $G$ -parity. Transitions through  $Z_b^+$  to the  $h_b(nP)$  saturate the observed  $\pi^+\pi^-h_b(nP)$  cross sections. The two masses of  $Z_b^+$  states are just a few MeV above the  $B^*\bar{B}$

See key on page 457

### Heavy Quarkonium Spectroscopy

and  $B^*\bar{B}^*$  thresholds, respectively. The  $Z_b^+$  cannot be simple mesons because they are charged and have  $b\bar{b}$  content.

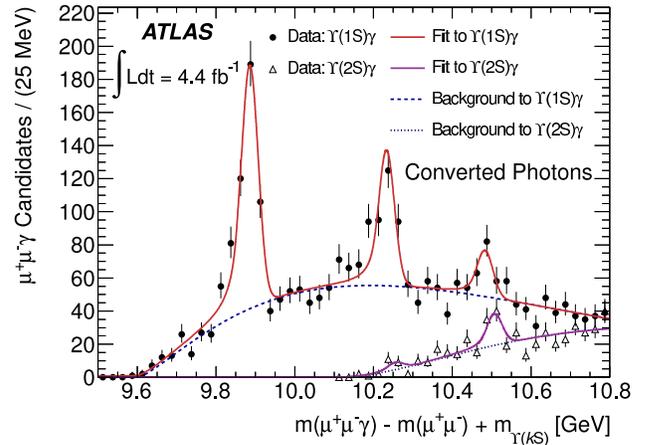

**Figure 2:** From Belle [74]  $e^+e^-$  collision data taken near the peak of the  $\Upsilon(5S)$  for events with a  $\pi^+\pi^-$ -missing mass consistent with a  $\Upsilon(nS)2$ , (a) the maximum of the two possible single  $\pi^\pm$ -missing-mass-squared combinations vs. the  $\pi^+\pi^-$ -mass-squared; and (b) projection of the maximum of the two possible single  $\pi^\pm$ -missing-mass combinations (*points with error bars*) overlaid with a fit (*curve*). Events to the left of the vertical line in (a) are excluded from further analysis. The two horizontal stripes in (a) and two peaks in (b) correspond to the two  $Z_b^+$  states. Adapted from [74] with kind permission, copyright (2011) The American Physical Society.

**Figure 3:** From Belle [30]  $e^+e^-$  collision data taken near the peak of the  $\Upsilon(5S)$ , the  $h_b(1P)$  event yield vs. the mass recoiling against the  $\pi^+\pi^-$ -missing mass (corrected for misreconstructed  $\pi^+\pi^-$ ), where the  $h_b(1P)$  yield is obtained by fitting the mass recoiling against the  $\pi^+\pi^-$  (*points with error bars*). The fit results (*solid histograms*) for signal plus background and background alone are superimposed. Adapted from [30] with kind permission, copyright (2011) The American Physical Society.

The third Belle result to flow from these data is confirmation of the  $\eta_b(1S)$  and measurement of the  $h_b(1P) \rightarrow \gamma\eta_b(1S)$  branching fraction, expected to be several tens of percent. To accomplish this, events with the  $\pi^+\pi^-$  recoil mass in the  $h_b(1P)$  mass window and a radiative photon candidate are selected, and the  $\pi^+\pi^-$  recoil mass queried for correlation with non-zero  $h_b(1P)$  population in the  $\pi^+\pi^-$  missing mass spectrum, as shown in Fig. 3. A clear peak is observed, corresponding to the  $\eta_b(1S)$ . A fit is performed to extract the  $\eta_b(1S)$  mass, and first measurements of its width and the branching fraction for  $h_b(1P) \rightarrow \gamma\eta_b(1S)$  (the latter of which is  $(49.8 \pm 6.8_{-5.2}^{+10.9})\%$ ). The mass determination has comparable uncertainty to and a larger central value (by 10 MeV, or  $2.4\sigma$ ) than the average of previous measurements, thereby reducing the new world average hyperfine splitting by nearly 5 MeV, as shown in Table 3.

**Figure 4:** From ATLAS [35]  $pp$  collision data (*points with error bars*) taken at  $\sqrt{s} = 7$  TeV, the effective mass of  $\chi_{bJ}(1P, 2P, 3P) \rightarrow \gamma\Upsilon(1S, 2S)$  candidates in which  $\Upsilon(1S, 2S) \rightarrow \mu^+\mu^-$  and the photon is reconstructed as an  $e^+e^-$  conversion in the tracking system. Fits (*smooth curves*) show significant signals for each triplet (merged- $J$ ) on top of a smooth background. From [35] with kind permission, copyright (2012) The American Physical Society.

The  $\chi_{bJ}(nP)$  states have recently been observed at the LHC by ATLAS [35] for  $n = 1, 2, 3$ , although in each case the three  $J$  states are not distinguished from one another. Events are sought which have both a photon and an  $\Upsilon(1S, 2S) \rightarrow \mu^+\mu^-$  candidate which together form a mass in the  $\chi_b$  region. Observation of all three  $J$ -merged peaks is seen at significance in excess of  $6\sigma$  for both unconverted and converted photons. The mass plot for converted photons, which provide better mass resolution, is shown in Fig. 4. This marks the first observation of the  $\chi_{bJ}(3P)$  triplet, quite near the expected mass.

## Charmonium, $\eta_c(1S)$

### c $\bar{c}$ MESONS

THE CHARMONIUM SYSTEM

The level scheme of the  $c\bar{c}$  states showing experimentally established states with solid lines. Singlet states are called  $\eta_c$  and  $h_c$ , triplet states  $\psi$  and  $\chi_{cJ}$ , and unassigned charmonium-like states  $X$ . In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. Only observed hadronic transitions are shown; the single photon transitions  $\psi(nS) \rightarrow \gamma\eta_c(mP)$ ,  $\psi(nS) \rightarrow \gamma\chi_{cJ}(mP)$ , and  $\chi_{cJ}(1P) \rightarrow \gamma J/\psi$  are omitted for clarity.

### $\eta_c(1S)$

$$I^G(J^{PC}) = 0^+(0^{-+})$$

#### $\eta_c(1S)$ MASS

1 Accounts for interference with non-resonant continuum.  
 2 Taking into account interference with the non-resonant  $J^P = 0^-$  amplitude.  
 3 From a fit of the  $J/\psi$  recoil mass spectrum. Supersedes ABE,K 02 and ABE 04c.  
 4 Using mass of  $\psi(2S) = 3686.00$  MeV.  
 5 From a simultaneous fit of five decay modes of the  $\eta_c$ .  
 6 MITCHELL 09 observes a significant asymmetry in the lineshapes of  $\psi(2S) \rightarrow \gamma\eta_c$  and  $J/\psi \rightarrow \gamma\eta_c$  transitions. If ignored, this asymmetry could lead to significant bias whenever the mass and width are measured in  $\psi(2S)$  or  $J/\psi$  radiative decays.  
 7 Using an  $\eta_c$  width of 13.2 MeV.  
 8 Weighted average of the  $\psi(2S)$  and  $J/\psi(1S)$  samples.  
 9 Not independent from the measurements reported by LEES 10.  
 10 From the fit of the kaon momentum spectrum. Systematic errors not evaluated.  
 11 Superseded by LEES 10.

See key on page 457

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt; 0.012</b>	90	HIMEL	80B MRK2	$\psi(2S) \rightarrow \eta_c\gamma$

49 The quoted branching ratios use  $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = 0.0127 \pm 0.0036$ . Where relevant, the error in this branching ratio is treated as a common systematic in computing averages.

50 ABLIKIM 06A reports  $[\Gamma(\eta_c(1S) \rightarrow K^*0\bar{K}^*0\pi^+\pi^-)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (1.91 \pm 0.64 \pm 0.48) \times 10^{-4}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

51 Using  $B(B^+ \rightarrow \eta_c K^+) = (1.25 \pm 0.12 \pm 0.10 \pm 0.12) \times 10^{-3}$  from FANG 03 and  $B(\eta_c \rightarrow K\bar{K}\pi) = (5.5 \pm 1.7) \times 10^{-2}$ .

52 ABLIKIM 06A reports  $[\Gamma(\eta_c(1S) \rightarrow \phi 2(\pi^+\pi^-))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] < 0.603 \times 10^{-4}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = 1.7 \times 10^{-2}$ .

53 We are assuming  $B(\eta(980) \rightarrow \eta\pi) > 0.5$ .

54 ABLIKIM 04M reports  $[\Gamma(\eta_c(1S) \rightarrow f_2(1270)f_2(1270))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (1.3 \pm 0.3 \pm 0.3 \pm 0.4) \times 10^{-4}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

55 Determined from the ratio of  $B(B^\pm \rightarrow K^\pm\eta_c)B(\eta_c \rightarrow K\bar{K}\pi) = (7.4 \pm 0.5 \pm 0.7) \times 10^{-5}$  reported in AUBERT,B 04B and  $B(B^\pm \rightarrow K^\pm\eta_c) = (8.7 \pm 1.5) \times 10^{-3}$  reported in AUBERT 06E.

56 Average from  $K^+K^-\pi^0$  and  $K^\pm K_S^0\pi^\mp$  decay channels.

57 Estimated using  $B(\psi(2S) \rightarrow \gamma\eta_c(1S)) = 0.0028 \pm 0.0006$ .

58 We have multiplied the value of  $\Gamma(K^+K^-\pi^+\pi^-\pi^0)/\Gamma(K_S^0K^\pm\pi^\mp)$  reported in DEL-AMO-SANCHEZ 11M by a factor 1/3 to obtain  $\Gamma(K^+K^-\pi^+\pi^-\pi^0)/\Gamma(K\bar{K}\pi)$ . Not independent from other measurements reported in DEL-AMO-SANCHEZ 11M.

59 ABLIKIM 06A reports  $[\Gamma(\eta_c(1S) \rightarrow K^+K^-2(\pi^+\pi^-))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (1.21 \pm 0.32 \pm 0.24) \times 10^{-4}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

60 Normalized to the sum of  $B(\eta_c \rightarrow K^\pm K_S^0\pi^\mp)$ ,  $B(\eta_c \rightarrow \phi\phi)$ ,  $B(\eta_c \rightarrow K^+K^-\pi^+\pi^-)$ , and  $B(\eta_c \rightarrow 2\pi^+2\pi^-)$ .

61 ABLIKIM 06A reports  $[\Gamma(\eta_c(1S) \rightarrow 3(\pi^+\pi^-))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (2.59 \pm 0.32 \pm 0.47) \times 10^{-4}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

62 WU 06 reports  $[\Gamma(\eta_c(1S) \rightarrow \rho\bar{\rho})/\Gamma_{total}] \times [B(B^+ \rightarrow \eta_c K^+)] = (1.42 \pm 0.11 \pm 0.16 \pm 0.20) \times 10^{-6}$  which we divide by our best value  $B(B^+ \rightarrow \eta_c K^+) = (9.6 \pm 1.2) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

63 WU 06 reports  $[\Gamma(\eta_c(1S) \rightarrow \Lambda\bar{\Lambda})/\Gamma_{total}] \times [B(B^+ \rightarrow \eta_c K^+)] = (0.95 \pm 0.25 \pm 0.08 \pm 0.22 \pm 0.11) \times 10^{-6}$  which we divide by our best value  $B(B^+ \rightarrow \eta_c K^+) = (9.6 \pm 1.2) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

64 Not independent from other  $\eta_c \rightarrow \Lambda\bar{\Lambda}, \rho\bar{\rho}$  branching ratios reported by WU 06.

4 From a simultaneous fit to e+ e-, mu+ mu- and hadronic channels assuming Gamma(e+ e-) = Gamma(mu+ mu-).

J/psi(1S) WIDTH

Table with 5 columns: VALUE (keV), EVTS, DOCUMENT ID, TECN, COMMENT. Row 1: 92.9 ± 2.8 OUR AVERAGE Error includes scale factor of 1.1. Row 2: 96.1 ± 3.2 13k 5 ADAMS 06A CLEO e+ e- -> mu+ mu- gamma. Row 3: 84.4 ± 8.9 BAI 95B BES e+ e-. Row 4: 91 ± 11 ± 6 6 ARMSTRONG 93B E760 p-bar p -> e+ e-. Row 5: 85.5 ± 6.1 / 5.8 7 HSUEH 92 RVUE See T mini-review. Row 6: 94.1 ± 2.7 8 ANASHIN 10 KEDR 3.097 e+ e- -> e+ e-, mu+ mu-. Row 7: 93.7 ± 3.5 7.8k 5 AUBERT 04 BABR e+ e- -> mu+ mu- gamma.

- 5 Calculated by us from the reported values of Gamma(e+ e-) x B(mu+ mu-) using B(e+ e-) = (5.94 ± 0.06)% and B(mu+ mu-) = (5.93 ± 0.06)%.
6 The initial-state radiation correction reevaluated by ANDREOTTI 07 in its Ref. [4].
7 Using data from COFFMAN 92, BALDINI-CELIO 75, BOYARSKI 75, ESPOSITO 75B, BRANDELIK 79C.
8 Assuming Gamma(e+ e-) = Gamma(mu+ mu-) and using Gamma(e+ e-)/Gamma\_total = (5.94 ± 0.06)%.

J/psi(1S) DECAY MODES

Table with 4 columns: Mode, Fraction (Gamma\_i/Gamma), Scale factor/Confidence level. Row 1: Gamma\_1 hadrons (87.7 ± 0.5) %. Row 2: Gamma\_2 virtual gamma -> hadrons (13.50 ± 0.30) %. Row 3: Gamma\_3 g g g (64.1 ± 1.0) %. Row 4: Gamma\_4 gamma g g (8.8 ± 1.1) %. Row 5: Gamma\_5 e+ e- (5.94 ± 0.06) %. Row 6: Gamma\_6 e+ e- gamma [a] (8.8 ± 1.4) x 10^-3. Row 7: Gamma\_7 mu+ mu- (5.93 ± 0.06) %.

Decays involving hadronic resonances

Table with 4 columns: Gamma\_i, Mode, Fraction (Gamma\_i/Gamma), S=2.4. Row 1: Gamma\_8 rho pi (1.69 ± 0.15) %. Row 2: Gamma\_9 rho^0 pi^0 (5.6 ± 0.7) x 10^-3. Row 3: Gamma\_10 a\_2(1320) rho (1.09 ± 0.22) %. Row 4: Gamma\_11 omega pi+ pi+ pi- pi- (8.5 ± 3.4) x 10^-3. Row 5: Gamma\_12 omega pi+ pi- pi^0 (4.0 ± 0.7) x 10^-3. Row 6: Gamma\_13 omega pi+ pi- (8.6 ± 0.7) x 10^-3. Row 7: Gamma\_14 omega f\_2(1270) (4.3 ± 0.6) x 10^-3. Row 8: Gamma\_15 K\*(892)^0 K\*(892)^0 (2.3 ± 0.7) x 10^-4. <sup>120</sup>Using  $B(B^+ \rightarrow J/\psi K^+) = (1.01 \pm 0.05) \times 10^{-3}$ .

<sup>121</sup>Superseded by AUBERT 07AK. AUBERT 05D reports  $[\Gamma(J/\psi(1S) \rightarrow 2(K^+ K^-))/\Gamma_{\text{total}}] \times [\Gamma(J/\psi(1S) \rightarrow e^+ e^-)] = (4.0 \pm 0.7 \pm 0.6) \times 10^{-3}$  keV which we divide by our best value  $\Gamma(J/\psi(1S) \rightarrow e^+ e^-) = 5.55 \pm 0.14 \pm 0.02$  keV. Our first error is their experiment's error and our second error is the systematic error from using our best value.

155 ABLIKIM 06v reports $[\Gamma(J/\psi(1S) \rightarrow \gamma f_2(1270))/\Gamma_{total}] \times [B(f_2(1270) \rightarrow \pi\pi)] = (1.371 \pm 0.010 \pm 0.222) \times 10^{-3}$ which we divide by our best value $B(f_2(1270) \rightarrow \pi\pi) = (84.8^{+2.4}_{-1.2}) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.				
156 ABLIKIM 06v reports $[\Gamma(J/\psi(1S) \rightarrow \gamma f_2(1270))/\Gamma_{total}] \times [B(f_2(1270) \rightarrow \pi\pi)] = (1.200 \pm 0.027 \pm 0.174) \times 10^{-3}$ which we divide by our best value $B(f_2(1270) \rightarrow \pi\pi) = (84.8^{+2.4}_{-1.2}) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.				
157 Estimated using $B(f_2(1270) \rightarrow \pi\pi) = 0.843 \pm 0.012$ . The errors do not contain the uncertainty in the $f_2(1270)$ decay.				
158 Restated by us to take account of spread of E1, M2, E3 transitions.

BRANCHING RATIOS OF  $\psi(2S)$  AND  $\chi_{c0,1,2}$ 

Updated May 2012 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Genova)

Since 2002, the treatment of the branching ratios of the  $\psi(2S)$  and  $\chi_{c0,1,2}$  has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the *Review of Particle Physics* (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles Ref. 1, Ref. 2 as discussed in more detail in earlier editions of this mini-review.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles,  $\psi(2S)$ ,  $\chi_{c0}$ ,  $\chi_{c1}$ , and  $\chi_{c2}$ , and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [3].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the

quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the  $\chi_{c0,1,2}$  are measured independently of the  $\psi(2S)$  radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

## FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 25 combinations of partial widths, 7 branching ratios, and 77 combinations of branching ratios. Of the latter 57 involve decays of more than one particle.

The overall fit uses 223 measurements to determine 49 parameters and has a  $\chi^2$  of 312.2 for 174 degrees of freedom.

The relatively high  $\chi^2$  of the fit, 1.8 per d.o.f., can be traced back to a few specific discrepancies in the data. No rescaling of errors has been applied.

In the listing we provide the correlation coefficients  $< \delta x_i \delta x_j > / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the corresponding parameter  $x_i$ .

<sup>1</sup> Recalculated by ANDREOTTI 05A, using the value of  $\psi(2S)$  mass from AULCHENKO 03.

<sup>2</sup> Using mass of  $\psi(2S) = 3686.0$  MeV.

<sup>3</sup>  $J/\psi(1S)$  mass constrained to 3097 MeV.

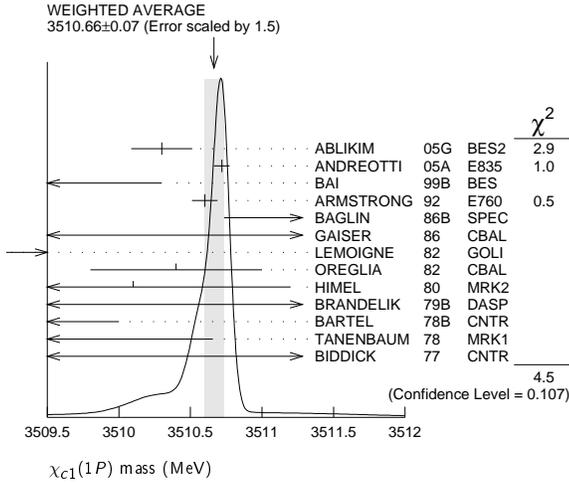

<sup>4</sup> Mass value shifted by us by amount appropriate for  $\psi(2S)$  mass = 3686 MeV and  $J/\psi(1S)$  mass = 3097 MeV.

<sup>5</sup> From a simultaneous fit to radiative and hadronic decay channels.

**CONSTRAINED FIT INFORMATION**

A multiparticle fit to  $\chi_{c1}(1P)$ ,  $\chi_{c0}(1P)$ ,  $\chi_{c2}(1P)$ , and  $\psi(2S)$  with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 223 measurements to determine 49 parameters. The overall fit has a  $\chi^2 = 312.2$  for 174 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{total}$ .

3686.00 ± 0.10	413	4 ZHOLENTZ	80	OLYA $e^+e^-$

• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> From the scans in 2004 and 2006. ANASHIN 12 reports the value 3686.114 ± 0.007 ± 0.011 +0.002 -0.012 MeV, where the third uncertainty is due to assumptions on the interference between the resonance and hadronic continuum. We combined the two systematic uncertainties.

<sup>2</sup> Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85).

<sup>3</sup> Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 93B, using the value for the  $J/\psi(1S)$  mass from AULCHENKO 03.

<sup>4</sup> Superseded by ARTAMONOV 00.

$m_{\psi(2S)} - m_{J/\psi(1S)}$

### CONSTRAINED FIT INFORMATION

A multiparticle fit to  $\chi_{c1}(1P)$ ,  $\chi_{c0}(1P)$ ,  $\chi_{c2}(1P)$ , and  $\psi(2S)$  with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 223 measurements to determine 49 parameters. The overall fit has a  $\chi^2 = 312.2$  for 174 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ .

### $\psi(2S)$ $\Gamma(i)\Gamma(e^+ e^-)/\Gamma(\text{total})$

This combination of a partial width with the partial width into  $e^+ e^-$  and with the total width is obtained from the integrated cross section into channel(i) in the  $e^+ e^-$  annihilation. We list only data that have not been used to determine the partial width  $\Gamma(i)$  or the branching ratio  $\Gamma(i)/\text{total}$ .

#### $\Gamma(\text{hadrons}) \times \Gamma(e^+ e^-)/\Gamma_{\text{total}}$ $\Gamma_1 \Gamma_6 / \Gamma$

- Taking into account interference between the resonant and non-resonant  $D\bar{D}$  production.
- Reanalysis of data presented in BAI 02C. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the  $\psi(3770)$ ,  $\psi(4040)$ ,  $\psi(4160)$ , and  $\psi(4415)$  resonances. Phase angle fixed in the fit to  $\delta = 0^\circ$ .
- Interference between the resonant and non-resonant  $D\bar{D}$  production not taken into account.

**$m_{\psi(3770)} - m_{\psi(2S)}$**

OUR FIT includes measurements of  $m_{\psi(2S)}$ ,  $m_{\psi(3770)}$ , and  $m_{\psi(3770)} - m_{\psi(2S)}$ .

**$\psi(3770)$  DECAY MODES**

In addition to the dominant decay mode to  $D\bar{D}$ ,  $\psi(3770)$  was found to decay into the final states containing the  $J/\psi$  (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to  $\phi\eta$  only (ADAMS 06).

## CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 3 branching ratios uses 23 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 20.0$  for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

<sup>16</sup> Neglecting interference.

<sup>17</sup> Obtained by comparing a measurement of the total cross section (corrected in BESSON 10) with that of  $D\bar{D}$  reported by CLEO in DOBBS 07.

<sup>18</sup> Using  $\sigma_{\text{obs}} = 7.07 \pm 0.58$  nb and neglecting interference.

<sup>19</sup> Not independent of ABLIKIM 08b.

<sup>20</sup> From a measurement of  $\sigma(e^+ e^- \rightarrow D\bar{D})$  at  $\sqrt{s} = 3773$  MeV, using the  $\psi(3770)$  resonance parameters measured by ABLIKIM 06L.

<sup>21</sup> See ADLER 88c for older measurements of this quantity.

27 HUANG	06A	CLEO $e^+ e^- \rightarrow \psi(3770)$

22 Comparing cross sections at  $\sqrt{s} = 3.773$  GeV and  $\sqrt{s} = 3.671$  GeV, neglecting interference, and using  $\sigma(\psi(3770) \rightarrow D\bar{D}) = 6.39 \pm 0.20$  nb.

23 Assuming that interference effects between resonance and continuum can be neglected and using  $\sigma^{obs}(e^+ e^- \rightarrow \psi(3770)) = 7.15 \pm 0.38$  nb.

24 Data suggest possible destructive interference with continuum.

25 Using  $\sigma(e^+ e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = (6.38 \pm 0.08 \pm 0.41 \pm 0.30)$  nb from BESSON 06 and  $B(K_S^0 \rightarrow \pi^+ \pi^-) = 0.6895 \pm 0.0014$ .

26 Using  $B(K_S^0 \rightarrow \pi^+ \pi^-) = 0.6860 \pm 0.0027$ .

27 Using  $\sigma_{tot}(e^+ e^- \rightarrow \psi(3770)) = 7.9 \pm 0.6$  nb at the resonance.

28 Using  $\sigma^{obs} = 7.15 \pm 0.27 \pm 0.27$  nb and neglecting interference.

## $X(3872)$

$$I^G(J^{PC}) = 0^2(??^+)$$

Seen by CHOI 03 in  $B \rightarrow K\pi^+\pi^- J/\psi(1S)$  decays as a narrow peak in the invariant mass distribution of the  $\pi^+\pi^- J/\psi(1S)$  final state, but not seen in the  $\gamma\chi_{c1}$  final state of these decays. Possibly absent in the invariant mass spectrum of the final state  $\pi^+\pi^- J/\psi(1S)$  in  $e^+e^-$  collisions. Interpretation as a  $1^{--}$  charmonium state not favored. Isovector hypothesis excluded by AUBERT 05B and CHOI 11. A helicity amplitude analysis of the  $X(3872) \rightarrow J/\psi\pi^+\pi^-$  decay gives two possible  $J^{PC}$  assignments:  $J^{PC} = 1^{++}$  and  $2^{--}$  (ABULENCIA 07E and CHOI 11). A study of the  $3\pi$  invariant mass distribution in  $J/\psi\omega$  decays slightly favors  $J^P = 2^-$  (DEL-AMO-SANCHEZ 10B).

See our note on "Developments in Heavy Quarkonium Spectroscopy".

### $\psi(4040)$ DECAY MODES

Due to the complexity of the c $\bar{c}$  threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle’s central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

## Meson Particle Listings

 $\psi(4160)$  $\psi(4160)$  DECAY MODES

Due to the complexity of the  $c\bar{c}$  threshold region, in this listing, "seen" ("not seen") means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle's central mass value, more (less) than  $2\sigma$  above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

Meson Particle Listings

$\psi(4415)$

- <sup>1</sup> Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the  $\psi(3770)$ ,  $\psi(4040)$ ,  $\psi(4160)$ , and  $\psi(4415)$  resonances. Phase angle fixed in the fit to  $\delta = (234 \pm 88)^\circ$ .
- <sup>2</sup> Reanalysis of data presented in BAI 00 and BAI 02c. From a global fit over the center-of-mass energy 3.8–4.8 GeV covering the  $\psi(4040)$ ,  $\psi(4160)$  and  $\psi(4415)$  resonances and including interference effects.
- <sup>3</sup> Systematic uncertainties not estimated.
- <sup>4</sup> From a fit to Crystal Ball (OSTERHELD 86) data.
- <sup>5</sup> From a fit to BES (BAI 02c) data.

- <sup>6</sup> Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the  $\psi(3770)$ ,  $\psi(4040)$ ,  $\psi(4160)$ , and  $\psi(4415)$  resonances. Phase angle fixed in the fit to  $\delta = (234 \pm 88)^\circ$ .
- <sup>7</sup> Reanalysis of data presented in BAI 00 and BAI 02c. From a global fit over the center-of-mass energy 3.8–4.8 GeV covering the  $\psi(4040)$ ,  $\psi(4160)$  and  $\psi(4415)$  resonances and including interference effects.
- <sup>8</sup> Systematic uncertainties not estimated.
- <sup>9</sup> From a fit to Crystal Ball (OSTERHELD 86) data.
- <sup>10</sup> From a fit to BES (BAI 02c) data.

$\psi(4415)$  DECAY MODES

Due to the complexity of the  $c\bar{c}$  threshold region, in this listing, “seen” (“not seen”) means that a cross section for the mode in question has been measured at effective  $\sqrt{s}$  near this particle’s central mass value, more (less) than  $2\sigma$  above zero, without regard to any peaking behavior in  $\sqrt{s}$  or absence thereof. See mode listing(s) for details and references.

## Meson Particle Listings

Bottomonium,  $\eta_b(1S)$ ,  $\Upsilon(1S)$ 

The total width  $\Gamma$  is then obtained from Eq. (1). We do not list  $\Gamma_{ee}$  and  $\Gamma$  values of individual experiments. The  $\Gamma_{ee}$  values in the Meson Summary Table are also those defined in Eq. (1).

 $\eta_b(1S)$ 

$$J^G(J^{PC}) = 0^+(0^{-+})$$

OMITTED FROM SUMMARY TABLE

Quantum numbers shown are quark-model predictions. Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ .

22 BESSON 11 reports  $(4.0 \pm 1.3 \pm 0.6) \times 10^{-5}$  from a measurement of  $[\Gamma(\Upsilon(1S) \rightarrow \gamma f_2'(1525))/\Gamma_{\text{total}}] \times [B(f_2'(1525) \rightarrow K\bar{K})]$  assuming  $B(f_2'(1525) \rightarrow K\bar{K}) = (88.8 \pm 3.1) \times 10^{-2}$ , which we rescale to our best value  $B(f_2'(1525) \rightarrow K\bar{K}) = (88.7 \pm 2.2) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. The result also assumes  $B(K_S^0 \rightarrow \pi^+ \pi^-) = (69.20 \pm 0.05)\%$  and  $B(f_2'(1525) \rightarrow K\bar{K}) = 4 B(f_2'(1525) \rightarrow K_S^0 K_S^0)$ .

23 Assuming  $B(f_2'(1525) \rightarrow K\bar{K}) = 0.71$ .

$\Upsilon(1D)$

$I^G(J^{PC}) = 0^-(2^{--})$

First observed by BONVICINI 04 in the decay to  $\gamma\gamma \Upsilon(1S)$  and confirmed by DEL-AMO-SANCHEZ 10R in the decay to  $\pi^+ \pi^- \Upsilon(1S)$ . Data consistent with  $J^P = 2^-$ . The states with  $J = 1$  and 3 also possibly seen, but need confirmation.

$\chi_{b0}(2P)$

$I^G(J^{PC}) = 0^+(0^{++})$   
J needs confirmation.

Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .

### $\chi_{b1}(2P)$

$$J^G(JPC) = 0^+(1^{++})$$

J needs confirmation.

Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .

## $\chi_{b2}(2P)$

$$J^G(J^{PC}) = 0^+(2^{++})$$

$J$  needs confirmation.

Observed in radiative decay of the  $\Upsilon(3S)$ , therefore  $C = +$ . Branching ratio requires E1 transition, M1 is strongly disfavored, therefore  $P = +$ .

$\Upsilon(4S)$  BRANCHING RATIOS

$B\bar{B}$  DECAYS

The ratio of branching fraction to charged and neutral B mesons is often derived assuming isospin invariance in the decays, and relies on the knowledge of the  $B^+/B^0$  lifetime ratio. "OUR EVALUATION" is obtained based on averages of rescaled data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account the common dependence of the measurement on the value of the lifetime ratio.

$0.721^{+0.039}_{-0.038} \pm 0.050$	711	DRUTSKOY 10	BELL $\Upsilon(5S) \rightarrow B^+ X$

- <sup>13</sup> Not independent of DRUTSKOY 10 values for  $\Upsilon(5S) \rightarrow B^{\pm,0} \text{ anything}$ .  
<sup>14</sup> Using measurements or limits from AQUINES 06.  
<sup>15</sup> Assuming isospin conservation.  
<sup>16</sup> Using  $B(D_s^+ \rightarrow \phi\pi^+) = (4.4 \pm 0.6)\%$  from PDG 06.  
<sup>17</sup> Supersedes ARTUSO 05B. Combining inclusive  $\phi$ ,  $D_s$ , and  $B$  measurements. Using  $B(D_s^+ \rightarrow \phi\pi^+) = 4.4 \pm 0.6\%$  from PDG 06.  
<sup>18</sup> Uses a model-dependent estimate  $B(B_s \rightarrow D_s X) = (92 \pm 11)\%$ .  
<sup>19</sup> From a measurement of  $\sigma(e^+e^- \rightarrow B_s^* \bar{B}_s^*) / \sigma(e^+e^- \rightarrow B_s^{(*)} \bar{B}_s^{(*)})$  at  $\sqrt{s} = 10.86$  GeV.  
<sup>20</sup> Assuming that the observed events are solely due to the  $\Upsilon(5S)$  resonance.

<sup>21</sup> ARTUSO 05B reports  $[\Gamma(\Upsilon(10860) \rightarrow D_s \text{ anything} + \text{c.c.})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)] = 0.0198 \pm 0.0019 \pm 0.0038$  which we divide by our best value  $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

10.9 ± 2.2 ± 1.3	<sup>18</sup> FEDERSPIEL 91	CNTR	$\gamma p$ Compton scattering
<sup>13</sup> BEANE 03 uses effective field theory and low-energy $\gamma p$ and $\gamma d$ Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) $\alpha_N = (13.0 \pm 1.9 \pm 3.9) \times 10^{-4} \text{ fm}^3$ and $\beta_N = (-1.8 \pm 1.9 \pm 2.1) \times 10^{-4} \text{ fm}^3$ .			
<sup>14</sup> BLANPIED 01 gives $\alpha_p + \beta_p$ and $\alpha_p - \beta_p$ . The separate $\alpha_p$ and $\beta_p$ are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.			
<sup>15</sup> This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4} \text{ fm}^3$ . See the paper for a discussion.			
<sup>16</sup> MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.			
<sup>17</sup> BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$ .			
<sup>18</sup> FEDERSPIEL 91 obtains for the (static) electric polarizability $\alpha_p$ , defined in terms of the induced electric dipole moment by $\mathbf{D} = 4\pi\epsilon_0\alpha_p\mathbf{E}$ , the value $(7.0 \pm 2.2 \pm 1.3) \times 10^{-4} \text{ fm}^3$ .			

 $\rho$  MAGNETIC POLARIZABILITY  $\beta_p$ 

The electric and magnetic polarizabilities are subject to a dispersion sum-rule constraint  $\bar{\alpha} + \bar{\beta} = (14.2 \pm 0.5) \times 10^{-4} \text{ fm}^3$ . Errors here are anticorrelated with those on  $\bar{\alpha}_p$  due to this constraint.

 $\rho$  CHARGE RADIUS

This is the rms electric charge radius,  $\sqrt{\langle r_E^2 \rangle}$ .

Most measurements of the radius of the proton involve electron-proton interactions, and most of the more recent values agree with one another. The most precise of these is  $r_p = 0.879(8) \text{ fm}$  (BERNAUER 10). The

CODATA 10 value (MOHR 12), obtained from the electronic results, is 0.8775(51). However, a measurement using muonic hydrogen finds  $r_p = 0.84184(67) \text{ fm}$  (POHL 10), which is eight times more precise and seven standard deviations (using the CODATA 10 error) from the electronic results.

Since POHL 10, there has been a lot of discussion about the disagreement, especially concerning the modeling of muonic hydrogen. Here is an incomplete list of papers: DERUJULA 10, CLOET 11, DISTLER 11, DERUJULA 11, ARRINGTON 11, BERNAUER 11, and HILL 11.

Until the difference between the  $ep$  and  $\mu p$  values is understood, it does not make much sense to average all the values together. For the present, we stick with the less precise (and provisionally suspect) CODATA 2010 value (MOHR 12). It is up to workers in this field to solve this puzzle.

<sup>25</sup>ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of a neutron from the  $s$  shell of <sup>12</sup>C.

<sup>26</sup>AHMED 04 looks for the de-excitation of a residual <sup>15</sup>O\* or <sup>15</sup>N\* following the disappearance of a neutron or proton in <sup>16</sup>O.

<sup>27</sup>BACK 03 looks for decays of unstable nuclides left after  $N$  decays of parent <sup>12</sup>C, <sup>13</sup>C, <sup>16</sup>O nuclei. These are "invisible channel" limits.

<sup>28</sup>ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.

<sup>29</sup>AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.

<sup>30</sup>BERNABEI 00B looks for the decay of a <sup>128</sup><sub>53</sub>I nucleus following the disappearance of a proton in the otherwise-stable <sup>129</sup>Xe nucleus.

<sup>31</sup>EVANS 77 looks for the daughter nuclide <sup>129</sup>Xe from possible <sup>130</sup>Te decays in ancient Te ore samples.

See key on page 457

Baryon Particle Listings

*p*

<sup>32</sup>This mean-life limit has been obtained from a half-life limit by dividing the latter by  $\ln(2) = 0.693$ .  
<sup>33</sup>FLEROV 58 looks for the spontaneous fission of a <sup>232</sup>Th nucleus after the disappearance of one of its nucleons.

**$\bar{p}$  MEAN LIFE**

Of the two astrophysical limits here, that of GEER 00d involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also "p Partial Mean Lives" after "p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is  $7 \times 10^5$  years, for  $\bar{p} \rightarrow e^- \gamma$ . We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	EVTs	DOCUMENT ID	TECN	COMMENT

$\rho$

## $\rho$ PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on  $\tau/B_j$ , where  $\tau$  is the total mean life for the proton and  $B_j$  is the branching fraction for the mode in question.

Decaying particle:  $p$  = proton,  $n$  = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

39 In estimating the background, this HIRATA 89c limit (as opposed to the later limits of WALL 00b and MCGREW 99) does not take into account present understanding that the flux of  $\nu_\mu$  originating in the upper atmosphere is depleted. Doing so would reduce the background and thus also would reduce the limit here.

40 We have calculated 90% CL limit from 1 confined event.

41 We have converted 2 possible events to 90% CL limit.

42 We have converted half-life to 90% CL mean life.

>0.000012	90	5	9.7	BERGER 91B	FREJ	$\tau$ per iron nucleus

76 ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of two neutrons from the  $s$  shell of  $^{12}\text{C}$ .  
 77 TRETAYAK 04 uses data from an old Homestake-mine radiochemical experiment on limits for invisible decays of  $^{39}\text{K}$  to  $^{37}\text{Ar}$ .  
 78 BACK 03 looks for decays of unstable nuclides left after  $NN$  decays of parent  $^{12}\text{C}$ ,  $^{13}\text{C}$ ,  $^{16}\text{O}$  nuclei. These are "invisible channel" limits.  
 79 BERNABEI 00b looks for the decay of a  $^{127}\text{Xe}$  nucleus following the disappearance of an  $nn$  pair in the otherwise-stable  $^{129}\text{Xe}$  nucleus. The limit here applies as well to  $nn \rightarrow \nu_\mu \bar{\nu}_\mu$ ,  $nn \rightarrow \nu_\tau \bar{\nu}_\tau$ , or any "disappearance" mode.

$\tau(nn \rightarrow \nu_\mu \bar{\nu}_\mu)$  774

$\bar{p}$  PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on  $\bar{\tau}/B_i$ , where  $\bar{\tau}$  is the total mean life for the antiproton and  $B_i$  is the branching fraction for the mode in question.

$\tau(\bar{p} \rightarrow e^- \gamma)$  777

**n**

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+) \text{ Status: } ***$$

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Anyone interested in the neutron should look at these two new review articles: D. Dubbers and M.G. Schmidt, "The neutron and its role in cosmology and particle physics," *Reviews of Modern Physics* **83** 1111 (2011); and F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," *Reviews of Modern Physics* **83** 1173 (2011).

**n MASS (atomic mass units u)**

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

VALUE (u)	DOCUMENT ID	TECN	COMMENT
<b>1.00866491600 ± 0.0000000043</b>	MOHR 12	RVUE	2010 CODATA value

**n MASS (MeV)**

The mass is known much more precisely in u (atomic mass units) than in MeV. The conversion from u to MeV,  $1 u = 931.494 061(21) \text{ MeV}/c^2$  (MOHR 12, the 2010 CODATA value), involves the relatively poorly known electronic charge.

<sup>10</sup> Calculated by us from the COHEN 87 ratio  $m_n/m_p = 1.001378404 \pm 0.000000009$ . In u,  $m_n - m_p = 0.001388434 \pm 0.000000009 u$ .

**n MEAN LIFE**

Limits on lifetimes for *bound* neutrons are given in the section "p PARTIAL MEAN LIVES."

The mean life of the neutron,  $878.5 \pm 0.8$  s, obtained by SEREBROV 05 (for a more detailed account, see SEREBROV 08a) was so far from our average of seven other measurements,  $885.7 \pm 0.8$  s, that it made no sense to include it in our average. Thus our 2006, 2008, and 2010 *Reviews* stayed with  $885.7 \pm 0.8$  s; but we noted that in light of SEREBROV 05 our value should be regarded as suspect until further experiments clarified matters.

However, after our 2010 *Review*, PICHLMAIER 10 obtained a mean life of  $880.7 \pm 1.8$  s, and we averaged the best seven results to get  $881.5 \pm 1.5$  s for our 2011 off-year web update. And since then, ARZUMANOV 12, responding to comments of SEREBROV 10b, recalculated the systematic corrections to its 2000 measurement (ARZUMANOV 00) and lowered its value from  $885.4 \pm 0.9 \pm 0.4$  s to  $881.6 \pm 0.8 \pm 1.9$  s. Thus the trend is definitely toward a shorter lifetime.

There seems little better to do than to again average the best seven measurements. The result,  $880.1 \pm 1.1$  s (including a scale factor of 1.8), is 5.6 s lower than the value we gave in 2010—a drop of 7.0 old and 5.1 new standard deviations.

For a full review of all matters concerning the neutron lifetime, see F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," *Reviews of Modern Physics* **83** 1173 (2011). In particular, there is a full discussion of the experimental methods and results; and an average lifetime is obtained making several different selections of those results. (The revised ARZUMANOV 12 mean life was not yet available.)

<sup>16</sup> LAMOREAUX 07 faults BAKER 06 for not including in the estimate of systematic error an effect due to the Earth's rotation. BAKER 07 replies (1) that the effect was included implicitly in the analysis and (2) that further analysis confirms that the BAKER 06 limit is correct as is. See also SILENKO 07.

<sup>17</sup> This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the results of these two experiments has been criticized by LAMOREAUX 00.

***n* MEAN-SQUARE CHARGE RADIUS**

The mean-square charge radius of the neutron,  $\langle r_n^2 \rangle$ , is related to the neutron-electron scattering length  $b_{ne}$  by  $\langle r_n^2 \rangle = 3(m_e a_0 / m_n) b_{ne}$ , where  $m_e$  and  $m_n$  are the masses of the electron and neutron, and  $a_0$  is the Bohr radius. Numerically,  $\langle r_n^2 \rangle = 86.34 b_{ne}$ , if we use  $a_0$  for a nucleus with infinite mass.

***n* ELECTRIC POLARIZABILITY  $\alpha_n$**

Following is the electric polarizability  $\alpha_n$  defined in terms of the induced electric dipole moment by  $\mathbf{D} = 4\pi\epsilon_0\alpha_n\mathbf{E}$ . For a review, see SCHMIED-MAYER 89.

For a very complete review of the "polarizability of the nucleon and Compton scattering," see SCHUMACHER 05. His recommended values for the neutron are  $\alpha_n = (12.5 \pm 1.7) \times 10^{-4} \text{ fm}^3$  and  $\beta_n = (2.7 \mp 1.8) \times 10^{-4} \text{ fm}^3$ , which agree with our averages within errors.

VALUE ( $10^{-4} \text{ fm}^3$ )	DOCUMENT ID	TECN	COMMENT
<b>11.6 ± 1.5 OUR AVERAGE</b>			
12.5 ± 1.8 <sup>+1.6</sup> / <sub>-1.3</sub>	<sup>19</sup> KOSSERT 03	CNTR	$\gamma d \rightarrow \gamma pn$

8 ± 10	KOESTER 88	CNTR	<i>n</i> Pb, <i>n</i> Bi transmission
12 ± 10	SCHMIEDM... 88	CNTR	<i>n</i> Pb, <i>n</i> C transmission

<sup>19</sup> KOSSERT 03 gets  $\alpha_n - \beta_n = (9.8 \pm 3.6 <sup>+2.1</sup>/<sub>-1.1</sub> \pm 2.2) \times 10^{-4} \text{ fm}^3$ , and uses  $\alpha_n + \beta_n = (15.2 \pm 0.5) \times 10^{-4} \text{ fm}^3$  from LEVCHUK 00. Thus the errors on  $\alpha_n$  and  $\beta_n$  are anti-correlated.

<sup>20</sup> LUNDIN 03 measures  $\alpha_n - \beta_n = (6.4 \pm 2.4) \times 10^{-4} \text{ fm}^3$  and uses accurate values for  $\alpha_p$  and  $\alpha_n$  and a precise sum-rule result for  $\alpha_n + \beta_n$ . The second error is a model uncertainty, and errors on  $\alpha_n$  and  $\beta_n$  are anticorrelated.

<sup>21</sup> KOLB 00 obtains this value with a lower limit of  $7.6 \times 10^{-4} \text{ fm}^3$  but no upper limit from this experiment alone. Combined with results of ROSE 90, the 1- $\sigma$  range is  $(7.6-14.0) \times 10^{-4} \text{ fm}^3$ .

<sup>22</sup> KOESTER 95 uses natural Pb and the isotopes 208, 207, and 206. See this paper for a discussion of methods used by various groups to extract  $\alpha_n$  from data.

## LIMIT ON *nπ* OSCILLATIONS

### Mean Time for *nπ* Transition in Vacuum

A test of  $\Delta B=2$  baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for *nπ* oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for *n* →  $\bar{\pi}$  transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table. See MOHAPATRA 09 for a recent review.

<sup>33</sup> NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition $^{71}\text{Ga} \rightarrow ^{71}\text{Ge} + \text{neutrals}$ rather than to solar-neutrino reactions.					

## BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

### Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\bar{B}_f [ f_1(q^2)\gamma_\lambda + i f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5q_\lambda ] B_i \quad (1)$$

Here  $B_i$  and  $\bar{B}_f$  are spinors describing the initial and final baryons, and  $q = p_i - p_f$ , while the terms in  $f_1, f_2, g_1$ , and  $g_3$  account for vector, induced tensor (“weak magnetism”), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer,  $f_1$  reduces to the vector coupling constant  $g_V$ , and  $g_1$  reduces to the axial-vector coupling constant  $g_A$ . The latter coefficients are related by Cabibbo’s theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The  $g_3$  term is negligible for transitions in which an  $e^\pm$  is emitted, and gives a very small correction, which can be estimated by PCAC [4], for  $\mu^\pm$  modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f}, \quad (2)$$

where  $m_i$  and  $m_f$  are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are

derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher  $q^2$ , it is necessary to modify the form factors at  $q^2 = 0$  by a “dipole”  $q^2$  dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio  $g_A/g_V$  may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}} . \quad (3)$$

The presence of a “triple correlation” term in the transition probability, proportional to  $\text{Im}(g_A/g_V)$  and of the form

$$\sigma_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (4)$$

for initial baryon polarization or

$$\sigma_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (5)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle  $\phi$  has been measured precisely only in neutron decay (and in  $^{19}\text{Ne}$  nuclear beta decay), and the results are consistent with  $T$  invariance.

### Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_\pi^2 \cdot \bar{B}_f (A - B\gamma_5) B_i , \quad (6)$$

where  $A$  and  $B$  are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma \hat{\omega}_f \cdot \hat{\omega}_i + (1 - \gamma)(\hat{\omega}_f \cdot \hat{\mathbf{n}})(\hat{\omega}_i \cdot \hat{\mathbf{n}}) + \alpha(\hat{\omega}_f \cdot \hat{\mathbf{n}} + \hat{\omega}_i \cdot \hat{\mathbf{n}}) + \beta \hat{\mathbf{n}} \cdot (\hat{\omega}_f \times \hat{\omega}_i) , \quad (7)$$

where  $\hat{\mathbf{n}}$  is a unit vector in the direction of the final baryon momentum, and  $\hat{\omega}_i$  and  $\hat{\omega}_f$  are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.)

The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  are defined as

$$\begin{aligned} \alpha &= 2 \text{Re}(s^*p) / (|s|^2 + |p|^2) , \\ \beta &= 2 \text{Im}(s^*p) / (|s|^2 + |p|^2) , \\ \gamma &= (|s|^2 - |p|^2) / (|s|^2 + |p|^2) , \end{aligned} \quad (8)$$

where  $s = A$  and  $p = |\mathbf{p}_f| B / (E_f + m_f)$ ; here  $E_f$  and  $\mathbf{p}_f$  are the energy and momentum of the final baryon. The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1 . \quad (9)$$

If the hyperon polarization is  $\mathbf{P}_Y$ , the polarization  $\mathbf{P}_B$  of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \hat{\mathbf{n}}) + \gamma\hat{\mathbf{n}} \times (\mathbf{P}_Y \times \hat{\mathbf{n}})}{1 + \alpha\mathbf{P}_Y \cdot \hat{\mathbf{n}}} . \quad (10)$$

Here  $\mathbf{P}_B$  is defined in the rest system of the baryon, obtained by a Lorentz transformation along  $\hat{\mathbf{n}}$  from the hyperon rest frame, in which  $\hat{\mathbf{n}}$  and  $\mathbf{P}_Y$  are defined.

An additional useful parameter  $\phi$  is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi . \quad (11)$$

In the Listings, we compile  $\alpha$  and  $\phi$  for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give  $\alpha$ ,  $\phi$ , and  $\Delta$  (defined below) with errors, and also give the value of  $\gamma$  without error.

Time-reversal invariance requires, in the absence of final-state interactions, that  $s$  and  $p$  be relatively real, and therefore that  $\beta = 0$ . However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s| e^{i\delta_s} \text{ and } p = |p| e^{i\delta_p} , \quad (12)$$

where  $\delta_s$  and  $\delta_p$  are the pion-baryon  $s$ - and  $p$ -wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p) . \quad (13)$$

One also defines  $\Delta = -\tan^{-1}(\beta/\alpha)$ . If  $T$  invariance holds,  $\Delta = \delta_s - \delta_p$ . For  $\Lambda \rightarrow p\pi^-$  decay, the value of  $\Delta$  may be compared with the  $s$ - and  $p$ -wave phase shifts in low-energy  $\pi^-p$  scattering, and the results are consistent with  $T$  invariance.

See also the note on “Radiative Hyperon Decays” in the  $\Xi^0$  Listings in this *Review*.

35 MOSTOVOI 01 measures the two  $P$ -odd correlations  $A$  and  $B$ , or rather  $SA$  and  $SB$ , where  $S$  is the  $n$  polarization, in free neutron decay.  
36 YEROZOLIMSKY 97 makes a correction to the EROZOLIMSKII 91 value.  
37 These experiments measure the absolute value of  $g_A/g_V$  only.  
38 KROHN 75 includes events of CHRISTENSEN 70.  
39 KROPF 74 reviews all data through 1972.

 $e^-$  ASYMMETRY PARAMETER A

This is the neutron-spin electron-momentum correlation coefficient. Unless otherwise noted, the values are corrected for radiative effects and weak magnetism. In the Standard Model,  $A$  is related to  $\lambda \equiv g_A/g_V$  by  $A = -2(\lambda^2 - |\lambda|) / (1 + 3\lambda^2)$ ; this assumes that  $g_A$  and  $g_V$  are real.

40 This is the combined result of ABELE 02 and ABELE 97D.

41 YEROZOLIMSKY 97 makes a correction to the EROZOLIMSKII 91 value.

42 MOSTOVOI 01 calculates this from its measurement of  $\lambda = g_A/g_V$  above.

43 These results are not corrected for radiative effects and weak magnetism, but the corrections are small compared to the errors.

 $\tau_e$  ASYMMETRY PARAMETER B

This is the neutron-spin antineutrino-momentum correlation coefficient. In the Standard Model,  $B$  is related to  $\lambda \equiv g_A/g_V$  by  $B = 2\lambda(\lambda - 1) / (1 + 3\lambda^2)$ ; this assumes that  $g_A$  and  $g_V$  are real.

44 MOSTOVOI 01 calculates this from its measurement of  $\lambda = g_A/g_V$  above.

## PROTON ASYMMETRY PARAMETER C

Describes the correlation between the neutron spin and the proton momentum. In the Standard Model,  $C$  is related to  $\lambda \equiv g_A/g_V$  by  $C = -x_c(A + B) = x_c 4\lambda / (1 + 3\lambda^2)$ , where  $x_c = 0.27484$  is a kinematic factor; this assumes that  $g_A$  and  $g_V$  are real.

# Baryon Particle Listings

## $N$ 's and $\Delta$ 's

### $N$ AND $\Delta$ RESONANCES

Written April 2012 by E. Klempt (University of Bonn) and R.L. Workman (George Washington University).

#### I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The Breit-Wigner masses and widths, the pole positions, and the elasticities of the  $N$  and  $\Delta$  resonances in the Baryon Summary Table come largely from partial-wave analyses of  $\pi N$  total, elastic, and charge-exchange scattering data. The most comprehensive analyses were carried out by the Karlsruhe-Helsinki (KH80) [1], Carnegie Mellon-Berkeley (CMB80) [2], and George Washington U (GWU) [3] groups. Partial-wave analyses have also been performed on much smaller  $\pi N$  reaction data sets to get  $N\eta$ ,  $\Lambda K$ , and  $\Sigma K$  branching fractions. Other branching fractions come from analyses of  $\pi N \rightarrow N\pi\pi$  data. A number of groups have undertaken multichannel analyses of these and associated photo-induced reactions (see Sec. VI).

Table 1. The status of the  $N$  resonances. Only those with an overall status of \*\*\* or \*\*\*\* are included in the main Baryon Summary Table.

Particle	$J^P$	Status		Status as seen in —

\*\*\*\* Existence is certain, and properties are at least fairly well explored.  
 \*\*\* Existence is very likely but further confirmation of quantum numbers and branching fractions is required.  
 \*\* Evidence of existence is only fair.  
 \* Evidence of existence is poor.

In recent years, a large amount of data on photoproduction of many final states has been accumulated, and these data are beginning to make a significant impact on the properties of

baryon resonances. A survey of data on photoproduction can be found in the proceedings of recent conferences [4] and workshops [5], and in a recent review [6].

#### II. Naming scheme for baryon resonances

In the past, when nearly all resonance information came from elastic  $\pi N$  scattering, it was common to label resonances with the incoming partial wave  $L_{2I,2J}$ , as in  $\Delta(1232)P_{33}$  and  $N(1680)F_{15}$ . However, most recent information has come from  $\gamma N$  experiments. Therefore, we have replaced  $L_{2I,2J}$  with the spin-parity  $J^P$  of the state, as in  $\Delta(1232) 3/2^+$  and  $N(1680) 5/2^+$ . This applies to all baryons, including those such as the  $\Xi$  resonances and charm baryons that are not produced in formation experiments. Names of the stable baryons ( $N, \Lambda, \Sigma, \Xi, \Omega, \Lambda_c, \dots$ ) have no spin, parity, or mass attached.

Table 2. The status of the  $\Delta$  resonances. Only those with an overall status of \*\*\* or \*\*\*\* are included in the main Baryon Summary Table.

Particle	$J^P$	Status		Status as seen in —									
		overall	$\pi N$	$\gamma N$	$N\eta$	$N\sigma$	$N\omega$	$\Lambda K$	$\Sigma K$	$N\rho$	$\Delta\pi$

$\Delta(2750)$	$13/2^-$	**	**										
$\Delta(2950)$	$15/2^+$	**	**										

\*\*\*\* Existence is certain, and properties are at least fairly well explored.  
 \*\*\* Existence is very likely but further confirmation of quantum numbers and branching fractions is required.  
 \*\* Evidence of existence is only fair.  
 \* Evidence of existence is poor.

#### III. Using the $N$ and $\Delta$ listings

Tables 1 and 2 list all the  $N$  and  $\Delta$  entries in the Baryon Listings and give our evaluation of the overall status, the status from  $\pi N \rightarrow N\pi$  scattering data and from photoproduction experiments, and the status channel by channel. Only the established resonances (overall status 3 or 4 stars) are promoted to the Baryon Summary Table. We have omitted from the Listings information from old analyses, prior to KH80 and CMB80 which can be found in earlier editions. A rather complete survey of older results was given in our 1982 edition [7].

The star rating assigned to a resonance depends on the data base and the analysis. As a rule, we award an overall status \*\*\* or \*\*\*\* only to those resonances which are confirmed by independent analyses and which are derived from analyses based on complete information, *i.e.*, for analyses based on three observables in  $\pi N$  scattering or eight properly chosen observables in photoproduction. Use of dispersion relations (as in the KH80, CMB80, and GWU analyses) may lift these requirements. Three and four-star resonances should be observed in one of their strongest decay modes. Weak signals or signals emerging in analyses with incomplete experimental information are given \*\* or \* status. We do not consider new results without proper error evaluation.

In the Data Listings, we give first the Breit-Wigner mass and width but warn the reader that Breit-Wigner parameters depend on the formalism used, such as for angular momentum barrier factors or cut-off parameters, and the assumed or modeled background. Then we give pole-related quantities, such as the position of the pole and its elastic residue. For the first time, we give residues and phases of hadronic transition amplitudes and helicity amplitudes. Branching ratios and photoproduction amplitudes follow.

#### IV. Properties of resonances

Resonances are defined by poles of the scattering amplitude in the complex energy  $w = \sqrt{s}$  plane [8]. In contrast to other quantities related to resonance phenomena, such as the Breit-Wigner mass or the K-matrix pole, a pole of the scattering amplitude does not depend on the chosen field parameterization, and production and decay properties factorize. It is the pole position which should be compared to eigenvalues of the Hamiltonian of full QCD.

Examining the Listings, one finds a much larger spread in Breit-Wigner parameters compared to pole parameters. In his *pole-emic* against Breit-Wigner parameters, Hohler [9] concluded: “*In contrast to the conventional (Breit-Wigner) parameters, the pole positions and speed plots have a well-defined relation to S-matrix theory. They also give more information on the resonances and thresholds and can be used for the prediction on other reactions that couple to the excited states [italics in original].*”

In scattering theory, the amplitude for the scattering process leading from the initial state  $a$  to the final state  $b$  is given by the  $S$  matrix, which can be decomposed as follows:

$$S_{ab} = I_{ab} + 2i\sqrt{\rho_a}T_{ab}\sqrt{\rho_b}. \quad (1)$$

Here  $I_{ab}$  is the identity operator, and  $T_{ab}$  describes the transition from the initial state to the final state (e.g.  $\pi N$  to  $\Sigma K$ ).  $T_{ab}$  contains coupling constants, the decay momenta  $k$  to the power  $L$  to yield the correct threshold behavior when angular momenta are involved, and a correction  $F(L, r^2, k^2)$ , e.g. in Blatt-Weisskopf form, with a range parameter  $r$ . The two-body phase-space  $\rho$  is given (see Eq. 39.17 in Sec. 39) by

$$\rho(s) = \frac{1}{16\pi} \frac{2|\vec{k}|}{\sqrt{s}}. \quad (2)$$

The transition amplitude  $T$  contains poles due to resonances and background terms. Above the threshold for inelastic reactions, a resonance is associated with a cluster of poles in different Riemann sheets. The pole closest to the real axis has the strongest impact on the data. It is situated on the second Riemann sheet, starting at the highest threshold below the pole position. If the threshold is close to the pole position, poles in other sheets may have an important impact as well.

Other complications may occur: Broad resonances are difficult to disentangle from background amplitudes, *e.g.*, due to left-hand cuts originating from meson and baryon exchange forces. A two-particle subsystem generates a square-root singularity at its threshold; poles in a two-body subsystem, *e.g.*, the  $\rho$  meson in the  $\pi\pi$  system, lead to branch points in the complex energy plane. Neglecting some of these aspects leads to a model dependence of the pole position. These uncertainties increase with the particle width.

Several particle properties are related to poles. First, poles exist on multiple Riemann sheets. In the Listings, we give for each resonance the position of the most relevant pole. The poles of the scattering amplitude can be found by analytic continuation of the amplitude. The real part of the pole position in the complex energy plane defines the particle mass, the imaginary part its half width:  $w_{\text{pole}} = m_{\text{pole}} - i\Gamma_{\text{pole}}/2$ . Residues of transition amplitudes are the first term in a Laurent expansion and can be calculated through a contour integral of the amplitude  $T_{ab}$  around the pole position in the energy plane:

$$\begin{aligned} \text{Res}(a \rightarrow b) &= \oint \frac{d\sqrt{s}}{2\pi i} \sqrt{\rho_a} T_{ab}(s) \sqrt{\rho_b} \\ &= \frac{1}{2w_{\text{pole}}} \sqrt{\rho_a(s_{\text{pole}})} g_a g_b \sqrt{\rho_b(s_{\text{pole}})}, \end{aligned} \quad (4)$$

where  $g_a$  and  $g_b$  are coupling constants. In the Listings, we give normalized residues,  $2 \text{Res}(a \rightarrow b)/\Gamma_{\text{pole}}$ . For elastic scattering, *e.g.*, for  $\pi N \rightarrow N\pi$ , this gives the elastic residue:

$$\text{Res}(a \rightarrow a) = \frac{1}{2w_{\text{pole}}} \rho_a(s_{\text{pole}}) g_a^2. \quad (5)$$

Branching ratios of a pole can be defined by

$$BR_{\text{pole}}(\text{channel } b) = \frac{|\text{Res}(\pi N \rightarrow b)|^2}{|\text{Res}(\pi N \rightarrow N\pi)| \cdot (\Gamma_{\text{pole}}/2)}. \quad (6)$$

This information is, however, not given in the literature.

Within models, background amplitudes can be parameterized using an effective Lagrangian approach (as in dynamical coupled-channel approaches), or by low-order polynomial functions. In the latter case, resonances are then added, sometimes in the form of Breit-Wigner amplitudes. In the Listings, particle properties related to fits to data using Breit-Wigner amplitudes are given as well. These are the Breit-Wigner mass and width, the partial decay widths, and the branching ratios. It should be noted that Breit-Wigner parameters depend on the background parameterization.

# Baryon Particle Listings

## $N$ 's and $\Delta$ 's

The multichannel relativistic Breit-Wigner amplitude is given by

$$A_{ab} = \sqrt{\rho_a} T_{ab} \sqrt{\rho_b} = \frac{-g_a g_b \sqrt{\rho_a \rho_b}}{s - m_{\text{BW}}^2 + i \sum_a g_a^2 \rho_a}, \quad (7)$$

where  $m_{\text{BW}}$  is called the Breit-Wigner mass. In the case of two channels, Eq. (7) is known as the Flatté formula. The inclusion of angular momenta leads to additional factors. The energy-dependent partial decay widths, defined by  $\sqrt{s} \Gamma_a(s) = g_a^2 \rho_a(s)$ , can be used to bring Eq. (7) into the form of Eq. (39.57). Evaluated at the Breit-Wigner mass, it gives the partial decay width  $\Gamma_a$  at the resonance position

$$m_{\text{BW}} \Gamma_a = g_a^2 \rho_a(m_{\text{BW}}^2). \quad (8)$$

The branching ratio for the decay of a resonance into channel  $a$ ,

$$BR_a = \Gamma_a / \Gamma_{\text{BW}}, \quad (9)$$

vanishes by definition for decay modes with thresholds above the Breit-Wigner mass. That the sum  $\sum_a BR_a$  equals one follows from the definition. Unobserved decay modes lead to the inequality  $\sum_a BR_a \leq 1$ . In the case of broad resonances, definitions (8) and (9) may be counter-intuitive. Branching ratios can also be defined as

$$BR'_a = \int_{\text{threshold}}^{\infty} \frac{ds}{\pi} \frac{g_a^2 \rho_a(s)}{(m_{\text{BW}}^2 - s)^2 + (\sum_a g_a^2 \rho_a(s))^2}. \quad (10)$$

Here  $\rho(s)$  should not be continued below threshold. These branching ratios include decays of resonances into channels with thresholds above their nominal masses. The relation  $\sum_a BR'_a = 1$  is needed for normalization.

### V. Electromagnetic interactions

A new approach to the nucleon excitation spectrum is provided by dedicated facilities at the Universities of Bonn and Mainz, and at the national laboratories Jefferson Lab in the US and SPring-8 in Japan. High-precision cross sections and polarization observables in photoproduction of pseudoscalar mesons provide a data set that is nearly a “complete experiment,” one that fully constrains the four complex amplitudes describing the spin-structure of the reaction. A large number of photoproduction reactions has been studied.

In photoproduction, the spins of the photon and nucleon can be parallel or anti-parallel, and there are spin-flip and non-flip transitions. Four independent amplitudes can be defined using the photon polarization and the hadronic current [10]. The amplitudes can be expanded in a series of electric and magnetic multipoles. In general, two amplitudes, one electric and one magnetic, contribute to one  $J^P$  combination. For a given resonance, these two amplitudes are related to the helicity amplitudes  $A_{1/2}$  and  $A_{3/2}$ . The final state may have isospin  $I = 1/2$  or  $I = 3/2$ .

If a Breit-Wigner parametrization is used, the  $N\gamma$  partial width,  $\Gamma_\gamma$ , is given in terms of the helicity amplitudes  $A_{1/2}$  and  $A_{3/2}$  by

$$\Gamma_\gamma = \frac{k_{\text{BW}}^2}{\pi} \frac{2m_N}{(2J+1)m_{\text{BW}}} (|A_{1/2}|^2 + |A_{3/2}|^2). \quad (11)$$

Here  $m_N$  and  $m_{\text{BW}}$  are the nucleon and resonance masses,  $J$  is the resonance spin, and  $k_{\text{BW}}$  is the photon c.m. decay momentum. Most earlier analyses have quoted the real quantities  $A_{1/2}$  and  $A_{3/2}$ .

Other more recent studies have quoted related complex quantities, evaluated at the T-matrix pole. The complex helicity amplitudes for photoproduction of the final state  $b$ ,  $\tilde{A}_{1/2}$  and  $\tilde{A}_{3/2}$ , are given by

$$\text{Res}((\gamma N)_h \rightarrow b) = \frac{\tilde{A}_b^h g_b}{2w_{\text{pole}}} |k_{\text{pole}}| \sqrt{\frac{2m_N}{(2J+1)\pi} \cdot \rho_b(w_{\text{pole}}^2)}. \quad (12)$$

$\tilde{A}_{1/2}$  and  $\tilde{A}_{3/2}$  are defined at the pole position, and are normalized to reproduce Eq. (11) when the pole position is replaced by the Breit-Wigner mass.

The amplitudes  $\tilde{A}_{1/2}$  and  $\tilde{A}_{3/2}$ , the elastic residues, and the residues of the transition amplitudes are complex numbers. Eq. (8) defines  $g_{N\pi}$  up to a sign. (Here,  $g_{N\pi}$  is the  $N\pi$  decay constant of a resonance, not the  $\pi N$  coupling constant!) Due to Eq. (12), the phase of the helicity amplitude depends on this definition. We define the phase of  $g_{N\pi}$  clockwise.

The determination of eight real numbers from four complex amplitudes (with one overall phase undetermined) requires at least seven independent data points. At least one further measurement is required to resolve discrete ambiguities that result from the fact that data are proportional to squared amplitudes. Photon beams and nucleon targets can be polarized (with linear or circular polarization  $P_\perp$ ,  $P_\odot$ , and  $\vec{T}$ , respectively); and the recoil polarization of the outgoing nucleon  $\vec{R}$  can be measured. Experiments can be divided into three classes: those with polarized photons and a polarized target (BT); and those measuring the baryon recoil polarization and using either a polarized photon (BR) or a polarized target (TR). Different sign conventions are used in the literature, as summarized in Ref. 12.

A large number of polarization observables has been determined that constrain energy-dependent partial-wave solutions. One of the best studied reactions is  $\gamma p \rightarrow \Lambda K^+$ . Published data include differential cross sections, the beam asymmetry  $\Sigma$ , the target asymmetry  $T$ , the recoil polarization  $P$ , and the BR double-polarization variables  $C_x, C_z, O_x$ , and  $O_z$ . For  $\gamma p \rightarrow p\pi^0$ ,  $\gamma p \rightarrow n\pi^+$ , and  $\gamma p \rightarrow p\eta$ , differential cross sections and beam asymmetries have been published; BT data for  $E, F, G$ , and  $H$  have been presented at conferences [13].

Electroproduction of mesons provides information on the internal structure of resonances. The helicity amplitudes become functions of the momentum transfer, and a third amplitude,  $S_{1/2}$ , contributes to the process. Recent experimental results and their interpretation are reviewed by I.G. Aznauryan and

V.D. Burkert [14] and by L. Tiator, D. Drechsel, S.S. Kamalov, and M. Vanderhaeghen [15].

## VI. Partial wave analyses

Several PWA groups are now actively involved in the analysis of the new data. Of the three “classical” analysis groups at KH, CMB, and GWU, only the GWU group is still active. This group maintains a nearly complete database, covering reactions from  $\pi N$  and  $KN$  elastic scattering to  $\gamma N \rightarrow N\pi$ ,  $N\eta$ , and  $N\eta'$ . It is presently the only group determining energy-independent  $\pi N$  elastic amplitudes from scattering data. Given the high-precision of photoproduction data already collected and to be taken in the near future, we estimate that an improved spectrum of  $N$  and  $\Delta$  resonances should become available in the forthcoming years.

Energy-dependent fits are performed by various groups with the aim to understand the reaction dynamics and to identify  $N$  and  $\Delta$  resonances. Ideally, the Bethe-Salpeter equation should be solved to describe the data. For practical reasons, approximations have to be made. We mention here: (1) The Mainz unitary isobar model [16] focusses on the correct treatment of the low-energy domain; resonances are added to the unitary amplitude as a sum of Breit-Wigner amplitudes. (2) Multichannel analyses using K-matrix parameterizations derive background terms from a chiral Lagrangian—providing a microscopical description of the background—(Giessen [17,18]), or from phenomenology (Bonn-Gatchina [19]). (3) Several groups (Argonne-Osaka [20], Bonn-Jülich [22,23], Dubna-Mainz-Taipeh [21], EBAC-Jlab [24], Valencia [25]) use dynamical reaction models, driven by chiral Lagrangians, which take dispersive parts of intermediate states into account. The Giessen group pioneered multichannel analyses of large data sets on pion- and photo-induced reactions [17,18]. The Bonn-Gatchina group included recent high-statistics data and reported systematic searches for new baryon resonances in all relevant partial waves. A summary of their results can be found in Ref. 19.

### $N(1440)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ARNDT 06 also finds a second-sheet pole with real part = 1388 MeV,  $-2 \times$  imaginary part = 165 MeV, and residue with modulus 86 MeV and phase =  $-46$  degrees.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ARNDT 04 also finds a second-sheet pole with real part = 1385 MeV,  $-2 \times$  imaginary part = 166 MeV, and residue with modulus 82 MeV and phase =  $-51^\circ$ .
- ARNDT 95 also finds a second-sheet pole with real part = 1383 MeV,  $-2 \times$  imaginary part = 210 MeV, and residue with modulus 92 MeV and phase =  $-54^\circ$ .
- ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV,  $-2 \times$  imaginary part = 256 MeV, and residue =  $(78-153i)$  MeV.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.
- WADA 84 is inconsistent with other analyses; see the Note on  $N$  and  $\Delta$  Resonances.

 $N(1520)$  DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	55–65 %
$\Gamma_2$ $N\eta$	$(2.3 \pm 0.4) \times 10^{-3}$
$\Gamma_3$ $N\pi\pi$	20–30 %
$\Gamma_4$ $\Delta\pi$	15–25 %
$\Gamma_5$ $\Delta(1232)\pi$ , S-wave	10–20 %
$\Gamma_6$ $\Delta(1232)\pi$ , D-wave	10–15 %
$\Gamma_7$ $N\rho$	15–25 %
$\Gamma_8$ $N\rho$ , $S=3/2$ , S-wave	$(9.0 \pm 1.0)$ %
$\Gamma_9$ $N(\pi\pi)_{S=0}^0$	< 8 %
$\Gamma_{10}$ $p\gamma$	0.31–0.52 %
$\Gamma_{11}$ $p\gamma$ , helicity=1/2	0.01–0.02 %
$\Gamma_{12}$ $p\gamma$ , helicity=3/2	0.30–0.50 %
$\Gamma_{13}$ $n\gamma$	0.30–0.53 %
$\Gamma_{14}$ $n\gamma$ , helicity=1/2	0.04–0.10 %
$\Gamma_{15}$ $n\gamma$ , helicity=3/2	0.25–0.45 %

**N(1520) FOOTNOTES**

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.
- MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze  $\eta$  photoproduction data. The ratio of the  $A_{3/2}$  and  $A_{1/2}$  amplitudes is determined, with less model dependence than the amplitudes themselves, to be  $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$ .

**N(1535) FOOTNOTES**

- <sup>1</sup> LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- <sup>2</sup> From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- <sup>3</sup> KRUSCHE 97 fits with the mass fixed at 1544 MeV.
- <sup>4</sup> See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- <sup>5</sup> ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
- <sup>6</sup> LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- <sup>7</sup> The best value ARMSTRONG 99B obtains is  $\approx 0.55$ ; this assumes  $S_{11}$  dominance in the reaction  $p(e, e'p)\eta$  at  $Q^2 = 4$  (GeV/c)<sup>2</sup>.
- <sup>8</sup> This STAROSTIN 03 value is an estimate made using simplest assumptions.
- <sup>9</sup> BENMERROUCHE 91 uses an effective Lagrangian approach to analyze  $\eta$  photoproduction data.
- <sup>10</sup> This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is  $(20 \pm 15)^\circ$ .
- <sup>11</sup> This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is  $(20 \pm 20)^\circ$ .

 $N(1650)$  DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	50-90 %
$\Gamma_2$ $N\eta$	5-15 %
$\Gamma_3$ $\Lambda K$	3-11 %
$\Gamma_4$ $\Sigma K$	
$\Gamma_5$ $N\pi\pi$	10-20 %
$\Gamma_6$ $\Delta\pi$	0-25 %
$\Gamma_7$ $\Delta(1232)\pi, D$ -wave	0-25 %
$\Gamma_8$ $N\rho$	4-12 %

$\Gamma_9$	$N\rho, S=1/2, S\text{-wave}$	(1.0±1.0) %
$\Gamma_{10}$	$N\rho, S=3/2, D\text{-wave}$	(13.0±3.0) %
$\Gamma_{11}$	$N(\pi\pi)_{S\text{-wave}}^{J=0}$	<4 %
$\Gamma_{12}$	$N(1440)\pi$	<5 %
$\Gamma_{13}$	$p\gamma$	0.04–0.20 %
$\Gamma_{14}$	$p\gamma, \text{helicity}=1/2$	0.04–0.20 %
$\Gamma_{15}$	$n\gamma$	0.003–0.17 %
$\Gamma_{16}$	$n\gamma, \text{helicity}=1/2$	0.003–0.17 %

 **$N(1650)$  FOOTNOTES**

- ARNDT 95 finds two distinct states.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.
- This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is  $(25 \pm 20)^\circ$ .
- This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is  $(30 \pm 25)^\circ$ .

***N*(1675) DECAY MODES**

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	35-45 %
$\Gamma_2$ $N\eta$	( 0.0 ± 1.0 ) %
$\Gamma_3$ $\Lambda K$	< 1 %
$\Gamma_4$ $\Sigma K$	
$\Gamma_5$ $N\pi\pi$	50-60 %
$\Gamma_6$ $\Delta\pi$	50-60 %
$\Gamma_7$ $\Delta(1232)\pi, D$ -wave	( 50 ± 15 ) %
$\Gamma_8$ $\Delta(1232)\pi, G$ -wave	
$\Gamma_9$ $N\rho$	< 1-3 %
$\Gamma_{10}$ $N\rho, S=1/2, D$ -wave	( 0.0 ± 1.0 ) %
$\Gamma_{11}$ $N\rho, S=3/2, D$ -wave	( 1.0 ± 1.0 ) %
$\Gamma_{12}$ $N\rho, S=3/2, G$ -wave	
$\Gamma_{13}$ $N(\pi\pi)_{S=0}^0$	( 7.0 ± 3.0 ) %
$\Gamma_{14}$ $p\gamma$	0-0.02 %
$\Gamma_{15}$ $p\gamma, \text{helicity}=1/2$	0-0.01 %
$\Gamma_{16}$ $p\gamma, \text{helicity}=3/2$	0-0.01 %
$\Gamma_{17}$ $n\gamma$	0-0.15 %
$\Gamma_{18}$ $n\gamma, \text{helicity}=1/2$	0-0.05 %
$\Gamma_{19}$ $n\gamma, \text{helicity}=3/2$	0-0.10 %

 **$N(1675)$  FOOTNOTES**

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- SAXON 80 finds the coupling phase is near 90°.
- LONGACRE 77 considers this coupling to be well determined.

$(\Gamma_i\Gamma_j)^{1/2}/\Gamma_{total}$ in $N\pi \rightarrow N(1680) \rightarrow \Lambda K$	$(\Gamma_1\Gamma_3)^{1/2}/\Gamma$
Coupling to $\Lambda K$ not required in the analyses of SAXON 80 or BELL 83.	

Note: Signs of couplings from  $\pi N \rightarrow N\pi\pi$  analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the  $\Delta(1620) S_{31}$  coupling to  $\Delta(1232)\pi$ .

### $N(1680)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.

### $N(1685) ? ?$

$$I(J^P) = \frac{1}{2}(?^?) \text{ Status: } *$$

#### OMITTED FROM SUMMARY TABLE

There is a small literature (which we do not try to cover) on this possible narrow state. See KUZNETSOV 11A, MART 11, and the other papers for further references. This state does not gain status by being a sought-after member of a baryon anti-decuplet.

### $N(1700) 3/2^-$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-) \text{ Status: } ***$$

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various partial-wave analyses do not agree very well.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

## N(1700) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	(12 ± 5) %
$\Gamma_2$ $N\eta$	(0.0 ± 1.0) %
$\Gamma_3$ $\Lambda K$	< 3 %
$\Gamma_4$ $\Sigma K$	
$\Gamma_5$ $N\pi\pi$	85-95 %
$\Gamma_6$ $\Delta\pi$	
$\Gamma_7$ $\Delta(1232)\pi, S\text{-wave}$	10-90 %
$\Gamma_8$ $\Delta(1232)\pi, D\text{-wave}$	< 20 %
$\Gamma_9$ $N\rho$	< 35 %
$\Gamma_{10}$ $N\rho, S=1/2, D\text{-wave}$	
$\Gamma_{11}$ $N\rho, S=3/2, S\text{-wave}$	(7.0 ± 1.0) %
$\Gamma_{12}$ $N\rho, S=3/2, D\text{-wave}$	
$\Gamma_{13}$ $N(\pi\pi)_{S\text{-wave}}^{J=0}$	
$\Gamma_{14}$ $p\gamma$	0.01-0.05 %
$\Gamma_{15}$ $p\gamma, \text{helicity}=1/2$	0.0-0.024 %
$\Gamma_{16}$ $p\gamma, \text{helicity}=3/2$	0.002-0.026 %
$\Gamma_{17}$ $n\gamma$	0.01-0.13 %
$\Gamma_{18}$ $n\gamma, \text{helicity}=1/2$	0.0-0.09 %
$\Gamma_{19}$ $n\gamma, \text{helicity}=3/2$	0.01-0.05 %

### $N(1700)$ FOOTNOTES

- The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.
- The range given is from the four best solutions.

## N(1710) FOOTNOTES

- BATINIC 10 finds evidence for a second  $P_{11}$  state with all parameters except for the phase of the pole residue very similar to the parameters we give here.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

## N(1720) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $N\pi$	(11 ± 3) %
$\Gamma_2$ $N\eta$	(4 ± 1) %
$\Gamma_3$ $\Lambda K$	1-15 %
$\Gamma_4$ $\Sigma K$	
$\Gamma_5$ $N\pi\pi$	>70 %
$\Gamma_6$ $\Delta\pi$	
$\Gamma_7$ $\Delta(1232)\pi, P\text{-wave}$	(75 ± 15) %
$\Gamma_8$ $N\rho$	70-85 %
$\Gamma_9$ $N\rho, S=1/2, P\text{-wave}$	large
$\Gamma_{10}$ $N\rho, S=3/2, P\text{-wave}$	
$\Gamma_{11}$ $N(\pi\pi)_{S\text{-wave}}^{L=0}$	
$\Gamma_{12}$ $p\gamma$	0.05-0.25 %
$\Gamma_{13}$ $p\gamma, \text{helicity}=1/2$	0.05-0.15 %
$\Gamma_{14}$ $p\gamma, \text{helicity}=3/2$	0.002-0.16 %
$\Gamma_{15}$ $n\gamma$	0.0-0.016 %
$\Gamma_{16}$ $n\gamma, \text{helicity}=1/2$	0.0-0.01 %
$\Gamma_{17}$ $n\gamma, \text{helicity}=3/2$	0.0-0.015 %

 **$N(1720)$  FOOTNOTES**

- <sup>1</sup> LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- <sup>2</sup> From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- <sup>3</sup> See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- <sup>4</sup> LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

**N(1860) 5/2<sup>+</sup>**

$I(J^P) = \frac{1}{2}(\frac{5}{2}^+)$  Status: \*\*

OMITTED FROM SUMMARY TABLE

Before the 2012 Review, all the evidence for a  $J^P = 5/2^+$  state with a mass above 1800 MeV was filed under a two-star N(2000). There is now some evidence from ANISOVICH 12A for two  $5/2^+$  states in this region, so we have split the older data (according to mass) between two two-star  $5/2^+$  states, an N(1860) and an N(2000).

**N(1875) 3/2<sup>-</sup>**

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$  Status: \*\*\*

Before the 2012 Review, all the evidence for a  $J^P = 3/2^-$  state with a mass above 1800 MeV was filed under a two-star N(2080).

There is now evidence from ANISOVICH 12A for two  $3/2^-$  states in this region, so we have split the older data (according to mass) between a three-star N(1875) and a two-star N(2120).

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

**$N(1875)$  FOOTNOTES**

- CUTKOSKY 80 finds a lower mass  $D_{13}$  resonance, as well as one in this region. Both are listed here.
- The range given for DEANS 75 is from the four best solutions. Disagrees with  $\pi^+ p \rightarrow \Sigma^+ K^+$  data of WINNIK 77 around 1920 MeV.

**$N(1875)$  REFERENCES**

OMITTED FROM SUMMARY TABLE

Before our 2012 *Review*, this state appeared in our Listings as the  $N(2090)$ . Any structure in the  $S_{11}$  wave above 1800 MeV is listed here. A few early results that are now obsolete have been omitted.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

### N(1895) PHOTON DECAY AMPLITUDES

$N(1895) \rightarrow \rho\gamma$ , helicity-1/2 amplitude  $A_{1/2}$

VALUE	DOCUMENT ID	TECN	COMMENT
0.012±0.006	2 ANISOVICH	12A	DPWA Phase = (120 ± 50)°

### N(1895) FOOTNOTES

- <sup>1</sup> LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- <sup>2</sup> This ANISOVICH 12A value is the complex helicity amplitude at the pole position.

**N(2000) 5/2<sup>+</sup>**

$I(J^P) = \frac{1}{2}(5/2^+)$  Status: \*\*

OMITTED FROM SUMMARY TABLE

Before the 2012 Review, all the evidence for a  $J^P = 5/2^+$  state with a mass above 1800 MeV was filed under a two-star N(2000). There is now some evidence from ANISOVICH 12A for two  $5/2^+$  states in this region, so we have split the older data (according to mass) between two two-star  $5/2^+$  states, an N(1860) and an N(2000).

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-) \text{ Status: } **$$

OMITTED FROM SUMMARY TABLE

Before the 2012 Review, all the evidence for a  $J^P = 3/2^-$  state with a mass above 1800 MeV was filed under a two-star  $N(2080)$ .There is now evidence from ANISOVICH 12A for two  $3/2^-$  states in this region, so we have split the older data (according to mass) between a three-star  $N(1875)$  and a two-star  $N(2120)$ . $N(2120)$  BREIT-WIGNER MASS

**$N(\sim 3000)$  Region  
Partial-Wave Analyses**

## OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an  $N(3245)$ , an  $N(3690)$ , and an  $N(3755)$ , each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an  $N(3030)$ , deduced from total cross-section and  $180^\circ$  elastic cross-section measurements; it is the KOCH 80  $L_{1,15}$  state below.

<sup>5</sup> This ARNDT 97 value is very sensitive to the database being fitted. The result is from a fit to the full pion photoproduction database, apart from the BLANPIED 97 cross-section measurements.

$\Delta(1232)$  MAGNETIC MOMENTS

$\Delta(1232)^{++}$  MAGNETIC MOMENT

The values are extracted from UCLA and SIN data on  $\pi^+ p$  bremsstrahlung using a variety of different theoretical approximations and methods. Our estimate is *only* a rough guess of the range we expect the moment to lie within.

$\Delta(1600) 3/2^+$

$I(J^P) = \frac{3}{2}(\frac{3}{2}^+)$  Status: \*\*\*

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various analyses are not in good agreement.

 $\Delta(1600)$  FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- The range given is from the four best solutions. DEANS 75 disagrees with  $\pi^+ p \rightarrow \Sigma^+ K^+$  data of WINNIK 77 around 1920 MeV.
- LONGACRE 77 considers this coupling to be well determined.
- WADA 84 is inconsistent with other analyses — see the Note on  $N$  and  $\Delta$  Resonances.

 $\Delta(1620)$  FOOTNOTES

- <sup>1</sup> CHEW 80 reports two  $S_{31}$  resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.
- <sup>2</sup> LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- <sup>3</sup> From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- <sup>4</sup> See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of  $N$  and  $\Delta$  resonances as determined from Argand diagrams of  $\pi N$  elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- <sup>5</sup> LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to  $\pi N \rightarrow N\pi\pi$  data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- <sup>6</sup> LONGACRE 77 considers this coupling to be well determined.
