<sup>103</sup> BATLEY 07E includes data from BATLEY 06A. Uses quadratic parametrization and PDG 06 value  $g = 0.626 \pm 0.007$  to obtain  $g_+ - g_- = (2.2 \pm 2.1 \pm 0.7) \times 10^{-4}$ . Neglects any possible charge asymmetries in higher order slope parameters  $h$  or  $k$ .

<sup>104</sup> Asymmetry obtained assuming that  $g_+ + g_- = 2 \times 0.652$  (PDG 02) and that asymmetries in  $h$  and  $k$  are zero.

<sup>105</sup> Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters  $h$  or  $k$  are neglected.

**ALTERNATIVE PARAMETRIZATIONS OF  $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$  DALITZ PLOT**

The following functional form for the matrix element suggested by  $\pi\pi$  rescattering in  $K^+ \rightarrow \pi^+ \pi^+ \pi^- \rightarrow \pi^+ \pi^0 \pi^0$  is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element =  $M_0 + M_1$  where  $M_0 = 1 + (1/2)g_0 u + (1/2)h' u^2 + (1/2)k_0 v^2$  with  $u = (s_3 - s_0)/(m_{\pi^+})^2$ ,  $v = (s_2 - s_1)/(m_{\pi^+})^2$  and where  $M_1$  takes into account the non-analytic piece due to  $\pi\pi$  rescattering amplitudes  $a_0$  and  $a_2$ ; The parameters  $g_0$  and  $h'$  are related to the parameters  $g$  and  $h$  of the matrix element squared given in the previous section by the approximations  $g_0 \sim g^{PDG}$  and  $h' \sim h^{PDG} - (g/2)^2$  and  $k_0 \sim k^{PDG}$ .

In addition, we also consider the effective field theory framework of COLANGELO 06A and BISSEGGER 09 to extract  $g_{BB}$  and  $h'_{BB}$ .

 **$K_{\ell 3}$  AND  $K_{\ell 3}^0$  FORM FACTORS**

Updated March 2012 by T.G. Trippe (LBNL) and C.-J. Lin (LBNL).

Assuming that only the vector current contributes to  $K \rightarrow \pi \ell \nu$  decays, we write the matrix element as

$$M \propto f_+(t) [(P_K + P_\pi)_\mu \bar{\ell} \gamma_\mu (1 + \gamma_5) \nu] + f_-(t) [m_\ell \bar{\ell} (1 + \gamma_5) \nu], \quad (1)$$

where  $P_K$  and  $P_\pi$  are the four-momenta of the  $K$  and  $\pi$  mesons,  $m_\ell$  is the lepton mass, and  $f_+$  and  $f_-$  are dimensionless form factors which can depend only on  $t = (P_K - P_\pi)^2$ , the square of the four-momentum transfer to the leptons. If time-reversal invariance holds,  $f_+$  and  $f_-$  are relatively real.  $K_{\mu 3}$  experiments, discussed immediately below, measure  $f_+$  and  $f_-$ , while  $K_{e 3}$  experiments, discussed further below, are sensitive only to  $f_+$  because the small electron mass makes the  $f_-$  term negligible.

**$K_{\mu 3}$  Experiments.** Analyses of  $K_{\mu 3}$  data frequently assume a linear dependence of  $f_+$  and  $f_-$  on  $t$ , i.e.,

$$f_\pm(t) = f_\pm(0) [1 + \lambda_\pm (t/m_{\pi^+}^2)]. \quad (2)$$

Most  $K_{\mu 3}$  data are adequately described by Eq. (2) for  $f_+$  and a constant  $f_-$  (i.e.,  $\lambda_- = 0$ ).

There are two equivalent parametrizations commonly used in these analyses:

**(1)  $\lambda_+$ ,  $\xi(0)$  parametrization.** Older analyses of  $K_{\mu 3}$  data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t). \quad (3)$$

# Meson Particle Listings

## $K^\pm$

The  $K_{\mu 3}$  decay distribution is then described by the two parameters  $\lambda_+$  and  $\xi(0)$  (assuming time reversal invariance and  $\lambda_- = 0$ ).

(2)  $\lambda_+, \lambda_0$  parametrization. More recent  $K_{\mu 3}$  analyses have parametrized in terms of the form factors  $f_+$  and  $f_0$ , which are associated with vector and scalar exchange, respectively, to the lepton pair.  $f_0$  is related to  $f_+$  and  $f_-$  by

$$f_0(t) = f_+(t) + [t/(m_K^2 - m_\pi^2)] f_-(t). \quad (4)$$

Here  $f_0(0)$  must equal  $f_+(0)$  unless  $f_-(t)$  diverges at  $t = 0$ . The earlier assumption that  $f_+$  is linear in  $t$  and  $f_-$  is constant leads to  $f_0$  linear in  $t$ :

$$f_0(t) = f_0(0) [1 + \lambda_0(t/m_{\pi^+}^2)]. \quad (5)$$

With the assumption that  $f_0(0) = f_+(0)$ , the two parametrizations,  $(\lambda_+, \xi(0))$  and  $(\lambda_+, \lambda_0)$  are equivalent as long as correlation information is retained.  $(\lambda_+, \lambda_0)$  correlations tend to be less strong than  $(\lambda_+, \xi(0))$  correlations.

Since the 2006 edition of the *Review* [4], we no longer quote results in the  $(\lambda_+, \xi(0))$  parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the  $K_{\mu 3}^0$  parameters, correlations, and conversion between parametrizations.

**Quadratic Parametrization.** More recent high-statistics experiments have included a quadratic term in the expansion of  $f_+(t)$ ,

$$f_+(t) = f_+(0) \left[ 1 + \lambda'_+(t/m_{\pi^+}^2) + \frac{\lambda''_+}{2}(t/m_{\pi^+}^2)^2 \right]. \quad (6)$$

If there is a non-vanishing quadratic term, then  $\lambda_+$  of Eq. (2) represents the average slope, which is then different from  $\lambda'_+$ . Our convention is to include the factor  $\frac{1}{2}$  in the quadratic term, and to use  $m_{\pi^+}$  even for  $K_{e3}^+$  and  $K_{\mu 3}^+$  decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the “ $K_{e3}^\pm$  and  $K_{e3}^0$  Form Factors” sections of the Listings.

**Pole Parametrization.** The pole model describes the  $t$ -dependence of  $f_+(t)$  and  $f_0(t)$  in terms of the exchange of the lightest vector and scalar  $K^*$  mesons with masses  $M_v$  and  $M_s$ , respectively:

$$f_+(t) = f_+(0) \left[ \frac{M_v^2}{M_v^2 - t} \right], \quad f_0(t) = f_0(0) \left[ \frac{M_s^2}{M_s^2 - t} \right]. \quad (7)$$

**Dispersive Parametrization** [7,8]. This approach uses dispersive techniques and the known low-energy  $K$ - $\pi$  phases to parametrize the vector and scalar form factors:

$$f_+(t) = f_+(0) \exp \left[ \frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right]; \quad (8)$$

$$f_0(t) = f_+(0) \exp \left[ \frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t)) \right], \quad (9)$$

where  $\Lambda_+$  is the slope of the vector form factor, and  $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$  is the logarithm of the scalar form factor at

the Callan-Treiman point. The functions  $H(t)$  and  $G(t)$  are dispersive integrals.

**$K_{e3}$  Experiments:** Analysis of  $K_{e3}$  data is simpler than that of  $K_{\mu 3}$  because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here  $f_+$  can be assumed to be linear in  $t$ , in which case the linear coefficient  $\lambda_+$  of Eq. (2) is determined, or quadratic, in which case the linear coefficient  $\lambda'_+$  and quadratic coefficient  $\lambda''_+$  of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1 + \gamma_5)\nu + (2f_T/m_K)(P_K)_\lambda(P_\pi)_\mu \bar{\ell}\sigma_{\lambda\mu}(1 + \gamma_5)\nu, \quad (10)$$

where  $f_S$  is the scalar form factor, and  $f_T$  is the tensor form factor. In the case of the  $K_{e3}$  decays where the  $f_-$  term can be neglected, experiments have yielded limits on  $|f_S/f_+|$  and  $|f_T/f_+|$ .

**Fits for  $K_{e3}$  Form Factors.** For  $K_{e3}$  data, we determine best values for the three parametrizations: linear ( $\lambda_+$ ), quadratic ( $\lambda'_+, \lambda''_+$ ) and pole ( $M_v$ ). For  $K_{\mu 3}$  data, we determine best values for the three parametrizations: linear ( $\lambda_+, \lambda_0$ ), quadratic ( $\lambda'_+, \lambda''_+, \lambda_0$ ) and pole ( $M_v, M_s$ ). We then assume  $\mu - e$  universality so that we can combine  $K_{e3}$  and  $K_{\mu 3}$  data, and again determine best values for the three parametrizations: linear ( $\lambda_+, \lambda_0$ ), quadratic ( $\lambda'_+, \lambda''_+, \lambda_0$ ), and pole ( $M_v, M_s$ ). When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two  $K_{e3}$  cases where there is only one parameter: linear ( $\lambda_+$ ) and pole ( $M_v$ ).

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter  $\lambda''_+$  is highly correlated with the linear parameter  $\lambda'_+$ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The “Kaon Particle Listings” show the results with and without assuming  $\mu$ - $e$  universality. The “Meson Summary Tables” show all of the results assuming  $\mu$ - $e$  universality, but most results not assuming  $\mu$ - $e$  universality are given only in the Listings.

 **$K_{e3}^\pm$  FORM FACTORS**

In the form factor comments, the following symbols are used.

$f_+$  and  $f_-$  are form factors for the vector matrix element.

$f_S$  and  $f_T$  refer to the scalar and tensor term.

$$f_0 = f_+ + f_- t / (m_{K^+}^2 - m_{\pi^0}^2).$$

$t =$  momentum transfer to the  $\pi$ .

$\lambda_+$  and  $\lambda_0$  are the linear expansion coefficients of  $f_+$  and  $f_0$ :

$$f_{\pm}(t) = f_{\pm}(0) (1 + \lambda_{\pm} t / m_{\pi^+}^2)$$

For quadratic expansion

$$f_{\pm}(t) = f_{\pm}(0) (1 + \lambda'_{\pm} t / m_{\pi^+}^2 + \frac{\lambda''_{\pm}}{2} t^2 / m_{\pi^+}^4)$$

as used by KTeV. If there is a non-vanishing quadratic term, then  $\lambda_+$  represents an average slope, which is then different from  $\lambda'_+$ .

NA48 and ISTRA quadratic expansion coefficients are converted with

$$\lambda'_{+PDG} = \lambda_{+NA48} \text{ and } \lambda''_{+PDG} = 2 \lambda'_{+NA48}$$

$$\lambda'_{+PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_{+ISTRA} \text{ and}$$

$$\lambda''_{+PDG} = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda'_{+ISTRA}$$

ISTRA linear expansion coefficients are converted with

$$\lambda_{+PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_{+ISTRA} \text{ and } \lambda_0^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0^{ISTRA}$$

The pole parametrization is

$$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$$

$$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$$

where  $M_V$  and  $M_S$  are the vector and scalar pole masses.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI =  $\pi$  spectrum analysis.

MU =  $\mu$  spectrum analysis.

POL =  $\mu$  polarization analysis.

BR =  $K_{e3}^\pm / K_{e3}^\pm$  branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

 **$\lambda_+$  (LINEAR ENERGY DEPENDENCE OF  $f_+$  IN  $K_{e3}^\pm$  DECAY)**

These results are for a linear expansion only. See the next section for fits including a quadratic term. For radiative correction of the  $K_{e3}^\pm$  Dalitz plot, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review " $K_{e3}^\pm$  and  $K_{e3}^0$  Form Factors" above. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

 $K_{\mu 4}^\pm$  FORM FACTORS

Based on the parametrizations of AMOROS 99, the  $K_{\mu 4}^\pm$  form factors can be expressed as

$$F_S = f_S + f'_S q^2 + f''_S q^4 + f'_e S_e / 4m_\pi^2$$

$$F_P = f_P + f'_P q^2$$

$$G_P = g_P + g'_P q^2$$

$$H_P = h_P + h'_P q^2$$

where  $q^2 = (S_\pi / 4m_\pi^2) - 1$ ,  $S_\pi$  is the invariant mass squared of the dipion, and  $S_e$  is the invariant mass squared of the dilepton.

**DECAY FORM FACTOR FOR  $K^\pm \rightarrow \pi^0 \pi^0 e^\pm \nu$** 

Given in BOLOTOV 86B, BARMIN 88B, and SHIMIZU 04.

 **$K^\pm \rightarrow \ell^\pm \nu \gamma$  FORM FACTORS**

For definitions of the axial-vector  $F_A$  and vector  $F_V$  form factor, see the "Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors" in the  $\pi^\pm$  section. In the kaon literature, often different definitions  $a_K = F_A/m_K$  and  $v_K = F_V/m_K$  are used.

 **$F_A + F_V$ , SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR  $K \rightarrow e\nu\gamma$**

### T-VIOLATION PARAMETER IN $K^0$ - $\bar{K}^0$ MIXING

The asymmetry  $A_T = \frac{\Gamma(\bar{K}^0 \rightarrow K^0) - \Gamma(K^0 \rightarrow \bar{K}^0)}{\Gamma(\bar{K}^0 \rightarrow K^0) + \Gamma(K^0 \rightarrow \bar{K}^0)}$  must vanish if  $T$  invariance holds.

### ASYMMETRY $A_T$ IN $K^0$ - $\bar{K}^0$ MIXING

VALUE (units 10 <sup>-3</sup> )	EVTS	DOCUMENT ID	TECN
<b>6.6 ± 1.3 ± 1.0</b>	640k	ANGELOPO... 98E	CPLR

<sup>1</sup>ANGELOPOULOS 98E measures the asymmetry  $A_T = \frac{\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) - \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})}{\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) + \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})}$  as a function of the neutral-kaon eigentime  $\tau$ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions  $p\bar{p} \rightarrow K^- \pi^+ K^0$  and  $p\bar{p} \rightarrow K^+ \pi^- \bar{K}^0$ . The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of  $A_T$  over the interval  $1\tau_S < \tau < 20\tau_S$ . From this value of  $A_T$  ANGELOPOULOS 01B, assuming  $CPT$  invariance in the  $e\pi\nu$  decay amplitude, determine the  $T$ -violating as  $\Delta S = \Delta S$  conserving parameter (for its definition, see Review below)  $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$ .

### CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Updated April 2012 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

$CPT$  theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in  $K^0 - \bar{K}^0$  system, described by the equation

$$i \frac{d}{dt} \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix} = [M - i\Gamma/2] \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix},$$

where  $M$  and  $\Gamma$  are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [4] for notations and previous literature), allows a very accurate test of  $CPT$  symmetry; indeed since  $CPT$  requires  $M_{11} = M_{22}$  and  $\Gamma_{11} = \Gamma_{22}$ , the mass and width eigenstates,  $K_{S,L}$ , have a  $CPT$ -violating piece,  $\delta$ , in addition to the usual  $CPT$ -conserving parameter  $\epsilon$ :

$$K_{S,L} = \frac{1}{\sqrt{2(1+|\epsilon_{S,L}|^2)}} \left[ (1 + \epsilon_{S,L}) K^0 + (1 - \epsilon_{S,L}) \bar{K}^0 \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[ M_{11} - M_{22} - \frac{i}{2}(\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta. \tag{1}$$

Using the phase convention  $\Im(\Gamma_{12}) = 0$ , we determine the phase of  $\epsilon$  to be  $\varphi_{SW} \equiv \arctan \frac{2(m_L - m_S)}{\Gamma_S - \Gamma_L}$ . Imposing unitarity to an arbitrary combination of  $K^0$  and  $\bar{K}^0$  wave functions, we obtain the Bell-Steinberger relation [5] connecting  $CP$  and

# Meson Particle Listings

## $K^0$

$CPT$  violation in the mass matrix to  $CP$  and  $CPT$  violation in the decay; in fact, neglecting  $\mathcal{O}(\epsilon)$  corrections to the coefficient of the  $CPT$ -violating parameter,  $\delta$ , we can write [4]

$$\left[ \frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{\text{SW}} \right] \left[ \frac{\Re(\epsilon)}{1 + |\epsilon|^2} - i \Im(\delta) \right] = \frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f), \quad (2)$$

where  $A_{L,S}(f) \equiv A(K_{L,S} \rightarrow f)$ . We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle \mathcal{A}_L(i) \mathcal{A}_S^*(i) \rangle = \eta_i \mathcal{B}(K_S \rightarrow i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^-(\gamma), 3\pi^0, \pi^0 \pi^+ \pi^-(\gamma), \quad (3)$$

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 4 has been updated by using the recent measurements of  $K_L$  branching ratios from KTeV [6,7], NA48 [8,9], and the results described in the  $CP$  violation in  $K_L$  decays minireview)

$$\alpha_{\pi^+ \pi^-} = ((1.112 \pm 0.010) + i(1.061 \pm 0.010)) \times 10^{-3},$$

$$\alpha_{\pi^0 \pi^0} = ((0.493 \pm 0.005) + i(0.471 \pm 0.005)) \times 10^{-3},$$

$$\alpha_{\pi^+ \pi^- \pi^0} = ((0 \pm 2) + i(0 \pm 2)) \times 10^{-6},$$

$$|\alpha_{\pi^0 \pi^0 \pi^0}| < 7 \times 10^{-6} \quad \text{at 95\% CL.} \quad (4)$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y),$$

$$\mathcal{A}(K^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*)(x_+ - x_-)^*,$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*),$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y)(x_+ + x_-), \quad (5)$$

where  $x_+$  ( $x_-$ ) describes the violation of the  $\Delta S = \Delta Q$  rule in  $CPT$ -conserving (violating) decay amplitudes, and  $y$  parametrizes  $CPT$  violation for  $\Delta S = \Delta Q$  transitions. Taking advantage of their tagged  $K^0(\bar{K}^0)$  beams, CPLEAR has measured  $\Im(x_+)$ ,  $\Re(x_-)$ ,  $\Im(\delta)$ , and  $\Re(\delta)$  [11]. These determinations have been improved in Ref. 4 by including the information  $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$ , where  $A_{L,S}$  are the  $K_L$  and  $K_S$  semileptonic charge asymmetries, respectively, from the PDG [12] and KLOE [13]. Here we are also including the  $T$ -violating asymmetry measurement from CPLEAR [14].

**Table 1:** Values, errors, and correlation coefficients for  $\Re(\delta)$ ,  $\Im(\delta)$ ,  $\Re(x_-)$ ,  $\Im(x_+)$ , and  $A_S + A_L$  obtained from a combined fit, including KLOE [4] and CPLEAR [14].

	value	Correlations coefficients

$\Im(x_+)$	$(0.02 \pm 0.22) \times 10^{-2}$	-0.38	-0.14	0.47	1
$A_S + A_L$	$(-0.40 \pm 0.83) \times 10^{-2}$	-0.10	-0.63	0.99	0.43

The value  $A_S + A_L$  in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\sum_{\pi l \nu} \langle \mathcal{A}_L(\pi l \nu) \mathcal{A}_S^*(\pi l \nu) \rangle$$

$$= 2\Gamma(K_L \rightarrow \pi l \nu)(\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta)))$$

$$= 2\Gamma(K_L \rightarrow \pi l \nu)((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))). \quad (6)$$

Defining

$$\alpha_{\pi l \nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi l \nu} \langle \mathcal{A}_L(\pi l \nu) \mathcal{A}_S^*(\pi l \nu) \rangle + 2i \frac{\tau_{K_S}}{\tau_{K_L}} \mathcal{B}(K_L \rightarrow \pi l \nu) \Im(\delta), \quad (7)$$

we find:

$$\alpha_{\pi l \nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5}.$$

Inserting the values of the  $\alpha$  parameters into Eq. (2), we find

$$\Re(\epsilon) = (161.1 \pm 0.5) \times 10^{-5},$$

$$\Im(\delta) = (-0.7 \pm 1.4) \times 10^{-5}. \quad (8)$$

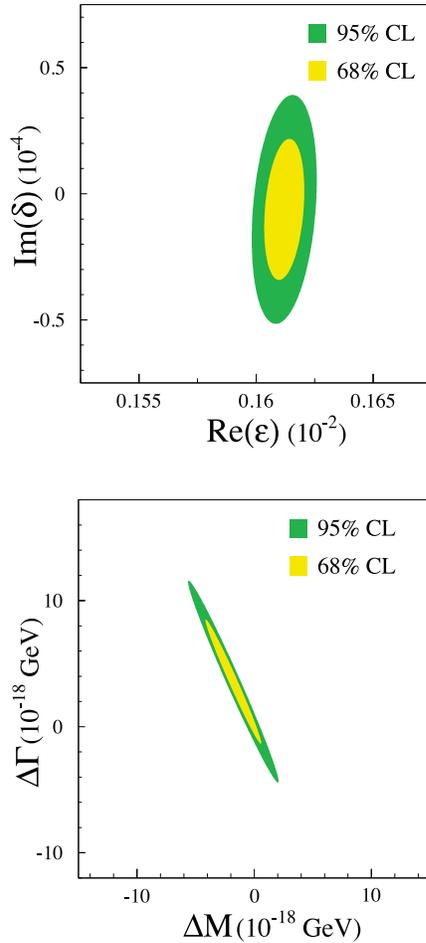

The complete information on Eq. (8) is given in Table 2.

**Table 2:** Summary of results: values, errors, and correlation coefficients for  $\Re(\epsilon)$ ,  $\Im(\delta)$ ,  $\Re(\delta)$ , and  $\Re(x_-)$ .

	value	Correlations coefficients			
$\Re(\epsilon)$	$(161.1 \pm 0.5) \times 10^{-5}$	+1			
$\Im(\delta)$	$(-0.7 \pm 1.4) \times 10^{-5}$	+0.09	1		
$\Re(\delta)$	$(2.4 \pm 2.3) \times 10^{-4}$	+0.08	-0.12	1	
$\Re(x_-)$	$(-4.1 \pm 1.7) \times 10^{-3}$	+0.14	0.22	-0.43	1

Now the agreement with  $CPT$  conservation,  $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$ , is at 18% C.L.

The allowed region in the  $\Re(\epsilon) - \Im(\delta)$  plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

**Figure 1:** Top: allowed region at 68% and 95% C.L. in the  $\Re(\epsilon)$ ,  $\Im(\delta)$  plane. Bottom: allowed region at 68% and 95% C.L. in the  $\Delta M$ ,  $\Delta\Gamma$  plane.

The process giving the largest contribution to the size of the allowed region is  $K_L \rightarrow \pi^+\pi^-$ , through the uncertainty on  $\phi_{+-}$ .

The limits on  $\Im(\delta)$  and  $\Re(\delta)$  can be used to constrain the  $K^0 - \bar{K}^0$  mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\bar{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\bar{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)].$$

The allowed region in the  $\Delta M = (m_{K^0} - m_{\bar{K}^0})$ ,  $\Delta\Gamma = (\Gamma_{K^0} - \Gamma_{\bar{K}^0})$  plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 12) and in the limit  $\Gamma_{K^0} - \Gamma_{\bar{K}^0} = 0$  we obtain

$$-4.0 \times 10^{-19} \text{ GeV} < m_{K^0} - m_{\bar{K}^0} < 4.0 \times 10^{-19} \text{ GeV} \quad \text{at } 95\% \text{ C.L.}$$

<sup>2</sup> AMBROSINO 06H KLOE

<sup>3</sup> LAI 05A NA48

<sup>2</sup> AMBROSINO 06H uses Bell-Steinberger relations with the following measurements:  $B(K_L^0 \rightarrow \pi^+\pi^-)$  in AMBROSINO 06F,  $B(K_S^0 \rightarrow \pi^0\pi^0\pi^0)$  in AMBROSINO 05B, the  $K_S^0$ -semileptonic charge asymmetry in AMBROSINO 06E, and  $K^0$ -semileptonic results in ANGELOPOULOS 98F.

<sup>3</sup> LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of  $\eta_{000}$  and combining other data from PDG 04 and APOSTOLAKIS 99B.

## CPT-VIOLATION PARAMETERS

In  $K^0 - \bar{K}^0$  mixing, if *CP*-violating interactions include a *T* conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle] / \sqrt{1 + |\epsilon + \delta|^2}$$

$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle] / \sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\bar{K}^0\rangle] / \sqrt{2}$$

$$|K_2\rangle = [|K^0\rangle - |\bar{K}^0\rangle] / \sqrt{2}$$

and

$$|\bar{K}^0\rangle = CP|K^0\rangle.$$

The parameter  $\delta$  specifies the *CPT*-violating part.

## Meson Particle Listings

 $K^0, K_S^0$ 

Estimates of  $\delta$  are given below assuming the validity of the  $\Delta S = \Delta Q$  rule. See also THOMSON 95 for a test of  $CP$ -symmetry conservation in  $K^0$  decays using the Bell-Steinberger relation.

REAL PART OF  $\delta$ 

A nonzero value violates  $CPT$  invariance.

$(7.8 \pm 8.4) \times 10^{-18}$	21 ANGELOPO... 99B	RVUE	
21 ANGELOPOULOS 99B assumes only unitarity and combines CPLEAR with other results. Correlated with $(m_{K^0} - m_{\bar{K}^0}) / m_{\text{average}}$ with a correlation coefficient of $-0.95$ .			

TESTS OF  $\Delta S = \Delta Q$  RULERe( $x_{\pm}$ )

A non-zero value would violate the  $\Delta S = \Delta Q$  rule in  $CPT$  conserving transitions.  $x_{\pm}$  is defined above in the Re( $x_{\pm}$ ) section.

VALUE (units $10^{-3}$ )	EVTS	DOCUMENT ID	TECN	COMMENT
$-0.9 \pm 3.0$		OUR AVERAGE		
$-2 \pm 10$		22 BATLEY 07D	NA48	
$-0.5 \pm 3.6$	13k	23 AMBROSINO 06E	KLOE	
$-1.8 \pm 6.1$		24 ANGELOPO... 98D	CPLR	

22 Result obtained from the measurement  $\Gamma(K_S^0 \rightarrow \pi e \nu) / \Gamma(K_L^0 \rightarrow \pi e \nu) = 0.993 \pm 0.34$ , neglecting possible  $CPT$  non-invariance and using PDG 06 values of  $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$ ,  $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$  s and  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.

23 Re( $x_{\pm}$ ) can be shown to be equal to the following combination of rates:

$$\text{Re}(x_{\pm}) = \frac{1}{2} \frac{\Gamma(K_S^0 \rightarrow \pi e \nu) - \Gamma(K_L^0 \rightarrow \pi e \nu)}{\Gamma(K_S^0 \rightarrow \pi e \nu) + \Gamma(K_L^0 \rightarrow \pi e \nu)}$$

which is valid up to first order in terms violating  $CPT$  and/or the  $\Delta S = \Delta Q$  rule.

24 Obtained neglecting  $CPT$  violating amplitudes.

<sup>1</sup> The two ABOUZAID 11 values use the same full KTeV dataset from 1996, 1997, and 1999. The first enters the "assuming *CPT*" fit and the second enters the "not assuming *CPT*" fit.

<sup>2</sup> ABOUZAID 11 fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_\epsilon$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  as free parameters. See  $\text{Im}(\epsilon'/\epsilon)$  in the " $K_L^0$  CP violation" section for correlation information.

<sup>3</sup> ABOUZAID 11 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_\epsilon$  to the Superweak value, i.e. assumes *CPT*. This  $\tau_S$  value is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  measurement in the  $K_L^0$  listings. The correlation coefficient  $\rho(\tau_S, \Delta m) = -0.670$ .

<sup>4</sup> Fit to the proper time distribution.

<sup>5</sup> This ALAVI-HARATI 03 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_{+-}$  to the Superweak value, i.e. assumes *CPT*. This  $\tau_S$  value is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  measurement in the  $K_L^0$  listings. The correlation coefficient  $\rho(\tau_S, \Delta m) = -0.396$ . Superseded by ABOUZAID 11.

<sup>6</sup> This ALAVI-HARATI 03 fit has  $\Delta m$ ,  $\phi_{+-}$ , and  $\tau_{K_S^0}$  free. See  $\phi_{+-}$  in the " $K_L$  CP violation" section for correlation information. Superseded by ABOUZAID 11.

<sup>7</sup> ARONSON 82 find that  $K_S^0$  mean life may depend on the kaon energy.

<sup>8</sup> CARITHERS 75 measures the  $\Delta m$  dependence of the total decay rate (inverse mean life) to be  $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m] 10^{10}/s$ , or, in terms of mean life, CARITHERS 75 measures  $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348] (10^{-10} s)$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>9</sup> HILL 68 has been changed by the authors from the published value  $(0.865 \pm 0.009)$  because of a correction in the shift due to  $\eta_{+-}$ . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

<sup>10</sup> Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

[a] See the Particle Listings below for the energy limits used in this measurement.

[b] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Not a measurement. Calculated as  $0.666 \cdot B(\pi^\pm e^\mp \nu_e)$ .

## CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.1$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

-1.8 -0.7 24 THOMSON 94 E621 Sup. by ZOU 96

20 BATLEY 05 is obtained by measuring the interference parameters in  $K_S, K_L \rightarrow \pi^+ \pi^- \pi^0$ .  $\text{Re}(\lambda) = 0.038 \pm 0.008 \pm 0.006$  and  $\text{Im}(\lambda) = -0.013 \pm 0.005 \pm 0.004$ ; the correlation coeff. between  $\text{Re}(\lambda)$  and  $\text{Im}(\lambda)$  is 0.66 (statistical only).

21 ADLER 97B find the CP-conserving parameters  $\text{Re}(\lambda) = (28 \pm 7 \pm 3) \times 10^{-3}$ ,  $\text{Im}(\lambda) = (-10 \pm 8 \pm 2) \times 10^{-3}$ . They estimate  $B(K_S^0 \rightarrow \pi^+ \pi^- \pi^0)$  from  $\text{Re}(\lambda)$  and the  $K_L^0$  decay parameters. See also ANGELOPOULOS 98c.

22 ZOU 96 is from the the measured quantities  $|\rho_{+-0}| = 0.039^{+0.009}_{-0.006} \pm 0.005$  and  $\phi_\rho = (-9 \pm 18)^\circ$ .

23 ADLER 96E is from the measured quantities  $\text{Re}(\lambda) = 0.036 \pm 0.010^{+0.002}_{-0.003}$  and  $\text{Im}(\lambda)$  consistent with zero. Note that the quantity  $\lambda$  is the same as  $\rho_{+-0}$  used in other footnotes.

24 THOMSON 94 calculates this branching ratio from their measurements  $|\rho_{+-0}| = 0.035 \pm 0.019 \pm 0.004$  and  $\phi_\rho = (-59 \pm 48)^\circ$  where  $|\rho_{+-0}| e^{i\phi_\rho} = A(K_S^0 \rightarrow \pi^+ \pi^- \pi^0, I = 2)/A(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)$ .

7.05 ± 0.09 13k 38 AMBROSINO 06E KLOE Not fitted

••• We do not use the following data for averages, fits, limits, etc. •••

7.2 ± 1.4 75 AKHMETSHIN 99 CMD2 Tagged  $K_S^0$  using  $\phi \rightarrow K_L^0 K_S^0$

36 Reconstructed from  $K^0(\bar{K}^0)(t) \rightarrow \pi e \nu$  distributions using PDG values of  $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$ ,  $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$  s and  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.

37 Uses the PDG 00 value for  $B(K_S^0 \rightarrow \pi^+ \pi^-)$ .

38 Obtained by imposing  $\Sigma_i B(K_S^0 \rightarrow i) = 1$ , where  $i$  runs over all the four branching ratios  $\pi^+ \pi^-$ ,  $\pi^0 \pi^0$ ,  $\pi e \nu$ , and  $\pi \mu \nu$ . Input value of  $B(K_S^0 \rightarrow \pi^+ \pi^-) / B(K_S^0 \rightarrow \pi^0 \pi^0)$  from AMBROSINO 06c is used. To derive  $\Gamma(K_S^0 \rightarrow \pi^+ \mu \nu) / \Gamma(K_S^0 \rightarrow \pi^+ e \nu)$ , lepton universality is assumed, radiative corrections from ANDRE 07 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their  $\Gamma(\pi^\pm e^\mp \nu_e) / \Gamma(\pi^+ \pi^-)$  branching ratio measurement.

$\Gamma(\pi^\pm \mu^\mp \nu_\mu)/\Gamma_{\text{total}}$   $\Gamma_9/\Gamma$

The PDG 06 value below has not been measured but is computed to be 0.666 times the  $K_S \rightarrow \pi^\pm e^\mp \nu_e$  branching fraction. It is included in the fit that constrains the four branching ratios  $\pi^+ \pi^-$ ,  $\pi^0 \pi^0$ ,  $\pi e \nu$ , and  $\pi \mu \nu$  to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the  $\pi^+ \pi^-$  and  $\pi^0 \pi^0$  modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 07, and phase space integrals from KTeV, ALEXOPOULOS 04A.

 $K_S^0$  FORM FACTORS

For discussion, see note on  $K_{e3}$  form factors in the  $K^\pm$  section of the Particle Listings above. Because the semileptonic branching fraction is smaller in  $K_S^0$  than  $K_L^0$  by the ratio of the mean lives, the  $K_S^0$  semileptonic form factor has so far been measured only in the  $K_{e3}$  mode using the linear expansion  $f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^\pm}^2)$ , which gives the vector form factor  $f_+(t)$  relative to its value at  $t = 0$ .

CP VIOLATION IN  $K_S \rightarrow 3\pi$ 

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay  $K^0 \rightarrow \pi^+ \pi^- \pi^0$  have isospin  $I = 0, 1, 2$ , and 3. The  $I = 0$  and  $I = 2$  states have  $CP = +1$  and  $K_S$  can decay into them without violating  $CP$  symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The  $I = 1$  and  $I = 3$  states, which have no centrifugal barrier, have  $CP = -1$  so that the  $K_S$  decay to these requires  $CP$  violation.

In order to see  $CP$  violation in  $K_S \rightarrow \pi^+ \pi^- \pi^0$ , it is necessary to observe the interference between  $K_S$  and  $K_L$  decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \rightarrow \pi^+ \pi^- \pi^0)}{A(K_L \rightarrow \pi^+ \pi^- \pi^0)}. \quad (1)$$

If  $\eta_{+-0}$  is obtained from an integration over the whole Dalitz plot, there is no contribution from the  $I = 0$  and  $I = 2$  final

states and a nonzero value of  $\eta_{+-0}$  is entirely due to  $CP$  violation.

Only  $I = 1$  and  $I = 3$  states, which are  $CP = -1$ , are allowed for  $K^0 \rightarrow \pi^0 \pi^0 \pi^0$  decays and the decay of  $K_S$  into  $3\pi^0$  is an unambiguous sign of  $CP$  violation. Similarly to  $\eta_{+-0}$ ,  $\eta_{000}$  is defined as

$$\eta_{000} = \frac{A(K_S \rightarrow \pi^0 \pi^0 \pi^0)}{A(K_L \rightarrow \pi^0 \pi^0 \pi^0)}. \quad (2)$$

If one assumes that  $CPT$  invariance holds and that there are no transitions to  $I = 3$  (or to nonsymmetric  $I = 1$  states), it can be shown that

$$\begin{aligned} \eta_{+-0} &= \eta_{000} \\ &= \epsilon + i \frac{\text{Im } a_1}{\text{Re } a_1}. \end{aligned} \quad (3)$$

With the Wu-Yang phase convention,  $a_1$  is the weak decay amplitude for  $K^0$  into  $I = 1$  final states;  $\epsilon$  is determined from  $CP$  violation in  $K_L \rightarrow 2\pi$  decays. The real parts of  $\eta_{+-0}$  and  $\eta_{000}$  are equal to  $\text{Re}(\epsilon)$ . Since currently-known upper limits on  $|\eta_{+-0}|$  and  $|\eta_{000}|$  are much larger than  $|\epsilon|$ , they can be interpreted as upper limits on  $\text{Im}(\eta_{+-0})$  and  $\text{Im}(\eta_{000})$  and so as limits on the  $CP$ -violating phase of the decay amplitude  $a_1$ .

CP-VIOLATION PARAMETERS IN  $K_S^0$  DECAY

$A_S = [\Gamma(K_S^0 \rightarrow \pi^- e^+ \nu_e) - \Gamma(K_S^0 \rightarrow \pi^+ e^- \bar{\nu}_e)] / \text{SUM}$   
 Such asymmetry violates  $CP$ . If  $CPT$  is assumed then  $A_S = 2 \text{Re}(\epsilon)$ .

<sup>45</sup>BARMIN 85 find  $\text{Re}(\eta_{+-0}) = (0.05 \pm 0.17)$  and  $\text{Im}(\eta_{+-0}) = (0.15 \pm 0.33)$ . Includes events of BALDO-CEOLIN 75.

$\text{Im}(\eta_{+-0}) = \text{Im}(A(K_S^0 \rightarrow \pi^+ \pi^- \pi^0, CP\text{-violating}) / A(K_L^0 \rightarrow \pi^+ \pi^- \pi^0))$

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
<b><math>-0.002 \pm 0.009^{+0.002}_{-0.001}</math></b>	500k	46 ADLER 97B	CPLR	

• • • We do not use the following data for averages, fits, limits, etc. • • •

$-0.002 \pm 0.018 \pm 0.003$	137k	47 ADLER 96D	CPLR	Sup. by ADLER 97B
$-0.015 \pm 0.017 \pm 0.025$	272k	48 ZOU 94	SPEC	

<sup>46</sup>ADLER 97B also find  $\text{Re}(\eta_{+-0}) = -0.002 \pm 0.007^{+0.004}_{-0.001}$ . See also ANGELOPOULOS 98c.

<sup>47</sup>The ADLER 96D fit also yields  $\text{Re}(\eta_{+-0}) = 0.006 \pm 0.013 \pm 0.001$  with a correlation +0.66 between real and imaginary parts. Their results correspond to  $|\eta_{+-0}| < 0.037$  with 90% CL.

<sup>48</sup>ZOU 94 use theoretical constraint  $\text{Re}(\eta_{+-0}) = \text{Re}(\epsilon) = 0.0016$ . Without this constraint they find  $\text{Im}(\eta_{+-0}) = 0.019 \pm 0.061$  and  $\text{Re}(\eta_{+-0}) = 0.019 \pm 0.027$ .

$\text{Im}(\eta_{000})^2 = \Gamma(K_S^0 \rightarrow 3\pi^0) / \Gamma(K_L^0 \rightarrow 3\pi^0)$

$CPT$  assumed valid (i.e.  $\text{Re}(\eta_{000}) \simeq 0$ ). This limit determines branching ratio  $\Gamma(3\pi^0)/\Gamma_{\text{total}}$  above.

VALUE	CL%	EVTS	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.1	90	632	49 BARMIN 83	HLBC	
<0.28	90	50	GJESDAL 74B	SPEC	Indirect meas.

<sup>49</sup>BARMIN 83 find  $\text{Re}(\eta_{000}) = (-0.08 \pm 0.18)$  and  $\text{Im}(\eta_{000}) = (-0.05 \pm 0.27)$ . Assuming  $CPT$  invariance they obtain the limit quoted above.

<sup>50</sup>GJESDAL 74B uses  $K_{2\pi}$ ,  $K_{\mu 3}$ , and  $K_{e3}$  decay results, unitarity, and  $CPT$ . Calculates  $|\langle \eta_{000} \rangle| = 0.26 \pm 0.20$ . We convert to upper limit.

## Meson Particle Listings

 $K_S^0, K_L^0$ 

$\text{Im}(\eta_{000}) = \text{Im}(A(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0)/A(K_L^0 \rightarrow \pi^0 \pi^0 \pi^0))$   
 $K_S^0 \rightarrow \pi^0 \pi^0 \pi^0$  violates CP conservation, in contrast to  $K_S^0 \rightarrow \pi^+ \pi^- \pi^0$  which has a CP-conserving part.

 $K_L^0$ 

$$I(J^P) = \frac{1}{2}(0^-)$$

 $m_{K_L^0} - m_{K_S^0}$ 

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings. The result labeled "OUR FIT Assuming CPT" ["OUR FIT Not assuming CPT"] includes all measurements except those with the comment "Not assuming CPT" ["Assuming CPT"]. Measurements with neither comment do not assume CPT and enter both fits.

Meson Particle Listings

$K_L^0$

- <sup>1</sup> The two ABOUZAID 11 values use the same data. The first enters the "assuming *CPT*" fit and the second enters the "not assuming *CPT*" fit.
- <sup>2</sup> ABOUZAID 11 fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_\epsilon$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  as free parameters. See  $\text{Im}(\epsilon'/\epsilon)$  in the " $K_L^0$  CP violation" section for correlation information.
- <sup>3</sup> ABOUZAID 11 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_\epsilon$  to the Superweak value, i.e. assumes *CPT*. See " $K_L^0$  Mean Life" section for correlation information.
- <sup>4</sup> Fits  $\Delta m$  and  $\phi_{+-}$  simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20–160 GeV *K* beams.
- <sup>5</sup> GIBBONS 93 value assume  $\phi_{+-} = \phi_{00} = \phi_{\text{SW}} = (43.7 \pm 0.2)^\circ$ , i.e. assumes *CPT*. 20–160 GeV *K* beams.
- <sup>6</sup> These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.
- <sup>7</sup> GJESDAL 74 uses charge asymmetry in  $K_{S3}^0$  decays.
- <sup>8</sup> ALAVI-HARATI 03 fit  $\Delta m$  and  $\tau_{K_S^0}$  simultaneously.  $\phi_{+-}$  is constrained to the Superweak value, i.e. *CPT* is assumed. See " $K_L^0$  Mean Life" section for correlation information. Superseded by ABOUZAID 11.
- <sup>9</sup> ALAVI-HARATI 03 fit  $\Delta m$ ,  $\phi_{+-}$ , and  $\tau_{K_S}$  simultaneously. See  $\phi_{+-}$  in the " $K_L$  CP violation" section for correlation information. Superseded by ABOUZAID 11.
- <sup>10</sup> ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.
- <sup>11</sup> Uses  $K_{e3}^0$  and  $K_{\mu 3}^0$  strangeness tagging at production and decay. Assumes *CPT* conservation on  $\Delta S = -\Delta Q$  transitions.
- <sup>12</sup> ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.
- <sup>13</sup> ARONSON 82 find that  $\Delta m$  may depend on the kaon energy
- <sup>14</sup> ARONSON 70 and CARNEGIE 71 use  $K_S^0$  mean life =  $(0.862 \pm 0.006) \times 10^{-10}$  s. We have not attempted to adjust these values for the subsequent change in the  $K_S^0$  mean life or in  $\eta_{+-}$ .

$K_L^0$  MEAN LIFE

VALUE ( $10^{-8}$ s)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>5.116 ± 0.021 OUR FIT</b>				Error includes scale factor of 1.1.
<b>5.099 ± 0.021 OUR AVERAGE</b>				
5.072 ± 0.011 ± 0.035	13M	1 AMBROSINO 06	KLOE	$\sum_i B_i = 1$
5.092 ± 0.017 ± 0.025	15M	AMBROSINO 05c	KLOE	
5.154 ± 0.044	0.4M	VOSBURGH 72	CNTR	
• • •				We do not use the following data for averages, fits, limits, etc. • • •
5.15 ± 0.14		DEVLIN 67	CNTR	

<sup>1</sup> AMBROSINO 06 uses  $\phi \rightarrow K_L K_S$  with  $K_L$  tagged by  $K_S \rightarrow \pi^+ \pi^-$ . The four major  $K_L$  BR's are measured, the small remainder ( $\pi^+ \pi^-, \pi^0 \pi^0, \gamma \gamma$ ) is taken from PDG 04. This KLOE  $K_L$  lifetime is obtained by imposing  $\sum_i B_i = 1$ . The correlation matrix among the four measured  $K_L$  BR's and this  $K_L$  lifetime is

	$K_{e3}$	$K_{\mu 3}$	$3\pi^0$	$\pi^+ \pi^- \pi^0$	$\tau_{K_L}$
$K_{e3}$	1	-0.25	-0.56	-0.07	0.25
$K_{\mu 3}$		1	-0.43	-0.20	0.33
$3\pi^0$			1	-0.39	-0.21
$\pi^+ \pi^- \pi^0$				1	-0.39
$\tau_{K_L}$					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05c is  $(5.084 \pm 0.023) \times 10^{-8}$  s.

$\Gamma_{36}$ $\pi^0 \mu^\pm e^\mp$	LF [a] < 7.6 × 10 <sup>-11</sup>	CL=90%
$\Gamma_{37}$ $\pi^0 \pi^0 \mu^\pm e^\mp$	LF < 1.7 × 10 <sup>-10</sup>	CL=90%

[a] The value is for the sum of the charge states or particle/antiparticle states indicated.

[b] This mode includes gammas from inner bremsstrahlung but not the direct emission mode  $K_L^0 \rightarrow \pi^+ \pi^- \gamma$  (DE).

[c] See the Particle Listings below for the energy limits used in this measurement.

[d] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.

[e] Allowed by higher-order electroweak interactions.

[f] Violates *CP* in leading order. Test of direct *CP* violation since the indirect *CP*-violating and *CP*-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 15 branching ratios uses 27 measurements and one constraint to determine 11 parameters. The overall fit has a  $\chi^2 = 37.4$  for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

<sup>1</sup> ABOUZAID 08 reports  $(1.29 \pm 0.03 \pm 0.05) \times 10^{-6}$  from a measurement of  $[\Gamma(K_L^0 \rightarrow \pi^0 2\gamma) / \Gamma_{\text{total}}] / [B(K_L^0 \rightarrow \pi^0 \pi^0)]$  assuming  $B(K_L^0 \rightarrow \pi^0 \pi^0) = (8.69 \pm 0.04) \times 10^{-4}$ , which we rescale to our best value  $B(K_L^0 \rightarrow \pi^0 \pi^0) = (8.64 \pm 0.06) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>2</sup> LAI 02B reports  $[\Gamma(K_L^0 \rightarrow \pi^0 2\gamma) / \Gamma_{\text{total}}] / [B(K_L^0 \rightarrow \pi^0 \pi^0)] = (1.467 \pm 0.032 \pm 0.032) \times 10^{-3}$  which we multiply by our best value  $B(K_L^0 \rightarrow \pi^0 \pi^0) = (8.64 \pm 0.06) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. They also find that  $B(\pi^0 2\gamma, m_{\gamma\gamma} < 110 \text{ MeV}) < 0.6 \times 10^{-8}$  (90% CL).

<sup>3</sup> ALAVI-HARATI 99B finds that  $\Gamma(\pi^0 2\gamma, m_{\gamma\gamma} < 240 \text{ MeV}) / \Gamma(\pi^0 2\gamma) = (17.3 \pm 1.3 \pm 1.5)\%$ . Superseded by ABOUZAID 08.

<sup>4</sup> BARR 92 find that  $\Gamma(\pi^0 2\gamma, m_{\gamma\gamma} < 240 \text{ MeV}) / \Gamma(\pi^0 2\gamma) < 0.09$  (90% CL).

<sup>5</sup> BARR 90c superseded by BARR 92.

 $\Gamma(\pi^0 \gamma e^+ e^-) / \Gamma_{\text{total}}$  $\Gamma_{16}/\Gamma$

 $V_{ud}, V_{us}$ , THE CABIBBO ANGLE, AND CKM UNITARITY

Updated March 2012 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters  $(\lambda, A, \rho, \eta)$  [3] nicely illustrates the orthonormality constraint of unitarity and central role played by  $\lambda$ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle,  $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$ . Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Unfortunately, the precise value of  $\lambda$  has been somewhat controversial in the past, with kaon decays suggesting [4]  $\lambda \simeq 0.220$ , while hyperon decays [5] and indirect determinations via nuclear  $\beta$ -decays imply a somewhat larger  $\lambda \simeq 0.225 - 0.230$ . That discrepancy is often discussed in terms of a deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1. \quad (2)$$

For many years, using a value of  $V_{us}$  derived from  $K \rightarrow \pi e \nu$  ( $K_{e3}$ ) decays, that sum was consistently 2–2.5 sigma below unity, a potential signal [6] for new physics effects. Below, we discuss the current status of  $V_{ud}$ ,  $V_{us}$ , and their associated unitarity test in Eq. (2). (Since  $|V_{ub}|^2 \simeq 1 \times 10^{-5}$  is negligibly small, it is ignored in this discussion.)

$V_{ud}$

The value of  $V_{ud}$  has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of  $V_{ud}$  comes from superallowed nuclear beta-decays [6] ( $0^+ \rightarrow 0^+$  transitions). Measuring their half-lives,  $t$ , and  $Q$  values which give the decay rate factor,  $f$ , leads to a precise determination of  $V_{ud}$  via the master formula [7–9]

$$|V_{ud}|^2 = \frac{2984.48(5) \text{ sec}}{ft(1 + \text{RC})} \quad (3)$$

where RC denotes the entire effect of electroweak radiative corrections, nuclear structure, and isospin violating nuclear effects. RC is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays. The most recent analysis of Hardy and Towner [10, 11] gives a weighted average (with errors combined in quadrature) of

$$V_{ud} = 0.97425(22) \text{ (superallowed)}, \quad (4)$$

which, assuming unitarity, corresponds to  $\lambda = 0.2255(10)$ . The new average value of  $V_{ud}$  is shifted upward compared to our 2007 value of 0.97418(27) primarily because of improvements in the experimental  $ft$  values and nuclear isospin breaking corrections employed. We note, however, that the possibility of additional nuclear coulombic corrections has been raised recently [12].

Combined measurements of the neutron lifetime,  $\tau_n$ , and the ratio of axial-vector/vector couplings,  $g_A \equiv G_A/G_V$ , via neutron decay asymmetries can also be used to determine  $V_{ud}$ :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n(1 + 3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [8] due to hadronic loop effects. Those effects have been recently updated and their error was reduced by about a factor of 2 [9], leading to a  $\pm 0.0002$  theoretical uncertainty in  $V_{ud}$  (common to all  $V_{ud}$  extractions). Using the world averages from this *Review*

$$\begin{aligned} \tau_n^{\text{ave}} &= 880.1(1.1) \text{ sec} \\ g_A^{\text{ave}} &= 1.2701(25) \end{aligned} \quad (6)$$

leads to

$$V_{ud} = 0.9773(6)_{\tau_n(16)g_A(2)_{\text{RC}}} \quad (7)$$

with the error dominated by  $g_A$  uncertainties (which have been expanded due to experimental inconsistencies). The new shorter neutron lifetime average (since the last review) now leads to a value of  $V_{ud}$  that is inconsistent with the superallowed nuclear beta decay result in Eq. (4). That disagreement suggests that a shift of  $g_A$  to about 1.275 (consistent with more modern day measurements [14]) is likely. Future neutron studies are expected to resolve these inconsistencies and significantly reduce the uncertainties in  $g_A$  and  $\tau_n$ , potentially making them the best way to determine  $V_{ud}$ .

The recently completed PIBETA experiment at PSI measured the very small ( $\mathcal{O}(10^{-8})$ ) branching ratio for  $\pi^+ \rightarrow \pi^0 e^+ \nu_e$  with about  $\pm 1/2\%$  precision. Their result gives [15]

$$V_{ud} = 0.9749(26) \left[ \frac{BR(\pi^+ \rightarrow e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for  $BR(\pi^+ \rightarrow e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$  [7], rather than the experimental branching ratio from this *Review* of  $1.230(4) \times 10^{-4}$  which would lower the value to  $V_{ud} = 0.9728(30)$ . Theoretical uncertainties in that determination are very small; however, much higher statistics would be required to make this approach competitive with others.

### $V_{us}$

$|V_{us}|$  may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used  $K\ell 3$  decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW} (1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here,  $\ell$  refers to either  $e$  or  $\mu$ ,  $G_F$  is the Fermi constant,  $M_K$  is the kaon mass,  $S_{EW}$  is the short-distance radiative correction,  $\delta_K^\ell$  is the mode-dependent long-distance radiative correction,  $f_+(0)$  is the calculated form factor at zero momentum transfer for the  $\ell\nu$  system, and  $I_K^\ell$  is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays,  $\delta_{SU2}$  is the deviation from one of the ratio of  $f_+(0)$  for the charged to neutral kaon decay; it is zero for the neutral kaon.  $C^2$  is 1 (1/2) for neutral (charged) kaon decays. Most determinations of  $|V_{us}|$  have been based only on  $K \rightarrow \pi e \nu$  decays;  $K \rightarrow \pi \mu \nu$  decays have not been used because of large uncertainties in  $I_K^\mu$ . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for  $S_{EW}$ ,  $\delta_K^\ell$ ,  $\delta_{SU2}$ , and  $f_+(0)$ .

Many new measurements during the last few years have resulted in a significant shift in  $V_{us}$ . Most importantly, recent measurements of the  $K \rightarrow \pi e \nu$  branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [16] in the charged kaon system and then by KTeV [17,18] in the neutral kaon system; subsequent measurements were made by KLOE [19–22], NA48 [23–25], and ISTRA+ [26]. Current averages (*e.g.*, by the PDG [27] or Flavianet [28]) of the semileptonic branching fractions are based only on recent, high-statistics experiments where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [29] and form factors [30–34], have resulted in improved precision for all of the experimental inputs to  $V_{us}$ . Precise measurements of form factors for  $K_{\mu 3}$  decay now make it possible to use both semileptonic decay modes to extract  $V_{us}$ .

Following the analysis of the Flavianet group [28], one finds the values of  $|V_{us}|f_+(0)$  in Table 1. The average of these measurements gives

$$f_+(0)|V_{us}| = 0.21664(48). \quad (10)$$

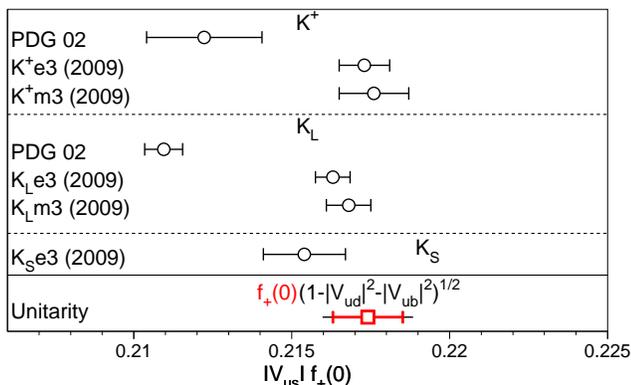

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [35], as well as  $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$ , the expectation for  $f_+(0)|V_{us}|$  assuming unitarity, based on  $|V_{ud}| = 0.9742 \pm 0.0003$ ,  $|V_{ub}| = (3.6 \pm 0.7) \times 10^{-3}$ , and the lattice calculation of  $f_+(0) = 0.9644 \pm 0.0049$  [36] (Lattice calculations of  $f_+(0)$  have improved significantly in recent years, and therefore replace the classic calculation of Leutwyler and Roos [37].) Combining the result in Eq. (10) with the above value of  $f_+(0)$  gives

$$|V_{us}| = \lambda = 0.2246 \pm 0.0012. \quad (11)$$

## Meson Particle Listings

 $K_L^0$ **Table 1:**  $|V_{us}|f_+(0)$  from  $K\ell 3$ .

Decay Mode	$ V_{us} f_+(0)$
$K^\pm e 3$	$0.2173 \pm 0.0008$
$K^\pm \mu 3$	$0.2176 \pm 0.0011$
$K_L e 3$	$0.2163 \pm 0.0006$
$K_L \mu 3$	$0.2168 \pm 0.0007$
$K_S e 3$	$0.2154 \pm 0.0013$
Average	$0.2166 \pm 0.0005$

**Figure 1:** Comparison of determinations of  $|V_{us}|f_+(0)$  from this review (labeled 2009), from the PDG 2002, and with the prediction from unitarity using  $|V_{ud}|$  and the lattice calculation of  $f_+(0)$  [36]. For  $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$ , the inner error bars are from the quoted uncertainty in  $f_+(0)$ ; the total uncertainties include the  $|V_{ud}|$  and  $|V_{ub}|$  errors.

A value of  $V_{us}$  can also be obtained from a comparison of the radiative inclusive decay rates for  $K \rightarrow \mu\nu(\gamma)$  and  $\pi \rightarrow \mu\nu(\gamma)$  combined with a lattice gauge theory calculation of  $f_K/f_\pi$  via [42]

$$\frac{|V_{us}|f_K}{|V_{ud}|f_\pi} = 0.2387(4) \left[ \frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} \right]^{\frac{1}{2}} \quad (12)$$

with the small error coming from electroweak radiative corrections. Employing

$$\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} = 1.3337(46), \quad (13)$$

which averages in the KLOE result [43],  $B(K \rightarrow \mu\nu(\gamma)) = 63.66(9)(15)\%$  and [44]

$$f_K/f_\pi = 1.189(7) \quad (14)$$

along with the value of  $V_{ud}$  in Eq. (4) leads to

$$|V_{us}| = 0.2259(5)(13). \quad (15)$$

It should be mentioned that hyperon decay fits suggest [5]

$$|V_{us}| = 0.2250(27) \text{ Hyperon Decays} \quad (16)$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a recent representative effort [45] that incorporates SU(3) breaking found  $V_{us} = 0.226(5)$ . Similarly, inclusive strangeness changing tau decays give [46]

$$|V_{us}| = 0.2208(34) \text{ Tau Decays} \quad (17)$$

where the central value depends on the strange quark mass. However, a recent BaBar study [47] of  $\tau \rightarrow K\nu/\tau \rightarrow \pi\nu$  using the lattice value of  $f_K/f_\pi$  from Eq. (14) finds  $V_{us} = 0.2255(24)$ , in good agreement with other determinations.

Employing the value of  $V_{ud}$  in Eq. (4) and  $V_{us} = 0.2252(9)$ , the average of the  $K\ell 3$  (Eq. (11)) and  $K\mu 2$  (Eq. (15)) determinations of  $V_{us}$ , leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(4)(4). \quad (18)$$

where the first error is the uncertainty from  $|V_{ud}|^2$  and the second error is the uncertainty from  $|V_{us}|^2$ .

### CKM Unitarity Constraints

The current good experimental agreement with unitarity,  $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(6)$ , provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on “New Physics” effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays,  $K$  decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant,  $G_\mu = 1.166371(6) \times 10^{-5} \text{GeV}^{-2}$ .

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50] (beyond ordinary muon decay  $\mu^+ \rightarrow e^+\nu_e\bar{\nu}_\mu$ ) and (2) new heavy quark mixing  $V_{uD}$  [51]. Other examples in the literature [52,53] include  $Z_\chi$  boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

### Exotic Muon Decays

If additional lepton flavor violating decays such as  $\mu^+ \rightarrow e^+\bar{\nu}_e\nu_\mu$  (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays  $\Gamma(\text{exotic } \mu \text{ decays})$ , they should be subtracted before the extraction of  $G_\mu$  and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \geq 0.9989 \quad (19)$$

or

$$BR(\text{exotic } \mu \text{ decays}) < 0.001. \quad (20)$$

This bound is a factor of 10 better than the direct experimental bound on  $\mu^+ \rightarrow e^+\bar{\nu}_e\nu_\mu$ .

New Heavy Quark Mixing

Heavy  $D$  quarks naturally occur in fourth quark generation models and some heavy quark “new physics” scenarios such as  $E_6$  grand unification. Their mixing with ordinary quarks gives rise to  $V_{ud}$  which is constrained by unitarity (one sided 95% CL)

$$\begin{aligned} |V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 &= 1 - |V_{cd}|^2 > 0.9989 \\ |V_{ud}| &< 0.03. \end{aligned} \quad (21)$$

A similar constraint applies to heavy neutrino mixing and the couplings  $V_{\mu N}$  and  $V_{eN}$ .

- Quadratic dependence required by some experiments. (See sections on "QUADRATIC COEFFICIENT  $h$ " and "QUADRATIC COEFFICIENT  $k$ " below.) Correlations prevent us from averaging results of fits not including  $g, h,$  and  $k$  terms.
- BISI 74 value comes from quadratic fit with quad. term consistent with zero.  $g$  error is thus larger than if linear fit were used.
- BUCHANAN 70 result revised by BUCHANAN 75 to include radiative correlations and to use more reliable  $K_L^0$  momentum spectrum of second experiment (had same beam).

Linear coeff.  $g$  for  $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$  matrix element squared

-6.1 ± 0.9 ± 0.5	14.7M	<sup>2</sup> LAI	01B NA48
-3.3 ± 1.1 ± 0.7	5M	<sup>2,3</sup> SOMALWAR	92 E731

- Result obtained using CI3pl model of CABIBBO 05 to include  $\pi\pi$  rescattering effects. The systematic error includes an external error of  $1.06 \times 10^{-3}$  from the parametrization input of  $(a_0 - a_2) m_{\pi^+} = 0.268 \pm 0.017$  from BATLEY 06B.
- LAI 01B and SOMALWAR 92 results do not include  $\pi\pi$  final state rescattering effects.
- SOMALWAR 92 chose  $m_{\pi^+}$  as normalization to make it compatible with the Particle Data Group  $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$  definitions.

## $K_L^0$ FORM FACTORS

For discussion, see note on form factors in the  $K^\pm$  section of the Particle Listings above.

In the form factor comments, the following symbols are used.

$f_+$  and  $f_-$  are form factors for the vector matrix element.

$f_S$  and  $f_T$  refer to the scalar and tensor term.

$$f_0(t) = f_+(t) + f_-(t) t / (m_K^2 - m_\pi^2)$$

$t$  = momentum transfer to the  $\pi$ .

$\lambda_+$  and  $\lambda_0$  are the linear expansion coefficients of  $f_+$  and  $f_0$ :

$$f_+(t) = f_+(0) (1 + \lambda_+ t / m_\pi^2)$$

For quadratic expansion

$$f_+(t) = f_+(0) (1 + \lambda'_+ t / m_\pi^2 + \lambda''_+ t^2 / m_\pi^4)$$

as used by KTeV. If there is a non-vanishing quadratic term, then  $\lambda_+$

represents an average slope, which is then different from  $\lambda'_+$ .

NA48 ( $K_{e3}$ ) and ISTRA quadratic expansion coefficients are converted with

$$\lambda'_+{}^{PDG} = \lambda_+{}^{NA48} \text{ and } \lambda''_+{}^{PDG} = 2 \lambda'_+{}^{NA48}$$

$$\lambda'_+{}^{PDG} = (\frac{m_{\pi^\pm}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA} \text{ and}$$

$$\lambda''_+{}^{PDG} = 2 (\frac{m_{\pi^\pm}}{m_{\pi^0}})^4 \lambda'_+{}^{ISTRA}$$

ISTRA linear expansion coefficients are converted with

$$\lambda_+{}^{PDG} = (\frac{m_{\pi^\pm}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA} \text{ and } \lambda_0{}^{PDG} = (\frac{m_{\pi^\pm}}{m_{\pi^0}})^2 \lambda_0{}^{ISTRA}$$

The pole parametrization is

$$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$$

$$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$$

where  $M_V$  and  $M_S$  are the vector and scalar pole masses.

The dispersive parametrization is

$$f_+(t) = f_+(0) \exp[\frac{t}{m_\pi^2} (\Lambda_+ + H(t))];$$

$$f_0(t) = f_0(0) \exp[\frac{t}{m_K^2 - m_\pi^2} (\ln[C] - G(t))];$$

where  $\Lambda_+$  is the slope parameter and  $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$

is the logarithm of the scalar form factor at the Callan-Treiman point.

$H(t)$  and  $G(t)$  are dispersive integrals.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI =  $\pi$  spectrum analysis.

MU =  $\mu$  spectrum analysis.

POL =  $\mu$  polarization analysis.

BR =  $K_{\mu 3}^0 / K_{e 3}^0$  branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

## $\lambda_+$ (LINEAR ENERGY DEPENDENCE OF $f_+$ IN $K_{e 3}^0$ DECAY)

For radiative correction of  $K_{e 3}^0$  DP, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review " $K_{e 3}^0$  and  $K_{\mu 3}^0$  Form Factors" in the  $K^\pm$  Listings. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

**CP VIOLATION IN  $K_L$  DECAYS**

Updated April 2012 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL), and T.G. Trippe (LBNL).

The symmetries  $C$  (particle-antiparticle interchange) and  $P$  (space inversion) hold for strong and electromagnetic interactions. After the discovery of large  $C$  and  $P$  violation in the weak interactions, it appeared that the product  $CP$  was a good symmetry. In 1964  $CP$  violation was observed in  $K^0$  decays at a level given by the parameter  $\epsilon \approx 2.3 \times 10^{-3}$ .

A unified treatment of  $CP$  violation in  $K$ ,  $D$ ,  $B$ , and  $B_s$  mesons is given in "CP Violation in Meson Decays" by

# Meson Particle Listings

## $K_L^0$

D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine  $CP$  violation parameters is given in a book by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of  $CP$  violation in  $K_L$  decays, and a description of our fits for the best values of these parameters.

### 1. Formalism for $CP$ violation in Kaon decay:

$CP$  violation has been observed in the semi-leptonic decays  $K_L^0 \rightarrow \pi^\mp \ell^\pm \nu$ , and in the nonleptonic decay  $K_L^0 \rightarrow 2\pi$ . The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-) \\ = |\eta_{+-}| e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0) \\ = |\eta_{00}| e^{i\phi_{00}} \quad (1c)$$

$CP$  violation can occur either in the  $K^0 - \bar{K}^0$  mixing or in the decay amplitudes. Assuming  $CPT$  invariance, the mass eigenstates of the  $K^0 - \bar{K}^0$  system can be written

$$|K_S\rangle = p|K^0\rangle + q|\bar{K}^0\rangle, \quad |K_L\rangle = p|K^0\rangle - q|\bar{K}^0\rangle. \quad (2)$$

If  $CP$  invariance held, we would have  $q = p$  so that  $K_S$  would be  $CP$ -even and  $K_L$   $CP$ -odd. (We define  $|\bar{K}^0\rangle$  as  $CP |K^0\rangle$ .)  $CP$  violation in  $K^0 - \bar{K}^0$  mixing is then given by the parameter  $\tilde{\epsilon}$  where

$$\frac{p}{q} = \frac{(1 + \tilde{\epsilon})}{(1 - \tilde{\epsilon})}. \quad (3)$$

$CP$  violation can also occur in the decay amplitudes

$$A(K^0 \rightarrow \pi\pi(I)) = A_I e^{i\delta_I}, \quad A(\bar{K}^0 \rightarrow \pi\pi(I)) = A_I^* e^{i\delta_I}, \quad (4)$$

where  $I$  is the isospin of  $\pi\pi$ ,  $\delta_I$  is the final-state phase shift, and  $A_I$  would be real if  $CP$  invariance held. The  $CP$ -violating observables are usually expressed in terms of  $\epsilon$  and  $\epsilon'$  defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon'. \quad (5a)$$

One can then show [2]

$$\epsilon = \tilde{\epsilon} + i (\text{Im } A_0 / \text{Re } A_0), \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\text{Re } A_2 / \text{Re } A_0) (\text{Im } A_2 / \text{Re } A_2 - \text{Im } A_0 / \text{Re } A_0), \quad (5c)$$

$$A_L = 2\text{Re } \epsilon / (1 + |\epsilon|^2) \approx 2\text{Re } \epsilon. \quad (5d)$$

In Eqs. (5a), small corrections [3] of order  $\epsilon' \times \text{Re } (A_2/A_0)$  are neglected, and Eq. (5d) assumes the  $\Delta S = \Delta Q$  rule.

The quantities  $\text{Im } A_0$ ,  $\text{Im } A_2$ , and  $\text{Im } \tilde{\epsilon}$  depend on the choice of phase convention, since one can change the phases of  $K^0$  and  $\bar{K}^0$  by a transformation of the strange quark state  $|s\rangle \rightarrow |s\rangle e^{i\alpha}$ ; of course, observables are unchanged. It is possible by a choice of phase convention to set  $\text{Im } A_0$  or  $\text{Im } A_2$  or  $\text{Im } \tilde{\epsilon}$  to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice  $\text{Im } A_0 = 0$  is called the

Wu-Yang phase convention [4], in which case  $\epsilon = \tilde{\epsilon}$ . The value of  $\epsilon'$  is independent of phase convention, and a nonzero value demonstrates  $CP$  violation in the decay amplitudes, referred to as direct  $CP$  violation. The possibility that direct  $CP$  violation is essentially zero, and that  $CP$  violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying  $CPT$  invariance and unitarity the phase of  $\epsilon$  is given approximately by

$$\phi_\epsilon \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.52 \pm 0.05^\circ, \quad (6a)$$

while Eq. (5c) gives the phase of  $\epsilon'$  to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ, \quad (6b)$$

where the numerical value is based on an analysis of  $\pi - \pi$  scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct  $CP$  violation is very small in all  $K^0$  decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of  $\epsilon'$  and of  $\eta_{+-}$  and  $\eta_{00}$ , the  $CP$ -violation parameters in the decays  $K_S \rightarrow \pi^+ \pi^- \pi^0$  [7], and  $K_S \rightarrow \pi^0 \pi^0 \pi^0$  [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase  $\phi_{SW}$ . An important point for the analysis is that  $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$ . The consequence is that only two real quantities need be measured, the magnitude of  $\epsilon$  and the value of  $(\epsilon'/\epsilon)$ , including its sign. The measured quantity  $|\eta_{00}/\eta_{+-}|^2$  is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re } (\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon, \quad (7a)$$

$$\text{Re } (\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|). \quad (7b)$$

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}, \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.5)^\circ, \quad (8b)$$

$$\text{Re } (\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.23) \times 10^{-3}, \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.5)^\circ, \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.34 \pm 0.32)^\circ, \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3}. \quad (8f)$$

Direct  $CP$  violation, as indicated by  $\epsilon'/\epsilon$ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of  $A_L$  agrees with Eq. (5d). The values of  $\phi_{+-}$  and  $\phi_{00} - \phi_{+-}$  are used to set limits on  $CPT$  violation [see "Tests of Conservation Laws"].

## 2. Fits for $K_L^0$ $CP$ -violation parameters:

In recent years,  $K_L^0$   $CP$ -violation experiments have improved our knowledge of  $CP$ -violation parameters, and their consistency with the expectations of  $CPT$  invariance and unitarity. To determine the best values of the  $CP$ -violation parameters in  $K_L^0 \rightarrow \pi^+\pi^-$  and  $\pi^0\pi^0$  decay, we make two types of fits, one for the phases  $\phi_{+-}$  and  $\phi_{00}$  jointly with  $\Delta m$  and  $\tau_S$ , and the other for the amplitudes  $|\eta_{+-}|$  and  $|\eta_{00}|$  jointly with the  $K_L^0 \rightarrow \pi\pi$  branching fractions.

**Fits to  $\phi_{+-}$ ,  $\phi_{00}$ ,  $\Delta\phi$ ,  $\Delta m$ , and  $\tau_S$  data:** These are joint fits to the data on  $\phi_{+-}$ ,  $\phi_{00}$ , the phase difference  $\Delta\phi = \phi_{00} - \phi_{+-}$ , the  $K_L^0 - K_S^0$  mass difference  $\Delta m$ , and the  $K_S^0$  mean life  $\tau_S$ , including the effects of correlations.

Measurements of  $\phi_{+-}$  and  $\phi_{00}$  are highly correlated with  $\Delta m$  and  $\tau_S$ . Some measurements of  $\tau_S$  are correlated with  $\Delta m$ . The correlations are given in the footnotes of the  $\phi_{+-}$  and  $\phi_{00}$  sections of the  $K_L^0$  Listings, and the  $\tau_S$  section of the  $K_S^0$  Listings.

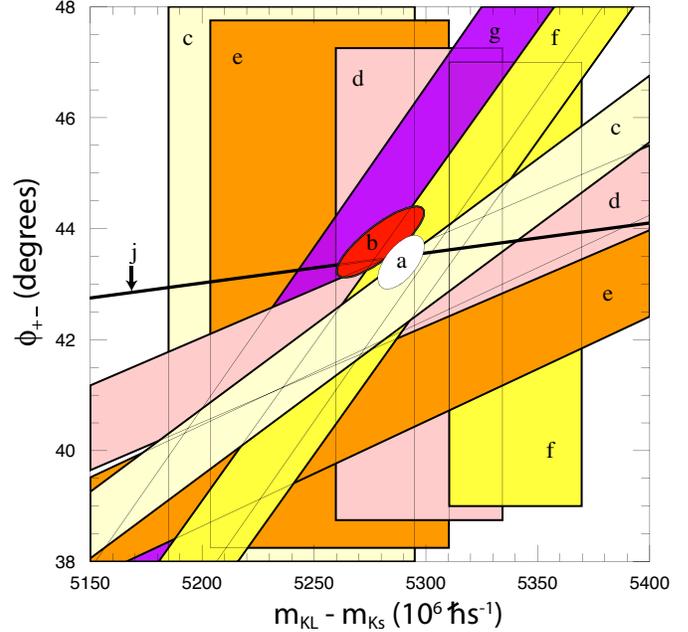

In most cases, the correlations are quoted as 100%, *i.e.*, with the value and error of  $\phi_{+-}$  or  $\phi_{00}$  given at a fixed value of  $\Delta m$  and  $\tau_S$ , with additional terms specifying the dependence of the value on  $\Delta m$  and  $\tau_S$ . These cases lead to diagonal bands in Figs. 1 and 2. The KTeV experiment [10] quotes its results as values of  $\Delta m$ ,  $\tau_S$ ,  $\phi_\epsilon$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  with correlations, leading to the ellipses labeled “b.” The correlations for the KTeV measurements are given in the  $\text{Im}(\epsilon'/\epsilon)$  section of the  $K_L^0$  Listings. For small  $|\epsilon'/\epsilon|$ ,  $\phi_{+-} \approx \phi_\epsilon + \text{Im}(\epsilon'/\epsilon)$ .

**Table 1:** References, Document ID’s, and sources corresponding to the letter labels in the figures. The data are given in the  $\phi_{+-}$  and  $\Delta m$  sections of the  $K_L$  Listings, and the  $\tau_S$  section of the  $K_S$  Listings.

j	this Review	SUPERWEAK 12	

The data on  $\tau_S$ ,  $\Delta m$ , and  $\phi_{+-}$  shown in Figs. 1 and 2 are combined with data on  $\phi_{00}$  and  $\phi_{00} - \phi_{+-}$  in two fits, one without assuming  $CPT$ , and the other with this assumption. The results without assuming  $CPT$  are shown as ellipses labeled “a.” These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{\text{SW}} = \tan^{-1} \left( \frac{2\Delta m}{\Delta\Gamma} \right) = \tan^{-1} \left( \frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)} \right). \quad (9)$$

**Figure 1:**  $\phi_{+-}$  vs  $\Delta m$  for experiments which do not assume  $CPT$  invariance.  $\Delta m$  measurements appear as vertical bands spanning  $\Delta m \pm 1\sigma$ , cut near the top and bottom to aid the eye. Most  $\phi_{+-}$  measurements appear as diagonal bands spanning  $\phi_{+-} \pm \sigma_\phi$ . Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows  $\phi_{\text{SW}}$ . The ellipse “a” shows the  $\chi^2 = 1$  contour of the fit result.

In Figs. 1 and 2,  $\phi_{\text{SW}}$  is shown as narrow bands labeled “j.”

Table 2 column 2, “Fit w/o  $CPT$ ,” gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled “a” in Fig. 1 and Fig. 2 are the  $\chi^2 = 1$  contours for this fit.

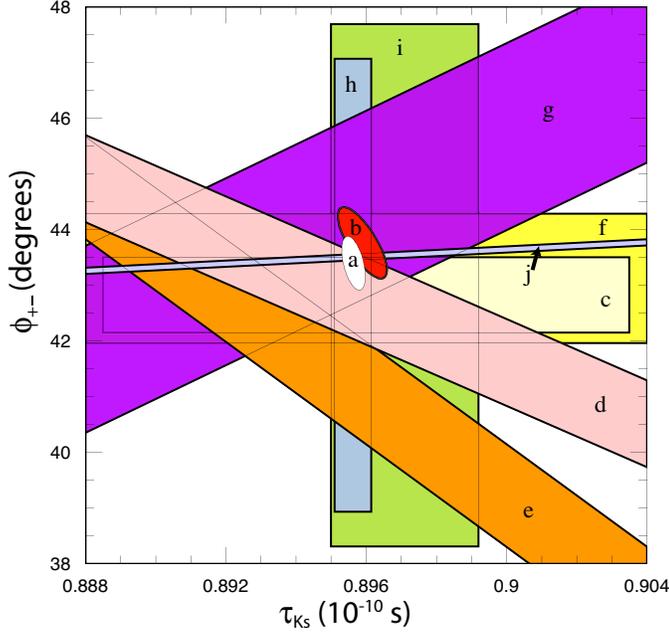

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the  $\phi_{\text{SW}}$  bands.

If  $CPT$  invariance and unitarity are assumed, then by Eq. (6a), the phase of  $\epsilon$  is constrained to be approximately equal to

$$\phi_{\text{SW}} = (43.5165 \pm 0.0002)^\circ + 54.1(\Delta m - 0.5290)^\circ + 32.0(\tau_S - 0.8958) \quad (10)$$

where we have linearized the  $\Delta m$  and  $\tau_S$  dependence of Eq. (9). The error  $\pm 0.0002$  is due to the uncertainty in  $\tau_L$ . Here  $\Delta m$  has units  $10^{10} \hbar s^{-1}$  and  $\tau_S$  has units  $10^{-10} s$ .

If in addition we use the observation that  $\text{Re}(\epsilon'/\epsilon) \ll 1$  and  $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$ , as well as the numerical value of  $\phi_{\epsilon'}$  given in

**Figure 2:**  $\phi_{+-}$  vs  $\tau_S$ .  $\tau_S$  measurements appear as vertical bands spanning  $\tau_S \pm 1\sigma$ , some of which are cut near the top and bottom to aid the eye. Most  $\phi_{+-}$  measurements appear as diagonal or horizontal bands spanning  $\phi_{+-} \pm \sigma_\phi$ . Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows  $\phi_{SW}$ . The ellipse “a” shows the fit result’s  $\chi^2 = 1$  contour.

**Table 2:** Fit results for  $\phi_{+-}$ ,  $\Delta m$ ,  $\tau_S$ ,  $\phi_{00}$ ,  $\Delta\phi = \phi_{00} - \phi_{+-}$ , and  $\phi_\epsilon$  without and with the *CPT* assumption.

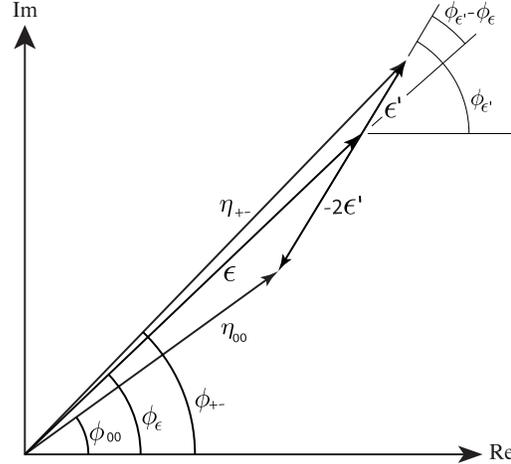

Quantity(units)	Fit w/o <i>CPT</i>	Fit w/ <i>CPT</i>
$\phi_{+-}(\circ)$	$43.4 \pm 0.5$ (S=1.2)	$43.51 \pm 0.05$ (S=1.2)
$\Delta m(10^{10}\hbar s^{-1})$	$0.5289 \pm 0.0010$	$0.5293 \pm 0.0009$ (S=1.3)
$\tau_S(10^{-10}s)$	$0.89564 \pm 0.00033$	$0.8954 \pm 0.0004$ (S=1.1)

$\chi^2$	16.4	20.0
# Deg. Free.	14	16

Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3 \operatorname{Im} \left( \frac{\epsilon'}{\epsilon} \right) \\ &\approx -3 \operatorname{Re} \left( \frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx 0.006^\circ \pm 0.008^\circ, \end{aligned} \quad (11)$$

so that  $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{SW}$ .

In the fit assuming *CPT*, we constrain  $\phi_\epsilon = \phi_{SW}$  using the linear expression in Eq. (10), and constrain  $\phi_{00} - \phi_{+-}$  using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 12. Some additional data for which the authors assumed *CPT* are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

**Figure 3:** Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, “Fit w/*CPT*,” and the correlation matrix is shown in Table 4. The  $\Delta m$  precision is improved by the *CPT* assumption.

**Table 3:** Correlation matrix for the results of the fit without the *CPT* assumption

**Fits for  $\epsilon'/\epsilon$ ,  $|\eta_{+-}|$ ,  $|\eta_{00}|$ , and  $B(K_L \rightarrow \pi\pi)$** 

We list measurements of  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\epsilon'/\epsilon$ . Independent information on  $|\eta_{+-}|$  and  $|\eta_{00}|$  can be obtained from measurements of the  $K_L^0$  and  $K_S^0$  lifetimes ( $\tau_L$ ,  $\tau_S$ ), and branching ratios (B) to  $\pi\pi$ , using the relations

$$|\eta_{+-}| = \left[ \frac{B(K_L^0 \rightarrow \pi^+\pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^+\pi^-)} \right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[ \frac{B(K_L^0 \rightarrow \pi^0\pi^0)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^0\pi^0)} \right]^{1/2}. \quad (12b)$$

For historical reasons, the branching ratio fits and the  $CP$ -violation fits are done separately, but we want to include the influence of  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\epsilon'/\epsilon$  measurements on  $B(K_L^0 \rightarrow \pi^+\pi^-)$  and  $B(K_L^0 \rightarrow \pi^0\pi^0)$  and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the  $K_L^0$  branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{+-}/\eta_{00}|$ , and  $\epsilon'/\epsilon$  measurements. The results from fit 1, along with the  $K_S^0$  values from this edition, are used to compute values of  $|\eta_{+-}|$  and  $|\eta_{00}|$ , which are included as measurements in the  $|\eta_{00}|$  and  $|\eta_{+-}|$  sections with a document ID of BRFIT 12. Thus, the fit values of  $|\eta_{+-}|$  and  $|\eta_{00}|$  given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct  $|\eta|$  measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 12 values) are used along with the  $K_L^0$  and  $K_S^0$  mean lives and the  $K_S^0 \rightarrow \pi\pi$  branching fractions to compute the  $K_L^0$  branching ratio  $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$ . This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 12. Thus, the  $K_L^0$  branching ratio fit values in this edition include the results of the direct measurement of  $|\eta_{00}/\eta_{+-}|$  and  $\epsilon'/\epsilon$ . Most individual measurements of  $|\eta_{+-}|$  and  $|\eta_{00}|$  enter our fits directly via the corresponding measurements of  $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(\text{total})$  and  $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(\text{total})$ , and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

 **$CP$ -VIOLATION PARAMETERS IN  $K_L^0$  DECAYS****CHARGE ASYMMETRY IN  $K_{S3}^0$  DECAYS**

Such asymmetry violates  $CP$ . It is related to  $Re(\epsilon)$ .

 **$A_L$  = weighted average of  $A_L(\mu)$  and  $A_L(e)$** 

In previous editions and in the literature the symbol used for this asymmetry was  $\delta_L$  or  $\delta$ . We use  $A_L$  for consistency with  $B^0$  asymmetry notation and with recent  $K_S^0$  notation.

$K_L^0$

## PARAMETERS FOR $K_L^0 \rightarrow 2\pi$ DECAY

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+\pi^-) / A(K_S^0 \rightarrow \pi^+\pi^-)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0\pi^0) / A(K_S^0 \rightarrow \pi^0\pi^0)$$

The fitted values of  $|\eta_{+-}|$  and  $|\eta_{00}|$  given below are the results of a fit to  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\text{Re}(e'/\epsilon)$ . Independent information on  $|\eta_{+-}|$  and  $|\eta_{00}|$  can be obtained from the fitted values of the  $K_L^0 \rightarrow \pi\pi$  and  $K_S^0 \rightarrow \pi\pi$  branching ratios and the  $K_L^0$  and  $K_S^0$  lifetimes. This information is included as data in the  $|\eta_{+-}|$  and  $|\eta_{00}|$  sections with a Document ID "BRFIT." See the note "CP violation in  $K_L$  decays" above for details.

$$|\eta_{00}| = |A(K_L^0 \rightarrow 2\pi^0) / A(K_S^0 \rightarrow 2\pi^0)|$$

<sup>1</sup> Value obtained from the NA48 measurements of  $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(K_L^0 \rightarrow \pi e \nu_e)$  and  $\tau_{K_S^0}$  and KLOE measurements of  $B(K_S^0 \rightarrow \pi^+\pi^-)$  and  $\tau_{K_L^0}$ .  $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$

is defined to include the inner bremsstrahlung component  $\Gamma(K_L^0 \rightarrow \pi^+\pi^-\gamma(\text{IB}))$  but exclude the direct emission component  $B(K_S^0 \rightarrow \pi^+\pi^-(\text{DE}))$ . Their  $|\eta_{+-}|$  value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

<sup>2</sup> AMBROSINO 06F uses KLOE branching ratios and  $\tau_L$  together with  $\tau_S$  from PDG 04. Their  $|\eta_{+-}|$  value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

<sup>3</sup> ALEXOPOULOS 04  $|\eta_{+-}|$  uses their  $K_L^0 \rightarrow \pi\pi$  branching fractions,  $\tau_S = (0.8963 \pm 0.0005) \times 10^{-10}$  s from the average of KTeV and NA48  $\tau_S$  measurements, and assumes that  $\Gamma(K_S^0 \rightarrow \pi e \nu_e) = \Gamma(K_L^0 \rightarrow \pi e \nu_e)$  giving  $B(K_S^0 \rightarrow \pi e \nu_e) = 0.118\%$ . Their  $|\eta_{+-}|$  is not directly used in our fit, but enters our fit via their branching ratio measurements.

<sup>4</sup> APOSTOLAKIS 99C report ( $2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934] \times 10^{-3}$ ). We evaluate for our 2006 best value  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.

<sup>5</sup> ADLER 95B report ( $2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926] \times 10^{-3}$ ). We evaluate for our 1996 best values  $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10} \text{hs}^{-1}$  and  $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}$  s. Superseded by APOSTOLAKIS 99C.

$$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$$

This expression is a very good approximation, good to about one part in  $10^{-4}$  because of the small measured value of  $\phi_{00} - \phi_{+-}$  and small theoretical ambiguities.

0.9899 ± 0.0020 ± 0.0025		1 BURKHARDT	88 NA31	

<sup>1</sup> This is the square root of the ratio  $R$  given by BURKHARDT 88 and BARR 93D.

<sup>2</sup> This is the combined results from BARR 93D and BURKHARDT 88, taking into account a common systematic uncertainty of 0.0014.

<sup>3</sup> We calculate  $|\eta_{00}/\eta_{+-}| = 1 - 3(\epsilon'/\epsilon)$  from WOODS 88 ( $\epsilon'/\epsilon$ ) value.

$$\text{Re}(\epsilon'/\epsilon) = (1 - |\eta_{00}/\eta_{+-}|)/3$$

We have neglected terms of order  $\omega \cdot \text{Re}(\epsilon'/\epsilon)$ , where  $\omega = \text{Re}(A_2)/\text{Re}(A_0) \approx 1/22$ . If included, this correction would lower  $\text{Re}(\epsilon'/\epsilon)$  by about  $0.04 \times 10^{-3}$ . See SOZZI 04.

<sup>1</sup> The two ABOUZAID 11 values use the same data. The fits are performed with and without CPT invariance requirement.

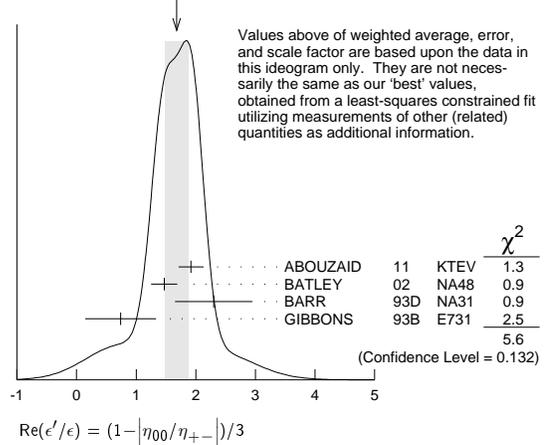

<sup>2</sup> These values are derived from  $|\eta_{00}/\eta_{+-}|$  measurements. They enter the average in this section but enter the fit via the  $|\eta_{00}/\eta_{+-}|$  only.

<sup>3</sup> This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

<sup>4</sup> We use ABOUZAID 11  $\text{Re}(\epsilon'/\epsilon)$  value with CPT assumption in our fits for  $|\eta_{+-}|$ ,  $|\eta_{00}|$ , and  $\text{Re}(\epsilon'/\epsilon)$ .

<sup>5</sup> These values are derived from  $|\eta_{00}/\eta_{+-}|$  measurements.

WEIGHTED AVERAGE  
1.68±0.20 (Error scaled by 1.4)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

## $\phi_{+-}$ , PHASE OF $\eta_{+-}$

The dependence of the phase on  $\Delta m$  and  $\tau_S$  is given for each experiment in the comments below, where  $\Delta m$  is the  $K_L^0 - K_S^0$  mass difference in units  $10^{10} \text{hs}^{-1}$  and  $\tau_S$  is the  $K_S$  mean life in units  $10^{-10}$  s. We also give the regeneration phase  $\phi_r$  in the comments below.

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings. Most experiments in this section are included in both the "Not Assuming CPT" and "Assuming CPT" fits. In the latter fit, they have little direct influence on  $\phi_{+-}$  because their errors are large compared to that assuming CPT, but they influence  $\Delta m$  and  $\tau_S$  through their dependencies on these parameters, which are given in the footnotes.

- <sup>1</sup> APOSTOLAKIS 99c measures  $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300 [\Delta m - 0.5301]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>2</sup> SCHWINGENHEUER 95 measures  $\phi_{+-} = (43.53 \pm 0.76) + 173 [\Delta m - 0.5282] - 275 [\tau_S - 0.8926]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>3</sup> These experiments measure  $\phi_{+-} - \phi_f$  and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of  $0.35^\circ [0.5^\circ]$  for uncertainties in their modeling of the regeneration amplitude.
- <sup>4</sup> GIBBONS 93 measures  $\phi_{+-} = (42.21 \pm 0.9) + 189 [\Delta m - 0.5257] - 460 [\tau_S - 0.8922]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports  $\phi_{+-} (42.2 \pm 1.4)^\circ$ . They measure  $\phi_{+-} - \phi_f$  and calculate the regeneration phase  $\phi_f$  from the power law momentum dependence of the regeneration amplitude using analyticity. An error of  $0.6^\circ$  is included for possible uncertainties in the regeneration phase.
- <sup>5</sup> CAROSI 90 measures  $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579 [\Delta m - 0.5351] + 303 [\tau_S - 0.8922]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>6</sup> GEWENIGER 74B measures  $\phi_{+-} = (49.4 \pm 1.0) + 565 [\Delta m - 0.540]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>7</sup> Not independent of other phase parameters reported in ABOUZAID 11.
- <sup>8</sup> ALAVI-HARATI 03  $\phi_{+-}$  is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  and  $\tau_{K_S}$  measurements in the  $K_L^0$  and  $K_S^0$  sections respectively. The correlation coefficients are  $\rho(\phi_{+-}, \Delta m) = +0.955$ ,  $\rho(\phi_{+-}, \tau_S) = -0.871$ , and  $\rho(\tau_S, \Delta m) = -0.840$ . *CPT* is not assumed. Uses scintillator Pb regenerator. Superseded by ABOUZAID 11.
- <sup>9</sup> ADLER 96c measures  $\phi_{+-} = (43.82 \pm 0.41) + 339 [\Delta m - 0.5307] - 252 [\tau_S - 0.8922]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>10</sup> ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).
- <sup>11</sup> ADLER 95B measures  $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316 [\Delta m - 0.5274] + 30 [\tau_S - 0.8926]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>12</sup> ADLER 92B quote separately two systematic errors:  $\pm 0.4$  from their experiment and  $\pm 1.0$  degrees due to the uncertainty in the value of  $\Delta m$ .
- <sup>13</sup> KARLSSON 90 systematic error does not include regeneration phase uncertainty.
- <sup>14</sup> CARITHERS 75 measures  $\phi_{+-} = (45.5 \pm 2.8) + 224 [\Delta m - 0.5348]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.  $\phi_f = -40.9 \pm 2.6^\circ$ .

 **$\phi_{00}$ , PHASE OF  $\eta_{00}$** 

See comment in  $\phi_{+-}$  header above for treatment of  $\Delta m$  and  $\tau_S$  dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings.

50.8 ± 7.1 ± 1.7	<sup>4</sup> ADLER 96B	CPLR	Sup. by ANGELOPOULOS 98
47.4 ± 1.4 ± 0.9	<sup>5</sup> KARLSSON 90	E731	

- <sup>1</sup> CAROSI 90 measures  $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579 [\Delta m - 0.5351] + 252 [\tau_S - 0.8922]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>2</sup> Not independent of other phase parameters reported in ABOUZAID 11.
- <sup>3</sup> ANGELOPOULOS 98 measures  $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240 [\Delta m - 0.5307]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values. The  $\tau_S$  dependence is negligible.
- <sup>4</sup> ADLER 96B identified initial neutral kaon individually as being a  $K^0$  or a  $\bar{K}^0$ . The systematic uncertainty is  $\pm 1.5^\circ$  combined in quadrature with  $\pm 0.8^\circ$  due to  $\Delta m$ .
- <sup>5</sup> KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$$

This expression is a very good approximation, good to about  $10^{-3}$  degrees because of the small measured values of  $\phi_{00} - \phi_{+-}$  and  $\text{Re } \epsilon'/\epsilon$ , and small theoretical ambiguities.

VALUE ( $^\circ$ )	DOCUMENT ID	TECN	COMMENT
<b>43.52 ± 0.05 OUR FIT</b>			Error includes scale factor of 1.2. Assuming <i>CPT</i>
<b>43.5 ± 0.5 OUR FIT</b>			Error includes scale factor of 1.3. Not assuming <i>CPT</i>
43.5164 ± 0.0002 ± 0.0518	<sup>1</sup> SUPERWEAK 12		Assuming <i>CPT</i>
43.86 ± 0.63	<sup>2</sup> ABOUZAID 11	KTEV	Not assuming <i>CPT</i>

- <sup>1</sup> SUPERWEAK 12 is a fake measurement used to impose the *CPT* or Superweak constraint  $\phi_{+-} = \phi_{SW} = \tan^{-1} [2 \frac{\Delta m}{\hbar} (\frac{\tau_S \tau_L}{\tau_L - \tau_S})]$ . This "measurement" is linearized using values near the RPP 2004 edition values of  $\Delta m$ ,  $\tau_S$  and  $\tau_L$ , and then adjusted to our current values as described in the following "measurement". SUPERWEAK 12 measures  $\phi_\epsilon = (43.50258 \pm 0.00021) + 54.1 [\Delta m - 0.5289] + 32.0 [\tau_S - 0.89564]^\circ$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ ,  $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.
- <sup>2</sup> ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. See  $\text{Im}(\epsilon'/\epsilon)$  section for correlation information.

$$\text{Im}(\epsilon'/\epsilon) = -(\phi_{00} - \phi_{+-})/3$$

For small  $|\epsilon'/\epsilon|$ ,  $\text{Im}(\epsilon'/\epsilon)$  is related to the phases of  $\eta_{00}$  and  $\eta_{+-}$  by the above expression.

VALUE ( $^\circ$ )	DOCUMENT ID	TECN	COMMENT
<b>-0.002 ± 0.005 OUR FIT</b>			Error includes scale factor of 1.7. Assuming <i>CPT</i>

0.012 ± 0.026			SCHMIDT	79 CNTR	Repl. by MORSE 80

<sup>1</sup> CLARK 77 value has additional  $\xi(0)$  dependence  $+0.21\text{Re}[\xi(0)]$ .

<sup>2</sup> SANDWEISS 73 value corrected from value quoted in their paper due to new value of  $\text{Re}(\xi)$ . See footnote 4 of SCHMIDT 79.

CPT-INVARIANCE TESTS IN  $K_L^0$  DECAYS

$$\text{PHASE DIFFERENCE } \phi_{00} - \phi_{+-}$$

Test of CPT.

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
<b>0.006 ± 0.014 OUR FIT</b>	Error includes scale factor of 1.7. Assuming CPT		
<b>0.34 ± 0.32 OUR FIT</b>	Not assuming CPT		
0.006 ± 0.008	<sup>1</sup> SUPERWEAK 12		Assuming CPT
-0.30 ± 0.88	<sup>2</sup> SCHWINGEN...95		Combined E731, E773
0.30 ± 0.35	<sup>3</sup> ABOUZAID 11	KTEV	Not assuming CPT
0.39 ± 0.22 ± 0.45	<sup>4</sup> ALAVI-HARATI 03	KTEV	
0.62 ± 0.71 ± 0.75	<sup>5</sup> SCHWINGEN...95	E773	
-1.6 ± 1.2	<sup>6</sup> GIBBONS 93	E731	
0.2 ± 2.6 ± 1.2	<sup>6</sup> CAROSI 90	NA31	
-0.3 ± 2.4 ± 1.2	KARLSSON 90	E731	

<sup>1</sup> SUPERWEAK 12 is a fake experiment to constrain  $\phi_{00} - \phi_{+-}$  to a small value as described in the note "CP violation in  $K_L$  decays."

<sup>2</sup> This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

<sup>3</sup> Not independent of other phase parameters reported in ABOUZAID 11.

<sup>4</sup> ALAVI-HARATI 03 fit  $\text{Re}(\epsilon'/\epsilon)$ ,  $\text{Im}(\epsilon'/\epsilon)$ ,  $\Delta m$ ,  $\tau_S$ , and  $\phi_{+-}$  simultaneously, not assuming CPT. Phase difference is obtained from  $\phi_{00} - \phi_{+-} \approx -3\text{Im}(\epsilon'/\epsilon)$  for small  $|\epsilon'/\epsilon|$ . Superseded by ABOUZAID 11.

<sup>5</sup> GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the  $K_S^0$  mean life) and mass difference (see the section on  $m_{K_L^0} - m_{K_S^0}$ ).

<sup>6</sup> CAROSI 90 is excluded from the fit because it is not independent of  $\phi_{+-}$  and  $\phi_{00}$  values.

PHASE DIFFERENCE  $\phi_{+-} - \phi_{SW}$ 

Test of CPT. The Superweak phase  $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$  where  $\Delta m = m_{K_L^0} -$

$$m_{K_S^0} \text{ and } \Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L\tau_S).$$

VALUE (°)	DOCUMENT ID	TECN
<b>0.61 ± 0.62 ± 1.01</b>	<sup>1</sup> ALAVI-HARATI 03	KTEV

<sup>1</sup> ALAVI-HARATI 03 fit is the same as their  $\phi_{+-}$ ,  $\tau_{K_S}$ ,  $\Delta m$  fit, except that the parameter  $\phi_{+-} - \phi_{SW}$  is used in place of  $\phi$ .

$$\text{Re}(\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}) - \frac{A_f}{2}$$

Test of CPT

VALUE (units $10^{-6}$ )	DOCUMENT ID	TECN	COMMENT
<b>-3 ± 35</b>	<sup>1</sup> ALAVI-HARATI 02	E799	Uses $A_L$ from $K_{e3}$ decays

<sup>1</sup> ALAVI-HARATI 02 uses PDG 00 values of  $\eta_{+-}$  and  $\eta_{00}$ .

 $\Delta S = \Delta Q$  IN  $K^0$  DECAYS

The relative amount of  $\Delta S \neq \Delta Q$  component present is measured by the parameter  $x$ , defined as

$$x = A(\bar{K}^0 \rightarrow \pi^- \ell^+ \nu)/A(K^0 \rightarrow \pi^- \ell^+ \nu).$$

We list  $\text{Re}\{x\}$  and  $\text{Im}\{x\}$  for  $K_{e3}$  and  $K_{\mu 3}$  combined.

$$x = A(\bar{K}^0 \rightarrow \pi^- \ell^+ \nu)/A(K^0 \rightarrow \pi^- \ell^+ \nu) = A(\Delta S = -\Delta Q)/A(\Delta S = \Delta Q)$$

$K_0^*(800)$ ,  $K^*(892)$

- 7 Not seen by KOPP 01 using 7070 events of  $D^0 \rightarrow K^- \pi^+ \pi^0$ . LINK 02E and LINK 05I show clear evidence for a constant non-resonant scalar amplitude rather than  $K_0^*(800)$  in their high statistics analysis of  $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$ .
- 8 AUBERT 07T does not find evidence for the charged  $K_0^*(800)$  using 11k events of  $D^0 \rightarrow K^- K^+ \pi^0$ .
- 9 S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.
- 10 T-matrix pole.
- 11 A Breit-Wigner mass and width.
- 12 S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the  $\kappa$  an s-dependent width with an Adler zero near threshold.
- 13 Breit-Wigner parameters. A significant S-wave can be also modeled as a non-resonant contribution.
- 14 Using ASTON 88.
- 15 T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.
- 16 T-matrix pole. Reanalysis of ASTON 88 data.
- 17 Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

- 18 The Breit-Wigner parameters from a fit with seven intermediate resonances. The S-matrix pole position is  $(764 \pm 63^{+71}_{-54}) - i(306 \pm 149^{+143}_{-85})$  MeV.
- 19 S-matrix pole.
- 20 From a fit including ten additional resonances and energy-independent Breit-Wigner width.
- 21 A fit in the  $K_0^*(800) + K^*(892) + K^*(1410)$  model with mass and width of the  $K_0^*(800)$  from ABLIKIM 06c well describes the left slope of the  $K_S^0 \pi^-$  invariant mass spectrum in  $\tau^- \rightarrow K_S^0 \pi^- \nu_\tau$  decay studied by EPIFANOV 07.
- 22 S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.
- 23 Not seen by KOPP 01 using 7070 events of  $D^0 \rightarrow K^- \pi^+ \pi^0$ . LINK 02E and LINK 05I show clear evidence for a constant non-resonant scalar amplitude rather than  $K_0^*(800)$  in their high statistics analysis of  $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$ .
- 24 AUBERT 07T does not find evidence for the charged  $K_0^*(800)$  using 11k events of  $D^0 \rightarrow K^- K^+ \pi^0$ .
- 25 S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.

- 26 T-matrix pole.
- 27 A Breit-Wigner mass and width.
- 28 S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the  $\kappa$  an s-dependent width with an Adler zero near threshold.
- 29 Statistical error only. A fit to the Dalitz plot including the  $K_0^*(800)^\pm$ ,  $K^*(892)^\pm$ , and  $\phi$  resonances modeled as Breit-Wigners. A significant S-wave can be also modeled as a non-resonant contribution.
- 30 Using ASTON 88.
- 31 T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.
- 32 T-matrix pole. Reanalysis of ASTON 88 data.
- 33 Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

WEIGHTED AVERAGE  
895.94 ± 0.22 (Error scaled by 1.4)

$K^*(892)^0$  mass (MeV)

- Inclusive reaction. Complicated background and phase-space effects.
- Mass errors enlarged by us to  $\Gamma/\sqrt{N}$ . See note.
- Number of events in peak reevaluated by us.
- K-matrix pole.
- From a partial wave amplitude analysis.
- From a fit in the  $K_S^0(800) + K^*(892) + K^*(1410)$  model.
- From the pole position of the  $K\pi$  vector form factor using EPIFANOV 07 and constraints from  $K_J$  decays in ANTONELLI 10.
- Systematic uncertainties not estimated.
- From the pole position of the  $K\pi$  vector form factor in the complex  $s$ -plane and using EPIFANOV 07 data.
- Reanalysis of EPIFANOV 07 using resonance chiral theory.
- Calculated by us from the shift by  $4.7 \pm 0.9$  MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.
- With mass and width of the  $K^*(1410)$  fixed at 1412 MeV and 227 MeV, respectively.
- From the isobar model with a complex pole for the  $\kappa$ .
- Fit to  $K\pi$  mass spectrum includes a non-resonant scalar component.
- From pole extrapolation.
- This value comes from a fit with  $\chi^2$  of 178/117.

 $K^*(892)$  MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple “realistic” tests for the minimum errors on the determination of a mass and width from a sample of  $N$  events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4 \frac{\Gamma}{\sqrt{N}}. \quad (1)$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

## CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 7.8$  for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$x_5 \begin{array}{|c|} \Gamma & \begin{array}{cc} -100 & \\ 19 & -19 \end{array} \\ \hline & x_2 \quad x_5 \end{array}$$

Mode	Rate (MeV)
$\Gamma_2$ $(K\pi)^\pm$	50.7 ± 0.9
$\Gamma_5$ $K^\pm \gamma$	0.050 ± 0.005

## CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 21 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 51.2$  for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$x_4 \begin{array}{|c|} \Gamma & \begin{array}{cc} -100 & \\ 18 & -18 \end{array} \\ \hline & x_3 \quad x_4 \end{array}$$

- S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.
- From the isobar model with a complex pole for the  $\kappa$ .
- From a non-parametric analysis.
- A Breit-Wigner mass and width.
- S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the  $\kappa$  with an s-dependent width and an Adler zero near threshold.
- S-matrix pole. Using ASTON 88 and assuming  $K_0^*(800)$ ,  $K_0^*(1950)$ .
- Using ASTON 88 and assuming  $K_0^*(800)$ .
- T-matrix pole. Reanalysis of ASTON 88 data.
- Breit-Wigner fit. Using ASTON 88.
- Assuming a low-mass scalar  $K\pi$  resonance,  $\kappa(800)$ .
- T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.
- $J^P$  not determined, could be  $K_2^*(1430)$ .
- T-matrix pole.
- Uses a model for the background, without this background they get a mass 1340 MeV, where the phase shift passes  $90^\circ$ .
- Mass defined by pole position.
- From elastic  $K\pi$  partial-wave analysis.

- S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.
- From the isobar model with a complex pole for the  $\kappa$ .
- From a non-parametric analysis.
- A Breit-Wigner mass and width.
- S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the  $\kappa$  with an s-dependent width and an Adler zero near threshold.
- S-matrix pole. Using ASTON 88 and assuming  $K_0^*(800)$ ,  $K_0^*(1950)$ .
- Using ASTON 88 and assuming  $K_0^*(800)$ .
- T-matrix pole. Reanalysis of ASTON 88 data.
- Breit-Wigner fit. Using ASTON 88.
- Assuming a low-mass scalar  $K\pi$  resonance,  $\kappa(800)$ .
- T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.
- $J^P$  not determined, could be  $K_2^*(1430)$ .
- T-matrix pole.
- From elastic  $K\pi$  partial-wave analysis.

## CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 20.2$  for 24 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

## CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 2.9$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	-36	
$x_3$	-39	-72
	$x_1$	$x_2$

- <sup>1</sup> From energy-independent partial-wave analysis.
- <sup>2</sup> From a fit to  $Y_6^2$  moment.  $J^P = 3^-$  found.
- <sup>3</sup> Confirmed by phase shift analysis of ESTABROOKS 78, yields  $J^P = 3^-$ .
- <sup>4</sup> From a partial wave amplitude analysis.
- <sup>5</sup> From a fit to the  $Y_6^0$  moment.

$\Gamma_5$ $K_2^*(1430)\pi$	< 16 %	95%

### CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.0$  for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	85		
$x_3$	18	21	
$x_4$	-98	-94	-27
	$x_1$	$x_2$	$x_3$

## Meson Particle Listings

## K(3100)

**K(3100)**

$$J^{PC} = ?^{?}(???)$$

OMITTED FROM SUMMARY TABLE

Narrow peak observed in several ( $\Lambda\bar{p}$  + pions) and ( $\bar{\Lambda}p$  + pions) states in  $\Sigma^-$  Be reactions by BOURQUIN 86 and in  $np$  and  $nA$  reactions by ALEEV 93. Not seen by BOEHNLEIN 91. If due to strong decays, this state has exotic quantum numbers ( $B=0, Q=+1, S=-1$  for  $\Lambda\bar{p}\pi^+\pi^+$  and  $I \geq 3/2$  for  $\Lambda\bar{p}\pi^-$ ). Needs confirmation.

<sup>2</sup>BARLAG 90c estimates the systematic error to be negligible.

### $D^+$ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Inclusive modes</b>		
$\Gamma_1$ $D^+ \rightarrow e^+$ semileptonic	(16.07 ± 0.30) %	
$\Gamma_2$ $D^+ \rightarrow \mu^+$ anything	(17.6 ± 3.2) %	
$\Gamma_3$ $D^+ \rightarrow K^-$ anything	(25.7 ± 1.4) %	
$\Gamma_4$ $D^+ \rightarrow \bar{K}^0$ anything + $K^0$ anything	(61 ± 5) %	
$\Gamma_5$ $D^+ \rightarrow K^+$ anything	(5.9 ± 0.8) %	
$\Gamma_6$ $D^+ \rightarrow K^*(892)^-$ anything	(6 ± 5) %	
$\Gamma_7$ $D^+ \rightarrow \bar{K}^*(892)^0$ anything	(23 ± 5) %	
$\Gamma_8$ $D^+ \rightarrow K^*(892)^0$ anything	< 6.6 %	CL=90%
$\Gamma_9$ $D^+ \rightarrow \eta$ anything	(6.3 ± 0.7) %	
$\Gamma_{10}$ $D^+ \rightarrow \eta'$ anything	(1.04 ± 0.18) %	
$\Gamma_{11}$ $D^+ \rightarrow \phi$ anything	(1.03 ± 0.12) %

$\Gamma_{135}$	Unaccounted decay modes	$(51.2 \pm 1.0) \%$			
[a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.					
[b] These subfractions of the $K^- 2\pi^+$ mode are uncertain: see the Particle Listings.					
[c] Submodes of the $D^+ \rightarrow K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+ \pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters <b>B667</b> 1 (2008), for those results.					
[d] The unseen decay modes of the resonances are included.					
[e] This is <i>not</i> a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.					
[f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.					

## Meson Particle Listings

## DALITZ PLOT ANALYSIS FORMALISM

Revised March 2012 by D. Asner (Pacific Northwest National Laboratory) and C. Hanhart (Forschungszentrum Jülich).

**Introduction:** Weak nonleptonic decays of  $D$  and  $B$  mesons are expected to proceed dominantly through resonant two-body decays [1]; see Ref. 2 for a review of resonance phenomenology. The amplitudes are typically calculated with the Dalitz-plot analysis technique [3], which uses the minimum number of independent observable quantities. For three-body decays of a spin-0 particle to all pseudo-scalar final states, such as  $D$  or  $B \rightarrow abc$ , the decay rate [4] is

$$\Gamma = \frac{1}{(2\pi)^3 32\sqrt{s^3}} |\mathcal{M}|^2 dm_{ab}^2 dm_{bc}^2, \quad (1)$$

where  $m_{ij}$  is the invariant mass of particles  $i$  and  $j$ . Here the prefactor contains all kinematic factors, while  $|\mathcal{M}|^2$  contains the dynamics. The scatter plot in  $m_{ab}^2$  versus  $m_{bc}^2$  is the Dalitz plot. If  $|\mathcal{M}|^2$  is constant, the kinematically allowed region of the plot will be populated uniformly with events. Any variation in the population over the Dalitz plot is due to dynamic rather than kinematic effects. It is straightforward to extend the formalism beyond three-body final states.

**Formalism:** The amplitude for the process  $R \rightarrow rc, r \rightarrow ab$  where  $R$  is a  $D$  or  $B$  meson,  $r$  is an intermediate resonance, and  $a, b, c$  are pseudo-scalars, is given by

$$\begin{aligned} \mathcal{M}_r(J, L, l, m_{ab}, m_{bc}) &= \sum_{\lambda} \langle ab|r_{\lambda} \rangle T_r(m_{ab}) \langle cr_{\lambda}|R_J \rangle \quad (2) \\ &= Z(J, L, l, \vec{p}, \vec{q}) B_L^R(|\vec{p}|) B_L^r(|\vec{q}|) T_r(m_{ab}). \end{aligned}$$

The sum is over the helicity states  $\lambda$  of  $r$ ;  $J$  is the total angular momentum of  $R$  (for  $D$  and  $B$  decays,  $J = 0$ );  $L$  is the orbital angular momentum between  $r$  and  $c$ ;  $l$  is the orbital angular momentum between  $a$  and  $b$ ; (the spin of  $r$ );  $\vec{p}$  and  $\vec{q}$  are the momenta of  $c$  and of  $a$  in the  $r$  rest frame;  $Z$  describes the angular distribution of the final-state particles;  $B_L^R$  and  $B_L^r$  are

# Meson Particle Listings

$D^\pm$

the barrier factors for the production of  $rc$  and of  $ab$ ; and  $T_r$  is the dynamical function describing the resonance  $r$ .  $T_r$  is a phenomenological object, with the resonances modeled often by a Breit-Wigner form, although some more recent analyses use a  $K$ -matrix formalism [5–7] with the  $P$ -vector approximation [8] to describe the  $\pi\pi$  S-wave.

The nonresonant (NR) contribution to  $D \rightarrow abc$  is parametrized as constant (S-wave), with no variation in magnitude or phase across the Dalitz plot. The available phase space is much greater for  $B$  decays than for  $D$  decays, and the nonresonant contribution to  $B \rightarrow abc$  requires a more sophisticated parametrization. Experimentally, several parametrizations have been used [9,10]. Differences in the parametrizations of the NR contributions, and in  $Z$ ,  $B_L$ , and  $T_r$ , as well as in the set of resonances  $r$ , complicate the comparison of results from different experiments.

**Angular distribution  $Z$ :** The tensor or Zemach formalism [11,12] and the helicity formalism [13,12] yield identical descriptions of the angular distributions for the decay process  $R \rightarrow rc, r \rightarrow ab$  when  $a$ ,  $b$  and  $c$  all have spin 0. The angular distributions for  $L = 0, 1$ , and  $2$  are given in Table 1. For a derivation of the expressions, see, *e.g.*, Ref. 12. For final-state particles with non-zero spin (*e.g.*, radiative decays), the helicity formalism is required.

**Table 1:** Angular distributions for  $L = 0, 1, 2$  for the decay process  $R \rightarrow rc, r \rightarrow ab$  when  $a$ ,  $b$  and  $c$  all have spin 0. Here  $\theta$  is the angle between particles  $a$  and  $c$  in the rest frame of resonance  $r$ ,  $\sqrt{1+\zeta^2} = E_r/m_{ab}$  is a relativistic correction, where  $E_r = (m_R^2 + m_{ab}^2 - m_c^2)/2m_R$  is the energy of resonance  $r$  in the rest frame of  $R$ .

$J \rightarrow L+l$	Angular distribution
$0 \rightarrow 0+0$	uniform
$0 \rightarrow 1+1$	$(1+\zeta^2) \cos^2 \theta$
$0 \rightarrow 2+2$	$\left(\zeta^2 + \frac{3}{2}\right)^2 (\cos^2 \theta - 1/3)^2$

**Barrier Factor  $B_L$ :** The maximum angular momentum  $L$  in a strong decay is limited by the linear momentum  $q$ —the relative momentum of the decay particles in the center of mass frame of the decaying resonance. Decay particles moving slowly with an impact parameter (meson radius)  $d$  of order 1 fm have difficulty generating sufficient angular momentum to conserve the spin of the resonance. The Blatt-Weisskopf [14,15] functions  $B_L$ , given in Table 2, weight the reaction amplitudes to account for this spin-dependent effect. These functions are normalized to give  $B_L = 1$  for  $z = (|q|d)^2 = 1$ . Another common formulation,  $B'_L$ , also in Table 2, is normalized to give  $B'_L = 1$  for  $z = z_0 = (|q_0|d)^2$  where  $q_0$  is the value of  $q$  when  $m_{ab} = m_r$ . An important difference between the  $B_L$  and the  $B'_L$  is that the former include explicitly the centrifugal barrier,

while it is to be moved to the dynamical functions in the case of  $B'_L$ .

**Table 2:** Blatt-Weisskopf barrier factors weight the reaction amplitudes to account for spin-dependent effects (c.f. Sec. VIII.5 of Ref. 14). Two formulations with different normalization conditions (described in text) are shown.  $B_L$  is commonly used in Dalitz plot analyses;  $B'_L$  is commonly used with the helicity formalism.

$L$	$B_L(q)$	$B'_L(q, q_0)$
0	1	1
1	$\sqrt{\frac{2z}{1+z}}$	$\sqrt{\frac{1+z_0}{1+z}}$
2	$\sqrt{\frac{13z^2}{(z-3)^2+9z}}$	$\sqrt{\frac{(z_0-3)^2+9z_0}{(z-3)^2+9z}}$

where  $z = (|q|d)^2$  and  $z_0 = (|q_0|d)^2$

**Dynamical Function  $T_r$ :** The dynamical function  $T_r$  is derived from the  $S$ -matrix formalism [5]. In general, the amplitude that a final state  $f$  couples to an initial state  $i$  is  $S_{fi} = \langle f|S|i\rangle$ , where the scattering operator  $S$  is unitary:  $SS^\dagger = S^\dagger S = I$ . The Lorentz-invariant transition operator  $\hat{T}$  is defined by separating the probability that  $f = i$ , yielding

$$S = I + 2iT = I + 2i\{\rho\}^{1/2} \hat{T} \{\rho\}^{1/2}, \quad (3)$$

where  $I$  is the identity operator and  $\rho$  is the diagonal phase-space matrix. If channel  $i$  denotes the two-body state  $ab$ , then

$$\rho_{ii} = \rho_i = \frac{2q_i}{m_{ab}} \theta [m_{ab} - (m_a + m_b)], \quad (4)$$

where  $m_{ab}$  is the invariant mass of the system;

$$q_i = \frac{1}{2m_{ab}} \sqrt{(m_{ab}^2 - (m_a + m_b)^2)(m_{ab}^2 - (m_a - m_b)^2)} \quad (5)$$

is the momentum of  $a$  in the  $r$  rest frame, and  $\theta[\dots]$  is the step function. In the single-channel case, unitarity allows one to express  $S$  through a single parameter,  $S = e^{2i\delta}$ , and

$$\hat{T} = \frac{1}{\rho} e^{i\delta} \sin \delta. \quad (6)$$

There are three common formulations of the dynamical function. The Breit-Wigner form—the first term in a Taylor expansion about a  $T$ -matrix pole—is the simplest. The  $K$ -matrix formalism [5] is more general (allowing more than one  $T$ -matrix pole and coupled channels while preserving unitarity). The Flatté distribution [16] is used to parametrize resonances near threshold, located at  $s = (m_a + m_b)^2$ , and is equivalent to a one-pole, two-channel  $K$ -matrix.

**Breit-Wigner Formulation:**

The common formulation of a Breit-Wigner resonance decaying to spin-0 particles  $a$  and  $b$  is

$$T_r(m_{ab}) \propto \frac{1}{m_r^2 - m_{ab}^2 - im_r \Gamma_{ab}(m_{ab})}. \quad (7)$$

A standard formulation for the “mass-dependent” width  $\Gamma_{ab}$  reads

$$\Gamma_{ab}(m_{ab}) = \sum_i \Gamma_i^r \left( \frac{q_i}{q_r} \right)^{2L_i+1} \left( \frac{m_r}{m_{ab}} \right) B_{L_i}'(q_i, q_0)^2, \quad (8)$$

where  $q_i$ ,  $L_i$ ,  $\Gamma_i^r$  and  $B_{L_i}'(q_i, q_0)$  are the momentum and angular momentum of the decay products, the partial width and Blatt-Weisskopf barrier factor (see Table 2) for the decay of resonance  $r$  into channel  $i$ , respectively. A Breit-Wigner parametrization best describes isolated, non-overlapping resonances far from the threshold of additional decay channels. For the  $\rho(770)$  and  $\rho(1450)$  a more complex parametrization suggested by Gounaris-Sakurai [17] is often used [18-22]. Unitarity is violated when the dynamical function is parametrized as the sum of two or more overlapping Breit-Wigners — see the discussion below Eq. (13). The proximity of a threshold to a resonance distorts the line shape from a simple Breit-Wigner. Here the Flatté formula provides a better description and is discussed below.

***K*-matrix Formulation**

The  $T$  matrix can be written as

$$\hat{T} = (I - i\hat{K}\rho)^{-1}\hat{K}, \quad (9)$$

where  $\hat{K}$  is the Lorentz-invariant  $K$ -matrix describing the scattering process and  $\rho$  is the phase-space factor defined below Eq. (3). Resonances appear as poles in the  $K$ -matrix:

$$\hat{K}_{ij} = \sum_\alpha \frac{\sqrt{m_\alpha \Gamma_{\alpha i}(m) m_\alpha \Gamma_{\alpha j}(m)}}{(m_\alpha^2 - m^2) \sqrt{\rho_i \rho_j}}. \quad (10)$$

The  $K$ -matrix is real by construction, and so the associated  $T$ -matrix respects unitarity. However, in the given form it has the wrong analytic structure. To improve it, some authors use the analytic continuation for the momentum  $q_i$ , defined in Eq. (5), to below-threshold values, where for  $m_a \neq m_b$  the phase space factor needs to be modified to avoid false singularities (see, *e.g.*, Ref. 7, Sec. 2.1). For further improvements see below.

For a single pole in a single channel,  $K = \rho\hat{K}$  is

$$K = \frac{m_0 \Gamma(m)}{m_0^2 - m^2} \quad (11)$$

and

$$T = K(1 - iK)^{-1} = \frac{m_0 \Gamma(m)}{m_0^2 - m^2 - im_0 \Gamma(m)}, \quad (12)$$

which is the relativistic Breit-Wigner formula. For two poles in a single channel,  $K$  is

$$K = \frac{m_\alpha \Gamma_\alpha(m)}{m_\alpha^2 - m^2} + \frac{m_\beta \Gamma_\beta(m)}{m_\beta^2 - m^2}. \quad (13)$$

If  $m_\alpha$  and  $m_\beta$  are far apart relative to the widths, the  $T$  matrix is approximately the sum of two Breit-Wigners,  $T(K_\alpha + K_\beta) \approx T(K_\alpha) + T(K_\beta)$ , each of the form of Eq. (12). This approximation is not valid for two nearby resonances, for it violates unitarity. For example, for  $m = m_\alpha$  the full, unitary  $K$ -matrix expression gives  $\text{Im}(T)=1$ , while the imaginary part of  $T(K_\alpha) + T(K_\beta)$  is  $1 + (m_\beta \Gamma_\beta)^2 / [(m_\beta^2 - m_\alpha^2)^2 + (m_\beta \Gamma_\beta)^2]$ .

This formulation, which applies to  $S$ -channel production in two-body scattering,  $ab \rightarrow cd$ , can be generalized to describe the production of resonances in processes such as the decay of charm mesons. The key assumption here is that the two-body system described by the  $K$ -matrix does *not* interact with the rest of the final state [8]. The validity of this assumption varies with the production process and is appropriate for reactions such as  $\pi^- p \rightarrow \pi^0 \pi^0 n$  in the several-GeV regime, and for semileptonic decays such as  $D \rightarrow K\pi\ell\nu$ . The assumption may be of limited validity for production processes such as  $p\bar{p} \rightarrow \pi\pi\pi$ ,  $D \rightarrow \pi\pi\pi$ ,  $D \rightarrow K\pi\pi$  and  $J/\psi \rightarrow \omega\pi\pi$ . In the last two cases, additional three-body rescatterings were found to be relevant. In the  $J/\psi$  decays, they appeared where the two-body amplitudes were very small [23]; in the  $D$  decays, they were shown to lead to a significant difference between the  $K\pi$  scattering phase and the phase extracted from the production process [24]. If three-body interactions are neglected, the two-body Lorentz-invariant amplitude,  $\hat{F}$ , is given by

$$\hat{F}_i = (I - i\hat{K}\rho)_{ij}^{-1} \hat{P}_j = (\hat{T}\hat{K}^{-1})_{ij} \hat{P}_j, \quad (14)$$

where  $P$  is the production vector that parametrizes the resonance production in the open channels.

For the  $\pi\pi$  S-wave, a common formulation of the  $K$ -matrix [7,20,21,25] is

$$K_{ij}(s) = \left[ \sum_\alpha \left( \frac{g_i^{(\alpha)} g_j^{(\alpha)}}{m_\alpha^2 - s} \right) + f_{ij}^{sc} \frac{1 + s_0^{sc}}{s + s_0^{sc}} \right] \left[ \frac{(s - s_A)}{(s + s_{A0})} \right]. \quad (15)$$

The factor  $g_i^{(\alpha)}$  is the real coupling constant of the  $K$ -matrix pole  $m_\alpha$  to meson channel  $i$ ; the parameters  $f_{ij}^{sc}$  and  $s_0^{sc}$  describe a smooth part of the  $K$ -matrix elements; the second factor in square brackets, with  $s_A \sim (0.1-0.5)m_\pi^2$  contains the Adler zero and at the same time suppresses a false kinematical singularity; *e.g.*, in Ref. 25,  $s_{A0} = 0.15 \text{ GeV}^2$  and  $s_A = 0.5m_\pi^2$  were used. The number 1 has units  $\text{GeV}^2$ .

The production vector, with  $i = 1$  denoting  $\pi\pi$ , is

$$P_j(s) = \left[ \sum_\alpha \left( \frac{\beta_\alpha g_j^{(\alpha)}}{m_\alpha^2 - s} \right) + f_{1j}^{pr} \frac{1 + s_0^{pr}}{s + s_0^{pr}} \right], \quad (16)$$

where the free parameters of the Dalitz-plot fit are the complex production couplings  $\beta_\alpha$  and the production-vector background parameters  $f_{1j}^{pr}$  and  $s_0^{pr}$ . All other parameters are fixed by scattering experiments. Ref. 6 describes the  $\pi\pi$  scattering data with a 4-pole, 2-channel ( $\pi\pi$ ,  $K\bar{K}$ ) model, while Ref. 7 describes the scattering data with a 5-pole, 5-channel ( $\pi\pi$ ,  $K\bar{K}$ ,  $\eta\eta$ ,  $\eta'\eta'$  and  $4\pi$ ) model. The former has been implemented by

# Meson Particle Listings

## $D^\pm$

CLEO [26] and the latter by FOCUS [21] and BABAR [20]. In both cases, only the  $\pi\pi$  channel was analyzed. A more complete coupled-channel analysis would simultaneously fit all final states accessible by rescattering.

### Flatté Formalism

The Flatté formulation is used when a second channel opens close to a resonance. This situation occurs in the  $\pi\pi$  S-wave where the  $f_0(980)$  is near the  $K\bar{K}$  threshold, and in the  $\pi\eta$  channel where the  $a_0(980)$  also lies near the  $K\bar{K}$  threshold. The  $T$ -matrix is parameterized as

$$\hat{T}(m_{ab})_{ij} = \frac{g_i g_j}{m_i^2 - m_{ab}^2 - i(\rho_1 g_1^2 + \rho_2 g_2^2)}, \quad (17)$$

where  $\rho_1 g_1^2 + \rho_2 g_2^2 = m_0 \Gamma_r$ , when the phase spaces are evaluated at the resonance mass. For the  $a_0(980)$  resonance, the relevant coupling constants are  $g_1 = g_{\pi\eta}$  and  $g_2 = g_{KK}$ , and the phase space terms are  $\rho_1 = \rho_{\pi\eta}$  and  $\rho_2 = \rho_{KK}$ , with  $\rho_i$  defined in Eq. (4). For the  $f_0(980)$  the relevant coupling constants are  $g_1 = g_{\pi\pi}$  and  $g_2 = g_{KK}$ , and the phase space terms are  $\rho_1 = \rho_{\pi\pi}$  and  $\rho_2 = \rho_{KK}$ . The charged and neutral  $K$  channels are usually assumed to have the same coupling constant but different phase space factors, due to  $m_{K^+} \neq m_{K^0}$ ; the result is

$$\rho_{KK} = \frac{1}{2} \left( \sqrt{1 - \left( \frac{2m_{K^\pm}}{m_{KK}} \right)^2} + \sqrt{1 - \left( \frac{2m_{K^0}}{m_{KK}} \right)^2} \right). \quad (18)$$

The effect of using this expression compared to using the averaged kaon masses is confined in the region very near threshold and is significant only in between the two kaon thresholds. If the coupling of a resonance to the channel opening nearby is strong, the Flatté parametrization shows a scaling invariance and does not allow for an extraction of the parameters individually, but only of ratios [27].

### Further improvements:

The  $K$ -matrix described above usually allows one to get a proper fit of physical amplitudes and it is easy to deal with. However, it also has an important deficit: it violates constraints from analyticity — *e.g.*,  $\rho_{ii}$  has a pole at  $s = 0$ , and for unequal masses develops an unphysical cut. An analytic continuation of the amplitudes into the complex plane is not controlled, and typically the parameters of broad resonances come out wrong (see, *e.g.*, the minireview on scalar mesons). A method to improve the analytic properties was suggested in Refs. [25,28–30]. It basically amounts to replacing the phase-space factor  $i\rho_i$  in Eqs. 9 and 14 with an analytic function that produces the identical imaginary part. In the simplest case of a channel with equal masses the expressions are

$$-\frac{\rho_i}{\pi} \log \left| \frac{1 + \rho_i}{1 - \rho_i} \right|, \quad -\frac{2\rho_i}{\pi} \arctan \left( \frac{1}{\rho_i} \right), \quad -\frac{\rho_i}{\pi} \log \left| \frac{1 + \rho_i}{1 - \rho_i} \right| + i\rho_i$$

for  $m^2 < 0$ ,  $0 < m^2 < (m_a + m_b)^2$ , and  $(m_a + m_b)^2 < m^2$ , respectively. Here  $\rho_i = \sqrt{|1 - (m_a + m_b)^2/m^2|}$  for all values of  $m^2$ , extending the expression of Eq. (4) into the regime

below threshold. The more complicated expression for the case of different masses can be found, *e.g.*, in Ref. 29.

**Branching Ratios from Dalitz Plot Fits:** A fit to the Dalitz plot distribution using either a Breit-Wigner or a  $K$ -matrix formalism factorizes into a resonant contribution to the amplitude  $\mathcal{M}_j$  and a complex coefficient,  $a_j e^{i\delta_j}$ , where  $a_j$  and  $\delta_j$  are real. The definition of a rate of a single process, given a set of amplitudes  $a_j$  and phases  $\delta_j$ , is the square of the relevant matrix element (see Eq. (1)). The “fit fraction” is usually defined as the integral over the Dalitz plot ( $m_{ab}$  vs.  $m_{bc}$ ) of a single amplitude squared divided by the integral over the Dalitz plot of the square of the coherent sum of all amplitudes, or

$$\text{fit fraction}_j = \frac{\int |a_j e^{i\delta_j} \mathcal{M}_j|^2 dm_{ab}^2 dm_{bc}^2}{\int |\sum_k a_k e^{i\delta_k} \mathcal{M}_k|^2 dm_{ab}^2 dm_{bc}^2}, \quad (19)$$

where  $\mathcal{M}_j$  is defined in Eq. (2) and described in Ref. 31. In general, the sum of the fit fractions for all components will not be unity due to interference.

When the  $K$ -matrix of Eq. (9) is used to describe a wave (*e.g.*, the  $\pi\pi$  S-wave), then  $\mathcal{M}_j$  refers to the entire wave. In this case, it may not be straightforward to separate  $\mathcal{M}_j$  into a sum of individual resonances unless these are narrow and well separated.

**Reconstruction Efficiency and Resolution:** The efficiency for reconstructing an event as a function of position on the Dalitz plot is in general non-uniform. Typically, a Monte Carlo sample generated with a uniform distribution in phase space is used to determine the efficiency. The variation in efficiency across the Dalitz plot varies with experiment and decay mode. Most recent analyses utilize a full GEANT [32] detector simulation.

Finite detector resolution can usually be safely neglected, as most resonances are comparatively broad. Notable exceptions where detector resolution effects must be modeled are  $\phi \rightarrow K^+ K^-$ ,  $\omega \rightarrow \pi^+ \pi^-$ , and  $a_0 \rightarrow \eta \pi^0$ . One approach is to convolve the resolution function in the Dalitz-plot variables  $m_{ab}^2$  and  $m_{bc}^2$  with the function that parametrizes the resonant amplitudes. In high-statistics data samples, resolution effects near the phase-space boundary typically contribute to a poor goodness of fit. The momenta of the final-state particles can be recalculated with a  $D$  or  $B$  mass constraint, which forces the kinematic boundaries of the Dalitz plot to be strictly respected. If the three-body mass is not constrained, then the efficiency (and the parametrization of background) may also depend on the reconstructed mass.

**Backgrounds:** The contribution of background to  $D$  and  $B$  samples varies by experiment and final state. The background naturally falls into six categories: (1) Purely combinatoric background containing no resonances. (2) Combinatoric background containing intermediate resonances, such as a real  $K^*$  or  $\rho$ , plus additional random particles. (3) Final states containing identical particles as in  $D^0 \rightarrow K_S^0 \pi^0$  background to  $D^0 \rightarrow \pi^+ \pi^- \pi^0$

and  $B \rightarrow D\pi$  background to  $B \rightarrow K\pi\pi$ . (4) Mistagged decays such as a real  $\overline{D}^0$  or  $\overline{B}^0$  incorrectly identified as a  $D^0$  or  $B^0$ . (5) Particle misidentification of the decay products, such as  $D^+ \rightarrow \pi^-\pi^+\pi^+$  or  $D_s^+ \rightarrow K^-K^+\pi^+$  reconstructed as  $D^+ \rightarrow K^-\pi^+\pi^+$ . (6) Background from decays of charged pions or kaons in flight.

The contribution from combinatoric background with intermediate resonances is distinct from the resonances in the signal because the former do *not* interfere with the latter since they are not from true resonances. The usual identification tag of the initial particle as a  $D^0$  or a  $\overline{D}^0$  is the charge of the distinctive slow pion in the decay sequence  $D^{*+} \rightarrow D^0\pi_s^+$  or  $D^{*-} \rightarrow \overline{D}^0\pi_s^-$ . Another possibility is the identification or “tagging” of one of the  $D$  mesons from  $\psi(3770) \rightarrow D^0\overline{D}^0$ , as is done for  $B$  mesons from  $\Upsilon(4S)$ . The mistagged background is subtle and may be mistakenly enumerated in the *signal* fraction determined by a  $D^0$  mass fit. Mistagged decays contain true  $\overline{D}^0$ 's or  $\overline{B}^0$ 's and so the resonances in the mistagged sample exhibit interference on the Dalitz plot.

## REVIEW OF D-MESON DALITZ PLOT ANALYSES

Revised April 2010 by D. Asner (Pacific Northwest National Laboratory)

The formalism of Dalitz-plot analysis is reviewed in the preceding note. Recent studies of multi-body decays of charm mesons probe a variety of physics, including  $\gamma/\phi_3$ ,  $D^0$ - $\overline{D}^0$  mixing, searches for  $CP$  violation, doubly Cabibbo-suppressed decays, and properties of S-wave  $\pi\pi$ ,  $K\pi$ , and  $K\overline{K}$  resonances. In the following, we discuss: (1)  $D^0 \rightarrow K_S^0\pi^+\pi^-$ ; (2) doubly Cabibbo-suppressed decays; and (3)  $CP$  violation. The properties of the light meson resonances determined in D-meson Dalitz-plot analyses are reported in the light unflavored meson section of this *Review*.

$D^0 \rightarrow K_S^0\pi^+\pi^-$ : Several experiments have analyzed  $D^0 \rightarrow K_S^0\pi^+\pi^-$  decay. A CLEO analysis [1] included ten resonances:  $K_S^0\rho^0$ ,  $K_S^0\omega$ ,  $K_S^0f_0(980)$ ,  $K_S^0f_2(1270)$ ,  $K_S^0f_0(1370)$ ,  $K^*(892)^-\pi^+$ ,  $K_0^*(1430)^-\pi^+$ ,  $K_2^*(1430)^-\pi^+$ ,  $K^*(1680)^-\pi^+$ , and the doubly Cabibbo-suppressed (DCS) mode  $K^*(892)^+\pi^-$ . The CLEO model does not provide a good description of higher-statistics BABAR and Belle data samples. An improved description is obtained in three ways: First, by adding more Breit-Wigner resonances. Second, following the methodology of FOCUS [2], by applying a  $K$ -matrix model [3–5] to the  $\pi\pi$  S-wave [6,7]. Third, by adding a parameterization to the  $K\pi$  S-wave motivated by the LASS experiment [8].

A BABAR analysis [7,9,10] added to the CLEO model the  $K^*(1410)^-\pi^+$ ,  $K_S^0\rho^0(1450)$ , the DCS modes  $K_0^*(1430)^+\pi^-$  and  $K_2^*(1430)^+\pi^-$ , and two Breit-Wigner  $\pi\pi$  S-wave contributions. A Belle analysis [11–13] included all the components of BABAR and added two more DCS modes,  $K^*(1410)^+\pi^-$  and

# Meson Particle Listings

## $D^\pm$

$K^*(1680)^+\pi^-$ . Recently, BABAR has modeled the  $\pi\pi$  S-wave using a  $K$ -matrix model for the  $\pi\pi$  and  $K\pi$  S-waves [14].

The primary motivation for the analysis of the decay  $D^0 \rightarrow K_S^0\pi^+\pi^-$  is to study  $D^0 - \bar{D}^0$  oscillations and the CKM angles. The quasi-two-body intermediate states include both  $CP$ -even and  $CP$ -odd eigenstates as well as doubly Cabibbo-suppressed channels. Time-dependent analyses of the Dalitz plot from CLEO [15] and Belle [6] simultaneously determined the strong transition amplitudes and phases, the mixing parameters  $x$  and  $y$  without phase or sign ambiguity, and the  $CP$ -violating parameter  $|q/p|$  and  $\text{Arg}(q/p)$ . See the note on “ $D^0 - \bar{D}^0$  Mixing” for a discussion.

The CKM angle  $\gamma/\phi_3$  [16] and the quark-mixing parameter  $\cos 2\beta/\phi_1$  [17] can be determined using the decays  $B^- \rightarrow D^{(*)}K^{(*)-}$  and  $\bar{B}^0 \rightarrow Dh^0$ , respectively, followed by the decay  $D \rightarrow K_S^0\pi^+\pi^-$ . The Belle and BABAR experiments measured  $\gamma/\phi_3$  (Belle [11–13] and BABAR [7,9,10,14,18]) and  $\cos 2\beta/\phi_1$  (Belle [19], BABAR [20]). In these analyses, a large systematic uncertainty in the relative phase between the  $D^0$  and  $\bar{D}^0$  amplitudes point by point across the Dalitz plot remains to be fully understood.

The quantum entangled production of  $D^0\bar{D}^0$  pairs from  $\psi(3770)$  enables a model-independent determination of the  $D^0/\bar{D}^0$  relative phase. Studying  $CP$ -tagged Dalitz plots [21,22] provides sensitivity to the cosine of the relative phase, while studying double-tagged Dalitz plots [22] probes both the cosine and sine of the  $D^0/\bar{D}^0$  phase difference. CLEO analyzed [23] the  $D^0 \rightarrow K_S^0\pi^+\pi^-$  and  $D^0 \rightarrow K_L^0\pi^+\pi^-$  samples using the  $CP$ -even tag modes  $K^+K^-$ ,  $\pi^+\pi^-$ ,  $K_L^0\pi^0$  (vs.  $K_S^0\pi^+\pi^-$  only), the  $CP$ -odd tag modes  $K_S^0\pi^0$ ,  $K_S^0\eta$ , and the double-tag modes  $(K_S^0\pi^+\pi^-)^2$  and  $(K_S^0\pi^+\pi^-)(K_L^0\pi^+\pi^-)$ . These measurements can reduce the model uncertainty on  $\gamma/\phi_3$  to about  $3^\circ$ .

**Doubly Cabibbo-Suppressed Decays:** There are two classes of multibody doubly Cabibbo-suppressed (DCS) decays of  $D$  mesons. The first consists of those in which the DCS and corresponding Cabibbo-favored (CF) decays populate distinct Dalitz plots; the pairs  $D^0 \rightarrow K^+\pi^-\pi^0$  and  $D^0 \rightarrow K^-\pi^+\pi^0$ , or  $D^+ \rightarrow K^+\pi^+\pi^-$  and  $D^+ \rightarrow K^-\pi^+\pi^+$ , are examples. Our average of three measurements of  $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0)/\Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$  is  $(2.20 \pm 0.10) \times 10^{-3}$ . Our average of four measurements of  $\Gamma(D^+ \rightarrow K^+\pi^-\pi^+)/\Gamma(D^+ \rightarrow K^-\pi^+\pi^+)$  is  $(5.77 \pm 0.22) \times 10^{-3}$ ; see the Particle Listings.

The second class consists of decays in which the DCS and CF modes populate the same Dalitz plot; for example,  $D^0 \rightarrow K^*\pi^+$  and  $D^0 \rightarrow K^*\pi^-$  both contribute to  $D^0 \rightarrow K_S^0\pi^+\pi^-$ . In this class, the potential for interference of DCS and CF amplitudes increases the sensitivity to the DCS amplitude and allows direct measurement of the relative strong phases between amplitudes. CLEO [1] and Belle [6] have measured the relative phase between  $D^0 \rightarrow K^*(892)^+\pi^-$  and  $D^0 \rightarrow K^*(892)^-\pi^+$  to be  $(189 \pm 10 \pm 3_{-5}^{+15})^\circ$  and  $(171.9 \pm 1.3)^\circ$  (statistical error only). These results are close to the  $180^\circ$  expected from Cabibbo factors and a small strong phase.

In addition, Belle [6] has results for both the relative phase (statistical errors only) and ratio  $R$  (central values only) of the DCS fit fraction relative to the CF fit fractions for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ ,  $K_2^*(1430)^+\pi^-$ ,  $K^*(1410)^+\pi^-$ , and  $K^*(1680)^+\pi^-$ . The systematic uncertainties on  $R$  must be evaluated. The values for  $R$  in units of  $\tan^4\theta_c$  are  $2.94 \pm 0.12$ ,  $22.0 \pm 1.6$ ,  $34 \pm 4$ ,  $87 \pm 13$ , and  $500 \pm 500$ . For  $K^+\pi^-$ , the corresponding value for  $R_D$  is  $(1.28 \pm 0.02) \times \tan^4\theta_c$ . Similarly, BABAR [7] has reported central values for  $R$  for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ , and  $K_2^*(1430)^+\pi^-$ . The values for  $R$  in units of  $\tan^4\theta_c$  are  $3.45 \pm 0.31$ ,  $7.7 \pm 3.0$ , and  $1.7 \pm 1.7$ , respectively. Recently, BABAR [14] has used a  $K$ -matrix formalism to describe the  $\pi\pi$  S-wave in  $K_S^0\pi^+\pi^-$ . The reported values for  $R$  in units of  $\tan^4\theta_c$  are  $2.78 \pm 0.11$ ,  $0.5 \pm 0.2$ , and  $1.4 \pm 0.5$ , respectively. The large differences in  $R$  among these final states could point to an interesting role for hadronic effects.

There are other ways, not involving DCS decays, in which  $D^0$  and  $\bar{D}^0$  singly Cabibbo-suppressed decays can populate the same Dalitz plot. Examples are  $D^0$  and  $\bar{D}^0$  decays to  $K_S^0K^+\pi^-$ , or to  $K_S^0K^-\pi^+$ . These final states can be used to study  $D^0$ - $\bar{D}^0$  mixing and the CKM angle  $\gamma/\phi_3$ .

**$CP$  Violation:** In the limit of  $CP$  conservation, charge conjugate decays will have the same Dalitz-plot distribution. The  $D^{*\pm}$  tag enables the discrimination between  $D^0$  and  $\bar{D}^0$ . The integrated  $CP$  violation across the Dalitz plot is determined in two ways. The first uses

$$A_{CP} = \int \left( \frac{|\mathcal{M}|^2 - |\bar{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\bar{\mathcal{M}}|^2} \right) dm_{ab}^2 dm_{bc}^2 / \int dm_{ab}^2 dm_{bc}^2, \quad (1)$$

where  $\mathcal{M}$  and  $\bar{\mathcal{M}}$  have the same normalization and represent the  $D^0$  and  $\bar{D}^0$  Dalitz-plot amplitudes for the three-body decay  $D \rightarrow abc$ , and  $m_{ab}$  ( $m_{bc}$ ) is the invariant mass of  $ab$  ( $bc$ ). The second uses the asymmetry in the efficiency-corrected  $D^0$  and  $\bar{D}^0$  yields,

$$A_{CP} = \frac{N_{D^0} - N_{\bar{D}^0}}{N_{D^0} + N_{\bar{D}^0}}. \quad (2)$$

These expressions are less sensitive to  $CP$  violation than are the individual resonant submodes [24–26]. Our Particle Listings give limits on  $CP$  violation for 12  $D^+$ , 52  $D^0$ , and 13  $D_S^\pm$  decay modes. No evidence of  $CP$  violation has been observed in  $D$ -meson decays.

The possibility of interference between  $CP$ -conserving and  $CP$ -violating amplitudes provides a more sensitive probe of  $CP$  violation. The constraints on the square of the  $CP$ -violating amplitudes obtained in the resonant submodes of  $D^0 \rightarrow K_S^0\pi^+\pi^-$  range from  $3.5 \times 10^{-4}$  to  $28.4 \times 10^{-4}$  at 95% confidence level [24]. A similar analysis has been performed by CLEO [25] searching for  $CP$  violation in  $D^+ \rightarrow K^+K^-\pi^+$ . The constraints on the square of the  $CP$ -violating amplitudes in the resonant submodes range from  $4 \times 10^{-4}$  to  $51 \times 10^{-4}$  at 95%. BABAR finds no evidence for  $CP$ -violating amplitudes in the resonant submodes of  $D^0 \rightarrow K^+K^-\pi^0$  and  $D^0 \rightarrow \pi^+\pi^-\pi^0$  [26].

 $\Gamma((K^-\pi^+)_{S\text{-wave}})/\Gamma(K^-2\pi^+)$   $\Gamma_{41}/\Gamma_{40}$ 

This is the "fit fraction" from the Dalitz-plot analysis. The  $K^-\pi^+$  S-wave includes a broad scalar  $\kappa$  ( $\bar{K}_0^*(800)$ ), the  $\bar{K}_0^*(1430)^0$ , and non-resonant background.

<sup>35</sup> This LINK 09 model-independent partial-wave analysis of the  $K^-\pi^+$  S-wave slices the  $K^-\pi^+$  mass range into 39 bins.

<sup>36</sup> The BONVICINI 08A QMIPWA (quasi-model-independent partial-wave analysis) of the  $K^-\pi^+$  S-wave amplitude slices the  $K^-\pi^+$  mass range into 26 bins but keeps the Breit-Wigner  $\bar{K}_0^*(1430)^0$ .

<sup>37</sup> This LINK 07B fit uses a K matrix. The  $K^-\pi^+$  S-wave fit fraction given above breaks down into (207.3 ± 25.5 ± 12.4)% isospin-1/2 and (40.5 ± 9.6 ± 3.2)% isospin-3/2 — with large interference between the two. The isospin-1/2 component includes the  $\kappa$  (or  $\bar{K}_0^*(800)^0$ ) and  $\bar{K}_0^*(1430)^0$ .

 $\Gamma(\bar{K}_0^*(800)^0\pi^+, \bar{K}_0^*(800) \rightarrow K^-\pi^+)/\Gamma(K^-2\pi^+)$   $\Gamma_{42}/\Gamma_{40}$ 

This is the "fit fraction" from the Dalitz-plot analysis.

<b><math>-3.5 \pm 10.7 \pm 0.9</math></b>	343 ± 37	MENDEZ	10	CLEO $e^+e^-$ at 3774 MeV

 $D^+ - D^-$  T-VIOLATING DECAY-RATE ASYMMETRIES $A_{Tviol}(K_S^0 K^\pm \pi^+ \pi^-)$  in  $D^\pm \rightarrow K_S^0 K^\pm \pi^+ \pi^-$ 

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a  $T$ -odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta for the  $D^+$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $D^-$ .  $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$  would, in the absence of strong phases, test for  $T$  violation in  $D^+$  decays (the  $\Gamma$ 's are partial widths). With  $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ , the asymmetry  $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$  tests for  $T$  violation even with nonzero strong phases.

 $D^0 - \bar{D}^0$  MIXING

Revised March 2012 by D. Asner (Pacific Northwest National Laboratory)

The detailed formalism for  $D^0 - \bar{D}^0$  mixing is presented in the note on “ $CP$  Violation in Meson Decays” in this *Review*. For completeness, we present an overview here. The time evolution of the  $D^0 - \bar{D}^0$  system is described by the Schrödinger equation

$$i \frac{\partial}{\partial t} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix} = \left( \mathbf{M} - \frac{i}{2} \mathbf{\Gamma} \right) \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix}, \quad (1)$$

where the  $\mathbf{M}$  and  $\mathbf{\Gamma}$  matrices are Hermitian, and  $CP$  invariance requires that  $M_{11} = M_{22} \equiv M$  and  $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$ . The off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because  $CP$  violation is expected to be quite small here, it is convenient to label the mass eigenstates by the  $CP$  quantum number in the limit of  $CP$  conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\bar{D}^0\rangle, \quad (2)$$

where

$$\left( \frac{q}{p} \right)^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}. \quad (3)$$

The normalization condition is  $|p|^2 + |q|^2 = 1$ . Our phase convention is  $CP|D^0\rangle = +|\bar{D}^0\rangle$ , and the sign is chosen so that  $D_1$  has  $CP$  even, or nearly so.

## Meson Particle Listings

 $D^0$ 

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2}\Gamma_{1,2} = \left(M - \frac{i}{2}\Gamma\right) \pm \frac{q}{p} \left(M_{12} - \frac{i}{2}\Gamma_{12}\right), \quad (4)$$

where  $m_{1,2}$  and  $\Gamma_{1,2}$  are the masses and widths of the  $D_{1,2}$ .

We define dimensionless mixing parameters  $x$  and  $y$  by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \quad (6)$$

where  $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$ . If  $CP$  is conserved, then  $M_{12}$  and  $\Gamma_{12}$  are real,  $\Delta m = 2M_{12}$ ,  $\Delta\Gamma = 2\Gamma_{12}$ , and  $p = q = 1/\sqrt{2}$ . The signs of  $\Delta m$  and  $\Delta\Gamma$  are to be determined experimentally.

The parameters  $x$  and  $y$  are measured in several ways. The most precise values are obtained using the time dependence of  $D$  decays. Since  $D^0\text{--}\bar{D}^0$  mixing is a small effect, the identifying tag of the initial particle as a  $D^0$  or a  $\bar{D}^0$  must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence  $D^{*+} \rightarrow D^0\pi^+$  or  $D^{*-} \rightarrow \bar{D}^0\pi^-$ . In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the  $B$ -factories allow the production flavor to also be determined by fully reconstructing charm on the ‘‘other side’’ of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the  $D$ 's produced from  $\psi(3770) \rightarrow D^0\bar{D}^0$  decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the  $D^0$  and  $\bar{D}^0$  do not travel far enough), the quantum-coherent  $C = -1$   $\psi(3770) \rightarrow D^0\bar{D}^0$  state provides time-integrated sensitivity [2,3].

**Time-Dependent Analyses:** We extend the formalism of this *Review's* note on ‘‘ $CP$  Violation in Meson Decays.’’ In addition to the ‘‘right-sign’’ instantaneous decay amplitudes  $\bar{A}_f \equiv \langle f|H|\bar{D}^0\rangle$  and  $A_{\bar{f}} \equiv \langle \bar{f}|H|D^0\rangle$  for  $CP$  conjugate final states  $f = K^+\pi^-, \dots$  and  $\bar{f} = K^-\pi^+, \dots$ , we include ‘‘wrong-sign’’ amplitudes  $\bar{A}_{\bar{f}} \equiv \langle \bar{f}|H|\bar{D}^0\rangle$  and  $A_f \equiv \langle f|H|D^0\rangle$ .

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral  $D$ -meson mean lifetime,  $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$ . Starting from a pure  $|D^0\rangle$  or  $|\bar{D}^0\rangle$  state at  $t = 0$ , the time-dependent rates of decay to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{|\langle f|H|D^0(t)\rangle|^2}{|\bar{A}_f|^2} = \left|\frac{q}{p}\right|^2 \left|g_+(t)\lambda_f^{-1} + g_-(t)\right|^2, \quad (7)$$

and

$$\bar{r}(t) \equiv \frac{|\langle \bar{f}|H|\bar{D}^0(t)\rangle|^2}{|A_{\bar{f}}|^2} = \left|\frac{p}{q}\right|^2 \left|g_+(t)\lambda_{\bar{f}} + g_-(t)\right|^2. \quad (8)$$

where

$$\lambda_f \equiv q\bar{A}_f/pA_f, \quad \lambda_{\bar{f}} \equiv q\bar{A}_{\bar{f}}/pA_{\bar{f}}, \quad (9)$$

and

$$g_{\pm}(t) = \frac{1}{2} \left( e^{-iz_1 t} \pm e^{-iz_2 t} \right), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}. \quad (10)$$

Note that a change in the convention for the relative phase of  $D^0$  and  $\bar{D}^0$  would cancel between  $q/p$  and  $\bar{A}_f/A_f$  and leave  $\lambda_f$  unchanged. We expand  $r(t)$  and  $\bar{r}(t)$  to second order in  $x$  and  $y$  for modes in which the ratio of decay amplitudes,  $R_D = |A_f/\bar{A}_f|^2$ , is very small.

**Semileptonic decays:** Consider the final state  $f = K^+\ell^-\bar{\nu}_\ell$ , where  $A_f = \bar{A}_{\bar{f}} = 0$  in the Standard Model. The final state  $f$  is only accessible through mixing and  $r(t)$  is

$$r(t) = |g_-(t)|^2 \left|\frac{q}{p}\right|^2 \approx \frac{e^{-t}}{4} (x^2 + y^2) t^2 \left|\frac{q}{p}\right|^2. \quad (11)$$

For  $\bar{r}(t)$   $q/p$  is replaced by  $p/q$ . In the Standard Model,  $CP$  violation in charm mixing is small and  $|q/p| \approx 1$ . In the limit of  $CP$  conservation,  $r(t) = \bar{r}(t)$ , and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t) dt = \left|\frac{q}{p}\right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} = \frac{1}{2}(x^2 + y^2). \quad (12)$$

**Table 1:** Results for  $R_M$  in  $D^0$  semileptonic decays.

Year	Exper.	Final state(s)	$R_M (\times 10^{-3})$	90% C.L.

1996	E791 [9]	$K^+\ell^-\bar{\nu}_\ell$	$(1.1 \pm 3.0) \times 10^{-3}$	$< 5.0 \times 10^{-3}$
HFAG [10]			$0.13 \pm 0.27$	

\*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the BaBar result has been superseded by Ref. 1, and the Belle result has been superseded by Ref. 4.

Table 1 summarizes results for  $R_M$  from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is  $R_M = (1.30 \pm 2.69) \times 10^{-4}$ .

**Wrong-sign decays to hadronic non- $CP$  eigenstates:**

Consider the final state  $f = K^+\pi^-$ , where  $A_f$  is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\bar{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left|\frac{A_f}{\bar{A}_f}\right| \sim O(\tan^2 \theta_c), \quad (13)$$

where  $R_D$  is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate,  $\delta_f$  is the strong phase difference between DCS and CF processes, and  $\theta_c$  is the Cabibbo angle. The minus sign originates from the sign of  $V_{us}$  relative to  $V_{cd}$ .

We characterize the violation of  $CP$  with the real-valued parameters  $A_M$ ,  $A_D$ , and  $\phi$ . We adopt the parametrization (see Refs. 11 and 12)

$$\left|\frac{q}{p}\right|^2 = \sqrt{\frac{1+A_M}{1-A_M}}, \quad (14)$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\bar{A}_f} = -\sqrt{R_D} \left( \frac{(1+A_D)(1-A_M)}{(1-A_D)(1+A_M)} \right)^{1/4} e^{-i(\delta_f+\phi)}, \quad (15)$$

$$\lambda_{\bar{f}} \equiv \frac{q\bar{A}_{\bar{f}}}{pA_{\bar{f}}} = -\sqrt{R_D} \left( \frac{(1-A_D)(1+A_M)}{(1+A_D)(1-A_M)} \right)^{1/4} e^{-i(\delta_f-\phi)}, \quad (16)$$

and  $A_D$  is a measure of direct  $CP$  violation, while  $A_M$  is a measure of  $CP$  violation in mixing. From these relations, we obtain

$$\sqrt{\frac{1+A_D}{1-A_D}} = \frac{|A_f/\bar{A}_f|}{|\bar{A}_{\bar{f}}/A_{\bar{f}}|}, \quad (17)$$

The angle  $\phi$  measures  $CP$  violation in interference between mixing and decay. While  $A_M$  is independent of the decay process,  $A_D$  and  $\phi$ , in general, depend on  $f$ .

In general,  $\lambda_{\bar{f}}$  and  $\lambda_f^{-1}$  are independent complex numbers. More detail on  $CP$  violation in meson decays can be found in Ref. 13. To leading order, for  $A_D$  and  $A_M \ll 1$ ,

$$r(t) = e^{-t} \left[ R_D(1+A_D) + \sqrt{R_D(1+A_M)(1+A_D)} y'_- t + \frac{1}{2}(1+A_M)R_M t^2 \right] \quad (18)$$

and

$$\bar{r}(t) = e^{-t} \left[ R_D(1-A_D) + \sqrt{R_D(1-A_M)(1-A_D)} y'_+ t + \frac{1}{2}(1-A_M)R_M t^2 \right] \quad (19)$$

Here

$$y'_\pm \equiv y' \cos \phi \pm x' \sin \phi \\ = y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi), \quad (20)$$

where

$$x' \equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi}, \\ y' \equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi}, \quad (21)$$

and  $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$  is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of  $CP$  violation. In the limit of  $CP$  conservation,  $A_M$ ,  $A_D$ , and  $\phi$  are all zero. Then

$$r(t) = \bar{r}(t) = e^{-t} \left( R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right), \quad (22)$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) dt = R_D + \sqrt{R_D} y' + R_M. \quad (23)$$

The ratio  $R$  is the most readily accessible experimental quantity. In Table 2 are reported the measurements of  $R$ ,  $R_D$  and  $A_D$  in  $D^0 \rightarrow K^+\pi^-$ , and their HFAG average [20] from a general fit; all allow for both mixing and  $CP$  violation. Typically, the fit parameters are  $R_D$ ,  $x'^2$ , and  $y'$ . Table 3 summarizes the results for  $x'^2$  and  $y'$ . Allowing for  $CP$  violation, the separate contributions to  $R$  can be extracted by fitting the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^-\pi^+$  decay rates.

**Table 2:** Results for  $R$ ,  $R_D$ , and  $A_D$  in  $D^0 \rightarrow K^+\pi^-$ .

Year	Exper.	$R(\times 10^{-3})$	$R_D(\times 10^{-3})$	$A_D(\%)$
2007	CDF [14]	$4.15 \pm 0.10$	$3.04 \pm 0.55$	—
2007	BaBar [15]	$3.53 \pm 0.08 \pm 0.04$	$3.03 \pm 0.16 \pm 0.10$	$-2.1 \pm 5.2 \pm 1.5$
2006	Belle [16]	$3.77 \pm 0.08 \pm 0.05$	$3.64 \pm 0.17$	$2.3 \pm 4.7$
2005*	FOCUS [17]	$4.29^{+0.63}_{-0.61} \pm 0.28$	$5.17^{+1.47}_{-1.58} \pm 0.76$	$13^{+33}_{-25} \pm 10$
2000*	CLEO [18]	$3.32^{+0.63}_{-0.65} \pm 0.40$	$4.8 \pm 1.2 \pm 0.4$	$-1^{+16}_{-17} \pm 1$
1998	E791 [19]	$6.8^{+3.4}_{-3.3} \pm 0.7$	—	—
Average		$3.80 \pm 0.05$	$3.31 \pm 0.08$ [20]	$-1.7 \pm 2.4$ [20]

\*These measurements are excluded from the HFAG average due to poor precision.

**Table 3:** Results on the time-dependence of  $r(t)$  in  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^-\pi^+$  decays. The CDF result assumes no  $CP$  violation. The FOCUS, CLEO, and Belle results restrict  $x'^2$  to the physical region. The confidence intervals from FOCUS, CLEO, and BaBar are obtained from the fit, whereas Belle uses a Feldman-Cousins method, and CDF uses a Bayesian method.

Year	Exper.	$y'$ (%)	$x'^2 (\times 10^{-3})$
2007	CDF [14]	$0.85 \pm 0.76$	$-0.12 \pm 0.35$
2007	BaBar [15]	$0.97 \pm 0.44 \pm 0.31$	$-0.22 \pm 0.30 \pm 0.21$
2006	Belle [16]	$-2.8 < y' < 2.1$	$< 0.72$ (95% C.L.)
2005	FOCUS [17]	$-11.2 < y' < 6.7$	$< 8.0$ (95% C.L.)
2000	CLEO [18]	$-5.8 < y' < 1.0$	$< 0.81$ (95% C.L.)

Extraction of the mixing parameters  $x$  and  $y$  from the results in Table 3 requires knowledge of the relative strong phase  $\delta_{K\pi}$ . An interference effect that provides useful sensitivity to  $\delta_{K\pi}$  arises in the decay chain  $\psi(3770) \rightarrow D^0 \bar{D}^0 \rightarrow (f_{CP})(K^+\pi^-)$ , where  $f_{CP}$  denotes a  $CP$ -even or -odd eigenstate from  $D^0$  decay, such as  $K^+K^-$  or  $K_S^0\pi^0$ , respectively [23]. Here, the amplitude relation

$$\sqrt{2} A(D_\pm \rightarrow K^-\pi^+) = A(D^0 \rightarrow K^-\pi^+) \pm A(\bar{D}^0 \rightarrow K^-\pi^+). \quad (24)$$

where  $D_\pm$  denotes a  $CP$ -even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \rightarrow K^-\pi^+)|^2 - |A(D_- \rightarrow K^-\pi^+)|^2}{2\sqrt{R_D} |A(D^0 \rightarrow K^-\pi^+)|^2}. \quad (25)$$

This neglects  $CP$  violation and uses  $\sqrt{R_D} \ll 1$ .

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although  $x$  and  $y$  do not vary across the space, knowledge of the resonant substructure is

# Meson Particle Listings

## $D^0$

needed to extrapolate the strong phase difference  $\delta$  from point to point to determine  $x$  and  $y$ .

A time-dependent analysis of the process  $D^0 \rightarrow K^+\pi^-\pi^0$  from BaBar [21,22] determines the *relative* strong phase variation across the Dalitz plot and reports  $x'' = (2.61_{-0.68}^{+0.57} \pm 0.39)\%$ , and  $y'' = (-0.06_{-0.64}^{+0.55} \pm 0.34)\%$ , where  $x''$  and  $y''$  are defined as

$$\begin{aligned} x'' &\equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0}, \\ y'' &\equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0}, \end{aligned} \quad (26)$$

in parallel to  $x'$ ,  $y'$ , and  $\delta_{K\pi}$  of Eq. (21). Here  $\delta_{K\pi\pi^0}$  is the remaining strong phase difference between the DCS  $D^0 \rightarrow K^+\rho^-$  and the CF  $\overline{D}^0 \rightarrow K^+\rho^-$  amplitudes and does not vary across the Dalitz plot. Both strong phases,  $\delta_{K\pi}$  and  $\delta_{K\pi\pi^0}$ , can be determined from time-integrated  $CP$  asymmetries in correlated  $D^0\overline{D}^0$  produced at the  $\psi(3770)$  [23,24].

Both the sign and magnitude of  $x$  and  $y$  without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody  $D^0$  decays [25,26]. In  $D^0 \rightarrow K_S^0\pi^+\pi^-$ , the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phases. CLEO [27], Belle [26], and BaBar [28] have measured the relative phase between  $D^0 \rightarrow K^*(892)^-\pi^+$  and  $D^0 \rightarrow K^*(892)^+\pi^-$  to be  $(189 \pm 10 \pm 3_{-5}^{+15})^\circ$ ,  $(171.9 \pm 1.3$  (stat. only) $^\circ$ , and  $(177.6 \pm 1.1$  (stat. only) $^\circ$ , respectively. These results are close to the  $180^\circ$  expected from Cabibbo factors and a small strong phase. Table 4 summarizes the results of a time-dependent Dalitz-plot analyses.

**Table 4:** Results from time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0\pi^+\pi^-$  (CLEO and Belle) and  $D^0 \rightarrow K_S^0\pi^+\pi^-, K_S^0K^+K^-$  (BaBar). The errors are statistical, experimental systematic, and decay-model systematic, respectively.

No $CP$ Violation			
Year	Exper.	$x \times 10^{-3}$	$y \times 10^{-3}$
2010	BaBar [28]	$1.6 \pm 2.3 \pm 1.2 \pm 0.8$	$5.7 \pm 2.0 \pm 1.3 \pm 0.7$
2007	Belle [26]	$8.0 \pm 2.9_{-0.7}^{+0.9} \pm 1.4$	$3.3 \pm 2.4_{-1.2}^{+0.8} \pm 0.8$
2005	CLEO [25]	$19_{-33}^{+32} \pm 4 \pm 4$	$-14 \pm 24 \pm 8 \pm 4$
HFAG [20]		$4.2 \pm 2.1$	$4.6 \pm 1.9$
With $CP$ Violation			
Year	Exper.	$ q/p $	$\phi$
2007	Belle [26]	$0.86_{-0.29}^{+0.30} \pm 0.06_{-0.03} \pm 0.08$	$(-14_{-18}^{+16} \pm 5 \pm 2)^\circ$

In addition, Belle [26] has results for both the relative phase (statistical errors only) and ratio  $R$  (central values only) of the DCS fit fraction relative to the CF fit fractions for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ ,  $K_2^*(1430)^+\pi^-$ ,  $K^*(1410)^+\pi^-$ , and  $K^*(1680)^+\pi^-$ . The systematic uncertainties on  $R$  must be evaluated. The values for  $R$  in units of  $\tan^4\theta_c$  are  $2.94 \pm 0.12$ ,  $22.0 \pm 1.6$ ,  $34 \pm 4$ ,  $87 \pm 13$ , and  $500 \pm 500$ , respectively. For  $K^+\pi^-$ , the corresponding value for  $R_D$  is  $(1.28 \pm 0.02) \times \tan^4\theta_c$ .

Similarly, BaBar [28–30] has reported central values for  $R$  for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ , and  $K_2^*(1430)^+\pi^-$ . The large differences in  $R$  among these final states could point to an interesting role for hadronic effects.

**Decays to  $CP$  Eigenstates:** When the final state  $f$  is a  $CP$  eigenstate, there is no distinction between  $f$  and  $\bar{f}$ , and  $A_f = A_{\bar{f}}$  and  $\overline{A}_{\bar{f}} = \overline{A}_f$ . We denote final states with  $CP$  eigenvalues  $\pm 1$  by  $f_\pm$  and write  $\lambda_\pm$  for  $\lambda_{f_\pm}$ .

The quantity  $y$  may be measured by comparing the rate for  $D^0$  decays to non- $CP$  eigenstates such as  $K^-\pi^+$  with decays to  $CP$  eigenstates such as  $K^+K^-$  [12]. If decays to  $K^+K^-$  have a shorter effective lifetime than those to  $K^-\pi^+$ ,  $y$  is positive.

In the limit of slow mixing ( $x, y \ll 1$ ) and the absence of direct  $CP$  violation ( $A_D = 0$ ), but allowing for small indirect  $CP$  violation ( $|A_M|, |\phi| \ll 1$ ), we can write

$$\lambda_\pm = \left| \frac{q}{p} \right| e^{\pm i\phi}. \quad (27)$$

In this scenario, to a good approximation, the decay rates for states that are initially  $D^0$  and  $\overline{D}^0$  to a  $CP$  eigenstate have exponential time dependence:

$$r_\pm(t) \propto \exp(-t/\tau_\pm), \quad (28)$$

$$\bar{r}_\pm(t) \propto \exp(-t/\bar{\tau}_\pm), \quad (29)$$

where  $\tau$  is measured in units of  $1/\Gamma$ .

The effective lifetimes are given by

$$1/\tau_\pm = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi), \quad (30)$$

$$1/\bar{\tau}_\pm = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi). \quad (31)$$

The effective decay rate to a  $CP$  eigenstate combining both  $D^0$  and  $\overline{D}^0$  decays is

$$r_\pm(t) + \bar{r}_\pm(t) \propto e^{-(1 \pm y_{CP})t}. \quad (32)$$

Here

$$y_{CP} = \frac{1}{2} \left( \left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left( \left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (33)$$

$$\approx y \cos \phi - A_M x \sin \phi. \quad (34)$$

If  $CP$  is conserved,  $y_{CP} = y$ .

All measurements of  $y_{CP}$  and  $A_\Gamma$  are relative to the  $D^0 \rightarrow K^-\pi^+$  decay rate. Table 5 summarizes the current status of measurements. Belle [35], BaBar [32,34], and LHCb [31] have reported  $y_{CP}$  and the decay-rate asymmetry for  $CP$  even final states

$$A_\Gamma = \frac{\bar{\tau}_+ - \tau_+}{\bar{\tau}_+ + \tau_+} = \frac{(1/\tau_+) - (1/\bar{\tau}_+)}{(1/\tau_+) + (1/\bar{\tau}_+)} \quad (35)$$

$$= \frac{1}{2} \left( \left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left( \left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) x \sin \phi \quad (36)$$

$$\approx A_M y \cos \phi - x \sin \phi. \quad (37)$$

**Table 5:** Results for  $y_{CP}$  from  $D^0 \rightarrow K^+K^-$  and  $\pi^+\pi^-$ .

Year	Exper.	final state(s)	$y_{CP}(\%)$	$A_\Gamma(\times 10^{-3})$

1999	E791 [39]	$K^+K^-$	$0.8 \pm 2.9 \pm 1.0$	—
HFAG [20]			$1.06 \pm 0.21$	$0.03 \pm 0.23$

\*This measurement is included in the result reported by Ref. 32.

Belle [33] has also reported  $y_{CP}$  for the final state  $K_S^0 K^+ K^-$  which is dominated by the  $CP$  odd final state  $K_S^0 \phi$ . If  $CP$  is conserved,  $A_\Gamma = 0$ .

Substantial work on the time-integrated  $CP$  asymmetries in decays to  $CP$  eigenstates are consistent [40]. Recently, LHCb has reported  $3.5\sigma$  evidence for the difference in time-integrated  $CP$  asymmetry,  $\Delta A_{CP} = A_K - A_\pi$ , between  $D^0 \rightarrow K^-K^+$  and  $D^0 \rightarrow \pi^- \pi^+$ , yielding  $\Delta A_{CP} = [-0.82 \pm 0.21(stat.) \pm 0.11(sys.)]\%$  [41]. Subsequently, CDF has reported  $\Delta A_{CP} = [-0.62 \pm 0.21(stat.) \pm 0.10(sys.)]\%$  [42].

**Coherent  $D^0\bar{D}^0$  Analyses:** Measurements of  $R_D$ ,  $\cos\delta_{K\pi}$ ,  $\sin\delta_{K\pi}$ ,  $x$ , and  $y$  can be determined simultaneously from a combined fit to the time-integrated single-tag (ST) and double-tag (DT) yields in correlated  $D^0\bar{D}^0$  produced at the  $\psi(3770)$  [23,24].

Due to quantum correlations in the  $C = -1$  and  $C = +1$   $D^0\bar{D}^0$  pairs produced in the reactions  $e^+e^- \rightarrow D^0\bar{D}^0(\pi^0)$  and  $e^+e^- \rightarrow D^0\bar{D}^0\gamma(\pi^0)$ , respectively, the time-integrated  $D^0\bar{D}^0$  decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from  $D^0-\bar{D}^0$  mixing.

The following categories of final states are considered:

**$f$  or  $\bar{f}$ :** Hadronic states accessed from either  $D^0$  or  $\bar{D}^0$  decay but that are not  $CP$  eigenstates. An example is  $K^- \pi^+$ , which results from Cabibbo-favored  $D^0$  transitions or DCS  $\bar{D}^0$  transitions.

**$\ell^+$  or  $\ell^-$ :** Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent  $D^0$ .

**$f_+$  or  $f_-$ :**  $CP$ -even and  $CP$ -odd eigenstates, respectively.

The decay rates for  $D^0\bar{D}^0$  pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both  $C = -1$  and  $C = +1$ , reproducing the work of Ref. 3. Such  $D^0\bar{D}^0$  combinations, where both  $D$  final states are specified, are double tags. In addition, the rates for single tags, where either the  $D^0$  or  $\bar{D}^0$  is identified and the other neutral  $D$  decays generically are given in Ref. 2.

CLEO-c has reported results using 818 pb $^{-1}$  of  $e^+e^- \rightarrow \psi(3770)$  data [43–45], where the quantum-coherent  $D^0\bar{D}^0$  pairs are in the  $C = -1$  state. The values of  $y$ ,  $R_M$ ,  $\cos\delta_{K\pi}$ , and  $\sin\delta_{K\pi}$  are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are  $K^- \pi^+$  ( $f$ ),  $K^+ \pi^-$  ( $\bar{f}$ ),  $K^- K^+$  ( $f_+$ ),  $\pi^+ \pi^-$  ( $f_+$ ),  $K_S^0 \pi^0 \pi^0$  ( $f_+$ ),  $K_L^0 \pi^0$  ( $f_+$ ),  $K_L^0 \eta$  ( $f_+$ ),  $K_L^0 \omega$  ( $f_+$ ),  $K_S^0 \pi^0$  ( $f_-$ ),  $K_S^0 \eta$  ( $f_-$ ),  $K_S^0 \omega$  ( $f_-$ ), and  $K_L^0 \pi^0 \pi^0$  ( $f_-$ ), and  $K_S^0 \pi^+ \pi^-$  (mixture of  $f, \bar{f}, f_+$ , and  $f_-$ ). The two flavored final states,  $K^- \pi^+$  and  $K^+ \pi^-$ , can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one  $D$  is fully reconstructed in one of the hadronic modes listed above, and the other  $D$  is partially reconstructed in either  $D \rightarrow K\ell\nu$  or  $D \rightarrow K\mu\nu$ . When the lepton is accompanied by a flavor tag ( $D \rightarrow K^- \pi^+$  or  $K^+ \pi^-$ ), both the “right-sign” and “wrong-sign” DT samples are used, where the electron and kaon charges are the same and opposite, respectively.

The main results of the CLEO-c analysis are the determination of  $\cos\delta_{K\pi} = 0.98^{+0.27}_{-0.20} \pm 0.08$ ,  $\sin\delta_{K\pi} = -0.04 \pm 0.49 \pm 0.08$ , and World Averages for the mixing parameters from an “extended” fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [45]. These fits allow  $\cos\delta_{K\pi}$ ,  $\sin\delta_{K\pi}$  and  $x^2$  to be unphysical. Constraining  $\cos\delta_{K\pi}$  and  $\sin\delta_{K\pi}$  to  $[-1, +1]$ —that is interpreting  $\delta_{K\pi}$  as an angle—yields  $\delta_{K\pi} = (15^{+11}_{-17} \pm 7)^\circ$ . Note that measurements of  $y$  (Table 4 and Table 5) and  $y'$  (Table 3) contribute to the determination of  $\delta_{K\pi}$ .

**Summary of Experimental Results:** Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For  $D^0 \rightarrow K^+ \pi^-$ , BaBar [15] and CDF [14] find evidence for oscillations with  $3.9\sigma$  ( $\Delta\text{Log}\mathcal{L}$ ) and  $3.8\sigma$  (Bayesian), respectively. The most precise measurement for mixing parameters is from Belle [16], which excludes  $x^2 = y' = 0$  at  $2.1\sigma$ .

For  $y_{CP}$  in  $D^0 \rightarrow K^+ K^-$  and  $\pi^+ \pi^-$ , Belle [35] and BaBar [32] find  $3.2\sigma$  and  $4.1\sigma$  effects. The most sensitive measurement of  $x$  and  $y$  is in  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ ,  $K_S^0 K^+ K^-$  from BaBar [28] and the no mixing solution is only excluded at  $1.9\sigma$ . The current situation would benefit from better knowledge of the strong phase difference  $\delta_{K\pi}$  than provided by the current CLEO-c result [45]. This would allow one to unfold  $x$  and  $y$  from the  $D^0 \rightarrow K^+ \pi^-$  measurements of  $x'^2$  and  $y'$ , and directly compare them to the  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$  results.

The experimental data consistently indicate that the  $D^0$  and  $\bar{D}^0$  do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to short-range processes, significant constraints on a variety of new physics models are obtained [46]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. However, recent evidence opens the window to searches for  $CP$  violation in mixing, which would provide unequivocal evidence of New Physics. The evidence for time

## $D^0$

integrated  $CP$ -violation,  $\Delta A_{CP} \neq 0$ , observed by LHCb is intriguing. This result is marginally consistent with Standard Model expectation [47–49].

### HFAG Averaging of Charm Mixing Results:

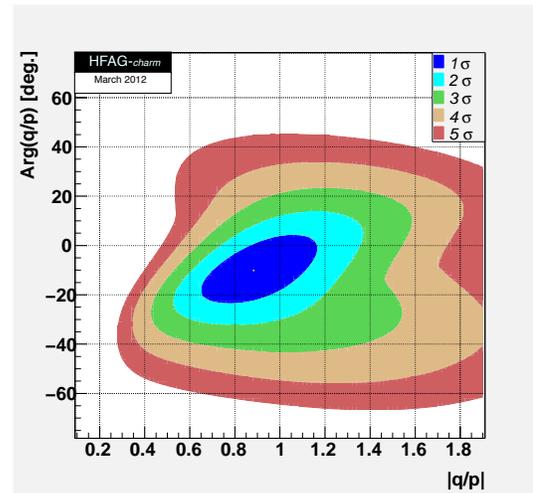

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of  $x$ ,  $y$ ,  $\delta_{K\pi}$ ,  $\delta_{K\pi\pi^0}$ ,  $R_D$ ,  $A_D \equiv (R_D^+ - R_D^-)/(R_D^+ + R_D^-)$ ,  $|q/p|$ ,  $\text{Arg}(q/p) \equiv \phi$ , and the time-integrated  $CP$  asymmetries  $A_K$  and  $A_\pi$ . Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of  $D^0 \rightarrow K^{(*)}\ell^-\bar{\nu}$ ,  $K^+K^-$ ,  $\pi^+\pi^-$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ ,  $K_S^0\pi^+\pi^-$ , and  $K_S^0K^+K^-$  decays, as well as CLEO- $c$  results for double-tagged branching fractions measured at the  $\psi(3770)$  are used.

**Figure 1:** Two-dimensional  $1\sigma$ - $5\sigma$  contours for  $(x, y)$  from measurements of  $D^0 \rightarrow K^{(*)}\ell\nu$ ,  $h^+h^-$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ ,  $K_S^0\pi^+\pi^-$ , and  $K_S^0K^+K^-$  decays, and double-tagged branching fractions measured at the  $\psi(3770)$  resonance (from HFAG [20]).

**Table 6:** HFAG Charm Mixing Average allowing for  $CP$  violation [20].

Parameter	HFAG average	95% C.L. interval
$x(\%)$	$0.63^{+0.19}_{-0.20}$	[0.24, 0.99]
$y(\%)$	$0.75 \pm 0.12$	[0.51, 0.98]
$R_D(\%)$	$0.331 \pm 0.008$	[0.315, 0.347]
$\delta_{K\pi}(\circ)$	$22.1^{+9.7}_{-11.1}$	[-2.6, 40.6]
$\delta_{K\pi\pi^0}(\circ)$	$19 \pm 22$	[-26, 62]
$A_D(\%)$	$-1.7 \pm 2.4$	[-6.4, 3.0]
$ q/p $	$0.88^{+0.18}_{-0.16}$	[0.59, 1.26]
$\phi(\circ)$	$-10.1^{+9.5}_{-8.9}$	[-27.4, 8.7]
$A_K$	$-0.31 \pm 0.24$	[-0.78, 0.15]
$A_\pi$	$0.36 \pm 0.25$	[-0.13, 0.86]

**Figure 2:** Two-dimensional  $1\sigma$ - $5\sigma$  contours for  $(|q/p|, \text{Arg}(q/p))$  from measurements of  $D^0 \rightarrow K^{(*)}\ell\nu$ ,  $h^+h^-$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ ,  $K_S^0\pi^+\pi^-$ , and  $K_S^0K^+K^-$  decays, and double-tagged branching fractions measured at the  $\psi(3770)$  resonance (from HFAG [20]).

For the global fit, confidence contours in the two dimensions  $(x, y)$  and  $(|q/p|, \phi)$  are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to-5  $\sigma$  contours. The fits exclude the no-mixing point  $(x = y = 0)$  at  $10.2\sigma$ , whether or not  $CP$  violation is allowed. The parameters  $x$  and  $y$  differ from zero by  $2.7\sigma$  and  $6.0\sigma$ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 6.

From the results of the HFAG averaging, the following can be concluded: (1) Since  $CP$  violation is small and  $y_{CP}$  is positive, the  $CP$ -even state is shorter-lived, as in the  $K^0\bar{K}^0$  system; (2) However, since  $x$  appears to be positive, the  $CP$ -even state is heavier, unlike in the  $K^0\bar{K}^0$  system; (3) The strong phase difference  $\delta_{K\pi}$  is consistent with the SU(3) expectation of zero but large values are not excluded; (4) There is no evidence yet for  $CP$ -violation in  $D^0\bar{D}^0$  mixing. Observing  $CP$ -violation in mixing at the current level of sensitivity would indicate new physics.

$$|m_{D_1^0} - m_{D_2^0}| = x \Gamma$$

The  $D_1^0$  and  $D_2^0$  are the mass eigenstates of the  $D^0$  meson, as described in the note on " $D^0$ - $\bar{D}^0$  Mixing," above. The experiments usually present  $x \equiv \Delta m/\Gamma$ . Then  $\Delta m = x \Gamma = x \hbar/\tau$ .

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group, see the note on " $D^0$ - $\bar{D}^0$  Mixing."

<sup>1</sup> DEL-AMO-SANCHEZ 10b uses 540,800 ± 800  $K_S^0 \pi^+ \pi^-$  and 79,900 ± 300  $K_S^0 K^+ K^-$  events in a time-dependent amplitude analysis of the  $D^0$  and  $\bar{D}^0$  Dalitz plots. No evidence was found for CP violation, and the values here assume no such violation.

<sup>2</sup> The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+} \pi^-$  and  $\bar{D}^0 \rightarrow K^{*+} \pi^-$ . This value allows CP violation and is sensitive to the sign of  $\Delta m$ .

<sup>3</sup> The AUBERT 09AN values are inferred from the branching ratio  $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0 \text{ via } \bar{D}^0)/\Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$  given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between  $D^0 \rightarrow K^+ \pi^- \pi^0$  and  $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$  is assumed to be small. The width difference here is  $y''$ , which is not the same as  $y_{CP}$  in the note on  $D^0$ - $\bar{D}^0$  mixing.

<sup>4</sup> LOWREY 09 uses quantum correlations in  $e^+e^- \rightarrow D^0 \bar{D}^0$  at the  $\psi(3770)$ . See below for coherence factors and average relative strong phases for both  $D^0 \rightarrow K^- \pi^+ \pi^0$  and  $D^0 \rightarrow K^- \pi^- 2\pi^+$ . A fit that includes external measurements of charm mixing parameters gets  $\Delta m = (2.34 \pm 0.61) \times 10^{10} \text{ h s}^{-1}$ .

<sup>5</sup> The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. AUBERT 03Z assumes the strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$  amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.

<sup>6</sup> This LINK 05H limit is inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$  is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

<sup>7</sup> This GODANG 00 limit is inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between  $D^0 \rightarrow K^+ \pi^-$  and  $\bar{D}^0 \rightarrow K^+ \pi^-$  is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

<sup>8</sup> AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that  $A_D = A_R = 0$ . See the note on " $D^0$ - $\bar{D}^0$  Mixing," above.

<sup>9</sup> This limit is inferred from  $R_M$  for  $f = K^+ \pi^-$  and  $f = K^+ \pi^- \pi^+ \pi^-$ . See the note on " $D^0$ - $\bar{D}^0$  Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from  $D^0$ - $\bar{D}^0$  mixing.

<sup>10</sup> This limit is inferred from  $R_M$  for  $f = K^+ \ell^- \bar{\nu}_\ell$ . See the note on " $D^0$ - $\bar{D}^0$  Mixing," above.

## Meson Particle Listings

 $D^0$ 

<sup>11</sup> ANJOS 88c assumes that  $y = 0$ . See the note on " $D^0$ - $\bar{D}^0$  Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$$

The  $D_1^0$  and  $D_2^0$  are the mass eigenstates of the  $D^0$  meson, as described in the note on " $D^0$ - $\bar{D}^0$  Mixing," above.

Due to the strong phase difference between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ , we exclude from the average those measurements of  $y'$  that are inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^- \text{ via } \bar{D}^0) / \Gamma(K^+\pi^-)$  given near the end of this  $D^0$  Listings.

Some early results have been omitted. See our 2006 Review (Journal of Physics, G **33** 1 (2006)).

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group, see the note on " $D^0$ - $\bar{D}^0$  Mixing."

- <sup>1</sup> Compared the lifetimes of  $D^0$  decay to the  $CP$  eigenstate  $K^+K^-$  with  $D^0$  decay to  $\pi^+K^-$ . The values here assume no  $CP$  violation.
- <sup>2</sup> DEL-AMO-SANCHEZ 10D uses 540,800 ± 800  $K_S^0\pi^+\pi^-$  and 79,900 ± 300  $K_S^0K^+K^-$  events in a time-dependent amplitude analyses of the  $D^0$  and  $\bar{D}^0$  Dalitz plots. No evidence was found for  $CP$  violation, and the values here assume no such violation.
- <sup>3</sup> This combines the  $y_{CP} = (\tau_{K^+\pi^-}/\tau_{K^+K^-}) - 1$  using untagged  $K^-\pi^+$  and  $K^+K^+$  events of AUBERT 09A1 with the disjoint  $y_{CP}$  using tagged  $K^-\pi^+$ ,  $K^-K^+$ , and  $\pi^-\pi^+$  events of AUBERT 08U.
- <sup>4</sup> ZUPANC 09 uses a method based on measuring the mean decay time of  $D^0 \rightarrow K_S^0K^+K^-$  events for different  $K^+K^-$  mass intervals.
- <sup>5</sup> STARIC 07 compares the lifetimes of  $D^0$  decay to the  $CP$  eigenstates  $K^+K^-$  and  $\pi^+\pi^-$  with  $D^0$  decay to  $K^-\pi^+$ .
- <sup>6</sup> The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0\pi^+\pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+}\pi^-$  and  $\bar{D}^0 \rightarrow K^{*+}\pi^-$ . This limit allows  $CP$  violation.
- <sup>7</sup> LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between  $D^0 \rightarrow K^-K^+$  ( $CP$ even) decays and  $D^0 \rightarrow K^-\pi^+$  ( $CP$ mixed) decays, or  $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .
- <sup>8</sup> CSORNA 02 measures the lifetime difference between  $D^0 \rightarrow K^-K^+$  and  $\pi^-\pi^+$  ( $CP$ even) decays and  $D^0 \rightarrow K^-\pi^+$  ( $CP$ mixed) decays, or  $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .
- <sup>9</sup> The AUBERT 09AN values are inferred from the branching ratio  $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0 \text{ via } \bar{D}^0) / \Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$  given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between  $D^0 \rightarrow K^+\pi^-\pi^0$  and  $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$  is assumed to be small. The width difference here is  $y''$ , which is not the same as  $y_{CP}$  in the note on  $D^0$ - $\bar{D}^0$  mixing.
- <sup>10</sup> LOWREY 09 uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ . See below for coherence factors and average relative strong phases for both  $D^0 \rightarrow K^-\pi^+\pi^0$  and  $D^0 \rightarrow K^-\pi^-2\pi^+$ . A fit that includes external measurements of charm mixing parameters gets  $2y = (1.62 \pm 0.32) \times 10^{-2}$ .

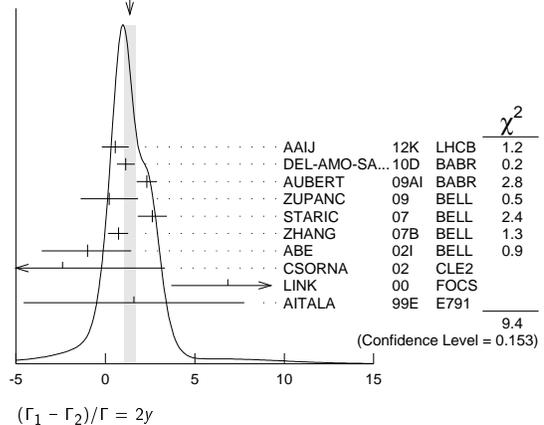

<sup>11</sup> The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07W, and AALTONEN 08E limits are inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^- \text{ (via } \bar{D}^0)) / \Gamma(K^-\pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07W and AALTONEN 08E also allow  $CP$  violation. The phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  is assumed to be small. This is a measurement of  $y'$  and is not the same as the  $y_{CP}$  of our note above on " $D^0$ - $\bar{D}^0$  Mixing."

<sup>12</sup> This value combines the results of AUBERT 08U and AUBERT 03P.

<sup>13</sup> The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.

<sup>14</sup> AUBERT 03P measures  $Y \equiv 2\tau^0 / (\tau^+ + \tau^-) - 1$ , where  $\tau^0$  is the  $D^0 \rightarrow K^-\pi^+$  (and  $\bar{D}^0 \rightarrow K^+\pi^-$ ) lifetime, and  $\tau^+$  and  $\tau^-$  are the  $D^0$  and  $\bar{D}^0$  lifetimes to  $CP$ -even states (here  $K^-K^+$  and  $\pi^-\pi^+$ ). In the limit of  $CP$  conservation,  $Y = y \equiv \Delta\Gamma / 2\Gamma$  (we list  $2y = \Delta\Gamma/\Gamma$ ). AUBERT 03P also uses  $\tau^+ - \tau^-$  to get  $\Delta Y = -0.008 \pm 0.006 \pm 0.002$ .

WEIGHTED AVERAGE  
1.36 ± 0.33 (Error scaled by 1.3)

 $|q/p|$ 

The mass eigenstates  $D_1^0$  and  $D_2^0$  are related to the  $C = \pm 1$  states by  $|D_{1,2}^0\rangle = p|D^0\rangle + q|\bar{D}^0\rangle$ . See the note on " $D^0$ - $\bar{D}^0$  Mixing" above.

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group. This would include as-yet-unpublished results, see the note on " $D^0$ - $\bar{D}^0$  Mixing."

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.88 ± 0.16</b>			<b>OUR EVALUATION</b> HFAG fit; see the note on " $D^0$ - $\bar{D}^0$ Mixing."
<b>0.86 ± 0.30 ± 0.10</b>	1 ZHANG	07B BELL	$e^+e^- \approx \Upsilon(4S)$
<b>-0.29 ± 0.08</b>			

<sup>1</sup> The phase of  $p/q$  is  $(-14 \pm 16 \pm 5)^\circ$ . The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0\pi^+\pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^{*+}\pi^-$  and  $\bar{D}^0 \rightarrow K^{*+}\pi^-$ . This value allows  $CP$  violation.

 $A_\Gamma$ 

$A_\Gamma$  is the decay-rate asymmetry for  $CP$ -even final states  $A_\Gamma = (\bar{\tau}_+ - \tau_+) / (\bar{\tau}_+ + \tau_+)$ . See the note on " $D^0$ - $\bar{D}^0$  Mixing" above.

 $D^0$  DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

**CONSTRAINED FIT INFORMATION**

An overall fit to 3 branching ratios uses 3 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.0$  for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

<sup>1</sup> The event samples in this AUBERT 07Bg result include radiative photons. The  $D^0 \rightarrow K^- e^+ \nu_e$  form factor at  $q^2 = 0$  is  $f_+(0) = 0.727 \pm 0.007 \pm 0.005 \pm 0.007$ .

<sup>2</sup> BEAN 93c uses  $K^- \mu^+ \nu_\mu$  as well as  $K^- e^+ \nu_e$  events and makes a small phase-space adjustment to the number of the  $\mu^+$  events to use them as  $e^+$  events. A pole mass of  $2.00 \pm 0.12 \pm 0.18$  GeV/ $c^2$  is obtained from the  $q^2$  dependence of the decay rate.

<sup>3</sup> CRAWFORD 91B uses  $K^- e^+ \nu_e$  and  $K^- \mu^+ \nu_\mu$  candidates to measure a pole mass of  $2.1_{-0.2}^{+0.4+0.3}$  GeV/ $c^2$  from the  $q^2$  dependence of the decay rate.

<sup>4</sup> ANJOS 89F measures a pole mass of  $2.1_{-0.2}^{+0.4} \pm 0.2$  GeV/ $c^2$  from the  $q^2$  dependence of the decay rate.

4.3 ± 1.0	130	<sup>9</sup> PERUZZI	77	LGW $e^+ e^-$ 3.77 GeV

<sup>1</sup> DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

<sup>2</sup> This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

<sup>3</sup> ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97c use  $D^*(2010)^+ \rightarrow D^0 \pi^+$  decays. The  $\pi^+$  is both slow and of low  $p_T$  with respect to the event thrust axis or nearest jet ( $\approx D^{*+}$  direction). The excess number of such  $\pi^+$ 's over background gives the number of  $D^*(2010)^+ \rightarrow D^0 \pi^+$  events, and the fraction with  $D^0 \rightarrow K^- \pi^+$  gives the  $D^0 \rightarrow K^- \pi^+$  branching fraction.

<sup>4</sup> ARTUSO 98, following ALBRECHT 94, uses  $D^0$  mesons from  $\bar{B}^0 \rightarrow D^*(2010)^+ X \ell^- \bar{\nu}_\ell$  decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

<sup>5</sup> COAN 98 assumes that  $\Gamma(B \rightarrow \bar{D} X \ell^+ \nu)/\Gamma(B \rightarrow X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$ , the last term accounting for  $\bar{B} \rightarrow D_s^+ K X \ell^- \bar{\nu}$ . COAN 98 is included in the CLEO average in ARTUSO 98.

<sup>6</sup> ALBRECHT 94 uses  $D^0$  mesons from  $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$  decays. This is a different set of events than used by ALBRECHT 94F.

<sup>7</sup> This AKERIB 93 value includes radiative corrections; without them, the value is  $0.0391 \pm 0.0008 \pm 0.0017$ . AKERIB 93 is included in the CLEO average in ARTUSO 98.

<sup>8</sup> SCHINDLER 81 (MARK-2) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.24 \pm 0.02$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.

<sup>9</sup> PERUZZI 77 (MARK-1) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.25 \pm 0.05$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.

6.7 <sup>+1.6</sup><sub>-1.7</sub> <sup>1</sup>BARLAG 92c ACCM  $\pi^- Cu$  230 GeV

<sup>1</sup>BARLAG 92c computes the branching fraction using topological normalization.

 $\Gamma(K_S^0 \pi^+ \pi^- \pi^0)/\Gamma(K_S^0 \pi^+ \pi^-)$   $\Gamma_{75}/\Gamma_{34}$ 

Branching fractions for submodes of this mode with narrow resonances (the  $\eta$ ,  $\omega$ ,  $\eta'$ ) are fairly well determined (see below). COFFMAN 92B gives fractions of  $K^*$  and  $\rho$  submodes, but with only 140 ± 28 events above background could not determine them with much accuracy. We omit those measurements here; they are in our 2008 Review (Physics Letters **B667** 1 (2008)).

• • • We do not use the following data for averages, fits, limits, etc. • • •				
<0.026	95	<sup>1</sup> CRONIN-HEN..05	CLEO	$e^+ e^- \approx 10$ GeV

<sup>1</sup>The CRONIN-HENNESSY 05 fit here includes, in addition to the three  $\rho\pi$  charged states, only the  $f_0(980)\pi^0$  mode. See also the next entries for limits obtained in the same way for the  $f_0(500)\pi^0$  mode and for an S-wave  $\pi^+ \pi^-$  parametrized using a K-matrix. Our  $\rho\pi$  branching ratios, given above, use the fit with the K-matrix S wave.

$\Gamma(f_0(500)\pi^0, f_0(500) \rightarrow \pi^+\pi^-)/\Gamma(\pi^+\pi^-\pi^0)$   $\Gamma_{144}/\Gamma_{133}$   
The  $f_0(500)$  is the  $\sigma$ .

<b>&lt;0.001</b>	90	BITENC	05	BELL $e^+ e^- \approx 10.6$ GeV

This is a limit on  $R_M$  without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. The experiments use  $D^{*+} \rightarrow D^0 \pi^+$  (and charge conjugate) decays to identify the charm at production and the charge of the  $e$  to identify the charm at decay. These limits do not allow  $CP$  violation. For the limits on  $|m_1 - m_2|$  and  $(\Gamma_1 - \Gamma_2)/\Gamma$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt;0.001</b>	90	BITENC	05	BELL $e^+ e^- \approx 10.6$ GeV

This is  $R$ , the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " $D^0$ - $\bar{D}^0$  Mixing," near the start of the  $D^0$  Listings.

The experiments here use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0) \pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born. The  $D^0 \rightarrow K^+ \pi^-$  decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by  $D^0 \rightarrow \bar{D}^0$  mixing followed by  $\bar{D}^0 \rightarrow K^+ \pi^-$  decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio  $R_D$ , and the following data block for limits on the mixing ratio  $R_M$ . See the section on  $CP$ -violating asymmetries near the end of this  $D^0$  Listing for values of  $A_D$ , and the note on " $D^0$ - $\bar{D}^0$  Mixing" for limits on  $x'$  and  $y'$ .

Some early limits have been omitted from this Listing; see our 1998 edition (The European Physical Journal **C3** 1 (1998)) and our 2006 edition (Journal of Physics, G **33** 1 (2006)).

This is  $R_D$ , the doubly Cabibbo-suppressed ratio when mixing is allowed.

<sup>1</sup> This AUBERT 07W result is the same whether or not  $CP$  violation is allowed.

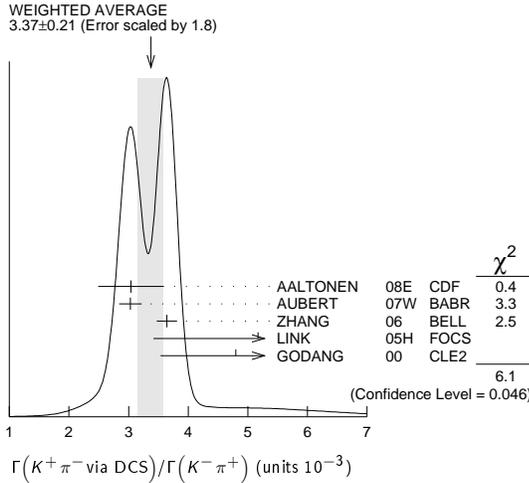

<sup>2</sup> This ZHANG 06 assumes no  $CP$  violation.

<sup>3</sup> This LINK 05H result allows  $CP$  violation. Allowing mixing but not  $CP$  violation,  $R_D = (3.81 \pm 1.67 \pm 0.92) \times 10^{-3}$ .

<sup>4</sup> This GODANG 00 result allows  $CP$  violation.

<sup>5</sup> This AUBERT 03Z result allows  $CP$  violation. If only mixing is allowed, the 95% confidence level interval is  $(2.4 < R_D < 4.9) \times 10^{-3}$ .

<sup>6</sup> This AITALA 98 result assumes no  $CP$  violation.

$\Gamma(K^+\pi^- \text{ via } \bar{D}^0)/\Gamma(K^-\pi^+)$   $\Gamma_{214}/\Gamma_{31}$

This is  $R_M$  in the note on " $D^0-\bar{D}^0$  Mixing" near the start of the  $D^0$  Listings. The experiments here (1) use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on  $|m_1 - m_2|$  and  $(\Gamma_1 - \Gamma_2)/\Gamma$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

- This ZHANG 06 result allows  $CP$  violation, but the result does not change if  $CP$  violation is not allowed.
- This LI 05A result allows  $CP$  violation. The limit becomes  $< 0.00042$  (95% CL) if  $CP$  violation is not allowed.
- LINK 05H obtains the same result whether or not  $CP$  violation is allowed.
- This AUBERT 03Z result allows  $CP$  violation and assumes that the strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  is small, and limits only  $D^0 \rightarrow \bar{D}^0$  transitions via off-shell intermediate states. The limit on transitions via on-shell intermediate states is 0.0016.
- This GODANG 00 result allows  $CP$  violation and assumes that the strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  is small, and limits only  $D^0 \rightarrow \bar{D}^0$  transitions via off-shell intermediate states. The limit on transitions via on-shell intermediate states is 0.0017.
- This BARATE 98W result assumes no interference between the DCS and mixing amplitudes ( $\gamma = 0$  in the note on " $D^0-\bar{D}^0$  Mixing" near the start of the  $D^0$  Listings). When interference is allowed, the limit degrades to 0.036 (95% CL).
- This ANJOS 88c result assumes no interference between the DCS and mixing amplitudes ( $\gamma = 0$  in the note on " $D^0-\bar{D}^0$  Mixing" near the start of the  $D^0$  Listings). When interference is allowed, the limit degrades to 0.019.

$\Gamma(K_S^0\pi^+\pi^- \text{ in } D^0 \rightarrow \bar{D}^0)/\Gamma(K_S^0\pi^+\pi^-)$   $\Gamma_{215}/\Gamma_{34}$

This is  $R_M$  in the note on " $D^0-\bar{D}^0$  Mixing" near the start of the  $D^0$  Listings. The experiments here (1) use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on  $|m_1 - m_2|$  and  $(\Gamma_1 - \Gamma_2)/\Gamma$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<0.0063	95	1	ASNER 05	CLEO $e^+e^- \approx 10$ GeV

- This ASNER 05 limit allows  $CP$  violation. If  $CP$  violation is not allowed, the limit is 0.0042 at 95% CL.

$\Gamma(K^+\pi^-\pi^0)/\Gamma(K^-\pi^+\pi^0)$   $\Gamma_{219}/\Gamma_{49}$

The experiments here use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born. The  $D^0 \rightarrow K^+\pi^-\pi^0$  decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by  $D^0 \rightarrow \bar{D}^0$  mixing followed by  $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$  decay.

<b>5.25 ± 0.25 ± 0.12</b>		AUBERT 09AN	BABR	$e^+e^-$ at 10.58 GeV

- We do not use the following data for averages, fits, limits, etc. •••
- | VALUE | CL% | DOCUMENT ID | TECN         | COMMENT                          |
|-------|-----|-------------|--------------|----------------------------------|
| <0.54 | 95  | 1           | AUBERT,B 06N | BABR $e^+e^- \approx \gamma(4S)$ |

- This AUBERT,B 06N limit assumes no  $CP$  violation. The measured value corresponding to the limit is  $(2.3 \pm 1.8 \pm 0.4) \times 10^{-4}$ . If  $CP$  violation is allowed, this becomes  $(1.0 \pm 2.2 \pm 0.7 \pm 0.3) \times 10^{-4}$ .

$\Gamma(K^+\pi^+2\pi^-)/\Gamma(K^-2\pi^+\pi^-)$   $\Gamma_{221}/\Gamma_{66}$

The experiments here use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born. The  $D^0 \rightarrow K^+\pi^+\pi^-$  decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by  $D^0 \rightarrow \bar{D}^0$  mixing followed by  $\bar{D}^0 \rightarrow K^+\pi^+\pi^-$  decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio; in the next data block we give the limits on the mixing ratio.

Some early limits have been omitted from this Listing; see our 1998 edition (EPJ C3 1).

<18	90	5 ± 12	3	ANJOS 88c	E691 Photoproduction

- AMMAR 91 cannot and DYTMAN 01 and TIAN 05 do not distinguish between doubly Cabibbo-suppressed decay and  $D^0-\bar{D}^0$  mixing.
- This AITALA 98 result assumes no  $D^0-\bar{D}^0$  mixing ( $R_M$  in the note on " $D^0-\bar{D}^0$  Mixing"). It becomes  $-0.0020 \pm 0.0117 \pm 0.0035$  when mixing is allowed and decay-time information is used to distinguish doubly Cabibbo-suppressed decays from mixing.
- ANJOS 88c uses decay-time information to distinguish doubly Cabibbo-suppressed (DCS) decays from  $D^0-\bar{D}^0$  mixing. However, the result assumes no interference between the DCS and mixing amplitudes ( $\gamma = 0$  in the note on " $D^0-\bar{D}^0$  Mixing" near the start of the  $D^0$  Listings). When interference is allowed, the limit degrades to 0.033.

$\Gamma(K^+\pi^+2\pi^- \text{ via } \bar{D}^0)/\Gamma(K^-2\pi^+\pi^-)$   $\Gamma_{222}/\Gamma_{66}$

This is a  $D^0-\bar{D}^0$  mixing limit. The experiments here (1) use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on  $|m_{D_1^0} - m_{D_2^0}|$  and  $(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma_{D^0}$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

VALUE	CL%	EVTS	DOCUMENT ID	TECN	COMMENT
<0.005	90	0 ± 4	1	ANJOS 88c	E691 Photoproduction

- ANJOS 88c uses decay-time information to distinguish doubly Cabibbo-suppressed (DCS) decays from  $D^0-\bar{D}^0$  mixing. However, the result assumes no interference between the DCS and mixing amplitudes ( $\gamma = 0$  in the note on " $D^0-\bar{D}^0$  Mixing" near the start of the  $D^0$  Listings). When interference is allowed, the limit degrades to 0.007.

$\Gamma(K^+\pi^- \text{ or } K^+\pi^+2\pi^- \text{ via } \bar{D}^0)/\Gamma(K^-\pi^+ \text{ or } K^-2\pi^+\pi^-)$   $\Gamma_{223}/\Gamma_0$

This is a  $D^0-\bar{D}^0$  mixing limit. For the limits on  $|m_{D_1^0} - m_{D_2^0}|$  and  $(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma_{D^0}$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••				

<0.0085	90	1	AITALA 98	E791	$\pi^-$ nucleus, 500 GeV
<0.0037	90	2	ANJOS 88c	E691	Photoproduction

- AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from  $D^0-\bar{D}^0$  mixing. The fit allows interference between the two amplitudes, and also allows  $CP$  violation in this term. The central value obtained is  $0.0039 \pm 0.0036 \pm 0.0032 \pm 0.0016$ . When interference is disallowed, the result becomes  $0.0021 \pm 0.0009 \pm 0.0002$ .
- This combines results of ANJOS 88c on  $K^+\pi^-$  and  $K^+\pi^+\pi^-$  (via  $\bar{D}^0$ ) reported in the data block above (see footnotes there). It assumes no interference.

 $D^0$  CP-VIOLATING ASYMMETRY DIFFERENCES
 $\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-)$ 

CP violation in these modes can come from the decay amplitudes (direct) and/or from mixing or interference of mixing and decay (indirect). The difference  $\Delta A_{CP}$  is primarily sensitive to the direct component, and only retains a second-order dependence on the indirect component for measurements where the mean decay time of the  $K^+K^-$  and  $\pi^+\pi^-$  samples are not identical. The results below are averaged assuming the indirect component can be neglected.

-0.86±0.60±0.07	120k	STARIC	08	BELL Time-integrated

<sup>1</sup> Calculated from the AUBERT 08M values of  $A_{CP}(K^+K^-)$  and  $A_{CP}(\pi^+\pi^-)$ . The systematic error here combines the systematic errors in quadrature, and therefore somewhat over-estimates it.

 $D^0, \bar{D}^0$  T-VIOLATING DECAY-RATE ASYMMETRIES

$D^0$  and  $\bar{D}^0$  are distinguished by the charge of the parent  $D^*$ :  $D^{*+} \rightarrow D^0\pi^+$  and  $D^{*-} \rightarrow \bar{D}^0\pi^-$ . Assuming CPT is good, T violation implies CP violation.

 $A_{Tviol}(K^+K^-\pi^+\pi^-)$  in  $D^0, \bar{D}^0 \rightarrow K^+K^-\pi^+\pi^-$ 

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a T-odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta (evaluated in the  $D^0$  rest frame) for the  $D^0$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $\bar{D}^0$ .

 $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ 

would, in the absence of strong phases, test for T violation in  $D^0$  decays (the  $\Gamma$ 's are partial widths). With

 $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ ,

the asymmetry  $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$  tests for T violation even with nonzero strong phases.

 $D^0$  CPT-VIOLATING DECAY-RATE ASYMMETRIES
 $A_{CPT}(K^{\mp}\pi^{\pm})$  in  $D^0 \rightarrow K^-\pi^+, \bar{D}^0 \rightarrow K^+\pi^-$ 

$A_{CPT}(t)$  is defined in terms of the time-dependent decay probabilities  $P(D^0 \rightarrow K^-\pi^+)$  and  $\bar{P}(\bar{D}^0 \rightarrow K^+\pi^-)$  by  $A_{CPT}(t) = (\bar{P} - P)/(\bar{P} + P)$ . For small mixing parameters  $x \equiv \Delta m/\Gamma$  and  $y \equiv \Delta\Gamma/2\Gamma$  (as is the case), and times  $t$ ,  $A_{CPT}(t)$  reduces to  $[y \operatorname{Re} \xi - x \operatorname{Im} \xi] \Gamma t$ , where  $\xi$  is the CPT-violating parameter.

The following is actually  $y \operatorname{Re} \xi - x \operatorname{Im} \xi$ .

## CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a  $\chi^2 = 0.5$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

### $D_1(2420)^0$ POLARIZATION AMPLITUDE $A_{D_1}$

A polarization amplitude  $A_{D_1}$  is a parameter that depends on the initial polarization of the  $D_1$  and is sensitive to a possible S-wave contribution to its decay. For  $D_1$  decays the helicity angle,  $\theta_h$ , distribution varies like  $1 + A_{D_1} \cos^2\theta_h$ , where  $\theta_h$  is the angle in the  $D^*$  rest frame between the two pions emitted by the  $D_1 \rightarrow D^*\pi$  and the  $D^* \rightarrow D\pi$ .

Unpolarized  $D_1$  decaying purely via D-wave is predicted to give  $A_{D_1} = 3$ .

# CHARMED, STRANGE MESONS ( $C = S = \pm 1$ )

$$D_s^+ = c\bar{s}, D_s^- = \bar{c}s, \text{ similarly for } D_s^{* \prime s}$$

## $D_s^\pm$

$$J(P) = 0(0^-)$$

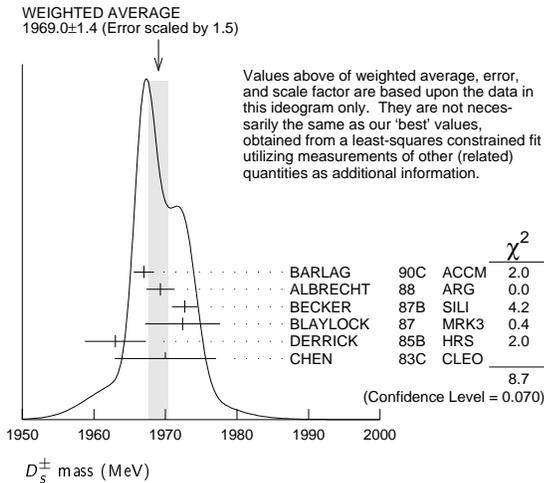

The angular distributions of the decays of the  $\phi$  and  $\bar{K}^*(892)^0$  in the  $\phi\pi^+$  and  $K^+\bar{K}^*(892)^0$  modes strongly indicate that the spin is zero. The parity given is that expected of a  $c\bar{s}$  ground state.

### $D_s^\pm$ MASS

The fit includes  $D_s^\pm, D^0, D_s^{*\pm}, D^{*0}, D_s^{* \prime \pm}, D_1(2420)^0, D_2^*(2460)^0$ , and  $D_{s1}(2536)^\pm$  mass and mass difference measurements. Measurements of the  $D_s^\pm$  mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

[a] This is the purely  $e^+$  semileptonic branching fraction: the  $e^+$  fraction from  $\tau^+$  decays has been subtracted off. The sum of our (non- $\tau$ )  $e^+$  exclusive fractions — an  $e^+ \nu_e$  with an  $\eta, \eta', \phi, K^0, K^{*0}$ , or  $f_0(980)$  — is  $7.0 \pm 0.4$  %

[b] This fraction includes  $\eta$  from  $\eta'$  decays.

[c] Two times (to include  $\mu$  decays) the  $\eta' e^+ \nu_e$  branching fraction, plus the  $\eta' \pi^+, \eta' \rho^+$ , and  $\eta' K^+$  fractions, is  $(18.6 \pm 2.3)$ %, which considerably exceeds the inclusive  $\eta'$  fraction of  $(11.7 \pm 1.8)$ %. Our best guess is that the  $\eta' \rho^+$  fraction,  $(12.5 \pm 2.2)$ %, is too large.

[d] This branching fraction includes all the decay modes of the final-state resonance.

[e] A test for  $u\bar{u}$  or  $d\bar{d}$  content in the  $D_s^+$ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and  $\omega-\phi$  mixing is an unlikely explanation for any fraction above about  $2 \times 10^{-4}$ .

[f] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[g] We decouple the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the  $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$  branching fraction obtained from the Dalitz-plot analysis of  $D_s^+ \rightarrow K^+ K^- \pi^+$ . That is, the ratio of these two branching fractions is not exactly the  $\phi \rightarrow K^+ K^-$  branching fraction 0.491.

[h] This is the average of a model-independent and a  $K$ -matrix parametrization of the  $\pi^+ \pi^-$   $S$ -wave and is a sum over several  $f_0$  mesons.

[i] This mode is not a useful test for a  $\Delta C=1$  weak neutral current because both quarks must change flavor in this decay.

[j] This is *not* a test for the  $\Delta C=1$  weak neutral current, but leads to the  $\pi^+ \ell^+ \ell^-$  final state.

See key on page 457

## CONSTRAINED FIT INFORMATION

An overall fit to 16 branching ratios uses 17 measurements and one constraint to determine 12 parameters. The overall fit has a  $\chi^2 = 2.4$  for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

 $D_s^+$  BRANCHING FRACTIONS

Written April 2010 by J.L. Rosner (University of Chicago) and C.G. Wohl (LBNL).

More than a dozen papers on the  $D_s^+$ , most of them from the CLEO experiment, have been published since the 2008 Review. We now know enough to attempt an overview of the branching fractions. Figure 1 shows a partial breakdown of the fractions. The rest of this note is about how the figure was constructed. The values shown make heavy use of CLEO measurements of inclusive branching fractions [1]. For other data and references cited in the following, see the Listings.

**Modes with leptons:** The bottom  $(20.0 \pm 0.9)\%$  of Fig. 1 shows the fractions for the exclusive modes that include leptons. Measured  $e^+\nu_e$  fractions have been doubled to get the semileptonic  $\ell^+\nu$  fractions. The sum of the exclusive  $e^+\nu_e$  fractions is  $(6.9 \pm 0.4)\%$ , consistent with an inclusive semileptonic  $e^+\nu_e$  measurement of  $(6.5 \pm 0.4)\%$ . There seems to be little missing here.

**Inclusive hadronic  $K\bar{K}$  fractions:** The Cabibbo-favored  $c \rightarrow s$  decay in  $D_s^+$  decay produces a final state with both an  $s$  and an  $\bar{s}$ ; and thus decay modes with a  $K\bar{K}$  pair or with an  $\eta$ ,  $\omega$ ,  $\eta'$ , or  $\phi$  predominate (see, for example, in Fig. 1 the fractions with leptons). We consider the  $K\bar{K}$  modes first. A complete picture of the exclusive  $K\bar{K}$  charge modes is not yet possible, because branching fractions for more than half of those modes have yet to be measured. However, CLEO has measured the inclusive  $K^+$ ,  $K^-$ ,  $K_S^0$ ,  $K^+K^-$ ,  $K^+K_S^0$ ,  $K^-K_S^0$ , and  $2K_S^0$  fractions (which include modes with leptons) [1]. And each of these inclusive fractions  $f$  with a  $K_S^0$  is equal to the corresponding fraction with a  $K_L^0$ :  $f(K^+K_L^0) = f(K^+K_S^0)$ ,  $f(2K_L^0) = f(2K_S^0)$ , etc. Therefore, of all inclusive fractions pairing a  $K^+$ ,  $K_S^0$ , or  $K_L^0$  with a  $K^-$ ,  $K_S^0$ , or  $K_L^0$ , we know all but  $f(K_S^0K_L^0)$ .

**Figure :** A partial breakdown of  $D_s^+$  branching fractions. Shading indicates parts of bins allotted to as-yet unmeasured exclusive modes. The inclusive hadronic  $\phi$  fraction is spread over three bins. See the text for further explanations.

We can get that fraction. The total  $K_S^0$  fraction is

$$f(K_S^0) = f(K^+K_S^0) + f(K^-K_S^0) + 2f(2K_S^0) + f(K_S^0K_L^0) + f(\text{single } K_S^0),$$

where  $f(\text{single } K_S^0)$  is the sum of the branching fractions for modes such as  $K_S^0\pi^+2\pi^0$  with a  $K_S^0$  and no second  $K$ . The  $K_S^0\pi^+2\pi^0$  mode is in fact the only unmeasured single- $K_S^0$  mode (throughout, we shall assume that fractions for modes with a  $K$  or  $K\bar{K}$  and more than three pions are negligible), and we shall take its fraction to be the same as for the  $K_S^02\pi^+\pi^-$  mode,  $(0.29 \pm 0.11)\%$ . Any reasonable deviation from this value would be too small to matter much in the following. Adding the several small single- $K_S^0$  branching fractions, including those from semileptonic modes, we get  $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$ .

## Meson Particle Listings

 $D_s^\pm$ 

Using this, we have:

$$\begin{aligned} f(K_S^0 K_L^0) &= f(K_S^0) - f(K^+ K_S^0) - f(K^- K_S^0) - 2f(2K_S^0) \\ &\quad - f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \\ &\quad - 2 \times (1.70 \pm 0.32) - (1.67 \pm 0.26) \\ &= (6.2 \pm 1.4)\% . \end{aligned}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors will be secondary.

There is a check on our result: The  $\phi$  inclusive branching fraction is  $(15.7 \pm 1.0)\%$ , of which 34%, or  $(5.34 \pm 0.34)\%$  of  $D_s^\pm$  decays, produces a  $K_S^0 K_L^0$ . Our  $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$  has to be at least this large—and it is.

We now make a table. The first column gives the various particle pairings; here we use  $f(K^+ \bar{K}^0) = 2f(K^+ K_S^0)$ , and likewise for  $f(K^- K^0)$ . The second column gives the inclusive branching fractions; the third column gives the fractions for  $K^+ K^-$  and  $K_S^0 K_L^0$  from  $\phi \ell^+ \nu$  decay; the last column subtracts these off to get the purely hadronic  $K\bar{K}$  inclusive fractions.

$K^+ K^-$	15.8 (0.7)%	2.44 (0.14)%	13.4 (0.7)%
$K^+ \bar{K}^0$	11.6 (1.0)		11.6 (1.0)
$K^- K^0$	3.8 (0.8)		3.8 (0.8)
$K_S^0 K_S^0 + K_L^0 K_L^0$	3.4 (0.64)		3.4 (0.64)
$K_S^0 K_L^0$	6.2 (1.4)	1.69 (0.10)	4.5 (1.4) .

The values in the last column are shown in Fig. 1. Their sum is  $(36.7 \pm 2.1)\%$ .

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

$K^+ K^-$  modes—The sum of measured  $K^+ K^- \pi^+$ ,  $K^+ K^- \pi^+ \pi^0$ , and  $K^+ K^- 2\pi^+ \pi^-$  branching fractions is  $(12.0 \pm 0.6)\%$ . That leaves  $(1.4 \pm 0.9)\%$  for the  $K^+ K^- \pi^+ 2\pi^0$  mode, which is the only other  $K^+ K^-$  mode with three or fewer pions. In Fig. 1, this unmeasured part of the  $K^+ K^-$  bin is shaded.

$K^+ \bar{K}^0$  modes—Twice the sum of measured  $K^+ K_S^0$  and  $K^+ K_S^0 \pi^+ \pi^-$  branching fractions is  $(4.9 \pm 0.3)\%$ . This leaves  $(6.7 \pm 1.0)\%$  for the unmeasured  $K^+ \bar{K}^0$  modes (there are four such modes with three or fewer pions). This is shaded in the figure.

$K^- K^0$  modes—Twice the  $K^- K_S^0 2\pi^+$  fraction is  $(3.28 \pm 0.24)\%$ , which leaves about  $(0.5 \pm 0.8)\%$  for  $K^- K^0 2\pi^+ \pi^0$ , the only other  $K^- K^0$  mode with three or fewer pions.

$K^0 \bar{K}^0$  modes—The only measurement of  $K^0 \bar{K}^0$  decays is of the  $2K_S^0 2\pi^+ \pi^-$  fraction,  $(0.084 \pm 0.035)\%$ ; so nearly everything is shaded here. However, most of the  $K_S^0 K_L^0$  fraction is accounted for by  $\phi$  decays (see below).

**Inclusive hadronic  $\eta$ ,  $\omega$ ,  $\eta'$ , and  $\phi$  fractions:** These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2)  $\eta$  mesons that are included in the inclusive  $\eta'$  fraction; and (3)  $K^+ K^-$  and  $K_S^0 K_L^0$  from  $\phi$  decays:

$$\begin{aligned} f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 f(\eta' \text{ inclusive}) \\ &\quad - f(\eta \ell^+ \nu) = (17.0 \pm 3.1)\% \end{aligned}$$

$$\begin{aligned} f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.03 f(\eta' \text{ inclusive}) \\ &= (5.7 \pm 1.4)\% \end{aligned}$$

$$\begin{aligned} f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\ &= (9.7 \pm 1.9)\% \end{aligned}$$

$$\begin{aligned} f(\phi \text{ hadronic, } \not\rightarrow K\bar{K}) &= 0.17 [f(\phi \text{ inclusive}) \\ &\quad - f(\phi \ell^+ \nu)] = (1.8 \pm 0.2)\% . \end{aligned}$$

The factors 0.65, 0.03, and 0.17 are the  $\eta' \rightarrow \eta$ ,  $\eta' \rightarrow \omega$ , and  $\phi \not\rightarrow K\bar{K}$  branching fractions. Figure 1 shows the results; the sum is  $(34.2 \pm 3.9)\%$ , which is about equal to the hadronic  $K\bar{K}$  total.

Note that the bin marked  $\phi$  near the top of Fig. 1 includes neither the  $\phi \ell^+ \nu$  decays nor the 83% of other  $\phi$  decays that produce a  $K\bar{K}$  pair. Compared to the size of that  $\phi$  bin, there is twice as much  $\phi$  in the  $K_S^0 K_L^0$  bin, and nearly three times as much in the  $K^+ K^-$  bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

$\eta$  modes—The sum of  $\eta \pi^+$ ,  $\eta \rho^+$ , and  $\eta K^+$  branching fractions is  $(10.6 \pm 0.8)\%$ , which leaves a good part of the inclusive hadronic  $\eta$  fraction,  $(17.0 \pm 3.1)\%$ , to be accounted for. This is shaded in the figure.

$\omega$  modes—The sum of  $\omega \pi^+$ ,  $\omega \pi^+ \pi^0$ , and  $\omega 2\pi^+ \pi^-$  fractions is  $(4.6 \pm 0.9)\%$ , which is nearly as large as the inclusive hadronic  $\omega$  fraction,  $(5.7 \pm 1.4)\%$ .

$\eta'$  modes—The sum of  $\eta' \pi^+$ ,  $\eta' \rho^+$ , and  $\eta' K^+$  fractions is  $(16.5 \pm 2.2)\%$ , which is much larger than the inclusive hadronic  $\eta'$  fraction,  $(9.7 \pm 1.9)\%$ . If an exclusive measurement is at fault, it almost has to be the  $\eta' \rho^+$  fraction, which is  $(12.5 \pm 2.2)\%$ . It has been suggested that some of this signal might instead be misidentified kinematic reflections of other modes [2].

**Cabibbo-suppressed modes:** Remaining is  $(9.1 \pm 4.5)\%$  for hadronic Cabibbo-suppressed modes having no  $\eta$ ,  $\omega$ ,  $\eta'$ , or  $\phi$ . The contributions are:

$K^0 + \text{pions}$ —Above, we found that  $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$ ; subtracting leptonic contributions leaves  $(1.20 \pm 0.24)\%$ . The hadronic single- $K^0$  fraction is twice this,  $(2.40 \pm 0.48)\%$ .

$K^+ + \text{pions}$ —The  $K^+ \pi^0$  and  $K^+ \pi^+ \pi^-$  fractions sum to  $(0.77 \pm 0.05)\%$ . Much of the  $K^+ n\pi$  modes, where  $n \geq 3$ , is already in the  $\eta$ ,  $\omega$ , and  $\eta'$  bins, and the rest is not measured. The total  $K^+$  fraction wanted here is probably in the 1-to-2% range.

$\text{Multi-pions}$ —The  $2\pi^+ \pi^-$ ,  $\pi^+ 2\pi^0$ , and  $3\pi^+ 2\pi^-$  fractions total  $(2.6 \pm 0.2)\%$ . Modes not measured might double this.

The sum of the three contributions is certainly not inconsistent with the Cabibbo-suppressed total of  $(9.1 \pm 4.5)\%$ . The sum of actually measured fractions is  $(4.2 \pm 0.2)\%$ .

**A model:** With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a “statistical isospin” model [2]. Consider, say, the  $D_s^+ \rightarrow K\bar{K}\pi$  charge modes: the  $K^+K^-\pi^+$  branching fraction is measured, the  $K^+\bar{K}^0\pi^0$  and  $K^0\bar{K}^0\pi^+$  fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for  $D_s^+ \rightarrow K\bar{K}\pi$  decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that  $D_s^+ \rightarrow K\bar{K}\pi$  decay is dominated by  $\phi\pi^+$ ,  $K^+\bar{K}^{*0}$ , and  $K^{*+}\bar{K}^0$  submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of  $D_s^+$  decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of  $\pi^+$ ,  $K_S^0$ , etc., were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

$D_s^\pm$

## DECAY CONSTANTS OF CHARGED PSEUDO-SCALAR MESONS

Revised February 2012 by J. Rosner (Univ. Chicago) and S. Stone (Syracuse Univ.)

**Introduction:** Charged mesons formed from a quark and an antiquark can decay to a charged lepton pair when these objects annihilate via a virtual  $W$  boson [1]. Fig. 1 illustrates this process for the purely leptonic decay of a  $D^+$  meson.

**Figure 1:** The annihilation process for pure  $D^+$  leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual  $W^+$  to the  $\ell^+\nu$  final states occur for the  $\pi^+$ ,  $K^+$ ,  $D_s^+$ , and  $B^+$  mesons. (Charge-conjugate particles and decays are implied.) Let  $P$  be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \rightarrow \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2}\right)^2 |V_{q_1 q_2}|^2. \quad (1)$$

Here  $M_P$  is the  $P$  mass,  $m_\ell$  is the  $\ell$  mass,  $V_{q_1 q_2}$  is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks  $q_1 \bar{q}_2$  in  $P$ , and  $G_F$  is the Fermi coupling constant. The parameter  $f_P$  is the decay constant, and is related to the wave-function overlap of the quark and antiquark.

The decay  $P^\pm$  starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the  $\ell^\pm$  must then also be left-handed or right-handed, respectively. In the  $m_\ell = 0$  limit, the decay is forbidden, and can only occur as a result of the finite  $\ell$  mass. This helicity suppression is the origin of the  $m_\ell^2$  dependence of the decay width.

There is a complication in measuring purely leptonic decay rates. The process  $P \rightarrow \ell\nu\gamma$  is not simply a radiative correction, although radiative corrections contribute. The  $P$  can make a transition to a virtual  $P^*$ , emitting a real photon, and the  $P^*$  decays into  $\ell\nu$ , avoiding helicity suppression. The importance of this amplitude depends on the decaying particle and the detection technique. The  $\ell\nu\gamma$  rate for a heavy particle such as  $B$  decaying into a light particle such as a muon can be larger than the width without photon emission [2]. On the other hand, for decays into a  $\tau^\pm$ , the helicity suppression is mostly broken and these effects appear to be small.

Measurements of purely leptonic decay branching fractions and lifetimes allow an experimental determination of the product  $|V_{q_1 q_2}| f_P$ . If the CKM element is well known from other

measurements, then  $f_P$  can be well measured. If, on the other hand, the CKM element is not well measured, having theoretical input on  $f_P$  can allow a determination of the CKM element. The importance of measuring  $\Gamma(P \rightarrow \ell\nu)$  depends on the particle being considered. For example, the measurement of  $\Gamma(B^- \rightarrow \tau^- \bar{\nu})$  provides an indirect determination of  $|V_{ub}|$  provided that  $f_B$  is provided by theory. In addition,  $f_B$  is crucial for using measurements of  $B^0$ - $\bar{B}^0$  mixing to extract information on the fundamental CKM parameters. Knowledge of  $f_{B_s}$  is also needed, but it cannot be directly measured as the  $B_s$  is neutral, so the violation of the SU(3) relation  $f_{B_s} = f_B$  must be estimated theoretically. This difficulty does not occur for  $D$  mesons as both the  $D^+$  and  $D_s^+$  are charged, allowing the direct measurement of SU(3) breaking and a direct comparison with theory.

For  $B^-$  and  $D_s^+$  decays, the existence of a charged Higgs boson (or any other charged object beyond the Standard Model) would modify the decay rates; however, this would not necessarily be true for the  $D^+$  [3,4]. More generally, the ratio of  $\tau\nu$  to  $\mu\nu$  decays can serve as one probe of lepton universality [3,5].

As  $|V_{ud}|$  has been quite accurately measured in super-allowed  $\beta$  decays [6], with a value of 0.97425(22) [7], measurements of  $\Gamma(\pi^+ \rightarrow \mu^+\nu)$  yield a value for  $f_\pi$ . Similarly,  $|V_{us}|$  has been well measured in semileptonic kaon decays, so a value for  $f_K$  from  $\Gamma(K^- \rightarrow \mu^-\bar{\nu})$  can be compared to theoretical calculations. Lattice gauge theory calculations, however, have been claimed to be very accurate in determining  $f_K$ , and these have been used to predict  $|V_{us}|$  [8].

**$D^+$  and  $D_s^+$  decay constants:** We review current measurements, starting with the charm system. The CLEO collaboration has performed the only measurement of the branching fraction for  $D^+ \rightarrow \mu^+\nu$  [9]. CLEO uses  $e^+e^-$  collisions at the  $\psi(3770)$  resonant energy where  $D^-D^+$  pairs are copiously produced. They fully reconstruct one of the  $D$ 's, find a candidate muon track of opposite sign to the tag, and then use kinematical constraints to infer the existence of a missing neutrino and hence the  $\mu\nu$  decay of the other  $D$ . They find  $\mathcal{B}(D^+ \rightarrow \mu^+\nu) = (3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$ . We use the well-measured  $D^+$  lifetime of 1.040(7) ps, and assuming  $|V_{cd}|$  equals  $|V_{us}| = 0.2246(12)$  [7] minus higher order correction terms [10], we find  $|V_{cd}| = 0.2245(12)$ . The CLEO branching fraction result then translates into a value of

$$f_{D^+} = (206.7 \pm 8.5 \pm 2.5) \text{ MeV}.$$

This result includes a 1% correction (lowering) of the rate due to the presence of the radiative  $\mu^+\nu\gamma$  final state based on the estimate by Dobrescu and Kronfeld [11].

Before we compare this result with theoretical predictions, we discuss the  $D_s^+$ . Measurements of  $f_{D_s^+}$  have been made by several groups and are listed in Table 1 [12–16]. We exclude older values obtained by normalizing to  $D_s^+$  decay modes that are not well defined. Many measurements, for example, used

the  $\phi\pi^+$  mode. This decay is a subset of the  $D_s^+ \rightarrow K^+K^-\pi^+$  channel which has interferences from other modes populating the  $K^+K^-$  mass region near the  $\phi$ , the most prominent of which is the  $f_0(980)$ . Thus the extraction of effective  $\phi\pi^+$  rate is sensitive to the mass resolution of the experiment and the cuts used to define the  $\phi$  mass region [17,18]. The CLEO, BaBar, and Belle  $\mu^+\nu$  results rely on fully reconstructing all the final-state particles except for the neutrino and using a missing-mass technique to infer the existence of the neutrino. CLEO uses  $e^+e^- \rightarrow D_s D_s^*$  collisions at 4170 MeV, while Babar and Belle use  $e^+e^- \rightarrow DKn\pi D_s^*$  collisions at energies near the  $\Upsilon(4S)$ .

**Table 1:** Experimental results for  $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$ ,  $\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)$ , and  $f_{D_s^+}$ . Numbers for  $f_{D_s^+}$  have been extracted using updated values for masses and  $|V_{cs}|$  (see text). Radiative corrections and systematic uncertainties for errors on the  $D_s^+$  lifetime and mass have been included. Common systematic errors in the CLEO results have been taken into account.

Experiment	Mode	$\mathcal{B}(\%)$	$f_{D_s^+}$ (MeV)
CLEO-c [12]	$\mu^+\nu$	$0.565 \pm 0.045 \pm 0.017$	$257.6 \pm 10.3 \pm 4.3$
BaBar [16]	$\mu^+\nu$	$0.602 \pm 0.038 \pm 0.034$	$265.9 \pm 8.4 \pm 7.7$
Belle [13]	$\mu^+\nu$	$0.638 \pm 0.076 \pm 0.057$	$274 \pm 16 \pm 12$
Average	$\mu^+\nu$	$0.589 \pm 0.033$	$263.0 \pm 7.3$
CLEO-c [12]	$\tau^+\nu$ ( $\pi^+\bar{\nu}$ )	$6.42 \pm 0.81 \pm 0.18$	$278.0 \pm 17.5 \pm 4.4$
CLEO-c [14]	$\tau^+\nu$ ( $\rho^+\bar{\nu}$ )	$5.52 \pm 0.57 \pm 0.21$	$257.8 \pm 13.3 \pm 5.2$
CLEO-c [15]	$\tau^+\nu$ ( $e^+\nu\bar{\nu}$ )	$5.30 \pm 0.47 \pm 0.22$	$252.6 \pm 11.1 \pm 5.2$
BaBar [16]	$\tau^+\nu$ ( $e^+/\mu^+\nu\bar{\nu}$ )	$5.00 \pm 0.35 \pm 0.49$	$245.4 \pm 8.6 \pm 12.2$
Average	$\tau^+\nu$	$5.43 \pm 0.31$	$255.7 \pm 7.2$

When selecting the  $\tau^+ \rightarrow \pi^+\bar{\nu}$  and  $\tau^+ \rightarrow \rho^+\bar{\nu}$  decay modes, CLEO uses both calculation of the missing-mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged  $D_s^-$  and the  $\tau^+$  decay products. The  $\tau^+ \rightarrow e^+\nu\bar{\nu}$  mode, however, uses only no extra energy. BaBar measures  $\Gamma(D_s^+ \rightarrow \tau^+\nu)/\Gamma(D_s^+ \rightarrow \bar{K}^0 K^+)$  using the  $\tau^+ \rightarrow e^+\nu\bar{\nu}$  mode.

We extract the decay constant from the measured branching ratios using the  $D_s^+$  mass of 1.96847(33) GeV, the  $\tau^+$  mass of 1.77682(16) GeV, and a lifetime of 0.500(7) ps. We use the first-order correction  $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$  [10]; taking  $|V_{ud}| = 0.97425(22)$  [6], and  $|V_{cb}| = 0.04$  from an average of exclusive and inclusive semileptonic  $B$  decay results as discussed in Ref. [19], we find  $|V_{cs}| = 0.97345(22)$ . CLEO has included the radiative correction of 1% in the  $\mu^+\nu$  rate listed in the Table [11] (the  $\tau^+\nu$  rates need not be corrected). Other theoretical calculations show that the  $\mu^+\nu\gamma$  rate is a factor of 40–100 below the  $\mu^+\nu$  rate for charm [20]. As this is a small effect we do not attempt to correct the other measurements.

The average decay constant cannot simply be obtained by averaging the values in Table 1 since there are correlated errors between the  $\mu^+\nu$  and  $\tau^+\nu$  values. Table 2 gives the average values of  $f_{D_s}$  where the experiments have included the correlations.

**Table 2:** Experimental results for  $f_{D_s^+}$  taking into account the common systematic errors in the  $\mu^+\nu$  and  $\tau^+\nu$  measurements.

Experiment	$f_{D_s^+}$ (MeV)
CLEO-c	$259.0 \pm 6.2 \pm 3.0$
BaBar	$258.8 \pm 6.4 \pm 7.5$
Belle	$273.8 \pm 16.3 \pm 12.2$
Average of $\mu^+\nu + \tau^+\nu$	$260.0 \pm 5.4$

Our experimental average is

$$f_{D_s^+} = (260.0 \pm 5.4) \text{ MeV.}$$

Furthermore, the ratio of branching fractions is found to be

$$R \equiv \frac{\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)}{\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)} = 9.2 \pm 0.7,$$

where a value of 9.76 is predicted in the Standard Model. Assuming lepton universality then we can derive improved values for the leptonic decay branching fractions of

$$\mathcal{B}(D_s^+ \rightarrow \mu^+\nu) = (5.75 \pm 0.24) \times 10^{-3}, \quad \text{and}$$

$$\mathcal{B}(D_s^+ \rightarrow \tau^+\nu) = (5.61 \pm 0.24) \times 10^{-2}.$$

The experimentally determined ratio of decay constants is  $f_{D_s^+}/f_{D^+} = 1.26 \pm 0.06$ .

Table 3 compares the experimental  $f_{D_s^+}$  with theoretical calculations [21–27]. While most theories give values lower than the  $f_{D_s^+}$  measurement, the errors are sufficiently large, in most cases, to declare success.

Upper limits on  $f_{D^+}$  and  $f_{D_s}$  of 230 and 270 MeV, respectively, have been determined using two-point correlation functions by Khodjamirian [28]. Both the  $D^+$  and  $D_s^+$  values are safely below this limit.

Akeroyd and Chen [29] pointed out that leptonic decay widths are modified in two-Higgs-doublet models (2HDM). Specifically, for the  $D^+$  and  $D_s^+$ , Eq. (1) is modified by a factor  $r_q$  multiplying the right-hand side [30]:

$$r_q = \left[ 1 + \left( \frac{1}{m_c + m_q} \right) \left( \frac{M_{D_q}}{M_{H^+}} \right)^2 \left( m_c - \frac{m_q \tan^2 \beta}{1 + \epsilon_0 \tan \beta} \right) \right]^2,$$

## Meson Particle Listings

 $D_s^\pm$ 

**Table 3:** Theoretical predictions of  $f_{D_s^+}$ ,  $f_{D^+}$ , and  $f_{D_s^+}/f_{D^+}$ . Quenched lattice calculations are omitted, while PQL indicates a partially-quenched lattice calculation. (Only selected results having errors are included.)

Model	$f_{D_s^+}$ (MeV)	$f_{D^+}$ (MeV)	$f_{D_s^+}/f_{D^+}$
Experiment (our averages)	$260.0 \pm 5.4$	$206.7 \pm 8.9$	$1.26 \pm 0.06$
Lattice (HPQCD) [21]	$248.0 \pm 2.5$	$213 \pm 4$	$1.164 \pm 0.018$
Lattice (FNAL+MILC) [22]	$260.1 \pm 10.8$	$218.9 \pm 11.3$	$1.188 \pm 0.025$
PQL [23]	$244 \pm 8$	$197 \pm 9$	$1.24 \pm 0.03$
QCD sum rules [24]	$205 \pm 22$	$177 \pm 21$	$1.16 \pm 0.01 \pm 0.03$
QCD sum rules [25]	$245.3 \pm 15.7 \pm 4.5$	$206.2 \pm 7.3 \pm 5.1$	$1.193 \pm 0.025 \pm 0.007$
Field correlators [26]	$260 \pm 10$	$210 \pm 10$	$1.24 \pm 0.03$
Light front [27]	$268.3 \pm 19.1$	206 (fixed)	$1.30 \pm 0.04$

where  $m_{H^+}$  is the charged Higgs mass,  $M_{D_q}$  is the mass of the  $D$  meson (containing the light quark  $q$ ),  $m_c$  is the charm quark mass,  $m_q$  is the light-quark mass, and  $\tan\beta$  is the ratio of the vacuum expectation values of the two Higgs doublets. In models where the fermion mass arises from coupling to more than one vacuum expectation value  $\epsilon_0$  can be non-zero, perhaps as large as 0.01. For the  $D^+$ ,  $m_d \ll m_c$ , and the change due to the  $H^+$  is very small. For the  $D_s^+$ , however, the effect can be substantial.

A major concern is the need for the Standard Model (SM) value of  $f_{D_s^+}$ . We can take that from a theoretical model. Our most aggressive choice is that of the unquenched lattice calculation [21], because it claims the smallest error. Since the charged Higgs would lower the rate compared to the SM, in principle, experiment gives a lower limit on the charged Higgs mass. However, the value for the predicted decay constant using this model is 2.0 standard deviations *below* the measurement. If this small discrepancy is to be taken seriously, either (a) the model of Ref. [21] is not representative; (b) no value of  $m_{H^+}$  in the two-Higgs doublet model will satisfy the constraint at 99% confidence level; or (c) there is new physics, different from the 2HDM, that interferes constructively with the SM amplitude such as in the R-parity-violating model of Akeroyd and Recksiegel [31].

To sum up, the situation is not clear. To set limits on new physics we need an independent calculation of  $f_{D_s}$  with comparable accuracy, and more precise measurements would also be useful.

**The  $B^+$  decay constant:** The Belle and BaBar collaborations have found evidence for  $B^- \rightarrow \tau^- \bar{\nu}$  decay in  $e^+e^- \rightarrow B^- B^+$  collisions at the  $\Upsilon(4S)$  energy. The analysis relies on reconstructing a hadronic or semi-leptonic  $B$  decay tag, finding a  $\tau$  candidate in the remaining track and or photon candidates, and examining the extra energy in the event which should be close to zero for a real  $\tau^-$  decay to  $e^- \bar{\nu}$  or  $\mu^- \bar{\nu}$  opposite a  $B^+$  tag. The results are listed in Table 4.

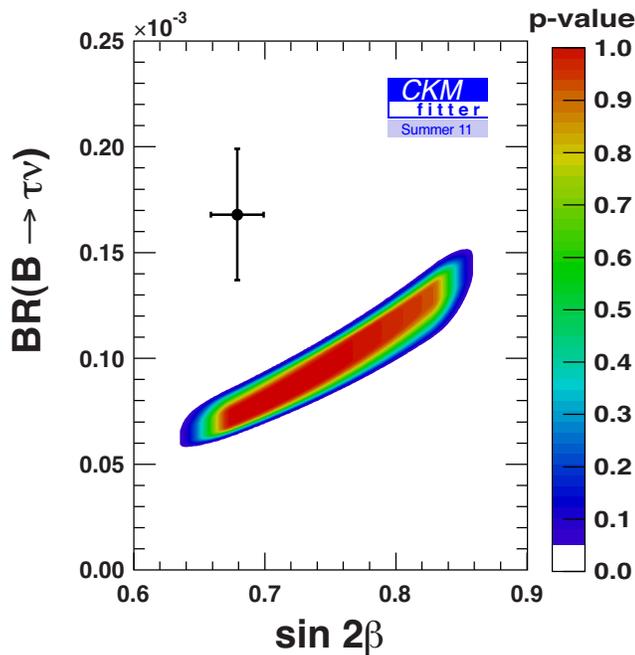

**Table 4:** Experimental results for  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ . We have computed an average for the two Belle measurements assuming that the systematic errors are fully correlated.

Experiment	Tag	$\mathcal{B}$ (units of $10^{-4}$ )
Belle [32]	Hadronic	$1.79_{-0.49-0.51}^{+0.56+0.46}$
Belle [33]	Semileptonic	$1.54_{-0.37-0.31}^{+0.38+0.29}$
Belle	Our average	$1.62 \pm 0.40$
BaBar [34]	Hadronic	$1.80_{-0.54}^{+0.57} \pm 0.26$
BaBar [35]	Semileptonic	$1.7 \pm 0.8 \pm 0.2$
BaBar	Average [34]	$1.76 \pm 0.49$
	Our average	$1.68 \pm 0.31$

There are large backgrounds under the signals in all cases. The systematic errors are also quite large, on the order of 20%. Thus, the significance of the signals is not that large. Belle quotes  $3.5\sigma$  and  $3.6\sigma$  for their hadronic and semileptonic tags, while BaBar quotes  $3.3\sigma$  and  $2.3\sigma$  for these tags. We note that the four central values are remarkably close to the average considering the large errors on all the measurements. More accuracy would be useful to investigate the effects of new physics.

We extract a SM value using Eq. (1). Here theory provides a value of  $f_B = (194 \pm 9)$  MeV [36]. We also need a value for  $|V_{ub}|$ . Here significant differences arise between using inclusive charmless semileptonic decays and the exclusive decay  $B \rightarrow \pi \ell^+ \nu$  [37]. The inclusive decays give rise to a value of  $|V_{ub}| = (4.27 \pm 0.38) \times 10^{-3}$  while the exclusive measurements yield  $|V_{ub}| = (3.38 \pm 0.36) \times 10^{-3}$ , where the errors are dominantly theoretical [38]. Their average, enlarging the error in the standard manner because the results differ, is  $|V_{ub}| = (3.80 \pm 0.44) \times 10^{-3}$ . Using these values and the PDG values for the  $B^+$  mass and lifetime, we arrive at the SM prediction for the  $\tau^- \bar{\nu}$  branching fraction of  $(0.96 \pm 0.24) \times 10^{-4}$ . This value is about

a factor of two smaller than the measurements. There is a 6.6% probability that the data and the SM prediction are consistent. This difference is more clearly seen by examining the correlation between the CKM angle  $\beta$  and  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ . The CKM fitter group provides a fit to a large number of measurements involving heavy quark transitions [39]. The point in Fig. 2 shows the directly measured values, while the predictions from their fit without the direct measurements are also shown. There is about a factor of two discrepancy between the measured value of  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$  and the fit prediction.

**Figure 2:** Measured and predicted values of  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$  versus  $\sin 2\beta$  from the CKM fitter group [39]. The point with error bars shows the measured values, while the predictions are in shaded contours, with the shading related to the confidence level.

**$\pi^+$  and  $K^+$  decay constants:** The sum of branching fractions for  $\pi^- \rightarrow \mu^- \bar{\nu}$  and  $\pi^- \rightarrow \mu^- \bar{\nu} \gamma$  is 99.98770(4)%. The two modes are difficult to separate experimentally, so we use this sum, with Eq. (1) modified to include photon emission and radiative corrections [40]. The branching fraction together with the lifetime 26.033(5) ns gives

$$f_{\pi^-} = (130.41 \pm 0.03 \pm 0.20) \text{ MeV} .$$

The first error is due to the error on  $|V_{ud}|$ , 0.97425(22) [6]; the second is due to the higher-order corrections, and is much larger.

Similarly, the sum of branching fractions for  $K^- \rightarrow \mu^- \bar{\nu}$  and  $K^- \rightarrow \mu^- \bar{\nu} \gamma$  is 63.55(11)%, and the lifetime is 12.3840(193) ns [41]. Measurements of semileptonic kaon decays provide a

value for the product  $f_+(0)|V_{us}|$ , where  $f_+(0)$  is the form-factor at zero four-momentum transfer between the initial state kaon and the final state pion. We use a value for  $f_+(0)|V_{us}|$  of 0.21664(48) [41]. The  $f_+(0)$  must be determined theoretically. We follow Blucher and Marciano [7] in using the lattice calculation  $f_+(0) = 0.9644 \pm 0.0049$  [42], since it appears to be more precise than the classic Leutwyler-Rooos calculation  $f_+(0) = 0.961 \pm 0.008$  [43]. [Other recent averages are  $0.956 \pm 0.008$  [49] and  $0.9588 \pm 0.0044$  [44].] Using the value from Ref. [42], the result is  $|V_{us}| = 0.2246 \pm 0.0012$ , consistent with the hyperon decay value of  $0.2250 \pm 0.0027$  [45]. We derive

$$f_{K^-} = (156.1 \pm 0.2 \pm 0.8 \pm 0.2) \text{ MeV} .$$

The first error is due to the error on  $\Gamma$ ; the second is due to the CKM factor  $|V_{us}|$ , and the third is due to the higher-order corrections. The largest source of error in these corrections depends on the QCD part, which is based on one calculation in the large  $N_c$  framework. We have doubled the quoted error here; this would probably be unnecessary if other calculations were to come to similar conclusions. A large part of the additional uncertainty vanishes in the ratio of the  $K^-$  and  $\pi^-$  decay constants, which is

$$f_{K^-}/f_{\pi^-} = 1.197 \pm 0.002 \pm 0.006 \pm 0.001 .$$

The first error is due to the measured decay rates; the second is due to the uncertainties on the CKM factors; the third is due to the uncertainties in the radiative correction ratio.

These measurements have been used in conjunction with calculations of  $f_K/f_\pi$  in order to find a value for  $|V_{us}|/|V_{ud}|$ . Three recent lattice predictions of  $f_K/f_\pi$  are  $1.189 \pm 0.007$  [46],  $1.192 \pm 0.007 \pm 0.006$  [47], and  $1.197 \pm 0.002^{+0.003}_{-0.007}$  [48], yielding an average by the FLAG group of  $1.195 \pm 0.005$  [49]. (A new average  $1.1872 \pm 0.0041$  is quoted with statistical errors only [50]). Together with the precisely measured  $|V_{ud}|$ , this gives an independent measure of  $|V_{us}|$  [8,41].

$7.4 \pm 2.8 \pm 2.4$	16	<sup>17</sup> ACCIARRI 97f	L3	$D_s^{*+} \rightarrow \gamma D_s^+$ from Z's	

<sup>12</sup> DEL-AMO-SANCHEZ 10j uses  $\mu^+ \nu_\mu$  and  $\tau^+ \nu_\tau$  events together to get  $f_{D_s} = (258.6 \pm 6.4 \pm 7.5)$  MeV.

<sup>13</sup> ALEXANDER 09, NAIK 09A, and ONYISI 09 use different  $\tau$  decay modes and are independent. The three papers combined give  $f_{D_s} = (259.7 \pm 7.8 \pm 3.4)$  MeV.

<sup>14</sup> ECKLUND 08 and PEDLAR 07A are independent: ECKLUND 08 uses  $\tau^+ \rightarrow e^+ \nu_e \bar{\nu}_\tau$  events, PEDLAR 07A uses  $\tau^+ \rightarrow \pi^+ \bar{\nu}_\tau$  events.

<sup>15</sup> HEISTER 02i combines its  $D_s^+ \rightarrow \tau^+ \nu_\tau$  and  $\mu^+ \nu_\mu$  branching fractions to get  $f_{D_s} = (285 \pm 19 \pm 40)$  MeV.

<sup>16</sup> This ABBIENDI 01L value gives a decay constant  $f_{D_s}$  of  $(286 \pm 44 \pm 41)$  MeV.

<sup>17</sup> The second ACCIARRI 97f error here combines in quadrature systematic (0.016) and normalization (0.018) errors. The branching fraction gives  $f_{D_s} = (309 \pm 58 \pm 33 \pm 38)$  MeV.

24 ALEXANDER 08 uses single- and double-tagged events in an overall fit. The correlation matrix for the branching fractions is used in the fit.					

$\Gamma(\phi\pi^+)/\Gamma_{\text{total}}$					$\Gamma_{33}/\Gamma$
The results here are model-independent. For earlier, model-dependent results, see our PDG 06 edition. We decouple the $D_s^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+K^-\pi^+$ . That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+K^-$ branching fraction 0.491.					
VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN	COMMENT	
<b>4.5 ± 0.4 OUR AVERAGE</b>					
4.62±0.36±0.51		25 AUBERT 06N	BABR	$e^+e^-$ at $\gamma(4S)$

3.59±0.77±0.48		27 ARTUSO 96	CLE2	$e^+e^-$ at $\gamma(4S)$	
••• We do not use the following data for averages, fits, limits, etc. •••					
3.9	+5.1 +1.8 -1.9 -1.1	28 BAI	95c BES	$e^+e^-$ 4.03 GeV	

25 This AUBERT 06N measurement uses $\bar{B}^0 \rightarrow D_s^{(*)-}D^{(*)+}$ and $B^- \rightarrow D_s^{(*)-}D^{(*)0}$ decays, including some from other papers. However, the result is independent of AUBERT 05v.					
26 AUBERT 05v uses the ratio of $B^0 \rightarrow D^{*-}D_s^{*+}$ events seen in two different ways, in both of which the $D^{*-} \rightarrow \bar{D}^0\pi^-$ decay is fully reconstructed: (1) The $D_s^{*+} \rightarrow D_s^+\gamma$ , $D_s^+ \rightarrow \phi\pi^+$ decay is fully reconstructed. (2) The number of events in the $D_s^+$ peak in the missing mass spectrum against the $D^{*-}\gamma$ is measured.					
27 ARTUSO 96 uses partially reconstructed $\bar{B}^0 \rightarrow D^{*+}D_s^{*-}$ decays to get a model-independent value for $\Gamma(D_s^- \rightarrow \phi\pi^-)/\Gamma(D^0 \rightarrow K^-\pi^+)$ of $0.92 \pm 0.20 \pm 0.11$ .					
28 BAI 95c uses $e^+e^- \rightarrow D_s^+D_s^-$ events in which one or both of the $D_s^\pm$ are observed to obtain the first model-independent measurement of the $D_s^+ \rightarrow \phi\pi^+$ branching fraction, without assumptions about $\sigma(D_s^\pm)$ . However, with only two “doubly-tagged” events, the statistical error is very large.					

$\Gamma(\phi\pi^+, \phi \rightarrow K^+K^-)/\Gamma(K^+K^-\pi^+)$					$\Gamma_{34}/\Gamma_{32}$
This is the “fit fraction” from the Dalitz-plot analysis. We decouple the $D_s^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+K^-\pi^+$ . That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+K^-$ branching fraction 0.491.

$\Gamma(\pi^+ (\pi^+ \pi^-)_{S\text{-wave}})/\Gamma(2\pi^+ \pi^-)$				$\Gamma_{57}/\Gamma_{55}$
This is the "fit fraction" from the Dalitz-plot analysis. See also KLEMP 08, which uses 568 $D^+ \rightarrow 3\pi$ decays (over 280 background events) from FNAL E791 to study various parametrizations of the decay amplitudes. The emphasis there is more on S-wave $\pi\pi$ decay products — 20 different solutions are given — than on $D_S^+$ fit fractions.				
VALUE	DOCUMENT ID	TECN	COMMENT	
$0.833 \pm 0.020$ OUR AVERAGE

$0.8704 \pm 0.0560 \pm 0.0438$	33	LINK	04	FOCS Dalitz fit, 1475 ± 50 evts

<sup>32</sup>AUBERT 09o gives the amplitude and phase of the  $\pi^+ \pi^-$  S-wave in 29  $\pi^+ \pi^-$  invariant-mass bins.

<sup>33</sup>LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full  $\pi\pi$  S-wave isoscalar scattering amplitude to describe the  $\pi^+ \pi^-$  S-wave component of the  $\pi^+ \pi^+ \pi^-$  state. The fit fraction given above is a sum over five  $f_0$  mesons, the  $f_0(980)$ ,  $f_0(1300)$ ,  $f_0(1200-1600)$ ,  $f_0(1500)$ , and  $f_0(1750)$ . See LINK 04 for details and discussion.

$\Gamma(f_0(980) \pi^+, f_0 \rightarrow \pi^+ \pi^-)/\Gamma(2\pi^+ \pi^-)$				$\Gamma_{58}/\Gamma_{55}$
This is the "fit fraction" from the Dalitz-plot analysis. See above for the full $\pi^+ (\pi^+ \pi^-)_{S\text{-wave}}$ fit fraction.

<sup>41</sup> To compare with previous measurements, this AUBERT 08AN value is from a fit that fixes the pole masses at  $m_A = 2.5$  GeV/ $c^2$  and  $m_V = 2.1$  GeV/ $c^2$ . A simultaneous fit to  $r_2, r_V, r_0$  (a significant  $s$ -wave contribution) and  $m_A$ , gives  $r_V = 1.849 \pm 0.060 \pm 0.095$ .

 $\Gamma_L/\Gamma_T$  in  $D_s^+ \rightarrow \phi\ell^+\nu_\ell$

$D_s^{*+}$  DECAY MODES

$D_s^{*-}$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1 D_s^+ \gamma$	(94.2 ± 0.7) %
$\Gamma_2 D_s^+ \pi^0$	(5.8 ± 0.7) %

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a  $\chi^2 = 0.0$  for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{total}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$x_2 \begin{matrix} | & -100 \\ \hline & x_1 \end{matrix}$$

$\Gamma_7$ $D_s^+ \pi^0 \pi^0$		
$\Gamma_8$ $D_s^+ \gamma \gamma$		

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 8 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 3.4$  for 4 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

SUN	09	PR D80 074037	Z.-F. Sun, X. Lin
-----	----	---------------	-------------------

**BOTTOM MESONS**

$$(B = \pm 1)$$

$$B^+ = u\bar{d}, B^0 = d\bar{b}, \bar{B}^0 = \bar{d}b, B^- = \bar{u}b, \text{ similarly for } B^{*s}$$

***B*-particle organization**

Many measurements of *B* decays involve admixtures of *B* hadrons. Previously we arbitrarily included such admixtures in the  $B^\pm$  section, but because of their importance we have created two new sections: “ $B^\pm/B^0$  Admixture” for  $\Upsilon(4S)$  results and “ $B^\pm/B^0/B_s^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and  $\chi_b$  at high energy are found in the Admixture sections.  $B^0$ - $\bar{B}^0$  mixing data are found in the  $B^0$  section, while  $B_s^0$ - $\bar{B}_s^0$  mixing data and  $B$ - $\bar{B}$  mixing data for a  $B^0/B_s^0$  admixture are found in the  $B_s^0$  section. *CP*-violation data are found in the  $B^\pm$ ,  $B^0$ , and  $B^\pm/B^0$  Admixture sections. *b*-baryons are found near the end of the Baryon section. Recently, we also created a new section: “ $V_{cb}$  and  $V_{ub}$  CKM Matrix Elements.”

The organization of the *B* sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

[Production and Decay of *b*-flavored Hadrons]

[A Short Note on HFAG Activities]

- $B^\pm$ 
  - mass, mean life
  - branching fractions
  - polarization in  $B^\pm$  decay
  - CP* violation
- $B^0$ 
  - mass, mean life
  - branching fractions
  - [Polarization in *B* decay]
  - polarization in  $B^0$  decay
  - [ $B$ - $\bar{B}$  Mixing]
  - $B^0$ - $\bar{B}^0$  mixing
  - CP* violation
- $B^\pm/B^0$  Admixture
  - branching fractions, *CP* violation
  - CP* violation
- $B^\pm/B^0/B_s^0/b$ -baryon Admixture
  - mean life
  - production fractions
  - branching fractions
  - $\chi_b$  at high energy

**PRODUCTION AND DECAY OF *b*-FLAVORED HADRONS**

Updated March 2012 by M. Kreps (U. of Warwick, Coventry, UK), J.G. Smith (U. of Colorado, Boulder, USA), and Y. Kwon (Yonsei U., Seoul, Korea).

The *b* quark belongs to the third generation of quarks and is the weak-doublet partner of the *t* quark. The existence of the third-generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix (“CKM” matrix), and confirmed four years later by the first observation of a  $b\bar{b}$  meson [2]. In the KM model, *CP* violation is explained within the Standard Model (SM) by an irreducible phase of the  $3 \times 3$  unitary matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the SM, including the fermion masses, and the elements of the CKM matrix.

Since the *b* quark is the lighter element of the third-generation quark doublet, the decays of *b*-flavored hadrons occur via generation-changing processes through this matrix. Because of this, and the fact that the CKM matrix is close to a  $3 \times 3$  unit matrix, many interesting features such as loop and box diagrams, flavor oscillations, as well as large *CP* asymmetries, can be observed in the weak decays of *b*-flavored hadrons.

The CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of *CP* violation in *B* meson decays. A crucial milestone was the first observation of *CP* violation in the *B* meson system in 2001, by the BaBar [3] and Belle [4] collaborations. They measured a large value for the parameter  $\sin 2\beta$  ( $= \sin 2\phi_1$ ) [5], almost four decades after the discovery of a small *CP* asymmetry in neutral kaons. A more detailed discussion of the CKM matrix and *CP* violation can be found elsewhere in this Review [6,7].

Recent developments in the physics of *b*-hadrons include the observation of direct *CP* violation, results for rare higher-order weak decays, investigations of heavier *b*-hadrons ( $B_s$ ,  $B_c$ , baryons, excited states), measurement of the  $B_s$ -mixing frequency, increasingly accurate determinations of the CKM matrix parameters.

The structure of this mini-review is organized as follows. After a brief description of theory and terminology, we discuss *b*-quark production and current results on spectroscopy

# Meson Particle Listings

## *b*-flavored hadrons

and lifetimes of *b*-flavored hadrons. We then discuss some basic properties of *B*-meson decays, followed by summaries of hadronic, rare, and electroweak penguin decays of *B*-mesons. There are separate mini-reviews for  $B\bar{B}$  mixing [8] and the extraction of the CKM matrix elements  $V_{cb}$  and  $V_{ub}$  from *B*-meson decays [9] in this *Review*.

**Theory and terminology:** The ground states of *b*-flavored hadrons decay via weak interactions. In most hadrons, the *b*-quark is accompanied by light-partner quarks (*d*, *u*, or *s*), and the decay modes are well described by the decay of the *b* quark (spectator model) [10]. The dominant decay mode of a *b* quark is  $b \rightarrow cW^{*-}$  (referred to as a “tree” or “spectator” decay), where the virtual *W* materializes either into a pair of leptons  $\ell\bar{\nu}$  (“semileptonic decay”), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from  $W^*$  to form one of the final state hadrons are suppressed by a factor  $\sim (1/3)^2$ , because the colors of the two quarks from different sources must match (“color-suppression”).

Many aspects of *B* decays can be understood through the Heavy Quark Effective Theory (HQET) [11]. This has been particularly successful for semileptonic decays. For further discussion of HQET, see for instance Ref. 12. For hadronic decays, one typically uses effective Hamiltonian calculations that rely on a perturbative expansion with Wilson coefficients. In addition, some form of the factorization hypothesis is commonly used, where, in analogy with semileptonic decays, two-body hadronic decays of *B* mesons are expressed as the product of two independent hadronic currents, one describing the formation of a charm meson (in case of the dominant  $b \rightarrow cW^{*-}$  decays), and the other the hadronization of the remaining  $\bar{u}d$  (or  $\bar{c}s$ ) system from the virtual  $W^-$ . Qualitatively, for a *B* decay with a large energy release, the  $\bar{u}d$  pair (produced as a color singlet) travels fast enough to leave the interaction region without influencing the charm meson. This is known to work well for the dominant spectator decays [13]. There are several common implementations of these ideas for hadronic *B* decays, the most common of which are QCD factorization (QCDF) [14], perturbative QCD (pQCD) [15], and soft collinear effective theory (SCET) [16].

The transition  $b \rightarrow u$  is suppressed by  $|V_{ub}/V_{cb}|^2 \sim (0.1)^2$  relative to  $b \rightarrow c$  transitions. The transition  $b \rightarrow s$  is a flavor-changing neutral-current (FCNC) process, and although not allowed in the SM as a tree-process, can occur via more complex loop diagrams (denoted “penguin” decays). The rates for such processes are comparable or larger than CKM-suppressed  $b \rightarrow u$  processes. Penguin processes involving  $b \rightarrow d$  transitions are also possible, and have been observed [17,18]. Other decay processes discussed in this *Review* include *W*-exchange (a *W* is exchanged between initial-state quarks), penguin annihilation (the gluon from a penguin loop attaches to the spectator quark, similar to an exchange diagram), and pure-annihilation (the initial quarks annihilate to a virtual *W*, which then decays).

**Production and spectroscopy:** The bound states of a  $\bar{b}$  antiquark and a *u*, *d*, *s*, or *c* quark are referred to as the  $B_u$  ( $B^+$ ),  $B_d$  ( $B^0$ ),  $B_s$ , and  $B_c$  mesons, respectively. The  $B_c$  is the heaviest of the ground-state *b*-flavored mesons, and the most difficult to produce: it was observed for the first time in the semileptonic mode by CDF in 1998 [19], but its mass was accurately determined only in 2006, from the fully reconstructed mode  $B_c^+ \rightarrow J/\psi\pi^+$  [20].

The first excited meson is called the  $B^*$  meson, while  $B^{**}$  is the generic name for the four orbitally excited ( $L = 1$ ) *B*-meson states that correspond to the *P*-wave mesons in the charm system,  $D^{**}$ . Excited states of the  $B_s$  meson are similarly named  $B_s^*$  and  $B_s^{**}$ . Of the possible bound  $\bar{b}b$  states, the  $\Upsilon$  series (S-wave) and the  $\chi_b$  (P-wave) are well studied. The pseudoscalar ground state  $\eta_b$  also has been observed by BaBar [21] (and confirmed by CLEO [22]), indirectly through the decay  $\Upsilon(3S) \rightarrow \gamma\eta_b$ . See Ref. 23 for classification and naming of these and other states.

Experimental studies of *b* decays have been performed in  $e^+e^-$  collisions at the  $\Upsilon(4S)$  (ARGUS, CLEO, Belle, BaBar) and  $\Upsilon(5S)$  (CLEO, Belle) resonances, as well as at higher energies, at the *Z* resonance (SLC, LEP) and in  $p\bar{p}$  collisions (Tevatron). The  $e^+e^- \rightarrow b\bar{b}$  production cross-section at the *Z*,  $\Upsilon(4S)$ , and  $\Upsilon(5S)$  resonances are about 6.6 *nb*, 1.1 *nb*, and 0.3 *nb* respectively. High-energy hadron collisions produce *b*-flavored hadrons of all species with much larger cross-sections:  $\sigma(p\bar{p} \rightarrow bX, |\eta| < 1) \sim 30 \mu\text{b}$  at the Tevatron ( $\sqrt{s} = 1.96 \text{ TeV}$ ), and even higher at the energies of the LHC  $pp$  collider (up to a factor of ten at  $\sqrt{s} = 14 \text{ TeV}$ ).

BaBar and Belle have accumulated respectively 560  $\text{fb}^{-1}$  and 1020  $\text{fb}^{-1}$  of data, of which 433  $\text{fb}^{-1}$  and 710  $\text{fb}^{-1}$  respectively are at the  $\Upsilon(4S)$  resonance; CDF and D0 have currently accumulated about 10  $\text{fb}^{-1}$  each. At the LHC, CMS and ATLAS have collected 5  $\text{fb}^{-1}$  of data and LHCb has collected about 1  $\text{fb}^{-1}$ . These numbers indicate that the majority of *b*-quarks have been produced in hadron collisions, but the large backgrounds cause the hadron collider experiments to have lower selection efficiency. Only the few decay modes for which triggering and reconstruction are easiest have been studied so far in hadron collisions. These have included final states with leptons, and exclusive modes with all charged particles in the final state. In contrast, detectors operating at  $e^+e^-$  colliders (“B-Factories”) have a high efficiency for most decays, and have provided large samples of a rich variety of decays of  $B^0$  and  $B^+$  mesons.

In hadron collisions, most production happens as  $b\bar{b}$  pairs, either via *s*-channel production or gluon-splitting, with a smaller fraction of single *b*-quarks produced by flavor excitation. The total *b*-production cross section is an interesting test of our understanding of QCD processes. For many years, experimental measurements have been several times higher than predictions. With improved measurements [24], more accurate input parameters, and more advanced calculations [25], the discrepancy between theory and data is now much reduced, although the

presence of inconsistencies among existing measurements makes further studies desirable.

Each quark of a  $b\bar{b}$  pair produced in hadron collisions hadronizes separately and incoherently from the other, but it is still possible, although difficult, to obtain a statistical indication of the charge of a produced  $b/\bar{b}$  quark (“flavor tag” or “charge tag”) from the accompanying particles produced in the hadronization process, or from the decay products of the other quark. The momentum spectrum of produced  $b$ -quarks typically peaks near the  $b$ -quark mass, and extends to much higher momenta, dropping by about a decade for every ten GeV. This implies typical decay lengths of the order of a millimeter; the resolution for the decay vertex must be more precise than this to resolve the fast oscillations of  $B_s$  mesons.

In  $e^+e^-$  colliders, since the  $B$  mesons are very slow in the  $\Upsilon(4S)$  rest frame, asymmetric beam energies are used to boost the decay products to improve the precision of time-dependent measurements that are crucial for the study of  $CP$  violation. At KEKB, the boost is  $\beta\gamma = 0.43$ , and the typical  $B$ -meson decay length is dilated from  $\approx 20 \mu\text{m}$  to  $\approx 200 \mu\text{m}$ . PEP-II uses a slightly larger boost,  $\beta\gamma = 0.55$ . The two  $B$  mesons produced in  $\Upsilon(4S)$  decay are in a coherent quantum state, which makes it easier than in hadron collisions to infer the charge state of one  $B$  meson from observation of the other; however, the coherence also requires determination of the decay time of both mesons, rather than just one, in order to perform time-dependent  $CP$ -violation measurements.

For the measurement of branching fractions, the initial composition of the data sample must be known. The  $\Upsilon(4S)$  resonance decays predominantly to  $B^0\bar{B}^0$  and  $B^+B^-$ ; the current experimental upper limit for non- $B\bar{B}$  decays of the  $\Upsilon(4S)$  is less than 4% at the 95% confidence level (CL) [26]. The only known modes of this category are decays to lower  $\Upsilon$  states and a pion pair, observed with branching fractions of order  $10^{-4}$  [27]. The ratio  $f_+/f_0$  of the fractions of charged to neutral  $B$  productions from  $\Upsilon(4S)$  decays has been measured by CLEO, BaBar, and Belle in various ways. They typically use pairs of isospin-related decays of  $B^+$  and  $B^0$ , such that it can be assumed that  $\Gamma(B^+ \rightarrow x^+) = \Gamma(B^0 \rightarrow x^0)$ . In this way, the ratio of the number of events observed in these modes is proportional to  $(f_+\tau_+)/ (f_0\tau_0)$  [28–31]. BaBar has also performed an independent measurement of  $f_0$  with a different method that does not require isospin symmetry or the value of the lifetime ratio, based on the number of events with one or two reconstructed  $B^0 \rightarrow D^{*-}\ell^+\nu$  decays [32]. The combined result, from the current average of  $\tau_+/\tau_0$ , is  $f_+/f_0 = 1.055 \pm 0.025$  [33]. Though the current  $2.2\sigma$  discrepancy with equal production of  $B^+B^-$  and  $B^0\bar{B}^0$  pairs is somewhat larger than previous averages, we still assume  $f_+/f_0 = 1$  in this mini-review except where explicitly stated otherwise. This assumption is also supported by the near equality of the  $B^+$  and  $B^0$  masses: our fit of CLEO, ARGUS, and CDF measurements yields  $m(B^0) = 5279.50 \pm 0.33 \text{ MeV}/c^2$ ,  $m(B^+) = 5279.13 \pm 0.31 \text{ MeV}/c^2$ , and  $m(B^0) - m(B^+) = 0.37 \pm 0.24 \text{ MeV}/c^2$ . The latest measurement

from the LHCb agrees well with those and further improves precision [34].

CLEO and Belle have also collected some data at the  $\Upsilon(5S)$  resonance [35,36]. Belle has accumulated more than  $100 \text{ fb}^{-1}$  at this resonance. This resonance does not provide the simple final states of the  $\Upsilon(4S)$ : there are seven possible final states with a pair of non-strange  $B$  mesons and three with a pair of strange  $B$  mesons ( $B_s^*\bar{B}_s^*$ ,  $B_s^*\bar{B}_s$ , and  $B_s\bar{B}_s^*$ ). The fraction of events with a pair of  $B_s$  mesons over the total number of events with a pair of  $b$ -flavored hadrons has been measured to be  $f_s[\Upsilon(5S)] = 0.199 \pm 0.030$ , of which 90% is  $B_s^*\bar{B}_s^*$  events. A few branching fractions of the  $B_s$  have been measured in this way; if the precision of  $f_s$  were improved, they would become the most accurate. Belle has observed a few new  $B_s$  modes that are difficult to reconstruct in hadron colliders and the most precise mass measurement of the  $B_s^*$  meson has been obtained [36,37]. However, the small boost of  $B_s$  mesons produced in this way prevents resolution of their fast oscillations for time-dependent measurements; these are only accessible in hadron collisions or at the  $Z$  peak.

In high-energy collisions, the produced  $b$  or  $\bar{b}$  quarks can hadronize with different probabilities into the full spectrum of  $b$ -hadrons, either in their ground or excited states. Table 1 shows the measured fractions  $f_d$ ,  $f_u$ ,  $f_s$ , and  $f_{\text{baryon}}$  of  $B^0$ ,  $B^+$ ,  $B_s^0$ , and  $b$  baryons, respectively, in an unbiased sample of weakly decaying  $b$  hadrons produced at the  $Z$  resonance or in  $p\bar{p}$  collisions [33]. The results were obtained from a fit where the sum of the fractions were constrained to equal 1.0, neglecting production of  $B_c$  mesons. The observed yields of  $B_c$  mesons at the Tevatron [19] yields  $f_c = 0.2\%$ , in agreement with expectations [38], and well below the current experimental uncertainties in the other fractions.

**Table 1:** Fractions of weakly-decaying  $b$ -hadron species in  $Z \rightarrow b\bar{b}$  decay, in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.8 \text{ TeV}$  and combination of fractions in  $Z \rightarrow b\bar{b}$  decay at Tevatron,  $p\bar{p}$  and  $pp$  collisions at LHC.

$b$ hadron	Fraction at Z [%]	Fraction at $p\bar{p}$ [%]	Combined [%]
$B^+, B^0$	$40.3 \pm 0.9$	$33.9 \pm 3.9$	$40.1 \pm 0.8$
$B_s$	$10.3 \pm 0.9$	$11.1 \pm 1.4$	$10.5 \pm 0.6$
$b$ baryons	$9.0 \pm 1.5$	$21.2 \pm 6.9$	$9.3 \pm 1.6$

The combined values assume identical hadronization in  $p\bar{p}$  collisions and in  $Z$  decay. These could in principle differ, because of the different momentum distributions of the  $b$ -quark in these processes; the sample used in the  $p\bar{p}$  measurements has momenta close to the  $b$  mass, rather than  $m_Z/2$ . A test of the agreement between production fractions may be given by comparison of values of the average time-integrated mixing probability parameter  $\bar{\chi} = f_d\chi_d + f_s\chi_s$  [8]. This is an important input in the determination of the world-averages of production fractions. The current measurements of  $\bar{\chi}$  from LEP and the

# Meson Particle Listings

## $b$ -flavored hadrons

Tevatron differ by  $1.8\sigma$  [33]. This slight discrepancy increases the uncertainty in the combined fractions in Table 1. It should be noted that the combination is not well defined as both the CDF and LHCb experiments observe a significant dependence of the  $\Lambda_b$  production fraction on transverse momentum. With the availability of large samples of  $b$ -flavored mesons and baryons at  $p\bar{p}$  colliders, the limited knowledge of these fractions has become an important limiting factor in the determination of their branching fractions.

Excited  $B$ -meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the  $B^*-B$  mass difference is  $45.78 \pm 0.35 \text{ MeV}/c^2$ . Evidence for  $B^{**}$  ( $L=1$ ) production has been initially obtained at LEP [39], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Detailed results from exclusive modes have been obtained at the Tevatron, allowing separation of the narrow states  $B_1$  and  $B_2^*$  and also a measurement of the  $B_2^*$  width [40].

Also the narrow  $B_s^{**}$  states, first sighted by OPAL as a single broad enhancement in the  $B^+K$  mass spectrum [41], have now been clearly observed and separately measured at the Tevatron [42]:  $M(B_{s1}) = 5829.4 \pm 0.7 \text{ MeV}/c^2$  (CDF) and  $M(B_{s2}^*) = 5839.7 \pm 0.7 \text{ MeV}/c^2$  (CDF),  $M(B_{s2}^*) = 5839.6 \pm 1.1 \pm 0.7 \text{ MeV}/c^2$  (D0).

Baryon states containing a  $b$  quark are labeled according to the same scheme used for non- $b$  baryons, with the addition of a  $b$  subscript [23]. For many years, the only well-established  $b$  baryon was the  $\Lambda_b^0$  (quark composition  $udb$ ), with only indirect evidence for  $\Xi_b$  ( $dsb$ ) production from LEP [43]. This situation has changed dramatically in the past few years due to the large samples being accumulated at the Tevatron and LHCb. Clear signals of four strongly-decaying baryon states,  $\Sigma_b^+$ ,  $\Sigma_b^{*+}$  ( $uub$ ),  $\Sigma_b^-$ ,  $\Sigma_b^{*-}$  ( $ddb$ ) have been obtained by CDF in  $\Lambda_b^0\pi^\pm$  final states [44]. The strange bottom baryon  $\Xi_b^\pm$  was observed in the exclusive mode  $\Xi_b^\pm \rightarrow J/\psi\Xi^\pm$  by D0 [45], and CDF [46]. More recently CDF has also observed the  $\Xi_b$  in the  $\Xi_c\pi$  final state [47]. The relative production of  $\Xi_b$  and  $\Lambda_b$  baryons has been found to be consistent with the  $B_s$  to  $B_d$  production ratio [45]. Observation of the doubly-strange bottom baryon  $\Omega_b^-$  has been published by both D0 [48] and CDF [49]. However the masses measured by the two experiments show a large discrepancy. The resolution appears to be provided by LHCb; they recently presented a preliminary measurement of the  $\Omega_b^-$  mass consistent with the CDF measurement [50]. Apart from the discrepancy on  $\Omega_b^-$  mass, the masses of all these new baryons have been measured to a precision of a few  $\text{MeV}/c^2$ , and found to be in agreement with predictions from HQET.

**Lifetimes:** Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in  $CP$  violation, such as the determination of  $V_{cb}$  and  $B_s\bar{B}_s$  mixing parameters. In the naive spectator model, the heavy quark can decay only via the external spectator

mechanism, and thus, the lifetimes of all mesons and baryons containing  $b$  quarks would be equal. Non-spectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for  $b$ -flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as  $1/m_Q^2$ , where  $m_Q$  is the mass of the heavy quark, the variations in the  $b$  system are expected to be only 10% or less [51]. We expect:

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s) > \tau(\Lambda_b^0) \gg \tau(B_c^+) . \quad (1)$$

For the  $B_c^+$ , both quarks decay weakly, so the lifetime is much shorter.

Measurements of the lifetimes of the different  $b$ -flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the  $b$  sector. Over the past decade, the precision of silicon vertex detectors and the increasing availability of fully-reconstructed samples has resulted in much-reduced statistical and systematic uncertainties ( $\sim 1\%$ ). The averaging of precision results from different experiments is a complex task that requires careful treatment of correlated systematic uncertainties; the world averages given in Table 2 have been determined by the Heavy Flavor Averaging Group (HFAG) [33].

**Table 2:** Summary of inclusive and exclusive world-average  $b$ -hadron lifetime measurements. For the two  $B_s$  averages, see text below.

Particle	Lifetime [ps]
$B^+$	$1.641 \pm 0.008$
$B^0$	$1.519 \pm 0.007$
$B_s$ (flavor-specific)	$1.463 \pm 0.032$
$B_s$ ( $1/\Gamma_s$ )	$1.495 \pm 0.015$
$B_c^+$	$0.453 \pm 0.041$
$\Lambda_b^0$	$1.425 \pm 0.032$
$\Xi_b^-$	$1.56^{+0.27}_{-0.25}$
$\Omega_b^-$	$1.13^{+0.53}_{-0.40}$
$\Xi_b$ mixture	$1.49^{+0.19}_{-0.18}$
$b$ -baryon mixture	$1.382 \pm 0.029$
$b$ -hadron mixture	$1.568 \pm 0.009$

The short  $B_c^+$  lifetime is in good agreement with predictions [52]. For precision comparisons with theory, lifetime ratios are more sensitive. Experimentally we find:

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.079 \pm 0.007, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 0.984 \pm 0.011,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.938 \pm 0.022,$$

while theory makes the following predictions [51,53]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 1.00 \pm 0.01, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.88 \pm 0.05.$$

The ratio of  $B^+$  to  $B^0$  lifetimes has a precision of better than 1%, and is significantly different from 1.0, in agreement

with predictions [51]. The ratio of  $B_s$  to  $B^0$  lifetimes is expected to be very close to 1.0; while there used to be mild tension between experiment and theory, the discrepancy is disappearing with newer measurements with large samples of fully reconstructed  $B_s$  decays [54]. The  $\Lambda_b$  lifetime has a history of discrepancies. Predictions were higher than data before the introduction of higher-order effects lowered them. The precision of the measurements has recently been improved by more than a factor of two by two CDF measurements [57,58]. The measurements are in marginal agreement with each other and previous measurements; the new world average is somewhat larger than the theoretical predictions. The most significant discrepancy comes from the CDF measurement in  $\Lambda_b \rightarrow J/\psi \Lambda$  channel which differs by  $3.3\sigma$  from the average of all other measurements. With more data available at both D0 and CDF and large samples available at LHCb, new results will hopefully resolve this discrepancy in the near future.

Neutral  $B$  mesons are two-component systems similar to neutral kaons, with a light (L) and a heavy (H) mass eigenstate, and independent decay widths  $\Gamma_L$  and  $\Gamma_H$ . The SM predicts a non-zero width difference  $\Delta\Gamma = \Gamma_L - \Gamma_H > 0$  for both  $B_s$  and  $B_d$ . For  $B_d$ ,  $\Delta\Gamma_d/\Gamma_d$  is expected to be  $\sim 0.2\%$ . Analysis of BaBar and DELPHI data on  $CP$ -specific modes of the  $B^0$  yield a combined result:  $\Delta\Gamma_d/\Gamma_d = 0.015 \pm 0.018$  [33]. The issue is much more interesting for the  $B_s$ , since the SM expectation for  $\Delta\Gamma_s/\Gamma_s$  is of order 10%. This potentially non-negligible difference requires care when defining the  $B_s$  lifetime. As indicated in Table 2, two different lifetimes are defined for the  $B_s$  meson: one is defined as  $1/\Gamma_s$ , where  $\Gamma_s$  is the average width of the two mass eigenstates  $(\Gamma_L + \Gamma_H)/2$ ; the other is obtained from “flavor-specific” (*e.g.*, semileptonic) decays and depends both on  $\Gamma_s$  and  $\Delta\Gamma_s$ . Experimentally, the quantity  $\Delta\Gamma_s$  can be accessed by measuring lifetimes in decays into  $CP$  eigenstates, which in the standard model are expected to be close approximations to the mass eigenstates. This has been done with the  $J/\psi\phi$  mode, where the two  $CP$  eigenstates are distinguished by angular distributions, and in  $B_s \rightarrow K^+K^-$  or  $B_s \rightarrow J/\psi f_0(980)$  which are  $CP$ -eigenstates. The current experimental information is dominated by measurements on the  $J/\psi\phi$  mode performed by CDF, D0 and LHCb experiments. By appropriately combining all published measurements of  $J/\psi\phi$  lifetimes and flavor-specific lifetimes, the HFAG group obtains a world-average  $\Delta\Gamma_s/\Gamma_s = 0.092^{+0.051}_{-0.054}$  [33], which is compatible with zero; the latest theoretical predictions yield  $\Delta\Gamma_s/\Gamma_s = 0.133 \pm 0.032$  [59], in agreement with measurements within the large uncertainties on both. From the theoretical point of view, the best quantity to use is  $\Delta\Gamma_s/\Delta M_s$ , which is much less affected by hadronic uncertainties [59]. Exploiting the very accurate measurement of  $\Delta M_s$  now available [60], this can be turned into a SM prediction with an uncertainty of only 20%:  $\Delta\Gamma_s/\Gamma_s = 0.137 \pm 0.027$ . This is likely to be of importance in future comparisons, as the experimental precision improves with the growth of Tevatron samples. Further improvements are coming from lifetime measurements in the  $CP$ -eigenstates

such as  $B_s \rightarrow K^+K^-$  [61] and  $B_s \rightarrow J/\psi f_0(980)$  [62], and alternative (model-dependent) determinations via the  $B_s \rightarrow D_s^{(*)+}D_s^{(*)-}$  branching fraction [63].

The width difference  $\Delta\Gamma_s$  is connected to the  $B_s$  mixing phase  $\phi_s$  by  $\Delta\Gamma_s = \Gamma_{12} \cos \phi_s$ , where  $\Gamma_{12}$  is the off-diagonal term of the decay matrix [6,8,59]. The early measurements by CDF [64] and D0 [65] have produced CL contours in the  $(\phi_s, \Delta\Gamma)$  plane, and both observe a mild deviation, in the same direction, from the expectation of the Standard model of the phase  $\phi_s$  near  $\Delta\Gamma = 0$ . The possibility of a large value of  $\phi_s$  has attracted significant interest, as it would be very clean evidence for the existence of new sources of  $CP$  violation beyond the standard model. However the latest measurements from CDF [66], D0 [67] and LHCb [68], which provide significant improvements over initial measurements, show good agreement with the standard model. The LHCb experiment also used the decay  $B_s \rightarrow J/\psi f_0(980)$  to measure  $\phi_s$  [69]. While this measurement is not as precise as the one from  $B_s \rightarrow J/\psi\phi$ , it does not require analysis of angular distributions, which simplifies the analysis. It should be noted that all above measurements have a two-fold ambiguity in their results. We can resolve this ambiguity using the interference between the decays to  $J/\psi\phi$  and  $J/\psi K^+K^-$ , where  $K^+K^-$  is in relative S-wave state. This has been used by LHCb experiment to determine the sign of the  $\Delta\Gamma_s$  to be positive [70].

***B meson decay properties:*** Semileptonic  $B$  decays  $B \rightarrow X_c \ell \nu$  and  $B \rightarrow X_u \ell \nu$  provide an excellent way to measure the magnitude of the CKM elements  $|V_{cb}|$  and  $|V_{ub}|$  respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive and inclusive decays can be used, and the nature of uncertainties are quite complementary. For exclusive decay analysis, knowledge of the form factors for the exclusive hadronic system  $X_{c(u)}$  is required. For inclusive analysis, it is usually necessary to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator-product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of  $B$  semileptonic decays and the extraction of  $|V_{cb}|$  and  $|V_{ub}|$  is given elsewhere in this *Review* [9].

On the other hand, hadronic decays of  $B$  are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects. Pure-penguin decays were first established by the observation of  $B \rightarrow K^* \gamma$  [71]. Some observed decay modes such as  $B^0 \rightarrow D_s^- K^+$ , may be interpreted as evidence of a  $W$ -exchange process [72]. The evidence for the decay  $B^+ \rightarrow \tau^+ \nu$  from Belle [73] and BaBar [74] is the first sign of a pure annihilation decay. There

# Meson Particle Listings

## *b*-flavored hadrons

is growing evidence that penguin annihilation processes may be important in decays with two vector mesons in the final state [75].

**Hadronic decays:** Most of the hadronic  $B$  decays involve  $b \rightarrow c$  transition at the quark level, resulting in a charmed hadron or charmonium in the final state. Other types of hadronic decays are very rare and will be discussed separately in the next section. The experimental results on hadronic  $B$  decays have steadily improved over the past few years, and the measurements have reached sufficient precision to challenge our understanding of the dynamics of these decays. With the good neutral particle detection and hadron identification capabilities of  $B$ -factory detectors, a substantial fraction of hadronic  $B$  decay events can be fully reconstructed. Because of the kinematic constraint of  $\Upsilon(4S)$ , the energy sum of the final-state particles of a  $B$  meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables,  $\Delta E$  (energy difference) and  $M_B$  ( $B$  candidate mass with a beam-energy constraint) are very effective for suppressing combinatorial background both from  $\Upsilon(4S)$  and  $e^+e^- \rightarrow q\bar{q}$  continuum events. In particular, the energy-constraint in  $M_B$  improves the signal resolution by almost an order of magnitude.

The kinematically clean environment of  $B$  meson decays provides an excellent opportunity to search for new states. For instance, quark-level  $b \rightarrow c\bar{c}s$  decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BaBar discovered a new narrow charm-strange state  $D_{sJ}^*(2317)$  [76], and CLEO observed a similar state  $D_{sJ}(2460)$  [77]. The properties of these new states were studied in the  $B$  meson decays,  $B \rightarrow DD_{sJ}^*(2317)$  and  $B \rightarrow DD_{sJ}(2460)$  by Belle [78]. Further studies of  $D_{sJ}^{(*)}$  meson production in  $B$  decays have been made by Belle [79] and BaBar [80]. Now these charm-strange meson states are identified as  $D_{s0}^*(2317)$  and  $D_{s1}(2460)$ , respectively.

More recently, Belle observed a new  $D_{sJ}$  meson produced in  $B^+ \rightarrow \bar{D}^0 D_{sJ} \rightarrow \bar{D}^0 D^0 K^+$  [81]. Combined with a subsequent measurement by BaBar [82], the mass and width of this state are determined to be  $2709_{-6}^{+9}$  MeV/ $c^2$  and  $125 \pm 30$  MeV, respectively. An analysis of the helicity angle distribution determines its spin-parity to be  $1^-$ .

A variety of exotic particles have been discovered in  $B$  decays. Belle found the  $X(3872)$  state [83], which is confirmed by CDF [84] and BaBar [85]. Analyzing their full  $\Upsilon(4S)$  data sample, Belle finds a new upper limit on the width of  $X(3872)$  to be  $\Gamma_{X(3872)} < 1.2$  MeV [86], improving on the existing limit by nearly a factor of 2. Radiative decays of  $X(3872)$  can play a crucial role in understanding the nature of the particle. For example, in the molecular model the decay of  $X(3872)$  to  $\psi'\gamma$  is expected to be highly suppressed in comparison to the decay to  $J/\psi\gamma$  [87]. BaBar has seen the evidence for the decay to  $J/\psi\gamma$  [88]. The ratio  $R \equiv \mathcal{B}(X(3872) \rightarrow \psi'\gamma)/\mathcal{B}(X(3872) \rightarrow J/\psi\gamma)$  is measured to be  $3.4 \pm 1.4$  by BaBar [89], while Belle obtains  $R < 2.1$  at 90% CL [90].

Belle has observed a near-threshold enhancement in the  $J/\psi\omega$  invariant mass for  $B \rightarrow J/\psi\omega K$  decays [91]. BaBar has studied  $B \rightarrow J/\psi\pi^+\pi^-K$ , finding an excess of  $J/\psi\pi^+\pi^-$  events with a mass just above 4.2 GeV/ $c^2$ ; this is consistent with the  $Y(4260)$  that was observed by BaBar in ISR (Initial State Radiation) events [93]. A Belle study of  $B \rightarrow \psi'K\pi^\pm$  [94] finds a state called  $X(4430)^\pm$  that decays to  $\psi'\pi^\pm$ . Since it is charged, it could not be a charmonium state. This state was searched for by BaBar with similar sensitivity but was not found [95]. In a Dalitz plot analysis of  $\bar{B}^0 \rightarrow \chi_{c1}K^-\pi^+$ , Belle has observed two resonance-like structures in the  $\chi_{c1}\pi^+$  mass distribution [96], labelled as  $X(4050)^\pm$  and  $X(4250)^\pm$  in this *Review*, while no evidence is found by BaBar in a search with similar sensitivity [97].

The hadronic decays  $\bar{B}^0 \rightarrow D^{(*)0}h^0$ , where  $h^0$  stands for light neutral mesons such as  $\pi^0, \eta^{(\prime)}, \rho^0, \omega$ , proceed through color-suppressed diagrams, hence they provide useful tests on the factorization models. Both Belle and BaBar have made comprehensive measurements of such color-suppressed hadronic decays of  $\bar{B}^0$  [98].

Information on  $B_s$  and  $\Lambda_b$  decays is limited, though improving with recent studies of large samples at the Tevatron and LHC experiments. Recent additions are decays of  $B_s \rightarrow J/\psi f_0(980)$  [62,99],  $B_s \rightarrow J/\psi f_2'(1525)$  [100], and  $\Lambda_b \rightarrow \Lambda_c\pi^+\pi^-\pi^-$  [101]. For the later, not only the total rate is measured, but also structure involving decays through excited  $\Lambda_c$  and  $\Sigma_c$  baryons.

There have been hundreds of publications on hadronic  $B$  decays to open-charm and charmonium final states mostly from the  $B$ -factory experiments. These results are nicely summarized in a recent report by HFAG [33].

**Rare  $B$  decays:** All  $B$ -meson decays that do not occur through the  $b \rightarrow c$  transition are usually called rare  $B$  decays. These include both semileptonic and hadronic  $b \rightarrow u$  decays that are suppressed at leading order by the small CKM matrix element  $V_{ub}$ , as well as higher-order  $b \rightarrow s(d)$  processes such as electroweak and gluonic penguin decays.

Charmless  $B$  meson decays into two-body hadronic final states such as  $B \rightarrow \pi\pi$  and  $K\pi$  are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct  $CP$  violations. Since the final state particles in these decays tend to have larger momenta than average  $B$  decay products, the event environment is cleaner than for  $b \rightarrow c$  decays. Branching fractions are typically around  $10^{-5}$ . Over the past decade, many such modes have been observed by BaBar, Belle, and CLEO. More recently, comparable samples of the modes with all charged final particles have been reconstructed in  $p\bar{p}$  collisions by CDF by triggering on the impact parameter of the charged tracks. This has also allowed observation of charmless decays of the  $B_s$ , in final states such as  $\phi\phi$  [102],  $K^+K^-$  [103], and  $K^-\pi^+$  [104], and of charmless decays of the  $\Lambda_b^0$  baryon [104]. Charmless  $B_s$  modes are related to corresponding  $B^0$  modes by U-spin symmetry, and are determined

by similar amplitudes. Combining the observables from  $B_s$  and  $B^0$  modes is a further way of eliminating hadronic uncertainties and extracting relevant CKM information [105].

Because of relatively high-momenta for final state particles, the dominant source of background in  $e^+e^-$  collisions is  $q\bar{q}$  continuum events; sophisticated background suppression techniques exploiting event shape variables are essential for these analyses. In hadron collisions, the dominant background comes from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematic and isolation requirements. The results are in general consistent among the experiments.

BaBar [106] and Belle [107] have observed the decays  $B^+ \rightarrow \bar{K}^0 K^+$  and  $B^0 \rightarrow K^0 \bar{K}^0$ . The world-average branching fractions are  $\mathcal{B}(B^0 \rightarrow K^0 \bar{K}^0) = (0.96_{-0.18}^{+0.20}) \times 10^{-6}$  and  $\mathcal{B}(B^+ \rightarrow \bar{K}^0 K^+) = (1.36 \pm 0.27) \times 10^{-6}$ . These are the first observations of hadronic  $b \rightarrow d$  transitions, with significance  $> 5\sigma$  for all four measurements.  $CP$  asymmetries have even been measured for these modes, though with large errors.

Most rare decay modes including  $B^0 \rightarrow K^+ \pi^-$  have contributions from both  $b \rightarrow u$  tree and  $b \rightarrow sg$  penguin processes. If the size of the two contributions are comparable, the interference between them may result in direct  $CP$  violation, seen experimentally as a charge asymmetry in the decay rate measurement. BaBar [108], Belle [109], and CDF [103] have measured the direct  $CP$  violating asymmetry in  $B^0 \rightarrow K^+ \pi^-$  decays. The BaBar and Belle measurements constitute observation of direct  $CP$  violation with a significance of more than  $5\sigma$ . The world average for this quantity is now rather precise,  $-0.098 \pm 0.013$ . There are sum rules [110] that relate the decay rates and decay-rate asymmetries between the four  $K\pi$  charge states. The experimental measurements of the other three modes are not yet precise enough to test these sum rules.

There is now evidence for direct  $CP$  violation in three other decays:  $B^+ \rightarrow \rho^0 K^+$  [111],  $B^+ \rightarrow \eta K^+$  [112], and  $B^0 \rightarrow \eta K^{*0}$  [113]. The significance is typically 3–4 $\sigma$ , though the significance for the  $B^+ \rightarrow \eta K^+$  decay is now nearly  $5\sigma$  with the recent Belle measurement [112]. In at least the first two cases, a large direct  $CP$  violation might be expected since the penguin amplitude is suppressed so the tree and penguin amplitudes may have comparable magnitudes.

The decay  $B^0 \rightarrow \pi^+ \pi^-$  can be used to extract the CKM angle  $\alpha$ . This is complicated by the presence of significant contributions from penguin diagrams. An isospin analysis [114] can be used to untangle the penguin complications. The decay  $B^0 \rightarrow \pi^0 \pi^0$ , which is now measured by both BaBar and Belle, is crucial in this analysis. Unfortunately the amount of penguin pollution in the  $B \rightarrow \pi\pi$  system is rather large. In the past few years, measurements in the  $B^0 \rightarrow \rho\rho$  system have produced more precise values of  $\alpha$ , since penguin amplitudes are generally smaller for decays with vector mesons. An important ingredient in the analysis is the  $B^0 \rightarrow \rho^0 \rho^0$  branching fraction. The average of measurements from BaBar and Belle BaBar [115] yields a branching fraction of  $(0.73 \pm 0.28) \times 10^{-6}$ . This is only 3% of the

$\rho^+ \rho^-$  branching fraction, much smaller than the corresponding ratio in the  $\pi\pi$  system.

The decay  $B \rightarrow a_1 \pi$  has been seen by BaBar. An analysis of the time evolution of this decay [116] together with measurements of other related decays has been used to measure the CKM angle  $\alpha$  [117] in agreement with the more precise measurements from the  $\rho\rho$  system.

Since  $B \rightarrow \rho\rho$  has two vector mesons in the final state, the  $CP$  eigenvalue of the final state depends on the longitudinal polarization fraction  $f_L$  for the decay. Therefore, a measurement of  $f_L$  is needed to extract the CKM angle  $\alpha$ . Both BaBar and Belle have measured  $f_L$  for the decays  $\rho^+ \rho^-$  and  $\rho^+ \rho^0$  and in both cases the measurements show  $f_L > 0.9$ , making a complete angular analysis unnecessary.

By analyzing the angular distributions of the  $B$  decays to two vector mesons, we can learn a lot about both weak- and strong-interaction dynamics in  $B$  decays. Decays that are penguin-dominated surprisingly have values of  $f_L$  near 0.5. The list of such decays has now grown to include  $B \rightarrow \phi K^*$ ,  $B \rightarrow \rho K^*$ , and  $B \rightarrow \omega K^*$ . The reasons for this "polarization puzzle" are not fully understood. A detailed description of the angular analysis of  $B$  decays to two vector mesons can be found in a separate mini-review [118] in this *Review*.

There has been substantial progress in measurements of many other rare- $B$  decays. The decay  $B \rightarrow \eta' K$  stood out as the largest rare- $B$  decay for many years. The reasons for the large rate are now largely understood [14,119]. However, there are now measurements of several 3-body or quasi-3-body modes with similarly large branching fractions. States seen so far include  $K\pi\pi$  (three charge states) [120],  $KKK$  (four charge states) [121], and  $K^* \pi\pi$  (two charged states) [122]. Many of these analyses now include Dalitz plot treatments with many intermediate resonances. There has also been an observation of the decay  $B^+ \rightarrow K^+ K^- \pi^+$  by BaBar [123], noteworthy because an even number of kaons is typically indicative of suppressed  $b \rightarrow d$  transitions as discussed above.

Belle [73] and BaBar [74] have found evidence for  $B^+ \rightarrow \tau^+ \nu$ ; the average branching fraction, with a significance of nearly  $5\sigma$  is  $(165 \pm 34) \times 10^{-6}$ . This is somewhat larger than, though consistent with, the value expected in the SM. This is the first observation of a pure annihilation decay. A substantial region of parameter space of charged Higgs mass vs.  $\tan\beta$  is excluded by the measurements of this mode.

**Electroweak penguin decays:** More than a decade has passed since the CLEO experiment first observed an exclusive radiative  $b \rightarrow s\gamma$  transition,  $B \rightarrow K^*(892)\gamma$  [71], thus providing the first evidence for the one-loop FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BaBar have updated this analysis [124] with an average branching fraction  $\mathcal{B}(B^0 \rightarrow K^{*0}\gamma) = (43.3 \pm 1.5) \times 10^{-6}$ , and have added several new decay modes such as  $B \rightarrow K_{1\gamma}$ ,  $K_2^*(1430)\gamma$ , etc. [125]. With a sample of 24 fb $^{-1}$  at  $\Upsilon(5S)$ , Belle observed the radiative penguin decay of  $B_s \rightarrow \phi\gamma$  with a branching fraction  $(57_{-19}^{+22}) \times 10^{-6}$  [126].

## *b*-flavored hadrons

Compared to  $b \rightarrow s\gamma$ , the  $b \rightarrow d\gamma$  transitions such as  $B \rightarrow \rho\gamma$ , are suppressed by the small CKM element  $V_{td}$ . Both Belle and BaBar have observed these decays [17,18]. The world average  $\mathcal{B}(B \rightarrow (\rho, \omega)\gamma) = (1.28 \pm 0.21) \times 10^{-6}$ . This can be used to calculate  $|V_{td}/V_{ts}|$  [127]; the measured values are  $0.233_{-0.032}^{+0.033}$  from BaBar [18] and  $0.195_{-0.024}^{+0.025}$  from Belle [17].

The observed radiative penguin branching fractions can constrain a large class of SM extensions [128]. However, due to the uncertainties in the hadronization, only the inclusive  $b \rightarrow s\gamma$  rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in  $B$  decay. By combining the measurements of  $B \rightarrow X_s\gamma$  from CLEO, BaBar, and Belle experiments [129,130], HFAG obtains the new average:  $\mathcal{B}(B \rightarrow X_s\gamma) = (3.55 \pm 0.24 \pm 0.09) \times 10^{-4}$  [33] for  $E_\gamma \geq 1.6$  GeV. Consistent results have been reported by ALEPH for inclusive  $b$ -hadrons produced at the  $Z$ . The measured branching fraction can be compared to theoretical calculations. Recent calculations of  $\mathcal{B}(b \rightarrow s\gamma)$  at NNLO level predict the values of  $(3.15 \pm 0.23) \times 10^{-4}$  [131] and  $(2.98 \pm 0.26) \times 10^{-4}$  [132], where the latter is calculated requiring  $E_\gamma \geq 1.6$  GeV.

The  $CP$  asymmetry in  $b \rightarrow s\gamma$  is extensively studied theoretically both in the SM and beyond [133]. According to the SM, the  $CP$  asymmetry in  $b \rightarrow s\gamma$  is smaller than 1%, but some non-SM models allow significantly larger  $CP$  asymmetry ( $\sim 10\%$ ) without altering the inclusive branching fraction. The current world average is  $A_{CP} = -0.012 \pm 0.028$ , again dominated by BaBar and Belle [134]. In addition to the  $CP$  asymmetry, BaBar also measured the isospin asymmetry  $\Delta_{0-} = 0.06 \pm 0.17$  in  $b \rightarrow s\gamma$  by measuring the companion  $B$  with full reconstruction in the hadronic decay modes [135].

In addition, all three experiments have measured the inclusive photon energy spectrum for  $b \rightarrow s\gamma$ , and by analyzing the shape of the spectrum they obtain the first and second moments for photon energies. Belle has measured these moments covering the widest range in the photon energy ( $1.7 < E_\gamma < 2.8$  GeV) [130]. These results can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element  $V_{ub}$ .

Additional information on FCNC processes can be obtained from  $B \rightarrow X_s\ell^+\ell^-$  decays, which are mediated by electroweak penguin and  $W$ -box diagrams. Their branching fractions have been measured by Belle [136], BaBar [137], and CDF [138]. Average branching fractions over all charged and neutral modes have been determined from BaBar and Belle data for  $B \rightarrow K\ell^+\ell^-$ :  $(0.45 \pm 0.04) \times 10^{-6}$  and for  $B \rightarrow K^*(892)\ell^+\ell^-$ :  $(1.08 \pm 0.11) \times 10^{-6}$ , consistent with the SM expectation.  $B$ -factory experiments also measured the branching fractions for inclusive  $B \rightarrow X_s\ell^+\ell^-$  decays [139], with an average of  $(3.66_{-0.77}^{+0.76}) \times 10^{-6}$  [140]. Recently corresponding decays of  $B_s$  and  $\Lambda_b$  were observed [138,141]. Branching fraction for the decay  $B_s \rightarrow \phi\mu^+\mu^-$  is measured to be  $(1.47 \pm 0.24 \pm 0.46) \times 10^{-6}$  and for the decay  $\Lambda_b \rightarrow \Lambda\mu^+\mu^-$  to be  $(1.73 \pm 0.42 \pm 0.55) \times 10^{-6}$ . Excitement was generated by measurements of forward-backward

asymmetry in  $B \rightarrow K^*(892)\ell^+\ell^-$  decays, which exhibited mild tension with the standard model in earlier measurements. The most recent measurements by CDF [142] and LHCb [143] agree with standard model, suggesting that the earlier discrepancy was mainly due to statistical fluctuations.

Finally the decays  $B_{(s)}^0 \rightarrow e^+e^-$  and  $\mu^+\mu^-$  are interesting since they only proceed at second order in weak interactions in the SM, but may have large contributions from supersymmetric loops, proportional to  $(\tan\beta)^6$ . Experiments at Tevatron,  $B$ -factories and now also LHC have obtained results that exclude a portion of the region allowed by SUSY models. The most stringent limits in these modes are obtained by LHCb. The limits in the  $\mu^+\mu^-$  mode are:  $< 1.4 \times 10^{-8}$  and  $< 3.2 \times 10^{-9}$  at 95% confidence level, respectively, for  $B_s$  and  $B^0$  [144]. For the  $B_s$  mode, the result is about factor of five above SM predictions [145]. It should be noted, that the most recent search by CDF observes an excess above expected background [146]. While the branching fraction for decay  $B_s \rightarrow \mu^+\mu^-$  of  $(1.8_{-0.9}^{+1.1}) \times 10^{-8}$  is extracted, CDF concludes that most plausible explanation for the excess is a statistical fluctuation. The limits for the  $e^+e^-$  modes are:  $< 2.8 \times 10^{-7}$  and  $< 8.3 \times 10^{-8}$ , respectively, for  $B_s$  and  $B^0$  [147]. There are also limits for lepton flavor-violating channels  $B_{(s)}^0 \rightarrow e^+\mu^-$ , which are around  $10^{-7}$  [147].

**Summary and Outlook:** The study of  $B$  mesons continues to be one of the most productive fields in particle physics. With the two asymmetric  $B$ -factory experiments Belle and BaBar, we now have a combined data sample of well over  $1 \text{ ab}^{-1}$ .  $CP$  violation has been firmly established in many decays of  $B$  mesons. Evidence for direct  $CP$  violation has been observed. Many rare decays resulting from hadronic  $b \rightarrow u$  transitions and  $b \rightarrow s(d)$  penguin decays have been observed, and the emerging pattern is still full of surprises. Despite the remarkable successes of the  $B$ -factory experiments, many fundamental questions in the flavor sector remain unanswered.

At Fermilab, CDF and D0 each has accumulated about  $10 \text{ fb}^{-1}$ , which is the equivalent of about  $10^{12}$   $b$ -hadrons produced. In spite of the low trigger efficiency of hadronic experiments, a selection of modes have been reconstructed in large quantities, giving a start to a program of studies on  $B_s$  and  $b$ -flavored baryons, in which a first major step has been the determination of the  $B_s$  oscillation frequency.

As Tevatron and  $B$ -factories stop their taking data, the new experiments at the LHC have become very active. The LHC accelerator performed very well in 2011. The general purpose experiments ATLAS and CMS collected about  $5 \text{ fb}^{-1}$  while LHCb collected about  $1 \text{ fb}^{-1}$ . LHCb, which is almost fully dedicated to studies of  $b$ - and  $c$ -hadrons, has a very large data sample. Of particular note is the sensitivity of the LHC experiments for the decay  $B_s \rightarrow \mu^+\mu^-$  which is expected to approach the standard model level in 2012.

In addition, two projects for next generation high-luminosity  $B$ -factories at KEK and Frascati are approved. Their aim to increase samples to  $\sim 50 \text{ ab}^{-1}$  will make it possible to explore the

See key on page 457

indirect evidence of new physics beyond the SM in the heavy-flavor particles (*b*, *c*, and  $\tau$ ), in a way that is complementary to the LHC.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and *CP*-violating phenomena.

5. Currently two different notations ( $\phi_1, \phi_2, \phi_3$ ) and ( $\alpha, \beta, \gamma$ ) are used in the literature for CKM unitarity angles. In this mini-review, we use the latter notation following the other mini-reviews in this *Review*. The two notations are related by  $\phi_1 = \beta$ ,  $\phi_2 = \alpha$  and  $\phi_3 = \gamma$ .

### A NOTE ON HFAG ACTIVITIES

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of the LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the  $b$ -flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ, LEP, SLD, and LHCb.

In the averaging the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taken into account. The HFAG has seven sub-groups providing averages for  $b$ -hadron lifetimes and  $B$ -oscillation parameters,  $CP$ -violation measurements, semileptonic parameters, rare branching fractions,  $b$ -hadron decays to charm, charm mixing and decays, and  $\tau$  decays. The averages provided by the HFAG are listed as "OUR EVALUATION" with a corresponding note.

The most up-to-date and complete listing of averages and more detailed information on the averaging procedures are available at:

<http://www.slac.stanford.edu/xorg/hfag>.

**$B^\pm$**

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the  $B^\pm/B^0$  ADMIXTURE and  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

### $B^\pm$ MASS

The fit uses  $m_{B^\pm}$ , ( $m_{B^0} - m_{B^\pm}$ ), and  $m_{B^0}$  to determine  $m_{B^\pm}$ ,  $m_{B^0}$ , and the mass difference.

<sup>1</sup> Uses  $B^\pm \rightarrow J/\psi K^\pm$  fully reconstructed decays.

<sup>2</sup> Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+\mu^-$  decays.

<sup>3</sup> CSORNA 00 uses fully reconstructed 526  $B^\pm \rightarrow J/\psi(\ell^+)K^\pm$  events and invariant masses without beam constraint.

<sup>4</sup> ALBRECHT 90J assumes 10580 for  $\Upsilon(4S)$  mass. Supersedes ALBRECHT 87c and ALBRECHT 87D.

<sup>5</sup> Found using fully reconstructed decays with  $J/\psi(1S)$ . ALBRECHT 87D assume  $m_{\Upsilon(4S)} = 10577$  MeV.

### $B^\pm$ MEAN LIFE

See  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on  $B$ -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

<sup>1</sup> Measured mean life using fully reconstructed decays ( $J/\psi K^{(*)}$ ).

<sup>2</sup> Measured using  $B^- \rightarrow D^0 \pi^-$  with  $D^0 \rightarrow K^- \pi^+$  events that were selected using a silicon vertex trigger.

<sup>3</sup> Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.

<sup>4</sup> Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.

<sup>5</sup> Measured mean life using fully reconstructed decays.

<sup>6</sup> Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.

<sup>7</sup> Data analyzed using  $D/D^* \ell X$  event vertices.

<sup>8</sup> Data analyzed using charge of secondary vertex.

<sup>9</sup> ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$ .

<sup>10</sup> Data analyzed using vertex-charge technique to tag  $B$  charge.

<sup>11</sup> Combined result of  $D/D^* \ell X$  analysis and fully reconstructed  $B$  analysis.

<sup>12</sup> Combined ABREU 95q and ADAM 95 result.

### $B^+$ DECAY MODES

$B^-$  modes are charge conjugates of the modes below. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0 \bar{B}^0$  and 50%  $B^+ B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D, D_s, D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

- [a] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.  
 [b] An  $CP(\pm 1)$  indicates the  $CP=+1$  and  $CP=-1$  eigenstates of the  $D^0$ - $\bar{D}^0$  system.  
 [c]  $D$  denotes  $D^0$  or  $\bar{D}^0$ .  
 [d]  $D_{CP^\pm}^0$  decays into  $D^0 \pi^0$  with the  $D^0$  reconstructed in  $CP$ -even eigenstates  $K^+ K^-$  and  $\pi^+ \pi^-$ .  
 [e]  $\bar{D}^{**}$  represents an excited state with mass  $2.2 < M < 2.8$  GeV/c<sup>2</sup>.  
 [f]  $X(3872)^+$  is a hypothetical charged partner of the  $X(3872)$ .  
 [g]  $\Theta(1710)^{++}$  is a possible narrow pentaquark state and  $G(2220)$  is a possible glueball resonance.  
 [h]  $(\bar{\Lambda}_c^- p)_s$  denotes a low-mass enhancement near 3.35 GeV/c<sup>2</sup>.

### CONSTRAINED FIT INFORMATION

An overall fit to 18 branching ratios uses 48 measurements and one constraint to determine 12 parameters. The overall fit has a  $\chi^2 = 38.8$  for 37 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

10.1 ± 1.8 ± 1.5	ATHANAS 94 CLE2 Sup. by ARTUSO 97

- <sup>1</sup> URQUIJO 07 report a measurement of  $(10.34 \pm 0.23 \pm 0.25)\%$  for the partial branching fraction of  $B^+ \rightarrow e^+ \nu_e X_c$  decay with electron energy above 0.6 GeV. We converted the result to  $B^+ \rightarrow e^+ \nu_e X$  branching fraction.  
<sup>2</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .  
<sup>3</sup> ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^* \ell \nu_\ell$  and inclusive semileptonic branching ratio from BARISH 96b  $(0.1049 \pm 0.0017 \pm 0.0043)$ .  
<sup>4</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- <sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\mathcal{T}(4S)$ .  
<sup>2</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^0 \ell^- \bar{\nu}_{\ell} X$  in the recoil.  
<sup>3</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^{(*)0} \ell^- \bar{\nu}_{\ell} X$  in the recoil.  
<sup>4</sup> The analysis is based on a sample of events with one fully reconstructed tag  $B$  in a hadronic decay mode  $B^- \rightarrow D^{(*)0} X^-$ .  
<sup>5</sup> The energy-flow and  $b$ -tagging algorithms were used.  
<sup>6</sup> ACCIARRI 97F uses missing-energy technique and  $f(b \rightarrow B^-) = (38.2 \pm 2.5)\%$ .  
<sup>7</sup> ALBRECHT 95D uses full reconstruction of one  $B$  decay as tag.  
<sup>8</sup> BUSKULIC 95 uses same missing-energy technique as in  $\bar{b} \rightarrow \tau^+ \nu_{\tau} X$ , but analysis is restricted to endpoint region of missing-energy distribution.

- Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .
- ABULENCIA 06J reports  $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{\text{total}}] / [B(B^0 \rightarrow D^- \pi^+)] = 1.97 \pm 0.10 \pm 0.21$  which we multiply by our best value  $B(B^0 \rightarrow D^- \pi^+) = (2.68 \pm 0.13) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.
- Uses a missing-mass method. Does not depend on  $D$  branching fractions or  $B^+/B^0$  production rates.
- AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of  $B^0$  and  $B^+$ , which is not included here.
- Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses the MarkIII branching fractions for the  $D$ .
- BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.
- AUBERT,B 04P reports  $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{\text{total}}] \times [B(D^0 \rightarrow K^- \pi^+)] = (1.846 \pm 0.032 \pm 0.097) \times 10^{-4}$  which we divide by our best value  $B(D^0 \rightarrow K^- \pi^+) = (3.88 \pm 0.05) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ALAM 94 assume equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and use the CLEOII absolute  $B(D^0 \rightarrow K^- \pi^+)$  and the PDG 1992  $B(D^0 \rightarrow K^- \pi^+ \pi^0)/B(D^0 \rightarrow K^- \pi^+)$  and  $B(D^0 \rightarrow K^- 2\pi^+ \pi^-)/B(D^0 \rightarrow K^- \pi^+)$ .
- ALBRECHT 88k assumes  $B^0 \bar{B}^0 : B^+ B^-$  ratio is 45:55. Superseded by ALBRECHT 90J.

• • • We do not use the following data for averages, fits, limits, etc. • • •  
 <1.9      90      <sup>5</sup> ALBRECHT 90j ARG  $e^+ e^- \rightarrow \Upsilon(4S)$

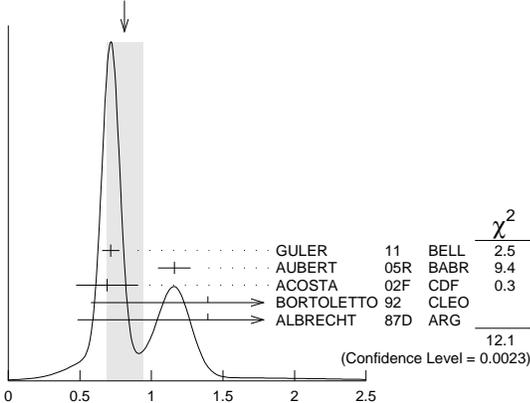

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .  
<sup>2</sup> ACOSTA 02F uses as reference of  $B(B \rightarrow J/\psi(1S) K^+) = (10.1 \pm 0.6) \times 10^{-4}$ . The second error includes the systematic error and the uncertainties of the branching ratio.

<sup>3</sup> BORTOLETTO 92 reports  $(1.2 \pm 0.6 \pm 0.4) \times 10^{-3}$  from a measurement of  $[\Gamma(B^+ \rightarrow J/\psi(1S) K^+ \pi^+ \pi^-) / \Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+ e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+ e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+ e^-) = (5.94 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>4</sup> ALBRECHT 87D reports  $(1.2 \pm 0.8) \times 10^{-3}$  from a measurement of  $[\Gamma(B^+ \rightarrow J/\psi(1S) K^+ \pi^+ \pi^-) / \Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+ e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+ e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+ e^-) = (5.94 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. They actually report  $0.0011 \pm 0.0007$  assuming  $B^+ B^- / B^0 \bar{B}^0$  ratio is 55/45. We rescale to 50/50. Analysis explicitly removes  $B^+ \rightarrow \psi(2S) K^+$ .

<sup>5</sup> ALBRECHT 90j reports  $< 1.6 \times 10^{-3}$  from a measurement of  $[\Gamma(B^+ \rightarrow J/\psi(1S) K^+ \pi^+ \pi^-) / \Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+ e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+ e^-) = 0.069$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+ e^-) = 5.94 \times 10^{-2}$ . Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>1</sup> LEES 11i reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \pi\pi)] = (1.53 \pm 0.66 \pm 0.27) \times 10^{-6}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow \pi\pi) = (8.5 \pm 0.4) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>2</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .  
<sup>3</sup> AUBERT 08A1 reports  $(0.70 \pm 0.10^{+0.12}_{-0.10}) \times 10^{-6}$  for  $B(B^+ \rightarrow \chi_{c0} K^+) \times B(\chi_{c0} \rightarrow \pi^+ \pi^-)$ . We compute  $B(B^+ \rightarrow \chi_{c0} K^+)$  using the PDG value  $B(\chi_{c0} \rightarrow \pi\pi) = (8.5 \pm 0.4) \times 10^{-3}$  and 2/3 for the  $\pi^+ \pi^-$  fraction. Our first error is their experiment's error and the second error is systematic error from using our best value.

<sup>4</sup> Measured in the  $B^+ \rightarrow K^+ K^- K^+$  decay.  
<sup>5</sup> AUBERT, BE 06M reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S))] = (6.1 \pm 2.6 \pm 1.1) \times 10^{-6}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S)) = (1.17 \pm 0.08) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. The significance of the observed signal is  $2.4 \sigma$ .

<sup>6</sup> WICHT 08 reports  $[\Gamma(B^+ \rightarrow \chi_{c0}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \gamma\gamma)] < 0.11 \times 10^{-6}$  which we divide by our best value  $B(\chi_{c0}(1P) \rightarrow \gamma\gamma) = 2.23 \times 10^{-4}$ .

<sup>7</sup> Perform measurements of absolute branching fractions using a missing mass technique.

<sup>8</sup> AUBERT, B 05N reports  $(0.66 \pm 0.22 \pm 0.08) \times 10^{-6}$  for  $B(B^+ \rightarrow \chi_c^0 K^+) \times B(\chi_c^0 \rightarrow \pi^+ \pi^-)$ . We compute  $B(B^+ \rightarrow \chi_c^0 K^+)$  using the PDG value  $B(\chi_c^0 \rightarrow \pi^+ \pi^-) = (7.1 \pm 0.6) \times 10^{-3}$  and 2/3 for the  $\pi^+ \pi^-$  fraction.

<sup>9</sup> The measurement performed using decay channels  $\chi_c^0 \rightarrow \pi^+ \pi^-$  and  $\chi_c^0 \rightarrow K^+ K^-$ . The ratio of the branching ratios for these channels is found to be consistent with world average.

<sup>10</sup> AUBERT 04P reports  $B(B^+ \rightarrow \chi_c^0 K^+) \times B(\chi_c^0 \rightarrow \pi^+ \pi^-) = (1.5 \pm 0.4 \pm 0.1) \times 10^{-6}$  and used PDG value of  $B(\chi_c^0 \rightarrow \pi\pi) = (7.4 \pm 0.8) \times 10^{-3}$  and Clebsch-Gordan coefficient to compute  $B(B^+ \rightarrow \chi_c^0 K^+)$ .

<sup>11</sup> ABE 02B measures the ratio of  $B(B^+ \rightarrow \chi_c^0 K^+)/B(B^+ \rightarrow J/\psi(1S) K^+) = 0.60 \pm 0.21 - 0.18 \pm 0.05 \pm 0.08$ , where the third error is due to the uncertainty in the  $B(\chi_c^0 \rightarrow \pi^+ \pi^-)$ , and uses  $B(B^+ \rightarrow J/\psi(1S) K^+) = (10.0 \pm 1.0) \times 10^{-4}$  to obtain the result.

<sup>12</sup> EDWARDS 01 assumes equal production of  $B^0$  and  $B^+$  at the  $\Upsilon(4S)$ . The correlated uncertainties (28.3)% from  $B(J/\psi(1S) \rightarrow \eta\eta_c)$  in those modes have been accounted for.

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>2</sup> Uses  $\chi_{c1,2} \rightarrow J/\psi\gamma$ . Assumes  $B(\Upsilon(4S) \rightarrow B^+ B^-) = (51.6 \pm 0.6)\%$  and  $B(\Upsilon(4S) \rightarrow B^0 \bar{B}^0) = (48.4 \pm 0.6)\%$ .

<sup>3</sup> Perform measurements of absolute branching fractions using a missing mass technique.

<sup>4</sup> ACOSTA 02F uses as reference of  $B(B \rightarrow J/\psi(1S) K^+) = (10.1 \pm 0.6) \times 10^{-4}$ . The second error includes the systematic error and the uncertainties of the branching ratio.

<sup>5</sup> AUBERT, BE 06M reports  $[\Gamma(B^+ \rightarrow \chi_{c1}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S))] = (1.76 \pm 0.07 \pm 0.12) \times 10^{-4}$  which we divide by our best value  $B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S)) = (34.4 \pm 1.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>6</sup> AUBERT 02 reports  $(7.5 \pm 0.9 \pm 0.8) \times 10^{-4}$  from a measurement of  $[\Gamma(B^+ \rightarrow \chi_{c1}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S))]$  assuming  $B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S)) = 0.273 \pm 0.016$ , which we rescale to our best value  $B(\chi_{c1}(1P) \rightarrow \gamma J/\psi(1S)) = (34.4 \pm 1.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>7</sup> ALBRECHT 92E assumes no  $\chi_{c2}(1P)$  production and  $B(\Upsilon(4S) \rightarrow B^+ B^-) = 50\%$ .

$\Gamma(\chi_{c1}(1P) K^+)/\Gamma(J/\psi(1S) K^+) \quad \Gamma_{236}/\Gamma_{185}$

<260 90 <sup>6</sup> AVERY 87 CLEO  $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>2</sup> AUBERT 04P reports a central value of  $(3.9 \pm 1.2^{+1.3}_{-3.5}) \times 10^{-6}$  for this branching ratio.

<sup>3</sup> Uses a reference decay mode  $B^+ \rightarrow \bar{D}^0\pi^+$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  with  $B(B^+ \rightarrow \bar{D}^0\pi^+) \times B(\bar{D}^0 \rightarrow K^+\pi^-) = (20.3 \pm 2.0) \times 10^{-5}$ .

<sup>4</sup> ABE 00C assumes  $B(Z \rightarrow b\bar{b}) = (21.7 \pm 0.1)\%$  and the  $B$  fractions  $f_{B^0} = f_{B^+} = (39.7 \pm 1.8^{+2.2}_{-2.2})\%$  and  $f_{B_s} = (10.5 \pm 1.8^{+2.2}_{-2.2})\%$ .

<sup>5</sup> Assumes production fractions  $f_{B^0} = f_{B^-} = 0.39$  and  $f_{B_s} = 0.12$ .

<sup>6</sup> AVERY 89B reports  $< 7 \times 10^{-5}$  assuming the  $\Upsilon(4S)$  decays 43% to  $B^0\bar{B}^0$ . We rescale to 50%.

 $\Gamma(K_2^*(1430)^0\pi^+)/\Gamma_{\text{total}}$   $\Gamma_{276}/\Gamma$

POLARIZATION IN  $B^+$  DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (||) or perpendicular ( $\perp$ ) to each other with the parameters  $\Gamma_L/\Gamma$ ,  $\Gamma_{\perp}/\Gamma$ , and the relative phases  $\phi_{||}$  and  $\phi_{\perp}$ . See the definitions in the note on "Polarization in B Decays" review in the  $B^0$  Particle Listings.

<sup>1</sup> Uses Dalitz plot analysis of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ ,  $K_S^0 K^+ K^-$  decays from  $B^+ \rightarrow D^{(*)} K^+$ ,  $D K^{*+}$  modes. The corresponding two standard deviation interval for  $\gamma$  is  $39^\circ < \gamma < 98^\circ$ . CP conservation in the combined result is ruled out with a significance of 3.5 standard deviations.

<sup>2</sup> Uses Dalitz plot analysis of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays from  $B^+ \rightarrow D^{(*)} K^+$  modes. The corresponding two standard deviation interval for  $\gamma$  is  $54.2^\circ < \gamma < 100.5^\circ$ . CP conservation in the combined result is ruled out with a significance of 3.5 standard deviations.

<sup>3</sup> Reports confidence intervals for the CKM angle  $\gamma$  from the measured values of the GLW parameters using  $B^\pm \rightarrow D K^\pm$  decays with  $D$  mesons decaying to non-CP( $K\pi$ ), CP-even ( $K^+ K^-$ ,  $\pi^+ \pi^-$ ), and CP-odd ( $K_S^0 \pi^0$ ,  $K_S^0 \omega$ ) states.

<sup>4</sup> Uses Dalitz plot analysis of  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  and  $\bar{D}^0 \rightarrow K_S^0 K^+ K^-$  decays coming from  $B^\pm \rightarrow D^{(*)} K^{(*)\pm}$  modes. The corresponding two standard deviation interval is  $29^\circ < \gamma < 122^\circ$ .

<sup>5</sup> Uses a Dalitz plot analysis of the  $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$  decays; Combines the  $D K^+$ ,  $D^* K^+$  and  $D K^{*+}$  modes. The corresponding two standard deviations interval for gamma is  $8^\circ < \gamma < 111^\circ$ .

<sup>6</sup> Uses a Dalitz plot analysis of neutral  $D \rightarrow K_S^0 \pi^+ \pi^-$  decays coming from  $B^\pm \rightarrow D K^\pm$  and  $B^\pm \rightarrow D^{*0} K^\pm$  followed by  $D^{*0} \rightarrow D \pi^0$ ,  $D \gamma$ . The corresponding two standard deviations interval for gamma is  $12^\circ < \gamma < 137^\circ$ . AUBERT,B 05Y also reports the amplitude ratios and the strong phases.

<sup>7</sup> Uses a Dalitz plot analysis of the 3-body  $D \rightarrow K_S^0 \pi^+ \pi^-$  decays coming from  $B^\pm \rightarrow D K^\pm$  and  $B^\pm \rightarrow D^* K^\pm$  followed by  $D^* \rightarrow D \pi^0$ ; here we use  $D$  to denote that the neutral  $D$  meson produced in the decay is an admixture of  $D^0$  and  $\bar{D}^0$ . The corresponding two standard deviations interval for  $\gamma$  is  $26^\circ < \gamma < 126^\circ$ . POLUEKTOV 04 also reports the amplitude ratios and the strong phases.

### $B^0$

$$\langle J^P \rangle = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the  $B^\pm/B^0$  ADMIXTURE and  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

See the Note "Production and Decay of  $b$ -flavored Hadrons" at the beginning of the  $B^\pm$  Particle Listings and the Note on " $B^0$ - $\bar{B}^0$  Mixing" near the end of the  $B^0$  Particle Listings.

### $B^0$ MASS

The fit uses  $m_{B^{*+}}$ , ( $m_{B^0} - m_{B^{*+}}$ ), and  $m_{B^0}$  to determine  $m_{B^{*+}}$ ,  $m_{B^0}$ , and the mass difference.

1 Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+\mu^-$  decay.  
 2 Uses the  $B$ -momentum distributions in the  $e^+e^-$  rest frame.  
 3 Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+\mu^-$  decays.  
 4 BEBEK 87 actually measure the difference between half of  $E_{cm}$  and the  $B^\pm$  or  $B^0$  mass, so the  $m_{B^0} - m_{B^\pm}$  is more accurate. Assume  $m_{\Upsilon(4S)} = 10580$  MeV.

**$B^0$  MEAN LIFE**

See  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on  $B$ -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

1 Measured mean life using fully reconstructed decays ( $J/\psi K^{(*)}$ ).  
 2 Measured mean life using  $B^0 \rightarrow J/\psi K^{*0}$  decays.  
 3 Measured mean life using  $B^0 \rightarrow J/\psi K_S$  decays.  
 4 Measured using a simultaneous fit of the  $B^0$  lifetime and  $\bar{B}^0 B^0$  oscillation frequency  $\Delta m_d$  in the partially reconstructed  $B^0 \rightarrow D^{*-} \ell \nu$  decays.  
 5 Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.  
 6 Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.  
 7 AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed  $B^0 \rightarrow D^{*}(2010)^- \ell \nu$  and simultaneously measures the lifetime and oscillation frequency.  
 8 Measurement performed with decays  $B^0 \rightarrow D^{*-} \pi^+$  and  $B^0 \rightarrow D^{*-} \rho^+$  using a partial reconstruction technique.  
 9 Measured mean life using fully reconstructed decays.  
 10 Data analyzed using partially reconstructed  $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}$  decays.  
 11 Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.  
 12 Data analyzed using  $D/D^* \ell X$  event vertices.  
 13 Data analyzed using charge of secondary vertex.  
 14 Data analyzed using inclusive  $D/D^* \ell X$ .  
 15 Measured mean life using partially reconstructed  $D^{*-} \pi^+ X$  vertices.  
 16 ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$ .  
 17 Data analyzed using vertex-charge technique to tag  $B$  charge.  
 18 AKERS 95T assumes  $B(B^0 \rightarrow D_s^{(*)} D^{0(*)}) = 5.0 \pm 0.9\%$  to find  $B^+/B^0$  yield.  
 19 Measured using the time-dependent angular analysis of  $B_d^0 \rightarrow J/\psi K^{*0}$  decays.  
 20 Combined result of  $D/D^* \ell X$  analysis, fully reconstructed  $B$  analysis, and partially reconstructed  $D^{*-} \pi^+ X$  analysis.  
 21 Combined ABREU 95Q and ADAM 95 result.  
 22 WAGNER 90 tagged  $B^0$  mesons by their decays into  $D^{*-} e^+ \nu$  and  $D^{*-} \mu^+ \nu$  where the  $D^{*-}$  is tagged by its decay into  $\pi^- \bar{D}^0$ .  
 23 AVERILL 89 is an estimate of the  $B^0$  mean lifetime assuming that  $B^0 \rightarrow D^{*+} + X$  always.

**MEAN LIFE RATIO  $\tau_{B^+}/\tau_{B^0}$**

**$\tau_{B^+}/\tau_{B^0}$  (direct measurements)**

- <sup>4</sup> Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.
- <sup>5</sup> Measured using fully reconstructed decays.
- <sup>6</sup> Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.
- <sup>7</sup> Data analyzed using charge of secondary vertex.
- <sup>8</sup> ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$ .
- <sup>9</sup> Data analyzed using vertex-charge technique to tag  $B$  charge.
- <sup>10</sup> AKERS 95T assumes  $B(B^0 \rightarrow D_s^{(*)} D^0)^{(*)} = 5.0 \pm 0.9\%$  to find  $B^+/B^0$  yield.
- <sup>11</sup> Combined result of  $D/D^* \ell X$  analysis and fully reconstructed  $B$  analysis.

 $\tau_{B^+}/\tau_{B^0}$  (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for  $B^0$  and  $B^+$ . We do not use measurements which assume equal production of  $B^0$  and  $B^+$  because of the large uncertainty in the production ratio.

“OUR EVALUATION” has been obtained by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

- <sup>1</sup> ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^* \ell \nu_\ell$  and independent of  $B^0$  and  $B^+$  production fraction.
- <sup>2</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .
- <sup>3</sup> ATHANAS 94 uses events tagged by fully reconstructed  $B^-$  decays and partially or fully reconstructed  $B^0$  decays.
- <sup>4</sup> Assumes equal production of  $B^0$  and  $B^+$ .
- <sup>5</sup> ALBRECHT 92G data analyzed using  $B \rightarrow D_s \bar{D}, D_s \bar{D}^*, D_s^* \bar{D}, D_s^* \bar{D}^*$  events.
- <sup>6</sup> BEAN 87B assume the fraction of  $B^0 \bar{B}^0$  events at the  $\Upsilon(4S)$  is 0.41.

 $\text{sgn}(\text{Re}(\lambda_{CP})) \Delta\Gamma_{B_d^0} / \Gamma_{B_d^0}$ 

$\Gamma_{B_d^0}$  and  $\Delta\Gamma_{B_d^0}$  are the decay rate average and difference between two  $B_d^0$   $CP$  eigenstates (light – heavy). The  $\lambda_{CP}$  characterizes  $B^0$  and  $\bar{B}^0$  decays to states of charmonium plus  $K_L^0$ , see the review on “ $CP$  Violation” in the reviews section.

 $B^0$  DECAY MODES

$\bar{B}^0$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0 \bar{B}^0$  and 50%  $B^+ B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D, D_s, D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
$\Gamma_1$ $\ell^+ \nu_\ell$ anything	[a] ( 10.33 ± 0.28 ) %	
$\Gamma_2$ $e^+ \nu_e X_C$	( 10.1 ± 0.4 ) %	
$\Gamma_3$ $D \ell^+ \nu_\ell$ anything	( 9.2 ± 0.8 ) %	
$\Gamma_4$ $D^- \ell^+ \nu_\ell$	[a] ( 2.18 ± 0.12 ) %	
$\Gamma_5$ $D^- \tau^+ \nu_\tau$	( 1.1 ± 0.4 ) %	
$\Gamma_6$ $D^*(2010)^- \ell^+ \nu_\ell$	[a] ( 4.95 ± 0.11 ) %	
$\Gamma_7$ $D^*(2010)^- \tau^+ \nu_\tau$	( 1.5 ± 0.5 ) %	S=1.4
$\Gamma_8$ $\bar{D}^0 \pi^- \ell^+ \nu_\ell$	( 4.3 ± 0.6 ) × 10 <sup>-3</sup>	
$\Gamma_9$ $D_0^*(2400)^- \ell^+ \nu_\ell \times$ $B(D_0^{*-} \rightarrow \bar{D}^0 \pi^-)$	( 3.0 ± 1.2 ) × 10 <sup>-3</sup>	S=1.8
$\Gamma_{10}$ $D_2^*(2460)^- \ell^+ \nu_\ell \times$ $B(D_2^{*-} \rightarrow \bar{D}^0 \pi^-)$	( 1.21 ± 0.33 ) × 10 <sup>-3</sup>	S=1.8
$\Gamma_{11}$ $\bar{D}^*(n) \pi^- \ell^+ \nu_\ell$ (n ≥ 1)	( 2.3 ± 0.5 ) %	
$\Gamma_{12}$ $\bar{D}^{*0} \pi^- \ell^+ \nu_\ell$	( 4.9 ± 0.8 ) × 10 <sup>-3</sup>	
$\Gamma_{13}$ $D_1(2420)^- \ell^+ \nu_\ell \times$ $B(D_1^- \rightarrow \bar{D}^{*0} \pi^-)$	( 2.80 ± 0.28 ) × 10 <sup>-3</sup>	
$\Gamma_{14}$ $D_1'(2430)^- \ell^+ \nu_\ell \times$ $B(D_1'^- \rightarrow \bar{D}^{*0} \pi^-)$	( 3.1 ± 0.9 ) × 10 <sup>-3</sup>	
$\Gamma_{15}$ $D_2^*(2460)^- \ell^+ \nu_\ell \times$ $B(D_2^{*-} \rightarrow \bar{D}^{*0} \pi^-)$	( 6.8 ± 1.2 ) × 10 <sup>-4</sup>	
$\Gamma_{16}$ $\rho^- \ell^+ \nu_\ell$	[a] ( 2.34 ± 0.28 ) × 10 <sup>-4</sup>	
$\Gamma_{17}$ $\pi^- \ell^+ \nu_\ell$	[a] ( 1.44 ± 0.05 ) × 10 <sup>-4</sup>	
$\Gamma_{18}$ $\pi^- \mu^+ \nu_\mu$		

## Inclusive modes

$\Gamma_{19}$ $K^\pm$ anything	( 78 ± 8 ) %	
$\Gamma_{20}$ $D^0 X$	( 8.1 ± 1.5 ) %	
$\Gamma_{21}$ $\bar{D}^0 X$	( 47.4 ± 2.8 ) %

[a] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.

[b]  $\bar{D}^{**}$  represents an excited state with mass  $2.2 < M < 2.8$  GeV/ $c^2$ .

[c]  $X(3872)^+$  is a hypothetical charged partner of the  $X(3872)$ .

[d] Stands for the possible candidates of  $K^*(1410)$ ,  $K_0^*(1430)$  and  $K_2^*(1430)$ .

[e]  $B^0$  and  $B_s^0$  contributions not separated. Limit is on weighted average of the two decay rates.

[f] This decay refers to the coherent sum of resonant and nonresonant  $J^P = 0^+$   $K\pi$  components with  $1.60 < m_{K\pi} < 2.15$  GeV/ $c^2$ .

[g]  $X(214)$  is a hypothetical particle of mass 214 MeV/ $c^2$  reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005)

[h] The value is for the sum of the charge states or particle/antiparticle states indicated.

[i]  $\Theta(1540)^+$  denotes a possible narrow pentaquark state.

### CONSTRAINED FIT INFORMATION

An overall fit to 20 branching ratios uses 56 measurements and one constraint to determine 14 parameters. The overall fit has a  $\chi^2 = 37.3$  for 43 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

### $B^0$ BRANCHING RATIOS

For branching ratios in which the charge of the decaying  $B$  is not determined, see the  $B^\pm$  section.

$\Gamma(\ell^+ \nu_\ell \text{ anything}) / \Gamma_{\text{total}}$  is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

10.9 ± 0.7 ± 1.1	ATHANAS 94	CLE2	Sup. by ARTUSO 97

- • • We do not use the following data for averages, fits, limits, etc. • • •
- <sup>1</sup> URQUIJO 07 report a measurement of  $(9.80 \pm 0.29 \pm 0.21)\%$  for the partial branching fraction of  $B \rightarrow e \nu_e X_e$  decay with electron energy above 0.6 GeV. We converted the result to  $B \rightarrow e \nu_e X$  branching fraction.
- <sup>2</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ $c$  in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .
- <sup>3</sup> ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^* \ell \nu_\ell$  and inclusive semileptonic branching ratio from BARISH 96B (0.1049 ± 0.0017 ± 0.0043).
- <sup>4</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ $c$  in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

- 1 Uses fully reconstructed  $D^{*-} \ell^+ \nu$  events ( $\ell = e$  or  $\mu$ ).
- 2 Uses a fully reconstructed  $B$  meson as a tag on the recoil side.
- 3 Measured using fully reconstructed  $D^*$  sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters:  $\rho^2 = 1.191 \pm 0.048 \pm 0.028$ ,  $R_1(1) = 1.429 \pm 0.061 \pm 0.044$ , and  $R_2(1) = 0.827 \pm 0.038 \pm 0.022$ .
- 4 Measured using fully reconstructed  $D^*$  sample.
- 5 Uses the combined fit of both  $B^0 \rightarrow D^*(2010)^- \ell \nu$  and  $B^+ \rightarrow \bar{D}^*(2007)^0 \ell \nu$  samples.
- 6 ABREU 01H measured using about 5000 partial reconstructed  $D^*$  sample.
- 7 ABBIENDI 00Q assumes the fraction  $B(b \rightarrow B^0) = (39.7 \pm 1.8)_2\%$ . This result is an average of two methods using exclusive and partial  $D^*$  reconstruction.
- 8 BUSKULIC 97 assumes fraction ( $B^+$ ) = fraction ( $B^0$ ) = (37.8 ± 2.2)% and PDG 96 values for  $B$  lifetime and  $D^*$  and  $D$  branching fractions.
- 9 Combines with previous partial reconstructed  $D^*$  measurement.
- 10 Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .
- 11 The results are based on the same analysis and data sample reported in ADAM 03.
- 12 ACKERSTAFF 97G assumes fraction ( $B^+$ ) = fraction ( $B^0$ ) = (37.8 ± 2.2)% and PDG 96 values for  $B$  lifetime and branching ratio of  $D^*$  and  $D$  decays.
- 13 ABREU 96P result is the average of two methods using exclusive and partial  $D^*$  reconstruction.
- 14 BARISH 95 use  $B(D^0 \rightarrow K^- \pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$  and  $B(D^{*+} \rightarrow D^0 \pi^+) = (68.1 \pm 1.0 \pm 1.3)\%$ .
- 15 BUSKULIC 95N assumes fraction ( $B^+$ ) = fraction ( $B^0$ ) = 38.2 ± 1.3 ± 2.2% and  $\tau_{B^0} = 1.58 \pm 0.06$  ps.  $\Gamma(D^{*-} \ell^+ \nu_\ell)/total = [5.18 - 0.13(\text{fraction}(B^0) - 38.2) - 1.5(\tau_{B^0} - 1.58)]\%$ .
- 16 ALBRECHT 94 assumes  $B(D^{*+} \rightarrow D^0 \pi^+) = 68.1 \pm 1.0 \pm 1.3\%$ . Uses partial reconstruction of  $D^{*+}$  and is independent of  $D^0$  branching ratios.
- 17 ALBRECHT 93 reports 0.052 ± 0.005 ± 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94  $B(D^0 \rightarrow K^- \pi^+)$ . We have taken their average  $e$  and  $\mu$  value. They also obtain  $\alpha = 2\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$ ,  $A_{FB} = 3/4 * (\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$  and a value of  $|V_{cb}| = 0.036 - 0.045$  depending on model assumptions.
- 18 Combining  $\bar{D}^{*0} \ell^+ \nu_\ell$  and  $\bar{D}^{*-} \ell^+ \nu_\ell$  SANGHERA 93 test  $V-A$  structure and fit the decay angular distributions to obtain  $A_{FB} = 3/4 * (\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$ . Assuming a value of  $V_{cb}$ , they measure  $V, A_1,$  and  $A_2$ , the three form factors for the  $D^* \ell \nu_\ell$  decay, where results are slightly dependent on model assumptions.
- 19 ANTREASIAN 90B is average over  $B$  and  $\bar{D}^*(2010)$  charge states.
- 20 The measurement of ALBRECHT 89C suggests a  $D^*$  polarization  $\gamma_L/\gamma_T$  of 0.85 ± 0.45, or  $\alpha = 0.7 \pm 0.9$ .
- 21 ALBRECHT 89J is ALBRECHT 87J value rescaled using  $B(D^*(2010)^- \rightarrow D^0 \pi^-) = 0.57 \pm 0.04 \pm 0.04$ . Superseded by ALBRECHT 93.
- 22 We have taken average of the BORTOLETTO 89B values for electrons and muons, 0.046 ± 0.005 ± 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94  $B(D^0 \rightarrow K^- \pi^+)$ . The measurement suggests a  $D^*$  polarization parameter value  $\alpha = 0.65 \pm 0.66 \pm 0.25$ .
- 23 ALBRECHT 87J assume  $\mu-e$  universality, the  $B(\Upsilon(4S) \rightarrow B^0 \bar{B}^0) = 0.45$ , the  $B(D^0 \rightarrow K^- \pi^+) = (0.042 \pm 0.004 \pm 0.004)$ , and the  $B(D^*(2010)^- \rightarrow D^0 \pi^-) = 0.49 \pm 0.08$ . Superseded by ALBRECHT 89J.

<3.0	90	<sup>2</sup> LIVENTSEV 08	BELL	$e^+ e^- \rightarrow \Upsilon(4S)$
------	----	---------------------------	------	------------------------------------

<sup>1</sup> Uses a simultaneous fit of all  $B$  semileptonic decays without full reconstruction of events.

AUBERT 09Y reports  $B(B^0 \rightarrow \bar{D}_2^-(2460)^- \ell^+ \nu_\ell) \cdot B(\bar{D}_2^-(2460)^- \rightarrow \bar{D}^{*0} \pi^-) = (1.77 \pm 0.26 \pm 0.11) \times 10^{-3}$  and the authors have provided us the individual measurement.

<sup>2</sup> Uses a fully reconstructed  $B$  meson as a tag on the recoil side.

 $\Gamma(\rho^- \ell^+ \nu_\ell) / \Gamma_{\text{total}}$   $\Gamma_{16} / \Gamma$ 

$\ell = e$  or  $\mu$ , not sum over  $e$  and  $\mu$  modes.

"OUR EVALUATION" has been obtained by the Heavy Flavor Averaging Group (HFAG) by including both  $B^0$  and  $B^+$  decays. The average assumes equality of the semileptonic decay width for these isospin conjugate states.

1.8 ± 0.4 ± 0.4	<sup>10</sup> ALEXANDER	96T	CLE2 Repl. by ATHAR 03

- Using isospin relation, B<sup>+</sup> and B<sup>0</sup> branching fractions are combined.
- Uses the neutrino reconstruction technique. Assumes B(T(4S) → B<sup>+</sup>B<sup>-</sup>) = (51.6 ± 0.6)% and B(T(4S) → B<sup>0</sup>B<sup>0</sup>) = (48.4 ± 0.6)%.
- The B<sup>0</sup> and B<sup>+</sup> results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the T(4S).
- Also report the rate for q<sup>2</sup> > 16 GeV<sup>2</sup> of (0.41 ± 0.08 ± 0.04) × 10<sup>-4</sup> from which they obtain |V<sub>ub</sub>| = 3.6 ± 0.4 ± 0.2<sup>+0.6</sup><sub>-0.4</sub> (last error is from theory).
- The signal events are tagged by a second B meson reconstructed in the semileptonic mode B → D<sup>(\*)</sup>ℓνℓ.
- The analysis uses events in which the signal B decays are reconstructed with an innovative loose neutrino reconstruction technique.
- The signals are tagged by a second B meson reconstructed in a semileptonic or hadronic decay. The B<sup>0</sup> and B<sup>+</sup> results are combined assuming the isospin symmetry.
- B<sup>+</sup> and B<sup>0</sup> decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.
- ATHAR 03 reports systematic errors 0.11 ± 0.01 ± 0.07, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.
- ALEXANDER 96T gives systematic errors ±0.3 ± 0.2 where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin symmetry: Γ(B<sup>0</sup> → π<sup>-</sup>ℓ<sup>+</sup>ν) = 2 × Γ(B<sup>+</sup> → π<sup>0</sup>ℓ<sup>+</sup>ν).

$3.1 \pm 1.3 \pm 1.0$	7	<sup>5</sup> ALBRECHT	88K	ARG $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>2</sup> Uses a missing-mass method. Does not depend on  $D$  branching fractions or  $B^+/B^0$  production rates.

<sup>3</sup> AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of  $B^0$  and  $B^+$ , which is not included here.

<sup>4</sup> BORTOLETTO 92 assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$ .

<sup>5</sup> ALBRECHT 88K assumes  $B^0\bar{B}^0:B^+B^-$  production ratio is 45:55. Superseded by ALBRECHT 90J which assumes 50:50.

<sup>6</sup> BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

<sup>7</sup> AUBERT, B 04O reports  $[\Gamma(B^0 \rightarrow D^- \pi^+)/\Gamma_{total}] \times [B(D^+ \rightarrow K_S^0 \pi^+)] = (42.7 \pm 2.1 \pm 2.2) \times 10^{-6}$  which we divide by our best value  $B(D^+ \rightarrow K_S^0 \pi^+) = (1.47 \pm 0.07) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>8</sup> ALAM 94 reports  $[\Gamma(B^0 \rightarrow D^- \pi^+)/\Gamma_{total}] \times [B(D^+ \rightarrow K^- 2\pi^+)] = (0.265 \pm 0.032 \pm 0.023) \times 10^{-3}$  which we divide by our best value  $B(D^+ \rightarrow K^- 2\pi^+) = (9.13 \pm 0.19) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

$700 \pm 500$		5	<sup>5</sup> BEHREND	83	CLEO $e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>2</sup> No assumption about the intermediate mechanism is made in the analysis.

<sup>3</sup> BORTOLETTO 92 assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$ . The product branching fraction into  $D_S^*(2340)\pi$  followed by  $D_S^*(2340) \rightarrow D^0 \pi$  is  $< 0.0001$  at 90% CL and into  $D_S^*(2460)$  followed by  $D_S^*(2460) \rightarrow D^0 \pi$  is  $< 0.0004$  at 90% CL.

<sup>4</sup> BEBEK 87 assume the  $\Upsilon(4S)$  decays 43% to  $B^0\bar{B}^0$ . We rescale to 50%.  $B(D^0 \rightarrow K^- \pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$  and  $B(D^0 \rightarrow K^- \pi^+ \pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$  were used.

<sup>5</sup> Corrected by us using assumptions:  $B(D^0 \rightarrow K^- \pi^+) = (0.042 \pm 0.006)$  and  $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 50\%$ . The product branching ratio is  $B(B^0 \rightarrow \bar{D}^0 \pi^+ \pi^-)B(\bar{D}^0 \rightarrow K^+ \pi^-) = (0.39 \pm 0.26) \times 10^{-2}$ .

Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 3 Uses a missing-mass method. Does not depend on  $D$  branching fractions or  $B^{\pm}/B^0$  production rates.
- 4 BRANDENBURG 98 assume equal production of  $B^+$  and  $B^0$  at  $\Upsilon(4S)$  and use the  $D^*$  reconstruction technique. The first error is their experiment's error and the second error is the systematic error from the PDG 96 value of  $B(D^* \rightarrow D\pi)$ .
- 5 ALAM 94 assume equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and use the CLEO II  $B(D^*(2010)^+ \rightarrow D^0\pi^+)$  and absolute  $B(D^0 \rightarrow K^-\pi^+)$  and the PDG 1992  $B(D^0 \rightarrow K^-\pi^+\pi^0)/B(D^0 \rightarrow K^-\pi^+)$  and  $B(D^0 \rightarrow K^-2\pi^+\pi^-)/B(D^0 \rightarrow K^-\pi^+)$ .
- 6 BORTOLETTO 92 reports  $(4.0 \pm 1.0 \pm 0.7) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$  assuming  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$ , which we rescale to our best value  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$ .
- 7 ALBRECHT 90J reports  $(2.8 \pm 0.9 \pm 0.6) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$  assuming  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$ , which we rescale to our best value  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$ .
- 8 BEBEK 87 reports  $(2.8^{+1.5+1.0}_{-1.2-0.6}) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$  assuming  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$ , which we rescale to our best value  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90J.
- 9 Assumes  $B(Z \rightarrow b\bar{b}) = 0.217$  and 38%  $B_d$  production fraction.
- 10 ALBRECHT 87c use PDG 86 branching ratios for  $D$  and  $D^*(2010)$  and assume  $B(\Upsilon(4S) \rightarrow B^+B^-) = 55\%$  and  $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 45\%$ . Superseded by ALBRECHT 90J.
- 11 ALBRECHT 86f uses pseudomass that is independent of  $D^0$  and  $D^+$  branching ratios.
- 12 Assumes  $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.60^{+0.08}_{-0.15}$ . Assumes  $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 0.40 \pm 0.02$ . Does not depend on  $D$  branching ratios.

<0.042	90	<sup>7</sup> BEBEK 87	CLEO	$e^+e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .  
<sup>2</sup> ALAM 94 assume equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and use the CLEO II  $B(D^*(2010)^+ \rightarrow D^0 \pi^+)$  and absolute  $B(D^0 \rightarrow K^- \pi^+)$  and the PDG 1992  $B(D^0 \rightarrow K^- \pi^+ \pi^0)/B(D^0 \rightarrow K^- \pi^+)$  and  $B(D^0 \rightarrow K^- 2\pi^+ \pi^-)/B(D^0 \rightarrow K^- \pi^+)$ .  
<sup>3</sup> The three pion mass is required to be between 1.0 and 1.6 GeV consistent with an  $a_1$  meson. (If this channel is dominated by  $a_1^+$ , the branching ratio for  $\bar{D}^* a_1^+$  is twice that for  $\bar{D}^* \pi^+ \pi^+ \pi^-$ .)

<sup>4</sup> BORTOLETTO 92 reports  $0.0159 \pm 0.0028 \pm 0.0037$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- \pi^+ \pi^+ \pi^-)/\Gamma_{total}] \times [B(D^*(2010)^+ \rightarrow D^0 \pi^+)]$  assuming  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 0.57 \pm 0.06$ , which we rescale to our best value  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$ .  
<sup>5</sup> ALBRECHT 90J reports  $0.012 \pm 0.003 \pm 0.004$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- \pi^+ \pi^+ \pi^-)/\Gamma_{total}] \times [B(D^*(2010)^+ \rightarrow D^0 \pi^+)]$  assuming  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 0.57 \pm 0.06$ , which we rescale to our best value  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = (67.7 \pm 0.5) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$ .  
<sup>6</sup> ALBRECHT 87c use PDG 86 branching ratios for  $D$  and  $D^*(2010)$  and assume  $B(\Upsilon(4S) \rightarrow B^+ B^-) = 55\%$  and  $B(\Upsilon(4S) \rightarrow B^0 \bar{B}^0) = 45\%$ . Superseded by ALBRECHT 90J.  
<sup>7</sup> BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

<sup>1</sup> AUBERT 06N reports  $(0.71 \pm 0.13 \pm 0.09) \times 10^{-2}$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$  assuming  $B(D_s^+ \rightarrow \phi \pi^+) = 0.0462 \pm 0.0062$ , which we rescale to our best value  $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>2</sup> AUBERT 03i reports  $0.0103 \pm 0.0014 \pm 0.0013$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$  assuming  $B(D_s^+ \rightarrow \phi \pi^+) = 0.036$ , which we rescale to our best value  $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>3</sup> AHMED 00B reports  $0.0110 \pm 0.0018 \pm 0.0011$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$  assuming  $B(D_s^+ \rightarrow \phi \pi^+) = 0.036$ , which we rescale to our best value  $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>4</sup> ALBRECHT 92G reports  $0.014 \pm 0.010 \pm 0.003$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$  assuming  $B(D_s^+ \rightarrow \phi \pi^+) = 0.027$ , which we rescale to our best value  $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990  $D^+$  and  $D^*(2010)^+$  branching ratios, e.g.,  $B(D^0 \rightarrow K^- \pi^+) = 3.71 \pm 0.25\%$ ,  $B(D^+ \rightarrow K^- 2\pi^+) = 7.1 \pm 1.0\%$ , and  $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 55 \pm 4\%$ .

<sup>5</sup> BORTOLETTO 92 reports  $0.016 \pm 0.009 \pm 0.006$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$  assuming  $B(D_s^+ \rightarrow \phi \pi^+) = 0.030 \pm 0.011$ , which we rescale to our best value  $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses Mark III branching fractions for the  $D$  and  $D^*(2010)$ .

<sup>6</sup> GIBAUT 96 reports  $0.0093 \pm 0.0023 \pm 0.0016$  from a measurement of  $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$  assuming  $B(D_s^+ \rightarrow \phi \pi^+) = 0.035$ , which we rescale to our best value  $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.  
<sup>7</sup> BORTOLETTO 90 assume  $B(D_s \rightarrow \phi \pi^+) = 2\%$ . Superseded by BORTOLETTO 92.

13 ALAM 86      CLEO      Repl. by BEBEK 87

1 AUBERT 07AV reports  $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow p\bar{p})] = (2.82^{+0.30+0.36}_{-0.28-0.35}) \times 10^{-6}$  which we divide by our best value  $B(J/\psi(1S) \rightarrow p\bar{p}) = (2.17 \pm 0.07) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

2 Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

3 ABE 98O reports  $[B(B^0 \rightarrow J/\psi(1S)K^*(892)^0)]/[B(B^+ \rightarrow J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$ . We multiply by our best value  $B(B^+ \rightarrow J/\psi(1S)K^+) = (9.9 \pm 1.0) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

4 Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

5 BORTOLETTO 92 reports  $(1.1 \pm 0.5 \pm 0.3) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

6 ALBRECHT 90J reports  $(1.1 \pm 0.5 \pm 0.2) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

7 BEBEK 87 reports  $(3.5 \pm 1.6 \pm 0.3) \times 10^{-3}$  from a measurement of  $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$  assuming  $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$ , which we rescale to our best value  $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

8 ABE 96H assumes that  $B(B^+ \rightarrow J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$ .

9 The neutral and charged  $B$  events together are predominantly longitudinally polarized,  $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$ . This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the  $B \rightarrow \psi K^*$  decay is dominated by the  $CP = -1$   $CP$  eigenstate. Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

10 ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal,  $\Gamma_T/\Gamma = 0.03 \pm 0.16 \pm 0.15$  making the neutral decay a  $CP$  eigenstate when the  $K^*$  decays through  $K_S^0\pi^0$ .

11 ALBAJAR 91E assumes  $B^0$  production fraction of 36%.

12 ALBRECHT 87D assume  $B^+B^-/B^0\bar{B}^0$  ratio is 55/45. Superseded by ALBRECHT 90J.

13 ALAM 86 assumes  $B^\pm/B^0$  ratio is 60/40. The observation of the decay  $B^+ \rightarrow J/\psi K^*(892)^+$  (HAAS 85) has been retracted in this paper.

$< 7$	90	<sup>1</sup> BATTLE 93	CLE2	$e^+e^- \rightarrow \Upsilon(4S)$

- <sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .  
<sup>2</sup> Obtains this result from  $B(K^+ K^-)/B(K^+ \pi^-) = 0.020 \pm 0.008 \pm 0.006$ , assuming  $B(B^0 \rightarrow K^+ \pi^-) = (19.4 \pm 0.6) \times 10^{-6}$ .  
<sup>3</sup> ABULENCIA,A 06D obtains this from  $\Gamma(K^+ K^-)/\Gamma(K^+ \pi^-) < 0.10$  at 90% CL, assuming  $B(B^0 \rightarrow K^+ \pi^-) = (18.9 \pm 0.7) \times 10^{-6}$ .  
<sup>4</sup> ABE 00c assumes  $B(Z \rightarrow b\bar{b}) = (21.7 \pm 0.1)\%$  and the  $B$  fractions  $f_{B^0} = f_{B^+} = (39.7^{+1.8}_{-2.2})\%$  and  $f_{B_s} = (10.5^{+1.8}_{-2.2})\%$ .  
<sup>5</sup> ADAM 96D assumes  $f_{B^0} = f_{B^-} = 0.39$  and  $f_{B_s} = 0.12$ . Contributions from  $B^0$  and  $B_s$  decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral  $B$  mesons.  
<sup>6</sup> BUSKULIC 96v assumes PDG 96 production fractions for  $B^0, B^+, B_s, b$  baryons.  
<sup>7</sup> Assumes a  $B^0, B^-$  production fraction of 0.39 and a  $B_s$  production fraction of 0.12. Contributions from  $B^0$  and  $B_s^0$  decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral  $B$  mesons.

## Meson Particle Listings

 $B^0$ 

- <sup>1</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .  
<sup>2</sup> ABE 00c assumes  $B(Z \rightarrow b\bar{b}) = (21.7 \pm 0.1)\%$  and the  $B$  fractions  $f_{B^0} = f_{B^+} = (39.7 \pm 1.8)\%$  and  $f_{B_s} = (10.5 \pm 1.8)\%$ .  
<sup>3</sup> ADAM 96d assumes  $f_{B^0} = f_{B^+} = 0.39$  and  $f_{B_s} = 0.12$ .  
<sup>4</sup> BUSKULIC 96v assumes PDG 96 production fractions for  $B^0$ ,  $B^+$ ,  $B_s$ ,  $b$  baryons.  
<sup>5</sup> Assumes a  $B^0$ ,  $B^-$  production fraction of 0.39 and a  $B_s$  production fraction of 0.12.  
<sup>6</sup> Assumes  $B(Z \rightarrow b\bar{b}) = 0.217$  and  $B_d^0$  ( $B_s^0$ ) fraction 39.5% (12%).  
<sup>7</sup> Paper assumes the  $\Upsilon(4S)$  decays 43% to  $B^0\bar{B}^0$ . We rescale to 50%.

POLARIZATION IN  $B$  DECAYS

Revised February 2012 by A. V. Gritsan (Johns Hopkins University) and J. G. Smith (University of Colorado at Boulder).

We review the notation used in polarization measurements in particle production and decay, with a particular emphasis on the  $B$  decays and the  $CP$ -violating observables in polarization measurements. We look at several examples of vector-vector and vector-tensor  $B$  meson decays, while more details about the theory and experimental results in  $B$  decays can be found in a separate mini-review [1] in this *Review*.

Figure 1 illustrates angular observables in an example of the sequential process  $ab \rightarrow X \rightarrow P_1 P_2 \rightarrow (p_{11} p_{12})(p_{21} p_{22})$  [2]. The angular distributions are of particular interest because they are sensitive to spin correlations and reveal properties of particles and their interactions, such as quantum numbers and couplings. In the case of a spin-zero particle  $X$ , such as  $B$  meson or a Higgs boson, there are no spin correlations in the production mechanism and the decay chain is to be analyzed. The angular distribution of decay products can be expressed as a function of three helicity angles which describe the alignment of the particles in the decay chain. The analyzer of the  $B$ -daughter polarization is normally chosen for two-body decays, as the direction of the daughters in the center-of-mass of the parent (*e.g.*,  $\rho \rightarrow 2\pi$ ) [3], and for three-body decays as the normal to the decay plane (*e.g.*,  $\omega \rightarrow 3\pi$ ) [4]. An equivalent set of transversity angles is sometimes used in polarization analyses [5]. The differential decay width depends on complex amplitudes  $A_{\lambda_1 \lambda_2}$ , corresponding to the  $X$ -daughter helicity states  $\lambda_i$ .

In the case of a spin-zero  $B$ -meson decay, its daughter helicities are constrained to  $\lambda_1 = \lambda_2 = \lambda$ . Therefore we simplify amplitude notation as  $A_\lambda$ . Moreover, most  $B$ -decay polarization analyses are limited to the case when the spin of one of the  $B$ -meson daughters is 1. In that case, there are only three independent amplitudes corresponding to  $\lambda = 0$  or  $\pm 1$  [6], where the last two can be expressed in terms of parity-even and parity-odd amplitudes  $A_{\parallel, \perp} = (A_{+1} \pm A_{-1})/\sqrt{2}$ . The overall decay amplitude involves three complex terms proportional to the above amplitudes and the Wigner  $d$  functions of helicity angles. The exact angular dependence would depend on the quantum numbers of the  $B$ -meson daughters and of their decay products, and can be found in the literature [6,7]. The

**Figure 1:** Definition of the production and helicity angles in the sequential process  $ab \rightarrow X \rightarrow P_1 P_2 \rightarrow (p_{11} p_{12})(p_{21} p_{22})$ . The three helicity angles include  $\theta_1$  and  $\theta_2$ , defined in the rest frame of the two daughters  $P_1$  and  $P_2$ , and  $\Phi$ , defined in the  $X$  frame as the angle between the two decay planes. The two production angles  $\theta^*$  and  $\Psi$  are defined in the  $X$  frame, where  $\Psi$  is the angle between the production plane and the average of the two decay planes.

differential decay rate would involve six real quantities  $\alpha_i$ , including interference terms,

$$\frac{d\Gamma}{\Gamma d \cos \theta_1 d \cos \theta_2 d\Phi} = \sum_i \alpha_i f_i(\cos \theta_1, \cos \theta_2, \Phi), \quad (1)$$

where each  $f_i(\cos \theta_1, \cos \theta_2, \Phi)$  has unique angular dependence specific to particle quantum numbers, and the  $\alpha_i$  parameters are defined as:

$$\alpha_1 = \frac{|A_0|^2}{\sum |A_\lambda|^2} = f_L, \quad (2)$$

$$\alpha_2 = \frac{|A_\parallel|^2 + |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L), \quad (3)$$

$$\alpha_3 = \frac{|A_\parallel|^2 - |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L - 2f_\perp), \quad (4)$$

$$\alpha_4 = \frac{\Im m(A_\perp A_\parallel^*)}{\sum |A_\lambda|^2} = \sqrt{f_\perp(1 - f_L - f_\perp)} \sin(\phi_\perp - \phi_\parallel), \quad (5)$$

$$\alpha_5 = \frac{\Re e(A_\parallel A_0^*)}{\sum |A_\lambda|^2} = \sqrt{f_L(1 - f_L - f_\perp)} \cos(\phi_\parallel), \quad (6)$$

$$\alpha_6 = \frac{\Im m(A_\perp A_0^*)}{\sum |A_\lambda|^2} = \sqrt{f_\perp f_L} \sin(\phi_\perp), \quad (7)$$

where the amplitudes have been expressed with the help of polarization parameters  $f_L$ ,  $f_\perp$ ,  $\phi_\parallel$ , and  $\phi_\perp$  defined in Table 1. Note that the terms proportional to  $\Re e(A_\perp A_\parallel^*)$ ,  $\Im m(A_\parallel A_0^*)$ , and  $\Re e(A_\perp A_0^*)$  are absent in Eqs. (2-7). However, these terms may appear for some three-body decays of a  $B$ -meson daughter, see Ref. 7.

**Table 1:** Rate, polarization, and  $CP$ -asymmetry parameters defined for the  $B$ -meson decays to mesons with non-zero spin. Numerical examples are shown for the  $B^0 \rightarrow \varphi K^*(892)^0$  decay. The first six parameters are defined under the assumption of no  $CP$  violation in decay, while they are averaged between the  $\bar{B}$  and  $B$  parameters in general. The last six parameters involve differences between the  $\bar{B}$  and  $B$  meson decay parameters. The phase convention  $\delta_0$  is chosen with respect to a single  $A_{00}$  amplitude from a reference  $B$  decay mode, which is  $B^0 \rightarrow \varphi K_0^*(1430)^0$  for numerical results.

parameter	definition	average
$\mathcal{B}$	$\Gamma/\Gamma_{\text{total}}$	$(9.8 \pm 0.6) \times 10^{-6}$
$f_L$	$ A_0 ^2/\sum  A_\lambda ^2$	$0.480 \pm 0.030$

$\phi_\perp - \pi$	$\arg(A_\perp/A_0) - \pi$	$-0.75 \pm 0.13$
$\delta_0 - \pi$	$\arg(A_{00}/A_0) - \pi$	$-0.32 \pm 0.17$
$A_{CP}$	$(\bar{\Gamma} - \Gamma)/(\bar{\Gamma} + \Gamma)$	$+0.01 \pm 0.05$
$A_{CP}^0$	$(\bar{f}_L - f_L)/(\bar{f}_L + f_L)$	$+0.04 \pm 0.06$
$A_{CP}^\perp$	$(\bar{f}_\perp - f_\perp)/(\bar{f}_\perp + f_\perp)$	$-0.11 \pm 0.12$
$\Delta\phi_\parallel$	$(\bar{\phi}_\parallel - \phi_\parallel)/2$	$+0.11 \pm 0.22$
$\Delta\phi_\perp$	$(\bar{\phi}_\perp - \phi_\perp - \pi)/2$	$+0.08 \pm 0.22$
$\Delta\delta_0$	$(\bar{\delta}_0 - \delta_0)/2$	$+0.27 \pm 0.16$

Overall, six real parameters describe three complex amplitudes  $A_0$ ,  $A_\parallel$ , and  $A_\perp$ . These could be chosen to be the four polarization parameters  $f_L$ ,  $f_\perp$ ,  $\phi_\parallel$ , and  $\phi_\perp$ , one overall size normalization, such as decay rate  $\Gamma$ , or branching fraction  $\mathcal{B}$ , and one overall phase  $\delta_0$ . The phase convention is arbitrary for an isolated  $B$  decay mode. However, for several  $B$  decays, the relative phase could produce meaningful and observable effects through interference with other  $B$  decays with the same final states, such as for  $B \rightarrow VK_J^*$  with  $J = 0, 1, 2, 3, 4, \dots$ . The phase could be referenced to the single  $B \rightarrow VK_0^*$  amplitude  $A_{00}$  in such a case, as shown in Table 1. Here  $V$  stands for any spin-one vector meson.

Moreover,  $CP$  violation can be tested in the angular distribution of the decay as the difference between the  $B$  and  $\bar{B}$ . Each of the six real parameters describing the three complex amplitudes would have a counterpart  $CP$ -asymmetry term, corresponding to three direct- $CP$  asymmetries in three amplitudes, and three  $CP$ -violating phase differences, equivalent to the phase measurements from the mixing-induced  $CP$  asymmetries in the time evolution of  $B$ -decays [1]. In Table 1 and Ref. 8, these are chosen to be the direct- $CP$  asymmetries in the overall decay rate  $\mathcal{A}_{CP}$ , in the  $f_L$  fraction  $\mathcal{A}_{CP}^0$ , and in the  $f_\perp$  fraction  $\mathcal{A}_{CP}^\perp$ , and three weak phase differences:

$$\Delta\phi_\parallel = \frac{1}{2} \arg(\bar{A}_\parallel A_0 / A_\parallel \bar{A}_0), \quad (8)$$

$$\Delta\phi_\perp = \frac{1}{2} \arg(\bar{A}_\perp A_0 / A_\perp \bar{A}_0) - \frac{\pi}{2}, \quad (9)$$

## Meson Particle Listings

 $B^0$ 

$$\Delta\delta_0 = \frac{1}{2}\arg(\bar{A}_{00}A_0/A_{00}\bar{A}_0). \quad (10)$$

The  $\frac{\pi}{2}$  term in Eq. (9) reflects the fact that  $A_\perp$  and  $\bar{A}_\perp$  differ in phase by  $\pi$  if  $CP$  is conserved. The two parameters  $\Delta\phi_\parallel$  and  $\Delta\phi_\perp$  are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [9]. The  $CP$ -violating phase difference in the reference decay mode [8] is, in the Wolfenstein CKM quark-mixing phase convention,

$$\Delta\phi_{00} = \frac{1}{2}\arg(A_{00}/\bar{A}_{00}). \quad (11)$$

This can be measured only together with the mixing-induced phase difference for some of the neutral  $B$ -meson decays similar to other mixing-induced  $CP$  asymmetry measurements [1].

It may not always be possible to have a phase-reference decay mode which would define  $\delta_0$  and  $\Delta\delta_0$  parameters. In that case, it may be possible to define the phase difference directly similarly to Eq. (11):

$$\Delta\phi_0 = \frac{1}{2}\arg(A_0/\bar{A}_0). \quad (12)$$

One can measure the angles of the CKM unitarity triangle, assuming Standard Model contributions to the  $\Delta\phi_0$  and  $B$ -mixing phases. Examples include measurements of  $\beta = \phi_1$  with  $B \rightarrow J/\psi K^*$  and  $\alpha = \phi_2$  with  $B \rightarrow \rho\rho$ .

Most of the  $B$  decays that arise from tree-level  $b \rightarrow c$  transitions have the amplitude hierarchy  $|A_0| > |A_+| > |A_-|$  which is expected from analyses based on quark-helicity conservation [10]. The larger the mass of the vector-meson daughters, the weaker the inequality. The  $B$  meson decays to heavy vector particles with charm, such as  $B \rightarrow J/\psi K^*$ ,  $\psi(2S)K^*$ ,  $\chi_{c1}K^*$ ,  $D^*\rho$ ,  $D^*K^*$ ,  $D^*D^*$ , and  $D^*D_s^*$ , show a substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons ( $A_{\pm 1}$ ), in agreement with the factorization prediction. The detailed amplitude analysis of the  $B \rightarrow J/\psi K^*$  decays has been performed by the BABAR [11], Belle [12], CDF [13], CLEO [14], and D0 [15] collaborations. Most analyses are performed under the assumption of the absence of direct  $CP$  violation. The parameter values are given in the particle listing of this *Review*. The difference between the strong phases  $\phi_\parallel$  and  $\phi_\perp$  deviates significantly from zero. The recent measurements [11,12] of  $CP$ -violating terms similar to those in  $B \rightarrow \varphi K^*$  [8] shown in Table 1 are consistent with zero.

In addition, the mixing-induced  $CP$ -violating asymmetry is measured in the  $B^0 \rightarrow J/\psi K^{*0}$  decay [1,11,12] where angular analysis allows one to separate  $CP$ -eigenstate amplitudes. This allows one to resolve the sign ambiguity of the  $\cos 2\beta$  ( $\cos 2\phi_1$ ) term that appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases  $\phi_\parallel$  and  $\phi_\perp$ , as discussed below. The BABAR experiment used a method based on the dependence on the  $K\pi$  invariant mass of the interference between the  $S$ - and  $P$ -waves to resolve the discrete ambiguity in the determination of the

strong phases ( $\phi_\parallel, \phi_\perp$ ) in  $B \rightarrow J/\psi K^*$  decays [11]. The result is in agreement with the amplitude hierarchy expectation [10]. The CDF [16], D0 [17], and LHCb [18] experiments have studied the  $B_s^0 \rightarrow J/\psi\varphi$  decay and provided the lifetime, polarization, and phase measurements.

The amplitude hierarchy  $|A_0| \gg |A_+| \gg |A_-|$  was expected in  $B$  decays to light vector particles in both penguin transitions [19,20] and tree-level transitions [10]. There is confirmation by the BABAR and Belle experiments of predominantly longitudinal polarization in the tree-level  $b \rightarrow u$  transition, such as  $B^0 \rightarrow \rho^+\rho^-$  [21],  $B^+ \rightarrow \rho^0\rho^+$  [22], and  $B^+ \rightarrow \omega\rho^+$  [23]; this is consistent with the analysis of the quark helicity conservation [10]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current  $B$  samples, and limits on the transverse amplitude fraction are obtained. The fraction of transverse polarization is large in decays to heavier mesons such as  $B^0 \rightarrow a_1(1260)^+a_1(1260)^-$  [24]. Only limits have been set for  $B^0 \rightarrow \omega\rho^0, \omega\omega$  [23]; there is some evidence for  $B^0 \rightarrow \rho^0\rho^0$  [25] decays. The small values for these branching fractions indicates that  $b \rightarrow d$  penguin pollution is small in the charmless, strangeless vector-vector  $B$  decays.

The interest in the polarization and  $CP$ -asymmetry measurements in penguin transition, such as  $b \rightarrow s$  decays  $B \rightarrow \varphi K^*$ ,  $\rho K^*$ ,  $\omega K^*$ , or  $B_s^0 \rightarrow \varphi\varphi$ , and  $b \rightarrow d$  decay  $B \rightarrow K^*\bar{K}^*$ , is motivated by their potential sensitivity to physics beyond the Standard Model. The decay amplitudes for  $B \rightarrow \varphi K^*$  have been measured by the BABAR and Belle experiments [8,26,27]. The fractions of longitudinal polarization are  $f_L = 0.50 \pm 0.05$  for the  $B^+ \rightarrow \varphi K^{*+}$  decay and  $f_L = 0.48 \pm 0.03$  for the  $B^0 \rightarrow \varphi K^{*0}$  decay. These indicate significant departure from the naive expectation of predominant longitudinal polarization, suggesting other contributions to the decay amplitude, previously neglected, either within the Standard Model, such as penguin annihilation [28] or QCD rescattering [29], or from physics beyond the Standard Model [30]. The complete set of twelve amplitude parameters measured in the  $B^0 \rightarrow \varphi K^{*0}$  decay is given in Table 1. Several other parameters could be constructed from the above twelve parameters, as suggested in Ref. 31.

The discrete ambiguity in the phase ( $\phi_\parallel, \phi_\perp, \Delta\phi_\parallel, \Delta\phi_\perp$ ) measurements has been resolved by BABAR in favor of  $|A_+| \gg |A_-|$  through interference between the  $S$ - and  $P$ -waves of  $K\pi$ . The search for vector-tensor and vector-axialvector  $B \rightarrow \varphi K_J^{(*)}$  decays with  $J = 1, 2, 3, 4$  revealed a large fraction of longitudinal polarization in the decay  $B \rightarrow \varphi K_2^*(1430)$  with  $f_L = 0.90_{-0.07}^{+0.06}$  [8,32], but large contribution of transverse amplitude in  $B \rightarrow \varphi K_1(1270)$  with  $f_L = 0.46_{-0.15}^{+0.13}$  [33].

Like  $B \rightarrow \varphi K^*$ , the decays  $B \rightarrow \rho K^*$  and  $B \rightarrow \omega K^*$  may be sensitive to New Physics. Measurements of the longitudinal polarization fraction in  $B^+ \rightarrow \rho^0 K^{*0}$ ,  $B^+ \rightarrow \rho^+ K^{*0}$  [34] and in both vector-vector and vector-tensor final states of  $B \rightarrow \omega K_J^*$  [23] reveal a large fraction of transverse polarization, indicating an anomaly similar to  $B \rightarrow \varphi K^*$  except for a different

pattern in vector-tensor final states. A large transverse polarization is also observed in the  $B_s^0 \rightarrow \varphi\varphi$  decays by CDF [37] and  $B_s^0 \rightarrow K^{*0}\bar{K}^{*0}$  decays by LHCb [36]. At the same time, first measurement of the polarization in the  $b \rightarrow d$  penguin decays  $B \rightarrow K^*\bar{K}^*$  indicates a large fraction of longitudinal polarization [35]. The polarization pattern in penguin-dominated  $B$ -meson decays is not fully understood [28,29,30].

The three-body semileptonic  $B$ -meson decays, such as  $B \rightarrow V\ell_1\ell_2$ , share many features with the two-body  $B \rightarrow VV$  decays. Their differential decay width can be parameterized with the two helicity angles defined in the  $V$  and  $(\ell_1\ell_2)$  frames and with the azimuthal angle, as defined in Fig. 1. However, since the  $(\ell_1\ell_2)$  pair does not come from an on-shell particle, the angular distribution is unique to each point in the dilepton mass  $m_{\ell\ell}$  spectrum. The polarization measurements as a function of  $m_{\ell\ell}$  provide complementary information on physics beyond the Standard Model, as discussed for  $B \rightarrow K^*\ell^+\ell^-$  decay in Ref. 38. The current data in this mode has been analyzed by the BABAR, Belle, and CDF experiments [39].

The examples of the angular distributions and observables in  $B \rightarrow K^*\ell^+\ell^-$  are discussed in Ref. 38. Typically two angular observables have been measured in this decay in certain ranges of the dilepton mass  $m_{\ell\ell}$  [39]. One parameter is the fraction of longitudinal polarization  $F_L$ , which is determined by the  $K^*$  angular distribution and is similar to  $f_L$  defined for exclusive two-body decays. The other parameter is the forward-backward asymmetry of the lepton pair  $A_{FB}$ , which is the asymmetry of the decay rate with positive and negative values of  $\cos\theta_1$ .

In summary, there has been considerable recent interest in the polarization measurements of  $B$ -meson decays because they reveal both weak- and strong-interaction dynamics [28–30,40]. New measurements will further elucidate the pattern of spin alignment measurements in rare  $B$  decays, and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the  $B$ -decay amplitudes.

POLARIZATION IN  $B^0$  DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel ( $\parallel$ ) or perpendicular ( $\perp$ ) to each other with the parameters  $\Gamma_L/\Gamma$ ,  $\Gamma_\perp/\Gamma$ , and the relative phases  $\phi_\parallel$  and  $\phi_\perp$ . See the definitions in the note on "Polarization in  $B$  Decays" review in the  $B^0$  Particle Listings.

 $\Gamma_L/\Gamma$  in  $B^0 \rightarrow J/\psi(1S)K^*(892)^0$

 $B^0-\bar{B}^0$  MIXING

Updated April 2012 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral  $B^0-\bar{B}^0$  meson systems,  $B_d^0-\bar{B}_d^0$  and  $B_s^0-\bar{B}_s^0$  (generically denoted  $B_q^0-\bar{B}_q^0$ ,  $q = s, d$ ), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume  $CPT$  conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{L,H}\rangle = p|B_q^0\rangle \pm q|\bar{B}_q^0\rangle, \quad (1)$$

have a mass difference  $\Delta m_q = m_H - m_L > 0$ , and a total decay width difference  $\Delta\Gamma_q = \Gamma_L - \Gamma_H$ . In the absence of  $CP$  violation in the mixing,  $|q/p| = 1$ , these differences are given by  $\Delta m_q = 2|M_{12}|$  and  $|\Delta\Gamma_q| = 2|\Gamma_{12}|$ , where  $M_{12}$  and  $\Gamma_{12}$  are the

off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure  $|B_q^0\rangle$  or  $|\bar{B}_q^0\rangle$  state at  $t = 0$  is given by

$$|B_q^0(t)\rangle = g_+(t)|B_q^0\rangle + \frac{q}{p}g_-(t)|\bar{B}_q^0\rangle, \quad (2)$$

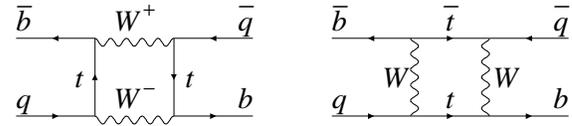

$$|\bar{B}_q^0(t)\rangle = g_+(t)|\bar{B}_q^0\rangle + \frac{p}{q}g_-(t)|B_q^0\rangle, \quad (3)$$

which means that the flavor states remain unchanged (+) or oscillate into each other (-) with time-dependent probabilities proportional to

$$|g_{\pm}(t)|^2 = \frac{e^{-\Gamma_q t}}{2} \left[ \cosh\left(\frac{\Delta\Gamma_q}{2}t\right) \pm \cos(\Delta m_q t) \right], \quad (4)$$

where  $\Gamma_q = (\Gamma_H + \Gamma_L)/2$ . In the absence of  $CP$  violation, the time-integrated mixing probability  $\int |g_-(t)|^2 dt / (\int |g_-(t)|^2 dt + \int |g_+(t)|^2 dt)$  is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2 + 1)}, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}. \quad (5)$$

**Figure 1:** Dominant box diagrams for the  $B_q^0 \rightarrow \bar{B}_q^0$  transitions ( $q = d$  or  $s$ ). Similar diagrams exist where one or both  $t$  quarks are replaced with  $c$  or  $u$  quarks.

*Standard Model predictions and phenomenology*

In the Standard Model, the transitions  $B_q^0 \rightarrow \bar{B}_q^0$  and  $\bar{B}_q^0 \rightarrow B_q^0$  are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two  $W$  bosons and two up-type quarks (see Fig. 1), as is the case for  $K^0-\bar{K}^0$  mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral  $B$  meson systems, because the large  $B$  mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2} S_0(m_i^2/m_W^2) (V_{tq}^* V_{tb})^2, \quad (6)$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta'_B m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[ (V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb} \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2 \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right) \right], \quad (7)$$

where  $G_F$  is the Fermi constant,  $m_W$  the  $W$  boson mass, and  $m_i$  the mass of quark  $i$ ;  $m_{B_q}$ ,  $f_{B_q}$  and  $B_{B_q}$  are the  $B_q^0$  mass, weak decay constant and bag parameter, respectively. The known function  $S_0(x_t)$  can be approximated very well by  $0.784 x_t^{0.76}$  [4], and  $V_{ij}$  are the elements of the CKM matrix [5].

The QCD corrections  $\eta_B$  and  $\eta'_B$  are of order unity. The only non-negligible contributions to  $M_{12}$  are from box diagrams involving two top quarks. The phases of  $M_{12}$  and  $\Gamma_{12}$  satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right), \quad (8)$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the  $K^0-\bar{K}^0$  system, the heavy state is expected to have a smaller decay width than that of the light state:  $\Gamma_H < \Gamma_L$ . Hence,  $\Delta\Gamma = \Gamma_L - \Gamma_H$  is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left|\frac{\Gamma_{12}}{M_{12}}\right| \simeq \frac{3\pi}{2} \frac{m_b^2}{m_W^2} \frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \quad (9)$$

is small, and a power expansion of  $|q/p|^2$  yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right| \sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right). \quad (10)$$

Therefore, considering both Eqs. (8) and (9), the  $CP$ -violating parameter

$$1 - \left|\frac{q}{p}\right|^2 \simeq \text{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \quad (11)$$

is expected to be very small:  $\sim \mathcal{O}(10^{-3})$  for the  $B_d^0-\bar{B}_d^0$  system and  $\lesssim \mathcal{O}(10^{-4})$  for the  $B_s^0-\bar{B}_s^0$  system [6].

In the approximation of negligible  $CP$  violation in mixing, the ratio  $\Delta\Gamma_q/\Delta m_q$  is equal to the small quantity  $|\Gamma_{12}/M_{12}|$  of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the  $B_d^0-\bar{B}_d^0$  and  $B_s^0-\bar{B}_s^0$  systems. Calculations [7] yield  $\sim 5 \times 10^{-3}$  with a  $\sim 20\%$  uncertainty. Given the published experimental knowledge [8] on the mixing parameter  $x_q$

$$\begin{cases} x_d = 0.770 \pm 0.008 & (B_d^0-\bar{B}_d^0 \text{ system}) \\ x_s = 26.49 \pm 0.29 & (B_s^0-\bar{B}_s^0 \text{ system}) \end{cases}, \quad (12)$$

the Standard Model thus predicts that  $\Delta\Gamma_d/\Gamma_d$  is very small (below 1%), but  $\Delta\Gamma_s/\Gamma_s$  considerably larger ( $\sim 10\%$ ). These width differences are caused by the existence of final states to which both the  $B_q^0$  and  $\bar{B}_q^0$  mesons can decay. Such decays involve  $b \rightarrow c\bar{q}$  quark-level transitions, which are Cabibbo-suppressed if  $q = d$  and Cabibbo-allowed if  $q = s$ .

A complete set of Standard Model predictions for all mixing parameters in both the  $B_d^0-\bar{B}_d^0$  and  $B_s^0-\bar{B}_s^0$  systems can be found in Ref. 7.

### Experimental issues and methods for oscillation analyses

Time-integrated measurements of  $B^0-\bar{B}^0$  mixing were published for the first time in 1987 by UA1 [9] and ARGUS [10], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced  $b\bar{b}$  pairs. Such analyses cannot easily separate the contributions from the different  $b$ -hadron species, therefore, the clean environment of  $\Upsilon(4S)$  machines (where only  $B_d^0$  and charged  $B_u$  mesons are produced) is in principle best suited to measure  $\chi_d$ .

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies  $\Delta m_d$  and  $\Delta m_s$ , from the proper time distributions of  $B_d^0$  or  $B_s^0$  candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the  $B_s^0-\bar{B}_s^0$  system, where the large value of  $x_s$  implies maximal mixing, *i.e.*,  $\chi_s \simeq 1/2$ . In such analyses, the  $B_d^0$  or  $B_s^0$  mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a  $b \rightarrow \ell^-$  decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron, LHC), the proper time  $t = \frac{m_B}{p}L$  is measured from the distance  $L$  between the production vertex and the  $B$  decay vertex, and from an estimate of the  $B$  momentum  $p$ . At asymmetric  $B$  factories (KEKB, PEP-II), producing  $e^+e^- \rightarrow \Upsilon(4S) \rightarrow B_d^0\bar{B}_d^0$  events with a boost  $\beta\gamma$  ( $= 0.425, 0.55$ ), the proper time difference between the two  $B$  candidates is estimated as  $\Delta t \simeq \frac{\Delta z}{\beta\gamma c}$ , where  $\Delta z$  is the spatial separation between the two  $B$  decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance  $\mathcal{S}$  of a  $B_d^0$  or  $B_s^0$  oscillation signal can be approximated as [11]

$$\mathcal{S} \approx \sqrt{N/2} f_{\text{sig}} (1 - 2\eta) e^{-(\Delta m \sigma_t)^2/2}, \quad (13)$$

where  $N$  is the number of selected and tagged candidates,  $f_{\text{sig}}$  is the fraction of signal in that sample,  $\eta$  is the total mistag probability, and  $\sigma_t$  is the resolution on proper time (or proper time difference). The quantity  $\mathcal{S}$  decreases very quickly as  $\Delta m$  increases; this dependence is controlled by  $\sigma_t$ , which is therefore a critical parameter for  $\Delta m_s$  analyses. At high-energy colliders, the proper time resolution  $\sigma_t \sim \frac{m_B}{\langle p \rangle} \sigma_L \oplus t \frac{\sigma_p}{p}$  includes a constant contribution due to the decay length resolution  $\sigma_L$  (typically 0.04–0.3 ps), and a term due to the relative momentum resolution  $\sigma_p/p$  (typically 10–20% for partially reconstructed decays), which increases with proper time. At  $B$  factories, the boost of the  $B$  mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller  $B$  boost).

In order to tag a  $B$  candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities,  $\eta_i$  and  $\eta_f$ , degrade  $\mathcal{S}$  by a total factor  $(1 - 2\eta) = (1 - 2\eta_i)(1 - 2\eta_f)$ . In lepton-based analyses, the final state is tagged by the charge of the lepton from  $b \rightarrow \ell^-$  decays; the largest contribution to  $\eta_f$  is then due to  $\bar{b} \rightarrow \bar{c} \rightarrow \ell^-$  decays. Alternatively, the charge of a reconstructed charm meson ( $D^{*-}$  from  $B_d^0$  or  $D_s^-$  from  $B_s^0$ ), or that of a kaon hypothesized to come from a  $b \rightarrow c \rightarrow s$  decay [12], can be used. For fully-inclusive analyses based on topological vertexing, final-state tagging techniques include jet-charge [13] and charge-dipole [14,15] methods. At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided into two groups: the ones that tag

# Meson Particle Listings

## $B^0$

the initial charge of the  $\bar{b}$  quark contained in the  $B$  candidate itself (same-side tag), and the ones that tag the initial charge of the other  $b$  quark produced in the event (opposite-side tag). On the same side, the sign of a charged pion or kaon from the primary vertex is correlated with the production state of the  $B_d^0$  or  $B_s^0$  if that particle is a decay product of a  $B^{**}$  state or the first in the fragmentation chain [16,17]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from  $b \rightarrow \ell^-$  or of a kaon from  $b \rightarrow c \rightarrow s$  can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the  $Z \rightarrow b\bar{b}$  decays, and provided another very interesting and effective initial state tag based on the polar angle of the  $B$  candidate [14]. Initial state tags have also been combined to reach  $\eta_i \sim 26\%$  at LEP [17,18], or even 22% at SLD [14] with full efficiency. In the case  $\eta_f = 0$ , this corresponds to an effective tagging efficiency  $Q = \epsilon D^2 = \epsilon(1 - 2\eta)^2$ , where  $\epsilon$  is the tagging efficiency, in the range 23 – 31%. The equivalent figure achieved by CDF during Tevatron Run I was  $\sim 3.5\%$  [19], reflecting the fact that tagging is more difficult at hadron colliders. The current CDF and DØ analyses of Tevatron Run II data reach  $\epsilon D^2 = (1.8 \pm 0.1)\%$  [20] and  $(2.5 \pm 0.2)\%$  [21] for opposite-side tagging, while same-side kaon tagging (for  $B_s^0$  analyses) is contributing an additional 3.7 – 4.8% at CDF [20], and pushes the combined performance to  $(4.7 \pm 0.5)\%$  at DØ [22]. LHCb, operating in the forward region at the LHC where the environment is different in terms of track multiplicity and  $b$ -hadron production kinematics, has reported  $\epsilon D^2 = (2.10 \pm 0.25)\%$  [23] for opposite-side tagging and  $(1.3 \pm 0.4)\%$  [24] for same-side kaon tagging.

At  $B$  factories, the flavor of a  $B_d^0$  meson at production cannot be determined, since the two neutral  $B$  mesons produced in a  $\Upsilon(4S)$  decay evolve in a coherent  $P$ -wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where  $t$  is replaced with  $\Delta t$  (which will take negative values half of the time). Hence, the “initial state” tag of a  $B$  can be taken as the final-state tag of the other  $B$ . Effective tagging efficiencies  $Q$  of 30% are achieved by BaBar and Belle [25], using different techniques including  $b \rightarrow \ell^-$  and  $b \rightarrow c \rightarrow s$  tags. It is worth noting that, in this case, mixing of the other  $B$  (*i.e.*, the coherent mixing occurring before the first  $B$  decay) does not contribute to the mistag probability.

In the absence of experimental observation of a decay-width difference, oscillation analyses typically neglected  $\Delta\Gamma$  in Eq. (4), and described the data with the physics functions  $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$  (high-energy colliders) or  $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$  (asymmetric  $\Upsilon(4S)$  machines). As can be seen from Eq. (4), a non-zero value of  $\Delta\Gamma$  would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of  $\Delta m$  are usually extracted from the data using a maximum likelihood fit.

### $\Delta m_d$ and $\Delta\Gamma_d$ measurements

Many  $B_d^0$ - $\bar{B}_d^0$  oscillations analyses have been published [26] by the ALEPH [27], DELPHI [15,28], L3 [29], OPAL [30,31] BaBar [32], Belle [33], CDF [16], DØ [21], and LHCb [34] collaborations. Although a variety of different techniques have been used, the individual  $\Delta m_d$  results obtained at high-energy colliders have remarkably similar precision. Their average is compatible with the recent and more precise measurements from asymmetric  $B$  factories. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or  $b$ -hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the  $b$ -hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of  $b$  hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [15,16,21,27–34] and accounting for all identified correlations yields  $\Delta m_d = 0.507 \pm 0.003(\text{stat}) \pm 0.003(\text{syst}) \text{ ps}^{-1}$  [8], a result dominated by the  $B$  factories.

On the other hand, ARGUS and CLEO have published time-integrated measurements [35–37], which average to  $\chi_d = 0.182 \pm 0.015$ . Following Ref. 37, the width difference  $\Delta\Gamma_d$  could in principle be extracted from the measured value of  $\Gamma_d$  and the above averages for  $\Delta m_d$  and  $\chi_d$  (see Eq. (5)), provided that  $\Delta\Gamma_d$  has a negligible impact on the  $\Delta m_d$  measurements. However, direct time-dependent studies published by DELPHI [15], BaBar [38] and Belle [39] provide stronger constraints, which can be combined to yield [8]

$$\text{sign}(\text{Re}\lambda_{\text{CP}})\Delta\Gamma_d/\Gamma_d = 0.015 \pm 0.018,$$

where  $\text{sign}(\text{Re}\lambda_{\text{CP}}) = +1$  is expected in the Standard Model.

Assuming  $\Delta\Gamma_d = 0$  and no  $CP$  violation in mixing, and using the measured  $B_d^0$  lifetime of  $1.519 \pm 0.007 \text{ ps}$ , the  $\Delta m_d$  and  $\chi_d$  results are combined to yield the world average

$$\Delta m_d = 0.507 \pm 0.004 \text{ ps}^{-1} \quad (14)$$

or, equivalently,

$$\chi_d = 0.1862 \pm 0.0023. \quad (15)$$

This  $\Delta m_d$  value provides an estimate of  $2|M_{12}|$ , and can be used with Eq. (6) to extract  $|V_{td}|$  within the Standard Model [40]. The main experimental uncertainties on the result come from  $m_t$  and  $\Delta m_d$ , but are completely negligible with respect to the uncertainty due to the hadronic matrix element  $f_{B_d}\sqrt{B_{B_d}} = 211 \pm 12 \text{ MeV}$  obtained from lattice QCD calculations [41].

### $\Delta m_s$ and $\Delta\Gamma_s$ measurements

After many years of intense search at LEP and SLC,  $B_s^0$ - $\bar{B}_s^0$  oscillations were first observed in 2006 by CDF using  $1 \text{ fb}^{-1}$  of Tevatron Run II data [20]. A year later DØ reported an independent preliminary evidence using  $2.4 \text{ fb}^{-1}$  of data [46]. Recently LHCb obtained the most precise results

using  $0.036 \text{ fb}^{-1}$  [34] and  $0.34 \text{ fb}^{-1}$  [24] of data collected at the LHC in 2010 and 2011, respectively. While the average of the published measurements of  $\Delta m_s$  [20,34] is

$$\Delta m_s = 17.69 \pm 0.08 \text{ ps}^{-1}, \quad (16)$$

including also the preliminary LHCb measurement [24] and taking systematic correlations into account yields

$$\Delta m_s = 17.719 \pm 0.036(\text{stat}) \pm 0.023(\text{syst}) \text{ ps}^{-1}. \quad (17)$$

The information on  $|V_{ts}|$  obtained in the framework of the Standard Model is hampered by the hadronic uncertainty, as in the  $B_d^0$  case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}} \xi^2 \left| \frac{V_{ts}}{V_{td}} \right|^2, \quad (18)$$

where  $\xi = (f_{B_s} \sqrt{B_{B_s}}) / (f_{B_d} \sqrt{B_{B_d}}) = 1.237 \pm 0.032$  is an SU(3) flavor-symmetry breaking factor obtained from lattice QCD calculations [41]. Using the measurements of Eqs. (14) and (16), one can extract

$$\left| \frac{V_{td}}{V_{ts}} \right| = 0.2111 \pm 0.0010(\text{exp}) \pm 0.0055(\text{lattice}), \quad (19)$$

in good agreement with (but much more precise than) the value obtained from the ratio of the  $b \rightarrow d\gamma$  and  $b \rightarrow s\gamma$  transition rates observed at the  $B$  factories [40].

The CKM matrix can be constrained using experimental results on observables such as  $\Delta m_d$ ,  $\Delta m_s$ ,  $|V_{ub}/V_{cb}|$ ,  $\epsilon_K$ , and  $\sin(2\beta)$  together with theoretical inputs and unitarity conditions [40,47,48]. The constraint from our knowledge on the ratio  $\Delta m_s/\Delta m_d$  is more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the  $\Delta m_d$  measurements alone, due to the reduced hadronic uncertainty in Eq. (18). We also note that the measured value of  $\Delta m_s$  is consistent with the Standard Model prediction obtained from CKM fits where no experimental information on  $\Delta m_s$  is used, *e.g.*,  $19.0 \pm 1.5 \text{ ps}^{-1}$  [47] or  $18.1^{+2.2}_{-2.1} \text{ ps}^{-1}$  [48].
