#### Abstract

The SCALE Code System is a widely-used modeling and simulation suite for nuclear safety analysis and design that is developed, maintained, tested, and managed by the Reactor and Nuclear Systems Division (RNSD) of Oak Ridge National Laboratory (ORNL). SCALE provides a comprehensive, verified and validated, user-friendly tool set for criticality safety, reactor and lattice physics, radiation shielding, spent fuel and radioactive source term characterization, and sensitivity and uncertainty analysis. Since 1980, regulators, licensees, and research institutions around the world have used SCALE for safety analysis and design. SCALE provides an integrated framework with dozens of computational modules including three deterministic and three Monte Carlo radiation transport solvers that are selected based on the desired solution strategy. SCALE includes current nuclear data libraries and problem-dependent processing tools for continuous-energy (CE) and multigroup (MG) neutronics and coupled neutron-gamma calculations, as well as activation, depletion, and decay calculations. SCALE includes unique capabilities for automated variance reduction for shielding calculations, as well as sensitivity and uncertainty analysis. SCALE's graphical user interfaces assist with accurate system modeling, visualization of nuclear data, and convenient access to desired results.

SCALE 6.2 provides many new capabilities and significant improvements of existing features.
New capabilities include:

- ENDF/B-VII. 1 nuclear data libraries CE and MG with enhanced group structures,
- Neutron covariance data based on ENDF/B-VII. 1 and supplemented with ORNL data,
- Covariance data for fission product yields and decay constants,
- Stochastic uncertainty and correlation quantification for any SCALE sequence with Sampler,
- Parallel calculations with KENO,
- Problem-dependent temperature corrections for CE calculations,
- CE shielding and criticality accident alarm system analysis with MAVRIC,
- CE depletion with TRITON (T5-DEPL/T6-DEPL),
- CE sensitivity/uncertainty analysis with TSUNAMI-3D,
- Simplified and efficient LWR lattice physics with Polaris,
- Large scale detailed spent fuel characterization with ORIGAMI and ORIGAMI Automator,
- Advanced fission source convergence acceleration capabilities with Sourcerer,
- Nuclear data library generation with AMPX, and
- Integrated user interface with Fulcrum.

Enhanced capabilities include:

- Accurate and efficient CE Monte Carlo methods for eigenvalue and fixed source calculations,
- Improved MG resonance self-shielding methodologies and data,
- Resonance self-shielding with modernized and efficient XSProc integrated into most sequences,
- Accelerated calculations with TRITON/NEWT (generally 4x faster than SCALE 6.1),
- Spent fuel characterization with 1470 new reactor-specific libraries for ORIGEN,
- Modernization of ORIGEN (Chebyshev Rational Approximation Method [CRAM] solver, API for high-performance depletion, new keyword input format)
- Extension of the maximum mixture number to values well beyond the previous limit of 2147 to $\sim 2$ billion,
- Nuclear data formats enabling the use of more than 999 energy groups,
- Updated standard composition library to provide more accurate use of natural abundances, and
- Numerous other enhancements for improved usability and stability.

The user documentation for SCALE has also been substantially updated and reorganized. SCALE 6.2.1 provides numerous minor enhancements and increased stability relative to SCALE 6.2.

## Introduction

The SCALE Code System is a widely-used modeling and simulation suite for nuclear safety analysis and design that is developed, maintained, tested, and managed by the Reactor and Nuclear Systems Division (RNSD) of Oak Ridge National Laboratory (ORNL). SCALE provides a comprehensive, verified and validated, user-friendly tool set for criticality safety, reactor physics, radiation shielding, radioactive source term characterization, and sensitivity and uncertainty analysis. Since 1980, regulators, licensees, and research institutions around the world have used SCALE for safety analysis and design. SCALE provides an integrated framework with dozens of computational modules including 3 deterministic and 3 Monte Carlo radiation transport solvers that are selected based on the desired solution strategy. SCALE includes current nuclear data libraries and problem-dependent processing tools for continuous-energy (CE) and multigroup (MG) neutronics and coupled neutron-gamma calculations, as well as activation, depletion, and decay calculations. SCALE includes unique capabilities for automated variance reduction for shielding calculations, as well as sensitivity and uncertainty analysis. SCALE's graphical user interfaces assist with accurate system modeling, visualization of nuclear data, and convenient access to desired results. SCALE 6.2 represents one of the most comprehensive revisions in the history of SCALE, providing several new capabilities and significant improvements in many existing features.

New capabilities include:

- ENDF/B-VII. 1 nuclear data libraries CE and MG with enhanced group structures,
- Neutron covariance data based on ENDF/B-VII. 1 and supplemented with ORNL data,
- Covariance data for fission product yields and decay constants,
- Stochastic uncertainty and correlation quantification for any SCALE sequence with Sampler,
- Parallel calculations with KENO,
- Problem-dependent temperature corrections for CE calculations,
- CE shielding and criticality accident alarm system analysis with MAVRIC,
- CE depletion with T5-DEPL/T6-DEPL,
- CE sensitivity/uncertainty analysis with TSUNAMI-3D,
- Simplified and efficient LWR lattice physics with Polaris,
- Simplified spent fuel characterization with ORIGAMI and ORIGAMI Automator,
- Advanced fission source convergence acceleration capabilities with Sourcerer,
- Nuclear data library generation with AMPX,
- Integrated user interface with Fulcrum, and
- Many other new features.

Enhanced capabilities include:

- Accurate and efficient CE Monte Carlo methods for eigenvalue and fixed source calculations,
- Improved MG resonance self-shielding methodologies and data,
- Resonance self-shielding with modernized and efficient XSProc integrated into most sequences,
- Accelerated calculations with TRITON (generally $4 x$ faster than SCALE 6.1),
- Spent fuel characterization with 1470 new reactor-specific libraries for ORIGEN,
- Keyword input for ORIGEN,
- Extension of the maximum mixture number to values well beyond the previous limit of 2147 to ~2 billion,
- Nuclear data formats enabling the use of more than 999 energy groups,
- Updated standard composition library to provide more accurate use of natural abundances, and
- Numerous other enhancements for improved usability and stability.

The user documentation for SCALE has also been substantially updated and reorganized around capabilities instead of the historical division of function modules, control modules, etc. SCALE 6.2.1 provides numerous minor enhancements and increased stability relative to SCALE 6.2.

This getting started guide provides an overview of many of the updated features of SCALE 6.2, instructions on how to install SCALE, instructions on using all the features of the SCALE runtime environment command line interface, and instructions on how to build SCALE. The SCALE user manual provides comprehensive documentation of all computational capabilities, nuclear data, input requirements, and output edits. Additional resources are available in the SCALE primers, located in the docs/primers directory after installation. These primers provide step-by-step instructions for running SCALE. However, at the time of release, not all primers have been updated to reflect the latest features and user interface of SCALE 6.2. Additional resources are available on the SCALE website at http://scale.ornl.gov or by e-mailing scalehelp@ornl.gov.

## Updates in SCALE 6.2

Nuclear Data

## ENDF/B-VII. 1 Cross-section Libraries

ENDF/B-VII. 1 nuclear data libraries are introduced in SCALE 6.2. CE data are available for general-purpose neutron, gamma, and coupled neutron/gamma calculations. MG neutron libraries in the 252- and 56-group structure are available, where the 252 -group library is for general-purpose applications and the 56-group library is intended for light water reactor analysis. Coupled neutron/gamma MG libraries are available in a fine 200-neutron/47-gamma group structure and a broad 28 -neutron/19-gamma structure. An additional 8 -group neutron library is available for code testing purposes but is not intended for production use.

## Neutron Cross-section Covariance Data

Updated cross-section covariance libraries are provided with SCALE 6.2 for use with the sensitivity and uncertainty modules. The data has been assembled from a variety sources, including high-fidelity covariance evaluations from ENDF/B-VII.1, other domestic and international evaluations, as well as approximate uncertainties obtained from a collaborative project performed by Brookhaven National Laboratory, Los Alamos National Laboratory, and ORNL. In addition, the covariance library now uses a 56-group structure for broad group analysis, which is suitable for most applications, as well as the 252-group structure for fine group analysis, such as for energy-dependent reaction rates. These libraries are generated for compatibility with the ENDF/B-VII. 1 56-group lattice physics library, 252-group criticality library, and continuous-energy analysis. The current SCALE covariance library spans the full energy range of the multigroup cross-section libraries. The new 56 -group and 252 -group covariance libraries (56groupcov7.1 and 252groupcov7.1) are recommended for all applications. However, the previous library (44groupcov) distributed with SCALE 6.0 and SCALE 6.1 is retained for backwards compatibility. Covariance data are available for 456 materials, including some duplication for materials with multiple thermal scattering kernels. The SCALE 6.2 56group covariance library (56groupcov7.1) is the default library for uncertainty calculations, but other libraries can be accessed by setting the appropriate parameter in the sensitivity/uncertainty analysis codes.

## Continuous-energy Data Processing

Investigations into the CE data generated by the AMPX code system for deployment in SCALE 6.0 and 6.1 revealed a need for improvement in the $S(\alpha, \beta)$ treatment, especially for forward-peaked kinematics. The SCALE 6.2 ENDF/B-VII. 0 and ENDF/B-VII. 1 data libraries have been generated using new AMPX processing procedures, and the benchmark testing results with SCALE 6.2 show substantially improved results relative to SCALE 6.0 and 6.1. Select critical benchmark results for thermal mixed oxide (MOX) systems are provided in Figure 1, which shows that the bias in the SCALE 6.2 ENDF/B-VII. 0 CE results is reduced relative to SCALE 6.1. Additional testing has revealed that biases for burned light water reactor (LWR) fuel as large as 1000 pcm are

Getting Started — 3
resolved with the improved treatment. Additional details and further results are provide in Ref. 1.

Figure 1. SCALE calculated results for International Criticality Safety Benchmark Evaluation Project (ICSBEP) thermal mixed oxide critical systems.

Additionally, the probability tables that provide CE treatment in the unresolved resonance range have been improved, primarily through the inclusion of additional resolution and error correction. Testing with the new probability tables has shown reduced biases for systems that are sensitive to the intermediate energy range. ${ }^{1}$

Historically, only neutron CE data libraries with a specific reaction subset of the ENDF libraries have been supported in KENO Monte Carlo criticality safety codes. To support CE depletion, sensitivity analysis, and coupled neutron-gamma shielding analysis, AMPX capabilities for the generation of CE neutron data have been improved and extended. Capabilities were added to generate gamma interaction data and to produce gamma yield data from neutron interactions. In addition, wide ranges of neutron interactions were also added in order to support creating reaction responses in Monaco.

The improved CE data has been comprehensively reviewed and verified and validated with approximately 5000 infinite medium eigenvalue tests, 6300 fixed-source transmission tests, and 400 criticality and shielding benchmark experiments to ensure robust and accurate calculations.

## Multigroup Data Processing

For MG analyses, ORNL has performed detailed comparisons between SCALE CE and MG results, and historically a bias of 200-500 pcm has been observed where the 238-group library is applied to LWR systems. The new 252-group structure for SCALE 6.2 provides a more detailed representation of the ${ }^{238} \mathrm{U}$ resonance structure. AMPX has been used to develop a new 56- and 252-energy-group ENDF/B-VII. 1 neutron crosssection libraries. In addition to the new group structures, these libraries have been

Getting Started — 4
generated using a new weighting spectrum with improved resonance self-shielding parameters. Specifically, for actinides and hydrogen in $\mathrm{H}_{2} \mathrm{O}$, a temperature-dependent CE flux spectrum has been generated with the CE CENTRM module for a PWR pin cell, and the CE flux spectrum has been used as a weighting function for library generation. Intermediate resonance parameters (lambdas) for all isotopes have been included in the library, which provides a capability for improved self-shielding with the Bondarenko method and Polaris. Bondarenko shielding factors, as a function of background cross section and temperature, were computed for all actinides (except ${ }^{235} \mathrm{U},{ }^{238} \mathrm{U},{ }^{239} \mathrm{Pu},{ }^{240} \mathrm{Pu}$, and ${ }^{241} \mathrm{Pu}$ ) using CE spectra calculated by CENTRM for homogeneous mixtures of the resonance material and hydrogen, corresponding to the respective background cross section. For the nuclides ${ }^{235} \mathrm{U},{ }^{238} \mathrm{U},{ }^{239} \mathrm{Pu},{ }^{240} \mathrm{Pu}$, and ${ }^{241} \mathrm{Pu}$, the Bondarenko factors are based on CENTRM CE calculations for heterogeneous pin cell models that span the range of anticipated self-shielding conditions. The thermal cutoff for moderators and the free-gas approximation has been raised from 3 eV to 5 eV . The new library has been tested by analyzing a wide variety of critical benchmark experiments and by comparing results with CE Monte Carlo results. The 252-group results presented in Figure 1 demonstrate consistent performance with the SCALE 6.2 CE results for the thermal MOX critical benchmark experiments. Based on additional studies with the 252-group library, computational benchmark comparisons with CE results at room temperature and elevated temperatures show agreement within 100 pcm in most cases.

## Nuclear Data File Formats

A new binary data format is introduced to SCALE and applied to modernize the format of the AMPX multigroup cross section data libraries, replacing the AMPX Working and Master formats that were designed in the 1960s. The previous formats were restricting the extension of capabilities desired to provide improved physics.

BOFF (Binary Object Formatted File) is a binary data format designed for flexibility and compactness and is intended to compete with native binary file formats that incorporate optimization tricks implicit to the developer and the data being stored. BOFF revolves around the steadfast data structures of primitive, array, and object data and can provide backward and forward data format compatibility. BOFF provides the capability to store data in a hierarchical manner utilizing objects, arrays, and keyed-values. The BOFF format is implemented in the AMPX multigroup format to provide the ability to incorporate additional data in future updates.

## Modernized Material Input Processing and Resonance Self-Shielding

Several SCALE sequences have been updated to use modern material and cross section processing module of SCALE (XSProc), which was developed for SCALE 6.2 to prepare data for continuous-energy and multigroup calculations. XSProc expands material input from Standard Composition Library definitions into atom number densities and, for multigroup calculations, performs cross section resonance self-shielding, energy group collapse, and spatial homogenization. XSProc implements capabilities for problemdependent temperature interpolation, calculation of Dancoff factors, resonance selfshielding using Bondarenko factors with full-range intermediate resonance treatment, as well as use of continuous energy resonance self-shielding in the resolved resonance

Getting Started - 5
region. XSProc integrates and enhances the capabilities previously implemented independently in BONAMI, CENTRM, PMC, WORKER, ICE, and XSDRNPM, along with some additional capabilities that were provided by MIPLIB and SCALELIB. With XSProc runtime and memory requirements are substantially improved, especially when performing calculations with many unit cells. Generally speedups in self shielding of about $3 x$ are realized, but in an extreme test case using an as-loaded spent nuclear fuel storage package with hundreds of unique materials, the cross section processing and cell homogenization time was reduced from 5 days to 3.7 minutes, while still obtaining equivalent results. XSProc is only partially implemented across most SCALE sequences, as shown in Table 1, where modernized sequences with XSProc and legacy sequences that run that standalone codes are identified.

Table 1. SCALE Sequence Modernization

| TSUNAMI-3D_K6 |  |  |

XSProc provides for infinite homogeneous medium, lattice cell, multiregion, and double heterogeneous cell types. For all but the double heterogeneous cells, a new capability is implemented for accelerated self-shielding using intermediate resonance (IR) approximation Bondarenko treatment for the full energy range (PARM=BONAMI) as well as the more rigorous option of continuous-energy treatment in the resolved resonance range (PARM=CENTRM), with default treatment set as continuous-energy. Only the CENTRM path is available for double heterogeneous cell types.

XSProc provides capabilities for:

- Material input processing,
- Resonance self-shielding of microscopic data,
- Macroscopic cross sections for mixtures,
- One-dimension multigroup transport calculations to calculate eigenvalues and flux weighting functions,
- Group collapsing of cross sections using flux spectra from the one-dimensional eigenvalue calculation or user input fixed source spectra, and
- Spatial homogenization of cross sections across material zones.

Sequence-specific control for the generation of on-disk or in-memory data libraries for microscopic or macroscopic data containing selected reaction cross sections and scattering data is available with this modernized tool.

## Missing Cross-Section Messages

There are several nuclides that occur in natural abundance distributions for elements that are not present in the current generation of nuclear data libraries. For example, the natural abundance for oxygen contains $0.20 \%{ }^{18} \mathrm{O}$, but ENDF evaluations do not provide cross sections for this isotope.

In previous versions of SCALE, the Standard Composition Library made several nonphysical adjustments to facilitate the use of nuclear data libraries with missing nuclides. In the case of ${ }^{18} \mathrm{O}$, the standard compositions $\mathrm{UO}_{2}, \mathrm{O}$, and others assumed oxygen to consist of $100 \%{ }^{16} \mathrm{O}$ instead of its true natural abundance. If the user input the standard composition name OXYGEN, the true natural abundances would be used and the calculation would immediately stop on an error that ${ }^{18} \mathrm{O}$ was not present on the nuclear data library. For source terms calculations, the absence of ${ }^{17} \mathrm{O}$ can non-conservatively reduce neutron sources by several percent.

In SCALE 6.2, this behavior has changed in that true natural abundances are consistently applied for all standard composition materials (i.e., $U O_{2}, O$, and $O X Y G E N$ now all include natural abundances for ${ }^{16} \mathrm{O},{ }^{17} \mathrm{O}$, and ${ }^{18} \mathrm{O}$ ), warning messages are presented for missing nuclides, and the calculation continues with the nuclide removed from the model, which will produce identical radiation transport and very similar activation/depletion results as using a cross section of 0.0 for each of the missing nuclides. The explicit number densities of every nuclide in the mixture are provided so that the user has a choice of accepting adjusted material composition or updating the input for the model to compensate for the missing material in some other way such as increasing the density of some other nuclide. In most cases, the missing nuclides do not make up a large fraction of the natural abundance and making some other adjustments will have a negligible impact on computed results. The isotopes that occur in the Standard Composition Library but have no corresponding nuclear data in ENDF/B-VII. 0 or -VII. 1 are shown in Table 2.

Table 2. Isotopes with No ENDF/B-VII. 0 or -VII. 1 Nuclear Data

| Element | SCALE <br> standard <br> composition ID | Missing <br> Isotopes | ZA numbers | \% Abundance |
| :---: | :---: | :---: | :---: | :---: |

(3) no data for any of the six naturally occurring platinum isotopes

## CENTRM/PMC

A new two-dimensional CENTRM option is available to explicitly treat the boundary of square-pitched and triangular-pitched light water reactor fuel pins with a Method-ofCharacteristics (MoC) CE transport option, resulting in approximately 100 pcm reduction in bias between MG and CE calculations. This is now the default option for fuel lattice calculations using CENTRM through XSProc within SCALE sequences.

New options are available in CENTRM/PMC to address the effects of resonance self-shielding on scattering matrices, using the $N 2 D=$ option in centrm data in celldata. $N 2 D=2$ performs self-shielding corrections on the $0^{\text {th }}$ order scattering data (like default the $N 2 D=-1$ method) but also corrects the higher order Legendre moments with corresponding higher order fluxes. $N 2 D=-2$ similarly treats the higher order Legendre moments and explicitly treats within-group elastic scattering removal. The impact of these options is demonstrated on the IEU-MET-FAST-005-001 fast system with a steel reflector with $\mathrm{k}_{\text {eff }}$ results shown in Figure 2. Here it is observed that the use of the $\mathrm{N} 2 \mathrm{D}=2$ option produces MG results that are more consistent with the reference CE Monte Carlo results. However, these results are not universal for all calculations, so the $N 2 D=-2$ option should be applied after careful investigation of each system type. In particular, the use of this option for systems with large reflectors is not recommended.

Figure 2. $\mathbf{k}_{\text {eff }}$ values for IEU-MET-FAST-005-001 with different MG options.

## Bondarenko Self-Shielding

BONAMI has been rewritten as part of the overall SCALE modernization effort. BONAMI now implements IR approximation theory as well as the previous narrow resonance (NR) approximation. The IR approximation allows for improved accuracy for systems with overlapping resonances and provides a rapid self-shielding option using only full-range Bondarenko factors. This technique produces accurate results and provides up to a 10x speedup relative to CE treatment with CENTRM. IR theory is described in the updated BONAMI section, Section 8.2. To enable this option set $P A R M=B O N A M I$ on the sequence specification record (e.g. $=t$-depl $P A R M=B O N A M I$ ) and $\operatorname{IROPT}=1$ in the more data section of celldata.

## Graphical User Interface - Fulcrum

Fulcrum is a cross platform graphical user interface designed to create, edit, validate and visualize SCALE input, output, and data files. Historically, SCALE has provided several special-purpose graphical user interfaces, which operate only on specific platforms and are loosely integrated with SCALE's computational and data components. Fulcrum, in contrast, is intended to provide a single user interface that directly integrates with SCALE's internal resources to provide a consistent experience between Fulcrum and SCALE's command line interface.

The concept of Fulcrum is based on decades of feedback from our user community through the release of numerous interfaces. In contrast to the SCALE 6.1 GeeWiz interface with many layers of dialog boxes, Fulcrum directly connects the user with the text form of the input file, while providing inline features to assist with building correct inputs. Fulcrum provides input editing and navigation, interactive geometry visualization for KENO V.a, KENO-VI and NEWT, job execution, overlay of mesh results within a geometry view, and plotting of data from most SCALE file formats. An error checker interactively identifies poorly formed input with spelling errors or data entry omissions for all SCALE sequences. The Hierarchical Input Validation Engine (HIVE) identifies allowed data ranges and interdependencies in the input and reports inconsistencies to the user. Fulcrum interactively processes standard composition data to produce a mixing
table, lists expanded input aliases for review, provides an internal listing of input as is required for Sampler material and geometry perturbation analysis, and launches the SCALE sample problems.

The layout of panels in Fulcrum is highly configurable to accommodate the preferences of many users, as shown in Figure 3.

Figure 3. SCALE Graphical User Interface - Fulcrum.

The Fulcrum user interface provides numerous features, such as:

- Operates on all supported platforms, Linux, Mac and Windows;
- Can edit, view, and run multiple inputs simultaneously;
- Context aware auto-completion input generation menus are presented when ctrl+space is pressed within an input file,
- Graphical forms-based input is available to assist users with the creation of sequence blocks and specific input components (press ctrl+space and select a configurable item);
- Input is validated as it is entered, and erroneous or missing input is identified in the Validation panel;
- Geometry models can be visualized for sequences that use KENO V.a, KENO-VI, Monaco, and NEWT (View... menu shown in toolbar associated with relevant input file);
- Fulcrum is pre-configured to run SCALE 6.2, but can be custom configured for other codes;
- Associated files (such as .out, .msg, plot, or data files) are shown in contextual pop-up menu for each for file in the navigation panel and can be opened (right-click on input file name in navigation panel);
- Associated files not supported in Fulcrum open a local tool for appropriate viewing (e.g. .html files launch the system web browser);
- Mesh tallies stored in .3dmap files can be overlaid with geometry view (Meshes on toolbar in geometry view, right click in Available Meshes panel to load a .3dmap file).
- Data plotting is available for the following SCALE files:
- Multigroup and continuous-energy cross section data;
- Cross section covariance data;
- ORIGEN gamma data;
- UNF-STANDARDS time series;
- ORIGEN concentration file (f71) with integrated unit conversion (OPUS capability);
- Sensitivity data file (.sdf);
- KENO reaction rate and flux file (.kmt);
- Ptolemy plot file (.ptp) (previously Javapeño 2D plot, .plt);
- MAVRIC Chart Plot file (.chart).
- Data files with file extensions (e.g. .sdf, .kmt, etc.) are access through File/Open file...;
- Other file types, especially SCALE nuclear data files, have a specific menu item in the File menu (e.g. Open continuous-energy library...);
- Plots can now be saved in an editable format as a SCALE Plot File (.spf);
- Data tables are available for data shown in a plot;
- Geometry volumes can be computed for KENO and Monaco models;
- Online help is available; as well as
- Too many features to list here.

As Fulcrum is a new user interface, users are directed to the Help menu within the application itself for Help documentation.

## Criticality Safety

KENO has been substantially improved for SCALE 6.2, especially for the accuracy and efficiency of CE calculations, CE temperature corrections, source convergence diagnostics and acceleration, and parallel capabilities.

## Reduction in Memory Requirement of CE Internal Storage

Numerous improvements were made to enhance the CE capabilities of KENO, especially to reduce the memory requirements of the calculations. CE calculations now require $40-99 \%$ less memory than previous versions with no loss of accuracy in the results. Improved memory efficiency will be observed for all calculations, but especially for models with many materials and/or temperatures. Models that previously would have required 100s of GB of memory with SCALE 6.0 and 6.1 can now be performed with only a few GB of memory.

User controllable options:

- UUM: Optional unionization of mixture-dependent cross section data results in a $50-90 \%$ reduction in memory requirements for a single material, with no additional memory required for the use of the same nuclide in more than one Getting Started - 11
mixture. Previous burned fuel calculations that previously would have required 100s of GB of memory can now be run with just a few GB through the use of the default setting of $U U M=n o$ in the KENO parameter data.
- M2U: Optional nuclide level energy grid unionization (map2union) controls the unionization of all reaction types within a single nuclide. The default behavior, $M 2 U=y e s$, in KENO parameter data helps to reduce runtime and was the default behavior in SCALE 6.0 and 6.1. Optionally disabling map2union ( $M 2 U=n o$ ) results in $\sim 20 \%$ reduction in memory with $\sim 10 \%$ increase in runtime.

Other internal optimizations include:

- Removed redundant copies of temperature independent data to improve memory efficiency for models with multiple temperatures. Previously, each set of temperature dependent cross sections also included a redundant copy of the temperature independent data, which caused an almost linear increase in memory for each new temperature. With this update, the temperature independent data are shared by all temperatures, resulting in $>50 \%$ memory savings for the addition of each temperature relative to the techniques implemented in SCALE 6.0 and 6.1.
- Kinematics (scattering) data structures were updated to optimize data storage, especially with an updated structure in the CE data itself. These updates result in $\sim 40 \%$ reduction in memory requirements using the same runtime.
- Changed internal data storage precision from double precision to single precision where possible, resulting in a $15-45 \%$ reduction in memory requirements, depending on the nuclides used in the model.
- Introduced optional data loading by filtering data during reading instead of loading all available data whether it is needed or not. Filtering methods such as energy range, reaction types, data types, etc., results in $\sim 20 \%$ reduction in memory requirements.

## Fission Source Convergence Diagnostics

Prior to SCALE 6.2, KENO provided only plots of $k_{\text {eff }}$ by generation and average $k_{\text {eff }}$ for visual inspection of source convergence, followed by a $\chi^{2}$ statistical assessment of convergence. With SCALE 6.2, Shannon Entropy fission source convergence diagnostic techniques have been implemented in KENO to provide improved confidence in the computed results, as well reduced simulation times in some cases. Confirming the convergence of the fission source distribution is especially useful to avoid the false convergence of $k_{\text {eff }}$ and neutron flux tallies that can be caused by insufficient sampling of important portions of the system. ${ }^{2}$ Source convergence diagnostics are enabled with $S C D=y e s$ (default) in the KENO parameter data.

## Problem-Dependent Doppler Broadening

The CE data libraries distributed with SCALE are provided with only about five temperatures per isotope. The Doppler broadening temperature corrections using only a Getting Started - 12
few temperatures may not match the desired temperature of the calculation. When temperatures of the KENO model are different from those present on the library, KENO selects the nearest temperature, which can be several hundred degrees from the desired temperature, producing results that can vary significantly from those that would be produced at the correct temperature.

New methods have been developed and implemented to provide problem-dependent temperature corrections by Doppler broadening the pointwise data in the resolved resonance region and the probability tables in the unresolved resonance region when the cross sections are loaded for the calculation. ${ }^{3}$ The thermal scattering data are also updated to requested temperature. The runtime penalty for this methodology is negligible, as all temperature corrections are performed as the calculation begins, typically requiring only a few seconds to a few minutes depending on the number of nuclides and temperatures used.

The eigenvalues computed for a typical fresh pressurized water reactor (PWR) pin cell using the nearest selected CE temperature, and problem-dependent CE temperature treatments are shown in Figure 4. Problem-dependent Doppler broadening is controlled with $D B X=0$ to select the nearest temperature, $D B X=1$ to perform problem-dependent corrections for the resolved and unresolved resonance ranges, and $D B X=2$ (default) to perform also corrections for the $S(\alpha, \beta)$ thermal scattering data.

Figure 4. Eigenvalues computed for a PWR pin cell with different temperature treatments.

## Doppler Broadened Rejection Correction

The implementation of Doppler Broadened Rejection Correction (DBRC) techniques provides further enhancements for calculations with elevated temperatures. ${ }^{4}$ As shown in Table 2, DBRC in KENO presents a reactivity correction of approximately 300 pcm relative to the default methodology for a 1200 K LWR fuel pin, consistent with that predicted with MCNPX by the originators of the methodology. ${ }^{5}$ DBRC is enabled with $D B R=$ in the KENO parameter data. Available options are $D B R=0$ to disable the
correction (default), $D B R=1$ to perform DBRC for ${ }^{238} \mathrm{U}$ only, and $D B R=2$ to perform DBRC for all major actinides. The use of DBRC only impacts calculations at elevated temperatures, and there is a runtime penalty for the use of this methodology. As such, it is not recommended for calculations near room temperature and

Table 3. Effect of DBRC on $\boldsymbol{k}_{\text {inf }}$ for a LWR fuel pin at 1200 K

| Case | Default | DBRC | Difference <br> $($ pcm $)$ |
| :---: | :---: | :---: | :---: |
| MCNPX | $1.31137+/-9 E-5$ | $1.30791+/-9 \mathrm{E}-5$ | -346 |
| KENO-VI | $1.31029+/-15 \mathrm{E}-5$ | $1.30730+/-15 \mathrm{E}-5$ | -299 |

## Sourcerer - Hybrid Method for Starting Source Distribution

The Sourcerer sequence introduced in SCALE 6.2 uses the Denovo ${ }^{6}$ discrete-ordinates code to generate a starting fission source distribution in a KENO Monte Carlo calculation. Initial studies ${ }^{7,8}$ have shown that using a starting fission distribution that is similar to the true fission distribution can both reduce the number of skipped generations required for fission source convergence and significantly improve the reliability of the final $k_{\text {eff }}$ result.

For many criticality safety applications, the additional step of performing a deterministic calculation to initialize the starting fission source distribution is not necessary. However, for the most challenging criticality safety analyses, such as spent nuclear fuel loaded transportation packages with a mixed loading of low- and high-burnup fuel, even a lowfidelity deterministic solution for the fission source produces more reliable results than the typical starting distributions of uniform or cosine functions over the fissionable regions, as demonstrated in a recent study. ${ }^{9}$ In that study, a cask holding 24 spent fuel assemblies was examined using a uniformly distributed starting source and a deterministically calculated starting source. Multiple clones of KENO were run (with different random number seeds) for different values of skipped cycles. The number of clones that gave an incorrect result for $k_{\text {eff }}$ was then tabulated. The results from that study, presented in Figure 5, show that using a deterministic starting source significantly increases the $k_{\text {eff }}$ reliability. See the Sourcerer documentation, Section 2.4 for full details.

Figure 5. Fraction of failure to agree with the reference $\boldsymbol{k}_{\text {eff }}$ value for KENO calculations with different starting sources (Figure 4 from Ref. 9).

## Distributed Memory Parallelism via MPI

In addition to the numerous improvements described that directly affect solution accuracy and efficiency, parallel computation capabilities, especially for Linux clusters, have been added to KENO to provide reductions in wall clock time, especially for $\mathrm{S} / \mathrm{U}$ analysis or Monte Carlo depletion on computer clusters. By introducing a simple master-slave approach via Message Passing Interface (MPI), ${ }^{10}$ KENO runs different random walks concurrently on the replicated geometry within the same generation. The fission source and other tallied quantities are gathered at the end of each generation by the master process; then, they are processed either for final edits or next generations.

The parallel performance of KENO as used in a CE calculation for a graphite-moderated reactor model is shown in Figure 6. These tests were conducted on a heterogeneous Linux cluster where the size of the nodes varies from 4 to 16 cores with differing processor speeds, much like SCALE users may encounter in practice. Tests were conducted with systematically increasing numbers of particles per generation, and various combinations of options were enabled to develop the distributions of speedups for each number of MPI processes shown in the figure. With larger numbers of particles per generation, KENO provides nearly linear speedup on the 64 processors tested here and has been successfully demonstrated on hundreds of processors.

Figure 6. Speedup for parallel KENO-VI calculations for a graphite-moderated reactor model.

## Reaction Tallies

User configurable reaction rate tallies are now available within KENO CE calculations. The tallies are specified in the REACTION block of KENO.

## Reactor Physics

## Polaris - New Advanced Lattice Physics Module

Polaris is a new 2D lattice physics code for SCALE that utilizes a new MG self-shielding method called the Embedded Self-Shielding Method (ESSM) ${ }^{11}$ and a new MoC transport solver. Polaris provides simplified input, where only a few lines are required to describe the entire model. Polaris provides substantially simplified input requirements and improved runtime performance compared to TRITON (see Polaris section, Section 3.2).

The ESSM approach computes MG self-shielded cross sections using Bondarenko interpolation. The background cross section utilized in the interpolation is determined by a series of 2D MoC fixed-source calculations, similar to the subgroup method that does not require explicit celldata input. Additionally, heterogeneous lattices are explicitly treated without the need to externally compute Dancoff factors. Additional details on ESSM are provided in Ref. 11.

Polaris currently employs ESSM with either the 252-group or 56-group ENDF/B-VII. 1 libraries. Each library contains cross sections, IR parameters, and full-range Bondarenko factors for all nuclides.

Polaris utilizes the self-shielded cross sections within a MG 2D eigenvalue calculation using the new MoC transport solver. The MoC solver has been developed within Denovo, which was originally developed for parallel 3D Cartesian mesh MG discrete ordinates $\left(\mathrm{S}_{\mathrm{N}}\right)$ calculations. ${ }^{6}$ Polaris also provides a critical spectrum calculation for correcting the flux distribution for computing both few-group homogenized cross-section edits and depletion reaction rates.

Polaris is integrated with ORIGEN for depletion calculations. The depletion of each pin, or radial subregion of the pin, is based on the local normalized flux distribution. Crosssection values in the ORIGEN transition matrix are updated from the MG self-shielded cross sections and the MG flux distribution for each depletion region. The criticalspectrum correction to the flux distribution for depletion is controlled by an input user option. The cross-section updates are performed in-memory as compared to the file-based approach utilized in the TRITON lattice physics sequence. Polaris supports branch calculations for the generation of few group constants for reactor core simulators.

## Continuous-Energy Monte Carlo Depletion

SCALE 6.1 provided MG Monte Carlo depletion that coupled SCALE MG cross-section processing capabilities with KENO and ORIGEN. A new CE-based KENO/ORIGEN Monte Carlo depletion capability has been developed and can be utilized by simply changing the input library specification. CE depletion is especially useful for models with complex geometry that present difficulties in obtaining accurate resonance self-shielded MG data, and for models with many depletion regions where run-time to generate and store the resonance self-shielded cross-section data for each material is prohibitive.

## Lattice Physics with TRITON

Two-dimensional lattice physics calculations with TRITON will realize substantial speedups due to the use of XSProc for resonance self-shielding as well as numerous optimizations within the NEWT code. Speedups of 2-6x faster calculations are common, and some models have realized speedups of 30x relative to previous versions of NEWT. Calculation times for 1470 TRITON calculations used to generate the ORIGEN reactor libraries for SCALE 6.1.3 and SCALE 6.2 are shown in Figure 7. For the calculation, the average calculation time was reduced by a factor of 4 .

Figure 7. Comparison of calculation times for 1470 TRITON calculations.

A material SWAP capability is now available within the TIMETABLE block of TRITON. This feature allows a user to switch the material present during a depletion calculation and is especially useful for removable absorber materials.

The ASSIGN capability of TRITON is available for many calculations, where the same resonance self-shielding calculation can be applied to many similar materials. Unfortunately, ASSIGN is not yet implemented for BRANCH, TIMETABLE, or SWAP calculations.

## Bias Reduction for Depletion

Historical SCALE biases have been mitigated as a result of the numerous enhancements included in SCALE 6.2.

Figure 8 shows the results for a reference PWR pin cell burnup calculation using SCALE 6.1 and SCALE 6.2. Here, the SCALE 6.2 continuous-energy results are the reference, and the SCALE 6.1 continuous-energy results are simply eigenvalue statepoints using the isotopics provide by the SCALE 6.2 results, as CE depletion is not available in SCALE 6.1. The 1000 pcm bias in the SCALE 6.1 CE results are due to erroneous treatment of thermal scattering data in the AMPX CE data distributed with SCALE 6.1. The SCALE 6.1 TRITON 238 group results using the default settings from SCALE 6.1 demonstrate the typical 400-500 pcm bias observed for SCALE 6.1 LWR calculations. The TRITON 252 group results apply the improved nuclear data library, the CENTRM MoC solver, and the enhanced within group treatment for CENTRM/PMC, $N 2 D=-2$. The SCALE 6.2 Polaris results apply the default settings in Polaris with the ESSM methodology and IR factors on the library. These calculations demonstrate the impact of improvements in both the multigroup libraries and resonance self-shielding
techniques as well as improvements in the continuous-energy treatments from SCALE 6.1 to SCALE 6.2.

Figure 8. Comparison of computational biases as a function of burnup.

## Radioactive Source Term Characterization

## ORIGEN

SCALE includes the ORIGEN code and its comprehensive depletion, activation, decay, gamma-ray, and x-ray library with over 2,200 nuclides. ORIGEN and its nuclear data libraries have been updated to provide convenient modular interfaces within SCALE, and these interfaces also provide easy access to ORIGEN's robust capabilities by other software packages.

The input for ORIGEN has been updated to provide a modern interface using the SCALE's own Standard Object Notation (SON). The legacy FIDO input interface will continue to be supported for backwards compatibility, but users are encouraged to begin using the modern input through input files as well as the forms-based input in Fulcrum. An excerpt from an example problem is included below to show this new structured and keyword based input.

```
=origen
'three cycles of irradiation plus decay
bounds {neutron="xn27g19v7.0" gamma="xn27g19v7.0"}
case(c1){
    lib{ file="ft33f001" pos=1 }
    time=[8i 50 500]
    power=[10r40]
    mat{ iso=[u235=4e3 u238=960e3] }
}
case(c2){
    lib{ pos=2 }
    time=[8i 550 1000]
    power=[10r40]
}
case(c3){
    lib{ pos=3 }
    time=[8i 1050 1500]
    power=[10r40]
}
case(cool){
    time{ start=0 t=[20L 0.001 100] units=YEARS }
    save{ file="snf.f71" time_offset=1500 }
    gamma{ sublib=ALL brem_medium=U02 }
    print{ neutron{ spectra=yes } }
    neutron{ alphan_medium=U02 }
}
end
```

The ENDF/B-VII. 0 based fission product yields used by ORIGEN are updated to provide improved agreement with burst fission experiments for ${ }^{235} \mathrm{U},{ }^{238} \mathrm{U},{ }^{239} \mathrm{Pu}$, and ${ }^{241} \mathrm{Pu}$. The changes correct inconsistencies that were introduced in ENDF/B when updating the nuclear decay data in ENDF/B VII. 0 and not updating the fission product yields that are based on England and Rider (1994). These yield adjustments improve the consistency between the direct fission yields and decay data, and the cumulative yields in ENDF/B-VII.0.

ORIGEN has been enhanced to provide an alternative solver based on the Chebyshev Rational Approximation Method (CRAM). When compared to a robust reference solution for a depletion problem, the traditional matrix power series and Bateman solver predicts isotopic concentrations with an average relative error of about 10E-5, where the CRAM solver produces an average relative error of about 10E-15 for the same case. The CRAM solver can also handle essentially arbitrary step lengths through internal substepping with minimal computational cost, so the runtimes are generally faster for large depletion problems. The previously mentioned depletion case required 550 ms to execute 8 substeps with the traditional solver, where CRAM completed the more accurate calculation in 44 ms . However, CRAM is slower than the traditional solver for decay
problems or problems with small libraries. CRAM also allows for time dependent source terms and adjoint calculations, enabling the extension of ORIGEN to new classes of calculations. CRAM is currently available as an optional solver in stand-alone ORIGEN calculations.

## ORIGAMI - New Advanced Used Fuel Assembly Characterization

SCALE 6.2 includes the new ORIGAMI (ORIGEN Assembly Isotopics) tool to compute detailed isotopic compositions for LWR assemblies containing $\mathrm{UO}_{2}$ fuel by using the ORIGEN transmutation code with pre-generated ORIGEN libraries, for a specified assembly power distribution. The assembly may be represented by a single lumped model with only an axial power distribution, or by a square array of fuel pins with variable pin-powers as well as an axial distribution. In either case, ORIGAMI performs ORIGEN burnup calculations for each of the specified power regions to obtain the spatial distribution of isotopes in the burned fuel. Multiple cycles with varying burn-times and down-times may be used. ORIGAMI produces files containing SCALE and MCNP formatted composition data for axial burnup distribution at the last time-step, as well as a file containing the axial decay-heat at the final time-step, and a file specifying the energydependent radioactive source for use in shielding calculations.

## ORIGEN Reactor Libraries

A new series of 1470 pre-generated burnup libraries for use in ORIGEN and ORIGAMI are introduced to SCALE 6.2. These libraries are generated under quality assurance with TRITON using the ENDF/B-VII. 1252 -group nuclear data library through the use of a new template and script system. These libraries are intended to replace the ORIGENARP libraries that were generated with a previous version of SCALE with varying levels of quality assurance. Libraries are available for a variety of fuel assemblies for commercial and research reactors, as detailed in Table 3 and Table 4.

Table 4. Assembly and Lattices Types with Available ORIGEN Reactor Libraries

| Assembly type (Number of Libraries) |  | Lattice types |
| :---: | :---: | :---: |
| PWR | Babcock \& Wilcox | $15 \times 15$ |
|  | Westinghouse | $14 \times 14,15 \times 15,17 \times 17,17 \times 17-$ OFA |
|  | Combustion Engineering | $14 \times 14,16 \times 16$ |
|  | Siemens | $14 \times 14,18 \times 18$ |
| BWR | ABB | $8 \times 8-1$ |
|  | Atrium | $9 \times 9-9,10 \times 10-9$ |
|  | General Electric | $8 \times 8-4,9 \times 9-7,7 \times 7-0,8 \times 8-1,8 \times 8-2,9 \times 9-2,10 \times 10-8$ |
|  | SVEA | $64(8 \times 8-1), 96(10 \times 10-4), 100(10 \times 10-0)$ |
| MOX | BWR Lattices (75) | ABB $8 \times 8-1$, Atrium $9 \times 9-9,10 \times 10-9$; GE $7 \times 7-0,8 \times 8-$ $1,8 \times 8-2,9 \times 9-2,10 \times 10-8$; SVEA- $64,96,100$ |
|  | PWR Lattices (15) | Siemens $14 \times 14,18 \times 18$; CE $14 \times 14,16 \times 16$; B\&W 15×15; <br> Westinghouse $14 \times 14,15 \times 15,17 \times 17,17 \times 17-$ OFA |
| Other | AGR (6) |  |
|  | CANDU (1) | 19-pin, 28-pin, 37-pin |

## ORIGAMI Automation Tool

ORIGAMI Automator, a graphical user interface integrated with Fulcrum facilitates the quantification of isotopics as a function of time for a large set of fuel assemblies. This tool was developed to support the Nuclear Regulatory Commission (NRC) in MELCOR analyses, but can be adapted to many other uses. The ORIGAMI Automator is an integrated graphical user interface that leverages many of modern components developed for SCALE 6.2 to enable the analyst to (1) easily create, view, and edit the reactor site and assembly information, (2) automatically create and run ORIGAMI inputs, and (3) analyze the results from ORIGAMI. The Automator uses the standard ORIGEN binary concentrations files produced by ORIGAMI, with concentrations available at all time points in each assembly's life. ORIGAMI Automator enables plotting of results such as mass, concentration, activity, and decay heat using an OPUS component. The ORIGAMI Automator Primer includes a description and user guide, a step-by-step tutorial for a simplified scenario, and appendices that document the file structures used.

Figure 9. ORIGAMI Automator.

## Radiation Shielding

The SCALE fixed-source Monte Carlo capability with automated variance reduction has been enhanced to enable CE calculations. The new CE capabilities will provide enhanced solution fidelity while still implementing the unique acceleration techniques of the FW-CADIS (Forward-Weighted Consistent Adjoint Driven Importance Sampling) methodology for deep penetration shielding and criticality accident alarm system modeling.

## Continuous-energy Shielding Calculations

Prior to SCALE 6.2, the MAVRIC/Monaco capabilities relied on the MG approach for radiation transport. The MG approach is suitable for many applications but can be problematic for others. For example, deep penetration shielding through iron, where the MG-averaged cross section for capture resonances may not accurately represent the true transmission of neutrons due to fine "windows" through (i.e., minima in) the cross section. Additionally, MG cannot adequately resolve discrete gamma emission lines, such as those of ${ }^{60} \mathrm{Co}$. With the CE treatment introduced in SCALE 6.2, improved solution fidelity is available. The generation of CE nuclear data and the implementation of CE physics in Monaco are based on a first-principles approach, where the simulation is represented as realistically as possible. This approach will lead to higher-fidelity results, but runtimes may be substantially increased over more approximate methods.

Monaco also includes capabilities to import sources generated with ORIGAMI and to access gamma sources directly from ORIGEN data.

## Sensitivity and Uncertainty Analysis

## CE Eigenvalue Sensitivity Analysis

With SCALE 6.2, the MG eigenvalue sensitivity and uncertainty analysis methods that use KENO for transport analysis are extended to provide CE capabilities through the implementation of the CLUTCH (Contributon-Linked eigenvalue sensitivity/Uncertainty estimation via Tracklength importance CHaracterization) methodology and IFP (Iterated Fission Probability) methods ${ }^{12}$ CLUTCH is an efficient methodology that has been demonstrated to provide high-fidelity results with manageable run-times and memory requirements. State-of-the-art sensitivity methods make CE calculations easier to use than MG in several ways; for example, CE calculations do not require resonance selfshielding calculations to determine implicit sensitivity effects, the simulation of a separate adjoint transport calculation, or the use of a flux mesh for tallying fluxes and flux moments.

The new capabilities enable improvements in sensitivity coefficient accuracy compared to MG. Table 5 compares the accuracy of the total nuclide sensitivity coefficients estimated by the each sensitivity method for the MIX-COMP-THERM-004-001 system. ${ }^{13}$ The MG analysis produced a ${ }^{238} \mathrm{U}$ total nuclide sensitivity that disagreed with the reference direct perturbation sensitivity by 2.80 effective standard deviations ( $\sigma_{e f f}$ ), while
the CE methods (IFP and CLUTCH) sensitivities were within almost 1 standard deviation of the reference sensitivity coefficients for all of the nuclides examined.

Figure 10 compares the figures of merit for the nuclide sensitivity coefficients presented in Table 5. Figure 10 indicates that the CE sensitivity calculations are of a comparable efficiency to the MG calculations, and in some cases the CE CLUTCH method is more efficient than MG method. This is remarkable because of the use of CE physics, which can impose relatively long cross-section lookup times, and indicates the efficiency of the CLUTCH method.

Table 6. MIX-COMP-THERM-004-001 total nuclide sensitivity coefficient comparison.

| $\begin{aligned} & \text { Sensitivit } \\ & \mathrm{y} \end{aligned}$ | Reference | MG TSUNAMI | CE TSUNAMI |  |

Figure 10. MIX-COMP-THERM-004-001 total nuclide sensitivity Figure of Merit comparison.

Table 6 gives the amount of computational memory required by each method for the sensitivity coefficient calculations. These memory requirements were obtained by subtracting the memory requirements of each eigenvalue-only calculation from the memory requirements of each sensitivity coefficient calculation. As seen below, the CLUTCH method excels in terms of memory usage, and can readily compute sensitivities for complex systems on a typical personal computer.

Table 7. Sensitivity method memory usage.

| Model | MG TSUNAMI | CE TSUNAMI |  |
| :---: | :---: | :---: | :---: |
|  |  | IFP | CLUTCH |
| MIX-COMP-THERM-004-001 | $13,785 \mathrm{MB}$ | $10,643 \mathrm{MB}$ | 63 MB |

TSUNAMI-3D also includes a Generalized Perturbation Theory (GPT) capability to compute the sensitivity of ratios of reaction rates to cross section data by introducing the GEneralized Adjoint Responses in Monte Carlo (GEAR-MC) method. The two GEARMC implementations are available for use in continuous-energy (CE) Monte Carlo simulations.

GPT sensitivity coefficients now share the same input at the previous multigroup GPT methods implemented in TSUNAMI-1D and TSUNAMI-2D. The Definitions block is used to define reaction rates in terms of material, reactions and energy ranges, and the SystemResponses block is used to define ratios for which sensitivity coefficients will be computed. A separate SDF file is generated each ratio defined in SystemResponses detailing the sensitivity of the reaction rate ratio to the cross-section data on an energy
dependent basis. The uncertainty in each ratio due to cross-section covariance data is also provided in the output file.

## Sampler

A new stochastic uncertainty quantification capability has been added with the SCALE 6.2 Sampler module that implements stochastic techniques to quantify the uncertainty in any computed result from any SCALE sequence due to uncertainties in

- neutron cross sections,
- fission yield and decay data, and
- any user input parameter, such as geometry, material density, isotopic composition, temperature, etc.
Sampler propagates these uncertainties through complex analysis sequences, such as depletion calculations, and provides the variation in the output quantities due to variations in any combination of input data, as shown in Figure 11. ${ }^{14}$ Correlations between systems with shared uncertainties are also computed, which is especially useful for quantifying correlated uncertainties in benchmark experiments, required for generalized linear least-squares techniques implemented by the SCALE module TSURFER. ${ }^{15}$

Figure 11. Uncertainty in plutonium isotopics as function of burnup.
The Medusa module of the XSUSA program ${ }^{16}$ is used to generate perturbation factors for the 1 D cross sections on the MG library, assuming that the probability density functions are multivariate normal distributions with covariances given in the SCALE nuclear data covariance library. Uncertainty libraries for fission product yields are implemented from ENDF/B-VII. 1 data for the major actinides ${ }^{235} \mathrm{U},{ }^{238} \mathrm{U},{ }^{239} \mathrm{Pu}$, and ${ }^{241} \mathrm{Pu}$. These libraries are used directly by Sampler to assess uncertainty in fission product concentrations due to yield uncertainties. Covariance data are developed from fission models and a Bayesian method applied to ensure that uncertainties in the cumulative fission yields are consistent with the independent yields in each chain. Multiplicative perturbation factors for fission
product yields have been generated with XSUSA. The decay uncertainty data has 4 major components: decay constant uncertainty, q-value uncertainty, fraction of q value in photons, and branch ratio uncertainty. Perturbation factors for these 4 components are generated using uncertainties from the ENDF/B-VII. 1 library. Correlations are accounted for decays with multiple decay modes to ensure the sum of branching is unity. No uncertainties are applied for data that does not have associated uncertainty information. Perturbations are applied using the covariance information with XSUSA to provide 1000 ORIGEN decay libraries. The uncertainty information has presently not been consolidated as a single file of perturbation factors.

Currently, decay data sampling is available for ORIGEN and ORIGAMI calculations, but is not operational with TRITON calculations without additional user-supplied preliminary calculations.

Sampler also provides the ability to perform multivariate parametric studies for variables with uniform distributions.

Note that Sampler can be built with MPI enabled for parallel computations (see Build Instructions below), but it can only sample the execution of serial codes. Threading is available with the default binary distribution (use the "-I" option of scalerte) when executing Sampler.

## Other Updates

SCALE 6.2 includes a number of other improvements, such as the extension of the maximum allowed number of materials from around 2,000 to around 2 billion. Some older features are removed such as ENDF/B-V and -VI nuclear data, the point kernel shielding capability, and a material optimization search sequence. Additionally, the default temperature for materials with no temperature explicitly specified has been modified from 300 K to 293 K for improved consistency between MG and CE calculations.

## Known Issues

In this release, there are a few issue scheduled to be resolved in the future:

1. CELLMIX and DOUBLEHET treatments are not implemented for radiation shielding problems using MAVRIC;
2. The TRITON ASSIGN capability is not implemented for cases that use BRANCH, TIMETABLE, or SWAP input blocks.
3. Calculations with CE TSUNAMI-3D-K5 with CLUTCH have been observed to infrequently (only one test case out of dozens) produce erroneous sensitivity coefficients and statistical uncertainties where excessive particle splitting occurs. As always, users are urged to confirm sensitivity coefficients with direct perturbation calculations. When this issue occurs, the sensitivity tallies are far from the expected values ( $\sim 50 \%$ error), and their associated uncertainties are unusually large. A workaround is to repeat the calculation with a different random number seed (RND input parameter) or increase the splitting weight (WTH input parameter) to a very large number, such as 100 .

Getting Started - 28

## System Requirements

## System Architecture:

- Linux 64-bit (RHEL 6 or newer)
- Mac OS X (Darwin) 10.9.5 or newer
- Windows 7, 64-bit or newer

## System requirements:

Minimum requirements: 4 GB RAM per CPU, 40 GB of disk space + additional space to store output results

Recommended requirements: 8 GB RAM per CPU, 40 GB of disk space +100 GB of scratch space + additional space to store output results

Production requirement for large models: 64 GB RAM, 40 GB of disk space +500 GB of scratch space + additional space to store output results

## Java Requirements:

Java1.6 or newer.

## Installation Instructions

SCALE 6.2.1 installation has been broken into three components: 64-bit pre-compiled binaries, source code and the data. The pre-compiled binaries are available in platform familiar installers: NSIS on Windows, Drag-N-Drop bundle on Mac and Tar GZip on Linux. For deployments that include source code, it is available as a zip file and the data is available as a self-extracting IzPack installer. Other systems may require a custom build of SCALE, from source code, using the build instructions provided later in this document. Pre-Compiled Binaries

Note: After you install the Binaries, you still must install the nuclear data. After completing the binary installation following the instructions in this section, please follow the instructions for SCALE 6.2 Data.

## Windows

After double-clicking the SCALE-6.2.1-setup.exe you may see a "loading..." dialog briefly popup.
scale

Please wait while Setup is loading...
verifying installer: 56\%

Figure 12. NSIS installer loading...

Once loaded, a "Welcome" dialog will prompt to begin the installation. Click "Next >" to continue.

Figure 13. NSIS "Welcome" dialog.

Next, the installer will prompt the "License Agreement". Clicking "I Agree" will continue.

Figure 14. NSIS SCALE License Agreement.

Next, the "Choose Install Location" dialog is displayed. Clicking "Next >" will continue.

Figure 15. NSIS Choose Install Location.
Next, the "Choose Start Menu Folder" is prompted. This defaults to installing Start Menu shortcuts. You may click "Do not create shortcuts" to disable Start Menu shortcuts. Desktop shortcuts are always installed. Clicking "Install" will continue.

Figure 16. NSIS Choose Start Menu Folder.

Upon clicking "Install" the install starts and progress will be shown. Once complete, clicking "Next >" will continue.

Figure 17. NSIS progress dialog.
Finally, installation is complete and you may click "Finish" to exit the NSIS installer, and then follow the instructions to install SCALE 6.2 Data.

Figure 18. NSIS complete dialog.

Note that Norton Antivirus on Windows requires an exception for the SCALE Runtime Environment program, scalerte.exe. If using Norton Antivirus, please establish this exception prior to installing or SCALE 6.2.1 will not be able to execute.

## Mac OSX

After double-clicking the SCALE-6.2.1-setup.dmg you will see an opening dialog.

## Opening "SCALE-6.2.1-setup.dmg"...

## Cancel

## Finishing...

Figure 19. Mac OS $X$ opening dialog.

Upon accepting, a Finder window will be raised showing "Applications" and "SCALE6.2.1.app". Simply drag "SCALE-6.2.1.app" onto "Applications" to install SCALE-6.2.1, and then follow the instructions given below to install SCALE 6.2 Data.

Figure 20. Mac OS X bundle contents.

## Linux

Copy the SCALE-6.2.1.tar.gz to the installation directory. Invoke 'tar -xzf SCALE6.2.1.tar.gz'. This will create the SCALE-6.2.1 directory. Follow the instructions given below to install SCALE 6.2 Data.

Figure 21. Linux Tar GZip.

## Source Code

If you received the source code version, you can unzip SCALE-6.2-serial-6.2.1Source.zip file to any location on your computer.

For example, on a Windows platform, double click the SCALE-6.2-serial-6.2.1Source.zip file. This will extract the files into the "SCALE-6.2-serial-6.2.1-Source" directory.

On Linux and Mac OS X create a destination directory for the source and copy the SCALE-6.2-serial-6.2.1-Source.zip into that directory.

Change to the directory and invoke 'unzip SCALE-6.2-serial-6.2.1-Source.zip to deploy the source code.

## SCALE 6.2 Data

Note that if you have SCALE 6.2 data installed from a prior SCALE 6.2 installation, you can copy or link the data into the SCALE 6.2.1 directory. To link pre-installed SCALE 6.2 data, open a command prompt and change the directory to the SCALE 6.2.1 installation directory (C:ISCALE-6.2.1, /Applications/SCALE6.2.1/Contents/Resources, etc).

On Windows, the following will link the SCALE 6.2 data into the SCALE 6.2.1 installation (May require admin privileges):
mklink /D data C:\SCALE-6.2\data
On OS X , the following will link the SCALE 6.2 data into the SCALE 6.2.1 installation:

## ln -s /Applications/SCALE-6.2.1.app/Contents/Resources/data data

On Linux, the following will link the SCALE 6.2 data into the SCALE 6.2.1 installation:
ln -s /scale/scale6.2.1/data data

To begin installation of SCALE 6.2 data, copy the scale-6.2-data-setup.jar to your local disk. Double-click this jar file. If the installer does not start then bring up a command prompt or terminal window and issue the following command: java - jar scale-6.2-data-setup.jar in the location where the installer jar file was copied.

After launching the installer, a dialog should appear as shown below.

Figure 22. SCALE 6.2 data installer welcome dialog.

Please continue by pressing Next.
You will be prompted to review and accept the terms of the license agreement.
© Please read the following license agreement carefully:

```

(o) I accept the terms of this license agreement.

- I do not accept the terms of this license agreement.
(Made with IzPack - http://izpack.org/)

Figure 22. SCALE license agreement.

To proceed, check that you accept the terms and press next.
You will be prompted to choose the destination of your installation.
For Windows users, the recommended installation path is inside your SCALE-6.2.1 directory:
c: \SCALE-6.2.1
For Linux, a typical location is:
/scale/scale6.2.1
For Mac, a typical location is:
/Applications/SCALE-6.2.1.app/Contents/Resources

Figure 24. Setting typical data installation path on Windows.

Figure 25. Setting a typical data installation path on Linux.

Figure 26. Setting a typical data installation path on Mac OS X.

For some systems, the installer will not be allowed to create a new directory. If you encounter a message like the one shown below, simply create the directory manually (e.g. using Windows Explorer) then return to the installer and continue.

Figure 27. Data installer directory creation error message.

In most cases, the installer will present a prompt to confirm the creation of a new directory; if that target directory is correct you can simply press OK.

If the directory was manually created, the installer will notify you that it is about to overwrite any previous contents. Press Yes to continue.

Figure 28. Directory overwrite dialog.

The installer then presents a dialog for available data sets you wish to install.

Figure 29. Data selection dialog.

Please select the data needed to perform your desired SCALE calculations.

- Basic Data - Composition data, physical constants, and other foundational data required for all SCALE calculations.
- ENDF/B-VII. 0 Data - Nuclear Data from ENDF/B-VII. 0 for continuous-energy and multi-group calculations; Coupled n-gamma data from ENDF/B-VII. 0 for multi-group calculations; SCALE 6.0/6.1 44-group neutron covariance data. Optional for most calculations, but provided for backwards compatibility.
- ENDF/B-VII. 1 Data - Nuclear Data from ENDF/B-VII. 1 for continuous-energy and multi-group calculations; Coupled n-gamma data from ENDF/B-VII. 1 for multi-group calculations; ENDF/B-VII. 1 neutron covariance data. Recommended for most calculations and required to run the SCALE sample problems.
- Perturbation data - 1000 samples of data each for: ENDF/B-VII. 1 neutron covariance data, SCALE 6.0/6.1 neutron covariance data, fission product yield covariance data, and radioactive decay covariance data. Required for Sampler calculations.
- ORIGEN Data - Activation, depletion and decay data from ENDF/V-VII. 1 and JEFF 3.1. Required for activation, depletion and decay calculations.
- ORIGEN-ARP Data - Pre-generated ORIGEN reactor libraries for many fuel types. Required for spent fuel characterization and source terms calculations.

Next, the installer may ask for the location of the data .pak files that are unpacked during the installation process. Please direct the installer to the location of these data files, which are part of the SCALE distribution and may be on the distribution media or copies to a local directory as shown below.

Figure 23. Media selection dialog.

The installer will post the progress of the installation. If installing from a DVD set, part way through the installation you will be prompted for installer.pak.1. Please insert the PAK. 1 disk and click Apply.

The installation from PAK. 1 will complete and prompt for installer.pak. 2. Please insert the PAK. 2 disk and click Apply.

PAK. 2 will finish. Proceed with all DVDs or files in the delivery until you have completed your installation of SCALE 6.2 data.

## Running SCALE

SCALE is run by using the Fulcrum user interface or by invoking the SCALE Runtime Environment, scalerte, from the command line. Note that this release does not include the previous interface GeeWiz or OrigenArp for running SCALE on Windows, as Fulcrum should be used instead. Additionally, previous shortcuts like runscale are not implemented.

## Running SCALE from Fulcrum

The most convenient way to run SCALE from a desktop is by launching Fulcrum. The Fulcrum executable is provided in the bin directory where SCALE was installed (e.g. C:\SCALE-6.2.1 lbin\Fulcrum.exe). Fulcrum includes an online help document to assist users with its many features and includes links to the user manual and primers.

## Windows

For a Windows installation, a Fulcrum shortcut is provided in the SCALE-6.2.1 shortcuts folder on the desktop.

Figure 24. Windows desktop SCALE-6.2.1 shortcuts folder.

## Linux

For Linux, launch Fulcrum from the bin directory of the SCALE installation (e.g. /scale/scale6.2.1/bin/Fulcrum).

## Mac OS X

For a Mac installation, please use the SCALE-6.2.1 app in the Applications directory.

Figure 25. Mac SCALE-6.2.1 app in the Applications folder.

## Running SCALE from the Command Line

Using the command line, SCALE can be executed using the scalerte command from the bin directory inside the SCALE installation. Paths for each platform are shown below based on recommended installation directories. Your directory may differ based on the installation.

## Windows

C:SSCALE-6.2.1 \bin\scalerte.exe
*Note that Norton Antivirus may require an exception for scalerte.exe on Windows to prevent the executable from being quarantined.

## Linux

/scale/scale6.2.1/bin/scalerte

## Mac

/Applications/SCALE -6.2.1.app/Contents/Resources/bin/scalerte

The SCALE runtime environment provides several command line options. The usage is as follows.
scalerte [options] inputfile(s) [options] [inputfile(s)]
Where inputfile(s)are one or more files or file patterns (test.inp, or test*inp, etc.).
Where options are:
-a: Specify alias file.
-a path/to/aliasesfile
-f: Add hostname to output filename. Produces inputfile.hostname.out
-h: Print this information as a help message

- I: Number of threads to use for MPI/OpenMP directives. - I 4
-m: Print information messages as SCALE executes
- M: Specify a machine names file for SCALE parallel capabilities.
-M /path/to/machine/names/file
-n: Nice level on Nix systems, ignored on Windows. Default: - n 2
- N : Number of MPI processes to run. -N 20
- o: Overrides the default inputfile.out output name. The .out extension is appended by scalerte, so there is no need to specify the extension.
-o path/to/outputfile
NOTE: If the path/to/outputfile already exists, it will be deleted. If this option is specified while in stack mode (multiple input files), the value provided is prepended to the inputfile's basename.
scalerte triton* -o myout results in output names myout.triton*.out
-r: Keep the temporary working directory after execution
- $t$ : No new temporary working directory. Uses last temporary working directory, $-r$ is implied.
-T: Specify temporary working directory.
-T directory/path

NOTE: If - T is specified while in stack mode (multiple input files) the value provided is appended with the index of the file.
scalerte t0.inp t1.inp t2.inp -T mytmp
results in mytmp, mytmp1, and mytmp2 temporary directories.

- V : Turn on verbose activity printing for scalerte.
-V: Print the scalerte version date.
- x : Do not return XSDRNPM output in a .xsdrnfiles directory.
-z : Add date to the output filename.
Produces output files in the form of inputfile.yyyy.MM.ddThh.mm.ss.out

Where:

- yyyy- is the year of execution.
- MM- is the month of execution.
- dd- is the day of execution.
- hh- is the hour of execution.
- mm- is the minute of execution.
- ss- is the second of execution.

## Example Invocation

For users familiar with previous invocation of the SCALE batch script, this usage is no longer valid. The only valid entry point is scalerte. Scalerte can be executed from anywhere with a fully qualified path such as c:\SCALE-6.2.1\bin C scalerte or /scale/scale6.2.1/bin/scalerte, for example.

Invoke SCALE on a single input file named HelloWorld.inp
scalerte HelloWorld
or
scalerte HelloWorld.inp
Invoke SCALE on all input files patterned HelloWorld*.inp
scalerte HelloWorld*.inp
Invoke SCALE on all input files patterned HelloWorld*.inp and print runtime messages to the console
scalerte HelloWorld*.inp -m

Invoke SCALE on all input files patterned HelloWorld*.inp and include hostname and date/time in the output file's name

```
scalerte HelloWorld*.inp -fz
```

or
scalerte HelloWorld*.inp -f -z
Invoke SCALE on HelloWorld.inp and rename output to be MyHello.out
scalerte HelloWorld -o MyHello
or
scalerte HelloWorld.inp -o MyHello
Invoke SCALE on all files patterned HelloWorld*.inp and rename output to be MyHelloWorld*.out.

NOTE: When SCALE is run in stack mode (multiple inputs), the output override is prepended to the input file's name.
scalerte HelloWorld*.inp -o My
Invoke SCALE on HelloWorld.inp and keep the working directory.
scalerte HelloWorld.inp -r
Invoke SCALE on HelloWorld.inp and override and keep the working directory.
scalerte HelloWorld.inp -r -T myHelloWorldTempDir
Invoke SCALE on HelloWorld.inp and specify the number of threads to be 4.
scalerte HelloWorld.inp -I 4

## SCALE Variables

This section describes the environment variable used within scalerte. These variables can be accessed through SCALE's shell module to populate the working directory, and/or to return SCALE-generated files that are not returned by scalerte.

Shell is used to perform system commands inside a problem either before, after, or between explicitly called modules. It is usually used in SCALE to link a file from one name and place to another name and place, delete files or directories, and move or copy files. The use of shell in an input has the following form:

```
=shel|
*** System Commands ***
```

end
Where System Commands are any UNIX or DOS command(s). This is particularly useful in tandem with the following environment variables when files not automatically returned are desired. The following example shell command copies the x16 file back alongside the output file.
=shell
cp x16 \$ \{OUTBASENAME\}. x16
end

Please note the syntax of Nix and Windows environment variables, \$\{VAR\} and \%VAR\% respectively, are interchangeable as scalerte and shell understand both.

There are seven primary locations known by scalerte. These primary locations are:

- The user's home directory, HOME.
*Nix systems, \$\{HOME \}, /home/uid.
*Windows, \%HOME\%, C:\Users\uid.
- The directory of SCALE, SCALE.
*Nix systems, \$\{SCALE\}, location of user's installation. Typically /scale/scale\#.
*Windows, \%SCALE\%, location of user's installation. Typically C:ISCALE\#.
- The directory of the input file, INPDIR.
*Nix systems, \$\{INPDIR \}.
*Windows, \%INPDIR\%.
- The directory of the output file, OUTDIR, by default, this is the same as INPDIR, because the output file is written next to the input file.
*Nix systems, \$\{OUTDIR \}.
*Windows, \%OUTDIR\%.
- The directory from which SCALE was invoked, the return directory, RTNDIR. This is the directory your console will return to upon completion.
*Nix systems, \$\{RTNDIR\}.
*Windows, \%RTNDIR\%.
- The directory that contains the SCALE data, DATA.

Getting Started — 49
*Nix systems, \$\{DATA\}.
*Windows, \%DATA\%.

- The working directory for a given input file, TMPDIR, or shorthand TMP.
*Nix systems, \$\{TMPDIR \}, \$\{TMP\}.
*Windows, \%TMPDIR\%, \%TMP\%.
There are several secondary locations, located in the SCALE directory tree. These are as follows:
- The directory containing the platform-specific compiled programs, PGMDIR, or legacy PGM_DIR.
*Nix systems, \$\{PGMDIR \}, \$\{PGM_DIR \}.
*Windows, \%PGMDIR\%, \%PGM_DIR\%.
Lastly, there are several environment variables provided for convenience, and/or associated with output data that can be useful.
- The directory containing the ORIGEN data files, ORIGENDIR.
*Nix systems, \$\{ORIGENDIR \}.
*Windows, \%ORIGENDIR\%.
- The base name of the input file, BASENAME. This is the name of the input file without both absolute path and extension.
*Nix systems, \$\{BASENAME \}, or \$\{CASE_NAME\}.
*Windows, \%BASENAME\%, or \%CASE_NAME\%.
- The base name of the output file, OUTBASENAME, or legacy CASE_NAME. This is the name of the output file without both absolute path and extension.
*Nix systems, \$\{OUTBASENAME\}, or \$\{CASE_NAME \}.
*Windows, \%OUTBASENAME\%, or \%CASE_NAME\%.
- The base name of the output file, OUTBASE. This is the absolute name of the output file without absolute file extension.
*Nix systems, \$\{OUTBASE \}.
*Windows, \%OUTBASE\%.
- The absolute path to the input file, INPUTFILE.
*Nix systems, \$\{INPUTFILE\}.
Getting Started - 50
*Windows, \%INPUTFILE\%.
- The absolute path to the output file, OUTFILE.
*Nix systems, \$\{OUTFILE\}.
*Windows, \%OUTFILE\%.
- The directory containing USLSTATS output, USLDIR. If USLSTATS data were output, these data will be located in OUTDIR\OUTBASENAME.uslstats directory.
*Nix systems, \$\{USLDIR \}.
*Windows, \%USLDIR\%.
- The directory containing CENTRM output, CENTRMDIR. If CENTRM data were output, these data will be located in OUTDIR\OUTBASENAME.centrmfiles directory.
*Nix systems, \$CENTRMDIR.
*Windows, \%CENTRMDIR\%.
- The directory containing XSDRNPM output, XSDRNDIR. If XSDRNPM data were output, these data will be located in OUTDIR\OUTBASENAME.xsdrnfiles directory.
*Nix systems, \$XSDRNDIR.
*Windows, \%XSDRNDIR\%.
- The platform specific file separator, FS. This is either back slash ( $($ ) on Windows, or forward slash (/) on Nix systems.
*Nix systems, \$\{FS\}.
*Windows, \%FS\%.

## Parallel Execution Capability

SCALE 6.2 contains five modules and sequences that have distributed memory (MPI) parallelism; KENO V.a, KENO-VI, Sampler, ORIGAMI, and Runner. However, the binary executable files distributed with SCALE do not have MPI enabled. In order to run one of these codes in parallel the user must first build SCALE with MPI enabled (see build instructions in this guide). Control modules, like CSAS6, T6-DEPL, and TSUNAMI-3D-K6, automatically initiate the parallel version of KENO-VI in a parallel SCALE build if the user provides the required arguments as summarized below. When running a standalone code in parallel (such as KENO-VI), a "\%" prefix on the sequence specification record in the input file (e.g. $=\%$ keno-vi). Parallel code execution is currently available on Linux and Mac systems but is not available on Windows PCs.

The executable binary code distributed with SCALE only enables serial calculations. If MPI parallelism is desired, the source code must be compiled with MPI support enabled
for the particular platform and configuration where the code will be executed in parallel. The SCALE build configuration sets some variables (SCALEMPI, SCALECMDS, and MPIRUN) depending on the third party MPI package for the SCALE driver, which prepares two different execution environments with these variable sets for both serial and parallel code execution.

Executing SCALE in parallel is initiated by scalerte when the user provides the necessary MPI command line arguments with the two options, $-N$ and $-M$, which specify the number of MPI processes and machine names, respectively. To run an input called HelloWorld.inp from an MPI build on SCALE on two nodes specified in the machine file mach use the command:

```
scalerte -N 2 -M mach HelloWorld.inp
```

With these options, scalerte sets NTASKS and MACHINEFILE variables depending on the user request, and passes them to the SCALE driver. During the parallel code execution process, the driver invokes the MPIRUN wrapper and passes some variables ${ }^{1}$ to all MPI processes to setup run time environment on each process and to run the parallel functional module across MPI processes. An additional variable MPIARGS was also defined in the driver to pass some user defined MPI options to MPIRUN wrapper.

[^0]
## SCALE Sample Problems

The SCALE sample problems are carefully designed by the SCALE developers to verify the installation and functionality of SCALE relative to expected results. Users are urged to run the sample problems to verify the proper installation of SCALE. ORNL has provided a set of reference results from each sample problem against which the results of each installation can be compared.

The Sample Problems are most easily run through Fulcrum by selecting Run SCALE Verification from the Run menu on the main menubar. This will run all of the Sample Problems sequentially and present any differences from the ORNL-generated results.

The SCALE Runtime Environment, scalerte described in the subsequent section, has a built-in scripting interface to allow for invocation of several groupings of sample problems, from individual problems, problems for a specific module, subsets of modules, or all samples. The sample problems will print a message indicating the currently running sample problem, followed by the differences between ORNL-generated results and the newly generated results for the sample problem(s). Note that there may be a significant delay (i.e., as much as an hour) before messages are printed to the console. The final message will indicate that the "Process finished with a 0 return code; . . ." If no differences or minimal differences are noted for a particular sample problem, SCALE has been properly installed for the tested functionality.

The set of sample problems is located in the samples directory of the SCALE installation.
To run all sample problems, execute the following command.
scalerte @samples/samples
To invoke sample problems for a particular module or sequence, use
scalerte @samples/samples modulename
where modulename is the name of the module or sequence to test, e.g. centrm
To invoke a single sample problem, do the following.
scalerte @samples/samples problemname
where problemname is the name of the specific sample problem to test, e.g., centrmpwr.inp

The above modulename and problemname examples can be combined and repeated to exercise sets of sample problems of interest. E.g., run csas and origen sequence sample problems in addition to the centrm-pwr.inp sample.
scalerte @samples/samples csas centrm-pwr.inp origen
As the sample problems execute, feedback will be provided to the screen such as shown in the example below. Where no differences or only small differences are reported

$$
\text { Getting Started — } 53
$$

between the ORNL results and the currently generated results for each sample, SCALE has been properly installed and configured for the tested functionality.

Figure 26. Sample problem output messages.

For any problems or questions, please contact scalehelp@ornl.gov.

## Build Instructions

These instructions are only for those who wish to recompile their SCALE binaries. If you are running SCALE using the precompiled binary executable files distributed with SCALE, please disregard this section.

For SCALE 6.2, the build configuration has been completely renewed relative to all previous versions. The SCALE build is now based on CMake from KitWare, which supports a consistent experience on Linux, Mac, and Windows.

## Overview

There are four main steps to create and install SCALE binaries

1. Install compilers and third-party libraries (TPLs)
2. CMake configuration - This generates a native build tree
3. Compilation - This compiles all executables and libraries
4. Installation - This deploys all executables into a configuration ready for execution

## Required Resources

SCALE required the following programs in order to compile:

1. Fortran Compiler
i. Windows - Intel Fortran compiler 15.0.
ii. Linux - Intel Fortran compiler 14.1+/GNU gfortran 4.8.3+ compiler.
iii. Mac OS - GNU gfortran 4.8.5+ compiler.
2. $\mathrm{C} / \mathrm{C}++$ Compiler
i. Windows - Intel C/C++ compiler 15.0.
ii. Linux - Intel C/C++ compiler 14.1+ / GNU g++/gcc 4.8.3+ compiler.
iii. Mac OS - GNU g++/gcc 4.8.5+ compiler.
3. CMake 2.8.12.2+ - Platform independent build configuration for Linux and Darwin and CMake 3.3.2+ for Windows.

SCALE requires the following libraries, which are not distributed with SCALE:

1. LAPACK libraries:module
a. lapack
b. blas

You must modify the LAPACK variable in configure_scale_gnu.sh to point to your installation of LAPACK prior to configuration.

Following optional package is required by SCALE if MPI support is desired:

1. OpenMPI-1.8.1+ - Optional for SCALE build with MPI support on Linux and Mac OS (currently, SCALE does not support MPI for Windows)

## Mac OSX Resources

Mac OSX does not come preloaded with the necessary resources for compiling SCALE. Macports provides a simple mechanism for retrieving almost all of the required resources necessary to compile SCALE on a Mac. This process has only been tested on MacOSX 10.9.5.

You can download the latest macports from: http://www.macports.org/. You will need XCode(Free from App Store), with commandline tools installed, for macports to work.

You will need administrative privileges to install macports and the necessary resources.

Please see macports instructions for xcode installation/requirements. http://guide.macports.org/\#installing.xcode

After installing these resources, a new shell session is necessary to access the new tools.
NOTE if your rsync port is blocked by for firewall (as is the case at ORNL), you may synchronize over http by updating your /opt/local/etc/macports/sources.conf file to change the line:

```
rsync://rsync.macports.org/release/tarballs/ports.tar [default]
```

to
http://www.macports.org/files/ports.tar.gz [default]
The following commands will install all necessary resources.
If rsync port is blocked use:

```
$> sudo port -d sync
```

If rsync port is open:
\$>sudo port selfupdate
Regardless of rsync status execute the following commands:
\$>sudo port install gcc48
\$>sudo port select gcc mp-gcc48
\$>sudo port install qt4-mac
These commands upgrade the default compilers from gcc-4.2.2 to gcc-4.8.3 as well as install qt4.8.6.

## CMake Configuration

Throughout SCALE you will find 'CMakeLists.txt' files. From the SCALE root directory these CMakeLists.txt files create a tree of included directories called the SOURCE TREE. Namely the source directories:
packages/AmpxLib
XSProc
ScaleLib
etc..
To configure a build call 'cmake' on the root CMakeLists.txt file, namely scale_dir/CMakeLists.txt. CMake takes your source tree and creates a BUILD TREE. The build tree contains or will contain your build configuration, Make or NMake files, and all compilation output, i.e., object files, archive libraries and binary executables.

SCALE requires several TPLs, namely: QT and Lapack. These TPLs must be specified at the time of configuration. For ease of use, configuration scripts for every supported platform are available in the 'scripts' directory of the source code. These scripts describe the necessary variables to define. A user's modifications to these scripts should be limited to the path to the root directories for the TPLs.

## Recommended Configuration Procedure

After unpacking out the source code, navigate to the root scale directory (<SCALE_SRC_ROOT>. You should see CMakeLists.txt, PackagesList.cmake and CTestConfig.cmake. This is the root of the source tree, what you will point CMake at. This example will demonstrate creating build trees for multiple configurations for your working copy.

## Linux and Mac Configuration

## - Make Build Directory

 mkdir build mkdir -p build/intel **this could be any directory or```
mkdir -p build/gcc
```

## - CMake Initialization

Copy the cmake script from the 'scripts' directory to your build directory. Update the cmake script with your TPL specifications.

Getting Started - 57
o Serial SCALE (without MPI support)

$$
\begin{aligned}
& \text { cp <SCALE_SRC_ROOT>/script/configure_scale_gnu.sh } \\
& \text { build/gcc }
\end{aligned}
$$

```
chmod u+x build/gcc/configure_scale_gnu.sh
```

o Parallel SCALE (with MPI support) cp script/configure_scale_mpi.sh build/gcc chmod u+x build/gcc/configure_scale_mpi.sh

## - Create Your Configuration

Create your configuration by pointing this script at the source tree root cd build/gcc

Edit the CMakelists.txt file in <SCALE_SRC_ROOT>/Trilinos/packages/anasazi/src/ so as to comment out the following line:

ASSERT_DEFINED(Anasazi_ENABLE_Tpetra)
o Serial SCALE (without MPI support)
./configure_scale_gnu.sh ../..
o Parallel SCALE (with MPI support)
./configure_scale_mpi.sh ../..
/*** Configuration Output.... ***/
**Be aware: if you add or remove source files from the source tree, CMake will NOT see these modifications unless a CMake file is modified (CMakeLists.txt,PackagesList.cmake,etc...). CMake will re-evaluate the entire source tree when any CMake file has been modified. If CMake does not pick up the addition/removal of sources files, the easiest way to update your build tree is to 'touch' any CMake file in the source tree.

## Windows Configuration

Instructions are not documented here. Please contact scalehelp@ornl.gov for assistance.

## Compilation

Every library and executable is a TARGET. Calling 'make' on Linux and Mac and 'nmake' on Windows from the root of your build tree Getting Started - 58
(<SCALE_SRC_ROOT>/build/gcc from the previous example) will build ALL targets. There are two options when building specific targests. For example MavricUtilities contains a number of executables: mtadder, mtaverager, and so on.

You may invoke 'make mtadder' to build mtadder alone. Alternatively you can, from build/gcc, 'cd packages/MavricUtilities' and 'make', which will compile ALL targets in mavricUtilities.

## Compilation Flags

You may modify CMAKE_Fortran_FLAGS, CMAKE_C_FLAGS, CMAKE_CXX_FLAGS in on the cmake command invocation line.

## Installation

CMake provides the 'install' target, which installs all binaries from the current directory down. For example, 'make install' from build/gcc will install any targets, which would install aim, mavric, mtadder, mtaverager, etc. You can also 'cd packages/Mavric' and 'make install' will only install targets declared in the Mavric directory.
***Things to know are that 'make install' re-evaluates the build for all dependencies. Take for example package A, which depends on packages B and D . Package D depends on package E. 'make install' for package A would result in packages E, D, and B being re-evaluated and rebuilt if necessary. Thus, if you know you want to build and install, you can save time building by simply doing a 'make install'. An alternative is 'make install/fast' which will skip the dependency checking and only execute the install operations.

### 1.0 INTRODUCTION

The SCALE code system is a widely used modeling and simulation suite for nuclear safety analysis and design that is developed, maintained, tested, and managed by the Reactor and Nuclear Systems Division (RNSD) of the Oak Ridge National Laboratory (ORNL). SCALE provides a comprehensive, verified and validated, user-friendly tool set for criticality safety, reactor physics, radiation shielding, radioactive source term characterization, and sensitivity and uncertainty analysis. Since 1980, regulators, licensees, and research institutions around the world have used SCALE for safety analysis and design. SCALE provides an integrated framework with dozens of computational modules, including three deterministic and three Monte Carlo radiation transport solvers selected based on the user's desired solution strategy. SCALE includes current nuclear data libraries and problem-dependent processing tools for continuous energy and multigroup neutronics and coupled neutron-gamma calculations, as well as activation, depletion, and decay calculations. SCALE includes unique capabilities for automated variance reduction for shielding calculations, as well as sensitivity and uncertainty analysis. SCALE's graphical user interfaces assist with accurate system modeling and convenient access to desired results.

This manual documents version 6.2 of the SCALE code system, released in 2016. Users are directed to the README file for details on updates available in version 6.2 relative to 6.1, as well as instructions on installing or building SCALE, testing the configuration with the sample problems, and beginning analysis. This introduction provides historical information on SCALE, an overview of current features, information on technical assistance, code availability, and acknowledgments.

### 1.1 BACKGROUND

The history of the SCALE code system dates back to 1969, when ORNL began providing the transportation package certification staff at the US Atomic Energy Commission (AEC) with computational support in the use of the new KENO code. KENO was used to perform criticality safety assessments with the statistical Monte Carlo method. From 1969 to 1976, the AEC certification staff relied on ORNL personnel to assist them in the correct use of codes and data for criticality, shielding, and heat transfer analyses of transportation packages. However, the certification staff learned that occasional users had difficulty in becoming proficient in performing the calculations often needed for an independent safety review. Thus, shortly after the certification staff was moved to the US Nuclear Regulatory Commission (NRC), the NRC proposed development of an easy-to-use analysis system that provided the technical capabilities of the individual modules with which they were familiar. With this proposal, the concept of SCALE as a comprehensive modeling and simulation suite for nuclear safety analysis and design was born.

The NRC staff provided ORNL with some general development criteria for SCALE: (1) focus on applications related to nuclear fuel facilities and package designs, (2) use well-established computer codes and data libraries, (3) design an input format for the occasional or novice user, (4) prepare standard analysis sequences (control modules) to automate the use of multiple codes (functional modules) and data to perform a system analysis, and (5) provide complete documentation and public availability. With these criteria, the ORNL staff laid out the framework for the SCALE system and began development efforts. The initial version of SCALE (Version 0) was distributed in July 1980. Although the capabilities of the system continue to evolve, the philosophy established with the initial release still serves as the foundation of SCALE 6.2 more than 35 years later.
In July 1980, the initial version of SCALE was made available to the Radiation Safety Information Computational Center (RSICC) at ORNL. This system was packaged and released by RSICC as CCC-288/SCALE 0. Subsequent additions and modifications resulted in the following releases: CCC-424/SCALE 1 in 1981; CCC-450/SCALE 2 in 1983; CCC-466/SCALE 3 in 1985;

CCC-545/SCALE 4.0 in 1990; SCALE 4.1 in 1992; SCALE 4.2 in 1994; SCALE 4.3 in 1995; SCALE 4.4 in 1998; SCALE 4.4a in 2000; CCC-725/SCALE 5 in 2004; CCC-732/SCALE 5.1 in 2006; CCC-750/SCALE 6.0 in 2009; CCC-785/SCALE 6.1 in 2011; CCC-834/SCALE 6.2 in 2016.

### 1.2 SYSTEM OVERVIEW

A primary goal of SCALE is to provide robust calculations while reducing requirements for user input and knowledge of the intricacies of the underlying code and data architecture. As such, SCALE provides standardized sequences to integrate many modern and advanced capabilities into a seamless calculation that the user controls from a single input file. Additional utility modules are provided primarily for post processing data generated from the analysis sequences for advanced studies. Input for SCALE sequences is provided in the form of text files using free-form input with extensive use of keywords and engineering-type input requirements. A graphical user interface is provided to assist in the creation of input files, visualization of geometry and nuclear data, execution of calculations, viewing output, and visualization of results. An overview of the major SCALE capabilities and the analysis areas they serve is provided in Table 1 with additional descriptions provided below.

Table 1. Summary of major SCALE capabilities

| Analysis area | Modules/ libraries | Analysis function(s) | Documentation section |
| :---: | :---: | :---: | :---: |
| Criticality safety | $\begin{aligned} & \text { CSAS5/ } \\ & \text { CSAS6 } \end{aligned}$ | 3D multigroup and continuous energy eigenvalue Monte Carlo analysis and criticality search capability |  |
|  | STARBUCS | Burnup credit analysis using 3D Monte Carlo | 2 |
|  | Sourcerer | Hybrid 3D deterministic/Monte Carlo analysis with optimized fission source distribution |  |
| Reactor physics | TRITON | 1D and 2D general purpose lattice physics depletion calculations and generation of few-group cross section data for use in nodal core simulators | 3 |
|  |  | 3D multigroup and continuous energy Monte Carlo depletion analysis |  |
|  |  | 2D eigenvalue and reaction rate sensitivity analysis |  |
|  | Polaris | 2D streamlined light water reactor lattice physics depletion calculations and generation of few-group cross section data for use in nodal core simulators |  |

### 1.2.1 Criticality Safety

SCALE provides a suite of computational tools for criticality safety analysis that is primarily based on the KENO Monte Carlo codes for eigenvalue neutronics calculations. Two variants of KENO provide identical solution capabilities with different geometry packages. KENO V.a uses a simple, efficient geometry package sufficient for modeling many systems of interest to criticality safety and reactor physics analysts. KENO-VI uses the SCALE Generalized Geometry Package, which provides a quadraticbased geometry system with much greater flexibility in problem modeling but with slower runtimes. Both versions of KENO perform eigenvalue calculations for neutron transport primarily to calculate multiplication factors ( $k_{e f f}$ ) and flux distributions of fissile systems in continuous energy and multigroup
modes and are typically accessed through Criticality Safety Analysis Sequence with KENO V.a (CSAS5) and Criticality Safety Analysis Sequence with KENO-VI (CSAS6). The CSAS sequences implement XSProc to process material input and provide a temperature and resonance-corrected cross section library based on the physical characteristics of the problem being analyzed. If a continuous energy cross section library is specified, no resonance processing is needed, and the continuous energy cross sections are used directly in KENO, with temperature corrections provided as the cross sections are loaded.

A search capability is available with CSAS5 to find desired values of $k_{\text {eff }}$ as a function of dimensions or densities. The two basic search options offered are (1) an optimum search seeking a maximum or minimum value of $k_{\text {eff }}$ and (2) a critical search seeking a fixed value of $k_{\text {eff }}$. For continuous energy calculations, reaction rate tallies can be requested within the CSAS input, and for multigroup calculations, reaction rate calculations are performed using the KMART (KENO Module for Activity-Reaction Rate Tabulation) post-processing tools. A conversion tool is provided to up-convert KENO V.a input to KENO-VI either as a direct KENO input K5toK6, or more commonly, as a CSAS sequence C5toC6.

The Standardized Analysis of Reactivity for Burnup Credit using SCALE (STARBUCS) performs criticality calculations for spent fuel systems employing burnup credit. STARBUCS automates the criticality safety analysis of spent fuel configurations by coupling the depletion and criticality aspects of the analysis, thereby eliminating the need to manually process the spent fuel nuclide compositions into a format compatible with criticality safety codes. For burnup loading curve iterative calculations, STARBUCS employs the search algorithm from CSAS5 to determine initial fuel enrichments that satisfy a convergence criterion for the calculated $k_{\text {eff }}$ value of the spent fuel configuration.

The Sourcerer sequence applies the Denovo discrete ordinates code to generate the starting fission source distribution in a KENO Monte Carlo calculation. This sequence is especially applied to burnup credit transportation and storage analysis of as-loaded canister of used fuel.

### 1.2.2 Reactor Physics

The Transport Rigor Implemented with Time-dependent Operation for Neutronic depletion (TRITON) control module provides flexible capabilities to meet the challenges of modern reactor designs by providing 1D pin-cell depletion capabilities using XSDRNPM, 2D lattice physics capabilities using the NEWT flexible mesh discrete ordinates code, or 3D Monte Carlo depletion using KENO V.a or KENO-VI, including continuous energy treatment with problem-dependent temperature corrections. For multigroup analysis, TRITON implements XSProc to process material input and provide a temperature and resonancecorrected cross section library. TRITON allows users to input Dancoff factors to account for nonuniform lattices. In all cases, ORIGEN is implemented for depletion and decay calculations. Additionally, TRITON can produce assembly-averaged few group cross sections for use in core simulators. There are few limitations to the types of systems that can be modeled with TRITON, but the input complexity and long runtimes can be burdensome on users for detailed analysis.

Polaris is an optimized tool that produces assembly-averaged few group cross sections for light water reactor (LWR) analysis with core simulators. Polaris provides simplified input; only a few lines are required to describe the entire model. Polaris uses a multigroup self-shielding method called the Embedded Self-Shielding Method (ESSM) and Method-of-Characteristics (MoC) transport solver. The ESSM approach computes multigroup self-shielded cross sections using Bondarenko interpolation. The background cross section used in the interpolation is determined by a series of 2D MoC fixed-source calculations similar to the subgroup method that does not require explicit celldata input. Additionally, heterogeneous lattices are explicitly treated without the need to externally compute Dancoff factors. Like TRITON, Polaris implements ORIGEN for depletion and decay calculations.

### 1.2.3 Radiation Shielding

The Monaco with Automated Variance Reduction using Importance Calculations (MAVRIC) fixedsource radiation transport sequence is designed to apply the multigroup and continuous-energy fixedsource Monte Carlo code, Monaco, to solve problems too challenging for standard, unbiased Monte Carlo methods. The intention of the sequence is to calculate fluxes and dose rates with low uncertainties in reasonable times, even for deep penetration problems. MAVRIC is based on the Consistent Adjoint Driven Importance Sampling (CADIS) methodology, which uses an importance map and a biased source that are derived to work together. MAVRIC generates problem-dependent cross section data, and then it automatically performs a coarse mesh 3D discrete ordinates transport calculation using Denovo to determine the adjoint flux as a function of position and energy, and apply the information to optimize the shielding calculation in Monaco. In the Forwarded-Weighted CADIS (FW-CADIS) methodology, an additional Denovo calculation is performed to further optimize the Monaco model to obtain uniform uncertainties for multiple tally locations. Several utility modules are also provided for data introspection and conversion.

### 1.2.4 Activation, Depletion, and Decay

The Oak Ridge Isotope Generation (ORIGEN) code calculates time-dependent concentrations, activities, and radiation source terms for a large number of isotopes simultaneously generated or depleted by neutron transmutation, fission, and radioactive decay. Provisions are made to include continuous nuclide feed rates and continuous chemical removal rates that can be described with rate constants for application to reprocessing or other systems that involve nuclide removal or feed. ORIGEN includes the ability to use multigroup cross sections processed from standard ENDF/B evaluations. Within SCALE, transport codes can be used to model user-defined systems, and the COUPLE code can be applied to calculate problemdependent neutron-spectrum-weighted cross sections representative of conditions within any given reactor or fuel assembly and then convert these cross sections into a library to be used by ORIGEN. Time-dependent cross section libraries can be produced to reflect fuel composition variations during irradiation. An alternative sequence for depletion/decay calculations is ORIGEN-ARP, which interpolates pregenerated ORIGEN cross section libraries versus enrichment, burnup, and moderator density.

ORIGEN Assembly Isotopics (ORIGAMI) computes detailed isotopic compositions for LWR assemblies containing $\mathrm{UO}_{2}$ fuel by using the ORIGEN code with pregenerated ORIGEN libraries for a specified assembly power distribution. The assembly may be represented by a single lumped model with only an axial power distribution or by a square array of fuel pins with variable pin powers, as well as an axial distribution. Multiple cycles with varying burn times and down times may be used. ORIGAMI produces files containing SCALE and MCNP composition input for material in the burnup distribution, files containing decay heat for use in thermal analysis, and energy-dependent radioactive source for use in shielding calculations.
A series of 1470 pregenerated burnup libraries for use in ORIGEN and ORIGAMI are provided with SCALE for 61 fuel assemblies for commercial and research reactors.

### 1.2.5 Sensitivity and Uncertainty Analysis

SCALE provides a suite of computational tools for sensitivity and uncertainty analysis to (1) identify important processes in safety analysis and design, (2) provide a quantifiable basis for neutronics validation for criticality safety and reactor physics analysis based on similarity assessment, and (3) quantify the effects of uncertainties in nuclear data and physical parameters for safety analysis.

The TSUNAMI-1D, TSUNAMI-2D and TSUNAMI-3D analysis sequences compute the sensitivity of $k_{\text {eff }}$ and reaction rates to energy-dependent cross section data for each reaction of each nuclide in a system
model. The one-dimensional (1D) transport calculations are performed with XSDRNPM, the twodimensional (2D) transport calculations are preformed using NEWT, and the three-dimensional (3D) calculations are performed with KENO V.a or KENO-VI. The Monte Carlo capabilities of TSUNAMI-3D provide for $\mathrm{S} / \mathrm{U}$ analysis from either continuous energy or multigroup neutron transport, where the deterministic capabilities of TSUNAMI-1D and TSUNAMI-2D only operate in multigroup mode. The Sensitivity Analysis Module for SCALE (SAMS) is applied within each analysis sequence to provide the requested $\mathrm{S} / \mathrm{U}$ data. Whether performing a continuous-energy or multigroup calculation, energydependent sensitivity data are stored in group form in a sensitivity data file (SDF) for subsequent analysis. These sequences use the energy-dependent cross section covariance data to compute the uncertainty in the response value due to the cross section covariance data.

Tool for Sensitivity Analysis of Reactivity Responses (TSAR) computes the sensitivity of the reactivity change between two $k_{\text {eff }}$ calculations using SDFs from TSUNAMI-1D, TSUNAMI-2D, and/or TSUNAMI-3D. TSAR also computes the uncertainty in the reactivity difference due to the cross section covariance data.

TSUNAMI Indices and Parameters (TSUNAMI-IP) computes correlation coefficients that determine the amount of shared uncertainty between each target application and each benchmark experiment considered in the analysis. TSUNAMI-IP offers a wide range of options for more detailed assessment of system-tosystem similarity. Additionally, TSUNAMI-IP can generate input for the Upper Subcritical Limit Statistical Software (USLSTATS) trending analysis and compute a penalty or additional margin needed for the gap analysis.

Tool for S/U Analysis of Response Functions Using Experimental Results (TSURFER) is a bias and bias uncertainty prediction tool that implements the generalized linear least-squares (GLLS) approach to data assimilation and cross section data adjustment that also uses the SDFs generated from TSUNAMI-1D, $-2 D,-3 D$, or TSAR. The data adjustments produced by TSURFER are not used to produce adjusted cross section data libraries for subsequent use; rather, they are used only to predict biases in application systems.

The graphical user interface Extensible SCALE Intelligent Text Editor (ExSITE) facilitates analysis with TSUNAMI-IP, TSURFER, TSAR, and USLSTATS, and the Validation, Interpretation and Bias Estimation (VIBE) interface is applied to examine SDF files, create sets of benchmark experiments for subsequent analysis, and gather additional information about each benchmark experiment.

Sampler is a super-sequence that performs general uncertainty analysis by stochastically sampling uncertain parameters that can be applied to any type of SCALE calculation, propagating uncertainties throughout a computational sequence. Sampler treats uncertainties from two sources: (1) nuclear data and (2) input parameters. Sampler generates the uncertainty in any result generated by any computational sequence through stochastic means by repeating numerous passes through the computational sequence, each with a randomly perturbed sample of the requested uncertain quantities.

### 1.2.6 Material Specification and Cross Section Processing

Cross (X) Section Processing (XSProc) provides material input and multigroup cross section preparation for most SCALE sequences. XSProc allows users to specify problem materials using easily remembered and easily recognizable keywords associated with mixtures, elements, nuclides, and fissile solutions provided in the SCALE Standard Composition Library. For multigroup calculations, XSProc provides cross section temperature correction and resonance self-shielding, as well as energy group collapse and spatial homogenization for systems that can be represented in celldata input as infinite media, finite 1D systems, or repeating structures of 1D systems such as uniform arrays of fuel units. Improved resonance self-shielding treatment for nonuniform lattices can be achieved through the use the Monte Carlo Dancoff (MCDancoff) code that generates Dancoff factors for generalized 3D geometries for subsequent use in

XSProc. Cross sections are generated on a microscopic and/or macroscopic basis as needed. Although XSProc is most often used as part of an integrated sequence, it can be run without subsequent calculations to generate problem-dependent multigroup data for use in other tools.

### 1.2.7 Nuclear Data

The cross section data provided with SCALE include comprehensive continuous energy neutron and coupled neutron-gamma data based on ENDF/B-VII. 0 and ENDF/B-VII.1. These data have been generated with the AMPX codes. The multigroup data are provided in several energy-group structures optimized for different application areas, including criticality safety, lattice physics, and shielding analysis. The comprehensive ORIGEN data libraries are based on ENDF/B-VII. 1 and recent JEFF evaluations, and they include nuclear decay data, neutron reaction cross sections, neutron-induced fission product yields, delayed gamma ray emission data and neutron emission data for over 2,200 nuclides. The photon yield data libraries are based on the most recent ENSDF nuclear structure evaluations. The libraries used by ORIGEN can be coupled directly with detailed and problem-dependent physics calculations to obtain self-shielded, problem-dependent cross sections based on the most recent evaluations. There are no limitations with regard to compositions or energy spectra. SCALE also contains a comprehensive library of neutron cross section covariance data for neutron interactions, fission product yields, and decay data for use in sensitivity and uncertainty analysis with the TSUNAMI codes as well as Sampler.

The full suite of AMPX codes for generating multigroup and continuous energy neutron, gamma and coupled neutron/gamma libraries and covariance data are also included in the SCALE distribution, allowing users to create their own nuclear data libraries using differing sources of data and energy group structures than those provided with SCALE.

### 1.2.8 Graphical User Interfaces

Fulcrum is a cross platform graphical user interface designed to create, edit, validate and visualize SCALE input, output, and data files. Historically, SCALE has provided several special purpose graphical user interfaces which operate only on specific platforms and are loosely integrated with SCALE's computational and data components. Fulcrum is intended to provide a single user interface that directly integrates with SCALE's internal resources to provide a consistent experience between Fulcrum and SCALE's command line interface.

Fulcrum provides input editing and navigation, interactive geometry visualization for KENO V.a, KENO-VI, and NEWT, job execution, overlay of mesh results within a geometry view, and plotting of data from most SCALE file formats. An error checking parser interactively identifies poorly constructed input with spelling errors or data entry omissions for all SCALE sequences. The Hierarchical Input Validation Engine (HIVE) will identify allowed data ranges and interdependencies in the input and report inconsistencies to the user. Fulcrum will interactively process standard composition data to produce a mixing table, list expanded input aliases for review, provide an internal listing of input as is required for Sampler material and geometry perturbation analysis, and launch the SCALE sample problems. The layout of panels in Fulcrum is highly configurable to accommodate the preferences of many users.

ORIGAMI Automator, a graphical user interface integrated with Fulcrum, facilitates the quantification of isotopics as a function of time for a large set of fuel assemblies such as the complete inventory of a spent fuel pool. This tool was developed to support the NRC in severe accident analyses, but it can be adapted to many other uses.

Additional user interfaces include the KENO3D interactive visualization program for Windows for solidbody rendering of KENO geometry models, as well as the previously mentioned ExSITE and VIBE
interfaces for sensitivity and uncertainty analysis. Several codes provide HTML-formatted output, in addition to the standard text output, to provide convenient navigation using most common Web browsers through the computed results with interactive color-coded output and integrated data visualization tools.

### 1.3 USER GUIDANCE AND TECHNICAL ASSISTANCE

This SCALE Manual serves as the primary reference for SCALE users. The fundamental theory and all code options are documented herein. Several SCALE primers are available to serve as step-by-step guides for new users performing common calculations using the graphical user interfaces. SCALE training courses are presented several weeks each year, where users can interact directly with the software developers and expert users from ORNL.

Additional technical information on SCALE can be found at http://scale.ornl.gov, including training course schedules, a link to an online user forum, newsletters, benchmark reports, and downloads. Technical assistance is also provided via e-mail to scalehelp@ornl.gov.

### 1.4 AVAILABILITY

The SCALE code system is packaged and distributed by the Radiation Safety Information Computational Center (RSICC) and is also distributed through the Organization for Economic Cooperation and Development (OECD) Nuclear Energy Agency (NEA) Data Bank in France and the Research Organization for Information Science and Technology (RIST) in Japan.

### 1.5 ACKNOWLEDGEMENTS

The SCALE team consists of over 40 staff members across RNSD, as well as several external collaborators. SCALE 6.2 is the culmination of many years of this team's effort under the guidance of the SCALE Leadership Team:
Brad Rearden - Manager, SCALE Code System
Matt Jessee - Deputy Manager, SCALE Code System
Steve Bowman - Group Leader, Reactor Physics
Mike Dunn - Group Leader, Nuclear Data and Criticality Safety
Bob Grove - Group Leader, Radiation Transport
Rob Lefebvre - SCALE Software Development Coordinator
Mark Williams - Distinguished Developer, Nuclear Data and Reactor Physics

Most team members are credited for their authorship of the sections in this manual that correspond to their work. A few individuals have been essential to the development and maintenance of SCALE but are not credited by authorship. These individuals include S. Y. Walker for user interactions and documentation; J. P. Lefebvre and T. D. Walsh, who provide essential computer science infrastructure for building, testing, and deploying SCALE; and B. J. Ade, M. L. Baird, R. J. Ellis, A. T. Godfrey, J. Hu, D. Ilas, G. Ilas, K. S. Kim, B. J. Marshall, U. Mertyurek, D. E. Mueller, T. M. Miller, J. L. Peterson, and J. M. Risner for extensive testing and recommendations for improvements to provide a better-quality product to the end users.

The SCALE system is maintained and modernized at ORNL to keep pace with technical advancements in computing, nuclear data, and analysis areas of interest to our sponsors and the user community. Over the years, numerous individuals within these sponsoring organizations have played key roles in ensuring that the SCALE system remained a readily available, reliable system for the analysis of nuclear fuel facilities and packages. The individuals who have worked with the ORNL staff to coordinate maintenance and development activities include R. H. Odegaarden (NRC, ret.), G. H. Bidinger (NRC, ret.), C. Mauck (DOE, ret.), E. P. Easton (NRC), W. H. Lake (NRC and DOE, ret.), M. E. Wangler (DOE), M. G. Bailey (NRC), C. J. Withee (NRC, ret.), A. B. Barto (NRC), M. Aissa (NRC), D. R. Algama (NRC), T. D. Powell (NRC), J. N. McKamy (DOE), and J. M. Shuler (DOE).

Special acknowledgement is also due to R. M. Westfall and G. E. Whitesides (ret.) who worked with R. H. Odegaarden of the NRC to develop the concept and long-range goals of the SCALE system in the late 1970s. The current management team is grateful to previous SCALE project leaders: C. V. Parks, who served in this role for the first 15 years of SCALE, and S. M. Bowman, who served in this role for the following 14 years. Additional acknowledgements are due to L. M. Petrie, who for nearly 50 years has consistently provided consultation and advice on nearly every module and cross section library in the present system.

Bradley T. Rearden, Ph.D. Manager, SCALE Code System

### 2.0 CRITICALITY SAFETY

Introduction by B. T. Rearden

SCALE provides a suite of computational tools for criticality safety analysis that is primarily based on the KENO Monte Carlo code for eigenvalue neutronics calculations. ${ }^{1}$ Two variants of KENO provide identical solution capabilities with different geometry packages. KENO V.a uses a simple and efficient geometry package sufficient for modeling many systems of interest to criticality safety and reactor physics analysts. KENO-VI uses the SCALE Generalized Geometry Package, which provides a quadraticbased geometry system with much greater flexibility in problem modeling but with slower runtimes. Both versions of KENO perform eigenvalue calculations for neutron transport primarily to calculate multiplication factors ( $k_{\text {eff }}$ ) and flux distributions of fissile systems in both continuous energy and multigroup modes. They are typically accessed through the integrated SCALE sequences described below. KENO's grid geometry capability extends region-based features for accumulating data for source or biasing parameter specifications, as well as for tallying results from a calculation for visualization or communication of data into or out of a calculation. Criticality safety analysts may also be interested in the sensitivity and uncertainty analysis techniques that can be applied for code and data validation as described elsewhere in this document.

## Criticality Safety Analysis Sequences

The Criticality Safety Analysis Sequences (CSAS) with KENO V.a (CSAS5) and KENO-VI (CSAS6) provide a reliable, efficient means of performing $k_{\text {eff }}$ calculations for systems routinely encountered in engineering practice. The CSAS sequences implement XSProc to process material input and provide a temperature and resonance-corrected cross section library based on the physical characteristics of the problem being analyzed. If a continuous energy cross section library is specified, no resonance processing is needed, and the continuous energy cross sections are used directly in KENO, with temperature corrections provided as the cross sections are loaded.

A search capability is available with CSAS5 to find desired values of $k_{\text {eff }}$ as a function of dimensions or densities. The two basic search options offered are (1) an optimum search seeking a maximum or minimum value of $k_{\text {eff }}$ and (2) a critical search seeking a fixed value of $k_{\text {eff. }}$.

For continuous energy calculations, reaction rate tallies can be requested within the CSAS input, and for multigroup calculations, reaction rate calculations are performed using the KENO Module for ActivityReaction Rate Tabulation (KMART) post-processing tools. A conversion tool is provided to up-convert KENO V.a input to KENO-VI either as a direct KENO input (K5toK6) or, more commonly, as a CSAS sequence (C5toC6).

## STARBUCS: Burnup-Credit Analysis Sequence

The Standardized Analysis of Reactivity for Burnup Credit using SCALE (STARBUCS) ${ }^{2,3}$ is a control module to perform criticality calculations for spent fuel systems employing burnup credit. STARBUCS automates the criticality safety analysis of spent fuel configurations by coupling the depletion and criticality aspects of the analysis, thereby eliminating the need to manually process the spent fuel nuclide compositions into a format compatible with criticality safety codes.

STARBUCS performs a depletion analysis calculation for each spatially varying burnup region (if an axial or horizontal burnup profile is specified) of a spent fuel assembly using the ORIGEN-ARP methodology of SCALE. If a multigroup calculation is to be performed in KENO, the spent fuel compositions are then used to generate resonance self-shielded cross sections for each burnup-dependent fuel region. Finally, a KENO criticality calculation is performed to determine the neutron multiplication factor for the system.

The STARBUCS input format has been designed around the existing depletion analysis and criticality safety sequences of SCALE. Only a minimal amount of input beyond that typically required for a freshfuel calculation is needed to perform a burnup-credit calculation.

STARBUCS was developed to facilitate studies of major burnup-credit phenomena, such as those identified in the US Nuclear Regulatory Commission’s Interim Staff Guidance 8, ${ }^{4}$ but it is restricted to modeling one assembly type with the same starting enrichment loaded throughout the transportation or storage model. Greater flexibility is available by computing individual assembly burnup compositions with the ORIGAMI code and then creating a KENO model to implement these compositions.

For burnup loading curve iterative calculations, STARBUCS employs the search algorithm from CSAS5 to determine initial fuel enrichments that satisfy a convergence criterion for the calculated $k_{\text {eff }}$ value of the spent fuel configuration.

## Sourcerer: Hybrid Method for Starting Source Distribution

As the fidelity of criticality models continues to increase, especially for storage and transportation systems, the ability of the Monte Carlo codes to consistently provide a converged fission source can be challenging. Studies have shown that using a starting fission distribution similar to the true fission distribution can reduce the number of skipped generations required for fission source convergence, and it can significantly improve the reliability of the final $k_{\text {eff }}$ result. ${ }^{5,6}$ The Sourcerer sequence applies the Denovo ${ }^{7}$ discrete ordinates code to generate a starting fission source distribution in a KENO Monte Carlo calculation. The discrete ordinates calculation is performed on a user-defined Cartesian grid geometry where macroscopic material definitions are automatically created from the Monte Carlo model and multigroup group cross sections are appropriately generated.

For many criticality safety applications, the additional step of performing a deterministic calculation to initialize the starting fission source distribution is not necessary. However, for challenging criticality safety analyses such as as-loaded spent nuclear fuel transportation packages with a mixed loading of lowand high-burnup fuel, even a low-fidelity deterministic solution for the fission source produces more reliable results than the typical starting distributions of uniform or cosine functions over the fissionable regions, as demonstrated in a recent study. ${ }^{8}$

## Criticality Accident Alarm System Analysis with KENO and MAVRIC

Criticality accident alarm systems (CAAS) safety analyses modeling presents challenges because the analysis consists of a criticality problem and a deep-penetration shielding problem. ${ }^{9}$ Modern codes are typically optimized to handle one of these types of problems, but not both. The two problems also differ in size - the criticality problem depends on materials relatively close to the fissionable materials, whereas the shielding problem can cover a much larger range.
CAAS analysis can be performed using the CSAS6 criticality sequence and the MAVRIC shielding sequence. First, the fission distribution (in space and energy) is determined via CSAS6. This information is collected on a grid geometry that overlies the physical geometry model and is saved as a Monaco mesh source file. The mesh source is then used as the source term in MAVRIC. The absolute source strength is set by the user to the total number of fissions (based on the total power released) during the criticality excursion. MAVRIC can be optimized to calculate a specific detector response at one location or to calculate multiple responses/locations with roughly the same relative uncertainty.

#### Abstract

The Criticality Safety Analysis Sequences with KENO V.a (CSAS5) provides reliable and efficient means of performing $k_{\text {eff }}$ calculations for systems that are routinely encountered in engineering practice. In the multigroup calculation mode, CSAS5 uses XSProc to process the cross sections for temperature corrections and problem-dependent resonance self-shielding and calculates the $k_{\text {eff }}$ of a three-dimensional (3-D) system model. If the continuous energy calculation mode is selected no resonance processing is needed and the continuous energy cross sections are used directly in KENO V.a, with temperature corrections provided as the cross sections are loaded. The geometric modeling capabilities available in KENO V.a coupled with the automated cross-section processing within the control sequences allow complex, 3-D systems to be easily analyzed. A search capability is achieved by repeatedly activating the control module MODIFY, to alter either the system dimensions or densities, and the functional module KENO V.a to calculate the $k_{\text {eff }}$ for the modified dimensions or densities.

## ACKNOWLEDGMENTS

CSAS5 and its related Criticality Safety Analysis Sequences are based on the old CSAS2 control module (no longer in SCALE) and the KENO V.a functional module described in the KENO V.a chapter. Therefore, special acknowledgment is made to J. A. Bucholz, R. M. Westfall, and J. R. Knight who developed CSAS2. G. E. Whitesides is acknowledged for his contributions through early versions of KENO. Appreciation is expressed to C. V. Parks and S. M. Bowman for their guidance in developing CSAS5.

Special appreciation is expressed to S. J. Poarch and S. Y. Walker for their efforts in formatting this document.

### 2.1.1 Introduction

Criticality Safety Analysis Sequence with KENO V.a (CSAS5) provides reliable and efficient means of performing $k_{\text {eff }}$ calculations for systems that are routinely encountered in engineering practice, especially in the calculation of $k_{\text {eff }}$ of three-dimensional (3-D) system models. CSAS5 implements XSProc to process material input and provide a temperature and resonance-corrected cross-section library based on the physical characteristics of the problem being analyzed. If a continuous energy cross-section library is specified, no resonance processing is needed and the continuous energy cross sections are used directly in KENO V.a, with temperature corrections provided as the cross sections are loaded. A search capability is available to find a desired values of $k_{\text {eff }}$ as a function of dimensions or densities. The two basic search options offered are (1) an optimum search seeking a maximum or minimum value of $k_{\text {eff }}$ and (2) a critical search seeking a fixed value of $k_{\text {eff. }}$.

All the control sequences in the CSAS5 control module are listed in Table 2.1.1 with the modules they invoke. The first four sequences are subsets of the CSAS5 sequence.

Table 2.1.1. CSAS5 sequences for criticality safety

| Control <br> sequence | Function |  | Functional modules executed by the control sequence <br> (for multigroup libraries) |
| :--- | :--- | :--- | :---: | :--- |
| CSAS5 | $k_{\text {eff }}(3-D)$ | XSProc | KENO V.a |
| CSAS5S | $k_{\text {eff }}(3-D)$ search XSProc | KENO V.a | MODIFY |

### 2.1.2 Sequence Capabilities

In order to minimize human error, the SCALE data handling is automated as much as possible. CSAS5 and many other SCALE sequences apply a standardized procedure to provide appropriate number densities and cross sections for the calculation. XSProc is responsible for reading the standard composition data and other engineering-type specifications, including volume fraction or percent theoretical density, temperature, and isotopic distribution as well as the unit cell data. XSProc then generates number densities and related information, prepares geometry data for resonance self-shielding and flux-weighting cell calculations, if needed, and (if needed) provides problem-dependent multigroup cross-section processing. Sequences that execute KENO V.a include a KENO V.a Data Processor to read and check the KENO V.a data. Sequences that execute a search use a Search Data Processor to read and check the search data. When the data checking has been completed, the control sequence executes XSProc to prepare a resonance-corrected microscopic cross-section library in the AMPX working library format if a multigroup library has been selected.

For each unit cell specified as being cell-weighted, XSProc performs the necessary calculations and produces a cell-weighted microscopic cross-section library. KENO V.a may be executed to calculate the $k_{\text {eff }}$ or neutron multiplication factor using the cross-section library that was prepared by the control sequence. MODIFY may be invoked to perform a search ${ }^{1}$ by repeatedly altering the unit cell (multigroup mode only) and KENO V.a data prior to executing the next pass through the calculation. Cross sections are updated at the
beginning of each search pass with the modified data. If unit cell data is altered as part of the search, i.e., pitch or material search, the cross-sections are correctly processed with the updated data.

The search capability is implemented by the control module MODIFY. It performs operations according to the specified search data to determine (1) the maximum or minimum value of $k_{\text {eff }}$ as a function of pitch, dimensions or densities or (2) the pitch, dimensions, or densities corresponding to a specified value of $k_{\text {eff. }}$ An iterative procedure is used, making use of all previous information to modify the dimensions or densities to achieve the desired result. The procedures for conducting optimum and critical searches are summarized in the following sections.

### 2.1.2.1 Optimum (minimum/maximum) search

Because only an initial value of $k_{\text {eff }}$ and a set of boundary constraints are available, four initial points are generated spanning the range defined by the constraints. The search package identifies the type of cubic equation [i.e., a cubic with no local extrema (type A) or a cubic with two local extrema (type B)] and utilizes this knowledge in determining the pitch, dimensions, or material densities corresponding to the maximum (or minimum) value of $k_{\text {eff. }}$. The optimum search procedure is summarized as follows:

1. Calculate $k_{\text {eff }}$ for the specified problem.
2. Calculate $k_{\text {eff }}$ for the minimum constraint.
3. Calculate $k_{\text {eff }}$ for the maximum constraint.
4. Calculate $k_{\text {eff }}$ for a fourth point that lies approximately equidistant between the initial guess and the constraint that is farthest from it.
5. Utilize a weighted least-squares fit to a cubic polynomial on the data points.
6. Determine the type of cubic. For a type A cubic, go to step 11.
7. Take the first derivative of the least-squares cubic.
8. Solve the quadratic for its roots.
9. Take the second derivative of the least-squares cubic to determine which root is the maximum (or minimum), and if it falls within the constraints, use this root as the next guess. Otherwise, convergence has been defined as occurring at the constraint with the maximum (or minimum) $k_{\text {eff. }}$.
10. Calculate the $k_{\text {eff }}$ corresponding to the next guess. Go to step 5. Repeat this procedure until convergence is achieved.
11. If the cubic equation is a type A cubic, the optimum lies on one of the boundaries. If the fit shows that the cubic is actually a type $B$ cubic, go to step 7 and continue.

Convergence is defined as occurring when a $k_{\text {eff }}$ has been calculated for a point on the curve where the value of the curve is within epsilon of the maximum (or minimum) of the curve. Additionally, the calculated $k_{\text {eff }}$ must be within two standard deviations of the value of the curve at that point. The search is terminated when convergence is achieved, when the code determines there is no local maximum within the constraints, or the maximum number of search iterations is reached.

NOTE: At the beginning of each search pass, the cross sections are updated using the updated values of pitch, dimensions, or material densities. Also, the unit or material being modified can be directly tied to a unit cell, so that unit cell is updated during the search. Therefore, the final result should be consistent with the results obtained by running a non-search problem using the data from the last pass.

### 2.1.2.2 Critical search

The critical search option searches for the pitch, dimensions, or material densities corresponding to a specified value of $k_{\text {eff. }}$. If the calculated value of $k_{\text {eff }}$ is within the specified search tolerance (EPS) of the desired $k_{\text {eff, }}$ the search is considered to be complete. The critical search procedure is summarized as follows:

1. Calculate $k_{\text {eff }}$ for the specified problem. If it is within EPS of the specified $k_{\text {eff, }}$ convergence has been achieved.
2. Calculate $k_{\text {eff }}$ for one of the constraints. If the specified $k_{e f f}$ of the system does not fall between the initial value and the $k_{e f f}$ of the constraint, calculate the $k_{\text {eff }}$ of the other constraint. If the calculated $k_{\text {eff }}$ is within EPS of the specified $k_{e f f}$, convergence has been achieved.
3. Calculate $k_{\text {eff }}$ for a point chosen from a linear fit of the two existing points closest to the specified $k_{\text {eff. }}$
4. Repeat step 3 until convergence has been achieved, the program determines that the specified value lies outside the constraints, or the maximum number of search iterations is reached. Convergence has been achieved when the calculated $k_{e f f}$ is within EPS of the specified $k_{\text {eff- }}$.
5. If convergence is achieved, calculate $k_{\text {eff }}$ for a point determined from fitting the previous points to a cubic and solving the cubic for the point closest to the desired $k_{\text {eff. }}$. If all roots lie outside the constraints, the problem is terminated and an appropriate message is written. If the maximum number of iterations is reached without the problem converging, the problem is terminated and an appropriate message is written.

NOTE: At the beginning of each search pass, the cross sections are updated using the updated values of pitch, dimensions, or material densities. Also, the unit or material being modified can be directly tied to a unit cell, so that unit cell is updated during the search. Therefore, the final result should be consistent with the results obtained by running a non-search problem using the data from the last pass.

### 2.1.2.3 Multigroup CSAS5 limitations

The CSAS5 control module was developed to use simple input data and prepare problem-dependent cross sections for use in calculating the effective neutron multiplication factor of a 3-D system using KENO V.a. An attempt was made to make the system as general as possible within the constraints of the standardized methods chosen to be used in SCALE. Standardized methods of data input were adopted to allow easy data entry and for quality assurance purposes. Some of the limitations of the CSAS5 multigroup sequences are a result of using preprocessed multigroup cross sections. Inherent limitations in multigroup CSAS5 calculations are as follows:

1. Two-dimensional (2-D) effects such as fuel rods in assemblies where some positions are filled with control rod guide tubes, burnable poison rods and/or fuel rods of different enrichments. The cross sections are processed as if the rods are in an infinite lattice of identical rods. If the user inputs a Dancoff factor for the cell (such as one computed by MCDancoff), XSProc can produce an infinite lattice cell, which reproduces that Dancoff. This can mitigate some two dimensional lattice effects

### 2.1.2.4 Continuous energy CSAS5 limitations

When continuous energy KENO calculations are desired, none of the resonance processing capabilities of XSProc are applicable or needed. The continuous energy cross sections are directly used in KENO. An existing multigroup input file can easily be converted to a continuous energy input file by simply specifying the continuous energy library. In this case, all cell data is ignored. However, the following limitations exist:

1. If CELLMIX is defined in the cell data, the problem will not run in the continuous energy mode. CELLMIX implies new mixture cross sections are generated using XSDRNPM-calculated cell fluxes and therefore is not applicable in the continuous energy mode.
2. Only VACUUM, MIRROR, PERIODIC, and WHITE boundary conditions are allowed. Other albedos, e.g., WATER, CARBON, POLY, etc. are for multigroup only.
3. Problems with DOUBLEHET cell data are not allowed as they inherently utilize CELLMIX feature.

### 2.1.3 Input Data Guide

This section describes the input data required for CSAS5. Several subsets of the CSAS5 sequences listed in Table 2.1.1 are available to achieve several different levels of processing.

The input data for these CSAS5 sequences are composed of three broad categories of data. The first is XSProc, including Standard Composition Specification Data and Unit Cell Geometry Specification. This first category specifies the cross-section library and defines the composition of each mixture and optionally unit cell geometry that may be used to process the cross sections. This data block is necessary for all CSAS5 sequences. The second category of data, the KENO V.a input data, is used to specify the geometric and boundary conditions that represent the physical 3-D configuration of a KENO V.a problem. Both data blocks are necessary for CSAS5 and CSAS5S. The last category of data is the search data and is required only for CSAS5S.

All data are entered in free form, allowing alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. Up to 252 columns of data entry per line are allowed. Data can usually start or end in any column with a few exceptions. As an example, the word END beginning in column 1 and followed by two blank spaces or a new line will end the problem and any data following will be ignored. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating-point values. For example, 10 will be interpreted as 10.0 . Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0 E 4 would be correctly interpreted as $1.0 \times 10^{4}$.

The word "END" is a special data item. An "END" may have a name or label associated with it (e.g., "END DATA"). The name or label associated with an "END" is separated from the "END" by a single blank and is a maximum of 12 characters long. At least two blanks or a new line MUST follow every labeled and unlabeled "END." It is the user's responsibility to ensure compliance with this restriction. Failure to observe this restriction can result in the use of incorrect or incomplete data without the benefit of warning or error messages.

Multiple entries of the same data value can be achieved by specifying the number of times the data value is to be entered, followed by either R , *, or \$, followed by the data value to be repeated. Imbedded blanks are not allowed between the number of repeats and the repeat flag. For example, 5R12, 5*12, 5\$12, or $5 R 12$, etc., will enter five successive 12 s in the input data. Multiple zeros can be specified as nZ where n is the number of zeroes to be entered.

The purpose of this section is to define the input data in discrete subsections relating to a particular type of data. Tables of the input data are included in each subsection, and the entries are described in more detail in the appropriate sections.

Resonance-corrected cross sections are generated using the appropriate boundary conditions for the unit cell description (i.e., void for the outer surface of a single unit, white for the outer surface of an infinite array of cylinders). As many unit cells as needed may be specified in a problem. A unit cell is cellweighted by using the keyword "CELLMIX=" followed by a unique user specified mixture number in the unit cell data.

To check the input data without actually processing the cross sections, the words "PARM=CHECK" or "PARM=CHK" should be entered, as shown below.

$$
\begin{gathered}
\text { =CSAS5 PARM=CHK } \\
\text { or } \\
\text { \#CSAS5 PARM=CHK }
\end{gathered}
$$

This will cause the input data for CSAS5 to be checked and appropriate error messages to be printed. If plots are specified in the data, they will be printed. This feature allows the user to debug and verify the input data while using a minimum of computer time.

### 2.1.3.1 XSProc data

The XSProc reads the standard composition specification data and the unit cell geometry specifications. It then produces the mixing table and unit cell information necessary for processing the cross sections if needed. The XSProc section of this manual provides a detailed description of the input data and processing options.

### 2.1.3.2 KENO V.a data

If the problem utilizes a sequence that contains KENO V.a as a functional module, the input to KENO V.a comes after the XSProc input. Table 2.1.2 contains the outline for the KENO V.a input and the SEARCH input, which is required for a search case (i.e., CSAS5S). The KENO V.a input is divided into 13 data blocks and CSAS5S includes an additional block of search data. A brief outline of commonly used data blocks is shown in Table 2.1.2. Note that parameter data must precede all other

KENO data blocks. Information on all KENO V.a input is provided in the KENO chapter of this document and will not be repeated here.

Table 2.1.2. Outline of KENO data

| Type of data | Starting flag | Comments | Termination flag |
| :--- | :--- | :--- | :--- |
| Parameters* | READ PARAMETER | Enter desired parameter data | END PARAMETER |
| Geometry | READ GEOMETRY | Enter desired geometry data | END GEOMETRY |
| Array data | READ ARRAY | Enter desired array data | END ARRAY |
| Boundary conditions | READ BOUNDS | Enter desired boundary <br> conditions <br> Energy group boundaries | READ ENERGY |
| Enter desired neutron energy | END BOUNDS |  |  |
| Start data or initial source | READ START | End ENERGY |  |
| Plot data | READ PLOT | Enter desired start data | END START |
| Grid geometry data | READ GRID | Enter desired mesh data | END PLOT |
| Reaction | READ REACTION | Enter desire reaction tallies (CE <br> mode only) | END REACTION |
| KENO V.a data terminus | END DATA | Enter to signal the end of all |  |
| Search data | READ SEARCH | Enter for CSAS5 |  |

*Must precede all other data blocks in this table.

### 2.1.3.3 Search Data

Search data must be entered for CSAS5S. The search data enable the code to perform a search according to the instructions specified by the user. The code begins reading search data when it encounters the words READ SEARCH and continues reading search data until it encounters the words END SEARCH. Search data consist of the search type specification and auxiliary search commands.

### 2.1.3.3.1 Search type specification

These data are used to define the type of search and to set the parameters that provide limits for the search. The search type specification data consist of (a) a search descriptor, (b) the search type, and (c) optional search parameters as described below.

### 2.1.3.3.1.1 SEARCH DESCRIPTOR is used to define the search mode.

Use OPTIMUM if the maximum value of $k_{\text {eff }}$ is to be determined.
Use CRITICAL if a specified value of $k_{\text {eff }}$ is to be obtained.
Use MINIMUM if the minimum value of $k_{\text {eff }}$ is to be determined.

### 2.1.3.3.1.2 SEARCH TYPE is used to specify the variable that is to be changed during the search procedure.

Use PITCH to alter the center-to-center spacing between the units at the lowest array level. By default only the spacing in the X and Y directions will be altered. Use DIMENSION to alter the dimensions of one or more geometry regions in one or more units. Use CONCENTRATION to alter the concentration of one or more standard compositions in one or more mixtures.

The combination of the search descriptor and the search type defines the search method. Each search type has a set of predefined defaults and the ability to change the default settings and expand the scope of the search. Only one SEARCH DESCRIPTOR and one SEARCH TYPE are allowed in a problem.

An OPTIMUM PITCH search determines the pitch that gives the maximum value of $k_{\text {eff. }}$ By default the X spacing will be altered for slab arrays, the X and Y spacing will be altered for arrays of cylinders, and the $\mathrm{X}, \mathrm{Y}$, and Z spacing will be altered for spherical arrays. Auxiliary search commands can be used to instruct the code to change any of these defaults.

An OPTIMUM DIMENSION search determines the maximum value of $k_{\text {eff }}$ by altering the dimensions of one or more geometry regions in one or more units in accordance with the specified auxiliary search commands. Only the dimensions specified in the search commands will be modified. The relative variations in dimensions are determined by the search constants specified for each dimension.

An OPTIMUM CONCENTRATION search determines the maximum value of $k_{\text {eff }}$ by altering the concentration of standard compositions in mixtures in accordance with specified search commands. Only the standard compositions in the materials specified are altered. The relative variations in concentrations are determined by the search constants specified for each composition.

A CRITICAL PITCH search alters the spacing between units in the same manner as an optimum pitch search to achieve the specified value of $k_{\text {eff. }}$ By default the X spacing will be altered for slab arrays, the X and Y spacing will be altered for arrays of cylinders, and the $\mathrm{X}, \mathrm{Y}$, and Z spacing will be altered for spherical arrays. Auxiliary search commands can be used to instruct the code to change any of these defaults.

A CRITICAL DIMENSION search alters the dimensions of one or more geometry regions in accordance with the specified auxiliary search commands to achieve the specified value of $k_{\text {eff. }}$. Only the dimensions specified in the search commands will be modified. The relative variations in dimensions are determined by the search constants specified for each dimension.

A CRITICAL CONCENTRATION search alters the concentration of standard compositions in mixtures in accordance with the specified auxiliary search commands to achieve the specified value of $k_{e f f}$. Only the standard compositions in the materials specified are altered. The relative variations in concentrations are determined by the search constants specified for each composition.

A MINIMUM PITCH search determines the pitch that gives the minimum value of $k_{\text {eff. }}$ By default the X spacing will be altered for slab arrays, the X and Y spacing will be altered for arrays of cylinders, and the X , Y , and Z spacing will be altered for spherical arrays. Auxiliary search commands can be used to instruct the code to change any of these defaults.

A MINIMUM DIMENSION search determines the minimum value of $k_{\text {eff }}$ by altering the dimensions of one or more geometry regions in one or more units in accordance with the specified auxiliary search commands. Only the dimensions specified in the search commands will be modified. The relative variations in dimensions are determined by the search constants specified for each dimension.

A MINIMUM CONCENTRATION search determines the minimum value of $k_{\text {eff }}$ by altering the concentration of standard compositions in mixtures in accordance with specified search commands. Only the standard compositions in the materials specified are altered. The relative variations in concentrations are determined by the search constants specified for each composition.

OPTIONAL SEARCH PARAMETERS are entered after the SEARCH DESCRIPTOR AND SEARCH TYPE and are used to alter the default values of the optional search parameters. Only one set of optional search parameters can be entered for a problem. The optional search parameters are listed below.

PAS=nn is used to set the maximum number of times the search will calculate $k_{\text {eff }}$. The first pass calculates the $k_{\text {eff }}$ corresponding to the initial geometry dimensions. The second pass calculates the $k_{\text {eff }}$ corresponding to one of the constraints, and the third pass often corresponds to the other constraint. After the third pass, the search dimensions or concentrations are changed based on a fit to a quadratic or cubic equation. The default value of nn is 10 .
$\mathrm{NPM}=\mathrm{nn} \quad$ is used to set the number of search parameters. The default value of nn is 1 and should not be overridden.

EPS=ff is used to set the search convergence tolerance (the amount by which $k_{\text {eff }}$ is allowed to vary from the desired $k_{e f f}$. An optimum or minimum search is terminated when the calculated $k_{e f f}$ is within EPS of the optimum or minimum value as indicated by the mathematical fit to the calculated points. A critical search is terminated when the calculated $k_{e f f}$ is within EPS of the specified $k_{e f f}$. The default value of ff is 0.005 .

KEF=ff is used only for a CRITICAL search. The default value of ff is 1.000 .
MINPITCH=ff is allowed ONLY for a PITCH search. It is used to specify the minimum allowed pitch (center-to-center spacing in the X ; $\mathrm{X}, \mathrm{Y}$; or $\mathrm{X}, \mathrm{Y}, \mathrm{Z}$ directions depending on array type) between the units in an array. The search will terminate if the pitch becomes smaller than the specified minimum pitch. The default value of ff is the pitch at which the region immediately inside the outer most region of the unit touches the same region in an adjacent unit. It is much easier to specify the minimum allowed pitch than to calculate the appropriate value of the minimum constraint.

MAXPITCH=ff is allowed ONLY for a PITCH search. It is used to specify the maximum allowed pitch (center-to-center spacing in the $\mathrm{X} ; \mathrm{X}, \mathrm{Y}$; or $\mathrm{X}, \mathrm{Y}, \mathrm{Z}$ directions depending on array type) between units in an array. The search will terminate if the specified pitch is exceeded. The default value of ff is the pitch corresponding to -5 times the parameter that corresponds to the minimum pitch. It is much easier to specify a maximum allowed pitch than to calculate the appropriate value of the maximum constraint.

MORE is used to terminate the optional search parameters and initiate the auxiliary search commands. Do not enter MORE unless auxiliary search commands are to be entered. This command may only be entered once, immediately prior to the auxiliary search commands.

The input data for the CSAS5S search sequence are provided in Table 2.1.3.

Table 2.1.3. Outline of search type specification

| Entry No. | Type of data | Data entry | Comments |
| :---: | :---: | :---: | :---: |
| 1 | Search descriptor | OPTIMUM | Initiates a search for the maximum value of $k_{\text {eff }}$. |
|  |  | CRITICAL | Initiates a search for a specified value of $k_{\text {eff }}$. |
|  |  | MINIMUM | Initiates a search for the minimum value of $k_{\text {eff }}$. |
| 2 | Search type | PITCH | Vary the pitch of an array. |
|  |  | DIMENSION | Vary one or more dimensions in one or more regions of one or more units. |
|  |  | CONCENTRATION | Vary the concentration of one or more standard compositions in one or more mixtures. |
| 3 | Optional search parameters |  | Optional search parameters allow changing default values. Any or all may be entered in any order. |
| 3 a | No. of search passes | PAS= | Enter the keyword PAS= followed by the desired number of search passes. Default=10. |
| 3 b | No. of search parameters | NPM= | Enter the keyword NPM= followed by the number of search parameters. Present capability is limited to 1. |
| 3c | Search convergence tolerance | EPS= | Enter the keyword EPS= followed by the desired convergence tolerance. Default=0.005. |
| 3d | Desired value of $k_{\text {eff }}$ | $\mathrm{KEF}=$ | Enter the keyword KEF= followed by the desired <br>  <br> DO NOT ENTER FOR OPTIMUM OR MINIMUM SEARCHES. |
| 3 e | Maximum allowed pitch | MAXPITCH= | Enter the keyword MAXPITCH= followed by the maximum allowed pitch for a search whose search type, entry 2 above, is PITCH. The default value is the pitch corresponding to -5.0 times the parameter at the minimum possible pitch. |
| 3 f | Minimum allowed pitch | MINPITCH= | Enter the keyword MINPITCH= followed by the minimum allowed pitch for a search whose search type, entry 2 above, is PITCH. The default value is the minimum possible pitch (i.e., the pitch at which the shapes in the array touch). |
| 4 | Additional search data | MORE | Enter the delimiter MORE. This delimiter ends the optional search commands and initiates the auxiliary search commands found in Table 2.1.4. |

### 2.1.3.3.2 Auxiliary search commands and constraints

Auxiliary search commands are entered only if MORE, item 4, of the search type specification data is entered (see Table 2.1.3). Individual search commands are used to specify search constraints and to communicate to the search program. Searches can alter geometric dimensions (PITCH or DIMENSION Search) or alter standard composition number densities (CONCENTRATION Search).

A PITCH or DIMENSION search may require the user to specify the units that will be altered, the regions that will be altered within those units, and the faces or surfaces of those regions that will be altered. For a PITCH search, the program automatically assigns the units in the arrays to a unit cell if possible. If multiple units are contained in the array, each unit could be assigned a unit cell if the data in the unit cells match the geometry data of the units in the array. This data may be overridden in the MORE section of the search data. For a DIMENSION search, if the user wishes to tie a unit to unit cell this must be explicitly done in the MORE section of the search data. Several examples of search problems are provided in Sect. 2.1.1.

A CONCENTRATION search requires the user to specify the mixture, standard composition name, and the search constant for the component being altered. For a CONCENTRATION search, the program automatically assigns the material being changed to a unit cell. This data may be overridden in the MORE section of the search data. Several examples of search problems are provided in Sect. 2.1.1.

The data comprising the auxiliary search commands are listed in Table 2.1.4. All data except items 1a, 1b, and 1c are keyworded (i.e., the data are entered by specifying a keyword, followed by a value). An explanation of each individual search command follows the table.

1 Command definition. A command definition tells the code what action is to be taken. A new search command is initiated whenever an item 1a through 1c is encountered. The code will vary the geometry according to subsequent commands.

1a. ALTER Alter geometry regions. These words specify that modifications will be made to

CHANGE MODIFY

1b. MAINTAIN Maintain the thickness. The thickness of the specified geometry region(s) will be maintained when the interior regions grow or shrink (i.e., the specified region will grow or shrink in conjunction with the interior region in such a way as to maintain the original distance between the two regions). This means that the original thickness of the region is preserved. For instance, the inner radius of a pipe can be altered and the wall thickness can be preserved by applying the MAINTAIN command to the region defining the outer radius of the pipe.

1c. KEEP HOLD Keep the original specification. This command causes the specified geometry region(s) to be reset to their original input value for every search pass. Therefore they go through the entire search process unchanged.

2 PAR= Parameter number. The search parameter number is not functional. The default number is 1 and should not be overridden.

Maximum constraint. Enter the maximum value you wish to allow the search parameter to obtain. The maximum constraint must be larger than the minimum constraint. For a DIMENSION or PITCH search the default value of the maximum constraint is $10^{11}$. For a CONCENTRATION search the default value of the maximum constraint is as follows:

$$
\begin{aligned}
& +\mathrm{CON}=\min (-1 / \mathrm{FACTOR}), \text { if any } \mathrm{FACTOR}<0 \\
& +\mathrm{CON}=-5^{*}(-\mathrm{CON}), \text { if all FACTOR }>0
\end{aligned}
$$

NOTE: For a PITCH search, the maximum constraint is redefined and is calculated from the data entered for MAXPITCH. +CON should not be entered if a value was entered for MAXPITCH. If constraints, $+\mathrm{CON}=$ and $/$ or $-\mathrm{CON}=$ are not entered as data, the code computes the minimum constraint corresponding to the pins touching, and the maximum constraint is then negative five times the magnitude of the minimum constraint. unit (specified by item 6) that is to be altered according to the search command (item 1a, 1b, or 1c). The region(s) are altered according to the search constants (items 9a, 9b, 9c, and/or 9d).

Last region to be altered. This item is entered to specify the last region to be altered, starting with the region specified by REG=. For example, assume unit 3 contains eight regions and you wish to make changes to regions $4,5,6,7$, and 8 . These regions are identified by entering the following data. UNIT=3 REG=4 TO 8.

Geometric search constants. A search constant is the proportionality factor utilized to alter a geometry region. A search constant must be entered for each surface of a region that is to be altered. A nonzero search constant will cause the region dimension for that surface to be changed. A search constant of 0.0 will cause the region dimension to remain unchanged. The default value of the search constant is 0.0 .

9 ALL=
$-\mathrm{X}=\quad$ Search constant for -X face. This parameter is used to specify the value of the search constant for the -X face of a cuboid.
$+\mathrm{Y}=\quad$ Search constant for +Y face. This parameter is used to specify the value of the search constant for the +Y face of a cuboid.
Search constant for all surfaces. All of the surfaces in a region are altered simultaneously by using this search command.

9a. $+X=$
$-\mathrm{Y}=$
+Z=
$-\mathrm{Z}=$

Search constant for +X face. This parameter is used to specify the value of the search constant for the +X face of a cuboid.

Search constant for -Y face. This parameter is used to specify the value of the search constant for the -Y face of a cuboid.

Search constant for +Z face. This parameter is used to specify the value of the search constant for the $+Z$ face of a cuboid.

Search constant for $-Z$ face. This parameter is used to specify the value of the search constant for the -Z face of a cuboid.

NOTE: If it is desirable to change all the faces of a cuboid except the $-Z$ face by some amount (search constant of 1.0), items 9a and $9 b$ can be used together as follows: $\mathrm{ALL}=1.0-\mathrm{Z}=0.0$. This is the same as entering $+\mathrm{X}=1.0-\mathrm{X}=1.0+\mathrm{Y}=1.0-\mathrm{Y}=1.0+\mathrm{Z}=1.0$. If both Z faces are to remain unchanged, items 8 a and 8 b can be entered as: $\mathrm{ALL}=1.0$ $+\mathrm{Z}=0.0-\mathrm{Z}=0.0$ or as $+\mathrm{X}=1.0-\mathrm{X}=1.0+\mathrm{Y}=1.0-\mathrm{Y}=1.0$.

9b. RADIUS $=$ Search constant for radius. This parameter is used to specify the value of the search constant for the radius of a sphere, hemisphere, cylinder, or hemicylinder.

9c. +HEIGHT= Search constant for +height. This parameter is used to specify the value of the search constant for the +height of a cylinder or hemicylinder.
-HEIGHT $=$ Search constant for -height. This parameter is used to specify the value of the search constant for the -height of a cylinder or hemicylinder.

9d. $\quad$ CHORD $=$

10 MIX=

11 SCNAME=
Search constant for chord. This parameter is used to specify the value of the search constant for the chord of a hemisphere or hemicylinder.

Search constant for mixture. This parameter is the mixture number containing the standard composition that is to be changed during the search.

Search constant for the standard composition name. This parameter is the standard composition name associated with the material that is to be changed during the search. Only compositions listed in the Standard Composition Library section of the Standard Composition Library chapter are allowed. Standard compositions beginning with SOLN cannot be altered directly.

NOTE: If the standard composition name specified in the Material Information Data begins with SOLN and the Concentration Search Data specifies SCNAME=UO2(NO3)2, the amount of UO2(NO3)2 in the solution is altered but the amount of H 2 O and nitric acid is not altered during the search. The resulting mixture, when the search is finished, may no longer meet the criteria associated with the SOLN specification.

12 FACTOR= Concentration search factor used to specify the value of the search constant used in the concentration search. It is a proportionality factor used to alter the specified mixture standard composition. A search constant must be entered for each standard composition that is altered. A non-zero search constant will cause the concentration of the associated standard composition to be altered. The default value of the search constant is 1.0 . A set of concentration search data consists of the mixture to be altered, the standard composition to be altered in the mixture, and the search factor. Keywords are used to enter the data. Each set of data consists of items 10, 11, and 12. The keywords used in this data may be entered using terse notation.

Table 2.1.4. Outline of auxiliary search commands and constraints

| Entry no. | Keyword name | Type of data | Comments |
| :---: | :---: | :---: | :---: |
| GENERIC SEARCH DATA - May be used with all Search Types - |  |  |  |
| 1a | ALTER CHANGE MODIFY | Begin a new search command | These words are used to specify that modifications will be made to the geometry or concentration according to subsequent commands (entries 3 through 12 as required to specify the desired changes). |
| 1 b | MAINTAIN | Begin a new search command | The spacing (thickness) of the specified geometry regions will be maintained when the interior regions grow or shrink. |
| 1c | KEEP <br> HOLD | Begin a new search command | This command resets the specified geometry to the original input specifications. |
| 2 | PAR= | Parameter number | Enter the parameter number that the current command (ALTER, MAINTAIN, KEEP) applies to. Default=1 and should not be changed. |
| 3 | $+\mathrm{CON}=$ | Maximum constraint | Enter the maximum constraint for the current parameter. Default = +10E10. |
| 4 | - $\mathrm{CON}=$ | Minimum constraint | Enter the minimum constraint for the current parameter. $\text { Default }=-10 \mathrm{E} 10 .$ |
| 5 | CELL= | Unit Cell Associated with search data | Default values are assigned for PITCH and CONCENTRATION searches. Associated Unit Cells must be entered for a DIMENSION search if desired. |
| PITCH \& DIMENSION SEARCH DATA - Defines Geometric Changes - |  |  |  |
| 6 | UNIT= | Unit to which the current command applies | Enter the unit in which regions are to be altered. |
| 7 | REGION $=$ | First region to be altered in the unit | Enter the first or only region in the unit that the search constants (entry 9a, b, c and/or d) apply to. Default is the first region. |
| 8 | TO | Last region to be altered in the unit | Enter the last region in the unit to which the search constants apply (entry 9a, b, c and/or d). Default is the first region. |
|  |  |  | NOTE: Entry 7 must be entered in order to alter a single region in a unit. Entries 7 and 8 must both be entered in order to alter more than one region in a unit. |

Table 2.1.4. Outline of auxiliary search commands and constraints (continued)

| Entry no. | Keyword name | Type of data | Comments |
| :---: | :---: | :---: | :---: |
| 9 | ALL= | Search constant for all surfaces (faces) of the region(s) | Enter a value for the search constants for the specified regions. This value will be applied to all surfaces of the region(s). |
| 9a | $+\mathrm{X}=$ | Search constant for +X face of cuboid | Enter a value for the search constant for the +X face of a cuboid. |
|  | $-\mathrm{X}=$ | Search constant for -X face of cuboid | Enter a value for the search constant for the $-X$ face of a cuboid. |
|  | $+\mathrm{Y}=$ | Search constant for $+Y$ face of cuboid | Enter a value for the search constant for the +Y face of a cuboid. |
|  | $-\mathrm{Y}=$ | Search constant for -Y face of cuboid | Enter a value for the search constant for the $-Y$ face of a cuboid. |
|  | +Z= | Search constant for $+Z$ face of cuboid | Enter a value for the search constant for the $+Z$ face of a cuboid. |
|  | $-\mathrm{Z}=$ | Search constant for $-Z$ face of cuboid | Enter a value for the search constant for the $-Z$ face of a cuboid. |
| 9b | RADIUS= | Search constant for radius | Enter a value for the search constant for the radius of a sphere or a cylinder. |
| 9c | +HEIGHT= | Search constant for +height | Enter a value for the search constant for the +height of a cylinder. |
|  | - $\mathrm{HEIGHT}=$ | Search constant for -height | Enter a value for the search constant for the -height of a cylinder. |
| 9d | CHORD= | Search constant for chord | Enter a value for the search constant for the chord face of a hemisphere or hemicylinder. |
| CONCENTRATION SEARCH DATA - Defines concentration changes - |  |  |  |
| 10 | MIX= | Search constant for mixture | Enter the mixture number containing the standard composition to be changed. |
| 11 | SCNAME= | Search constant for Standard Composition | Enter the standard composition name whose density is to be changed. |
| 12 | FACTOR= | Search proportionality constant | Enter the value of the search constant for the concentration search. |

### 2.1.4 Example Problems

This section contains example problems to demonstrate some of the options available in CSAS5 and its associated sequences. A brief problem description and the associated input data for multigroup mode of calculation are included for each problem. The same sample problems may be executed in the continuous energy mode by changing the library name from "v7-238" to "ce-v7". Note that sample problems 3,7 , and 8 do not run in the continuous energy mode because they use CELLMIX or DOUBLEHET cell type. See Appendix A for additional and historical examples.

### 2.1.4.1 Sample problem $1 \boldsymbol{k}_{\text {eff }}$ calculation

The purpose of this problem is to calculate the k-effective of a system. This problem is the same as the KENO V.a sample problem 12 in Appendix B except the cross-section library and KENO V.a mixing table are prepared by CSAS. The problem represents a critical experiment consisting of a composite array ${ }^{2,3}$ of four highly-enriched ( $93.2 \%$ ) uranium metal cylinders having a density of $18.76 \mathrm{~g} / \mathrm{cc}$ and four 5.0677-L Plexiglas containers filled with uranyl nitrate solution. The uranium metal cylinders have a radius of 5.748 cm and a height of 10.765 cm . The uranyl nitrate solution has a specific gravity of 1.555 and contains 415 g of uranium per liter. The ID of the Plexiglas bottle is 19.05 cm and the inside height is 17.78 cm . The Plexiglas is 0.635 cm thick. The center-to-center spacing between the metal units is 13.18 cm in the Y direction and 13.45 cm in the Z direction. The center-to-center spacing between the solution units is 21.75 cm in the Y direction and 20.48 cm in the Z direction. The spacing between the Y-Z plane that passes through the centers of the metal units and the Y-Z plane that passes through the centers of the solution units is 17.465 cm in the X direction.

The metal units in this experiment are designated in Table II of Ref. 2 as cylinder index 11 and reflector index 1. A photograph of the experiment, Fig. 9 in Ref. 3, is given in Figure 2.1.4.1.

### 2.1.4.2 Sample problem 2 optimum pitch search using detailed geometry

This problem represents an attempt to optimize the reactivity of PWR-like fuel bundles in a storage pool. The storage array is an infinite planar array of flooded fuel bundles. Each bundle consists of a $17 \times 17 \times 1$ array of $2.35 \%$-enriched $\mathrm{UO}_{2}$ pins, density $9.21 \mathrm{~g} / \mathrm{cc}$, clad with Zircaloy- 2 . The fuel is 0.823 cm in diameter, the clad diameter is 0.9627 cm , and the length of each pin is 366 cm . Each fuel bundle is encased in a Boral sheath. There is a $1 / 4-\mathrm{in}$. gap flooded with water between the bundle and the sheath. The Boral sheath is $3 / 8 \mathrm{in}$. thick. One inch of water separates the fuel bundle sheaths in the horizontal plane, and 15 cm of water is present on the top and bottom of the array.

The KENO V.a geometry represents each fuel pin in the bundle discretely. The search should determine the optimum pitch within the fuel bundle. The gap between the bundle and the Boral remains fixed, as does the thickness of the sheath and the spacing between sheaths.

### 2.1.4.3 Sample problem 3 optimum pitch search using homogenized geometry

This problem illustrates the use of a cell-weighted mixture to represent a PWR-like fuel bundle. The cask contains a $2 \times 2 \times 1$ array of fuel bundles. Each fuel bundle consists of a $17 \times 17 \times 1$ array of Zircaloy- 2 clad, $2.35 \%$-enriched $\mathrm{UO}_{2}$ fuel pins with a density of $9.21 \mathrm{~g} / \mathrm{cc}$ arranged in a square pitch. The pin diameter is 0.823 cm , and its length is 366 cm . The clad is 0.06985 cm thick, and the pitch is 1.275 cm . Each fuel bundle is contained in a $0.6625-\mathrm{cm}$-thick Boral sheath. The bundles are separated by 1 cm of water, representing a flooded cask. The square aluminum cask is $10-\mathrm{cm}$ thick on all faces and is reflected by 15 cm of water.

By using CELLMIX=, a cell-weighted cross section is created to represent the fuel bundle. The KENO V.a geometry utilizes the cell-weighted mixture (500) and the overall dimensions of the fuel bundle to represent the entire fuel bundle as a single homogeneous region. The first reflector entry represents the fuel cask, and the second reflector entry represents the $15-\mathrm{cm}$ reflector. Because this problem utilizes a cell-weighted mixture, which is not applicable in the continuous energy mode, the problem will end with an error message in the continuous energy mode.

### 2.1.4.4 Sample problem 4 search for a specified value of $\boldsymbol{k}_{\text {eff }}$

Find the pitch at which a $2 \times 2 \times 2$ array of cylinders of highly enriched (93.2\%) uranium metal with a density of $18.76 \mathrm{~g} / \mathrm{cc}$ are critical. Each cylinder has a radius of 5.748 cm and a height of 10.765 cm . The surface-to-surface spacing between the units is the same in all directions. The initial guess for the critical surface-to-surface spacing was 3.0 cm . The experimentally critical surface-to-surface separation for this system is 2.248 cm . The input data for this problem are given below.

### 2.1.4.5 Sample problem 5 solution conc. search for a specified $\boldsymbol{k}_{\text {eff }}$

Consider a large spherical tank partially filled with $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. The tank has a radius of 34.6 cm and is filled with solution to a height of 30.0 cm above the midpoint. The tank is composed of a 0.759 cm thick Al shell. The $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution is composed of three standard compositions: UO2F2, HF acid, and H2O. The code combines these using a set algorithm. This may or may not produce a solution at the desired density. If the density of the solution is known it should be entered. Also, extra acid can be added to the solution by specifying a non-zero acid molarity.

A critical concentration search is performed on the solution yielding system $k_{\text {eff }}=1.0$ for various densities of $\mathrm{UO}_{2} \mathrm{~F}_{2}$ in the solution. In the MORE search data, MIX=1 and SCNAME=UO2F2 specify that the $\mathrm{UO}_{2} \mathrm{~F}_{2}$ component of the mixture 1 solution is to be altered during the search. The code calculates the density of the solution. The initial uranium fuel density is $300 \mathrm{gm} /$ /iter. The maximum allowed uranium density is $600 \mathrm{gm} / \mathrm{liter}$. The minimum allowed uranium density is $150 \mathrm{gm} / l i t e r$.

### 2.1.4.6 Sample problem 6 dimension chord search for a specified $\boldsymbol{k}_{\text {eff }}$

Consider a large spherical tank partially filled with $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. The tank has a radius of 34.6 cm and is filled with solution to an initial height of 10.0 cm above the midpoint. The tank is composed of a 0.759 cm thick Al shell. The $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution is composed of three standard compositions: UO2F2, HF acid, and H2O. The code combines these using a set algorithm. This may or may not produce a solution at the desired density. If the density of the solution is known it should be entered. Also, extra acid can be added to the solution by specifying a non-zero acid molarity.

A critical dimension search is performed on the chord length yielding system $k_{\text {eff }}=0.98$. In the MORE search data, UNIT=1 REG=1 CHORD=1.0 specify that the chord length in region 1 of unit 1 is to be altered during the search. The constraints are set so the chord length varies from -10.0 cm to just under 34.6 cm.

### 2.1.4.7 Sample problem 7 two material conc. search for a specified $\boldsymbol{k}_{\text {eff }}$

The fuel bundles in this problem represent $17 \times 17$ PWR fuel assemblies. The fuel pin lattice is homogenized, making a cell-weighted mixture 100. Because this problem utilizes a cell-weighted mixture, which is not applicable in the continuous energy mode, the problem will end with an error message in the continuous energy mode. The fuel pins consist of $4.35 \mathrm{wt} \%{ }^{235} \mathrm{U}$ having a diameter of 0.823 cm , zirconium cladding having an outer diameter of 0.9627 cm , and a pitch of 1.275 cm . The fuel bundle is represented as a $10.8375 \mathrm{~cm} \times 10.8375 \mathrm{~cm} \times 366 \mathrm{~cm}$ cuboid of mixture 100 surrounded by Boral and then water. The Boral has a density of $2.61 \mathrm{~g} / \mathrm{cm}^{3}$ and has an initial composed of $50.0 \mathrm{wt} \%$ $\mathrm{B}_{4} \mathrm{C}$ and $50.0 \mathrm{wt} \% \mathrm{Al}$. The fuel bundles are at a fixed pitch of 13.0 cm . Boral plates surrounding the X and $Y$ sides of each fuel assembly are 0.1625 cm thick. Full density water is between the Boral plates.

A critical concentration search is performed on the Boral plates searching for a system $k_{\text {eff }}=0.95$. The Boral plates are at a fixed density of $2.61 \mathrm{gm} / \mathrm{cc}$. As the density of the $\mathrm{B}_{4} \mathrm{C}$ changes, the density of the Al changes in the opposite direction maintaining a constant Boral density. There are two entries in the MORE search data. The first entry, MIX=4 SCNAME=b4c factor=1.0 specifies that the $\mathrm{B}_{4} \mathrm{C}$ of mixture 4 is to be altered during the search. The second entry, MIX=4 SCNAME=al factor=-1.0 specifies that aluminum is to be changed in the opposite direction and proportionally to $\mathrm{B}_{4} \mathrm{C}$ during the search. Both $\mathrm{B}_{4} \mathrm{C}$ and Al have the same initial density of $0.5 * 2.61=1.305 \mathrm{gm} / \mathrm{cc}$.

### 2.1.4.8 Sample problem $8 \mathbf{k}_{\infty}$ for a pebble bed fuel

This problem demonstrates setting up a fuel pebble from a pebble bed reactor, and calculating its $\mathrm{k}_{\infty}$. The pebble consists of a fuel grain of $\mathrm{UO}_{2} 0.025 \mathrm{~cm}$ in radius, coated with 0.003 cm of pyrolitic carbon, a further coat of 0.0035 cm thick silicon carbide, with a final coat of 0.004 cm thick pyrolitic carbon. 15000 grains are packed with graphite into an internal fuel sphere of 2.5 cm radius clad with a 0.5 cm thick covering of carbon and surrounded by helium. The fuel is $8.2 \%$ enriched ${ }^{235} \mathrm{U}$. The pebbles are stacked into an infinite square pitched array with a pitch of 6 cm .

This problem uses DOUBLEHET cell type, which is applicable only in the multigroup mode of KENO calculations. Therefore, the continuous energy version of this problem will end with an error message.

### 2.1.5 Warning and error messages

CSAS5 contains two types of warning and error messages. Warning messages appear when a possible error is encountered. It is the responsibility of the user to verify whether the data are correct when a warning message is encountered. The functional modules activated by CSAS5 sequences will be executed if no error messages are generated and a warning message has been generated.

When an error is recognized, an error message is written and an error flag is set so the functional modules will not be activated. The code stops immediately if the error is too severe to allow continuation of input. However, it will continue to read and check the data if it is able. When the data reading is completed, execution is terminated if an error flag was set when the data were being processed. If the error flag has not been set, execution continues. When error messages are present in the output, the user should focus on the first error message, because subsequent messages may have been caused by the error that generated the first message.

The following messages originate in the part of CSAS5 that reads, checks, and prepares data for KENO V.a and the search module MODIFY.

## CS-10 *** ERROR *** CONCENTRATION SEARCH MATERIAL WAS NOT SPECIFIED IN THE STANDARD COMPOSITION.

This self-explanatory message from subroutine CNCN indicates that the indicated material is not in the standard composition data. Recheck the standard composition data and the search data, correct the input, and resubmit the problem.

CS-11 *** ERROR *** CONCENTRATION SEARCH DATA HAS BEEN DESTROYED. $\mathrm{I}=\ldots \quad \mathrm{ICMND}=\ldots \quad \mathrm{IPNUM}=\ldots \quad$ MIXUR $=\ldots \quad$ SCNAME $=$

This message from subroutine CNCSRH indicates that the search data could not be read properly. This usually indicates either: search data that is required for the specified search type is missing or search data
inappropriate for the specified search type is present. Recheck the search data, correct the input, and resubmit the problem.

## CS-16 ***WARNING*** READ FLAG NOT FOUND. ASSUME KENO V PARAMETER DATA FOLLOWS.

This message from subroutine CPARAM indicates that the word READ is not the first word of KENO V.a data following the Material Information Processor input data. If parameter data is to be entered, the code expects the words READ PARAMETERS to precede the parameter input data. If the word READ is not the first word, the code assumes the data are parameter input data.

CS-21 A UNIT NUMBER WAS ENTERED FOR THE CROSS-SECTION LIBRARY. (LIB= IN PARAMETER DATA.) THE DEFAULT VALUE SHOULD BE USED IN ORDER TO UTILIZE THE CROSS SECTIONS GENERATED BY CSAS5. MAKE CERTAIN THE CORRECT CROSS-SECTION LIBRARY IS BEING USED.

This message is from subroutine CPARAM. It indicates that a value has been entered for the crosssection library in the KENO V.a parameter data. The cross-section library created by the analytical sequence should be used. MAKE CERTAIN THAT THE CORRECT CROSS SECTIONS ARE BEING USED.

CS-50 *** ERROR *** SEARCH COMMAND NUMBER IS UNABLE TO PERFORM A PITCH SEARCH BECAUSE THE DIMENSIONS OF $\overline{\text { REGION }}$ $\qquad$ ARE NOT EXPLICITLY DEFINED.

This message from subroutine PCHSRH indicates that the specified search command is not valid for the specified region. An ARRAY or CORE region cannot be altered; nor can a REPLICATE or REFLECTOR region immediately following an ARRAY or CORE region.

```
CS-55 *** ERRORS WERE ENCOUNTERED IN PROCESSING THE CSAS-KENO5 DATA.
    EXECUTION IS IMPOSSIBLE. ***
```

This message from subroutine SASSY is printed if errors were found in the KENO V.a input data for CSAS5. If a search is being made, data reading will continue until all the data have been entered or a fatal error terminates the data reading. When the data reading and checking have been completed, the problem will terminate without executing. Check the printout to locate the errors responsible for this message.

## CS-62 *** ERROR *** MIXTURE IN THE GEOMETRY WAS NOT CREATED IN THE STANDARD COMPOSITIONS SPECIFICATION DATA.

This message from subroutine MIXCHK indicates that a mixture specified in the KENO V.a geometry was not created in the standard composition data.

## CS-68 *** ERROR *** AN INPUT DATA ERROR HAS BEEN ENCOUNTERED IN THE DATA ENTERED FOR THIS PROBLEM.

This message from the main program, CSAS5, is printed if the subroutine library routine LRDERR returns a value of "TRUE," indicating that a reading error has been encountered in the "KENO PARAMETER" data or the CSAS5 "SEARCH" data. The appropriate data type is printed in the message. Locate the unnumbered message stating "****** ERROR IN INPUT. CARD IMAGE PRINTED ON NEXT LINE *****." Correct the data and resubmit the problem.

## CS-69 ***ERROR*** MIXTURE IS AN INAPPROPRIATE MIXTURE NUMBER FOR USE IN THE KENO GEOMETRY DATA BECAUSE IT IS A COMPONENT OF THE CELLWEIGHTED MIXTURE CREATED BY XSDRNPM.

This message from subroutine CMXCHK indicates that a mixture that is a component of a cell-weighted mixture has been used in the KENO V.a geometry data.

## CS-70 ***** ERROR ***** SEARCH OR OPTIMIZATION DATA MUST BE ENTERED FOR CSAS5. NO SEARCH DATA WAS ENTERED.

This message from subroutine RDOPT is self-explanatory. If the user does not desire to run a search, another sequence such as CSAS5 should be chosen.

CS-71 *** ERROR *** IS NOT A VALID SEARCH TYPE.
This message is from subroutine RDOPT. The allowed search types include PITCH, DIMENSION, and CONCENTRATION. The first four characters of the search data after the words READ SEARCH must be PIT, PITC, DIM, DIME, DMSN, CON, or CONC. The data may be misspelled or out of order.

CS-72 *** ERROR *** THE SEARCH TYPE IS INVALID. I= $\qquad$ .

This message is from subroutine RDOPT. The numerical index, I, should be 1 for an optimum pitch search, 2 for a dimension search, and 3 for a concentration search. If it is none of these, the search type has been incorrectly specified or a code error has been introduced.

## CS-73 ***** AN END OF FILE WAS ENCOUNTERED BEFORE ALL THE SEARCH DATA WAS READ.

This self-explanatory message is from subroutine RDOPT. Check the input data to be sure nothing was omitted or misspelled.

CS-74 ***** AN END SEARCH FLAG WAS READ BEFORE ALL THE SEARCH DATA WAS READ.

This self-explanatory message is from subroutine RDOPT. Check the input data for omissions and correct order.

CS-75 *** ERROR *** READ SEARCH FLAG WAS NOT FOUND. $\qquad$ WAS READ INSTEAD.

This self-explanatory message is from subroutine RDOPT. READ SEARCH was expected but was not found. Check the input data for omissions and correct order.

CS-76 *** ERROR *** END SEARCH FLAG WAS NOT FOUND. $\qquad$ WAS READ INSTEAD.

This self-explanatory message from subroutine RDOPT indicates that an end of file was encountered when looking for READ SEARCH. Check the input data for omissions, correct order, and spelling.

## CS-77 *** ERROR *** AN END OF FILE WAS FOUND WHEN THE READ SEARCH FLAG WAS EXPECTED.

This self-explanatory message is from subroutine RDOPT. Check the input data for omissions, correct order, and spelling.

CS-78 ${ }^{* * *}$ ERROR ***___ IS NOT A VALID SEARCH TYPE.
This message is from subroutines SRCHTYP. It indicates that an invalid search type was read. The valid search names include PITCH, CONCENTRATION, and DIMENSION. Either the data was entered improperly or a code error has been introduced. A STOP 215 is executed when this message is printed.

CS-80 *** ERROR *** SEARCH DATA HAS BEEN DESTROYED. I= ICMND=
$\qquad$ IPNUM= $\qquad$ II= $\qquad$ IGEOM= $\qquad$
This message from subroutines DIMSRH indicates that the search data cannot be interpreted. This usually indicates either: search data that is required for the specified search type is missing or search data inappropriate for the specified search type is present. Recheck the search data, correct the input, and resubmit the problem.

## CS-82 *** AN ERROR WAS ENCOUNTERED IN ONE OF THE FUNCTIONAL MODULES.

This message from CSAS5 or MODIFY indicates that an error was encountered during execution of one of the functional modules such as CRAWDAD, BONAMI, CENTRM, PMC, XSDRNPM, or KENO V.a. Check the printout to locate and correct the error.

## CS-83 ***** NO FEASIBLE SOLUTION WAS FOUND IN THE SEARCH PACKAGE. EXECUTION

 IS TERMINATED.This message comes from the MODIFY search package, and indicates that it is unable to find a solution to the problem as presented. This usually occurs when a solution is not within the range specified. For this case the user must decide what to change to improve the possibility of a solution. Fairly rarely, for an optimum problem, there may be 2 maximums within the range specified, and the package has found the wrong one. For this case, the user would tighten the range to be searched to eliminate the unwanted peak. The package uses least mean square fitted cubic polynomials to make guesses as to where a solution is. If the Keffectives have too much variance, the polynomials may not be a good representation of the actual behavior of the system. For this case the user could rerun the problem using more histories per pass to reduce the variance.

CS-85 *** ERROR *** ALL OF THE ROOTS FOR K=____ LIE OUTSIDE THE PARAMETER CONSTRAINTS

This message from MODIFY indicates that the polynomial fit to the Keffectives already calculated only has solutions for the Keffective asked for outside the parameter constraints specified. Keffectives with large variances can lead to polynomials which fit the actual behavior of a system poorly. The user could rerun the case with more histories to reduce the variance, if this is the problem. If the variance is not the problem, then extending the parameter range, or making some other change to the problem definition to change the Keffective range will be necessary.

CS-89 *** ERROR *** IS AN INVALID DIMENSION SEARCH COMMAND.
This message from subroutine DMSN indicates that the dimension search data are out of order, a search command is spelled incorrectly, or the search data are specified incorrectly.

CS-90 *** ERROR ***___ IS AN INVALID SEARCH PARAMETER.
This message printed from subroutines CNCTYP, DIMTYP, and PCHTYP indicates that a parameter entered in the search type specification data is not valid. The data could be misspelled or out of order. Omission of the keyword MORE before entering the individual search commands can cause this error.

CS-91 *** ERROR ***___ IS AN INVALID CONCENTRATION SEARCH COMMAND.
This message from subroutine CNCN is caused by a misspelled or illegal search command when attempting to do a concentration search.

## CS-94 *** ERROR *** REG=_ IS AN INVALID SEARCH DATA ENTRY. THE REGION NUMBER MUST BE GREATER THAN ZERO AND NO LARGER THAN THE NUMBER OF REGIONS IN THE UNIT.

This message from subroutine DMSN indicates that the region to be altered is incorrectly specified. For example, if the unit being altered contains five geometry regions, the value specified for REG= can be as small as 1 and as large as 5 .

```
CS-95 *** ERROR *** AN ERROR WAS ENCOUNTERED IN THE SEARCH DATA. THE LAST
REGION NUMBER MUST BE AT LEAST AS LARGE AS THE FIRST REGION NUMBER.
CHECK THE SEARCH DATA PRINTED BELOW. keyword UNIT
```

$\qquad$

``` REGIONS
```

$\qquad$

``` TO
``` \(\qquad\)
``` PARAMETER=_SEARCH CONSTANTS ARE
``` \(\qquad\)

This message from subroutine DMSN indicates that the search data specified an invalid region number for the final region to be altered. Check the printed data and correct as appropriate.
CS-96 *** ERROR *** AN ERROR WAS ENCOUNTERED IN THE SEARCH DATA. THE REGION NUMBERS MUST BE GREATER THAN ZERO AND NO LARGER THAN THE NUMBER OF REGIONS IN THE UNIT. CHECK THE SEARCH DATA PRINTED BELOW. keyword UNIT REGIONS \(\qquad\) TO \(\qquad\) PARAMETER= \(\qquad\) SEARCH CONSTANTS ARE \(\qquad\)

This message from subroutine DMSN indicates that one of the specified region numbers is incorrect. Check the printed data and correct as appropriate.

CS-97 *** ERROR *** NO VALID SEARCH COMMANDS WERE FOUND IN THE DATA.
This message is accompanied by a STOP 235 and is printed from subroutines PCHSRH, CNCSRH, and DIMSRH. A common cause of this error is the omission of the MORE command before the individual search commands are entered.

\section*{CS-99 *** ERROR *** THIS PROBLEM WILL NOT BE RUN BECAUSE PARM=CHECK WAS ENTERED IN THE ANALYTICAL SEQUENCE SPECIFICATION.}

This message from subroutine CSAS5 indicates that the problem data were read and checked and no errors were found. To execute the problem, remove the PARM=CHECK or PARM=CHK from the analytical sequence indicator data entry.

\section*{CS-100*** ERROR *** THIS PROBLEM WILL NOT BE RUN BECAUSE ERRORS WERE ENCOUNTERED IN THE INPUT DATA.}

This message from subroutine CSAS5 is self-explanatory. Examine the printout to locate the error or errors in the input data. Correct them and resubmit the problem.
```

CS-101*** ERROR *** THE CONSTRAINTS ARE NOT VALID FOR PARAMETER SET. -CON=

``` \(\qquad\)
``` +CON=
``` \(\qquad\)

This message is printed from either subroutine CNCN or DMSN if the parameter set is invalid. For a parameter set to be valid, -CON must be less than 0.0 and + CON must be greater than 0.0 . They can be explicitly set or calculated using default or provided data.
```

CS-102*** ERROR *** THE UNIT CELL SPECIFICATION FOR UNIT I_ IS OUT OF
BOUNDS. CELL NUMBER WAS SPECIFIED. THE SPECIFIED CELL MUST BE BETWEEN 1 AND THE NUMBER OF CELLS

``` \(\qquad\)
``` .
```

This self-explanatory message from subroutine DMSN indicates that the unit cell specified is not between 1 and the number of unit cells present in the problem. Recheck the unit cell number specified in the search data, correct the input, and resubmit the problem.

```
CS-103*** ERROR *** THE UNIT CELL SPECIFICATION FOR MIXTURE
```

$\qquad$

``` IS OUT OF BOUNDS. CELL NUMBER WAS SPECIFIED. THE SPECIFIED CELL MUST BE BETWEEN 1 AND THE NUMBER OF UNIT CELLS
``` \(\qquad\)
``` .
```

This self-explanatory message from subroutine CNCN indicates that the unit cell specified for the indicated mixture is not between 1 and the number of unit cells present in the problem. Recheck the unit cell number specified in the search data, correct the input, and resubmit the problem.

### 2.1.A Additional Example Applications of CSAS5

Several example uses of CSAS5 are shown in this section for a variety of applications. Note that many of these examples have been provided since the earliest versions of the CSAS sequences and output data shown may not represent the most current version.

### 2.1.A. 1 Typical Search

EXAMPLE 1. CSAS5S — Determine the optimum pitch for an array of Example 4 fuel assemblies
Consider a $4 \times 4 \times 1$ array of fuel assemblies in a square aluminum cask. Each assembly consists of a $17 \times 17 \times 1$ array of zirconium-clad, $2.35 \%$-enriched $\mathrm{UO}_{2}$ fuel pins in a square pitched array. The $\mathrm{UO}_{2}$ has a density of $9.21 \mathrm{~g} / \mathrm{cc}$. The pin diameter is 0.8 cm and is 366 cm long. The clad is 0.07 cm thick, and the pitch is 1.3 cm . Each fuel bundle is contained in a $0.65-\mathrm{cm}$-thick Boral sheath. The bundles are separated by an edge-to-edge spacing of 1 cm . The array of bundles is centered in a 10 -cm-thick aluminum cask whose inside dimensions are 0.5 cm beyond the outer edges of the fuel bundles. Search for the assembly spacing that yields the maximum value of $k_{\text {eff. }}$. Because the spacing between the assemblies is to be altered, the last region of unit 2 will be altered. In order to do this, the fuel assembly shroud cannot be defined as a replicate, because the code does not know the size of the array until later. In order to perform a pitch or dimension search, the code calculates the distance between the outermost region of the unit and the region interior to it. Therefore, the fuel assembly gap must be defined as a cuboid, and the water gap between assemblies can be entered as either a cuboid or a replicate. This search has been defined as an optimum dimension search. The input data for this problem follow.

```

An alternative method of entering the search data for this problem is to define the search as an optimum pitch search and require that the spacing of the fuel pin cells remain unchanged. Because a pitch search is always conducted at the lowest array level, in this case the spacing between the pins in the fuel assembly (the outer region of unit 1), it is necessary to countermand the automatic alteration of the outer region of unit 1 by entering the KEEP command. Search constants must be entered for the X and Y faces to instruct the code to KEEP those dimensions unchanged. It is easier to use the keyword ALL, which applies the KEEP command to all of the faces since the optimum pitch search would have changed only the X and Y faces leaving the Z faces unchanged. The ALTER command must then be entered to instruct the search to alter the spacing between the fuel assemblies (region 3 of unit 2). Only the X and Y dimensions are to be altered; so the search constants are entered individually for those dimensions. It is acceptable to enter ALL=1 $+\mathrm{Z}=0-\mathrm{Z}=0$ rather than $+\mathrm{X}=1-\mathrm{X}=1+\mathrm{Y}=1-\mathrm{Y}=1$. It is not necessary to enter the constraints for an optimum pitch search ( $+\mathrm{CON}=$ and $-\mathrm{CON}=$ ). They were entered in this case to ensure that the alternative data more nearly duplicate the optimum dimension search data from the previous example. These alternative search data are:

```
READ SEARCH OPTIMUM PITCH MORE
KEEP UNIT=1 REG=3 ALL=1
ALTER UNIT=2 REG=3 +X=1 -X=1 +Y=1 -Y=1 END
SEARCH
```

### 2.1.A. 2 Auxiliary search commands

Auxiliary search commands are entered ONLY if the word MORE was entered in the search type specification data. These data are used to define the method the search will use to alter the pitch, geometry or concentration data and to set the constraints for the parameter search. The auxiliary search commands consist of (1) INDIVIDUAL SEARCH COMMANDS and (2) SEARCH PARAMETER CONSTRAINTS.

## EXAMPLE 1

Consider an example in which region 2 of unit 1 is a cuboid and all of the dimensions of the cuboid are to be altered. The search data could be entered as:

```
ALTER UNIT=1 REG=2 ALL=1.0
```

or

ALTER UNIT=1 REG=2 $+\mathrm{X}=1.0-\mathrm{X}=1.0+\mathrm{Y}=1.0-\mathrm{Y}=1.0+\mathrm{Z}=1.0-\mathrm{Z}=1.0$
Because all of the search constants are nonzero, all of the dimensions will be changed. Because the search constants are identical, the original relationship between the dimensions will be preserved as they are altered.

For example, if region 2 of unit 1 is a cylinder and if all the dimensions of the cylinder are to be altered, and if unit 1 is tied to unit cell 1 the search data could be entered as:

```
ALTER UNIT=1 REG=2 ALL=1.0 CELL=1
```

or
ALTER UNIT=1 REG=2 RADIUS=1.0 + $\mathrm{H}=1.0$ ? $\mathrm{H}=1.0$ CELL=1

Because all of the search constants are nonzero, all of the dimensions will be changed. Because the search constants are identical, the original relationship between the dimensions will be preserved as they are altered. If the original height-to-diameter ratio is 1.5 , that ratio will be preserved throughout the search only if the search constants for the radius and + and - height are identical.

Search constants can be entered sequentially with each new entry overriding only identical previous entries. For example, if region 2 of unit 1 is a cuboid and if all of the dimensions except the -Z dimension are to be altered, the search data could be entered as:

```
ALTER UNIT=1 REG=2 +X=1.0 -X=1.0 +Y=1.0 -Y=1.0 +Z=1.0
```

or

ALTER UNIT=1 REG=2 ALL=1.0 -Z=0.0
In the second example, all of the search constants corresponding to the cuboid's dimensions are set to 1.0 by using the ALL= command. This includes the -Z dimension. To reset the search constant for the -Z dimension to zero, $-\mathrm{Z}=0.0$ is added following the $\mathrm{ALL}=1.0$ command. If the search commands are reversed, $-\mathrm{Z}=0.0$ ALL=1.0, the -Z dimension will also be altered because the -Z portion of the $\mathrm{ALL}=$ command will override the previously entered $-\mathrm{Z}=0.0$ command.

## EXAMPLE 2

A search command must be entered for each unit and region specification. Consider a problem having units 1, 2, and 3. Unit 1 consists of three concentric spheres in a cuboid. Unit 2 consists of a single sphere in a cuboid, and unit 3 contains three concentric cuboids. A search is to be made that changes the inner sphere and outer cuboid of unit 1 , and the sphere and cuboid of unit 2 , and the exterior cuboid of unit 3 . The thicknesses of the outer spheres of unit 1 are to be maintained, and the two inner cuboids of unit 3 are to remain unchanged. The search data for this problem can be entered as follows:

ALTER UNIT=1 REG=1 ALL=1.0
ALTER UNIT=1 REG=4 ALL=1.0 MAINTAIN UNIT=1
REG=2 TO 3 ALL=1.0 ALTER UNIT=2 REG=1 TO 2
ALL=1.0 ALTER UNIT=3 REG=3 ALL=1.0

### 2.1.A. 3 Search constraints for dimension or pitch searches

SEARCH PARAMETER CONSTRAINTS set the parameter limits for the search. The minimum constraint is the minimum value of the parameter allowed in the search. The maximum constraint is the maximum value of the parameter allowed in the search. The initial geometry configuration corresponds to a parameter value of 0.0 . A physical limit occurs when the value of the parameter causes geometry intersections. Constraints should be entered for a DIMENSION search. Only one set of constraints (i.e., min and max) are allowed per problem. These constraints apply to all the dimensions that are being altered.

For a DIMENSION search, the constraints are given by Eqs. (2.1.1) and (2.1.2):

$$
\begin{align*}
& \mathrm{C}_{\text {min }}=\left(\left(\mathrm{D}_{\min } / \mathrm{D}_{\mathrm{i}}\right)-1.0\right) / \mathrm{SC},  \tag{2.1.1}\\
& \mathrm{C}_{\max }=\left(\left(\mathrm{D}_{\max } / \mathrm{D}_{\mathrm{i}}\right)-1.0\right) / \mathrm{SC}, \tag{2.1.2}
\end{align*}
$$

where
$\mathrm{C}_{\text {min }}$ is the minimum constraint for the search
$\mathrm{C}_{\max }$ is the maximum constraint for the search
$\mathrm{D}_{\text {min }}$ is the minimum allowed dimension for the search [For a chord, $\mathrm{D}_{\text {min }}=\left(\right.$ Radius $_{\text {min }}+$ Chord $_{\text {min }}$ )/ 2 Radius ] min
$\mathrm{D}_{\max }$ is the maximum allowed dimension for the search [For a chord, $\mathrm{D}_{\text {max }}=\left(\right.$ Radius ${ }_{\text {max }}+$ Chord $_{\text {max }}$ )/ 2 Radius $_{\text {max }}$ ]
$\mathrm{D}_{\mathrm{i}} \quad$ is the initial dimension [For a chord, $\mathrm{D}_{\mathrm{i}}=\left(\right.$ Radius $_{\text {initial }}+$ Chord $\left._{\text {initial }}\right) / 2$ Radius $_{\text {initial }}$ ]
SC is the search constant for that dimension (i.e., $+\mathrm{X},-\mathrm{X}$, RADIUS, etc.)
For example, the initial radius of a sphere is 6 cm , and a search is to be conducted to determine the radius at which the sphere is critical. The minimum radius the user wishes to allow is 3 cm , and the maximum radius to be allowed is 9 cm . A nonzero search constant must be entered to cause the radius to be changed. A search constant of 1.0 , will be used for the radius (RADIUS=1.0). The constraints calculated from Eqs. (2.1.1) and (2.1.2) are:

$$
\begin{aligned}
& \mathrm{C}_{\min }=((3.0 / 6.0)-1.0) / 1.0=-0.5 \\
& \mathrm{C}_{\max }=((9.0 / 6.0)-1.0) / 1.0=0.5
\end{aligned}
$$

The constraints would be entered in the problem by entering the following data:

$$
-C O N=-0.5+C O N=0.5
$$

For a PITCH search, the minimum constraint defines the limit for shrinking the system, and the maximum constraint defines the limit for expanding the system:

$$
\begin{aligned}
& \mathrm{C}_{\text {min }}-\mathrm{MAX}\left[\mathrm{D}_{+}, \mathrm{D}_{-}\right] \text {nor shmer of faces } \\
& i=1 \\
& C_{\text {max }}-\operatorname{MIN}\left[\begin{array}{c}
i=\text { number of faces } \\
D_{+}
\end{array}, D_{-}\right] \text {for expanding, } \\
& i=1
\end{aligned}
$$

where
$\mathrm{C}_{\text {min }}$ is the minimum constraint,
$\mathrm{C}_{\text {max }}$ is the maximum constraint,
$D_{+} \quad$ are face constraints for the positive dimensions,
D_ are face constraints for the negative dimensions.

Face constraints must be calculated for each face using Eqs. (2.1.3) and (2.1.4):

$$
\begin{align*}
& \mathrm{D}_{+}=\frac{\left(\mathrm{X}_{\mathrm{d}+}-\mathrm{X}_{\mathrm{i}+}\right)\left(\mathrm{SC}_{+} \times \operatorname{del}_{+} \mathrm{SC}_{-} \times \text {del }_{-}\right)}{\left(\mathrm{X}_{\mathrm{i}+}-\mathrm{X}_{\mathrm{i}-}\right)\left(\mathrm{SC}_{+}^{* *}{ }^{* *} 2 \times \text { del }_{+}\right)},  \tag{2.1.3}\\
& \mathrm{D}_{-}=\frac{\left(\mathrm{X}_{\mathrm{d}-}-\mathrm{X}_{\mathrm{i}}\right)\left(\mathrm{SC}_{+} \times \operatorname{del}_{+} \mathrm{SC}_{-} \times \operatorname{del}_{-}\right)}{\left(\mathrm{X}_{\mathrm{i}+}-\mathrm{X}_{\mathrm{i}-}\right)\left(\mathrm{SC}_{-}^{* *} 2 \times \text { del }_{-}\right)}, \tag{2.1.4}
\end{align*}
$$

where
$\mathrm{X}_{\mathrm{d}+} \quad$ is the desired limit of the positive dimension of the spacing cuboid in that direction (positive dimension of X , Y , or Z , whichever dimension is under consideration)
$\mathrm{X}_{\mathrm{i}+} \quad$ is the initial positive dimension of the spacing cuboid in that direction (positive dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)
$\mathrm{X}_{\mathrm{d}-}$ is the desired limit of the negative dimension of the spacing cuboid in that direction (negative dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)
$\mathrm{X}_{\mathrm{i}-}$ is the initial negative dimension of the spacing cuboid in that direction (negative dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)
$\mathrm{SC}_{+}$is the search constant for the positive dimension of the spacing cuboid in that direction (positive dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)

SC_ is the search constant for the negative dimension of the spacing cuboid in that direction (negative dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)

NOTE: Using a search constant of 1.0 simplifies the determination of $\mathrm{C}_{\max }$ and $\mathrm{C}_{\min }$ when the dimensions are to change proportionately.
del $_{+}$is the initial distance from the spacing cuboid to the closest interior region in the positive direction (positive dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)
del_ is the initial distance from the spacing cuboid to the closest interior region in the negative direction (negative dimension of $\mathrm{X}, \mathrm{Y}$, or Z , whichever dimension is under consideration)

The search parameter constraints are entered using the following keywords:
-CON=pp is used to set the minimum constraint for the current parameter. The value of pp is defaulted to -10 E 10 for a dimension search. The value of pp is defaulted to a value that allows geometry regions to touch for a pitch search unless a value was entered for MINPITCH, in which case the parameter corresponding to that pitch is calculated and used.
$+\mathrm{CON}=\mathrm{rr} \quad$ is used to set the maximum constraint for the current parameter. The value of rr is defaulted to +10 E 10 for a dimension search and to $-5 \times \mathrm{pp}$ for a pitch search.

NOTE: A search will reset a constraint (entered using the keyword $+\mathrm{CON}=$ or $-\mathrm{CON}=$ ) that falls outside the default range to the default value. If a PITCH search is specified and if a value has been entered for MAXPITCH and/or MINPITCH, values should not be entered for the constraints. If values are entered for $+\mathrm{CON}=$ and $/$ or $-\mathrm{CON}=$ for a PITCH search and if MAXPITCH and/or MINPITCH were specified in the optional search parameters, the maximum and minimum constraints will be set to the values corresponding to MAXPITCH and MINPITCH, even though the value of MINPITCH may result in an intersection.

### 2.1.A.3.1.1 Individual concentration search commands

An INDIVIDUAL SEARCH COMMAND for a concentration search consists of (1) a command definition, (2) the mixture number of the mixture to be altered, (3) the name of the standard composition to be altered, (4) a search constant, and (5) a unit cell containing the mixture. A series of individual search commands can be entered to govern the search process. A new search command is initiated whenever a command definition, item (1) above, is encountered.

The COMMAND DEFINITION defines the action to be taken for the specified mixture and standard composition component. ALTER, CHANGE, or MODIFY are used to cause the concentration (number densities) of the specified standard composition in the specified mixture to be modified.

> ALTER The commands to the left are command definitions, item (1) above. These commands CHANGE instruct the code to modify the specified concentration data. MODIFY

The MIXTURE NUMBER, item (2) above, defines the mixture that contains the standard composition whose concentration is to be varied during the search. The keyword MIX= is entered, followed by the mixture number, nn.

MIX=nn is used to define the mixture number associated with the component that is to be changed. The keyword MIX= is entered, followed by the mixture number, nn. There is no default value of $n$.

The STANDARD COMPOSITION NAME, item (3) above, defines the standard composition whose concentration will be changed in the defined mixture. Only standard compositions listed in the Standard Composition Library chapter can be entered.

SCNAME $=\mathrm{mm}$ is used to specify the standard composition name of the component that is to be altered. The keyword SCNAME= is entered, followed by the mixture number, mm. There is no default value for mm.

NOTE: If the standard composition component name specified in the Material Information Data (item 1 of the Standard Composition Specification Data) is a solution, for example, SOLNUO2(NO3)2, and the Concentration Search Data specifies SCNAME=UO2(NO3)2, the amount of UO2(NO3)2 in the solution will be altered, but the amount of water and nitric acid will not be changed. Thus, the resultant mixture may no longer meet the criteria associated with the SOLN specification.

The SEARCH CONSTANT for a concentration search, item (4) above, is a proportional factor that applies to the standard composition being altered. The keyword FACTOR= followed by a proportionality search constant is used to specify the search constant for a concentration search.

FACTOR=pc is used to specify the search constant. The keyword FACTOR= is entered, followed by the value of the search constant or proportionality factor, pc.

The UNIT CELL NUMBER, item (5) above, defines the unit cell containing the mixture to be varied during the search. The keyword CELL= is entered, followed by the unit cell number, mm.

CELL=mm is used to link mixture nn to unit cell mm. The keyword CELL= is entered, followed by the unit cell number, mm. The code defaults the cell number to the unit cell containing the mixture specified using MIX=.

## ENTERING AUXILIARY SEARCH COMMANDS IN THE CONCENTRATION SEARCH DATA

EXAMPLE 1

Consider an example in which the density of water is to be varied and is contained in unit cell 2. Full density water, mixture 1, was specified in the standard composition specification data as: H2O 1 END The auxiliary search data could be entered as follows:

```
ALTER MIX=1 SCNAME=H20 FACTOR=1.0 CELL=2
```

or

```
ALTER MIX=1 SCNA=H20 FAC=1.0 CE=2
```

or
ALTER $\mathrm{M}=1 \quad \mathrm{~S}=\mathrm{H} 20 \quad \mathrm{~F}=1.0 \quad \mathrm{C}=2$

Note that terse input allows truncation of the keywords.
EXAMPLE 2

Consider an example in which the density of $\mathrm{UO}_{2} \mathrm{~F}_{2}$, is to be varied in mixture 2 contained in unit cell 4, a uranyl fluoride solution. The uranyl fluoride solution was specified as:

| SOLNUO2F2 | 2 | 300 | 0 | 1 | 293 | 92235 | 5 | 92238 | 95 | END |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The auxiliary search data could be entered as follows:

```
ALTER MIX=2 SCNAME=U02F2 FACTOR=1 CELL=4
```

or

```
ALTER M=2 S=U02F2 F=1 C=4
```

The terse input option allows truncation of the keywords.

### 2.1.A. 4 Search constraints for concentration searches

A SEARCH PARAMETER CONSTRAINT for concentration searches sets the parameter limits for the search. The minimum constraint is the minimum value of the parameter allowed in the search. The maximum constraint is the maximum value of the parameter allowed in the search. The initial concentration corresponds to a parameter value of 0.0 . A physical limit occurs when the value of the parameter causes the density of the specified standard composition to become negative. The search can produce an unrealistically high density. Users should manually eliminate those results or set constraints to avoid them. Only one set of constraints (i.e., min and max) are allowed per problem. These constraints apply to all the standard compositions that are being altered.

For a CONCENTRATION search, the constraints are given by Eqs. (2.1.5) and (2.1.6). The maximum constraint must be larger than the minimum constraint.

$$
\begin{align*}
& C_{\min }=\left(\left(\frac{D_{\min }}{D_{i}}\right)-1\right) / \text { FACTOR },  \tag{2.1.5}\\
& C_{\max }=\left(\left(\frac{D_{\max }}{D_{i}}\right)-1\right) / \text { FACTOR }, \tag{2.1.6}
\end{align*}
$$

where
$\mathrm{C}_{\min } \quad$ is the minimum constraint for the search,
$\mathrm{C}_{\text {max }} \quad$ is the maximum constraint for the search,
$\mathrm{D}_{\text {min }} \quad$ is the minimum allowed density for the specified standard composition,
$\mathrm{D}_{\max } \quad$ is the maximum allowed density for the specified standard composition,
$D_{i} \quad$ is the initial density of the specified standard composition,
FACTOR is the search constant for the standard composition that is being varied.

Default search constraints are calculated if +CON and -CON are not entered. The default concentration search constraints are calculated as follows:

$$
\begin{aligned}
& +\mathrm{CON}=\left\{\begin{array}{l}
\min (1 / \mathrm{FACTOR}), \text { if any FACTOR }<0 \\
-\mathrm{S} \times(-\mathrm{CON}), \text { if all FACTOR }>0
\end{array}\right\}, \\
& -\mathrm{CON}=\left\{\begin{array}{l}
-\mathrm{S}(+\mathrm{CON}), \text { if all FACTOR }<0 \\
\max (-1 / \text { FACTOR }), \text { if any FACTOR }>0
\end{array}\right\} .
\end{aligned}
$$

### 2.1.A. 5 Search considerations

DIMENSION, PITCH, and CONCENTRATION searches can be performed using CSAS5S. A DIMENSION search alters only those regions specified in the search data. A PITCH search alters the center-to-center spacing of units in an array and any other dimensions specified in the auxiliary data. A CONCENTRATION search alters the density of the standard compositions in the mixtures specified.

By default a pitch search is performed at the lowest array level and changes the spacing in either the X dimension for a slab, the X and Y dimensions for an array of cylinders, or the $\mathrm{X}, \mathrm{Y}$ and Z dimensions for an array of spheres. For example, if an array of fuel assemblies is described in the geometry, the lowest array level is the array of fuel pins comprising an assembly. Therefore, an optimum pitch search would alter the spacing between the fuel pins within the assembly. The spacing can be expanded until the array intersects the first region external to it. The exterior size of the fuel pin array would grow or shrink within the confines of the exterior region (fuel assembly shroud). If the external regions are described using replicate regions, the array can grow or shrink within the confines of the maximum and minimum constraints.

If replicate regions are used outside an altered region or an array whose spacing units are altered, the dimensions of the replicate regions are recalculated (maintaining the thickness) at each search pass without having to enter search data for those regions. However, geometry regions specified by a geometry shape (sphere, cuboid, cylinder, etc.) that exist outside an altered region or an array whose spacing units are being altered will remain unchanged unless search data are provided for them. In other words, REPLICATE regions will grow and shrink in response to changes in the dimensions of the interior region, but other geometry shapes will not.

Some of the limitations applicable to a pitch or dimension search are:

1. A pitch search is performed only at the lowest array level unless search commands are entered to keep the lowest array level unit unchanged and other commands are entered to cause other units to be altered.
2. A pitch search alters the spacing in either the $X$ dimension for a slab, the $X$ and $Y$ dimensions for an array of cylinders, or the X Y and Z dimensions for an array of spheres. Entering a search constant of zero for $+\mathrm{X},-\mathrm{X},+\mathrm{Y},-\mathrm{Y},+\mathrm{Z}$, and/or -Z will keep the corresponding dimension from being altered.
3. A pitch search alters only the outer region of the unit(s) used in the array at the lowest array level unless the search data specifying otherwise is input.
4. A search cannot alter a region whose boundaries are set by the code (i.e., an ARRAY, CORE BOUNDARY, or REPLICATE following an ARRAY). If the dimensions of a replicate region are to be altered, the dimensions of the region interior to it must be explicitly defined. For example, the interior region can be a standard geometry shape (sphere, cylinder, cuboid, etc.), but cannot be a replicate following an array or core boundary.

## 5. All searches allow auxiliary search data.

Concentration searches can also be performed using CSAS5S. A concentration search alters only those standard compositions specified in the search data. Care must be taken when searching on standard compositions beginning with SOLN, ATOM, WTPT, or ARBM (predecessor to ATOM and WTPT in earlier SCALE versions). One or more of their components can be altered but this will not directly affect the other components. For example, if the standard composition component name specified in the material information data is SOLN (SOLNUO2F2) and the concentration search data specifies SCNAME=UO2F2, the amount of uranyl fluoride salt, UO2F2, in the solution will be altered, but the amount of water and hydrofluoric acid in the solution will remain unchanged. Therefore, the resultant mixture may no longer meet the criteria for a solution (SOLN) specification.

Physically, the concentration can vary from zero to some upper limit. The code will prevent the concentration from falling below zero, but the user is responsible for setting constraints that prevent the concentration from exceeding reasonable values. The theoretical density is a reasonable upper limit.

### 2.1.A. 6 Optimum pitch search

An optimum pitch search searches for the pitch that yields the highest value of $k_{\text {eff }}$. An optimum pitch search is activated by entering "OPTIMUM PITCH" in the search data. By default, the search is performed at the lowest array level and only the spacing in the X -direction for slabs, the X and Y-directions for cylindrical arrays, and the X, Y, and Z-directions for spherical arrays. The search constants are defaulted to 1.0 for the applicable $+\mathrm{X},-\mathrm{X},+\mathrm{Y},-\mathrm{Y},+\mathrm{Z}$, and -Z dimensions of the outermost region. The dimensions of other geometry regions will not be changed (their search constants are defaulted to 0.0 ) unless additional search data containing appropriate instructions are supplied.

The limits for an optimum pitch search can be set using either the MAXPITCH= and MINPITCH= options in the optional search parameters or the $+\mathrm{CON}=$ and $-\mathrm{CON}=$ options in the search parameter constraints of the auxiliary search commands. MAXPITCH= and MINPITCH= are used to enter a value of the maximum allowed pitch and minimum allowed pitch respectively. $+\mathrm{CON}=$ and $-\mathrm{CON}=$ are used to enter values for the parameter constraints (i.e., the maximum and minimum allowed value of the search parameter). Typically, it is easier to set the maximum allowed pitch and minimum allowed pitch using MAXPITCH= and MINPITCH= than it is to calculate the value of the parameter corresponding to those pitches. The default minimum constraint corresponds to MINPITCH, the pitch at which the largest interior region of a unit used in the array is in contact with the spacing cuboid of that unit. The maximum constraint is defaulted to -5 times the minimum constraint. In the first search pass, the code calculates $k_{\text {eff }}$ for the initial problem geometry. The next two passes calculate the $k_{\text {eff }}$ for the dimensions corresponding to the minimum constraint and maximum constraint. Subsequent passes fit the previous results to a cubic equation to select new dimensions.

Consider a $10 \times 10 \times 10$ array of uranium spheres surrounded by water having a "square" pitch. The uranium spheres are 2 cm in radius, and the center-to-center spacing is 8 cm . The uranium spheres and their associated spacing are defined to be unit 1 , and the $10 \times 10 \times 10$ array is defined to be array 1 . Search data and results for some optimum pitch searches using this example are given in inputs 1 through 6 below.

## Default Search - Array of Centered Spheres

This problem contains search data for a default optimum pitch search. The problem consists of a $10 \times 10 \times 10$ array of uranium spheres surrounded by low density water. The spheres are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$ and have a radius of 2.0 cm . The spheres are originally centered on an $8.0 \mathrm{~cm} \mathrm{X}, \mathrm{Y}$, and Z pitch
with interstitial low density ( $0.01 \mathrm{gm} / \mathrm{cc}$ ) water. The problem searches for the pitch that will produce the maximum $k_{\text {eff }}$ for the system.

```
=CSAS5S
10x10x10 ARRAY DEFAULT PITCH SEARCH
V7-238
READ COMP

END GEOMETRY
READ ARRAY
ARA=1 NUX=10 NUY=10 NUZ=10 FILL F1 END FILL
END ARRAY
END DATA
READ SEARCH OPTIMUM PITCH END SEARCH
END
```

This data will cause the code to alter the $+\mathrm{X},-\mathrm{X},+\mathrm{Y},-\mathrm{Y},+\mathrm{Z}$, and -Z dimensions of the outer region of unit 1 and search for the dimensions that give the maximum $k_{\text {eff. }}$. Because the next to last outer dimension of the unit contained in the array are spheres, all six dimensions are altered. The original relationship between the dimensions is preserved (i.e., the original ratio of the X to Y to Z dimensions of the cuboid is preserved throughout the search). Because this is an optimum pitch search, the sphere dimensions will not be changed. For this particular example, results for six passes are given. A final search results for the problem follow:

## Default Search - Array of Off-Centered Spheres

This is the same problem as described above except the spheres are now off-centered in the X and Y dimensions. The input data and the final search results for this problem follow:

```

## Default Search - Array of Centered Cylinders

This problem contains search data for a default optimum pitch search. The problem consists of a $10 \times 10 \times 10$ array of uranium cylinders surrounded by low density water. The cylinders are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$ and have a radius of 2.0 cm and a length of 20 cm . The cylinders are originally centered on an 8.0 cm X and Y pitch and a 24 cm Z pitch with interstitial low density ( $0.01 \mathrm{gm} / \mathrm{cc}$ ) water. The problem searches for the pitch that will produce the maximum $k_{\text {eff }}$ for the system. Because this is an array of cylinders, by default only the X and Y dimensions are modified during the search. The input data and the final search results for this problem follow:

```

### 2.1.A. 7 Minimum pitch search

A minimum pitch search searches for the pitch that yields the lowest value of $k_{\text {eff. }}$ A minimum pitch search is activated by entering "MINIMUM PITCH" in the search data. By default, the search is performed at the lowest array level and only the spacing in the X -direction for slabs, the X and Y directions for cylindrical arrays, and the X, Y, and Z directions for spherical arrays. The search constants are defaulted to 1.0 for the applicable $+\mathrm{X},-\mathrm{X},+\mathrm{Y},-\mathrm{Y},+\mathrm{Z}$, and -Z dimensions of the outermost region. The dimensions of other geometry regions will not be changed (their search constants are defaulted to 0.0 ) unless additional search data containing appropriate instructions are supplied.

The limits for a minimum pitch search are the same as an optimum pitch search as described in the previous section.

## Array of Centered Uranium Slabs

Consider a $10 \times 1 \times 1$ array of uranium metal slabs. The uranium slabs are 2 cm in thick in the X dimension and 200 cm thick in the Y and Z dimensions. On each side of the uranium slab in the X dimension is 1 cm of $\mathrm{H}_{2} \mathrm{O}$, then 1 cm of Boral, then 1 cm of $\mathrm{H}_{2} \mathrm{O}$ resulting in an initial center-to-center spacing is 8.0 cm . The slabs are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$, the water is full density, and the Boral is $36.7 \% \mathrm{~B}_{4} \mathrm{C}$. The uranium slabs and their associated materials are defined to be unit 1 , and the $10 \times 1 \times 1$ array is defined to be array 1 . A minimum pitch of 6.01 cm is specified, MINPITCH $=6.01$, and a maximum pitch of 14.0 cm is specified, MAXPITCH=14.0. The input data and the final search results for this problem follow:

k-effective $=8.04815 \mathrm{E}-01+$ or $-1.47600 \mathrm{E}-03$ the corresponding geometry follows;
media bias geometry description for those units utilized in this problem

$\qquad$

### 2.1.A. 8 Critical pitch search

A critical pitch search alters the outer region of the unit or units at the lowest array level in search of a specified value of $k_{\text {eff. }}$. A critical pitch search is activated by entering "CRITICAL PITCH" in the search data. By default, the search is performed at the lowest array level, and only the spacing in the X and Y directions (the X and Y dimensions of the outermost region of the unit(s) used in the array at the lowest array level) will be changed. The search constants are defaulted to 1.0 for the $+\mathrm{X},-\mathrm{X},+\mathrm{Y}$, and -Y dimensions of the region. The dimensions of other geometry regions will not be changed (their search constants are defaulted to 0.0 ) unless additional search data containing appropriate instructions are supplied.

The limits for a critical pitch search can be set using either MAXPITCH= and MINPITCH= in the optional search parameters or $+\mathrm{CON}=$ and $-\mathrm{CON}=$ in the search parameter constraints of the auxiliary search commands. MAXPITCH= and MINPITCH= are used to enter a value of the maximum allowed pitch and minimum allowed pitch respectively. Parameters $+\mathrm{CON}=$ and $-\mathrm{CON}=$ are used to enter values for the parameter constraints (i.e., the maximum and minimum allowed value of the search parameter). Typically, it is easier to set the maximum allowed pitch and minimum allowed pitch using MAXPITCH= and MINPITCH= than it is to calculate the value of the parameter corresponding to those pitches. The default minimum constraint corresponds to MINPITCH, the pitch at which the largest interior region of a unit used in the array is in contact with the spacing cuboid of that unit. The maximum constraint is defaulted to -5 times the minimum constraint. The code calculates $k_{\text {eff }}$ for the initial geometry first. Then the dimensions corresponding to the minimum constraint and maximum constraint are calculated.

## Default Search - Array of Centered Spheres

This problem contains search data for a default critical pitch search with $k_{\text {eff }}$ specified to be 0.95 . The problem consists of a $10 \times 10 \times 10$ array of uranium spheres surrounded by low density water. The spheres are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$ and have a radius of 2.0 cm . The spheres are originally centered on an 8.0 cm X , Y, and Z pitch with interstitial low density ( $0.01 \mathrm{gm} / \mathrm{cc}$ ) water. The problem searches for the pitch that will produce a $k_{\text {eff }}=0.95$ for the system.

### 2.1.A. 9 Optimum dimension search

An optimum dimension search searches for the geometry dimensions that yield the highest value of $k_{\text {eff }}$. An optimum dimension search is activated by entering "OPTIMUM DIMENSION" in the search data. There are no defaulted search data in a dimension search. The user must specify the dimensions to be changed and the manner in which they will be changed as described in the auxiliary search commands .

A dimension search is performed by altering the regions having nonzero search constants specified in the auxiliary search commands portion of the search data. By default, the search constants for every dimension in the problem are zero. Only those dimensions having a nonzero search constant are altered by the code.

By default, a dimension search sets the minimum constraint to -10E10 and the maximum constraint to +10 E 10 . The relationship between the constraints and the search constants are given in Eqs. (2.1.1) and (2.1.2). If the default values of the constraints are used, appropriate search constants must be calculated using these equations. It may be simpler to set the search constants to 1.0 and calculate the corresponding maximum and minimum constraints. Several dimension search examples are shown below.

## Array of Centered Spheres - Search in X, Y, and Z Dimensions

Consider a $10 \times 10 \times 10$ array of uranium spheres arranged in an array having a "square" pitch. The uranium spheres are 2 cm in radius, and the center-to-center spacing is 8 cm . The uranium spheres and their associated spacing are defined to be unit 1 , and the $10 \times 10 \times 10$ array is defined to be array 1 . The constraints are set to be consistent with those of this optimum pitch search case. The search data and results for an optimum dimension search that alters the $\mathrm{X}, \mathrm{Y}$, and Z dimensions of region 2 of unit 1 are given as follows.

```
=CSAS5S
10\times10\times10 ARRAY - DIMENSION SEARCH
V7-238
READ COMP
URANIUM 1 1.0 300.0 92235 90.0 92238 10.0 END
H2O 2 0.01 300.0 END
END COMP
READ CELLDATA
LATTICECELL SPHSQUAREP PITCH=8.0 2 FUELD=4.0 1 END
END CELLDATA
READ GEOMETRY
UNIT 1
SPHERE 1 1 2.0
CUBOID 2 1 6P4.0
END GEOMETRY
READ ARRAY
ARA=1 NUX=10 NUY=10 NUZ=10 FILL F1 END FILL
END ARRAY
```

```
END DATA
READ SEARCH OPTIMUM DIMENSION MORE
ALTER UNIT=1 REG=2 ALL=1.0
-CON=-0.5 +CON=2.5
END SEARCH
END
```

These MORE search data will cause the code to alter the $+\mathrm{X},-\mathrm{X},+\mathrm{Y},-\mathrm{Y},-\mathrm{Z}$, and +Z dimensions of the outer region (region 2 ) of unit 1 and search for the dimensions that give the maximum $k_{\text {eff. }}$. Since all the UNIT 1 outer dimensions are the same ( 4 or -4 ) and all the search constants are the same (ALL=1.0) the code will alter each dimension the same amount for a search pass thus preserving the original relationship between dimensions. Because this is an optimum pitch search, the sphere dimensions will not be changed. The optimum dimension for this problem is when the spheres touch as shown in the output data above.

## Array of Centered Spheres - Search in X and Y Dimensions

This is the same problem as described above except the spacing is only varied in the X and Y dimensions. Since only changes in the X and Y dimensions of the outer region are desired, the $+\mathrm{X},-\mathrm{X},+\mathrm{Y}$, and -Y search constants must be set. Since all dimensions are to change at the same rate and have the same initial value, the search constants for the changing surfaces must be the same. The +Z and -Z search constants by default are zero so these dimensions will not change. The input data and the final search results for this problem follow:

```

## Array of Offset Spheres - Search in X and Y Dimensions

This is the same problem as described above except the spheres are now off-centered in the X and Y dimensions. Since only changes in the X and Y dimensions of the outer region are desired, the $+\mathrm{X},-\mathrm{X},+\mathrm{Y}$, and -Y search constants must be set. All dimensions are to change at the same rate but they have different initial values. The search constants specify how surfaces change relative to each other. For this case the search constants were chosen so that the moderator spacing for the X and Y dimensions will change at the same rate. The +Z and -Z search constants by default are zero so these dimensions will not change.

The input data and the final search results for this problem follow:

## Array of Cylinders - Search in X, Y, and Z Dimensions

This is the same array of cylinder problem as described in the previous section, except the search is an optimum dimension search. Since changes in the X, Y, and Z dimensions of the outer region are desired, the $+\mathrm{X},-\mathrm{X},+\mathrm{Y},-\mathrm{Y},+\mathrm{Z}$, and -Z search constants must be set. The search data ALL=1.0 sets all the outer region search constants to 1.0 . However, a constant ratio for the center-to-center spacing of the units in desired so the Z dimensions will need to be reset to a lower value of 0.333333 . This will ensure that the Z dimensions change at $1 / 3$ the rate of the X and Y dimensions relative to their initial values. The input data and the final search results for this problem follow:

### 2.1.A.10 Minimum dimension search

A minimum dimension search searches for the geometry dimensions that yield the lowest value of $k_{\text {eff. }}$ A minimum dimension search is activated by entering "MINIMUM DIMENSION" in the search data. There are no defaulted search data in a dimension search. The user must specify the dimensions to be changed and the manner in which they will be changed as described in the auxiliary search commands.

A dimension search is performed by altering the regions having nonzero search constants specified in the auxiliary search commands portion of the search data. By default, the search constants for every dimension in the problem are zero. Only those dimensions having a nonzero search constant are altered by the code.

By default, a dimension search sets the minimum constraint to -10 E 10 and the maximum constraint to +10 E 10 . The relationship between the constraints and the search constants are given in Eqs. (2.1.1) and (2.1.2). If the default values of the constraints are used, appropriate search constants must be calculated using these equations. In some cases it may be simpler to set the search constants to 1.0 and calculate the corresponding maximum and minimum constraints. Several dimension search examples are shown below.

## Infinite Array of Fuel Bundles Separated by Flux Traps - Search in X and Y-Dimensions

The fuel bundles in this problem represent $17 \times 17$ PWR fuel assemblies. The fuel pins are smeared together, making a mixture 100. The fuel pins consist of $2.35 \mathrm{wt} \%{ }^{235} \mathrm{U}$ having a diameter of 0.823 cm , zirconium cladding having an outer diameter of 0.9627 cm , and a pitch of 1.275 cm . The fuel bundle is
represented as a $10.8375 \mathrm{~cm} \times 10.8375 \mathrm{~cm} \times 366 \mathrm{~cm}$ cuboid of mixture 100 surrounded by Boral and then water. The Boral has a density of $2.65 \mathrm{~g} / \mathrm{cm}^{3}$ and is composed of $35.17 \mathrm{wt} \% \mathrm{~B}_{4} \mathrm{C}$ and $64.83 \mathrm{wt} \% \mathrm{Al}$. The fuel bundles are at a fixed pitch of 13.0 cm . The problem searches for the thickness of Boral that will produce the lowest system $k_{\text {eff. }}$. The input data and the final search results for this problem follow:

## Two Uranium Slabs Separated by a Flux Trap - Search in +X Dimensions

This problem consists of two $90 \mathrm{wt} \%$ enriched uranium metal slabs separated by a flux trap. Each uranium slab is 3.0 cm thick. The spacing between the slabs is 4 cm . Between the slabs is a Boral plate at each slab surface and water in between the two Boral plates. This problem searches for the thickness of the Boral plates and separating water that produces the lowest system $k_{\text {eff. }}$. The input data and the final search results for this problem follow:

### 2.1.A. 11 Critical dimension search

A critical dimension search searches for the geometry dimensions that yield a specified value of $k_{\text {eff. }}$. A critical dimension search is activated by entering "CRITICAL DIMENSION" in the search data. No defaulted search data are in a dimension search. The user must specify the dimensions to be changed and the manner in which they will be changed.

A dimension search is performed by altering the regions having nonzero search constants specified in the individual search commands portion of the search data. By default, the search constants for every dimension in the problem are zero. Only those dimensions having a nonzero search constant are altered by the code.

By default, a dimension search sets the minimum constraint to - 10E10 and the maximum constraint to +10 E 10 . The relationship between the constraints and the search constants is given in Eqs. (2.1.1) and (2.1.2). If the default values of the constraints are used, appropriate search constants must be calculated using these equations. It may be simpler to set the search constants to 1.0 and calculate the corresponding maximum and minimum constraints. Several critical dimension search examples are shown below.

## Array of Centered Spheres - Search in X, Y, and Z Dimensions

Consider a $10 \times 10 \times 10$ array of uranium spheres arranged in an array having a "square" pitch. The uranium spheres are 2 cm in radius, and the center-to-center spacing is 8 cm . The uranium spheres and their associated spacing are defined to be unit 1 , and the $10 \times 10 \times 10$ array is defined to be array 1 . A critical dimension search is performed on the outer dimension of the cuboid that will produce a system $k_{\text {eff }}$ of 1.0. In the MORE search data, All=1.0 on region 2 of unit 1 specifies all six surfaces of the cuboid change identically. The search constraints are set to search from a sphere center-to-center spacing of 4 cm to 20 cm . The search data and results are given below.

```

## Array of Centered Cylinders - Search in X and Y Dimensions

This problem contains search data for a critical dimension search with $k_{\text {eff }}$ specified to be 0.95 . The problem consists of a $10 \times 10 \times 2$ array of uranium cylinders surrounded by low density water. The cylinders are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$ and have a radius of 2.0 cm and a length of 20 cm . The cylinders are originally centered on an 8.0 cm X and Y pitch and a 24 cm Z pitch with interstitial low density ( $0.01 \mathrm{gm} / \mathrm{cc}$ ) water. The problem searches for the cylinder center-to-center spacing that will produce a $k_{\text {eff }}=0.95$ for the system. Because this is a dimension search, all search data must be specified. The $+\mathrm{X},-\mathrm{X},+\mathrm{Y}$, and -Y search constants are specified as well as the -CON and +CON search constraints. The search data is set up to alter the cylinder center-to-center spacing from 4.0 cm to 16.0 cm during the search. The MORE search data CELL=1 ties the search data to the first unit cell thus ensuring they change in unison properly modifying the cross-section processing. The input data and the final search results for this problem follow:

```

## Array of Centered Uranium Slabs

Consider a $10 \times 1 \times 1$ array of uranium metal slabs. The uranium slabs are 2 cm thick in the X dimension and 200 cm thick in the Y and Z dimensions. On each side of the uranium slab in the X dimension is 1 cm of $\mathrm{H}_{2} \mathrm{O}$, then 1 cm of Boral, then 1 cm of $\mathrm{H}_{2} \mathrm{O}$ resulting in an initial center-to-center spacing of 8.0 cm . The slabs are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$, the water is full density, and the Boral is $36.7 \% \mathrm{~B}_{4} \mathrm{C}$. The uranium slabs and their associated materials are defined to be Unit 1, and the $10 \times 1 \times 1$ array is defined to be array 1. The problem searches for the slab center-to-center spacing that will produce a $k_{\text {eff }}=1.0$ for the system, which is the default search value. Because this is a dimension search all search data must be specified. The +X and -X search constants are specified as well as the -CON and +CON search constraints. The search data is set up to alter the cylinder change the water slab thickness between the Boral plates from 0.8 cm to 10.0 cm thick during the search. The MORE search data CELL=1 ties the search data to the first unit cell thus ensuring they change in unison properly modifying the cross-section processing. ## $\mathrm{UO}_{2} \mathrm{~F}_{2}$ Solution Tank - Critical Search on Chord Length

Consider a large spherical tank partially filled with $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. The tank has a radius of 34.6 cm and is initially filled with solution to a height of 10.0 cm above the midpoint. The tank is composed of a $0.759-\mathrm{cm}$-thick Al shell. The $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution is composed of three standard compositions: $\mathrm{UO}_{2} \mathrm{~F}_{2}$, HF acid, and $\mathrm{H}_{2} \mathrm{O}$. The code combines these using a set algorithm. This may or may not produce a solution at the desired density. If the density of the solution is known it should be entered. Also, extra acid can be added to the solution by specifying a non-zero acid molarity.

A critical dimension search is performed on the length of the chord yielding system $k_{\text {eff }}=0.98$. In the MORE search data, UNIT=1 REG=1 CHORD=1 specifies that the chord length of region 1 in Unit 1 is to be altered with the limits defined by the search constraints. The minimum search constraint is set so region 1 consists of the part of the sphere below an $\mathrm{X}-\mathrm{Y}$ plane 10.0 cm below the sphere's midpoint. The maximum search constraint is set so region 1 consists of almost the entire sphere.

The constraints are calculated as follows:

$$
\begin{aligned}
& \left.\mathrm{D}_{\mathrm{i}}=\left(\text { Radius }_{\mathrm{i}}+\text { Chord }_{\mathrm{i}}\right) /\left(2 * \text { Radius }_{\mathrm{i}}\right)=(34.6+20.0) / 2 * 34.6\right)=0.6445 \\
& \left.\mathrm{D}_{\min }=\left(\text { Radius }_{\text {min }}+\text { Chord }_{\min }\right) /\left(2 * \text { Radius }_{\min }\right)=(34.6+-10.0) / 2 * 34.6\right)=0.3555 \\
& \left.\mathrm{D}_{\max }=\left(\text { Radius }_{\text {max }}+\text { Chord }_{\text {max }}\right) /\left(2 * \text { Radius }_{\text {max }}\right)=(34.6+34.6) / 2 * 34.6\right)=1.0
\end{aligned}
$$

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=\left[\left(\mathrm{D}_{\max } / \mathrm{D}_{\mathrm{i}}\right)-1.0\right] / \mathrm{CHORD}=[(1.0 / 0.6445)-1.0] / 1.0=0.5515
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=\left[\left(\mathrm{D}_{\max } / \mathrm{D}_{\mathrm{i}}\right)-1.0\right] / \mathrm{CHORD}=[(0.3555 / 0.6445)-1.0] / 1.0=-0.4484
$$

### 2.1.A. 12 Optimum concentration search

An optimum concentration search alters the concentration of the specified standard composition in the specified mixture to determine the highest value of $k_{\text {eff. }}$. The limits for an optimum concentration search are governed by the values entered for the parameter constraints. An optimum concentration search is activated by entering "OPTIMUM CONCENTRATION" in the search data. No defaulted search data are in a concentration search. The user must specify the material and standard composition name to be changed and the manner in which they will be changed.

A concentration search is performed by altering the atom densities of the specified standard compositions in the specified materials. The ratio of how the standard compositions change relative to each other is controlled using FACTOR. If a material and standard composition is not listed in the search data it remains unchanged. The concentration search can vary from zero to some upper limit. The code will prevent the concentration from falling below zero, but the user is responsible for setting constraints that prevent the concentration from exceeding reasonable values. In most cases the theoretical density is a reasonable upper limit.

## Array of Spheres in $\mathrm{H}_{2} \mathrm{O}$ - Search on $\mathrm{H}_{2} \mathrm{O}$ Density

Consider a $10 \times 10 \times 10$ array of uranium spheres arranged in an array having a "square" pitch. The uranium spheres are 2 cm in radius, and the center-to-center spacing is 8 cm . The uranium spheres and their associated spacing are defined to be unit 1 , and the $10 \times 10 \times 10$ array is defined to be array 1 . The spheres are initially moderated by $1 / 2$ density water.

An optimum concentration search is performed on the water yielding the maximum system $k_{\text {eff }}$ for various densities of water. In the MORE search data, MIX=2 and SCNAME=H2O specify that the water component of mixture 2 is to be altered during the search. The maximum allowed density is full density water. The minimum allowed density is 0.05 density water.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=\left(\frac{\mathrm{D}_{\max }}{\mathrm{D}_{\text {initial }}}-1\right) / \text { FACTOR } \quad+\mathrm{CON}=\left(\frac{1.0}{0.5}-1\right) / 1=1 / 0
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=\left(\frac{\mathrm{D}_{\min }}{\mathrm{D}_{\text {initial }}}-1\right) / \text { FACTOR } \quad-\mathrm{CON}=\left(\frac{0.05}{0.5}-1\right) / 1=-0.9
$$

The search data and final search results for this problem follow:

## Array of Cylinders in $\mathrm{H}_{2} \mathrm{O}$ - Search on $\mathrm{H}_{2} \mathrm{O}$ Density

This problem contains search data for an optimum concentration search. The problem consists of a $10 \times 10 \times 1$ array of uranium cylinders surrounded initially by $0.5 \mathrm{gm} / \mathrm{cc}$ density water. The cylinders are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$ and have a radius of 2.0 cm and a length of 200 cm . The cylinders are originally centered on an 8.0 cm X and Y pitch with interstitial low density ( $0.5 \mathrm{gm} / \mathrm{cc}$ ) water. The problem searches for the $\mathrm{H}_{2} \mathrm{O}$ density that will produce the maximum system $k_{\text {eff. }}$. In the MORE search data, MIX $=2$ and SCNAME $=$ H2O specify that the water component of mixture 2 is to be altered during the search. The maximum allowed density is full density water. The minimum allowed density is 0.05 density water.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=\left(\frac{\mathrm{D}_{\max }}{\mathrm{D}_{\text {initial }}}-1\right) / \text { FACTOR } \quad+\mathrm{CON}=\left(\frac{1.0}{0.5}-1\right) / 1=-1.0 .
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=\left(\frac{\mathrm{D}_{\text {min }}}{\mathrm{D}_{\text {initial }}}-1\right) / \text { FACTOR } \quad-\mathrm{CON}=\left(\frac{0.05}{0.5}-1\right) / 1=-0.9 .

## Cell-Weighted Array of Uranium Cylinders in $\mathrm{H}_{2} \mathrm{O}$ - Search on $\mathrm{H}_{2} \mathrm{O}$ Density

This problem contains search data for an optimum concentration search. The problem consists of a single material representing a $10 \times 10 \times 1$ array of uranium cylinders surrounded initially by $0.5 \mathrm{gm} / \mathrm{cc}$ density water. The cylinders are $90 \%{ }^{235} \mathrm{U}$ and $10 \%{ }^{238} \mathrm{U}$ and have a radius of 2.0 cm and a length of 200 cm . The cylinders are originally centered on an 8.0 cm X and Y-pitch with interstitial low density ( $0.5 \mathrm{gm} / \mathrm{cc}$ ) water. The keyword CELL=100 in the unit cell data indicates this will be a cell-weighted problem with mixture 100 representing the array of uranium rods in water. The problem searches for the $\mathrm{H}_{2} \mathrm{O}$ density that will produce the maximum system $k_{\text {eff. }}$. In the MORE search data, MIX=2 and SCNAME $=\mathrm{H}_{2} \mathrm{O}$ specify that the water component of mixture 2 is to be altered during the search. On each pass the water density is altered, XSDRNPM is run to produce a new mixture 100, and mixture 100 is used in KENO V.a to calculate a new system $k_{\text {eff. }}$. The cylinder and cuboid in unit 1 and the array contained in the above problem are replaced by a cuboid of the same size as the array containing mixture 100. The maximum allowed density is full density water. The minimum allowed density is 0.05 density water.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=\left(\frac{\mathrm{D}_{\max }}{\mathrm{D}_{\text {initial }}}-1\right) / \text { FACTOR } \quad+\mathrm{CON}=\left(\frac{1.0}{0.5}-1\right) / 1=-1.0 .
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=\left(\frac{\mathrm{D}_{\text {min }}}{\mathrm{D}_{\text {initial }}}-1\right) / \text { FACTOR } \quad-\mathrm{CON}=\left(\frac{0.05}{0.5}-1\right) / 1=-0.9 .
$$

### 2.1.A. 13 Minimum concentration search

A minimum concentration search searches for the standard composition density that yields the lowest value of $k_{\text {eff }}$ A minimum concentration search is activated by entering "MINIMUM CONCENTRATION" in the search data. There are no defaulted search data in a concentration search. The user must specify the material and standard composition name to be changed and the manner in which they will be changed as described in the auxiliary search commands.

A concentration search is performed by altering the atom densities of the specified standard compositions in the specified materials. The ratio of how the standard compositions change relative to each other is controlled using FACTOR. If a material and standard composition is not listed in the search data it remains unchanged. The concentration search can vary from zero to some upper limit. The code will prevent the concentration from falling below zero, but the user is responsible for setting constraints that prevent the concentration from exceeding reasonable values. In most cases the theoretical density is a reasonable upper limit.

## Infinite Array of Fuel Bundles Separated by Flux Traps - Search on $\mathrm{H}_{2} \mathrm{O}$ Density in Trap

The fuel bundles in this problem represent $17 \times 17$ PWR fuel assemblies. The fuel pins are smeared together, making a mixture 100. The fuel pins consist of $2.35 \mathrm{wt} \%{ }^{235} \mathrm{U}$ having a diameter of 0.823 cm , zirconium cladding having an outer diameter of 0.9627 cm , and a pitch of 1.275 cm . The fuel bundle is represented as a $10.8375 \mathrm{~cm} \times 10.8375 \mathrm{~cm} \times 366 \mathrm{~cm}$ cuboid of mixture 100 surrounded by Boral and then water. The Boral has a density of $2.65 \mathrm{~g} / \mathrm{cm}^{3}$ and is composed of $35.17 \mathrm{wt} \% \mathrm{~B}_{4} \mathrm{C}$ and $64.83 \mathrm{wt} \% \mathrm{Al}$. The fuel bundles are at a fixed pitch of 13.0 cm . This is the same problem as described for a minimum dimension search above with the water component of the trap size optimized, thus producing a minimum system $k_{\text {eff. }}$ The input data and the final search results for this problem follow:

### 2.1.A.14 Critical concentration search

A critical concentration search alters the concentration of the specified standard composition in the specified mixture to obtain a specified value of $k_{\text {eff }}$ A critical concentration search is activated by entering "CRITICAL CONCENTRATION" in the search data. There are no defaulted search data in a critical concentration search except for the value of $k_{\text {eff. }}$. If something other than $k_{\text {eff }}=1.0$ is desired the user must specify $\mathrm{KEF}=* *$, where ${ }^{* *}$ is the desired value of $k_{\text {eff. }}$. The remaining data is entered after the keyword MORE in the search data block. The user must specify the material and standard composition name to be changed and the manner in which they will be changed as described in the auxiliary search commands.

A concentration search is performed by altering the atom densities of the specified standard compositions in the specified materials. The ratio of how the standard compositions change relative to each other is controlled using FACTOR. If a material and standard composition is not listed in the search data it remains unchanged. The concentration search can vary from zero to some upper limit. The code will prevent the concentration from falling below zero, but the user is responsible for setting constraints that prevent the concentration from exceeding reasonable values. In most cases the theoretical density is a reasonable upper limit.

## Array of Spheres in $\mathrm{H}_{2} \mathrm{O}$ - Search on $\mathrm{H}_{2} \mathrm{O}$ Density

Consider a $10 \times 10 \times 10$ array of uranium spheres arranged in an array having a "square" pitch. The uranium spheres are 2 cm in radius, and the center-to-center spacing is 8 cm . The uranium spheres and their associated spacing are defined to be unit 1 , and the $10 \times 10 \times 10$ array is defined to be array 1.0 cm . The spheres are initially moderated by $1 / 2$ density water.

A critical concentration search is performed on the water yielding system $k_{\text {eff }}=1.0$ for various densities of water. In the MORE search data, MIX=2 and SCNAME=H2O specify that the water component of mixture 2 is to be altered during the search from an initial density of $0.5 \mathrm{gm} / \mathrm{cc}$. The maximum allowed density is full density water ( $1.0 \mathrm{gm} / \mathrm{cc}$ ). The minimum allowed water density is $0.0005 \mathrm{gm} / \mathrm{cc}$.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=(1.0 / 0.5-1) / 1.0=1.0
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=(0.0005 / 0.5-1) / 1.0=-0.999
$$

The search data and final search results for this problem follow:

## Array of Spheres in $\mathrm{H}_{2} \mathrm{O}$ - Search on $\mathrm{H}_{2} \mathrm{O}$ Density

This is the same problem as described above with the exception of the initial water density, which is now $0.25 \mathrm{gm} / \mathrm{cc}$. A critical concentration search is performed on the water yielding a system $k_{\text {eff }}=1.0$ for various densities of water. In the MORE search data, MIX=2 and SCNAME=H2O specify that the water component of mixture 2 is to be altered during the search from an initial value of $0.25 \mathrm{gm} / \mathrm{cc}$. The maximum allowed density is $1 / 2$ density water ( $0.5 \mathrm{gm} / \mathrm{cc}$ ). The minimum allowed water density is $0.1 \mathrm{gm} / \mathrm{cc}$.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=(5.0 / 0.25-1) / 1.0=1.0
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=(0.1 / 0.25-1) / 1.0=-0.6
$$

The search data and final search results for this problem follow:

## $\mathbf{U O}_{2} \mathbf{F}_{2}$ Solution Tank - Critical Search on $\mathbf{U O}_{2} \mathbf{F}_{\mathbf{2}}$ Density

Consider a large spherical tank partially filled with $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. The tank has a radius of 34.6 cm and is filled with solution to a height of 30.0 cm above the midpoint. The tank is composed of a 0.759 cm thick Al shell. The $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution is composed of three standard compositions: UO2F2, HF acid, and H2O. The code combines these using a set algorithm. This may or may not produce a solution at the desired density. If the density of the solution is known it should be entered. Also, extra acid can be added to the solution by specifying a non-zero acid molarity.

A critical concentration search is performed on the water yielding system $k_{\text {eff }}=1.0$ for various densities of $\mathrm{UO}_{2} \mathrm{~F}_{2}$ in the solution. In the MORE search data, MIX=1 and SCNAME=UO2F2 specify that the $\mathrm{UO}_{2} \mathrm{~F}_{2}$ component of the mixture 1 solution is to be altered during the search. The code calculates the density of the solution. The initial uranium fuel density is $300 \mathrm{gm} / \mathrm{liter}$. The maximum allowed uranium density is $600 \mathrm{gm} /$ liter. The minimum allowed uranium density is $150 \mathrm{gm} / \mathrm{liter}$.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=(600 / 300-1) / 1.0=1.0
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=(150 / 300-1) / 1.0=-0.5
$$

The search data and final search results for this problem follow:

```

```

based on the preceding data, the best estimate of the parameter is 6.69249E-01
the mixing table corresponding to this parameter follows:
solution tank - critical concentration search mixing table
number of scattering angles $=2$
cross section message threshold $=5.7 \mathrm{E}-02$

The final solution for this search contains $500 \mathrm{gm} /$ liter of uranium. The search, however, did not change the amount of acid or water in the solution. To get a better estimation of the solution density and $k_{\text {eff }}$ for this concentration of uranium the problem should be run again with an initial uranium density of $500 \mathrm{gm} /$ liter as shown below.

## $\mathrm{UO}_{2} \mathrm{~F}_{2}$ Solution Tank - Critical Search on $\mathrm{UO}_{2} \mathrm{~F}_{2}$ Density, Check

This is the same $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution tank problem examined above except the initial uranium density is $500 \mathrm{gm} /$ liter. This problem is run again so the code will calculate water and acid densities associated with this density of uranium. The search data has also been modified to account for the new density of uranium.

A critical concentration search is performed on the water yielding system $k_{\text {eff }}=1.0$ for various densities of $\mathrm{UO}_{2} \mathrm{~F}_{2}$ in the solution. In the MORE search data, MIX=1 and SCNAME=UO2F2 specify that the $\mathrm{UO}_{2} \mathrm{~F}_{2}$ component of the mixture 1 solution is to be altered during the search. The code calculates the density of the solution. The initial uranium fuel density is $500 \mathrm{gm} / \mathrm{liter}$. The maximum allowed uranium density is $600 \mathrm{gm} /$ liter. The minimum allowed uranium density is $400 \mathrm{gm} / \mathrm{liter}$.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=(600 / 500-1) / 1.0=0.2
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=(400 / 500-1) / 1.0=-0.2
$$

The search data and final search results for this problem follow:

```

                                    keff= 9.99662E-01 + or - 1.40567E-03
                                    the parameter was 0.00000E+00
                                    solution tank - critical concentration search
```

This problem converged on the first pass, so the amount of uranium, HF acid, and water in the solution were reasonably good estimates. For this problem the HF acid and $\mathrm{H}_{2} \mathrm{O}$ only changed marginally and, therefore, had very little effect on the system $k_{\text {eff. }}$. This is not always the case; therefore if a search is being done on a solution, the problem should always be rerun with the final search densities.

## Fuel Bundles Separated by Flux Traps - Critical Search Boron and Al Densities

The fuel bundles in this problem represent $17 \times 17$ PWR fuel assemblies. The fuel pins are smeared together, making a mixture 100. The fuel pins consist of $4.35 \mathrm{wt} \%{ }^{235} \mathrm{U}$ having a diameter of 0.823 cm , zirconium cladding having an outer diameter of 0.9627 cm , and a pitch of 1.275 cm . The fuel bundle is represented as a $10.8375 \mathrm{~cm} \times 10.8375 \mathrm{~cm} \times 366 \mathrm{~cm}$ cuboid of mixture 100 surrounded by Boral and then water. The Boral has a density of $2.61 \mathrm{~g} / \mathrm{cm}^{3}$ and has an initial composed of $50.0 \mathrm{wt} \% \mathrm{~B}_{4} \mathrm{C}$ and
$50.0 \mathrm{wt} \% \mathrm{Al}$. The fuel bundles are at a fixed pitch of 13.0 cm . Boral plates surrounding the X and Y sides of each fuel assembly are 0.1625 cm thick. Full density water is between the Boral plates.

A critical concentration search is performed on the Boral plates searching for a system $k_{\text {eff }}=0.95$. The Boral plates are at a fixed density of $2.61 \mathrm{gm} / \mathrm{cc}$. As the density of the $\mathrm{B}_{4} \mathrm{C}$ changes, the density of the Al changes in the opposite direction maintaining a constant Boral density. There are two entries in the MORE search data. The first entry, MIX=4 SCNAME=b4c factor=1.0 specifies that the $\mathrm{B}_{4} \mathrm{C}$ of mixture 4 is to be altered during the search. The second entry, MIX=4 SCNAME=al factor $=-1.0$ specifies that aluminum is to be changed in the opposite direction and proportionally to $\mathrm{B}_{4} \mathrm{C}$ during the search. Both $\mathrm{B}_{4} \mathrm{C}$ and Al have the same initial density of 0.5 * $2.61=1.305 \mathrm{gm} / \mathrm{cc}$.

The maximum constraint is calculated according to:

$$
+\mathrm{CON}=(2.59695 / 1.305-1) / 1.0=0.99
$$

The minimum constraint is calculated according to:

$$
-\mathrm{CON}=(0.1305 / 1.305-1) / 1.0=-0.9
$$

# 2.2 CSAS6: CONTROL MODULE FOR ENHANCED CRITICALITY SAFETY ANALYSIS WITH KENO-VI 

L. M. Petrie, K. B. Bekar, D. F. Hollenbach, ${ }^{1}$ S. Goluoglu ${ }^{1}$

#### Abstract

The Criticality Safety Analysis Sequence with KENO-VI (CSAS6) provides reliable and efficient means of performing $k_{\text {eff }}$ calculations for systems that are routinely encountered in engineering practice. In the multigroup calculation mode, CSAS6 uses XSProc to process the cross sections for temperature corrections and problem-dependent resonance self-shielding and calculates the $k_{\text {eff }}$ of three-dimensional (3-D) system models. If the continuous energy calculation mode is selected no resonance processing is needed and the continuous energy cross sections are used directly in KENO-VI, with temperature corrections provided as the cross sections are loaded. The geometric modeling capabilities available in KENO-VI coupled with the automated crosssection processing within the control sequences allow complex, 3-D systems to be easily analyzed.

## ACKNOWLEDGMENTS

The CSAS6 Criticality Safety Analysis Sequence is based on the CSAS control module, and the KENO-VI functional module, described in their respective chapters. G. E. Whitesides is acknowledged for his contributions through early versions of KENO. Appreciation is expressed to C. V. Parks and S. M. Bowman for their guidance in developing CSAS6.

### 2.2.1 Introduction

Criticality Safety Analysis Sequence with KENO-VI (CSAS6) provides reliable and efficient means of performing $k_{\text {eff }}$ calculations for systems that are routinely encountered in engineering practice, especially in the calculation of $k_{\text {eff }}$ of three-dimensional (3-D) system models. CSAS6 implements XSProc to process material input and provide a temperature and resonance-corrected cross-section library based on the physical characteristics of the problem being analyzed. If a continuous energy cross-section library is specified, no resonance processing is needed and the continuous energy cross sections are used directly in KENO-VI, with temperature corrections provided as the cross sections are loaded.

### 2.2.2 Sequence Capabilities

CSAS6 is designed to prepare a resonance-corrected cross-section library for subsequent use in KENO-VI. In order to minimize human error, the SCALE data handling is automated as much as possible. CSAS6 and many other SCALE sequences apply a standardized procedure to provide appropriate number densities and cross sections for the calculation. XSProc is responsible for reading the standard composition data and other engineering-type specifications, including volume fraction or percent theoretical density, temperature, and isotopic distribution as well as the unit cell data. XSProc then generates number densities and related information, prepares geometry data for resonance self-shielding and flux-weighting cell calculations, if needed, and (if needed) provides problem-dependent multigroup cross-section processing. CSAS6 invokes a KENO-VI Data Processor to read and check the KENO-VI data. When the data checking has been completed, the control sequence executes XSProc to prepare a resonance-corrected microscopic cross-section library in the AMPX working library format if a multigroup library has been selected.

For each unit cell specified as being cell-weighted, XSProc performs the necessary calculations and produces a cell-weighted microscopic cross-section library. KENO-VI may be executed to calculate the $k_{\text {eff }}$ or neutron multiplication factor using the cross-section library that was prepared by the control sequence.

### 2.2.3 Multigroup CSAS6 limitations

The CSAS6 control module was developed to use simple input data and prepare problem-dependent cross sections for use in calculating the effective neutron multiplication factor of a 3-D system using KENO-VI and possibly XSDRNPM. An attempt was made to make the system as general as possible within the constraints of the standardized methods chosen to be used in SCALE. Standardized methods of data input were adopted to allow easy data entry and for quality assurance purposes. Some of the limitations of the CSAS6 sequence are a result of using preprocessed multigroup cross sections. Inherent limitations in CSAS6 are as follows:

1. Two-dimensional (2-D) effects such as fuel rods in assemblies where some positions are filled with control rod guide tubes, burnable poison rods and/or fuel rods of different enrichments. The cross sections are processed as if the rods are in an infinite lattice of rods. If the user inputs a Dancoff factor for the cell (such as one computed by MCDancoff), XSProc can produce an infinite lattice cell, which reproduces that Dancoff. This can mitigate some two dimensional lattice effects.

It is strongly recommended that the user perform CSAS6 calculations of benchmark experiments similar to the problem of interest to demonstrate the validity of the cross-section data and processing for that type of problem.

### 2.2.3.1 Continuous energy CSAS6 limitations

When continuous energy KENO calculations are desired, none of the resonance processing modules are applicable or needed. Moreover, the MG limitations noted in the previous section are eliminated. The continuous energy cross sections are directly used in KENO. An existing multigroup input file can easily be converted to a continuous energy input file by simply specifying the continuous energy library. In this case, all cell data is ignored. However, the following limitations exist:

1. If CELLMIX is defined in the cell data, the problem will not run in the continuous energy mode. CELLMIX implies new mixture cross sections are generated using XSDRNPM-calculated cell fluxes and therefore is not applicable in the continuous energy mode.
2. Only VACUUM, MIRROR, PERIODIC, and WHITE boundary conditions are allowed. Other albedos, e.g., WATER, CARBON, POLY, etc. are for multigroup only.
3. Problems with DOUBLEHET cell data are not allowed as they inherently utilize CELLMIX feature.

### 2.2.4 Input Data Guide

The input data for CSAS6 are composed of two broad categories of data. The first is XSProc, including Standard Composition Specification Data and Unit Cell Geometry Specification. This first category specifies the cross-section library and defines the composition of each mixture and optionally the unit cell geometry that may be used to process the cross sections. The second category of data, the KENO-VI input data, is used to specify the geometric and boundary conditions that represent the physical 3-D configuration of the problem. Both data blocks are necessary for CSAS6.

All data are entered in free form, allowing alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. Up to 252 columns of data entry per line are allowed. Data can usually start or end in any column with a few exceptions. As an example, the word END beginning in column 1 and followed by two blank spaces or a new line will end the problem and any data following will be ignored. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating values. For example, 10 will be interpreted as 10.0 . Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0E 4 would be correctly interpreted as $1.0 \times 10^{4}$.

The word "END" is a special data item. An "END" may have a name or label associated with it. The name or label associated with an "END" is separated from the "END" by a single blank and is a maximum of 12 characters long. At least two blanks or a new line MUST follow every labeled and unlabeled "END." It is the user's responsibility to ensure compliance with this restriction. Failure to observe this restriction can result in the use of incorrect or incomplete data without the benefit of warning or error messages.

Multiple entries of the same data value can be achieved by specifying the number of times the data value is to be entered, followed by either R , *, or \$, followed by the data value to be repeated. Imbedded blanks are not allowed between the number of repeats and the repeat flag. For example, 5R12, 5*12, 5\$12, or 5 R 12 , etc., will enter five successive 12 s in the input data. Multiple zeros can be specified as nZ where n is the number of zeroes to be entered.

The purpose of this section is to define the input data in discrete subsections relating to a particular type of data. Tables of the input data are included in each subsection, and the entries are described in more detail in the appropriate sections.

Resonance-corrected cross sections are generated using the appropriate boundary conditions for the unit cell description (i.e., void for the outer surface of a single unit, white for the outer surface of an infinite array of cylinders, spheres, or planes). As many unit cells as needed may be specified in a problem. A unit cell is cell-weighted by using the keyword CELLMIX= followed by a unique user specified mixture number in the unit cell data.

To check the input data without actually processing the cross sections, the words "PARM=CHECK" or "PARM=CHK" should be entered, as shown below.

```
=CSAS6 PARM=CHK
    or
#CSAS6 PARM=CHK
```

This will cause the input data for CSAS6 to be checked and appropriate error messages to be printed. If plots are specified in the data, they will be printed. This feature allows the user to debug and verify the input data while using a minimum amount of computer time.

### 2.2.4.1 XSProc data

The XSProc reads the standard composition specification data and the unit cell geometry specifications. It then produces the mixing table and unit cell information necessary for processing the cross sections if needed. The XSProc section of this manual provides a detailed description of the input data and processing options.

### 2.2.4.2 KENO-VI data

Table 2.2.1 contains the outline for the KENO-VI input. The KENO-VI input is divided into 13 data blocks. A brief outline of commonly used data blocks is shown in Table 2.2.1. Note that parameter data must precede all other KENO data blocks. Information on all KENO-VI input is provided in the KENO chapter of this document and will not be repeated here.

Table 2.2.1. Outline of KENO data

| KENO-VI data terminus | END DATA | mode only) |  |

*Must precede all other data blocks in this table.

### 2.2.5 Sample Problems

This section contains sample problems to demonstrate some of the options available in CSAS6. A brief problem description and the associated input data for multigroup mode of calculation are included for each problem. The same sample problems may be executed in the continuous energy mode by changing the library name to an continuous-energy library. See Appendix A for additional examples.

### 2.2.5.1 Sample Problem 1 Aluminum 30 Degree Pipe Angle Intersection

The purpose of this problem is to calculate the k-effective of a system composed of intersecting aluminum pipes, in the shape of a Y , filled with a $5 \%$ enriched $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. The $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution at $299^{\circ} \mathrm{K}$ contains $907.0 \mathrm{gm} / \mathrm{l}$ of uranium, no excess acid, and has a specific gravity of $2.0289 \mathrm{gm} / \mathrm{cm}^{3}$. The assembly is composed of a 212.1 cm long vertical pipe and a second pipe that intersects the vertical pipe 76.7 cm from the outside bottom at an angle of 29.26 degrees with the upper vertical pipe. Both pipes have 13.95 cm inner diameters and 14.11 cm outer diameters. The vertical pipe is open on the top and 1.3 cm thick on the bottom. The Y-leg pipe, in the YZ-plane, is 126.04 cm in length with the sealed end 0.64 cm thick. The assembly is filled with solution to a height 129.5 cm above the outside bottom of the vertical pipe. From the point where the pipes intersect the assembly is surrounded by water 37.0 cm in the $\pm \mathrm{X}$ directions, 100 cm in the +Y direction, -37 cm in the -Y direction, to the top of the assembly in the +Z direction, and -99.6 cm in the -Z direction.

### 2.2.5.2 Sample Problem 2 Plexiglas Cross

The purpose of this problem is to calculate the k-effective of a system composed of intersecting Plexiglas pipes, in the shape of a cross, filled with a $5 \%$ enriched $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. The room temperature $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution contains $896.1 \mathrm{gm} / 1$ of uranium, no excess acid, and has a specific gravity of $2.015 \mathrm{gm} / \mathrm{cm}^{3}$. The pipes have a 13.335 cm inner diameter and 16.19 cm outer diameter. The vertical pipe is open on the top and 3.17 cm thick on the bottom. The horizontal pipe ends are 3.17 thick. The vertical pipe is 210.19 cm in length and filled with solution to a height of 117.2 cm . The two horizontal legs, positioned in the XZ-plane, intersect the vertical pipe 91.44 cm from the outside bottom at an 89 degree angle with the upper section of the pipe. Each horizontal is 91.44 cm in length and filled with the above specified $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution. A water reflector surrounding the solution filled pipes extends out from the point where the pipes intersect 111.76 cm in the $\pm \mathrm{X}$ directions, 20.64 cm in the $\pm \mathrm{Y}$ directions, 29.03 cm in the +Z direction, and -118.428 cm in the -Z direction.

### 2.2.5.3 Sample Problem 3 Sphere

This problem models an assembly consisting of a $93.2 \%$ enriched bare uranium sphere, 8.741 cm in radius, having a density of $18.76 \mathrm{gm} / \mathrm{cm}^{3}$. Problem 3 models the assembly as a single bare sphere. The second problem models the assembly as a hemisphere with mirror reflection on the flat surface. The next three problems model the sphere using chords. This set of four problems is designed to illustrate the use of multiple chords in a problem.

### 2.2.5.7 Sample Problem 7 Grotesque without the Diaphragm

The purpose of this problem is to calculate the $k_{\text {eff }}$ of a system composed of eight enriched uranium units placed on a diaphragm, with an irregularly shaped centerpiece positioned in the center hole of the diaphragm. ${ }^{1}$ The assembly and centerpiece are shown in Figure 2.2.3, which is Fig. 4 from Ref. 1. The eight units consist of an approximate parallelepiped with an irregular top, a parallelepiped, and six cylinders of various sizes. The centerpiece, which penetrates the hole in the diaphragm, consists of a cylinder topped by a parallelepiped topped by a hemisphere. The diaphragm is not modeled in this example.

### 2.2.5.8 Sample Problem 8 Infinite Array of MOX and UO2 Assemblies

The purpose of this problem is to calculate the $k_{\text {eff }}$ of a system composed of an infinite array of MOX assemblies interspersed between $\mathrm{UO}_{2}$ assemblies. Both assembly types contain 331 pins in a hexagonal lattice with a pin pitch of 1.275 cm and an assembly pitch of 23.60 cm as shown in Figure 2.2.4. The moderator is borated water at $306^{\circ} \mathrm{C}$ having a density of $0.71533 \mathrm{gm} / \mathrm{cc}$ and composed of $99.94 \mathrm{wt} \% \mathrm{H}_{2} \mathrm{O}$ and $0.06 \mathrm{wt} \%$ natural boron. Each fuel rod is 355 cm in length, has a radius of $0.3860 \mathrm{~cm}, 0.722-\mathrm{cm}$-thick Zr cladding with no gap, and is at a temperature of $754^{\circ} \mathrm{C}$.

The $\mathrm{UO}_{2}$ fuel consists of $4.4 \mathrm{wt} \%{ }^{235} \mathrm{U}$ and $95.6 \mathrm{wt} \%{ }^{238} \mathrm{U}$ at a density of $8.7922 \mathrm{gm} / \mathrm{cc}$. The $\mathrm{UO}_{2}$ fuel also contains $9.4581 \mathrm{E}-9$ atoms/b-cm of ${ }^{135} \mathrm{Xe}$ and $7.3667 \mathrm{E}-8$ atoms $/ \mathrm{b}-\mathrm{cm}$ of ${ }^{149} \mathrm{Sm}$.

The MOX fuel consists of $96.38 \mathrm{wt} \% \mathrm{UO}_{2}$ and $3.62 \mathrm{wt} \% \mathrm{PuO}_{2}$ at a density of $8.8182 \mathrm{gm} / \mathrm{cc}$. The $\mathrm{UO}_{2}$ fuel is composed of $2.0 \mathrm{wt} \%{ }^{235} \mathrm{U}$ and $98.0 \mathrm{wt} \%{ }^{238} \mathrm{U}$. The $\mathrm{PuO}_{2}$ fuel is composed of $93.0 \mathrm{wt} \%{ }^{239} \mathrm{Pu}$, $6.0 \mathrm{wt} \%{ }^{240} \mathrm{Pu}$ - and $1.0 \mathrm{wt} \%{ }^{241} \mathrm{Pu}$. The MOX fuel also contains $9.4581 \mathrm{E}-9$ atoms $/ \mathrm{b}-\mathrm{cm}$ of ${ }^{135} \mathrm{Xe}$ and $7.3667 \mathrm{E}-8$ atoms/b-cm of ${ }^{149} \mathrm{Sm}$.

These two assemblies are placed so they represent an infinite array in the X and Y dimensions as shown in Figure 2.2.5. There is 20 cm of water above and below fuel assemblies. This problem uses CENTRM/PMC as the resolved resonance processor cross section. Since an infinite array cannot be explicitly modeled, a section of the array is modeled and the X and Y sides have mirror reflection.

### 2.2.6 Warning and Error Messages

CSAS6 contains two types of warning and error messages. The first type of message is from XSProc is common to many of the SCALE analytical sequences. The second type of message is from the CSAS6 subroutines and is identified by CS- followed by a number. These messages are listed in numerical order in Sect. 0. For additional information concerning a message, simply look up the number in this section.

Warning messages appear when a possible error is encountered. It is the responsibility of the user to verify whether the data are correct when a warning message is encountered. The functional modules activated by CSAS6 and related sequences will be executed even though a warning message has been generated.

When an error is recognized, an error message is written and an error flag is set so the functional modules will not be activated. The code stops immediately if the error is too severe to allow continuation of input. However, it will continue to read and check the data if it is able. When the data reading is completed,
execution is terminated if an error flag was set when the data were being processed. If the error flag has not been set, execution continues. When error messages are printed, the user should focus on the first error message, because subsequent messages may have been caused by the error that generated the first message.

The following messages originate in the part of CSAS6 that reads, checks, and prepares data for KENO-VI. The same set of error messages are also used for CSAS5 that reads, checks, and prepares data for KENO V.a and MODIFY. CSAS6 is not capable of performing searches at this time. An error message referring to a SEARCH routine, from a CSAS6 problem, indicates a code error.

## CS-16 ***WARNING*** READ FLAG NOT FOUND. ASSUME KENO V PARAMETER DATA FOLLOWS.

This message from subroutine CPARAM indicates that the word READ is not the first word of KENO-VI data following the Material Information Processor input data. If parameter data is to be entered, the code expects the words READ PARAMETERS to precede the parameter input data. If the word READ is not the first word, the code assumes the data are parameter input data.

CS-21 A UNIT NUMBER WAS ENTERED FOR THE CROSS-SECTION LIBRARY. (LIB= IN PARAMETER DATA.) THE DEFAULT VALUE SHOULD BE USED IN ORDER TO UTILIZE THE CROSS SECTIONS GENERATED BY CSAS. MAKE CERTAIN THE CORRECT CROSS-SECTION LIBRARY IS BEING USED.

This message is from subroutine CPARAM. It indicates that a value has been entered for the crosssection library in the KENO-VI parameter data. The cross-section library created by the analytical sequence should be used. MAKE CERTAIN THAT THE CORRECT CROSS SECTIONS ARE BEING USED.

## CS-55 *** ERRORS WERE ENCOUNTERED IN PROCESSING THE CSAS-KENO6 DATA. EXECUTION IS IMPOSSIBLE. ***

This message from subroutine SASSY is printed if errors were found in the KENO-VI input data for CSAS. If a search is being made, data reading will continue until all the data have been entered or a fatal error terminates the data reading. When the data reading and checking have been completed, the problem will terminate without executing. Check the printout to locate the errors responsible for this message.

CS-62 *** ERROR *** MIXTURE $\qquad$ IN THE GEOMETRY WAS NOT CREATED IN THE STANDARD COMPOSITIONS SPECIFICATION DATA.

This message from subroutine MIXCHK indicates that a mixture specified in the KENO-VI geometry was not created in the standard composition data.

CS-68 *** ERROR *** AN INPUT DATA ERROR HAS BEEN ENCOUNTERED IN THE DATA ENTERED FOR THIS PROBLEM.

This message from the main program, CSAS6, is printed if the subroutine library routine LRDERR returns a value of "TRUE," indicating that a reading error has been encountered in the "KENO PARAMETER" data. The appropriate data type is printed in the message. Locate the unnumbered message stating "****** ERROR IN INPUT. CARD IMAGE PRINTED ON NEXT LINE *****." Correct the data and resubmit the problem.
$\qquad$ IS AN INAPPROPRIATE MIXTURE NUMBER FOR USE IN THE KENO GEOMETRY DATA BECAUSE IT IS A COMPONENT OF THE CELL-WEIGHTED MIXTURE CREATED BY XSDRNPM.

This message from subroutine CMXCHK indicates that a mixture that is a component of a cell-weighted mixture has been used in the KENO-VI geometry data.

## CS-82 *** AN ERROR WAS ENCOUNTERED IN ONE OF THE FUNCTIONAL MODULES.

This message from CSAS6 indicates that an error was encountered during execution of one of the functional modules such as CRAWDAD, BONAMI, CENTRM, PMC, XSDRNPM, or KENO-VI. Check the printout to locate and correct the error.

## CS-99 THIS PROBLEM WILL NOT BE RUN BECAUSE PARM=CHECK WAS ENTERED IN THE ANALYTICAL SEQUENCE SPECIFICATION.

This message from subroutine CSAS indicates that the problem data were read and checked and no errors were found. To execute the problem, remove the PARM=CHECK or PARM=CHK from the analytical sequence indicator data entry.

CS-100 THIS PROBLEM WILL NOT BE RUN BECAUSE ERRORS WERE ENCOUNTERED IN THE INPUT DATA.

This message from subroutine CSAS is self-explanatory. Examine the printout to locate the error or errors in the input data. Correct them and resubmit the problem.

### 2.2.A Additional Example Applications of CSAS6

Several example uses of CSAS6 are shown in this section for a variety of applications.

### 2.2.A. 1 Run KENO-VI using CSAS6

CSAS6 creates a microscopic working format library and a mixing table that is passed to KENO-VI. The library is created using CENTRM/PMC/WORKER to process the cross section data in the resolved resonance regions of the isotopes contained in the library. CSAS6 then executes KENO-VI, which calculates $k_{e f f}$ for the problem. The following examples are for using the multigroup mode of calculation for KENO-VI. Using the continuous energy mode can be accomplished by simply changing the library name to one of the continuous energy libraries.

EXAMPLE 1. CSAS6 - Determine the $k_{\text {eff }}$ of a system.
Consider a problem consisting of eight uranium metal cylinders that are $93.2 \%$ wt enriched, having a density of $18.76 \mathrm{~g} / \mathrm{cm}^{3}$. The cylinders are arranged in a $2 \times 2 \times 2$ array. Each has a radius of 5.748 cm and a height of 10.765 cm . The center-to-center spacing in the horizontal ( $\mathrm{X}-\mathrm{Y}$ ) plane is 13.74 cm and the vertical center-to-center spacing is 13.01 cm . Because the cross section processing will be done assuming an infinite homogeneous medium and no cell mixtures are used, there is no unit cell data. The input data for this problem follow.

EXAMPLE 2. CSAS6 - Determine the $k_{\text {eff }}$ of an array of fuel pellets in a $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution.
Consider a 60 cm inside diameter cylindrical tank filled with $5.0 \%$-enriched $\mathrm{UO}_{2}$ fuel rods and $5.0 \%$-enriched $\mathrm{UO}_{2} \mathrm{~F}_{2}$ solution at $295 \mathrm{gm} /$ liter. A $51 \times 51 \times 1$ array of fuel rods is centered on the bottom of the tank. The fuel rods are 366 cm long, 0.45 cm in radius, clad with $0.01-\mathrm{cm}-$ thick Al , and at a pitch of 1.5 cm . The fuel rods sit on the bottom of the container and the container and solution rise 5.0 cm above the top of the rods. The container is 10 cm thick in the side and bottom and open at the top. Determine the $k_{\text {eff }}$ of the system. Input data for this problem follow.

### 2.2.A. 2 Run KENO-VI containing cell-weighted mixtures

CSAS6 creates a microscopic working format library and a mixing table that is passed to KENO-VI. The microscopic cross sections of the nuclides used in the unit cell geometry description are cell-weighted by specifying CELLMIX= followed by a unique mixture number. This mixture number utilizes the cellweighted cross sections that represent the heterogeneous system. CSAS6 executes KENO-VI and calculates $k_{\text {eff }}$ for the problem.

EXAMPLE 1. CSAS6 - Calculate the $k_{\text {eff }}$ of an array of fuel assemblies using cell-weighted cross sections.

Consider the $4 \times 4 \times 1$ array of fuel assemblies in a square aluminum cask described in Sect. 2.2.A.1.1, Example 2. Calculate the $k_{\text {eff }}$ of the system by using the cell-weighted mixture 200 to represent the fuel pins in the fuel assembly. Note that mixtures 1,2 , and 3 , representing $\mathrm{UO}_{2}$, zirconium, and water, respectively, are used in the unit cell description. Cell-weighting is applied to the microscopic cross sections that are used in the cell, making them incorrect for use elsewhere. Because water is used both inside the cell and between the fuel assemblies, an additional mixture, mixture 6, has been added to represent the water between the fuel assemblies. The input data for this problem follow.

### 2.2.A. 3 Run KENO-VI containing multiple unit cells

CSAS6 can create a microscopic working format library and a mixing table that contains more than one unit cell. Each unit cell is explicitly defined in the CELLDATA section of the standard composition data. Materials may appear in only one unit cell. All materials in the standard composition that are not contained in a unit cell are processed assuming infinite homogeneous media. CSAS6 passes the created working library to KENO-VI which calculates $k_{\text {eff }}$ for the problem.

EXAMPLE 1. CSAS6 - Calculate the $k_{\text {eff }}$ of a system using two unit cell descriptions.
Consider an infinite XY-array composed of two types of fuel assemblies in a checkerboard pattern moderated by water. Each assembly consists of a $17 \times 17 \times 1$ array of zirconium-clad, enriched $\mathrm{UO}_{2}$ fuel pins in a square pitched array. In one array the uranium is $3.5 \%$-enriched and in the other array the uranium is $2.9 \%$-enriched. The $\mathrm{UO}_{2}$ has a density of $9.21 \mathrm{~g} / \mathrm{cm}^{3}$. The pin diameter is 0.8 cm and is 366 cm long. The clad is 0.07 cm thick, and the pitch is 1.3 cm . Each fuel bundle is contained in a $0.65-$ cm-thick Boral sheath. The bundles are separated by an edge-to-edge spacing of 1.0 cm . The water and zirconium is input in the standard composition data once for every unit cell in which it appears because a material may appear in only one unit cell. Determine the $k_{\text {eff }}$ of the infinite array. Note that periodic boundary conditions are required to obtain an infinite checkerboard array. Input data for this problem follow.

# 2.3 STARBUCS: A SCALE CONTROL MODULE FOR AUTOMATED CRITICALITY SAFETY ANALYSES USING BURNUP CREDIT 

G. Radulescu and I. C. Gauld

#### Abstract

STARBUCS is an analysis sequence in SCALE for automating criticality safety and burnup loading curve analyses of spent fuel systems employing burnup credit. STARBUCS requires only the fresh fuel composition, an irradiation history, and the KENO model for a spent fuel configuration to be provided in an input file. It automatically performs all necessary calculations to determine spent fuel compositions, self-shielded cross sections, and the $k_{\text {eff }}$ of the spent fuel configuration. In addition, for burnup loading curve analyses, STARBUCS performs iterative calculations to search for initial fuel enrichments that result in an upper subcritical limit. STARBUCS allows the user to simulate axial- and horizontal-burnup gradients in a spent fuel assembly, select the specific actinides and/or fission products that are to be included in the criticality analysis, and apply isotopic correction factors to the predicted spent fuel nuclide inventory to account for calculational bias and uncertainties. A depletion analysis calculation for each of the burnup-dependent regions of a spent fuel assembly, or any other system containing spent nuclear fuel, is performed using the ORIGEN-ARP sequence of SCALE. For criticality safety calculations employing multigroup cross-section data, the spent fuel compositions are used to generate resonance self-shielded cross sections for each region of the problem. The region dependent nuclide concentrations and cross sections are applied in a three-dimensional criticality safety calculation using the KENO code. Both KENO V.a and KENO-VI criticality codes are supported for single criticality safety calculations using burnup credit, but only KENO V.a can be used in criticality calculations for burnup loading curve analyses. Although STARBUCS was developed specifically to address the burnup-credit analysis needs for spent fuel transport and storage applications, it provides sufficient flexibility to allow criticality safety assessments involving many different potential configurations of $\mathrm{UO}_{2}$ spent nuclear fuel.

### 2.3.1 Introduction

The U.S. Nuclear Regulatory Commission (NRC) issued Revision 2 of the Interim Staff Guidance 8 (ISG-8) (Ref. 1) on burnup credit in September, 2002. ISG-8 provides guidance on the application of burnup-credit in criticality safety analyses for pressurized-water reactor (PWR) spent fuel in transportation and storage casks. Burnup credit is the concept of taking credit for the reduction in reactivity in spent fuel due to burnup. The reduction in reactivity that occurs with fuel burnup is due to the change in concentration (net reduction) of fissile nuclides and the production of actinide and fissionproduct neutron absorbers. In contrast to criticality safety analyses that employ a fresh-fuel assumption (i.e., conservatively assuming unirradiated fuel compositions), credit for burnup requires the prediction of both fissile material and absorber nuclide concentrations in spent nuclear fuel (SNF) and consideration of many burnup-related phenomena, in addition to the criticality issues.

Consideration of the depletion aspects in the criticality assessment of SNF places an increasing reliance on computational tools and methods, and significantly increases the overall complexity of the criticality safety analysis. The use of spent fuel nuclide concentrations in the criticality evaluation also necessitates consideration of many additional sources of uncertainty associated with fuel depletion. ISG-8 highlights, for example, the need for applicants employing burnup credit in criticality safety assessments to address the axial and horizontal variation of the burnup within a spent fuel assembly, uncertainties and bias in the nuclide predictions, and the additional reactivity margin available from fission products and actinides not credited in the licensing basis.

To assist in performing and reviewing criticality safety assessments of transport and storage casks that apply burnup credit, a new control sequence called STARBUCS (Standardized Analysis of Reactivity for Burnup Credit using SCALE) was developed in SCALE 5. STARBUCS automates the generation of spatially-varying nuclide compositions in a spent fuel assembly, and applies the assembly compositions in a three-dimensional (3-D) Monte Carlo analysis of the system. STARBUCS automatically prepares input files for each of the modules in the sequence, executes the modules through the SCALE driver, and performs all flow control, module interface, and data management functions. The STARBUCS sequence uses well-established code modules currently available in SCALE. STARBUCS also performs iterations over a range of initial fuel enrichments to determine the initial enrichments below which $\mathrm{UO}_{2}$ commercial spent fuel may be loaded in a transport/storage cask for specified burnup values. With this capability, STARBUCS assists in generating burnup loading curves for criticality safety analyses of spent fuel in transport and storage casks.

The STARBUCS sequence automates the depletion calculations using the ORIGEN-ARP methodology to perform a series of cross-section preparation and depletion calculations to generate a comprehensive set of spent fuel isotopic inventories for each spatially-varying burnup region of an assembly. The spent fuel nuclide concentrations are subsequently input to either CSAS5 or CSAS6 to and perform a criticality calculation of the system using the KENO V.a or KENO-VI code, respectively, to determine the neutron multiplication factor ( $k_{\text {eff }}$ ) for the system. Only minimal input is required by the user to perform a typical burnup-credit analysis. The user can specify the assembly-average irradiation history, the axial density variation of the reactor moderator, the axial- and horizontal-burnup profile, and the nuclides that are to be applied in the criticality safety analysis. Nuclide correction factors may also be applied to the predicted concentrations to account for known bias and/or uncertainty in the predicted SNF compositions.

### 2.3.2 Methodology

The STARBUCS control module is a burnup-credit sequence designed to perform 3-D Monte Carlo criticality safety calculations that include the effects of spatially-varying burnup in SNF configurations.

STARBUCS offers two options: either perform a single criticality safety calculation with burnup credit or perform iterative calculations for burnup loading curve analyses of commercial $\mathrm{UO}_{2}$ spent fuels. The sequence contains a set of instructions designed to automatically process input data, execute code modules currently available in SCALE for depletion, resonance cross section, and criticality calculations. In addition, for burnup loading curve analyses, STARBUCS checks whether $k_{\text {eff }}$ converges to a userprovided upper subcritical limit, adjusts the initial fuel enrichment using the least squares method, and repeats the sequence until either convergence is achieved or determine that no solution can be found. The overall program structures and flow for a single criticality calculation and for burnup loading curve calculations are illustrated in Figure 2.3.1 and Figure 2.3.2, respectively.

The sequence uses well-established code modules currently available in the SCALE code system. These modules include ARP and ORIGEN to perform the depletion analysis phase of the calculations. ORIGEN-ARP is a sequence within the SCALE system that serves as a faster alternative to the TRITON depletion sequence of SCALE to perform point-irradiation calculations with the ORIGEN code using problem-dependent cross sections. ARP uses an algorithm that enables the generation of cross-section libraries for the ORIGEN code by interpolation over pregenerated cross-section libraries. The ORIGEN code performs isotopic generation and depletion calculations to obtain the spent fuel nuclide compositions. For criticality safety calculations using multigroup cross-section data, problem dependent cross sections are processed with the resonance self-shielding capabilities of XSProc using the regiondependent compositions from the depletion analyses. Finally, the region dependent nuclide concentrations and cross sections are applied in a 3-D criticality calculation for the system using either KENO V.a or KENO-VI to calculate the $k_{\text {eff }}$ value.

The ORIGEN-ARP depletion analysis methodology represents a significant increase in computational speed as compared to equivalent calculations performed using the SCALE depletion analysis sequences that use two-dimensional transport methods, with virtually no sacrifice in accuracy. ARP uses an algorithm that enables the generation of cross-section libraries for the ORIGEN code by interpolating on cross sections available in pre-generated data libraries. For uranium-based fuels the interpolation parameters available are initial fuel enrichment, burnup and, optionally, moderator density. STARBUCS creates input files for ARP and ORIGEN for each burnup-dependent region of an assembly and calculates the spent fuel nuclide concentrations for the region using a user-specified assembly irradiation history, cooling time, and burnup profiles. The ARP cross-section libraries must be available in advance of a STARBUCS burnup-credit calculation. These libraries may be created using TRITON. The ARP libraries include the effects of assembly design and operating conditions on the neutron cross sections used in the burnup analysis. Several ARP libraries are distributed in the SCALE code system and can be applied in a STARBUCS analysis. Alternatively, a user may create a specific ARP library for other assembly types or operating conditions not available in the default libraries. The generation of ARP libraries is discussed in ORIGENARP's Appendix A.

The depletion phase of the analysis is performed using ARP and ORIGEN to calculate the compositions of each discrete fuel region (axial or horizontal). After a single ORIGEN-ARP depletion calculation is completed, control is passed back to the STARBUCS module which reads the spent fuel nuclide inventories generated by ORIGEN, saves them, prepares the ARP and ORIGEN input files for the next burnup region, and executes the codes in sequence. This cycle continues until the fuel compositions for all axial and horizontal regions have been calculated and saved, completing the depletion phase of the analysis. The depletion calculations for each axial and radial zone are performed using an initial fuel basis of 1 MTHM ( $10^{6} \mathrm{~g}$ heavy metal).

After all depletion calculations are completed, STARBUCS reads the spent fuel nuclide inventories for all regions and prepares input for the criticality calculation. The concentrations of all nuclides in the

ORIGEN depletion analysis are converted from gram-atom units (per MTU) to units of atoms/b-cm applied in the criticality calculation. The criticality calculation is performed using the capabilities in the CSAS5 or CSAS6 control module of SCALE. Specifically, STARBUCS prepares input for the CSAS5 module when criticality calculations are to be performed using KENO V.a, and for the CSAS6 sequence when using KENO-VI. Note that only the criticality safety sequence CSAS5 of SCALE can be used for burnup loading curve calculations.

For burnup loading curve iterative calculations, STARBUCS employs the search algorithm described in CSAS5 section on Optimum (Minimum/Maximum) Search to determine initial fuel enrichments that satisfy a convergence criterion for the $\mathrm{k}_{\text {eff }}$ of the spent fuel configuration. If convergence is not achieved in a search pass, the initial fuel enrichment is automatically adjusted. This sequence repeats until either $\mathrm{k}_{\text {eff }}$ converges to an upper subcritical limit or until the algorithm determines that a solution is not possible. The procedure is repeated for each requested burnup value. The maximum allowable iterations, upper subcritical limit, tolerance for convergence, and a range of initial fuel enrichments can be set by the user. The lower and upper enrichment bounds as well as the burnup values for spent fuel regions must be contained within the range of enrichment and burnup values used to generate the applicable ORIGENARP library. The control module prepares a STARBUCS input file for each search pass requesting a single criticality calculation using the calculated spent fuel compositions. In this input file, the burnup history data block and/or the fuel mixture compositions are updated based on the outcome of the search sequence. The pre-burnup compositions for the two minor uranium isotopes, ${ }^{234} \mathrm{U}$ and ${ }^{236} \mathrm{U}$, are updated in the STARBUCS input file for a new pass only if they were included in the initial input file prepared by the user. Their updated weight percentages are based on the assumption that the mass ratios ${ }^{234} \mathrm{U} /{ }^{235} \mathrm{U}$ and ${ }^{236} \mathrm{U} /{ }^{235} \mathrm{U}$ do not change with fuel enrichment.

STARBUCS

Figure 2.3.2. Modules and flow of STARBUCS sequence for burnup loading curve calculations.

### 2.3.3 Capabilities and Limitations

STARBUCS is designed to facilitate criticality safety analyses employing burnup credit by automating and linking the depletion and criticality calculations. The STARBUCS sequence has been designed to readily allow analysts and reviewers to assess the subcritical margins associated with many of the important phenomena that need to be evaluated in the context of the current regulatory guidance on burnup credit. However, STARBUCS is sufficiently general to allow virtually any configuration involving irradiated nuclear material to be analyzed. Limitations and some of the key capabilities of the STARBUCS sequence are described below.

1. STARBUCS limitations include the use of a single $\mathrm{UO}_{2}$ fuel type and, for analyses employing multigroup cross-section data, the use of geometry configurations consisting of spent fuel rod arrays. However, the type of spent fuel configurations that can be analyzed is entirely general. STARBUCS can be used to perform criticality safety assessments of individual fuel assemblies, a spent fuel cask, a spent fuel storage pool, or any nuclear system containing $\mathrm{UO}_{2}$ irradiated nuclear fuel.
2. Only the criticality safety sequence CSAS5 of SCALE can be used for burnup loading curve calculations; therefore KENO V.a geometry description must be available in a STARBUCS input file for burnup loading curve calculations.
3. Burnup calculations can incorporate any desired operating history. The user may enter the specific power, cycle lengths, cycle down time, post-irradiation cooling time, etc. The axial-water-moderator density variation may also be specified in the depletion analysis, provided the ARP cross-section library contains such data.
4. The effects of assembly design, soluble boron concentrations, burnable poison exposure, reactor operating conditions, etc., are accounted for in the ARP (Automatic Rapid Processing) cross-section libraries used in the ORIGEN depletion calculations. Libraries for several fuel assembly designs are distributed with SCALE. These libraries can also be readily created for any reactor and fuel assembly design that can be represented in the depletion analysis sequences of the SCALE system.
5. The user can select the specific actinide and/or fission product nuclides to be included in the criticality safety analysis. The user also has the option to perform a criticality calculation employing all nuclides for which cross-section data exist.
6. Isotopic correction factors may be input to adjust the calculated nuclide inventories to account for known bias and/or uncertainties associated with the depletion calculations.

Minimal user input is required to perform many types of analyses. Default values are supplied for many of the input parameter keywords. The user may select from built-in burnup-dependent 18 -axial-zone profiles taken from Ref. 2, or the user may input an arbitrary user-defined burnup distribution with up to 100 -axial zones and up to 7 -horizontal zones. The depletion analysis calculations for each zone are performed for all nuclides (the ORIGEN data libraries contain cross-section and decay data for more than 1000 unique actinides, fission products, and structural activation products). The specific nuclides to be considered in the $k_{\text {eff }}$ analysis may be input by the user. If no nuclide set is explicitly selected, then all nuclides that have cross-section data in the ORIGEN library are automatically applied in the criticality analysis, resulting in a "full" burnup-credit criticality assessment. A capability to adjust the calculated isotopic inventories using correction factors that can account for biases and/or uncertainties in the calculated isotopic concentrations is also provided.

An appropriate ARP cross-section library for $\mathrm{UO}_{2}$ fuel must be available for the depletion analysis using STARBUCS. The user may use the libraries distributed with SCALE (e.g., ge $7 \times 7-0$, ge $8 \times 8-4$, ce $14 \times 14$, w15 $\times 15$, w17 $\times 17$ _ofa) or the user may generate their own problem-specific libraries using the TRITON depletion analysis sequence available in SCALE. A complete list of ARP libraries distributed with SCALE and methods for generating ARP libraries are both described in ORIGENARP's Appendix A. The range of initial fuel enrichment and requested burnup values to be used in the STARBUCS calculations must be contained within the range of the enrichments and burnups used to generate the applicable ARP cross-section library.

The user is required to provide a complete KENO V.a model of the spent fuel configuration for burnup loading curve calculations and a complete KENO V.a or KENO-VI model of the spent fuel configuration for single criticality calculations using burnup credit. The initial material composition information is defined in a standard composition data block. The fuel material is automatically depleted in the sequence for each of the burnup-dependent regions or zones in the problem. The nuclide concentrations after irradiation and decay are automatically applied to the KENO criticality analysis. The mixture numbers for each of the fuel regions are identified by unique mixture numbers assigned automatically by

STARBUCS based on the axial and horizontal region in the problem (see Figure 2.3.3). The user is required to specify the geometry/extent of the axial and horizontal zones in the KENO model and apply the appropriate mixture numbers for the desired configuration based on the mixture identifying scheme. STARBUCS performs no checking of the criticality model to verify that all mixtures in the problem have been used or that the order of the mixture numbers in the KENO model corresponds to the corresponding order of the input burnup profile. This provides the user a great deal of flexibility in setting up problems. However, it also requires that the user accurately prepare the input files to ensure that the spent fuel zone mixtures are assigned to the correct KENO V.a or KENO-VI geometry regions. For instance, the user could (intentionally) reverse the order of the axial-material identifiers in the KENO model to simulate inverted fuel, or zone mixtures could be omitted to simulate a problem using only a subset of the available fuel zones that were simulated in the depletion analysis.

Fuel mixture numbers
Mixture numbers available for additional geometry materials
Moderator mixture numbers
Gap mixture numbers
Clad mixture numbers

Figure 2.3.5. Example of mixture numbering scheme used in STARBUCS.

There are several conventions that must be followed when using STARBUCS. In general, these relate to the specification of materials and mixture numbering of the cross-section mixing table.

1. The maximum number of horizontal zones is restricted to seven if there is no gap or second moderator mixture, six if a gap or second moderator mixture is defined, and five if both a gap and a second moderator are defined. The number of axial-fuel zones is limited such that the product of horizontal zones $*$ axial zones is less than or equal to 100 . These limits constrain the maximum mixture number used for burned fuel in the KENO criticality calculation to less than 1000 and assign unique mixture numbers to clad, moderator, and gap mixtures for lattice cell descriptions. The convention used to number the depleted fuel zones is to start at mixture 101 and increment by 1 for each axial-burnup region. Thus, for a case with 10 axial-burnup regions, the fuel mixtures used in the criticality analysis would range from 101 to 110. For a similar case having two horizontal zones in addition to the axial zones, the mixture numbers would also include mixtures 201 to 210.
2. Mixture numbers for the clad, gap (if applicable), and moderator may also be used directly in the KENO model. Additional unique mixture numbers are required by the code for the lattice cell
descriptions for each separate fuel zone (except for mixture 0 for void). These additional mixtures are assigned automatically by the code and are shown in Figure 2.3 .3 for a lattice cell consisting of fuel, gap, clad, and moderator. The additional mixture numbers may also be used directly in the KENO model. Mixture number allocation is illustrated in Figure 2.3 .5 for an example case where the number of different horizontal zones is four and the maximum number of axial zones is limited to 25 .
3. All structural materials in the problem must have mixture numbers different from the numbers automatically generated by the code (see Figure 2.3.5 for an example of available mixture numbers). For the example shown in Figure 2.3.5, mixtures 5-100, 126-200, 226-300, 326-400, 501, 601, 701, 426-500, and 801-2147 are not allocated by STARBUCS and may be defined by the user in the composition data block and used in the geometry model. If the constraints in paragraph 1 are followed, mixture numbers less than 100 that were not used for fuel, gap, clad, moderator and mixture numbers from 1001 to 2147 are always available for structural materials. Note that STARBUCS does not provide a warning or stop program execution if a mixture number assigned to a structural material has also been generated internally by the computer code. The mixture numbers for structural materials are not changed and are thus applied in the KENO model in a one-to-one correspondence with the standard composition mixture as done for typical CSAS calculations. Therefore, the use of a mixture number for structural materials that is identical to one of the mixture numbers automatically generated by the code results in the combination of both materials in the composition for the mixture number.
4. Not all SCALE standard composition alphanumeric names (see the Standard Composition Library chapter) are currently recognized by STARBUCS. The use of special materials (e.g., C-GRAPHITE, NIINCONEL, H-POLY), particularly as fuel materials, that have nuclide identifiers that are not readily translated to ORIGEN ZA numbers should be avoided since these materials cannot be depleted.
5. A single STARBUCS calculation is limited to a single initial fuel type (composition, enrichment, assembly design, etc.). Configurations involving multiple fuel types may be solved by running a separate STARBUCS case for each type, saving the corresponding CSAS cases generated by STARBUCS that contain the irradiated fuel nuclide compositions, and manually merging the cases in such a way that all required fuel types are represented in the final case.

### 2.3.4 Input Description

STARBUCS input is divided into different data blocks containing related types of information. The standard composition data block used to define initial (fresh) fuel composition and all other materials in the criticality analysis problem, is read and processed by the Material Information Processor of SCALE and conforms to the standard input conventions (see Chapter M7). In addition to the standard composition data, three more input data blocks are required by STARBUCS. The data blocks are entered in the form

## READ XXXX input data END XXXX

where $\mathbf{X X X X}$ is the data block keyword for the type of data being entered. The types of data blocks that are entered include general control parameter information, irradiation history and decay data or search parameter data, and the KENO V.a or KENO-VI input specifications. The valid block keywords for a single criticality safety calculation using burnup credit and for burnup loading curve calculations are listed in Table 2.3.2 and Table 2.3.3, respectively. A minimum of four characters is required for most keywords. The exception is the criticality model input data block READ KENOVA or READ KENOVI
in which case the code must check additional character positions to determine the CSAS control sequence to be executed. The keywords can be up to twelve characters long, the first four of which must be input exactly as listed in the table. Entering the words READ XXXX followed by one or more blanks activates the data block input. All input data pertinent to block XXXX are then entered. Entering END XXXX followed by two or more blanks terminates data block XXXX.

Table 2.3.1. Valid data block keywords for a single criticality safety calculation using burnup credit

| Data block type | Block keyword |
| :--- | :--- |
| Control parameters | CONTROL |
| Burnup history | HISTORY or BURNDATA |
| KENO V.a input | KENOVA or KENO5 |
| KENO-VI input | KENOVI or KENO6 |

Table 2.3.2. Valid data block keywords for burnup loading curve calculations

| Data block type | Block keyword |
| :--- | :--- |
| Control parameters | CONTROL |
| Search parameters | SEARCH |
| KENO V.a input | KENOVA or KENO5 |

All input within a data block is entered using keywords and is free format. Keyword entries may be of variable or array type. Variable keyword entries include the keyword plus the "=", followed by the value. Array keywords are usually followed by a series of entries, each separated by a blank or comma, and must always be terminated with an END that does not begin in column one. In some instances a single value may be input as an array entry; however, the word END is still always required. Within a given input data block the keyword entries may be in any order.

A single data entry may be entered anywhere on a line but cannot be divided between two lines; however, array data entries may be divided over many lines. The code identifies data keywords using only the first four (maximum) characters in the keyword name. Beyond the first four characters, the user may enter any alphanumeric or special character acceptable in FORTRAN, including single blanks, before the "=" character. Floating-point data may be entered in various forms; for example, the value 12340.0 may be entered as: $12340,12340.0,1.234+4,1.234 \mathrm{E}+4,1.234 \mathrm{E} 4$, or $1.234 \mathrm{E}+04$. Also, the value 0.012 may be entered as $12 \mathrm{E}-3,12-3,1.2-2$, etc. Numeric data must be followed immediately by one or more blanks or a comma.

### 2.3.4.1 Overview of input structure

An overview of the input to the STARBUCS sequence is given in Table 2.3.3. This table provides an outline of the input data block structure. The input data in positions 1 to 5 (see Table 2.3.3) are read and processed by the Material Information Processor of SCALE. These are the first data read by the code and
must be in the order indicated. Data positions 6, 7 or 8 , and 9 are read directly by STARBUCS and may be entered in any order.

Table 2.3.3. Outline of input data for the STARBUCS sequence

| Data <br> position | Type of data | Data entry | Comments |
| :---: | :--- | :---: | :--- |
|  | Sequence name | =STARBUCS | Start in column one |

### 2.3.4.2 Sequence specification card

The STARBUCS analytical sequence is initiated with "=STARBUCS" beginning in column 1 of the input. This instructs the SCALE driver module to execute the STARBUCS sequence. The input data are then entered in free-format. The input is terminated with the word "END" starting in column 1. An "END" is a special data item, which may be used to delimit an input data block, end an array of input items, and terminate the input for the case. In the context of input data blocks, the "END" has a name or label associated with it. An "END" used to terminate an array of entries must not begin in column 1 as this instructs the SCALE driver to terminate input to the sequence.

### 2.3.4.3 Optional sequence parameters

To check the input data, run STARBUCS and specify PARM=CHECK or PARM=CHK after the analytical sequence specification as shown below.
$=$ STARBUCS $\quad$ PARM $=\mathrm{CHK}$
Other optional input for the PARM field to control multigroup resonance self-shielding calculations are described in the XSProc section of this manual.

### 2.3.4.4 XSProc

The XSProc is used to read and process the standard composition specification data that define the initial compositions of the fuel and all structural materials in the problem, into mixing tables and unit cell geometry information that are used by STARBUCS. All composition data required for the problem are entered as standard composition entries. A detailed description of this portion of the input can be found in the section on XSProc. Only one $\mathrm{UO}_{2}$ fuel type is permitted in STARBUCS. Therefore, a single fuel mixture defining the fresh fuel composition and, for criticality safety calculations employing multigroup cross sections, the geometry description of a single fuel lattice cell are required in a STARBUCS input file.

### 2.3.4.5 Control parameter data

The control parameter data block allows the user to specify control parameters and array data related to many of the burnup-credit analysis parameters to be used in the problem. All input is by keyword entry. All keywords are three-character identifiers that must be followed immediately by an equals sign ("="). The keywords may be in any order within a data block. Input to the parameter data block is initiated with the data block keywords READ CONTROL (only first four characters of block name are required). The data block is terminated by the keywords END CONTROL.

The types of control parameter data that may be input are summarized in Table 2.3.4. The individual keyword entries are described below.

1. $\mathrm{ARP}=\mathrm{NAME}$ OF THE ARP LIBRARY TO BE USED. A character string with the name of the ARP library to be used in the depletion calculation. This is a required entry. The library must be defined in the SCALE text file ARPDATA.TXT that contains the cross-section library names and interpolation data used by ARP. A description of an ARP input and the location of the ARP cross-section libraries are provided in ARP Input Description
located in the ORIGENARP chapter. STARBUCS calculations are limited to $\mathrm{UO}_{2}$ spent fuels.
2. NAX $=$ NUMBER OF AXIAL ZONES. This is the number of axial-burnup subdivisions. For a user-input profile the value of NAX is determined automatically by the code, and the NAX keyword is optional, provided the AXP= array has been entered. The maximum value of NAX must be chosen such that due product of NAX * NHZ is less than or equal to 100 (i.e., $\mathrm{NAX}_{\text {max }}$ is $100,50,33,25,20,16$, or 14 when the number of horizontal zones is $1,2,3,4,5,6$, or 7 , respectively). By default, the profile is automatically normalized to unity by the code unless NPR=NO. Built-in burnup-dependent 18 -axial-zone profiles may be selected with an entry of -18 . These built-in profiles and the burnup range over which they are applied, are listed in Table 2.3.5. These profiles have been proposed elsewhere (Ref. 2) as bounding axial profiles and are included as options for convenience only. The default value of NAX is -18 (use built-in profiles).
3. NHZ $=$ NUMBER OF HORIZONTAL ZONES. This is the number of horizontal-burnup subdivisions in the assembly. An optional entry if no horizontal profile is requested. The maximum value is seven zones. The exact limit is determined by the number of mixtures defined in the lattice cell description. If a gap and second moderator type are used the number of horizontal zones is limited to five.
4. NUC $=$ BURNUP-CREDIT NUCLIDES used in the criticality calculation. A list of actinides and/or fission products that are to be included in the KENO criticality safety calculation. This is an array entry keyword and is delimited by the keyword END. The nuclides are entered using their standard composition alphanumeric names, as listed in the Standard Composition Library chapter of the SCALE manual. Isotopic correction factors may be entered, optionally, immediately following the nuclide name. The isotopic correction factors will be multiplied times the spent fuel nuclide concentrations to account for isotopic composition bias. The concentration of any nuclide that does not have a correction factor is not adjusted. To select all available actinide and fission product nuclides (with cross-section data and atom densities greater than $1.0 \mathrm{E}-29$ ) for the criticality calculation, the user may select NUC= ALL, without an END terminator. This is the only situation where an array entry does not require an END. The available nuclides for this entry are included in the ORIGEN data library and the format of the library is documented in Decay Data Library of the ORIGENLIB chapter.
5. FLE $=$ FUEL LIGHT ELEMENT NUCLIDES. A user-provided list of light element nuclides that are to be included in the irradiated fuel compositions for a CSAS5 or a CSAS6 calculation. This is an array entry keyword and is delimited by the keyword END. The nuclides are entered using their standard composition alphanumeric names, as listed in Standard Composition Library chapter of the SCALE manual. To select all available light element nuclides (with cross-section data and atom densities greater than $1.0 \mathrm{E}-29$ ) for the criticality calculation, the user may specify FLE= ALL, without an END terminator. This is the only situation where an array entry does not require an END. The available nuclides for this entry are included in the ORIGEN data library and the format of the library is documented in Decay Data Library of the ORIGENLIB chapter. The use of the keyword FLE is not required if only o-16 is to be included in the composition of irradiated uranium oxide fuel pellets. For these material mixtures, $0-16$ will be automatically included in irradiated fuel compositions due to its significant concentration. Isotopic correction factors are not allowed for light element nuclides.
6. AXP $=$ AXIAL-BURNUP PROFILE. The user-supplied axial-burnup profile of the assembly to be used in the analysis. This entry is required unless use of the built-in burnup-dependent axial profiles shown in Table 2.3.5 is requested (NAX $=-18$ ). If NAX is set to anything other than -18 , the AXP array must contain NAX entries. Otherwise, the value of NAX is determined automatically by the code. By default (NPR=YES), the profile is automatically normalized by the code; this may be disabled by setting NPR=NO. If the burnup profile is normalized, it is implicitly assumed that the height/volume of each axial region is uniform when determining the average fuel burnup (i.e., the burnup of each axial region is equally weighted). The user is cautioned that if fuel region subdivisions of unequal volume are used, normalization should not be applied and the user must ensure a correct correspondence between the axial-profile input and the axial regions specified in the criticality calculation. AXP is an array entry and must be delimited by an END that must not start in the first column.
7. HZP $=$ HORIZONTAL-BURNUP PROFILE. An optional array entry used to specify a burnup gradient across assemblies. The elements of the array are the ratios of the burnups of horizontal subdivisions in the assembly to average assembly burnup (entry for the POWER= keyword described in Sect. 2.3.5.6). If NHZ is input, the HZP array must contain NHZ entries delimited by an END that must not start in the first column. Otherwise, the value of NHZ is determined automatically by the code. The profile will be normalized if NPR=YES (default). Sample problem 5 illustrates use of this option.
8. FIX $=$ FIXED ASSEMBLY POWER OPTION. Option to select a constant specific power level for the depletion analysis for all axial and horizontal zones of the assembly. For FIX=YES, the depletion analysis for all zones is performed using the specific power input in the power history data block for the POWER= keyword. The irradiation time is adjusted to achieve the desired burnup. The default of FIX=NO applies a variable power for all zones and a constant irradiation time as defined by the BURN= keyword.
9. NPR= NORMALIZE PROFILE. Option to control whether the user input axial- and horizontalburnup profiles will be normalized. The input profiles are automatically normalized using NPR=YES (default). If fuel region subdivisions of unequal volume are used, NPR=NO should be specified.
10. MOD $=$ AXIAL MODERATOR DENSITY. This is an array entry keyword and is delimited by the keyword END. The array dimension is equal to the number of axial zones (NAX entry) and the array values are provided in the same order as the AXP array elements. This input array is required only if the applicable ARP library contains variable moderator density cross sections.
11. BUG= DEBUG PRINT OPTION. BUG=YES will print program debugging variables and arrays in STARBUCS. The default is BUG=NO.

Table 2.3.4. Table of control parameter data

| Keyword name | Data type | Default value | Comments |
| :---: | :---: | :---: | :---: |
| READ CONTROL |  |  | Initiate reading the control parameter block of data |
| ARP $=$ | Character | None | Name of the ARP library to be used. Required. Library must be defined in SCALE text file ARPDATA.TXT. |
| NAX $=$ | Integer | -18 | Number of axial-burnup subdivisions in fuel assembly. The value of NAX is determined automatically if an axial profile is input using AXP= entries. The maximum value of NAX is 100 . Default value ( -18 ) applies a built-in 18 -axial-region-burnup profile. |
| NHZ= | Integer | 1 | Number of horizontal-burnup subdivisions. Maximum value of $5-7$ zones (see Sect. 2.3.5.5). No entry is required if horizontal profile is not used. |
| NUC= | Character and real mixed array ${ }^{a}$ | None | List of burnup-credit nuclides, and optionally the corresponding isotopic correction factors, to be included in the criticality calculation. Array entry generally delimited by END, unless ALL is selected. Nuclides are input using their standard composition alphanumeric identifiers. |
| FLE= | Character array ${ }^{\text {a }}$ | o-16 | List of light element nuclides to be included in the criticality calculation. Array entry generally delimited by END, unless ALL is selected. Nuclides are input using their standard composition alphanumeric identifiers. |
| AXP= | Real array ${ }^{\text {a }}$ | See NAX | Axial-burnup-profile array. Required if NAX $>0$. NAX entries that define the axial-burnup shape. The profile is automatically normalized if NPR=YES (default). Delimited by END. |
| HZP= | Real array ${ }^{\text {a }}$ | None | Horizontal-burnup-profile array. Required if NHZ > 1. <br> Array containing NHZ entries that define the horizontal, or radial, burnup profile for the analysis. Array is automatically normalized by the code. Delimited by END. |
| MOD= | Real array ${ }^{\text {a }}$ | None | Axial-moderator density, applied in the fuel depletion analysis. Note that MOD= is required only if the ARP library contains variable moderator density cross sections. NAX entries ordered as AXP= array. Delimited by END. Moderator density default values are not available in STARBUCS for variable moderator density cross sections. |
| FIX $=$ | Character | NO | Option to select a constant specific power level for all axial and horizontal zones of the assembly using FIX=YES. |
| $\mathrm{NPR}=$ | Character | YES | Option to normalize user-input axial- and horizontal-burnup profiles. Default is to automatically normalize profiles. |
| BUG= | Character | NO | Optional debug printout with BUG=YES. |
| END CONTROL |  |  | End of the control parameter block of data |

[^3]Table 2.3.5. Built-in burnup-dependent axial profiles, NAX=-18 from Ref. 2)

### 2.3.4.6 Burnup history data

The burnup history data block defines the irradiation history for the assembly. These data are entered by keyword. The keywords are summarized in Table 2.3.6. Only the first four characters of the keywords are required (i.e., any characters after the first four characters are optional). A minimum of two entries are required for each cycle, (1) the average assembly power (POWER=) and (2) the irradiation time ( $\mathrm{BURN}=$ ). The decay time ( $\mathrm{DOWN}=$ ), if any, at the end of the cycle, and the number of cross-section libraries (NLIB=) are optional. The word END is required to delimit the entries for each cycle. The entries within a given cycle may be in any order.

The burnup history data block reading is initiated with the keywords READ HISTORY (or BURNDATA) and terminated by END HISTORY (or BURNDATA).

POWER= THE AVERAGE SPECIFIC POWER OF THE ASSEMBLY FOR THIS CYCLE. The units of the specific power are in MW/MTU (W/g) of initial uranium. The axial and horizontal profiles are multiplied by the specific power to achieve the desired spatially-dependent
burnup profiles for the assembly when FIX=NO (default). If FIX=YES, the specific power input using this keyword is assumed to be uniform over all fuel regions (axial and horizontal) and the code will adjust the irradiation time to obtain the desired burnup for each region.

BURN= THE IRRADIATION TIME FOR THIS CYCLE. The cycle irradiation time in days.
DOWN $=$ CYCLE DOWN TIME. An optional entry to specify the down time, in days, at the end of an irradiation cycle. The down time is simulated as an irradiation time step of effectively zero power after the irradiation cycle. The down time for the last cycle is simulated as a separate ORIGEN decay case with nine equally-spaced time steps. If a negative down time is input, the time steps are spaced logarithmically.

NLIB= LIBRARIES PER CYCLE. An optional entry to request multiple cross-section libraries during a depletion cycle. If requested, the code automatically subdivides the cycle in NLIB segments of uniform duration and generates a separate library for the depletion analysis for each segment using ARP. Generating multiple libraries provides a more accurate representation of the time-dependent cross-section variation during the burnup analysis. Each segment of the cycle is assumed to have the same specific power, and no down time is assumed between each segment of the cycle.

END The word END is required to terminate the input for each cycle.
Repeat the above entries for each cycle to define the complete assembly power history.

Table 2.3.6. Table of power history data

| Keyword name | Data type | Default value | Comments |
| :---: | :---: | :---: | :---: |
| READ <br> HISTORY (or <br> BURNDATA) ${ }^{\text {a }}$ |  |  | Start of burnup history data block |
| POWER= | Real variable | None | Average assembly power for this cycle (MW/MTU) |
| BURN= | Real variable | None | Cycle irradiation time (days) |
| DOWN= | Real variable | 0 | End-of-cycle decay time (days). Optional. A negative down time may be used to select logarithmic decay time intervals for the last decay case. |
| NLIB/CYCLE= | Integer variable | 1 | Number of libraries to be applied in this cycle. Optional. If multiple libraries are requested for this cycle, the cycle is subdivided into equal time segments, and an updated library is generated for each segment. No down time is simulated between segments. |
| END |  |  | Required. Defines the end of the data for the current cycle. Repeat the above entries for each cycle in the irradiation history. An END, not to begin in column 1, must terminate each cycle definition. |
| END <br> HISTORY (or BURNDATA) ${ }^{a}$ |  |  | End block |

[^4]
### 2.3.4.7 Search parameter data

The search parameter data block defines input data for burnup loading curve analyses for commercial $\mathrm{UO}_{2}$ spent fuels. Burnup history input data are not allowed in an input file that supplies search parameters. A burnup history data block is generated in STARBUCS for subsequent iterative calculations using the initial user-supplied search parameter data. STARBUCS sample problem starbucs1.input contains a search data block to request burnup loading curve analyses for spent fuel at various burnups. The search data block reading is initiated with the keywords READ SEARCH and terminated by END SEARCH. The keywords are summarized in Table 2.3.7. These keywords may be in any order.

USL $=$ THE UPPER SUBCRITICAL LIMIT FOR BURNUP LOADING.
EPS $=$ TOLERANCE ON CONVERGENCE. The convergence criterion used in the search for initial fuel enrichment so that user-specified $k_{\text {eff }}$ value is within USL $\pm$ EPS. The tolerance value must be greater that the standard deviation of the calculated $\mathrm{k}_{\text {eff }}$ for the solution to converge.

ITMAX= MAXIMUM ITERATIONS ALLOWED FOR EACH ENRICHMENT SEARCH. The search for initial fuel enrichment stops when the number of iterations exceeds this parameter and a warning message is provided to the user.

ECL $=$ LOWER ENRICHMENT CONSTRAINT. The unit for this parameter is wt $\%{ }^{235} \mathrm{U}$. The lower enrichment constraint must be within the enrichment interval used in the ARP library specified in READ CONTROL data block.

ECH $=$ UPPER ENRICHMENT CONSTRAINT. The unit for this parameter is wt $\%{ }^{235}$ U. The upper enrichment constraint must be within the enrichment interval used in the ARP library specified in READ CONTROL data block.
$\mathrm{BU}=\quad$ ARRAY OF REQUESTED BURNUP VALUES (GWd/MTU). The word END is required to terminate this array. The user inputs a series of discharge burnup values for which the initial fuel enrichments that result in a desired $k_{\text {eff }}$ value (USL $\pm$ EPS) are to be determined.

AVGBU= AVERAGE BURNUP PER CYCLE (GWd/MTU). An optional entry used to determine the number of irradiation cycles as the ratio of a burnup value in the BU array to AVGBU.

POWER= THE AVERAGE SPECIFIC POWER OF THE ASSEMBLY. The units of the specific power are in MW/MTU (W/g) of initial uranium. This entry has the same function as the entry for POWER= keyword in the HISTORY data block (see Sect. 2.3.5.6). It is also used to determine cycle irradiation time as the ratio of a burnup value in the BU array to average assembly power.

FDT $=$ FRACTIONAL DOWNTIME. An optional entry used to determine down time between irradiation cycles (the entry for DOWN= keyword in the HISTORY data block) if fuel irradiation requires two or more cycles. For example, for a cycle with 365 days of irradiation followed by a 30-day downtime, FDT $=30 / 395=0.07595$. STARBUCS uses the userprovided FDT to compute cycle downtime as the irradiation time per cycle multiplied by FDT and divided by (1-FDT).

DEC $=$ DECAY TIME AFTER IRRADIATION. An optional entry to specify the decay time, in days, after fuel discharge. A negative value may be used to select logarithmic decay time intervals.

NLIB= NUMBER OF LIBRARIES PER CYCLE. An optional entry to request multiple crosssection libraries during a depletion cycle. Generating multiple libraries provides a more accurate representation of the time-dependent cross-section variation during the burnup analysis. Each segment of the cycle is assumed to have the same specific power.

FFE $=\quad$ FRESH FUEL ENRICHMENT. The purpose of this option is to help in reducing the total number of iterations needed to achieve convergence. There are two options implemented in STARBUCS for the fresh fuel enrichment value to be used in the first inner iterations over fuel enrichment, FFE=SEARCH (default) and FFE=INPUT. With the default option (FFE=SEARCH), the lower enrichment bound and the starting fresh fuel enrichment at the beginning of a search are adjusted based on the results of the previous outer iteration over burnup. The procedure includes the following steps. First, the user requested burnup values are sorted in ascending order so that STARBUCS outer iterations over burnup proceed from the lowest to the highest burnup value. Then, the initial fresh fuel for the lowest burnup is changed to the mid-value of the enrichment interval, (ECL+ECU)/2, and the search for the fresh fuel enrichment corresponding to the lowest burnup is initiated and completed. Suppose that a solution for this burnup step exists. This solution becomes the lower enrichment constraint (ECL) in the search passes for the next burnup value and the initial fresh fuel enrichment is chosen as the middle point of the enrichment interval. The procedure is applied for the entire set of the requested burnups. The average number of iterations for each burnup step with this option is approximately 4. The alternate option (FFE=INPUT) starts a search for fuel enrichment with the user supplied fresh fuel enrichment.

PRT= OUTPUT PRINT OPTION FOR BURNUP LOADING CURVE CALCULATIONS. The STARBUCS output file for default option (PRT=LONG) provides ARP, ORIGEN, and CSAS5 outputs for the last search pass for each of the burnup values in BU array in addition to STARBUCS summary information. The STARBUCS output file for option PRT=SHORT provides only summary information prepared by STARBUCS, such as fresh fuel enrichments for search passes, spent fuel compositions and the CSAS5 $k_{\text {eff }}$ result for each of the search passes, and a summary table providing burnup loading curve data, i.e., the fresh fuel enrichments that satisfy the user supplied convergence criterion for the requested burnup values.

Table 2.3.7. Table of search data

| Keyword Name | Data type | Default value | Comments |
| :---: | :---: | :---: | :---: |
| READ SEARCH ${ }^{a}$ |  |  | Initiate reading the search block of data. |
| USL= | Real | 1.0 | Upper subcritical limit. |
| EPS= | Real | 0.005 | Tolerance on convergence. |
| ITMAX $=$ | Integer | 10 | Iteration limit. |
| ECL= | Real | 1.5 | Lower initial fuel enrichment constraint (U-235 wt\%). |
| ECH= | Real | 5.0 | Upper initial fuel enrichment constraint (U-235 wt\%). |
| BU | Real ${ }^{\text {b }}$ | None | Array entry of requested burnup values (GWd/MTU). ${ }^{\text {c }}$ |
| AVGBU= | Real | 20.0 | Average burnup per cycle. |
| POWER= | Real | 25.0 | Average specific power (W/g). |
| FDT= | Real | 0.2 | Fractional downtime. |
| DEC= | Real | 1825.0 | Decay time (days). |
| NLIB= | Integer | 2 | Libraries per cycle. |
| FFE= | Character | SEARCH | Fresh fuel option. FFE=INPUT starts the outer iterations over the burnup values with user supplied fresh fuel composition. FFE=SEARCH helps in reducing the number of search passes (approximately 4 in average). |
| PRT= | Character | LONG | Print option. PRT=LONG generates STARBUCS summary output, ARP, ORIGEN, and CSAS outputs for the last search passes. PRT=SHORT generates only STARBUCS summary output. |
| END SEARCH |  |  | End of the search data |

${ }^{\text {a }}$ Only the first four characters are required.
${ }^{\mathrm{b}}$ Terminate array data entries with END. Do not place this END in column 1.
${ }^{\text {c }}$ There are no restraints on the maximum number of the burnup values requested in burnup loading curve calculations. A user may consider computer time and resources in assessing the maximum number of burnup values in this array.

### 2.3.4.8 KENO input data

The KENO input for the problem is specified in the KENO data block. Input to the data block is initiated with the data block keywords READ KENO or READ KENOVA and is terminated by the keywords END KENO or END KENOVA for criticality calculations using KENO V.a. Input to the data block is initiated with the data block keywords READ KENOVI or READ KENO6 and is terminated by the keywords END KENOVI or END KENO6 for criticality calculations using KENO VI. STARBUCS performs no error checking of the KENO input. The data within the data block delimiters is copied, without change, to the CSAS input file and executed. The user is therefore advised to ensure that the KENO input is free of errors by first running the case within CSAS5 or CSAS6 before applying the input in STARBUCS.

The input requirements for KENO V.a and KENO-VI are not described in this section, but are described in detail in the KENO chapter of this manual. This section describes only the input requirements as related to the execution of KENO within STARBUCS and the conventions used for module compatibility.

The mixture numbers for each of the non-fuel materials applied to the material regions of the KENO model are defined as the mixture numbers (MX) specified in the standard composition input. STARBUCS automatically defines the MIXTURE ID for each of the fuel regions according to the axial and/or horizontal zones defined by the NAX and NHZ entries in the burnup-profile arrays. The first axial-zone mixture is assigned $\mathrm{MX}=101$, and is incremented by one for each additional axial zone. Therefore, in a problem that defines 18 axial zones, spent fuel mixtures will be generated with identifiers that range from 101 to 118 . The correspondence of these mixtures to the assembly locations is determined by the ordering of the $\mathrm{AXP}=$ input array that defines the axial-burnup profile for the assembly. If the AXP= array orders the burnup profile from the bottom of the assembly to the top of the assembly, the resulting $\mathrm{MX}=101$ will correspond to the bottom axial-zone segment, and $\mathrm{MX}=118$ would correspond to the top axial zone. If multiple horizontal zones are defined, then the numbering sequence of the second horizontal zone will start at $M X=201$ and, in the example given here, would range up to $\mathrm{MX}=218$. Refer to Sect. 2.3.3 for limitations in the mixture-numbering scheme. The mixture-numbering scheme is illustrated in Figure 2.3.3.

### 2.3.5 Sample Problems

A series of example problems are presented to illustrate the application of STARBUCS to burnup-credit criticality safety and burnup loading curve analyses. Sample problem 1 is a simple pin-cell problem for burnup loading curve iterative calculations. The fuel pin contains a single axial-burnup zone (i.e., uniform-axial burnup). It is useful to illustrate the main features of the system and demonstrate functionality of the system modules within SCALE. Problem 2 illustrates the same problem with 18-axial burnup-dependent zones. Problem 3 extends the pin-cell model to an array of spent fuel assemblies residing in a water-filled pool. The models apply 18-axial-burnup-dependent zones. Problem 4 is a generic cask model, and this problem exercises more of the burnup credit options available in STARBUCS. Problem 5 illustrates the use of the horizontal-burnup option for a simple $4 \times 4$ array of spent fuel assemblies residing in water. Sample problem 6 uses KENO-VI to model a hexagonal VVER-440 fuel assembly.

### 2.3.5.1 Sample problem 1

Sample problem 1, listed in Table 2.3.8, defines a simple infinite $\mathrm{UO}_{2}$ pin-cell model with uniform-axial burnup for burnup loading curve calculations. The initial fuel enrichment is $2.0 \mathrm{wt} \%$. The control
parameter data block specifies that the standard Westinghouse (W) $17 \times 17$ ARP library is to be used for the depletion analysis. The burnup-credit criticality calculation uses a subset of the major actinides as defined in the NUC= array. The sample problem contains a "read search" data block, which provides an upper limit for subcriticality, usl, a tolerance value for the search algorithm, eps, the lower and upper enrichment bounds, ecl and ech, respectively, the maximum number of iterations for each burnup value requested, imaxl, average specific power in W/g, power, decay time after irradiation in days, dec, number of libraries per cycle, nlib, average burnup per cycle in GWd/MTU, avgbu, fractional downtime, fdt, and a set of burnup values, bu array.

### 2.3.5.2 Sample problem 2

Sample problem 2, listed in Table 2.3.9, illustrates a simple pin-cell model using 18-axial-burnupdependent zones. In this example, the built-in axial profiles for three burnup ranges are applied using the NAX $=-18$ option (see profiles in Table 2.3.5). STARBUCS determines the average assembly burnup from the power history data input, and automatically selects the appropriate profile based on the discharge assembly burnup. The axial-profile data were developed for a predefined axial-zoning structure (i.e., fraction of the assembly height). It is important that the KENO V.a geometry model therefore also reflect this axial-zone structure. That is, the height of each axial zone in the criticality model must conform to the axial zones for the profile applied in the analysis. In this example, the total pin height is 365.7 cm (144 in.), which is subdivided into 18 equal-height segments of 20.32 cm each.

The burnup-dependent cross sections generated for the criticality analysis have material identifiers ranging from 101 (bottom) to 118 (top). There is no constraint on how the fuel materials can be applied in the KENO V.a model. For example, the order of the material numbers could easily be reversed, which would effectively invert the profile and could be used to simulate an assembly loaded upside down. It is also not necessary to use all of the materials in the problem. For instance, all fuel regions in the KENO V.a model could be assigned the same fuel mixture number to represent a flat axial profile having a burnup value equal to that of the particular mixture used. The average assembly burnup would also be equal to that of the particular mixture used, and not that defined by the power history data block.

### 2.3.5.3 Sample problem 3

Sample problem 3, listed in Table 2.3.10, performs a burnup-credit criticality safety calculation using the SCALE 238-group ENDF/B-VI cross-section library (V6-238) for an array of Combustion Engineering (CE) $14 \times 14$ spent fuel assemblies in water. A subset of burnup-credit actinides and fission products are included in the criticality calculation. A user-supplied 18-axial-region-burnup profile of the assemblies is input. This profile was obtained from the axial-burnup-profile database ${ }^{3}$ for Maine Yankee assembly N863. Note that the axial profile will be normalized automatically by the code using NPR=YES (default). The normalization is performed such that the average value of the profile values is unity (i.e., the sum of the profile values is equal to the number of axial zones). The $3.3 \mathrm{wt} \%$ enriched $\mathrm{UO}_{2}$ fuel is assumed to achieve a discharge burnup of $37,626 \mathrm{MWd} / \mathrm{MTU}$ in three cycles of approximately $12.5 \mathrm{GWd} / \mathrm{MTU}$ per cycle and a downtime per cycle of 80 days, followed by a cooling time of 5 years after discharge ( 1826 days). An average assembly power level of $32 \mathrm{MW} / \mathrm{MTU}$ is used for the depletion calculation. Two libraries per cycle are requested during the depletion. Note that by increasing the number of libraries generated per cycle, the cross sections used in the burnup analysis are updated more frequently to reflect the changes that occur with burnup. The nominal CE $14 \times 14$ assembly design specifications were obtained from Ref. 4. The assembly pitch in the criticality calculations is 22.78 cm . A cross-section view of the assembly geometry, a $2 \times 8$ array of water reflected assemblies, is illustrated in Figure 2.3.6.

Figure 2.3.6. Plot of the CE $14 \times 14$ assembly array geometry in sample problem 3.

### 2.3.5.4 Sample problem 4

Sample problem 4, listed in Table 2.3.11, illustrates the application of STARBUCS for a criticality safety analysis of a burnup-credit cask. The cask geometry in this example is based on a 32 -assembly generic burnup-credit cask model and is illustrated in Figure 2.3.7.

The assemblies are assumed to be W $17 \times 17$ OFA assemblies with an initial enrichment of $4.98 \mathrm{wt} \%$. The standard composition description for this problem includes the fuel assembly and all cask structural material definitions. The analysis applies built-in 18-axial-zone profiles, and actinide-only burnup credit (i.e., only a subset of actinides and no fission products). The assembly is irradiated to an average burnup of about $50 \mathrm{GWd} / \mathrm{MTU}$. The axial-burnup profile is automatically selected by the code based on the average assembly burnup. Isotopic correction factors are applied to the calculated actinide inventories. The correction factors were obtained from Ref. 4. An axial-moderator density is also applied. Note that actual entries in the MOD= array are not realistic for a PWR and are only intended to illustrate the use of this feature. Since the ARP library applied in this calculation does not have variable moderator density, the values in the MOD= array have no effect on the calculation. The criticality evaluation of the cask is performed following a cooling time of 1826 days ( 5 years).

Figure 2.3.7. Cutaway view of the generic 32 -assembly burnup-credit cask showing the cask bottom half with a quarter of the model removed.

### 2.3.5.5 Sample problem 5

Sample problem 5, listed in Table 2.3.12, uses the CE $14 \times 14$ assembly design from problem 3, and performs a burnup-credit calculation using the horizontal burnup-profile option. The assembly configuration is taken to be a simple $2 \times 2$ assembly array with water reflection. This problem is only designed to illustrate the basic features of the horizontal profile option. In this example, it is assumed that there is a burnup gradient across the assemblies, such that half the fuel pins have a burnup exceeding the average assembly burnup by $10 \%$ and half the pins have a burnup of $10 \%$ less than the average, with the two burnup regions separated by the assembly diagonal. The input card required to simulate the two horizontal burnup regions in an assembly is

$$
h z p=0.91 .1 \text { end }
$$

STARBUCS applies these factors to calculate compositions for each of the horizontally-varying burnup regions in each zone of the problem. It is important to note that the option inherently assumes that there is an equal volume/mass of fuel in each of the horizontal (or axial) zones since the code weights all regions equally when determining the average assembly burnup. To illustrate this, consider modeling an assembly with only one quadrant having a burnup that is $10 \%$ higher than the other three quadrants. The user would enter data for each of the four horizontal assembly quadrants or zones, e.g.,

$$
\text { hzp }=0.97660 .97660 .97661 .0700 \text { end }
$$

such that the average of the HZP array entries is unity. This ensures that the average assembly burnup will be that specified in the power history data block. Note that this array is automatically normalized if

NPR=YES (default). However, the user could substantially reduce the computational time involved by specifying only two fuel regions, e.g.,

```
hzp= 0.9766 1.0700 end
```

and turning off the normalization option (e.g., NPR=NO). The normalization option must be turned off to prevent the profile from being altered (since the sum is not equal to 2 ). This allows the user to account for the fact that, in this scenario, there are three quadrants having a lower burnup (and consequently three times the mass) and just one quadrant having an elevated burnup compared to the average. However, it is the responsibility of the user to ensure that the profiles and the KENO V.a problem description produce the desired average burnup.

In this sample problem the four assemblies are aligned so the lower burnup regions of the assemblies are adjacent to one another to maximize the system reactivity. The assembly geometry showing the different burnup regions of the assemblies is illustrated in Figure 2.3.8. The criticality calculation is performed using the SCALE ENDF/B-VII continuous cross-section library (CE_V7).

Following the STARBUCS calculation, the KENO V.a geometry model could be readily altered to simulate other assembly configurations (e.g., shuffle the fuel assembly locations). The CSAS5 case could subsequently be executed as a standalone case since all of the material compositions have already been created during the initial STARBUCS run. This facilitates the rapid evaluation of different fuel configurations without the need to regenerate the material compositions using STARBUCS.

### 2.3.5.6 Sample problem 6

The last sample problem uses KENO-VI to model a hexagonal VVER-440 fuel assembly. In this example the axial burnup profile is simulated using five axial regions of non-uniform volume (height). In this case the profile input in the AXP= array is not normalized by the code (i.e., NPR=NO). The criticality calculation is performed using actinide credit only. The input file is listed in Table 2.3.13 and is the geometry is illustrated in Figure 2.3.9.

# 2.4 SOURCERER: DETERMINISTIC STARTING SOURCE FOR CRITICALITY CALCULATIONS 

D. E. Peplow, A. M. Ibrahim, K. B. Bekar, C. Celik, and B. T. Rearden

#### Abstract

The Sourcerer sequence in SCALE deterministically computes a fission distribution and uses it as the starting source in a Monte Carlo eigenvalue criticality calculation. Using a reasonably accurate starting source, developed from the Denovo discrete-ordinates code through the DEVC sequence, Sourcerer improves the KENO/CSAS Monte Carlo calculation in two ways. First, the number of skipped generations required to converge the fission source distribution in the KENO solution is reduced. Second, for problems with loosely coupled fissionable areas, the reliability of the final eigenvalue ( $k_{\text {eff }}$ ) is increased. Several convergence diagnostic capabilities available in the KENO codes help the user better measure when the fission source actually convergences.

### 2.4.1 Introduction

Monte Carlo eigenvalue calculations have been used in evaluating critical and sub-critical systems for decades. Calculations are typically done iteratively - starting with a set of fission neutrons, transporting them through the geometry until they leak or are absorbed, and then tabulating the fission sites for the next iteration. Each iteration corresponds to a generation in a chain reaction, and the eigenvalue, $k_{\text {eff }}$, is the ratio of the number of fissions in one generation to the number in the previous generation. Once the fission source distribution (the eigenfunction) has converged, many generations are simulated to obtain more estimates of $k_{\text {eff }}$ with lower statistical uncertainty.

Two common questions that concern practitioners are (1) how many generations (skipped generations) are required before the fission source distribution is sufficiently converged that generational estimates of $k_{\text {eff }}$ can be included in the final average of the eigenvalue (the active generations) and (2) has the fission source converged to the correct distribution, such that the final value of the eigenvalue will be correct? For most calculations, the final value of the $k_{\text {eff }}$ eigenvalue is all that matters, so the convergence of the generational value of $k_{\text {eff }}$ is used to determine the number of skipped generations. Fluxes and reaction rates computed during the active generations are more sensitive to the entire fission distribution and should only be accumulated when the fission distribution is sufficiently converged - which is not necessarily as soon as the generational value of $k_{\text {eff }}$ has converged. To address this concern, tools such as Shannon entropy ${ }^{1}$ can be used to measure the convergence of the fission source distribution eigenfunction. ${ }^{2,3}$

For the second question, the reliability in the final $k_{\text {eff }}$ eigenvalue depends on whether the fission source converges to the correct distribution. Because no tool currently exists in SCALE to verify that the fission distribution is correct, models are often run for many generations using many histories per generation to ensure that the result does not change. Another approach to verify eigenvalue accuracy is to run several clones of the same problem, but each starting with different random numbers seed, and ensure that they all predict the same value for $k_{\text {eff }}$. Addressing this concern relies heavily on the engineering judgment of the practitioner.

Initial studies ${ }^{4,5}$ have shown that the use of a starting fission distribution that is similar to the true fission distribution can both reduce the number of skipped generations required for fission source convergence and significantly improve the reliability of the final $k_{\text {eff }}$ result. A recent study ${ }^{6}$ focusing on criticality calculations of a spent nuclear fuel cask showed that the chance of a low eigenvalue result due to undersampling from an unconverged source was dramatically reduced when using a deterministic starting source. In that study, a cask holding 24 assemblies was examined using a uniform starting source, a deterministic starting source with loose convergence criteria, and a deterministic starting source with tight convergence criteria. Multiple clones of KENO were run (with different random number seeds) for different values of skipped cycles. The number of clones that gave an incorrect result for $k_{\text {eff }}$ was then tabulated. The results from that study, presented in Figure 2.4.1, show that using a deterministic starting source significantly increases the $k_{\text {eff }}$ reliability.

The Sourcerer sequence in SCALE uses the solution from the Denovo ${ }^{7}$ discrete-ordinates code (through the DEVC sequence) as that starting fission source distribution in a CSAS/KENO Monte Carlo ${ }^{8}$ calculation. For challenging criticality safety analyses, such as as-loaded spent nuclear fuel transportation packages with a mixed loading of low- and high-burnup fuel, even a low-fidelity deterministic solution for the fission source should be more accurate than the typical starting guesses of uniform or cosine shape over the fissionable regions. The Sourcerer sequence is fairly automated and uses an input very similar to standard CSAS (KENO V.a or KENO-VI) inputs, along with a short description of the mesh and other parameters for the Denovo calculation.

Figure 2.4.1. Fraction of failure to agree with the reference $\boldsymbol{k}_{\text {eff }}$ value for KENO calculations with different starting sources (Figure 4 from Ref. 6).

### 2.4.2 Capabilities

The Sourcerer sequence calls a series of other sequences and utilities in SCALE - most importantly DEVC (for Denovo) and one of the CSAS sequences. Because DEVC can only use KENO-VI geometry, the utility c5toc6 geometry converter is used for KENO V.a geometries. The utility dso2msl is used to convert the Denovo spatial output (*.dso file) into a mesh source lite (*.msl) file that can be read as a starting source in KENO. All of the steps in Sourcerer are described in Table 2.4.1.

The sequence can be terminated at several points throughout the calculation using the "parm=" control on the "=sourcerer" line that starts the sequence. This capability can be used to stop the sequence between steps to ensure that the problem is progressing correctly or used to make a single source distribution that can be used with many variants of the final CSAS problem. Also when running several versions of a problem, if a file that is normally created by the Sourcerer sequence is supplied, then that step will be skipped, thus saving time. Note that files that use the name of the input file (input.inp) will be copied back to the user's working directory automatically when the sequence finishes. Files that do not use the input file name can be copied back to the user's working area with an extra "=shell" directive in the input.inp input file.

The Sourcerer sequence can be used with KENO V.a or KENO-VI geometries. Either multi-group (MG) or continuous energy cross-section libraries can be used for the final CSAS calculation. Denovo only uses multi-group libraries, and self-shielding can be done like any MG sequence in SCALE. For efficient calculations, the user should understand the basics of Denovo eigenvalue calculations, how to use macromaterials, and how to use the KENO convergence metrics.

Table 2.4.1. Steps in Sourcerer for an input file named input.inp

| Step | Module/Task | Creates file | To stop after |
| :--- | :--- | :--- | :--- |
| 0 | Check user input | parm=check |  |
| 1 | c5toc6 - For KENO V.a sequences, the geometry is <br> translated into KENO-VI geometry. | input.geom0... <br> 00.inp |  |
| 2a | Create Denovo input and AMPX cross sections | xkba_b.inp <br> ft02f001 <br> input.mmt | parm=deninp |

### 2.4.2.1 Using DEVC/Denovo

Some discussion is required about the extent and level of detail needed in the grid geometry that will be used in the Denovo calculation and the mesh-based starting source. When using discrete-ordinates transport ( $\mathrm{S}_{\mathrm{N}}$ ) methods alone for solving radiation transport problems, a good rule of thumb is to use mesh cell sizes on the order of a mean-free path of the particle. For complex problems, this could lead to an extremely large number of mesh cells, especially when considering the size of the mean-free path of the lowest energy neutrons.

In Sourcerer, the goal is to use the $S_{N}$ calculation for a quick estimate. Accuracy is not paramount-just getting an approximation of the overall shape of the true fission source distribution will benefit the CSAS Monte Carlo calculation. With a more accurate starting source, fewer skipped generations may be required. At some point there is a time trade-off where calculating the starting source guess requires more time than the saved skipped generations would have used. Large numbers of mesh cells, as a result of using very small mesh sizes, for $\mathrm{S}_{\mathrm{N}}$ calculations also use a great deal of computer memory.

Because the $\mathrm{S}_{\mathrm{N}}$ calculation is only used to establish the initial distribution of source neutrons, the runtime and memory requirements for Sourcerer can be reduced by using larger/coarser mesh cell sizes than is typical for a stand-alone $\mathrm{S}_{\mathrm{N}}$ analysis. Some general guidelines to consider when creating a mesh for the Denovo eigenvalue calculation/mesh-based starting source are as follows.

- All fissionable areas of the geometry and areas where neutrons can reasonably affect the eigenvalue should be included in the mesh.
- More detail should be used in the fissionable areas.
- Mesh planes should be placed at significant material boundaries.
- Neighboring cell mesh sizes should not be drastically different.

### 2.4.2.2 Convergence Metrics in KENO

KENO provides several tools that can be used to examine the convergence of $k_{\text {eff }}$ and the fission source distribution. These include tools based on Shannon Entropy ${ }^{1,3}$ and tools based on the mesh tally metrics described in Ref. 9. Running Sourcerer should accelerate Shannon Entropy convergence for KENO calculations, and Sourcerer/KENO users should always check that the calculation Shannon Entropy has converged before active generations begin.

### 2.4.3 Sequence Input

The input file for a Sourcerer calculation is similar to a CSAS input, as shown in Table 2.4.2. There are two major differences between Sourcerer and CSAS: the beginning/end syntax of the CSAS input and the presence of the "read detSource" block for specifying the deterministic starting source. The CSAS input appears as one block in the Sourcerer sequence - instead of "=csasXX" use "read csasXX" and instead of "end data" use "end csasXX". If any parm= parameters are required for the CSAS sequence, they can be listed as "read csasX parm=(...)". Because Sourcerer runs both the DEVC and CSAS sequences, which will most likely use different cross-section data libraries (coarse group for $\mathrm{S}_{\mathrm{N}}$ and fine group or continuous energy for Monte Carlo), the library for DEVC is listed in the new "read detSource" block, along with other parameters used by the Sourcerer sequence.

One important note about the geometry in Sourcerer is that for KENO V.a geometries, an outer boundary region should be added for an accurate internal conversion to a KENO-VI geometry prior to ray tracing. Also note that when using CSAS methods with the search capability, the Denovo mesh must encompass any changes to the size of the geometry.

Parameters used for building the deterministic starting source and establishing the CSAS sequence are specified in the detSource block. The library name for the Denovo calculation and the grid for the Denovo calculations are required. Many optional parameters are available for controlling the Denovo solver and applying boundary conditions (in the eigenValParams sub-block). The grid geometry is defined in a sub-block, or the keyword "gridGeometryID=n" can be used to point to a grid geometry defined in its own input block. The use of macromaterials to construct a more representative mesh model from the Monte Carlo geometry is controlled with the "mmSubCell=" and "mmTolerance=" parameters in the macromaterial sub-block.

The overall layout of the detSource block is shown in Table 2.4.3. The more common keywords for the eigenValParams sub-block are shown in Table 2.4.4 and Table 2.4.5. A full list of the Denovo parameters appears in Appendix A. Macromaterials are explained in detail in the DEVC manual, and a list of keywords is given in Table 2.4.6.

Table 2.4.2. Input file for a Sourcerer calculation (and differences with a CSAS input file, where black text is the same as CSAS and green text is new for Sourcerer sequence)

```
=sourcerer parm=... Parm: check, deninp, denovo, csasinp
read csasXX the problem The CSASXX input (change "=csas" to "read csasXX")
    v7-252n
    read xxx
    end xxx
    read bounds
    end bounds
    read start
    end start
    read gridGeometry m
    end gridGeometry
    read xxx
    end xxx
end csasXX
read detSource
    dLibrary="..."
    dParmString="..."
    gridGeometry n
    end gridGeometry
    gridGeometryID=m
    macromaterial
            mmSubCells=3
            mmTolerance=0.1
    end macromaterial
    eigenValParams
    end eigenValParams
end detSource
end data
end
```

Table 2.4.3. The detSource block

| keyword | type | required | restrictions/comments |
| :---: | :---: | :---: | :---: |
| read detSource |  |  |  |
| For the preliminary Denovo calculation |  |  |  |
| dLibrary= | character | yes | multi-group library for Denovo calculation |
| dParmString= | character | no | any parameters for the DEVC parm=(). |
| gridGeometry id |  | yes* | covers a cuboid where all points are in defined regions |
| $x$ planes ... end | real array |  | adds list of $x$ plane values (order not important) |
| $x$ Linear $n$ min max | int real real |  | adds $n+1 \times$ planes ( $n$ cells) evenly from min to max |
| $y$ planes ... end | real array |  | adds list of $y$ plane values (order not important) |
| $y$ Linear $n$ min max | int real real |  | adds $n+1$ y planes ( $n$ cells) evenly from min to max |
| $z$ planes ... end | real array |  | adds list of $z$ plane values (order not important) |
| $z$ Linear $n$ min max | int real real |  | adds $n+1$ z planes ( $n$ cells) evenly from min to max |
| tolerance= make3dmap | real |  | for removing duplicate planes from *planes or *Linear makes a *.3dmap file showing the grid geometry |
| xdivide= | integer | no | once all xplanes are entered, further divide them by this |
| ydivide= | integer | no | once all yplanes are entered, further divide them by this |
| zdivide= | integer | no | once all zplanes are entered, further divide them by this |
| end gridGeometry |  |  |  |
| gridGeometryID= | integer | yes* | *either define a grid geoemtry in a sub block or refer to a grid geometry defined in its own block |
| macroMaterial |  | no | parameters for the macro material calculation to |
| end macroMaterial | end macroMaterial |  | create a more representative Denovo model |
| eigenValParams |  | no | parameters for eigenvalue Denovo calculation, including |
| ... |  |  | legendre=, quadrature=, tolerance=, |
| end detSource |  |  | kTolerance=, etc. |

Table 2.4.4. Common Denovo parameters in the eigenValParams sub-block

| keyword | type | default | restrictions/comments |
| :--- | :--- | ---: | :--- |
| eigenValParams |  |  |  |
| quadType= | integer | 2 | 0-level symmetric, 1-Gauss-Legendre product, 2-QR |
| legendre= | integer | 0 | $\mathrm{P}_{\mathrm{L}}, \mathrm{L}=$ highest Legendre polynomial, $\mathrm{L}=0,1,2,3, \ldots$ |
| quadrature= | integer | 8 | level symmetric $\mathrm{S}_{\mathrm{N}}$ quadrature, $\mathrm{N}=2,4,6,8,10,12,14,16$ |
| polarsPerOct= | integer | 2 | Gauss-Legendre product quadrature or QR |
| azimuthsPerOct= | integer | 2 | Gauss-Legendre product quadrature or QR |
| diagnostics= | integer | 0 | 0-no diganostics, 1-all diagnostics |
| output= | integer | 0 | 0-no ouput, 1-all output |
| tolerance $=$ | double | 1.E-04 | tolerance used in convergence test |
| toleranceMG= | double | 1.E-04 | tolerance used in convergence test |
| kTolerance= | double | $1 . \mathrm{E}-05$ | tolerance on k |
| diagnosticLevel= | integer | 0 | 0-off, 1-on |
| l2Tolerance= | double | 0.01 | tolerance on the L-2 norm |
| linfTolerance= | double | 0.001 | tolerance on L-inf |
| end eigenValParams |  |  |  |

Table 2.4.5. Boundary conditions in the eigenValParams sub-block

| keyword | type | default | restrictions/comments |
| :--- | :--- | :---: | :---: |
| eigenValParams |  |  |  |

| ymin= | integer | 0 | 1 - reflective |
| ymax $=$ | integer | 0 | 2 - periodic |
| zmin= | integer | 0 | 3 - white |
| zmax= | integer | 0 | (these will override the "read bounds" block if specified here.) |
| end eigenValParams |  |  |  |

Table 2.4.6. Macromaterial sub-block input

| keyword | type | length default | restrictions/comments |
| :---: | :--- | :--- | :--- |
| macromaterial <br> mmSubCell= <br> mmTolerance $=$ | integer <br> real | 1 | rays per dimension to throw at each voxel <br> smallest volume fraction for macromaterial |
| mmSubCells | integer | 6 | 0.01 |

### 2.4.4 Sequence Output

In addition to the data contained in the main Sourcerer text output file, many other files are created containing the intermediate data used by the sequence. These files are listed in Table 2.4.7. Some of the files produced can be viewed using the Java Mesh File Viewer, which is distributed with SCALE.

Note that files that use the name of the input file (input.inp) will be copied back to the user's working directory automatically when the sequence finishes. Files that do not use the input file name can be copied back to the user's working area with an extra "=shell" directive in the input.inp input file.

Instructions on how to use the Java Mesh File Viewer to view the various output files listed in Table 2.4.7 as well as how to use the macromaterial table file are located in the DEVC manual and the Mesh File Viewer help file, which is accessible through the Help/Help menu.

Table 2.4.7. Files created by Sourcerer for an input file named input.inp

| Filename | Viewer | Description |
| :---: | :---: | :---: |
| Output Summary input.out input.msg |  | main text output file, contains results summary messages file |
| Geometry Conversion <br> i_c5toc6 <br> input.geom000....inp |  | input file for c5toc6 module KENO-VI version of a KENO V.a geometry, if applicable |
| Denovo i_devc xkba_b.inp | $\mathrm{V}^{a}$ | input file for DEVC sequence <br> input file for Denovo - if this file is renamed to have a *.dsi extension (Denovo simple input), it is viewable in the Mesh File Viewer |
| ft02f001 input.dso input.mmt | $\begin{aligned} & \text { V } \\ & \text { V } \end{aligned}$ | AMPX formatted cross sections for Denovo Denovo fission source distribution macromaterial table, use with *.dso or *.dsi file |
| Mesh Source Conversion i_util input.msl | V | input file for dso2msl utility mesh source lite file, the starting source distribution |
| CSAS <br> i_csasXX <br> input.fissionSource.3dmap input.kenoNuBar.txt | V | input file for the final CSASXX sequence mesh tally of fission source distribution from KENO text file containing value of nu-bar |

${ }^{a} \mathrm{~V}$ - can be displayed with the Mesh File Viewer.

### 2.4.5 Sample Problems

In addition to the sample problems described in this section (with input files included with SCALE), the reader is referred to the paper by Ibrahim et al. ${ }^{10}$ for a detailed study using a real used nuclear fuel transport and storage canister containing assemblies with a range of initial enrichments and burnups.

### 2.4.5.1 Jezebel

Consider the Jezebel critical assembly [PU-MET-FAST-001 in Volume I of the International Handbook of Evaluated Criticality Safety Benchmark Experiments, NEA/NSC/DOC(95)03, Organisation for Economic Cooperation and Development, Nuclear Energy Agency (OECD-NEA), September 2012]. This is a very simple problem (a single sphere) to solve with CSAS and can be useful as a way to demonstrate the Sourcerer sequence.

### 2.4.5.1.1 Input File

The standard CSAS inputs for Jezebel are shown below using both KENO V.a and KENO-VI geometries.

The above inputs can be easily changed into the following Sourcerer inputs (with geometry additions in blue and extra Sourcerer input in green).

| KENO V.a geometry | KENO-VI geometry |
| :---: | :---: |
| =sourcerer | =sourcerer |
| read csas5 | read csas6 |
| Jezebel | Jezebel |
| v7-252n | v7-252n |
| read composition | read composition |
| pu-239 1000.037047 end | pu-239 1 0 0.037047 end |
| pu-240 100.0017512 end | pu-240 100.0017512 end |
| pu-241 100.00011674 end | pu-241 100.00011674 end |
| ga 100.0013752 end | ga 100.0013752 end |
| end composition | end composition |
| read parameters | read parameters |
| gen=110 npg=1000 nsk=10 | gen=110 npg=1000 nsk=10 |
| end parameters | end parameters |
| read geometry | read geometry |
| global unit 2 | global unit 2 |
| sphere 116.38493 | sphere 516.38493 |
| cuboid $017.0-7.07 .0-7.0$ 7.0-7.0 | media 1151 vol=1090. 3277 boundary 51 |
| end geometry | end geometry |
| end csas5 | end csas6 |
| read detSource | read detSource |

```
    dLibrary="v7-27n19g"
    gridGeometry 7
        xLinear 14 -7.0 7.0
        yLinear 14 -7.0 7.0
        zLinear 14-7.0 7.0
    end gridGeometry
end detSource
end data
end
```

```
```

    dLibrary="v7-27n19g"
    ```
```

    dLibrary="v7-27n19g"
    gridGeometry 7
    gridGeometry 7
    xLinear 14 -7.0 7.0
    xLinear 14 -7.0 7.0
    yLinear 14 -7.0 7.0
    yLinear 14 -7.0 7.0
    zLinear 14 -7.0 7.0
    zLinear 14 -7.0 7.0
    end gridGeometry
    end gridGeometry
    end detSource
end detSource
end data
end data
end

```
```

end

```
```

With either of these variations of the Jezebel problem, the fission source distribution can be tallied by KENO and saved to a mesh tally (*.3dmap) file by adding the following to the input:

```
read parameters
    cds=1
end parameters
read gridGeometry 1
    title="Mesh for collecting fission source distribution"
    xLinear 28 -7.0 7.0
    yLinear 28-7.0 7.0
    zLinear 28 -7.0 7.0
end gridGeometry
```

Note that the mesh grid used for the KENO mesh tally can be different from the mesh grid used by Denovo to create a starting source in the Sourcerer sequence. Also note that more total histories (more particles per generation or more active generations) would be required to produce a KENO fission source tally with low relative uncertainties in every voxel.

### 2.4.5.1.2 Output File

The results for the standard CSAS calculations and the Sourcerer results are shown in Table 2.4.8 for calculations with the 252-energy-group and continuous-energy cross sections.

## Table 2.4.8. Eigenvalue results for the Jezebel problem

|  | Sample Problem | CSAS | Sourcerer |
| :--- | :--- | :---: | :---: |
| 1. | KENO V.a geometry, v7-252 | $1.0045 \pm 0.0017$ | $1.0054 \pm 0.0018$ |
| 2. | KENO-VI geometry, v7-252 | $0.9998 \pm 0.0018$ | $1.0007 \pm 0.0020$ |
| 3. | KENO V.a geometry, ce_v7 | $1.0058 \pm 0.0027$ | $1.0026 \pm 0.0017$ |
| 3. | KENO-VI geometry, ce_v7 | $0.9990 \pm 0.0023$ | $1.0041 \pm 0.0016$ |

The Denovo fission source provides a reliable starting source that is similar to the actual fission source distribution computed by KENO (using $n p g=250000$ ), as shown in Figure 2.4.2.

Figure 2.4.2. Fission source distribution from Denovo (left) and KENO (right).

### 2.4.5.1.3 Other Variations

To increase the Denovo calculation speed (but decrease the fidelity of the fission source result), the discretization in angle (quadrature= or polarsPerOct=/azimuthsPerOct=) can be coarsened and/or the tolerance parameters can be loosened. To reduce the amount of memory required by Denovo, the number of Legendre moments in the scattering cross-section expansion can be reduced (legendre=). Using macromaterials can help increase the fidelity of the Denovo calculation with only a small increase in model setup time. Macromaterials do not impact the Denovo run time. Denovo diagnostic messages can be turned on and will print to the messages file.

| Macromaterials (higher fidelity) | Looser tolerances (faster Denovo) | Screen messages | Higher fidelity (slower Denovo) |
| :---: | :---: | :---: | :---: |
| read detSource | read detSource | read detSource | read sequence |
| ... | ... | ... | ... |
| ```macromaterial mmSubCell=3 mmTolerance=0.001 end macromaterial end detSource``` | eigenValParams | eigenValParams | eigenValParams |
|  |  | ... | ... |
|  | tolerance=1.0e-2 <br> kTolerance=1.0e-3 end eigenValParams | diagnostics=1 <br> output=1 <br> diagnosticLevel=1 | quadType=2 <br> polarsPerOct=4 <br> azimuthsPerOct=4 |
|  | end detSource | end eigenValParams end detSource | legendre=3 |
|  |  |  | end eigenValParams end sequence |

Sample problems sourcerer.smpl01.inp, sourcerer.smpl02.inp, sourcerer.smpl03.inp, and sourcerer.smpl04.inp in the SCALE sample problems directory are the four cases for Jezebel using combinations of KENO V.a/KENO-VI geometry and v7-252 multi-group/continuous-energy v7 cross sections.

### 2.4.A DEVC: Denovo EigenValue Calculation

Douglas E. Peplow and Cihangir Celik

### 2.4.A. 1 Introduction

The DEVC (Denovo EigenValue Calculation) sequence is an interface to the Denovo discrete-ordinates package ${ }^{1}$ for calculating criticality eigenvalue problems. This sequence reads an input file very similar to a CSAS6 input file ${ }^{2}$ that contains an extra block of input for describing the Denovo mesh grid and calculational parameters. Many of the subroutines are shared from the MAVRIC routines that interface with Denovo for fixed-source calculations.

This manual assumes that the user is familiar with the discrete-ordinates method for radiation transport and the Denovo package. DEVC provides an easy way for users to modify existing CSAS6 inputs and use them to run Denovo. The DEVC sequence also provides a way to create mesh geometry for Denovo from the combinatorial solid geometry description used by KENO-VI.

The steps in the DEVC sequence are listed in Table 2.4.A.1.
Table 2.4.A.1. Steps in DEVC for an input file named input.inp

| Step | Module/Task | Creates file | To stop after |
| :--- | :--- | :--- | :--- |
| 0 | Check user input |  |  |
| 1 | Self-shielding (celldata/cellmix) calculations | parm=check |  |

| 3 | Creates AMPX cross sections for the "real" materials | ft02f001 | pren |
| 4 | Creates Denovo binary stream input file and the <br> macromaterial table file | xkba_b.inp <br> input.mmt | parm=input |
| 5 | Runs Denovo to compute $k_{\text {eff }}$ and either the fluxes or the <br> fission source | input.dff <br> or <br> input.dso |  |

The DEVC sequence uses KENO-VI geometry. Users can specify what output Denovo will generate: fluxes by space and energy in a binary *.dff (Denovo flux file) file or the space-only fission source distribution in a binary *.dso (Denovo spatial output) file. The eigenvalue is printed in the main output text file.

Some of the more common KENO starting source types are supported. Other starting source types may be added or extended to all of the different array types in the future. Currently, starting sources are not sent to Denovo because the Arnoldi solver does not use it. This may change in the future.

### 2.4.A. 2 Sequence Input

The input file for a DEVC calculation looks similar to a CSAS6 input file, as shown in Table 2.4.A.2. The major difference is that the parameter block contains information for the Denovo calculation, not the KENO Monte Carlo calculation. A macromaterial block is used to describe how the KENO-VI materials are mapped onto the Denovo mesh grid. Only multi-group cross-section libraries can be used with Denovo.

Table 2.4.A.2. Input file for a DEVC calculation (and differences with a CSAS6 input file, where black text is the same as CSAS6 and green text is new for DEVC sequence)

### 2.4.A.2.1 Parameters Block

This block contains the parameters for the Denovo eigenvalue calculation, the grid geometry, and the macromaterials. Boundary conditions listed in the parameters block will override those listed in the bounds block (using CSAS6 syntax). Table 2.4.A.3 lists the Denovo calculation parameters and their default values, and Table 2.4.A. 4 lists the keywords for the setting the boundary conditions and file
saving options. The grid geometry is defined in a sub-block in the parameters block, or the keyword "gridGeometryID=n" can be used to point to a grid geometry defined in its own input block.

Table 2.4.A.3. Denovo parameters in the parameters block

| keyword | type | default | restrictions/comments |
| :---: | :---: | :---: | :---: |
| read parameters |  |  |  |
| discretization= | integer | 4 | 0-diamond difference, 1-DD with flux fix-up:lin0, 2-theta-weighted DD, 3-linear discontinuous finite element, 4-step characteristics, 5-trilinear discontinuous finite element |
| quadType= | integer | 2 | 0-level symmetric, 1-Gauss-Legendre product, 2-QR |
| legendre= | integer | 3* | $P_{L}$, $L=h i g h e s t$ Legendre polynomial, $L=0,1,2,3, \ldots$ <br> *default is to use min(the highest available in the data,3) |
| tportcorrection= | integer | 1 | transport correction: 0-none, 1-diagonal, 2-Cesaro ${ }^{*} \mathrm{P}_{2}$ or higher is required for Cesaro |
| upScatter= | integer | 1 | upscatter iterations: 0-none, 1-yes, 2-ignore |
| xblocks= | integer | 1 | parallel calcs - how many divisions in x |
| yblocks= | integer | 1 | parallel calcs - how many divisions in y |
| zblocks= | integer | 1 | parallel calcs - how many commication layers in z |

| ymin= | integer | 0 | 2- periodic |
| ymax= | integer | 0 | 3 - white |
| zmin= | integer | 0 | (these will override the "read bounds" block if specified here.) |
| zmax= |  | save space/energy fluxes (default) |  |
|  |  | save the space-only fission source |  |
| fluxes |  |  |  |
| fissionSource |  |  |  |
| end parameters |  |  |  |

### 2.4.A.2.2 Grid Geometry Block

Grid geometries ("gridGeometry id") require an identification number and then a description of a threedimensional rectangular mesh by specifying the bounding planes of the cells in each of the $x, y$, and $z$ dimensions. The keyword "xPlanes ... end" can be used to list plane values (in any order). The keyword "xLinear n a b" can be used to specify $n$ cells between $a$ and $b$. The keywords " $x P l$ anes" and "xLinear" can be used together and multiple times - they will simply add planes to any already defined for that dimension. Any duplicate planes will be removed. Similar keywords are used for the $y$ and $z$ dimensions.

When using multiple instances of the keywords *Linear and *Planes for a given dimension, duplicates should be removed from the final list. In some cases, double precision math will leave two planes that are nearly identical but not removed (e.g., 6.0 and 5.9999999 ). To prevent this, a default tolerance is set to remove planes that are within $10^{-6} \mathrm{~cm}$ of each other. The user is free to change this by using the keyword "tolerance=" and specifying something else. Note that the tolerance can be reset to a different value in between each use of *Linear or *Planes.

The keyword "make3dmap" for a particular grid geometry definition will create a file called "outputName.gridid.3dmap", which can be visualized using the Java Mesh File Viewer. These files will contain crude geometry information (unit, region, material) that corresponds to the center of each voxel.

Keywords for the grid geometry block are listed in Table 2.4.A.5.

Table 2.4.A.5. Grid geometry input keywords

| keyword | type | restrictions/comments |
| :---: | :---: | :---: |
| read parameters |  |  |
| gridGeometry id |  | covers a cuboid where all points are in defined regions |
| title= | character | contained in double quotes (title="yada yada yada") |
| $x$ planes ... end | real array | a list of $x$ plane values (order not important) |
| $x$ Linear $n$ min max | int real real | adds $n+1 \times$ planes ( $n$ cells) evenly from min to max |
| $y$ planes ... end | real array | a list of $y$ plane values (order not important) |
| $y$ Linear $n$ min max | int real real | adds $n+1$ y planes ( $n$ cells) evenly from min to max |
| z planes ... end | real array | a list of $z$ plane values (order not important) |
| $z$ Linear $n$ min max | int real real | adds $n+1 z$ planes ( $n$ cells) evenly from min to max |
| tolerance= make3dmap | real | for removing duplicate planes from *planes or *Linear makes a *.3dmap file showing the grid geometry |
| xdivide= | integer | once all xplanes are entered, further divide them by this |
| ydivide= | integer | once all yplanes are entered, further divide them by this |
| zdivide= | integer | once all zplanes are entered, further divide them by this |
| end gridGeometry |  |  |
| gridGeometryID= | integer | Either define a grid geoemtry in a sub block or refer to a grid geometry defined in its own block |
| end parameters |  |  |

### 2.4.A.2.3 Macromaterial Block

In order to get more accurate solutions from a coarse-mesh discrete-ordinates calculation, Denovo can represent the material in each voxel of the mesh as a volume-weighted mixture of the real materials in the problem. When constructing the Denovo input, DEVC can estimate the volume fraction taken by each real material in each voxel by a sampling method. The user can specify parameters for how to sample the geometry. Note that finer sampling makes more accurate estimates of the material fraction but requires more setup time to create the Denovo input. Users should understand how the macromaterials are sampled and consider that when constructing a mesh grid. This is especially important for geometries that contain arrays. Careful consideration should be given when overlaying a mesh on a geometry that contains arrays of arrays.

Because the list of macromaterials could become large, the user can also specify a tolerance for how close two different macromaterials can be to be considered the same, thereby reducing the total number of macromaterials. The macromaterial tolerance, "mmTolerance=", is used for creating a different macromaterial from the ones already created by looking at the infinity norm between two macromaterials. The number of macromaterials does not appreciably impact Denovo run time or memory requirements.

Keywords for the macromaterial block are listed Table 2.4.A.6. Two different sampling methods are available - ray tracing ${ }^{3}$ with the keyword mmRayTest and point testing ${ }^{4}$ with the keyword mmPointTest.

Table 2.4.A.6. Macromaterial block input

| keyword | type | length default | restrictions/comments |
| :---: | :---: | :---: | :---: |
| read macromaterial |  |  |  |
| mmSubCell= | integer | 1 | rays per dimension to throw at each voxel |
| mmTolerance= | real | 0.01 | smallest volume fraction for macromaterial |
| mmSubCells | integer | 6 | rays per dimension to throw (x:ny,nz; y:nx, nz; z: nx, ny) |
| mmPointTest |  |  | use recursive bisection point testing method |
| mmRayTest |  |  | use ray tracing method |
| mmRTSpeed |  |  | optimize ray-tracing method for speed |
| mmRTMemory |  |  | optimize ray-tracing method for memory conservation |
| end macromaterial |  |  |  |

### 2.4.A.2.3.1 Ray Tracing

This method estimates the volume of different materials in the Denovo mesh grid elements by throwing rays through the KENO-VI geometry and computing the average track lengths through the each material. Rays are traced in all three dimensions to better estimate the volume fractions of materials within each voxel. The mmSubCell parameter controls how many rays to trace in each voxel in each dimension. For example, if mmSubCell $=n$, then when tracing rays in the $z$ dimension, each column of voxels uses a set of $n \times n$ rays starting uniformly spaced in the $x$ and $y$ dimensions. With rays being cast from all three orthogonal directions, then a total of $3 n^{2}$ rays are used to sample each voxel. One can think of subcells as an equally spaced sub-mesh with a single ray positioned at each center. The number of subcells in each direction, and hence the number of rays, can be explicitly given with mmSubCells ny nz nx nz nx ny end keyword for rays parallel to the $x$ axis, $y$ axis, and $z$ axis. Figure 2.4.A. 1 shows different subcell configurations (in two dimensions) for a given voxel.

Ray tracing is a more robust method compared to the simple point testing method used in previous versions

Figure 2.4.A.1. Ray positions within a voxel with different mmSubCells parameters. of SCALE/MAVRIC; however, it requires more memory than point testing. Ray tracing gives more accurate estimates of volume fractions because track lengths across a voxel give more information than a series of test points. Ray tracing is also much faster than point testing because the particle tracking routines are optimized for quickly determining lists of materials and distance along a given ray.

Ray tracing operates on the grid geometry supplied by the user and shoots rays in all three directions starting from the lower bounds of the mesh grid. An example of arbitrary assembly geometry is shown in Figure 2.4.A.2. A ray consists of a number of steps that corresponds to crossing a different material along the path of the ray. Ratios of each step's length to the voxel length in the ray's direction determine the material volume fraction of that step in that voxel, and summation of the same material volume fractions gives the material volume fraction of that material in that voxel. Ray tracing through a single voxel that contains a fuel pin is illustrated in Figure 2.4.A.3.

Figure 2.4.A.2. Geometry model (left) and the Denovo representation (right) of an assembly using macromaterials determined by ray tracing.

The final constructed macromaterials for this model are also shown in Figure 2.4.A.2. Voxels that contain only a single material are assigned that original material number in the constructed macromaterials. For the voxels that contain a fuel pin with three different materials, the result is a new macromaterial consisting of the volume weighted fractions of each original material.

After the rays are shot in all three directions, the material volume fractions are updated and macromaterials are created by using these material volume fractions. Material volume fraction calculations for a single voxel, as shown in Figure 2.4.A.3, are given by

$$
F_{m}=\sum_{d=x, y, z} \sum_{r=1}^{N_{r}} \sum_{s=1}^{N_{s}}\left\{\begin{aligned}
\frac{L_{d, r, s}}{L_{d}}, & m_{s}==m \\
0, & \text { otherwise }
\end{aligned} \quad \text { and } \quad V_{m}=\frac{F_{m}}{\sum_{n=1}^{N_{m} F_{n}}},\right.
$$

where $F_{m}=$ sampled fraction of material $m$ in the voxel,
$d=$ direction of the rays $(x, y, z)$,
$r=$ ray number,
$N_{r}=$ total number of rays in the voxel for direction of $d$,
$s=$ step number,
$N_{s}=$ total number of steps for ray $r$ in the voxel for direction of $d$,
$L_{d, r, s}=$ length of the steps $s$ for ray $r$ in the voxel for direction of $d$,
$L_{d,}=$ length of the voxel along direction of $d$,
$m_{s}=$ material of step $s$,
$m=$ material number,
$N_{m}=$ total number of materials in the voxel, and
$V_{m}=$ volume fraction of material $m$ in the voxel.

Figure 2.4.A.3. Ray tracing (in two dimensions) through a voxel.

### 2.4.A.2.3.2 Point Testing

The recursive bisection method uses a series of point tests to determine the macromaterial fractions. For a given voxel, the material at the center is compared to the material at the eight corners. If they are all the same, the entire volume is considered to be made of that material. If different, the volume is divided into two in each dimension. Each subvolume is tested, and the method is then applied to the subvolumes that are not of a single material. When the ratio of the volume of the tested region to the original voxel becomes less than a user-specified tolerance (in the range of $10^{-1}$ to $10^{-4}$ ), then further subdivision and testing are stopped. This is illustrated in Figure 2.4.A.4.

Figure 2.4.A.4. Progression of the recursive bisection method (from upper left to lower right).

In point testing, the keyword "mmTolerance= $\rho$ " is interpreted to be where $f$ is the smallest fraction of the voxel volume to consider. This same tolerance $f$ is also used to limit the number of macromaterials. Before a new macromaterial is created, if one already exists where the fraction of each actual material matches to within the given tolerance, then the existing material will be used. If using only a single point at the center of each voxel, use "mmTolerance=1". The mmSubCell keyword is not used in point testing.

### 2.4.A.2.3.3 Example

Figure 2.4.A. 5 shows an example of a cask geometry with two types of spent fuel (yellows), steel (blue), resin (green), and other metals (gray). When the Denovo geometry is set up by testing only the center of each mesh cell, the curved surfaces are not well represented (upper right). By applying the ray-tracing method and defining a new material made of partial fractions of the original materials, an improved Denovo model can be made. In the lower left of the figure, the Denovo model was constructed using one ray (in each dimension) per voxel and a tolerance of 0.1 . This gives 20 new materials that are a mixture of the original 13 actual materials and void. With mmSubCells=3 and an mmTolerance $=0.01$, 139 macromaterials are created.

A macromaterial table listing the fractions of each macromaterial is saved to a file called "outputName.mmt", where outputName is the name the user chose for his or her output file. This file can be used by the Mesh File Viewer to display the macromaterials as mixtures of the actual materials, as seen in lower row of Figure 2.4.A.5. See the Mesh File Viewer help pages for more information on how to use colormap files and macromaterial tables.

Figure 2.4.A.5. Cask geometry model (upper left) and the Denovo representation using (upper right) cell center testing. Representations using macromaterials determined by ray tracing are shown for (lower left) $\mathrm{mmSubCell}=1 / \mathrm{mmTolerance}=0.1$ and (lower right) $\mathrm{mmSubCell}=3 / \mathrm{mmTolerance}=0.01$.

### 2.4.A.2.4 Starting Sources Block

The default KENO-VI starting source is "flat over the volume specified by the unrotated, untranslated geometry record specified in the first position of the global unit boundary record in fissile material only". For DEVC, the default starting source strength is uniform in the fissile voxels contained within the bounding box of the global unit (uniform density). If macromaterials are used, the amounts in each voxel
are volume averaged between fissile and non-fissile materials. Table 2.4.A. 7 and Table 2.4.A. 8 describe the starting sources available in the DEVC interface to Denovo.

Table 2.4.A.7. Starting source types (within the fissile areas of the listed shape)

|  | KENO-VI start type | DEVC |
| :---: | :---: | :---: |
| nst=0 | the first surface of boundary (default) | The bounding box of global unit |
| nst=0 | Within boundary of global array having a reflector key set to false | Not supported |
| nst=0 | A cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP | Supported |
| nst=1 | A cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP with cosine distributions | Supported |
| nst=2 | Arbitrary fraction (FCT) in element NXS, NYS, NZS of the global array with the remainder in a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP with cosine distributions | Supported for some array types (see Table 2.4.A.8) |
| nst=3 | At the location TFX, TFY, TFZ in the element NXS, NYS, NZS of the global array | Supported for some array types (see Table 2.4.A.8) |
| nst=4 | At the location TFX, TFY, TFZ in units NBX of the global array | Supported |
| nst=5 | Across units NBX in the global array | Not supported |
| nst=6 | List of points TFX, TFY, TFZ in global coordinates | Limited to 1 point |
| nst=6 | List of points TFX, TFY, TFZ in element NXS, NYS, NZS of the global array | Limited to 1 point and only for some array types (see Table 2.4.A.8) |
| nst=7 | Flat distributions in X and Y with $\left[1-\cos ^{2}(\mathrm{z})\right.$ ] in Z for a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP | Supported |
| nst=8 | Flat distributions in X and Y with a segmented distribution in Z for a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP | Not supported |
| nst=9 | Use a mesh source lite file | Not supported |

Table 2.4.A.8. Supported array types for starting sources

| no arrays supported <br> cuboid supported <br> hexagonal supported <br> shexagonal no <br> rhexagonal no <br> dodecahedral no |
| :--- | :--- |

The starting source initialized in Denovo is always a volumetric source - DEVC does not create point sources (which would activate the first collision option in Denovo).

### 2.4.A. 3 Sequence Output

The main text output file consists of the output from the cross-section processing codes and Denovo. The user should examine the output and pay attention to any warnings or errors. Table 2.4.A.9 lists the files generated during the DEVC sequence.

Table 2.4.A.9. Files created by DEVC for an input file named input.inp

| Filename | Viewer | Description |
| :---: | :---: | :---: |
| Output Summary <br> input.out <br> input.msg |  | main text output file, contains $k_{\text {eff }}$ <br> messages file |
| Denovo <br> xkba_b.inp | $\mathrm{V}^{\text {a }}$ | input file for Denovo - if this file is renamed to have <br> a *.dsi extension (Denovo simple input), it is viewable <br> in the Mesh File Viewer |
| ft02f001 |  |  |
| input.mmt | V | AMPX formatted cross sections for Denovo <br> macromaterial table, use with *.dso or *.dsi file |
| input.dff <br> input.dso | V | Denovo fission fluxes <br> Denovo fission source distribution |

${ }^{a} \mathrm{~V}$ - can be displayed with the Mesh File Viewer.

### 2.4.A.3.1 Using the Mesh File Viewer

The Mesh File Viewer is a Java utility shipped with SCALE that is used for viewing mesh tallies from Monaco, as well as importance maps and mesh-based sources in MAVRIC. The Mesh File Viewer can be used with DEVC to view the Denovo input file (*.dsi, showing the starting source), the Denovo output fission source distribution (*.dso) file, or the Denovo output flux (*.dff) file.

With any Denovo file, material information for each voxel can be displayed. Users can use the graphical user interface to select colors for each material in the DEVC input and save them to a colormap text file (*.cmp) for later use. For example, Figure 2.4.A. 6 shows a cask model that has 13 materials with the default colors assigned by the viewer. A better color map (uranium is yellow, steel is blue, etc.) and an image using that color map are also shown in Figure 2.4.A.6.

Figure 2.4.A.6. Viewing material information with the Mesh File Viewer.

If the Denovo input was made using the mixed macromaterials, that can also be shown with the Mesh File Viewer. When one of the mesh files is loaded and the geometry is displayed (e.g., the materials for a cask model shown in Figure 2.4.A.7), there will be many values since each macromaterial is treated by the Java viewer as a separate material. Redefining the color map using the GUI is not realistic.

A colormap needs to be defined for the original materials of the problem. For this example, there are 13 original materials, but when using macromaterials, 73 macromaterials are used in the discrete-ordinates model (as listed in the *.mmt file). The colormap file should only contain values for the 13 original materials. When loading the colormap, a corresponding *.mmt file can also be loaded. This will display mixed colors for the macromaterials, as shown in Figure 2.4.A.7.

The final result is an image where the colors for the different values of the geometry attribute (which in the above example is material) are mixed in the ratio of the macromaterial definition.

Figure 2.4.A.7. Viewing material information from a Denovo input file.

### 2.4.A.3.2 Viewing the Starting Source

The Java MeshFileViewer (scale/cmds/meshview) can be used to visualize the Denovo binary stream input file to show materials and starting source strengths. An example is shown in Figure 2.4.A.8.

## Material Numbering

The cross sections produced by the SCALE cross-section mixing module ICE typically have a number of materials equal to the maximum material ID specified by the user in the "read composition" block. For a user input that contains materials 1,3 , and 5 , the GIP-formatted cross-section file will contain five entries. For each lattice cell calculation that uses a cellmix= parameter, one more entry is contained in the GIP file. Hence, the GIP file does not contain the user's value from the "cellmix=" parameter but instead numbers the cellmix materials sequentially starting from $1+$ maximum(material ID). The Denovo geometry input and macroMixTable file produced by DEVC are modified to match the GIP cross-section file. When viewing the Denovo binary input file with the Mesh File Viewer, the GIP numbering for materials will be seen.

Figure 2.4.A.8. Fine-mesh version of sample problem 8, showing the materials using macromaterial blending of $\mathrm{UO}_{2}, \mathrm{MOX}$, clad, and water (left) and the starting source strength limited to cells with fissionable material (right).

### 2.4.A. 4 Sample Problems

Sample problems have been made that correspond to the eight CSAS6 sample problems. In each problem, the KENO parameters block was commented out, a parameters block containing Denovo calculation parameters was added, and a grid geometry block was added. These sample problems use a coarse discretization and loose tolerances to obtain a short runtime. Users will typically use much finer discretization (mesh, quadrature) and higher fidelity parameter settings for real eigenvalue calculations. The voxelized geometry and starting source distribution are shown below in Figure 2.4.A.9.

Results for the sample problems are displayed in Table 2.4.A.10. The sample problems used QR $1 / 1$, a $\mathrm{P}_{0}$ scattering expansion, a k tolerance of 0.001 and coarse meshes for speed. The higher fidelity runs used finer spatial meshes, default parameters of $\mathrm{QR} 2 / 2, P_{0}$ scattering expansion, and the default $k$ tolerance $\left(10^{-5}\right)$. Results for the longer-time CSAS6 and higher fidelity Denovo calculations are shown in Figure 2.4.A.10.

Figure 2.4.A.9. Denovo geometry (left) and starting source distribution (right) for the sample problems.

Figure 2.4.A.10. Fission source distributions computed by CSAS6 (left) and Denovo (right).

Table 2.4.A.10. Sample problem results

|  | CSAS6 |  |  |  |  |  | Denovo using DEVC |  |  |  |

### 2.5 KMART5 AND KMART6: POSTPROCESSORS FOR KENO V.A AND KENO-VI

L. M. Petrie

#### Abstract

KMART5 and KMART6 (Keno Module for Activity-Reaction Rate Tabulation) are modules whose primary purpose is to postprocess a KENO V.a or KENO-VI restart file with the corresponding working cross-section library to generate nuclide activity tables. It also allows collapsing and printing fluxes calculated by KENO. The KENO problem must have a mixing table, must calculate the fluxes, and must write a restart file containing the calculated data. KMART calculations are generally imbedded within a CSAS5 or CSAS6 input file immediately following the CSAS input as a stacked input case.

### 2.5.1 Introduction

KMART5 and KMART6 (Keno Module for Activity-Reaction Rate Tabulation) are modules whose primary purpose is to postprocess a KENO V.a or KENO-VI restart file with the corresponding working cross-section library to generate nuclide activity tables. It also allows collapsing and printing fluxes calculated by KENO. The KENO problem must have a mixing table, must calculate the fluxes, and must write a restart file containing the calculated data.

### 2.5.2 KMART Input Data

Input data for KMART is read into the program using free form blocked input similar to KENO. The data blocks are started with a READ BLOCK NAME and ended with an END BLOCK NAME. There are three data blocks that KMART can read. The first data block is named INITIAL, and the input starts with the keywords READ INITIAL. There are ten possible keyworded entries in this block that may be entered in any order.
\(\left.$$
\begin{array}{lll}\text { Keyword } \\
\text { PRTVOLS }\end{array}

## Description

A flag to turn on generating a collapsed cross section file for TRITON.

The logical unit number on which to write an AMPX weighted library of the 1-D neutron cross sections.

A sample data block is given below.
READ INITIAL KUNIT=35 XUNIT=4 END INITIAL

One of the next two blocks is required, but both can be specified if desired. If both are entered, either one can be first. The next data block specified is named ACTIVITY, and the input starts with the keywords READ ACTIVITY. It contains the data specifying which activities are to be calculated. The activities are specified by pairs of numbers giving the nuclide identifier and the reaction type identifier desired. A list of reaction types, also known as MT numbers, can be found in Appendix A of the XSLib chapter. These pairs are repeated until all the desired activities have been specified. If the nuclides are identified by the SCALE scheme, then the nuclide can be specified most explicitly by following the nuclide by the keyword MIX= and the mixture number the nuclide is in. By specifying a mixture of zero the activity will be calculated for each region in which the nuclide occurs. If the nuclide specifies a natural element identifier $\left(1000^{*} \mathrm{Z}\right)$ and individual isotopes occur on the cross-section library, the isotope activities will be summed to produce the total activity for the element. If the nuclide is a special nuclide, i.e., identified with a prefix id times a million + a ZA, then MIX= must be specified as a mixture the nuclide occurs in. The data pair is described below.

Keyword Variable Description
NUCLIDE The nuclide identification number on the cross-section library for this activity request.

MIX MIXTURE Mixture number of the nuclide for this activity request. This is an optional entry, and defaults to 0 .

REACTION The reaction type identifier for this activity request.
If no activities are desired, then the block can be omitted. A sample block is given below.

## READ ACTIVITY 92235189223527922351452 END ACTIVITY

The other input block is named COLLAPSE, and starts with the keywords READ COLLAPSE. There are two keyword entries that may be input in this block. A flux factor to normalize the fluxes by can be specified. It defaults to 1 . The last fine group in the current broad group is the other entry. The broad groups are specified sequentially starting with group one. If the flux factor is specified more than once, the last value given is used. The data is specified as below.

| Keyword | Variable | Description |
| :--- | :--- | :--- |
| FACTOR | FACTOR | A flux multiplier used to scale the fluxes before <br> printing (default 1.0). |
| LASTG $=$ | LAST_GROUP | The last fine group to be included in the current <br> broad group. The broad groups are input sequentially <br> starting with group one. |

If no collapsed fluxes are desired, then the block can be omitted. A sample block is given below.

```
READ COLLAPSE FACTOR 1.0 LASTG=10 LASTG=20 LASTG=30 LASTG=56
    END COLLAPSE
```

### 2.6.1 Introduction

Program K5TOK6 can be used to automatically convert a KENO V.a input file to a KENO-VI input file. Program C5TOC6 can be used to automatically convert a CSAS5 input file to a CSAS6 input file. This functionality can be useful when converting a KENO V.a validation sequence to a KENO-VI validation sequence. It removes the problem of introducing a mistake or inadvertently changing the data when remodeling a geometry to the KENO-VI format. For some cases, however, the converted model may be a very inefficient KENO-VI model.

### 2.6.2 Description and Input Guide

Program K5TOK6 is a utility program that can be used to automatically convert a KENO V.a input file to a KENO-VI input file. Program C5TOC6 is a utility program that can be used to automatically convert a CSAS5 input file to a CSAS6 input file. For program K5TOK6, the "=KENOVA" record in the input stream is replaced by "=K5TOK6". The output file is then named _geomnnnnnnn where nnnnnnn is a unique 7-digit number. This allows a string of KENO V.a problems to be converted in one job. For program C5TOC6 the " $=$ CSASBB" record in the input stream (where the $B B$ is 5,25 , or 2 x ) is replaced by "=C5TOC6 PARM=CSAS5." The output file is named _geomnnnnnnn where nnnnnnn is a unique 7-digit number.

For large problems, the output file may need to be edited to specify an increased value for parameter NB8 in KENO-VI and also an increased value for parameter $D A B$ in CSAS6. The conversion makes no attempt to optimize the output file, so it almost surely will be inefficient in its use of storage, and in its use of bodies. This can lead to models that are very inefficient in their running time also.

The input/output (I/O) units for K6TOK6 and C5TOC6 are given below. Note that K5TOK6 requires the cross-section library designated by the "LIB=" parameter in the KENO V.a input file.

Sample K5TOK6 input file is shown in Figure 2.6.1 and the corresponding converted KENO-VI input file is shown in Figure 2.6.2. Likewise, a C5TOC6 sample input file and corresponding converted CSAS6 input file are shown in Figure 2.6.3 and Figure 2.6.4, respectively.

### 3.0. REACTOR PHYSICS

## Introduction by M. A. Jessee

SCALE supports a wide range of reactor physics analysis capabilities. SCALE reactor physics calculations couple neutron transport calculations with ORIGEN to simulate the time-dependent transmutation of various materials of interest. The two reactor physics analysis tools within SCALE are TRITON and Polaris. TRITON is SCALE's modular reactor physics sequence for a wide variety of system types; Polaris is SCALE's light water reactor (LWR) lattice physics sequence.
The primary function of TRITON is to simulate the time-dependent evolution of nuclide inventories of a reactor system through a series of multigroup transport calculations and depletion/decay calculations. Before each multigroup transport calculation, TRITON executes the XSProc module to calculate multigroup cross sections for each user-designated depletion material. The XSProc calculation is performed based on the time-dependent material compositions and the user-defined cross section processing definitions. TRITON provides maximum modeling flexibility, supporting the full range of cross section processing options in XSProc along with support for four different multigroup transport modules available in SCALE. These transport modules include the following:

- XSDRN: one-dimensional discrete ordinates $\left(\mathrm{S}_{\mathrm{N}}\right)$ transport module for modeling simple slab, cylindrical, and spherical geometries,
- NEWT: two-dimensional (2D) $\mathrm{S}_{\mathrm{N}}$ polygon-mesh deterministic transport module with arbitrary geometry model definitions, and
- KENO-V.a and KENO-VI: three-dimensional Monte Carlo transport modules with arbitrary geometry model definitions.

In addition to the multigroup-based calculation sequences, TRITON supports continuous-energy (CE) transport calculations with KENO-V.a and KENO-VI. For each depletion material, the CE Monte Carlo calculation tallies energy-integrated nuclide-dependent reaction rates to couple the transport solution to the ORIGEN depletion calculation. Both the multigroup- and CE-based KENO depletion calculations are parallelizable and can run on an arbitrary number of processors.
TRITON provides easy-to-use input options to define the time-dependent reactor condition, including power history, material temperatures, and material compositions. TRITON also provides the option to perform lattice physics calculations, with input options to define branch calculations, homogenization edits, few-group energy structures, and assembly discontinuity factors. The homogenized few-group cross sections are archived onto auxiliary data files for subsequent in-reactor core calculations.
TRITON generates several data files for follow-on SCALE analysis. It creates the ORIGEN binary concentration file (.f71 extension) that stores all of the material inventories at each depletion/decay step. This file can be used as input to ORIGEN, ORIGAMI, and MAVRIC to support spent fuel characterization and shielding analysis. TRITON also creates the ORIGEN binary library file (.f33 extension) that stores the ORIGEN transition matrix for each depletion material at each depletion/decay step. The ORIGEN library files can be used as input to ORIGEN or ORIGAMI for rapid assessment of spent fuel inventories. Finally, TRITON also generates the aforementioned lattice physics few-group cross section archive (xfile016) for reactor core calculations.
In addition to the TRITON reactor physics sequence, SCALE supports an alternative easy-to-use LWR depletion sequence for generating lattice physics data for full-core reactor calculations. The Polaris lattice physics sequence couples 2D multigroup transport calculations with ORIGEN depletion to simulate LWR fuel assemblies. Polaris provides easy-to-use input definitions for defining the primary inputs necessary for lattice physics analysis, namely the pin and lattice geometry, the material compositions, and specifications for the power history and branch calculations. Polaris supports
systematic input defaults for analysis of both fuel and reflector models for both pressurized water reactor (PWR) and boiling water reactor (BWR) geometries. It uses a new approach for cross section processing called the Embedded Self Shielding Method (ESSM). The hallmark feature of ESSM is that the self-shielding calculation is performed on the 2D fuel assembly geometry, eliminating the need for user-defined cross section processing definitions. The ESSM calculation and the $\mathrm{k}_{\text {eff }}$ calculation are performed with a new deterministic transport module based on the Method of Characteristics (MOC) approach. The Polaris sequence generates the lattice physics archive file (.t16 and .x16 extension), the ORIGEN binary concentration file (.f71 extension), and a geometry plot file (.png extension).

# 3.1 TRITON: A MULTIPURPOSE TRANSPORT, DEPLETION, AND SENSITIVITY AND UNCERTAINTY ANALYSIS MODULE 

M. A. Jessee, D. Wiarda, K. T. Clarno, U. Mertyurek, K. Bekar

#### Abstract

The TRITON computer code is a multipurpose SCALE control module for transport, depletion, and sensitivity and uncertainty analysis. TRITON can be used to provide automated, problem-dependent cross section processing followed by multigroup transport calculations for one-, two-, and three-dimensional (1D, 2D, and 3D) configurations. Additionally, this functionality can be used in tandem with the ORIGEN depletion module to predict isotopic concentrations, source terms, and decay heat, as well as to generate few-group homogenized cross sections for nodal core calculations.

TRITON has been designed using the modular approach that is a hallmark of SCALE functionality. TRITON provides the capability to perform deterministic transport analysis for 1D geometries using XSDRNPM and for 2D geometries using NEWT. TRITON also includes 3D Monte Carlo depletion capabilities using KENO V.a and KENO-VI. For Monte Carlo depletion calculations, TRITON supports both multigroup and continuous-energy options.

The TSUNAMI-2D sequence in TRITON provides calculation of 2D forward and adjoint transport solutions in NEWT, calculation of sensitivity coefficients, and calculation of the uncertainty in $k_{\text {eff }}$ and other responses due to cross section covariance data. The SAMS module is used to determine the sensitivity of the calculated value of responses to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. The uncertainty in the calculated value of the response, resulting from uncertainties in the basic nuclear data used in the calculation, is estimated using energy-dependent cross section covariance matrices. The implicit effects of the cross section processing calculations are also treated.

## ACKNOWLEDGMENTS

The authors express gratitude to B. T. Rearden for supervision of the SCALE project and review of the manuscript. The authors acknowledge R. Y. Lee and M. Aissa of the U.S. Nuclear Regulatory Commission (NRC) for their support of this project and Mark DeHart, as the original developer of TRITON.

### 3.1.1 Introduction

TRITON (Transport Rigor Implemented with Time-dependent $\underline{\text { Operation for Neutronic depletion) is a }}$ multipurpose SCALE control module for transport, depletion, and sensitivity and uncertainty analysis for reactor physics applications. TRITON can be used to provide automated, problem-dependent cross section processing followed by multigroup (MG) neutron transport calculations for one-, two-, and threedimensional (1D, 2D, and 3D) configurations. Additionally, this functionality can be used in tandem with the ORIGEN depletion module to predict isotopic concentrations, source terms, and decay heat.

Most notable improvements to TRITON in this latest release are the reduced run-time due to the integration of the XSProc module for cross section processing coupled with improvements in the NEWT transport module and the capability to perform continuous energy (CE) transport calculations using Monte Carlo transport codes KENO-V.a and KENO-VI (MG Monte Carlo depletion existed in previous versions).

TRITON has been designed using the modular approach that is a hallmark of SCALE functionality. TRITON provides the capability to perform deterministic transport analysis for 1D geometries using XSDRNPM and for 2D geometries using NEWT. TRITON also includes 3D Monte Carlo depletion capabilities using KENO V.a and KENO-VI.

The sensitivity and uncertainty ( $\mathrm{S} / \mathrm{U}$ ) analysis sequence in TRITON, TSUNAMI-2D, provides calculation of the 2 D forward and adjoint transport solutions in NEWT; calculation of sensitivity coefficients; and calculation of the uncertainty in $k_{\text {eff }}$ and other responses due to cross section covariance data. The SAMS module is used to determine the sensitivity of the calculated value of the response to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. The uncertainty in the calculated value of the response, resulting from uncertainties in the basic nuclear data used in the calculation, is estimated using energy-dependent cross section covariance matrices. The implicit effects of the cross section processing calculations are predicted using SENLIB and BONAMIST. The energy-dependent sensitivity data computed with TSUNAMI-2D are stored in a sensitivity data file (.sdf file) that is suitable for assessing system similarity for code validation purposes using TSUNAMI-IP or for data assimilation using TSURFER.

As a SCALE control module, TRITON automates execution of SCALE functional modules and manages data transfer and input/output processes for multiple analysis sequences. Each of TRITON's nine calculational sequences is provided in Table 3.1.1, which lists the sequence name keyword, the sequence description, and the function modules invoked within each sequence. The method for cross section processing is selected using a separate "parm=" keyword, which is described in more detail in the next section.

Table 3.1.1. Sequences available in TRITON

| Sequence keyword | Primary SCALE modules | parm= options | Sequence function |
| :---: | :---: | :---: | :---: |
| Cross section processing sequences |  |  |  |
| =T-XSEC | XSProc | bonami centrm ${ }^{a}$ xslevel=1/2/3/4 | Preparation of multigroup (MG) cross section library. |
| Transport sequences |  |  |  |
| =T-XSDRN | XSProc, XSDRNPM | bonami centrm ${ }^{a}$ | 1D MG deterministic transport calculation. |
| =T-NEWT | XSProc, NEWT | $\begin{aligned} & \text { xslevel=1/2/3/4 } \\ & \text { weight }^{b} \end{aligned}$ | 2D MG deterministic transport calculation. |
| Depletion sequences |  |  |  |
| =T-DEPL-1D | XSProc, XSDRNPM, ORIGEN, OPUS | ```bonami centrm xslevel \(=1 / 2 / 3^{a} / 4\) addnux \(=0 / 1 / 2^{a} / 3 / 4\) weight \({ }^{b}\)``` | 1D MG deterministic transport, coupled with ORIGEN depletion. |
| =T-DEPL | XSProc, NEWT, ORIGEN, OPUS |  | 2D MG deterministic transport, coupled with ORIGEN depletion. |
| =T5-DEPL | XSProc ${ }^{c}$, KENO-V.a, ORIGEN, OPUS |  | 3D, Monte Carlo transport (KENOV.a), coupled with ORIGEN depletion. |
| =T6-DEPL | XSProc ${ }^{c}$, KENOVI, ORIGEN, OPUS |  | 3D, Monte Carlo transport (KENO- <br> VI), coupled with ORIGEN depletion. |
| Sensitivity and Uncertainty Analysis sequences |  |  |  |
| $\begin{aligned} & \text { =TSUNAMI-2D } \\ & =T S U N A M I-2 D C \end{aligned}$ | XSProc, NEWT, SAMS, BONAMIST | bonamist bonami centrm ${ }^{a}$ | 2D forward and adjoint transport calculations, followed by S/U analysis with SAMS |
| ${ }^{a}$ Default parm value. Note that centrm is equivalent to xslevel=4. See Sect. 3.1.3.7.2 for details. ${ }^{b}$ parm=weight is used to generate a broad group cross section library. This parm option is only available for the T-DEPL sequence. ${ }^{c}$ T5-DEPL and T6-DEPL is also available in CE-mode, which does not invoke XSProc for cross section processing. |  |  |  |

### 3.1.2 Overview of TRITON Sequences

The TRITON control module supports nine calculational sequences, each with its own design and applications. Each of these sequences is described in the following subsections.

The first subsection covers the basic cross section processing sequence T-XSEC. The T-XSEC sequence prepares problem-dependent multigroup cross sections for subsequent transport analysis. The second subsection covers TRITON's transport analysis sequences, while the third subsection discusses TRITON's depletion analysis sequences. The final subsection is dedicated to the TSUNAMI-2D sensitivity and uncertainty analysis sequences in TRITON.

### 3.1.2.1 Cross section processing sequence (T-XSEC)

The T-XSEC sequence provides the ability to prepare a problem-dependent multigroup cross section library using SCALE cross section processing modules to appropriately account for spatial and energy self-shielding effects. The problem-dependent cross section library contains microscopic cross sections for each nuclide for each material composition defined in the TRITON input. SCALE provides several unit cell types (e.g., a lattice of pins, an infinite medium, a multiregion problem, or a doubly heterogeneous cell) to correct the cross sections for spatial and energy self-shielding. Multiple cell
calculations can be used in the same calculation. The calculation of multigroup cross sections is executed by XSProc.

### 3.1.2.2 Transport sequences (T-XSDRN, T-NEWT)

The TRITON transport sequences build upon the cross section processing sequence by automating a transport calculation after cross section processing. Both 1D and 2D discrete-ordinates transport calculations can be performed using XSDRNPM and NEWT, respectively. The T-XSDRN sequence calls XSDRNPM for transport analysis in slab, sphere, or cylindrical geometries, while the T-NEWT sequence calls NEWT for analyses in 2D xy-geometries. In addition to the input necessary for cross section processing, an XSDRN or NEWT input model is also required. The XSDRN model input is discussed in Appendix A of TRITON; the NEWT model input requirements are described in the NEWT chapter. Similar capabilities and applications for KENO-V.a and KENO-VI are handled through the CSAS5 and CSAS6 sequences, respectively.

### 3.1.2.3 Depletion sequences (T-DEPL, T-DEPL-1D, T5-DEPL, T6-DEPL)

The TRITON depletion sequences build upon the transport sequences by automating depletion/decay calculations after the transport calculations for each material designated for depletion. One or more materials in the model can be designated for depletion. Each designated material is depleted using regionaveraged reaction rates, accounting for all regions in the model associated with a given depletion material. The TRITON depletion calculation procedure is described further in the next subsection. TRITON automates the various computational processes-cross section processing, transport, and depletion-over a series of depletion and decay intervals supplied by the user. The depletion procedure is discussed in Sect. 3.1.2.3.1. The 2D TRITON depletion sequence (T-DEPL), which uses NEWT for the transport calculations, also provides the capability to generate lattice-physics data for nodal core calculations. These lattice physics capabilities are discussed in Sect. 3.1.2.3.2.

Within TRITON depletion calculations, TRITON invokes the ORIGEN depletion module for the timedependent transmutation of each user-defined material. TRITON provides ORIGEN the neutron flux space-energy distribution, the multigroup cross sections, material concentrations, and material volumes. ORIGEN performs the flux normalization, cross section collapse, and multi-material depletion/decay operations to determine new isotopic concentrations for the next calculation.

### 3.1.2.3.1 Predictor-corrector depletion process

For all depletion sequences, TRITON automates cross section processing, transport, and depletion calculations over a series of depletion-decay intervals supplied by the user. A depletion interval represents a time interval in which the model power level is assumed constant. A depletion model that exhibits various power level changes will require multiple depletion intervals to accurately model the changes in power. Each depletion interval can be followed by a decay calculation over a user-specified decay interval.

Within a given depletion interval (e.g., an LWR operating at constant power for a 12-month fuel cycle), the isotope concentrations of different depletion materials change, which induces changes in the problemdependent multigroup cross sections (through spatial and energy self-shielding effects) as well as the neutron flux distribution, leading to different power distributions and transmutation rates in depletion materials. This requires TRITON to represent each depletion interval as a series of smaller time intervals in which cross section processing and transport solutions are recomputed to accurately model these timedependent effects. A depletion subinterval represents a time interval in which TRITON performs cross
section processing and transport calculations to determine cross sections and flux distributions used in the depletion calculations. All depletion subintervals for a given depletion interval have the same length-for example, one 12 -month depletion interval can be represented as a series of 12 one-month depletion subintervals, or as 6 two-month depletion subintervals. Alternatively, the 12 -month depletion interval can be modeled as two consecutive 6-month depletion intervals, each one having a different number of subintervals. Therefore the formulation of a depletion scheme in TRITON is highly flexible. A depletion scheme is the set of user-defined depletion and decay intervals with associated power levels and number of subintervals. TRITON does not provide automated means to determine the appropriate depletion scheme for a given application. The user must determine the accurate depletion scheme specific to his or her application.

TRITON uses a predictor-corrector approach to process the user-defined depletion scheme. The predictorcorrector approach performs cross section processing and transport calculations based on anticipated isotope concentrations at the midpoint of a depletion subinterval. Depletion calculations are then performed over the full subinterval using cross sections and flux distributions predicted at the midpoint. Depletion calculations are then extended to the midpoint of the next subinterval (possibly through a decay interval and into a new depletion interval), followed by cross section processing and transport calculations at the new midpoint. The iterative process is repeated until all depletion subintervals are processed. In order to start the calculation, a "bootstrap case" is required using initial isotope concentrations for the initial cross section processing and transport calculation. The bootstrap calculation is used to determine the anticipated isotope concentrations at the midpoint of the first depletion subinterval.

The predictor-corrector approach is best explained by an example. Figure 3.1.1 illustrates the predictorcorrector process for a hypothetical depletion scheme with two depletion intervals. The first depletion interval contains two subintervals, followed by a decay interval. The second depletion interval contains one subinterval and is also followed by a decay interval. In Figure 3.1.1, cross section processing and transport calculations are represented by the "T" label, and depletion calculations are represented by the "D" label. For this example, four sets of calculations would be necessary: one for each of the three depletion subintervals, and one for the initial "bootstrap case." These calculations are represented in the following eight steps.

Step $1 \mathrm{~T}_{0}$ : Cross section processing and transport calculation using initial (i.e., time-zero) isotope concentrations.

Step $2 \mathrm{D}_{1}$ : Depletion calculation from time-zero to the midpoint of the first depletion subinterval. The dashed horizontal arrow denotes a "predictor" depletion step.

Step $3 \mathrm{~T}_{1}$ : Cross section processing and transport calculation at the midpoint of the first depletion subinterval.

Step $4 D_{1}$ : Depletion calculation for the first depletion subinterval. The solid horizontal arrow across the subinterval denotes a "corrector" depletion step. Corrector steps use cross sections and flux distribution computed at the subinterval midpoint. This is represented by a solid arrow from $\mathrm{T}_{1}$ to $\mathrm{D}_{1}$.
$\mathrm{D}_{2}$ : Predictor depletion calculation for the second depletion subinterval. Predictor steps use cross sections and flux distribution computed at the previous subinterval midpoint. This is represented as the dashed arrow from $\mathrm{T}_{1}$ to $\mathrm{D}_{2}$.

Step $5 \mathrm{~T}_{2}$ : Cross section processing and transport calculation at the midpoint of the second depletion subinterval.

Step $6 \mathrm{D}_{2}$ : Corrector depletion calculation for the second depletion subinterval, followed by the decay calculation at the end of the first depletion interval.
$\mathrm{D}_{3}$ : Predictor depletion calculation for the third depletion subinterval. The third depletion subinterval is the first and only subinterval associated with the second depletion interval.

Step $7 \mathrm{~T}_{3}$ : Cross section processing and transport calculation at the midpoint of the third depletion subinterval.

Step $8 \mathrm{D}_{3}$ : Corrector depletion calculation for the third depletion subinterval. This calculation is followed by a second decay calculation.

Figure 3.1.1. Predictor/corrector depletion algorithm used by TRITON.

The depletion calculations are performed by ORIGEN and span either the first half of a subinterval (predictor step) or the full subinterval (corrector step). ORIGEN performs these depletion calculations and possible decay calculations over a series of smaller time intervals. The ORIGEN time intervals are automatically determined by TRITON depending on the length of the depletion subinterval and decay interval. Additionally, TRITON will automatically adjust the number of subintervals per depletion interval if the time length of the user-defined subinterval is large (i.e., $>400$ days). TRITON writes the utilized depletion scheme near the top of the output file. The depletion scheme output edit is further described in Sect. 3.1.5.4.1.

### 3.1.2.3.2 Lattice physics analysis

The 2D depletion sequence (T-DEPL) may be used to generate lattice physics data for subsequent core analysis calculations using core simulator software. Core simulators typically employ few-group nodal diffusion theory for neutronic calculations, coupled with other calculation methods for thermal hydraulics, fuel performance, and plant operation (e.g., soluble boron letdown or control rod movement). Core simulation requires the use of pretabulated lattice physics data for the neutronic calculations-that is, few-group homogenized cross sections, with appropriate discontinuity factors, pin powers, and kinetic parameters, functionalized in terms of burnup and other system conditions such as fuel temperature and moderator density.

To support lattice physics database preparation, the NEWT transport module contains flexible input options to define the few-group energy structure, spatial homogenization regions, and discontinuity factors. After the transport calculation at the midpoint of each depletion subinterval, NEWT computes the lattice physics data and stores this data on a temporary file. TRITON reads the temporary file and archives the lattice physics data onto a separate database file. In addition, the $T$-DEPL sequence supports branch calculations in which perturbations may be applied to certain system conditions such as fuel temperatures and moderator density. TRITON automates the cross section processing and transport calculations for each branch condition at the midpoint of the depletion subinterval. NEWT computes the lattice physics data for the branch calculations, and TRITON archives this data onto the lattice physics database file.

The TRITON input options for branch calculations are described in Sect. 3.1.3.3.2, and the file format of the lattice physics database is provided in the Appendix B of TRITON. The TRITON input options for branch calculations are designed to be highly flexible to support a large range of core analyses; therefore, TRITON does not provide automated means to determine the branch calculations. The user must determine the necessary branch calculations for his or her core analysis and be knowledgeable of the capabilities and limitations of the cross section treatment of the core simulator. The TRITON Lattice Physics Primer has been developed to provide guidance on appropriate TRITON branch calculations for LWR core analysis (NUREG/CR-7041) and in "Cross Section Generation Guidelines for TRACEPARCS" (NUREG/CR-7164).

### 3.1.2.4 S/U analysis sequences (TSUNAMI-2D, TSUNAMI-2DC)

TRITON supports a 2D sequence (TSUNAMI-2D) to support cross section sensitivity and uncertainty (S/U) analysis. The TSUNAMI-2D sequence is similar in function to the 2D transport sequence T NEWT, except that TRITON sets up additional calculations to perform S/U analysis. After the initial transport calculation, a second transport calculation is performed to compute the adjoint flux solution. Both the forward and adjoint fluxes are saved to different files that are read by the SAMS module to compute sensitivity coefficients and the uncertainty in $k_{\text {eff. }}$. In addition to $\mathrm{S} / \mathrm{U}$ analysis for $k_{\text {eff, }}$, the TSUNAMI-2D sequence allows for S/U analysis of user-defined ratios of forward flux responses, such as flux-weighted cross sections, reaction rate ratios, and power-peaking factors. For each user-defined response ratio, TRITON automates additional fixed-source adjoint transport calculations in NEWT, followed by S/U calculations in SAMS. TRITON iteratively calls NEWT and SAMS for each response ratio definition. TRITON also automatically sets up the fixed-source input for NEWT, which is implicitly defined by the response ratio specification.

For TSUNAMI-2D calculations, the TRITON input is similar to 2D transport calculations (T-NEWT) with some additional input options. Input data blocks are available to define response ratios for $\mathrm{S} / \mathrm{U}$ analysis. Additional input data blocks are available for the SAMS module to control various aspects of the
sensitivity and uncertainty calculations and output formatting. The $\mathrm{S} / \mathrm{U}$ input options are further discussed in the TSUNAMI-1D manual. Examples of TSUNAMI-2D models are provided in Sect. 3.1.6.

Although TSUNAMI-2D is similar to the T-NEWT sequence, enhanced versions of the cross section processing codes are used to compute sensitivity data necessary for the SAMS calculation. In place of the BONAMI code used by T-NEWT, TSUNAMI-2D utilizes a sensitivity version called BONAMIST. This enhanced code computes the problem-dependent multigroup cross sections along with their sensitivities to the input data, the so-called "implicit sensitivities." Implicit sensitivity effects from ENDF/B-VII cross sections are now treated with full-range Bondarenko factors present on the multigroup library with BONAMIST.

The NEWT-based TSUNAMI-2D sequence is functionally similar to the TSUNAMI-1D and TSUNAMI-3D_K5/TSUNAMI-3D_K6 sequences of SCALE, in which cross section processing, forward and adjoint transport calculations, and S/U calculations are automated using XSDRN and KENO V.a/KENO-VI, respectively. Like these S/U sequences, TRITON supports an auxiliary sequence, TSUNAMI-2DC, which does not perform the additional adjoint transport calculations and SAMS calculations. The TSUNAMI2DC sequence does not employ the sensitivity version of the cross section processing code, BONAMIST, as the sensitivity data from this code is not used in the calculation sequence. The TSUNAMI-2DC sequence is identical to the T-NEWT sequence with one exception: if user-defined response ratios are provided in the input, then TSUNAMI-2DC will compute the response ratios and edit their values in the output file.

During the development of SCALE 6.2, the cross section processing routines were significantly modernized to use XSProc for all of the TRITON sequence except TSUNAMI-2D; therefore, the run times will be slower for each T-NEWT calculation and the solution will be somewhat different. However, the other TSUNAMI sequences do use XSProc.

### 3.1.3 Input Description

TRITON input is free-form and keyword based, similar in form to many other modules in SCALE. With a few exceptions, the following formatting rules apply:

- Data is limited to 255 columns but may wrap into as many lines as are needed.
- Comment lines start with a tick mark (') in the first column of a line and may be placed anywhere in the input.
- The keyword-based input is case insensitive.
- TRITON input is organized into blocks of data. Each data block begins with read blockname and terminates with end blockname.
- Blocks of data may appear in any order. Each block of data may appear only once in the input.
- Input can be redirected from an auxiliary file by using the open angle bracket ( $<$ ) and the name of the file-for example, </path/to/auxiliary_input_file.

The first three lines of input and the last line of the input are unique. The first line of input contains the TRITON sequence name along with parameter specifications, e.g., parm=centrm. The second line contains the case title (up to 80 characters), and the third line contains the cross section library identifier. The last line of the input contains the end keyword and terminates the input file. An example TRITON input is as follows:

```
=t-xsec parm=(centrm,check)
TRITON Input Example
V7-252
end
```

In this example, the first line of input declares this calculation to use the T-XSEC sequence. The name of the sequence is preceded by the " $=$ " sign. After the sequence name, two parameter options are specified. Parameters are optional. If specified, the keyword parm= must precede the parameter options. Multiple parameter options can be provided in a comma-separated list enclosed in parentheses. In this example, the centrm option specifies the CENTRM-based discrete-ordinates sequence is used by default. The check option implies that TRITON will read all input and ensure that no input errors are present, without running additional calculations. The second input line provides the case title: TRITON Input Example. The third input line provides the cross section library: V7-252. This example input file is terminated at the end keyword. The end keyword must appear by itself at the beginning of the final line of the input file.

The TRITON input section is organized by sequences. The first section summarizes the input requirements for the cross section processing sequence T-XSEC, which includes discussion of the COMPOSITION and CELLDATA block. The second section summarizes the input requirements for the TRITON transport sequences T-XSDRN and T-NEWT. The XSDRN MODEL block is described in Appendix B of TRITON. The third section summarizes the input for TRITON depletion sequences: T-DEPL-1D, T-DEPL, T5-DEPL, and T6-DEPL. The depletion sequence input section includes discussion of the DEPLETION, BURNDATA, TIMETABLE, BRANCH, and OPUS blocks. The fourth section summarizes the input requirements for the TRITON S/U sequences TSUNAMI-2D and TSUNAMI-2DC.

The input requirements for the depletion sequences and the $\mathrm{S} / \mathrm{U}$ sequences build upon the input requirements for the cross section processing sequence and the transport sequences, so the user should be familiar with these first two sections. However, the input requirements for the depletion and $\mathrm{S} / \mathrm{U}$ sequences are independent, so the user can skip over these sections as needed.

The fifth and sixth section of the input description is dedicated to two TRITON-specific blocks of data to simplify model development and output control: the ALIAS block and the KEEP_OUTPUT block, respectively. The final section describes TRITON control parameters used in the parm= specification.

### 3.1.3.1 Cross section processing

An example input structure for a cross section processing sequence calculation is provided in Figure 3.1.2.

```
=t-xsec parm=(options)
Title or description of up to 80 characters
x-sect_lib_name
read alias
[List of user-defined aliases (optional)]
end alias
read composition
[List of material specifications (standard SCALE format)]
end composition
read celldata
[unit cell specifications for multigroup processing(optional)]
```

```
end celldata
```

Figure 3.1.2. Structure of T-XSEC input.

In this input, the title can be any descriptive title, and the cross section library $x$-sect_lib_name can be any multigroup SCALE cross section library (or continuous-energy library if KENO is used). The three blocks of data highlighted in red-ALIAS, COMPOSITION, and CELLDATA—must appear in the order shown above. However, the ALIAS and CELLDATA blocks are optional. If the ALIAS block is not used, the COMPOSITION block follows the cross section library line. If the CELLDATA block is not used, the input is terminated after the COMPOSITION block.

The input requirements for the ALIAS block are deferred to Sect. 3.1.3.5 as the ALIAS block impacts many different blocks of data for all TRITON sequences. The COMPOSITION block is used to define material compositions and temperatures. The CELLDATA block is used to specify unit cell calculations used to generate problem-dependent multigroup cross sections. The input requirements for the COMPOSITION and CELLDATA blocks are comprehensively described in the XSProc manual and are not repeated here. Figure 3.1 .3 shows an example input for a cross section processing calculation. In this input file, cross section processing calculations are performed for two different square-pitched $\mathrm{UO}_{2}$ fuel pins surrounded by Zircaloy-4 cladding and borated $\mathrm{H}_{2} \mathrm{O}$ moderator. The first fuel pin (material 1) is $2.5 \%$ enriched in ${ }^{235} \mathrm{U}$. The second fuel pin (material 4) is $4.5 \%$ enriched in ${ }^{235} \mathrm{U}$. These materials are used in two separate unit cell definitions in the CELLDATA block.

```
=t-xsec
Simple T-XSEC input
v7.1-252n
read composition
'cell 1
    uo2 1 den=9.550 1 750 92235 2.5 92238 97.5 end

    h2o 3 den=0.75 1 550 end
    boron 3 den=0.75 600e-6 550 end
'cell 2
    uo2 4 den=9.550 1 750 92235 4.5 92238 95.5 end
    zirc4 5 1 600 end
    h2o 6 den=0.75 1 550 end
    boron 6 den=0.75 600e-6 550 end
end composition
read celldata
    latticecell squarepitch fueld=0.95 1 cladd=1.05 2 pitch=1.4 3 end
    latticecell squarepitch fueld=0.95 4 cladd=1.05 5 pitch=1.4 6 end
end celldata
end
```

Figure 3.1.3. Example T-XSEC input.

One key observation in this example is the duplicate definitions for the clad material (materials 2 and 5) and the moderator material (materials 3 and 6). For practical use in subsequent transport calculations, only four material compositions need to be defined: one each for the different fuel pin enrichments and one definition each for the clad and moderator material compositions. However, as described in the XSProc manual, the same material identifier cannot be used in multiple unit cell definitions. Because this example requires two separate unit cell definitions to appropriately generate cross sections for each fuel pin enrichment, duplicate definitions are required for the clad and moderator compositions. The unique mixture number input requirement can lead to many duplicate definitions of clad and moderator materials, depending on model complexity. To simplify model development, duplicate material compositions and
similar unit cell definitions can be defined simultaneously through the use of aliases. The ALIAS block is discussed further in Sect. 3.1.3.5.

### 3.1.3.1.1 Combined two-region and $\mathrm{S}_{\mathrm{N}}$ cross section processing

It is possible to use the both the CENTRM-based two-region method and the CENTRM-based $\mathrm{S}_{\mathrm{N}}$ method within the same input file. Figure 3.1.4 shows a modified input file of the previous example in which the first unit cell uses $\mathrm{S}_{\mathrm{N}}$ cross section processing and the second unit cell uses two-region cross section processing. Each unit cell contains a centrmdata keyword specification after the latticecell specification. The centrmdata specification contains a set of additional keyword specifications used to identify the $\mathrm{S}_{\mathrm{N}}$ and the two-region options in CENTRM.

The input centrmdata $n p x s=1$ end centrmdata instructs TRITON to use $\mathrm{S}_{\mathrm{N}}$ cross section processing, whereas the input centrmdata npxs=5 end centrmdata instructs TRITON to use tworegion cross section processing. These keyword options are described in detail in the XSProc manual. The default cross section option for TRITON is $\mathrm{S}_{\mathrm{N}}$; therefore, the first centrmdata specification is not needed (but still acceptable). If parm=centrm was specified, the first centrmdata specification would not be needed (but still acceptable), whereas the second centrmdata specification would be required to activate the two-region option. Conversely, if parm=2region was specified, the second centrmdata specification is not needed (but still acceptable), whereas the first centrmdata specification would be required to activate the $\mathrm{S}_{\mathrm{N}}$ option.

The centrmdata specifications may also be applied to other unit cell types (e.g., multiregion); however, the two-region method is only valid for specific unit cell configurations described in the XSProc manual. The user should determine the applicability of the two-region method by comparing calculation results with continuous-energy calculations or multigroup calculations using the CENTRM-based $\mathrm{S}_{\mathrm{N}}$ method.

### 3.1.3.1.2 User-defined Dancoff factors

Like other SCALE calculations, TRITON uses Dancoff factors as part of its cross section processing calculations. The user can specify Dancoff factors for various materials by using the centrmdata specification and the dan2pitch keyword. Here is an example.

```
read celldata
    latticecell squarepitch fueld=0.95 1 cladd=1.05 2 pitch=1.4 3 end
    centrmdata dan2pitch=0.51 end centrmdata
    latticecell squarepitch fueld=0.95 4 cladd=1.05 5 pitch=1.4 6 end
    centrmdata dan2pitch=0.65 end centrmdata
end celldata
```

In this example, fuel materials 1 and 4 were assigned a Dancoff factor of 0.51 and 0.65 , respectively. These Dancoff factor values can be computed using the SCALE MCDANCOFF sequence. Only one dan2pitch keyword is allowed for a given centrmdata specification.

### 3.1.3.2 Transport sequences

An example input structure for a transport sequence calculation is provided in Figure 3.1.5.

```

[keep_output options (optional)]
end keep_output
read model
[specification of XSDRN or NEWT model]
end model
end
```

Figure 3.1.5. Structure of T-NEWT or T-XSDRN input.

The MODEL block contains a full transport model input description and is required for both the T-NEWT and T-XSDRN sequences. The MODEL block must be the last block of data in the input file. The MODEL block provides the physical layout of the configuration for which the transport calculation is to be performed, along with general control parameters. The nature of data embedded within the MODEL block depends on the sequence selected. For the T-NEWT sequence, the MODEL block contains a complete NEWT input listing. NEWT input is fully described in the NEWT chapter and is not repeated here. For the T-XSDRN sequence, the MODEL block is described in the Appendix B of TRITON. Sample problems for both the T-NEWT and T-XSDRN sequences are provided in Sect. 3.1.6. The optional KEEP_OUTPUT block is described in Sect. 3.1.3.6.

### 3.1.3.3 Depletion sequences input

An example input structure for a depletion calculation is provided in Figure 3.1.6.

```

end
```

Figure 3.1.6. Structure of depletion sequence input.

The TRITON depletion sequences support the blocks of data highlighted in red: the DEPLETION, BURNDATA, OPUS, BRANCH, and TIMETABLE data blocks. These data blocks, along with the KEEP_OUTPUT block, may appear only once, in any order, and must follow the COMPOSITION and CELLDATA blocks and must precede the MODEL block. The DEPLETION and BURNDATA blocks are always required for depletion calculations.

The MODEL block contains a full transport model input description and is required for all depletion sequences. For the $T$-DEPL sequence, the MODEL block contains a complete NEWT input listing. NEWT input is fully described in NEWT chapter and is not repeated here. For the T-DEPL-1D sequence, the MODEL block is described in Appendix A of TRITON. For T5-DEPL and T6-DEPL sequences, the MODEL block contains input for KENO V.a and KENO-VI, respectively. The details of KENO V.a and KENO-VI input formats are described in the KENO V.a and KENO-VI chapters and are not repeated here.

TRITON reads the MODEL block at the beginning of the sequence to process the input and save data to appropriate data in memory (or on a restart file for KENO). Reading the MODEL block at the beginning of the sequence allows TRITON to check all transport module data and to terminate immediately if errors are found in the model input. When the transport module is eventually invoked by the sequence, TRITON uses the processed data in memory (or reads it from the restart file), allowing for transport iterations
(XSDRN, NEWT) or neutron histories (KENO) to begin immediately, eliminating the need for recalculation of geometry data each time the transport module is invoked.

### 3.1.3.3.1 BURNDATA block

The BURNDATA data block allows specification of the depletion scheme for the model and is used only by the four depletion sequences in TRITON. As described in Sect. 3.1.2.3.1, the depletion scheme consists of a series of depletion intervals-time intervals of constant power operation-which may be partitioned into many depletion subintervals-intervals over which cross section processing and transport calculations are performed to update cross sections and flux distributions used in the depletion calculation. Moreover, depletion intervals may be optionally followed by a decay interval-a time interval for zero-power decay.

The depletion intervals that define the depletion scheme are specified in the BURNDATA block in chronological order within the BURNDATA block, with the following format.

```
READ burndata
power=P burn=B down=D nlib=N end
power=P burn=B down=D nlib=N end
END burndata
where
\(P=\) average specific power in the basis material(s), in megawatts per metric tonne of initial heavy metal (MW/MTHM) (typically MW/MTU for uranium-only models);
\(B=\) length of depletion interval in days;
\(D=\) length of decay interval in days following the depletion interval (optional, default \(=0.0\) );
\(N=\) number of depletion subintervals for the depletion interval (optional, default \(=1\) ).
```

The average specific power is provided for the basis material(s). In other words, localized power distributions are uniformly scaled accordingly in the transport solution such that the average power in the basis material(s) matches the power specified in input. By default, the basis consists of all materials in the model, so that local powers are scaled to obtain a problem-wide average power matching the power specified in input. The basis can be set as a single material or set of materials in the DEPLETION data block. The DEPLETION data block is described in Sect. 3.1.3.3.4.

Each depletion interval specification must be terminated by an end keyword. As many depletion intervals as necessary may be entered to model the depletion scheme. At least one depletion interval must always be entered; hence, the BURNDATA block is always required in depletion calculations. The number of depletion subintervals can be used to refine the temporal discretization to force more cross section processing and transport calculations per depletion interval, as discussed in Sect. 3.1.2.3.1.

An example of a BURNDATA block is shown in Figure 3.1.7. The example case in Figure 3.1.7 contains three depletion intervals, with the first interval at power $26.54 \mathrm{MW} / \mathrm{MTHM}$ in the basis materials (the basis is defined in the DEPLETION block), for an interval of 121 days. This is followed by a second depletion interval at power 38.01 MW/MTHM for 201.5 days and then 30 days of zero-power operation. In the third depletion interval, the basis materials are depleted at a $31.44 \mathrm{MW} / \mathrm{MTHM}$ power level for 386.25 days, followed by 5 years (1826.25 days) of decay. In this model, three, two, and one depletion subintervals are used for the first, second, and third depletion intervals, respectively.

```
READ burndata
power=26.54 burn=121.0 nlib=3 end
power=38.01 burn=201.5 down=30 nlib=2 end
power=31.44 burn=386.25 down=1826.25 end
END burndata
```

Figure 3.1.7. Example BURNDATA block input.

### 3.1.3.3.2 BRANCH block

The T-DEPL sequence in TRITON supports the ability to perform branch calculations during depletion calculations. Branch calculations are not supported for the 3D depletion sequences, nor are branch calculations supported for problems that require doubly heterogeneous cross section processing. A branch calculation is a recalculation of cross section processing and transport calculations with one or more of a limited set of input parameters modified. These calculations are performed at the same location in the depletion scheme as in the nominal cross section processing and transport calculations-that is, at $t=0$ and at the midpoint of the depletion subintervals (see Sect. 3.1.2.3.1 for more details on the TRITON predictor-corrector depletion scheme). Branch calculations allow for the quantification of changes in system responses of interest (eigenvalue, pin powers, homogenized few-group cross sections, and kinetic parameters) due to changes in system parameters. TRITON saves the responses of interest for the nominal and each perturbed (branch) state, for each evaluation within the TRITON depletion scheme. These responses of interest-in particular, homogenized cross sections-may be subsequently extracted for use in nodal core simulation calculations.

Branch calculations represent a branch from the primary depletion scheme at each depletion subinterval. With branching enabled, selected properties or conditions (fuel temperature, moderator temperature, moderator density, soluble boron concentration, and control rod insertion, or any combination thereof) can be varied from the reference state for as many branches as are desired. Depletion calculations, however, are performed for reference-state conditions only. Figure 3.1.8 illustrates the branch loop during a T-DEPL sequence calculation. Although not technically a branch state, the reference state is considered to be branch 0 for numbering purposes within TRITON. For each branch calculation $>0$, TRITON updates the appropriate parameters and re-executes the cross section processing and transport calculations. Responses of interest are saved to a database file (i.e., the txtfile16 file) for both the nominal and perturbed-state conditions, and TRITON reverts to cross sections and fluxes from the reference branch 0 to proceed with the depletion calculation. The process repeats following each depletion subinterval, until all depletion subintervals are simulated. Responses of interest are added to the database file for all branches at each depletion subinterval.

Figure 3.1.8. Schematic illustration of T-DEPL branch calculations during depletion.

Branch perturbations may be applied to any of the following five parameters: fuel temperature, moderator temperature, moderator density, moderator soluble boron concentration, and control rod insertion. These properties may be varied individually or simultaneously. Branch calculations are specified in the TRITON $B R A N C H$ data block. The BRANCH data block has the following form.

```
READ branch
define deftype 泣涪 \ldots.. In end
tf=fueltemp tm=modtemp dm=moddens sb=boronconc cr=inout end
END branch
```

where

```
deftype = 'fuel,' 'mod,' 'crout', or 'crin',
I}=\mp@code{list of materials associated with type definition deftype,
fueltemp = branch fuel temperature (K),
modtemp = branch moderator temperature (K),
moddens = branch moderator density (g/cm )}\mathrm{ ),
boronconc = soluble boron concentrations (ppm),
inout = control rod/blade state (out = 0, in = 1).
```

The type definitions must come first within the BRANCH block, and at least one definition is always required. The 'fuel' type definition is used to specify which of the problem materials are considered to be fuel during branch calculations; similarly, the 'mod' type definition specifies the material or materials that are to be considered moderator. The 'crout' definition specifies the materials that are in place in the transport model when control structures are withdrawn, while the 'crin' definition specifies the materials that are present in the transport model when a control structure is inserted. The 'fuel' definition must be
present if any fuel temperature branches are performed. The 'mod' type definition must be present whenever moderator temperature, moderator density, or soluble boron branches are performed. Both the 'crout' and 'crin' definitions must be present if control rod branches are requested. Definitions may not be repeated-for example, 'define fuel' may occur only once.

Type definitions are followed by branch specifications. For each branch, one or more branch specifications may be given; if a particular property is omitted, then the reference conditions of the original model and material specifications are used. The first branch specification must describe the nominal conditions, and all parameters must be specified for this branch. Each branch specification can optionally define up to five branch keywords before terminating with the end keyword. The five branch keywords are as follows.

```
tf= fuel temperature (K),
tm= moderator temperature (K),
dm= moderator density (g/cm}\mp@subsup{}{}{3})\mathrm{ ,
sb= soluble boron concentration (ppm boron), and
cr= control rod state (out = 0, in = 1).
```

The format of a BRANCH block is best illustrated by an example. Figure 3.1 .9 shows a complete branch data block for a five-branch calculation, with embedded descriptions of each branch. Note that there are six entries; the first branch is the reference or branch 0 state.

In this example, materials 11 and 12 are specified as 'fuel', and fuel temperature perturbations will be applied to only these materials. The nominal temperature for both materials is determined from the branch 0 input ( 901 K ). The nominal fuel temperature must be the same for all materials in the definition and must be consistent with the initial standard composition input. Similarly, materials 13 and 14 are defined as the moderator materials. The temperature ( 559 K ), density ( $0.76 \mathrm{~g} / \mathrm{cm}^{3}$ ), and soluble boron concentrations (655 ppm) for the reference state must be identical to those of the initial material specifications and must be identical for all materials defined as moderator.

```
READ branch
define fuel 11 12 end
define mod 13 14 end
define crout 20 21 end
define crin 30 31 end
'reference state
tf=901 tm=559 dm=.4 cr=0 sb=655 end
'moderator density branch
dm=.80 cr=0 end
'moderator density + control rod insertion branch
dm=.80 cr=1 end
'moderator density + soluble boron (low) branch
sb=20 dm=.8 end
'moderator density + soluble boron (high) branch
sb=1300 dm=.8 end
'moderator density + fuel temperature branch
tf=559 dm=0.8 end
END branch
```

Figure 3.1.9. Example BRANCH block input.

In a reactor core, when a control structure (rod, blade, etc.) is withdrawn, the volume occupied by the structure is replaced by something else. Thus, in a branch calculation with rod insertion and withdrawal, the material(s) present for both states must be specified. If the reference condition is defined as control
rods withdrawn (i.e., cr = 0), the NEWT geometry model must contain the materials defined by 'crout'. For a control rod insertion branch ( $\mathrm{cr}=1$ ), TRITON exchanges the materials specified in the 'crin' definition $(30,31)$ with corresponding materials in the 'crout' definition (20,21). Conversely, if the reference condition is defined as control rods inserted (i.e., cr $=1$ ), the NEWT geometry model must contain the materials defined by 'crin'. For a control rod withdrawal branch (cr = 0), TRITON exchanges the materials specified in the 'crout' definition with corresponding materials in the 'crin' definition. For this reason, unique material numbers must be paired between crin and crout definitions. For example, consider a zirc-clad $\mathrm{B}_{4} \mathrm{C}$ control rod inserted during a control rod insertion branch, with materials 30 and 31 representing the clad and rod materials, respectively. In the withdrawn position, both the clad and poison materials are replaced by the moderator. To have consistent definitions of 'crin' and 'crout', two moderator materials must be defined for the withdrawn state: one corresponding to the clad material and one corresponding to the rod material.

As mentioned earlier, only one condition keyword is required per branch, but all five may be used. However, the reference state (branch 0 ) entry must specify all five conditions. For subsequent branches, when a specific branch state is not specified, the reference state is used. In the above example, the first entry, branch zero, specifies the reference state with a fuel temperature of 901 K , moderator temperature of 559 K , moderator density of $0.4 \mathrm{~g} / \mathrm{cm}^{3}$, control rod withdrawn, and a soluble boron concentration of 655 ppm . The second entry (branch 1) specifies a moderator density of $0.80 \mathrm{~g} / \mathrm{cm}^{3}$ and the control rod state as withdrawn. Since the reference state is for a withdrawn control rod, the statement $\mathrm{cr}=0$ is redundant (but completely acceptable). The next branch is identical to the previous branch, except that in this case the control rod is inserted. For both cases, reference fuel and moderator temperatures were used. In the following branch, the soluble boron concentration is changed to 20 ppm , and the moderator density is again set to a value of $0.8 \mathrm{~g} / \mathrm{cm}^{3}$. In fact, this moderator density is applied to all five branches. Along with the moderator density change, the soluble boron concentration is changed to 1300 ppm for the next branch. And finally, in the last branch, in addition to the moderator density change, the fuel temperature is changed to 559 K . For this case, reference conditions are used for boron concentration, moderator temperature, and control rod state.

Note that TRITON compares the reference values of fuel temperature, moderator temperature, moderator density, and soluble boron concentration with the data entered in the COMPOSITION block. TRITON prints warning messages if the data in the COMPOSITION block and BRANCH block are inconsistent. Also note that each branch calculation is independent of other branch calculations. Thus, the order in which branch calculations are computed is not important.

Branch calculations are usually requested for lattice physics analysis, where the objective is to generate a database of few-group homogenized cross sections for nodal core calculations. Thus, BRANCH blocks are used in tandem with the NEWT's COLLAPSE, HOMOGENIZATION, and ADF blocks. With these blocks of data, TRITON will archive lattice physics data-few-group homogenized cross sections, assembly discontinuity factors (ADFs), homogenized kinetic parameters, pin powers, and form factorsto a binary file called xfile016 in the SCALE temporary working directory. An auxiliary text-formatted data file called txtfile16 is also created in the SCALE temporary working directory. This file format is documented in Appendix A of TRITON.

### 3.1.3.3.3 BRANCH block with user-defined Dancoff factors

As previously mentioned in Sect. 3.1.3.1.2, TRITON uses Dancoff factors as part of its cross section processing calculations. Dancoff factors play an important role in characterizing spatial self-shielding effects. The XSProc module computes the Dancoff factors based on the CELLDATA input. For a squarepitched lattice cell example, Dancoff factors are computed by DANCOFF by assuming that the fuel pin is
within an infinite lattice of identical fuel pins. The assumption of an infinite uniform lattice of fuel pins may lead to inaccurate Dancoff factors for certain configurations such as BWR assembly designs, leading to inappropriate problem-dependent multigroup cross sections. Moreover, the Dancoff factors may change significantly for certain branch conditions, such as changing the in-channel moderator density in a BWR assembly.

The TRITON BRANCH block allows the user to specify material-dependent Dancoff factors for various branch conditions. Branch-specific Dancoff factors may be utilized by defining a new set of materialdependent Dancoff factors using the $d 2 p s e t$ type definition. The set of Dancoff factors may be included in a branch specification by using the $d 2 p=$ keyword. The BRANCH block now has the following format.

```
READ branch
define deftype }\mp@subsup{I}{1}{}\mp@subsup{I}{2}{}\ldots\ldots\mp@subsup{I}{n}{}\mathrm{ end
define d2pset id M}\mp@subsup{M}{1}{}\mp@subsup{D}{1}{}\mp@subsup{M}{2}{}\mp@subsup{D}{2}{}\ldots\ldots.\mp@subsup{M}{n}{}\mp@subsup{D}{n}{}\mathrm{ end
tf=fueltemp tm=modtemp dm=moddens sb=boronconc cr=inout d2p=d2pID end
END branch
```

In the type definition section, the $d 2 p$ set keyword is followed by a positive integer identifier, which is subsequently followed by pairs of material identifiers and their user-defined Dancoff factor value. Multiple material/Dancoff pairs may be entered for a particular set definition, as long as the material identifiers are unique. Multiple set definitions are allowed, as long as the set identifiers are unique.

The $d 2 p=$ keyword in the branch specification can be assigned to any set identifier defined in the branch definition section. If $d 2 p=$ is utilized, the material/Dancoff pairs in the set definition are applied for the given branch condition. The values $d 2 p=0$ and $d 2 p=-1$ have special meaning. If $d 2 p=$ is set to 0 , the material/Dancoff pairs defined in the CELLDATA block are utilized. If $d 2 p=$ is set to -1 , the default MIPLIBcomputed Dancoff factors will be utilized, even if material/Dancoff pairs are defined in the CELLDATA block using the dan2pitch keyword available there. The nominal (branch 0) condition must use the material/Dancoff pairs (if defined) in the CELLDATA block; therefore, the first branch specification must not set the $d 2 p$ keyword to anything other than zero. (Note: $d 2 p=0$ need not be defined for the first branch condition since this is always the case.)

In Figure 3.1.10, the BRANCH block from the previous example has been modified to use branch-specific Dancoff factors. In this example, the nominal branch defines the reference moderator density to be $0.4 \mathrm{~g} / \mathrm{cm}^{3}$, and five branches use a higher moderator density of $0.8 \mathrm{~g} / \mathrm{cm}^{3}$. The Dancoff factors for the higher moderator density condition are different from the reference moderator density. To account for the different Dancoff factors at the higher moderator density condition, a set of material/Dancoff pairs are defined with the set identifier of 400 . In the set, fuel material 11 has a Dancoff factor of 0.4, and fuel material 12 has a Dancoff factor of 0.5 . The set of Dancoff factors is used for the five branch states through the specification of the $d 2 p=$ keyword to 400 .

```
READ branch
define fuel 11 12 end
define mod 13 14 end
define crout 20 21 end
define crin 30 31 end
define d2pset 400 11 0.4 12 0.5 end
'reference state
tf=901 tm=559 dm=.4 cr=0 sb=655 end
'moderator density branch
dm=.80 cr=0 d2p=400 end
'moderator density + control rod insertion branch
dm=.80 cr=1 d2p=400 end
'moderator density + soluble boron (low) branch
```

```
sb=20 dm=.8 d2p=400 end
'moderator density + soluble boron (high) branch
sb=1300 dm=.8 d2p=400 end
'moderator density + fuel temperature branch
tf=559 dm=0.8 d2p=400 end
END branch
```

Figure 3.1.10. Example BRANCH block input with Dancoff factors.

### 3.1.3.3.4 DEPLETION block

The DEPLETION block, used by the four depletion sequences, is simple in concept but performs four important functions. First, this block specifies the materials for which depletion calculations are to be performed. In general, it is desirable to perform depletion calculations only for fuel and target materials of interest. Calculating the depletion of gas gaps, cladding, moderator, or coolant is usually of little value unless the material contains components that will be significantly depleted with burnup. Additionally, it is not usually desirable to deplete soluble poisons in reactor coolants. Therefore, the DEPLETION block requires that the user specify the materials to be depleted. There are no defaults; hence, the block is required for all depletion sequences.

The second function of the DEPLETION block is to specify the basis to which the model power is normalized. In general, the average time-dependent power to which an irradiated object is exposed is known. For example, an LWR fuel assembly discharged from a reactor is known to have operated at certain power levels for one or more time periods. The individual pins in the assembly will have varying power levels depending on position and assembly design. In such a case, the basis for the input power is the full assembly. Fluxes computed in the transport solution will be normalized by TRITON based on reaction rates and energies in all problem materials (depleted and nondepleted materials) such that the assembly-wide power will match the power given in BURNDATA block. However, it is often the case in radiochemical assay analysis that the burnup history of a specific pin is known and isotopic concentrations for that pin are desired. It is still necessary to model the full assembly in order to properly characterize the fluxes in that pin. In such a case, it would be advantageous to specify the operating history for the pin instead of the full assembly. When this is done, the average specific power of the full assembly will be different from that of the pin and will be computed automatically based on power distributions calculated for the assembly. In other words, powers for other materials in the assembly will be normalized such that the power in the pin of interest matches that specified in the BURNDATA block. The material of that pin becomes the basis for power normalization.

Section 3.1.3.3.4.1 below describes the general format of the DEPLETION block that is available to all four depletion sequences. The third function of the DEPLETION block is an optional function used to specify ORIGEN solver options and ORIGEN depletion mode for each depletion material. These options are further described in Sect. 3.1.3.3.4.2. The fourth function of the DEPLETION block is to define optional deletion instructions used to simplify cross section processing using the ASSIGN function. Special provisions have been made in the 1D and 2D depletion sequence (T-DEPL-1D and T-DEPL) to reduce the number of cross section processing calculations in order to decrease calculation run-time. The ASSIGN functionality is further described in Sect. 3.1.3.3.4.3.

### 3.1.3.3.4.1 Basic DEPLETION block format

The basic format of the DEPLETION block is as follows:

```
READ depletion M M M M M ... M M END depletion
```

where $\mathrm{M}_{\mathrm{i}}$ represents the SCALE material numbers for materials to be depleted. As discussed above, the DEPLETION block can also be used to specify the basis for the input power. Power normalization is accomplished by prefixing the material number(s) with a negative sign ( - ). For example, consider a problem in which materials 1,2 , and 3 are being depleted, but the power for material 1 is known. The DEPLETION block for this case is

READ depletion -1 23 END depletion
In this case, powers for all materials will be normalized such that the power in material 1 matches the input power specification in the BURNDATA block.

Note that multiple materials can be used as a power basis. Consider a fuel assembly with three fuel types represented by materials 1,2 , and 3 , and also containing cladding as material 4 and water as material 5 . Table 3.1.2 illustrates multiple ways that the power basis for this assembly might be specified and describes the effect of each specification.

Table 3.1.2. Effects of different power basis specifications

| READ depletion <br> 12 <br> END depletion | The assembly-averaged power is normalized to match the input specific power |
| :--- | :--- |
| READ depletion <br> -123 <br> END depletion | The assembly-averaged power is normalized such that the power of material 1 <br> matches the input specific power |
| READ depletion <br> $-1-23$ <br> END depletion | The assembly-averaged power is normalized such that the average power in materials <br> 1 and 2 matches the input specific power |
| READ depletion <br> 12445 <br> END depletion | The assembly-averaged power is normalized to match input specific powers. <br> TRITON will attempt to do depletion in cladding and moderator materials too. (Note <br> that cladding and moderator materials should be depleted using the deplete-by-flux <br> option described in the next subsection) |
| READ depletion <br> $-1-2-3$ <br> END depletion | The assembly-averaged power is normalized such that the average power in materials <br> $1-3 ~ m a t c h e s ~ t h e ~ i n p u t ~ s p e c i f i c ~ p o w e r . ~ T h i s ~ i s ~ n o t ~ t h e ~ s a m e ~ a s ~ t h e ~ n o r m a l i z i n g ~$ |

### 3.1.3.3.4.2 ORIGEN depletion options

ORIGEN provides two input options for the flux used in the depletion calculation: direct specification of fluxes (i.e., deplete by flux) or indirect specification of fluxes in terms of power (i.e., deplete by power). The ORIGEN depletion is based on a known flux; however, it is more often the case that one knows the specific power in a depletion region rather than the actual flux. When ORIGEN is used in deplete-bypower mode, ORIGEN will internally determine the corresponding flux from the input-specific power and internal tables of fission and capture energy releases for the nuclides present and the macroscopic cross sections of those nuclides. Additionally, at each ORIGEN time interval, ORIGEN recalculates the material power density as nuclide inventories change. Hence, the deplete-by-power mode will result in a time-varying flux, whereas the deplete-by-flux mode will result in a constant flux over the calculation time interval. Since reactors typically operate at a constant (or nearly so) power level, with varying local fluxes, the deplete-by-power option is closer to reality. However, the choice of approach is generally not an issue. Significant differences between calculation results between the two depletion modes would indicate that the TRITON depletion subintervals are too large.

By default, all TRITON depletion materials use the deplete-by-power mode. However, there exist some circumstances where deplete-by-flux is more appropriate. In deplete-by-power mode, ORIGEN will often halt when an attempt to maintain constant power results in a large change in flux between ORIGEN time intervals. Large changes in flux can occur in media where isotope contents are changing rapidly with time, such as in a gadolinium-bearing burnable absorber rod, where gadolinium is being rapidly depleted with time. Another circumstance pertains to activation analysis of nonfuel materials. The flux for these materials is typically governed by external power sources (i.e., fuel materials located elsewhere in the problem domain) rather than by internal power sources. Therefore, the deplete-by-flux option is recommended for these materials.

TRITON provides the option to specify deplete-by-flux mode for selected depletion materials using a modified form of the depletion specification:

Materials preceding the flux keyword are depleted using the deplete-by-power mode; materials following the flux keyword are depleted using the deplete-by-flux mode. For example, consider a problem in which materials 1-6 are to be depleted, but materials 3 and 4 represent nonfuel materials that do not contribute significantly to the total power and are therefore to be depleted assuming constant flux. The DEPLETION block for this situation could be specified as follows.

```
READ depletion 1 2 5 6 flux 3 4 END depletion
```

The DEPLETION block also supports the specification of the ORIGEN calculation method. The default option is solver=matrex, which represents the matrix exponential option. The other option is solver=cram, which represents the new CRAM solver option in ORIGEN. An example depletion specification for the cram solver is as follows.

```
READ depletion 1 2 5 6 flux 3 4 solver=cram END depletion
```

### 3.1.3.3.4.3 Cross section processing simplification using ASSIGN

When depleting a large number of fuel materials, considerable time may be spent in the cross section processing calculations prior to the multigroup transport calculation. Fuel assembly designs may require 20-200 unique depletion materials across the different fuel pins in the assembly. In such cases, an assembly model may require hours of run-time for each pin-wise cross section processing calculation in order to perform a 10-minute transport solution.

Although highly rigorous, such a cross section processing process is extremely burdensome for depletion calculations, especially if branch calculations are requested. To reduce run-time, the 2D depletion sequence ( $T-D E P L$ ) provides the option to group depletion materials together such that they are tracked independently in the depletion calculation but use a common set of microscopic cross sections. The microscopic cross sections for a given depletion group are computed using the average composition of all the depletion materials within the group. Typically, this grouping is applied to fuel pins of identical initial composition. Although the nuclide number densities of such pins will diverge with burnup as a function of location within an assembly, the cross sections of these pins are well represented by a single pin cell calculation with an average composition representative of all these pins.

Although the material grouping option introduces approximations in the cross section processing calculations, which in turn affects the transport and depletion calculations, internal investigations have
shown that solution accuracy can be maintained for a wide range of assembly designs while significantly improving the run-time.

The alternate format of the DEPLETION block for simplified cross section processing is as follows.

```
READ depletion M M M M M . .. M M END
assign N}\mp@subsup{N}{1}{}\mp@subsup{M}{a}{}\mp@subsup{M}{b}{}\ldots..\mp@subsup{M}{x}{}\mathrm{ end
assign N}\mp@subsup{N}{2}{}\mp@subsup{M}{f}{}\mp@subsup{M}{g}{}\ldots...My en
assign N N M M M M ... M M end
END depletion
```

Similar to the basic format, each material designated for depletion $\left(\mathrm{M}_{\mathrm{i}}\right)$ is listed after READ depletion and before the END keyword. Each designated depletion material must be present in the 2D NEWT model. After the first END keyword, the alternate format contains a list of material "assignments" used to simplify cross section processing for a group of depletion materials. The material assignments begin with the assign keyword and terminate with the end keyword. After the assign keyword, a unique representative material identifier $\left(\mathrm{N}_{\mathrm{j}}\right)$ is defined. The representative material is associated with the group of depletion materials that immediately follows in the assign definition. The representative material identifier is used in the COMPOSITION and CELLDATA blocks to define the initial composition, temperature, and cell definition for the group of depletion materials. Thus, the assign definitions in TRITON are currently constrained such that each depletion material group must have the same initial composition. After the last assign definition, the depletion block is terminated with END depletion.

Only depletion materials may be assigned to representative materials. The group of depletion materials assigned to a particular representative material must not appear in the COMPOSITION and CELLDATA blocks.

The use of material assignments is best illustrated by an example. Figure 3.1.11 shows a complete T-DEPL input that uses material assignments. A 2D plot of the model is shown in Figure 3.1.12. In this example, two fuel materials are defined as materials 1 and 2 in the COMPOSITON block. In the DEPLETION block, the list of depletion materials includes materials $1,20,30$, and 40 . Depletion materials 20, 30, and 40 are "assigned" to representative material 2 . Material 2 does not appear in the depletion list or the transport model; materials 20, 30, and 40 do. But only material 2 is defined in the COMPOSITION and CELLDATA blocks. In the transport model, four units are defined, one for each material. An array is used to place each unit in its own location.

The initial calculation uses material 2 to define the compositions of materials 20,30 , and 40 , since all are initially identical. Microscopic cross sections computed for material 2 are used for each of the three assigned depletion materials during the transport calculation and the depletion calculation. After the first depletion calculation, materials 20,30 , and 40 will have different isotopic concentrations because of different locations in the nonsymmetric transport model. At this time, the number densities in each of these three materials are averaged and used to update the concentration of representative material 2. A new set of cell calculations will be performed for materials 1 and 2; this will be followed by a transport calculation that uses the microscopic cross sections for material 2 along with local nuclide number densities for materials 20,30 , and 40 to calculate new and unique macroscopic cross sections for each. The transport and subsequent depletion calculation are then run. The iterative process will continue until all depletion steps have been completed.

Figure 3.1.11. Example input with material assignments.

Figure 3.1.12. Example 2D model plot of material assignments.

The use of assignments can make a considerable difference in run-time performance with minimal sacrifice in accuracy. The above example ran 1.8 times faster using the assignment of three similar pins to one initial specification. A larger BWR calculation, in which 41 pin positions were depleted independently, was run in an assessment of the accuracy of the method. Using this approach, the simplified representation ran 20 depletion steps in $20 \%$ of the time required for the explicitly modeled cells. Figure 3.1.13 shows a comparison of the eigenvalues using the simplified (with assignments) and
explicit (without assignments) models. Also shown on the figure is the percent difference between the approximate and explicit models. For this model, the error in $k_{\text {eff }}$ remains well below $0.05 \%$.

Note that one can combine depletion mode control with material assignments, as follows.

```
READ depletion 1 2 5 6
    flux 3 4 end
    assign 11 1 2 end
    assign 12 3 4 end
    assign 13 5 6 end
END depletion
```

Figure 3.1.13. Eigenvalue comparison of simplified cross section processing example.

### 3.1.3.3.5 TIMETABLE block

In many depletion analyses, material properties can change due to influences outside the depletion process (e.g., boron letdown in pressurized water reactors [PWRs], the insertion or removal of poisons during or between fuel cycles, or changes in temperatures of materials with time). The TIMETABLE block has been provided to allow modification of properties during a depletion calculation. Timetables may be entered for any material or for select nuclides within a material and allow changes in number densities or temperatures. Timetables may also be entered to swap a material in and out of the geometry during depletion.

The TIMETABLE block takes the following general format.

```
READ timetable
[time dependent specifications for a given material]
[time dependent specifications for a given material]
[time dependent specifications for a given material]
END timetable
```

Three different material specifications are allowed to modify temperature, density, or swap materials.
Temperature timetable entries are specified in the format
temperature I t1 K1 t2 K2 t3 K3...tc KC end
where
$I=$ material ID number;
$t_{i}=$ time (days) in calculation where temperature $\mathrm{K}_{i}$ is set, $i=1$ to C ;
$K_{i}=$ temperature (in K) of specified materials at time $t_{i}, i=1$ to C;
$C=$ number of time steps.
Density entries have an analogous specification, with the addition of a couple of extra terms:

$$
\text { density } \quad I \quad M N_{1} N_{2} N_{3} \ldots N_{M} \quad t_{1} \quad D_{1} \quad t_{2} \quad D_{2} \quad t_{3} \quad D_{3} \ldots . t_{c} \quad D_{c} \text { end }
$$

where
$I=$ material ID number;
$M=$ number of nuclides to which this change is applied;
$N_{i}=$ nuclide ID for the ith nuclide in the list, $i=1$ to M ;
$t_{j}=$ time (days) in calculation where density multiplier $D_{j}$ is set, $i=1$ to C;
$D_{j}=$ density multiplier (fractional change) of specified nuclides at time $t_{j}, i=1$ to C;
$C=$ number of time steps.

In both formats, time and data (temperature or density multiplier) must be entered in pairs. Note that density changes may be applied to specific nuclides, while for temperature the change must be applied to all nuclides within the material simultaneously. If $M$ (the number of nuclides for which the density is to be modified) is specified as 0 and no nuclide IDs are entered, then the timetable values are applied to all nuclides in the material.

Note that timetable entries are specified at distinct times in the calculation. These times are measured relative to the beginning of the calculation and are continuous (as opposed to BURNDATA entries, which give burn times or down times in increments per depletion interval). The initial timetable entry should always begin at $\mathrm{t}=0$ days. To allow for time-dependent changes in properties, TRITON applies linear interpolation between data pairs. To hold a parameter constant over a time interval, that parameter should be specified at the same value at both the beginning and the end of this time interval.

The application of timetable entries is best illustrated by example. Consider the depletion scheme described by the BURNDATA block of Figure 3.1.7, which contains three depletion intervals. Assume that the moderator, material 3 , has temperatures and boron concentrations that vary over the three depletion intervals in the following manner:

| Interval | Boron concentration <br> (ppm) |  | Temperature <br> $\mathbf{( K )}$ |
| :---: | :---: | :---: | :---: |
|  | $\mathbf{B O C}$ | EOC |  |
| 1 | 1000 | 100 | 615 |
| 2 | 1250 | 130 | 685 |
| 3 | 980 | 100 | 610 |

Figure 3.1.14 demonstrates a TIMETABLE format that could be used to provide this information to TRITON. This is based on an initial input concentration of 1000 ppm boron in the standard composition specification for material 3 . The temperature of all nuclides in material 3 is constant over each depletion interval, while the density of only the soluble boron in the moderator changes linearly over each depletion interval.

Figure 3.1.14. Example temperature and density TIMETABLE block input.

It is important to note that time-dependent changes to temperatures and number densities are not applied continuously over the depletion calculation but instead are applied only at the times at which cross section processing and transport calculations are performed-that is, the midpoint of the depletion subintervals. The user must determine the accurate depletion scheme specific to his or her application to accurately model time-dependent changes in system properties.

Density timetable specifications can be used to effectively exchange compositions of a single material. One may construct a compound material comprised of two distinct materials at their design densities; a timetable specification can be used to set the density multiplier to 1.0 for the nuclides initially present and to use a multiplier of 0.0 for all nuclides in materials that are not intended to be present at time zero. The timetable can then affect the exchange by changing the multipliers from 0 to 1 , and from 1 to 0 , at the time of the material exchange. One must bear in mind that timetable processing within TRITON performs linear interpolation between time points; if the exchange is intended to occur at a specific moment in time, then the timetable should be set up with the exchange occurring within a very short period. Moreover, it is important to note that material exchanges for two materials that have common nuclides are more difficult to model. For example, a $\mathrm{B}_{4} \mathrm{C}$ absorber material and borated $\mathrm{H}_{2} \mathrm{O}$ moderator material both contain boron nuclides in common. In order to exchange the $\mathrm{B}_{4} \mathrm{C}$ absorber material and the borated $\mathrm{H}_{2} \mathrm{O}$ moderator
material, the carbon, oxygen, and hydrogen density multipliers would be 0 or 1 , but the boron density multipliers would need to be derived from the boron concentrations in both materials.

Material exchange timetables offer another option to users to exchange one material with another material during depletion calculations.

Material exchange timetable has a similar format to temperature timetables:

```
swap I1 I2 t1 S1 t2 S2 t3 S3...tC SC end
```

where

```
I1 = first material ID
I2 = second material ID
t
S
C = number of time steps.
```

The first two entries in the timetable specify the material IDs for swap materials. The remaining entries are entered in pairs: the first pair value is a time value, the second pair value is either " 0 " or " 1 ". " 0 " instructs TRITON to model the swap materials as defined in the nominal model. "1" instructs TRITON to swap the materials (swap every I1 for every I2 and swap every I2 for every I1). The swap state persists until the next time entry in the timetable. For the last time entry in the timetable, the swap state persists for the duration of the calculation. For the example:

```
read timetable
    swap 5 6 0 0 100 1 200 0 end
read timetable
```

- Do not perform the material swap on the interval [0, 100],
- Perform the material swap on the interval [100, 200], and
- Return to the nominal state at time 200 days until the duration of the calculation.

Depending on the BURNDATA specification, there may be one or more depletion/decay steps between timetable entries. Moreover, for accurate depletion modeling, material exchanges must not occur during a depletion subinterval. If a material exchange occurs during a depletion interval, TRITON will subdivide the depletion subinterval at the time of the material exchange. Extending the example above, assume the BURNDATA block is as follows:

```
read timetable
    swap 5 6 0 0 100 1 200 0 end
read timetable
read burndata
    power=40 burn=300 nlib=4 end
end burndata
```

Without the material exchange table, the depletion subintervals are [0, 75], [75, 150], [150, 225], and [225, 300]. With the material exchange table, the subintervals are:

- $[0,75]$ - Swap value is 0
- $[75,100]$ - Swap value is 0
- [100-150] - Swap value is 1, i.e. materials 5 and 6 swap definitions
- [150-200] - Swap value is 1 , i.e. materials 5 and 6 swap definitions
- [200-225] - Swap value is 0 , materials 5 and 6 return to their original definitions
- [225-300] - Swap value is 0

As a limitation of the material exchange timetable, if a depletion material is removed from the geometry, the isotope concentrations at the time of removal are stored in-memory, and then reused upon re-entry into the geometry. In other words, the depletion material does not undergo radioactive decay for the period of time outside the problem geometry.

### 3.1.3.3.6 OPUS block

The OPUS module of SCALE is fully documented in the OPUS chapter of the SCALE manual. OPUS provides the ability to extract specific data from ORIGEN output libraries, perform unit conversions, and generate plot data for post-calculation analysis. In essence, OPUS is an ORIGEN post-processor that provides data in the desired form for a desired subset of nuclides. TRITON by default calls OPUS to extract nuclide concentrations for selected nuclides for all depletion materials and for the most important nuclides. TRITON provides the capability to specify the full set of OPUS commands to tailor OPUS calculations to obtain specific information. TRITON allows a stacked set of OPUS calculations in order to retrieve selected data for selected nuclides.

The content of the OPUS block is based on standard OPUS input parameters, as described in the OPUS chapter; the details of OPUS control and use are not repeated here. However, additional input is necessary to support TRITON operations with OPUS, because TRITON enables additional capabilities beyond those provided for in standard OPUS input. For example, OPUS is designed to process the output file from a single ORIGEN calculation; because ORIGEN is a point depletion solver, the output represents data from a single material. TRITON is typically used to perform multiple depletion calculations at each depletion step-one calculation for each material being depleted. Hence, multiple OPUS calculations are needed to obtain results from multiple materials. The OPUS calculations are performed automatically by TRITON but require the user to specify the materials for which OPUS processing is desired. Additionally, TRITON supports stacked OPUS cases within the READ OPUS data block; hence, keywords are introduced to separate stacked cases.

There are two alternatives available to SCALE users that are complimentary to the OPUS block within TRITON. First, standalone OPUS case(s) can be used to post process the ORIGEN binary concentration file (.f71 extension). This file is automatically saved in the output directory with the file name $\$\{O U T B A S E N A M E\} . f 71$. (e.g. if the input file is reactor.inp, the concentration file is saved in the output directory as reactor.f71) Second, the user may also open the concentration file within Fulcrum to enable similar post-processing capabilities.

### 3.1.3.3.6.1 Selection of materials for OPUS processing

Beyond standard OPUS input keywords (see OPUS chapter), TRITON reads a matl= keyword to allow specification of ID number(s) for the material(s) in the problem for which outputs are desired. The matl $=$...end input keyword accepts one or more materials from the DEPLETION data block for which OPUS processing is desired. If omitted, OPUS processing will be performed for all materials in the DEPLETION block. For example, consider the following DEPLETION and OPUS data blocks:

```
READ depletion 1 2 3 4 5 6 END depletion
READ opus
units=gram symnuc=u-234 u-235 u-236 u-238 pu-238 pu-239
pu-240 pu-241 pu-242 pu-243 np-237 end
time=year
```

In this example, OPUS processing will be performed for all depletion materials, 1-6. Adding a subset of materials using the matl $=$ keyword, for example.

```
READ depletion 1 2 3 45 6 END depletion
READ opus
units=gram symnuc=u-234 u-235 u-236 u-238 pu-238 pu-239
pu-240 pu-241 pu-242 pu-243 np-237 end
time=year
matl=1 2 3 end
END opus
```

will result in OPUS calculations for materials 1, 2, and 3 only.
Although ORIGEN calculations are performed only for individual materials, TRITON provides the capability of combining the results of all or a subset of all depletion materials to get a multimaterial average set of ORIGEN responses. TRITON provides two special ID numbers for combining material results. Specification of material ID 0 will return system-averaged results for the entire set of depletion materials (typically, all fuel elements in a depletion model). Specification of material -1 returns the average of only those materials with ID > 0 present in the matl = list. Again, this is best illustrated by example. Specification of the data blocks

```
READ depletion 1 2 3 4 5 6 END depletion
READ opus
units=gram symnuc=u-234 u-235 u-236 u-238 pu-238 pu-239
pu-240 pu-241 pu-242 pu-243 np-237 end
time=year
matl=1 2 3 0 -1 end
END opus
```

will result in five OPUS calculations and five sets of results-one for each of materials 1,2 , and 3 , one for the average of materials 1-6 (due to input of material ID 0 ), and one for the average of materials 1-3 (due to input of material ID -1).

### 3.1.3.3.6.2 Specification of stacked OPUS cases

In a given calculation, multiple output units may be desired (e.g., grams, curies, and watts), or multiple time scales (e.g., seconds and years), or a combination of these or other parameters. TRITON provides the ability to stack inputs such that multiple cases may be run within a single TRITON calculation. In order to stack cases, the keywords new case are entered in the input stream. Any parameters following these keywords are used to define a new OPUS case.

There is no limit on the number of stacked cases that may be input; however, the matl= specification may be used only in the first case. OPUS calculations are run for each of the materials in this list, for all cases.

Consider a depletion calculation where gadolinium pins are present in the assembly design. One may wish to determine the quantities of gadolinium nuclides from the initial poison rods (tracked as a light element by ORIGEN within TRITON) and from fission (tracked as a fission product by ORIGEN). One may also need masses of selected actinides as well as the total $(\alpha, n)$ reaction rate. Figure 3.1.15 shows how the new case keyword set is used to define unique OPUS calculations. In this example, the new case keywords are shown in upper case and on a line by themselves, but this has been done only for readability. The text may be entered in lower case and on the same line as other keywords. Note, however, that the matl = specification is given only in the first case. All OPUS calculations will be performed for materials 1, 2, and 3 and for the average of these three materials.

```

[specification of NEWT model]
end model
end
```

Figure 3.1.16. Structure of $\mathrm{S} / \mathrm{U}$ analysis input.

The TRITON S/U sequences support the blocks of data highlighted in red: the SAMS, HTML, COVARIANCE, DEFINITIONS, and SYSTEMRESPONSES data blocks. These data blocks, along with the KEEP_OUTPUT block, may appear only once, in any order, and must follow the COMPOSITION and CELLDATA blocks and must precede the MODEL block. If specified, the HTML and COVARIANCE blocks must follow the SAMS block.

These five blocks of data serve the same function as described in the TSUNAMI-1D manual, and the information is not repeated here.

The MODEL block contains a full NEWT transport model input description and is required for both S/U analysis sequences. The MODEL block must be the last block of data in the input file. The MODEL block provides the physical layout of the configuration for which the transport calculation is to be performed, along with general control parameters. The NEWT input is described fully in the NEWT chapter and is not repeated here.

### 3.1.3.5 ALIAS block

The optional ALIAS block may be used to simplify model development within TRITON by defining a set of material numbers that will be inserted in place of the alias when that alias is used in subsequent data blocks. Aliases function as variables for which a user-defined set of materials are inserted; they are identified by a dollar character (\$) preceding a single-word alphanumeric label. The ALIAS block is used to preprocess an input, creating a new, modified input deck with all alias variable substitutions included. TRITON then processes the modified input deck before proceeding with the calculation.

The use of an alias variable is best illustrated by a brief example. Assume that the alias \$fuel is defined as materials 1,2 , and 3 , and \$mod as materials 4, 5 , and 6 . (The input format for defining aliases is described below.) The user wishes to create three identical sets of materials and use them in three identical pin cell specifications. In the COMPOSITION data block, specifications could be written in the following form

```
uo2 $fuel den=10.29 0.9322 920 92235 3.0 92238 97.0 end
h2o $mod den=0.6616 1.0 595 end
wtpt-boron $mod 0.6616 1 5000 100 655e-6 595 end
```

TRITON would create a modified input with the alias expanded as follows:

```
uo2 1 den=10.29 0.9322 920 92235 3.0 92238 97.0 end
uo2 2 den=10.29 0.9322 920 92235 3.0 92238 97.0 end
uo2 3 den=10.29 0.9322 920 92235 3.0 92238 97.0 end
h2o 4 den=0.6616 1.0 595 end
h2o 5 den=0.6616 1.0 595 end
h2o 6 den=0.6616 1.0 595 end
wtpt-boron 4 0.6616 1 5000 100 655e-6 595 end
wtpt-boron 5 0.6616 1 5000 100 655e-6 595 end
wtpt-boron 6 0.6616 1 5000 100 655e-6 595 end
```

Similarly, if the alias were used in the CELLDATA block as

```
latticecell squarepitch pitch=1.26 $mod fuelr=0.4095 $fuel end
```

then TRITON would expand the aliases to

```
latticecell squarepitch pitch=1.26 4 fuelr=0.4095 1 end
latticecell squarepitch pitch=1.26 5 fuelr=0.4095 2 end
latticecell squarepitch pitch=1.26 6 fuelr=0.4095 3 end
```

In a depletion calculation, one may wish to deplete a large number of fuel rods independently because of different geometric locations in a fuel assembly. Even though each fuel rod may have the same initial composition, each must be specified as a unique material composition in order to be depleted independently. Furthermore, multiple cell specifications must all use unique material identifiers for each cell component. Thus, if one desired to deplete 25 fuel materials in a fuel/clad/moderator pin cell, one would need to set up material composition definitions for 25 fuels, 25 moderators, and 25 clads. Then one would need to provide 25 pin cell specifications. By using aliases, one need only specify the material identifiers corresponding to each alias and then provide only one material composition specification for each alias type, and then one pin cell specification. TRITON will automatically expand the aliases and create a revised input with all materials and cell specifications explicitly defined. Note that although this will simplify the pin cell input in the CELLDATA, 25 pin cell calculations would still be required. The number of pin cell calculations can be reduced by using the ASSIGN function described in Sect. 3.1.3.3.4.3.

The purpose of the ALIAS block is to define a set of alias variables to be used in subsequent data blocks. The ALIAS block is optional, but aliases may not be used in other blocks if an ALIAS block is not present to define the aliases. An ALIAS block may contain as many aliases as desired. Each alias specification consists of three parts: the alias name, consisting of a dollar sign followed by up to 11 alphanumeric characters with no embedded spaces; the material number or numbers; and an end keyword. Material numbers may be entered in any order and may be separated by spaces or commas (or both). Material numbers may also be separated by a dash (-), but this represents an inclusive list. In other words, a material specification of 1-3 (or $1-3$ ) indicates materials 1,2 , and 3 . The example ALIAS block below illustrates the various means for assigning a set of materials for an alias definition.

```
read alias
$fueltype1 1 2 3 end
$fueltype2 4,5,6, 31-33 end
$clad1 21,22,23 end
$clad2 24 25 26 34-36 end
$mod1 11 - }13\mathrm{ end
$mod2 14-16, 37-39 end
end alias
```

The ALIAS block simply serves to assign material identifiers to specific variables, and the variables are used in subsequent data blocks. The same material identifier can be used in more than one alias if desired. As indicated earlier, TRITON will preprocess any input deck containing an ALIAS block and replace instances of alias variables with the appropriate material identifiers. The following subsections describe how aliases are implemented in TRITON's various input blocks, as the form of alias variable substitution is block dependent. Aliases are processed only in these input blocks; aliases used in other blocks will result in an error.

### 3.1.3.5.1 COMPOSITION block aliases

The COMPOSITION block uses aliases to create multiple copies of each standard composition specification, replacing the alias variable with each material identifier associated with the alias definition. For example, consider the following alias definition in an ALIAS block:

```
read alias
$fuel 1 2 10 end
end alias
```

and the standard composition specification:

```
uo2 $fuel den=10.045 1 800 92235 2.5 92238 97.5 end
```

A modified TRITON input would be created with the standard composition specification replaced by

```
uo2 1 den=10.045 1 800 92235 2.5 92238 97.5 end
uo2 2 den=10.045 1 800 92235 2.5 92238 97.5 end
uo2 10 den=10.045 1 800 92235 2.5 92238 97.5 end
```

### 3.1.3.5.2 CELLDATA block aliases

CELLDATA block latticecell specifications typically contain more than one material; therefore, multiple aliases are permitted in each cell specification. However, this constrains the set of aliases used in the cell specification to have the same number of material identifiers associated with it.

Consider the ALIAS block:

```
read alias
$fuel 1-3 10 end
$clad 4,5,6,11 end
$mod 7 8-9 12 end
end alias
```

All three aliases contain four materials each. One could then create a single cell specification that uses one or more of these alias variables, such as

```
latticecell squarepitch pitch=1.26 $mod fuelr=0.41 $fuel cladr=0.50 $clad end
```

This would result in the following alias expansion by TRITON:

```
latticecell squarepitch pitch=1.26 7 fuelr=0.41 1 cladr=0.50 4 end
latticecell squarepitch pitch=1.26 8 fuelr=0.41 2 cladr=0.50 5 end
latticecell squarepitch pitch=1.26 9 fuelr=0.41 3 cladr=0.50 6 end
latticecell squarepitch pitch=1.26 12 fuelr=0.41 10 cladr=0.50 11 end
```

Material identifiers are substituted according to their position in the alias definition (i.e., the first substitution will use the first material associated with each alias, and the second expansion will use the second material associated with each alias, etc.)

Material numbers should not be entered manually in a cell specification; for example,

```
latticecell triangpitch pitch=1.26 $mod fuelr=0.4095 1 end
```

TRITON would allow this to occur and would create a set of cell specifications as follows:

```
latticecell triangpitch pitch=1.26 2 fuelr=0.4095 1 end
latticecell triangpitch pitch=1.26 3 fuelr=0.4095 1 end
```

where $\$$ mod was defined as materials 2 and 3 . However, SCALE does not allow the same material identifier to occur in two different cell specifications, and the fact that material 1 occurs in two different cell specifications would result in TRITON ending with an error. Note that alias expansions for multiregion and doublehet cell specifications are not supported. Also note that TRITON will not copy centrmdata and moredata specifications that follow a cell specification that uses an alias variable.

### 3.1.3.5.3 DEPLETION block aliases

Aliases in the TRITON DEPLETION are simply replaced by the set of materials associated with the alias. For example, the ALIAS block

```
read alias
$fuel 1 2 10 end
end alias
```

and DEPLETION block

```
read depletion 7 8 9 $fuel end depletion
```

would be expanded to
read depletion 7891210 end depletion
Aliases may be mixed with actual material numbers in the depletion block, along with the flux and assign keywords. However, the negative sign-used to define the basis for power normalization-cannot precede an alias definition.

### 3.1.3.5.4 TIMETABLE block aliases

TIMETABLE block alias expansion is similar to that of the COMPOSITION block: TRITON will create a new timetable entry for each material associated with the alias used in the TIMETABLE definition. For the TIMETABLE block below, using the alias \$allmod, unique timetables will be created for each material identifier associated with this alias variable. Note that alias expansion of density timetable entries is not yet supported.

```
read timetable
temperature $allmod
0.0 615
121.0 615
121.01 685
322.5 685
352.5 610
738.75 610 end
end timetable
```

### 3.1.3.5.5 BRANCH block aliases

Aliases may be used within the define keyword definitions of the BRANCH block. Aliases are simply replaced by the list of materials associated with the alias, as is done for the DEPLETION block. Hence,

```
read alias
$fuel 1 2 10 end
end alias
used with
read branch
define fuel $fuel end
md=0.75 tm=559 tf=880 sb=0.0 cr=0 end
tf=1600 end
end branch
would be expanded to
read branch
define fuel 1 2 10 end
md=0.75 tm=559 tf=880 sb=0.0 cr=0 end
tf=1600 end
end branch
```

### 3.1.3.5.6 NEWT MATERIAL block aliases

The MATERIAL block within the NEWT model section of a TRITON input can also use aliases. As with COMPOSITION and TIMETABLE entries, TRITON will create a new material specification for each material represented by an alias. For the sample material block below, using the alias $\$$ fuel, unique material block entries will be created for each material associated with the alias variable.

```
read materials
mix=$fuel pn=1 com="3.25 wo uo2 fuel" end
mix=21 pn=1 com="zirc cladding" end
mix=31 pn=1 com="water" end
endd materials
```

If an alias were defined as
\$fuel 101112 end
then the MATERIAL block would be expanded to

```
read materials
mix=10 pn=1 com="3.25 wo uo2 fuel" end
mix=11 pn=1 com="3.25 wo uo2 fuel" end
mix=12 pn=1 com="3.25 wo uo2 fuel" end
mix=21 pn=1 com="zirc cladding" end
mix=31 pn=1 com="water" end
end materials
```

### 3.1.3.6 KEEP_OUTPUT block

When performing depletion calculations for a number of different materials, TRITON output can become quite voluminous. Often, much of that output is not needed for calculations that seek only eigenvalues,
sources, or concentrations as a function of irradiation history. TRITON provides the ability to trim output to only those portions for which output is desired. Output produced directly by the TRITON module is always provided and cannot be disabled, but output from any other code in the sequence can be automatically removed from the output listing. Retaining certain output is accomplished using the KEEP_OUTPUT data block.

The KEEP_OUTPUT data block provides the ability to preserve only selected outputs. The format of this data block is

```
read keep_output
module_1 module_1 ... module_i ... module_N
end keep_output
```

where module_i represents any valid module name from the list of modules invoked by TRITON, as listed here:
xsproc xsdrn newt kenova kenovi couple origen
By default, the output from all these modules is retained with the exception of XSProc COUPLE and ORIGEN. SAMS and OPUS output is always retained.

### 3.1.3.7 TRITON control parameters

TRITON supports the following of control parameter options:

```
parm=
    CHECK,
    CENTRM, 2REGION, XSLEVEL=N,
    WEIGHT, WEIGHT=N,
    ADDNUX=N,
    INFDCUTOFF= }X\mathrm{ ,
    CXM=N,
    MAXDAYS=N
```

If an invalid control parameter option is specified, including misspelled keywords, an error message will be generated and execution terminated. TRITON also provides the ability to nest several control parameter keywords together; to combine keywords (where appropriate), a list may be entered, enclosed in parentheses, and separated by commas. For example, to specify CHECK, 2REGION, and ADDNUX=1 at the same time, input would begin with

```
=t-depl parm=(check, 2region,addnux=1)
```

The following subsections provide more detail on each of the control parameters listed above.

### 3.1.3.7.1 Check mode: parm=check

Specification of parm=check will request that TRITON read all input and ensure that no input errors are present, without running additional calculations. In this mode, all input is set up as if a full calculation will be run, but the sequence exits without any functional module execution. The check mode is useful for debugging or obtaining processed standard composition data, without actually running a calculation. It can also be used to generate plot files for embedded NEWT and KENO inputs for additional review and checking of input specifications. Of course, some errors may be uncovered only by dynamically executing
the functional modules; hence, there are rare occasions where a parm=check run will complete with no errors but will fail when run outside of check mode as the problem begins to run.

### 3.1.3.7.2 Multigroup cross section processing options

The most common use of parm= sequence control is in the selection of an alternate multigroup cross section processing mode.

By default, XSProc enables both the BONAMI and CENTRM modules for cross section processing. BONAMI-only XSProc calculations can be performed using the control parameter parm=bonami.

TRITON also supports the control parameter parm=(xslevel=N). The xslevel parameter option initializes various CENTRM options for the XSProc calculations. The xslevel option is equivalent to initializing all unit cell calculations with the following centrmdata specifications:

```
parm=(xslevel=1):
centrmdata
    npxs=5 nfst=0 nthr=3 nmf6=-1 alump=0.3 demin=0.125 pmc_omit=1 pmc_dilute=5.0e5
end centrmdata
parm=(xslevel=2):
    centrmdata npxs=5 nfst=0 nthr=3 nmf6=-1 end centrmdata
parm=(xslevel=3):
    centrmdata alump=0.3 demin=0.125 pmc_omit=1 pmc_dilute=5.0e5 end centrmdata
parm=(xslevel=4):
    [no centrmdata statement]
```

The option parm=(xslevel=4) is equivalent to parm=centrm. The option parm=(xslevel=3) is the default for depletion sequences and is equivalent to parm=centrm but with some minor approximations to decrease run time. The option parm=(xslevel=2) is equivalent to parm=2region for all sequences.

Note that the xslevel $=1$ and $x$ slevel $=3$ options have additional specifications for keywords alump, demin, pmc_omit, and pmc_dilute. These keywords are further discussed in the XSProc chapter. The additional keyword specifications are used to decrease run-time for the CENTRM and PMC calculations. Internal investigations have shown that the approximations introduced by the additional keyword specifications have minimal impact on solution accuracy for a wide range of calculations. Therefore the additional keyword specifications are used by default for depletion calculations, where several CENTRM and PMC calculations are necessary. The additional keyword values are not used by default for nondepletion calculations to be consistent with the SCALE CSAS5 and CSAS6 criticality sequences.

The TSUNAMI-2D sequence also invokes the BONAMIST module, a modified version of BONAMI to support sensitivity calculations. TSUNAMI-2D calculations may use parm=centrm, 2region, bonami, or xslevel. However, these cross section processing options will not utilize the sensitivity-enabled version of BONAMI.

### 3.1.3.7.3 Creating a broad group library: parm=weight, parm=(weight=N)

Used in tandem with the TRITON T-NEWT sequence, the specification parm=weight extends the sequence by setting up and executing the MALOCS2 module to generate a weighted broad-group crosslibrary (AMPX master format). The spectrum generated in the NEWT transport calculation is used as the weighting function for the collapse. Additionally, the broad-group library energy structure is defined by the NEWT COLLASPE block.

The parm=weight option uses the problem-averaged flux spectrum for the weighting function in the collapse. The problem may be a simple pin cell or a full assembly. However, there may be cases where the flux in a specific region or material is most appropriate for the spectral collapse. TRITON allows identification of a specific material from which the collapsing spectrum should be used. When specified in the form parm=(weight=N), the average flux determined for material N is used in place of the total domain spectrum to perform the collapse.

TRITON sample problem 1 (Sect. 3.1.6.1) provides an example of the use of T-NEWT to produce a new broad-group library. Note that the broad-group library produced in this calculation will reside in the SCALE temporary working directory with the name newxnlib at the end of the calculation. If the library will be needed for future calculations, the user should use a shell script to copy the library back to a more permanent location, and perhaps give it a more meaningful name. In sample problem 1, the SCALE 252group master library is collapsed to 56 energy groups.

The process for creating a broad-group master library is also supported in the 2D depletion sequence T-DEPL. When parm=weight or parm=(weight=N) is specified in a depletion calculation, the input cross section library must be one of the SCALE 238 -group or 252 -group libraries, which will automatically be collapsed to the SCALE 49-group or 56-group structure, respectively. An initial fine group calculation is performed for the input configuration, and the flux from the solution is used to create the broad group library. The initial calculation is then repeated with the new broad group library, followed by the remainder of the depletion calculation. Note that for lattice physics calculations, the NEWT COLLAPSE block will be based on the 49-group (or 56-group) energy structure, not the fine group structure.

It is important to note that the 252-group library contains intermediate resonance parameters and other data that cannot be accurately collapsed into 56 -group data with the collapsing procedures available in MALOCS2. These parameters are important for bonami-only cross section processing calculations, i.e., parm=bonami. Therefore, the parm=centrm option is recommended for follow-on application of the collapsed 56 -group collapsed library. The 238 -group and 49 -group libraries do not contain intermediate resonance parameter data, and bonami-only processing is available, provided that this cross section processing option and group structure is suitable for the intended application.

### 3.1.3.7.4 Inclusion of additional nuclides for depletion: parm=(addnux=N)

For depletion calculations, it is important to add trace quantities ( $1 \times 10^{-20} \mathrm{at} / \mathrm{b}-\mathrm{cm}$ ) of certain nuclides to the inventories of depletion materials in order to accurately track the nuclides' impact on cross section processing and transport calculations as a function of burnup. By default, TRITON automatically adds to all fuel materials trace quantities of a set of nuclides that have been determined to be important in the characterization of spent fuel. TRITON recognizes fuel materials as any material containing quantities of heavy metals ( $Z>89$ ) in the standard composition specification.

TRITON provides user control of the set of nuclides added to a fuel material through the parm $=(\operatorname{addnux}=N)$ control parameter, where N is an integer value. For $\mathrm{N}=0$, no nuclides are added, which is generally a very poor approximation and should only be used when the ramifications are fully understood. For $\mathrm{N}=1$, a bare minimum set of 15 nuclides (actinides) are added; this will generate improved number density estimates for actinides in low-burnup fuels but will not update cross sections for fission products of primary importance. Again, use of this option is discouraged unless it addresses special modeling needs. For $\mathrm{N}=2$, the default setting for the TRITON depletion sequences, 95 nuclides are added. $\mathrm{N}=3$ and $\mathrm{N}=4$ add 231 and 388 nuclides, respectively. Note that in previous versions of TRITON, $\mathrm{N}=2$ would add 64 nuclides. The set of 64 nuclides is still supported by specifiying
parm=(addnux=-2) in the input. The default in the SCALE 6.1 release remains parm=(addnux=2). Table 3.1.3 through Table 3.1.7 list the set of nuclides added in trace quantities for each value of addnux.

Table 3.1.3. Additional nuclides added in trace quantities for parm=(addnux=1)

### 3.1.3.7.5 Few-group reaction cross section calculation control for continuous energy depletion: parm=(cxm=N)

In continuous energy depletion calculations, few group reaction cross sections are computed by KENO directly rather than using a post-processing approach that TRITON uses for multigroup mode. In addition to these region averaged multigroup reaction cross sections, KENO also provides problem-dependent region-averaged multigroup fluxes to TRITON that will be used by COUPLE to generate one-group cross section library for each depletion material.

Option parm $=(\operatorname{cxm}=N)$ is used to setup continuous-energy depletion calculation with different modes of calculation, which tells KENO the details of the tallying process for the reaction cross sections and mixture fluxes. Available calculations modes and their descriptions are presented in Table 3.1.8.

Table 3.1.8. cxm values and their descriptions

| cxm | cross sections |  | flux | description |
| :---: | :---: | :---: | :---: | :---: |
|  | reactions | number of energy groups | number of energy groups |  |
| 1 | All | NGP ${ }^{1}$ | NGP ${ }^{1}$ | KENO uses default NGP-group energy group boundaries to generate region-averaged reaction cross sections for all available reactions of the nuclides in each depletion mixture. KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. |
| $2^{2}$ | $\begin{aligned} & \text { Transmutation } \\ & \text { (MT=16-18, } \\ & 102-125) \end{aligned}$ | NGP ${ }^{1}$ | NGP ${ }^{1}$ | KENO uses default NGP-group energy group boundaries to generate region-averaged reaction cross sections for only transmutation reactions of the nuclides in each depletion mixture. KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. |
| 3 | All | 1 | NGP ${ }^{1}$ | KENO uses 1-group energy group boundaries to generate region-averaged reaction cross sections for all available reactions of the nuclides in each depletion mixture. <br> KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. |
| 4 | Transmutations $\begin{aligned} & (\mathrm{MT}=16-18, \\ & 102-125) \end{aligned}$ | 1 | NGP ${ }^{1}$ | KENO-VI uses 1-group energy group boundaries to generate region-averaged reaction cross sections for only transmutation reactions of the nuclides in each depletion mixture. <br> KENO-VI also computes region-averaged multigroup fluxes using the default NGP-group energy bins. |

${ }^{1}$ Energy group structure in KENO and associated number of energy groups, NGP, should be consistent with those from the ORIGEN library used in the problem.
$2 \mathrm{cxm}=2$ is the default mode for reaction cross section calculations.

### 3.1.3.7.6 Infinite dilution cutoff control: parm=(infdcutoff=X)

The addition of nuclides to depletion materials as described in the previous section can lead to increased run-times for CENTRM-based XSProc calculations. However, many nuclides (e.g., low-density nuclides) are effectively infinitely dilute and can be treated as such and omitted from the expensive point-wise cross section collapse operation. For the option parm=(infdcutoff=sigma0) sequence option, XSProc will compute an effective background microscopic cross section for each nuclide. If the computed background cross section is greater than the cutoff value sigma0, recommended as $5 \times 10^{5}$ barns, then the nuclide is considered infinitely dilute and the infinitely dilute multigroup cross section is utilized from the cross section library.

In general, a sigma0 cutoff value of $5 \times 10^{5}$ barns will be acceptable for most applications. However, TRITON and the centrmdata card in the CELLDATA block provide a means for the user to control the
cutoff value. The cutoff value may be assigned in either of two ways. A single global value may be assigned to all cells using the TRITON parm= specifier with the keyword infdcutoff, for example, parm=(infdcutoff=1e10). Addition of the specifier with a value of $1 \times 10^{10}$ will set the cutoff value to $1 \times 10^{10}$ for all cells in the problem, which is generally appropriate for most calculations. However, a provision is made to specify a unique cutoff value to each cell using the pmc_dilute keyword in a centrmdata specification. An example of this is shown in the description of parm=xslevel in Sect. 3.1.3.7.2.

The default value of sigma0 depends on the sequence and cross section processing option. For nondepletion sequences that use parm=centrm, the default is 0 . The default value of 0 instructs PMC to include all nuclides for PMC processing. For depletion sequences that use parm=centrm or for any sequence that uses parm $=2$ region, the default value is $5 \times 10^{5}$ barns.

### 3.1.3.7.7 Override of the maximum number of days per depletion subinterval: PARM=(MAXDAYS=N)

TRITON is set to limit ORIGEN time intervals to no more than 40 days to avoid potential numerical error that would be introduced if depletion were performed over a long time interval. For depletion subintervals of more than 400 days ( 10 time intervals of 40 days), TRITON will automatically increase the number of depletion subintervals in a depletion interval. The depletion subinterval is based on a rule of thumb for ORIGEN depletion. However, the rule breaks down when burning at very low powers for extended time intervals. Thus, TRITON allows the user to override the default behavior by specifying a new value for the maximum number of days per ORIGEN time interval. A 100-day limit per ORIGEN time interval may be set using parm=(maxdays=100). In overriding the default behavior, the user must be aware of any potential errors introduced in the approximation.

### 3.1.4 Output Files Ccreated by TRITON

TRITON produces a variety of output files that may be of use in related calculations. Of those files, only certain files are copied back to the return directory: the TRITON output file (.out); plot files generated by NEWT, KENO, or OPUS (.plt); SAMS sensitivity data files (.sdf), in the case of an S/U calculation; ORIGEN binary concentration files (.f71) and HTML-formatted output (.html), where available. The TRITON output file is a concatenated listing of outputs from TRITON and all modules for which output is kept. Other files of potential interest are not copied, and the user should be aware of these files and their names so that they may be retrieved using a SHELL script after TRITON execution is complete. The following subsections list those files and their purposes.

### 3.1.4.1 Standard composition restart files

At the end of all depletion calculations, standard composition files are automatically produced for each material, listing the nuclides and number densities of the materials at the time the transport calculation (i.e., XSDRN, NEWT, KENO) is performed. Only nuclides for which cross section data are available in the master cross section library are saved in these files. Files are saved using the file naming convention StdCmpMixNNNNN, where $N N N N N$ is the material identifier. The file contains compositions at the final time of the calculation. Additional files are saved with the file naming convention StdCmpMixNNNNN_MMMMM, where $M M M M M$ is an index to a particular time step in the depletion calculation. For example, if a calculation is completed with materials 1 and 40 for two depletion steps, then the following files will be created in the temporary working directory.

```
StdCmpMix00001_00000 (t=0)
StdCmpMix00001_00001 (midpoint of 1 }\mp@subsup{1}{}{\mathrm{ st }}\mathrm{ depletion step)
```

```
StdCmpMix00001_00002 (midpoint of 2nd depletion step)
StdCmpMix00001_00003 (final compositions, end of 2 }\mp@subsup{2}{}{\mathrm{ nd }}\mathrm{ depletion step)
StdCmpMix00001 (same as StdCmpMix00001_00003)
StdCmpMix00040_00000 (t=0)
StdCmpMix00040_00001 (midpoint of 1 1 st depletion step)
StdCmpMix00040_00002 (midpoint of 2nd depletion step)
StdCmpMix00040_00003 (final compositions, end of 2 }\mp@subsup{2}{}{\mathrm{ nd }}\mathrm{ depletion step)
StdCmpMix00040 (same as StdCmpMix00040_00003)
```

The contents of these files will be a standard composition description of each material by atomic contents-that is, SCALE standard nuclide IDs (e.g., U-235), number density, and temperature (using the temperature of the original material). Using SCALE's external file read capability, these outputs may be automatically included in a follow-on calculation that relies on depleted/decayed number densities. TRITON sample problem 7 (Sect. 3.1.6.7) provides an example of the use of these restart files. Standard composition restart files should be used only for follow-on criticality or shielding calculations.

### 3.1.4.2 Lattice physics parameters

During T-DEPL depletion calculations that use branch states and homogenization, a database of fewgroup cross sections is saved for each branch state and at each depletion step containing homogenized cross section data and other lattice physics parameters (e.g., discontinuity factors, pin power peaking factors, diffusion coefficients, etc.). The $x$ file 016 file is intended for post-processing, to be read and written in the desired format for subsequent nodal diffusion core simulator calculations. The $x$ file 016 file is a binary-formatted file, which is described in detail in Appendix A of TRITON. An auxiliary textformatted database file (txtfile16) is also created that contains the same data as the binary-formatted file.

### 3.1.4.3 ORIGEN binary library files

During depletion calculations, ORIGEN binary library files are created to archive cross sections for each depletion material at each depletion subinterval. These files can be used in future depletion calculations in ORIGEN, ORIGAMI, and ARP. For each depletion material, the ORIGEN binary library file is named $f t 33 f 001 . m i x N N N N$, where $N N N N$ is the material number for each depleted material. Additionally, the combined cross section file is saved with the name $f t 33 f 001 . c m b i n e d$. Here is an example of a script to retrieve cross section files.

POSIX:

```
=shell
    cp ft33f001.mix0001 ${0UTDIR}/pwr_mix01.arp
    cp ft33f001.cmbined ${0UTDIR}/pwr_asmb.arp
end
```

Windows:

```
=shell
    copy ft33f001.mix0001 %0UTDIR%\pwr_mix01.arp
    copy ft33f001.cmbined %0UTDIR%\pwr_asmb.arp
end
```

### 3.1.4.4 ORIGEN binary concentration file (.f71)

During depletion calculations, TRITON creates the ORIGEN binary concentration file (.f71). This file is created in the temporary directory as $f t 71 f 001$ and is copied back at the end of the SCALE calculation to the return directory with the name $\$$ \{OUTBASENAME \}.f71. TRITON archives computed concentrations
for each depletion material at the beginning and end of each depletion subinterval or decay interval. These files include concentrations and also decay heat term, photon and neutron data, and other quantities or interest computed by ORIGEN. These data may be post-processed by the OPUS module.

The .f71 file contains concentrations for each individual material, and it also contains the combined concentrations of the individual material results (i.e., the net response for the entire system). The TRITON output contains an index of the contents of this file (see Sect. 3.1.5.4.5).

### 3.1.5 Output Description

This section contains a brief description and explanation of TRITON output. As with any SCALE module, TRITON output begins with the SCALE header, the job information, the input file, and the program verification information. These outputs are common to all SCALE modules. Likewise, all SCALE calculations report a run-time summary at the end of the output file.

### 3.1.5.1 Control parameter edit

When TRITON control parameters are specified using the parm= command (see Sect.3.1.3.7), all specified parameters are echoed following the above output, with an explanation of the meaning of the parameter, as shown below. If no parameters are specified, no edit is provided.

```
*************************************************************************************************
```

The following TRITON control parameters were requested:
WEIGHT - Weighted collapsed master library option selected for $t-n e w t$ calculation, based
on system-averaged flux.
ADDNUX - specifies the set of additional nuclides added in trace quantities for depletion
calculations. Set 1 was selected. See TRITON manual for more information.

### 3.1.5.2 T-XSEC output

The T-XSEC sequence performs only cross section processing functions. The XSProc output is written to the output file as the calculation proceeds.

### 3.1.5.3 T-NEWT and T-XSDRN output

By default, the T-NEWT and T-XSDRN outputs include only the NEWT and XSDRN output respectively. The XSProc output can be included by using the KEEP_OUTPUT block (see Sect. 3.1.3.6).

### 3.1.5.4 Depletion sequence output

The output of TRITON depletion sequences contains several depletion edits. The edits are described in the following subsections. These output edits are written to the output file in the order in which they are computed during the calculation.

### 3.1.5.4.1 Burnup history summary (all depletion sequences)

TRITON generates the burnup history summary table after processing the BURNDATA block. An example of this table is as follows.

> Based on the supplied burnup history, triton will use the following time history to perform depletion calculations. This breakdown has been calculated so as to permit burn steps of no more than 40 days, and decay times using the rule of threes with a maximum first decay period of no more than 75 days.

8 time-dependent libraries will be created

| Sub-Interval No. | Depletion Interval | Sub-interval in interval | ```Specific Power(MW/MTIHM)``` | Burn Length <br> (d) | Decay Length <br> (d) | Library Burnup (MWd/MTIHM) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\bigcirc$ | ****Initial | Bootstrap Calcu | lation**** |  |  | $0.00000 \mathrm{E}+00$ |
| 1 | 1 | 1 | 30.0 | 357. | 0.00 | $5.35714 \mathrm{E}+03$ |
| 2 | 1 | 2 | 30.0 | 357. | 0.00 | $1.60714 \mathrm{E}+04$ |
| 3 | 1 | 3 | 30.0 | 357. | 0.00 | $2.67857 \mathrm{E}+04$ |
| 4 | 1 | 4 | 30.0 | 357. | 0.00 | $3.75000 \mathrm{E}+04$ |
| 5 | 1 | 5 | 30.0 | 357. | 0.00 | $4.82143 \mathrm{E}+04$ |
| 6 | 1 | 6 | 30.0 | 357. | 0.00 | $5.89286 \mathrm{E}+04$ |
| 7 | 1 | 7 | 30.0 | 357. | 0.00 | $6.96429 \mathrm{E}+04$ |

NOTE: Library Burnup is the cumulative burnup computed at the midpoint of the depletion sub-interval. Specific Power and Library Burnup depend on basis material(s) selected in DEPLETION block.

This table shows the results of a burnup history using one depletion interval with seven depletion subintervals. Column 1 is the cumulative depletion subinterval number. Column 2 is the depletion interval number, and column 3 is the depletion subinterval number within the current depletion interval. Columns 4-6 echo the specific power, depletion interval, and decay interval specified in the BURNDATA block. The final column shows the cumulative burnup at the midpoint of each depletion subinterval.

### 3.1.5.4.2 Embedded transport model output

The output from the initial transport calculation follows the burnup history edit. The output edits for NEWT, XSDRN, KENO-V.a, and KENO-VI are described in their respective manual sections.

### 3.1.5.4.3 System mass balance table

After the initial transport calculation output, a summary of system mass information is printed, an example of which is provided as follows.

```
** System total mass is 3.0330E+02 grams heavy metal per unit length. **
** Masses will
** system mass of 1.0000E+06 g of heavy metal
```

| Mix | Heavy Metal | Normalized HM | Fractional HM | Heavy Metal | Mixture |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| No. | Mass (g/cm) | Mass (g) | Mass (g) | Dens. (g/cc) | Dens. (g/cc) | Depletion Mode |
| $\bigcirc$ | $0.000000 \mathrm{E}+00$ | $0.000000 \mathrm{E}+00$ | 0.000000 | $0.000000 \mathrm{E}+00$ | $0.000000 \mathrm{E}+00$ | Not depleted |
| 6 | 0.000000E+00 | 0. $000000 \mathrm{E}+00$ | 0.000000 | $0.000000 \mathrm{E}+00$ | $7.940006 \mathrm{E}+00$ | Not depleted |

This table provides mass and density data for each material used in the transport model. Column 1 provides the material identifier, and columns 5 and 6 provide the material density and material heavy metal density, respectively, in units of grams per cubic centimeter. Heavy metal mass is determined from masses of all nuclides with an atomic number greater than 89. The final column provides the depletion mode for each material (see Sect. 3.1.3.3.4.2). Column 2 provides the "prenormalized" heavy metal mass of each material. The units for this mass value depend on the transport model. For 2D xy NEWT models, the units are grams per centimeter since there is no $z$ - dimension in the model. Similarly, the units are grams per centimeter for 1D cylinder XSDRN models, grams per square centimeter for 1D slab XSDRN models, and grams for 1D spherical XSDRN models and 3D KENO models. The total prenormalized heavy metal mass is printed in the final row of the table as well as in the table header (highlighted in red). The heavy metal mass is normalized such that a total system mass of 1 MTHM is present. The volume scaling factor used to normalize the system mass is also printed in the table banner (highlighted in red). The units of the volume scaling factor depend on the transport model. Column 3 prints the normalized material heavy metal mass in units of grams, which is equal to the prenormalized material heavy metal mass in column 2 multiplied by the volume scaling factor in the table header. The total normalized mass is printed in the final row and also in the table header (highlighted in red). The fourth column shows the fractional heavy metal mass of all materials, which is equal to the normalized heavy metal mass in column 3, divided by the total normalized system heavy metal mass in the table header.

### 3.1.5.4.4 Power balance tables

As the TRITON calculation proceeds, the results of the cross section processing and transport calculations are used to calculate fluxes and powers in each material. The output segment listed below shows the results for the first calculation based on the initial material compositions. The total power (column 2) represents the material-specific power in units of MW/MTHM of initial system mass. The fractional power (column 3 ) is equal to the total power for a material divided by the total system power (highlighted in red). The mixture power (column 4) represents material-specific power in units of MW/MTHM of initial material mass. The mixture power is equal to the total power of the material divided by the
fractional heavy metal mass of the material, which is provided in the system mass balance table (Sect. 3.1.5.4.3). If the material does not contain heavy metal, then " $\mathrm{N} / \mathrm{A}$ " is printed in the mixture power column. Columns 5 and 6 show the material thermal and total flux values, respectively, in units of neutrons $/ \mathrm{cm}^{2}$-sec. The thermal flux is determined by integrating multigroup flux values for energy groups below 0.625 eV . If the specific power is normalized to the total system power, the summation of the material powers in column 1 should match the input specification in the BURNDATA block (in the example given here, 20.86 MW/MTHM).

```
--- Material powers for depletion pass no. 0 (MW/MITHM) ---

\end{tabular}
    Total 21.715 1.00000
    * - Power normalized to this mixture.
NOTE: Total Power is the Mixture Power per 1 metric ton of HM of the initial system mass. Mixture Power is the Mixture Power per 1 metric ton of HM of the initial mixture mass. Mixture Thermal Flux determined using 0.625 eV cutoff: Groups 26 through 44.
```

In this example, material 7 has the input-specified power (20.86 MW/MTHM, highlighted in red), and the power in the remainder of the model materials is normalized according to this basis material.

### 3.1.5.4.5 ORIGEN binary concentration file listing

After all depletion calculations are completed, TRITON creates an ORIGEN binary concentration file (.f71) with isotopic concentrations for each depletion material. The order and content of the .f71 file is provided in the TRITON output. An example of this edit is shown below. For each depletion material, the
output gives the location in the file, the ORIGEN time interval number, the depletion interval time in days, the cumulative time in years, and a title. After all materials are added to the library, the system average of all libraries is computed and added to the library. In this case, with only one depletion material, the system average would be the same as the single material.

The requested OPUS output edits follow the .f71 file summary edit.

### 3.1.5.5 TSUNAMI-2D output

Output from the TSUNAMI-2D and TSUNAMI-2DC sequence is similar to that of the T-NEWT sequence, with the addition of the SAMS module output. If the user requests sensitivity and uncertainty analysis for non- $k_{e f f}$ responses via the DEFINITIONS and SYSTEMRESPONSES blocks, the TRITON output will edit out the computed values of these responses. An example of this is shown here for sample problem 9 in Sect. 3.1.6.9.

| Computed Response Ratio value for 'U235-abs' is: | $1.428612 \mathrm{E}+01$ |
| :--- | :--- | :--- |
| Computed Response Ratio value for 'U235-fis' is: | $1.155715 \mathrm{E}+01$ |
| Computed Response Ratio value for 'U238-abs' is: | $3.036017 \mathrm{E}-01$ |
| Computed Response Ratio value for 'U238-fis' is: | $3.393816 \mathrm{E}-02$ |

In addition to the text-formatted output, TRITON generates HTML-formatted output for TSUNAMI-2D calculations. The HTML output is fully described in the SAMS chapter.

### 3.1.6 TRITON Sample Cases

This section provides descriptions of the 13 TRITON sample problems included with SCALE. Note that all of these problems (along with all other SCALE sample problems) are typically executed in the initial SCALE installation to test the performance of various codes and options, for validation of the installation process. Because of the number of problems that are executed, these sample problems are adjusted to run as fast as possible so that all test problems may be completed in relatively short order. To accomplish this, crude modeling approximations (reduced convergence, few histories, simplified cross section processing, low-order quadrature and scattering approximations, coarse computational grids, reduced numbers of libraries per depletion cycle, etc.) may be used. Hence, although these problems provide guidance in setting up and executing TRITON problems, it is generally a good idea to review all control settings to ensure sufficient accuracy in one's own calculations.

Additional TRITON input files for several reactor types can be generated with the SCALE/ORIGEN Library Generator (SLIG). The SLIB documentation is available as Appendix B of Chapter 5 (i.e. the ORIGEN chapter).

### 3.1.6.1 TRITON sample problem 1: triton1.inp

Sample problem triton1.inp is an example of a T-NEWT transport calculation sequence. Input begins (as with all SCALE sequences) with a title card and cross section library specification; this calculation is performed using the 252-group ENDF/B-7.1 library. After the library specification, three materials are defined in the composition block, followed by a cell specification and the NEWT transport model.

This example includes an axial height of 37.1 cm and will therefore do a buckled calculation based on this height. The geometric model consists of a simple pin cell, with cylindrical fuel and clad regions inside a square moderator region, with a $6 \times 6$ base grid. The NEWT BOUNDS block specifies that periodic boundary conditions are used for this model.

This simple problem also demonstrates the use of TRITON's automatic cross section collapse capability—parm=weight. For T-NEWT calculations, TRITON uses the NEWT COLLAPSE block to define the broad-group energy structure. For this sample problem, the cross sections are collapsed to a 56 -group format. The new broad-group library will be identified as filename newxnlib in the temporary working directory, which can be used in follow-up SCALE calculations.

```

### 3.1.6.2 TRITON sample problem 2: triton2.inp

Sample problem triton2.inp is an example of a T-XSDRN transport calculation sequence. In this case, the parameter specification parm=2region instructs TRITON to perform cross section processing using the CENTRM-based two-region option in place of the default CENTRM-based $\mathrm{S}_{\mathrm{N}}$ option (see Sect. 3.1.2.1). As in sample problem 1, a simple square-pitched pin cell is modeled but in this case using an XSDRN model block rather than the NEWT model block. The moderator radius was defined in order to preserve the volume of the moderator region.

### 3.1.6.3 TRITON sample problem 3: triton3.inp

Sample problem 3 illustrates the input format for a T-DEPL-1D depletion calculation. In this case, a single square-pitched pin-cell model is depleted, where the fuel composition is comprised of $\mathrm{UO}_{2}$ fuel homogenized with aluminum and $\mathrm{B}_{4} \mathrm{C}$. Although this is not representative of real fuel, it does allow one to observe the effect of boron depletion during burnup; results will show an increasing multiplication factor as boron is depleted, followed by a decreasing eigenvalue after the fuel depletion becomes the dominant contributor to reactivity change. Three depletion intervals are specified with the same power and no decay intervals. Two depletion subintervals are specified for the first two depletion intervals, with only one depletion subinterval for the final depletion interval. Note that this may be insufficient to capture the effect of boron depletion early in life; fewer depletion subintervals are used here only to reduce the run-time for this sample problem. In this model, power is normalized such that material 1 has a power density of 21.22 MW/MTHM (or MT/MTU for $\mathrm{UO}_{2}$ fuel), and OPUS output is requested for 35 nuclides. The problem is run using the addnux=3 option set to add trace quantities of 231 nuclides to depletion materials.

### 3.1.6.4 TRITON sample problem 4: triton4.inp

Sample problem triton4.inp performs a large-scale depletion calculation for a one-fourth PWR assembly, taking advantage of symmetry to reduce the problem size. The same fuel material is used in each fuel rod, which will result in assembly-averaged isotopic compositions for all fuel rods. If one wanted to obtain an isotopic estimate for one or more unique fuel rod locations, then different materials would be specified for different rod positions. Even though all fuel is identical at the beginning of life, unique materials must be specified if one desires to perform tracking of the unique response of each unique fuel position.

The problem parameter specification parm=(weight) instructs TRITON to perform an automated cross section library collapse. For library collapse automation within depletion calculations (see Sect. 3.1.3.7.3), TRITON will perform a single 252-group calculation at $\mathrm{t}=0$ to generate the 56 -group cross section library. TRITON will restart the depletion calculation at $\mathrm{t}=0$ using the broad-group library after it is created. Because parm=weight is specified, the NEWT COLLAPSE block must comply with the

56-group energy structure and not the 252-group energy structure. The COLLAPSE block input is slightly different for the library collapse automation for $T-N E W T$ calculations, where the NEWT COLLAPSE block must comply with the 252-group energy structure.

Problem 4 also uses a timetable to specify boron letdown in the moderator. The initially specified boron concentration in the COMP (or COMPOSITION) data block is multiplied by a density multiplier at the time of each cross section processing and transport calculation (i.e., the midpoint of depletion subinterval). Linear interpolation is performed between values on the timetable to obtain the multiplier for a given time. Typically a multiplier of 1.0 is used for $t=0$, and the beginning-of-life boron concentration is input in the COMPOSITION block, but this example demonstrates that this is not necessary. For this calculation, a 500 ppm boron concentration is specified in the standard composition description, and a concentration of $(500 \mathrm{ppm}) *(1.832)$, or 916 ppm , would be used in the $\mathrm{t}=0$ transport calculation.

Problem 4 is also an example of a lattice physics calculation for a full fuel assembly. The NEWT model employs coarse-mesh finite-difference acceleration, whole-assembly homogenization, 2-energy-group collapse, and a pin-power print, and computes assembly discontinuity factors. Although this sample problem will create the cross section database file for core calculations, this sample problem does not contain branching calculations, nor do lattice physics calculations typically use boron letdown curves. Additional guidance for TRITON lattice physics calculations can be found in the lattice physics primer.

Because only one fuel material is used, only one cell specification is necessary. If multiple fuel materials were used, then a corresponding cell specification would be required for each fuel, with a unique clad and moderator material identifier for each cell. To apply boron letdown properly, the moderator present in each cell specification would need to have the same letdown curve specified. Hence, a letdown timetable would need to be specified for each moderator (even if the moderators are not all used in the NEWT model block). If multiple fuel materials are used, requiring corresponding multiple clad, moderation, cell, and timetable specifications, the use of an alias specification can simplify input. Aliases are described in Sect. 3.1.3.5; sample problems triton6.inp (Sect. 3.1.6.6), triton8.inp (Sect. 3.1.6.8), and triton12.inp (Sect. 3.1.6.12) demonstrate the use of aliases.

This case also illustrates the use of stacked OPUS cases within a single TRITON input file. Here, an OPUS calculation is requested to obtain the mass in grams of 26 actinides and fission products for material 1 and for the entire system; since material 1 is the entire set of depletion materials, the system output will be identical to the material 1 output. A second OPUS calculation is also specified, which requests a ranked output of the top 20 nuclides in terms of decay heat (in watts).

### 3.1.6.5 TRITON sample problem 5: triton5.inp

Sample problem triton5.inp is similar to triton4.inp, except that it is a T5-DEPL case; thus, a KENO V.a transport model is used in place of the NEWT model of the earlier case. The KENO V.a model, although 3D, is axially uniform with reflecting boundary conditions, so it is effectively the same model as the 2D model of triton4.inp. Moreover, the KENO V.a model represents the full assembly rather than a onefourth model. Hence, both cases will generate similar results. In the KENO model, only 300,000 neutron histories are retained, which is somewhat low to obtain good statistics on fluxes. The 238 ENDF/B-VII library is used for this sample problem compared to the 252 ENDF/B-VII. 1 library utilized in triton4.inp.

### 3.1.6.6 TRITON sample problem 6: triton6.inp

Sample problem triton6.inp performs T-DEPL depletion in a pin cell model; however, the pin is discretized into five equal-volume rings of fuel. Thus, CENTRM-based $\mathrm{S}_{\mathrm{N}}$ cross section processing is necessary to capture the radial burnup of the pin cell. A multiregion cell specification is given to allow specification of the varying radii for the fuel regions. Because the multiregion cell is cylindrical, the moderator volume is represented in terms of a radius that corresponds to the volume associated with the pin pitch. The right boundary condition for the cell is set to white; this is important, as the default right boundary condition for a multiregion cylinder is vacuum. In this case, addnux $=1$ is also requested in the parameter specification, simply for a faster (but less accurate) calculation. Material aliases are used to simplify input. The calculation is performed with the 238 ENDF/B-VII library. The TRITON TIMETABLE block is used to demonstrate time-dependent temperature changes to the moderator material.

### 3.1.6.7 TRITON sample problem 7: triton7.inp

Sample problem triton7.inp is an example of a T-DEPL depletion calculation for a full PWR fuel assembly model. Depletion is performed on the basis of material 7, which is located in a single fuel pin for which destructive assay measurements were performed. All other fuel is modeled as a single (average) material, material 1 . The parameter specification parm=(2region,addnux=1,weight) was chosen to reduce the run-time of the sample problem.

This sample problem also demonstrates the use of TRITON's standard composition restart files and SCALE external file reading capabilities to represent the time-dependent behavior of an assembly in which burnable poisons are removed after the first cycle of operation.

This problem consists of two TRITON 2D depletion cases. In the first case, the full assembly model contains borosilicate glass burnable poison rods (BPRs), material 4, which are included in the list of materials to be depleted. The calculation is run for the entirety of the first operational cycle, which included a 40 -day mid-cycle decay interval. The model also includes a 64 -day decay interval after the end of the operational cycle. When this calculation is completed, TRITON creates in the temporary working
directory a standard composition file for each material containing the isotopic inventories for each depletion material at the end of the 64-day decay interval. The second TRITON calculation reads the standard composition specifications for materials 1 and 7 as part of the input to provide the fuel state for the second calculation. In the second model, the BPRs are removed and replaced with the moderator in the embedded NEWT model. The initial depletion calculation uses the 252 ENDF/B-VII. 1 library. With the parm $=(\ldots$, weight) option, a 56 group library is created in the temporary directory called newxnlib. This library is used for the second T-NEWT calculation.

### 3.1.6.8 TRITON sample problem 8: triton8.inp

Sample problem triton8.inp is an example of TRITON's simplified cross section processing scheme in a BWR-like configuration. It uses the T-DEPL extended format for the DEPLETION block to allow material assignments to be made to reduce the number of cross section processing calculations required in a multimaterial depletion model. In this sample problem, the lower-left quadrant of a $6 \times 6$ fuel assembly is modeled (see Figure 3.1.17). The fuel pin layout is as follows: one $2.3 \%{ }^{235} \mathrm{U}$-enriched fuel pin in the southwest corner (red pin), one-fourth of a water rod in the northeast corner, five $3.6 \%{ }^{235} \mathrm{U}$-enriched fuel pins ( 2 green, 1 yellow, and 2 blue pins), and two gadolinium-bearing pins each modeled with three fuel rings. (Gadolinium-bearing pins are typically modeled with multiple fuel rings due to the strong spatial dependence of the flux.) Due to diagonal symmetry, only seven depletion material regions need to be defined: the red, green, yellow, and blue pins along with three regions for the gadolinium-bearing pins. Although seven depletion materials are defined, only three cell specifications are used: one for the gadolinium-bearing pin cell and one each for the $2.3 \%$ and $3.6 \%{ }^{235} \mathrm{U}$-enriched pin cells. This model makes extensive use of aliases. The sequence is run with parm=(addnux=0,...), which includes no extra nuclides, for an accelerated solution; however, this is an extremely poor approximation unless important nuclides are manually specified. This example also illustrates the use of the keyword flux in the DEPLETION data block to force flux-based ORIGEN calculations in place of power-based calculation for all three rings of the gadolinium-bearing fuel pins. Finally, this case uses the parm=(...,weight,...) directive to request the automatic collapse of the input 238 ENDF/B-VII library to a 49 group library (collapsed using the 238 -group system-averaged flux), which is then used for depletion calculations.

```
' THIS SAMPLE PROBLEM TEST THE FOLLOWING:
    ** t-depl sequence
    ** v7-238 group library
    ** centrm cross section processing
    ** parm=weight option for the t-depl sequence, which uses builtin 49-group collapse
    ** latticecell cross section processing option
    ** multi-region cross section processing option
    ** deplete-by-constant flux and by constant power
    ** parm=addnux=0 option to add 0 nuclides to fuel material
    ** system power normalization
    ** depletion assignments
    ** alias block
=t-depl parm=(addnux=0,weight)

Figure 3.1.17. BWR-like assembly design for triton8.

### 3.1.6.9 TRITON sample problem 9: triton9.inp

Sample problem triton9.inp illustrates the use of the TSUNAMI-2D sequence for sensitivity and uncertainty ( $\mathrm{S} / \mathrm{U}$ ) analysis of a PWR pin cell. The SCALE ENDF/B-VII 238-group library is used, with cross section processing performed by BONAMIST and CENTRM/PMC. In this sample problem, the DEFINITIONS and SYSTEMRESPONSES blocks are used to define four additional responses in addition to $k_{\text {eff }}$ for S/U analysis: ${ }^{235} \mathrm{U}$ one-group absorption cross section, ${ }^{235} \mathrm{U}$ one-group fission cross section, ${ }^{238} \mathrm{U}$ one-group absorption cross section, and ${ }^{238} \mathrm{U}$ one-group fission cross section. The SAMS block is also used to disable the HTML-formatted output for this model.

```

### 3.1.6.10 TRITON sample problem 10: triton10.inp

Sample problem triton10.inp performs NEWT-based depletion of a one-fourth symmetric assembly model. The primary intent of this sample problem is to test and to demonstrate the use of branches and archival of computed cross sections for a depletion case. The model includes two branch calculations-in addition to the nominal condition-that demonstrate the different perturbation outputs available in the BRANCH block. A two-group collapse is requested in the NEWT input, along with homogenization over all materials. (Note that the parameter specification parm=(addnux=1) is only used to reduce run-time of the sample problem.) At the end of the calculation, the binary file "xfile016" and text file "txtfile16" will exist in the temporary working directory and will contain all lattice physics parameters for all branches at all depletion states. These files are often copied back from the SCALE temporary working directory to another more permanent directory for subsequent post-processing.

```
' THIS SAMPLE PROBLEM TEST THE FOLLOWING:
' ** t-depl sequence
' ** v7-56 group library
' ** centrm cross section processing
' ** latticecell cross section processing option
' ** deplete-by-constant power
' ** parm=addnux=1 option to add }15\mathrm{ nuclides to fuel material
' ** system power normalization
' ** branch block to generate few-group cross sections.

### 3.1.6.11 TRITON sample problem 11: triton11.inp

Sample problem triton11.inp demonstrates the use of determining Dancoff factors for a BWR fuel assembly. The BWR assembly design contains a $7 \times 7$ array of fuel pins enclosed by a channel box (see Figure 3.1.18). The in-channel moderator void fraction is $40 \%$, and the bypass moderator void fraction is $0 \%$. The input file contains an MCDANCOFF input file that calculates the Dancoff factors for each fuel pin (See the MCDANCOFF chapter). The MCDANCOFF input is essentially the equivalent of the KENO-VI model of the 2D assembly design. Following the MCDANCOFF input, the T-NEWT input is provided that shows how the computed Dancoff factors are inserted into the TRITON model. The Dancoff factors are inserted into the model via the centrmdata keyword entry in the CELLDATA block.

Figure 3.1.18. triton11 BWR assembly design.

### 3.1.6.12 TRITON sample problem 12: triton12.inp

Sample problem triton12.inp illustrates the use of the TSUNAMI-2D sequence for sensitivity and uncertainty ( $\mathrm{S} / \mathrm{U}$ ) analysis of the BWR fuel assembly. The sample problem builds on the output of the previous sample problem. Sample problem 11 demonstrates how MCDANCOFF is used to compute fuel pin Dancoff factors for designs where nonuniform lattice effects play a critical role in cross section processing. The Dancoff factors are inserted into the follow-on T-NEWT model through the centrmdata keyword in the CELLDATA block. The output for the T-NEWT model in sample problem 11 provides an adjusted moderator pitch needed to preserve the user-specified Dancoff factor. These adjusted pitch values are used in triton12.inp for the S/U analysis of $k_{\text {eff }}$ for this assembly. As common in other sample problems, several input options were used to reduce the run-time-and therefore solution accuracy-of the sample problem.

```
' THIS SAMPLE PROBLEM TESTS THE FOLLOWING:
' ** tsunami-2d sequence
' ** v7-238 library
' ** bonamist/centrm cross section processing option
' ** alias block to simplify input
' ** latticecell cross section processing option.
=tsunami-2d

### 3.1.6.13 TRITON6 sample problem 1: triton6-1.inp

Sample problem triton6-1.inp is an example of KENO-VI-based depletion for an infinite lattice of cylinders fabricated with particulate TRISO fuel dispersed in a graphite matrix. This provides an example of the cross section processing specification of a doubly heterogeneous (DOUBLEHET) media and use of the resultant homogenized media in a depletion calculation.

```
' THIS SAMPLE PROBLEM TEST THE FOLLOWING:

### 3.1.A XSDRN Model Block Description

The model data block for $T-X S D R N$ and $T-D E P L-1 D$ calculations allows specification of the 1 D geometry model and various control parameters used in the transport solution. The XSDRN MODEL block input is arranged in blocks of data that are similar to the NEWT MODEL block input described in Chapter 9.2. The XSDRN model input starts with an optional 80-character title, followed by a PARAMETER block, and then the following three data blocks in any order: the GEOMETRY data block, the MATERIAL data block, and the optional COLLAPSE data block. If the PARAMETER, GEOMETRY, and MATERIAL data block are not specified, an error message is printed and the problem is terminated. Sample input files for $T-X S D R N$ and $T$-DEPL-1D calculations are provided in TRITON sample problem 2 and sample problem 3 , respectively, in the TRITON chapter.

### 3.1.A. 1 XSDRN PARAMETER block

PARAMETER Block keyword = parm, para, parameter, or parameters
Valid PARAMETER block specifications are described below. For each keyword, allowable values are listed in parentheses, and the default is listed in brackets. Input that can take an arbitrary integer value is indicated by an IN; similarly, any parameter that can take an arbitrary real/floating point value is indicated by RN as the allowable value. SCALE read routines allow the input of integers for real numbers, and vice versa, and the number will be converted accordingly. The order of the parameters within the block is arbitrary and may be skipped if a default value is desired for that parameter. If a parameter is listed multiple times, the final specified value is used.
bf=(RN) - Buckling factor, equal to twice the extrapolation distance multiplier used to determine the zero point of the asymptotic flux. [1.420892]
collapse=(yes/no) - If collapse=yes is specified, a flux-weighted collapse is performed by material number; cross sections for each nuclide in each material in the problem are collapsed to a specified (or default) group structure based on the average flux in that material. If collapse=yes, TRITON will look for the COLLAPSE block; if not found, TRITON will generate cross sections based on the original group structure. [no]
deltay=(RN) - The first transverse dimension in centimeters used in a buckling correction to calculate leakage normal to the principal calculation direction (i.e., the height of a slab or a cylinder).
deltaz=(RN) - The second transverse dimension in centimeters used in a buckling correction (i.e., the width of a slab).
difftreatment=(mg_1d_sigtr/mg_0d_diff/mg_0d_sigtr/1g_0d_sigtr) - Diffusion treatment option for transverse leakage corrections. The mg_1d_sigtr option uses zone-dependent transport cross-sections for the transverse leakage correction. The mg_0d_diff option uses flux-volume-weighted homogenized diffusion coefficients. The mg_0d_sigtr option uses flux-volume weighted homogenized transport crosssections. The 1g_0d_sigtr option uses a one-group homogenized transport cross-section. [1g_0d_sigtr]
epsglobal=(RN) - Overall problem convergence criteria. [1.0e-6]
epsouter=(RN) - Scalar flux convergence criteria. [1.0e-6]
inners=(IN) - Maximum number of inner iterations in an energy group. [20]
outers=(IN) - Maximum number of outer iterations. [100]
prtflux=(yes/no) - Flag indicating whether or not scalar flux values are should be printed in problem output. [no]
prtangflux=(yes/no) - Flag indicating whether or not angular flux values should be printed in problem output. [no]
prtbalnc=(yes/no) - Flag indicating whether or not fine-group material balance tables should be printed in problem output. [no]
prtmxsec=(yes/no/1d) - Flag indicating whether or not material macroscopic cross sections should be printed in problem output. The 1D option indicates that 2D scattering tables are not to be printed. [no]
$\mathbf{s n}=(2 / 4 / 6 / 8 / 16 / 32)$ - Sn quadrature order for the transport calculations.

## XSDRN GEOMETRY block

GEOMETRY Block keyword = geom, geometry
The GEOMETRY block is used to specify the geometry type (e.g., slab, cylinder, or sphere), the boundary conditions, the 1D material mesh (i.e., zone mesh), and the 1D spatial mesh used in the transport calculation. The order of the parameters entered in the GEOMETRY block is arbitrary and can be any of the following supported keyword specifications or keyword array specifications.
geom=(slab/cylinder/sphere) - Problem geometry. Keywords geometry=, ige=, and cyl for cylinder are also allowed. [slab]
leftbc=(vaccum/periodic/white/albedo/mirror) - Left-hand boundary condition. Keywords ibl=, vac for vacuum, refl for mirror, and reflected for mirror are also allowed. [mirror]
rightbc=(vaccum/periodic/white/albedo/mirror) - Right-hand boundary condition. Keywords ibr=, vac for vacuum, refl for mirror, and reflected for mirror are also allowed. [mirror]
left_albedo RN1 RN2 ... RNN end left_albedo - The left-hand boundary albedo values as a function of energy group. The left_albedo array is ignored if leftbc= is vacuum, periodic, white, or mirror. If the left_albedo array is omitted and leftbc=albedo, white boundary conditions are used. If the number of entries in the left_albedo array does not equal the number of energy groups in the cross-section library, an error message is printed and the problem is terminated.
right_albedo RN1 RN2 ... RNN end right_albedo - The right-hand boundary albedo values as a function of energy group. The right_albedo array is ignored if rightbc= is vacuum, periodic, white, or mirror. If the right_albedo array is omitted and rightbc=albedo, white boundary conditions are used. If the number of entries in the right_albedo array does not equal the number of energy groups in the cross-section library, an error message is printed and the problem is terminated.
zoneids IN1 IN2 ... INN end zoneids - Material composition number by zone. The number of entries in the zoneids array defines the number of zones for the problem. If the zoneids array is not defined, an error message is printed and the problem is terminated.
zonedimensions RN1 RN2 ... RNN end zonedimensions - The right-hand boundary for each zone is given in centimeters. Note that the left-hand boundary of the first zone is 0.0 and must not be entered. If the zonedimensions array is not defined or the number of entries does not equal the number of entries in the zoneids array, then an error message is printed and the problem is terminated.
zoneintervals IN1 IN2 ... INN end zoneintervals - Number of spatial mesh of constant width per each problem zone. If specified, the number of entries of the zonedimensions array must equal the number of entries in the zoneids array. Otherwise, an error message is printed and the problem is terminated.
mesh RN1 RN2 ... RNN end mesh - The right-hand boundary for each spatial mesh in centimeters. The spatial mesh is the discretization used in the transport calculation. Note that the left-hand boundary of the first spatial mesh is 0.0 and must not be entered. The zone boundaries in the zonedimensions array must be a subset of the spatial mesh boundaries in the mesh array. Otherwise, an error message is printed and the problem is terminated. The mesh array is optional and is not used if the zoneintervals array is specified. If neither the zoneintervals array nor the mesh array is specified, an error message is printed and the problem is terminated.

### 3.1.A. 2 XSDRN MATERIAL block

MATERIAL Block keyword = matl, mat, material, materials

The MATERIAL block is used to specify the material numbers for each material used in the calculation in the order of scattering cross section to be used for each material. The format of the MATERIAL block is identical to the NEWT MATERIAL block that is described in detail in (Chapter 9.2). Although source and description specifications are allowed, these options are not used by XSDRN.

### 3.1.A. 3 XSDRN COLLAPSE block

COLLAPSE Block keyword = collapse, coll
The COLLAPSE block is used to define the energy group collapsing operation to calculate broad group cross-section libraries using the XSDRN flux solution. The format of the COLLAPSE block is identical to the NEWT COLLAPSE block that is described in detail in the NEWT chapter

### 3.1.B Data Structure for Cross Section Database File xfile016

When branch calculations are performed, TRITON archives collapsed homogenized cross sections in an unformatted, direct-access FORTRAN file called xfile016. The contents and format of this file are described in this appendix.

TRITON uses a library of SCALE subroutines to read and write blocks of data to direct-access FORTRAN files. The SCALE subroutine library allows the blocks of data to have variable length, even though direct-access FORTRAN files have a fixed record length. The data blocks can be retrieved from the file at random, provided the block length and block starting record position are known. The block length is expressed in terms of 4-byte words. For example, a block of 3-group macroscopic cross sections that contained the total, fission, capture, chi, and nubar cross sections would have a block length of 15 $(3 \times 5)$, assuming that the cross sections are stored in single precision 4-byte format.

The $x$ file016 file supports 11 different block types. The first seven block types appear only once in the file, each block type occupying one of the first seven record positions. The remaining four block types, types 8-11, are repeated for each branch, at each depletion step, starting at the eighth record position.

Branch-specific blocks, i.e., block types 8-11, are written in the following order, for N branch calculations over M depletion steps:

First ( $\mathrm{t}=0$ ) transport calculation, branch 0 (reference state)
First ( $\mathrm{t}=0$ ) transport calculation, branch 1
First ( $\mathrm{t}=0$ ) transport calculation, branch 2
First ( $\mathrm{t}=0$ ) transport calculation, branch N
Second transport calculation, branch 0 (reference state)
Second transport calculation, branch 1
Second transport calculation, branch 2
Second transport calculation, branch N
...
...
$(\mathrm{M}+1)^{\text {th }}$ transport calculation, branch 0 (reference state)
$(\mathrm{M}+1)^{\text {th }}$ transport calculation, branch 1
$(\mathrm{M}+1)^{\text {th }}$ transport calculation, branch 2
$(\mathrm{M}+1)^{\text {th }}$ transport calculation, branch N
Note that $(M+1) \times(N+1)$ sets are saved for $M$ depletion steps and $N$ branches. For each set, block types 8 and 9 are always written, whereas block types 10 and 11 are written only if pin data output was requested ( $n x \neq 0$ ).

## Block Type 1: block length data

Length: 13
Position: 1
Type: integer.
Data: datlen(13)

| datlen(1) | Length of block type 1 (this array), which is 13. |
| :--- | :--- |
| datlen(2) | Number of blocks allocated for this file (1000). Currently not used. |
| datlen(3) | Length of FORTRAN record for this file (512). |
| datlen(4) | Length of block type 2: general dimensioning data. |
| datlen(5) | Length of block type 3: depletion data. |
| datlen(6) | Length of block type 4: branching data. |
| datlen(7) | Length of block type 5: branching data for advanced branch block (not yet supported). |
| datlen(8) | Length of block type 6: currently not used. |
| datlen(9) | Length of block type 7: energy group boundaries. |
| datlen(10) | Length of block type 8: cross sections and misc data. |
| datlen(11) | Length of block type 9: corner discontinuity factors. |
| datlen(12) | Length of block type 10: pin power factors. |
| datlen(13) | Length of block type 11: groupwise form factors. |

## Block Type 2: general dimensioning data

Length: datlen(4)
Position: 2
Type: integer, unless specified otherwise
Data: brnchdepl, nobranch, nsets, igm, iftg, ndelay, nadf, ncdf, ipin, nxpin, nypin, ivers, adftype, branchflag

| brnchdepl | Number of depletion steps + 1. |
| :--- | :--- |
| nobranch | Number of branches. |
| nsets | Number of cross-section sets on library (typically 1). |
| igm | Number of energy groups in collapsed cross sections. |
| iftg | First thermal energy group (max upscatter group). |
| ndelay | Number of delayed neutron precursor groups (6). |
| nadf | Number of assembly discontinuity factors (ADFs). |
| ncdf | Number of corner discontinuity factors (CDFs). |
| ipin | Flag for pin data (0 = no pin data, 1 = pin data included). |
| nxpin | Number of pins in x-direction (0 if ipin = 0). |
| nypin | Number of pins in y-direction (0 if ipin = 0). |
| ivers | Format version number. This appendix describes version 5 of the database structure. |
| adftype | ADF type: (1= single-assembly, 2= reflector, 3= single-assembly on arbitrary grid lines). |
| branchflag | (logical) TRUE for simple BRANCH block format, FALSE for advanced format. |

## Block Type 3: depletion data

Length: datlen(5)
Position: 3
Type: real
Data: burnup(brnchdepl), time(brnchdepl), power(brnchdepl), sysHMdens
burnup(brnchdepl) Burnup (GWd/MTHM) at each transport step.
time(brnchdepl) Cumulative cycle time (days) at each transport step.
power(brnchdepl) Specific power (MW/MTHM) at each transport step.
sysHMdens $\quad$ System heavy metal mass density $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$.

## Block Type 4: branching data

## Length: datlen(6)

Position: 4
Type: integer, unless specified otherwise
Data: fuelused, modused, crused, fuelcount, modcount, crcount, crref, tfref, tmref, mdref, sbref, fuelmix(fuelcount), modmix(modcount), crinmix(crcount), croutmix(crcount), crstate(nobranch), tfuel(nobranch), tmod(nobranch), dmod(nobranch), sboron(nobranch)

| fuelused | (logical) TRUE if fuel mixtures were specified for branches. |
| :---: | :---: |
| modused | (logical) TRUE if moderator mixtures were specified for branches. |
| crused | (logical) TRUE if control rod mixtures were specified for branches. |
| fuelcount | Number of mixtures in fuel definition. |
| modcount | Number of mixtures in moderator definition. |
| crcount | Number of mixture pairs in control rod definition. |
| crref | Reference control rod state (0/1). |
| tfref | (real) Reference fuel temperature (K). |
| tmref | (real) Reference moderator temperature (K). |
| mdref | (real) Referenced moderator density (g/cm ${ }^{3}$ ). |
| sbref | (real) Reference soluble boron concentration (ppm). |
| fuelmix(fuelcount) | Mixtures defined as fuel. |
| modmix(modcount) | Mixtures defined as moderator. |
| crinmix(crcount) | Mixtures defined for the control-rod in state. |
| croutmix(crcount) | Mixtures defined for the control-rod out state. |
| crstate(nobranch) | Control rod state ( $0=$ withdrawn/1=inserted) for each branch. |
| tfuel(nobranch) | (real) Fuel temperature (K) for each branch. |
| tmod(nobranch) | (real) Moderator temperature (K) for each branch. |
| dmod(nobranch) | (real) Moderator density (g/cm ${ }^{3}$ ) for each branch. |
| sboron(nobranch) | (real) Soluble boron concentration (ppm) for each branch. |

## Block Type 5: advanced branching data

Length: datlen(7)
Position: 5
Type: integer
Data: Stores data for advanced branch block (not yet supported)
Block Type 6: currently not used

## Block Type 7: energy group boundary data

Length: datlen(9)
Position: 7
Type: real
Data: ebnds(igm+1)
ebnds $(\mathrm{igm}+1) \quad$ Energy group boundaries
Blocks 1-7 are written only once. Blocks 8 and 9 (plus 10 and 11 if pin power data is output) are written for each branch case at each depletion step.

## Block Type 8: cross-section data

Length: datlen(10)
Position: $8+(\operatorname{igm}+3)\left[i^{*}(\right.$ nobranch +1$\left.\left.)+j\right]\right), i=0, \ldots$, brnchdepl, $j=0, \ldots$, nobranch
Type: real
Data: \{kinf(i), beta_eff(1:ndelay, i), lam_eff(1:ndelay, i) , y_i135(i), y_xe135(i), y_pm149(i), id(i), nden(i), aden(i), $[\operatorname{sigt}(i, j), \operatorname{siga}(i, j), \quad x e m a c(i, j), \quad \operatorname{smmac}(i, j), \quad \operatorname{sigc}(i, j), \quad \operatorname{sigf}(i, j), \operatorname{sign} 2 n(i, j), \operatorname{sigtr}(i, j)$, nusigf(i,j), kappaf(i,j), nu(i,j), chi(i,j), diffcoef(i,j), flux(i,j), sigselas(i,j), sig_xe(i,j), sig_sm (i,j), detfis(i,j), detflx(i,j), invvel(i,j), sigtr2(i,j), sigtr(i,j), [(adf(i,j,k), k=1,nadf),(0,k=nadf+1,12), (current(i,j,k), $\mathrm{k}=1$,nadf),(0,k=nadf+1,12) ], (sigs(i,j,k), k=1,igm), $j=1, i g m], i=1, n s e t s\}$

Data is saved for $i=1$, nsets (number of homogenized regions):

| kinf(i) | k-infinity |
| :--- | :--- |
| beta_eff(1:ndelay,i) | Approximate delayed neutron fractions. |
| lam_eff(1:ndelay,i) | Approximate delayed neutron decay constants $\left(\mathrm{sec}^{-1}\right)$. |
| y_i135(i) | Fission product yield for ${ }^{135} \mathrm{I}$. |
| y_xe135(i) | Fission product yield for ${ }^{135} \mathrm{Xe}$. |
| y_pm149(i) | Fission product yield for ${ }^{149} \mathrm{Pm}$. |

Data is saved for $\mathrm{j}=1$, igm (number of energy groups):

| sigt(i,j) | Total cross section ( $\mathrm{cm}^{-1}$ ). |
| :---: | :---: |
| siga(i,j) | Effective absorption cross section ( $\mathrm{cm}^{-1}$ ). |
| xemac(i,j) | Macroscopic ${ }^{135}$ Xe cross section ( $\mathrm{cm}^{-1}$ ) |
| smmac(i,j) | Macroscopic ${ }^{149} \mathrm{Sm}$ cross section ( $\mathrm{cm}^{-1}$ ). |
| $\operatorname{sigc}(\mathrm{i}, \mathrm{j})$ | Capture cross section ( $\mathrm{cm}^{-1}$ ). |
| $\operatorname{sigf}(\mathrm{i}, \mathrm{j})$ | Fission cross section ( $\mathrm{cm}^{-1}$ ). |
| sign2n(i,j) | Effective n 2 n cross section ( $\mathrm{cm}^{-1}$ ). |
| sigtr(i,j) | Transport cross section ( $\mathrm{cm}^{-1}$ ), determined by outscatter approximation. |
| nusigf(i,j) | Average total number of neutrons/fission $\times$ fission cross section ( $\mathrm{cm}^{-1}$ ). |
| kappaf(i,j) | Energy released per capture $\times$ capture cross section + Energy released per fission $\times$ fission cross section (J/cm). |
| nu(i,j) | Average total number of neutrons released per fission (delayed + prompt). |
| chi(i,j) | Fission spectrum (delayed + prompt). |
| diffcoef(i,j) | Diffusion coefficient (cm), $1 /(3 \times \operatorname{sigtr}(\mathrm{i}, \mathrm{j})$ ). |
| flux(i,j) | Average flux ( $\mathrm{n} / \mathrm{cm}^{2}-\mathrm{sec}$ ). |
| sigselas(i,j) | Total elastic scattering cross section ( $\mathrm{cm}^{-1}$ ). |
| sig_xe(i,j) | Microscopic cross section for ${ }^{135} \mathrm{Xe}$ (barns). |
| sig_sm (i,j) | Microscopic cross section for ${ }^{149} \mathrm{Sm}$ (barns). |

| detfis(i,j) | Microscopic ${ }^{235} \mathrm{U}$ cross section at detector location (barns). |
| :---: | :---: |
| tflx(i,j) | Average flux in detector mixture ( $\mathrm{n} / \mathrm{cm}^{2}-\mathrm{sec}$ ). |
| invvel(i,j) | Inverse neutron velocity ( $\mathrm{sec} / \mathrm{cm}$ ) . |
| sigtr2(i,j) | Transport cross section ( $\mathrm{cm}^{-1}$ ), determined by inscatter approximation. |
| sigtr(i,j) | Transport cross section ( $\mathrm{cm}^{-1}$ ), determined by outscatter approximation. |
| adf(1:nadf,i,j) | Assembly discontinuity factors for up to 12 faces. |
| current(1:nadf,i,j) | Net current for up to 12 faces ( $\mathrm{n} / \mathrm{cm}^{2}-\mathrm{sec}$ ), adftype $=3$ only. |
| sigs(i,j,k), k=1,igm | Macroscopic scattering cross section, $\mathrm{j} \mathrm{k}\left(\mathrm{cm}^{-1}\right)$. |

End of data saved for $\mathrm{i}=1$,nsets

## Block Type 9: corner discontinuity factors

Length: datlen(11)
Position: $9+(\operatorname{igm}+3)\left[i^{*}(\right.$ nobranch +1$\left.\left.)+j\right]\right), i=0, \ldots$, brnchdepl, $j=0, \ldots$, nobranch
Type: real
Data: (( cdf(i,j), i=1,ncdf), j=1,igm)
Data is saved for $\mathrm{i}=1$, ncdf (number of "corner" discontinuity factors):
Data is saved for $\mathrm{j}=1$, igm (number of energy groups):
$\operatorname{cdf}(\mathrm{i}, \mathrm{j}) \quad$ Corner discontinuity factors
End of data saved for $\mathrm{j}=1$, igm

End of data saved for $\mathrm{i}=1$, ncdf

## Block Type 10: pin power peaking factors

Length: datlen(12)
Position: $10+(\mathrm{igm}+3)\left[\mathrm{i}^{*}(\right.$ nobranch +1$\left.\left.)+\mathrm{j}\right]\right), \mathrm{i}=0, \ldots$, brnchdepl, $\mathrm{j}=0, \ldots$, nobranch
Type: double precision
Data: (( ppf(i,j), i=1,nx), j=1,ny)
Data is saved for $\mathrm{j}=1$, ny (number of pins in y direction):
Data is saved for $\mathrm{i}=1, \mathrm{nx}$ (number of pins in x direction):
$\operatorname{ppf}(i, j) \quad$ Pin power (peaking) factors
End of data saved for $\mathrm{i}=1$, nx

End of data saved for $\mathrm{j}=1$, ny

## Block Type 11: group form factors

Length: datlen(13)
Position: $10+\mathrm{k}+(\mathrm{igm}+3)[\mathrm{i}$ * ( nobranch +1$)+\mathrm{j}])$,
$\mathrm{k}=1, \ldots$, igm, $\mathrm{i}=0, \ldots$, brnchdepl, $\mathrm{j}=0, \ldots$, nobranch
Type: double precision
Data: (( gff(i,j), i=1,nx), j=1,ny)

Data is saved for $\mathrm{j}=1$, ny (number of pins in y direction):

$$
\text { Data is saved for } \mathrm{j}=1 \text {, } \mathrm{nx} \text { (number of pins in } \mathrm{x} \text { direction): }
$$

gff(i,j,k) Groupwise form factors
End of data saved for $\mathrm{i}=1, \mathrm{nx}$
End of data saved for $\mathrm{j}=1$, ny
NOTE: Block Type 11 is repeated igm times where igm is the number of energy groups.
It is recommended that code written to process xfile016 include the SCALE subroutine library. Although possible to link in the appropriate files in the scalelib object library in SCALE, it may be more practical to copy the appropriate SCALE routines into a new FORTRAN code used in reading xfile016. All directaccess operations needed to operate on this file are contained in the file direct_access_M.f90 in the scale $\mathrm{src} / \mathrm{scalelib}$ directory. This file has dependencies and requires the following additional subroutines, all in the src/scalelib directory, in order to compile:

Error_functions_M.f90
common_unit_C.f90
Vast_kind_param_M.f90
separator_character_M.f90
Y0trns_M.f90
f_exit.c
The single C routine can be eliminated by eliminating the call to f_exit in subroutine stop of Error_function.f90, e.g., change

```
    if ( stopcode == 0 ) return
    write(npr,'(1x,a,i10)') 'stop code ',stopcode
call f_exit(npr)
end subroutine stop
```

to

```
if ( stopcode == 0 ) return
write(npr,'(1x,a,i10)') 'stop code ',stopcode
write(standard_output,'(a)')npr
stop
```

end subroutine stop

Alternatively, one can utilize the module listed on the following pages, developed by Mr. Benjamin Collins of the University of Michigan, which includes all necessary coding wrapped into a single Fortran module. Although developed from SCALE 5.1 routines, the format of SCALE direct access does not change and this source should remain compatible with later versions of SCALE.

```
module direct_access
! Module taken from SCALE 5.1 source code and modified to
eliminate
! dependencies to other scale modules

### 3.1.C The Flexible Branch Block

In support of various projects, the "flexible branch block" was developed to enable a broader set of perturbations than are available in the typical TRITON branch capability. The typical branch block allows the user to define a single set of mixtures for 'fuel,' 'mod,' 'crout', or 'crin'. Having only four material set definitions limits user's ability to specify more complex perturbations that may be possible in some reactors, especially under transient conditions. The flexible branch block was developed such that the user can specify any number of material sets, and then apply separate perturbations to those sets. This capability, for example, enables specification of bypass flow density branches in BWRs in which the inchannel coolant and out-channel moderator can set to different densities in the same branch calculation.

The flexible branch block was developed in the SCALE 6.1 implementation of TRITON and was not modernized for SCALE 6.2. As a result, the flexible branch block is available in SCALE 6.1 and in the legacy mode in SCALE 6.2. The legacy mode can be accessed using $t-d$ as the sequence name, rather than the more typical $t$-depl. The flexible branch block can be accessed using branchblock as the block name, rather than branch that is used for the typical branch block.

The following section of the manual explains the syntax of the branchblock and contains short examples of each element within the the branchblock. At the end of this section, a full example of a branchblock is provided so that users can gain an understanding of how to use all of the parts of the branchblock in order to define needed calculation branches.

## SYNTAX:

```
read branchblock
    [block keyword specifications]
    end branchblock
```

The advanced branchblock supports five different keyword specifications described below.

- mixset - used to define a set of mixtures which can be used in swap and perturbset definition,
- systemchange - used to define a system change to, temperatures, nuclide concentrations, and Dancoff factors,
- swap - used to define a set of mixtures to swap,
- perturbset - used to define a set of perturbations which apply the system changes defined by systemchange to a set of mixtures, and
- branch - used to define a branch calculation, composed of various swaps and perturbsets. Additional perturbations may also be defined.

NOTE: Several keywords in the branchblock are defined using strings. These strings must be must be delimited, i.e. starts and ends with an identifying marker. (Examples: title="cold", title=\#hot Doppler\#, title=!40\%void!, title=(80\%void)). As shown in the following examples, the string can optionally start with open angle bracket < and end with a closing angle bracket > (Example: title $=<$ cold $>$ ). All string-value inputs in the branchblock are delimited, alphanumeric strings with a maximum length of 80 characters. It is recommended that users choose a single type of delimiter, and then use that delimiter throughout the branchblock.

## systemchange

SYNTAX:
read branchblock
[...]
systemchange title
[systemchange keyword specifications]
end systemchange
[...]
end branchblock
systemchange supports the following keyword specifications:

```
title
dancoff=(real value)
temperature=(real value)
dendiv N
denmult N
```

title is required string input and must follow systemchange. Only one title keyword may be specified. Multiple systemchange specifications are allowed, so each specification must have a unique title.
dancoff is optional and is used to set a dancoff factor value in the interval [0,1]. Only one dancoff specification is allowed and can appear anywhere in the systemchange specification following the title.
temperature is optional and is used to set a system temperature in Kelvin. It must be nonnegative. Only one temperature specification is allowed and can appear anywhere in the systemchange specification following the title.
dendiv and denmult are keyword arrays used to define nuclide concentration dividers and multipliers respectively. The arrays must be terminated with the end keyword. Each array is defined by a series of nuclide/factor pairs where nuclide is the ZZZAAA identifier and factor is either a multiply or divide factor applied to that nuclide concentration (Note that the particular mixture for which the factor is applied is defined in the perturb specification described below). Multiply factors must be $>=0$. Divide factors must be $>0$. A nuclide identifier set to zero implies that the factor is applied to all nuclides that are not explicitly listed in the array. Multiple dendiv and denmult arrays are allowed and can appear anywhere in the systemchange specification following the title. TRITON applies the concentration factors in the order in which they are entered in the systemchange specification.

Multiple systemchange specifications are allowed in the branch block. They can appear in any order, but must have a unique title.

## EXAMPLE:

Define a temperature change to 60 kelvin. (The temperature change will be applied to a set of mixtures defined in the perturbset specification defined later.)

```
systemchange <60C>
    temperature=333.15
end systemchange
```

## swap

SYNTAX:
read branchblock
[...]
swap title
[swap keyword specifications]
end swap
[...]
end branchblock
swap supports the following keyword specifications:

```
title
group1 [mixture specifications] end
group2 [mixture specifications] end
```

title is required string and must follow swap. Only one title keyword may be specified. Multiple swap specifications are allowed, so each specification must have a unique title.
group1 and group2 are used to define a set of mixtures to exchange. group1 must follow the swap title. group2 must follow group1. Only one specification for each group is allowed and they must have the same number of mixtures.

The group1 and group2 keywords support the following keyword specifications:

```
mixture=(integer value)
mixtures }\mp@subsup{I}{1}{}\mp@subsup{I}{2}{}\ldots\ldots\mp@subsup{I}{N}{}\mathrm{ end
mixset=(string value)
```

mixture is used to define a single mixture. mixtures is used to define an array of mixtures and is terminated with the end keyword. mixset is used to substitute a mixset specification defined elsewhere in the branchblock. Multiple mixture, mixtures, and mixset are allowed and can be placed in any order. TRITON will remove any duplicated mixture identifier, however each mixture must be defined in the model input.

## EXAMPLES:

Exchange material 1 for 4.
swap <1 for 4>
group1 mixture=1 end
group2 mixtures 4 end end
end swap
Exchange a set of mixtures:
swap <RodInsertion>
group1 mixset=<crout> end
group2 mixset=<crin> end
end swap

## branch

SYNTAX:
read branchblock

```
    [...]
    branch title
        [branch keyword specifications]
    end branch
    [...]
end branchblock
```

branch supports the following keyword specifications.

```
title
swap=(string value)
perturbset=(string value)
perturb [perturb specification] end
```

title is required string and must follow branch. Only one title keyword may be specified. Multiple branch specifications are allowed, so each specification must have a unique title.
swap is used to swap different sets of mixtures. The swap value is a string which is the title of a swap specification defined elsewhere in the branchblock. (The swap specification is described below). Multiple swap specifications are allowed and can appear anywhere in the branch specification following the title.
perturbset is used to apply a series of system perturbations. The perturbset value is a string which is the title of a perturbset specification defined elsewhere in the branchblock. (The perturbset specification is described below). Multiple perturbset specifications are allowed and can appear anywhere in the branch specification following the title.
perturb is used to apply a system perturbation that is not defined through the use of a perturbset specification. perturb specifications must terminate with the end keyword.
perturb supports the following keyword specifications.

```
change=(string value)
mixture=(integer value)
mixtures }\mp@subsup{I}{1}{}\mp@subsup{I}{2}{}\ldots... I IN en
mixset=(string value)
```

change is a string which is the title of a systemchange specification defined elsewhere in the branchblock. Only one change specification is allowed and may appear anywhere in the perturb specification.

The system change is applied to a set of mixtures defined by the mixture, mixtures, and mixset specifications. Only one of each of these keywords is allowed (however all three may be used in the same perturb specification). mixture, mixtures, and mixset may be placed in any order. TRITON will remove any duplicated mixture, however each mixture must be defined in the model input. TRITON will perform swap and perturb operations in the order they appear in the input.

## EXAMPLES:

Define a branch to charactize the rodded, cold-zero-power condition. This requires the use of mixture swap entitled <CRodIn> along with the perturbset definition <ColdMod> which perturbs all of the moderator mixtures to a cold temperature and density. The fuel mixtures (defined as <FuelMix>) must also be set to a temperature of 300 K .

```
read branchblock
    [...] (contains definitions for <CRodIn>, <FuelMix>, and <ColdMod>)
    branch <CZP,rodded>
        perturbset=<ColdMod> swap=<CRodIn>
        perturb change=<300K> mixset=<FuelMix> end
    end branch
    systemchange <300K> temperature=300 end systemchange
end branchblock
```

Define a branch to characterize the BWR instantaneous $100 \%$ void branch. This requires that:

- in-channel moderator mixtures (<ChannelMod>) are perturbed from $40 \%$ void to $100 \%$ void (defined by systemchange $<40 \mathrm{vf}-100 \mathrm{vf}>$ ).
- Water-rod moderator mixtures (<WaterRodMod>) are perturbed from $0 \%$ void to $5 \%$ void ( $<0$ vf5vf>)
- Bypass moderator mixtures (<BypassMod>) are perturbed from $0 \%$ void to $3 \%$ void (<0vf-3vf>)
- Corner Rod Fuel mixture (mixture 1) dancoff factor changes (described by <100vf-cornerDF>)
- Edge Fuel Rod Mixtures (3,4,5,6,7,10) dancoff factor changes (described by <100vf-edgeDF>)

```
read branchblock
    [...] (contains all other definitions)
    branch <100VF>
        perturb change=<40vf-100vf> mixset=<ChannelMod> end
        perturb change=<0vf-5vf> mixset=<WaterRodMod> end
        perturb change=<0vf-3vf> mixset=<BypassMod> end
        perturb mixture=1 change=<100vf-cornerDF> end
        perturb mixtures 3 4 5 6 7 10 end change=<100vf-edgeDF> end
    end branch
end branchblock
```

mixset - used to define a set of mixtures used in swap, perturbset, and perturb specifications.
SYNTAX:
read branchblock
[...]
mixset title
[mixset keyword specifications]
end mixset
[...]
end branchblock
mixset supports the following keyword specifications:

```
title
mixture=(integer value)
mixtures }\mp@subsup{I}{1}{}\mp@subsup{I}{2}{}\ldots... I IN en
mixset=(string value)
```

title is required string and must follow mixset. Only one title keyword may be specified. Multiple mixset specifications are allowed, so each specification must have a unique title.
mixture is used to define a single mixture. mixtures is used to define an array of mixtures and is terminated with the end keyword. mixset is used to substitute a mixset specification defined elsewhere in
the branchblock. Multiple mixture, mixtures, and mixset are allowed and can be placed in any order. TRITON will remove any duplicated mixture identifier, however each mixture must be defined in the model input. If mixset is used to, the mixture set must be previously defined in the branchblock.

## EXAMPLE:

In previous example for $100 \%$ void fraction, define a mixture set to be used for the edge rod dancoff factor perturbation.

```
read branchblock
    [...] !contains all other definitions
    branch <100VF>
        perturb change=<40vf-100vf> mixset=<ChannelMod> end
        perturb change=<0vf-5vf> mixset=<WaterRodMod> end
        perturb change=<0vf-3vf> mixset=<BypassMod> end
        perturb mixture=1 change=<100vf-cornerDF> end
        perturb change=<100vf-edgeDF> mixset=<edge-fuel> end
    end branch
    mixset <edge-fuel>
        mixtures 3 4 5 6 7 10 end
    end mixset
end branchblock
```

perturbset - used to define a set of system perturbations that can be used in branch specifications.
SYNTAX:
read branchblock
[...]
perturbset title
[perturbset keyword specifications]
end perturbset
[...]
end branchblock
perturbset supports the following keyword specifications:

```
title
perturb [perturb specification] end
```

title is required string and must follow perturbset. Only one title keyword may be specified. Multiple perturbset specifications are allowed, so each specification must have a unique title.

After title, multiple perturb specifications can be used to defined a set of perturbations. The perturbset can then be used in branch specifications to simplify the branch input. TRITON will apply the perturbations in the order in which they appear in the perturbset specification.

## EXAMPLE:

In previous example for $100 \%$ void fraction, define a perturbset for the moderator perturbations, and a separate perturbset for the fuel perturbations.

```
read branchblock
    [...] !contains all other definitions
    perturbset <modChange>
        perturb change=<40vf-100vf> mixset=<ChannelMod> end
        perturb change=<0vf-5vf> mixset=<WaterRodMod> end
```

```
        perturb change=<0vf-3vf> mixset=<BypassMod> end
    end perturbset
    branch <100VF> perturbset=<modChange> perturbset=<fuelChange> end branch
    perturbset <fuelChange>
        perturb mixture=1 change=<100vf-cornerDF> end
        perturb change=<100vf-edgeDF> mixset=<edge-fuel> end
    end perturbset
    mixset <edge-fuel>
    mixtures 3 4 5 6 7 10 end
    end mixset
end branchblock
```

## branchblock Full Example

Because the branchblock input is so flexible, it may be difficult for users to know where to begin. For that reason, we have provided a sample branchblock that is typical to a BWR analysis. In this example, the open and close parentheses are using instead of angle brackets. In the example provided, the branchblock is separated into \#\#\# different sections: definition of mixsets, definition of systemchanges, definition of swaps, definition of perturbsets (which are composed of multiple systemchanges), and definition of branches. This example may appear complicated, but in essence, it is quite straightforward. First, all of the mixture IDs in the problem are defined into logical mixsets. Then, other large mixsets are composed of the individual mixsets. The first two systemchanges, ( $1 / \mathrm{nom}$ ) and ( $1 / \mathrm{liq}$ ), are a very important items. These systemchanges are density divisors that divide the number densities of a specified moderator mixture by the nominal or liquid density, making the resulting density 1.0. Then, systemchanges that are density multipliers are specified as the actual density, which make the branchblock much easier to read and understand. By using the special density divisors, an almost identical branchblock can be use for different nominal densities - only the density specified in ( $1 /$ nom) needs to be modified for a different nominal density.

Following the systemchanges, a number of perturbsets are defined to make multiple perturbations to the collant or moderator density. For example, the ( $00 \%$ Void 353 ) perturbset shown below makes six changes: (1) divide all coolant (in-channel) mixtures by the nominal density, then (2) multiple all coolant mixtures by the specified density, (3) divide all liquid water moderator (out-channel) features by the saturated liquid density, then (4) multiple all liquid water features by the specified density, and then, (5) and (6) change the Dancoff factors to their appropriate values corresponding to the coolant and moderator densities.

```
perturbset (00%Void353)
    perturb mixset=(coolant) change=(1/nom) end
    perturb mixset=(coolant) change=(00V-353) end
    perturb mixset=(solidmod) change=(1/liq) end
    perturb mixset=(solidmod) change=(00V-353) end
    perturb mixset=(cornerfuel) change=(00VCold-dfCO) end
    perturb mixset=(edgefuel) change=(00VCold-dfEO) end
end perturbset
```

To end the file, all branch calculations are specified in a single block using the previously defined perturbsets. Note that unlike the typical branch block, the flexible branchblock does not need the first branch to correspond to the nominal conditions. It is important to note that in the xfile016 and txtfile16 files, the branch conditions (moderator density, temperature, soluble boron, and CR state) will not be listed correctly in the file header as they are for the typical branch block. When using the branchblock input, TRITON no longer knows the condition for any given branch, however, the branch order specified in the input file is maintained in the $x$ file 016 and txtfile16 files.

Also note that in the example provided, no soluble boron changes have been specified (as this is a BWR example). However, soluble poisons (boron or other), are also fairly straightforward to specify using the density divisors and density multipliers.

## BWR branchblock Example

# 3.2 POLARIS - 2D LIGHT WATER REACTOR LATTICE PHYSICS MODULE 

M. A. Jessee, J. J. Jarrell, W. A. Wieselquist, M. L. Williams, K. S. Kim, T. M. Evans, S. P. Hamilton

#### Abstract

Polaris is a new module for SCALE 6.2 that provides 2D lattice physics analysis capability for light water reactor (LWR) fuel designs. Polaris uses a new multigroup self-shielding method called the Embedded Self Shielding Method (ESSM) and a new transport solver based on the Method of Characteristics (MoC). The ESSM computes multigroup self-shielded cross sections using Bondarenko interpolation methods. The background cross section used in the interpolation is determined by iterative 2D MoC fixed source transport calculations. Polaris is integrated with ORIGEN for depletion calculations. Each pin-or each radial subregion of the pin-is depleted based on the local power distribution. An optional critical spectrum calculation is incorporated into the depletion calculation and the output edits of few-group homogenized cross sections. Few-group cross sections are archived to an xfile016 file, which can be used in subsequent core simulator calculations. Polaris provides an easy-to-use input format to allow users to set up lattice models with minimal lines of input.

## ACKNOWLEDGMENTS

The authors express gratitude to Brad Rearden and Stephen Bowman for their supervision of Polaris development for the US Nuclear Regulatory Commission (NRC). The author acknowledges Don Algama and Mourad Aissa of the NRC for their support of the project. Appreciation is extended to the ATLAS development team—Jordan Lefebvre, Rob Lefebvre, and Adam Thompson-for their development of the ATLAS Ray Tracing Geometry package used in the Polaris MoC solver. Appreciation is also extended to Ugur Mertyurek, Brian Ade, Ben Betzler, Scott Palmtag, and Andrew Godfrey for testing and benchmarking efforts and also Sheila Walker for finalizing the publication of this document.

### 3.2.1 Introduction

Polaris is a new module for SCALE 6.2 that provides 2D lattice physics analysis capability for light water reactor (LWR) fuel designs. For multigroup cross section processing, Polaris uses the Embedded SelfShielding Method (ESSM) [1]. Unlike SCALE multigroup sequences that use XSProc, ESSM does not require user-defined unit cell definitions. ESSM computes multigroup cross sections using Bondarenko interpolation methods. The background cross section used in the interpolation is determined by iterative 2D fixed source transport calculations. Both the ESSM fixed source calculations and the keff calculation utilize a new Method of Characteristics (MoC) transport solver developed in the Exnihilo computational package.

Polaris is integrated with ORIGEN for depletion calculations. Each pin-or each radial subregion of the pin-is depleted based on the local power distribution. An optional critical spectrum calculation is incorporated into the depletion calculation and the output edits of few-group homogenized cross sections. Few-group cross sections are archived to an xfile016 file, which can be used in subsequent core simulator calculations. A complete description of the Polaris computational methods is provided in [2].

Polaris provides an easy-to-use input format to allow users to set up lattice models with minimal lines of input. All recognized Polaris commands are shown in Table 3.2.1. Note that many commands support short and long forms. The allowed basic Types for input are described in Table 3.2.2. The special Polaris TYPES are shown in Table 3.2.3. The convention used in this manual is that basic types appear italicized and capitalized (Type), while special Polaris types appear in all caps (TYPE).

Table 3.2.1. Polaris commands

| card | long <br> command | short <br> command(s) |
| :--- | :--- | :--- |
| system | system | sys |
| geometry | geometry | geom |
| composition | composition | comp |
| property | property | prop |
| material | material | Mat |
| burnup | bu or dbu | - |

Table 3.2.2. Basic Types in Polaris input

| basic <br> Type | description | examples | incorrect examples |
| :---: | :---: | :---: | :---: |
| Word | starts with a character A-Z or a-z and includes characters, numbers, underscores | uox <br> bor_water_500ppm FUEL | $\begin{aligned} & \text { uox_enr5.1 } \\ & \text { 316SS } \\ & \text { uox-3.1 } \end{aligned}$ |
| Int | integer | $\begin{aligned} & 17 \\ & 92235 \\ & 2 \\ & 565 \\ & \hline \end{aligned}$ | $\begin{aligned} & 31.4 \\ & \text { uox } \end{aligned}$ |
| Bool | Boolean/logical | yes <br> false | $\begin{aligned} & \text { TRUE } \\ & \text { No } \end{aligned}$ |
| Real | any number | 565 <br> 10.257 <br> 1.5e-6 | yes <br> bor_water |
| String | a single or double quoted string | "INFMED" <br> "Includes spaces" 'NONE' | Includes spaces |
| Value | any non-word |  | Int\|Bool|Real|String |

Table 3.2.3. Special Polaris Types

| Polaris Type | description | Variants |
| :--- | :--- | :--- |
| STYPE | system type | PWR\|BWR |
| GTYPE | geometry type | ASSM\|REFL |
| CTYPE | composition type | NUM\|WT|FORM|CONC|LW|UOX |
| PTYPE | property type | SOLP |
| ETYPE | control element type | RODLET |
| OTYPE | option type | KEFF\|BOND|ESSM|CRITSPEC|FG|DEPL|RUN|PRINT |

The Polaris input supports a very flexible input scheme that allows some elements to be suppressed for better readability. With key=value type input, when the standard order of keys is used, the keys may be suppressed. Consider the following input specification as an example.

```
geomet ry GNAME : ASSM npi ns=/ nt ppitch=Real [ symFFULL| SE]
```

The geometry card requires a geometry name (GNAME) in the first group, then a geometry type (GTYPE) which is ASSM here indicating an assembly geometry. The remaining arguments have keys: "npins" with an integer value, "ppitch" with a real value, and the optional "sym" with either FULL or SE values (optional arguments are always shown in square brackets: [sym= $\underline{F U L L} \mid S E$ ]. The default value is underlined: ( $\underline{F U L L}$ ). The pipe "|" shows an or relation i.e., $F U L L$ or $S E$ is an acceptable value ).
With the flexible input processing, the following inputs are all valid and identical.

```
geometry Fuel Node : ASSM npi ns=15 ppi tch=1. 43 symFFULL
geomet ry Fuel Node: ASSM 15 1.43 FULL
geometry Fuel Node: ASSM symFULL ppi tch=1.43 npi ns=15
geomet ry Fuel Node:ASSM 15 1.43
geometry Fuel Node ASSM 15 1.43
```

The group separator ":" is suppressed in the last variant. This is possible in any situation where (1) the group is implicitly terminated by running out of arguments or (2) the next type does not match the expected type in the current group. For example, consider the hgap card:
hgap [ d] [: M]
In this card, d and M are values (without keys) defined as Real and material name (MNAME), respectively. The following form would automatically bypass the Real value, which allows a default, and set the interassembly gap material name as COOL.2.

```
hgap COOL. }
```

### 3.2.2 Setup

The cards in this section generally appear at the beginning of an input file. Note that the manual is organized with each card starting a new page. This is especially convenient when printing a few cards across different sections.

### 3.2.2.1 title - case title lines

title Line ${ }_{1}$ Line $_{2} \ldots$ Line $_{i} \ldots$ Line $_{\text {N }}$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| Line $_{\mathrm{i}}$ | String | line | used in output file headers | "DEFAULT TITLE" |

## Examples:

title "Westinghouse $15 \times 15$ "
title "Westinghouse $15 \times 15$ "
"Condition: Hot Full Power"
"Dat e: 10/ 18/ 2012"

## Comments:

The title card gives a title to this Polaris case, which appears as a descriptive header on the output file. The additional lines may be used to document a subcase or to embed additional information in the output file in an orderly way (e.g., author, date, project identifier).

The title card is optional.

## See also:

lib

### 3.2.2.2 library - nuclear data libraries

lib [mg=String]

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| mg | String | multigroup library | multigroup cross section library | "fine_n" |

## Examples:

\% a name of library in the DATA di rectory
\% use SCALE 252g ENDF/ B- VI I. 1 I i brary
lib "fine_n" \% SAME AS "V7-252"
\% use SCALE 56g ENDF/ B- VII. 1 I i brary
libmg="broad_n" \% SAME AS mg="V7-56"
\% a name of a local li brary in the temporary working directory
\% (usef ul in $n$ SAMPLER cal cul at i ons)
li b "pertur bed_xs_li br ary"
\% fully specified path
I i b "C: \scal e6. $2 \backslash$ dat a scal e. rev04. xn252v7. 1"

## Comments:

The lib card specifies the multigroup library location. See SCALE's FileNameAliases.txt file in the installation directory for up-to-date library aliases for the fine and broad group libraries provided in SCALE's data directory. Only the 252 -group and the 56 -group cross section libraries can be used in Polaris. Full specification of the file path is acceptable, as in the final example shown above.

The lib card is optional.

title

### 3.2.3 Geometry

The highest level structures in the model are named and defined with a geometry card. The general outline for a geometry definition is shown below. Two types of geometry are currently supported, ASSM for pressurized water reactor (PWR) or boiling water reactor (BWR) assemblies with fuel elements in a square-pitch, and REFL for an assembly-adjacent reflector.
geom GNAME: GTYPE arguments

| argument | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| GNAME | Word | geometry name |  |  |
| GTYPE | - | geometry type |  |  |
|  | ASSM | assembly | see pin \& pinmap |  |
|  | REFL | reflector | see slab |  |
| arguments | - | remaining arguments | depends on GTYPE |  |

The control element geometry is also enumerated with types, as shown below. To model PWR-type rod cluster control assemblies (RCCAs), the RODLET element type is used in conjunction with pin definitions. In future releases of Polaris, other control element types, such as BWR-type control blades will be supported..

## control INAME : ETYPE arguments

| Argument | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| INAME | Word | control <br>  <br> name | element |  |
| ETYPE | - | control element type |  |  |
| arguments | RODLET | PWR-type RCCA | requires PINIDs |  |

For accurate solutions to lattice physics problems using the method of characteristics (MoC), the input geometry must be subdivided into smaller regions called cells. Although the defaults should be applicable in most cases, the capability to change the number of cells is provided through meshing options appearing at the end of many geometry cards. See the slab, pin, box, and hgap cards for details.

### 3.2.3.1 geometry<ASSM>- assembly

geom GNAME : ASSM
npins=Int
ppitch=Real
[sym=FULL|SE]

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| GNAME | Word | assembly name |  |  |
| GTYPE | ASSM |  |  |  |
| npins | Int | number of pins | on each side of <br> the assembly |  |
| ppitch | Real | pin pitch | units: cm |  |
| sym | FULL\|SE | symmetry | assembly symmetry | FULL |
|  |  |  | FULL: no symmetry |  |
|  |  |  | SE: south-east quarter |  |

## Examples:

\% si mpl e pi ncel I
geom MyPi $n$ : ASSM 1 1. 5
\% $17 \times 17$ Westinghouse with 1.26 cm pi n pitch in quarter symmetry geom Fuel Node : ASSM 17 1. 26 sym=SE

## Comments:

The assembly geometry describes the basic elements of an assembly. The pin and pinmap cards are required to finalize the assembly geometry. The hgap card specifies the interassembly half gap, and the channel specifies the channel material for the assembly.

See also:
pinmap, pin, hgap, box, channel, control, insert

### 3.2.3.2 geometry<REFL>- reflector

geom GNAME: REFL
thick=REAL
$[$ pos $=\underline{E}|S| W \mid N]$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| GNAME | Word | reflector name |  |  |
| GTYPE | $R E F L$ |  |  |  |
| thick | Real | thickness | units: cm <br> adjacent to assembly side | $E$ |
| pos | $E\|S\| W \mid N$ | position | east\|south|west|north |  |

## Examples:

\% defines a 20 cmreflector with default position geom Reflector Node : REFL 20 pos=E

## Comments:

The reflector geometry describes the basic elements of a simple slab-type reflector. The slab card can be used to define geometric dimensions and mesh for the reflector geometry.

## See also:

slab

### 3.2.3.3 channel - materials and mesh options

$$
\text { channel }\left[\mathrm{M}_{\text {chan }}=\mathrm{MCLASS}\right]\left[\mathrm{nr}_{\mathrm{chan}}=\mathrm{Int}\right]\left[\mathrm{ns}_{\mathrm{chan}}=\mathrm{Int}\right]
$$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{M}_{\text {chan }}$ | MCLASS | material class | initializes materials in outermost pin zone | $*$ |
| meshing options |  |  | $* *$ |  |
| $\mathrm{nr}_{\text {chan }}$ | Int | number of rings | initializes $\mathrm{nr}_{\text {out }}$ for pin | $* * *$ |
| $\mathrm{~ns}_{\text {chan }}$ | Int | number of sectors | initializes $\mathrm{ns}_{\text {out }}$ for pin | $*$ |

*By default, $\mathrm{M}_{\text {chan }}$ will be set to COOL by "system PWR" and "system BWR." Otherwise, $\mathrm{M}_{\text {chan }}$ is required.
** By default, nr ${ }_{\text {chan }}$ will be set to 1 by "system PWR" and "system BWR." Otherwise, the default is 0 .
*** By default, $n s_{\text {chan }}$ will be set to 8 by "system PWR" and "system BWR." Otherwise, the default is 1.

## Examples:

\% define the channel material class to be COOL, 2 rings, 16 sectors
channel COOL 216

## Comments:

The channel card is used to set the default channel material class and meshing options for the outermost region of each pin, typically containing reactor coolant. See the material card for a description of material classes.

## See also:

pin, material, geometry<ASSM>

### 3.2.3.4 hgap - half distance between assemblies

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{d}_{\mathrm{i}}$ | Real | list of widths with $i:$ | accepts 1, 2, or 4 values | 0.0 |
|  |  | E: east | $\mathrm{E}:$ all hgaps are same |  |
|  | $N:$ north | $\mathrm{E}+\mathrm{N}: \mathrm{d}_{\mathrm{E}}=\mathrm{d}_{\mathrm{S}}$ and $\mathrm{d}_{\mathrm{N}}=\mathrm{d}_{\mathrm{W}}$ |  |  |
|  |  |  |  |  |
|  | W: west |  |  |  |
|  |  |  |  |  |
|  |  |  |  |  |

| $\mathrm{M}_{\mathrm{i}}$ | MNAME | list of <br> material names | requires same \# as $\mathrm{d}_{\mathrm{i}}$ | $*$ |
| :--- | :--- | :--- | :--- | :--- |
| meshing options |  |  |  |  |
| $\mathrm{nf}_{\mathrm{i}}$ | Int | list of <br> number of faces per pin | requires same \# as $\mathrm{d}_{\mathrm{i}}$ | 2 |
| $\mathrm{nd}_{\mathrm{i}}$ | Int | list of <br> number of divisions | requires same \# as d $\mathrm{d}_{\mathrm{i}}$ | 1 |

*By default, hgap material will be set to COOL. 1 by "system PWR" and MOD. 1 by "system BWR." Otherwise hgap material is required.

## Examples:

\% defines a $17 \times 17$ Westinghouse assently with 1.26 cmpin pitch
$\%$ with 0.04 cm half-gap filled with material COOL. 1
geom w17x17: ASSM 17 1. 26 symaSE
hgap 0. 04 COOL. 1

```
\% defines a GE \(7 \times 7\) assenbl y with 1.88 cm pin pitch
\(\% \quad 0.48 \mathrm{~cm}\) narrow gap on east and south edge
\% 0.95 cm wi de gap on north and west edge
\% narrow gap mesh is 3
\% wi de gap mesh is 4
\% faces per pin is 2 for both narrow and wi de gap
geom ge7x7: ASSM 71.88
hgap 0. 48 0. 95 : MOD. 1 MDD. 1 : 22 : 34
```

## Comments:

The hgap specifies the outermost geometry region in an assembly. If a channel box exists, then hgap specifies the material and mesh from outer channel box edge to the problem boundary. Otherwise, hgap specifies the material and mesh from the edge of the fuel array to the problem boundary. In both cases, hgap represents the half-distance between adjacent assemblies for single assembly calculations. Fig. 3.2.1 shows some of the hgap meshing options. Referring to the south edge of the assembly, the number of faces per pin refers to the extra cells introduced by "splitting" the pin cell boundary, and the number of divisions refers to extra horizontal lines dividing half gap into smaller width cells.

## See also:

### 3.2.3.5 box -channel box

box [thick=Real] [rad=Real] [icdist=Real] [xrad=Real] [xlen=Real] [Mbox=MNAME] [nf=Int] [nd=Int] [icnf=Int] [icnd=Int]

| param | type | name | details | default |
| :---: | :---: | :---: | :---: | :---: |
| thick | Real | nominal thickness (cm) | must be >0 | none |
| rad | Real | inner corner radius (cm) | must be $>0$, | none |
| icdist | Real | in-channel distance (cm) | must be >0 | none |
| xrad | Real | extra corner thickness (cm) | must be >=0 | 0 |
| xlen | Real | extra corner length (cm) | excludes rounded corner length | 0 |
| $\mathrm{M}_{\text {box }}$ | MNAME | box material |  | * |
| meshing options |  |  |  |  |
| nf | Int | \# of faces per pin for the box |  | 2 |
| nd | Int | \# of divisions for the box |  | 1 |
| icnf | Int | \# of faces per pin for the in-channel region |  | 2 |
| icnd | Int | \# of divisions for the in-channel region |  | 1 |

*By default, box material will be set to CAN. 1 by "system BWR." Otherwise box material is required.

## Examples:

```
% GE 7x7 assembl y with 1.88 cm pi n pitch
% 0.48 cm narrow gap
% 0. 95 cm wi de gap
syst em BWR
geom ge7x7 : ASSM 7 1. }8
hgap 0. 48 0. }95\mathrm{ : MDD. 1 MDD. 1 : 2 2 : 3 4
% Box geometry
% 0. 2 t hi ckness
% 0. 97 i nner corner radi us
% 0. 14 i n-channel di stance
box 0.2 0.97 0.14
% Same exampl e, al l variabl es
box 0. 2 0.97 0.14 0 0 CAN. 1 2 1 2 1
```

## Comments:

The box specifies the channel box geometry, material, and mesh that surround the array of fuel pins. The box implementation in Polaris is targeted to support common BWR box dimensions; therefore, the geometry specification has several constraints, including:

- compute $X=($ pin_pitch/2+icdist) $\sqrt{ } 2$
- compute $\mathrm{Y}=\mathrm{X}-\operatorname{rad}(\sqrt{ } 2-1)$
- to prevent box from clipping the pin: pin outer radius $<\mathrm{Y}$
- implementation constraint: $\mathrm{Y}+$ thick + xrad $<\mathrm{X}$

Fig. 3.2.2 and Fig. 3.2.3 show some of the box meshing options. The number of faces per pin and the number of divisions are consistent with the definitions provided in the hgap card.

pi $n$ Wsize=2: 0.8
COOL
\%inn nmp must show adjacent W s
pi nnap
F F F F
F WWF
F W WF
F F F F

## Comments:

The pin card is one of the basic building blocks of the assembly model. It is the only geometry component which allows an integer (Int) identifier as well as a Word-all other geometric identifiers use Word. Note that the materials are required, except for the last $\mathrm{M}_{\text {out }}$, which can be used to overwrite the material given by a channel for the outermost region in the pincell. The various pin cell meshing options are displayed in
Fig. 3.2.4. Note that extra rings in the radial zones create equal area regions, whereas extra rings in the outermost region create equal distance divisions between the last radius and the pincell boundary. Extra sectors create additional azimuthal divisions.

The total number of cells used in the transport calculation is determined from both the number of rings and the number of sectors. With the MoC transport solver, the fidelity of the solution is also dictated by the number of azimuthal and polar angles and ray spacing. These parameters are changed on the option<KEFF> card.

Due to self-shielding and depletion, each cell could be modeled as a unique material with its own cross section data. However, this is prohibitively memory intensive and typically not necessary. The shield card provides the mechanism to control the additional self-shielded materials introduced.

## See also:

pinmap, control, insert, channel, system, option<KEFF>, shield

Fig. 3.2.4. Pincell meshing variants.

### 3.2.3.7 pinmap - pin layout

```
pinmap PINID 
    PINID
    \mp@subsup{PINID}{i}{}}
```

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| PINID $_{\mathrm{i}}$ | Word\|Int | list of <br> pin identifiers | supports full, quarter, or octant symmetry <br> quarter: assumes southeast (SE) <br> octant: assumes south-by-southeast (SSE) |  |

## Examples:

## Comments:

The pinmap card defines the layout of pin cells in the assembly. The symmetry is determined by the number of pin identifiers given on the card and must not be more general than the symmetry option given on the assembly geometry card (i.e., do not define a full pin map for a sys=SE assembly model).. If the pin has a large size specifier, size>1, then the pinmap must reflect that with those pins occurring in blocks of size $\times$ size.

See also:
pin, control, insert

### 3.2.3.8 control<RODLET>-RCCA-type layout

```
control INAME : RODLET
        PINID 
        PINID 2 ...
        \mp@subsup{PINID}{i}{}}
```

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| INAME | Word | insert name |  |  |
| ETYPE $^{\text {RODLET }}$ |  |  |  |  |
| PINID $_{i}$ | Word\|Int | list of | same format as pinmap |  |
|  |  | pin identifiers | "_" indicate empty locations |  |

## Examples:

```
% B4C control rods
nat GAS. 1 : FI LLGAS
mat CAD. 1 : Zl RC4
nat MDD.1 : LW
mat TUBE. 1: SS304
mat CNTL.1 : B4C
pin B: 0. 214 0. 231 0. 241 0. 427 0. 437 0.484 0.561 0. 602
        : GAS TUBE GAS CNTL GAS TUBE MDD CLAD
control BankD : RODLET
    -
    - -
    \overline{B}
    - - - - - B
    \overline{B}
    -
    - - - - - - - - - -
```

## Comments:

Note that control elements and inserts share the INAME identifiers, so an insert and a control element cannot have the same name. Different control rod banks may be included in a single input file using more than one control card with unique INAMEs. The main difference between the inserts defined by control element and insert cards is that by default, control element materials are not depleted, whereas insert materials are depleted.

The outer dimensions of the tube must be included in the pin card that is inserted, and size=2 pins must always be defined in the control element, even if the geometry has not changed.

## See also:

pinmap, control, insert, state

### 3.2.3.9 insert - insert layout

```
insert INAME :
        PINID
        PINID 2 ...
        \mp@subsup{PINID}{i}{}}
```

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| INAME $^{l}$ | Word | insert name |  |  |
| PINID $_{i}$ | Word\|Int | list of <br> pin identifiers | same format as pinmap |  |
|  |  |  |  |  |

## Examples:

```
%pyrex inserts
pin P: 0. 214 0. 231 0.241 0.427 0.437}0.4840.561 0.602
        : GAS TUBE GAS BP. }3\mathrm{ GAS TUBE COOL CLAD
insert Pyrexl nserts :
    -
    - -
    F = - P
    -- - - - P
    P - - P - - -
    - - - - - -
    - - - - - - - - -
```

## Comments:

The insert card defines a set of pins to be used to model inserts such as WABA. When the insert is "in," the insert pins replace overlapping regions of the pins defined on the assembly pinmap. An underscore (_) is used to indicate locations without inserts. See the notes on the control<RODLET> card for additional guidelines.

## See also:

pinmap, control, insert

### 3.2.3.10 slab - slab geometry

## slab [SLABID]

$: t_{1} \quad t_{2} \quad \ldots t_{i} \ldots t_{N}$
$: \mathrm{M}_{1} \mathrm{M}_{2} \ldots \mathrm{M}_{\mathrm{i}} \ldots \mathrm{M}_{\mathrm{N}}$
$\left[\begin{array}{llllll}: n x_{1} & \mathrm{nx}_{2} & \ldots & \mathrm{nx}_{\mathrm{i}} \ldots \mathrm{nx}_{\mathrm{N}}\end{array}\right]$
$\left[: \mathrm{ny}_{1} \mathrm{ny}_{2} \ldots \mathrm{ny}_{\mathrm{i}} \ldots \mathrm{ny}_{\mathrm{N}}\right]$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| SLABID Word  <br> $\mathrm{t}_{\mathrm{i}}$ Real slab geometry identifier <br> list of <br> slab thicknesses <br> $\mathrm{M}_{\mathrm{i}}$ MNAME units: cm <br> list of   <br> material names   | reflector GNAME |  |  |  |
| meshing options |  | 1 |  |  |
| $\mathrm{nx}_{\mathrm{i}}$ | Int | list of <br> number of x -divisions <br> list of <br> number of y -divisions | 1 |  |
| $\mathrm{ny}_{\mathrm{i}}$ | Int | nn |  |  |

## Examples:

```
%a reflector definition
% 2. 22 cm of baffle
% 15 cm of moderat or
geom Ref I ect or Node: REFL 17. 22
    sl ab 2. 22 15: BAFFLE. 1 MOD. 1
```

## Comments:

The slab card may be used to define three things: (1) the materials and thicknesses of a reflector initiated on a geometry card, (2) slabs in a control blade, and (3) spacer grids. If the first argument identifier is not present, then the first purpose of describing the various material thicknesses in a reflector is assumed. The meshing options allow each material slab to be spatially refined in $x$ and $y$, increasing the number of cells in the transport problem. The meshing option for the number of x divisions creates the equivalent of additional "sub-slabs" in each user-defined slab thickness. The y-divisions create additional cells vertically. The default of one y-division corresponds to the entire assembly.

## See also:

```
geometry<REFL>
```

### 3.2.4 Materials

A material contains two main types of information: (1) the composition, or distribution of nuclides, and (2) the properties which include basic (required) properties like density and temperature, and as well as (optional) properties like soluble poison content, void, or grid spacer smearing. The composition is defined by a composition card. The basic specification for a material is shown below.
mat MNAME : CNAME [dens=Real] [temp=Real] [: properties]

| argument | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| MNAME <br> MCLASS.MSUB | Word.Int | material name | used to reference <br> this material |  |
| CNAME | Word | composition <br> name <br> dens | Real | temperature |

A material name has two parts, the material class, or MCLASS, and a member identifier, or MSUB. For example, FUEL. 2 has an MCLASS=FUEL and an MSUB=2. All properties are defined by MCLASS. The composition referenced by CNAME is created with a composition card, as shown below.
comp CNAME: CTYPE arguments

| argument | type | Name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| CNAME | Word | composition name | used to reference this <br> composition later in materials <br> and property definitions |  |
|  |  |  |  |  |
| CTYPE | - | composition type |  |  |
|  | General Composition Constructors |  |  |  |
|  | NUM | number fraction |  |  |
|  | WT | weight fraction |  |  |
|  | FORM | Formula |  |  |
|  | CONC | Concentrations |  |  |
|  | Reactor Composition Constructors |  |  |  |
|  | LW | borated light water |  |  |
|  | UOX | uranium oxide fuel |  |  |
|  | - | remaining arguments | depends on CTYPE |  |
| arguments |  |  |  |  |

Additional properties are defined with the property card, which defines the property PNAME for a material class MCLASS. The property type, PTYPE, determines the remaining arguments.

## prop PNAME MCLASS : PTYPE arguments

| argument | type | name | details |  | default |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| PNAME | Word | property name | used | to | reference | this |

|  |  | property |  |
| :--- | :--- | :--- | :--- |
| PTYPE | PTYPE <br> SOLP | property type <br> soluble poison | used to define soluble boron <br> content |
| arguments | - | remaining arguments | depends on PTYPE |

### 3.2.4.1 material - material

> mat MNAME : CNAME [dens=Real] [temp=Real] $$
\left[: \mathrm{p}_{1}=\operatorname{val}_{1} \mathrm{p}_{2}=\mathrm{val}_{2} \ldots \mathrm{p}_{\mathrm{i}}=\operatorname{val}_{\mathrm{i}} \ldots \mathrm{p}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}\right]
$$

| argument | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| MNAME | Word.Int | material name | uses form |  |
| CNAME | Word | composition name | MCLASS.MSUB |  |
| dens | Real | density | basic property <br> units: $\mathrm{g} / \mathrm{cm}^{3}$ | composition <br> reference density |
| temp | Real | temperature | basic property <br> units: K | 293 |

## Examples:

```
% define a gas gap material
nat GAP. 1 : FI LLGAS
% define a 3.5% enriched fuel material
comp uox_e350 : UOX 3.5
mat FUEL.1 1 : uox_e350 dens=10.257 temp=900
% define a cl addi ng material
mat CLAD. 1 : Zl RC4
% define a gui de tube naterial
mat TUBE. 1 : SS304
% define a control rod material
mat CNTL. 1 : Al C
```

## Comments:

Material properties may be set on either a material card or on a state card. If a temperature is specified rather than a density, the "temp=" key must be used to skip over the density argument.

## See also:

state, composition, property

### 3.2.4.2 composition<NUM|WT> - general atom/wt fraction

```
comp CNAME : NUM|WT
```

```
    [norm=Bool]
    [refdens=Real]
```

| param | type | name | details | default |
| :---: | :---: | :---: | :---: | :---: |
| CNAME | Word | composition name |  |  |
| CTYPE | NUM | number fraction |  |  |
|  | WT | weight fraction |  |  |
| scale | PCT/ABS/PPM | scaling factor | all values are divided by this factor | PCT |
|  |  |  | PCT: percentage (divide by 100) |  |
|  |  |  | PPM: parts per million (divide by 1e6) |  |
|  |  |  | ABS: absolute (divide by 1 ) |  |
| norm <br> refdens | Bool | normalize | normalize values to 1 | false |
|  | Real | reference density | default density for materials using this composition | * |
|  |  |  | composition <br> units: $\mathrm{g} / \mathrm{cm}^{3}$ |  |
| $\mathrm{id}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}}$ | Word\|Int=Real | id/value pairs | value $<0$ fills the remainder up to value see acceptable id forms below |  |

*The density property must be defined for each material either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

## Examples:

```
% create a pl utoni umvect or and then pl ut oni um oxi de
comp puvec : WT scal e=PCT
    Pu238=1.2
    Pu239=63. 3
    Pu240=21.0
    Pu241=8. }
    Pu242=5. 9
comp puox : FORM puvec=1 O=2
% create an 85/ 10/5 Ag/l n/ Cd composition
% usi ng 10% I n, 5% Cd,
% and filling the remmi nder up to 100% wi th Ag
comp ai c : WT I n=10 Cd=5 Ag= 100
```

## Comments:

IDs in weight or number fraction-based compositions may be any of the following:

- nuclide IDs (Int), e.g., 92235,
- nuclide names (Word), e.g., U235 or u235,
- element Z numbers (Int), e.g., 92,
- element names (Word), e.g., U or u , or
- other composition names (CNAME).

## See also:

## composition<FORM>

### 3.2.4.3 composition<FORM>- general chemical formula

```
comp CNAME : FORM
    [refdens=Real]
```

| param | Type | name | details | default |
| :---: | :---: | :---: | :---: | :---: |
| CNAME | Word | composition name |  |  |
| CTYPE | FORM | formula |  |  |
| refdens | Real | reference density | default density for materials using this composition units: $\mathrm{g} / \mathrm{cm}^{3}$ | * |
| $\mathrm{id}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}}$ | Word\|Int=Real | id/value pairs | see acceptable id forms below values in atoms per molecule (e.g., $\mathrm{H}_{2} \mathrm{O}$ is given as " $\mathrm{H} "=2$ " $\mathrm{O} "=1$ ) |  |

*The density property must be defined for each material either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

## Examples:

```
% define Gd2O3 using el ement names
% (using el ements implies natural abundances used in isotopics)
comp gd2o3 : FORM Gd=2 O=3
% defi ne Gd2O3 usi ng 100% Gd 155
comp gd2o3 : FORM Gd155=2 O=3
% defi ne D2O using nuclide I Ds and el ement names
comp d2o : FORM 1002=2 8000=3
comp d2o : FORM H2=2 O=3
```

## Comments:

IDs in formula-based composition may be any of the following:

- nuclide IDs (Int), e.g., 92235,
- nuclide names (Word), e.g., U235 or u235,
- element Z numbers (Int), e.g., 92,
- element names (Word), e.g., U or u, or
- other composition names (CNAME).

## See also: <br> composition<NUM|WT>, composition<CONC>

### 3.2.4.4 composition<CONC>- general number density

> comp CNAME : CONC [refdens=Real] $$
\mathrm{id}_{1}=\operatorname{val}_{1} \mathrm{id}_{2}=\operatorname{val}_{2} \ldots \mathrm{id}_{\mathrm{i}}=\operatorname{val}_{\mathrm{i}} \ldots \mathrm{id}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}
$$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| CNAME | Word | composition <br> name |  |  |
| CTYPE CONC  <br> refdens Real reference density | default density for materials using this composition <br> units: $\mathrm{g} / \mathrm{cm}^{3}$ | $* *$ |  |  |
| $\mathrm{id}_{\mathrm{i}}=$ val $_{\mathrm{i}}$ | Int=Real | id/value pairs | see acceptable id forms below <br> note: cannot use other CNAMEs for IDs in CONC <br> input <br> units: \#/barn-cm |  |

${ }^{* *}$ A reference density is automatically calculated from concentrations input. If specified, it will simply scale up concentrations linearly.

## Examples:

```
% pyrex compositi on
comp pyrex el25 : CONC
        50}10=9.63266E-04
        5011=3. 90172E-03
        8016=4. 67761E-02
    14028=1. 81980E-02
    14029=9. 24474E-04
    14030=6. 10133E- 04
%fuel composition
comp uox e310 gd180 : CONC
    92234=3. 18096E-06
    92235=3. 90500E-04
    92236=1. 79300E-06
    92238=2. 10299E-02
    64152=3. 35960E-06
    64154=3. 66190E-05
    64155=2. 48606E-04
    64156=3. 43849E-04
    64157=2. 62884E-04
    64158=4. 17255E-04
    64160=3. 67198E-04
        8016=4. 53705E-02
% wet annul ar burnabl e absorber (WABA) composition
comp waba : CONC
    5010=2. 98553E-03
    5011=1. 21192E-02
    6000=3.77001E-03
    8016=5. 85563E-02
    13027=3. 90223E-02
```

## Comments:

IDs in concentration-based composition may be any of the following:

- nuclide IDs (Int), e.g., 92235,
- nuclide names (Word), e.g., U235 or u235,
- element Z numbers (Int), e.g., 92, and
- element names (Word), e.g., U or u.

Other composition names (CNAME) cannot be used in a concentration definition. To easily ensure consistency of input when comparing codes, the composition input should be used in the concentrations described here. In all other cases, the other composition constructors are recommended because they are much simpler and easier to use.

## See also:

composition<FORM>, composition<NUM|WT>

### 3.2.4.5 composition<LW>-borated light water

comp CNAME : LW [borppm=Real] [refdens=Real]

| param | Type | name | details | default |
| :---: | :---: | :---: | :---: | :---: |
| CNAME | Word | composition name |  |  |
| CTYPE | LW | light water |  |  |
| borppm | Real | boron | parts per million by weight of natural boron ( B ) in light water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ | * |
| refdens | Real | reference density | default density for materials using this composition units: $\mathrm{g} / \mathrm{cm}^{3}$ | 0.0 |

*The density property must be defined for each material either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

## Examples:

```
% define a 600ppm boron moder ator compositi on
comp nod_600ppm: LW 600
% same composition using FORM and WT
comp nod : FORM H=2 O=1
comp nod_600ppm: WT scal e=PPM nor m\not=yes
    mod=1e6 B=600
```

## Comments:

Internally, the borated light water composition is built from composition<FORM> and composition<WT> cards assuming natural boron. To use different boron isotopics such as depleted or enriched boron, the more general composition cards should be used.

## See also:

composition<FORM>, composition<WT>

### 3.2.4.6 composition<UOX>- $\mathbf{U O}_{2}$ fuel

comp CNAME : UOX enr=Real [bu=Real] [refdens=Real]

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |

| enr | Real | enrichment | U-235 wt. \% <br> (see composition<ENRU> for formula) <br> only available for 0 <br> units: GWu $\mathrm{GW} / \mathrm{MTU}$ <br> default density for materials using this composition <br> units: $\mathrm{g} / \mathrm{cm}^{3}$ | $0^{* *}$ |
| refdens | Real | reference density | burnup | Real |

*Generally, the burnup parameter should not be specified. It is provided for testing purposes only to create a fixed, representative, burned fuel composition. The composition is interpolated using linear interpolation from an internal burnup- and enrichment-dependent data matrix.
**The density property must be defined for each material either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

## Examples:

```
% define a 4.95% enriched fuel composition with a reference density
comp uox_495 : UOX 4.95 ref dens=10. 25
% same resul t as above
comp u_495 : ENRU 4. }9
comp uox_495 : FORM u_495=1 O=2
```

## Comments:

Internally, the $\mathrm{UO}_{2}$ composition is built from composition<FORM> and composition<ENRU> cards.

## See also:

composition<ENRU>, composition<FORM>

### 3.2.4.7 composition<ENRU>- enriched uranium

## comp CNAME : ENRU enr=Real [refdens=Real]

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| CNAME | Word | composition name |  | - |
| CTYPE | UOX | uranium dioxide |  | - |
| enr | Real | enrichment | *U-235 wt. \% |  |
| refdens | Real | reference density | default density for materials using this composition <br> units: $\mathrm{g} / \mathrm{cm}^{3}$ | $* *$ |

*The following formula from [3] is used to determine the ${ }^{234} \mathrm{U}$ and ${ }^{236} \mathrm{U}$ wt $\%$ from the ${ }^{235} \mathrm{U}$ enrichment. Note that this formula is only valid for U-235 enrichments less than $10 \mathrm{wt} \%$.
$\mathrm{w}_{\mathrm{u} 234}=0.007731 *(\mathrm{enr})^{1.0837}$
$\mathrm{w}_{\mathrm{u} 236}=0.0046 * \mathrm{enr}$
$\mathrm{w}_{\mathrm{u} 238}=100-\mathrm{w}_{\mathrm{u} 234}-\mathrm{enr}-\mathrm{w}_{\mathrm{u} 236}$
**The density property must be defined for each material either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

## Examples:

```
% 5% enri ched met al fuel
comp umet al : ENRU 5
```

## Comments:

This composition for enriched uranium is used internally to create $\mathrm{UO}_{2}$ using the composition<UOX> card.

## See also:

## composition<UOX>

### 3.2.4.8 composition library (pre-defined)

The Polaris composition library contains predefined compositions that may be used without a constructor by simply referencing the CNAME below. Each predefined library composition has a reference density, so it can be used directly on a material card.

Standard molecular compositions

| CNAME | Description |
| :--- | :--- |
| H2O | light water |
| B4C | Boron carbide burnable poison material |
| ER2O3 | Erbium oxide burnable poison material |
| GD2O3 | Gadolinium oxide burnable poison material |
| FILLGAS | Helium gas |
| $\quad$ Standard reactor mixtures and alloys |  |
| CNAME | Description |
| AIC | Ag-In-Cd control rod absorber material |
| PYREX | Pyrex glass |
| ZIRC2 | Zircaloy-2 clad material |
| ZIRC4 | Zircaloy-4 clad material |
| SS304 | Stainless Steel 304 |
| SS316 | Stainless Steel 316 |
| INC718 | Inconel 718 |
| WATER | Light water with trace amount of boron |

### 3.2.4.9 property<SOLP>-soluble poison by weight

## prop PNAME M1 ... : SOLP poison [scale= $\underline{P P M|P C T| A B S] ~}$

| param | Type | name | details | default |
| :---: | :---: | :---: | :---: | :---: |
| PNAME | Word | property name | property value $\mathrm{p} \geq 0$ |  |
| M1 ... | MCLASS | material class | one or more material classes to gain this property |  |
| PTYPE | SOLP | soluble poison |  |  |
| poison | CNAME | soluble poison composition name |  |  |
| scale | PCT/ABS/PPM | scaling factor | all values are divided by this factor PCT: percentage (divide by 100) PPM: parts per million (divide by 1e6) ABS: absolute (divide by 1) | PPM |

## Examples:

```
%define a sol ubl e bor on property for moderat or
% and cool ant material classes
%using natural boron
prop boron MDD COOL: SOLP B
% i nvestigate cool ant crud/i mpurity activation
% 1. define a general impurity property to mix in coolant,
    comp crud : NUM Ni=12.7 Cr=2.3 Fe= 100 %mostl y Fe
    prop i mpurity COOL : SOLP crud
% 2. create cool ant naterial with 100ppm of crud
    mat COOL. 1 : LW dens=0.75 : i mpurit y=100
% 3. make sure to "depl ete" cool ant so crud gets activated
    depl ete COOL=true
```

## Comments:

None

## See also:

pinmap, control, insert

### 3.2.4.10 deplete - material depletion and decay

```
deplete }\mp@subsup{\textrm{M}}{1}{}=\mathrm{ Bool M}\mp@subsup{\textrm{M}}{2}{}=\mathrm{ Bool ... M M }\mp@subsup{\textrm{M}}{\textrm{i}}{2}=\mathrm{ Bool ... M M
```

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{M}_{\mathrm{i}}$ | MNAME\|MCLASS | list of | use ALL for all materials |  |
|  |  | material |  |  |
|  |  | names or |  |  |
|  |  | material |  |  |
|  |  | classes |  |  |

NOTE: Only one deplete card is allowed in an input.
NOTE: ALL only applies in the first position
Examples:
\%turn on depl etion/ decay for two new materials sys PWR
depl ete MyMaterial =t rue My her Material =true
\% activate/ depl et e/ decay every material depl et e ALL=true
\%impose strict conditions
sys PWR
depl et e ALL=f al se FUEL=t rue CLAD=t rue

## Comments:

The deplete card not only instructs Polaris to deplete a material, but also to solve the Bateman equations with ORIGEN for that material. Thus if the flux/power is zero, only materials that are flagged to "deplete" will undergo decay. The deplete card modifies the depletables included in a system card to avoid the situation in which "deplete MyMaterial=true" would make only MyMaterial depletable. Thus to completely re-specify the depletable materials, "ALL=false" should be used as the first argument. This is in contrast to the basis card, which completely specifies a new power basis.

## See also:

material, shield, basis

### 3.2.4.11 basis - power basis materials

basis $\mathrm{M}_{1}=$ Bool $\mathrm{M}_{2}=$ Bool $\ldots \mathrm{M}_{\mathrm{i}}=$ Bool $\ldots \mathrm{M}_{\mathrm{N}}=$ Bool

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{M}_{\mathrm{i}}$ | $\mathrm{MNAME} \mid \mathrm{MCLASS}$ | list of | use ALL for all materials | ALL |
|  |  | material names or |  |  |
|  |  | material classes |  |  |

NOTE: Only one basis card is allowed per input.
NOTE: ALL is only allowed in the first position.

## Examples:

\% use only FUEL materials as the basis
basis ALL=no FUEL=YES
\% Specify FUEL. 3 as the basis
basis ALL=no FUEL. $3=Y E S$

## Comments:

The basis card is used to specify the materials to use in power normalization. By default, the energy release from all materials is taken into account, including (n,gamma) reactions in structural materials such as cladding. It is not recommended to change the default of ALL in most situations. Exceptions include (1) when comparing results to other codes that only use fuel in the basis and (2) fixing the power in a specific pin is known-a material should be created only for that pin, and the power basis should be specified for that material only. The basis card overrides any power basis imposed by a system card. Thus it behaves differently than a deplete card, which is combined with depletable materials imposed by a system card.

## See also:

material, shield, deplete

### 3.2.4.12 shield - cross section self-shielding expansion specification

shield $\mathrm{M}_{1}=$ XTYPE $\mathrm{M}_{2}=$ XTYPE $\ldots \mathrm{M}_{\mathrm{i}}=$ XTYPE $\ldots \mathrm{M}_{\mathrm{N}}=$ XTYPE

NOTE: Only one shield card is allowed per input.
NOTE: An equivalent shield is automatically introduced for each deplete card.
NOTE: ALL is only allowed in the first position.

## Examples:

\%reate a uni que self-shi el ded FUEL cross sections in each pin
\%onsider all other materials to have a single self-shiel ded cross section
shi el d ALL=N FUEL=P
\%ssess effect of self-shi el ding each pi n's cl adding
shi el d CLAD=P
\%e-specify self-shi el ding to be $P$ by default, $R$ for the FUEL
shi el d ALL=P FUEL=R

## Comments:

The shield card controls how materials are internally expanded for self-shielding purposes. By default, Polaris expands all materials across pins and rings (R). For example, a fuel region defined on a pin card as having 10 rings will be expanded internally to have 10 different self-shielded cross sections. Because the R option also implicitly includes the P option, each instance of that pin will also get different cross sections.

The depletion effect is the major concern when deciding whether to modify the shielding treatment, so the deplete card automatically introduces a consistent modification of the shielding.

When using specific systems (e.g., system $P W R$ ), this card is generally not needed. The shield card modifies the self-shielding options included in a system card. Thus, to completely re-specify the expansion, use "ALL=N" as the first argument. This is in contrast to the basis card, which completely specifies a new power basis.

## See also:

material, deplete, system

### 3.2.5 State

The idea of a "state" or "statepoint" is a standard concept in lattice physics calculations. In Polaris, the concept of state is mostly tied to the values of material properties. The base state for a calculation is determined as follows:

1. The base state is initialized with any property values set on material cards.
2. The base state is updated with any state cards that apply to ALL.
3. The base state is updated with any other state cards, and the power card is used to set the base state power.
This sequence ensures that the state does not change, even if the order of inputs changes. A time or burnup card is then used to initiate a calculation as a function of time or burnup, thus producing a sequence of states. A branch block is used to perform branches off the base state at specific times or burnups.

### 3.2.5.1 state<MNAME>-material state

## state MNAME|MCLASS:

$\mathrm{p}_{1}=\mathrm{val}_{1} \quad \mathrm{p}_{2}=\mathrm{val}_{2} \ldots \mathrm{p}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}} \ldots \mathrm{p}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| MNAME\|MCLASS | - | material name or | use ALL for all materials |  |
|  |  | material class |  |  |
| $\mathrm{p}_{\mathrm{i}}$ | PNAME | property name |  |  |
| val $_{\mathrm{i}}$ | Value | property value |  |  |

## Examples:

```
%reset to hot zero power conditions
state ALL : temp=565
state COOL : dens=0.75
% set channel / bypass materials to different ppm boron
state COOL : boron=0
state BYP \vdots boron=600
%set all materials with a boron property
state ALL : boron=300
```

## Comments:

The state card declares the base state for materials and the base state of possible control elements or insert elements. State changes may be specified in relative or absolute terms. If a relative change with "rel=true" is given, the change is applied to the reference state. The reference state is the state after evaluating material cards but before evaluating state. The formulas applied calculate the new property, $\mathrm{P}_{\text {new }}$, from values supplied on the state card. The reference state value, $\mathrm{P}_{\text {ref }}$, given incr and scale, are shown below.

| incr | scale | formula for new property value |
| :--- | :--- | :--- |
| false | ABS | $\mathrm{P}_{\text {new }}=$ val |
| false | PCT | $\mathrm{P}_{\text {new }}=(\mathrm{val} / 100) * \mathrm{P}_{\text {ref }}$ |
| true | ABS | $\mathrm{P}_{\text {new }}=\mathrm{val}+\mathrm{P}_{\text {ref }}$ |
| true | PCT | $\mathrm{P}_{\text {new }}=(\mathrm{val} / 100+1) * \mathrm{P}_{\text {ref }}$ |

## See also:

material, deplete, system

### 3.2.5.2 state<INAME>-insert/control state

```
state INAME : in=Bool
```

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| INAME | - | insert name or |  |  |
|  |  | control element name <br> in | Bool | insertion |

## Examples:

\%insert bank D control rods
state BankD: i n=true
\% renove inserts named Ins6A
state Ins6A false
\% performreflect or cal cul at i on
state Reflector Node : i $n=t r u e$

## Comments:

This form of the state card is required to insert any control element or inserts. By default, inserts and control elements are out when defined.

## See also:

material, deplete, system

### 3.2.5.3 state<GNAME>- geometry state

## state GNAME : pres=Bool

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| GNAME | - | geometry name |  |  |
| pres | Bool | present | "pres=" is required |  |

## Examples:

\% di sable reflector calculation even though
\%reflector geometry is present
state Reflector Node : presf al se

## Comments:

The geometry version of the state card is used to declare which geometric elements are present in the system. The geometry version of the add card is useful for performing branch calculations for reflector nodes. Note that an assembly geometry must be present to perform a calculation.

## See also:

geometry<REFL>, state<MNAME>, state<INAME>

### 3.2.5.4 power - total power

## Examples:

```
% set power to 35 W gl HM
power 35.0
% provi de a power hi story
% must have same number of val ues as foll owing time/ burnup card
power : 35.0 40.0 45.0 45.0 40.0 5.0 0.0
time : 10 10 20 30 40 50 60 70
```

## Comments:

The power card specifies the total power of the basis materials specified by a basis card. The power value may be specified only once.

See also:
t, bu, history, basis, state<MNAME>

### 3.2.5.5 bu - initiate calculation with cumulative burnups

```
bu [ [b, b
    [: units=GWD/MTIHM|MWD/MTIHM]
```

| param | Type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{b}_{\mathrm{i}}$ | Real | list of <br> absolute burnups | 0 |  |
| units | GWD/MTIHM\| <br> MWD/MTIHM | burnup units | GWD/MTIHM |  |

## Examples:

```
% si mple depl etion case wi th constant power and absol ute/cumul ati ve burnups
power 40
bu 0 5 10 15 20 30 40 50 60 80
% usi ng MWd/ MTI HM units wi th variabl e power
% 40 W gl HM for 0->5000 MND/ MTI HM then 30 W gl HM for 5000->10000 MND/ MTI HM
power 40 30
bu 0 5000 10000 MMD/ MTI HM
```

```
% combi ne burn/time cards
```

% combi ne burn/time cards
% 20 W gl HM for 0->5 then 5->10 GWD/ MTI HM steps, t hen
% 20 W gl HM for 0->5 then 5->10 GWD/ MTI HM steps, t hen
%40 W gl HM for a 5-day step then 30 W gl HM for a 5-day step
%40 W gl HM for a 5-day step then 30 W gl HM for a 5-day step
power 20
power 20
bu
bu
lower 40 30 l

```
lower 40 30 l
```

## Comments:

The bu card initiates a calculation for a given sequence of cumulative burnups. A burnup or time card usually follows a power card, the two effectively specifying the power history. If multiple burnups are given, then the power card must have either a single power or a list of powers the same size as the list times. A value of 0 is implicit at the beginning of the first burnup list. Multiple burnup/time cards may be specified in an input. This can be convenient for switching units or changing from burnup-based to timebased depletion. Internal automatic substeps are always in effect unless modified with the option<DEPL> card.

## See also:

## t, dt, dbu, power, option<DEPL>, branch, deplete

### 3.2.5.6 dbu - initiate calculation with incremental burnups

dbu $\left[\begin{array}{llll}\left.\mathrm{b}_{1} \mathrm{~b}_{2} \ldots \mathrm{~b}_{\mathrm{i}} \ldots \mathrm{b}_{\mathrm{N}}\right] \\ {[: \text { units }=\text { GWD/MTIHM } \mid M W D / M T I H M]}\end{array}\right.$

| param | Type | name | details |
| :--- | :--- | :--- | :--- |
| $\mathrm{b}_{\mathrm{i}}$ | Real | default |  |
| units | GWD/MTIHM <br> incremental burnups <br> MWD/MTIHM | burnup units | 0 |
|  | MWD/MTIHM |  |  |

## Examples:

```
% incremental burnups equi val ent to
% power 40
% bu 0 5 10 15 20 30 40 50 60 80
power 40
dbu 5 5 5 5 10 10 10 10 20
```

## Comments:

The dbu card initiates a calculation for a given sequence of incremental burnups. Otherwise, it is identical to the bu card for specifying cumulative burnups.

## See also:

t, dt, bu, power, option<DEPL>, branch, deplete

### 3.2.5.7 $\quad t$ - initiate calculation by cumulative time

$\mathbf{t}\left[\begin{array}{llll}\mathrm{t}_{1} \mathrm{t}_{2} & \ldots \mathrm{t}_{\mathrm{i}} \ldots \mathrm{t}_{\mathrm{N}}\end{array}\right]$
[: units=SECONDS|MINUTES|HOURS|DAYS|YEARS]

| param | Type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{t}_{\mathrm{i}}$ | Real | list of | 0 | 0 |
| units | SECONDS\|MINUTES| | times | time units |  |

## Examples:

```
% burn wi th 40 W gl HM for 300 days in 100-day i ncrements
power 40
t 100 200 300
% simul ate 2 cycl es of time-dependent irradi ati on with shut down cool ing
% note that time def aults to DAYs
%
%cycl e 1
\begin{tabular}{lrrr} 
power & 40 & 30 & 30 \\
t & 100 & 200 & 300 \\
\hline
\end{tabular}
power 0
t 415
%
%cycl e 2
\begin{tabular}{lrrr} 
power & 30 & 20 & 20 \\
\(t\) & 515 & 615 & 715 \\
t & 815
\end{tabular}
power 0
```

## Comments:

The $\mathbf{t}$ card initiates a calculation for a given sequence of cumulative/absolute times. One of the time cards ( $\mathbf{t}, \mathbf{d t}$, or $\mathbf{t i}$ ) is required to model periods of decay in conjunction with power 0 . Otherwise, the time card $\mathbf{t}$ is similar in functionality to the burnup bu card but with different units.

## See also:

dt, bu, dbu, power, option<DEPL>, branch, deplete

### 3.2.5.8 $\quad \mathrm{dt}$ - initiate calculation by incremental time

$\mathbf{t}\left[\mathrm{t}_{1} \mathrm{t}_{2} \ldots \mathrm{t}_{\mathrm{i}} \ldots \mathrm{t}_{\mathrm{N}}\right]$
$[:$ units $=$ SECONDS|MINUTES|HOURS|

| param | Type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{t}_{\mathrm{i}}$ | Real | list of <br> units | SECONDS $\mid$ MINUTES $\mid$ | time units |

## Examples:

\% burn with 40 W gl HM for 300 days in 100-day increments equi val ent to \% power 40
\% t 100200300
power 40
dt 100100100
\% decay for 30 minutes
power 0
dt 30 M NUTES

## Comments:

The dt card is identical to the cumulative time card $\mathbf{t}$ except that the values given are incremental.
See also:
t, bu, dbu, power, option<DEPL>, branch, deplete

### 3.2.5.9 branch - instantaneous change

```
read branch [BNAME]
    add ...
    [add ...]
end branch
```

| param | type | Name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| BNAME | Word | branch name |  | DEFAULT |
| allowed cards in branch block |  |  |  |  |
| Add | - | - | adds a list of states to branch on |  |

## Examples:

\%fuel tenperature and boron branches (results in 7 total states) read branch
add FUEL : t enp $=80010001200$
add COOL : boron=0 4008001400
end branch
\% branch to different
\% fuel tenp/ cool ant temp/cool ant density, synchronizing
\%states (results in 3 total states)
read branch
\% state $1 \quad 2 \quad 3$
add FUEL : tenp=800 10001200
COOL: t enp $=565585620$
COOL: dens $=0.730 .710 .68$
end branch

## Comments:

The branch card initiates so-called "branch" calculations, i.e., instantaneous changes of state at specific burnups/times during the base depletion sequence of calculations. The syntax for the add card is identical to the state card except, instead of taking a list of different properties and their values, it takes a single property and a list of values. Note that a time or burnup card is not necessary-if not found, branches will be performed at every burnup/time specified in the base state. The initial state for any branch card is the base state as specified in the main file. This means branch cards have no knowledge of one another.

## See also:

add, bu, t, title

### 3.2.5.10 add<MNAME>- material branch

```
add MNAME|MCLASS
    [incr=Bool]
    [scale=ABS |PCT] :
    PNAME=val l val 2 ... vali
    [MNAME[MCLASS
    ...]
```

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| MNAME\|MCLASS | - | material name or <br> material class | use ALL for all materials |  |
| incr | Bool | increment | values are added to reference value | false |
| scale | $A B S \mid P C T$ | Scaling | scaling | ABS |
| PNAME | - | property name <br> list of | PCT: percentage units |  |
| val $_{\mathrm{i}}$ | Value |  |  |  |

## Examples:

```
%fuel temperat ure branches using i ncrement al
% changes fromthe base state of 900 K
state FUEL : temp=900
read branch
    add FUEL i ncr =t rue : t emp= 200-100 +100 +200 +500
end branch
% material properties mmy be varied together (synchronized)
% by chai ni ng additional material/ properties together
%the first block below results in 2 states
%the second is 6 states
read branch
    add FUEL : temp=900 1200
    FUEL : dens=10.4 10.3
    COOL: dens=0.7 0.65
end branch
read branch
    add FUEL : tenp=900 1200
    add FUEL : dens=10.4 10.3
    add COOL : dens=0.7 0.65
end branch
```

## Comments:

The add card is only valid inside a branch block. This version adds a set of branches for a specific material name (MNAME) or class (MCLASS). Branches are always with respect to the base state. Although similar to the state card, the add card has a single property name and a list of values. The state card has a list of property=value pairs.

## See also:

material, state<MNAME>

### 3.2.5.11 add<INAME> - insert/control branch

## add INAME : in= $\mathrm{Bool}_{1}\left[\mathrm{Bool}_{2}\right]$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| INAME | - | insert name or |  |  |
|  |  | control element name |  |  |
| in | Bool | list of insertion states | "in=" is required |  |

## Examples:

```
%branch to renove WABA inserts
state I nsWABA4 : in=true
read branch
    add InsWABA4: i nर्fal se
end branch
%synchronize rods in with material branches (5 states)
read branch
    add BankD : i n=true fal se fal se fal se true
        FUEL : t emp=600 900 1200 2000 2000
end branch
% swap control banks
read branch
    add BankB: i n=true fal se fal se
        BankC: infal se true fal se
        BankD : in=f al se fal se true
end branch
```

## Comments:

This form of the add card is required to add branches to insert/remove control elements or inserts. Given that only two possible states exist, specifying "true false" will result in a calculation at the other state not specified by the base state.

## See also:

insert, control, state<INAME>

### 3.2.5.12 add<GNAME> - geometry branch

add GNAME : pres= $=\mathrm{Bool}_{1}\left[\mathrm{Bool}_{2}\right]$

| param | type | name | details | default |
| :--- | :--- | :--- | :--- | :--- |
| GNAME | - | geometry name |  |  |
| pres | Bool | list of geometry states | "pres=" is required |  |

## Examples:

```
%performa reflector cal cul ation on a branch
state Reflector Node : pres=no
read branch
    add Ref I ectorNode : pres=yes
end branch
```

## Comments:

This form of the add card is required to add branches for new geometry, such as reflector calculations. Given that only two possible states exist, specifying "true false" will result in a calculation at the other state not specified by the base state.

See also:
geometry, state<GNAME>

### 3.2.6 Options

An extensive set of options is provided for manipulating the solvers and output. Most option cards support a key=value style of input, with reasonable defaults in place for all parameters.

### 3.2.6.1 option<KEFF> - eigenvalue

| key | value <br> type | details | default |
| :--- | :--- | :--- | :--- |
| NumAzim | Int | number of azimuthal angles per octant | 20 |
| NumPolar | Int | number of polar angles per octant | 3 |
| PnOrder | Int | scattering order | 2 |
| RaySpacing | Real | spacing between MoC rays | 0.04 cm |

developer options (generally should not change)

| PolarScheme | String | polar quadrature <br> "TY": Tabuchi-Yamamoto quadrature <br> "DECART": DeCART quadrature <br> "LO": Leonard optimal quadrature <br> "CACTUS": Cactus quadrature | "TY" |
| :---: | :---: | :---: | :---: |
| EigSolver | String | eigenvalue solver type <br> "CMFD" (single-assembly default) <br> "POWER" (reflector default) |  |
| UpscatterSolver | String | upscatter solver type <br> "GAUSS_SEIDEL", (default if EigSolver="CMFD") <br> "BICGSTAB" (default if EigSolver="POWER") <br> "GMRES" |  |
| DownscatterSolver, UpscatterInnerSolver | String | ```within-group solver type "SOURCE", (default if EigSolver="CMFD") "BICGSTAB" (default if EigSolver="POWER") "GMRES"``` |  |
| EigMaxIterations | Int | maximum number of eigenvalue iterations | 1000 |

|  |  | "DECART": DeCART quadrature |
|  |  | "LO": Leonard optimal quadrature |
| "CACTUS": Cactus quadrature |  |  |$\quad$| "DECART" |
| :--- |

## Examples:

\% change the solver nethod to source iteration opt ESSM

Sol ver =" SOURCE"

### 3.2.6.3 option<BOND>-Bondarenko search

opt $B O N D\left[\operatorname{key}_{1}=\right.$ val $\left._{1} \operatorname{key}_{2}=\operatorname{val}_{2} \ldots \operatorname{key}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}} \ldots \mathrm{key}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}\right]$

| key | value <br> type | details | default |
| :--- | :--- | :--- | :--- |
| MaxIterations | Int | number of Bondarenko iterations (0 is disabled) | $0^{*}$ |
| ConvergenceXS | String | cross section used in Bondarenko convergence <br> iterations | "SIGA"** |
|  |  | "SIGA": absorption |  |
|  |  | "SIGT": total |  |

developer options (generally should not change)

| IterationCriteria | Real | $1 \mathrm{e}-3$ |
| :--- | :--- | :--- |
| TempSearchMaxIterations | Int | 20 |
| TempSearchCriteria | Real | $1 \mathrm{e}-8$ |
| TempSearchEqualTolerance | Real | $1 \mathrm{e}-3$ |
| TempSearchMaxPower | Real | 35.0 |
| SigOSearchMaxIterations | Int | 20 |
| SigOSearchCriteria | Real | $1 \mathrm{e}-8$ |
| SigOSearchEqualTolerance | Real | $1 \mathrm{e}-3$ |
| SigOSearchMaxPower | Real | 35.0 |

* By setting the Bondarenko iterations $>0$, resonance interference effects may be taken into account. The default MaxIterations=0 effectively disables the Bondarenko resonance interference model.
**In SCALE, the transport cross section ("SIGT") has historically been used in Bondarenko iterations.

## Examples:

\%introduce Bondarenko iterations on total cross section
opt BOND
Maxl ter at i ons=10
Conver genceXS=" SI GT"

### 3.2.6.4 option<DEPL> - depletion

opt DEPL $\left[\mathrm{key}_{1}=\mathrm{val}_{1} \operatorname{key}_{2}=\operatorname{val}_{2} \ldots \mathrm{key}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}} \ldots \mathrm{key}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}\right]$

| key | value type | details | default |
| :---: | :---: | :---: | :---: |
| TrackingSet | String | set of nuclides tracked in depletion calculations <br> "None": set of nuclides present in user input <br> "Complete": complete set of all nuclides available on ORIGEN data libraries | "Complete" |
| Solver | String | "MATREX": legacy ORIGEN solution method <br> "CRAM": Chebyshev Rational Approximation Method | "MATREX" |
| Method | String | "PREDICTOR" <br> "PREDICTOR_CORRECTOR" | "PREDICTOR_CORRECTOR" |
| StepRefinement | Int | divide the user input steps by this factor>0, i.e., refinement of 2 divides all steps by 2 (NOT ENABLED) | 1 |
| NumSubsteps | Int | Number of internal substeps for depletion calculations | 4 |
| DepleteMode | String | "BOSS" or "MOSS." The depletion power renormalization is done at the beginning of each substep (BOSS) or the middle of each substep (MOSS) | "BOSS" |

## Examples:

```
% Set the number of origen substeps per time steps to 2
% (nmy be usef ul for convergence studies)
opt DEPL
    NunSubst eps=2
% di sabl e the addition of depl etion nuclides to input materials
opt DEPL Tr acki ngSet =' NONE"
% use CRAM sol ver
opt DEPL Sol ver =' CRAM'
```

### 3.2.6.5 option<CRITSPEC>- critical spectrum

opt ${\text { CRITSPEC }\left[\mathrm{key}_{1}=\mathrm{val}_{1} \quad \mathrm{key}_{2}=\mathrm{val}_{2} \ldots \mathrm{key}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}} \ldots \mathrm{key}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}\right]}_{]}$

| key | value type | details | default |
| :--- | :--- | :--- | :--- |
| Mode | String | critical spectrum mode <br> "SEARCH": search for critical mode (k-eff=1) <br> "SPECIFIED": provide B2 below | "SEARCH" |
| B2 | Real | "NONE": do not use critical spectrum <br> value of critical buckling if Mode="SPECIFIED" <br> units: $\mathrm{cm}^{-2}$ | 0.0 |
| Method | String | critical spectrum system <br> "B1": solve the $\mathrm{B}_{1}$ equations <br> "P1": solve the $\mathrm{P}_{1}$ equations | "P1" |
|  |  |  |  |

## Examples:

\% enable eritical buckling search using B1 equations for a buckling of le-3 opt CRI TSPEC

Mbde=" SPECI FI ED"
B2=1e- 3
Met hod="B1"

### 3.2.6.6 option<PRINT>-printing

opt PRINT $\left[\mathrm{key}_{1}=\mathrm{val}_{1} \operatorname{key}_{2}=\mathrm{val}_{2} \ldots \mathrm{key}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}} \ldots \mathrm{key}_{\mathrm{N}}=\mathrm{val}_{\mathrm{N}}\right]$

| key | value type | details | default |
| :--- | :--- | :--- | :--- |
| XSSummary | Bool | print a cross section summary in the output file |  |
| CritSpecSummary | String | true |  |
|  |  | "NONE": no print out <br> "BUCKLING": limited buckling info | "BUCKLING" |
| XFile16 | "SPECTRUM": full spectrum |  |  |
| InputDataContainer | Bool | output a TRITON xfile016 nodal data library <br> print out the input data container | false |

## Examples:

\% print the xfile016
\%if input file is polaris.inp, file name will be polaris.x16
opt PRINT XFilel6=true

### 3.2.6.7 option<FG>-few-group cross section generation

opt $F G$
[AdjointMode=String InvVelMode=String]
$\left.\begin{array}{lcccc}{[:} & b_{1} & b_{2} & \ldots & b_{i} \\ {\left[: E_{1} E_{2} \ldots E_{i} \ldots E_{N-1}\right]} & & & b_{N} & \end{array}\right]$

| param | type | details | default |
| :---: | :---: | :---: | :---: |
| AdjointMode | String | type of adjoint calculation to use in few-group data generation <br> "INFMED": infinite medium adjoint <br> "CRITICAL": critical spectrum adjoint <br> "UNIFORM": uniform adjoint | "INFMED" |
| InvVelMode | String | weighting option for few-group inverse velocities <br> "FORWARD": forward flux weighting <br> "ADJOINT": adjoint flux weighting | "FORWARD" |
| $\mathrm{b}_{\text {i }}$ | Real | list of burnups to include in output few-group cross section database, e.g., XFile16 output units: GWd/MTHM | all burnups available |
| $\mathrm{E}_{\mathrm{i}}$ | Real | note descending order and only $\mathrm{N}-1$ divisions are needed for an N group structure <br> $\mathrm{E}_{0}$ is maximum energy (typically 2 e 7 eV ) <br> $\mathrm{E}_{\mathrm{N}}$ is minimum (typically $1 \mathrm{e}-5 \mathrm{eV}$ ) <br> units: eV | 0.625 eV division (two groups) |

## Examples:

\% enable the critical spectrum adjoint opt FG Adj oi nt Mbde=' CRI TI CAL"
\%nl y i ncl ude 0,10,15, 20 GWd/ MTHM bur nups in few gr oup out puts, incl udi ng XFile16 opt FG: 0101520
\% edefine group energy di visions for 3 groups with di visions at 10 and 0.625 eV opt FG: : 100.625

### 3.2.6.8 option<RUN>- run time

opt $R U N\left[\operatorname{key}_{1}=\operatorname{val}_{1} \operatorname{key}_{2}=\operatorname{val}_{2} \ldots \operatorname{key}_{\mathrm{i}}=\mathrm{val}_{\mathrm{i}} \ldots \operatorname{key}_{\mathrm{N}}=\operatorname{val}_{\mathrm{N}}\right]$

| key | value type | details | default |
| :--- | :--- | :--- | :--- |
| CheckOnly | Bool | check input and terminate | true |

## Examples:

\% check i nput
opt RUN CheckOnl y=t rue

### 3.2.7 System

The system cards provide a way to initialize a set of defaults to simplify input and add robustness for a well-known and well-characterized system.

## system STYPE

| argument | Type | name | details default |
| :--- | :--- | :--- | :--- |
| STYPE | - | system type |  |
|  | $P W R$ | pressurized water reactor |  |
|  | $B W R$ | boiling water reactor |  |
|  |  |  |  |

The system card performs the following actions:

1. defines a set of materials and properties, imposing standard names for the materials and properties;
2. warns user of potential mistakes; and
3. uses heuristics to modify unspecified mesh and solver options for robust results.

### 3.2.7.1 system<PWR>- pressurized water reactor

| shield | material self-shielding | shi el d CNTL=R | ALL $=\mathrm{N}$ | FUEL=R | $B P=R$ |

## Description

Nine reactor materials are initialized with compositions and densities from the predefined composition set. In most cases, all that remains is to define fuel materials, all material temperatures, and properties such as COOL/MOD soluble boron and density. Note that some rules are based on naming conventions. For example, burnable poisons (the material class BP) are declared to be depletable materials, whereas the CNTL (control elements) class of materials is not.

### 3.2.8 Sample Problems

Within the SCALE distribution, 27 Polaris sample problems are provided to demonstrate the differences in calculation and geometry options, and 21 sample problems consider the Consortium for Advanced Simulation of Light Water Reactors (CASL) Virtual Environment for Reactor Applications (VERA) benchmark problems for pin cell and lattice configurations described in [4]. The VERA pin cell problems are identified as polaris_1a_252g.inp through polaris_1e_252g.inp. The VERA lattice problems are identified as polaris_2a_252g.inp through polaris_2k_252g.inp, polaris_2l_56g.inp through polaris_2m_56g.inp, polaris_2o_252g.inp, and polaris_2p_252g.inp.

The remaining six sample problems are described as follows:

- polaris_TMI1_Cycle1-2.inp - $15 \times 15$ PWR geometry model with branch block definition for lattice physics calculations
- polaris_bench_taka3_sf97-4_assm.inp, polaris_bench_taka3_sf97-4_pin.inp - Takahama UOX depletion benchmark for radiochemical assay NT3G24-SF97-4 described in [5].
- polaris_bwr10x10.inp, polaris_bwr7 $\times 7 . \mathrm{inp}$ - example BWR geometry models for $10 \times 10$ and $7 \times 7$ fuel.
- polaris_dv1a.inp - simple PWR pin cell depletion calculation.

### 4.0 RADIATION SHIELDING

Introduction by D. E. Peplow and B. T. Rearden

The Monaco with Automated Variance Reduction using Importance Calculations (MAVRIC) fixedsource radiation transport sequence is designed to apply the multigroup and continuous energy fixedsource Monte Carlo code Monaco to solve problems too challenging for standard, unbiased Monte Carlo methods. ${ }^{1}$ The intention of the sequence is to calculate fluxes and dose rates with low uncertainties in reasonable times even for deep penetration problems. MAVRIC is based on the Consistent Adjoint Driven Importance Sampling (CADIS) methodology, which uses an importance map and biased source that are derived to work together. MAVRIC generates problem-dependent cross section data and then automatically performs a coarse mesh 3D discrete ordinates transport calculation using Denovo to determine the adjoint flux as a function of position and energy. MAVRIC then applies the information to optimize the shielding calculation in Monaco. In the Forward-Weighted CADIS (FW-CADIS) methodology, an additional Denovo calculation is performed to further optimize the Monaco model to obtain uniform uncertainties for multiple tally locations. Sources can be input using many spatial and energy distributions, or they can be imported from a previously generated mesh file. Responses can be generated from cross section reaction rates, flux-to-dose conversion factors, or user-defined functions; responses are tallied on geometry regions, Cartesian or cylindrical grids, or as point detectors.

MAVRIC enables users to import spent fuel isotopics from ORIGEN binary concentrations files such as those generated with ORIGAMI and to import gamma emission spectral data directly from the ORIGEN nuclear data files to streamline analysis and reduce the opportunity for human error.

Several utility modules are also provided for data introspection and conversion.

# 4.1 MAVRIC: MONACO WITH AUTOMATED VARIANCE REDUCTION USING IMPORTANCE CALCULATIONS 

D. E. Peplow and C. Celik

#### Abstract

The MAVRIC sequence (Monaco with Automated Variance Reduction using Importance Calculations) will perform radiation transport on problems that are too challenging for standard, unbiased Monte Carlo methods. The intention of the sequence is to calculate fluxes and dose rates with low uncertainties in reasonable times even for deep penetration problems. MAVRIC is based on the CADIS (Consistent Adjoint Driven Importance Sampling) and FW-CADIS (Forward-Weighted CADIS) methodologies, which use an importance map and biased source that are derived to work together. MAVRIC uses XSProc to generate cross sections for the materials input by the users. Using these multigroup cross sections and a user-specified spatial mesh, MAVRIC performs a three-dimensional, discrete-ordinates calculation using Denovo to determine the adjoint flux as a function of position and energy. This adjoint flux information is then used by MAVRIC to construct a space and energy-dependent importance map (i.e., weight windows) to be used for biasing during particle transport and a mesh-based biased source distribution. MAVRIC then passes the importance map and biased source distribution to the functional module Monaco, a threedimensional, fixed-source, multigroup, and continuous-energy Monte Carlo radiation transport code. In addition to materials input, the user will also supply the geometry description using the SCALE General Geometry Package; source description as a function of position, energy, and direction; tally descriptions (fluxes in which regions, at what point detectors, or over what mesh grids); response functions (function of energy); planes for the mesh used by Denovo; and which tally or tallies to use as the Denovo adjoint source. Output consists of tables detailing the region and point detector fluxes (and their responses), as well as files for mesh tallies.

### 4.1.1 Introduction

Monte Carlo particle transport calculations for deep penetration problems can require very long run times in order to achieve an acceptable level of statistical uncertainty in the final answers. Discrete-ordinates codes can be faster but have limitations relative to the discretization of space, energy, and direction. Monte Carlo calculations can be modified (biased) to produce results with the same variance in less time if an approximate answer or some other additional information is already known about the problem. If an importance can be assigned to different particles based on how much they will contribute to the final answer, more time can be spent on important particles with less time devoted to unimportant particles. One of the best ways to bias a Monte Carlo code for a particular tally is to form an importance map from the adjoint flux based on that tally. Unfortunately, determining the exact adjoint flux could be just as difficult as computing the original problem itself. However, an approximate adjoint can still be very useful in biasing the Monte Carlo solution. ${ }^{1}$ Discrete ordinates can be used to quickly compute that approximate adjoint. Together, Monte Carlo and discrete ordinates can be used to find solutions to thick shielding problems in reasonable times.

The MAVRIC (Monaco with Automated Variance Reduction using Importance Calculations) sequence is based on the CADIS (Consistent Adjoint Driven Importance Sampling) and FW-CADIS (ForwardWeighted CADIS) methodologies. ${ }^{2,3,4,7}$ MAVRIC automatically performs a three-dimensional, discreteordinates calculation using Denovo ${ }^{5}$ to compute the adjoint flux as a function of position and energy. This adjoint flux information is then used to construct an importance map (i.e., target weights for weight windows) and a biased source distribution that work together-particles are born with a weight matching the target weight of the cell into which they are born. The fixed-source Monte Carlo radiation transport Monaco ${ }^{6}$ then uses the importance map for biasing during particle transport and the biased source distribution as its source. During transport, the particle weight is compared with the importance map after each particle interaction and whenever a particle crosses into a new importance cell in the map.

For problems that do not require variance reduction to complete in a reasonable time, execution of MAVRIC without the importance map calculation provides an easy way to run Monaco. For problems that do require variance reduction to complete in a reasonable time, MAVRIC removes the burden of setting weight windows from the user and performs it automatically with a minimal amount of additional input. Note that the MAVRIC sequence can be used with the final Monaco calculation as either a multigroup (MG) or a continuous-energy (CE) calculation.

Monaco has a wide variety of tally options: it can calculate fluxes (by group) at a point in space, over any geometrical region, or for a user-defined, three-dimensional, rectangular grid. These tallies can also integrate the fluxes with either standard response functions from the cross section library or user-defined response functions. All of these tallies are available in the MAVRIC sequence.

While originally designed for CADIS, the MAVRIC sequence is also capable of creating importance maps using both forward and adjoint deterministic estimates. The FW-CADIS method ${ }^{7}$ can be used for optimizing several tallies at once, a mesh tally over a large region, or a mesh tally over the entire problem. Several other methods for producing importance maps are also available in MAVRIC and are explored in Appendix C.

### 4.1.2 CADIS Methodology

MAVRIC is an implementation of CADIS (Consistent Adjoint Driven Importance Sampling) using the Denovo $\mathrm{S}_{\mathrm{N}}$ and Monaco Monte Carlo functional modules. Source biasing and a mesh-based importance map, overlaying the physical geometry, are the basic methods of variance reduction. In order to make the best use of an importance map, the map must be made consistent with the source biasing. If the source
biasing is inconsistent with the weight windows that will be used during the transport process, source particles will undergo Russian roulette or splitting immediately, wasting computational time and negating the intent of the biasing.

### 4.1.2.1 Overview of CADIS

CADIS has been well described ${ }^{1-4}$ in the literature, so only a brief overview is given here. Consider a class source-detector problem described by a unit source with emission probability distribution function $q(\vec{r}, E)$ and a detector response function $\sigma_{d}(\vec{r}, E)$. To determine the total detector response, $R$, the forward scalar flux $\phi(\vec{r}, E)$ must be known. The response is found by integrating the product of the detector response function and the flux over the detector volume $V_{d}$.

$$
\begin{equation*}
R=\int_{V_{d}} \int_{E} \sigma_{d}(\vec{r}, E) \phi(\vec{r}, E) d E d V . \tag{4.1.1}
\end{equation*}
$$

Alternatively, if the adjoint scalar flux, $\phi^{+}(\vec{r}, E)$, is known from the corresponding adjoint problem with adjoint source $q^{+}(\vec{r}, E)=\sigma_{d}(\vec{r}, E)$, then the total detector response could be found by integrating the product of the forward source and the adjoint flux over the source volume, $V_{s}$.

$$
\begin{equation*}
R=\int_{V_{s}} \int_{E} q(\vec{r}, E) \phi^{+}(\vec{r}, E) d E d V \tag{4.1.2}
\end{equation*}
$$

Unfortunately, the exact adjoint flux may be just as difficult to determine as the forward flux, but an approximation of the adjoint flux can still be used to form an importance map and a biased source distribution for use in the forward Monte Carlo calculation.

Wagner ${ }^{1}$ showed that if an estimate of the adjoint scalar flux for the corresponding adjoint problem could be found, then an estimate of the response $R$ could be made using Eq. (4.1.2). The adjoint source for the adjoint problem is typically separable and corresponds to the detector response and spatial area of tally to be optimized: $q^{+}(\vec{r}, E)=\sigma_{d}(E) g(\vec{r})$, where $\sigma_{d}(E)$ is a flux-to-dose conversion factor and $g(\vec{r})$ is 1 in the tally volume and 0 otherwise. Then, from the adjoint flux $\phi^{+}(\vec{r}, E)$ and response estimate $R$, a biased source distribution, $\widehat{q}(\vec{r}, E)$, for source sampling of the form

$$
\begin{equation*}
\hat{q}(\vec{r}, E)=\frac{1}{R} q(\vec{r}, E) \phi^{+}(\vec{r}, E) \tag{4.1.3}
\end{equation*}
$$

and weight window target values, $\bar{w}(\vec{r}, E)$, for particle transport of the form

$$
\begin{equation*}
\bar{w}(\vec{r}, E)=\frac{R}{\phi^{+}(\vec{r}, E)} \tag{4.1.4}
\end{equation*}
$$

could be constructed, which minimize the variance in the forward Monte Carlo calculation of $R$.
When a particle is sampled from the biased source distribution $\hat{q}(\vec{r}, E)$, to preserve a fair game, its initial weight is set to

$$
\begin{equation*}
w_{0}(\vec{r}, E)=\frac{q(\vec{r}, E)}{\widehat{q}(\vec{r}, E)}=\frac{R}{\phi^{+}(\vec{r}, E)}, \tag{4.1.5}
\end{equation*}
$$

which exactly matches the target weight for that particle's position and energy. This is the "consistent" part of CADIS-source particles are born with a weight matching the weight window of the region/energy they are born into. The source biasing and the weight windows work together.

CADIS has been applied to many problems-including reactor ex-core detectors, well-logging instruments, cask shielding studies, and independent spent fuel storage facility models-and has demonstrated very significant speed-ups in calculation time compared to analog simulations.

### 4.1.2.2 Multiple sources with CADIS

For a typical Monte Carlo calculation with multiple sources (each with a probability distribution function $q_{i}(\vec{r}, E)$ and a strength $S_{i}$, giving a total source strength of $S=\sum S_{i}$ ), the source is sampled in two steps. First, the specific source $i$ is sampled with probability $p(i)=S_{i} / S$, and then the particle is sampled from the specific source distribution $q_{i}(\vec{r}, E)$.

The source sampling can be biased at both levels: which source to sample from and how to sample each source. For example, the specific source can be sampled using some arbitrary distribution, $\hat{p}(i)$, and then the individual sources can be sampled using distributions $\hat{q}_{i}(\vec{r}, E)$. Particles would then have a birth weight of

$$
\begin{equation*}
w_{0} \equiv(p(i) / \hat{p}(i))\left(q_{i}(\vec{r}, E) / \hat{q}_{i}(\vec{r}, E)\right) . \tag{4.1.6}
\end{equation*}
$$

For CADIS, a biased multiple source needs to be developed so that the birth weights of sampled particles still match the target weights of the importance map. For a problem with multiple sources (each with a distribution $q_{i}(\vec{r}, E)$ and a strength $\left.S_{i}\right)$, the goal of the Monte Carlo calculation is to compute some response $R$ for a response function $\sigma_{d}(\vec{r}, E)$ at a given detector.

$$
\begin{equation*}
R=\int_{V} \int_{E} \sigma_{d}(\vec{r}, E) \phi(\vec{r}, E) d E d V . \tag{4.1.7}
\end{equation*}
$$

Note that the flux $\phi(\vec{r}, E)$ has contributions from each source. The response, $R_{i}$, from each specific source ( $S_{i}$ with $q_{i}(\vec{r}, E)$ ) can be expressed using just the flux from that source, $\phi_{i}(\vec{r}, E)$, as

$$
\begin{equation*}
R_{i}=\int_{V} \int_{E} \sigma_{d}(\vec{r}, E) \phi_{i}(\vec{r}, E) d E d V . \tag{4.1.8}
\end{equation*}
$$

The total response is then found as $R=\sum_{i} R_{i}$.
For the adjoint problem, using the adjoint source of $q^{+}(\vec{r}, E)=\sigma_{d}(\vec{r}, E)$, the response $R$ can also be calculated as

$$
\begin{equation*}
R=\int_{V} \int_{E}\left[\sum_{i} S_{i} q_{i}(\vec{r}, E)\right] \phi^{+}(\vec{r}, E) d E d V \tag{4.1.9}
\end{equation*}
$$

with response contribution from each specific source being

$$
\begin{equation*}
R_{i}=\int_{V} \int_{E} S_{i} q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E) d E d V \tag{4.1.10}
\end{equation*}
$$

The target weights $\bar{w}(\vec{r}, E)$ of the importance map are found using

$$
\begin{equation*}
\bar{w}(\vec{r}, E)=R / S / \phi^{+}(\vec{r}, E) \tag{4.1.11}
\end{equation*}
$$

Each biased source $\hat{q}_{i}(\vec{r}, E)$ pdf is found using

$$
\begin{equation*}
\hat{q}_{i}(\vec{r}, E)=\frac{S_{i}}{R_{i}} q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E), \tag{4.1.12}
\end{equation*}
$$

and the biased distribution used to select an individual source is $\hat{p}(i)=R_{i} / \sum R_{i}=R_{i} / R$.
When using the biased distribution used to select an individual source, $\hat{p}(i)$, and the biased source distribution, $\hat{q}_{i}(\vec{r}, E)$, the birth weight of the sampled particle will be

$$
\begin{align*}
w_{0} & \equiv(p(i) / \hat{p}(i))\left(q_{i}(\vec{r}, E) / \hat{q}_{i}(\vec{r}, E)\right) \\
& =\binom{\left.\frac{S_{i}}{S} / \frac{R_{i}}{R}\right)\left(\begin{array}{c}
q_{i}(\vec{r}, E)
\end{array} / \frac{S_{i}}{R_{i}} q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E)\right.}{R / S / \phi^{+}(\vec{r}, E)}  \tag{4.1.13}\\
& =0
\end{align*}
$$

which matches the target weight, $\bar{w}(\vec{r}, E)$.

### 4.1.2.3 Multiple tallies with CADIS

The CADIS methodology works quite well for classic source/detector problems. The statistical uncertainty of the tally that serves as the adjoint source is greatly reduced since the Monte Carlo transport is optimized to spend more simulation time on those particles that contribute to the tally, at the expense of tracking particles in other parts of phase space. However, more recently, Monte Carlo has been applied to problems where multiple tallies need to all be found with low statistical uncertainties. The extension of this idea is the mesh tally-where each voxel is a tally where the user desires low statistical uncertainties. For these problems, the user must accept a total simulation time that is controlled by the tally with the slowest convergence and simulation results where the tallies have a wide range of relative uncertainties.

The obvious way around this problem is to create a separate problem for each tally and use CADIS to optimize each. Each simulation can then be run until the tally reaches the level of acceptable uncertainty. For more than a few tallies, this approach becomes complicated and time-consuming for the user. For large mesh tallies, this approach is not reasonable.

Another approach to treat several tallies, if they are in close proximity to each other, or a mesh tally covering a small portion of the physical problem is to use the CADIS methodology with the adjoint source near the middle of the tallies to be optimized. Since particles in the forward Monte Carlo simulation are optimized to reach the location of the adjoint source, all the tallies surrounding that adjoint source should converge quickly. The drawback to this approach is the difficult question of "how close." If the tallies are too far apart, certain energies or regions that are needed for one tally may be of low importance for getting particles to the central adjoint source. This may under-predict the flux or dose at the tally sites far from the adjoint source.

MAVRIC has the capability to have multiple adjoint sources with this problem in mind. For several tallies that are far from each other, multiple adjoint sources could be used. In the forward Monte Carlo, particles would be drawn to one of those adjoint sources. The difficulty with this approach is that typically the tally that is closest to the true physical source converges faster than the other tallies-showing the closest adjoint source seems to attract more particles than the others. Assigning more strength to the adjoint source further from the true physical source helps, but finding the correct strengths so that all of the tallies converge to the same relative uncertainty in one simulation is an iterative process for the user.

### 4.1.2.4 Forward-weighted CADIS

In order to converge several tallies to the same relative uncertainty in one simulation, the adjoint source corresponding to each of those tallies needs to be weighted inversely by the expected tally value. In order to calculate the dose rate at two points-say one near a reactor and one far from a reactor-in one simulation, then the total adjoint source used to develop the weight windows and biased source needs to have two parts. The adjoint source far from the reactor needs to have more strength than the adjoint source near the reactor by a factor equal to the ratio of the expected near dose rate to the expected far dose rate.

This concept can be extended to mesh tallies as well. Instead of using a uniform adjoint source strength over the entire mesh tally volume, each voxel of the adjoint source should be weighted inversely by the expected forward tally value for that voxel. Areas of low flux or low dose rate would have more adjoint source strength than areas of high flux or high dose rate.

An estimate of the expected tally results can be found by using a quick discrete-ordinates calculation. This leads to an extension of the CADIS method: forward-weighted CADIS (FW-CADIS). ${ }^{7}$ First, a forward $\mathrm{S}_{\mathrm{N}}$ calculation is performed to estimate the expected tally results. A total adjoint source is constructed where the adjoint source corresponding to each tally is weighted inversely by those forward tally estimates. Then the standard CADIS approach is used-an importance map (target weight windows) and a biased source are made using the adjoint flux computed from the adjoint $\mathrm{S}_{\mathrm{N}}$ calculation.

For example, if the goal is to calculate a detector response function $\sigma_{d}(E)$ (such as dose rate using flux-to-dose-rate conversion factors) over a volume (defined by $g(\vec{r})$ ) corresponding to mesh tally, then instead of simply using $q^{+}(\vec{r}, E)=\sigma_{d}(E) g(\vec{r})$, the adjoint source would be

$$
\begin{equation*}
q^{+}(\vec{r}, E)=\frac{\sigma_{d}(E) g(\vec{r})}{\int \sigma_{d}(E) \phi(\vec{r}, E) d E}, \tag{4.1.14}
\end{equation*}
$$

where $\phi(\vec{r}, E)$ is an estimate of the forward flux and the energy integral is over the voxel at $\vec{r}$. The adjoint source is nonzero only where the mesh tally is defined $(g(\vec{r}))$, and its strength is inversely proportional to the forward estimate of dose rate.

The relative uncertainty of a tally is controlled by two components: first, the number of tracks contributing to the tally and, second, the shape of the distribution of scores contributing to that tally. In the Monte Carlo game, the number of simulated particles, $m(\vec{r}, E)$, can be related to the true physical particle density, $n(\vec{r}, E)$, by the average Monte Carlo weight of scoring particles, $\bar{w}(\vec{r}, E)$, by

$$
\begin{equation*}
n(\vec{r}, E)=\bar{w}(\vec{r}, E) m(\vec{r}, E) \tag{4.1.15}
\end{equation*}
$$

In a typical Monte Carlo calculation, tallies are made by adding some score, multiplied by the current particle weight, to an accumulator. To calculate a similar quantity related to the Monte Carlo particle density would be very close to calculating any other quantity but without including the particle weight. The goal of FW-CADIS is to make the Monte Carlo particle density, $m(\vec{r}, E)$, uniform over the tally areas, so an importance map needs to be developed that represents the importance to achieving uniform Monte Carlo particle density. By attempting to keep the Monte Carlo particle density more uniform, more uniform relative errors for the tallies should be realized.

Two options for forward weighting are possible. For tallies over some area where the entire group-wise flux is needed with low relative uncertainties, the adjoint source should be weighted inversely by the forward flux, $\phi(\vec{r}, E)$. The other option, for a tally where only an energy-integrated quantity is desired, is to weight the adjoint inversely by that energy-integrated quantity, $\int \sigma_{d}(E) \phi(\vec{r}, E) d E$. For a tally where the total flux is desired, then the response in the adjoint source is simply $\sigma_{d}(E)=1$.

To optimize the forward Monte Carlo simulation for the calculation of some quantity at multiple tally locations or across a mesh tally, the adjoint source needs to be weighted by the estimate of that quantity. For a tally defined by its spatial location $g(\vec{r})$ and its optional response $\sigma_{d}(E)$, the standard adjoint source would be $q^{+}(\vec{r}, E)=\sigma_{d}(E) g(\vec{r})$. The forward-weighted adjoint source, $q^{+}(\vec{r}, E)$, depending on what quantity is to be optimized, is listed below.

| For the calculation of | Adjoint source |
| :--- | :---: |
| Energy and spatially dependent flux | $\phi(\vec{r}, E)$ |
| Spatially dependent total flux | $g(\vec{r})$ <br> $\phi(\vec{r}, E)$ |
| Spatially dependent total response | $\int \sigma_{d}(E) \phi(\vec{r}, E) d E$ |
| $\phi(\vec{r}, E) d E$ | $\frac{g(\vec{r})}{\int \sigma_{d}(E) \phi(\vec{r}, E) d E}$ |

The bottom line of FW-CADIS is that in order to calculate a quantity at multiple tally locations (or across a mesh tally) with more uniform relative uncertainties, an adjoint source needs to be developed for an objective function that keeps some non-physical quantity-related to the Monte Carlo particle density and similar in form to the desired quantity-constant. FW-CADIS uses the solution of a forward discreteordinates calculation to properly weight the adjoint source. After that, the standard CADIS approach is used.

### 4.1.2.5 MAVRIC implementation of CADIS

With MAVRIC, as with other shielding codes, the user defines the problem as a set of physical modelsthe material compositions, the geometry, the source, and the detectors (locations and response functions)-as well as some mathematical parameters on how to solve the problem (number of histories, etc.). For the variance reduction portion of MAVRIC, the only additional inputs required are (1) the mesh planes to use in the discrete-ordinates calculation(s) and (2) the adjoint source description-basically the location and the response of each tally to optimize in the forward Monte Carlo calculation. MAVRIC takes this information and constructs a Denovo adjoint problem. (The adjoint source is weighted by a Denovo forward flux or response estimate for FW-CADIS applications.) MAVRIC then uses the CADIS methodology: it combines the adjoint flux from the Denovo calculation with the source description and creates the importance map (weight window targets) and the mesh-based biased source. Monaco is then run using the CADIS biased source distribution and the weight window targets.

### 4.1.2.5.1 Denovo

Denovo is a parallel three-dimensional $\mathrm{S}_{\mathrm{N}}$ code that is used to generate adjoint (and, for FW-CADIS, forward) scalar fluxes for the CADIS methods in MAVRIC. For use in MAVRIC/CADIS, it is highly desirable that the $\mathrm{S}_{\mathrm{N}}$ code be fast, positive, and robust. The phase-space shape of the forward and adjoint fluxes, as opposed to a highly accurate solution, is the most important quality for Monte Carlo weightwindow generation. Accordingly, Denovo provides a step-characteristics spatial differencing option that produces positive scalar fluxes as long as the source (volume plus in-scatter) is positive. Denovo uses an orthogonal, nonuniform mesh that is ideal for CADIS applications because of the speed and robustness of calculations on this mesh type.

Denovo uses the highly robust GMRES (Generalized Minimum Residual) Krylov method to solve the $\mathrm{S}_{\mathrm{N}}$ equations in each group. GMRES has been shown to be more robust and efficient than traditional source (fixed-point) iteration. ${ }^{8}$ The in-group discrete $\mathrm{S}_{\mathrm{N}}$ equations are defined as

$$
\begin{equation*}
\boldsymbol{L} \psi=\boldsymbol{M} \boldsymbol{S} \phi+q \tag{4.1.16}
\end{equation*}
$$

where $\boldsymbol{L}$ is the differential transport operator, $\boldsymbol{M}$ is the moment-to-discrete operator, $\boldsymbol{S}$ is the matrix of scattering cross-section moments, $q$ is the external and in-scatter source, $\phi$ is the vector of angular flux moments, and $\psi$ is the vector of angular fluxes at discrete angles. Applying the operator $\boldsymbol{D}$, where $\phi=\boldsymbol{D} \psi$, and rearranging terms casts the in-group equations in the form of a traditional linear system, $\boldsymbol{A x}=b$,

$$
\begin{equation*}
\left(\boldsymbol{I}-D L^{-1} M S\right)=D L^{-1} q . \tag{4.1.17}
\end{equation*}
$$

The operation $\boldsymbol{L}^{-1} v$, where $v$ is an iteration vector, is performed using a traditional wave-front solve (transport sweep). The parallel implementation of the Denovo wave-front solver uses the well-known Koch-Baker-Alcouffe (KBA) algorithm, which is a two-dimensional block-spatial decomposition of a three-dimensional orthogonal mesh. ${ }^{9}$ The Trilinos package is used for the GMRES implementation. ${ }^{10}$ Denovo stores the mesh-based scalar fluxes in a double precision binary file (*.dff) called a Denovo flux file. Past versions of SCALE/Denovo used the TORT ${ }^{11}{ }^{*}$.varscl file format (DOORS package ${ }^{12}$ ), but this was limited to single precision. Since the rest of the MAVRIC sequence has not yet been parallelized, Denovo is currently used only in serial mode within MAVRIC.

### 4.1.2.5.2 Monaco

The forward Monte Carlo transport is performed using Monaco, a fixed-source, shielding code that uses the SCALE General Geometry Package (SGGP, the same as used by the criticality code KENO-VI) and the standard SCALE material information processor. Monaco can use either MG or CE cross section libraries. Monaco was originally based on the MORSE Monte Carlo code but has been extensively modified to modernize the coding, incorporate more flexibility in terms of sources/tallies, and read a userfriendly block/keyword style input.

Much of the input to MAVRIC is the same as Monaco. More details can be found in the Monaco chapter of the SCALE manual.

### 4.1.2.5.3 Running MAVRIC

The objective of a SCALE sequence is to execute several codes, passing the output from one to the input of the next, in order to perform some analysis-things that users typically had to do in the past. MAVRIC does this for difficult shielding problems by running approximate discrete-ordinates calculations, constructing an importance map and biased source for one or more tallies that the user wants to optimize in the Monte Carlo calculation, and then using those in a forward Monaco Monte Carlo calculation. MAVRIC also prepares the forward and adjoint cross sections when needed. The steps of a MAVRIC sequence are listed in Table 4.1.1. The user can instruct MAVRIC to run this whole sequence of steps or just some subset of the steps-in order to verify the intermediate steps or to reuse previously calculated quantities in a new analyses.

The MAVRIC sequence can be stopped after key points by using the "parm=parameter" operator on the "=mavric" command line, which is the first line of the input file. The various parameters are listed in Table 4.1.2. These parameters allow the user to perform checks and make changes to the importance map calculation before the actual Monte Carlo calculation in Monaco.

MAVRIC also allows the sequence to start at several different points. If an importance map and biased source have already been computed, they can be used directly. If the adjoint scalar fluxes are known, they can quickly be used to create the importance map and biased source and then begin the forward Monte Carlo. All of the different combinations of starting MAVRIC with some previously calculated quantities are listed in the following section detailing the input options.

When using MG cross-section libraries that do not have flux-to-dose-rate conversion factors, use "parm=nodose" to prevent the cross section processing codes from trying to move these values into the working library.

MAVRIC creates many files that use the base problem name from the output file. For an output file called "c:\path1\path2\outputName.out" or "/home/path1/path2/outputName.inp", spaces in the output name will cause trouble and should not be used.

Table 4.1.1. Steps in the MAVRIC sequence

| Cross section calculation | XSProc is used to calculate the forward cross sections for Monaco |
| :---: | :--- |
| Forward Denovo (optional) <br> Cross section calculation <br> Forward flux calculation | XSProc is used to calculate the forward cross sections for Denovo <br> Denovo calculates the estimate of the forward flux |
| Adjoint Denovo (optional) <br> Cross section calculation <br> Adjoint flux calculation | XSProc is used to calculate the adjoint cross sections for Denovo <br> Denovo calculates the estimate of the adjoint flux |
| CADIS (optional) | The scalar flux file from Denovo is then used to create the biased source <br> distribution and transport weight windows |
| Monte Carlo calculation | Monaco uses the biased source distribution and transport weight <br> windows to calculate the various tallies |

Table 4.1.2. Parameters for the MAVRIC command line ("parm=...")

| Parameter | MAVRIC will stop after |
| :--- | :--- |
| check | Input checking |
| forinp | Forward Denovo input construction (makes xkba_b.inp in the tmp area) |
| forward | The forward Denovo calculation |
| adjinp | Adjoint Denovo input construction (makes xkba_b.inp in the tmp area) |
| adjoint | The adjoint Denovo calculation |
| impmap | Calculation of importance map and biased source |

### 4.1.3 MAVRIC Input

The input file for MAVRIC consists of three lines of text ("=mavric" command line with optional parameters, the problem title, and SCALE cross section library name) and then several blocks, with each block starting with "read xxxx" and ending with "end xxxx". There are three required blocks and nine optional blocks. Material and geometry blocks must be listed first and in the specified order. Other blocks may be listed in any order.

Blocks (must be in this order):

- Composition - (required) SCALE standard composition, list of materials used in the problem
- Celldata - SCALE resonance self-shielding
- Geometry - (required) SCALE general geometry description
- Array - optional addition to the above geometry description
- Volume - optional calculation or listing of region volumes
- Plot - create 2D slices of the SGGP geometry

Other Blocks (any order, following the blocks listed above):

- Definitions - defines locations, response functions, and grid geometries used by other blocks
- Sources - (required) description of the particle source spatial, energy, and directional distributions
- Tallies - description of what to calculate: point detector tallies, region tallies, or mesh tallies
- Parameters - how to perform the simulation (random number seed, how many histories, etc.)
- Biasing - data for reducing the variance of the simulation
- ImportanceMap - instructions for creating an importance map based on a discrete-ordinates calculation

The material blocks (Composition and Celldata) and the physical model blocks (Geometry, Array, Volume, and Plot) follow the standard SCALE format. See the other SCALE references as noted in the following sections for details. The Biasing block and ImportanceMap block cannot both be used.

For the other six blocks, scalar variables are set by "keyword=value", fixed-length arrays are set with "keyword value ${ }_{1} \ldots$ value $_{\mathrm{N}}$ ", variable-length arrays are set with "keyword value ${ }_{1} \ldots$ value $_{\mathrm{N}}$ end", and some text and filenames are read in as quoted strings. Single keywords to set options are also used in some instances. The indention, comment lines, and upper/lowercase shown in this document are not requiredthey are used in the examples only for clarity. Except for strings in quotes (like filenames), SCALE is case insensitive.

After all input blocks are listed, a single line with "end data" should be listed. A final "end" should also be listed, to signify the end of all MAVRIC input. Nine of the blocks are the same input blocks used by the functional module Monaco, with a few extra keywords only for use with MAVRIC. These extra keywords are highlighted here, without relisting all of the standard Monaco keywords for those blocks. See Table 4.1.3 for an overview of MAVRIC input file structure.

### 4.1.3.1 Composition block

Material information input follows the standard SCALE format for material input. Basic materials known to the SCALE library may be used as well as completely user-defined materials (using isotopes with known cross sections). Input instructions are located in the XSProc chapter in the SCALE manual. The

Standard Composition Library chapter lists the different cross section libraries and the names of standard materials. An example is as follows:

```
read composition
    uo2 1 0.2 293.0 92234 0.0055 92235 3.5 92238 96.4945 end
    orconcrete 2 1.0 293.0 end
    ss304 3 1.0 293.0 end
end composition
```

Details on the cell data block are also included in the XSProc chapter. When using different libraries for the importance map production (listed at the top of the input) and the final Monte Carlo calculation (listed in the parameters block, if different), make sure that the materials are present in both libraries.

Table 4.1.3. Overall input format

| input file | Comment |
| :---: | :---: |
| =mavric | name of sequence |
| Some title for this problem | title |
| v7-27n19g | cross section library name |
| read composition | SCALE material compositions [required block] |
| end composition [requren |  |
| read celldata | SCALE resonance self-shielding [optional block] |
| end celldata [ |  |
| read geometry | SCALE SGGP geometry [required block] |
| end geometry |  |
| read array | SCALE SGGP arrays [optional block] |
| end array |  |
| read volume | SCALE SGGP volume calc [optional block] |
| end volume |  |
| read plot | SGGP Plots |
|  | [optional block] |
| end plot |  |
| read definitions | Definitions |
| end definitions |  |
| read sources | Sources definition [required block] |
| end sources |  |
| read tallies |  |
| end $\quad \cdots$ | [optional block] |
| end tallies |  |
| read parameters | Monte Carlo parameters [optional block] |
| end parameters |  |
| read biasing | Biasing information [optional block] |
| end biasing |  |
| read importanceMap | Importance map |
| . . . | [optional block] |
| end data | end of all blocks |
| end | end of MAVRIC input |

### 4.1.3.2 SGGP geometry blocks

MAVRIC uses the functional module Monaco for the forward Monte Carlo calculation. Monaco tracks particles through the physical geometry described by the SGGP input blocks as well as through the mesh importance map and any mesh tallies, which are defined in the global coordinates and overlay the
physical geometry. Because Monaco must track through all of these geometries at the same time, users should not use the reflective boundary capability in the SGGP geometry.

For more details on each SGGP Geometry block, see the following sections of the KENO-VI chapter of the SCALE Manual.

> Geometry - Geometry Data

Array - Array Data
Volume - Volume Data
Plot - Plot Data

### 4.1.3.3 Other blocks shared with Monaco

The definitions, sources, tallies, and biasing blocks are all the same as Monaco. They are all fully described in the Monaco chapter of the SCALE Manual.

Definitions - Definitions Block<br>Sources - Sources Block<br>Tallies - Tallies Block<br>Biasing - Biasing Block

In the parameters block, there are several extra keywords compared to Monaco (see the Parameter Block section of the Monaco chapter) which are used when the cross section library used in the importance calculations is different from the library used in the final forward Monaco Monte Carlo calculation. The library listed at the beginning of the MAVRIC input file will be used for the importance calculations (forward and adjoint Denovo calculation, formation of the importance map, and biased sources). To use a different MG library in the final Monaco simulation, use the keyword "library=" with the cross section library name in quotes. A cross section library for Monaco will be made using csas-mg. If there are any extra parameters to use ("parm=" in the "=csas-mg" line of the csas-mg input), they can be passed along using the keyword "parmString=" with the extra information in quotes. For example, the following input file would use a coarse-group library for the importance calculations and a fine-group library for the final Monaco, each with CENTRM processing.

```
=mavric parm=centrm
v7-27n19g
read parameters
    library="v7-200n47g" parmString="centrm"
end parameters
end data
end
```

To use a CE cross section in the final Monaco step, use the keyword "ceLibrary=" with the cross section library name in quotes. When using the "library=" or "ceLibrary=" keywords, they should precede the "neutron", "photon", "noNeutron", and "noPhoton" keywords. Table 4.1.4 summarizes all of the keywords in the MAVRIC parameter block.

When using two different cross section libraries, be sure that the responses and distributions are defined in ways that do not depend on the cross section library. For example, any response that is just a list of $n$ values (corresponding to a cross section library of $n$ groups) needs to have the group energies specifically listed so that it can be evaluated properly on the other group structure.

Table 4.1.4. Extra keywords for the parameters block

| block | keyword | type | length | default | required restrictions/comments |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| read parameters |  |  |  |  |  |  |
| All of the keywords listed in the Monaco manual still apply |  |  |  |  |  |  |
| Final Monaco Monte Carlo calculation is multi-group |  |  |  |  |  |  |
|  | String= | character character |  | not present not present | $\begin{aligned} & \text { no } \\ & \text { no } \end{aligned}$ | multi-group library for final Mona parm for MG cross section proc |
|  | Monaco rary= meters | calculation character | ontinuou | us energy not present |  | continuous energy library name |

### 4.1.3.4 Importance map block

The importance map block is the "heart and soul" of MAVRIC. This block lists the parameters for creating an importance map and biased source from one (adjoint) or two (forward, followed by adjoint) Denovo discrete-ordinates calculations. Without an importance map block, MAVRIC can be used to run Monaco and use its conventional types of variance reduction. If both the importance map and biasing blocks are specified, only the importance map block will be used. There are a variety of ways to use the importance map block, as explained in the subsections below. Keywords for this block are summarized at the end of this section, in Table 4.1.5.

### 4.1.3.4.1 Constructing a mesh for the $S_{N}$ calculation

All of the uses of the importance map block that run the discrete-ordinates code require the use of a grid geometry that overlays the physical geometry. Grid geometries are defined in the definitions block of the MAVRIC input. The extent and level of detail needed in a grid geometry are discussed in the following paragraphs.

When using $\mathrm{S}_{\mathrm{N}}$ methods alone for solving radiation transport in shielding problems, a good rule of thumb is to use mesh cell sizes on the order of a meanfree path of the particle. For complex shielding problems, this could lead to an extremely large number of mesh cells, especially when considering the size of the meanfree path of the lowest energy neutrons and photons in common shielding materials.

In MAVRIC, the goal is to use the $\mathrm{S}_{\mathrm{N}}$ calculation for a quick approximate solution. Accuracy is not paramount-just getting an idea of the overall shape of the true importance map will help accelerate the convergence of the forward Monte Carlo calculation. The more accurate the importance map, the better the forward Monte Carlo acceleration will be. At some point there is a time trade-off when the computational time for calculating the importance map followed by the Monte Carlo calculation exceeds that of a standard analog Monte Carlo calculation. Large numbers of mesh cells, coming from using very small mesh sizes, for $\mathrm{S}_{\mathrm{N}}$ calculations also use a great deal of computer memory.

Because the deterministic solution(s) for CADIS and FW-CADIS can have moderate fidelity and still provide variance reduction parameters that substantially accelerate the Monte Carlo solution, mesh cell sizes in MAVRIC applications can be larger than what most $\mathrm{S}_{\mathrm{N}}$ practioners would typically use. The use of relatively coarse mesh reduces memory requirements and the run time of the deterministic solution(s). Some general guidelines to keep in mind when creating a mesh for the importance map/biased source are:

- The true source regions should be included in the mesh with mesh planes at their boundaries.
- For point or very small sources, place them in the center of a mesh cell, not on the mesh planes.
- Any region of the geometry where particles could eventually contribute to the tallies (the "important" areas) should be included in the mesh.
- Point adjoint sources (corresponding to point detector locations) in standard CADIS calculations do not have to be included inside the mesh. For FW-CADIS, they must be in the mesh and should be located at a mesh cell center, not on any of the mesh planes.
- Volumetric adjoint sources should be included in the mesh with mesh planes at their boundaries.
- Mesh planes should be placed at significant material boundaries.
- Neighboring cell sizes should not be drastically different.
- Smaller cell sizes should be used where the adjoint flux is changing rapidly, for example, toward the surfaces of adjoint sources and shields (rather than their interiors).

Another aspect to keep in mind is that the source in the forward Monaco Monte Carlo calculation will be a biased, mesh-based source. Source particles will be selected by first sampling which mesh cell to use and then sampling a position uniformly within that mesh cell that meets the user criteria of "unit=", "region=", or "mixture=" if specified. The mesh should have enough resolution that the mesh source will be an accurate representation of the true source.

The geometry for the Denovo calculation is specified using the keyword "gridGeometryID=" and the identification number of a grid geometry that was defined in the definitions block. The material assigned to each voxel of the mesh is determined by testing the center point in the SGGP geometry (unless the macro-material option is used - see below).

### 4.1.3.4.2 Macromaterials for $\mathrm{S}_{\mathrm{N}}$ geometries

Part of the advantage of the CADIS method is that the adjoint discrete-ordinates calculation only needs to be approximate in order to form a reasonable importance map and biased source. This usually means that the mesh used is much coarser than the mesh that would be used if the problem were to be solved only with a discrete-ordinates code. This coarse mesh may miss significant details (especially curves) in the geometry and produce a less-than-optimal importance map.

In order to get more accurate solutions from a coarse-mesh discrete-ordinates calculation, Denovo can represent the material in each voxel of the mesh as a volume-weighted mixture of the real materials, called macromaterials, in the problem. When constructing the Denovo input, the Denovo EigenValue Calculation (DEVC, see section 2.4.A) sequence can estimate the volume fraction occupied by each real material in each voxel by a sampling method. The user can specify parameters for how to sample the geometry. Note that finer sampling makes more accurate estimates of the material fraction but requires more setup time to create the Denovo input. Users should understand how the macromaterials are sampled and consider that when constructing a mesh grid. This is especially important for geometries that contain arrays. Careful consideration should be given when overlaying a mesh on a geometry that contains arrays of arrays.

Because the list of macromaterials could become large, the user can also specify a tolerance for how close two different macromaterials can be to be considered the same, thereby reducing the total number of macromaterials. The macromaterial tolerance, "mmTolerance=", is used for creating a different macromaterial from the ones already created by looking at the infinity norm between two macromaterials. The number of macromaterials does not appreciably impact Denovo run time or memory requirements.

Two different sampling methods are available—point testing ${ }^{13}$ with the keyword mmPointTest and ray tracing ${ }^{14}$ with the keyword mmRayTest.

## Ray Tracing

This method estimates the volume of different materials in the Denovo mesh grid elements by tracing rays through the SGGP geometry and computing the average track lengths through the each material. Rays are traced in all three dimensions to better estimate the volume fractions of materials within each voxel. The mmSubCell parameter controls how many rays to trace in each voxel in each dimension. For example, if mmSubCell= $n$, then when tracing rays in the $z$ dimension, each column of voxels uses a set of $n \times n$ rays starting uniformly spaced in the x and y dimensions. With rays being cast from all three orthogonal directions, a total of $3 n^{2}$ rays are used to sample each voxel. One can think of subcells as an equally spaced sub-mesh with a single ray positioned at each center. The number of subcells in each direction, and hence the number of rays, can be explicitly given with mmSubCells ny $n z n x n z n x$ ny end keyword for rays parallel to the x axis, y axis, and z axis. Figure 4.1.1 shows different subcell configurations (in two dimensions) for a given voxel.

Figure 4.1.1. Ray positions within a voxel with different mmSubCells parameters.

Ray tracing is a more robust method compared to the simple point testing method used in previous versions of SCALE/MAVRIC; however, it requires more memory than point testing. Ray tracing gives more accurate estimates of volume fractions because track lengths across a voxel give more information than a series of test points. Ray tracing is also much faster than point testing because the particle tracking routines are optimized for quickly determining lists of materials and distance along a given ray.

Ray tracing operates on the grid geometry supplied by the user and shoots rays in all three directions starting from the lower bounds of the mesh grid. An example of an arbitrary assembly geometry is shown in Figure 4.1.2. A ray consists of a number of steps that each correspond to crossing a material boundary along the path of the ray. Ratios of each step's length to the voxel length in the ray's direction determine
the material volume fraction of that step in that voxel, and summation of the same material volume fractions gives the material volume fraction of that material in that voxel. Ray tracing through a single voxel that contains a fuel pin is illustrated in Figure 4.1.3.

Figure 4.1.2. Geometry model (left) and the Denovo representation (right) of an assembly using macromaterials determined by ray tracing.

Figure 4.1.3. Ray tracing (in two dimensions) through a voxel.

The final constructed macromaterials for this model are also shown in Figure 4.1.2. Voxels that contain only a single material are assigned the original material number in the constructed macromaterials. For
the voxels that contain a fuel pin with three different materials, the result is a new macromaterial consisting of the volume weighted fractions of each original material.

After the rays are shot in all three directions, the material volume fractions are updated and macromaterials are created by using these material volume fractions. Material volume fraction calculations for a single voxel, as shown in Figure 4.1.3, are given by

$$
F_{m}=\sum_{d=x, y, z} \sum_{r=1}^{N_{r}} \sum_{s=1}^{N_{s}}\left\{\begin{aligned}
\frac{L_{d, r, s}}{L_{d}}, & m_{s}==m \\
0, & \text { otherwise }
\end{aligned} \quad \text { and } \quad V_{m}=\frac{F_{m}}{\sum_{n=1}^{N_{m} F_{n}}},\right.
$$

where $F_{m}=$ sampled fraction of material $m$ in the voxel,
$d=$ direction of the rays $(x, y, z)$,
$r=$ ray number,
$N_{r}=$ total number of rays in the voxel for direction of $d$,
$s=$ step number,
$N_{s}=$ total number of steps for ray $r$ in the voxel for direction of $d$,
$L_{d, r, s}=$ length of the steps $s$ for ray $r$ in the voxel for direction of $d$,
$L_{d}=$ length of the voxel along direction of $d$,
$m_{s}=$ material of step $s$,
$m=$ material number,
$N_{m}=$ total number of materials in the voxel, and
$V_{m}=$ volume fraction of material m in the voxel.

## Point Testing

The recursive bisection method is utilized in point testing and uses a series of point tests to determine the macromaterial fractions. For a given voxel, the material at the center is compared to the material at the eight corners. If they are all the same, the entire volume is considered to be made of that material. If different, the volume is divided into two in each dimension. Each subvolume is tested, and the method is then applied to the subvolumes that are not of a single material. When the ratio of the volume of the tested region to the original voxel becomes less than a user-specified tolerance (in the range of 10-1 to 10-4), then further subdivision and testing are stopped. This is illustrated in Figure 4.1.4.

Figure 4.1.4. Successive steps in the recursive macro-material method.

In point testing, the keyword "mmTolerance=f" is interpreted to be where $f$ is the smallest fraction of the voxel volume that can be achieved by bisection method and hence the limiting factor for dividing the voxel. This same tolerance f is also used to limit the number of macromaterials. Before a new macromaterial is created, if one already exists where the fraction of each actual material matches to within the given tolerance, then the existing material will be used. If using only a single point at the center of each voxel, use "mmTolerance=1". The mmSubCell keyword is not used in point testing.

## Example

Figure 4.1.5 shows an example of a cask geometry with two types of spent fuel (yellows), steel (blue), resin (green), and other metals (gray). When the Denovo geometry is set up by testing only the center of each mesh cell, the curved surfaces are not well represented (upper right). By applying the ray-tracing method and defining a new material made of partial fractions of the original materials, an improved Denovo model can be made. In the lower left of the figure, the Denovo model was constructed using one ray (in each dimension) per voxel and a tolerance of 0.1. This gives 20 new materials that are a mixture of the original 13 actual materials and void. With mmSubCells=3 and an mmTolerance $=0.01,139$ macromaterials are created.

A macromaterial table listing the fractions of each macromaterial is saved to a file called "outputName.mmt", where outputName is the name the user chose for his or her output file. This file can be used by the Mesh File Viewer to display the macromaterials as mixtures of the actual materials, as seen in the lower row of Figure 4.1.5. See the Mesh File Viewer help pages for more information on how to use colormap files and macromaterial tables.

Figure 4.1.5. Cask geometry model (upper left) and the Denovo representation using cell center testing (upper right). Representations using macromaterials determined by ray tracing are shown for $\mathrm{mmSubCell}=1 / \mathrm{mmTolerance}=0.1$ (lower left) and $\mathrm{mmSubCell}=3 / \mathrm{mmTolerance}=0.01$ (lower right).

### 4.1.3.4.3 Optimizing source/detector problems

For standard source/detector problems where one tally is to be optimized in the forward Monte Carlo calculation, an adjoint source based on that tally needs to be constructed. An adjoint source requires a unique and positive identification number, a physical location, and an energy spectrum. The adjoint source location can be specified either by (1) a point location ("locationID=" keyword) or (2) a volume described by a box ("boundingBox" array). A bounding box is specified by maximum and minimum extent in each dimension- $x_{\max } x_{\min } \quad y_{\max } y_{\min } \quad z_{\max } \quad z_{\min }$ in global coordinates. The boundingBox should not be degenerate (should have volume $>0$ ) but can be optionally limited to areas matching a given unit number ("unit="), a given region number ("region="), or a given material mixture number ("mixture="). A mixture and a region cannot both be specified since that would either be redundant or mutually exclusive. The energy spectrum of an adjoint source is a response function ("responseID=") listing one of the ID numbers of the responses defined in the definitions block. An optional weight can be assigned to each adjoint source using the "weight=" keyword. If not given, the default weight is 1.0.

For example, to optimize a region tally, the user would construct an adjoint source located in the same place as the tally, with an adjoint source spectrum equal to the response function that the tally is computing. Note that the grid geometry 1 and response function 3 need to already be defined in the definitions block.

```
read importanceMap
    gridGeometryID=1
    adjointSource 24
        boundingBox 12.0 10.0 5.0 -5.0 10.0 -10.0
        unit=1 region=5
        responseID=3
    end adjointSource
end importanceMap
```

For optimizing a point detector for the calculation of total photon flux, the importance map block would look like the following:

```
read importanceMap
    adjointSource 21
        locationID=4
        responseID=1
    end adjointSource
    gridGeometryID=1
end importanceMap
```

where location 4 is the same location used by the point detector. Response function 1, to calculate total photon flux, must be defined in the definitions block similar to this response

```
read definitions
    response 1

which is independent of cross section library.

### 4.1.3.4.4 Multiple adjoint sources

In cases where there are several tallies in very close proximity and/or several different responses being calculated by the tallies, multiple adjoint sources can be used.

```
read importanceMap
    gridGeometryID=1
    adjointSource 1
            locationID=4 responseID=20
    end adjointSource
    adjointSource 2
            locationID=5 responseID=21
            weight=2.0
    end adjointSource
end importanceMap
```

Note that adjoint sources using point locations can be mixed with volumetric adjoint sources (using bounding boxes).

### 4.1.3.4.5 Options for Denovo $\mathrm{S}_{\mathrm{N}}$ calculations

While the default values for various calculational parameters and settings used by Denovo for the MAVRIC sequence should cover most applications, they can be changed if desired. The two most basic parameters are the quadrature set used for the discrete ordinates and the order of the Legendre polynomials used in describing the angular scattering. The default quadrature order that MAVRIC uses is a level symmetric $\mathrm{S}_{8}$ set, and the default scattering order is $\mathrm{P}_{3}$ (or the maximum number of coefficients contained in the cross-section library if less than 3 ). $\mathrm{S}_{8} / \mathrm{P}_{3}$ is an adequate choice for many applications, but the user is free to changes these. For complex ducts or transport over large distances at small angles, $\mathrm{S}_{12}$ may be required. $\mathrm{S}_{4} / \mathrm{P}_{1}$ or even $\mathrm{S}_{2} / \mathrm{P}_{0}$ would be useful in doing a very cursory run to confirm that the problem was input correctly, but would likely not be adequate for weight window generation for a problem that is complex enough to require advanced variance reduction.

These options, as well as the other Denovo options, are applied to both the forward and the adjoint calculations that are required from the inputs given in the importance map block.

In problems with small sources or media that are not highly scattering, discrete ordinates can suffer from "ray effects" 15,16 where artifacts of the discrete quadrature directions can be seen in the computed fluxes. To help alleviate the ray effects problem, Denovo has a first-collision capability to help alleviate ray effects. This method computes the uncollided flux in each mesh cell from a point source. The uncollided fluxes are then used as a distributed source in the main discrete-ordinates solution. At the end of the main calculation, the uncollided fluxes are added to the fluxes computed with the first collision source, forming the total flux. While this helps reduce ray effects in many problems, the first-collision capability can take a significant amount of time to compute on a mesh with many cells or for many point sources.

Adjoint sources that use point locations will automatically use the Denovo first-collision capability. Volumetric adjoint sources (that use a boundingBox) will be treated without the first-collision capability.

The keywords "firstCollision" and "noFirstCollision" will be ignored by MAVRIC for adjoint calculations. Keywords for Denovo options in the importance map block are summarized at the end of this section, in Table 4.1.6.

### 4.1.3.4.6 Starting with an existing adjoint flux file

An importance map can be made from an existing Denovo flux file by using the keyword "adjointFluxes=" with the appropriate file name in quotes. The file must be a binary file using the *.dff file format, and the number of groups must match the number of groups in the MAVRIC cross section library (i.e., the library entered on the third line of the MAVRIC input file). Instead of performing an adjoint calculation, the fluxes read from the file will be used to create both the mesh-based importance map and the biased mesh source.

```
read importanceMap
    adjointFluxes="c:\mydocu~1\previousRun.adjoint.dff"
    gridGeometry=7
end importanceMap
```

If the "adjointFluxes=" keyword is used and any adjoint sources are defined, an error will result. If a forward flux file is supplied for forward-weighting the adjoint source (see below), then an adjoint flux file cannot be specified.

The grid geometry is not required when using a pre-existing flux file. If grid geometry is not supplied, one will be created from the mesh planes that are contained in the Denovo flux file (which were used to compute the fluxes in that file).

### 4.1.3.4.7 Forward-weighting the adjoint source

To optimize a mesh tally or multiple region tallies/point detector tallies over a large region, instead of a uniform weighting of the adjoint source, a weighting based on the inverse of the forward response can be done. This requires an extra discrete-ordinates calculation but can help the forward Monte Carlo calculation compute the mesh tally or group of tallies with more uniform statistical uncertainties.

The same grid geometry will be used in both the forward calculation and the adjoint calculation, so the user needs to ensure that the mesh covers all of the forward sources and all of the adjoint sources, even if they are point sources.

To use forward-weighted CADIS, specify either of the keywords - "respWeighting" or "fluxWeighting". For either, MAVRIC will run Denovo to create an estimate of the forward flux, $\phi(\vec{r}, E)$. For response weighting ("respWeighting"), each adjoint source is inversely weighted by the integral of the product of the response function used in that adjoint source and the estimate of the forward flux. For an adjoint source described by the geometric function $g(\vec{r})$ and the response function $\sigma_{d}(E)$ (note that $\sigma_{d}(E)=1$ for computing total fluxes), the forward-weighted adjoint source becomes

$$
\begin{equation*}
q_{i}^{+}(\vec{r}, E)=\frac{\sigma_{d}(E) g(\vec{r})}{\int \sigma_{d}(E) \phi(\vec{r}, E) d E} . \tag{4.1.18}
\end{equation*}
$$

Response weighting will calculate more uniform relative uncertainties of the integral quantities of the tallies in the final Monte Carlo calculation.

To optimize the calculation of the entire group-wise flux with more uniform relative uncertainties in each group, the adjoint source should be weighted inversely by the forward flux, $\phi(\vec{r}, E)$, using the "fluxWeighting" keyword. For an adjoint source described by the geometric function $g(\vec{r})$ and the response function $\sigma_{d}(E)=1$, the forward-weighted adjoint source becomes

$$
\begin{equation*}
q_{i}^{+}(\vec{r}, E)=\frac{\sigma_{d}(E) g(\vec{r})}{\phi(\vec{r}, E)} . \tag{4.1.19}
\end{equation*}
$$

For example, consider a problem with a single source and two detectors, one near the source that measures flux and one far from the source that measures some response. In a standard Monte Carlo calculation, it is expected that since more Monte Carlo particles cross the near detector, it will have a much lower relative uncertainty than the far detector. Standard CADIS could be used to optimize the calculation of each in separate simulations:

| To optimize the flux in the near detector | To optimize the response in the far detector |
| :---: | :---: |
| read importanceMap | read importanceMap |
| gridGeometryID=1 | gridGeometryID=1 |
| adjointSource 1 | adjointSource 2 |
| boundingBox $x_{1} x_{2} y_{1} y_{2} z_{1} z_{2}$ responseID=1 | boundingBox $u_{1} u_{2} v_{1} v_{2} w_{1} w_{2}$ responseID=6 |
| end adjointSource | end adjointSource |
| end importanceMap | end importanceMap |

where response 1 was defined as $\sigma_{1}(E)=1$ and response 6 was defined as $\sigma_{6}(E)=$ flux-to-response conversion factors. The two options for forward-weighting allow the tallies for both detectors to be calculated in the same MAVRIC simulation. Using "fluxWeighting", the importance map and biased source will be made to help distribute Monte Carlo particles evenly through each energy group and every voxel in each both detectors, making the relative uncertainties close to uniform. With "respWeighting", the importance map and biased source will optimize the total integrated response of each tally.

| To optimize $\phi(\vec{r}, E)$ in each detector | To optimize a total response $\int \sigma_{d}(E) \phi(\vec{r}, E) d E$ (either total flux or total dose) |
| :---: | :---: |
| ```read importanceMap gridGeometryID=1 near detector adjointSource 1 boundingBox }\begin{array}{llllllll}{1}&{\mp@subsup{x}{2}{}}&{\mp@subsup{y}{1}{}}&{\mp@subsup{y}{2}{\prime}}&{\mp@subsup{z}{1}{}}&{\mp@subsup{z}{2}{}} responseID=1``` | ```read importanceMap gridGeometryID=1 near detector adjointSource 1 boundingBox \(x_{1} x_{2} y_{1} y_{2} z_{1} z_{2}\) responseID=1``` |
| end adjointSource | end adjointSource |
| ، far detector | - far detector |
| adjointSource 2 boundingBox $u_{1} u_{2} v_{1} v_{2} w_{1} w_{2}$ responseID=6 | adjointSource 2 boundingBox $u_{1} u_{2} v_{1} v_{2} w_{1} w_{2}$ responseID=6 |
| end adjointSource | end adjointSource |
| fluxWeighting | respWeighting |
| end importanceMap | end importanceMap |

Using flux weighting, the adjoint source will be

$$
\begin{equation*}
q^{+}(\vec{r}, E)=\frac{\sigma_{1}(E) g_{\mathrm{near}}(\vec{r})}{\phi(\vec{r}, E)}+\frac{\sigma_{6}(E) g_{\mathrm{far}}(\vec{r})}{\phi(\vec{r}, E)}, \tag{4.1.20}
\end{equation*}
$$

or using response weighting, the adjoint source will be

$$
\begin{equation*}
q^{+}(\vec{r}, E)=\frac{\sigma_{1}(E) g_{1}(\vec{r})}{\int \sigma_{1}(E) \phi(\vec{r}, E) d E}+\frac{\sigma_{6}(E) g_{2}(\vec{r})}{\int \sigma_{6}(E) \phi(\vec{r}, E) d E} . \tag{4.1.21}
\end{equation*}
$$

This implementation is slightly different from the original MAVRIC in SCALE 6. The current approach is simpler for the user and allows the importance parameters to optimize the final Monte Carlo calculation for the calculation of two different responses in two different areas.

If the number of mesh cells containing the true source is less than 10 , then MAVRIC will convert these source voxels to point sources and Denovo will automatically use its first-collision capability to help reduce ray effects in the forward calculation. The user can easily override the MAVRIC defaults-to force the calculation of a first-collision source no matter how many voxels contain source-by using the keyword "firstCollision". To prevent the calculation of a first-collision source, the keyword "noFirstCollision" can be used. If the keywords "firstCollision" or "noFirstCollision" are used, they will only apply to the forward calculation, not the subsequent adjoint calculation.

The keyword "saveExtraMaps" will save extra files that can be viewed by the Mesh File Viewer. The source used by the forward Denovo calculation is stored in "outputName.dofs.3dmap", where outputName is the name the user chose for his output file.

### 4.1.3.4.8 Forward-weighting with an existing forward flux file

Similar to the capability of using pre-existing adjoint flux files, MAVRIC can use a pre-existing forward flux file to create a forward-weighted adjoint source without performing the forward Denovo calculation. The user may specify the *.dff file containing the forward fluxes using the keyword "forwardFluxes=". The filename should be enclosed in quotes, and the file must be a binary file using the Denovo flux file format. The number of groups must match the number of groups in the MAVRIC cross section library (i.e., the library entered on the third line of the MAVRIC input file).

```
read importanceMap
    forwardFluxes="c:\mydocu~1\previousRun.forward.dff"
    gridGeometry=7
    adjointSource 1
        ...
    end adjointSource
    respWeighting
end importanceMap
```

When using a pre-existing forward flux file, either "respWeighting" or "fluxWeighting" must still be specified.

### 4.1.3.4.9 Using the importance map

An importance map produced by the importance map block consists of the target weight values as a function of position and energy. The upper weight window used for splitting and the lower weight window used for Russian roulette are set by the window ratio. The window ratio is simply the ratio of the weight window upper bound to the weight window lower bound, with the target weight being the average of the upper and lower.

The keyword "windowRatio=" can be used within the importance map block to specify what window ratio will be used with the importance map that is passed to the Monaco forward Monte Carlo calculation. For a windowRatio of $r$, the upper weights for splitting, $w_{\max }$, and the lower weights for Russian roulette, $w_{\text {min }}$, are set as

$$
\begin{equation*}
w_{\min }=\frac{2}{r+1} \bar{w} \tag{4.1.22}
\end{equation*}
$$

and

$$
\begin{equation*}
w_{\max }=\frac{2 r}{r+1} \bar{w} \tag{4.1.23}
\end{equation*}
$$

for the target weight $\bar{w}$ in each mesh cell and for each energy of the importance map. The default value for the windowRatio is 5.0.

### 4.1.3.4.10 Other notes on importance map calculations

Since the importance map calculations all take place using mesh geometry, one of the first steps that occurs is to create a mesh representation of the true source (the forward source) on the same grid. This procedure uses the same two methods as the Monaco mesh source saver routine. Mesh cells can be subdivided and tested to see if they are within the defined source, or a set number of points can be sampled from the source. The keywords "subCells=" and "sourceTrials=" are used in the importance map block to change the default settings for constructing the mesh representation of the forward source.

If macromaterials are used ("mmTolerance $<1$ ") and the adjoint source is limited to a particular material, the amount of adjoint source in a mesh voxel will be weighted by the material amount in that voxel.

In SCALE/MAVRIC, Denovo is called as a fixed-source $\mathrm{S}_{\mathrm{N}}$ solver and cannot model multiplying media. Neither forward nor adjoint neutron calculations from Denovo will be accurate when neutron multiplication is a major source component. If neutron multiplication is not turned off in the parameters block of the MAVRIC input (using "fissionMult=0"), a warning will be generated to remind the user of this limitation.

By default, MAVRIC instructs Denovo not to perform outer iterations for neutron problems if the crosssection library contains upscatter groups. This is because the time required calculating the fluxes using upscatter can be significantly longer than without. For problems where thermal neutrons are an important part of the transport or tallies, the user should specify the keyword "upScatter=1" in the importance map block. This will instruct Denovo to perform the outer iterations for the upscatter groups, giving more accurate results but taking a much longer time for the discrete-ordinates calculation.

When doing a MAVRIC calculation using a coarse-group energy structure for Denovo (for example with the 27/19 library) but a fine-group energy structure (with the 200/47 library) for the final Monaco calculation, the source biasing parameters are determined on the coarse-group structure. The importance map (*.mim) file and the biased mesh source (*.msm) files all use the coarse-group structure. The source biasing information is then applied to fine-group mesh versions of the sources, resulting in the *.sampling.*.msm files. This way, the biased sources used in the final Monaco calculation retain their fine-group resolution. This can be especially important in representing the high-energy portion of the fission neutron distribution for example. When using CE-Monaco, the source sampling routines first use the *.msm files to determine the source particle's voxel and energy group. From that voxel and energy group, the user-given source distributions are used to sample the specific starting location and specific energy of the source particle. This way, the CE-Monaco calculation samples the true CE distributions.

### 4.1.4 MAVRIC Output

### 4.1.4.1 Main text output file

Similar to other SCALE sequences, MAVRIC returns a text output file containing the output from the SCALE driver, the sequence itself, and all of the functional modules called. The SCALE driver output first displays the problem input file then the first reading of the input file by the MAVRIC sequence is shown (which includes some material processing information). If there are any errors or warnings about the input file, they will be shown next. Next in the output file are the different passes through the MAVRIC sequence, up to 10 parts. If any errors or warning messages (such as lack of memory) are generated during processing, they will be displayed here. Finally, the output files from each functional module are concatenated to the above output and shows the files returned to the user.

The Monaco section of output first reviews the input it received. First is a review of the geometryshowing which materials are used in each region and the volume of that region, if input or calculated. Then there is a detailed list of other Monaco input: cross section parameters, data definitions, the source description, the tallies, the Monte Carlo parameters, and the biasing parameters. For MAVRIC calculations, if an importance map is used, then its summary is also given. The "Mesh Importance Map

Characterization" shows where the importance map may be changing too rapidly and may require more refinement.

For each Monaco batch, the output file lists the batch time and the starting random number for the next batch, which may be useful in rerunning just a portion of a problem. Once all of the batches are completed, a list of the various tally files that have been created is given. Finally, the tallies are summarized in a section titled "Final Tally Results Summary." For each point detector, the total neutron and photon fluxes (uncollided and total) are given as well as the final response values for each response function. For each region tally, the total neutron and photon fluxes (both track-length and collision density estimates) are listed, followed by the final response values for each response function. Group-by-group details are saved to separate files for each tally.

### 4.1.4.2 Additional output files

In addition to the generous amount of data contained in the MAVRIC text output file, many other files are created containing the intermediate data used by the sequence and the final tally data. Many of the files produced can be viewed using the Mesh File Viewer or the Interactive Plotter capabilities of Fulcrum, which is distributed with SCALE. (Note that most of the images in this document were taken from the Mesh File Viewer from SCALE 6.1.) Table 4.1.7 lists the other output files, based on the name of the main output file (here called outputName), that are available to the user. These files will be copied back to the directory where the input file was located. Many of the files come from Monaco and are discussed in the Monaco chapter of the SCALE manual.

Other files that the user may be interested in are listed in Table 4.1.8. These files are kept in the temporary directory where SCALE executes and are not copied back to the directory where the input file was located, unless specifically requested using a SCALE "shell" command. Curious users may also be interested in viewing the various input files (i_*) that the MAVRIC sequence writes in order to run the SCALE functional modules.

Table 4.1.7. Output files that are copied back to user's area when the sequence finishes ${ }^{\boldsymbol{a}}$

| Filename | Viewer | Description |
| :---: | :---: | :---: |
| Output Summary |  |  |

### 4.1.5 Sample Problems

### 4.1.5.1 Graphite shielding measurements with CADIS

As shown in the Monaco sample problem for simulating the Ueki shielding experiments (Monaco chapter Graphite Shielding Measurements), as the amount of shielding material between a source and detector increases, the time required to reach a certain level of relative uncertainty increases quickly. This example will use the MAVRIC automated variance reduction capability to optimize the calculation of the dose rate at the detector location by specifying an importance map block with an adjoint source made from the detector response function and the detector location.

### 4.1.5.1.1 Input file

The following is a listing of the file mavric.graphiteCADIS.inp located in the SCALE samples \input directory. This calculation will use the coarse-group shielding library (27n19g) for all of the importance map calculations and the fine-group library (200n47g) for the final Monaco step. Additions, compared to the file monaco.graphite.inp, include a grid geometry for the Denovo computational mesh, a mesh tally to better visualize the particle flow, and the importance map block to optimize the Monte Carlo calculation of the point detector.

### 4.1.5.1.2 Output

MAVRIC results for the point detector response for the 20 cm case are shown below and in Figure 4.1.6.

This problem took only $\sim 2.5$ minutes ( 0.2 in Denovo and 2.3 minutes in Monaco) on the same processor as the 20 minute analog case. [The figure of merit (FOM) is 15 times higher than the analog.] Note that the point detector dose rate is the same as the Monaco analog sample problem, but the relative uncertainty is smaller with less computation time. CADIS has optimized the calculation by focusing on neutrons that contribute to the dose rate at the detector location, at the expense of neutrons in the paraffin block. This is demonstrated by the mesh tally of dose rates where the values for the dose rate are lower in the paraffin block and the relative uncertainties are higher. Since the calculation was optimized for the position of the detector, dose rates in other parts of the problem are underestimated and should not be believed.

The mesh tally shows that the CADIS calculation did not follow as many particles deep into the paraffin block, so the uncertainties are larger there, but that is what this problem was supposed to do-reduce the uncertainty at the point detector at the expense of the other portions of the problem.

Figure 4.1.6. Mesh tally showing neutron dose rate (rem/hr) and uncertainties for the analog case and the CADIS case.

### 4.1.5.2 Dose rates outside of a simple cask

This example problem is a full-size cylindrical cask model, which consists of an inner steel liner, a thick section of concrete, and an outer steel cover. This problem is intended to be used as a tool to teach users how to build MAVRIC input files. This is not a completely realistic shipping cask but has been simplified greatly for this purpose. The goal of this example it to show how to quickly calculate neutron and photon does rates at six points outside of the cask, including in front of the vent port.

### 4.1.5.2.1 Geometry and materials

The simple model of a cask is shown in Figure 4.1.7. Vent ports at the top and bottom of the cask are modeled as void all of the way around the cask. The interior of the cask was modeled using materials from about 20 typical pressurized-water reactor (PWR) fuel assemblies (including the $\mathrm{UO}_{2}, \mathrm{Zr}, \mathrm{Fe}, \mathrm{Ni}, \mathrm{Cr}$, Sn , and other constituents), homogenized over the interior volume. The total mass of the fuel/assembly hardware in this region is 10.6 metric tonnes. Separate end regions of the assemblies are not modeled in this simple example. Also note that the fuel material is based on fresh fuel, not spent fuel with its hundreds of fission products.

Figure 4.1.7. Cask geometry and detector locations.

### 4.1.5.2.2 Sources and responses

Spent fuel from a typical mid-sized PWR was used to determine the source term. ORIGEN was used to deplete a full core ( 46.1 metric tonnes of uranium, $4.2 \%$ enriched, with $\mathrm{O}, \mathrm{Zr}, \mathrm{Fe}, \mathrm{Ni}, \mathrm{Cr}, \mathrm{Sn}$, and other constituents) to 55,000 MWdays/MTU. The contents of the modeled fuel represent typical values for PWR fuel. ORIGEN then computed the neutron and photon spectra in 27 group and 19 group energy structures for the fuel following a 10 year cooling period after the last irradiation. The total neutron source strength for the cask ( $1 / 6$ of a full core - about 20 assemblies) was $8.577 \times 10^{9}$ neutrons/s. The total photon source strength was $7.155 \times 10^{16}$ photons/s.

Two cases will be done for this example: one for calculating the neutron dose rates from the spent fuel neutrons and the other for calculating the photon dose rates from the spent fuel photons. The source spectra and response functions are shown in Figure 4.1.8 through Figure 4.1.11 and listed in Table 4.1.9. Note that in this example, the neutron source shown in Figure 4.1.8 and Table 4.1.9 is considered the final neutron source-no further neutron multiplication is considered.

Figure 4.1.8. Spent fuel neutron source spectrum, with strength $8.577 \times 10^{9} /$ second.

Figure 4.1.10. Spent fuel photon source spectrum, with strength $7.155 \times 10^{16} /$ second.

Energies listed are the bin upper energies. Source units are particles/s, normalized to a total of 1 particle/s. Response units are (rem/hr)/(particle/cm²/s).

### 4.1.5.2.3 Analog calculation

The analog model for this problem starts with the problem title and the cross-section library name, which in this example is the ENDF/B-VII. 027 neutron group/19 photon group library. This is in the SCALE samples input directory as mavric.caskAnalogn.inp and mavric.caskAnalogp.inp.

```
=mavric
Simplified cask model
v7-27n19g
```

Then the material compositions are listed for fresh fuel, concrete, and steel.

| read composition |  |  |  |  |  |  |  |
| :---: | ---: | ---: | :--- | ---: | ---: | ---: | ---: |
| wtptFuel | 1 | 0.913717475 | 18 | 6000 | 0.00939719 | 7014 | 0.00528993 |
|  |  | 8016 | 9.73397641 | 13000 | 0.00715715 | 14000 | 0.01031670 |

```
\begin{tabular}{rrrrrr}
15000 & 0.02227505 & 22000 & 0.00780567 & 24000 & 0.36655141 \\
25000 & 0.01716839 & 26000 & 0.72041451 & 27000 & 0.00523824 \\
28000 & 0.68955526 & 40000 & 15.78990702 & 41000 & 0.05130153 \\
42000 & 0.02844690 & 50118 & 0.25877903 & 92235 & 3.03560962 \\

1.0293 .0 end & & & \\
1.0 & 293.0 end & & & \\
1.0293 .0 end & & &
\end{tabular}
```

Then SGGP geometry is listed, with the origin of the coordinate system at the center of the cask.

The definitions block contains locations, response functions, grid geometries, and a distribution used by the source input block. For the neutron source/neutron dose problem, the definitions block is listed below.

```
read definitions
    location 1 position 180.0 0.0 0.0 end location
    location 2 position 0.0 0.0 295.6 end location
    location 3 position 180.0 0.0 267.9 end location
    location 4 position 270.0 0.0 0.0 end location
    location 5 position 0.0 0.0 385.6 end location
    location 6 position 270.0 0.0 385.6 end location
    response 1 specialDose=9029 end response
    distribution 1
        title="kewaunee core, 3 cycles and then 10 years"
        neutronGroups
        truePDF 2.040E-02 2.147E-01 2.365E-01 1.267E-01 1.586E-01
            1.587E-01 7.281E-02 1.073E-02 7.688E-04 5.694E-05
            4.479E-06 3.148E-07 4.983E-08 9.864E-09 1.117E-09
            3.286E-10 1.060E-10 9.203E-11 9.135E-11 1.755E-10
            2.590E-11 3.024E-11 3.451E-11 3.269E-12 5.447E-12
            4.089E-14 4.916E-14 end
    end distribution
end definitions
```

The neutron source from the spent fuel is then listed.

```
read sources
    src 1
        title="1/6 of kewaunee core, ~ 0.25 Ci"
        strength=8.577E+09
            neutrons
            zCylinder 95.0 228.6 -228.6
            eDistributionID=1
    end src
end sources
```

Six point detectors are used to evaluate dose rates radially, axially, and near the vent port.

```
read tallies
    pointDetector 1 locationID=1 responseID=1 end pointDetector
    pointDetector 2 locationID=2 responseID=1 end pointDetector
    pointDetector 3 locationID=3 responseID=1 end pointDetector
    pointDetector 4 locationID=4 responseID=1 end pointDetector
    pointDetector 5 locationID=5 responseID=1 end pointDetector
    pointDetector 6 locationID=6 responseID=1 end pointDetector
end tallies
```

The Monte Carlo parameters were tailored for the neutron problem to be 1 minute batches on a 2 GHz Linux computer. For the photon problem, the number per batch would be 91000 for 1 minute batches.

```
read parameters
    randomSeed=8655745280030001
    perBatch=25400 batches=600
    fissionMult=0 noPhotons
end parameters
```

No biasing is specified, which will use the default weight window target value of 1 for every energy group in every region. In order to allow the neutrons to penetrate into the cask wall before being rouletted, a larger window ratio is used, making the lower weight window bound to be 0.01 .

```
read biasing
    windowRatio=199.0
end biasing
```

The Monaco input is then ended.

```
end data
```

end

For the photon source/photon dose rate problem, the definitions block would instead contain a photon flux-to-dose-rate response function and the energy distribution for the source.

```
read definitions
    response 1
        specialDose=9504
    end response
    ".
        title="kewaunee core, 3 cycles and then 10 years"
        photonGroups
        truePDF 1.320E-12 7.185E-11 3.281E-10 1.672E-09 4.167E-09
                        8.086E-08 7.937E-07 1.164E-05 3.331E-05 8.160E-03
                3.511E-02 2.478E-02 4.827E-01 4.641E-02 9.736E-03

    end distribution
end definitions
```

The sources block would contain the photon source information.

```
read sources
    src 1
            title="1/6 of kewaunee core, ~ 2e6 Ci"
            strength=7.155e+16
            photons
            zCylinder 95.0 228.6 -228.6
            eDistributionID=1
    end src
end sources
```

Each of the two analog problems in the samples $\backslash i n p u t$ directory run for about 10 minutes. In this time, no meaningful results will be generated due to the difficulty of the problem. Analog results for each case running 110 hr are listed in Table 4.1.10 for the neutron source/neutron dose problem, while results for the photon problem are listed in Table 4.1.11. Note that after 110 hr , some of the relative uncertainties in the point detector tallies are still quite high and only one of the six tallies in each problem passed all of the statistical checks. Figure 4.1.12 is the convergence plot for the neutron dose rate at point detector 1, showing that the tally is not well converged and that some batches contain rare events that change the tally value a great deal.

Table 4.1.10. Analog Monaco results for the simplified cask model-neutron source/neutron dose rate

| detector | Dose Rate <br> (rem/hr) | relative <br> uncertainty |
| :---: | :---: | :---: |
| 1 | $8.78 \mathrm{E}-04$ | 0.1853 |
| 2 | $7.35 \mathrm{E}-03$ | 0.0408 |
| 3 | $1.54 \mathrm{E}-02$ | 0.0124 |

| 6 | $3.30 \mathrm{E}-01$ | 0.0244 |

Figure 4.1.12. Convergence plot for the neutron dose rate at point detector 1. Error bars show the 1-sigma tally uncertainties.

### 4.1.5.2.4 SAS4 calculations

Calculations for these two problems were also done using the SAS4 sequence in SCALE 5.1. SAS4 was specifically designed for cask geometries and used a one-dimensional discrete-ordinates calculation (either radially or axially) to determine weight windows. Results for the neutron problem are shown in Table 4.1.12, and results for the photon problem are shown in Table 4.1.13. Note that SAS4 using radial biasing is only expected to do well for the two radial point detector locations. Similarly, only the two axial point detectors are expected to do well when using axial biasing. SAS4 was not intended to do well for the points near the vent port, but the results using the axial biasing seem reasonable.

Table 4.1.12. SAS4 results, using radial biasing ( 361 minutes) and axial biasing ( $\mathbf{3 6 1}$ minutes), for the simplified cask modelneutron source/neutron dose rate

|  | Radial Biasing |  | Axial Biasing |  |

### 4.1.5.2.5 Calculations using CADIS

In the analog calculations, the dose rates at all six points could be calculated at the same time. With MAVRIC, using CADIS, the importance map will optimize the transport of particles towards only the selected detector. Hence, each detector will have a separate calculation with an importance map tailored to reduce the variance for just that detector. Close detectors could be done at the same time. For example, detectors 1 and 4 both need to push particles out of the cask in the positive $x$ direction, towards the $z=0$ plane. In this example, all six detectors will use separate importance maps.

For the importance map, the user lists in the input what planes to use for the adjoint discrete-ordinates calculation. These planes define cells, which are treated as homogenous parallelpipeds by Denovo, made of a macro material corresponding to a mixture of materials that are in the cell in the true geometry. Users should try to bound as many materials as possible with their selection of mesh planes. More mesh planes should be used where the importance (adjoint flux) varies quickly, for example near the adjoint sources (the detector positions). It is also important to have planes on the true source bounding box.

In this example problem, different sets of mesh planes will be used for the different detector positions. For detector positions 1 and 4, the mesh planes are shown in Figure 4.1.13 and Figure 4.1.14. Note that there are more planes closer to the detectors. Also note that in the $z$ dimension, it is quite easy to place mesh planes at every material boundary, but it is a bit harder to do so in the $x$ and $y$ dimensions due to the curved surfaces. Users need not worry about getting things perfect-an approximate importance map can still reduce Monte Carlo variances a great deal. The meshes used for detector positions $2 / 5$ and positions 3/6 are also shown in Figure 4.1.13 and Figure 4.1.14. Mesh parameters are listed in Table 4.1.14, and the mesh planes are listed in Table 4.1.15.

### 4.1.5.2.6 MAVRIC input files

With two sources and six detectors, this example problem will require 12 separate input files. Starting with the two input files for the analog calculations, these 12 input files will share most of the same features and differ only in blocks related to the importance map calculation: the location of the adjoint source and the planes used in the grid geometry.

To change the input for the neutron problem from an analog calculation to one using CADIS, the user first adds the mesh planes for the discrete-ordinates calculation as a grid geometry to the definitions block. This set of planes is tailored for the vent port direction, towards detectors 3 and 6.

```
gridGeometry 3
    title="for importance map for detectors 3,6"
    xplanes -170 -168 -146 -122 -100
        -95
        5}15\25 35 45 55 65 75 85 90 95 100
        104 108 112 116 120 124 128 132 136 140 144 148 152
        156 158 160 162
        164 165 166 167
        168 169 170 end
    yplanes -170 -168 -155 -141 -127 -113 -100
        -95 -90 -85 -75 -65 -55 -45 -35 -25 -15 -5
        5 15 25 35 45 55 65 75 85 90 95 100
        113 127 141 155 168 170 end
    zplanes -285.6 -280.6 -255.2 -240.6 -228.6 -210
        -190 -170 -150 -130 -110 -90 -70 -50 -30 -10
        10}30305070\quad90 110 130 150 170 190
        210 216.2 222.4
```

```
228.6 232.6 236.6
240.6 245.1 249.7 254.2
255.2 256.2 260.1 264 267.9 271.8 275.7 279.6
280.6 281.6 282.6 283.6 284.6 285.6 end
end gridGeometry
```

To help the mesh-based biased source represent the true source, "mixture=1" can be added to the source definition. This will ensure that particles sampled from the mesh source that are not in the fuel are rejected. Then an importance map block replaces the standard biasing block. In this case, the importance map will optimize the flow of particles to location 3 (where point detector 3 is defined).

```
read importanceMap
    adjointSource 1
        locationID=3
        responseID=1
    end adjointSource
    gridGeometryID=3
    macromaterial
        mmTolerance=0.01
    end macromaterial
end importanceMap
```

A mesh tally could be added with the following in the tallies block.

```
meshTally 1
    title="Shows how importance map changes the transport of particles"
    gridGeometryID=3
    responseID=1
end meshTally
```

The above mesh tally uses the same grid geometry as the CADIS calculations, but a different grid (or grids) could be used. The files mavric.caskCADISn.inp and mavric.caskCADISp.inp are available in the SCALE samples \input directory. These are for calculating the dose rates at detector position 3 but can be modified for the other five positions (by changing the geometry grid planes and the adjoint source location).

### 4.1.5.2.7 Neutron source/neutron response results

The above MAVRIC input file first performed the discrete-ordinates calculation to determine the adjoint flux from detector position 3. The adjoint Denovo flux file (*.adjoint.dff) produced can be viewed using the Mesh File Viewer and is shown in Figure 4.1.15 for several of the neutron energy groups.

MAVRIC then combined a mesh representation of the true source (space and energy) with the adjoint fluxes to create the importance map and mesh-based biased source. These are shown in Figure 4.1.16 for the fifth neutron group, covering the energy range of 0.9 to 1.4 MeV . Notice how the most important region (lowest target weights) is right around the vent port near detector position 3 . This is something we know qualitatively, but quantitative values for exactly how the importance changes with space and energy are difficult to guess. Also notice the "consistent" part of CADIS-the source particles are born with a weight that matches the target weight for the position they are born into. The biased source sampling distribution is shown in Figure 4.1.17, showing how the source particles nearest to detector 3 will be sampled more often.

The biased source distribution and the importance map were then used by Monaco to compute the dose equivalent rate response at detector 3 .

Figure 4.1.15. Adjoint neutron fluxes (/ $\mathrm{cm}^{2} / \mathrm{s}$ ) for groups $5(0.9-1.4 \mathrm{MeV}), 10(0.58-3.0 \mathrm{keV})$, and $19(0.8-1 \mathrm{eV})$ calculated by Denovo.

Figure 4.1.16. Neutron target weights from the importance map and source weights (at birth) for neutron group 5 ( 0.9 to $1.4 \mathbf{M e V}$ ).

Figure 4.1.17. Biased source sampling probability (neutrons/cm ${ }^{3}$ ) for neutron groups 5 ( $0.9-1.4 \mathrm{MeV}$ ), 10 (0.58-3.0 keV), and 19 (0.8-1 eV).

The results for all six neutron cases, each using their own importance map and biased source, are shown in Table 4.1.16.

The point of this example is to show that MAVRIC using CADIS gets the right answer much faster than the analog calculations. This is shown with a comparison to the results from the analog Monaco and SAS4 calculations, all of which are listed in Table 4.1.17.

To account for the time it takes to achieve a given level of uncertainties, the calculation figure-of-merit ( $\mathrm{FOM}=1 /$ time/(relative uncertainty) ${ }^{2}$ ) can be calculated for each of the codes. The ratios of each code FOM to the FOM of analog Monaco (speedup) are listed in Table 4.1.18 to show how much faster MAVRIC and SAS4 are compared to analog Monaco. The FOMs for MAVRIC include the Denovo calculation times. The FOMs for analog Monaco and SAS4 were modified to account for calculating all six detectors at once.

### 4.1.5.2.8 Photon source/photon response results

The results for the photon source/photon response are similar to the results of the neutron source/neutron response. For the MAVRIC calculation using the photon importance map made from an adjoint source located at detector position 3, Figure 4.1.18 details the adjoint photon flux. Figure 4.1.19 compares the
target weights from the importance map and the source birth weights. Figure 4.1 .20 shows the distribution of the sampled source positions from the biased source.

Table 4.1.19 shows the results from all six photon MAVRIC runs, each using their own importance map and biased source.

The MAVRIC results of the photon problem compare well against SAS4 and analog Monaco, as shown in Table 4.1.20 and Table 4.1.21.

Figure 4.1.18. Adjoint photon fluxes (/cm²/s) for groups $2(8-10 \mathrm{MeV}), 12(0.8-1.0 \mathrm{MeV})$, and 18 ( $\mathbf{4 5 - 1 0 0} \mathrm{keV}$ ) calculated by Denovo.

### 4.1.5.3 Gamma-ray litho-density logging tool using FW-CADIS

Consider a simple model of a gamma-ray litho-density tool ${ }^{17,18}$ used in well-logging studies, shown in Figure 4.1.21. This model uses a 10 cm diameter tool made of iron (with a tungsten density) in a 20 cm borehole filled with water. The near detector is a 2 cm diameter cylinder, 2 cm in length, located 20 cm from the source. The far detector is a 4 cm by 4 cm cylinder located 40 cm from the source. Each detector is made of NaI and collimated to look out into the formation. The source is contained in an angled collimator, aiming upward and into the formation. The collimators are filled with oxygen. The extent of the modeled formation is $100 \times 100 \times 140 \mathrm{~cm}$. The source is an isotropic ${ }^{137} \mathrm{Cs}$ source emitting $10^{11}$ photons/s ( 661.7 keV ). For these calculations, no response function is used-the goal of this example is to calculate the total photon flux within each detector volume.

Figure 4.1.21. Cutaway view of the litho-density tool in a rock formation.

Figure 4.1.22. Denovo mesh, $\mathbf{y}=0$ plane.

Figure 4.1.23. Denovo mesh, $\mathbf{z = 2 0}$ plane (through near detector).

### 4.1.5.3.1 Input file

The following input file represents the simple model of the litho-density tool. The following is a listing of the file mavric.lithoFW.inp located in the SCALE samples $\backslash$ input directory. The 27 neutron group/19 photon group library based on ENDF/B-VII. 0 data was used for the discrete-ordinates calculations, while the final Monte Carlo calculation used the 200 neutron group/47 photon group library.

The input file starts with the problem title, the library for the importance calculations, and the materials.

```

end geometry
```

The definitions block lists the response (total photon flux) in a way that can be understood by both libraries used in the problem. The mesh grid for the importance calculations used $49 \times 43 \times 59=124,313$ mesh cells, with particular emphasis on geometric representation of the collimators to ensure accurate importance maps. This mesh grid is shown in Figure 4.1.22 and Figure 4.1.23. The source is represented by a distribution in which the most probable bin is located right near the 661.7 keV line, which can be translated into one photon group in either library (from 600 to 800 keV in the $27 / 19$ library or from 600 to 700 keV in the 200/47 library).

The source is a simple point source. For more realistic calculations, the source strength could be modified so that the total energy emitted is preserved, $S^{\prime}=S(661.7 / 0.5(700+600))$, which uses the ratio of the line energy to the energy at the center of the group in the 200/47 library.

```
read sources
    src 1
        title="Cs-137 Source: 661.7 keV"
        strength=1.0e11
        photons

    randomSeed=00003ecd7b4e3e8b
    perBatch=466000 batches=24
    noNeutrons
end parameters
```

The importance map defines two adjoint sources, corresponding to the two tallies. Forward weighting, based on the response integrated over energy ("respWeighting"), is used. Because the true source is a point source, the subcell method of making a mesh source will fail, so the number of source trials is input.

This number is small since the source is a monoenergetic point source. The Denovo calculations used the default $\mathrm{S}_{8}$ quadrature and $\mathrm{P}_{3}$ Legendre order.

```
read importanceMap

        unit=1 region=4
        responseID=1
    end adjointSource
    respWeighting
    sourceTrials=100
end importanceMap
end data
end
```

### 4.1.5.3.2 Output

The results for the two region tallies, the first for the near detector and the second for the far detector after 60 minutes of computations (3 forward Denovo, 4 adjoint Denovo and 52 Monaco), were as follows.

Note that both detectors have similarly low relative uncertainties (about 1\%) even though the tally values differ by a factor of 30 . These results should be compared to analog results (no biasing at all) and optimizations of each detector in separate input files, as shown in Table 4.1.22. The CADIS calculations for each detector (near or far) do exactly what they were supposed to do - optimize the Monte Carlo calculation for one tally or the other. The FOMs for the FW-CADIS calculation were about half of the FOMs for the single-detector CADIS calculations. Hence, for this two-detector problem, two CADIS calculations are just as efficient as one FW-CADIS calculation. For modern well-logging tools with up to a dozen detectors, a single FW-CADIS would be much more efficient and manageable. Note that the near detector still needs more time to pass the second (uncertainty fit) and the fourth (VOV fit) statistical checks. Neither of the single-detector CADIS calculations passed the fourth statistical check within an hour.

Figure 4.1 .24 shows a mesh tally of total photon flux in the $y=0$ plane for all four of the simulations: analog, CADIS for the near detector, CADIS for the far detector, and the FW-CADIS calculation for both.

Table 4.1.22. Comparison of different CADIS techniques for the litho-density problem

|  | Time (min) |  |  | Near Detector |  |  | Far Detector |  |  |

### 4.1.5.4 AOS-100 using FW-CADIS and continuous-energy transport

The advanced variance reduction in MAVRIC can also be used when the final Monaco Monte Carlo transport calculation is performed using a CE cross section library. Simulations involving discrete-energy photon sources are best handled with CE. Consider the AOS-100, one of several radioactive material transport packaging systems developed by Alpha Omega Services Inc., and a cobalt-60 source. (International Isotopes Inc. of Idaho Falls, Idaho, distributes the AOS Radioactive Material Transport Packaging Systems.)

A simple model of the AOS-100 package, which is constructed primarily of steel and tungsten, is shown in Figure 4.1.25. The diameter is 71.12 cm and the height is 91.44 cm . The innermost cylinder ( 16.51 cm diameter and 50.8 cm height) typically contains the material to be transported, but in this study, this region is simply modeled as an air region containing a uniform source of 1 Ci of cobalt-60. This is conservative-it assumes the radioactive material containing the cobalt provides no selfshielding.

The objective in this study is to compute the dose rates around the cask. This can be done via using a mesh tally. Note that the dose rates inside the package are not of concern-only the dose rates outside the package are.

The results of a 15 -hour analog calculation (using only implicit capture with a lower weight limit of $10^{-7}$ ) are shown in Figure 4.1.26. Note that this calculation does not show many photons that have escaped the package into the air, which is similar to reality for this heavily shielded cask. In order to compute dose rates outside the package, variance reduction is

Figure 4.1.25. Simple AOS-100 cask geometry showing tungsten (brown) and steel (gray). needed.

Figure 4.1.26. Dose rates ( $\mathrm{mrem} / \mathrm{hr} / \mathrm{Ci}$ ) and relative uncertainties along the $\boldsymbol{y}=\mathbf{0}$ midplane of the cask as calculated by an analog calculation.

### 4.1.5.4.1 Input file

The sample problem file mavric.aos100.inp is located in the samples $\backslash i n p u t$ directory. For this demonstration, a very simplified geometry is used, with a few tungsten regions inside a steel cylinder. The library given at the beginning of the input is the MG library for the importance calculations. The final Monaco Monte Carlo calculation will use the CE library, which is specified in the parameters block. About 1 meter of air is modeled around the cask.

In the definitions block, the photon dose response function, the cobalt-60 line spectrum, two grid geometries, and an energy boundaries structure are all defined. The first grid geometry is used for the deterministic calculation, the importance map, and biased source. The second grid geometry is for the high-resolution (1 in.) mesh tally. The energyBounds defined here has a base structure of 30 bins that are 50 keV wide, with three bins that are 2 keV wide at the dominant cobalt line energies and the $511-\mathrm{keV}$ annihilation gamma energy.

The source is modeled as a uniform volumetric source in the center region of the cask. Because the distribution of cobalt gamma rays was entered as gammas per decay, the keyword "useNormConst" will set the source strength to be the total of the energy distribution-about 2 photons/decay. The "multiplier" keyword is used to multiply that strength by 37 e 9 decays/sec to get 1 Ci .

```
read sources
    src 1
        title="one Ci of cobalt-60"
        useNormConst
        multiplier=37e9
        cylinder 8.255 25.40 -25.40
        photons
        eDistributionID=1
    end src
end sources
```

A single mesh tally is defined and is limited to the air region outside of the cask. A multiplier of 1000 is used to convert the response values from rem/hr to $\mathrm{mrem} / \mathrm{hr}$.

```
read tallies
    meshTally 1
        photon
        gridGeometryID=8
        responseID=5
        unit=1 region=7
        energyBoundsID=1
    end meshTally
    multiplier=1000.0
end tallies
```

In this problem, the importance calculations will use the 200/47 MG library, which will transport all particles contained in the library by default. The keyword "noNeutrons" is used to turn off neutron transport during the Denovo calculations, saving time. The final Monaco calculation will use the CE library ("ceLibrary="), which only transports the particles specifically requested by the user (to avoid loading large amounts of cross section from disk to memory). Thus, the keyword "photons" is included to specifically tell the CE Monaco to transport photons.

```
read parameters
    randomSeed=00003ecd7b4e3e8b
    ceLibrary="ce_v7np_endf.xml"
    perBatch=2000000 batches=233
    photons noNeutrons
end parameters
```

The importance map uses FW-CADIS to construct a map and biased source that will optimize the photon dose rate in the air outside the cask. Since photon scatter is typically forward peaked, an $\mathrm{S}_{12}$ quadrature and $\mathrm{P}_{5}$ Legendre scattering expansion are used.

```
read importanceMap
    adjointSource 1
        boundingBox 139.7 -139.7 139.7 -139.7 152.4 -152.4

end importanceMap
```

### 4.1.5.4.2 Output file

Results for the mesh tally after 958 minutes ( 27 forward Denovo, 31 adjoint Denovo, and 900 CEMonaco) are shown in Figure 4.1.27. Note that since dose rates inside the package are not of concern, that region was excluded from the mesh tally. Due to the optimization that focused the Monte Carlo calculation on dose rates outside the cask, values of the dose rate inside the cask are underestimated and should not be used. Also note that voxels along the outer cylindrical edge of the package could show low dose rates, since the voxel value is an average and only part of the voxel is actually outside the package. The resolution of the mesh tally is 2.54 cm .

Figure 4.1.27. Dose rates ( $\mathrm{mrem} / \mathrm{hr} / \mathrm{Ci}$ ) and relative uncertainties from the CE, FW-CADIS calculation, showing the midplane views of the cask ( $z=0$ above and $y=0$ below).

The flux using the user-defined energy bin boundaries for a point 10 cm above the top of the package (along the axis) is shown in Figure 4.1.28. Note that since the importance map was made to optimize the photon dose rate, some of the lowenergy bins (that do not contribute to dose much) may have larger uncertainties.

Figure 4.1.29 and Figure 4.1.30 show the ratios of the dose rates computed using a MG calculation to the CE calculation. Dose rates inside the cask should not be compared because the importance map is focused on

Figure 4.1.28. Flux 10 cm above the cask. dose outside the cask, so low-energy photons are not simulated inside. The 47 group MG calculation is fairly close to the CE-calculation in dose rate (10\% high axially, $20 \%$ high radially), but the 19 group MG dose rates are much higher than the CE. Neither of the MG calculations shows the 1.17 and 1.33 MeV lines in the energy spectra.

Figure 4.1.29. Ratio of the $\mathbf{4 7}$ group MG computed dose rates to the CE dose rates ( $y=0$ left and $z=0$ right).

Figure 4.1.30. Ratio of the 19 group MG computed dose rates to the CE dose rates ( $y=0$ left and $z=0$ right).

### 4.1.5.5 Independent spent fuel storage installation

A good example of a problem where the dose rate needs to be known well everywhere-in low dose areas and high dose areas-is an independent spent fuel storage installation. The dose rates around these arrays of spent fuel casks need to be evaluated over a large area of ground in order to determine the boundary of the controlled area. This sample problem uses a simplified model of a cask array, shown in Figure 4.1.31 and Figure 4.1.32, to demonstrate the FW-CADIS method for obtaining the dose rates with reasonably low relative uncertainties over a mesh tally which covers a very large area.

Figure 4.1.31. Array of eight casks.

Figure 4.1.32. Cask detail.

### 4.1.5.5.1 Source term

The calculation of the spent fuel source term using data from the Kewaunee nuclear power plant is described in the cask example problem and is modeled in the first part of mavric.isfsi.inp with ORIGEN. The result of this calculation is a binary concentration (ft71f001) file. This file also contains a listing of the group-wise neutron source term ("total neutron spectra, neutrons/sec/basis") and photon source term ("gamma spectra, photons/sec/basis") for each time step. In this example problem, the source term for the MAVRIC calculation will be read directly from the binary concentration file. The file contains the concentration and source-term data at each of 64 time steps. For this analysis the photon source at the last time step will be used.

### 4.1.5.5.2 Input file

The following is a listing of the second part (the MAVRIC input) of the file mavric.isfsi.inp located
 account for dose near the ground. The mesh tally does not extend into the air above 2 meters since we are only concerned about the area near the ground where people could be. For MAVRIC to read the ORIGEN binary concentration file, it must be named as a Fortran unit file with a number matching the distribution input. In this example, unit 71 is used in both the ORIGEN input and MAVRIC input.

The source can be done in two ways. Since there are eight casks, eight sources could be defined, each over a cylinder with a strength of $7.155 \times 10^{16}$ photon/s. In this example of eight identical sources, one source region can be defined and then limited to only exist in the spent fuel material (the first material) but with a strength for all the casks of $5.724 \times 10^{17}$ photon/s.

```

### 4.1.5.5.3 Output

The MAVRIC calculational times were 3 minutes for the forward Denovo, 3.5 minutes for the adjoint Denovo, and 60 minutes for the Monaco forward Monte Carlo. Results for the mesh tally of dose rates are shown in Figure 4.1.33. For a longer Monaco calculation ( 64 hr ), the mesh tally results are shown in Figure 4.1.34. Note that the scale for the dose rate has been adjusted to only show the values outside of the cask array.

Using the Mesh File Viewer, the distribution of relative uncertainty in a mesh tally can be plotted. For this 1 hr calculation, $50 \%$ of the voxels in the mesh tally had less than $20 \%$ relative uncertainty. Figure 4.1.35 shows how the distribution of relative errors changes with longer run times. For the 64 hr run, $90 \%$ of the voxels had less than $10 \%$ relative uncertainty.

Figure 4.1.33. Photon dose rate values in rem/hr (left) and the relative uncertainty (right) for the area around the cask array ( $\mathbf{1} \mathrm{hr}$ Monaco).

Figure 4.1.34. Photon dose rate values in rem/hr (left) and the relative uncertainty (right) for the area around the cask array ( 64 hr Monaco). For the uncertainty plot, purple represents <=5\%.

Figure 4.1.35. Distribution of relative uncertainties for different run times of mavric.isfsi. inp. This plot shows what fraction of the mesh tally voxels had less than a given amount of relative uncertainty.

### 4.1.5.6 TN24-P spent fuel cask

As an example that uses multiple sources, user-defined distributions in those sources, macromaterials for improved $\mathrm{S}_{\mathrm{N}}$ calculations, and the automated variance reduction capabilities in MAVRIC, consider the model for the TN-24P cask, as used in previous SCALE shielding reports ${ }^{19}$ and shown in Figure 4.1.36. This model contains two types of PWR spent fuel assemblies (Types V and W, both Westinghouse $15 \times 15$ assemblies of different starting enrichments and burnups), each with specified neutron and photon sources, in an aluminum/boron fuel basket. The cask is made of forged steel for photon shielding with a resin layer for neutron shielding. Also included in the model are three activated hardware regions (bottom nozzle, top nozzle, and top plenum), which consist of specified amounts of ${ }^{60} \mathrm{Co}$ (a photon source). The task for this example is to calculate the total dose rate within 2 meters of the cask surface.

Figure 4.1.36. MAVRIC model of the TN24-P cask. Materials: spent fuel (light and dark yellow), steels (blues), resin (green), and other metals (gray).

For MAVRIC, this means the calculation of a dose rate mesh tally using FW-CADIS to ensure that each voxel has low relative uncertainty, independent of the dose rate. Without MAVRIC, the calculation of dose rate everywhere in three dimensions would be too challenging. Most likely, the dose rate would be evaluated with reasonable uncertainty at only a few locations. In fact, with analog calculations, this example would be a very difficult problem since most source particles never leave the cask, just as in the real-life situation. This type of problem really benefits from the CADIS-biased source distribution, in which source particles deep inside the cask are sampled very rarely since they do not contribute significantly to the response.

### 4.1.5.6.1 Input file

The following is a partial listing of the file mavric.tn24p.inp located in the SCALE samples $\backslash i n p u t$ directory. This calculation will use the coarse-group shielding library for all of the importance map calculations but then use the fine-group library for the final Monaco step. The full geometry and source distributions are not printed here due to their length.

    cylGeometryID=3
    responseID=2
    noGroupFluxes
end meshTally
end tallies
```

The goal of this example is to calculate the total dose outside the cask. Hence, the adjoint source uses the total dose rate response function for its energy component, while for the spatial component, it uses a large block around the cask. Note the "mixture=" keyword, which restricts the adjoint source to only exist where the material is air (13). There is no need to put adjoint source deep in the cask since the dose rates inside the cask are not of interest. Response weighting is used to put more adjoint source in the low dose areas outside the cask. Note that since this area is air, not many interactions/scatter take place, so we should not expect a great balance in relative uncertainties near and far from the cask. Macromaterials are used to improve the results from the discrete-ordinates calculations, which should improve the FOM of the final Monaco calculation. The geometry images in Section 4.1.3.4.2 are taken from this problem.

### 4.1.5.6.2 Output

The distributions used by the source descriptions of the TN24-P model are shown in Figure 4.1.38, and the responses used in this problem are shown in Figure 4.1.37. Figure 4.1.39 and Figure 4.1.40 show the total (neutron + photon) dose rate outside the TN24-P cask, up to 2 meters from each surface using a rectilinear and a cylindrical mesh tallies with 10 cm voxels. Uncertainties in the computed dose rates were $3-4 \%$ after this 16 hr calculation. The scale of the figure was adjusted to only show the dose rate outside the cask; dose rates inside the cask went as high as $6 \times 10^{5} \mathrm{rem} / \mathrm{hr}$. Likewise, the scale of the uncertainties ranged from 0 to $10 \%$ to highlight the uncertainties outside the cask. Relative uncertainties inside the cask were much higher (white areas) since those areas were deemed unimportant by the chosen adjoint source. Obtaining dose rates on a 10 cm mesh would not be achievable without the variance reduction capabilities of MAVRIC.

### 4.1.A CAAS Capability

### 4.1.A. 1 Introduction

Modeling criticality accident alarm systems (CAAS) presents challenges since the analysis consists of both a criticality problem and a deep-penetration shielding problem. ${ }^{1,2}$ Modern codes are typically optimized to handle one of those types of problems but usually not both. The two problems also differ in scale-the criticality problem depends on materials relatively close to the fissionable materials while the shielding problem can cover a much larger range. SCALE now contains fully three-dimensional tools to perform both parts of a CAAS analysis.

CAAS analysis can be performed with SCALE using the KENO-VI criticality code and the MAVRIC shielding sequence. First, the fission distribution (in space and energy) is determined by KENO-VI. This distribution is saved to a file using a user-specified three-dimensional mesh grid and an energy structure from the cross section library (or a user-defined energy structure). MAVRIC then uses the fission distribution as the source for a shielding calculation. MAVRIC is designed to implement advanced variance reduction methods to calculate dose rates or detector responses for difficult shielding problems.

For different types of shielding and different combinations of sources and detector locations, different strategies can be used within SCALE. ${ }^{3,4}$ Due to the way that cross sections for neutron reactions that create photons are stored in ENDF, some of the parameters used in the CAAS capability have changed since SCALE 6.1. Please be sure to understand and follow the new guidance for the correct accounting of secondary photons from neutron reactions. ${ }^{5,6,7}$

### 4.1.A. 2 Methods

The CAAS capability in SCALE is a two-step approach using KENO-VI and MAVRIC. The first step is the determination of the source distribution, done with the CSAS6 sequence which uses the KENO-VI functional module. Along with calculating the system $k_{e f f}$, KENO-VI has been modified to now accumulate the fission distribution over the non-skip generations. This information is collected on a threedimensional Cartesian mesh that overlays the physical geometry model and is saved as a Monaco mesh tally file. A utility program is used to convert the mesh tally into a Monaco mesh source.

The mesh source is then used in the second step as the source term in MAVRIC. The absolute source strength is set by the user based on the total number of fissions (based on the total power released) during the criticality excursion. Further neutron multiplication should be prevented in the MAVRIC transport calculation. Because the fission neutrons have already been accounted for in the KENO-VI calculation, failure to suppress neutron multiplication in the MARVIC sequence would lead to incorrect flux estimates. In addition, if further fissions were allowed, Monaco would add neutrons to its particle bank faster than they could be removed (since the system is at or above critical) and the simulation may never finish.

For the transport part of a CAAS analysis, MAVRIC can be optimized to calculate one specific detector response at one location using CADIS or can be optimized to calculate multiple responses/locations with roughly the same relative uncertainty using FW-CADIS. For calculating mesh tallies of fluxes or dose rates, MAVRIC also uses FW-CADIS to help balance the Monaco Monte Carlo calculation such that low flux voxels are computed with about the same relative uncertainty as high flux voxels.

With this two-step approach, users will have a great deal of flexibility in modeling CAAS problems. The CSAS6 step and the MAVRIC step could both use the same geometry and materials definitions or could
have different levels of detail included in each. The fission source distribution from one CSAS6 calculation could be used in a number of different MAVRIC building/detector models, with each MAVRIC calculation being optimized for a given type of detector.

### 4.1.A. 3 User input

The user can create either one input file containing both the CSAS6 and MAVRIC calculations or can create two input files-one for each sequence. The materials and geometry for these two models could be the same but do not have to be. For example, the CSAS6 sequence might only contain the materials and geometry important to the criticality calculation. Note, however, that the critical source geometry and materials should be modeled identically in both problems. This allows users greater flexibility in modeling their specific problems.

### 4.1.A.3.1 KENO-VI input

For the criticality problem, the only extra input a user needs to supply is the keyword "cds=yes" in the parameter block and a spatial mesh around all of the fissionable materials of the problem in its own gridGeometry block. Standard input for KENO-VI is described in the KENO-VI chapter and CSAS6 chapter. The mesh used for the fission source distribution is input using the "read gridGeometry id" block, where id is an identification number for that grid. Note that only one grid can be specified, but that may change in the future. The cells of the mesh are specified in each dimension separately by either (1) listing all of the planes bounding the cells (keyword "xplanes" followed by an "end"), (2) using keyword "xLinear $n a b$ " to specify $n$ cells between $a$ and $b$, or by (3) specifying the minimum plane, the maximum plane, and how many cells to make in that dimension ("xmin=", "xmax=", "numXCells="). The keywords "xplanes" and "xLinear" can be used together and multiple times. Similar keywords are used for the $y$ - and $z$-dimensions. An example CSAS6 input file that collects the fission distribution information would be as follows:

```
=csas6
CAAS Example
v7-238n
read composition
end composition
read parameters
    cds=yes
end parameters
read geometry
end geometry
read gridGeometry 1
    title="Mesh for Collecting Fission Source"
    xLinear 13 0.0 78.0
    yplanes 0 8 16 24 32 34 36 38 40 48 56 64 72 end
    zLinear 10 -2.54 77.46
end gridGeometry
end data
end
```

The fission source distribution collected by KENO-VI is saved to a Monaco mesh tally file and copied back to the home area with the name "problemName.fissionSource.3dmap". This file can be viewed with the Mesh File Viewer capability of Fulcrum that comes with SCALE. Note that the finer the mesh spacing is the more generations/histories will have to be simulated by the criticality calculation in order to reduce the stochastic uncertainty in each mesh voxel of the distribution. Regardless of the mesh size, creation of a fission mesh source file will take more iterations than the number required to find $k_{\text {eff. }}$.

KENO-VI also saves the value of the system $\bar{v}$, the average number of neutrons per fission, in a file called "problemName.kenoNuBar.txt". This value is needed to properly determine the source strength.

### 4.1.A.3.2 Mesh tally to mesh source conversion

A utility program is used to convert the Monaco mesh tally file into a Monaco mesh source file. It can be part of the CSAS6 input file. The user then needs to copy the resulting *.msm file back to his home area.

```
=csas6
end
=mt2msm
'fissionSource.3dmap' ! existing Keno fission source mesh tally
1 ! which family (for Keno files, there is only 1)
-1 ! use the whole family (keep all energy groups)
1 ! particle type for *.msm file (1-neutron, 2-photon)
'fissionSource.msm' ! name of newly created mesh source map file
end
=shell
    copy fissionSource.msm "C:\mydocu~1\caasExample"
end
```

Details on the conversion utility program are contained in Appendix B of the MAVRIC manual.
In SCALE 6.1, the fission source distribution mesh tally produced by KENO contained data representing the number of fissions in each mesh cell in each energy group. In SCALE 6.2, the data stored was changed to be the fissions per unit volume - the fission density. This is more consistent with other mesh tallies from Monaco which store flux or dose rates that represent averages over the mesh cells. This change also allows the Mesh File Viewer to display the KENO fission source distribution better. The mt 2 msm utility program also changed from SCALE 6.1 to SCALE 6.2 to account for the change in what is stored in the Keno mesh tally file. Therefore, KENO-produced fission source mesh tallies and the mt2msm utility should not be mixed-and-matched across versions of SCALE. Doing so would result in the final Monaco mesh source file being improperly normalized, which would not represent the KENO fission source distribution and would give incorrect results in subsequent MAVRIC calculations. Because there is not a specific 'version flag' in a mesh tally file or mesh source map file, the user must ensure that they have used the same version of SCALE for both the CSAS6 and MAVRIC sequences any time the CAAS capability is used.

### 4.1.A.3.3 MAVRIC input

The input for the MAVRIC portion of the CAAS problem should include the materials and geometry of the criticality model, use the fission distribution as a source, set the source strength, and set any optional modifiers to the source to change its location or add fission photons. The cross section library used by the MAVRIC calculation does not need to have the same group structure as the fission distribution. MAVRIC will automatically convert the fission source group structure to match the group structure of its cross section library.

The shielding calculation needs to specify that the source is the fission distribution file, which is typically "fissionSource.msm". The total source strength can be specified by either the number of fissions in the criticality accident (fission rate or total number) or by the number of released neutrons (the fission rate multiplied by $\bar{v}$ per fission). The value of $\bar{v}$ will be read from the file "kenoNuBar.txt" in the SCALE
temporary directory if it is not given in the source input with the keyword "nu-bar=". The mesh source can also be placed at different coordinates in the geometry using the "origin $x=x y=y \mathrm{z}=\mathrm{z}$ " keywords, if a different reference frame was used with the criticality geometry model that created the mesh source. Rotations of mesh sources are not available at this time. It is also recommended to use filters in the source block to define the source, such as the 'mixture=' filter to only allow source sampling from a specific mixture since the mesh source can be transformed from it's original origin or meshes can cover nonfissionable materials.

For example, using a KENO-VI fission distribution, placing it somewhere in the MAVRIC model and setting the source strength (in neutrons/s) to correspond to $10^{17}$ fission/s would look like

```
=shell
    copy "C:\mydocu~1\caasExample\kenoInput.kenoNuBar.txt" kenoNuBar.txt
end
=mavric
read sources
    src 1
        meshSourceFile "C:\mydocu~1\caasExample\fissionSource.msm"
            origin x=600 y=650 z=400
        fissions=1.0e17
    end src
end sources
end data
end
```

The source strength in neutrons/s will be calculated by MAVRIC to be the fission rate multiplied by the value of $\bar{v}$ read from the "kenoNuBar.txt" file. The neutron strength could have alternatively been specified using the standard source strength keyword "strength=2.5e17" (for an example with the average number of neutrons per fission of 2.5).

The Monte Carlo functional module used by MAVRIC, Monaco, is a fixed-source code. Unless told otherwise, neutrons will multiply in fissionable materials. Since all of the neutrons were part of the source, neutron multiplication should not be allowed and MAVRIC should be run with the keyword "fissionMult=0" in the parameters block. For systems at or near critical without the "fissionMult=0" keyword, Monaco simulations may not end since neutrons will be added to the particle bank at the same rate they leave the system or get killed.

The shielding calculation can be run using standard variance reduction methods (such as path length stretching, user-defined weight windows based on geometry regions, and user-defined source biasing) or using the automated tools which employ approximate discrete-ordinates calculations to determine the space/energy weight windows as well as a biased source distribution in space and energy. The automated tools can be used to optimize the shielding calculation to determine one specific tally using CADIS or several separate tallies or a mesh tally over a large volume of the problem space using FW-CADIS. When using these advanced variance reduction methods, remember to include planes in the discrete-ordinates mesh definition that correspond to the planes in the fission distribution that the source is based on. If they are not included, MAVRIC will resample the fission source on the discrete-ordinates mesh it is using for the importance map, possibly smearing or reducing the original resolution of the fission distribution.

### 4.1.A. 4 Example problem

Consider the Jezebel critical plutonium sphere experiment, shown in Figure 4.1.A.1, taking place inside a simple fictitious building, shown in Figure 4.1.A.2. The building has two rooms: an experiment room and a control room. In the control room there is a criticality alarm detector, and it is positioned furthest from the entry to the experiment room. For this example, assume that a criticality excursion results in a total of $10^{18}$ fissions. This example will calculate the neutron and photon doses seen by a detector in the control room, as well as calculate a dose map for the entire building.

Figure 4.1.A.1. Cutaway view of Jezebel.

Figure 4.1.A.2. Simple two-room building.

### 4.1.A.4.1 KENO-VI criticality and fission source distribution

For the criticality calculation, consider just a bare sphere of plutonium, with a radius of 6.38493 cm . Atom densities (atoms $/ \mathrm{b} \cdot \mathrm{cm}$ ) for the sphere material are ${ }^{239} \mathrm{Pu} 0.037047$; ${ }^{240} \mathrm{Pu} 0.0017512$; ${ }^{241} \mathrm{Pu}$ 0.00011674 ; and Cu 0.0013752 . This can be easily modeled as a sphere at the origin. For collecting the fission distribution, a uniform mesh grid can be constructed around the sphere, extending 7 cm in each direction, with a $1 \times 1 \times 1 \mathrm{~cm}$ voxel size. The first portion of the input files mavric.caasA.inp and mavric.caasB.inp looks like the following:

```
=csas6

| $k_{\text {eff }}$ | best estimate system k-eff | 1.00024 | 0.00014 |
| $\bar{\nu}$ | system nu bar | 3.15671 | $4.77938 \mathrm{E}-05$ |

Figure 4.1.A.3. Fission source spatial distribution for the center horizontal slice.

Figure 4.1.A.4. Fission source energy distribution for the center voxel.

### 4.1.A.4.2 MAVRIC transport calculations

Two MAVRIC calculations will be done-one that calculates the doses seen at the detector and one that computes mesh tallies of doses over the entire building. They will share the same materials, geometry, and source but will have different tally and variance reduction options.

The two-room building will be a simple model using concrete-block walls, a concrete floor, and a steel roof, with dimensions shown in Figure 4.1.A.5. The building exterior dimensions are 1200 cm long, 600 cm wide, and 300 cm high above the ground. The exterior and interior walls are all made of a double layer of typical concrete blocks (total of 40 cm thick.) Concrete blocks are typically $39 \times 19 \times 19 \mathrm{~cm}$ and weigh $\sim 13.5 \mathrm{~kg}$, since they have a volume fraction of $33.2 \%$. The floor is made of poured concrete, extending 60 cm into the ground. The roof and the exterior door ( 120 cm wide and 210 cm tall) are made of $1 / 8 \mathrm{in}$. $(0.3175 \mathrm{~cm})$ thick steel. The experiment room on the left connects to the control room on the right through a maze that prevents radiation streaming. Assume that the critical experiment was in the center of the experiment room, 100 cm above the floor. Assume the detector in the control room is a 30 cm diameter sphere located at position (1145, 55, 285).

Figure 4.1.A.5. Coordinates of the floor, walls, ceiling, and door of the simple block building model (in cm).

If the MAVRIC transport calculation is not in the same file as the CSAS6 calculation, the MAVRIC input would start by moving the KENO-VI results into the SCALE temporary area:

```
=shell
    copy %RTNDIR%\caas.kenovi.fissionSource.msm fissionSource.msm
    copy %RTNDIR%\caas.kenovi.kenoNuBar.txt kenoNuBar.txt
end
```

The materials and geometry blocks of the two MAVRIC input files for each of the two calculations, smplprbs/caas.mavricA.inp and smplprbs/caas.mavricB.inp, look like the following:

```
'------------------------------------------------------------------------------
' Composition Block
'-------------------------------------------------------------------------------

        com="detector"
        media 0 1 40 vol=14137.167
    boundary 10
end geometry
```

The response functions used to compute the doses will be the standard flux-to-dose rate conversion factors for neutrons and photons. These are defined in the definitions block. Note that these responses have units of (rem $/ \mathrm{hr}$ )/(/cm²$/ \mathrm{s}$ ).

```
' Definitions Block
'----------------------------------------------------------------------------------
read definitions
    response 5
        title="ANSI (1977) neutron flux-to-dose-rate"
        specialDose=9029
    end response
    response 6
        title="ANSI (1977) photon flux-to-dose-rate"
        specialDose=9504
    end response
end definitions
```

The source used by each MAVRIC simulation will be based on the fission distribution mesh source determined by KENO-VI. The strength of the source can be specified by the total number of fissions that occurred in the criticality event. Fission photons will be added for ${ }^{239} \mathrm{Pu}$. MAVRIC will determine the total source strength, including the fission photons, from the value of $\bar{v}$ saved by KENO-VI and the multiplicity data from the fission photon data file.

```
------------------------------------------------------------------------------
' Sources Block
'--------------------------------------------------------------------------------
read sources
    src 1
            meshSourceFile="fissionSource.msm"
            origin x=280 y=300 z=100
            fissions=1.0e18
            mixture=1
        end src
end sources
```

Note that further multiplication needs to be turned off in MAVRIC using the "fissionMult=0" keyword in the parameter block as shown below.

For the responses from the tallies, MAVRIC usually calculates dose rates (rem/hr) using a source strength in particles/s. For this example problem, instead of a source rate, we used a total number of particles (by specifying the number of fissions). Hence, the computed fluxes will have units of particles $/ \mathrm{cm}^{2}$ and the computed responses using the standard dose responses from the cross section libraries will have units of rem $\mathrm{s} / \mathrm{hr}$. To get a dose in rem, the responses need to be multiplied by $(3600 \mathrm{~s} / \mathrm{hr})^{-1}$. This can be done using the MAVRIC tally multiplier keyword.

Each MAVRIC simulation will need a discrete-ordinates mesh. The planes in each dimension where there are material changes are listed in Table 4.1.A.2. In addition to these planes, the discrete-ordinates mesh should also subdivide the thick shields in the direction of particle travel. For example, the walls of the maze should be divided to better model the radiation attenuation through the walls in the Denovo calculation. The interior walls of the building will reflect particles, so the first few centimeters are the most important to capture in the importance map. Mesh planes should also be added that correspond to the mesh source after it is placed into the geometry model.

Table 4.1.A.2. Main planes in the building

| $\boldsymbol{x}$ | $\boldsymbol{y}$ | $\boldsymbol{z}$ |
| :---: | ---: | :---: |
| 0 | 0 | -60 |

| 1199.68 | 600 |  |
| 1200 |  |  |

### 4.1.A.4.2.1 Detector doses using CADIS

The grid geometry for this calculation should also include planes that bound the adjoint source, which is the detector area (these values are shown in boldface below). The definitions block in smplprbs/caas.mavricA.inp also includes the location of the center of the detector, which is used in the adjoint source description.

```
location 1
    position 1145 55 285
end location
gridGeometry 1
    title="mesh for discrete ordinates 57 x 47 x 31 = 83049"
    xplanes 0 10 20 30 35
        120 160 240
        270 272 274 276 278 280 282 284 286 288 290
            360440
            520 525 530 550 555
            560 600
            640 645 650 670 675
            680 760 840 920 1000 1080
            1130 1140 1150
            1160 1165 1170 1180 1190
            1199.6825
            1200 end
    yplanes 0 10 10 20 30 35
            40 50 60 70
            120 125 130 140 200
            240 280 290 292 294 296 298 300 302 304 306 308 310
            320
            440 460 470 475
            480
            560 565 570 580 590
            600 end
    zplanes 
                    90 92 94 96 98 100 102 104 106 108 110
            140 175
            210 255 280 290
            300
            300.3175 end
end gridGeometry
```

The tallies are region tallies over the detector region (the 10th media card in unit 1) using the appropriate response function for the particle type of the tally. The volume of the detector sphere needs to be listed in
the geometry block so that the fluxes and tallies will be correctly computed. The importance map uses standard CADIS to bias the particles towards the detectors, optimizing the calculation of the total dose (by listing both response functions together, the total response will be used in the adjoint source).

```
'----------------------------------------------------------------------------
' Tallies Block
read tallies
    regionTally 1
        title="Doses seen by the detector"
        neutron

        multiplier=2.777778e-4
    end regionTally
    regionTally 2
        title="Doses seen by the detector"
        photon
        unit=1 region=10
        responseID=6
        multiplier=2.777778e-4
    end regionTally
end tallies
' Parameters Block - 3 min batch
'------------------------------------------------------------------------------
read parameters
    randomSeed=3263827
    perBatch=654000 batches=40
    fissionMult=0
end parameters
' Importance Map Block
'-------------------------------------------------------------------------------------
read importanceMap
    gridGeometryID=1
    adjointSource 1
        locationID=1
        responseIDs 5 6 end
    end adjointSource
end importanceMap
```

The results of this example problem are shown in Table 4.1.A.3. Calculation times were 12 minutes for Denovo and 135 minutes for Monaco. Note that the uncertainty for the photon dose is much higher than the neutron dose uncertainty. This is because the simulation was optimized for the calculation of total dose, and the photon component of the total dose is less than $2 \%$. Had a separate calculation been done that used an adjoint source of just the photon response, the photon dose rate uncertainty would have been much smaller but at the expense of the neutron dose rate uncertainty. A single calculation could have also been performed using two adjoint sources, one using the neutron dose response and one using the photon dose response, and forward weighting to help calculate each component of dose with more uniform relative uncertainties.

Table 4.1.A.3. Doses seen by the detector

| Dose | Value <br> (rem) | Rel. <br> Unc. |
| :--- | :---: | :---: |
| neutron | 1539 | $0.78 \%$ |
| photon | 30.0 | $8.00 \%$ |

### 4.1.A.4.2.2 Dose map using FW-CADIS

The grid geometry for this calculation does not need extra planes around the detector. The grid geometry in smplprbs/caas.mavricB.inp looks like the following:

```
gridGeometry 1
    title="mesh for discrete ordinates 46x36x23 = 38088"
    xplanes 0 10 20 30 35
                                120 160 240
                                270 272 274 276 278 280 282 284 286 288 290
                360440
            520 525 530 550 555
            560 600
            640 645 650 670 675
            680 760 840 920 1000 1080
            1160 1165 1170 1180 1190
            1199.6825
            1200 end
    yplanes 0 10 20 30 35
            40
            120 125 130 140 200
            240 280 290 292 294 296 298 300 302 304 306 308 310
                320
            360 440 460 470 475
            480 - < 
            560 565 570 580 590
            600 end
    zplanes -60 -30 -20 -10 -5
            0 45
                90 92 94 96 98 100 102 104 106 108 110
                140 175
            210 255
            300 300.3175 end
end gridGeometry
```

A second grid geometry also needs to be added to the definitions block for the mesh tally to use.

```
gridGeometry 2
    title="mesh for uniform mesh tally - 40x40x30 cm voxels"
    xLinear 30 0.0 1200.0
    yLinear 15 0.0 600.0
    zLinear 10 0.0 300.0
end gridGeometry
```

The mesh tallies for each particle type are listed, along with the appropriate response function. The importance map uses FW-CADIS to better spread the particles out over the entire geometry, optimized for the calculation of total dose in the void regions.

```
'------------------------------------------------------------------------------
' Tallies Block

    end adjointSource
    respWeighting
end importanceMap
```

This calculation used 5 minutes for the forward Denovo $S_{N}$ calculation, 6 minutes for the adjoint Denovo, and 120 minutes for the Monaco Monte Carlo. The resulting mesh tally is shown in Figure 4.1.A.6. The uncertainties for each voxel are shown in Figure 4.1.A.7. Note that the dose in the voxel containing the detector (not shown in the figures) is $1.552 \times 10^{3}$ rem with a relative uncertainty of $3.8 \%$, closely matching the value calculated with the first MAVRIC simulation.

Similar to the detector doses above, a single calculation could have also been performed for the dose maps using two adjoint sources, one using the neutron dose response and one using the photon dose response, and forward weighting to help calculate each component of dose with more uniform relative uncertainties.

Figure 4.1.A.6. Dose (rem) results for the $\mathbf{z}=100 \mathrm{~cm}$ plane (containing the source).

Figure 4.1.A.7. Relative uncertainties in the dose, most less than $1 \%$, for the $\mathbf{z = 1 0 0} \mathbf{~ c m}$ plane.

### 4.1.A. 5 Summary

SCALE now has the capability to do detailed simulations of criticality accident alarm systems. The advanced variance reduction capabilities of the MAVRIC radiation transport sequence allow for the full three-dimensional analysis of CAAS problems in reasonable amounts of computer time. This enables the use of more realistic source definitions, such as a detailed spatial/energy dependent fission source distribution determined by the KENO-VI criticality code, and the critical assembly itself can be included in the transport model.

### 4.1.B MAVRIC Utilities

### 4.1.B. 1 Introduction

Several utilities are provided to aid users in dealing with some of the output files produced by Monaco and MAVRIC. These utilities were developed at ORNL for specific projects and have been added to SCALE so that all users can benefit. More utilities have been added that deal with Denovo, including the older *.varscl files for flux output used in SCALE 6.1 and the current binary *.dff file for flux output used in SCALE 6.2. These tools do not have the modern block/keyword input structure but instead have a fixed format, which is fairly simple since each utility is made for a very specific function.

Each is described in the following sections. Five sample problems, mavricUtilities1.inp, mavricUtilities2.inp, mavricUtilities3.inp, mavricUtilities4.inp and mavricUtilities5.inp demonstrate the use of some of these. For all of these utilities, filenames should be enclosed in quotes.

### 4.1.B. 2 Utilities working with Monaco mesh tally (*.3DMAP) files

Mesh tally files (*.3dmap) are binary files describing the mesh, optional integer data sets and optional real data sets with their uncertainties organized into related 'families'. The integer data sets are generally used to describe aspects of the geometry or materials of the problem. An example of a family of real data sets would be flux by energy group. Each group flux could have an uncertainty and all of the groups can be added together to make the total flux. These utilities include:

| mt2ascii | Convert a mesh tally into an ASCII text file. |
| :---: | :---: |
| mt 2 msl | Convert a mesh tally into a mesh source lite. |
| mt 2 msm | Convert a mesh tally into a mesh source. |
| mt2silo | Convert a mesh tally file into a Silo file for VisIt. |
| mt2vtk | Convert one dataset of one family in a mesh tally to VTK format. |
| mtAdder | Add several Monaco mesh tally files together into one mesh tally. |
| mtAverager | Average several Monaco mesh tally files into one mesh tally. |
| mtBinOp | Binary operation of mesh tally files: sum, difference, product, and ratio. |
| mtDisp | Display the basics of a mesh tally file. |
| mtExpand | Expand a space-only mesh from a mesh tally with an energy function. |
| mtFilter | Perform various filters on a mesh tally file. |
| mtInv | Invert all of the values in a mesh tally. |
| mtMask | Keep only or remove specified voxels of a mesh tally based on geometry. |
| mtMinMax | Find the location/value of the min or max of each real mesh in a mesh tally. |
| mtMultiply | Multiply a mesh tally by a constant factor. |
| mtPull | Pull values from certain voxels out of a mesh tally file. |
| $m t$ Refine | Subdivide the mesh into smaller meshes for better visualization. |
| mtResp | Apply a response function to one family of a mesh tally file. |
| mtSplit | Split off part of a mesh tally file into a separate mesh tally file. |

mt2ascii - Convert a mesh tally into an ASCII text file.
Intended use: Since mesh tally files are in binary, the viewer can be used to list mesh values. To get the values from the entire file, this utility can be used to create an ASCII text version.

Input: The mesh tally file name and the filename for the resulting ASCII file
Output: An ASCII formatted file Example:

```
=mt2ascii
"/optional/path/meshTallyFilename.3dmap" ! the mesh tally
"/optional/path/outputFilename.txt" ! output file name
end
```

## mt2msl - Convert a mesh tally into a mesh source lite.

Intended use: Convert a fissionSource.3dmap mesh tally computed by KENO into a meshSoureLite (*.msl) file that can be used by a subsequent KENO run using starting source type nst=9.

Input: Name of mesh tally (*.3dmap) file
Output: A mesh source lite (*.msl) file
Example:

```
=mt2msl
"input.3dmap" ! mesh file (*.3dmap) name
1 ! family
14 ! group, or 0 for family total
"result.msl" ! mesh source lite (*.msl) file name
end
```

## mt2msm - Convert a mesh tally into a mesh source.

Intended use: Turn a tally of fission rate data into a mesh source file. Mesh tallies are stored in a generic *.3dmap format, which consist of several families, each with one or more datasets. A typical mesh tally (without the "noGroupFluxes" keyword) contains three families: the neutron fluxes with each energy group as a dataset, the photon fluxes with each energy group as a data set, and the responses with each response as a dataset. This program uses the spatial information of the mesh tally and combines a usergiven energy distribution for all voxels. A second way to use this program is to use a whole family (all the energy groups) without a user-given energy distribution.

Input:
Line 1: filename of mesh tally
Line 2: which family of tally
Line 3: which dataset of that family (or 0 for sum of family)
Line 4: source type: 1-neutron, 2-photon
Line 5: number of bins for mesh source
Lines : energy ( eV ) and pdf values
Lines : energy ( eV ) and pdf values
Lines : energy (eV) and pdf values
Line : energy (eV)
Line last: desired output name
Input:
Line 1 : filename of mesh tally

Line 2: which family of tally
Line 3: -1 (meaning use the whole family)
Line 4: source type: 1-neutron, 2-photon
Line 5: desired output name
Output: The resulting mesh source stored with the desired filename
Notes: Statistics of mesh tally are discarded.
Example:

```
=shell
    cp ${RTNDIR}/barrel1.mt1.3dmap .
end
=mt2msm
"barrel1.mt1.3dmap" ! mesh tally
3 ! mesh tally family (1-n, 2-p, 3-responses)
1 ! real mesh in that family (0 means total of family)
1 ! mesh source particle type 1-neutron, 2-photon
1 4 3 ~ ! ~ n u m b e r ~ o f ~ b i n s ~ i n ~ b i n n e d ~ h i s t o g r a m ~ d i s t r i b u t i o n
1.9640E+07 1.29403E-08 ! E_1 pdf_1
1.7332E+07 4.60970E-07 ! E_2 pdf_2
1.6905E+07 2.56619E-06 ! E_3 pdf_3
1.2341E+03 5.28408E-06 ! E_142 pdf_142
9.6112E+02 1.77756E-06 ! E_143 pdf_143
7.4852E+02 ! E_144
"barrel.fission.msm" ! output filename
end
=shell
    cp barrel.fission.msm ${RTNDIR}
end
```

Example:

```
=mt2msm
"fissionSource.3dmap"
1 ! neutron flux (for KENO 3dmap files there is only one family)
-1 ! use the whole family (keep all the energy groups)
1 ! particle type (neutron)
"caas.kenovi.fissionSource.msm"
end
```

In SCALE 6.1, the fission source distribution mesh tally produced by KENO contained data representing the number of fissions in each mesh cell in each energy group. In SCALE 6.2, the data stored was changed to be the fissions per unit volume - the fission density. This is more consistent with other mesh tallies from Monaco which store flux or dose rates that represent averages over the mesh cells. This change also allows the MeshFileViewer to display the KENO fission source distribution better. The mt 2 msm utility program also changed from SCALE 6.1 to SCALE 6.2 to account for the change in what is stored in the KENO mesh tally file. Therefore, KENO-produced fission source mesh tallies and the mt 2 msm utility should not be mixed-and-matched across versions of SCALE. Doing so would result in the final Monaco mesh source file being improperly normalized, which would not properly represent the KENO fission source distribution and would give incorrect results in subsequent MAVRIC calculations. Because there is not a specific 'version flag' in a mesh tally file or mesh source map file, the user must ensure that they have used the same version of SCALE for both the CSAS6 and MAVRIC sequences any time the CAAS capability is used.

## mt2silo - Convert a mesh tally file into a Silo file for VisIt.

Input: Name of mesh file (*.3dmap), name of a Silo file, and a format
Output: A new Silo file
Notes: For format, use either 2 (PDB) or 7 (HDF5).
Example:

```
=mt2silo
"perfect.3dmap" ! the existing mesh tally
"perfect.silo" ! the new silo file
7 ! format - HDF5
end
```

## mt2vtk - Convert one dataset of one family in a mesh tally to VTK format.

Intended use: This is a way to transfer Monaco mesh tally data into a common format that can be used by many data visualization packages, including VisIt. Mesh tallies are stored in a generic *.3dmap format, which consist of several families, each with one or more datasets. A typical mesh tally contains three families: the neutron fluxes with each energy group as a dataset, the photon fluxes with each energy group as a data set, and the responses with each response as a dataset. This program selects one dataset of one family and saves the data (and optionally the absolute uncertainties) in an ASCII file using a VTK file format.

Input: The mesh file name, which family, which dataset of that family, whether or not to include absolute uncertainties and the filename for the resulting VTK file

Output: An ASCII VTK-formatted file
Example:

```
=mt2vtk
"/optional/path/meshTallyFilename.3dmap" ! the mesh tally
1 ! neutron flux family
5 ! energy group 5
"/optional/path/outputFilename.vtk" ! output file name
end
```

true ! include uncertainties

Example:

```
=mt2vtk
"/optional/path/meshTallyFilename.3dmap" ! the mesh tally
3 ! the response family
1 ! first response
"/optional/path/outputFilename.vtk" ! output file name
end
```

false ! do not include uncertainties

## mtAdder - Add several Monaco mesh tally files together into one mesh tally.

Intended use: Add mesh tally results from different sources into one tally. The resulting mesh tally is the sum of all the components in the several mesh tallies-fluxes are added and responses are added. For
example, two runs of MAVRIC from two different sources can be made. The mesh tally results can then be added together, getting the total fluxes and total responses from each.

Input: The number of files, followed by the list of mesh tally filenames to add, then the name of the total mesh tally

```
=mtAdder
    n
    "filename_1"
    "filename_2"
    "filename_n"
    "resultFilename"
end
```

Output: A new mesh tally file
Notes: All of the mesh tally files must be the same size and shape (number of families, x cells, y cells, z cells, and energy groups in each family) and have the same number of responses. Responses (if any) must be consistent to calculate meaningful results.

Example:

```
=mtAdder
    3
"meshFilename_1.3dmap"
"meshFilename_2.3dmap"
"meshFilename_3.3dmap"
"meshFilenameTotal.3dmap"
end
```

## mtAverager - Average several Monaco mesh tally files into one mesh tally.

Intended use: Combine (average) separate runs of the same problem with different random number seeds into one tally. For example, if a user does 10 separate runs of the same problem (poor man's parallel) and wants to combine the results as if they were from one run, an average is needed. The average and uncertainties are weighted by the number of histories in each run, to maintain proper statistics.

Input: The number of files, each filename and how many histories, then the name of the total mesh tally

```
=mtAverager
n
"filename_1" histories_1
"filename_2" histories_2
"filename_n" histories_n
"resultFilename"
end
```

Output: A new mesh tally file
Notes: All of the mesh tally files must be the same size and shape (number of families, x cells, y cells, z cells, and energy groups in each family) and have the same number of responses. Responses (if any) must be consistent to calculate meaningful results.

Example:
=mtAverager

```
3
"meshFilename_1.3dmap" 800000
"meshFilename_2.3dmap" 900000
"meshFilename_3.3dmap" 800000
"/home/area/meshFilename.ave.3dmap"
end
```

## mtBinOp - Binary operation of mesh tally files: sum, difference, product, and ratio.

Intended use: Apply simple math to the results stored in mesh tally files
Input: The first mesh tally, the operator: add (or sum, + ), subtract (or difference, -), multiply (or product, $\mathrm{x},{ }^{*}$ ) and divide (or ratio, $\div$," /"), the second mesh tally name and then name of the resulting mesh tally file.

Output: A new mesh tally file
Notes: Uncertainties are propagated assuming the two mesh tallies are uncorrelated, which may not always be a good assumption. Mesh tallies need to have the same grid structure and number of families and groups. Dataset names in the results are inherited from the first mesh tally and may not make sense after the operation. When using the / (slash) for division, enclose it in quotes ("/").

Example:

```
=mtBinOp
"neutron.3dmap" ! first operand
divide ! operation
"total.3dmap" ! second operand
"ratio.3dmap" ! output file name
end
```

## mtDisp - Display the basics of a mesh tally file.

Input: A mesh tally (*.3dmap) file
Output: Some of the basic details of mesh file
Example:

```
=mtDisp
"simulation.mt2.dff" ! existing mesh file
end
```

mtExpand - Expand a space-only mesh from a mesh tally with an energy function
Input: A mesh tally (*.3dmap) file and some parameters
Output: A mesh file similar to a mesh source but with uncertainty

Example:

```
=mtExpand
'activate.mt1.3dmap'
2 1 ! response family, first response - cobalt activate rate
true ! multiply by voxel volumes
2 ! make photon source
19 ! groups
2.00E+07 0
1.00E+07 0
8.00E+06 0
6.50E+06 0
5.00E+06 0
4.00E+06 0
3.00E+06 0
2.50E+06 0
2.00E+06 0
1.66E+06 0.5
1.33E+06 1.5
1.00E+06 0
8.00E+05 0
6.00E+05 0
4.00E+05 0
3.00E+05 0
2.00E+05 0
1.00E+05 0
4.50E+04 0
1.00E+04
'photonSource.3dmap'
end
```

## mtFilter - Perform various filters on a mesh tally file.

Input: A *.3dmap mesh tally file and a group-wise response function
Output: A *.3dmap mesh tally file

Notes: Three basics types of filters: 0) flattening filter, 1) high-pass filter, 2) low-pass filter. For types 1 and 2, the values plus a given number of standard deviations will be compared to the criteria. The input list depends on filter type. Types 1 and 2 require a value and a number of standard deviations (n_sigma). A flattening filter turns any positive value into the value of " 1.0 ".

Filtering performed based on following comparisons;
value + n_sigmas*abs_unc > minValue (high-pass)
or
value + n_sigmas*abs_unc < maxValue (low-pass)

The number of sigmas can be positive or negative.

## Examples:

```
=mtFilter
"doseRates.3dmap" ! existing mesh tally file
1
0.150
-3.0 ! add -3.0 standard deviations to values before comparing
"above.3dmap" ! new mesh tally file
end
=mtFilter
```

```
"above.3dmap" ! existing mesh tally file
0 ! flattening filter
"boolean.3dmap" ! new mesh tally file
end
```

## mtInv - Invert all of the values in a mesh tally.

Intended use: Invert non-zero values in a mesh tally to be used in further processing.
Input: The original mesh tally, the name of the resulting mesh tally file
Output: A new mesh tally file
Notes: Uncertainties are propagated (the relative uncertainty of the reciprocal of a value is the same as the relative uncertainty of the value).

Example:

```
=mtInv
'someTally.3dmap' ! existing mesh tally file
'inverted.3dmap' ! new mesh tally file
end
```

## mtMask - Keep only or remove specified voxels of a mesh tally based on geometry.

Intended use: Only keep or remove certain portions of a mesh tally based on the unit, media, or mixture at the center of the voxel.

Input: A mesh tally file, an action (keeponly or remove), an operation (intersection or union) of the unit= u , media= r and mixture $=\mathrm{m}$, a replacement value for voxels not kept and the file name of the resulting mesh tally file. User can specify things such as 1 ) keep only the voxels that have unit=2 and mixture=5, 2) keep only the voxels that have media=3 or mixture=4, 3) remove voxels that have unit=2 and mixture $=5,4$ ) remove voxels that have media=3 or mixture=4. To not include the unit, media, or mixture in the specification, use a value of -1 .

Output: A new mesh tally file.
Notes: When processing a file before finding the maximum, make the replacement value something very low. If mtMask is being used before finding the minimum, then set the replacement value high. Media is the SGGP media number within the unit.

## Examples:

```
=mtMask
"theTally.3dmap" ! existing mesh tally file
keeponly ! use 'keeponly' or 'remove'
intersection ! use 'intersection' or 'union'
2 -1 5 ! unit=2 AND mixture=5
0.0 ! replacement value for voxels not kept
'new.3dmap' ! new mesh tally file
end
=mtMask
"theTally.3dmap" ! existing mesh tally file
remove ! use 'keeponly' or 'remove'
union ! use 'intersection' or 'union'
```

```
-1 3 4 ! media=3 OR mixture=4
0.0 ! replacement value for voxels removed
'new.3dmap' ! new mesh tally file
end
```

mtMinMax - Find the location/value of the min or max of each real mesh in a mesh tally.
Intended use: Determine the minimum or maximum values in a mesh tally.
Input: The mesh tally, what to find (minimums or maximums), how many mins/maxs for each real mesh in the mesh tally, and the name of the text output file to store the results

Output: A text output containing the values and locations of the minimums or maximums of each real mesh in a tally file

Notes: The same information is also in the main SCALE output file.
Example:

```
=mtMinMax
'bigOleMeshTally.3dmap' ! existing mesh tally file
maximum ! find either minimums or maximums
5 ! list top 5 maximum values in each real mesh
'theList.txt' ! file name to store all of the results
end
```

## mtMultiply - Multiply a mesh tally by a constant factor.

Intended use: Multiply every group of every family in a mesh tally for either a change in source strength or a change in units.

Input: The original mesh tally, the multiplier, and the name of the resulting mesh tally file
Output: A new mesh tally file
Example:

```
=mtMultiply
"simulation.mt1.3dmap" ! the mesh tally
25.0 ! source strength increase of 25
"simulation.bigger.3dmap" ! output file name
end
```

mtPull - Pull values from certain voxels out of a mesh tally file.
Intended use: Get energy-dependent fluxes for certain locations from a mesh file.
Input: A mesh file (*.3dmap) file and a list of positions and/or voxels
Output: Listing of energy-dependent fluxes from each desired location to an ASCII text file
Notes: Can pull fluxes either by a physical coordinate position or by voxel indices. Positions should be entered as a set of $\mathrm{x}, \mathrm{y}, \mathrm{z}$ for Cartesian coordinate system and $\mathrm{r}, \theta, \mathrm{z}$ for cylindrical coordinate system.

Example:

```
=mtPull
"duh.mt2.3dmap" ! existing mesh file
n ! number of x,y,z points to pull
x_1 y_1 z_1 ! coordinates of point 1
x_1 y_2 z_2 ! coordinates of point 2
x_n y_n z_n ! coordinates of point n
m ! number of i,j,k voxels to pull
i_1 j_1 k_1 ! indices of voxel 1
i_2 j_2 k_2 ! indices of voxel 2
:."
i_m j_m k_m ! indices of voxel m
"outputName.txt" ! name of output text file
=end
```

## mtRefine - Subdivide the mesh into smaller meshes.

Input: A *.3dmap mesh tally file with geometry mesh size (I,J,K) and three integers describing how many subdivisions of each voxel to create in each dimension

Output: A *.3dmap mesh tally file with geometry mesh size (I*nx,J*ny,K*nz)
Example:

```
=mtRefine
"fluxes.3dmap" ! existing *.3dmap mesh tally file (I,J,K)
nx ny nz ! how to subdivide each
"refined.3dmap" ! new (largerer) *.3dmap mesh tally file (I*nx,J*ny,K*nz)
end
```

## mtResp - Apply a response function to one family of a mesh tally file.

Intended use: Compute group-wise dose or reaction rates by combining a response function with the scalar fluxes.

Input: A *.3dmap mesh tally file and a group-wise response function
Output: A *.3dmap mesh tally file containing one family
Example:

| =mtResp |  |
| :--- | :--- |
| "fluxes.3dmap" | ! existing *.3dmap mesh tally file |
| 200 | ! number of bins in response |
| 1 | ! which family |
| $2.2675480 \mathrm{E}-04$ | ! response group 1 |
| $2.2283355 \mathrm{E}-04$ | ! response group 2 |
| $2.1878259 \mathrm{E}-04$ | ! response group 3 |
| .0 | ! response group nbins-2 |
| $3.6748440 \mathrm{E}-06$ ! response group nbins-1 <br> . $6748443 \mathrm{E}-06$ ! response group nbins <br> 3.6748436E-06 <br> "doseByGroup.3dmap" <br> end ! new (smaller) *.3dmap mesh tally file |  |

mtSplit - Split off part of a mesh tally file into a separate mesh tally file.

Intended use: Some mesh tallies may become so large that the MeshFileViewer cannot load the entire file to view. This utility allows users to split off one family or just one group of one family into a separate mesh tally file.

Input: The original mesh tally, which family (neutron, photon, or responses), and which dataset (usually a group). Instead of a dataset, users may specify 0 to get the total of a family or -1 to get all datasets for that family. The name of the resulting mesh tally also needs to be given.

Output: A new, smaller, mesh tally file

## Example:

```
=mtSplit
"mavricUtilities3.mt1.3dmap" ! the mesh tally
1 ! the family of neutron fluxes
" "mavricutilol fifth neutron flux group
"mavricUtilities3.nfluxg5.3dmap" ! output file name
end
```

### 4.1.B. 3 Utilities for working with DENOVO binary flux (*.dff) files

These utilities include the following:

| dff2dso | Convert a Denovo flux file into a Denovo spatial output file. |
| :--- | :--- |
| dff2mai | Convert a Denovo flux file into a mesh angular information file. |
| dff2mim | Invert a Denovo flux file and store as a mesh importance map. |
| dff2msl | Convert a Denovo flux file into a mesh source lite. |
| dffBinOp | Binary operation of Denovo flux files: sum, difference, product, and ratio. |
| dffDisp | Display the basics of a Denovo flux file. |
| dffExpand | Expand a space-only Denovo flux file by an energy function. |
| dffFilter | Perform various filters on a Denovo flux file. |
| dffFix | Fix the zero and negative values in a Denovo flux file. |
| dffInt | Integrate a single particle type from a Denovo flux file. |
| dffInv | Invert the values in a Denovo flux file. |
| dffMult | Multiply a Denovo flux file by a constant factor. <br> dffPull |
| Pull fluxes from certain voxels out of a Denovo flux file. |  |
| dffResp | Apply a response function to scalar fluxes in a Denovo flux file. |
| dffSplit | Split off a single particle type from a Denovo flux file. |

## dff2dso - Convert a Denovo flux file into a Denovo spatial output file.

Input: A binary (stream) Denovo flux file and which particle types to convert
Output: A binary (stream) Denovo Spatial Output file
Notes: For particle type, use 1 for neutron, 2 for photon, and 0 for all types.
Example:

```
=dff2dso
"neatStuff.dff" ! existing Denovo flux file
1 ! keep only neutron information
"neatStuff.dso" ! new Denovo spatial output file
end
```

## dff2mai - Convert a Denovo flux file into a mesh angular information file.

Intended use: Take the optional net current information from a Denovo flux file and create the adjoint current unit vectors and lambda parameters required for directional CADIS. This is stored in a mesh angular information (*.mai) file.

Input: A binary (stream) denovoFluxFile
Output: A binary (stream) meshAngularInfoFile, a mesh angular information file
Example:

```
=dff2mai
"mavricUtilities3.adjoint.dff" ! new denovoFluxFile
"mavricUtilities3.mai" ! mesh angular info file
end
```

dff2mim - Invert a Denovo flux file and store as a mesh importance map.
Intended use: Make weight targets without a consistent biased mesh source.
Input: A Denovo flux (*.dff) file, a scalar constant, and the name of Monaco mesh importance map (*.mim) file.

Output: A Monaco mesh importance map (*.mim) file.
Example:

```
=dff2mim
"adjoint.dff" ! existing adjoint denovoFluxFile
3.0e-10 ! constant targetWeight = constant/adjFlux
"test.mim" ! new Monaco mesh importance map
end
```

## dff2msl- Convert a Denovo flux file into a mesh source lite.

Intended use: Take Denovo fission source information stored in a *.dff file and convert it to a mesh source lite file (*.msl) to be used as a KENO starting source, nst=9.

Input: A Denovo flux (*.dff) file
Output: A mesh source lite (*.msl) file

Example:

```
=dff2msl
"wishfulThinking.dff" ! existing Denovo flux file
"startingSource.msl" ! mesh source lite file
end
```

## dffBinOp - Binary operation of Denovo flux files: sum, difference, product and ratio.

Intended use: Apply simple math to the results stored in Denovo flux files.
Input: The first flux file, the operator: add (or sum, + ), subtract (or difference, -), multiply (or product, x , *), or divide (or ratio, $\div$, "/"), the second flux file name, and the name of the resulting flux file

Output: A Denovo flux file
Notes: Flux files need to have the same grid structure and number of groups. When using the / (slash) for division, enclose it in quotes ("/").

Example:

```
=dffBinOp
"neutron.dff" ! first operand
divide ! operation
"total.dff" ! second operand
"ratio.dff" ! output file name
end
```

## dffDisp - Display the basics of a Denovo flux file.

Input: A Denovo flux (*.dff) file
Output: Some of the basic details of the Denovo flux file
Example:

```
=dffDisp
"fluxes.dff" ! existing Denovo flux file
end
```

dffExpand - Expand a space-only Denovo flux file by an energy function.
Input: A Denovo flux (*.dff) file (with a single group - a space-only function), one or more particle types, and an energy function for each

Output: A full space/energy Denovo flux file

Example:

```
=dffExpand
"spatialFluxes.dff" ! existing Denovo flux file (single group)
2 ! number of particles
1 ! particle type (1-neutron, 2-photon)
2 7 ~ ! ~ n u m b e r ~ o f ~ b i n s ~ i n ~ b i n n e d ~ h i s t o g r a m ~ d i s t r i b u t i o n
2.00000E+07 3.0658021E-09 ! E_1 amount_1
6.37630E+06 6.9767163E-09 ! E_2 amount_2
3.01190E+06 1.1495182E-08 ! E_3 amount_3
    \cdotsᄇᄋ
3.00000E-02 1.7127996E-04 ! E_26 amount_26
1.00000E-02 3.0910611E-04 ! E_27 amount_27
1.00000E-05 ! E_28
2 ! particle type (1-neutron, 2-photon)
1 9
2.00E+07 0.0 ! E_1 amount_1
1.00E+07 0.0 ! E_2 amount_2
8.00E+06 0.0 ! E_3 amount_3
00E+05 0.0 \cdots. ! E_17 amount 17
4.50E+04 0.0 ! E_18 amount_18
1.00E+04 ! E_19
"expanded.dff" ! new Denovo flux file
end
```

## dffFilter - Perform various filters on a Denovo flux file.

Intended use: Keep fluxes in a *.dff file where the flux or response meets a specified criterion.
Input: A Denovo flux file name, filter type, filter options, the output file name
Output: A Denovo flux file
Notes: There are three basics types of filters: 0) flattening filter, 1) high-pass filter, 2) low-pass filter. For types 1 and 2 , the criteria could be a computed response. The input list changes depending on the filter type and whether a response function is included. For no response function, use 0 for the number of groups. A flattening filter turns any positive value into the a value of " 1.0 ".

Examples:

```
=dffFilter
"some.dff" ! input Denovo flux filename
0 ! filter type
"flattened.dff" ! output Denovo flux filename
end
=dffFilter
"some.dff" ! input Denovo flux filename
2 ! filter type
10.0 ! maximum value
"simpleFiltered.dff"
number of groups for response function
"simpleFiltered.dff" ! output Denovo flux filename
end
=dffFilter
"some.dff"
1 ! filter type
10.0 ! minimum value
19
1.1620022E-05
8.7445696E-06
7.4596655E-06
6.3505804E-06
```

```
5.3994922E-06
4.6016462E-06
3.9522688E-06
3.4588520E-06
3.0130868E-06
2.6200121E-06
2.1944491E-06
1.8269592E-06
1.5149031E-06
1.1595382E-06
8.7044964E-07
6.2187445E-07
3.7080767E-07
2.6877788E-07
5.9327226E-07
"respFiltered.dff" ! output Denovo flux filename
end
```

dffFix - Fix the zero and negative values in a Denovo flux file.
Intended use: Replace zero or negative values with nearest good neighboring value. Checks previous group, previous x voxel, previous y voxel, then previous z voxel.

Input: A Denovo flux file
Output: A new Denovo flux file
Example:

```
=dffFix
"original.dff" ! existing Denovo flux file
"repaired.dff" ! new Denovo flux file
end
```

## dffint - Integrate a single particle type from a Denovo flux file.

Input: A Denovo flux file, which particle type to integrate (1-neutron, 2-photon), and the filename of the resulting integrated file

Output: A single-group Denovo flux file
Example:

```
=dffInt
"coupled.dff" ! existing Denovo flux file
2 ! particle type
"photonTotal.dff" ! new Denovo flux file (single group)
end
```

dffinv - Invert the values in a Denovo flux file.
Input: A Denovo flux file
Output: A Denovo flux file
Notes: Only non-zero values are inverted
Example:

```
=dffInv
"fluxes.dff" ! existing Denovo flux file
"inverted.dff" ! new Denovo flux file
end
```

## dffMult - Multiply a Denovo flux file by a constant factor.

Intended use: source strength change, change in units, etc.
Input: A Denovo flux file and a constant factor
Output: A Denovo flux file
Example:

```
=dffMult
"fluxes.dff" ! existing Denovo flux file
10000.0 ! change units from (/cm^2/s) to (/m^2/s)
"multiplied.dff" ! new Denovo flux file
end
```

## dffPull - Pull fluxes from certain voxels out of a Denovo flux file.

Intended use: Get energy-dependent fluxes for certain locations from a flux file.
Input: A Denovo flux file and a list of positions and/or voxels
Output: Listing of energy-dependent fluxes from each desired location to an ASCII text file
Notes: Can pull fluxes either by a physical coordinate position or by voxel indices.
Example:

```
=dffPull
"fluxes.dff" ! file with the scalar fluxes you want
n ! number of x,y,z points to pull
x_1 y_1 z_1 ! coordinates of point 1
x_1 y_2 z_2 ! coordinates of point 2
x_n y_n z_n ! coordinates of point n
m ! number of i,j,k voxels to pull
i_1 j_1 k_1 ! indices of voxel 1
i_2 j_2 k_2 ! indices of voxel 2
i_m j_m k_m ! indices of voxel m
"outputName.txt" ! name of output text file
=end
```

## dffResp - Apply a response function to scalar fluxes in a Denovo flux file.

Intended use: Compute group-wise dose or reaction rates by combining a response function with the scalar fluxes. This can be done for every particle type in the flux file or a single specific particle type.

Input: A Denovo flux file, particle indicator and a group-wise response function
Output: A Denovo flux file

Notes: 0-all particles, 1-neutron, 2-photon
Example:

| =dffResp <br> "fluxes.dff" | ! existing coupled Denovo flux file |
| :--- | :--- |
| 1 | ! keep only neutron information |
| 200 | ! number of bins in response |
| $2.2675480 \mathrm{E}-04$ | ! response group 1 |
| $2.2283355 \mathrm{E}-04$ | response group 2 |
| $2.1878259 \mathrm{E}-04$ | ! response group 3 |
| $\ldots$ | ! response group nbins-2 |
| $3.6748440 \mathrm{E}-06$ | ! response group nbins-1 |
| $3.6748443 \mathrm{E}-06$ | response group nbins |
| $3.6748436 \mathrm{E}-06$ | new (smaller) Denovo flux fle |
| "doses.dff" |  |

Or

| =dffResp <br> "fluxes.dff" | ! existing Denovo flux file |
| :--- | :--- |
| 0 | ! keep all particles information |
| 46 | ! number of bins in response |
| $1.6151395 E-04$ | ! response group 1, first neutron |
| $1.4451494 E-04$ | ! response group 2 |
| $1.2703618 \mathrm{E}-04$ | ! response group 3 |
| $\ldots$ | ! response group 27, last neutron |
| $3.6748447 \mathrm{E}-06$ | ! response group 28, first photon |
| $1.1620022 \mathrm{E}-05$ | ! response group 29 |
| $8.7445696 \mathrm{E}-06$ | response group 30 |
| $7.4596655 \mathrm{E}-06$ | ! response group 46, last photon |
| .. | ! new Denovo flux file |
| $5.9327226 \mathrm{E}-07$ |  |

## dffSplit - Split off a single particle type from a Denovo flux file.

Intended use: Make a flux file containing a single particle type from another Denovo flux file.
Input: A Denovo flux file and a particle type
Output: A (smaller) Denovo flux file
Notes: 1-neutron, 2-photon
Example:

```
=dffSplit
"coupled.dff" ! existing Denovo flux file
2 ! particle type
"photons.dff" ! new (smaller) Denovo flux file
end
```

### 4.1.B. 4 Utilities for working with DENOVO *.varscl (a TORT format) files

These utilities include the following:

$$
\begin{array}{ll}
\text { vs2dff } & \text { Convert a varscl file into a Denovo flux file. } \\
\text { vsAdder } & \text { Add two TORT *.varscl files together into one *.varscl file. } \\
\text { vsBinOp } & \text { Binary operation of TORT *.varscl files: sum, difference, product and ratio. } \\
\text { vsDisp } & \text { Display the basic contents of a TORT *.varscl file. } \\
\text { vsFilter } & \text { Perform various filters on a TORT *.varscl file. } \\
\text { vsInt } & \text { Integrate a single particle type from a TORT *.varscl file. } \\
\text { vsInv } & \text { Invert the values in a TORT *.varscl file. } \\
\text { vsMult } & \text { Multiply a TORT *.varscl file by a constant factor. } \\
\text { vsPull } & \text { Pull fluxes from certain voxels out of a TORT *.varscl file. } \\
\text { vsReGrp } & \text { Regroup a TORT *.varscl file. } \\
\text { vsResp } & \text { Apply a response function to scalar fluxes in a TORT *.varscl file. } \\
\text { vsSplit } & \text { Split off part of a TORT *.varscl file into a separate *.varscl file. }
\end{array}
$$

These utilities work with the *.varscl files produced with SCALE 6 and SCALE 6.1. The *.varscl format (a TORT format) is a single precision, binary format that has been replaced with the double precision, binary *.dff file (Denovo flux file) in SCALE 6.2. SCALE 6 and SCALE 6.1 users can request the executable binaries for these utilities by sending an email to scaleHelp@ornl.gov.
vs2dff - Convert a varscl file into a Denovo flux file.
Intended use: Convert a varscl file (used in previous versions of MAVRIC) into a Denovo flux file (introduced in SCALE 6.2).

Input: The *varscl file name, whether or not it is an adjoint flux, and the filename for the resulting denovoFluxfile

Output: A binary (stream) denovoFluxFile
Example:

```
=vs2dff
"mavricUtilities3.adjoint.varscl" ! the TORT varscl file
true ! it is an adjoint flux
"mavricUtilities3.adjoint.dff" ! new denovoFluxFile
end
```

vsAdder - Add two TORT *.varscl files together into one *.varscl file.
Intended use: Beta versions of MAVRIC used TORT and GRTUNC-3D and could add the *.varscl files from each together before using them to create importance maps. MAVRIC now uses Denovo and no longer needs to add separate GRTUNC/TORT files. This utility is designed for people wishing to use the older files with the latest MAVRIC.

Input: Two *.varscl file names, typically one from GRTUNC-3D and the other from TORT, the filename of the added file, whether you want lots of output displayed ("true" or "false") and whether or not there is a minimum value of flux to use. If so, it is then listed.

Output: A single *.varscl with the specified name
Notes: Addition is commutative, but not all varscl files are created equal. Do not mix up the GRTUNCL and the TORT files. GRTUNCL3D does not fill in the header info quite right, so the added varscl file takes header info only from the TORT varscl file.

Example:

```
=vsAdder
"/some/path/problem.gtunc.adjoint.varscl"
"/some/path/problem.tort.adjoint.varscl"
"total.varscl"
f
t
1.0e-25
end
=shell
    cp total.varscl ${RTNDIR}/total.varscl
end
```

## vsBinOp - Binary operation of TORT *.varscl files: sum, difference, product and ratio.

Intended use: Apply simple math to the results stored in TORT *.varscl files.
Input: The first flux file, the operator: add (or sum, +), subtract (or difference, -), multiply (or product, x , *), and divide (or ratio, $\div$, "/"), the second flux file name, and the name of the resulting flux file

Output: A TORT *.varscl file
Notes: Flux files need to have the same grid structure and number of groups. When using the / (slash) for division, enclose it in quotes ("/").

Example:

```
=vsBinOp
"neutron.varscl" ! first operand
false ! are these adjoint files?
divide ! operation
"total.varscl" ! second operand
"ratio.varscl" ! output file name
end
```

vsDisp - Display the basic contents of a TORT *.varscl file.
Input: A TORT *.varscl file name and adjoint flag
Output: Text display
Examples:

```
=vsDisp
"some.varscl" ! input TORT *.varscl filename
```

```
false ! is this an adjoint varscl?
end
=vsDisp
"some.varscl" ! input TORT *.varscl filename
adjoint ! is this an adjoint varscl?
end
```

vsFilter - Perform various filters on a TORT *.varscl file.
Intended use: Keep fluxes in a *.varscl file where the flux or response meets a specified criterion.
Input: A TORT *.varscl file name, filter type, filter options, the output file name
Output: A TORT *.varscl file
Notes: There are three basics types of filters: 0) flattening filter, 1) high-pass filter, 2) low-pass filter. For types 1 and 2, the criteria could be a computed response. The input list changes depending on the filter type and whether a response function is included. For no response function, use 0 for the number of groups.

## Examples:

```
=vsFilter
"some.varscl" ! input TORT *.varscl filename
false ! is this an adjoint varscl?
0 ! filter type
"flattened.varscl" ! output TORT *.varscl filename
end
=vsFilter
"some.varscl" ! input TORT *.varscl filename
false ! is this an adjoint varscl?
2 ! filter type
10.0 ! maximum value
0 ! number of groups for response function
"simpleFiltered.varscl" ! output TORT *.varscl filename
end
=vsFilter
"some.varscl" ! input TORT *.varscl filename
false ! is this an adjoint varscl?
1 ! filter type
10.0 ! minimum value
19}1.1620022E-0
1.1620022E-05
7.4596655E-06
6.3505804E-06
5.3994922E-06
4.6016462E-06
3.9522688E-06
3.4588520E-06
3.0130868E-06
2.6200121E-06
2.1944491E-06
1.8269592E-06
1.5149031E-06
1.1595382E-06
8.7044964E-07
6.2187445E-07
3.7080767E-07
2.6877788E-07
5.9327226E-07
"respFiltered.varscl" ! output TORT *.varscl filename
```

vsInt - Integrate a single particle type from a TORT *.varscl file.
Input: A TORT *.varscl file
Output: A single-group TORT *.varscl file
Example:

```
=vsInt
"coupled.varscl" ! existing TORT *.varscl file
false ! is this an adjoint file?
2 ! particle type (0-all, 1-neutron, 2-photon)
"photonTotal.varscl" ! new TORT *.varscl file (single group)
end
```

vsInv - Invert the values in a TORT *.varscl file.
Input: A TORT *.varscl file
Output: A TORT *.varscl file
Notes: Only non-zero values are inverted
Example:

```
=vsInv
"fluxes.varscl" ! existing TORT *.varscl file
false ! is this an adjoint file?
"inverted.varscl" ! new TORT *.varscl file
end
```

vsMult - Multiply a TORT *.varscl file by a constant factor.
Intended use: source strength change, change in units, etc.
Input: A TORT *.varscl file and a constant factor
Output: A TORT *.varscl file
Example:

```
=vsMult
"fluxes.varscl" ! existing TORT *.varscl file
false ! is this an adjoint file?
10000.0 ! change units from (/cm^2/s) to (/m^2/s)
"multiplied.varscl" ! new TORT *.varscl file
end
```

vsPull - Pull fluxes from certain voxels out of a TORT *.varscl file.
Intended use: Get energy-dependent fluxes for certain locations from a flux file.

Input: A TORT *.varscl file and a list of positions and/or voxels
Output: Listing of energy-dependent fluxes from each desired location to an ASCII text file
Notes: Can pull fluxes either by a physical coordinate position or by voxel indices.
Example:

```
=vsPull
"fluxes.varscl" ! file with the scalar fluxes you want
false ! is this an adjoint file?
n ! number of x,y,z points to pull
x_1 y_1 z_1 ! coordinates of point 1
x_1 y_2 z_2 ! coordinates of point 2
x_n y_n z_n ! coordinates of point n
m ! number of i,j,k voxels to pull
i_1 j_1 k_1 ! indices of voxel 1
i_2 j_2 k_2 ! indices of voxel 2
i_m j_m k_m ! indices of voxel m
"outputName.txt" ! name of output text file
end
```

## vsReGrp - Regroup a TORT *.varscl file.

Input: A TORT *.varscl file and adjoint flag, then a list of how the new groups should be formed from the old groups

Output: A smaller TORT *.varscl file
Example:

```
=vsReGrp
"coupled.varscl" ! existing TORT *.varscl file
false ! is this an adjoint file?
27 ! number of neutron groups in file
1 ! new group assignment for each
            existing neutron group
        must start with one
        each entry is same as last or
        increases by 1
new group assignment for neutron group 27
number of photon groups in file
new group assignment for each
            existing photon group
    must start with one
    each entry is same as last or
    increases by 1
    ! new group assignment for photon group 19
    ! new TORT *.varscl file name
```

vsResp - Apply a response function to scalar fluxes in a TORT *.varscl file.
Intended use: Compute group-wise dose or reaction rates by combining a response function with the scalar fluxes.

Input: A TORT *.varscl file and a group-wise response function

Output: A TORT *.varscl file
Example:

## vsSplit - Split off part of a TORT *.varscl file into a separate *.varscl file.

Intended use: Make a flux file containing a single particle type from another TORT *.varscl file.
Input: A TORT *.varscl file and a particle type
Output: A (smaller) TORT *.varscl file
Example:

```
=vsSplit
"coupled.varscl" ! existing TORT *.varscl file
false ! is this an adjoint file?
2 ! particle type (1-neutron, 2-photon)
"photons.varscl" ! new (smaller) TORT *.varscl file
end
```

### 4.1.B. 5 Miscellaneous utilities

These utilities include the following:

| dsi2asc | Convert a Denovo simple input (*.dsi) from binary to ASCII. |
| :--- | :--- |
| dsiDisp | Display the basics of a Denovo simple input file. |
| dso2msl | Use a Denovo spatial output to create a mesh source lite. |
| dsoDisp | Display the basics of a Denovo spatial output file. |
| mim2wwinp | Convert a mesh importance map into an MCNP weight window file. |
| mimDisp | Display the basics of a mesh importance map (*.mim) file. |
| mimNorm | Normalize a mesh importance map to a given location/energy. |
| msmDisp | Display the basics of a mesh source map (*.msm) file. |

## dsi2asc - Convert a Denovo simple input (*.dsi) from binary to ASCII.

Intended use: Check a Denovo input file for correctness.
Input: Names of original binary Denovo simple input (*.dsi) file and the desired ASCII text file

Output: Human-readable form of the Denovo input file
Example:

```
=dsi2asc
"input.dsi" ! Denovo simple input file (binary)
"ascii.txt" ! new ascii text file
end
```

## dsiDisp - Display the basics of a Denovo simple input file.

Input: A Denovo simple input (*.dsi) file
Output: Some of the basic details of the Denovo simple input file
Example:

```
=dsiDisp
"godiva.dsi" ! existing Denovo simple input file
end
```

dso2msl - Use a Denovo spatial output to create a mesh source lite.
Input: A *.dso file is made of three-dimensional data sets called fields. Which field to convert? 1-n: convert that field 0 : convert sum of all fields

Output: A mesh source lite (*.msl) file for KENO-VI.
Example:

```
=dso2msl
"fisSource.dso" ! Denovo spatial output file with many fields
1 ! which field to use
"test.msl" ! new Monaco mesh source lite
end
```

## dsoDisp - Display the basics of a Denovo spatial output file.

Input: A Denovo spatial output (*.dsi) file
Output: Some of the basic details of the Denovo spatial output file
Example:

```
=dsoDisp
```

"godiva.dso" ! existing Denovo spatial output file end

## mim2wwinp - Convert a mesh importance map into an MCNP weight window file.

Intended Use: To create an MCNP weight window file from a Monaco mesh importance map file outside of a MAVRIC calculation. Monaco mesh importance map files store target weights, but MCNP wwinp files store lower weight bounds. To convert, the user needs to supply the windowRatio, $r$ (the ratio of the upper weight bound for splitting to the lower weight bound for roulette). Target weights, $t$, are the average
of the upper, $u$, and lower, $l$, weight window bounds, so $l=2 t /(r+1)$. For example, for a Monaco target weight of 1.0 and a windowRatio of 10.0 , the MCNP lower weight bound will be $l=2(1.0) /(10.0+1)=0.1818$. To reduce the size of the map, the user can specify which neutron and photon groups to store in the new file. If the last group is less than the first group, no groups of that particle will be stored.

Input:
Line 1: filename of the Monaco mesh importance map file
Line 2: windowRatio (>1.0)
Line 3: first_neutron_group last_neutron_group
Line 4: first_photon_group last_photon_group
Line 5: filename of the MCNP weight window input file
Output: The resulting weight window input file stored with the desired filename
Notes: Geometry information in the Monaco mesh importance map file is lost since the MCNP wwinp format does not support it.

Example:

```
=mim2wwinp
"/scale/smplprbs/mavric.graphiteCADIS.mim" ! importance map
19.0 ! window ratio
52 ! save n groups 5-22
191 ! save no p groups
"/scale/test9/testmimww.wwinp" ! new file
end
```

mimDisp - Display the basics of a mesh importance map file.
Input: A mesh importance map (*.mim) file
Output: Some of the basic details of mesh importance map file
Example:

```
=mimDisp
"the.mim" ! existing mesh importance map file
end
```

## mimNorm - Normalize a mesh importance map to a given location/energy.

Input: A mesh importance map (*.mim) file, a location ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$ ), a particle type and energy, and a filename for the normalized map file. Use 1 for neutron and 2 for photon. Energy should be in eV . The new importance map file will be normalized such that the given location/energy has a target weight of 1 . If a particle type or energy is 0 , then the energy group with the minimum non-zero target value at the given location will be the group that is set to 1.0 in the new file. (This option is similar to the MCNP weight window generator.)

Output: A mesh importance map file

Example:

```
=mimNorm
"the.mim" ! existing mesh importance map file
27.5 -16.5 32.0 ! location
1 1.0e6 ! neutron, 1 MeV
"normed.mim" ! new file that is normalized
end
```

msmDisp - Display the basics of a mesh source map file.
Input: A mesh source map (*.msm) file
Output: Some of the basic details of mesh source map file
Example:

```
=msmDisp
"the.msm" ! existing mesh source map file
```

### 4.1.C Advanced Features

This appendix contains information on several advanced features that are still under development or are non-standard use of the MAVRIC sequence.

### 4.1.C. 1 Alternate normalization of the importance map and biased source

The importance map and biased source implemented in MAVRIC are only functions of space and energy only. The importance for a specific location and energy represents the average over all directions. For applications involving a collimated beam source, a space/energy importance map may not be representative of the true importance of the particles as they stream away from the source.

As an example, consider a 14.1 MeV active interrogation beam source 1 meter from a small spherical boat containing illicit nuclear material. The objective is to compute the fission rate in the nuclear material. To create the biasing parameters, an adjoint source is located within the nuclear material and the resulting importance map is shown in Figure 4.1.C.1. Note that in both the air and water, the importances change with distance from the ship, but for the beam source, the importance (to causing a fission in the nuclear material) anywhere along the beam should be the same, since there is little chance a 14.1 MeV neutron will interact with the air before striking the ship.

Figure 4.1.C.1. Importance map computed using standard CADIS.

The CADIS algorithm has done exactly what it was supposed to: it made a space/energy importance map and normalized it such that the target weight where the 14.1 MeV source particles are born is 1 . The problem with this is that the source particles will stream towards the ship and strike the hull where the target weight is 0.092 . Since source particles have little chance of interacting in the air, the weight windows are not used to split the particle as they travel towards the ship. When source particles cross into the ship, they are split by a factor of 11 to match the target weight. For this example, splitting each particle by a factor of 11 once they strike the ship is not so bad, but for longer distances, this will result in much larger splits. For a polyenergetic source, this could lead to undersampling of the source and could result in higher variances.

To remedy this problem when using beam sources, the normalization of the importance map and biased source should not be done at the source location but instead at the point where the source particles first interact with the ship. The keyword "shiftNormPos $\Delta x \Delta y \Delta z$ " will shift the source normalization position by the amounts $\Delta x, \Delta y$, and $\Delta z$ when the biased source and importance map are developed. For the Monaco Monte Carlo calculation, the source is returned to its normal position. The source input for the above problem would then be

```
read sources
    src 1
        title="14.1 DT neutrons - collimated"
        strength=1e30
        sphere 0 origin x=-195 y=0 z=0 (true source position)
        eDistributionID=1 (a mono-energetic 14.1 MeV distribution)
            direction 1.0 0.0 0.0
            dDistributionID=2 (a 2` beam )
        shiftNormPos 107.7 0.0 0.0 (just inside the hull)
    end src
end sources
```

where the shift moves the source position from $\mathrm{x}=-195$ to $\mathrm{x}=-87.3$, just inside the hull. The resulting target weights are shown in Figure 4.1.C.2. The source particles are born with weight 1 in a location with a target weight 10.9. The particle weight is not checked until the particle crosses into the hull, where the target weight is 1.0 .

Figure 4.1.C.2. Targets weights using the "shiftNormPos" keyword.

Other options to manipulate the importance map for special situations include the "mapMultiplier=f" keyword (in the importanceMap block or the biasing block), which will multiply every target weight by the factor $f$, and the keyword "noCheckAtBirth" in the parameters block will prevent the weight windows from being applied to source particles when they are started. When used in the MAVRIC sequence, the "shiftNormPos" capability automatically adds "noCheckAtBirth" to the Monaco input that is created.

### 4.1.C. 2 Importance maps with directional information

In MAVRIC, the CADIS method is implemented in space and energy, but in general, it could also include particle direction as well. This formulation would be the following.

True source:

$$
q(\vec{r}, E, \widehat{\Omega})
$$

Desired response:

$$
\sigma(\vec{r}, E, \widehat{\Omega})
$$

Adjoint angular flux using

$$
q^{+}(\vec{r}, E, \widehat{\Omega})=\sigma(\vec{r}, E, \widehat{\Omega})
$$

$$
\psi^{+}(\vec{r}, E, \widehat{\Omega})
$$

Estimate of detector response:

$$
\begin{equation*}
R=\iiint q(\vec{r}, E, \widehat{\Omega}) \psi^{+}(\vec{r}, E, \widehat{\Omega}) d \Omega d E d V \tag{4.1.C.1}
\end{equation*}
$$

Biased source:

$$
\begin{equation*}
\widehat{q}(\vec{r}, E, \widehat{\Omega})=\frac{1}{R} q(\vec{r}, E, \widehat{\Omega}) \psi^{+}(\vec{r}, E, \widehat{\Omega}) \tag{4.1.C.2}
\end{equation*}
$$

Target weight windows:

$$
\begin{equation*}
\bar{w}(\vec{r}, E, \widehat{\Omega})=\frac{R}{\psi^{+}(\vec{r}, E, \widehat{\Omega})} \tag{4.1.C.3}
\end{equation*}
$$

For a system using a deterministic method to compute the adjoint fluxes, this completely general, space/energy/angle, approach presents many difficulties in implementation, namely,
a. dealing with the amount of memory required for a ( $\vec{r}, E, \widehat{\Omega}$ ) importance map in memory,
b. interpolating the importance for particle directions in between quadrature angles, and
c. expressing the biased source in a form suitable for a general MC code since the above biased source is, in general, not separable.

### 4.1.C.2.1 Approaches incorporating directional information

Completely general space/energy/angle CADIS is most likely too difficult to implement and may not be necessary for most applications. In most real problems that involve directionally dependent source distributions, the directional dependence is azimuthally symmetric about some reference direction, $\hat{d}$. The angular distribution, $q_{i}(\widehat{\Omega})$, can be expressed as the product of the uniform azimuthal distribution and a polar distribution about reference direction $\hat{d}_{i}$ giving $\frac{1}{2 \pi} q_{i}\left(\widehat{\Omega} \cdot \hat{d}_{i}\right)$. The geometric size of these sources tends to be small, allowing each source distribution to be expressed as the product of two separable distributions: $q_{i}(\vec{r}, E, \widehat{\Omega}) \cong q_{i}(\vec{r}, E) q_{i}(\widehat{\Omega})$.

What is needed is a CADIS method that (1) can account for the importance of a particle traveling in a certain direction; (2) can be cast as a simple modification of the space/energy CADIS method using $\bar{w}(\vec{r}, E)$ and $\hat{q}(\vec{r}, E)$; and (3) is simpler than the full space/angle/energy approach. This can be done starting with the approximation that the angular component of the adjoint flux $\psi^{+}(\vec{r}, E, \widehat{\Omega})$ is separable and symmetric about the average adjoint current direction $\hat{n}(\vec{r}, E)$, such that

$$
\psi^{+}(\vec{r}, E, \widehat{\Omega}) \cong \phi^{+}(\vec{r}, E) \frac{1}{2 \pi} f(\widehat{\Omega} \cdot \hat{n})
$$

This is similar to the AVATAR approach ${ }^{1}$ but with explicitly including the azimuthal distribution so that the standard definition $\int \phi^{+}(\vec{r}, E) \frac{1}{2 \pi} f(\widehat{\Omega} \cdot \widehat{n}) d \widehat{\Omega}=\phi^{+}(\vec{r}, E)$ applies. The probability distribution function $f(\mu)$ describing the shape of the azimuthally symmetric current at $(\vec{r}, E)$ has the form of

$$
f(\mu)=\frac{\lambda e^{\lambda \mu}}{2 \sinh (\lambda)}
$$

with the single parameter $\lambda(\vec{r}, E)$ determined from $\bar{\mu}(\vec{r}, E)$, the average cosine of scatter.
From this, we can propose that weight window targets be developed that are inversely proportional to the approximation of the adjoint angular flux:

$$
\begin{equation*}
\bar{w}(\vec{r}, E, \widehat{\Omega})=\frac{2 \pi k}{\phi^{+}(\vec{r}, E) f(\widehat{\Omega} \cdot \hat{n})}, \tag{4.1.C.4}
\end{equation*}
$$

where $k$ is the constant of proportionality that will be adjusted to make the importance map consistent with the biased source(s). Two methods will be examined here, one without and one with biasing of the source directional dependence.

For both of the methods, the $\mathrm{S}_{\mathrm{N}}$ code Denovo was modified to report not only the adjoint scalar fluxes, $\phi^{+}(\vec{r}, E)$, but also the adjoint net currents in $x, y$, and $z$ directions: $J_{x}(\vec{r}, E), J_{y}(\vec{r}, E)$, and $J_{z}(\vec{r}, E)$. These currents are used to find $\hat{n}(\vec{r}, E)$ and $\lambda(\vec{r}, E)$. The following methods have been developed so that the standard CADIS routines can be used to compute space/energy quantities of the response per unit source $R$, the weight window target values $\bar{w}(\vec{r}, E)$, and biased source $\hat{q}(\vec{r}, E)$ with just the adjoint scalar fluxes. These quantities are then modified by the directional information.

### 4.1.C.2.2 Directionally dependent weight windows without directional source biasing

It is proposed that the biased source $\widehat{q}(\vec{r}, E, \widehat{\Omega})$ should be proportional to both the true source distribution and the space/energy component of the adjoint flux:

$$
\hat{q}(\vec{r}, E, \widehat{\Omega})=\frac{1}{R}\left[q(\vec{r}, E) \frac{1}{2 \pi} q(\widehat{\Omega} \cdot \hat{d})\right] \phi^{+}(\vec{r}, E),
$$

where the constant of proportionality, $R$, is determined by forcing $\hat{q}(\vec{r}, E, \widehat{\Omega})$ to be a pdf. Since the angular component of the adjoint flux is not included, the directional distribution of the biased source will be exactly the same as the true source. Note that this approach would be exact for cases where no directional biasing could be applied - beam sources.

For multiple sources (each with a probability distribution function $q_{i}(\vec{r}, E)$ and a strength $S_{i}$, giving a total source strength of $S=\sum S_{i}$ ), the user is required to provide one point in phase space ( $\vec{r}_{i}, E_{i}, \widehat{\Omega}_{\mathrm{i}}$ ) for each source $i$ that is representative of that entire source where the biased source will match the target weight windows. For each source, a vector $\hat{n}_{i}=\hat{n}\left(\vec{r}_{i}, E_{i}\right)$ is computed using that point. For the general case of multiple sources, the biased source sampling distribution, the biased source distributions, and the weight windows are computed using

$$
\begin{array}{rlrl}
R_{i} & =\iint q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E) d E d r & \text { (estimated response from source } i \text { ) } \\
\hat{p}(i) & =\frac{S_{i} R_{i} f\left(\widehat{\Omega}_{\mathrm{i}} \cdot \hat{n}_{i}\right)}{\sum S_{i} R_{i} f\left(\widehat{\Omega}_{\mathrm{i}} \cdot \hat{n}_{i}\right)} & \text { (biased sampling of source } i \text { ) } \\
\hat{q}_{i}(\vec{r}, E, \widehat{\Omega}) & =\frac{1}{R_{i}} q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E) \frac{1}{2 \pi} q_{i}\left(\widehat{\Omega} \cdot \hat{d}_{i}\right)=\hat{q}_{i}(\vec{r}, E) \frac{1}{2 \pi} q_{i}\left(\widehat{\Omega} \cdot \hat{d}_{i}\right)
\end{array}
$$

$$
\bar{w}(\vec{r}, E, \widehat{\Omega})=\frac{\sum S_{i} R_{i} f\left(\widehat{\Omega}_{\mathrm{i}} \cdot \hat{n}_{i}\right)}{S \phi^{+}(\vec{r}, E)} \frac{1}{f(\widehat{\Omega} \cdot \hat{n})} \quad=\frac{\sum S_{i} R_{i} f\left(\widehat{\Omega}_{\mathrm{i}} \cdot \hat{n}_{i}\right)}{\sum S_{i} R_{i}} \bar{w}(\vec{r}, E) \frac{1}{f(\widehat{\Omega} \cdot \hat{n})} .
$$

### 4.1.C.2.3 Directionally dependent weight windows with directional source biasing

Here it is proposed that the biased source be proportional to both the true source distribution and the approximation of the adjoint angular flux. With a small geometric source, it is also assumed that there is one vector, $\hat{n}_{0}=\hat{n}\left(\vec{r}_{0}, E_{0}\right)$, evaluated at a specific location and energy, which represents the adjoint current direction over that source. The biased source then looks like

$$
\begin{aligned}
\hat{q}(\vec{r}, E, \widehat{\Omega}) & =\frac{1}{R c} q(\vec{r}, E, \widehat{\Omega}) \psi^{+}(\vec{r}, E, \widehat{\Omega}) \\
& =\frac{1}{R c}\left[q(\vec{r}, E) \frac{1}{2 \pi} q\left(\widehat{\Omega} \cdot \hat{d}_{i}\right)\right]\left[\phi^{+}(\vec{r}, E) \frac{1}{2 \pi} f\left(\widehat{\Omega} \cdot \hat{n}_{0}\right)\right]
\end{aligned}
$$

where the constant $R c$ is used to make $\hat{q}$ a pdf. Note that if either the original source directional distribution $q(\widehat{\Omega})$ or the adjoint angular flux distribution at the source is isotropic, then $c=1 / 4 \pi$.

For the general case of multiple sources, the biased source sampling distribution, the biased source distributions and the weight windows are

$$
\begin{aligned}
R_{i} & =\iint q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E) d E d r \\
c_{i} & =\int \frac{1}{2 \pi} q_{i}\left(\widehat{\Omega} \cdot \hat{d}_{\mathrm{i}}\right) \frac{1}{2 \pi} f\left(\widehat{\Omega} \cdot \hat{n}_{i}\right) d \widehat{\Omega} \\
\hat{p}(i) & =\frac{S_{i} R_{i} c_{i}}{\sum S_{i} R_{i} c_{i}} \\
\hat{q}_{i}(\vec{r}, E, \widehat{\Omega}) & =\left[\frac{1}{R_{i}} q_{i}(\vec{r}, E) \phi^{+}(\vec{r}, E)\right]\left[\frac{1}{c_{i}} q_{i}(\widehat{\Omega}) f(\widehat{\Omega})\right] \\
\bar{w}(\vec{r}, E, \widehat{\Omega}) & =\frac{\sum S_{i} R_{i} c_{i}}{S \phi^{+}(\vec{r}, E)} \frac{2 \pi}{f(\widehat{\Omega} \cdot \hat{n})} \frac{1}{c_{i}} \frac{1}{2 \pi} q_{i}\left(\widehat{\Omega} \cdot \hat{d}_{\mathrm{i}}\right) \frac{1}{2 \pi} f\left(\widehat{\Omega} \cdot \hat{n}_{i}\right) \\
& =\frac{\sum S_{i} R_{i} c_{i}}{\sum S_{i} R_{i}} \bar{w}(\vec{r}, E) \frac{2 \pi}{f(\widehat{\Omega} \cdot \hat{n})} .
\end{aligned}
$$

More details on the development of these methods and their application for several problems have been presented. ${ }^{2,3}$

### 4.1.C.2.4 Using space/energy/angle CADIS in MAVRIC

The two angular CADIS methods that use the AVATAR-type approximation of adjoint flux are specified in MAVRIC with the "angularBiasing=" keyword in the importanceMap block. Values for this keyword are 1 or 2.

Space/Energy/Angle CADIS without directional biasing (for beam sources) - This method uses one specific location, $\vec{r}_{0}$, energy, $E_{0}$, and direction, $\widehat{\Omega}_{0}$, which is the reference direction of the source $\hat{d}$, where the weight of the biased source matches the weight window.

Space/Energy/Angle CADIS with directional biasing (for general sources) - This method uses one specific energy, $E_{0}$, to determine the adjoint current vector $\hat{n}_{0}$ and the $\lambda_{0}$ parameter for the biased angular distribution for each source.

With each method, the user must specify at what energy the importance map and the biased sources should be made consistent. The particle type must also be specified. This is done with the keywords "angBiasParType=" ( 1 for neutron or 2 for photon) and "angBiasEnergy=" (with a value in eV), also in the importanceMap block.

Note that all sources should have a direction $\hat{d}$ set, using "direction $u v w$ " within each source, even if the angular distribution for a given source is isotropic. The direction is used for source biasing and for aligning the weight windows and biased sources. Also note that for either angular biasing method, the Denovo $\mathrm{S}_{\mathrm{N}}$ calculation must use a Legendre order greater than 0 .

With angular biasing, a mesh angular information (*.mai) file is produced which can be visualized with the MeshFileViewer. This file contains the space/energy-dependent $\lambda(\vec{r}, E)$ values and components of the average adjoint current direction $\hat{n}(\vec{r}, E)=\left\langle n_{x}, n_{y}, n_{z}\right\rangle$. An existing mesh angular information (*.mai) file can be used in a separate MAVRIC problem by using the "meshAngInfoFile=" keyword in the biasing block.

### 4.1.C.2.5 Example problem

Consider the Ueki shielding problem used as sample problems in the Monaco and MAVRIC manuals. The goal is to calculate the neutron dose on one side of a shield from a partially collimated ${ }^{252} \mathrm{Cf}$ source on the other side of the shield. Both of the angular approaches discussed above can be compared to analog and standard space/energy CADIS calculations. For the analog calculations, no importanceMap block is used. For the other cases, the importance map blocks are shown below.

| CADIS | Angular CADIS 1 - without a biased source angular dist. | Angular CADIS 2 - with a biased source angular dist. |
| :---: | :---: | :---: |
| read importanceMap <br> adjointSource 1 locationID=1 <br> responseID=5 <br> end adjointSource <br> gridGeometryID=7 <br> macromaterial <br> mmTolerance=0.01 <br> end macromaterial <br> end importanceMap | ```read importanceMap adjointSource 1 locationID=1 responseID=5 end adjointSource gridGeometryID=7 macromaterial mmTolerance=0.01 end macromaterial angularbiasing=1 angBiasParType=1 angBiasEnergy=2.0e6 end importanceMap``` | ```read importanceMap adjointSource 1 locationID=1 responseID=5 end adjointSource gridGeometryID=7 macromaterial mmTolerance=0.01 end macromaterial angularbiasing=2 angBiasParType=1 angBiasEnergy=2.0e6 end importanceMap``` |

Note that the energy at which to tie the importance map to the biased source, 2 MeV , is about the average energy of the source energy distribution. The figure-of-merit (FOM) of the calculation could change as this parameter is varied.

Results, shown in Table 4.1.C.1, demonstrate that the two directional approaches improved the FOM for this problem by more than a factor of 2 . A larger boost is seen in method 2 where biasing is applied to the source directional distribution. In this case, the biased source distribution was an exponential distribution
with a power of 2.45 , significantly sampling more source neutrons in the direction of the shield than into the paraffin collimator block.

Note that the space/energy/angle CADIS methods require more memory to hold the importance information. Improvements to the CADIS calculation can also be made with a judicious choice of standard source direction biasing, without an increase in memory requirements. A simple distribution (where $\mu=0.924$ represents the edge of the cone cutout and $\mu=0.974$ is the center half of the shield dimension) added that to the source

```
distribution 2
    abscissa -1.0 0.924 .974 1.0 end
    truepdf 0.962 0.025 .013 end
    biasedpdf 0.500 0.250 0.250 end
end distribution
```

src 1
neutrons strength $=4.05 \mathrm{E}+07$
cuboid 0.010 .010000
eDistributionID=1
direction 1.00 .00 .0
dDistributionID=2
end src
results in an FOM improvement of nearly 3 over the standard CADIS without the overhead of the angular CADIS methods.

Table 4.1.C.1. Results of the Ueki Shielding Problem ( 35 cm graphite shield)

|  | Adj. S <br> N | MC <br> $(\mathrm{min})$ | dose rate <br> $(\mathrm{min})$ | relative <br> $($ rem $/ \mathrm{hr})$ | MC FOM <br> uncert |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $(/ \mathrm{min})$ |  |  |  |  |  |

A series of problems was used to compare the space/energy/angle CADIS to the standard space/energy CADIS. Most of the problems saw an improvement of a factor of about 2 or 3 . Some problems did not improve at all, and some photon problems actually performed worse. In that case (a photon litho-density gauge), it could be that the angular approximation for importance, an exponential function in $\mu$, cannot adequately describe the true importance.

Since the space/energy/angle CADIS methods are more difficult to explain (more theory, adjustable parameters set by the user), require more memory than standard CADIS, and may not offer any improvement over standard space/energy CADIS, they have not been made part of the main MAVRIC manual and have been left as an advanced/developing feature. These methods were not removed from the MAVRIC code since they may be helpful to future problems.

### 4.1.C. 3 University of Michigan methods for global variance reduction

The use of hybrid deterministic/Monte Carlo methods, particularly for global variance reduction, has been an active area of research by the transport team at the University of Michigan for a long time. One of the first approaches studied was a way to develop Monte Carlo weight window target values that were proportional to deterministically estimated values of the forward flux. ${ }^{4}$ For global problems using isotropic weight windows, this reference argues that in order to get uniform relative uncertainties in the Monte Carlo calculation, the weight windows should be set such that the number density of Monte Carlo
particles, $m(\vec{r})$, is constant. The physical particle density, $n(\vec{r})$, is related by the average weight, $\bar{w}(\vec{r})$, to the Monte Carlo particle density by

$$
n(\vec{r})=\bar{w}(\vec{r}) m(\vec{r}) .
$$

To make $m(\vec{r})$ constant over the geometry, the weight window targets $\bar{w}(\vec{r})$ need to be proportional to the physical particle density. Cooper and Larsen calculate the weight window targets from an estimate of the forward scalar flux $\phi(\vec{r})$ to be

$$
\bar{w}(\vec{r})=\frac{\phi(\vec{r})}{\max (\phi(\vec{r}))}
$$

Two approaches have since been developed, ${ }^{5}$ based on what global information the user desires from the simulation: global flux weight windows, for obtaining every energy group at every location, and global response weight windows, for obtaining an energy-integrated response at every spatial location. Both of these methods are designed for calculating the "global solution" - everywhere in the geometry of the problem - with nearly uniform statistics.

Note that none of the University of Michigan methods discussed here included the development of biased sources. These methods have all been extended to include a consistent biased source by ORNL during their implementation in the MAVRIC sequence of SCALE. The methods have also been extended by ORNL for multiple sources.

### 4.1.C.3.1 Weight windows using only forward estimates of flux

## Global flux weight windows

This method keeps the Monte Carlo particle distribution uniform in space and energy. Note that this is a space/energy version of the original space-only Cooper's Method. The target weight windows, $\bar{w}(\vec{r}, E)$, should be proportional to the estimate of the forward scalar flux, $\phi(\vec{r}, E)$.

$$
\bar{w}(\vec{r}, E)=c \phi(\vec{r}, E)
$$

A biased source distribution, $\hat{q}(\vec{r}, E)$, that is consistent with the target weight windows can be found from the true source distribution, $q(\vec{r}, E)$, and the forward flux to be

$$
\hat{q}(\vec{r}, E)=\frac{1}{c} \frac{q(\vec{r}, E)}{\phi(\vec{r}, E)}
$$

where the constant $c$ can be determined so that the biased source distribution is a probability distribution function,

$$
c=\int_{V} \int_{E} \frac{q(\vec{r}, E)}{\phi(\vec{r}, E)} d E d \vec{r}
$$

Thus, using the estimate of forward flux, we can first compute $c$ and then form a consistent set of weight window target values and a biased source distribution.

## Global response weight windows

For an energy-integrated response (such as dose) desired at all spatial locations, this method keeps the Monte Carlo particle distribution proportional to the integral of the product of the response function, $\sigma_{d}(\vec{r}, E)$, and the estimate of the forward flux, $\phi(\vec{r}, E)$. The energy-integrated response, $D(\vec{r})$, is found from the estimate of the forward flux as

$$
D(\vec{r})=\int_{E} \sigma_{d}(\vec{r}, E) \phi(\vec{r}, E) d E .
$$

The target weight windows, $\bar{w}(\vec{r}, E)$, should be

$$
\bar{w}(\vec{r}, E)=c \frac{D(\vec{r})}{\sigma_{d}(\vec{r}, E)} .
$$

A biased source distribution, $\hat{q}(\vec{r}, E)$, that is consistent with the target weight windows can be found from the true source distribution, $q(\vec{r}, E)$, and the forward dose estimate to be

$$
\widehat{q}(\vec{r}, E)=\frac{1}{c} \frac{q(\vec{r}, E) \sigma_{d}(\vec{r}, E)}{D(\vec{r})}
$$

using a proportionality constant of

$$
c=\int_{V} \frac{1}{D(\vec{r})} \int_{E} q(\vec{r}, E) \sigma_{d}(\vec{r}, E) d E d \vec{r} .
$$

## Implementation in MAVRIC

The global flux weight windows (GFWW) approach and the global response weight windows (GRWW) are both triggered by specifying an importance map block without any adjoint sources. For the GRWW approach, the response of interest is listed in the importance map block. If none is listed, GFWW is used.

For problems with multiple sources (each with probability distribution function $q_{i}(\vec{r}, E)$ and strength $S_{i}$, giving a total source strength of $S=\sum S_{i}$ ), the GWW methods require a biased mesh source for each. This was implemented in MAVRIC in a manner similar to the multiple source CADIS routines. Each biased source, $\hat{q}_{i}(\vec{r}, E)$, is developed as

$$
\hat{q}_{i}(\vec{r}, E)=\left\{\begin{array}{cc}
\frac{1}{c_{i}} \frac{q_{i}(\vec{r}, E)}{\phi(\vec{r}, E)} & \text { global flux weight windows } \\
\frac{1}{c_{i}} \frac{q_{i}(\vec{r}, E) \sigma_{d}(\vec{r}, E)}{D(\vec{r})} & \text { global response weight windows }
\end{array},\right.
$$

where $c_{i}$ is a normalization constant. The weight windows are then set to

$$
\bar{w}(\vec{r}, E)=\left\{\begin{array}{lc}
\frac{\sum c_{i}}{\sum S_{i}} \phi(\vec{r}, E) & \text { global flux weight windows } \\
\frac{\sum c_{i}}{\sum S_{i}} \frac{D(\vec{r})}{\sigma_{d}(\vec{r}, E)} & \text { global response weight windows }
\end{array} .\right.
$$

In the final Monte Carlo, the specific source $i$ is sampled with probability $p(i)=S_{i} / S$, and then the particle is sampled from the biased mesh source $\widehat{q}_{i}(\vec{r}, E)$. Unlike the CADIS method for multiple sources, there is no way to develop a biased probability distribution for which source to sample without knowing the contribution to the global estimate from each source separately.

For multiple source problems where the expected contribution from each source is very different from the true strengths of those sources, it may be more efficient to run a series of problems with one source each for different amounts of time. The resulting mesh tallies can then be added together using the mesh tally adder (part of the MAVRIC utilities).

### 4.1.C.3.2 Methods using forward and adjoint estimates

Becker ${ }^{6}$ proposed three methods for developing weight windows based on both forward and adjoint deterministic solutions. These three methods correspond to the portion of the phase space over which uniform relative uncertainties are desired: a small "detector" region, a region comprising a significant portion of the entire problem, and the global problem. In this discussion, only a brief outline of each method, focusing on its implementation into MAVRIC, will be given.

## Source/detector problems

For a small detector of volume $V_{D}$ where we want to optimize the MC calculation of the detector response

$$
R=\int_{V_{D}} \int_{0}^{\infty} \sigma(\vec{r}, E) \phi(\vec{r}, E) d E d V
$$

or optimize for the energy dependent flux at the detector, the following is used:

| forward flux estimate | $\phi(\vec{r}, E)$ |
| :---: | :---: |
| adjoint source for flux or | $\begin{equation*} q^{+}(\vec{r}, E)=1 / \phi(\vec{r}, E) \tag{4.1.C.5} \end{equation*}$ |
| for response | $q^{+}(\vec{r}, E)=\sigma(\vec{r}, E)$ |
| adjoint flux | $\phi^{+}(\vec{r}, E)$ |
| contributon flux | $\phi^{c}(\vec{r}, E)=\phi(\vec{r}, E) \phi^{+}(\vec{r}, E)$ |
| normalization constant | $C_{\mathrm{norm}}=V_{D} / \int_{V_{D}} \int_{0}^{\infty} \phi^{c}(\vec{r}, E) d E d V$ |
| space-only contributon flux | $\tilde{\phi}^{c}(\vec{r})=C_{\text {norm }} \int_{0}^{\infty} \phi^{c}(\vec{r}, E) d E$ |
| spatial parameter | $\alpha(\vec{r})=\left[1+\exp \left(\frac{\tilde{\phi}_{\max \in V_{D}}^{c}}{\tilde{\phi}^{c}(\vec{r})}-\frac{\tilde{\phi}^{c}(\vec{r})}{\tilde{\phi}_{\max \in V_{D}}^{c}}\right)\right]^{-1}$ |
| spatial parameter | $B(\vec{r})=\alpha(\vec{r}) \tilde{\phi}^{c}(\vec{r})+1-\alpha(\vec{r})$ |
| weight windows | $\begin{equation*} \bar{w}(\vec{r}, E)=\frac{B(\vec{r})}{\phi^{+}(\vec{r}, E)} \tag{4.1.C.6} \end{equation*}$ |

## Source-region problems

For a detector of volume $V_{D}$ and surface area $A_{D}$ (smaller than the entire problem) where we want to optimize the MC calculation of the detector response

$$
R(\vec{r})=\int_{0}^{\infty} \sigma(\vec{r}, E) \phi(\vec{r}, E) d E \quad \vec{r} \in V_{D}
$$

or optimize for the energy dependent flux in the region, the following is used:

adjoint flux estimate
contributon flux
normalization
constant

$$
C_{\text {norm }}=A_{D} / \int_{A_{D}} \int_{0}^{\infty} \phi^{c}(\vec{r}, E) d E d A
$$

$$
\tilde{\phi}^{c}(\vec{r})=C_{\mathrm{norm}} \int_{0}^{\infty} \phi^{c}(\vec{r}, E) d E
$$

spatial parameter
spatial parameter
weight windows

$$
\begin{equation*}
\bar{w}(\vec{r}, E)=\frac{B(\vec{r})}{\phi^{+}(\vec{r}, E)} \tag{4.1.C.8}
\end{equation*}
$$

Note that $A_{D}$ does not include surfaces of $V_{D}$ which are on the boundary of the problem.

## Global response problem

For optimizing the Monte Carlo calculation of a detector response everywhere in phase space

$$
R(\vec{r})=\int_{0}^{\infty} \sigma(\vec{r}, E) \phi(\vec{r}, E) d E
$$

or optimizing for the energy-dependent flux everywhere, the following is used:
forward flux
estimate

$$
\begin{equation*}
\phi(\vec{r}, E) \tag{4.1.C.9}
\end{equation*}
$$

$$
\begin{array}{lc}
\begin{array}{l}
\text { adjoint source } \\
\text { for flux } \\
\text { or } \\
\text { for response }
\end{array} & q^{+}(\vec{r}, E)=1 / \phi(\vec{r}, E) \\
\text { adjoint flux } \\
\text { estimate } \\
\text { contributon flux } \\
\text { space-only } \\
\text { contributon flux } \\
\text { spatial parameter } & q^{+}(\vec{r}, E)=\sigma(\vec{r}, E) / \int_{0}^{\infty} \sigma(\vec{r}, E) \phi(\vec{r}, E) d E \\
\text { weight windows } & \phi^{+}(\vec{r}, E) \\
& \phi^{c}(\vec{r}, E)=\phi(\vec{r}, E) \phi^{+}(\vec{r}, E) \\
& \phi^{c}(\vec{r})=\int_{0}^{\infty} \phi^{c}(\vec{r}, E) d E \\
B(\vec{r})=\phi^{c}(\vec{r}) \\
& \bar{w}(\vec{r}, E)=\frac{B(\vec{r})}{\phi^{+}(\vec{r}, E)}
\end{array}
$$

### 4.1.C.3.3 Implementation in MAVRIC

Like CADIS and FW-CADIS, the Denovo $\mathrm{S}_{\mathrm{N}}$ code is used to calculate the forward flux estimate, $\phi(\vec{r}, E)$, and the estimate of the adjoint flux, $\phi^{+}(\vec{r}, E)$, for all of the Michigan weight window methods.

None of the above discussions of the University of Michigan methods include information on how the weight window target values were adjusted to match the source sampling. When implemented into MAVRIC, each of the above problem types will compute a biased source, $\hat{q}(\vec{r}, E)$, along with the target weight, $\bar{w}(\vec{r}, E)$, that are produced. For a problem with a single source of strength $S$ and distribution $q(\vec{r}, E)$, the biased source distribution $\hat{q}(\vec{r}, E)$ is found by using

$$
\hat{q}(\vec{r}, E)=q(\vec{r}, E) / \bar{w}(\vec{r}, E) .
$$

The weight windows are multiplied by a factor of $R / S$, where $R$ is defined as

$$
R=\iint \hat{q}(\vec{r}, E) \phi^{+}(\vec{r}, E) d E d V .
$$

Sampled source particles will then be born with a weight that matches the weight window of the phase space where they are born.

For multiple sources, each with strength $S_{i}$ and distribution $q_{i}(\vec{r}, E)$, each biased source distribution $\hat{q}_{i}(\vec{r}, E)$ is found by using

$$
\widehat{q}_{i}(\vec{r}, E)=q_{i}(\vec{r}, E) / \bar{w}(\vec{r}, E)
$$

and the response from each source being

$$
R_{i}=\iint \hat{q}_{i}(\vec{r}, E) d E d V
$$

The individual sources are sampled with a biased probability of $\hat{p}(i)=R_{i} / \sum R_{i}$. The weight windows are then multiplied by a factor of

$$
\frac{\sum_{i} R_{i}}{\sum_{i} S_{i}}
$$

to match the source birth weights.
To use one of the Becker methods in MAVRIC, the keyword "beckerMethod=" is used with values of 1 , 2 , or 3 for the source/detector, source/region, or global method. Adjoint sources are described just like standard MAVRIC CADIS and FW-CADIS problems. To switch between optimizing flux in every group or optimizing a response, the keywords "fluxWeighting" and "respWeighting" are used. Just like FW-CADIS, the response listed in each adjoint source is the response that is optimized. Note that even when starting a calculation with known forward and adjoint flux files, the adjoint source(s) still need to be listed since they are used in the final normalization of the weight windows.

### 4.1.C.3.4 Example problems

## A source/detector problem

The first Becker method (source/detector) is demonstrated using the Ueki shielding problem (used as sample problems in the Monaco and MAVRIC manuals and above in the space/energy/angle CADIS example). The goal is to calculate the neutron dose on one side of a shield from a partially collimated ${ }^{252} \mathrm{Cf}$ source on the other side of the shield. For the analog calculations, no importanceMap block is used. For the other cases, the importance map blocks are shown below.

| CADIS | Becker 1 - flux optimization | Becker 2 - response optimization |
| :---: | :---: | :---: |
| read importanceMap <br> adjointSource 1 locationID=1 <br> responseID=5 <br> end adjointSource <br> gridGeometryID=7 <br> macromaterial <br> mmTolerance=0.01 <br> end macromaterial <br> end importanceMap | read importanceMap adjointSource 1 locationID=1 responseID=5 end adjointSource gridGeometryID=7 macromaterial mmTolerance=0.01 end macromaterial beckerMethod=1 fluxWeighting end importanceMap | read importanceMap adjointSource 1 locationID=1 responseID=5 end adjointSource gridGeometryID=7 macromaterial mmTolerance=0.01 end macromaterial beckerMethod=1 respWeighting end importanceMap |

The results are shown in Table 4.1.C.2. The Becker response-optimized source/detector method, which requires two deterministic estimates, does slightly better for this problem than standard CADIS, which only requires one deterministic estimate.

Table 4.1.C.2. Results of the Ueki Shielding Problem ( 35 cm graphite shield)

|  | For. $\mathrm{S}_{\mathrm{N}}$ Adj. $\mathrm{S}_{\mathrm{N}}$ |  | MC | dose rate | relative | MC FOM |

## A global problem

For an example of a global problem, consider a two-room block building with a criticality accident in one room. The objective is to find the photon dose everywhere in order to see the locations where criticality alarms would trigger. The building is 12 meters long, 6 meters wide, and 3 meters tall. A comparison will be made between an analog calculation, an FW-CADIS calculation (using response weighting), GRWW, Becker's source/region method (response optimization), and Becker's global method (response optimization). The MAVRIC importance map block of each calculation is as follows.

Note that Becker's source/region method is designed for regions smaller than the entire problem, so this is not a fair comparison, just a demonstration on how to use it in MAVRIC. The bounding box of the adjoint source in this case is set slightly smaller than the extent of the entire problem.

Results for the photon dose and its relative uncertainty using the five different methods of calculation are shown in Figure 4.1.C.3. Information on the distribution of relative uncertainties is shown in Figure 4.1.C.4. and listed in Table 4.1.C.3.

A more detailed comparison of the different hybrid methods for representative shielding problems can be found in Ref. 7 and Ref. 8.

Figure 4.1.C.3. Mesh tally results for the photon dose over the entire building use five different methods.

Figure 4.1.C.4. The fraction of mesh tally voxels with less than a given amount of relative uncertainty for the five different methods.

## Table 4.1.C.3. Comparison of the five different methods

|  | Forward | Adjoint | Monte <br> $\mathrm{S}_{\mathrm{N}}$ | fraction of voxels with  <br> $\mathrm{S}_{\mathrm{N}}$  <br> Carlo  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| relative uncertainties less than |  |  |  |  |  |  |
| Calculation Method | $(\mathrm{min})$ | $(\mathrm{min})$ | $(\mathrm{min})$ | $5 \%$ | $10 \%$ | $15 \%$ |
| Analog |  |  | 20.1 | 0.583 | 0.857 | 0.973 |

| Becker, global response | 4.2 | 4.4 | 20.4 | 0.016 | 0.358 | 0.832 |

### 4.1.C.3.5 Other special options for the importance map block input

In MAVRIC, the above methods have been extended to use biased sources. To turn off the use of a biased source, use the keyword "selfNormalize". For forward flux-based methods, this will scale the target weights in the importance map so that the largest value is 1 , which typically is at the source location. To use the forward-based Michigan methods (Cooper, GFWW, GRWW) or the van Wijk ${ }^{9}$ methods as they were presented (without the MAVRIC biased source), use this keyword.

Use the keyword "spaceOnly=n" to create an importance map that contains one energy group over the entire range of energy. Use a value of 1 for neutron problems or a value of 2 for photon problems. This option is not designed for coupled problems. Both of the methods that van Wijk presents use importance maps that are space only.

Use the keyword "forwardParam= $p$ " to allow the target weights to be proportional to the forward estimate (using Denovo) of flux raised to any power $p$.

$$
\bar{w}(\vec{r})=\frac{\phi^{p}(\vec{r})}{\max \left(\phi^{p}(\vec{r})\right)} .
$$

For Cooper's method or van Wijk's first method, $p=1$, which is the default if "forwardParam" is not specified. For van Wijk's second method, based on the relative error estimate $\operatorname{Re}(\vec{r}) \propto 1 / \sqrt{\phi(\vec{r})}$, set this parameter to $p=0.5$. Note that with a power less than 1 , the weight window targets will span a smaller range than the expected Monte Carlo flux values. Particles may be rouletted before they reach the lowest flux areas of the problem.

When applying FW-CADIS for a semi-global problem, the adjoint source should cover the area where the lowest uncertainties are desired. Sometimes the area where this is desired is not a fixed geometric area but instead an area that has a final answer of a certain range. For example, when finding dose rate maps, the user may only be interested in getting low uncertainties for areas below the dose limit - areas above the dose limit may not matter as much since people will not be allowed in those areas. Another example may be that the dose map should be optimized in those areas above the background dose rate, since dose rates below that are of no concern. To allow the adjoint source area to be tailored in this way, the keywords "minForwardValue=" and/or "maxForwardValue="can be used. Default values are 0 and $10^{100}$, respectively. For flux weighting, only the voxels within the adjoint source bounding box and containing a forward flux estimate between the min and max are included as adjoint sources.

A comparison ${ }^{10}$ of FW-CADIS to the University of Michigan methods and the Van Wijk methods showed that FW-CADIS performs better and is more straightforward to use than the other methods. These other methods were added to SCALE so that a fair comparison could be made and have been left in the code base for academic use in case some types of problems could benefit from them.

### 4.1.C.4 Using MAVRIC to run fixed-source Denovo calculations

The MAVRIC sequence of SCALE can be used to run the new discrete-ordinates code Denovo. ${ }^{11}$ The sequence is designed to use Denovo to compute an importance map for the Monte Carlo code Monaco but can be stopped without starting the final Monaco calculation. The full version of Denovo has a pythonbased user interface where the user must construct the geometry, source, and cross sections on their own. MAVRIC provides an easy interface to run the serial-only version of Denovo within SCALE (called 'xkba'). Denovo inputs made using MAVRIC can also be imported into the python interface for the HPC version of Denovo.

To create Denovo inputs or run Denovo using MAVRIC, input the composition, geometry (including arrays if needed), definitions (grid geometry and response information), and sources block as if an actual full MAVRIC case were being run. The sequence should then be started with a parm=xxx flag to indicate to MAVRIC to stop after making Denovo inputs or running Denovo.

| parm= | MAVRIC stops after |
| :--- | :--- |
| Forward Calculations <br> forinp <br> forward | Making cross sections and Denovo input <br> Running Denovo |
| Adjoint Calculations  <br> adjinp Making cross sections and Denovo input <br> adjoint Running Denovo |  |

For forward Denovo simulations, the importance map block should contain which grid geometry to use and any of the optional Denovo parameters:

```
read importanceMap
    gridGeometryID=7
end importanceMap
```

For adjoint Denovo calculations, the importance map block should contain which grid geometry to use, one or more adjoint sources, and any of the optional Denovo parameters:

```
read importanceMap
    gridGeometryID=7
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
end importanceMap
```

For either forward or adjoint, the following files will be produced and should be copied out of the SCALE temporary directory back to your home area:

$$
\begin{array}{ll}
\text { ft02f001 } & \text { the AMPX mixed working library cross section file } \\
\text { xkba_b.inp } & \text { binary input file for Denovo } \\
\text { *.dff } & \text { Denovo flux file (binary) - scalar fluxes }
\end{array}
$$

The scalar flux file is automatically copied back to the home area when SCALE completes. The others can be copied back if desired using a shell command at the end of the MAVRIC input file (windows example shown below):

```
=shell
    copy ft02f001 %{RTNDIR}%/mixed.ft02f001
    copy xkba_b.inp %{RTNDIR}%/denovo.dsi
end
```

The xkba_b.inp file and the *.dff file can both be viewed with the Java utility, Mesh File Viewer, that is shipped with SCALE. The xkba_b.inp file shows the Denovo source distribution (space and energy), and the *.dff shows the final computed scalar fluxes. The binary Denovo input file should be renamed with an extension of *.dsi (Denovo simple input) so that the viewer can properly interpret the data.

### 4.1.C.4.1 Optional Denovo parameters

The default values for various calculational parameters and settings used by Denovo for the MAVRIC sequence should cover most applications. These settings can be changed by the interested user in the importance map block. The two most basic parameters are the quadrature set used for the discrete ordinates and the order of the Legendre polynomials used in describing the angular scattering. The default quadrature order that MAVRIC uses is $\mathrm{S}_{8}$, and for the order of Legendre polynomials, the default is $\mathrm{P}_{3}$ (or the maximum number of coefficients contained in the cross section library, if less than 3 ). $\mathrm{S}_{8} / \mathrm{P}_{3}$ should be a good choice for many applications, but the user is free to changes these. For complex ducts or transport over large distance at small angles, $\mathrm{S}_{12}$ may be required. $\mathrm{S}_{4} / \mathrm{P}_{1}$ would be useful in doing a very cursory run just to check if the problem was input correctly. Other parameters that can be set by the user in the importance map block for Denovo calculations are listed in Table 4.1.C.4.

Table 4.1.C.4. Optional Denovo parameters for the MAVRIC Importance Map Block

| block keyword | type | length | default | require | restrictions/comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| importanceMap |  |  |  |  |  |
| Optional Denovo $\mathrm{S}_{N}$ code parameters |  |  |  |  |  |
| discretization= | integer |  | 4 | no | 0-diamond-difference, 1-diamond-difference with flux fix-up:lin0, 2-theta-weighted diamond-difference, 3-linear-discontinuous finite element, 4-step characteristics, 5-trilinear discontinuous finite elem |
| quadType= | integer |  | 0 | no | 0-level symmetric, 1-Gauss-Legendre product, 2-QR |
| legendre= | integer |  | 3* | no | $P_{\mathrm{L}}, \mathrm{L}=$ highest Legendre polynomial, $\mathrm{L}=0,1,2,3, \ldots$ <br> *default is to use min(the highest available in the data,3) |
| tportcorrection= | integer |  | $1 *$ | no | transport correction: 0-none, 1-diagonal, 2-Cesaro *For $\mathrm{P}_{2}$ or higher, the default is 2 (Cesaro) |
| upScatter= | integer |  | 0 | no | upscatter iterations: 0-none, 1-yes, 2-ignore |
| xblocks= | integer |  | 1 | no | parallel stuff |

| krylovSpaceSize= | integer |  | 10 | no | size in memory for Krylov space |
| tolerance= | double |  | 1.E-03 | no | tolerance used in convergence test |
| krylovType= | integer |  | 0 | no | 0-GMRES, 1-BiCGStab |
| eigenSolver= | integer |  | 0 | no | 0 -power iteration, 1-Arnoldi, 2-shifted inverse |
| multiGSolover= | integer |  | 0 | no | 0 -Gauss-Seidel, 1-Krylov |
| withinGSolver= | integer |  | 0 | no | 0-Krylov, 1-residual Krylov, 2-source iteration |
| mgSettings= | integer |  | 1 | no | 0 -user supplied, 1-automatic |
| upGroupSolver= | integer |  | 0 | no | 0 -same as within-group solver, 1-Krylov, 2-residual Krylov, 3-source iteration, 4-single source iteration |
| acceleration= | integer |  | 0 | no | 0 -none, 1-two grid |
| maxItersMG= | integer |  | 20 | no | maximum number of iterations |
| toleranceMG= end importanceMap | double |  | 0.001 | no | tolerance used in convergence test |

In problems with small sources or media that are not highly scattering, discrete ordinates can suffer from "ray effects"-where artifacts of the quadrature directions can be seen in the computed fluxes. To help alleviate the ray effects problem, Denovo has a first-collision capability. This computes the amount of uncollided flux in each mesh cell from a point source. These uncollided fluxes are then used as a distributed source in the main discrete-ordinates solution. At the end of the main calculation, the uncollided fluxes are added to the fluxes computed with the first-collision source, forming the total flux. While this helps reduce ray effects in many problems, the first-collision capability can take a long time to compute on a mesh with many cells or for many point sources.

The macromaterials option ("mmTolerance=") can be used to better represent the geometry in Denovo. Refer to the main MAVRIC manual for details on macromaterials.

### 4.1.C.4.2 Forward source preparations

The user-entered source description is converted to a mesh-based source for Denovo. To create the mesh source, MAVRIC determines if the defined source exists within each cell. This is done by dividing each mesh cell into $n \times n \times n$ subcells (from the keyword "subCells $=n$ " in the importance map block with a
default of $n=2$ ) and testing each subcell center. For every subcell center that is a valid source position (within the spatial solid and meets optional unit, region, or mixture requirements), an amount of source proportional to the subcell volume is assigned to the mesh cell. The keyword "subCells=" can be used to better refine how much source is computed for the mesh cells at the boundary of a curved source region. Of course, more subcell testing takes more time.

The above process may miss small sources or degenerate sources (surfaces, lines, points) that do not lie on the tested subcell centers. If none of the mesh cells contain any source after the subcell method, then random sampling of the source is used. A number of source positions are sampled from the source (set by the "sourceTrials=" keyword, default of 1000000) and then placed into the proper mesh cell. If this method is used, the resulting Denovo input file should be visualized to ensure that the statistical nature of the source trials method does not unduly influence the overall mesh source.

For forward calculations, if the number of mesh cells containing the true source is less than 10, then MAVRIC will convert these source voxels to point sources, to allow Denovo to use its first-collision capability to help reduce ray effects. The user can easily override the MAVRIC defaults-to force the calculation of a first-collision source no matter how many voxels contain source-by using the keyword "firstCollision." To prevent the calculation of a first-collision source, the keyword "noFirstCollision" can be used.

For coupled problems, there are two ways to make Denovo compute photon fluxes from a neutron source: 1) include a tally using a photon response or 2 ) manually specify the "startGroup=" and the "endGroup=" to cover the particles/energy groups that are desired in the final Denovo output.

### 4.1.C.4.3 Adjoint source preparation

For adjoint calculations, adjoint sources that use point locations will use the Denovo first-collision capability. Volumetric adjoint sources (that use a boundingBox) will be treated without the first-collision capability. The keywords "firstCollision" and "noFirstCollision" will be ignored by MAVRIC for adjoint calculations.

Note that for an adjoint Denovo calculation, the MAVRIC input must still list a forward source. Otherwise, the sequence will report an error and stop. The forward source is not used for an adjoint Denovo calculation, but it must be present to make a legal MAVRIC input. For a coupled problem using an adjoint photon source, using a neutron forward source will make Denovo compute both photon and neutron adjoint fluxes. If the forward source(s) and adjoint source(s) are all photon, then only photon adjoint fluxes will be computed. The keywords "startGroup=" and "endGroup=" can also be used to manually set the particles/energy groups that are desired in the final Denovo output.

### 4.1.C.4.4 Other notes

Denovo (in SCALE 6) is a fixed-source $\mathrm{S}_{\mathrm{N}}$ solver and cannot model multiplying media. Neither forward nor adjoint neutron calculations from Denovo will be accurate when neutron multiplication is a major source component. If neutron multiplication is not turned off in the parameters block of the MAVRIC input (using keyword "noFissions"), a warning will be generated to remind the user of this limitation.

By default, MAVRIC instructs Denovo not to perform outer iterations for neutron problems if the crosssection library contains upscatter groups. This is because the time required to calculate the fluxes using upscatter can be significantly longer than without. For problems where thermal neutrons are an important part of the transport or tallies, the user should specify the keyword "upScatter=1" in the importance map
block. This will instruct Denovo to perform the outer iterations for the upscatter groups, giving more accurate results but taking a longer time.

### 4.1.C.4.5 MAVRIC utilities for Denovo

Denovo simply calculates scalar fluxes for every mesh cell and energy group - it does not compute responses based on those fluxes. Several utilities have been added to the collection of MAVRIC utilities in order to allow the user to further process Denovo scalar flux results. The full details and input descriptions for these utilities can be found in the MAVRIC Utilities description in Appendix B.

| dffBinOp | Binary operation of Denovo flux files: sum, difference, product, and ratio. |
| dffDisp | Display the basics of a Denovo flux file. |
| dffFilter | Perform various filters on a Denovo flux file. |
| dffFix | Fix the zero and negative values in a Denovo flux file. |
| dffInt | Integrate a single particle type from a Denovo flux file. |
| dffInv | Invert the values in a Denovo flux file. |
| dffMult | Multiply a Denovo flux file by a constant factor. |
| dffPull | Pull fluxes from certain voxels out of a Denovo flux file. |
| dffResp | Apply a response function to scalar fluxes in a Denovo flux file. |
| dffSplit | Split off a single particle type from a Denovo flux file. |

There are also two utility programs that look at the Denovo simple input file (binary) that MAVRIC creates. In the SCALE temporary directory, the file is called xkba_b.inp. In order to display in the MeshFileViewer, Denovo simple input files need to be renamed with a *. dsi extension. The utilities are as follows.
dsi2asc Convert a Denovo simple input (*.dsi) from binary to ASCII (so the user can see every detail).
dsiDisp Display the basics of a Denovo simple input file.

### 4.1.C.4.6 Example problem

## Forward

As an example, consider a simulation based on the Ueki shielding experiments (see Monaco manual). A ${ }^{252} \mathrm{Cf}$ neutron source was placed in the center of a 50 cm cube of paraffin which had a $45^{\circ}$ cone cut-out. The goal is to calculate the neutron dose at a detector 110 cm from the source.

The input file (denovo1.inp) needs the compositions of the paraffin and graphite

```
read composition
    para(h2o) 3 1.0 293.0 end
    carbon 4 den=1.7 1.0 293.0 end
end composition
```

then the geometry

```
read geometry
    global unit 1
                cuboid 1 25.0 -25.0 25.0 -25.0 25.0 -25.0
                cone 2 10.35948 25.01 0.0 0.0 rotate a1=-90 a2=-90 a3=0
                cuboid 3 90.0 70.0
                cuboid 99 120.0 -30.0 50.0 -50.0 50.0 -50.0
                media 3 1 1 1 -2
                media 0 1 2
        media 4 1 3
        media 0 1 99 -1 -2 -3
    boundary }9
end geometry
```

then the position of the detector, the response of the detector and the mesh to use for Denovo

```
read definitions
    location 1
        position 110 0 0
    end location
    response 5
        title="ANSI standard (1977) neutron flux-to-dose-rate factors"
        specialDose=9029
    end response
    distribution 1
        title="Cf-252 neutrons, Watt spectrum a=1.025 MeV and b=2.926/MeV"
        special="wattSpectrum"
        parameters 1.025 2.926 end
    end distribution
    gridGeometry 7
        xLinear 4 -25 -5
        xLinear 15 -5 25
        xLinear 9 25 70
        xLinear 8 70 90
        xplanes -30 95 100 105 109 111 115 120 end
        yplanes -50 -40 40 50 end
        yLinear 5 -40 -15
        yLinear 15 -15 15
        yLinear 5 15 40
        zplanes -50 -40 40 50 end
        zLinear 5 -40 -15
        zLinear 15 -15 15
        zLinear 5 15 40
    end gridGeometry
end definitions
```

the description of the true source

```
read sources
    src 1
        neutrons strength=4.05E+07
        cuboid 0.01 0.01 0 0 0 0
        eDistributionID=1
    end src
end sources
```

and finally the importance map block to trigger the Denovo calculation

```
read importanceMap
    gridGeometryID=7
    mmTolerance=0.001
end importanceMap
```

An optional shell command can be used to retrieve the cross section file and the Denovo input file (linux example shown below)

```
=shell
    cp ft02f001 ${RTNDIR}/denovo1.ft02f001
    cp xkba_b.inp ${RTNDIR}/denovo1.xkba.dsi
```

The denovo1.xkba.dsi file (the Denovo simple input) contains both the source and mesh geometry that MAVRIC prepared for Denovo, as shown in Figure 4.1.C.5.

Figure 4.1.C.5. Forward Denovo source (left) and mesh geometry (right).

The result of the Denovo-only MAVRIC calculation is a file, denovo1.forward.dff, containing the scalar fluxes for each energy group. The Mesh File Viewer can be used to display each group or the total scalar flux, which is shown in Figure 4.1.C.6.

Figure 4.1.C.6. Total forward fluxes.

The MAVRIC utilities can be used to further process the Denovo flux into a detector response. The fluxes at the location of the detector need to be multiplied by the photon flux-to-dose conversion factors (the response function) and then summed. This is can be done in the same input file using

```
=dffResp
"denovo1.forward.dff"
1
27
1.6151395E-04

4.0974155E-06
3.8398102E-06
3.6748431E-06
3.6748440E-06
3.6748431E-06
3.6748447E-06
"denovo1.doses.dff"
end
```

and results in a neutron dose rate of $5.426 \times 10^{-3} \mathrm{rem} / \mathrm{hr}$, calculated in about 2 minutes. Other combinations of the MAVRIC utilities can be used to simply "pull" out the fluxes from the detector location and then use a spreadsheet to compute the dose rate. With upscatter on, the result is $5.424 \times 10^{-3} \mathrm{rem} / \mathrm{hr}$, showing that upscatter does not contribute to dose rate at the detector. Note that with upscatter on, the Denovo calculation required 81 minutes.

## Adjoint

For the same calculation of neutron dose as above, a Denovo adjoint calculation can be performed. The input file (denovo2.inp) has the same composition, geometry, definitions, and source blocks as the forward example. The adjoint input importance map block contains a description of the adjoint source

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    mmTolerance=0.001
end importanceMap
```

The result of this Denovo-only MAVRIC calculation is a file, denovo2.adjoint.dff, containing the scalar adjoint fluxes for each energy group, as shown in Figure 4.1.C.7.

Figure 4.1.C.7. Total adjoint fluxes.

As with the forward fluxes, the MAVRIC utilities can be used to further process the Denovo adjoint fluxes into a detector response. The adjoint fluxes at the location of the forward source need to be multiplied by the source distribution and strength and then summed. This is can be done using

```
=dffResp
"denovo2.adjoint.dff"

"denovo2.doses.dff"
end
```

and results in a neutron dose rate of $5.463 \times 10^{-3} \mathrm{rem} / \mathrm{hr}$.

The results of the example problems above used a fairly coarse mesh ( $44 \times 27 \times 27$ ) and the default values of $\mathrm{S}_{8}$ and $\mathrm{P}_{3}$. Run times were 2 minutes for the forward case and 2.5 minutes for the adjoint. With a finer mesh, larger quadrature order and larger numbers of Legendre moments for the scattering representation, the values calculated using Denovo should converge towards the Monte Carlo solution of $1.494 \times 10^{-2} \mathrm{rem} / \mathrm{hr} \pm 1.2 \%$.

# 5.0. DEPLETION, ACTIVATION, AND SPENT FUEL SOURCE TERMS 

## Introduction by W. A. Wieselquist

SCALE's general depletion, activation, and spent fuel source terms analysis capabilities are enabled through a family of modules related to the main ORIGEN depletion/irradiation/decay solver. The nuclide tracking in ORIGEN is based on the principle of explicitly modeling all available nuclides and transitions in the current fundamental nuclear data for decay and neutron-induced transmutation and relies on fundamental cross section and decay data in ENDF/B VII. Cross section data for materials and reaction processes not available in ENDF/B-VII are obtained from the JEFF-3.0/A special purpose European activation library containing 774 materials and 23 reaction channels with 12,617 neutroninduced reactions below 20 MeV . Resonance cross section corrections in the resolved and unresolved range are performed using a continuous-energy treatment by data modules in SCALE. All nuclear decay data, fission product yields, and gamma-ray emission data are developed from ENDF/B-VII. 1 evaluations. Decay data include all ground and metastable state nuclides with half-lives greater than 1 millisecond. Using these data sources, ORIGEN currently tracks 174 actinides, 1149 fission products, and 974 activation products.

The purpose of this chapter is to describe the stand-alone capabilities and underlying methodology of ORIGEN-as opposed to the integrated depletion capability it provides in all coupled neutron transport/depletion sequences in SCALE, as described in other chapters. Through the stand-alone capabilities, there is generality to handle arbitrary systems (e.g., fast reactor fuel depletion or structural activation) by providing arbitrary flux spectra and arbitrary one-group cross sections to the module COUPLE, which in turn creates ORIGEN library (.f33) files containing the problem-dependent, onegroup reaction coefficients required to solve the actual equations governing depletion/decay. These libraries are required input for the ORIGEN module, along with the initial isotopics and irradiation history, in terms of either a time-dependent power or flux level. Two high-performance equation solvers are available: the hybrid linear chains and matrix exponential method and a new Chebyshev Rational Approximation Method (CRAM). Typical execution times are on the order of a few seconds for a multi-step solution, with each individual solution (step) taking approximately 10 milliseconds. ORIGEN also includes capabilities for continuous feed and removal by element. Output capabilities include isotopics (moles or grams), source spectra (alpha, beta, gamma, and neutron), activity (becquerels or curies), decay heat (total watts or gamma only), and radiological hazard factors (maximum permissible concentrations in air or water). These results can be displayed in the output file (.out extension) and/or archived in an ORIGEN binary results file (.f71 extension).

The use of current, fundamental data resources is a key feature of ORIGEN, including nuclear decay data, multigroup neutron reaction cross sections, neutron-induced fission product yields, and decay emission data for photons, neutrons, alpha particles, and beta particles. The nuclear decay data are based primarily on ENDF/B-VII. 1 evaluations. The multigroup nuclear reaction cross section libraries now include evaluations from the JEFF-3.0/A neutron activation file containing data for 774 target nuclides, more than 12,000 neutron-induced reactions, and more than 20 different reaction types below 20 MeV , provided in various energy group structures. Energy-dependent ENDF/B-VII.0-based fission product yields are available for 30 fissionable actinides. Gamma-ray and x-ray emission data libraries are based on ENDF/B-VII.1. The photon libraries contain discrete photon line energy and intensity data for decay gamma-ray and x-rays emission for 1,132 radionuclides, prompt and delayed continuum spectra for spontaneous fission, ( $\alpha, \mathrm{n}$ ) reactions in oxide fuel, and bremsstrahlung from decay beta (electron and positron) particles slowing down in either a $\mathrm{UO}_{2}$ fuel or water matrix. Methods and data libraries used to calculate the neutron yields and energy spectra for spontaneous fission, ( $\alpha, \mathrm{n}$ ) reactions, and delayed neutron emission are adopted from the SOURCES4C code. Capabilities to calculate the beta and alpha particle emission source and spectra have also been added.

The ORIGEN reactor libraries distributed with SCALE include a set of pre-calculated ORIGEN libraries (with TRITON) for a variety of fuel assembly designs:

- BWR $7 \times 7,8 \times 8-1,8 \times 8-2,9 \times 9-2,9 \times 9-9,10 \times 10-9,10 \times 10-8$, SVEA-64, SVEA- 96 , and SVEA-100;
- PWR $14 \times 14,15 \times 15,16 \times 16,17 \times 17,18 \times 18$;
- CANDU reactor (19-, 28-, and 37-element bundle designs);
- Magnox graphite reactor;
- Advanced Gas-Cooled Reactor (AGR);
- VVER 440 and VVER 1000;
- RBMK;
- IRT;
- MOX BWR $7 \times 7,8 \times 8-1,8 \times 8-2,9 \times 9-2,9 \times 9-9,10 \times 10-9,10 \times 10-8$, SVEA- 64 , SVEA- 96 , and SVEA-100;
- MOX PWR $14 \times 14,15 \times 15,16 \times 16,17 \times 17,18 \times 18$.

These libraries may be used to rapidly assess spent fuel isotopics and source terms in these systems for arbitrary burnups and decay times. For $\mathrm{UO}_{2}$-based assembly isotopics, the new ORIGAMI sequence provides a very convenient, easy-to-use interface. The most general capability, and requiring more user input, is available using the ARP interpolator module in conjunction with the ORIGEN solver module.

Finally, with regards to user interfaces, ORIGEN has a new keyword-based input in SCALE 6.2 but also maintains the ability to read SCALE 6.1 input. Both ORIGEN and ORIGAMI are tightly integrated with the SCALE graphical user interface, Fulcrum, which includes syntax highlighting, input checking with immediate feedback, and (.f71) output viewing. Additionally, Fulcrum provides an ORIGAMI Automator project interface to characterize the fuel inventory for an entire reactor site and generate data needed for severe accident analysis. ORIGAMI Automator is not documented in this chapter, but a primer is available with step by step instructions on its use.

# 5.1 ORIGEN: NEUTRON ACTIVATION, ACTINIDE TRANSMUTATION, FISSION PRODUCT GENERATION, AND RADIATION SOURCE TERM CALCULATION 

W. Wieselquist, S. Hart, A. Isotalo ${ }^{1}$, F. Havlůj ${ }^{2}$, S. Skutnik ${ }^{3}$, R. Lefebvre, I. Gauld, D. Wiarda, J. Lefebvre, G. $\mathrm{Hu}^{4}$, N. Sly ${ }^{3}$, and D. Lago ${ }^{5}$

#### Abstract

ORIGEN (Oak Ridge Isotope Generation code) calculates time-dependent concentrations, activities, and radiation source terms for a large number of isotopes simultaneously generated or depleted by neutron transmutation, fission, and radioactive decay. ORIGEN is used internally within SCALE's TRITON and Polaris sequences to perform depletion and decay. As a stand-alone SCALE module, ORIGEN provides additional unique capabilities to (1) simulate continuous nuclide feed and chemical removal, which can be used to model reprocessing or liquid fuel systems, and (2) generate alpha, beta, neutron and gamma decay emission spectra. A standard decay library is provided to perform decay calculations. For neutron activation and fuel depletion problems, neutron spectrum-dependent ORIGEN libraries are required and may be created from (1) user-defined spectrum and self-shielded cross sections using the COUPLE module or (2) interpolation of existing ORIGEN reactor libraries (precalculated by TRITON) using the Automated Rapid Processing (ARP) module. Post-processing using the OPUS module allows calculated isotopics and spectra to be sorted, ranked, and converted to other units.

## ACKNOWLEDGMENTS

Development and maintenance of ORIGEN and related codes and methods have been sponsored by many organizations including the US Nuclear Regulatory Commission (NRC), the US Department of Energy (DOE), and nuclear power and research institutions.

## VERSION INFORMATION

The ORIGEN (Oak Ridge Isotope Generation) code ${ }^{1}$ was developed at Oak Ridge National Laboratory (ORNL) to calculate nuclide compositions and radioactivity of fission products, activation products, and products of heavy metal transmutation. Since 1991, ORIGEN has been developed as the depletion/decay module in SCALE with support from the NRC. ORIGEN in SCALE is the only version supported at ORNL, and it supersedes all earlier versions. The following is a brief description of the major enhancements in each version. Data are described in the ORIGEN Data Resources chapter.

## 6.2 (2016)

Code Responsible(s): W. A. Wieselquist
A major modernization effort for ORIGEN was initiated by I. Gauld in 2011 and has resulted in approximately 5 person-years of effort refactoring the ORIGEN and related codes to be more efficient and easily testable. The major enhancements and responsible parties are listed below.

- Extensive refactor and modernization of Fortran 77 to Fortran 90+ performed by F. Havlůj, including substantial extension of the output capability
- Implementation of an alpha and beta spectrum calculation by F. Havlůj and I. Gauld
- Introduction of C++ core data structures with Fortran bindings, implemented by S. Skutnik using R. Lefebvre's C++/C/Fortran binding generator created for this purpose
- Testing suite developed by S. Skutnik, W. Wieselquist, D. Lago, and N. Sly
- Standardization of codebase while developing application programming interface (API) for high-performance depletion in the Consortium for Advanced Simulation of Light Water Reactors (CASL) and Nuclear Energy Advanced Modeling and Simulation (NEAMS) projects performed by W. Wieselquist
- Unification of readers/writers for ORIGEN data files developed by W. Wieselquist
- Improvement of binary formats for the ORIGEN library (f33) and ORIGEN concentration file (f71) by J. Lefebvre, R. Lefebvre, and W. Wieselquist
- Implementation of Chebyshev Rational Approximation Method (CRAM) solver by A. Isotalo
- Development of new input format (ORIGEN sequence only) by S. Hart and W. Wieselquist using the SCALE Object Notation (SON) syntax developed by R. Lefebvre
- Improvement of cubic spline interpolation scheme for ARP by S. Skutnik and W. Wieselquist with monotonicity fix-up determined by G. Hu
- Major revision of manuals by W. Wieselquist, combining ORIGEN, ARP, COUPLE, and OPUS into a single manual

Additional guidance provided by D. Wiarda and I. Gauld with testing by J. W. Hu.

## 6.1 (2011)

The following section acknowledgements appeared in the SCALE 6.1 manual.

## ORIGEN

Code Responsible(s): I. C. Gauld
The ORIGEN code was first developed by M. J. Bell with contributions from J. P. Nichols and other members of the Chemical Technology Division at ORNL. Development of the ORIGEN code as a depletion module of the SCALE code system was performed by O. W. Hermann with contributions from R. M. Westfall, supported by the NRC.

## COUPLE

Code Responsible(s): D. Wiarda and I. C. Gauld
The COUPLE code was originally developed by O. W. Hermann with guidance from staff members including L. M. Petrie, N. M. Greene, W. E. Ford III, and R. M. Westfall, who contributed greatly to formulation of the methods, design of the data library interface with other modules, and testing. Many valuable suggestions concerning code applications were received from J. C. Ryman, J. R. Knight, and E. J. Allen.

ARP
Code Responsible(s): I. C. Gauld, S. M. Bowman, and J. E. Horwedel.
The authors thank S. B. Ludwig for his support in earlier stages of this work. The authors are grateful for the technical advice received from B. L. Broadhead, M. D. DeHart, N. M. Greene, O. W. Hermann, C. V. Parks, L. M. Petrie, and J. C. Ryman. The authors thank Germina Ilas and Georgeta Radulescu for reviewing the manual and Willena Carter for preparation of the manuscript.

## OPUS

Code Responsible(s): I. C. Gauld and J. E. Horwedel
The work of O. W. Hermann in developing the PLORIGEN program, from which OPUS was later developed, and the work of D. L. Barnett in developing the original version of PlotOPUS, are acknowledged. Appreciation is extended to J. C. Ryman for his review and testing of the program. Finally the authors thank S. J. Poarch for formatting the manuscript.

### 5.1.1 Introduction

ORIGEN solves the system of ordinary differential equations (ODEs) that describe nuclide generation, depletion, and decay,

$$
\begin{equation*}
\frac{d N_{i}}{d t}=\sum_{j \neq i}\left(l_{i j} \lambda_{j}+f_{i j} \sigma_{j} \Phi\right) N_{j}(t)-\left(\lambda_{i}+\sigma_{i} \Phi\right) N_{i}(t)+S_{i}(t), \tag{5.1.1}
\end{equation*}
$$

where

$$
\begin{aligned}
N_{i} & =\text { amount of nuclide } i \text { (atoms), } \\
\lambda_{i} & =\text { decay constant of nuclide } i(1 / \mathrm{s}), \\
l_{i j} & =\text { fractional yield of nuclide } i \text { from decay of nuclide } j, \\
\sigma_{i} & =\text { spectrum-averaged removal cross section for nuclide } i \text { (barn), } \\
f_{i j} & =\text { fractional yield of nuclide } i \text { from neutron-induced removal of nuclide } j, \\
\Phi & =\text { angle- and energy-integrated time-dependent neutron flux (neutrons/cm²}-\mathrm{s}), \text { and } \\
S_{i} & =\text { time-dependent source/feed term (atoms/s). }
\end{aligned}
$$

Note that Eq. (5.1.1) has no spatial dependence and can be interpreted as either a solution at a point in space or the spatial average over some volume. The latter interpretation is preferred here, such that $\Phi$ is the spatially averaged neutron flux magnitude, and all energy-dependence is embedded in the one-group flux-weighted average cross sections $\sigma_{i}$ and reaction yields $f_{i j}$. Eq. (5.1.1) is conveniently written in matrix form as

$$
\begin{equation*}
\frac{d \vec{N}}{d t}=A \vec{N}(t)+\vec{S}(t) \tag{5.1.2}
\end{equation*}
$$

with a $\boldsymbol{A}$ commonly referred to as the "transition matrix." The representation of the transition matrix as $\boldsymbol{A}=\boldsymbol{A}_{\sigma} \Phi+\boldsymbol{A}_{\lambda}$, where $\boldsymbol{A}_{\sigma}$ is the part of the transition matrix containing reaction terms and $\boldsymbol{A}_{\lambda}$ is the part containing decay terms, is convenient, as the numerical solution of this system of ODEs holds the reaction, flux, and feed terms constant over step $n$,

$$
\begin{align*}
& \frac{d \vec{N}}{d t}=\left(\boldsymbol{A}_{\sigma, n} \Phi_{n}+\boldsymbol{A}_{\lambda}\right) \vec{N}(t)+\vec{S}_{n}  \tag{5.1.3}\\
& \quad \text { over time step } t_{n-1} \leq t \leq t_{n}
\end{align*}
$$

Adding a continuous removal process described with rate constant $\lambda_{i, r e m}$ simply modifies the decay constant, $\lambda_{i} \rightarrow \lambda_{i}+\lambda_{i, r e m}$, whereas a continuous feed process defines a nonzero component of the $\vec{S}$ vector.

ORIGEN can also compute the alpha, beta, neutron, and gamma emission spectra during decay. For the "stand-alone" ORIGEN calculations described here, the transition matrix is loaded from an ORIGEN binary library file (f33), which uses sparse-matrix storage to store one or more transition matrices. The f33s may be created using COUPLE, saved from TRITON depletion calculations, or interpolated using ARP from a set of precompiled f33s distributed with SCALE.

Results from ORIGEN calculations may be stored on a binary concentration file (f71), which facilitates transfer of isotopics to other codes in SCALE. The $f 71$ file can also store calculated emission spectra. Within ORIGEN, the $f 71$ can be used to restart calculations from an existing set of compositions.

### 5.1.2 Methodology

This section describes the methodology used in performing the following main functions:

- generation of problem-dependent transition matrices,
- solution of the system of depletion/decay equations,
- conversion from power to flux (important for reactor applications),
- calculation of emission spectra, and
- interpolation of pregenerated sets of transition matrices.

### 5.1.2.1 Generation of Problem-dependent Transition Matrix

In the transition matrix $\boldsymbol{A}$ from Eq. (5.1.2), each matrix element $a_{i j}$ is the first-order rate constant for the formation of nuclide $i$ from nuclide $j$ given below.

$$
a_{i j}=\left\{\begin{array}{cr}
l_{i j} \lambda_{j}+f_{i j} \sigma_{j} \Phi & i \neq j  \tag{何.1.4}\\
-\lambda_{i}-\sigma_{i} \Phi & \text { otherwise }
\end{array}\right.
$$

The transition matrix coefficients for decay and reaction transitions are stored separately and reaction transitions are always stored with $\Phi=1$ and later during solution of the system, depending on the stepaverage flux level the actual transition matrix $\boldsymbol{A}_{n}=\boldsymbol{A}_{\sigma, n} \Phi_{n}+\boldsymbol{A}_{\lambda}$ is reconstructed using step-average flux, $\Phi_{n}$.

The decay coefficients $l_{i j} \lambda_{j}$ and $\lambda_{i}$ are generated directly from ORIGEN decay resource data. The reaction coefficients $f_{i j} \sigma_{j}$ and $\sigma_{i}$ are generated using the following two-stage procedure.

1. Calculate all removal cross sections $\sigma_{i}$ and yields $f_{i j}$, including isomeric branching ratios and fission yields, by folding provided flux spectrum $\phi^{g}$ with multigroup cross sections from the ORIGEN reaction resource and energy-dependent fission yield data from the ORIGEN yield resource.
2. Overwrite specific removal cross sections and yields based on a provided multigroup cross section library [SCALE Cross Section Libraries chapter] and/or user-provided one-group cross sections and yields.

The second stage is optional, but it is important for cases which there is significant self-shielding because ORIGEN's reaction resource assumes infinite dilution for its multigroup data. The decay, reaction, and yeld resources mentioned here are described in the ORIGEN Data Resources chapter. The collapse to a one-group cross section in either stage is given by

$$
\begin{equation*}
\sigma_{r i}=\frac{\sum_{g} \sigma_{r i}^{g} \phi^{g}}{\sum_{g} \phi^{g}} \tag{5.1.5}
\end{equation*}
$$

for reaction type $r$, nuclide $i$, and provided multigroup flux $\phi^{g}$. Different reaction types are recognized by their ENDF MT numbers [SCALE Cross Section Libraries chapter] on the appropriate data resource For example, $\mathrm{MT}=16$ is $(n, 2 n)$, and $\mathrm{MT}=107$ is $(n, \alpha)$. The removal cross section $\sigma_{i}$ is simply calculated as the sum over all relevant reactions for a particular nuclide, $\sigma_{i}=\sum_{r} \sigma_{r i}$. This type of reaction-dependent multigroup data may be contained in either the data sources available in stage 1 or 2 above. However, only two types of data are expected to be available in stage 1 reaction resource data: (1) isomeric branching and (2) fission yields.

The energy-dependent isomeric branching that describes the yield of each excited level (metastable state) of a daughter nucleus is calculated in a similar way,

$$
\begin{equation*}
f_{\text {rim }}=\frac{\sum_{g} f_{r i m}^{g} \sigma_{r i \phi}^{g} \phi^{g}}{\sum_{g} \sigma_{r i}^{g} \phi^{g}} \tag{5.1.6}
\end{equation*}
$$

where $m$ indicates the possible metastable states and the fractions always satisfy $\sum_{m} f_{\text {rim }}=1$.
Fission product yields are typically tabulated at discrete neutron energies such as thermal ( 0.0253 eV ), fission ( 500 keV ), and high energy ( 14 MeV ). The yield for each fissionable nuclide is calculated in stage 1 by linearly interpolating the tabulated data using the computed average energy of fission,

$$
\begin{equation*}
\bar{E}_{f i}=\frac{\sum_{g} \bar{E}^{g} \sigma_{f i}^{g} \phi^{g}}{\sum_{g} \sigma_{f i}^{g} \phi^{g}} \tag{5.1.7}
\end{equation*}
$$

where $\sigma_{f i}^{g}$ is the multigroup fission cross section, and $\bar{E}^{g}$ is the average energy in the group (simple midpoint energy used). In addition to generating transition data for daughter/residual nuclides, the coefficients for byproducts such as $\mathrm{He}-4 / \alpha$ byproducts from ( $n, \alpha$ ) reactions are also retained in the transition matrix and associated to an appropriate nuclide in the system: hydrogen, deuterium, tritium, ${ }^{3} \mathrm{He}$, or ${ }^{4} \mathrm{He}$.

### 5.1.2.2 Solution of the Depletion/Decay Equations

ORIGEN includes two solver kernels that can solve the depletion/decay equations of Eq. (5.1.3):

1. a hybrid matrix exponential/linear chains method (MATREX) and
2. a Chebyshev Rational Approximation Method (CRAM).

They are described in the following sections.

### 5.1.2.2.1 MATREX

Referring to the system of ODEs shown in Eq. (5.1.2) and setting the external feed/source $S(t)=0$, there is a formal solution by matrix exponential (an analog to the solution of a single ODE of this type by exponential),

$$
\begin{equation*}
\vec{N}(t)=\exp (\boldsymbol{A} t) \vec{N}(0) \tag{5.1.8}
\end{equation*}
$$

where $\vec{N}(0)$ is a vector of initial nuclide concentrations, by defining the series expansion of $\exp (\boldsymbol{A} \boldsymbol{t})$ to be

$$
\begin{equation*}
\exp (\boldsymbol{A} t)=\boldsymbol{I}+\boldsymbol{A} t+\frac{(\boldsymbol{A} t)^{2}}{2}+\cdots=\sum_{k=0}^{\infty} \frac{(\boldsymbol{A} t)^{k}}{k!} \tag{5.1.9}
\end{equation*}
$$

with $\boldsymbol{I}$ the identity matrix. Eqs. (5.1.8) and (5.1.9) describe the matrix exponential method, which yields a complete solution to the problem. However, in certain instances related to limitation in computer precision, difficulties occur in generating accurate values of the matrix exponential function. Under these
circumstances, alternative procedures using either the generalized Bateman equations ${ }^{2}$ or Gauss-Seidel iterative techniques are applied. These alternative procedures will be discussed in further sections.

A straightforward solution of Eqs. (5.1.8) through (5.1.9) would require storage of the complete transition matrix. To avoid excessive memory storage requirements, a recursion relation has been developed. Substituting Eq. (5.1.9) into Eq. (5.1.8),

$$
\begin{equation*}
\vec{N}(t)=\left[\boldsymbol{I}+\boldsymbol{A} t+\frac{(\boldsymbol{A} t)^{2}}{2}+\cdots\right] \vec{N}(0) \tag{}
\end{equation*}
$$

one may recognize a recursion relation for a particular nuclide, $N_{i}(t)$.

$$
\begin{align*}
N_{i}(t) & =N_{i}(0)+t \sum_{j} a_{i j} N_{j}(0)+\frac{t}{2} \sum_{k}\left[a_{i k} t \sum_{j} a_{k j} N_{j}(0)\right]  \tag{1}\\
& +\frac{t}{3} \sum_{m}\left\{a_{i m} \frac{t}{2} \sum_{k}\left[a_{m k} t \sum_{j} a_{k j} N_{j}(0)\right]\right\}+\cdots
\end{align*}
$$

where the range of indices, $j, k, m$, is 1 to $M$ for matrix $\boldsymbol{A}$ of size $M \times M$. The result is a series of terms that arise from the successive post-multiplication of the transition matrix by the vector of nuclide concentration increments produced from the computation of the previous terms. Within the accuracy of the series expansion approximation, physical values of the nuclide concentrations are obtained by summing a converged series of these vector terms. By defining the terms $C_{i}^{n}(t)$ as

$$
\begin{equation*}
C_{i}^{0}=N_{i}(0), \quad C_{i}^{n+1}=\frac{t}{n+1} \sum_{j} a_{i j} C_{j}^{n}, \tag{2}
\end{equation*}
$$

the solution for $N_{i}(t)$ is given as

$$
\begin{equation*}
N_{i}(t)=\sum_{n=0}^{\infty} C_{i}^{n} \tag{3}
\end{equation*}
$$

The use of Eqs. (5.1.12) and (5.1.13) requires storage of only two vectors- $\vec{C}^{n}$ and $\vec{C}^{n+1}$ —in addition to the current value of the solution. However, the series summation solution in Eq. (5.1.13) is not valid until a finite limit is identified which can achieve a reasonable accuracy, i.e.,

$$
\begin{equation*}
N_{i}(t)=\sum_{n=0}^{n_{\text {term }}} C_{i}^{n}+\epsilon_{\text {trunc }} \tag{4}
\end{equation*}
$$

where $n_{\text {term }}$ is the number of terms and $\epsilon_{\text {trunc }}$ is the truncation error. The key is to split the nuclides into two sets: those that are long-lived and permit a rapid, accurate solution via Eq. (5.1.14), and those that are short-lived and require an alternate solution.

### 5.1.2.2.1.1 Solution for Long-Lived Nuclides

This section describes the various tests used to ensure that the summations indicated in Eq. (5.1.14) do not lose accuracy due to large changes in magnitudes or small differences between positive and negative rate constants. Nuclides with large rate constants (short-lived) are removed from the transition matrix and treated separately. For example, in the decay chain $\mathrm{A} \rightarrow \mathrm{B} \rightarrow \mathrm{C}$, if the decay constant for B is large, a new rate constant is inserted in the matrix for $\mathrm{A} \rightarrow \mathrm{C}$. This technique was originally employed by Ball and Adams. ${ }^{3}$ The key to determining which transitions should be removed involves calculation of the matrix norm. The norm of matrix $\boldsymbol{A}$ is defined by Lapidus and Luus ${ }^{4}$ as being the smaller of the maximum-row absolute sum and the maximum-column absolute sum,

$$
\begin{equation*}
[\boldsymbol{A}]=\min \left\{\max _{\mathrm{j}} \sum_{i}\left|a_{i j}\right|, \max _{\mathrm{i}} \sum_{j}\left|a_{i j}\right|\right\} . \tag{}
\end{equation*}
$$

To maintain precision in performing the summations of Eq. (5.1.14), the matrix norm is used to balance the user-specified time step, $t$, with the precision associated with the word length employed in the machine calculation. The constraint on the matrix norm has been chosen as

$$
\begin{equation*}
[A] t \leq-2 \ln (0.001)=13.8155 . \tag{}
\end{equation*}
$$

The remainder of this section shows that this constraint serves two purposes.

- It allows reasonable accuracy for a reasonable number (20-60) of matrix exponential terms.
- It defines what "short-lived" means over a particular time step, dictating which concentrations must be solved by alternate means.

A relationship between $m$ digits of machine precision and $p$ significant digits required in all results can be stated by the following inequality: (Largest term in series) $\times 10^{-\mathrm{m}} \leq$ (Series result) $\times 10^{-\mathrm{p}}$.

In this particular series, the relationship may be represented as

$$
\begin{equation*}
\max _{n} \frac{\left.[\mid A] t\right|^{n}}{n!} 10^{-m} \leq e^{-[A] t} 10^{-p}, \tag{}
\end{equation*}
$$

or alternatively,

$$
\begin{equation*}
\max _{n} \frac{|[A] t|^{n}}{n!} e^{[A] t} \leq 10^{m-p} . \tag{}
\end{equation*}
$$

Lapidus and Luus have shown that the maximum term in the summation for any element in the matrix exponential function cannot exceed $\frac{([\boldsymbol{A}] t)^{n}}{n!}$, where $n$ is the largest integer not larger than $[\boldsymbol{A}] t$. For the constraint in Eq. (5.1.16), this yields $n=13$ and yields $\operatorname{limit} \frac{([A] t)^{n}}{n!} \approx 10^{5}$. With $e^{[A] t} \approx 10^{6}$ and standard double precision with $m=16$, Eq. (5.1.18) evaluates to $10^{11} \leq 10^{16-j}$, which indicates that five significant figures will be maintained in values as small as $10^{-6}$. The number of terms required to converge the matrix exponential series can be investigated by a plot of the $\frac{\| A]\left.t\right|^{n}}{n!} e^{[A] t}$ as a function of term index $n$ in Eq. (5.1.18), as shown in Figure 5.1.1.

Figure 5.1.1. Values of terms in Series for various values of the matrix norm.

The intersection between the black line in Figure 5.1.1 and the various curves indicates the number of terms needed to achieve $\epsilon_{\text {trunc }} \leq 0.1 \%$. For example, with $[A] t=13.8155, n_{\text {term }}=54$ is required, and with $[A] t=13.8155 / 2$, approximately $n_{\text {term }}=29$ is required. This behavior has been used to develop the heuristic

$$
n_{\text {term }}=7[\boldsymbol{A}] t / 2+6
$$

Thus it has been shown that the limit imposed in Eq. (5.1.16) leads to a maximum of $n_{\text {term }}=54$ terms with $\epsilon_{\text {trunc }} \leq 0.1 \%$.

It remains to be shown that any arbitrary system can be modified so that it does not violate Eq. (5.1.16). Because the time step $t$ is provided and fixed, $[A] t \leq-2 \ln (0.001)$ cannot be satisfied unless the system is modified. The physical nature of the system leads to $\max _{j} \sum_{i}\left|a_{i j}\right| \leq \max _{j} 2\left|a_{j j}\right|$ based on production rates equal to loss rates when both parent and daughter nuclide are included in the system. The maximum column sum in Eq. (5.1.15) can then be bounded by twice the maximum diagonal term, $\max _{j} 2\left|a_{j j}\right|$. Using this upper limit as the matrix norm and substituting into Eq. (5.1.16) yields

$$
\begin{equation*}
[A] t \leq 2 \max _{j}\left|a_{j j}\right| \leq-2 \ln (0.001) \tag{0}
\end{equation*}
$$

Rearranging Eq. (5.1.20) leads to the condition

$$
\begin{equation*}
e^{-\left|a_{j j}\right| t}<0.001 \tag{1}
\end{equation*}
$$

which is used to mark nuclide $j$ as a short-lived nuclide for this time step, to be solved with linear chains instead of the series-based matrix exponential. An alternative interpretation of the short-lived condition can be made by rewriting Eq. (5.1.21) in terms of an effective half-life, $t_{1 / 2}=\frac{\ln (2)}{\left|a_{j j}\right|}$, which results in
$t_{1 / 2}<\frac{-\ln (2)}{\ln (0.001)} t \approx 0.1 t$. In other words, when a nuclide's effective half-life (including destruction by both decay and reaction mechanisms) is less than $10 \%$ of the time step, it can be considered short-lived.

Finally, as a note, in applications where the nuclides of interest are in long transmutation chains, it has been found that the above algorithm may not yield accurate concentrations for those nuclides near the end of the chain that are significantly affected by those near the beginning of the chain. In these applications, specifying the minimum $n_{\text {term }}$ as

$$
n_{\text {term }} \geq|\Delta Z|+|\Delta A|+5
$$

where $\Delta Z$ is the atomic number difference and $\Delta A$ is the mass number difference, has been found to ameliorate the issue.

### 5.1.2.2.1.2 Solution for Short-Lived Nuclides

The condition in Eq. (5.1.21) forms the basis for declaring a nuclide short-lived, and its solution is found via solution of the nuclide chain equations. In conjunction with maintaining the transition matrix norm below the prescribed level, a queue is formed of the short-lived precursors of each long-lived isotope. These queues extend back up the several chains to the last preceding long-lived precursor. According to Eq. (5.1.21), the queues will include all nuclides whose effective half-lives are less than $10 \%$ of the time interval. A generalized form of the Bateman equations developed by Vondy ${ }^{5}$ is used to solve for the concentrations of the short-lived nuclides at the end of the time step. For an arbitrary forward-branching chain, Vondy's form of the Bateman solution is given by

$$
\begin{equation*}
N_{i}(t)=N_{i}(0) e^{-d_{i} t}+\sum_{k=1}^{i-1} N_{k}(0)\left[\sum_{j=k}^{i-1} \frac{e^{-d_{j} t}-e^{-d_{i} t}}{d_{i}-d_{j}} a_{j+1, j} \prod_{\substack{n=k \\ n \neq j}}^{i-1} \frac{a_{n+1, n}}{d_{n}-d_{j}}\right] \tag{3}
\end{equation*}
$$

where $N_{1}(0)$ is the initial concentration of the first precursor, $N_{2}(0)$ is that of the second precursor, etc. As in Eq. (5.1.4), $a_{i j}$ is the first-order rate constant, and $d_{i}=-a_{i i}$ which is the magnitude of the diagonal element. Bell recast Vondy's form of the solution through multiplication and division by $\prod_{n=k}^{i-1} d_{n}$ and rearranged to obtain

$$
\begin{equation*}
N_{i}(t)=N_{i}(0) e^{-d_{i} t}+\sum_{k=1}^{i-1} N_{k}(0) \prod_{n=k}^{i-1} \frac{a_{n+1, n}}{d_{n}}\left[\sum_{j=k}^{i-1} d_{j} \frac{e^{-d_{j} t}-e^{-d_{i} t}}{d_{i}-d_{j}} \prod_{\substack{n=k \\ n \neq j}}^{i-1} \frac{d_{n}}{d_{n}-d_{j}}\right] \tag{5.1.24}
\end{equation*}
$$

The first product over isotopes $n$ is the fraction of atoms that remains after the $k^{t h}$ particular sequence of decays and captures. If this product becomes less than $10^{-6}$, the contribution of this sequence to the concentration of nuclide $i$ is neglected. Indeterminate forms that arise when $d_{i}=d_{j}$ or $d_{n}=d_{j}$ are evaluated using L'Hôpital's rule. These forms occur when two isotopes in a chain have the same diagonal element.

Equation (5.1.24) is applied to calculate all contributions to the "queue end-of-interval concentrations" of each short-lived nuclide from the initial concentrations of all others in the queue described above. It is also applied to calculate contributions from the initial concentrations of all short-lived nuclides in the queue to the long-lived nuclide that follows the queue, in addition to the total contribution to its daughter products. These values are appropriately applied either before or after the matrix expansion calculation is performed to correctly compute concentrations of long-lived nuclides and the long-lived or short-lived
daughters. Equation (5.1.24) is also used to adjust to certain elements of the final transition matrix, which now excludes the short-lived nuclides. The value of the element must be determined for the new transition between the long-lived precursor and the long-lived daughter of a short-lived queue. The element is adjusted so that the end-of-interval concentration of the long-lived daughter calculated from the single link between the two long-lived nuclides (using the new element) is the same as what would be determined from the chain including all short-lived nuclides. The method assumes zero concentrations for precursors to the long-lived precursor. The computed values asymptotically approach the correct value with successive steps through time. For this reason, at least five to ten time intervals during the decay of discharged fuel is reasonable, because long-lived nuclides have built up by that time.

If a short-lived nuclide has a long-lived precursor, an additional solution is required. First, the amount of short-lived nuclide $i$ due to the decay of the initial concentration of long-lived precursor $j$ is calculated as

$$
\begin{equation*}
N_{j \rightarrow i}(t)=N_{j}(0) a_{i j} \frac{e^{-d_{j} t}}{d_{i}-d_{j}} \tag{5}
\end{equation*}
$$

from Eq. (5.1.23), assuming $e^{-d_{i} t} \ll e^{-d_{j} t}$. However, the total amount of nuclide $i$ produced depends on the contribution from the precursors of precursor $j$, in addition to that given by Eq. (5.1.25). The quantity of nuclide $j$ not accounted for in Eq. (5.1.25) is denoted by $N_{j}{ }^{\prime}(t)$, the end-of-interval concentration, minus the amount that would have remained had there been no precursors to nuclide $j$ :

$$
\begin{equation*}
N_{j}^{\prime(t)}=N_{j}(t)-N_{j}(0) e^{-d_{j} t} . \tag{}
\end{equation*}
$$

Then the short-lived daughter and subsequent short-lived progeny are assumed to be in secular equilibrium with their parents, which implies that the time derivative is zero,

$$
\begin{equation*}
\frac{d N_{i}}{d t}=\sum_{j} a_{i j} N_{j}(t)=0 \tag{7}
\end{equation*}
$$

The queue end-of-interval concentrations of all the short-lived nuclides following the long-lived precursor are augmented by amounts calculated with Eq. (5.1.24). The concentration of the long-lived precursor used in Eq. (5.1.26) is that given by Eq. (5.1.25). The set of linear algebraic equations given by Eq. (5.1.27) is solved by the Gauss-Seidel iterative technique. This algorithm involves an inversion of the diagonal terms and an iterated improvement of an estimate for $N_{i}(t)$ through the expression

$$
\begin{equation*}
N_{i}^{k+1}=-\frac{1}{a_{i i}} \sum_{j} a_{i j} N_{j}^{k} \tag{8}
\end{equation*}
$$

Since short-lived isotopes are usually not their own precursors, this iteration often reduces to a direct solution.

### 5.1.2.2.1.3 Solution of the Nonhomogeneous Equation

The previous sections have presented the solution of the homogeneous equation in Eq. (5.1.8), applicable to fuel burnup, activation, and decay calculations. However, the solution of a nonhomogeneous equation is required to simulate reprocessing or other systems that require an external feed term, $S(t) \neq 0$. The nonhomogeneous equation is given in matrix form (assumed constant over a step $n$ ) as

$$
\begin{equation*}
\frac{d \vec{N}}{d t}=A \vec{N}(t)+\vec{S} \tag{9}
\end{equation*}
$$

for a fixed feed or removal rate, $\vec{S}$. A particular solution of Eq. (5.1.29) will be determined and added to the solution of the homogeneous equation given by Eq. (5.1.10). As before, the matrix exponential method is used for the long-lived nuclides, and solution by linear chains is used for the short-lived nuclides. Assume $\vec{C}$ an arbitrary vector with which to test a particular solution of the form

$$
\begin{equation*}
\vec{N}(t)=\sum_{k=0}^{\infty} \frac{(\boldsymbol{A} t)^{k}}{(k+1)!} \vec{C} t . \tag{}
\end{equation*}
$$

Substituting Eq. (5.1.30) into Eq. (5.1.29) yields

$$
\sum_{k=0}^{\infty} \frac{A^{k} t^{k}}{k!} \vec{C}=\sum_{k=0}^{\infty} \frac{A^{k+1} t^{k+1}}{(k+1)!} \vec{C}+\vec{S}
$$

in which the $k=0$ term may be extracted from the LHS,

$$
\vec{C}+\sum_{k=1}^{\infty} \frac{A^{k} t^{k}}{k!} \vec{C}=\sum_{k=0}^{\infty} \frac{A^{k+1} t^{k+1}}{(k+1)!} \vec{C}+\vec{S},
$$

which allows the summations on the left and right to be easily shown equal. This proves the particular solution is indeed valid if the arbitrary vector is in fact the feed term $\vec{C}=\vec{S}$. The solution to the nonhomogeneous problem is therefore (as a series),

$$
\vec{N}(t)=\sum_{k=0}^{\infty} \frac{(\boldsymbol{A} t)^{k}}{k!} \vec{N}(0)+\sum_{k=0}^{\infty} \frac{(\boldsymbol{A} t)^{k}}{(k+1)!} \vec{S} t
$$

For the second term in Eq. (5.1.31), a new recursion relation is developed for the particular solution in the same manner as was done for the homogeneous solution,

$$
\begin{equation*}
N_{i}^{P}(t)=\sum_{n=1}^{\infty} D_{i}^{n} \tag{}
\end{equation*}
$$

where

$$
\begin{equation*}
D_{i}^{1}=S_{i} t ; D_{i}^{n+1}=\frac{1}{n+1} \sum_{j} a_{i j} D_{j}^{n} . \tag{5}
\end{equation*}
$$

For the short-lived nuclides, the secular equilibrium equations are modified to become

$$
\begin{equation*}
\frac{d N_{i}}{d t}=\sum_{j} a_{i j} N_{j}(t)+S_{i}=0 \tag{}
\end{equation*}
$$

The Gauss-Seidel iterative method is applied to determine the solution. The complete solution to the nonhomogeneous equation in Eq. (5.1.29) is given by the sum of the homogeneous solutions described in previous sections and the particular solutions described here.

### 5.1.2.2.2 CRAM

The solver kernel based on the Chebyshev Rational Approximation Method (CRAM) is described in detail in references ${ }^{6,7,8,9}$. Compared to the MATREX solver, CRAM generally has similar runtimes but is more accurate and robust on a larger range of problems. CRAM relies on the lower upper (LU) decomposition, so the SuperLU library has been used. The accuracy of CRAM is related to the order, with an order 16 solution having a truncation error less than $0.01 \%$ for all nuclides in most problems.

Unlike many methods for solving this type of system of ODEs, the length of a step does not significantly affect the accuracy of CRAM. However, any significant errors from CRAM will shrink rapidly over multiple steps as long as there are no large changes in reaction rates. The CRAM solver has an efficient internal substepping algorithm that can perform multiple same-sized substeps (with the same transition matrix) very efficiently by reusing the LU decomposition. When using internal substepping, 2-4 substeps are typical, with a large gain in accuracy for marginal increase in runtime.

### 5.1.2.3 Power Calculation

The following is formula is used to calculate power during irradiation ( $\Phi>0$ ),

$$
\begin{equation*}
P(t)=\sum_{i}\left(\kappa_{f i} \sigma_{f i}+\kappa_{c i} \sigma_{c i}\right) \Phi N_{i}(t) \tag{7}
\end{equation*}
$$

where $\kappa_{f i}$ and $\kappa_{c i}$ are nuclide-dependent energy released per fission and "capture," with capture defined as removal minus fission: $\sigma_{c i}=\sigma_{i}-\sigma_{f i}$. The $\sigma_{f i}$ and $\sigma_{c i}$ terms are extracted from the transition matrix itself, whereas the $\kappa_{f i}$ and $\kappa_{c i}$ are available from a separate ORIGEN energy resource (see ORIGEN Data Resources chapter). If the flux $\Phi$ is specified, then the power can be calculated at any time according to Eq. (5.1.35). However in reactor fuel systems, it is convenient to be able to specify the power produced by the system and internally to the depletion code, to convert the power to an equivalent flux. Solving Eq. (5.1.35) for the flux, however,

$$
\begin{equation*}
\Phi(t)=\frac{P}{\sum_{i}\left(\kappa_{f i} \sigma_{f i}+\kappa_{c i} \sigma_{c i}\right) N_{i}(t)}, \tag{}
\end{equation*}
$$

it is apparent that a fixed power over a time step $n$ does not lead to a fixed flux, due to changing isotopics that produce different amounts of power per fission and capture. ORIGEN performs a fluxcorrection calculation to obtain an estimate of the average flux over the step. The beginning-of-step flux is first calculated for the initial compositions: Eq. (5.1.36) is evaluated as $\Phi\left(t_{n-1}\right)$, and then Eq. (5.1.1) is solved with that flux. The flux is then recalculated at the end of step $\Phi\left(t_{n}\right)$ using the estimated end-ofstep isotopics, and the step-average flux $\Phi_{n}$ is estimated as the simple average of the beginning and end-of-step fluxes,

$$
\begin{equation*}
\Phi_{n}=0.5\left[\Phi\left(t_{n}\right)+\Phi^{\text {pred }}\left(t_{n+1}\right)\right] \tag{9}
\end{equation*}
$$

noting that the "predicted" flux at end-of-step $\Phi^{\text {pred }}\left(t_{n+1}\right)$ is based on "predicted" end-of-step isotopics, based on a beginning-of-step flux level.

### 5.1.2.4 Decay Emission Sources Calculation

ORIGEN can calculate the emission sources (and spectra) during decay for alpha, beta, neutron, and photon particles according to

$$
R_{x}^{g}(t)=\sum_{i} \lambda_{i} N_{i}(t) \int_{E^{g}}^{E^{g-1}} w_{i, x}(E) d E
$$

where $w_{i, x}(E)$ is the number of particles of type $x$ emitted per disintegration of nuclide $i$ at energy $E$, using provided energy bins defined by energy bounds $E^{g}$ to $E^{g-1}$, where $g$ is an energy index. The fundamental data resources for performing emission source calculations are described in the ORIGEN Data Resources chapter.

### 5.1.2.4.1 Neutron Sources

Computed neutron sources include neutrons spontaneous fission, ( $\alpha, \mathrm{n}$ ) reactions, and delayed ( $\beta^{-}, \mathrm{n}$ ) neutron emission,

$$
\begin{equation*}
w_{i, n}(E)=w_{i, S F n}(E)+w_{i,(\alpha, n)}(E)+w_{i, D n}(E), \tag{5.1.39}
\end{equation*}
$$

with components that will be described below. The method of computing the spontaneous fission and delayed neutron source is independent of the medium containing the fuel. However, ( $\alpha, \mathrm{n}$ ) production varies significantly with the composition of the medium. The homogeneous medium ( $\alpha, n$ ) calculation methodology has been adopted from the Los Alamos code SOURCES 4B. ${ }^{10,11}$

The total yield of spontaneous fission neutrons from decay of nuclide $i$ is

$$
\begin{equation*}
Y_{i, S F n}=\frac{\lambda_{i, S F n}}{\lambda_{i}}, \tag{}
\end{equation*}
$$

where $\frac{\lambda_{i, S F n}}{\lambda_{i}}$ is the fraction of decays which undergo spontaneous fission. The distribution of spontaneous fission neutrons, $w_{i, S F n}(E)$ is given by a Watt fission spectrum,

$$
\begin{equation*}
w_{i, S F n}(E)=Y_{i, S F n} C_{i} e^{-E / A_{i}} \sinh \sqrt{B_{i} E}, \tag{3}
\end{equation*}
$$

where $A_{i}, B_{i}$, and $C_{i}$ are model parameters.
The $(\alpha, \mathrm{n})$ neutron source is strongly dependent on the low-Z content of the medium containing the alphaemitting nuclides and requires modeling the slowing down of the alpha particles and the probability of neutron production as the $\alpha$ particle slows down. The calculation assumes (1) a homogeneous mixture in which the alpha-emitting nuclides are uniformly intermixed with the target nuclides and (2) that the dimensions of the target are much larger than the range of the alpha particles. Thus, all alpha particles are stopped within the mixture. The yield of a particular $\alpha$ is given by

$$
\begin{equation*}
Y_{\ell i, \alpha}=f_{\ell i, \alpha} \frac{\lambda_{i, \alpha}}{\lambda_{i}}, \tag{5.1.42}
\end{equation*}
$$

where $\frac{\lambda_{i, \alpha}}{\lambda_{i}}$ is the relative probability of $\alpha$-decay, and $f_{\ell i, \alpha}$ is the fraction of those $\alpha$-decays producing an $\alpha$ particle with initial energy $E_{\ell i, \alpha}$, and is considered fundamental data. The total neutron yield from an alpha particle $\ell$ emitted by nuclide $i$ and interacting with target $k$ is given by the following,

$$
\begin{equation*}
Y_{\ell i k,(\alpha, n)}=Y_{\ell i, \alpha} \frac{N_{k}}{N} \int_{0}^{E_{f i, \alpha}} \frac{\sigma_{k,(\alpha, n)}\left(E_{\alpha}\right)}{S\left(E_{\alpha}\right)} d E_{\alpha}, \tag{5.1.43}
\end{equation*}
$$

where $S\left(E_{\alpha}\right)$ is the total stopping power of the medium, $\sigma_{k,(\alpha, n)}\left(E_{\alpha}\right)$ is the $(\alpha, \mathrm{n})$ reaction cross section for target nuclide $k$, and $\frac{N_{k}}{N}$ is the fraction of atoms in the medium composed of nuclide $k$. This expression is used to calculate the neutron yield for each target nuclide and from each discrete-energy alpha particle emitted by all alpha-emitting nuclides in the material. The stopping power for compounds, rather than pure elements, is approximated using the Bragg-Kleeman additivity rule. The energydependent elemental stopping cross sections are determined as parametric fits to evaluated data. Eq. (5.1.43) is solved for the total neutron yields from the alpha particle, as it slows down in the medium by subdividing the maximum energy $E_{\ell i, \alpha}$ into a number of discrete energy bins and evaluating stopping power and ( $\alpha, \mathrm{n}$ ) reaction cross section at the midpoint energy of the bin. The distribution of ( $\alpha, \mathrm{n}$ ) neutrons as required Eq. (5.1.38) is

$$
\begin{equation*}
w_{i,(\alpha, n)}(E)=\sum_{k} \sum_{\ell \in i} Y_{\ell i k,(\alpha, n)} X_{\ell i k,(\alpha, n)}(E), \tag{}
\end{equation*}
$$

with the distribution of ( $\alpha, \mathrm{n}$ ) neutrons in energy, $X_{\ell i k,(\alpha, n)}(E)$, calculated using nuclear reaction kinematics, assuming that the ( $\alpha, \mathrm{n}$ ) reaction emits neutrons with an isotropic angular distribution in the center-of-mass system. The maximum and minimum permissible energies of the emitted neutron are determined by applying mass, momentum, and energy balance for each product's nuclide energy level. The product nuclide levels, the product level branching data, the ( $\alpha, \mathrm{n}$ ) reaction Q values, the excitation energy of each product nuclide level, and the branching fraction of ( $\alpha, \mathrm{n}$ ) reactions result in the production of product levels. A more detailed discussion of the theory and derivation of the kinematic equations can be found in Ref. 10.

Delayed neutrons are emitted by decay of short-lived fission products. The observed delay is due to the decay of the precursor nuclide. The total yield of delayed neutrons from decay of nuclide $i$ is

$$
\begin{equation*}
Y_{i, D n}=\frac{\lambda_{i, D n}}{\lambda_{i}} \tag{}
\end{equation*}
$$

where $\frac{\lambda_{i, D n}}{\lambda_{i}}$ is the fraction of decays which emit delayed neutrons. The delayed neutrons emitted per decay of nuclide $i$ at energy $E$ is given by

$$
w_{i, D n}(E)=Y_{i, d l n} X_{i, D n}(E),
$$

where the spectrum $X_{i, D n}(E)$ is fundamental library data. Delayed neutrons are not important in typical spent fuel applications due to the very short half-lives of the parent nuclides, dropping off significantly after $\sim 10$ seconds, but they may be of value in specialized applications where calculating time-dependent delayed neutron source spectra is important.

### 5.1.2.4.2 Alpha Sources

An $\alpha$ slowing down calculation is performed as part of the ( $\alpha, \mathrm{n}$ ) neutron calculation. However, the alpha source (i.e. without considering slowing down in the media) is also available, simply as the sum of delta functions at the discrete initial alpha particle energies $w_{i, \alpha}(E)=\sum_{\ell \in i} Y_{\ell i, \alpha} \delta\left(E-E_{\ell i, \alpha}\right)$ with yields $Y_{\ell i, \alpha}$, as required by Eq. (5.1.38).

### 5.1.2.4.3 Beta Sources

The beta source (i.e. without considering slowing down in the media) is available as the sum of the continuous emission spectra for each $\beta_{-}$decay in nuclide $i$. The total yield of beta particles from decay of nuclide $i$ is

$$
\begin{equation*}
Y_{i, \beta}=\frac{\lambda_{i, \beta}}{\lambda_{i}} \tag{}
\end{equation*}
$$

where $\frac{\lambda_{i, \beta}}{\lambda_{i}}$ is the fraction of decays which emit betas. The betas emitted by nuclide $i$ at energy $E$ is given by

$$
\begin{equation*}
w_{i, \beta}(E)=Y_{i, \beta} X_{i, \beta}(E), \tag{}
\end{equation*}
$$

where the spectrum $X_{i, \beta}(E)$ is fundamental data, independent of the media. The spectrum includes betas from allowed transitions and first, second, and third forbidden transitions.

### 5.1.2.4.4 Photon Sources

The total yield of photons from decay of nuclide $i$ is

$$
\begin{equation*}
Y_{i, \gamma}=\frac{\lambda_{i, \gamma}}{\lambda_{i}} \tag{}
\end{equation*}
$$

where $\frac{\lambda_{i, \gamma}}{\lambda_{i}}$ is the fraction of decays which emit photons. The photons emitted by nuclide $i$ at energy $E$ is given by

$$
w_{i, \gamma}(E)=Y_{i, \gamma} X_{i, \gamma}(E),
$$

where the spectrum $X_{i, \gamma}(E)$ is fundamental data and includes both line data from x-rays, gamma-rays and continuum data from Bremsstrahlung, spontaneous fission gamma rays, and gamma rays accompanying ( $\alpha, \mathrm{n}$ ) reactions. The Bremsstrahlung component of the photon source has been tabulated for various media and no on-the-fly slowing down calculation is performed.

### 5.1.2.5 Library Interpolation

Accurate solution of fuel depletion with Eq. (5.1.1) requires coupling to self-shielding and neutron transport to accurately capture the time-dependent change in space and energy flux distribution and 1 -group cross sections with isotopic change. This is in generally a fairly computationally intensive problem compared to stand-alone depletion. In typical assembly design and analysis, the same basic assembly problem must be solved repeatedly with variations in power history, different periods of decay/burnup, different moderator density, etc. A question naturally arises: could the isotopics from numerous well-constructed cases be saved and interpolated to the actual system? Interpolating the isotopics themselves is fraught with difficulty. For example, consider two cases with the same burnup but different periods of decay between cycles. A better approach-the ORIGEN Automated Rapid Processing (ORIGEN-ARP)—was developed with the key realization that one can reconstruct very accurate isotopics from stand-alone depletion calculations by interpolating transition matrices rather than isotopics.

The accuracy of the interpolation methodology compared to the coupled transport/depletion solution (e.g., with TRITON) depends on the suitability of the interpolation parameters and the deviation of the desired system from the systems used to create the library. For example, for thermal systems with uranium-based fuels, it was found that enrichment, water density, and burnup were the dominant
independent variables and thus were best suited for interpolation. An example of the variation of removal cross sections for key actinides is shown in Figure 5.1.2 for a Westinghouse $17 \times 17$ pressurized water reactor (PWR) assembly type with $5 \%$ initial enrichment in ${ }^{235} \mathrm{U}$. Each cross section has been divided by its initial value at zero burnup to show the variation more clearly. ${ }^{240} \mathrm{Pu}$ has been observed to have the most variation with spectral changes, with $\sim 60 \%$ reduction in cross section from beginning to end of life. The variations in ${ }^{240} \mathrm{Pu}$ with respect to enrichment and moderator density are shown in Figure 5.1.3, Figure 5.1.4, Figure 5.1.5, and Figure 5.1.6.

Currently there are two interpolation methods: a Lagrangian based on low-order polynomials and a cubic spline with an optional monotonicity fix-up.

Figure 5.1.2. Relative removal cross section as a function of burnup for key actinides (Westinghouse $17 \times 17$ assembly with $5 \%$ enrichment).

Figure 5.1.3. ${ }^{240} \mathrm{Pu}-240$ removal cross section as a function of burnup for various enrichments (GE $10 \times 10$ assembly).

Figure 5.1.4. ${ }^{240} \mathrm{Pu}$ removal cross section as a function of burnup for various moderator densities (GE $10 \times 10$ assembly).

Figure 5.1.5. ${ }^{240} \mathrm{Pu}$ removal cross section as a function of initial enrichment for various burnups (GE $10 \times 10$ assembly).

Figure 5.1.6. ${ }^{240} \mathrm{Pu}$ removal cross section as a function of moderator density
for various burnups (GE $10 \times 10$ assembly).

### 5.1.2.5.1 Lagrangian Interpolation

Lagrangian interpolation ${ }^{12}$ seeks the unique $n-1$ order polynomial that will pass through $n$-points of the function and then interpolating to the desired point by evaluating the polynomial,

$$
\begin{equation*}
y(x)=\prod_{i=1}^{n}\left(x-x_{i}\right) \sum_{k=1}^{n} \frac{y_{k}}{\left(x-x_{k}\right) \prod_{\substack{i=1 \\ i \neq k}}^{n}\left(x_{k}-x_{i}\right)^{\prime}} \tag{3}
\end{equation*}
$$

where $x_{i}$ and $y_{i}$ are the known $x$ - and y-values in the neighborhood of the desired $x$-value $x$, with $n$ the number of data points/order of Lagrangian interpolation. Note that Lagrangian interpolation is by definition local, involving only points in the neighborhood of the desired value. Global alternatives such as Hermite cubic splines use the entire data set to construct the interpolants. Common interpolation methods based on polynomials can have difficulty with data that vary quickly and have uneven $x$-spacing, as is expected with transition data. Polynomials tend to produce unphysical oscillations in these cases. In cases with very small $y$-values $\left(\sim 10^{-10}\right)$, oscillations of the interpolant can produce negative interpolated values.

### 5.1.2.5.2 Cubic Spline Interpolation

Cubic spline interpolation has been observed to produce fewer, lower frequency oscillations. Oscillations can be effectively eliminated by enforcing monotonicity on the interpolation: that is, additional max maxima or minima are not introduced by the interpolant between known values of the function. Monotonic cubic splines ${ }^{13}$ have shown particularly stable behavior and have been implemented as an interpolation option.

### 5.1.3 ORIGEN Family of Modules

This section describes how to perform the calculations and evaluations described in Sect. 5.1.2 using the ORIGEN family of modules in SCALE. These modules are summarized briefly below.

1. The COUPLE module is used to create ORIGEN libraries. The ORIGEN library contains transition matrices $\boldsymbol{A}$ and other relevant data in order to solve the depletion/decay equation of Eq. (5.1.1). COUPLE requires an input flux spectrum in order to perform the multigroup cross section collapse. Optionally, one-group self-shielded cross sections can be provided. Generally, in order to solve a non-decay problem, a library must be created with either COUPLE or ARP.
2. The ARP module is also used to create an ORIGEN library, but it is created by way of a special interpolation scheme on a set of existing libraries rather than by specifying a flux spectrum and one-group cross sections as in COUPLE. A set of ORIGEN libraries is distributed with SCALE for use with ARP and is described in ORIGEN Reactor Libraries chapter.
3. The ORIGEN module is used to solve depletion, decay, activation, and feed problems described by Eq. (5.1.1), as well as the decay emission calculations described by Eq. (5.1.38). For spent fuel calculations using the ARP interpolation methodology, it may be more convenient to use ORIGAMI, as described in ORIGAMI chapter.
4. The OPUS module is used to perform post processing and analysis on ORIGEN results contained in ORIGEN concentrations files, including sorting, ranking, and unit conversion.

Two types of files are an integral part of the ORIGEN family of modules: the library file and the concentrations files.

- The library file is a binary file, usually either with the complete filename "ft33f001" or with extension ".f33," and it contains a collection of transition matrices $\boldsymbol{A}$, usually corresponding to different burnups. It is typically called an "ORIGEN library," "ft33," or "f33" file.
- The concentrations file is also a binary file, usually either with the complete filename "ft71f001" or with extension ". f 71 ." The f 71 is a solution archive containing isotopics vectors $\vec{N}$ corresponding to different materials or different points in time.

### 5.1.3.1 COUPLE Module

COUPLE is a coupling code that prepares the transition matrix $\boldsymbol{A}$ from Eq. (5.1.1), which contains the decay and cross section transition rate constants according to the procedures defined in Sect. 5.1.2.1. The transition matrix and other important data are stored on an ORIGEN library (f33) file for use by other modules. COUPLE has two distinct modes of operation:

1. to create a new decay-only ORIGEN library from an ORIGEN decay resource, and
2. to add new or to update existing reaction transitions yield resource, reaction resource, and optionally an AMPX working library containing multigroup cross sections.

Details on the decay, yield, and reaction resources may be found in the ORIGEN Data Resources chapter.

### 5.1.3.1.1 Key Features

This section briefly highlights some key features in COUPLE and describes how they are used.

### 5.1.3.1.1.1 AMPX multigrouplibraries

AMPX multigroup libraries contain multigroup cross sections by nuclide and material-zone identifiers. If the working library is the result of a multiregion transport calculation, then it is important to specify the correct zone identifier, e.g. corresponding to the fuel in a problem with moderator, clad, and fuel zones. The neutron flux is also stored on the AMPX library associated with a nuclide and a zone as are the cross sections. An AMPX library flux can be used to perform the cross section collapse as an alternative to providing a flux spectrum in the COUPLE input. New transitions may be added to the ORIGEN binary library for all reactions for which there are data in the weighted AMPX library if both the target and product nuclides are present in the ORIGEN library.

### 5.1.3.1.1.2 Nuclide Specification

In COUPLE, the following nuclide identifier is used:
Nuclide identifier $=$ Z * $10000+\mathrm{A} * 10+\mathrm{I}$, where

> Z $\mathrm{A}=$ atomic number, $\mathrm{I}=$ mass number, $=$ metastable/isomeric state ( 0 is ground $/ 1$ is first metastable)

Examples include 922350 for ${ }^{235} \mathrm{U}$ and 952421 for ${ }^{242 \mathrm{~m}} \mathrm{Am}$. Note that this varies from the identifiers used in other ORIGEN-related modules in which the isomeric state $I$ comes first, as in 1095242 for ${ }^{242 \mathrm{~m}} \mathrm{Am}$.

### 5.1.3.1.1.3 Adding new transitions and user-defined transitions

The use of a transition matrix in ORIGEN allows any nuclide to transition to any other nuclide. By default, when the reaction data on the library is updated, then the transition matrix's sparse storage is expanded to include the new reaction transition if both the target and the reaction product nuclide are in the library. The user may request that the code does not add new transitions by setting Block1 $1 \$ \$$ $\mathrm{JADD}=0$. This option ensures that the matrix structure on the input library is identical to that of the output library. The user may explicitly set one-group transition coefficients by setting Block1 $1 \$ \$$ LBUP $=1$ and entering Block6 and Block8 data.

### 5.1.3.1.1.4 Unit numbers and Aliases

In COUPLE, a unit number is used instead of a full file name to specify files, where unit number XY links to the data file "ftXYf001" in the working directory. For example, unit number 33 means file $\mathrm{ft} 33 f 001$. There are several predefined unit numbers that are controlled by a special "origen_filenames" file, which creates an alias for the local file "ftXYf001" to a file in the data directory. Table 5.1.1 shows the basic COUPLE unit numbers, their aliases, and a description of the file.

Table 5.1.1. Basic COUPLE unit numbers

| Unit | Alias | Description |
| :--- | :--- | :--- |
| 17 | YIELDS | ORIGEN Yield Resource |
| 21 | END7DEC | ORIGEN library |
|  |  | ENDF/B-VII-based decay transitions only |
| 27 | DECAY | ORIGEN Decay Resource |
| 80 | JEFF252G | ORIGEN Reaction Resource (252 groups) |

An "origen_filenames" list which maps unit number 21 to alias "END7DEC" could link unit 21 to the file "\$\{DATA\}/origen.rev04.end7dec," where \$\{DATA\} is the path to the SCALE data directory. To override this association, COUPLE must find a file named "ft21f001" in the working directory. The entire set of unit numbers is given in the ORIGEN Data Resources chapter.

### 5.1.3.1.2 Input Description

COUPLE uses the FIDO input system, except for title entries. The input is arranged in blocks, with each block containing one or more arrays, followed by the FIDO block terminator "t." Each input parameter is named and defined below in the order in which it appears, with the index of the parameter in the array. Some options have been deprecated over time and thus the first available entry may not correspond to index " 1 " and some indices may be skipped. Default values are given in parentheses. In the SCALE code system, COUPLE input appears between "=couple" and "end."
5.1.3.1.2.1 Block1: titles, unit numbers, and case controls.

TITLE - Title lines
Title lines can provide information about the ORIGEN library created and printed when the library is used. The input Block1 1\$\$ NUMA allows title lines to be copied from the input library to the output library.

The first blank line terminates the title.
A maximum of 40 lines can be included in the library.
A special title of "DONE" in the first four columns marks the completion of a COUPLE input case.

0\$\$ Array - Logical Unit Assignments

1. NOUT - Printed output unit number (6)
2. LIBDEC- Unit number of ORIGEN decay resource (27)

Only used if 1\$\$ LBIN=1
3. JD - Unit number of ORIGEN reaction resource (80)
4. ND - Input ORIGEN binary library file (21)

Only used if $1 \$ \$$ LBIN=0
5. LD - Unit number of AMPX multigroup library file (0) Only used if $L D>0$; energy group structure must be consistent with that on ORIGEN reaction resource (JD)
6. MD - Unit number for output ORIGEN library file (33)
8. NY - Unit number of ORIGEN yield resource (17)

1\$\$ Array - Control Constants [19 entries]

1. LBIN - $1 / 0$ - Decay library creation/reaction update mode (0) In decay library creation mode with LBIN=1, the reaction resource (0\$\$ JD) is not used, any input associated with reaction processing is ignored, and Block2 and Block8 may not be entered. In reaction update mode with LBIN=0, Block3 may not be entered.
2. PRT - $1 / 0-$ Suppress all informational output / print informational output (0).
3. LBUP - $1 / 0$ - Update from user input cross sections (Block6 and Block8 Arrays) / no user update (0).
4. JADD - $1 / 0-\mathrm{Add} / \mathrm{do}$ not add new transitions to the library (1).
5. JEDT - $1 / 0$ - Edit input library only/normal library generation case (0).
6. NXX - $1 / 0-$ Allow/do not allow transitions with zero cross section (0).
7. NMO - Current month (as integer) for output library (0).
8. NDAY - Current day for output library (0).
9. NYR - Current year for output library (two digits) (0).
10. IDREF - Nuclide ID in AMPX multigroup library ( $0 \$ \$$ LD) containing neutron flux weighting spectrum to use in cross section collapse (0). If IDREF=0, uses first nuclide found in NZONE. Only used if NWGT=0.
11. NZONE - Zone ID (usually a mixture ID) in AMPX multigroup library (0\$\$ LD) from which to add/update transitions (0). If NZONE $=0$, the AMPX library must not contain zone IDs.
12. IEDOU $-1 / 0-$ Edit/no edit of transition cross sections ( 0 )
13. NFISW - Number of nuclides with fission yields (-1)
-1 fission yields included for all fissionable nuclides
0 no yields added
$\mathrm{N} \quad$ input N nuclides with fission yields (Block2 7\$\$ Array)
14. NUMA - Number of title lines to copy from the input ORIGEN library (0\$\$ ND) to the output ORIGEN library (0\$\$ MD) (0).
15. NWGT - Flux spectrum source (0).

0 flux spectrum from AMPX multigroup library (IDREF)
N input N-group flux spectrum (Block2, 9** Array)
T - Block1 terminator.
5.1.3.1.2.2 Block2: nuclides with fission yields and weighting flux spectrum

This block is only read if in reaction update mode (Block1 0\$\$ LBIN=0).
7\$\$ Array - Nuclide IDs with fission yields [Block1 1\$\$ NFISW entries]
9** Array - Weighting flux spectrum [Block1 1\$\$ NWGT entries]
The flux spectrum must be given in order of descending neutron energy according to the convention that group 1 is the highest energy group. The group structure (number of groups and group boundaries) must be consistent with the ORIGEN reaction resource (Block1 0\$\$ JD).

T - Block2 terminator.

### 5.1.3.1.2.3 Block3: array dimensions for decay library creation

This block is only read if in decay library creation mode (Block1 0\$\$ LBIN=1). The default values usually apply. The values are used only internally for memory allocation and may be set to a larger value than is required.

3\$ Array - Library constants
18. ITMAX - Total number of nuclides in library (2600)
19. ILMAX - Number of activation product nuclides (1000)
-1 , omits light-element library
20. IAMAX - Number of actinide nuclides (200) -1 , omits actinide library
21. IFMAX - Number of fission-product nuclides (1400)
-1 , omits fission-product library
22. IXMAX - Total number of decay transitions from one nuclide to another $(40,000)$

T-Block3 terminator.

### 5.1.3.1.2.4 Block6: number of user-defined transition coefficients

This block is only read if user-defined transition coefficients have been specified in decay library creation mode (Block1 1\$\$ LBUP=1).

15\$\$ Array - Number of user update nuclides

1. LBU - Total number of transitions to be entered in Block8 71\$\$, 72\$\$, and 73** Arrays (0)

T - Block6 terminator

### 5.1.3.1.2.5 Block8: user-defined transition coefficients

Block8 is only required only if a nonzero value is entered in the Block6 $15 \$ \$$ array. The three arrays (71\$\$, 72\$\$, and $73^{* *}$ ) represent the parent, daughter, and coefficients for Block6 LBU user-defined transitions, or the quantity $f_{i j} \sigma_{j}$ for a given parent $j$ and daughter $i$ from Eq. (5.1.4).

71\$\$ Array - Parent Nuclides [LBU entries]
ISN1 - Parent Nuclide ID
72\$\$ Array - Daughter Nuclides or Reaction MT number [LBU entries]
ISN2 - Daughter Nuclide ID for the reaction product of the corresponding entry in ISN1 or reaction MT number

NOTE: The reaction transition will be added if it does not already exist by setting Block1 1\$\$ JADD=1. Otherwise, new transitions are omitted.

73** Array - Reaction Cross Sections [LBU entries].
SIGMA - Reaction cross section (in barns) for the reaction described by ISN1 and ISN2 There are two special rules to facilitate modifying fission cross sections $\sigma_{f j}$ and removal cross sections $\sigma_{j}$.
if ISN1=ISN2, the removal cross section is set equal to the corresponding SIGMA. Note that this overrides the automatic calculation of the removal cross section as the sum of all transition cross sections.
if ISN1=-ISN2, the fission cross section is set equal to the corresponding SIGMA.
T -Block8 terminator.
This concludes the input for a single case in COUPLE. COUPLE allows for multiple cases in a single input and will automatically begin processing the next case's Block1 TITLE unless "DONE" (without quotes) is entered as the TITLE entry.

### 5.1.3.2 ARP Module

The ARP module performs multidimensional interpolation on a set of specially prepared ORIGEN libraries using interpolation methods discussed in Sect. 5.1.2.5, with available interpolators listed in Table 5.1.2. The ORIGEN reactor libraries distributed with this version of SCALE are described in the ORIGEN Reactor Libraries chapter, as well as details on how users can generate their own libraries. The ARP module has been validated extensively for light water reactor (LWR) spent fuel. ${ }^{14}$ Benchmarking studies for MOX fuel were also conducted. ${ }^{15}$

Table 5.1.2. Interpolation options in ARP

| Type | Interpolation <br> keyword | Comments |
| :--- | :--- | :--- |
| Nearest value | nearest | Searches for closest value to desired value. |
| Linear interpolation | linear | Uses nearest two values bounding the desired value. |
| Lagrangian <br> interpolation | lagrange(N) <br> with order $N$ from 1 <br> to 4 <br> lagrange <br> same as lagrange(4) | Uses N points near desired value and creates polynomial of <br> order N-1 using Eq. (5.1.51). The specification of <br> lagrange(1) is equivalent to nearest and lagrange(2) to linear. |
| Standard cubic spline | stdspline | Standard, natural cubic spline (without monotonicity fix-up). |
| Monotonic cubic <br> spline | Natural cubic spline with a monotonicity fix-up designed to <br> prevent nonphysical oscillations that in some cases cause |  |
| negative interpolated cross sections. |  |  |

Parametrizations for three types of problems have been developed: uranium-based fuel, mixed-oxide (MOX) fuel, and general activation.

- The parametrization for uranium-based fuel (e.g., $\mathrm{UO}_{2}$ ), as would be found in most LWRs, can interpolate on
o fuel enrichment,
o moderator density, and
o burnup.
- The parametrization for MOX fuel contains a mixture of plutonium and uranium oxide and can interpolate on
o total plutonium content in the heavy metal,
o plutonium isotopic vector ( Pu vector) that defines the relative concentrations of the Pu isotopes,
o moderator density, and
o burnup.
- The parametrization for general activation problems has only one-dimensional interpolation on fluence.

Variation of the absorption cross sections was observed to be near linear as a function of Pu content. Interpolation on the Pu vector is more complex than the uranium enrichment for $\mathrm{UO}_{2}$ fuel since the vector is composed of five different isotopes: ${ }^{238} \mathrm{Pu},{ }^{239} \mathrm{Pu},{ }^{240} \mathrm{Pu},{ }^{241} \mathrm{Pu}$, and ${ }^{242} \mathrm{Pu}$. Furthermore, the elements in the vector depend on one another and can therefore not be evaluated independently of one another since the entire vector must sum to $100 \%$. The scheme developed for the Pu vector was based on an evaluation of a large database of plutonium compositions from actual MOX fuel assemblies of European origin. It might be expect edthat the parametrization would need to include all Pu isotopes. However, an evaluation of the MOX fuel database indicated that there is a strong correlation between ${ }^{239} \mathrm{Pu}$ and the other isotopes in the vector that permits cross sections for the MOX fuel to be determined to sufficient accuracy using only the ${ }^{239} \mathrm{Pu}$ concentration.

### 5.1.3.2.1 Input Description

ARP has a simple input scheme, a different line-by-line input expected for each of the three problem types-uranium, MOX, or activation-with the input required for each type shown in Table 5.1.3, Table 5.1.4, and Table 5.1.5. Available input depends on what is available in the relevant arpdata.txt file and the arplibs directory.

Table 5.1.3. Input description for uranium fuels

| Entry no. | Data type | Entry requirements | Comment |
| :---: | :---: | :---: | :---: |
| 1 | Data set name | Line 1 <br> always required | Enter a uranium CONFIGNAM from the active arpdata.txt (see Table 5.1.6). |
| 2 | Enrichment | New line always | Enter the wt \% ${ }^{235} \mathrm{U}$ in total U . |
| 3 | Number of cycles | Always | Enter the number of irradiation cycles $N$. |
| 4 | Fuel irradiation period | Always | Enter the irradiation time for each cycle in days $\Delta T_{i}$, for $i=1,2, \ldots, N$. |
| 5 | Average power | Always | Enter the specific fission power (MW/MTHM) for each cycle, $P_{i}$, for $i=1,2, \ldots, N$. |
| 6 | Data interpolations per cycle | Always | Enter the number of cross section sets to interpolate during each cycle, $m_{i}$, for $i=1,2, \ldots, N$. |
| 7 | Moderator density | Always | Enter the moderator density ( $\mathrm{g} / \mathrm{cm}^{3}$ ). Enter only one value. |
| 8 | New library name | New line always | Enter the file name of the new ORIGEN library created from interpolation. |
| 9 | Interpolation keyword | Optional | Enter the interpolation algorithm which will be used from Table 5.1.2 (DEFAULT: spline) |

Table 5.1.4. Input description for MOX fuels

| Entry no. | Data type | Entry requirements | Comment |
| :---: | :---: | :---: | :---: |
| 1 | Data set name (starts with MOX) | Line 1 <br> always required | Enter a MOX CONFIGNAM from the active arpdata.txt (see Table 5.1.7). |
| 2 | Plutonium content | New line always | Enter the Pu content as wt \% Pu in total heavy metal. |
| 3 | ${ }^{239} \mathrm{Pu}$ isotopic vector | Always | Enter the ${ }^{239} \mathrm{Pu}$ isotopic concentration as wt \% of ${ }^{239} \mathrm{Pu}$ in total Pu . |
| 4 | Reserved parameter (not used) | Always | Enter a dummy value (e.g., 1.0). |
| 5 | Number of cycles | Always | Enter the number of irradiation cycles $N$. |
| 6 | Fuel irradiation period | Always | Enter the irradiation time for each cycle in days $\Delta T_{i}$, for $i=1,2, \ldots, N$. |
| 7 | Average power | Always | Enter the specific fission power (MW/MTHM) for each cycle, $P_{i}$, for $i=1,2, \ldots, N$. |
| 8 | Data interpolations per cycle | Always | Enter the number of cross section sets to interpolate during each cycle, $m_{i}$, for $i=1,2, \ldots, N$. |
| 9 | Moderator density | Always | Enter the water-moderator density ( $\mathrm{g} / \mathrm{cm}^{3}$ ). Enter only one value. |
| 10 | New library name | New line always | Enter the character name of the new interpolated library created by ARP. |
| 11 | Interpolation keyword | Optional | Enter the interpolation algorithm which will be used from Table 5.1.2 (DEFAULT: spline). |

Table 5.1.5. Input description for activation problems

| Entry no. | Data type | Entry requirements | Comment |
| :---: | :---: | :---: | :---: |
| 1 | Data set name (starts with ACT) | Line 1 always required | Enter an activation CONFIGNAM from the active arpdata.txt (see Table 5.1.8). |
| 2 | Dummy parameter | Always | Enter 1. |
| 3 | Number of cycles | Always | Enter the number of irradiation cycles $N$. |
| 4 | Fuel irradiation period | Always | Enter the irradiation time for each cycle in days $\Delta T_{i}$, for $i=1,2, \ldots, N$. |
| 5 | Average neutron flux | Always | Enter the average flux level ( $\mathrm{n} / \mathrm{cm}^{2}-\mathrm{s}$ ) for each cycle, $\Phi_{i}$, for $i=1,2, \ldots, N$. |
| 6 | Data interpolations per cycle | Always | Enter the number of cross section sets to interpolate during each cycle, $m_{i}$, for $i=1,2, \ldots, N$. |
| 7 | Flux type (flag) | Always | Enter 1. |
| 8 | New library name | New line always | Enter the character name of the new interpolated library created by ARP. |
| 9 | Interpolation keyword | Optional | Enter the interpolation algorithm which will be used from Table 5.1.2 (DEFAULT: spline). |

### 5.1.3.2.2 ARPDATA.TXT listing file

In addition to the user input file, ARP also reads a file named arpdata. txt when it runs. This file describes the parametrization of the ORIGEN libraries. The file is required because the cross section libraries contain no imbedded information on the reactor type, fuel type, or irradiation conditions. Both the file arpdata.txt and the directory of ORIGEN libraries named arplibs is searched for, first in the working directory so that a user can override the default libraries, and then to the SCALE data directory. An example arpdata. txt file is shown in Figure 5.1.7.

Figure 5.1.7. Examples of arpdata.txt entries.

As shown in Figure 5.1.7, the arpdata.txt is simply a list of entries, each beginning with a "!CONFIGNAM," where CONFIGNAM is the name to be used to reference the entire data set. Whether the entry is for a uranium, MOX, or activation problem is dictated by the actual CONFIGNAM. If it begins with MOX, it is a MOX entry, and if it begins with ACT, it is an activation entry. Otherwise it is uranium. The ORIGEN libraries listed must reside next to arpdata.txt, in a directory called arplibs. Each type of entry is described fully in Table 5.1.6, Table 5.1.7, and Table 5.1.8 for uranium, MOX, and activation, respectively.

Table 5.1.6. ARPDATA.TXT uranium type entry

| Line no. | Data name | Description | Comments |
| :---: | :---: | :---: | :---: |
| 1 | CONFIGNAM | Data set name <br> (40-character maximum) | Must begin with "!" in column one, followed by the alphanumeric name this data set will be referenced by. <br> May not begin with ACT or MOX. |
| 2 | $\begin{aligned} & \text { N1 } \\ & \text { N2 } \\ & \text { N3 } \end{aligned}$ | Number of enrichments <br> Number of water densities <br> Number of burnup steps | Entries pertain to the number of parameterized cross section data for each variable type. |
| 3 | ENR | Enrichment values (wt \% ${ }^{235} \mathrm{U}$ ); values at which ARP libraries were generated | N1 entries defining the discrete enrichment values for each library |
| 4 | DENS | Water density values (g/cm ${ }^{3}$ ) | N2 entries defining the discrete moderator density values for each library |
| 5 | FILES | Filenames of ORIGEN libraries for this fuel assembly type (Enclose each filename in single quotes with at least one space between each name.) | $\mathrm{N} 1 \times \mathrm{N} 2$ entries <br> Filenames are ordered first by density values, then by enrichment values. |
| 6 | BURN | Burnups (MWd/MTU) <br> corresponding to each position on the ORIGEN library | N3 entries <br> Each set of burnup-dependent cross sections is stored within a single ORIGEN binary library file (the first burnup is usually zero) |

NOTE: Repeat all of the above entries for each fuel assembly configuration type.

Table 5.1.7. ARPDATA.TXT MOX type entry

| Line <br> no. | Data name | Description | Comments |
| :---: | :--- | :--- | :--- |
| 1 | CONFIGNAM | Data set name <br> (40-character maximum) |  |

NOTE: Repeat all of the above entries for each fuel assembly configuration type.

Table 5.1.8. ARPDATA.TXT activation type entry

| Line <br> no. | Data name | Description | Comments |
| :---: | :--- | :--- | :--- |
| 1 | CONFIGNAM | Data set name <br> (40-character maximum) | Must begin with "!" in column <br> one followed by the <br> alphanumeric name by which |
| this data set will be referenced. |  |  |  |
| Must begin with ACT (e.g., |  |  |  |
| !actcntlrod). |  |  |  |

NOTE: Repeat all of the above entries for each fuel assembly configuration type.

### 5.1.3.3 ORIGEN Module

The ORIGEN module drives depletion, decay, and activation calculations as described in Sect. 5.1.2.4, including the conversion of generated powers to fluxes described in Sect. 5.1.2.3, as well as alpha, beta, gamma, and neutron source calculations described in Sect. 5.1.2.4.

### 5.1.3.3.1 Key Features

This section briefly highlights some key features in ORIGEN and describes how they are used.

### 5.1.3.3.1.1 Nuclide Specification and ORIGEN Sub-libraries

The nuclide identifiers in ORIGEN are more flexible than those in other modules of SCALE and even within the ORIGEN family. Table 5.1.9 shows the possible ways to specify nuclides (and elements).

Table 5.1.9. Nuclide/Element Specification in ORIGEN

| Identifier Form | Comments | Examples <br> nuclide $\rightarrow$ input id |  |
| :---: | :---: | :---: | :---: |
| IZZZAAA | Standard numeric identifier with one optional digit of isomeric state, three | ${ }^{235} \mathrm{U}$ | $\rightarrow 92235$ |
| I - isomeric state |  | ${ }^{235 m} \mathrm{U}$ | $\rightarrow 1092235$ |
| ZZZ - atomic number | digits of atomic number, three digit | ${ }^{135} \mathrm{Xe}$ | $\rightarrow 54135$ |
| AAA - mass number | of mass number; elements have mass number of 000 . | ${ }^{1} \mathrm{H}$ | $\rightarrow 1001$ |
|  |  | ${ }^{10} \mathrm{~B}$ | $\rightarrow 5010$ |
|  |  | Fe | $\rightarrow 54000$ |
| EAm <br> E - element symbol <br> A - mass number <br> m - metastable indicator | Standard symbolic identifier with element symbol followed by mass number, followed by optional metastable indicator; can include a dash between E and A (E-Am); case insensitive. | ${ }^{235} \mathrm{U}$ | $\rightarrow$ u235 |
|  |  | ${ }^{235 m} \mathrm{U}$ | $\rightarrow$ u235m |
|  |  | ${ }^{135} \mathrm{Xe}$ | $\rightarrow$ xe135 |
|  |  | ${ }^{1} \mathrm{H}$ | $\rightarrow \mathrm{h} 1$ |
|  |  | ${ }^{10} \mathrm{~B}$ | $\rightarrow$ b10 |
|  |  | Fe | $\rightarrow$ fe |

One important aspect ORIGEN users must be aware of is that the ORIGEN library (f33) being used dictates the set of nuclides available in a calculation and that there may be more than one version of a nuclide in a library. The duplicates arise in large part from the need to analyze fission products separately. For example, a gadolinia-doped uranium oxide fuel with burnup will have some ${ }^{155} \mathrm{Gd}$ from the initial gadolinia loading and some ${ }^{155} \mathrm{Gd}$ generated as a fission product. Although these fuels physically behave the same way, it is sometimes important to be able to analyze them separately. These groups, versions, or categories are referred to as sublibraries because in an ORIGEN library, they appear almost like three separate, smaller ORIGEN libraries. The three libraries are for

1. naturally occurring, light nuclides, sometimes called "light elements" or "activation products,"
2. actinides and their reaction and decay products, and
3. fission products.

Called "sublibs" for short, they are identified by a number or 2-character specifier:

1. light nuclides with "LT" or 1,
2. actinides with "AC" or 2 , and
3. fission products with "FP" or 3.

The production of fission products from actinides ( $2 / \mathrm{AC} \rightarrow 3 / \mathrm{FP}$ ) is the only type of transition in a typical ORIGEN library that spans sublibs. The sublib is optional in a nuclide specification and is indicated in parentheses after the identifier-IZZZAAA(S), EAm(S). If the sublib for a nuclide/element is not provided, it is guessed in the following manner:

1. If the nuclide is in fact an element, then it is placed in sublib=1/LT.
2. If the atomic number $\mathrm{Z}<26$, an attempt is made to place it in sublib=1/LT.
3. Otherwise ( $\mathrm{Z} \geq 26$ or attempt fails), sublibs are searched in reverse order, from $3 / \mathrm{FP}, 2 / \mathrm{AC}$, and then 1/LT.

The third rule, which is to search sublibs in reverse order, correctly handles spent reactor fuel, a common and important scenario. The other two conditions can be interpreted as exceptions. The first exception correctly handles activation scenarios where it is most convenient to specify the initial elemental
constituents. The second exception handles light nuclides that could not be real fission products, as fission products have $\mathrm{Z} \geq 26$ by definition. The byproducts ${ }^{1} \mathrm{H},{ }^{2} \mathrm{H},{ }^{3} \mathrm{H},{ }^{3} \mathrm{He}$, and ${ }^{4} \mathrm{He}$ actually exist in all sublibs, but FP and AC byproducts have a reduced set of transitions compared to the LT version, which has full decay and activation chains. Thus when a user specifies one of the byproduct nuclides as input, it is best to associate it to the LT version.

### 5.1.3.3.1.2 Physical Units in Calculations

A variety of units can be used in the input and specified for the output of an ORIGEN calculation. The input allows for initial concentrations in

1. grams,
2. moles (or gram-atoms),
3. number density in atoms/barn-cm, and
4. curies.

Time may be expressed in seconds, minutes, hours, days, years, or a user-defined unit. Irradiation may be expressed in terms of neutron flux ( $\mathrm{n} / \mathrm{cm}^{2}-\mathrm{s}$ ) or power (W). The allowed units for output include those for input, as well as the following decay quantities:

1. total decay heat power (W),
2. gamma decay heat power (W),
3. airborne toxicity $\left(\mathrm{m}^{3}\right)$ required to dilute activities to the Radiation Concentration Guide (RCG) limit for air,
4. ingestion toxicity $\left(\mathrm{m}^{3}\right)$ required to dilute activities to the RCG limit for water, and
5. alpha, beta, neutron, photon sources (particles/s or $\mathrm{MeV} / \mathrm{s}$ ).

Table 5.1.10 summarizes the available units in ORIGEN. During irradiation cases, the following can also be returned:

1. absorption rates (absorptions/s),
2. fission rates (fissions/s), and
3. infinite neutron multiplication constant, $\mathrm{k}_{\infty}$.

Table 5.1.10. Available physical units

| Unit name | Description | Input | Output (irrad.) | Output (decay) |
| :---: | :---: | :---: | :---: | :---: |
| GRAMS | Mass in grams | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| MOLES or GRAM-ATOMS | Number in moles (or legacy equivalent of gram-atoms) | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| ATOMS-PER-BARN-CM | Density in atoms/barn-cm ( $10^{-24} \mathrm{~cm} /$ barn $\times$ density in atoms $/ \mathrm{cm}^{3}$ ); requires volume input | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| CURIES | Activity in curies | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| BECQUERELS | Activity in becquerels | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| ATOMS_PPM | Atom fractions $\times 10^{6}$ |  | $\checkmark$ | $\checkmark$ |
| WEIGHT_PPM | Weight fractions $\times 10^{6}$ |  | $\checkmark$ | $\checkmark$ |
| WATTS | Total decay heat in watts |  |  | $\checkmark$ |
| G-WATTS | Total decay heat from photons in watts |  |  | $\checkmark$ |
| M3_AIR | Radiotoxicity in $\mathrm{m}^{3}$ for inhalation |  |  | $\checkmark$ |
| M3_WATER | Radiotoxicity in $\mathrm{m}^{3}$ for ingestion |  |  | $\checkmark$ |

### 5.1.3.3.1.3 Saving Results

ORIGEN can save any results (isotopics and source spectra) in a special ORIGEN binary concentrations file (f71). The file is a simple sequence of solutions, and new results are simply appended on to the end of an existing file. Note that no matter how initial isotopics are entered or what units are asked for in the output file, the ORIGEN f71 contains moles (gram-atoms) of each isotope and an optional volume to permit unit conversions to number density (atoms/barn-cm). Isotopics for an ORIGEN calculation can be initialized from any position on this file in an ORIGEN calculation. The $\mathfrak{f 7 1}$ can also be read by OPUS to perform various post-processing tasks.

### 5.1.3.3.2 Input Description

ORIGEN uses the Scale Object Notation (SON) language for its input, although it can also read FIDObased input for backwards compatibility with SCALE 6.1 ${ }^{16}$. The basic structure of an ORIGEN input is shown in Figure 5.1.8.

```
'SCALE comment
=origen
    % ORIGEN comment %
bounds{ ... }
solver{ ... }
options{ ... }
case(A){
    time=[31 365] % days
}
case(B){
}
% more cases?
end
```

Figure 5.1.8. ORIGEN input file overview.

The ORIGEN input is hierarchical, containing four levels, where level 0 is the "root" level, allowed between "=origen" and "end." The complete set of keywords is shown in Table 5.1.11, with arrays denoted with " $=[$ ", blocks with " $\{ \}$ ". Referring to the overview in Figure 5.1.11, at the root level, there is a "solver" block for changing solver options, a "bounds" block for entering the energy boundaries for various particle emissions, and an "options" block for altering the miscellaneous global options. These blocks may only appear once. The remainder of the input is a sequence of "case" blocks (in the above examples there are two cases with identifiers "A" and "B"), which each case is executed in order, with each case possibly depending on one or more of the previous cases.

Table 5.1.11. List of all available ORIGEN input commands
$\left.\begin{array}{l|l|l|l}\text { Level 0 } & \text { Level 1 } & \text { Level 2 } & \text { Level 3 } \\ \hline \text { case\{\} } & \text { title } & \text { start, t=[], units, custom_name, } \\ \text { custom_length }\end{array}\right)$

The percent sign (\%) is the comment character inside the ORIGEN sequence, between "=origen" and "end." The \% is a very flexible comment that may be placed almost anywhere in the input and continues until the end of the line. Outside the ORIGEN sequence, the SCALE comment character of a single quote ' at the beginning of a line must be used. Arrays in SON begin with "[" and end with "]" and
support the following special shortcuts inherited from FIDO. Note that the interpolation shortcuts (I and L) insert values between two specified values so that there will be $\mathrm{N}+2$ values in the final expanded array section.

Table 5.1.12. Array entry shortcuts

| Shortcut | Format | Examples <br> shortcut $\rightarrow$ expansion |
| :---: | :---: | :---: |
| Repeat ( $\mathbf{R}$ ) | $N \mathbf{R} X$ | $\begin{aligned} & \text { 3r1e14 } \rightarrow 1 \mathrm{e} 141 \mathrm{e} 141 \mathrm{e} 14 \\ & 6 \mathrm{r} 3 \rightarrow 33333 \end{aligned}$ |
| Linear interpolation (I) | NI $X$ Y | $\begin{aligned} & \text { 3i } 51 \rightarrow 54321 \\ & \text { 9i } 0.01 .0 \rightarrow 0.0 \underline{0.1} 0.20 .30 .40 .50 .60 .70 .80 .91 .0 \end{aligned}$ |
| Log interpolation (L) | $N \mathrm{~L} X Y$ | ```3l15 - 5l 1e-9 1e-3 -> 1e-9 1e-8 1e-7 1e-6 1e-5 1e-4 1e-3``` |

As an alternative to manually creating an ORIGEN input file via a text editor, the user may use the SCALE graphical user interface (GUI) Fulcrum to create ORIGEN input files. Advantages to using Fulcrum include syntax highlighting, autocomplete, immediate feedback when input is incorrect, and one-click running of calculations.

### 5.1.3.3.2.1 Calculation Case (case)

A single ORIGEN sequence may contain an unlimited number of case blocks. Each case block is processed in order and can represent either an independent calculation or continuation of a previous case. The complete contents of a single case block are shown in Figure 5.1.9.

```
case(ID){
    title="my title"
    lib{ ... }
    mat{ ... }
    time{ ... }
    flux{ ... } % or power{ ... }
    print{ ... }
    save{ ... }
    alpha{ ... }
    beta{ ... }
    gamma{ ...}
    neutron{ ... }
}
```

Figure 5.1.9. ORIGEN "case" overview.

The most important three components are the lib, mat, and time/power/flux inputs:

1. an ORIGEN library and the transition matrix data set on it to use (lib),
2. initial amounts of nuclides (mat), and
3. a power or flux history (time/power or time/flux).

The case identifier and case title string (shown as ID and title="my title" in Figure 5.1.9) are echoed in the output file and can be a convenient way to differential cases. Both are optional, with the ID defaulting to the case index, with " 1 " for the first case, " 2 " for the second, etc. The "print" and "save" blocks represent two ways to analyze the output from a calculation. The "print" block prints tables directly to the output file, and the "save" block saves the solution in a special ORIGEN binary concentration file (f71), e.g., for later post-processing. Finally, the "alpha," "beta," "gamma," and "neutron" blocks control the emission source calculations for alpha, beta, gamma, and neutron particles, respectively. The remaining subsections will describe the input for each of these blocks.

## Transition Matrix Specification (lib)

The transition matrix to use in a case is controlled by the "lib" shown in Figure 5.1.10.

```
lib{
    file="origen.f33" % ORIGEN library filename
    pos=1 % data set position on library
}
```

Figure 5.1.10. ORIGEN "lib" overview.

A "lib" must be present in the first case with a defined ORIGEN library file. The default position is "pos=1". The "lib" may be omitted in subsequent cases, and if so, the previous case's "lib" is used. The position refers to the set of transition coefficients (transition matrix $\boldsymbol{A}$ ) to load. To load another position on the same library file, the "lib" block with "pos=X" can be used to load position X. When ARP generates an ORIGEN library, it will contain a set of transition coefficients for each requested burnup. When COUPLE generates an ORIGEN library, it will contain a single position. For decay calculations, file="end7dec" can be used to load a decay-only library.

## Material Specification (mat)

The initial isotopics for a case a controlled by the "mat" shown in Figure 5.1.11. Note that the material specification has a few different variants, with only one allowed to specify the material in a given case.

```
% from iso
mat{
    iso=[ u235=1.0 u238=9.0 ] %id(sublib)=amount
    units=GRAMS %units in iso array
}
% from iso with number density input
mat{
    iso=[ u235=1e-2 u238=1e-1 ] %id(sublib)=amount
    units=ATOMS-PER-BARN-CM %units in iso array
    volume=200 %cm^3
}
% from position on f71 file
mat{
    load{ file="origen.f71" pos=11 }
}
% from previous case (previous=LAST is default)
mat{
    previous=4 %step index from previous case
}
```

Figure 5.1.11. ORIGEN "mat" block overview.

In the first variant in Figure 5.1.11, the isotopic distribution "iso" is used with "units." The "iso" array contains a sequence of "id=amount" pairs, where "id" is a nuclide identifier in the format described in Sect. 5.1.3.3.1.1, and the units of the amount are given by the "units" keyword, one of the unit names listed in the third column of Table 5.1.10. Default units are MOLES.

In the second variant, the number density (ATOMS-PER-BARN-CM) is specified which requires an additional specification of the "volume" in $\mathrm{cm}^{3}$. Internally, the number density will be converted to MOLES using that volume. For any type of units specified internally for calculations, isotopics are always converted to MOLES and then reconverted to the output units required.

In the third variant, the isotopics are loaded from a specific position on the $f 71$ file. Note that the position index starts at one (not zero) and because the f71 is always appended to, it may contain multiple materials, cases, timelines, etc. In the fourth and final variant, the isotopics are loaded from end of step 4 from the previous case ("previous=4"). The index zero (e.g., "previous=0") corresponds to the initial isotopics of the previous case. The keyword "LAST" may be used to load the isotopics from the end of the last step, "previous=LAST". This is the default behavior, used when a "mat" block is not present.There are two additional special material specifications shown in Figure 5.1.12: (1) with a feed rate term, $\vec{S}(t)$ in Eq. (5.1.4), or (2) the blend array. The feed specified is in the units specified per second and constant for the entire case. It is possible to perform a calculation with feed but with zero initial isotopics by specifying "iso=0". Feed can be negative, however, the calculation becomes undefined and will abort when the number of atoms of any nuclide becomes negative.

The blend array allows a fraction of each result from the previous cases to be loaded. The identifier is the case name, or the index of the case if a case name is not provided and the fraction is the atom fraction. The step index for the isotopics can be specified in parentheses. For example, $\mathrm{B}(2)=0.9$ indicates that $90 \%$ of the case(B) isotopics should be taken at the end of step 2. The default step index is the final step for the case. Only one blend is allowed in an ORIGEN input (between "=origen" and "end"). Multiple blends currently requires saving isotopics to an f 71 file and reloading in a subsequent calculation.

```
% with feed array
mat{
    % units for iso and feed
    units=GRAMS
    % material is natural sodium
    iso=[na=1.0e6]
    % with feed array, set initial isotopics of zero
    %iso=0
    % continuous feed of U-235 at 1 kg/day
    % converted to grams/second
    feed=[u235=0.01157]
}
% with blend array (only one allowed in an input)
case(A){ ... }
case(B){ ... }
case{
    mat{
        % case ID(step index)=fraction of atoms
        blend[ A=0.1 B(2)=0.9 ]
    }
}
```

Figure 5.1.12. ORIGEN "feed" and "blend" arrays.

## Operating History (power, flux, time)

The operating history is specified using "time," "power," and "flux," with examples shown in Figure 5.1.13. For decay cases, only the "time" array in units of days is required. For irradiation cases, either "power" or "flux" may be provided. When flux is used, it is the step-wise flux $\Phi_{n}\left(\frac{n}{\mathrm{~cm}^{2} s}\right)$ appearing directly in the depletion equations of Eq. (5.1.4). When power is used, it is the total stepaverage power- $P_{n}(M W)$-converted to step-wise average flux using Eq. (5.1.37). With irradiation cases using flux or power, the same number of entries must be specified on the time and flux/power array. The start time corresponding to the initial conditions is not included in the array of time values. Additionally, the time specification allows time units (including a custom unit) and a start time in which the block form of "time" must be used "time\{...\}."

```
% simple decay case (two steps 0}->31\mathrm{ and 31 
time = [ 31 365 ]
% flux irradiation (decay if flux=0)
time =[[\begin{array}{lll}{31}&{365}&{396}\end{array}]
flux = [ 2e14 1e14 0 ]
% power irradiation (decay if power=0)
time = [ 31 365 396 ]
power= [ 50 45 0 ] %50 MW, 45 MW, then decay
% changing units using time block
time{
    t = [ [ 5 15 300 ]
    units = HOURS
    % available units:
    % SECONDS, MINUTES, HOURS, DAYS, YEARS, CUSTOM
}
% custom units
time{
    t = [lllll}1122\mp@code{3}
    units = CUSTOM
    custom_name = "MONTH"
    custom_length = 2678400 %seconds per "MONTH"
}
% 10-step detailed power history
time=[[
power=[[lllllllllll
```

Figure 5.1.13. ORIGEN operating history blocks ("time," "flux," and "power").

To illustrate some aspects of specifying a power history, refer to Figure 5.1.14, where the black line ("actual power") shows a piecewise linear power history that is translated to a possible step-wise constant power history shown by the red line ("step-wise constant power"), with input shown in Figure 5.1.13 labeled "10-step detailed power history". The secondary (right) y-axis shows the step-wise flux, calculated from the step-wise power via the predictor-corrector approach of Eq. equation reference goes here (5.1.37). The dependence of the power-to-flux conversion on the actual material composition is shown in the comparison of flux results for an initial composition with $6 \%$ fissile ${ }^{235} \mathrm{U}$ (blue dotted line) versus $2 \%$ fissile ${ }^{235} \mathrm{U}$ (purple dashed line). The flux at the beginning of the irradiation is a factor of 3 higher with the $2 \%$ fissile case, due to approximately a factor of 3 lower fissile content. With time, fissile plutonium build-up closes the gap to a factor of 1.5.

Figure 5.1.14. Example of ORIGEN operating history and power-to-flux conversion.

```
% first case
case{
    mat{ ... }
    time=[ lllll}1025 50]
    flux=[ 4r1e14 ]
}
% continuation case (time zero is 50 days)
case{
    time{
        units=YEARS
        %without start, times must continue > 50 days
        %t=[50/365.+0.1 50/365.+0.3 ... ]
        %with start=0, times given assume start at zero
        start=0
        t=[lllllll
    }
}
```

Figure 5.1.15. ORIGEN "start" time usage.

By default, subsequent cases that continue operations on a material, continue the timeline of that material. Using "start=0" convenient when switching time units, for example from irradiation in days to decay time in years. Otherwise, one must convert the final time to years.

## Printing Options (print)

The "print" command is one of the most complex inputs, with options to set printing cutoffs and control the concentrations returned, broken down by nuclides and elements and emission sources for gamma, neutron, alpha, and beta particles. Additionally, there are options to print fission rates, absorption rates, and the ratio of fission rate to absorption rate. Each case is allowed a print block. The options for printing nuclides and elements are shown in Figure 5.1.16. The print block allows the "nuc" block and "ele" block for printing nuclide and element results, respectively.

Inside the "nuc" or "ele" blocks, there are three possible entries:

- a "sublibs" array (a list from LT, AC, FP, ALL),
- a "total" (yes or no), and
- a "units" array (see column 1of Table 5.1.10 for possible units).

The "total" is whether to sum over all "sublibs," i.e., if Gd-155 occurs in both LT and FP sublibs, then the total will be the sum of the two. It is possible to have "sublibs=[LT AC FP] total=yes," which results in four output tables, one for each of the sublibs and one for the total. The specification of "sublibs=ALL" is the same as "sublibs=[LT AC FP]."

Three parameters set the cutoff for printing a nuclide or element:

- "cutoff_step" sets the index on which to base the cutoff (default -1 means use an average over all steps),
- "rel_cutoff" determines whether to treat the cutoff as a percent of the total (default/yes) or an absolute amount (no), and
- the "cutoffs" array allows one to specify the cutoff for each unit in Table 5.1.10 as a sequence of "unit=cutoff" pairs.

```
% print each nuclide (total across all sublibs) in grams
print{
    nuc{ total=yes units=GRAMS }
}
% print each element (total across all sublibs)
% in moles, grams, and curies with cutoffs of 1%
print{
    ele{ total=yes units=[MOLES GRAMS CURIES] }
    cutoffs[ ALL=1.0 ]
}
% print decay heat and mass (by element)
% of fission products and actinides only
print{
    ele{ sublibs=[AC FP] units=[GRAMS WATTS] }
}
% change cutoff to absolute curies by element,
% in step of interest (7), but print GRAMS
print{
    cutoff_step = 7 % default -1 for average
    rel_cutoff = no % default is yes for cutoff in percent
    % only print above 1e-3 curies
    cutoffs[ CURIES=1e-3 ] % default is 1e-6 percent
    nuc{
        total=yes
        units=GRAMS
    }
}
```

Figure 5.1.16. ORIGEN nuclide and element "print" blocks.

The emission printing options are controlled by the "alpha," "beta," "gamma," and "neutron" emission blocks inside a "print" block (examples shown in Figure 5.1.17).

The "neutron" print options are

- "summary" (yes/no) controls the printing of a source strength summary,
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise), and
- "detailed" (yes/no) controls the printing of extra details about the neutron calculation.

The "gamma" print options are

- "summary" (yes/no) controls the printing of a source strength summary and
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise).

The gamma print allows a special output of the principal emitters in each energy group, controlled by setting the "principal_step" keyword to a specific step index in the case, with the "principal_cutoff" keyword used to set the minimum percent of the total a nuclide must have to be considered a principal emitter. For the gamma print there is a warning that can be enabled with "unbinned_warning=yes" if some gamma lines fall outside the user group structure and thus are not included.

The "alpha" print options are

- "summary" (yes/no) controls the printing of a source strength summary and
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise).

The "beta" print options are

- "summary" (yes/no) controls the printing of a source strength summary and
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise).

The beta print also allows a special output of the principal emitters by setting the "principal_step" keyword to a specific step index in the case, with the "principal_cutoff" keyword used to set the minimum percent of the total a nuclide must have to be considered a principal emitter.

The special printing options are shown in Figure 5.1.18.

```
print{
    % default neutron options
    neutron{
        summary=yes
        spectra=no
        detailed=no
    }
    % default gamma options
    gamma{
        summary=yes
        spectra=no
        principal_step=NONE %step index to calculate
                        %(NONE to suppress)
        principal_cutoff=2 %principal emitter cutoff
                %in percent
        unbinned_warning=no %print warning
                                    %when line not binned
    }
    % default alpha options
    alpha{
            summary=yes
            spectra=no
    }
    % default beta options
    beta{
        summary=yes
            spectra=no
            principal_step=NONE %step index to calculate
                                    %principal (NONE to suppress)
            principal_cutoff=2 %principal emitter cutoff
                %in percent
    }
} %end print
```

Figure 5.1.17. ORIGEN emission "print" blocks.

```
% defaults special printing options
print{
    absfrac_sublib = ALL %print absorption fractions for
                        %a specific sublib (LT,AC,FP)
                        %or ALL sublibs (DEFAULT)
    absfrac_step = 7 %if absfrac active, step to print
        % default is last step
    fisrate = NONE %print fission rates (default NONE)
        %absolute (ABS) or relative (REL)
    kinf = no %print fission/absorption (yes/no)
}
```

Figure 5.1.18. ORIGEN special "print" options.

## Saving Results (save)

Saving the results to an ORIGEN binary file (f71) is requested with the "save" block, which specifies both the name of the file and the step indices to save, as shown in Figure 5.1.19. The default for the filename is "file=ft71f001" and default for the steps is the special "steps=ALL" which saves all isotopics and spectra as a shortcut to having to specify "steps=[llllllll $\begin{array}{llll}1 & 2 & 3\end{array}$ LAST". The step index " 0 " corresponds to the initial isotopics and the step index "LAST" may be used as a shortcut for the last case index. There is a special rule for copying 771 files from SCALE’s temporary/working directory. If the file name "ft71f001" exists in the directory when SCALE finishes, it is copied to the user's "\$\{OUTDIR\}" as "\$\{BASENAME\}.f71", e.g. if my.inp produces "ft71f001" in the temporary/working directory then it will be copied to the same location as the main output file ("my.out") as "my.f71". Note that $\mathfrak{f 7 1}$ files are always appended to by ORIGEN. To save with the defaults, the shortcut "save=yes" is provided. The default is "save=no".

In order to change the time values written to the f 71 file, use "time_offset= $\mathrm{T}_{0}$ " which will write the current cumulative time minus $\mathrm{T}_{0}$ to the file. The "time_offset" is convenient, for example, when time since discharge is desired instead of the absolute, cumulative time. The "time_units" entry specifies the units of the "time_offset", with the same units available in the "time" block. The default is "time_units=DAYS".

```
case{
    mat{ ... }
    time=[ 1 10 100 1000 ] % 4 steps to 1000 days
    save{
        file="short.f71" % file name
        steps=[0 2 4] % save initial (0) and isotopics
                                % end-of-step 2 (10 days)
                                % end-of-step 4 (1000 days)
    }
    save{
        file="ft71f001" % file name (DEFAULT)
        steps=ALL % save ALL steps (DEFAULT)
    }
    save=yes % equivalent to the above
    save{
        file="last.f71" % file name
        steps=[LAST] % save only last (LAST=4 here)
        time_offset=1000 % write time - time_offset
        time_units=DAYS % units of time_offset
    }
}
```

Figure 5.1.19. ORIGEN "save" block.

## Decay Emission Calculations (alpha, beta, gamma, neutron)

A decay emission calculation is initiated with the appropriate block inside the calculation "case." The group structure for any emission spectra result is determined by the energy bounds provided as described in Sect. 5.1.3.3.2.2. Each type of emission calculation is activated by the existence of a calculation block named "alpha", "beta", "gamma", or "neutron" for those respective types of calculations. Alternatively, to turn on an emission calculation with defaults, use "alpha=yes", "beta=yes", "gamma=yes", or "neutron=yes" in a "case" block.

The neutron calculation (Sect. 5.1.2.4.1) is activated by the "neutron" calculation block. All neutron calculation options are to control the ( $\alpha, \mathrm{n}$ ) calculation.

Three ( $\alpha, \mathrm{n}$ ) options can be indicated with the "alphan_medium": a $\mathrm{UO}_{2}$ fuel matrix (alphan_medium=UO2), a borosilicate glass matrix (alphan_medium=BOROSILICATE), and the problem-dependent matrix defined by the user input compositions (alphan_medium=CASE). The numeric options 0 , 1 , and 2 are also valid for the UO2, BOROSILICATE, and CASE options, respectively. Note that the $\mathrm{UO}_{2}$ and borosilicate glass matrix options assume that the neutron source nuclides reside in these respective matrices, regardless of the actual composition of the material in the problem.

For oxide fuels, a significant neutron source can be produced from ${ }^{17} \mathrm{O}(\alpha, \mathrm{n})$ and ${ }^{18} \mathrm{O}(\alpha, \mathrm{n})$ reactions in the oxygen compounds of the fuel. For this reason, the $\mathrm{UO}_{2}$ matrix option (enabled by alphan_medium=UO2) is provided with natural isotopic distribution of ${ }^{17} \mathrm{O}$ and ${ }^{18} \mathrm{O}$. This includes the
impact of oxygen isotopes on the neutron source without having to include oxygen in the initial composition.

Another common use case is fuel storage in a borosilicate glass matrix (enabled by alphan_medium=BOROSILICATE), listed in Table 5.1.13.

Table 5.1.13. Borosilicate glass composition used in the borosilicate glass option

| Atomic number | Element symbol | ${\mathbf{W t ~} \boldsymbol{\%}^{\boldsymbol{a}}}$ | Atom $\%$ |
| :---: | :--- | :---: | :---: |
| 3 | $\mathrm{Li}^{b}$ | 2.18 | 6.296 |
| 5 | $\mathrm{~B}^{b}$ | 2.11 | 3.913 |
| 8 | $\mathrm{O}^{b}$ | 46.4 | 58.138 |
| 9 | $\mathrm{~F}^{b}$ | 0.061 | 0.0644 |
| 11 | $\mathrm{Na}^{b}$ | 7.65 | 6.671 |
| 12 | $\mathrm{Mg}^{b}$ | 0.49 | 0.404 |
| 13 | $\mathrm{Al}^{b}$ | 2.18 | 1.620 |
| 14 | $\mathrm{Si}^{b}$ | 25.4 | 18.130 |
| 17 | $\mathrm{Cl}^{b}$ | 0.049 | 0.0277 |
| 20 | Ca | 1.08 | 0.540 |
| 25 | Mn | 1.83 | 0.668 |

${ }^{a}$ Obtained from Ref. 11.
${ }^{b}$ Elements with ( $\alpha, \mathrm{n}$ ) yields.
In the last most rigorous option, the $(\alpha, \mathrm{n})$ neutron source and spectra are calculated using the source, target, and constituents determined using the material compositions in the problem at a particular time, dictated by "alphan_step" in the "neutron" print options. For spent fuel neutron source calculations, there are a large number of potential source, target, and constituent nuclides in the ( $\alpha, \mathrm{n}$ ) calculation and in order to remove low-importance nuclides from the calculation, the "alphan_step" and "alphan_cutoff" parameters are used. Only those nuclides with an $\alpha$-decay activity exceeding the product of "alphan_cutoff" times the total $\alpha$ activity are included as source nuclides in the ( $\alpha, \mathrm{n}$ ) neutron calculation. Additionally, only those nuclides with a constituent or target atom fraction less than "alphan_cutoff" are included unless the concentration is greater than 1 ppm , in which case it will be retained regardless of the cutoff. The "blend" array is particularly useful for creating a problem-dependent medium composed of fuel and another material.

The gamma (photon) calculation described in Sect. 5.1.2.4.4 is activated with the "gamma" block, as shown in Figure 5.1.21. The gamma block includes a host of options where the default should be appropriate in most cases.

- The "sublib" option (default "ALL") affects the sublibraries included in the gamma emission calculation. The "immediate" option (default "yes") includes immediate gamma and x-rays.
- The "spont" option (default "yes") includes photons emitted during spontaneous fission and $(\alpha, n)$.
- The "continuum" option (default "yes") enables mapping of continuum data stored artificially as lines to a continuum across the user-defined energy bins.

The following options may need to be modified in some scenarios.

- The "brem_medium" option (default "UO2") includes the photons emitted by beta particles as they slow down in a medium (Bremsstrahlung) in the gamma calculation. A problem-dependent medium is not available for "brem." The only options are "NONE," "H2O" (for Bremsstrahlung in water) and "UO2" (for uranium dioxide).
- The "conserve_line_energy" option (default "no") modifies the intensity of each gamma line within a group to conserve energy according to $I_{g}=I_{a} E_{\alpha} / E_{g}$, where $I_{a}$ is the original line intensity, $E_{a}$ the original line energy and $E_{g}$ is the group energy (simple midpoint energy). Note that this option modifies intensities and thus results in number of particles not being conserved.
- The "adjust_for_missing" option (default "no") accounts for the scenario where a nuclide has a known gamma decay mode with known recoverable energy release, but the spectral data do not exist in the available emission resource. If "adjust_for_missing=yes," the entire spectrum is scaled up to include the missing energy. If the missing energy is more than $1 \%$ of the total, a warning is printed.
- The "split_near_boundary" option (default "no") enables a splitting of a line when it appears very close to a bin boundary. If "split=yes" and a photon line is within $3 \%$ of an interior energy boundary, then the intensity is split equally between the adjacent groups.

    %beta=yes
}
```

Figure 5.1.22. ORIGEN "alpha" and "beta" calculation blocks.

## Processing Options (processing)

The processing options are contained inside the "processing" block (inside a "case") and have two ways to modify the isotopics vector: the "removal" block and the "retained" array (see Figure 5.1.23). Both operate on elements instead of nuclides.

- Each "removal" block specifies a list of elements and a rate of continuous removal in units (1/s). This removal is an artificial increase of the decay constant, as seen in Eq. (5.1.3), and it can be used to model any continuous system of removal, such as filtration. Note that more than one removal block may be specified.
- The "retained" array specifies a list of elements and the mole/atom fraction to be retained at the start of this case. Note that all unspecified elements become zero.

```
case{
    ..
    processing{
            %rate is in 1/s
            removal{ rate=1e-2 ele=[H Xe Ar] }
            removal{ rate=1e-7 ele=[U Pu] }
            %id=frac
            retained=[ u=1.0 pu=0.5 ]
    }
}
```

Figure 5.1.23. ORIGEN "processing" block.

### 5.1.3.3.2.2 Bounds Block

The "bounds" block appears outside all cases and is valid for the entire input, dictating the energy bins (i.e., groups) for emission spectra and source calculations (see Figure 5.1.24). The array shortcuts-"L" for logarithmically spaced intervals and "I" for linearly spaced intervals-can be particularly useful for specifying the bounds (see Table 5.1.12). The energy bounds are in units (eV) and can be given in increasing or decreasing order with the output convention of decreasing order. Additionally, neutron and gamma energy bounds can be read from a standard SCALE cross section library file by specifying the path to the file instead of the array bounds.

```
=origen
bounds{
    neutron=[1e6 1e3 1] %2-group with 1MeV, 1keV, 1eV
    gamma=[100L 1.0e7 1.0e-5] %101 logarithmically spaced bins
    alpha=[1e6 2e7] %high-energy bin between 1 and 20 MeV
    beta=[22I 1 100] %23 linear bins between 1 and 100 eV
    %read neutron bounds from SCALE multi-group library file
    %neutron="scale.rev04.xn252v7.1"
}
case{ ... }
end
```

Figure 5.1.24. ORIGEN "bounds" block.

### 5.1.3.3.2.3 Solver Block

The solver block controls high-level solver options, the most important of which is the actual solver kernel used, either the default MATREX (Sect. 5.1.2.2.1, Figure 5.1.25) or CRAM (5.1.2.2.2, Figure 5.1.26).

```
=origen
solver{
    type=MATREX %(DEFAULT)
    opt{
        terms=21 %number of expansion terms (DEFAULT)
        maxp=100 %maximum number of short-lived precursors
                % for a long-lived nuclide (DEFAULT)
        substeps=1 %number of time step divisions (DEFAULT)
    }
}
case{ ... }
end
```

Figure 5.1.25. ORIGEN "solver" block for MATREX.

```
=origen
solver{
    type=CRAM
    opt{
        order=16 %order of the method (DEFAULT)
        substeps=1 %number time step divisions (DEFAULT)
    }
}
case{ ... }
end
```

Figure 5.1.26. ORIGEN "solver" block for CRAM.

The MATREX kernel contains two parameters that are generally sufficient with the default values. The minimum number of "terms" is $n_{\text {terms }}=21$, which overrides the heuristic in Eq. (5.1.19). Experience indicates that high flux levels (e.g., greater than $10^{16} \mathrm{n} / \mathrm{cm}^{2}$-s) may require more terms. The second parameter, "maxp," is generally sufficient, describing the amount of storage available for the short-lived precursors of a long-lived isotope.

The CRAM kernel has a single parameter that impacts the numerical error: the "order." Both the CRAM and MATREX solver include the "substeps" parameter that adds substeps to each user-defined time step. Testing the same input with a different number of substeps (e.g., "substeps=1," "substeps=2," "substeps=4") can be a simple way to check that the time grid is sufficient.

### 5.1.3.3.2.4 Options Block

The "options" block contains miscellaneous global options that apply to all cases, as shown in Figure 5.1.27. The "print_xs" option enables output of the transition matrix $\boldsymbol{A}$ used in each case, the "digits" option enables high-precision output when set to 6, and the "fixed_fission_energy" allows 200 MeV per fission to be used everywhere instead of the nuclide-dependent energy release being used by default.

```
=origen
options{
    print_xs=no %print cross sections
    digits=4 %digits=6 is high-precision
    fixed_fission_energy=no %set to yes to use 200 MeV/fission
}
case{...}
end
```

Figure 5.1.27. ORIGEN "options" block.

### 5.1.3.4 OPUS Module

The analysis of ORIGEN results often involves evaluating large amounts of output data that may include time-dependent nuclide and element inventories, radiological decay properties, and neutron, alpha, beta and photon source spectra. Visualization of the output data from ORIGEN often provides a means of rapidly evaluating the dominant nuclides in a problem, identifying important trends in the results, and providing insight into the problem that is not easily obtained otherwise. The OPUS utility program has been developed to read and process ORIGEN binary concentration results file (f71) into a format easily entered into graphics-plotting packages.

### 5.1.3.4.1 Key Features

The output of OPUS is a PLT file with extension ".plt" which can be easily read by most graphics packages, including the SCALE GUI Fulcrum. An example of the PLT file is shown in Figure 5.1.28.

Figure 5.1.28. Example of the OPUS PLT file.

The various types of data that can be returned by OPUS fall into two separate classes, briefly described as (1) dominant or selected isotopes or elements and (2) photon, alpha, beta and neutron source spectra. These requested data may be extracted for either irradiation or decay time periods of interest. One key feature of the program is that by default, it will automatically extract the 40 most dominant nuclides or elements in the problem, rank them using the output response and time periods of interest as specified by the user, and give the total response. The returned data may be selected, ranked, and plotted according to the group (types) of nuclides in the problem. The groups include the actinides, fission products, activation products, fission products and actinides, or all nuclides in the problem. The totals are printed for all nuclides in the specified group, and a subtotal is generated for all nuclides in the printed list. The user may also specify any other nuclide or element to be included in the output, regardless of its importance to the problem. The nuclides may be ranked using different output units of mass, density, atomic density, activity, toxicity, decay heat, or isotopic fractions.

Default values are assigned to most input variables, allowing a comprehensive visual analysis of returned data with relatively little user input.

### 5.1.3.4.2 Input Description

OPUS input records are limited to a maximum of 80 columns. A single data entry may be entered anywhere in a record but cannot be divided between two records; however, array-data entries may be divided over many records. A data entry (from left to right) is composed of a keyword, an equal sign (=), and numeric or alphanumeric data. A data entry is illustrated in the following example:
title="PWR 33 GWD/MTU 3.3 wt \% U-235"

The program identifies keywords either by using only the first four characters in the keyword name or the full keyword name. In the example above, "titl" may be used, omitting the "e." ${ }^{6}$ Alphanumeric data (as titles or axis labels) must be enclosed in double quotes, with nuclide or element symbols being the notable exception.

Floating-point data may be entered in various forms; for example, the value 12340.0 may be entered as $12340,12340.0,1.234+4,1.234 \mathrm{E}+4,1.234 \mathrm{E} 4$, or 1.234 E 04 . Also, the value 0.012 may be entered as $12 \mathrm{E}-3,12-3,1.2-2$, etc. Numeric data must be followed immediately by one or more blanks.

Array data (alphanumeric floating-point and integer) for an array-type parameter must always be terminated with an END that does not begin in column one.

Input parameters in a single OPUS sequence input (i.e., between "=opus" and "end") may be entered in any order. Usually each sequence input produces a single plot file with the name " $\$\{O U T B A S E N A M E\} N . p l t "$ where $\$\{O U T B A S E N A M E\}$ is the base of the input file name, e.g., my.inp has the base name "my," and " N " is an 18 -digit integer that is incremented with each opus plot.

The OPUS input uses keywords. Keywords, descriptions, and allowed choices for each entry are listed in Table 5.1.14 for plot setup options and Table 5.1.15 for response units and nuclide selection. Input keywords and their choices occupy the first column. The next two columns indicate the type of plot in which the keyword may be entered. An " X " in these columns indicates the keyword is an available entry for that type of plot. An "NA" in these columns indicates it is not a keyword for that type of plot. The last column is a description of the input keyword.

| Input keywords |  |  |  |

Table 5.1.15. OPUS input for response units and nuclide selection

| Input keywords |  |  | Keyword description |
| :---: | :---: | :---: | :---: |
| NRANK=(40) | $\checkmark$ | NA | Total number of nuclides or elements to be returned for the plot. If user-selected nuclides or elements are requested (see SYMNUC), output will include these nuclides plus any remaining ones with the highest rankings for the quantity specified. The total and subtotal are always printed. Default is not used if SYMNUC is entered. |
| UNITS=(GATO) nuclide/element <br> (INTENSITY) spectrum <br> ABSORPTIONS | $\checkmark$ | NA | Requested data units. Gram-atoms are default for nuclide/element plots, and particles/s are default for spectrum plots. <br> Absorption/removal reaction rate (using removal XS on library). |
| AIRM**3 | $\checkmark$ | NA | Toxicity, cubic meters of air to dilute to $\mathrm{RCG}_{\mathrm{a}}$ |
| APELEM | $\checkmark$ | NA | Atom \% of element; isotopic atom percentages of all elements specified in SYMNUC. |
| ATOMS / B-CM | $\checkmark$ | NA | Atoms/barn-cm; requires VOLUME entry |
| BECQUERELS | $\checkmark$ | NA | Radioactivity, Bq. |
| CAPTURES | $\checkmark$ | NA | Capture reaction rate (removal minus fission; it is not the radiative capture) |
| CURIES | $\checkmark$ | NA | Radioactivity, Ci |
| FISSIONS | $\checkmark$ | NA | Fission reaction rate (using fission XS on library) |
| GAMWATTS | $\checkmark$ | NA | Gamma-ray thermal power, watts |
| GATOMS | $\checkmark$ | NA | Gram atoms, gram-atomic weights or moles |
| GPERCM ${ }^{* *} 3$ | $\checkmark$ | NA | Partial density, grams $/ \mathrm{cm}^{3}$; requires VOLUME entry |
| GRAMS | $\checkmark$ | NA | Mass, grams |
| H2OM**3 | $\checkmark$ | NA | Toxicity, cubic meters of water to dilute to $\mathrm{RCG}_{\mathrm{w}}$ |
| KILOGRAMS | $\checkmark$ | NA | Mass, kilograms |
| WPELEM | $\checkmark$ | NA | Weight \% of element; isotopic weight percentags of all elements specified in SYMNUC |
| WATTS | $\checkmark$ | NA | Total thermal power, watts |
| PARTICLES | NA | $\checkmark$ | Print spectra in units of particles/s |
| INTENSITY | NA | $\checkmark$ | Print spectra in units of particles/s/MeV (normalized to energy bin width) |
| ENERGY | NA | $\checkmark$ | Print spectra in units of $\mathrm{MeV} / \mathrm{s} / \mathrm{MeV}$ (normalized to energy bin width; multiplied by mean bin energy) |
| LIBTYPE=(ALL) | $\checkmark$ | NA | Identifies sublibrary to include for nuclide/element plots. Does not apply to spectrum plots. |
| LITE | $\checkmark$ | NA | Include only nuclides in the light-nuclide/activation product sub-library |
| ACT | $\checkmark$ | NA | Include only nuclides in the actinide sub-library |
| FISS | $\checkmark$ | NA | Include only nuclides in the fission product sub-library |

Table 5.1.15. OPUS input for response units and nuclide selection (continued)

| Input keywords |  | $\begin{aligned} & \overrightarrow{0} \\ & \text { a } \\ & \frac{\pi}{4} \\ & 0 \\ & \dot{N} \end{aligned}$ | Keyword description |
| :---: | :---: | :---: | :---: |
| FISACT <br> ALL | $\checkmark$ <br> $\checkmark$ | $\begin{aligned} & \text { NA } \\ & \text { NA } \end{aligned}$ | Include nuclides in both fission product and actinide sublibraries Include all nuclides across all sublibraries |
| SYMNUC= | $\checkmark$ | NA | Symbolic notation of nuclides or elements requested in the plot data. The list is an array terminated with an END. Nuclide entry is by chemical symbol and mass number, separated by a dash "-." Metastable states are indicated with an " $m$ " immediately following the mass number (e.g., ${ }^{242 \mathrm{~m}} \mathrm{Am}$ ). Element entry is by chemical symbol only (e.g., Pu). <br> Also, for nuclide entry it is allowed to use element identifier; in such case, all isotopes of the element found in the ORIGEN library are used. |
| SORT= | $\checkmark$ | NA | Option to sort user-requested nuclides input via the SYMNUC array by descending order of importance. If SORT is not given or is SORT=NO, the order of the nuclides in the plot table is the same as the input order. Options that can be given to SORT are the same as for UNITS. If SORT=YES, the same units provided in the UNITS entered are used. |
| RESPONSE= | $\checkmark$ | NA | Optional user-specified arbitrary response conversion factor array. These factors are applied to the individual nuclides after conversion to quantities in the units requested by UNITS. Entries are in nuclide ID - response factor pairs. Nuclide identifiers entered as legacy ORIGEN ZZAAAI 6-digit integer IDs, where the isomeric state is the last digit. The array must be terminated with an END. |

The default values are given in parentheses after the input keyword definitions. Only the first four characters of any keyword (the letters are in bold) plus the "=," are required; they can be used instead of the full keyword name. However, unlike in previous versions of OPUS, the only two options accepted are the full keyword name or its first four letters. The keyword default value is listed in parentheses, and values are provided for almost all numeric input and axis labels. For example, the user has the option to enter axis labels using XLABEL= and YLABEL= entries, or "built-in" axis labels based on the time units and the type of data units can be used.

The remaining sections give more detail on the nuclide/element plots, the spectra plots, and time range, and case selection to further filter the results on an $\mathfrak{f 7 1}$ file.

### 5.1.3.4.2.1 Nuclide/element plots

Various responses may be returned either by nuclide or by element, as a function of time, for a specified time interval. By default, the top nuclides/elements contributing to the response of interest over the time range are returned. An explicit list of nuclides/elements can also be entered, in which case these nuclides will always be included, regardless of their ranking. Results for nuclides in specific sublibraries may be filtered (e.g., to only see output of ${ }^{155} \mathrm{Gd}$ the fission product (FP) sublib and not the light nuclide version [LT] sublib. The default behavior is to sum over all sublibs.

Response totals are always generated for each plot. These totals represent the sum over all nuclides or elements in the specified library type. In addition, a subtotal is printed (both in the printout and the plot file) that represents the sum over the printed nuclides or elements. The subtotal can be very useful in identifying whether the nuclides in the printed list include all of the dominant nuclides in the problem.

OPUS allows the user to sort using any of the provided concentration units. For each nuclide/element, approximate integral value over all selected time steps is calculated in the selected units; nuclides/elements are then ranked according to this value. The NRANK cutoff is applied after the sort has been performed.

It is permitted to enter SORT=YES, which is equivalent to setting SORT= to the same value as UNITS=.

If the SORT key is not entered, nuclides/elements are sorted according to their position in the SYMNUC array.

### 5.1.3.4.2.2 Spectra plots

Alpha, beta, photon and neutron energy spectra calculated by ORIGEN may also be stored on the f71 file, and plotted by OPUS. One difference in the units of the spectra returned by OPUS and those printed by ORIGEN is that the intensities are typically converted from units of photons/s (stored on f 71 file) to particles/s-MeV by dividing by the energy-group width. This conversion produces intensities that are more easily comparable across different energy groups and energy-group structures. Energy-intensity spectra in units of $\mathrm{MeV} / \mathrm{s}-\mathrm{MeV}$ and intensity spectra in units of particles/s may also be requested.

### 5.1.3.4.2.3 Selection of plotting data

OPUS provides four basic options for selecting a subset of the data on an $f 71$ file:

1. a range of times with TMIN and TMAX (floating point numbers),
2. a range of positions on the f71 file with MINPOSITION and MAXPOSITION (integers),
3. a single CASE selection, and
4. a list of positions in the NPOSITION list.

A full overview of keywords that can be entered for time point selection is given in Table 5.1.16.

If no selection inputs are used, all available steps on the concentration file are printed. Range bounds (CASE, TMIN, TMAX, MINPOSITION, MAXPOSITION) are used as independent constraints, so any combination of those can be supplied, in which case all of the specified constraints are applied.

In case invalid positions are specified in the NPOSITION array, an error is raised, and no valid output is produced; the same happens if no steps fit into the specified selection.

The case number is useful for ORIGEN stacked cases. Furthermore, TRITON stores the mixture number (with 0 for the sum of all depletion materials and -1 for the sum of selected materials) as the case number, so this option can be used to obtain a plot of the desired depletion mixture without actually knowing the time step numbers=. When an ORIGEN f 71 file is accessed, a table of contents is printed in the output (.out) file. This can be very useful for understanding what is contained on the f 71 at each position.

Table 5.1.16. OPUS Input keywords for data set selection

| Input keywords | Type | Keyword description |
| :--- | :--- | :--- |
| NPOSITION= | Array | List of all requested position numbers of data (on NUMUNIT), <br> in ascending order. No other entries are required since <br> NPOSITION is a unique data set identifier. Terminate with <br> END. <br> NPOSITIONS cannot be specified together with any of TMIN, <br> TMAX, MINPOSITION or MAXPOSITION. <br> If none of the position selectors is entered, all available <br> positions on the data file will be returned. |
| CASE= | Variable | Number of ORIGEN case (or, a mixture number for TRITON- <br> produced f71 files). |
| MAXPOSITION= $=$ Variable | Minimum position number, used to request a range of positions <br> Maximum position number <br> All positions between MINPOSITION and MAXPOSITION, <br> inclusive, are requested. |  |
| TMIN= $=$ | MINPOSITION and/or MAXPOSITION cannot be specified <br> together with NPOSITIONS, but they can be specified at the <br> same time as TMIN and/or TMAX. Up to all four conditions <br> (TMIN, TMAX, MINPOSITION, MAXPOSITION) will be <br> used to constraint the selected time points. |  |
| If none of the position selectors is entered, all available |  |  |
| positions on the data file will be returned. |  |  |

### 5.1.3.4.3 Plot File Formats

The plot file produced by OPUS is a text file that contains plot information, including the title, axis labels, plot type, and the time-dependent data for inventory-type plots or energy-dependent data for spectral-type plots. The plot file is a free-format reading, so the column positions have no particular significance. However, the plot files created by OPUS are aligned by column to facilitate reading of the files by other graphics programs.

### 5.1.3.4.3.1 File header information

The format of the first five records of the plot file is common to all plot types. They are:
Record 1: TITL - problem title (maximum 32 characters)
Record 2: XHEA - x-axis label (maximum 20 characters)
Record 3: YHEA. y-axis label (maximum 20 characters)
Record 4: Plot type - The type of plot is selected by the words "nuclide," "element," "case," or "spec." The nuclide and element entries have the same effect and produce time-dependent plots of individual nuclides or elements in the specified units. The "case" entry is used to identify case comparisons of total quantities or individual nuclides. The "spec" entry identifies spectral-type plots.

The remaining records and formats depend on the plot type specified in Record 4.

### 5.1.3.4.3.2 Nuclide and element plot types

Record 5: NPTONC, KTOT - the number of time points (x-axis) for the plot data KTOT - the number of nuclides or elements in the plot; includes the last record that contains the totals, if present

Record 6: TIMES(NPTONC) - NPTONC entries for the times associated with each data point; units are in the units specified in Record 2 (XHEA)

Record 7: SYMBOL, (X(N,I), I=1, NPTONC) - SYMBOL is the alphanumeric symbol for the nuclide or element. No spaces are permitted in PlotOPUS. This symbol entry is followed by NPTONC entries containing the plot data for the nuclide or element SYMBOL with index N .

Record 8: Record 7 is repeated for all KTOT nuclides or elements.
Record 7+KTOT: Last record - contains the totals or other related quantity for the plot. The record has the same format as Record 7.

### 5.1.3.4.3.3 Spectral plot types

Record 5: NPTONC, NGP - the number of entries that follow to construct the spectral histogram, where $\mathrm{NGP}=(\mathrm{NG}+1)^{*} 2$ and NG is the number of energy groups. The histogram is made using a series of connecting lines, and therefore does not require any special histogram plotting capability in the graphics code.

Record 6: EN, YY - Each record contains a pair of entries: EN is the energy ( MeV ), and YY is the value for energy EN.

## Repeat Record 6 NGP times.

### 5.1.3.4.3.4 Case comparison plot types

Record 5: NCAS - the negative value of the total number of cases in the plot

Record 6: NPTONC - the number of time points (x-axis) for the plot data for the case (non-userentered data)

Record 7: INPOIN the number of time points (x-axis) for the plot data for user-entered data
Record 8: XINP(INPOIN) - INPOIN entries for the times associated with each data point of the userentered data

Record 9: YINP(INPOIN) - INPOIN entries containing the plot data for the user-entered data
Record 10: LEGEND - legend for the user-entered data case.
The remaining records contain the case comparison data for the non-user-input data. Repeat records 7, 8, 9 , and 10 for the case comparison plots, NPTONC times (same as case comparisons with no user-entered data).

### 5.1.4 Examples

The main problems solvable by the ORIGEN family of codes are enumerated below (with relevant components in parentheses).

1. Decay (ORIGEN)
2. Activation (COUPLE+ORIGEN)
3. Fuel irradiation (ARP+ORIGEN or ORIGAMI)
4. Emission spectra from decay (ORIGEN)
5. Processing, including batch/continuous chemical removal, isotopic feed, and stream blending (ORIGEN)
6. Unit conversions (OPUS)

Examples of the six variations above are contained in the following sections, except for fuel irradiation problems with ORIGAMI, as described in its own chapter.

### 5.1.4.1 Decay of ${ }^{238} U$

```
=origen
case{
    % use ENDF/VII-based decay library
    lib{ file="end7dec" }
    % create a material with 1 gram U-238
    mat{
        units=GRAMS
        iso=[u238=1.0]
    }
    time=[20L 1.0 1e9] %default units are days
    % save all information to f71
    save=yes
}
end
```

Figure 5.1.29. Decay of ${ }^{238} \mathrm{U}$
This example illustrates using the "end7dec" binary decay library and decaying one gram of ${ }^{238} \mathrm{U}$ for $10^{9}$ days using the logarithmic array shortcut to put 20 logarithmically spaced values between 1.0 and 1 e 9 days.

### 5.1.4.2 ${ }^{252}$ Cf neutron Emission Spectrum

```
=origen
bounds{
    neutron=[ 2.000000e+07 6.376300e+06 3.011900e+06 1.826800e+06
                    1.422700e+06 9.071800e+05 4.076200e+05 1.110900e+05 1.503400e+04
                        3.035400e+03 5.829500e+02 1.013000e+02 2.902300e+01 1.067700e+01
                        3.059000e+00 1.855400e+00 1.300000e+00 1.125300e+00 1.000000e+00
                        8.000000e-01 4.139900e-01 3.250000e-01 2.250000e-01 1.000000e-01
                        5.000000e-02 3.000000e-02 1.000000e-02 1.000000e-05 ]
}
case{
    title="Cf-252 decay"
    lib{ file="end7dec" pos=1 }
    time{
        units=YEARS
        t=[ 0.01 0.03 0.1 0.3 1 3 10 ]
    }
    mat{
        units=CURIES
        iso=[cf252=1.0]
    }
    %perform neutron calculation with defaults
    neutron=yes
    print{
        neutron{
            summary=yes
            spectra=yes
            detailed=yes
        }
    }
}
end
```

Figure 5.1.30. ${ }^{252} \mathbf{C f}$ neutron emission spectrum.
This example illustrates decay of 1 Ci of ${ }^{252} \mathrm{Cf}$ for ten years with calculation of the time- and energydependent neutron source. The case uses the binary decay library "end7dec." The neutron energy group structure is defined in the bounds block with array "neutron."

### 5.1.4.3 Simple Fuel Irradiation Plus Decay

```

=origen
case(irrad){
    % use xs data at pos=1 corresponds to midpoint burnup (200 d * 15MW/MTU)/2
    lib {
        file="w17x17_100d.f33" pos=1
    }
    % 1 MT of enriched uranium
    mat {
        units=GRAMS
        iso=[u234=356 u235=40000 u236=184 u238=959460]
    }
    % power history (at least 4 steps for MATREX)
    time=[ 50 100 150 200 ] %default time in days
    power=[ llllll}\begin{array}{lll}{15}&{15}&{15}\end{array}15] %power in MW
}
case(decay){
    time{
        units=YEARS
        start=0 %start time at 0 in this case for ease of input for t[]
        t=[0.1 0.3 0.9 1 2 3 4 5] %observe rule of threes
    }
    save{ file="discharge.f71" steps=[0 LAST] } %only save begin and end
}
end
```

Figure 5.1.31. Simple fuel irradiation plus decay.
This example illustrates the input for irradiation of a fuel assembly for 200 days at 15 MW in case "irrad," followed by decay for 5 years in the next case, "decay." The ORIGEN library (f33) was prepared by ARP to have a single position with a burnup of $1500 \mathrm{MWd} / \mathrm{MTU}$. The input material has been specified to have 1 MTU total with an enrichment of $4.0 \%$ in ${ }^{235} \mathrm{U}$. Note that there are consistency requirements between ARP and ORIGEN that cannot be checked by either module. Namely, the enrichment specified in ARP should be equivalent to the effective enrichment specified in the ORIGEN input, and the burnup-dependent cross section data on the ORIGEN library should be for the midpoint burnup of the case, which requires consistency between the operating history (power and time) and the initial isotopics heavy metal loading. In typical fuel depletion calculations, it is most convenient to specify a metric ton ( $10^{6}$ grams) of initial heavy metal, such that the power in MW may be interpreted as

MW/MTIHM. In the above example, the power history does not need to be constant but when combined with the time values should produce an average burnup of $1500 \mathrm{MWd} / \mathrm{MTU}$ in order that the cross sections interpolated by ARP in position 1 are valid.

It is important to note that with the MATREX solver, used by default, the recommendation for irradiation and decay of spent fuel is to use no fewer than four steps for the irradiation and begin the decay period with a time step on the order of weeks or a month, increasing the interval for each subsequent step by no more than a factor of three. In many continuation cases, such as the decay one described here, it is convenient to specify times starting from zero for the case with "start=0" in the time block.

### 5.1.4.4 Three Cycles of Irradiation Plus Decay

This example is similar to the previous one, except there are three sets of burnup-dependent transition cross sections (positions) generated by ARP and used in ORIGEN, and there are three cases, one corresponding to each cycle. Neutron and gamma sources are generated and saved to the f 71 file for the final decay case. The maximum burnup achieved is $60 \mathrm{GWd} / \mathrm{MTIHM}$.

}
end
```

Figure 5.1.32. Three cycles of irrradiation plus decay.

### 5.1.4.5 Load Isotopics from an f71 File

The "mat" block allows isotopics to be loaded from any position on an existing $\mathrm{f71}$ file. A table of contents is printed in the output file every time an f 71 is read or written. Inspection of this table can help identify the appropriate position on the f71, as shown in the table below, extracted from the output file.

```
'copy existing f71 file from input file directory to working directory
=shell
cp ${INPDIR}/discharge.f71 discharge2.f71
end
=origen
case(restart){
    % decay only library
    lib {
        file="end7dec" pos=1
    }
    % must know correct position
    mat {
        load{ file="discharge2.f71" pos=2 }
    }
    % continue timeline from previous case ending at 5 years
    time{
        units=YEARS
        start=5
        t=[ll0 20 40 80 160}
    }
    % append to file
    save{
        file="discharge2.f71" steps=[llllll
    }
}
end
```

Figure 5.1.33. Load isotopics from an $\mathbf{f 7 1}$ file using the "mat" block.

```
======================================================================================
= Restart F71 File for case 'restart' (#1/1) =
Data taken from position: 2
index time power flux fluence burnup libpos case step DCGNAB

G - gamma emission spectra present
N - neutron emission spectra present
A - alpha emission spectra present
B - beta emission spectra present
```

Figure 5.1.34. Table of contents printed when accessing the $\mathbf{f 7 1}$ file.
The simple input below can be used to print contents of an existing $f 71$ file. The file is renamed so that it does not have extension ".f71." This prevents the automatic copy back from the working directory to the input file directory. Note that the same is true with any ORIGEN libraries that have the extension ".f33." There is a rule in place that any file in the working directory with extension ".f71" or ".f33" is copied back to the input file's directory. To prevent this from occurring, the ".f71" or ".f33" extensions must not be used in the filename, or unneeded files with a shell command at the end must be explicitly deleted.

```
'avoid .f71 extension to prevent automatic copy back
=shell
cp /path/to/unknown.f71 f71
end
=origen
case(test){
    lib{ file="end7dec" pos=1 }
    mat{ load{ file="f71" pos=1 } }
    time=[1]
}
end
'remove any *.f71 or *.f33 in the working directory to prevent automatic copy back
'(not necessary in this example, but for reference)
=shell
rm -f *.f71
rm -f *.f33
end
```

Figure 5.1.35. Isotopics from an $\mathbf{f 7 1}$ or $\mathbf{f 3 3}$ file.

### 5.1.4.6 Continuous Feed and Removal

Both continuous feeding of nuclides into a system and chemical removal of elements from a system are required to simulate molten fuel systems such as the molten salt reactor (MSR). Simulation of removal can be used to represent other physical processes such as purification systems (i.e., removal of chemical species by filtration or ion-exchange columns) and ventilated systems in which the removal can be represented using a rate constant (1/s). The following example applies to simulation of a molten salt reactor system, and it uses both continuous feed of ${ }^{232} \mathrm{Th}$ and simultaneous removal of fission products according to their removal process. To actually simulate this system properly, an ORIGEN reactor library appropriate for the MSR must be generated.

There are 11 groups of nuclides in this example, each with the same removal constant. The groups, by element and removal rate in units of $(1 / \mathrm{s})$, are

- Group 1: Ca to As $\left(3.37 \times 10^{-9}\right)$;
- Group 2: Y, La, Ce, Pr, Nd, Pm, Sm, Gd ( $2.31 \times 10^{-7}$ );
- Group 3: Eu $\left(2.31 \times 10^{-8}\right)$;
- Group 4: Se, Nb, Mo, Tc, Ru, Rh, Pd, Ag, Sb, Te (5 $\times 10^{-2}$ );
- Group 5: Zr, Cd, In, Sn $\left(5.79 \times 10^{-8}\right)$;
- Group 6: Kr, Xe $\left(5 \times 10^{-2}\right)$;
- Group 7: $\mathrm{Br}, \mathrm{I}\left(1.93 \times 10^{-7}\right)$;
- Group 8: $\mathrm{Rb}, \mathrm{Sr}, \mathrm{Cs}, \mathrm{Ba}\left(3.37 \times 10^{-9}\right)$;
- Group 9: Th, Li, Be, F $\left(3.37 \times 10^{-9}\right)$;
- Group 10: $\mathrm{Pa}\left(3.86 \times 10^{-6}\right)$; and
- Group 11: Np, Pu, Am, Cm, Bk, Cf $\left(1.98 \times 10^{-9}\right)$.

A ${ }^{232} \mathrm{Th}$ feed rate of $2.0 \times 10^{-2}$ grams $/ \mathrm{s}$ is used.

```
=origen
case{
    title="Single fluid MSR depletion calculation"

                removal{rate=3.86e-6 ele=[91]}
                removal{rate=1.98e-9 ele=[\begin{array}{ll}{93}&{94}\\{95}&{96}\\{97}&{98}\end{array}]}
    }
    print{
            cutoffs=[ GRAMS=0.1 ] %do not show grams < 0.1% of total
            nuc{ units=[GRAMS] total=yes }
        kinf=yes %print k-infinity summary
        absfrac_sublib=LT %absorption fractions for light nuclides in FLiBe
    }
} %end case
end
```

Figure 5.1.36. Continuous feed and removal.
The absorption rates, fission rates, and k-infinity values are printed during irradiation, which can be used to evaluate the influence of the feed rates and removal constants on the time-dependent reactor performance. For the MSR in particular, the ability to self-sustain can be assessed from the "k-infinity" summary output, enabled by "kinf=yes" in print block (as well as the absorption fractions in the light nuclides in FLiBe ), and enabled by "absfrac_sublib=LT" in the print block. This example uses pure Li-7, whereas if natural Li is used, one will see a much larger fraction of absorptions in Li-6 and much lower "k-infinity."

\subsection*{5.1.4.7 Calculate Fuel ( \(\alpha, N\) ) Emissions in a Glass Matrix}

Batch processing options are provided to separate various components of the nuclide compositions into different streams and to recombine the streams to form new compositions. This example applies to the irradiation of typical commercial fuel and subsequent storage of separated fission products and actinides from fuel in a glass matrix. The matrix is important in determining the ( \(\alpha, \mathrm{n}\) ) component of the neutron source because the alpha particles interact with the light element constituents in the matrix, with ( \(\alpha, \mathrm{n}\) ) yields corresponding to the medium containing the \(\alpha\)-emitting nuclides. Therefore, an accurate calculation of the neutron source in a glass matrix requires combining the oxide fuel compositions after irradiation with the defined glass matrix. The calculation could be performed by creating a case by manually entering the calculated nuclide activities and the matrix composition. However, this is only practical if the number of source nuclides is small. This example applies batch processing and blending options to generate the required compositions.

The blending option is used to combine two streams: one stream from irradiated fuel, and the other stream defining the glass matrix composition.

An irradiation case-"irrad"-is performed first to generate spent nuclear fuel compositions. The next case "spent" decays the results for one year. At the start of the decay, only selected elements are retained in the stream by performing processing with the "retained" array. In this example, all elements are removed except for \(\mathrm{Se}(99.8 \%\) ); Rb, \(\mathrm{Sr}, \mathrm{Te}, \mathrm{Cs}, \mathrm{Ba}, \mathrm{Dy}\) (77.8\%); and U, Np, Pu, Am, Cm (1\%).

The glass matrix compositions are then defined in the third case, "glass."
The final case-"blend"-blends \(10 \%\) of each the last step's isotopics from the "spent" and "glass" cases. To test the dependence on the time when the blend is performed, the blend can be changed to "blend=[ spent(N)=0.1 glass=0.1 ]," where \(N\) is the index of the step from which to take isotopics from the spent case.

\subsection*{5.1.4.8 Create an ORIGEN Decay Library from a Decay Resource}

The following COUPLE input is all that is required to produce a binary decay library from the ORIGEN decay resource file in the SCALE data directory, which is linked by default to unit number 27. This means that to create a new decay library based on another decay resource, it could be copied to the working directory as "ft27f001." COUPLE, when looking for unit 27, will first look for file "ft27f001." If it is not found, then COUPLE will it look to the special file "origen_filenames" in the SCALE data directory and find that unit 27 is associated with "decay," shorthand for the decay resource.

Figure 5.1.39. ORIGEN decay library from decay resource.

\subsection*{5.1.4.9 Create an ORIGEN Reaction Library}

The following input example creates an ORIGEN reaction library from an AMPX library created using the SCALE csas1x sequence. After COUPLE completes, the ORIGEN library created (on default unit 33 or file "ft33f001") is copied to the input directory. There are two very important factors to verify when using COUPLE in this capacity.
1. The " \(0 \$ \$\) a5 4 " and " \(1 \$ \$\) a13 6 " entries are very important, as they dictate that the cross sections will be read from "ft04f001" for AMPX library zone 6 , which in this case is mixture ID " 6 " (related input highlighted in red). There are some AMPX libraries which do not contain zones, e.g. "ft03f001" produced by some sequences, representing the system-average cross sections. In this case the default should be used for " \(1 \$ \$\) a13" of " 0 " indicating that a specific zone ID is not desired. By accessing different zones with "1\$\$ a13", an ORIGEN library can be created for clad activation or boron depletion in water by choosing a different mixture.
2. The group structure of the reaction resource (" \(0 \$ \$\) a3 75 ") should be the same as the AMPX library produced (for example, "v7-56" in the csas1x input [related input highlighted in blue]). This requires inspection of the "origen_filenames" file to verify that unit 75 is associated with a 56-group library.

Figure 5.1.40. ORIGEN reaction library.

### 5.1.4.10 Create an ORIGEN Activation Library

Activation calculations typically do not require self-shielding, so an ORIGEN "activation" library is a means to refer to a library that is using infinitely dilute cross sections from the reaction resource. An ORIGEN activation library can be created very easily as long as the flux spectrum is available in one of the reaction resource group structures. In the example below, a 238 -group structure is used with reaction resource on unit 18 ( $0 \$ \$ \mathrm{a} 380$ ). Additionally, this case requests explicit fission yields only for ${ }^{235} \mathrm{U}$, ${ }^{238} \mathrm{U}$, ${ }^{239} \mathrm{Pu}$, and ${ }^{241} \mathrm{Pu}$ in the $7 \$ \$$ array. Other nuclides with fission cross sections will not generate fission products. In a library meant only for activation of standard structural materials, the library could be made
much smaller by not including any fission yields without any impact on the calculation as long as it did not include fissionable isotopes. Since the reaction resource contains 238 neutron groups, the userdefined weighting flux given in the $9^{* *}$ array has 238 entries (in order of descending energy).

### 5.1.4.12 Print the Cross Section Values on an ORIGEN Library in COUPLE

Cross sections can be printed when a library is generated in COUPLE by setting the $1 \$$ array entry 14 , IEDOU $=1$.

```
=shell
cp ${INPDIR}/my_rx.f33 ft33f001
end
=couple
edit reaction transition cross sections
0$$ a4 33 e
1$$ a5 1 a14 1 0 e t
done
end
```

Figure 5.1.44. Cross section values on an ORIGEN library in COUPLE.

### 5.1.4.13 Print the Cross Section Values on an ORIGEN Library in ORIGEN

Cross sections can also be printed when the library is used in ORIGEN by setting "print_xs=yes" in the options block.

```
=shell
cp ${INPDIR}/my_rx.f33 ft33f001
end
=origen
options{ print_xs=yes }
case{
    lib{ file="ft33f001" pos=1 }
    time=[1] %dummy time
    mat{ iso=[u235=1] } %dummy iso
}
end
```

### 5.1.4.14 Ranking Contribution to Toxicity

The following OPUS input creates a plot of the volume of various nuclides with the maximum permissible concentration (MPC) in water using the "snf.f71" produced by the "Three cycle plus decay" example (5.1.4.4). Only positions $6-16$ are plotted using "minposition" and "maxposition." Three nuclides ( ${ }^{242} \mathrm{Cm},{ }^{137 \mathrm{~m}} \mathrm{Ba}$, and ${ }^{99} \mathrm{Tc}$ ) are forced to be included via the "symnuc" list, with 17 more nuclides (for total "nrank=20") included according to their average rank in terms of the MPC in water. The total number of nuclides requested is 20. The $x$-axis label is set to "TIME (YEARS)," and the title is "SPENT FUEL AT 60 GWD/MTHM."

```
=shell
cp ${INPDIR}/snf.f71 f71
end
=opus
data="f71"
typarams=nucl
units=h2om**3
time=year
libtype=fisact
minposition=6 maxposition=16 nrank=20
title="SPENT FUEL AT 60 GWD/MTIHM "
xlabel="TIME (YEARS)"
symnuc=cm-242 ba-137m tc-99 end
end
```

Figure 5.1.46. Ranking contribution to toxicity.

### 5.1.4.15 Photon Spectrum Plot

The following OPUS input creates a plot of the photon spectrum for all times between 1 and 5 years, using "tmin=1" and "tmax=5" with "time=years."

```
=shell
cp ${INPDIR}/snf.f71 f71
end
=opus
data="f71"
typarams=gspectrum
units=intensity
tmin=1 tmax=5 time=years
end
```

Figure 5.1.47. Photon spectrum plot.
The following shows the output of the time-dependent gamma spectrum extracted from the f71 file by OPUS.

Figure 5.1.48. Photon spectrum plot - output of the time-dependent gamma spectrum.

### 5.1.4.16 Neutron Spectrum Plot

The following OPUS input creates a plot of the total neutron spectrum at all times.

```
=opus
data="f71"
typarams=nspe
units=intensity
end
```

Figure 5.1.49. Neutron spectrum plot.

### 5.1.4.17 Isotopic Weight Percentages for Uranium and Plutonium During Decay

The isotopic distributions in uranium and plutonium, in weight percent, may be plotted with the following OPUS input.

```
=opus
data="f71"
units=wpel
libtype=act
symnuc=u pu end
end
```

Figure 5.1.50. Isotopic weight percentages for uranium and plutonium during decay.

### 5.1.4.18 User-Specified Response Function in OPUS

The response conversion factor data are entered in the RESPONSE= array as nuclide-response factor pairs, with the nuclide id being the legacy nuclide ID (ZZAAAI), with ZZ two digits of atomic number, AAA three digits of mass number, and I one digit of isomeric state. For example, ${ }^{235 \mathrm{~m}} \mathrm{U}$ would be given as 922351 and $\mathrm{H}-1$ as 10010 . In this example, it is assumed that the response factors are activity based (response/Bq of nuclide), so the units of Becquerels are requested using the UNITS keyword. The usersupplied response conversion factors are applied to the Becquerel units for all nuclides in the RESPONSE= array, and the results for any nuclide for which no response factors are provided are zeroed.

```
=opus
data="f71"
units=becq
time=year
typarams=nucl

# 5.2 ORIGEN DATA RESOURCES 

I. C. Gauld, D. Wiarda, M. Pigni, W. Wieslequist

#### Abstract

ORIGEN data resources include nuclear decay data, multigroup neutron reaction cross sections, neutroninduced fission product yields, and decay emission data for photons, neutrons, alpha particles and beta particles. The nuclear decay data are based primarily on ENDF/B-VII. 1 evaluations. The multigroup nuclear reaction cross section libraries now include evaluations from the JEFF-3.0/A neutron activation file containing data for 774 target nuclides, more than 12,000 neutron-induced reactions, and more than 20 different reaction types below 20 MeV , provided in various energy group structures. Energydependent ENDF/B-VII.0-based fission product yields are available for 30 fissionable actinides. Gammaray and x-ray emission data libraries are based on ENDF/B-VII.1. The photon libraries contain discrete photon line energy and intensity data for decay gamma and x-rays emission for 1,132 radionuclides, prompt and delayed continuum spectra for spontaneous fission, $(\alpha, n)$ reactions in oxide fuel, and bremsstrahlung from decay beta (electron and positron) particles slowing down in either a $\mathrm{UO}_{2}$ fuel or water matrix. Methods and data libraries used to calculate the neutron yields and energy spectra for spontaneous fission, ( $\alpha, \mathrm{n}$ ) reactions, and delayed neutron emission are adopted from the SOURCES4C code. Capabilities to calculate the beta and alpha particle emission source and spectra have also been added.

## ACKNOWLEDGMENTS

Development and testing of ORIGEN data resources, libraries, and methods have been sponsored by many organizations including the US Nuclear Regulatory Commission (NRC), the US Department of Energy (DOE), and nuclear power and research institutions.

## VERSION INFORMATION

Following is a description of the data resources available for use with ORIGEN in different SCALE versions. Methodologies and algorithms used in applying the data are described in the ORIGEN chapter.

## 6.2 (2016)

Data lead(s): I. C. Gauld, D. Wiarda, M. Pigni, and W. Wieselquist
Nuclear data in ORIGEN are unchanged from SCALE 6.1.3 except for the modification of independent fission yields for thermal fission of ${ }^{235} \mathrm{U}$ and ${ }^{241} \mathrm{Pu}$ and fast fission of ${ }^{238} \mathrm{U}$ to provide greater compatibility between the direct and cumulative fission yields when using the updated decay data from ENDF/B-VII.1. Additionally, ORIGEN no longer has its own independent source of nuclide mass and abundance data and now relies on the SCALE Standard Composition library so that there is consistency in this data across SCALE. D. Mueller and W. Wieselquist are acknowledged for testing of the new yield data. W. Wieselquist and S. Hart are acknowledged for the revision of this chapter.

### 6.1.3 (2011)

Data lead (s): I. C. Gauld and D. Wiarda

SCALE 6.1 represented a complete revision and update of the nuclear data available in ORIGEN. The following is a summary from the SCALE 6.1 manual.

The ORIGEN data libraries include nuclear decay data, neutron reaction cross sections, neutron induced fission product yields, delayed gamma-ray emission data, and neutron emission data. The nuclear decay data libraries have been updated based on ENDF/B-VII evaluations and expanded to include 903 activation products and structural materials, 174 actinides, and 1149 fission products. The cross section libraries have been revised using evaluations from the JEFF3.0/A neutron activation file, containing data for 774 target nuclides, more than 12,000 neutroninduced reactions, and more than 20 different reaction types below 20 MeV . The JEFF-3.0/A activation file is processed into several multigroup cross section libraries, from 44 groups to 238 groups, that can be used to determine the neutron reaction transition rates in ORIGEN. Energydependent ENDF/B-VII fission product yields are provided for 30 fissionable actinides. Photon yield data libraries have been updated based on the most recent ENSDF nuclear structure evaluations processed using the NuDat program. The photon libraries contain discrete photon line energy and intensity data for decay gamma and x-rays emission for 982 radionuclides, prompt and equilibrium continuum fission product spectra from spontaneous fission, ( $\alpha, n$ ) reactions in oxide fuel, and bremsstrahlung from decay beta (negatron and positron) particles slowing down in either $\mathrm{UO}_{2}$ fuel or water matrix. Methods and data libraries used to calculate the neutron yields and energy spectra for spontaneous fission, ( $\alpha, n$ ) reactions in any matrix, and delayed neutron emission are adopted from the SOURCES code. The libraries used by ORIGEN can be coupled directly with detailed and problem-dependent physics calculations to obtain selfshielded problem-dependent cross sections based on the most recent evaluations of ENDF/B-VII.

In addition, the library formats allow multiple sets of cross section data to be stored on a library to represent the changes in cross sections during irradiation.

### 5.2.1 Introduction

ORIGEN data resources include nuclear decay data, multigroup neutron reaction cross sections, neutroninduced fission product yields, and decay emission data for photons, neutrons, alpha particles and beta particles. The available resources are summarized in Table 5.2.1 and described in greater detail in the subsequent sections. The "Unit" column shows the corresponding unit number for use with FIDO input systems (e.g. with COUPLE).

### 5.2.2 Decay Resource

The nuclear data stored on the decay resource is based on ENDF/B-VII. 1 evaluations, ${ }^{1}$ including halflives, decay modes and branching fractions, and recoverable energy per disintegration. Decay modes include beta $\left(\beta^{-}\right)$, positron ( $\beta^{+}$) and electron capture (EC), isomeric transition (IT), alpha ( $\alpha$ ), spontaneous fission (SF), delayed neutron ( $\beta^{-}$n) emission, neutron emission ( n ), double beta decay ( $\beta^{-} \beta^{-}$), and decay by beta and alpha emission $\left(\beta^{-} \alpha\right)$. The decay resource also includes radiotoxicity factors based on the radioactivity concentration guides (RCGs) for air and water as defined in Part 10, Title 20, of the Code of Federal Regulations ${ }^{2}$ (10CFR20). RCGs specify the maximum permissible concentrations of an isotope in soluble and insoluble forms for both ingestion and inhalation and for occupational and unrestricted exposure. The radiotoxicity is calculated as the dilution volume of a nuclide for cases of direct ingestion or inhalation. The values are defined to be the smaller (i.e., more toxic) of the values for soluble and insoluble forms of the isotope. The maximum permissible RCGs for air and water are the public exposure limits for adult ingestion and inhalation dose coefficients of ICRP Publication $72 .{ }^{3}$ External exposure dose coefficients for noble gases were obtained from the Environmental Protection Agency (EPA) Federal Guidance Report 12. ${ }^{4}$

Recoverable energy includes the delayed energy from all electron-related radiations (e.g., $\beta^{-}$, $\beta+$, Auger electrons), all gamma rays, $x$-rays, annihilation radiations, and the average energy of all heavy charged particles and delayed neutrons. The average alpha energy includes the energy of the recoil nucleus. A part of the recoverable energy per decay not included in the ENDF/B-VII. 1 values is the additional contribution from spontaneous fission. This energy was calculated as the product of the spontaneous fission branching fraction and recoverable energy per fission using a value of 200 MeV per fission and then added to the ENDF/B-VII. 1 recoverable Q energy. A value of 12.56 MeV gamma energy per fission was used in computing the fraction of recoverable spontaneous fission energy from gamma rays. External Bremsstrahlung radiation is not included in the Q -value since the Bremsstrahlung spectrum depends on electron interactions with the medium that contains the decay nuclide. The energy from capture gamma rays accompanying ( $\alpha, \mathrm{n}$ ) reactions is not included either since it also depends on the medium.

Appendix A describes the decay resource file format. It is important to note that the decay resource not only defines fundamental decay data, but also the complete ORIGEN nuclide set, including the "duplicates" of nuclides across sublibraries. For example, a version of ${ }^{155} \mathrm{Gd}$ is contained in both the light nuclide/activation product and fission product sublibraries. Appendix D includes the full list of the nuclides on the ORIGEN decay library "end7dec" created by COUPLE based on the current decay resource, including duplicates. Appendix E contains a list of the fundamental decay data only, without duplicates. To consider a different set of nuclides in an ORIGEN calculation, the current process is to alter the decay resource and then regenerate the "end7dec" decay library with COUPLE. By default, all subsequent libraries created from COUPLE using problem-dependent reaction transitions are based on the "end7dec" decay library and will therefore include the modified nuclide set.

### 5.2.3 Neutron Reaction Resource

The neutron cross sections defining the nuclear reaction transmutation rates use a comprehensive collection of nuclear data evaluations compiled from the JEFF-3.0/A neutron activation files. ${ }^{5}$ The JEFF3.0/A files contain continuous energy neutron data for 774 target nuclei, including ground and metastable excited states, and 12,617 neutron-induced reactions below 20 MeV . The JEFF-3.0/A cross section data are developed directly from the European Activation File (EAF-2003) ${ }^{6}$ formatted as standard ENDF-6 format data. JEFF-3.0/A cross sections are stored using File 3, multiplicities on File 10, and isomeric branching to different metastable levels using File 9.

The evaluations include many reactions that may be important for modeling fast fission and other highenergy systems. Neutron reactions are available for 23 reaction types, including ( $\mathrm{n}, \mathrm{n}$ '), ( $\mathrm{n}, 2 \mathrm{n}$ ), ( $\mathrm{n}, 3 \mathrm{n}$ ), $(\mathrm{n}, \mathrm{f}),\left(\mathrm{n}, \mathrm{n}^{\prime} \alpha\right),(\mathrm{n}, 2 \mathrm{n} \alpha),(\mathrm{n}, 3 \mathrm{n} \alpha),\left(\mathrm{n}, \mathrm{n}^{\prime} \mathrm{p}\right),(\mathrm{n}, \mathrm{n} 2 \alpha),\left(\mathrm{n}, \mathrm{n}^{\prime} \mathrm{d}\right),\left(\mathrm{n}, \mathrm{n}^{\prime} \mathrm{t}\right),\left(\mathrm{n}, \mathrm{n}^{\prime}{ }^{3} \mathrm{He}\right),(\mathrm{n}, 4 \mathrm{n}),(\mathrm{n}, 2 \mathrm{np}),(\mathrm{n}, \gamma),(\mathrm{n}, \mathrm{p})$, $(n, d),(n, t),\left(n,{ }^{3} H e\right),(n, \alpha),(n, 2 \alpha),(n, 2 p)$, and (n,p $\left.\alpha\right)$.

The JEFF-3.0/A evaluations also include extensive compilations of energy-dependent branching fractions that define neutron reaction transitions to ground and metastable energy states. Energy-dependent branching is fully implemented in the ORIGEN cross section libraries.

Implementation of the JEFF-3.0/A cross sections as ORIGEN multigroup data was accomplished by processing and collapsing the JEFF-3.0/A pointwise cross sections into a standard multigroup AMPX format using ENDF data-processing modules of the AMPX ${ }^{7}$ cross section processing code system. The collapse is performed using a thermal Maxwellian-1/E-fission-1/E weighting spectrum (see Figure 5.2.1) to provide infinite dilution multigroup cross sections.

Figure 5.2.1. Pointwise flux spectrum used to generate collapsed cross section libraries.

Neutron reactions with transitions to multiple states of the daughter product are represented using separate cross sections to the ground and metastable states. A special reaction identifier ( $\mathrm{MT}^{\prime}$ ) is defined for this implementation of metastable transitions as

$$
\mathrm{MT}^{\prime}=\mathrm{MT} * 10000+100 * \mathrm{LP}+\mathrm{LT},
$$

where MT is the reaction identifier, LP is the product metastable state, and LT is the target metastable state. Using the ${ }^{187} \mathrm{~W}(\mathrm{n}, 3 \mathrm{n}){ }^{185} \mathrm{~W}$ cross section (MT=17) as an example, the reaction identifier 170000 defines the partial cross section to the ground state of ${ }^{185} \mathrm{~W}$, and 170100 defines the cross section to metastable ${ }^{185 \mathrm{~m}} \mathrm{~W}$.

Cross section data from the JEFF-3.0/A neutron activation file are first converted to point-wise cross section data, are Doppler broadened to 900 K , and then they are collapsed to different group structures. The following group strucures are available in SCALE:

- 238-group neutron (thermal applications),
- 252-group neutron (thermal applications),
- 56-group neutron (thermal applications),
- 200-group neutron (fast applications and shielding),
- 47-group neutron (applications using the BUGLE shielding transport library),
- 49-group neutron (collapsed version of 238 groups),
- 44-group neutron (collapsed version of 238 groups), and
- 999-group neutron (multipurpose).

Several minor modifications were made to the JEFF-3.0/A data:

- The ${ }^{239} \mathrm{~Np}$ radiative neutron capture cross section was replaced with data from ENDF/B-VII.0. Neutron capture using JEFF-3.0/A cross sections was significantly larger than ENDF/B-VII. 0 due to differences in the resonance cross section region. Although experimental resonance parameters are not available for ${ }^{239} \mathrm{~Np}$, comparisons of ${ }^{240} \mathrm{Pu}$ production during irradiation ${ }^{8}$ obtained using the two evaluations showed that better agreement with the experiment was obtained using the ENDF/B-VII. 0 evaluation.
- The ${ }^{241} \mathrm{Am}(\mathrm{n}, \gamma)$ branching fraction to the ${ }^{242} \mathrm{Am}$ ground and metastable states was replaced by the evaluation from ENDF/B-VII. 0 to yield better agreement with the results of destructive radiochemical assay measurements of irradiated fuels. The branching fraction of ${ }^{241} \mathrm{Am}$ to ${ }^{242 \mathrm{~m}} \mathrm{Am}$ for thermal neutron capture changed from 8.2\% in JEFF-3.0/A to 10.0\% in ENDF/B-VII.0.

The cross section library header record information and a complete list of nuclides in JEFF-3.0/A libraries developed for ORIGEN are provided in Appendix E.

Because JEFF-3.0/A-based libraries are formatted as standard AMPX working libraries, they can be accessed and/or manipulated using standard AMPX utility modules in SCALE. For example, multigroup cross sections may be listed using the PALEALE module. Additionally, the data may be visualized using the Fulcrum user interface. Cross section plots of the 238-group JEFF-3.0/A library are illustrated in Figure 5.2.2 for $(n, \gamma),(n, \alpha),(n, 2 n)$, and $(n, 3 n)$ cross sections to the ground and metastable states.

Before the cross sections in ORIGEN can be used, they must be collapsed with a user-defined multigroup flux to a one-group cross section and added to the ORIGEN binary library (see the COUPLE input description).

Figure 5.2.2. 238-group JEFF-3.0/A cross sections for ${ }^{187} \mathbf{W}$.

### 5.2.4 Fission Yield Resource

The fission-yield resource contains the energy-dependent direct yields of each fission product for 30 fissionable actinides, including ${ }^{227,228,232} \mathrm{Th},{ }^{231} \mathrm{~Pa},{ }^{232-238} \mathrm{U},{ }^{238-242} \mathrm{Pu},{ }^{241,242 \mathrm{~m}, 243} \mathrm{Am},{ }^{237,238} \mathrm{~Np}$, ${ }^{242-246,248} \mathrm{Cm},{ }^{249,252} \mathrm{Cf}$, and ${ }^{254}$ Es. Independent (direct) fission product yields are stored as atom percent per fission, and except for ${ }^{235} \mathrm{U}$ (thermal), ${ }^{238} \mathrm{U}$ (fast), and ${ }^{241} \mathrm{Pu}$ (thermal), they are obtained from ENDF/B-VII. $0^{9}$ File 8 and MT=454.

Revised independent fission product yields for ${ }^{235} \mathrm{U}$ (thermal), ${ }^{238} \mathrm{U}$ (fast), and ${ }^{241} \mathrm{Pu}$ (thermal) were adopted to address inconsistencies between the direct and cumulative fission yields in ENDF/B-VII. 0 caused by the use of updated nuclear decay schemes in the decay sublibrary. ${ }^{10-11}$ Namely, recent changes in the decay data, particularly the delayed neutron branching fractions, result in calculated fission product concentrations that do not agree with the cumulative fission yields in the ENDF/B-VII.0 library. These issues were particularly evident for the three cited isotopes because their fissioning systems result in a preferential formation of fragments that are sensitive to the changes in the decay data. For example, a study on ${ }^{239} \mathrm{Pu}$ (thermal) showed negligible differences between cumulative yields calculated (using the recent decay data sublibrary) and the cumulative yields in ENDF/B-VII.0. Energy-dependent product yields are available for thermal, fast, and high-energy incident neutron energies. For fast fission, the value of the energy of incident neutron was modified from the value of 500 keV tabulated in ENDF/B-VII. 0 to more accurately represent the relationship between the energy distribution of the neutrons causing fission and the and the fission neutron spectrum energy. For this implementation of the yield data, the effective incident neutron energy for fast fission was adjusted from 500 keV to 2.0 MeV to better reflect the average fission energy of most nuclides. The neutron energies for thermal fission ( 0.0253 eV ) and high energy fission ( 14 MeV ) are unchanged.

The fission product yields also include cumulative ternary yields from the JEF-2.2 fission yield library ${ }^{12}$ for ${ }^{3} \mathrm{H}$ and ${ }^{4} \mathrm{He}$. The nuclide ${ }^{3} \mathrm{He}$ was also added to the fission product library since it is a decay product of tritium.

Note that inclusion of fission yields for each actinide in an ORIGEN library can be controlled by the user through COUPLE. Actinides not assigned with explicit yields do not produce fission products during fission.

Table 5.2.2. Fissionable isotopes having explicit fission yields

| Nuclide | Neutron-induced fission energies ${ }^{a}$ |  |  |
| :--- | :--- | :--- | :--- |
| ${ }^{227} \mathrm{Th}$ | Thermal |  |  |

[^8]
### 5.2.5 Energy Resource

The energy resource is a set of data defined internally to ORIGEN to compute the total power during irradiation if the flux is known, or the total flux if the power is known. The data include the energy contributed by fission and capture. The recoverable energy values taken primarily from ENDF/B evaluations are listed in Table 5.2.3 and Table 5.2.4. The recoverable energy for fission and neutron capture for nuclides not listed in the tables are assumed to be 200 MeV and 5.0 MeV , respectively.

Table 5.2.3. Recoverable energy (MeV) values for actinides

| Nuclide | Fission | Capture |
| :--- | :---: | :---: |
| ${ }^{230} \mathrm{Th}$ | 190.00 | 5.010 |
| ${ }^{232} \mathrm{Th}$ | 189.21 | 4.786 |
| ${ }^{233} \mathrm{Th}$ | 190.00 | 6.080 |
| ${ }^{231} \mathrm{~Pa}$ | 190.00 | 5.660 |
| ${ }^{233} \mathrm{~Pa}$ | 189.10 | 5.197 |
| ${ }^{232} \mathrm{U}$ | 200.00 | 5.930 |
| ${ }^{233} \mathrm{U}$ | 191.29 | 6.841 |

### 5.2.6 Emission Resources

The two main groups for emission resources are the photon (gamma) resource, which includes beta particle emission data, and the neutron resource, which includes alpha emission data.

### 5.2.6.1 Gamma Emission

The resources for gamma emission are stored as separate files (see Table 5.2.5) containing the photon data associated with different modes of decay or photon production. The photon data sets include decay gamma and x-ray line-energy data, gamma rays accompanying spontaneous fission, gamma rays accompanying ( $\alpha, n$ ) reactions in oxide fuels, and Bremsstrahlung spectra from decay electrons/positrons slowing down in $\mathrm{UO}_{2}$ and water. The photon energy spectra can be generated in any energy group structure for all activation products, actinides, and fission product nuclides with photon yield data.

Table 5.2.5. Photon data files

| File name | Description |
| :--- | :--- |
| MPDKXGAM | x-ray and gamma emissions line data |
| MPSFANGM | spontaneous fission and ( $\alpha, \mathrm{n}$ ) reactions |
| MPBRH2OM | bremsstrahlung from beta particles slowing down in water |
| MPBRH2OP | bremsstrahlung from positrons slowing down in water |
| MPBRUO2M | bremsstrahlung from beta particles slowing down in $\mathrm{UO}_{2}$ |
| MPBRUO2P | bremsstrahlung from positrons slowing down in $\mathrm{UO}_{2}$ |

All photon data sets are constructed with the same format (see Appendix C). The majority of the photon emissions are discrete energy lines. Photon continuum data, used to represent Bremstrahlung and some other gamma-ray emission spectra, are stored at discrete energies and approximately expanded to a continuum, as needed.

Gamma and x-ray yields are directly from ENDF/B-VII. 1 decay files containing spectral data for decay transitions of 1,132 nuclides. A separate file contains emission spectra for gamma rays accompanying spontaneous fission and for gamma rays accompanying ( $\alpha, \mathrm{n}$ ) reactions in oxide fuels. ${ }^{13}$ The spontaneous fission spectra combine prompt and equilibrium fission product gamma-ray components. The prompt spectrum is similar to that of ${ }^{235} \mathrm{U}$, and the delayed fission product gamma intensity at equilibrium is about 0.75 of that from the prompt fission gamma rays. Based on measured prompt fission gamma spectra from ${ }^{235} \mathrm{U}$, spontaneous fission spectra are computed from the following approximation:

$$
N(E) \cong\left\{\begin{array}{cc}
11.5 & \text { for } 0.1 \leq E<0.6 \mathrm{MeV}  \tag{5.2.1Y}\\
35.4 e^{-1.78 E} & \text { for } 0.6 \leq E<1.5 \mathrm{MeV} \\
12.6 e^{-1.09 E} & \text { for } 1.5 \leq E \leq 10.5 \mathrm{MeV} \\
0 & \text { otherwise }
\end{array}\right.
$$

where
$\mathrm{N}(\mathrm{E})=$ number of photons per unit energy per fission (photons/ MeV per fission) at energy E ,
where $E$ is the photon energy ( MeV ).

For medical and industrial spontaneous fission source applications, a more accurate simulation of the source may be desirable. Work has been performed on ${ }^{252} \mathrm{Cf}$ source modeling to explicity represent the fission product generation from fission and the delayed gamma emission. In this application, the equilibrium spontaneous fission gamma spectrum was replaced with an evaluation of the ${ }^{252} \mathrm{Cf}$ prompt gamma spectrum, and the delayed fission product gamma rays was modeled explicitly in ORIGEN by generating the time-dependent fission products using ${ }^{252} \mathrm{Cf}$ spontaneous fission product yields from ENDF/B-VII.0. ${ }^{14}$ This was performed by adding decay transitions to the ORIGEN library from the actinides to the fission products.

The spectrum of gamma rays accompanying ( $\alpha, \mathrm{n}$ ) reactions is based on reaction data for alpha interactions on ${ }^{18} \mathrm{O}$ and from studies for ${ }^{238} \mathrm{PuO}_{2}$ systems. The spectrum is computed from the approximation:

$$
\begin{equation*}
N(E) \cong 2.13 \times 10^{-8} e^{-1.38 E} \tag{5.2.£母}
\end{equation*}
$$

where

$$
\begin{array}{ll}
N(E)= & \text { number of photons per unit energy per alpha decay (photons/MeV per disintegration) at } \\
& \text { energy } \mathrm{E}(\mathrm{MeV}) .
\end{array}
$$

The photon yields in this data set are continuum spectra represented by discrete lines with an energy width of 500 keV and range from 250 keV to 10.25 MeV .

Two photon data sets contain bremsstrahlung spectra from decay electrons and positrons slowing down in a $\mathrm{UO}_{2}$ fuel matrix. The yields are in the form of continuum spectra represented in the data sets as discrete lines using up to 70 quasi-logarithmic spaced energy points over the energy range between 0 and 13.5 MeV . Two libraries contain bremsstrahlung spectra from decay electrons and positrons slowing down in water. Bremsstrahlung spectra were calculated using a computer program developed by Dillman et al. ${ }^{15}$ using beta spectra derived from Evaluated Nuclear Structure Data Files (ENSDF) decay data with a computer program written by Gove and Martin. ${ }^{16}$

### 5.2.6.2 Neutron Emission

There are four neutron emission resources used by ORIGEN to calculate the neutron intensities and spectra: (1) neutron decay data, (2) an $\alpha$-particle stopping power, (3) a target ( $\alpha, n$ ) cross section, and (4) a target ( $\alpha, n$ ) product level branching. All of the neutron data are stored in a text format with names and descriptions given in Table 5.2.6. The neutron decay data contain basic decay information for decay processes that lead to direct and indirect emission of neutrons, including spontaneous fission branching fractions, alpha decay branching fractions, delayed neutron branching fractions, $\alpha$-particle decay energies, watt fission spectrum parameters, and delayed neutron spectra. The stopping cross sections, $(\alpha, \mathrm{n})$ target cross sections, and product-level branching data are used in calculating the neutron yield and spectra from $(\alpha, n)$ reactions.

The neutron data were obtained directly from the updated SOURCES-4B code package. The sources of the neutron data are described in Shores $2000 .{ }^{17}$ An update was made to correct an error in the ${ }^{250} \mathrm{Cf}$ spontaneous fission neutron branching fraction in the neutron source decay data distributed with the SOURCES code. The ${ }^{250} \mathrm{Cf}$ branching fraction was incorrectly assigned the value from ${ }^{252} \mathrm{Cf}$ of $3.092 \times 10^{-2}$. A corrected value of $7.700 \times 10^{-4}$ from ENDF/B-VII. 1 is used.

Table 5.2.6. Neutron source data libraries

| File name | Description |
| :--- | :--- |
| ALPHDEC | Neutron source decay data |
| STCOEFF | Stopping cross section expansion coefficients |
| ALPHYLD | Target $(\alpha, \mathrm{n})$ product level branching |
| ALPHAXS | Target $(\alpha, \mathrm{n})$ cross section |

The neutron source decay contains spontaneous fission data for the 49 actinides listed in Table 5.2.7. These data include the spontaneous fission branching fraction, the number of neutrons per fission ( $v$ ), and the watt spectrum parameters for spontaneous fission. The spontaneous fission neutron energy spectrum is approximated using spectral parameters A and B, such that

$$
N(E) \cong C e^{-\frac{E}{A}} \sinh \sqrt{B E}
$$

where $E$ is the neutron energy and $C$ is a normalization constant.

Table 5.2.7. Nuclides with spontaneous fission data and spectral parameters

Neutron yields from $\alpha$-particle interaction are available for $19(\alpha, n)$ target nuclides: ${ }^{7} \mathrm{Li},{ }^{9} \mathrm{Be},{ }^{10} \mathrm{~B},{ }^{11} \mathrm{~B}$, ${ }^{13} \mathrm{C},{ }^{14} \mathrm{~N},{ }^{17} \mathrm{O},{ }^{18} \mathrm{O},{ }^{19} \mathrm{~F},{ }^{21} \mathrm{Ne},{ }^{22} \mathrm{Ne},{ }^{23} \mathrm{Na},{ }^{25} \mathrm{Mg},{ }^{26} \mathrm{Mg},{ }^{27} \mathrm{Al},{ }^{29} \mathrm{Si},{ }^{30} \mathrm{Si},{ }^{31} \mathrm{P}$, and ${ }^{37} \mathrm{Cl}$. The neutron decay data contain discrete $\alpha$-particle energies and branching fractions for 89 actinides and 7 fission products listed in Table 5.2.9. The sources of the level branching fraction data and the ( $\alpha, n$ ) cross section data are listed in Table 5.2.10. The stopping cross sections and $(\alpha, n)$ target cross section and product level branching
libraries are used in calculating the neutron yield and spectra from Ziegler $1977^{18}$ for all elements with $\mathrm{Z}<93$, and from Wilson $1983{ }^{19}$ for all elements $\geq 93$.

### 5.2.6.3 Beta Emission

Beta emission rates and energy spectra are calculated using an analytic expression for the kinetic energy of the emitted $\beta^{-}$particles ${ }^{16}$ :

$$
\begin{equation*}
N(Z, W)=\frac{g^{2}}{2 \pi^{3}} F(Z, W) \rho W\left(W_{0}-W\right)^{2} S_{n}(W) d W \tag{5.2.47}
\end{equation*}
$$

where
$Z=$ atomic number of the daugher nucleus,
$g=$ weak interaction coupling constant,
$W=$ kinetic energy of beta particle (in $m_{e} c^{2}$ units),
$F(Z, W)=$ Fermi function,
$W_{0}=$ endpoint beta energy,
$\rho=\sqrt{W^{2}-1}=$ electron momentum,
$S_{n}(W)=$ spectral shape factor based on transition type, and
$n=$ classification of the transition type .
Internal conversion electron emission is not considered.
The calculation requires nuclear data on the fraction of the beta transition to each exicited state of the daughter nucleus, the maximum endpoint energy of the transition ( $W_{0}$ ), and a classification of the beta transition ( $n$ ) defined by the spin and parity change of the transition which defines the spectral shape factor. The transition classification uses $n=0$ for allowed and forbidden non-unique transitions, $n=1$ for first forbidden unique transitions, $n=2$ for second forbidden unique transitions, and $n=3$ for third forbidden unique transitions. These data are not stored in the decay data resource but are included in a separate beta decay resource used only for the beta calculation.

The beta decay data are stored in the formatted file origen.rev00.ensdf95beta.data. The data are derived from ENSDF as compiled in 1995. The file includes beta decay information for 715 beta decay nuclides and has 8486 beta transition branches.

### 5.2.6.4 Alpha Emission

Calculation of the alpha emission intensity and spectrum requires detailed information that is not available on the decay resource. The calculation requires the alpha particle energy and branching fraction for each transition branch. Unlike the beta spectrum, the alpha particles are emitted with discrete energies, and the source spectrum may be generated by straightforward binning into the user-defined group structure. Alpha particle emission data are also used in the ( $\alpha, \mathrm{n}$ ) neutron source calculation. Therefore, the alpha emission spectra are calculated using the same alpha decay library in the neutron emission resource: origen.rev01.alphdec.data.

## APPENDIX 5.2.A - Decay Resour ce Format

The decay resource is a simple text format file that can be processed by COUPLE to create a binary decay-only library that can be used directly by ORIGEN. In general, this is not necessary, as the decay resource distributed with SCALE has already been processed with COUPLE to produce the end7dec ORIGEN decay-only binary library file. Modifying the decay data or the set of nuclides ORIGEN tracks requires modification of the decay resource file. The format is described in Table 5.2.11. Note that as of the SCALE 6.2 release, ORIGEN now uses the SCALE Standard Composition resource for abundance data and the "ABUND" field shown below is ignored by COUPLE when reading the decay resource.

Table 5.2.11. Definitions of data in the decay resource

| Data name | Definition |
| :--- | :--- |
| LIB | Nuclide sublib (used by COUPLE) |
| NUC1 | Nuclide identifier |
| IU | Units for the half life value (see Table 5.2.12) |
| HALFL | Value of the half life in IU units |
| FB1 | Beta decay transition leading to a daughter in the metastable state |
| FP | Positron emission decay fraction or orbital electron capture to the ground state |
| FP1 | Positron emission decay fraction or orbital electron capture to a metastable state |
| FA | Alpha particle emission decay fraction |
| FT | Isomeric transition decay fraction |
| LIB1 | Nuclide type in the library |
| FSF | Spontaneous fission decay fraction |
| FBN | Delayed neutron decay (beta particle and a neutron) fraction |
| Q | Recoverable energy per decay (MeV) |
| ABUND | Natural atom isotopic abundance in percent (no longer used) |
| AMPC | Maximum permissible concentration in air |
| WMPC | Maximum permissible concentration in water |
| LIB1 | Nuclide type in the library (used by COUPLE) |
| FG | Fraction of recoverable decay energy Q associated with gamma rays |
| FB | Beta decay transition leading to a daughter in the ground state |
| FBB | Double beta decay fraction |
| FN | Neutron decay fraction |
| FBA | Beta decay plus an alpha particle emission decay fraction |

The variable LIB (and LIB1)defines the nuclide sublibrary (1/2/3=activation product/actinide/fission product). Variable LIB1 is included for formatting purposes only.

The nuclide identifier is read in variable NUC1 and is subsequently stored in array NUCL. The nuclide identifier is given by

$$
\begin{equation*}
\text { NUCL }=\mathrm{Z} * 10000+\mathrm{A} * 10+\mathrm{I}, \tag{5.2.5}
\end{equation*}
$$

where Z is the atomic number, A is the atomic mass number, and I is the isomeric state, where $\mathrm{I}=0$ designates a ground state, and $\mathrm{I}=1$ is the first metastable state.

The variable HALFL is the physical half-life in units designated by the variable IU, as shown in Table 5.2.12. The definitions of 11 variables representing the different decay mode branching fractions are given in Table 5.2.11. The decay branching fractions are used in constructing the transition matrix.

Table 5.2.12. Units of half-life indicated by the variable IU

| $\mathbf{I U}$ | Units of half-life |
| :---: | :---: |
| 1 | seconds |
| 2 | minutes |
| 3 | hours |
| 4 | days |
| 5 | years |
| 6 | stable |
| 7 | $10^{3}$ years |
| 8 | $10^{6}$ years |
| 9 | $10^{9}$ years |

The variable Q is the total amount of recoverable energy $(\mathrm{MeV})$ per disintegration released by radioactive decay used for decay heat calculations. It does not include the energy of neutrinos emitted during beta decay transitions. The variable FG is the fraction of recoverable energy per disintegration that comes from gamma rays and x -rays. The value of Q is obtained directly from ENDF/B-VII. 1 as the sum of the average beta, gamma, and alpha decay energy values. The quantity includes the energy from all electron- related radiations such as $\beta^{-}, \beta+$, Auger electrons, etc., all gamma rays, $x$-rays, and annihilation radiations, and the average energy of all heavy charged particles and delayed neutrons. The contribution from alpha decay energy includes the energy of the recoil nucleus. A part of the recoverable energy per decay not included in the ENDF/B-VII. 1 values is the additional contribution from spontaneous fission. This energy was calculated as the product of the spontaneous fission branching fraction and recoverable energy per fission using a value of 200 MeV per fission and added to the ENDF/B-VII. 1 recoverable Q energy. A value of 12.56 MeV gamma energy per fission was used in computing the fraction of recoverable spontaneous fission energy from gamma rays.

External bremsstrahlung radiation is not included in the values of FG since the bremsstrahlung spectrum depends on electron interactions with the medium that contains the decay nuclide. The energy from capture gamma rays accompanying ( $\alpha, \mathrm{n}$ ) reactions is also not included since it also depends on the medium. The variable ABUND is the atom percent abundance of naturally occurring isotopes.

Figure 5.2.3. Example of the ENDF/B-VII. 1 decay data resource entries for selected fission products.

## APPENDIX 5.2.B -Fission Yield ResourceFormat

The independent fission product yields are stored as a formatted text file. The header record for each set of fission product yields includes the fissionable nuclide ID and an unused entry ( 0.0 ), followed by the number of incident neutron energies included for this nuclide. The fission yields for each energy are preceeded by a single record containing the incident neutron energy ( eV ), an unused entry ( 0.0 ), an index for the incident energy, the number of data entries per fission product, the total number of entries for each incident energy, and the number of fission products. The fission product yields for each fissionable nuclide and incident neutron energy are then listed as pairs of entries for the fission product nuclide ID and the independent (direct) fission yield as atom percent per fission. An example of the format is shown below in Figure 5.2.4 for ${ }^{227} \mathrm{Th}$.

The number and order of the fission product yields must be the same for all fissionable nuclides and must correspond to the fission products in the nuclear decay data. The fission product yields for each fissionable nuclide, excluding the yields for the terniary fission products ${ }^{3} \mathrm{H}$, ${ }^{3} \mathrm{He}$, and ${ }^{4} \mathrm{He}$, sum to 200 .

The fissionable nuclides and the tabulated incident neutron energies for which yields are available are listed in Table 5.2.2.

Figure 5.2.4. Fission yield format example showing a portion of ${ }^{227} \mathrm{Th}$.

## APPENDIX 5.2.C - Gamma Resource Format

An example of the photon data entries for the emissions from ${ }^{140}$ La decay is shown below in Figure 5.2.5. The header record for each nuclide contains the nuclide ID, the total number of emission lines in the evaluation, as well as the number of discrete x-ray lines, discrete gamma lines, and number of pseudo lines used to represent continuum data if present in an evaluation used to reconstruct continuous energy emission spectra from the discrete representation. The last entries in the header record include the total gamma energy ( MeV ), and the character nuclide name. The emission spectrum is listed using pairs of entries for the photon energy ( MeV ) and photon emission (photons per disintegration).

Figure 5.2.5. Gamma resource format example showing ${ }^{140}$ La decay photon emission.

## APPENDIX 5.2.D -ORIGEN "end7dec" Nuclide Set

Table 5.2.13 shows a list of the 2,237 nuclides on the origen.rev04.end7dec ORIGEN binary decay-only library, and because this library provides the basis for all other libraries, effectively the set of nuclides tracked by ORIGEN in any decay or irradiation calculation. The "index" column is the index of that nuclide in the set (internally every ORIGEN isotopics vector has this order), the "sublib" column is the sublibrary ( $\mathrm{LT}=$ light nuclide, $\mathrm{AC}=$ actinide, $\mathrm{FP}=$ fission product) in which the nuclide resides, the "nuclide" column is the nuclide identifier, the "mass" column is the mass of the nuclide in grams per mole, the "abundance" column is the natural abundance in atom percent for the nuclide (note only light nuclides have abundances), and the "decay" column is the decay constant. Note that the mass and abundance data are embedded on the library with the values from the current SCALE Standard Composition Library.

Table 5.2.13. Nuclide listing for "end7dec" ORIGEN library.

| index | sublib | nuclide | $\begin{gathered} \text { mass } \\ (\mathrm{g} / \mathrm{mol}) \end{gathered}$ | abundance (atom\%) | decay $(1 / \mathrm{s})$ |

## APPENDIX 5.2.E - Decay Resour ce Contents

A concise representation of the data contained in the decay resource is shown below in Figure 5.2.6. Note that the actual decay resource file currently also defines the complete ORIGEN nuclide set, including the multiple versions of some nuclides by sublibrary, e.g., ${ }^{155} \mathrm{Gd}-155$, as both a light nuclide/activation product and a fission product. The content list below contains no such duplication.

```
    ind: index
izzzaaa: 7-digit id composed of
            i: 1-digit isomeric (metastable) state
            zzz: 3-digit atomic number
            aaa: 3-digit mass number
symbol: element-aaa(m) where m is first metastable state
        dk: decay constant in 1/s
        Q: recoverable decay energy in MeV
    fQphot: fraction of Q decay energy associated with gamma rays
    mode: decay mode and yield pairs in the form
            decay_mode1(isomeric_states1) yield1
            decay_mode2(isomeric_states2) yield2
```

Figure 5.2.6. Contents of decay resource.

## APPENDIX 5.2.F -Reaction Resour ce Contents

A concise representation of the data contained in the reaction resource is shown below in Figure 5.2.7. This type of output may be generated from any AMPX multigroup library using the PALEALE utility.

JEFF-3.0/A Neutron Activation File
J-Ch Sublet, A J Koning, R A Forrest and J Kopecky March 2003

### 5.3.1 Description of ORIGEN Reactor Libraries in SCALE

The ARP code creates burnup-dependent ORIGEN cross-section libraries by interpolating over reactor cross-section libraries generated in advance using reactor physics transport methods. The reactor cross-section libraries distributed in SCALE include many classes of commercial power reactor designs and a range of fuel assembly designs.

Cross-section libraries suitable for use with ORIGEN are available in SCALE for the following reactor and fuel assembly designs:

- BWR $7 \times 7,8 \times 8-1,8 \times 8-2,9 \times 9-2,9 \times 9-9,10 \times 10-9,10 \times 10-8$, SVEA- 64 , SVEA- 96 , and SVEA-100;
- PWR $14 \times 14,15 \times 15,16 \times 16,17 \times 17,18 \times 18$;
- CANDU reactor (19-, 28-, and 37-element bundle designs);
- Magnox graphite reactor;
- Advanced Gas-Cooled Reactor (AGR);
- VVER 440 and VVER 1000;
- RBMK;
- IRT;
- MOX BWR $7 \times 7,8 \times 8-1,8 \times 8-2,9 \times 9-2,9 \times 9-9,10 \times 10-9,10 \times 10-8$, SVEA- 64 , SVEA- 96 , and SVEA-100;
- MOX PWR $14 \times 14,15 \times 15,16 \times 16,17 \times 17,18 \times 18$.

All of the libraries distributed with SCALE were developed using ENDF/B-VII.1-based 252group cross section libraries and the SCALE 6.2 TRITON module. The assembly design and the identifier for each library are summarized in Table 1. All TRITON templates used to generate these libraries are provided with the release; these templates have been developed to reflect the most recent publicly available data and to adhere to current SCALE best practices. MOX templates use the same set of BWR and PWR lattices, with MOX compositions replacing the $\mathrm{UO}_{2}$ fuel.

Additionally, a Python script (slig.py) has been developed to semi-automate the process of generating sets of libraries from information in these templates. This script calls another Python script to automatically generate a PDF documentation file with $\mathrm{LA}^{\mathrm{A}} \mathrm{E}_{\mathrm{X}}$. This SLIG script is made available to the user; more details are available in the SLIG manual.

Table 5.3.1. Summary of ORIGEN libraries ( 1470 total libraries).

| Reactor type | Assembly design description | Library Name(s) |
| :---: | :---: | :---: |
| PWR LEU* and $\mathrm{MOX}^{\dagger}$ | Babcock \& Wilcox $15 \times 15$ | bw15x15, mox_bw15x15 |

|  | IRT-4M (8 tube) | irt4m8tube |

[^11]The libraries for BWR and RBMK assembly designs all include variable coolant density. Table 2 lists the number of cross-section files associated with each individual assembly design; this number is often a product of the number of enrichments (or Pu contents for MOX assemblies) and the number of coolant density values. Unless otherwise noted in Table 2, the PWR and BWR LEU libraries were generated for seven enrichment values: $0.5,1.5,2.0,3.0,4.0,5.0$, and 6.0 $\mathrm{wt} \%{ }^{235} \mathrm{U}$. The cross sections are represented at several burnup values in the range from 0 to the maximum burnup listed. The number of burnup values on the library has been optimized with a post-processing script to minimize the size of the data libraries without losing significant fidelity in the cross section data. Note that these optimized burnup steps are not the same burnup steps used in the TRITON calculations; more burnup steps are used to calculate the depletion of the fuel. The fuel assembly designations used for many of the BWR designs include the basic lattice type, followed optionally by the number of empty (non fuel) lattice positions. For example, the $9 \times 9-9$ designation refers to the Atrium design with a $9 \times 9$ assembly lattice with 9 non-fuel (water) locations. Additional data on the reactor libraries is available in the library information PDF file released with SCALE. This document includes details on the fuel lattice type, the fuel vendor (where design information is specific to a vendor design), the assembly model, basic fuel design and reactor operating data, and the range of the variable parameters associated with the libraries (e.g., enrichment range, burnup range, etc.). This document references separate reports from which a more detailed description of the data for these libraries can be found.

Table 5.3.2. Additional information on ORIGEN libraries.

| Assembly <br> type | Enrichments <br> $[\%]$ | Coolant/moderator <br> densities [g/cm ${ }^{3}$ ] | Maximum burnup <br> [GWd/MTU] | Number of <br> Libraries |
| :--- | :--- | :--- | :---: | :---: |
| PWR LEU | $0.5,1.5,2,3,4,5,6$ | $\sim 0.73$ | 70.5 | 7 |

### 5.3.2 How to Generate ORIGEN Cross-Section Libraries

This section describes the basic procedures one needs to follow to generate ORIGEN crosssection libraries for fuel types not included in SCALE. Note that extension of the methods and data beyond 5 wt \% enrichment has not been widely investigated at ORNL because of a lack of accessible validation data for non-commercial reactor fuels. Such applications of the methodology should be tested carefully and validated. The following discussion and examples relate primarily to generating commercial LWR fuel libraries. Note that the parameter ranges used as examples are not necessarily appropriate to non-LWR applications, and will need to be modified for different reactor types and fuel designs.

The first step is to construct a physics model of the fuel lattice with the descriptions of the reactor assembly under consideration. For a given initial fuel enrichment, a TRITON depletion calculation is performed using one of the depletion analysis sequences of SCALE. TRITON can use either an explicit 2-D representation of the fuel assembly using the NEWT discrete ordinates transport code, or a 3-D representation of the assembly using the KENO Monte Carlo transport code. TRITON allows multiple fuel types to be defined and depleted independently.

The depletion analysis sequences are used to simulate irradiation and depletion of the fuel over the required irradiation history. A burnup analysis is typically modeled using a series of time intervals, or cycles. During the simulation, cross-sections that are representative of the mid-point of each cycle are created and saved in the library by the depletion sequence. In addition, cross sections that are representative of fresh fuel conditions (zero burnup) are now automatically saved in the library, without the need for the user to add a small burnup step to represent initial cross sections, as required in earlier versions of SCALE.

Past experience in creating LWR fuel libraries has indicated that depletion simulations with burnup steps of $3,000 \mathrm{MWd} / \mathrm{MTU}$ are generally adequate to represent the cross section variations with burnup. Each set of burnup-dependent cross sections is stored within the single library, and each set is accessed sequentially by its position in the library. The position 1 set contains freshfuel cross sections and the remaining cross-section sets (positions) correspond to burnup levels characterizing the midpoint of each burnup step in the depletion sequence calculation.

For fuels with multiple enrichment values, the above procedure is repeated for each enrichment. For fuels with a single enrichment value (e.g., natural uranium), only one depletion case is required. Cross-section changes with enrichment are generally represented using approximately $1.0 \mathrm{wt} \%$ increments, e.g., $0.5,1.5,2.0,3.0,4.0,5.0$, and $6.0 \mathrm{wt} \%$ of ${ }^{235} \mathrm{U}$. Because the crosssection variation is generally well behaved and smooth with changes in enrichment, it may be possible to maintain accuracy using fewer enrichment points. For BWR designs, or reactor designs involving considerable moderator density variations, one has also to consider the effect of water density variation on the cross sections. The recommended water density values for BWRs are typically 0.1 to $0.9 \mathrm{~g} / \mathrm{cm}^{3}$, with increments of about $0.2 \mathrm{~g} / \mathrm{cm}^{3}$. Again, fewer points may be adequate for many applications. Water density variation has typically not been included for PWR libraries developed at ORNL because of the relatively small variation in pressurized water reactors. When the variation in moderator density is considered, the libraries must be
calculated for each combination of enrichment and moderator density. This may involve a considerable number of depletion analysis simulations to prepare all of the required cross-section libraries.

The SLIG utility has been created to help automate the creation of input files that represent each of the discrete parameter combinations. Instead of having to manually create input files for each parameter value, a single template input file is constructed with generic flags substituted for the parameters that vary from case-to-case (i.e., enrichment and water density). The specific values required for each parameter are specified in the header of the template file; SLIG reads the template and substitutes the values for the generic flags in the input file. SLIG generates a unique subdirectory and input file for each parameter combination. A description of SLIG and examples are provided in the SLIG manual.

Another utility provides an optional procedure that can be used to reduce the size of the crosssection libraries by eliminating some of the burnup-dependent cross-section sets in the libraries in regimes where the cross sections do not vary appreciably with burnup. In general, the change in cross-section values is more pronounced early in irradiation, and tends to approach asymptotic values at higher burnup. Therefore, interpolation of the cross sections using fewer data points may yield acceptable accuracy in this range. This utility is currently unavailable in SCALE 6.2.

As an example of this procedure, the basic steps in creating a set of cross-section libraries for a typical PWR assembly are illustrated. In this example the burnup is calculated up to 72 GWd/MTU. To generate these basic cross-section libraries, the following steps are performed for each fuel enrichment value:

1. Create a 2-D or 3-D reactor physics model using TRITON for the fuel assembly design and fuel type being considered.
2. Run a depletion analysis calculation to the maximum burnup under consideration. For example, set a maximum burnup at $72 \mathrm{GWd} / \mathrm{MTU}$, and simulate using 24 intervals (cycles) with one library per cycle. Each of these cycles is $3 \mathrm{GWd} / \mathrm{MTU}$ in size. The library generated by this analysis will contain 25 sets of cross sections: initial fresh fuel cross sections plus 24 burnup-dependent cross sections.
3. Include as many extra nuclides in the fresh fuel composition specification as is practical in trace concentrations (e.g., 1E-20 atoms/barn-cm). This procedure ensures that updated cross sections for each nuclide added will be used in creating the ORIGEN library. The depletion analysis sequences automatically add many of the most important actinides and fission products. However, the addition of more nuclides by the user will result in more complete updating of the cross-section data. The addition of trace nuclides is handled automatically in TRITON using the ADDNUX= parameter entry.
4. The above procedure is repeated for each enrichment value. If moderator density variation is to be included, a separate calculation is required for each enrichment-moderator density value combination.
5. Finally, the ARPDATA.TXT file must be updated to include the data for the new crosssection libraries created. This file contains information on the library, including the number of values for each variable parameter, the parameter values, the burnup values for each
library position, and the actual library file names. The burnup values for each set of cross sections in the library are printed in the TRITON output file to assist the user in determining the appropriate library entries. Once the library information is registered in the ARPDATA.TXT file, it can be used directly by ORIGEN.

# 5.4 ORIGAMI: A CODE FOR COMPUTING ASSEMBLY ISOTOPICS WITH ORIGEN 

M. L. Williams, S. E. Skutnik ${ }^{1}$, I. C. Gauld, W. A. Wieselquist, and R. A. Lefebvre

#### Abstract

ORIGAMI computes detailed isotopic compositions for light water reactor assemblies containing $\mathrm{UO}_{2}$ fuel by using the ORIGEN transmutation code with pre-generated ORIGEN libraries, for a specified assembly power distribution. The fuel may be modeled using either lumped or pinwise representations with the option of including axial zones. In either case, ORIGAMI performs ORIGEN burnup calculations for each of the specified power regions to obtain the spatial distribution of isotopes in the burned fuel. Multiple cycles with varying burn-times and downtimes may be used. ORIGAMI produces several types of output files, including one containing stacked ORIGEN binary output data ("ft71 file") for each depletion zone; files with nuclide concentrations at the last time-step for each axial depletion region, in the format of SCALE standard composition input data or as MCNP material cards; a file containing the axial decay heat at the final time-step; and gamma and neutron radiation source spectra.

## ACKNOWLEDGMENTS

ORIGAMI is based on the PinDeplete code developed by Steve Skutnik of the University of Tennessee, and it also includes techniques taken from the Orella code written by Ian Gauld. Support for development of ORIGAMI was provided by the U.S. Department of Energy, Office of Nuclear Energy, Nuclear Fuels Storage and Transportation Planning Project.

### 5.4.1 Introduction

ORIGAMI (ORIGEN Assembly Isotopics) provides the capability to perform isotopic depletion and decay calculations for a light water reactor fuel assembly model using one or more ORIGEN calculations. The assembly may be modeled using either lumped or pinwise representations with the option of including axial zones. ORIGAMI automates the performance of ORIGEN depletion calculations for each region and thus simulates zero-, one-, two-, and three -dimensional (0D, 1D, 2D, and 3D) modeling of a fuel assembly. Multiple cycles with different specific powers and exposure and decay times may be treated, and the power distribution is described in terms of fractional pin powers in the XY plane and axial distributions along the Z axis, which define the burnup regions for the ORIGEN computations. ORIGAMI allows for easy and flexible material composition specification through the standard SCALE mixture processor for composition input, the same as in TRITON (see XSPROC chapter). While ORIGAMI cannot presently treat axially non-uniform lattice features (e.g. axially varying enrichment or the partial-length rods found in many boiling water reactor designs) within a single input, these problems can still be easily modeled by splitting the problem across sequential ORIGAMI input cases residing on the same file.

The ORIGEN calculations performed by ORIGAMI use the methodology originally established for the SCALE sequence ORIGEN-ARP (see ARP in section 5.1). This approach provides an efficient mechanism to perform stand-alone reactor depletion calculations using pre-generated ORIGEN libraries which contain self-shielded, collapsed one-group cross sections as a function of selected independent variables, such as burnup, enrichment, and moderator density, for different reactor systems. Typically the data in these libraries are obtained from 2D, multigroup lattice transport calculations (e.g., TRITON) coupled with depletion calculations for burnup. The library cross sections may be flux-weighted over the lattice to obtain data representative of the entire homogenized assembly for lumped depletion; or alternatively, it is also possible to generate multiple ORIGEN libraries corresponding to individual or groups of pins within the lattice for multi-pin depletion. The burnup-dependent ORIGEN libraries are analogous to the parameterized cross section data produced by lattice physics codes for reactor core simulators, except that data for many more nuclides and reactions are included to allow ORIGEN to compute detailed isotopics for more than 2200 nuclides.

ORIGAMI extends the capabilities previously provided by ORIGEN-ARP to perform a suite of ORIGEN calculations in order to represent the isotopic distribution of fuel within an assembly in more detail. The pre-generated ORIGEN libraries provided with SCALE tabulate the assembly-average one-group cross sections, in order to accurately reproduce assembly-average isotopics. When performing pin-by-pin calculations in ORIGAMI, users can increase the fidelity with respect to proximity to features such as assembly edges, water holes, burnable poison rods, etc. by creating and employing zone-specific libraries for different pins. By specifying the individual library assignments for each pin, users can capture these local spectrum changes in the ORIGAMI calculation through the use of one-group libraries based on these local conditions. Currently, the specification of individual libraries is limited to pin-level specification only (i.e., the same library is used for all axial zones corresponding to a pin for 3D cases) with an allowed axial moderator density distribution and radial and axial power distributions.

ORIGAMI can produce the following output files in addition to the standard ORIGEN output for each depletion zone:

- isotopics in ORIGEN binary concentration (ft71) files including
o in each depletion zone at times specified by the options block, $f t 71$ key and
o in each axial zone (summed over all pins at a particular axial level) at the final time;
- nuclide concentrations by axial zone, written as a SCALE "standard composition block" that can be used directly as input for SCALE transport codes such as the KENO Monte Carlo criticality code;
- axially-dependent decay heat source for input to a thermal analysis code such as COBRA, so that the temperature distribution within a storage cask can be computed;
- nuclide concentrations for each axial zone, given in the format of MCNP material cards; and
- space-dependent radiation source energy spectra and magnitudes in a simple text file.

ORIGAMI is tightly integrated with the SCALE Graphical User Interface, Fulcrum. Using Fulcrum and the "UO2 express form (configurable)", one can create a simple $\mathrm{UO}_{2}$ assembly depletion case in seconds (see Figure 5.4.1). Finally, ORIGAMI has the ability to perform the depletion/decay calculations for each zone in parallel using the MPI (Message Passing Interface), however this requires a special SCALE installation built with MPI in order to do so. ${ }^{1}$

### 5.4.2 Computational Methods

### 5.4.2.1 ORIGAMI assembly model

The basic model for ORIGAMI is a fuel assembly, which may be modeled in several ways with varying degrees of complexity. The most primitive model represents the assembly materials as a single mass lump that is depleted using the value of the specific power input in the power-history block. In this case, a single ORIGEN calculation is performed to obtain isotopics representing the entire assembly. This 0D model is equivalent to the current ORIGEN-ARP procedure. A more detailed model applies an input axial power profile to the (radially) lumped assembly materials. This lumped axial depletion model produces a 1 D axially varying burnup distribution, but no allowance is made for variations in the relative pin powers within the assembly. Thus, if the axial power distribution is defined by $\mathrm{N}_{\mathrm{Z}}$ axial zones, ORIGEN calculations are performed for $\mathrm{N}_{\mathrm{z}}$ different depletion regions. The 1 D axial depletion model has been found to be adequate for most criticality and decay heat analysis of spent fuel assemblies. ${ }^{2,3}$ Note that both the 0D and 1D modes are fully consistent with the 2D TRITON calculations used to generate ORIGEN reactor libraries distributed with SCALE, in that these modes employ spatially-homogenized cross-sections to represent assembly-averaged flux and cross-sections. For 2D and 3D depletion models (wherein individual pin-specific libraries may optionally be specified), the user is advised that the ORIGEN reactor data libraries distributed with SCALE are representative of an assembly axial plane as a whole; in as much, the user is advised to generate their own zone-specific libraries (i.e., based on individual material zones) within TRITON if they wish to capture regional neutronic effects within the assembly (such as proximity to water holes, burnable absorbers, etc.)

By specifying a radial pin-power map, a 2D or 3D calculation may be performed. Currently the axial and radial power shapes are fixed for the entire calculation but do still result in a fully 3D isotopic distribution. ${ }^{1,2}$ If there are $\mathrm{N}_{\mathrm{P}}$ pins in the assembly and each has $\mathrm{N}_{\mathrm{Z}}$ axial zones, ORIGAMI will perform ORIGEN calculations for $\mathrm{N}_{\mathrm{P}} \times \mathrm{N}_{\mathrm{Z}}$ depletion regions. For example, an assembly with a $17 \times 17$ array with 264 fuel pins and $N_{Z}=24$ axial zones requires 6336 independent ORIGEN calculations. For these types of simulations, the parallel mode with MPI is highly recommended.

### 5.4.2.2 Definition of initial composition

The initial mass in metric tons of heavy metal is $M_{m t u}$, set by the input parameter $m t u$. The default value of $m t u$ is equal to 1.0 , so that by default the ORIGEN calculations are performed on the basis of "per metric ton of heavy metal". Given that the sum over all zones must have the total heavy metal content ( $M_{m t u}$ ), one arrives at zone-wise heavy metal masses of:

$$
\begin{equation*}
\mathrm{M}_{\mathrm{XY}, \mathrm{Z}}=\frac{\mathrm{M}_{\mathrm{mtu}}}{\sum_{\mathrm{Z}=1}^{\mathrm{N}_{\mathrm{Z}}} \mathrm{f}_{\mathrm{Z}} \sum_{\mathrm{XY}=1}^{\mathrm{N}_{\mathrm{P}}} \mathrm{~m}_{\mathrm{XY}}} \mathrm{f}_{\mathrm{Z}} \mathrm{~m}_{\mathrm{XY}} \tag{5.4.1}
\end{equation*}
$$

where the relative amount of heavy metal in each radial position, $m_{X Y}$, is calculated from the mixture specification; fractional axial height, $f_{Z}$, from the zone specification; and $N_{P}$ and $N_{Z}$ are the total number of fuel pins and axial zones, respectively. Note that some pin locations in the assembly may not contain fuel, and these are not included in the value of $N_{p}$. The fractional axial height is given as
$\mathrm{f}_{\mathrm{z}}=\frac{\Delta \mathrm{Z}}{\mathrm{Z}_{\text {tot }}}$ is the fraction of the active fuel height occupied by axial zone Z
$\Delta \mathrm{Z}$ is the length of axial zone Z
$\mathrm{Z}_{\text {tot }}$ is the total length of the active fuel.
Whenever an axial zone mesh is input (with array meshz), the value of $f_{Z}$ is computed from the values of the zone boundaries (see input description in Sect. 5.4.3.6). If an axial mesh array is not input, the axial
zones are assumed to be uniformly distributed. In this case, the axial zones all have the same height, so that $f_{Z}=1 / N_{Z}$, where $N_{Z}$ is the number of uniform axial zones in the assembly.

The uranium mass in a single axial zone for all $N_{P}$ fuel pins in the assembly $\left(\mathrm{M}_{\mathrm{z}}\right)$ is thus:

$$
\begin{equation*}
\mathrm{M}_{\mathrm{Z}}=\mathrm{N}_{\mathrm{P}} \times \mathrm{M}_{\mathrm{XY}, \mathrm{Z}}=\mathrm{M}_{\mathrm{mtu}} \times \mathrm{f}_{\mathrm{Z}} \tag{5.4.2}
\end{equation*}
$$

In addition to the fuel mixture in an assembly, non-fuel materials (e.g., structural materials) may also be present. These materials contribute to the overall power production due to the energy produced by neutron capture reactions.. For a given value of the total assembly power, this reduces the power from the fuel mass and thus may slightly alter the fuel burnup and isotopics. In addition, activation of non-fuel materials produces additional radiation source terms in the spent fuel, which contribute to the decay heat and activity. Therefore ORIGAMI provides an option for including the non-fuel elements in the input array, nonfuel. The units of the non-fuel element masses are kg per MTU, and the materials are distributed uniformly within all fuel depletion zones. Note that the input non-fuel materials should not include oxygen in $\mathrm{UO}_{2}$ if $\mathrm{UO}_{2}$ is specified as the fuel material, as oxygen is already included in proportion to the uranium mass basis. Finally, because ORIGAMI accesses the StdComp library, any SCALE StdComp composition, e.g. "zirc4" for reactor cladding material Zircaloy-4, may be used in either structural or fuel materials.

### 5.4.2.3 Restart cases

ORIGAMI also allows the initial nuclide concentrations to be obtained from a previously produced ORIGEN binary output file. A restart case is indicated by setting restart=yes in the parameter array. The restart file has the name "assembly_restart.f71" and must be copied (or linked) to the SCALE temporary directory used for calculations. The restart file is normally obtained from an earlier ORIGAMI calculation, which always produces an ORIGEN restart file named "\$\{OUTBASENAME\}.assm.f71", where $\$\{$ OUTBASENAME $\}$ is an output prefix defined by the name of the input file and any userspecified prefix with the prefix= key. Generally the restart file from ORIGAMI contains stacked concentrations, corresponding to each axial zone and then a final entry for the lumped assembly concentrations; hence, the initial composition for a restart case varies with axial zone, unlike the case for fresh fuel. ORIGAMI does not currently allow pin-dependent restart calculations. A restart case may be useful for performing decay-only calculations of spent fuel inventory, using the burned fuel composition previously computed for the assembly exposure during reactor operation. For decay-only cases, a value for the input parameter $n z$ must be input in order to indicate the number of axial depletion regions in the previous burnup calculation.

### 5.4.2.4 Definition of power distribution

The radial power distribution is defined by the XY fractional pin powers in the input array pxy, and the axial fractional powers in the input array $p z$. The input values in arrays $p x y$ and $p z$ are normalized to unity by the code. The fractional power for a fuel pin "XY" is designated here to be $r_{X Y}$, with the normalization $\sum_{\mathrm{XY}=1}^{\mathrm{N}_{\mathrm{P}}} \mathrm{r}_{\mathrm{XY}}$. Similarly the fractional axial power for an axial zone Z is $\mathrm{a}_{\mathrm{Z}}$, which is normalized to $\sum_{\mathrm{Z}=1}^{\mathrm{N}_{\mathrm{Z}}} \mathrm{a}_{\mathrm{Z}}$. The shapes of both the radial XY and axial Z distributions must be obtained prior to the ORIGAMI calculation, either from neutron transport calculations or experimental measurements. The input distributions remain constant during the ORIGEN burn calculations for all cycles; but in reality, the power distributions may vary with time-for example, the initial axial power distribution tends to flatten after a period of burnup since the higher power zones deplete the fuel faster. For this reason it is strongly recommended to use the relative burnup distribution (at final discharge) rather than the relative power
density distribution for the input values. The burnup shape corresponds to the shape of the time-averaged flux distribution during the exposure period. This ensures that the final burnup distribution matches the desired shape.

For a given cycle, the assembly-specific power $\mathrm{P}^{(\mathrm{SP})}$ is equal to the value of input variable power, read in the power-history block (see Sect. 5.4.3.3). The assembly-specific power has units of megawatts per MTU (MW/MTU). Therefore, the total power produced by the fuel assembly is

$$
\begin{equation*}
P_{t o t}=P_{A}^{(S P)} \cdot M_{m t u} \tag{5.4.3}
\end{equation*}
$$

where $P_{\text {tot }}$ is the assembly total power, and $P_{A}^{(S P)}$ is the specific power for the assembly, read from input. The absolute power (MW) in fuel pin "XY" is:

$$
\begin{equation*}
\mathrm{P}_{\mathrm{P}}=\mathrm{P}_{\mathrm{tot}} \cdot \mathrm{r}_{\mathrm{xy}}=\mathrm{P}_{\mathrm{A}}^{(\mathrm{SP})} \cdot \mathrm{M}_{\mathrm{mtu}} \cdot \mathrm{r}_{\mathrm{xy}} \tag{5.4.4}
\end{equation*}
$$

and the power produced in axial zone Z of this fuel pin XY is:

$$
\begin{equation*}
\mathrm{P}_{\mathrm{XY}, \mathrm{Z}}=\mathrm{P}_{\mathrm{tot}} \cdot \mathrm{r}_{\mathrm{xy}} \cdot \mathrm{a}_{\mathrm{Z}}=\mathrm{P}_{\mathrm{A}}^{(\mathrm{SP})} \cdot \mathrm{M}_{\mathrm{mtu}} \cdot \mathrm{r}_{\mathrm{xy}} \cdot \mathrm{a}_{\mathrm{Z}} \tag{5.4.5}
\end{equation*}
$$

The absolute power produced in a single axial zone Z for all pins is:

$$
\begin{equation*}
\mathrm{P}_{\mathrm{Z}}=\sum_{\mathrm{XY}=1}^{\mathrm{N}_{\mathrm{P}}} \mathrm{P}_{\mathrm{XY}, \mathrm{Z}}=\mathrm{P}_{\mathrm{TOT}} \times \mathrm{a}_{\mathrm{Z}}=\mathrm{P}_{\mathrm{A}}^{(\mathrm{SP})} \times \mathrm{M}_{\mathrm{mtu}} \times \mathrm{a}_{\mathrm{Z}} \tag{5.4.6}
\end{equation*}
$$

The ORIGEN depletion calculations are performed with the absolute powers defined in Eqs. (5.4.4) and (5.4.6) for each depletion region in the 2D/3D pin-wise or 0D/1D axial depletion models, respectively. However, cross sections in the ORIGEN libraries are parameterized as a function of burnup, which depends on the specific power rather than absolute power for a given depletion region. The specific power (MW/MTU) in axial zone Z of pin XY is equal to:

$$
\begin{equation*}
P_{X Y, Z}^{(S P)}=\frac{P_{X Y, Z}}{M_{X Y, Z}} \tag{5.4.7}
\end{equation*}
$$

Substituting Eqs. (5.4.1) and (5.4.5) into Eq. (5.4.7) gives:

$$
\begin{equation*}
\mathrm{P}_{\mathrm{XY}, \mathrm{Z}}^{(\mathrm{SP})}=\frac{\mathrm{P}_{\mathrm{A}}^{(\mathrm{SP})} \cdot \mathrm{r}_{\mathrm{xy}} \cdot \mathrm{a}_{\mathrm{Z}} \cdot \mathrm{~N}_{\mathrm{P}}}{\mathrm{f}_{\mathrm{Z}}} \tag{5.4.8}
\end{equation*}
$$

In a similar manner, it can be shown that the specific power for all fuel pins in axial plane Z is:

$$
\begin{equation*}
\mathrm{P}_{\mathrm{Z}}^{(\mathrm{SP})}=\frac{\mathrm{P}_{\mathrm{A}}^{(\mathrm{SP})} \cdot \mathrm{a}_{\mathrm{Z}}}{\mathrm{f}_{\mathrm{Z}}} \tag{5.4.9}
\end{equation*}
$$

ORIGAMI permits two modes for user-specified power distributions along the axial and radial meshes: absolute fractions (i.e., where powers along the axial mesh points are expressed as fractions of the total assembly power in MW) and relative normalization (i.e., in which specific powers - in MW/MTU - of
axial zones are expressed as a relative modifiers of the assembly specific powers input in the power history block). Relative power shape modifiers assume that the specific powers expressed in the power history block represent the average assembly specific power(s) $\mathrm{P}_{\mathrm{A}}^{(S P)}$; thus, ORIGAMI will convert these factors into axial \& pin power fractions - i.e., the factors $\mathbf{r}_{\mathbf{X Y}}$ and $\mathbf{a}_{\mathrm{Z}}$ found in Eqs. (5.4.4) and (5.4.6) used to calculate the absolute pin power and axial zone power, respectively. The conversion from relative specific power modifiers to absolute power fractions is accomplished through the following normalization procedure:

$$
\begin{equation*}
\left(\mathrm{a}_{\mathrm{Z}}\right)_{\mathrm{i}}=\frac{\left(\mathrm{R}_{\mathrm{Z}}\right)_{\mathrm{i}} \cdot \mathrm{M}_{\mathrm{MTU}} \cdot\left(\frac{\Delta \mathrm{Z}}{\mathrm{Z}_{\mathrm{tot}}}\right)_{\mathrm{i}}}{\sum\left(\mathrm{R}_{\mathrm{Z}}\right)_{\mathrm{i}} \cdot \mathrm{M}_{\mathrm{MTU}} \cdot\left(\frac{\Delta \mathrm{Z}}{\mathrm{Z}_{\mathrm{tot}}}\right)_{\mathrm{i}}}=\frac{\left(\mathrm{R}_{\mathrm{Z}}\right)_{\mathrm{i}} \cdot\left(\frac{\Delta \mathrm{Z}}{\mathrm{Z}_{\mathrm{tot}}}\right)_{\mathrm{i}}}{\sum\left(\mathrm{R}_{\mathrm{Z}}\right)_{\mathrm{i}} \cdot\left(\frac{\Delta \mathrm{Z}}{\mathrm{Z}_{\mathrm{tot}}}\right)_{\mathrm{i}}} \tag{5.4.10}
\end{equation*}
$$

where $\left(\mathrm{a}_{\mathrm{Z}}\right)_{\mathrm{i}}$ is the axial power fraction for axial zone $i$ and $\left(\mathrm{R}_{\mathrm{Z}}\right)_{\mathrm{i}}$ is the relative axial zone specific power modifier for axial zone i. Obviously, for a uniformly-spaced axial mesh, the conversion from relative specific powers (using relative power modifiers) is precisely the same as that for absolute fractional axial zone powers; i.e., the relative power modifiers simply become axial power fractions by virtue of the fact that the term $\left(\frac{\Delta \mathrm{Z}}{\mathrm{Z}_{\text {tot }}}\right)_{\mathrm{i}}$ becomes a constant, thereby reducing Eq. (5.4.10) back to a direct calculation of the fractional axial power based on a relative power modifier following normalization.

Because it is assumed that the assembly mass is uniformly distributed across the pins, it can similarly be shown that the use of relative power modifiers for the XY pin map $\left(r_{X Y}\right)_{i}$ will always produce the same result as using pre-normalized absolute fractional powers in the pin map, i.e.:

$$
\begin{equation*}
\left(\mathrm{r}_{\mathrm{XY}}\right)_{\mathrm{i}}=\frac{\left(\mathrm{R}_{\mathrm{XY}}\right)_{\mathrm{i}} \cdot \frac{\mathrm{M}_{\mathrm{MTU}}}{\mathrm{~N}_{\mathrm{P}}}}{\sum\left(\mathrm{R}_{\mathrm{XY}}\right)_{\mathrm{i}} \cdot \frac{\mathrm{M}_{\mathrm{MTU}}}{\mathrm{~N}_{\mathrm{P}}}}=\frac{\left(\mathrm{R}_{\mathrm{XY}}\right)_{\mathrm{i}}}{\sum\left(\mathrm{R}_{\mathrm{XY}}\right)_{\mathrm{i}}} \tag{5.4.11}
\end{equation*}
$$

This option is provided as the relnorm option in the parameters block (discussed further in Sect. 5.4.3.2). The motivation for providing an alternative normalization for axial power shape factors is twofold. First, it is generally assumed that information on the axial power shape is obtained from axial measurements relative to an assembly-average value (i.e., axial gamma scans to determine the burnup profile based upon the gross gamma intensity or isotopic ratios of burnup indicators such as ${ }^{134} \mathrm{Cs} /{ }^{137} \mathrm{Cs}$, etc.). Therefore, by using the relative normalization option (i.e., treating axial power shape factors as relative modifiers of the assembly specific power), users can directly input shape factors obtained from techniques such as nondestructive analysis (NDA) fuel measurements into ORIGAMI to model assembly isotopic distributions.

The second motivation for the relative normalization option comes from potential problems that can arise if treating axial power shape factors as absolute fractional powers (relnorm=no) in conjunction with nonuniform axial mesh spacing defined by the user in the $z$ array (see Sect. 5.4.3.7 for details).

Important: If using the relnorm=no option, the fractional axial powers must be consistent with the axial mesh sizes defined or else incorrect zone specific powers will result from Eq. (5.4.9), therefore leading to incorrect results and likely causing the ARP sequence to fail (and therefore the ORIGAMI calculation to halt) due to calculated burnup values for the depletion zone being out of the library range. Users are thus strongly cautioned when using absolute fractional axial powers (relnorm=no) to ensure proper consistency between the axial power fractions and the axial mesh sizes.

For this reason, relative power shape factor normalization is turned on by default (relnorm=yes).

### 5.4.2.5 Computation of neutron and gamma energy spectra

ORIGAMI includes an option to generate multi-group neutron and gamma source spectra due to radioactive decay, for each depletion zone. Multi-group values are calculated by binning the discrete line and continuum spectra produced by radioactive decay and nuclear reactions into arbitrary energy group structures defined by user input. Whenever neutron energy group boundaries are input in array ngrp, neutron source spectra due to spontaneous fission, delayed neutron emission, and ( $\alpha, \mathrm{n}$ ) reactions are calculated. Similarly, gamma source spectra are computed if gamma energy group bounds are input in array ggrp. The gamma source includes photons produced by all types of radioactive decays, and also may include bremsstrahlung radiation produced by beta interactions. Input options can specify the type of nuclides included in the source term (i.e., light elements, actinides, fission products, or all nuclides), and the materials used for ( $\alpha, n$ ) reactions and bremsstrahlung production. If source spectra are calculated, the values are always included in the ORIGEN output ft71 binary file; and optionally the source spectra may also be output in a text file. The source text file only includes the average over all pins for each axial zone, while the ft 71 file includes sources for all pins and axial zones.

The source spectra output by ORIGAMI are calculated in ORIGEN using the following expression:

$$
\begin{equation*}
S_{Z . g}^{(p)}=\sum_{i=1}^{\text {itot }} Y_{i, g}^{(p)} \lambda_{i} \frac{M_{Z}^{(i)}}{A^{(i)}} \cdot N_{A} \tag{5.4.12}
\end{equation*}
$$

where

| $\mathrm{S}_{\mathrm{z} . \mathrm{g}}^{(\mathrm{p})}$ | $=$ source spectrum $(\mathrm{p} / \mathrm{s})$ in energy group $g$ for particles of type $p$ and axial zone $Z ;$ |
| :--- | :--- |
| $\mathrm{Y}_{\mathrm{i}, \mathrm{g}}^{(\mathrm{p})}$ | $=$ number of particles of type $p$ emitted per decay of nuclide $i$; with energy in group $g ;$ |
| $\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})}$ | $=$ mass $(\mathrm{g})$ of nuclide $i$ in axial zone $Z$, obtained from ORIGEN calculation; |
| $\mathrm{N}_{\mathrm{A}}$ | $=$ Avogadro's number (number atoms of nuclide $i$ per mole); ; |
| $\mathrm{A}^{(\mathrm{i})}$ | $=$ mass $(\mathrm{g})$ of 1 mole of nuclide $i ;$ |
| $\lambda_{\mathrm{i}}$ | $=$ decay constant $\left(\mathrm{s}^{-1}\right)$ for nuclide $i$, and |
| itot | $=$ total number of nuclides in burned fuel.. |

More details on the ORIGEN calculation of the source spectra can be found in the ORIGEN section of SCALE documentation.

### 5.4.3 ORIGAMI Input Description

ORIGAMI uses free-form, keyword-driven input with the SCALE Object Notation (SON) syntax also used for ORIGEN input, and is described in more detail there. The general outline of ORIGAMI input is as follows.
(a) Case Identifier Information
(b) Options Block
(c) Fuel Composition Block
(d) Power-History Block
(e) Source-Options Block
(f) Output-Print Options Block
(g) Input Data Arrays

The above input data may be entered in any order. Data blocks and parameters which are not needed, or for which default values are desired, can be omitted. Table 5.4.1 provides a template containing all of the ORIGAMI input data blocks and arrays, with example values assigned. Note that much of the information shown in the template is optional, and typically is not needed for many cases. The following subsections provide a more detailed description of the input.

Table 5.4.1. Template for ORIGAMI Input Data

### 5.4.3.1 Case and identifier information

ORIGAMI has three optional identifiers for the case. These are summarized in Table 5.4.2. The title is included as a descriptor in the printed output file. The character string prefix is added to the front of the output file names described in Section 5.4.4 and in Table 5.4.9. Finally, the integer variable asmid is an arbitrary assembly identifier used in defining mixture numbers in the SCALE standard composition output file. Equation (5.4.14) in Section 5.4.4.1 describes how the mixture ID is determined.

Table 5.4.2. Keywords for Case Identifier Information

| Keyword | Description | Default |
| ---: | :--- | :---: |
| title= | up to 50 characters describing the case title, quoted if embedded blanks | blank |
| prefix= | up to 16 characters (no embedded blanks) appended to output file names | blank |
| asmid= $=$integer used to identify mixture ID in generated SCALE standard <br> composition block [see Eq. (5.4.14)] | 1 |  |

### 5.4.3.2 Options block

The options block has the following form: options \{... keywords ...\}
Table 5.4.3 shows the Keywords for allowable parameters. An example parameter block is
options\{ stdcomp=yes decayheat=yes \}
Table 5.4.3. Keywords in options block

| Keyword | Description | Default |
| :---: | :---: | :---: |
| mtu= | Metric tons of heavy metal in the assembly | 1.0 |
| fracnf= | Total non-fuel mass in assembly, given as fraction of heavy metal mass defined by input $m t u=$. See description of input array nonfuel $=$ | none |
| nz= | Number of axial intervals. If not input, $n z$ is equal to the number of entries in the input axial power array $p z=$. Required for decay-only restarts. | Determined by code |
| nburn= | Number of substeps used in ORIGEN burn calculations | 10 |
| ndecay= | Number of substeps used in ORIGEN decay calculations | 10 |
| pitch= | Assembly pitch (cm), if $>0.0$. Only used to define XY mesh in viewing results. If this parameter is input, array $p x y=$ must also be entered. | 0.0 |
| temper= | Temperature (Kelvin) assigned to materials in standard composition file | 293.0 |
| offsetz= | Axial numbering offset; used for sequential ORIGAMI cases to uniquely identify axial zones (i.e., such as when using sequential cases to modify changing axial geometry). [integer] | 0 |
| relnorm= | Normalization of axial power shaping factors ( $p z=$ ) to be used no: axial power shape factors treated as absolute fractions (does not normalize all axial burnups to 1.00) <br> yes: axial power shape factors treated as relative modifiers of assembly specific power (i.e., power= entries in the power history block) [yes/no] | Yes |
| mcnp= | no/yes $\rightarrow$ do not /do generate an MCNP material and gamma/neutron file | Yes |
| stdcomp= | no/yes $\rightarrow$ do not /do generate a standard composition file containing burnup-credit nuclide number densities for each axial zone. | No |
| decayheat= | no/yes $\rightarrow$ do not/do produce a decay heat file containing heat sources for each axial zone. | No |
| restart= | no/yes $\rightarrow$ do not /do restart using initial composition from a previously generated ORIGEN ft71 file. | No |
| solver= | matrex/cram $\rightarrow$ use the standard ("MATREX") solver or the Chebyshev Rational Approximation Method (CRAM) solver. | Matrex |
| small= | no/yes $\rightarrow$ keep .out file small by suppressing all spectra and concentrations output except for lumped, assembly-averaged concentrations and spectra (note: all results are still written to relevant files). | No |
| interp= | lagrange/spline $\rightarrow$ method for interpolating cross sections in ARP | Lagrange |
| output= | last/cycle/all $\rightarrow$ time steps for output print edits | Last |
| ft71= | last/cycle/all $\rightarrow$ time steps included in output ft 71 file | Last |

(*) Required input value

Additional notes on input parameters
(a) pitch= is only used for visualization of the results, and may be omitted if this is not of interest;
(b) $m t u=$ is discussed in Sect. 5.4.2.2;
(c) $n z=$ is not required except decay-only restart cases; it must equal the number of entries in the array $p z=$;
(d) nburn $=$ and ndecay $=$ are discussed in Sect. 5.4.3.3;
(e) fracnf= is discussed in Sect. 5.4.3.7, where the input array of non-fuel materials is described;
(f) relnorm $=$ is discussed in Sect. 5.4.2.4, in the definition of the assembly power distribution;
(g) stdcomp $=$, fdens $=$, and temper $=$ are discussed in Sect.5.4.4;
(h) offsetz= is an optional feature designed to allow for ORIGAMI cases to be split across multiple inputs to capture axially-dependent features (such as partial-length rods); its use is discussed in further detail in the context of output generation in Sect. 5.4.4;
(i) decayheat= is discussed in Sect. 5.4.4.3;
(j) restart $=$ is discussed in Sect. 5.4.2.3.
(k) output=, ft71=, are discussed in Sect. 5.4.3.6.

### 5.4.3.3 Fuel composition block

The purpose of the fuelcomp block is to create a set of mixtures (via the mix blocks inside) to specify the pin-wise distribution of initial isotopics. The example below, defines three mixtures (with IDs 1, 2, and 3 ); these are referenced in the compmap array for this $2 \times 2$ array of fuel pins.

```
fuelcomp{
    uox(fuel_3pct){ enrich=3.20 dens=10.42 }
    uox(fuel_4pct){ enrich=4.00 dens=10.45 }
    uox(fuel_2pct){ enrich=2.10 dens=10.43 }
    mix(1){ comps[ fuel_3pct=99.0 Gd203=1.0 ] }
    mix(2){ comps[ fuel_4pct=100] }
    mix(3){ comps[ fuel_2pct=100] }
}
compmap=[[\begin{array}{ll}{1}&{2}\end{array}]
        2 3 ]
```

The mix block defines an array of compositions by their weight \%. E.g., in the case of mix 2 and 3 , it is $100 \%$ the "fuel_4pct" and "fuel_2pct" compositions defined on the uox blocks above. In the case of mix 1, it is $99 \%$ by weight "fuel_3pct" and $1 \%$ by weight the SCALE StdComp Gd2O3 (gadolinia). Each mixture number (defined by numbered mix objects) is then referenced in the compmap array to define an individual pin composition. For $\mathrm{UO}_{x}$-based fuels, ORIGAMI automatically calculates the pin enrichment for cross-section library interpolation via ARP. (Interpolation for MOX-based fuels is not supported by ORIGAMI at this time.)

The uox keyword is an ORIGAM-specific shortcut to allow for easy specification of $\mathrm{UO}_{2}$-based fuels along with their enrichment; ORIGAMI automatically expands the uox keyword into a SCALE StdComp block with a $\mathrm{UO}_{2}$ base and explicitly-calculated uranium isotopics per Table 5.4.4. For example, the uox block "fuel_3pct" expands to the following:

```
stdcomp(fuel_3pct){
    base=uo2
    iso[92234=0.02848 92235=3.2 92236=0.01472 92238=96.7568]
}
```

For uox-based entries, the uranium isotopic distribution is calculated from the user-specified enrichment per the following formula ${ }^{4,5}$ :

Table 5.4.4. Uranium isotope dependence on X wt $\%{ }^{235} \mathrm{U}$ enrichment

| Isotope | Isotope wt\% |
| :--- | :--- |
| ${ }^{233} \mathrm{U}$ | 0.0089 X |
| ${ }^{235} \mathrm{U}$ | 1.0000 X |
| ${ }^{236} \mathrm{U}$ | 0.0046 X |
| ${ }^{238} \mathrm{U}$ | $100-1.0135 \mathrm{X}$ |

Users may also specify materials directly using SCALE mixture processor conventions; for example, the user could simply enter fuel mixture 2 directly as a StdComp as follows:

```
mix(2){
    stdcomp(fuel_4pct){ base=uo2
        iso[92234=XXX 92235=XXX 92236=XXX 92238=XXX]
    }
}
```

Or similarly:

```
stdcomp(fuel_4pct){ base=uo2
    iso[92234=XXX 92235=XXX 92236=XXX 92238=XXX]
}
mix(2){ comps[ fuel_4pct=100.0 ] }
```

The uox keyword is thus useful when a user wishes to quickly specify a $\mathrm{UO}_{2}$-based fuel; however, in cases where the user wishes to specify the isotopic fractions of each uranium isotope, the use of a StdComp object is recommended.

CAVEAT: The mixture composition system in ORIGAMI is very flexible but it should be cautioned ORIGAMI does not rigorously check that the specified composition is neutronically similar to that used to generate the ORIGEN library used in the calculation. For example, use of gadolinia burnable absorbers in the ORIGAMI input will yield incorrect results if the ORIGEN library was generated without gadolinia, due to the extreme thermal flux depression that gadolinia creates. It is therefore up to the user to verify that the libraries specified for the depletion zone are matched neutronically to the compositions specified.

### 5.4.3.4 Power history block

The data contained in the power history block is the same as in the BURNDATA block of the TRITON lattice physics depletion sequence in SCALE (see TRITON chapter, section BURNDATA block). The power-history block describes the burnup and decay of the assembly and has the following general form:

```
hist[
    cycle{ keywords for cycle-1 }
    cycle{ keywords for cycle-2 }
    ... (repeat for total number of cycles) ...
]
```

Because the cycles must be processed in order, the array syntax with "[]" is used for the "hist" block. (The block syntax "\{\}" implies no order for its contents.) The "hist" array consists of one or more "cycle" blocks, each describing the assembly irradiation and/or decay for some period of time. Each cycle is defined by (a) the assembly total specific power; (b) number of exposure days at this power; (c) the number of ORIGEN library burnup interpolations during the exposure period; and (d) number of days of decay following the exposure period. The keywords defining this information are given in Table 5.4.5.

Table 5.4.5. Keywords in hist Block(*)

| Keyword | Description | Default |
| :---: | :--- | :---: |
| power $=$ | assembly specific power (MW/MTU) for the cycle | 0.0 |
| burn $=$ | length of the cycle exposure period in days | 0.0 |
| nlib= $=$ | number of ORIGEN library burnup-interpolations during the cycle | 1 |
| down $=$ | downtime in days following the exposure | 0.0 |

(*) Keywords are repeated for each cycle.
The following is an example for the power-history block for four cycles:

ORIGAMI discretizes time intervals first by cycles (composed of a fixed power over a set burn time interval and / or decay time), where each cycle is composed of a number of substeps. The power-history block, along with values of nburn= and ndecay= from the input parameter block, define various types of nested time intervals (substeps) for the ORIGEN calculations. The entire time period for an ORIGAMI case is first of all divided into the cycles defined within the power-history block. Each cycle is divided into an exposure interval (burn=) and a decay (down=) interval. The exposure interval has a constant specific power, but it is further subdivided into a number of equally spaced burnup steps defined by nlib= in the power-history block. This parameter specifies the number of burnup-dependent ORIGEN libraries to use during the exposure interval. Cross section values for each burnup step are interpolated using the burnup at the midpoint of the step and remain constant throughout the burnup step. The burnup period associated with a single ORIGEN library, or a decay period, is called a time "step." Finally, each burnup step, as well as the entire decay step, is divided into a number of computational "substeps"-the actual time steps used in the ORIGEN solver kernel. The number of substeps in each burnup step is given by the value of nburn=, while the number of decay substeps is equal to the value ndecay=. The default number of substeps for both burnup and decay is equal to 10 . The substeps for irradiation are equally spaced but for decay follow the rule of threes, i.e. each substep increases in duration by a factor of three over the previous substep.

For the example given above, there are four cycles. The first three cycles include both exposure and decay intervals, while the last cycle is decay only. In the first cycle, the assembly-specific power is
35.6 MW/MTU, which remains constant over the 400-day exposure interval; therefore, the total burnup for the exposure period is $400 * 35.6=14240$ MWD/MTU. This exposure period is divided into six burnup steps of 66.67 days, each with a cross-section library based on the midpoint burnup of that step. Thus, ORIGEN libraries are interpolated at 1186.7, 3560.0, 5933.3, 8306.7, 10680.0, and 13053.3 MWD/MTU. Each of the six burnup steps is further subdivided into 10 computational substeps. Likewise, the decay interval of 30 days is divided into 10 computational substeps.

### 5.4.3.5 Source options block

This block defines options used in computing neutron and gamma sources. The block is only used if the input energy group boundary arrays ggrp= or ngrp= is given, which indicates that radiation decay source spectra are to be computed. The general form of this block is:

$$
\operatorname{srcopt}\{\text {... keyword-value pairs ... \}}
$$

Keywords are defined in Table 5.4.6. The following is an example of the srcopt input block:

```
srcopt{
    sublib=ac
    brem_medium=h2o
    alphan_medium=uo2
    print=yes
}
```

If "print=yes" then text files with axial neutron and gamma sources are created.
Table 5.4.6. Keywords in srcopt block

| Keyword | Description | Default |
| ---: | :--- | :---: |
| sublib= $=$lt / fp / ac / all $\rightarrow$ gamma sources from: <br> light elements / fission products / actinides / all <br> nuclides | all |  |
| brem_medium= $=$none / $\mathrm{H} 2 \mathrm{O} / \mathrm{UO} 2 / \rightarrow$ bremsstrahlung production <br> based on: <br> no bremsstrahlung / water / $\mathrm{UO}_{2}$ | uo2 |  |
| alphan_medium= $=$ | UO2 / borosilicate/ case $\rightarrow$ (alpha,n) source <br> computed for: <br> UO $/$ borosilicate glass / case-specific mixture | case |
| print $=$ | yes / no $\rightarrow$ write output text file containing sources / <br> only write sources in binary output ft71 file | no |

### 5.4.3.6 Output print-options block

This block defines the desired ORIGEN output response edits to be printed by ORIGAMI.
The following is an example input which edits response values for the mass in grams, activities in Curies, and concentrations in atoms/barn-cm, for all nuclides (isotopes) broken down by actinides or fission products as well as curies by element, totaled over all nuclide sub-libraries (sublibs).

```
print{
    nuc{ units=[grams curies atoms-per-barn-cm] sublibs=[fp ac] }
    ele{ units=[curies] total=yes }
}
```

Table 5.4.7. Keywords in print block

| Keyword | Description | Default |
| :---: | :--- | :---: |
| nuc / ele | Specify print options for output by individual nuclides / elements | N/A |
|  | moles / gram-atoms / grams / curies / becquerels / watts / $g$-watts / <br> m3_air / m3_water / weight_ppm / atoms_ppm / <br> atoms-per-barn-cm | all |
| units= | Output concentrations in units of gram-atoms (moles), grams, <br> curies, becquerels, total thermal power (alpha, beta, and gamma), <br> thermal power from gammas only, radiotoxicity / dilution factors <br> for air and water, mass fraction (in ppm), atom fraction (in ppm), <br> atoms / barn-cm, respectively. | all |
| sublibs= | le / fp /ac /all $\rightarrow$ output concentration units for light element / <br> fission product / actinide sub-libraries. | yes |
| total= | yes / no $\rightarrow$ print out total concentration for nuclides / elements for <br> each output unit type |  |

### 5.4.3.7 Input data arrays

Table 5.4.8 shows the remaining input arrays for ORIGAMI. The input values for all arrays are entered in either of the general forms (with or without "=")

```
array[ ... values ... ]
array=[ ... values ... ]
```

The array libs=, which defines the ORIGEN library files, is the only one that is strictly required for all cases. Cases that simulate 0D or 1D lumped-assembly models typically only require one entry for a single ORIGEN library (assuming uniform axial enrichment), while the simulated 3D depletion model may utilize multiple libraries if specific ORIGEN libraries are pre-generated for different pin locations (e.g., adjacent to a water hole, Gd rods, etc.). If multiple libraries are used, the array libmap= is required to identify the pin locations associated with the input libraries. The numbering of these libraries in the libmap array corresponds to the ordering of libraries in the libs= array; i.e., a " 1 " corresponds to the first library specified, " 2 " to the second, and so on. A zero-value entry in the array indicates that the location is not to be depleted (i.e., a non-fuel region, such as a water hole or guide tube).

For single array values, the array bracket syntax is not required. For example, each of the following is equivalent:

```
compmap=[1]
    compmap[1]
    compmap=1
```

Note that the assignment operator (=) is likewise optional for arrays when using the square-bracket syntax.

Unless the 0D lumped-assembly model (i.e., lumped mass with no axial power variation) is used, at least one of the arrays ( $p z, p x y$ ) describing the power variations must also be entered. The 1D axial depletion model requires that the $p z=$ array be entered, while the pin-wise depletion model additionally requires the array $p x y=$. The data in arrays $p x y=$ and $p z=$ correspond to the variables $r_{X Y}$ and $a_{z}$, respectively, described in Sect. 5.4.2.3. The axial and XY power distributions are normalized to unity inside the code, so that only the ratios of the input array values are significant. As discussed in Sect. 5.4.2.3, it is generally recommended to use the final burnup distributions rather than the relative power distributions for the values in the $p x y$ and $p z$ arrays.

The array nuccomp defines the nuclides to be included in the output compBlock file, described in more detail in Sect.5.4.4. The nuclides in the array are identified by their seven digit IZZZAAA identifier defined as ID = I * $1000000+Z$ * $1000+$ A, where Z is the atomic number; A is the mass number, and I is the isomeric state ( $\mathrm{I}=0$ for ground; $\mathrm{I}=1$ for first metastable; etc.). For example, identifiers for ${ }^{16} \mathrm{O}$ and ${ }^{242 \mathrm{~m}} \mathrm{Am}$ are 8016 and 1095242, respectively. If this array is omitted, the nuclides in Table 5.4.10 are used. This is described in more detail in Sect.5.4.4.1.

The optional array describing the non-fuel elements in the assembly contains pairs of values (element, mass), where "element" is the chemical symbol for a particular element, and "mass" is the mass of the element in kilograms per MTU. For example, the array

$$
\text { nonfuel=[ } \quad z r=520.3 \quad s n=8.4 \quad]
$$

indicates that the assembly contains 520.3 kilograms of zirconium and 8.4 kilograms of tin for each metric ton of uranium (MTU) in the assembly. Note that elemental masses are specified - the isotopic masses are computed internally by the code using natural abundances in the data library. It is also possible to normalize the total mass of non-fuel elements to a specified fraction of the MTU mass using the parameter fracnf= in the parameter block. In this case, only the relative amounts of each non-fuel element are needed for the nonfuel array. Non-fuel masses are distributed uniformly among all the fuel depletion regions.

Table 5.4.8. ORIGAMI Input Array Description.

| Array Name | Description | Default |
| ---: | :--- | :---: |
| $\left(^{*}\right)$ libs | List of ORIGEN library file names for fuel in assembly. [characters] | None |
| libmap | XY map of library identifiers associated with each pin in assembly. <br> Library identifiers correspond to the order of the ORIGEN libraries <br> entered in the libs block. [integers] | 1 |
| compmap | XY map of mixture identifiers that correspond to the mixture ID in the <br> fuelcomp block. [integers] | 1 |
| pxy | XY map of pin power shaping factors / fractional powers. Must be a <br> square array (e.g., 15×15). Defaults to lumped assembly model (no <br> individual pins). [real numbers] | 1.0 |
| pz fractional power distribution for the | Axial (Z) power shaping factors / fre <br> assembly. [real numbers] | 1.0 |

| meshz | Axial mesh boundaries (cm) for the axial relative power zones. Only <br> required to define axial mesh for viewing results; but if entered, it must <br> be consistent with axial power shape. The number of entries should be <br> one greater than number of entries in $p z=$ array. <br> [real numbers] | None |
| :---: | :--- | :---: |
| modz | Axial variation in water density (g/cc) corresponding to the axial <br> power zones. [real numbers] | 0.723 |
| nonfuel | Non-fuel materials contained in assembly. Values are entered in pairs <br> of (element-symbol=mass(kg) per mtu of HM ). If parameter fracnf is <br> input, mass of non-fuel materials is normalized to this fraction of fuel <br> mtu. <br> NOTE: Oxygen mass in UO U $_{2}$ should not be entered here (i.e., this is <br> pre-supplied by ORIGAMI). [character / real number pairs] | None |
| ggrp | Energy boundaries (eV) for defining decay gamma source spectrum. <br> [real numbers] | None |
| ngrp | Energy boundaries (eV) for defining (a,n) and spontaneous fission <br> neutron source spectrum. [real numbers] | None |
| nuccomp | List of nuclide IZZZAAAs to be included in output compBlock file. | Table 5.4.10 <br> Nuclides |

(*) indicates required input

### 5.4.4 ORIGAMI Input/Output Files

Table 5.4.9 gives the input and output files for ORIGAMI. ORIGAMI produces printed output results as well as several optional output files described in this section. In order to reduce the potentially voluminous amount of printout, by default ORIGAMI only prints the concentrations in grams for selected actinides in each axial zone of every pin, and only for the last time step (e.g., decay step) of the last cycle in the power-history block. Time-dependent results are given for all substeps in the last step (i.e, there are nburn and ndecay substeps within a burn step or decay step, respectively) In addition, the blended actinide concentrations over all pins are printed for each axial zone, and for the entire lumped assembly. Additional types of printed output can be specified in the print block. The concentrations, as well as optional neutron and gamma source spectra information, for all nuclides, in all pins and axial zones are also stored in the ORIGEN binary output file, often called an "ft71" file. The contents and format of the binary file are described in the ORIGEN documentation of the SCALE manual. The binary file information can be edited by the OPUS module in SCALE. Like the printed output, the ft71 file is written by default only for the last step of the last cycle. However, both the printed output and binary file results can be obtained at additional time steps by specifying the input variables output and ft71, respectively, in the OPTIONS input block. These input parameters can have the keywords:
ft71=last, cycle, all ; and/or, output=last, cycle, all ;
where:

$$
\begin{aligned}
& \text { last => save results only for the substeps in last step of the last cycle (default) } \\
& \text { cycle => save results for substeps in the last irradiation and decay steps in every cycle } \\
& \text { all => save results for all substeps of all irradiation and decay steps in every cycle }
\end{aligned}
$$

The output files are written in the user output directory for the calculation (i.e., the same directory where the printed output file is written - the default is the directory from where the case was submitted). File names are prefixed by an extension consisting of the input file base-name appended to an optional
character string given by the input keyword prefix= . For example, if the ORIGAMI input file is named ORIGAMICase.inp, the base-name is ORIGAMICase. Thus, if the keyword prefix= is not included in the input, the file containing the axial decay heat results is named ORIGAMICase_AxialDecayHeat. On the other hand, if the input contains the keyword prefix=CE16X16, the file is named ORIGAMICase_CE16X16_AxialDecayHeat.

In order to capture axially dependent features of an assembly (such as partial-length rods), users may elect to construct sequential ORIGAMI cases that modify the XY pin map features (e.g., library and enrichment maps) between cases. In order to allow for these types of "continuation" cases (in which the sequential case represents an adjacent axial span of the assembly), the offsetz= feature is provided, which adjusts the axial numbering for ORIGAMI outputs (such as for MCNP materials \& spectra cards, axial decay heat, etc.). The offsetz= parameter offsets the axial numbering for these output files, where the (integer) value provided corresponds to the last axial zone number calculated by ORIGAMI (default: 0). For more details on the syntax of the options block, see Sect. 5.4.3.2.

Table 5.4.9. ORIGAMI Input/Output Files

| File Name (*) | Description | Type | Format |
| :--- | :--- | :---: | :---: |
| compBlock | Mixture compositions in standard composition <br> format for input to SCALE codes such as KENO | out | text |
| MCNP_matls.inp | Nuclide identifiers and weight fractions in format <br> for MCNP material cards | out | text |
| MCNP_gamma.inp | Total gamma source intensity in MCNP source <br> format. Only output if gamma energy group <br> boundaries are entered in input array ggrp= | out | text |
| MCNP_neutron.inp | Total neutron source intensity in MCNP source <br> format. Only output if neutron energy group <br> boundaries are entered in input array ngrp= | out | text |
| AxialGammaSpec | Gamma spectrum (photons/sec) by axial zone, <br> enabled by "srcopt\{ print=yes \}". | out | text |
| AxialNeutSpec | Neutron spectrum (neutron/sec) by axial zone, <br> enabled by "srcopt\{ print=yes \}". | out | text |
| AxialDecayHeat | Decay heat source (watts) by axial zone, enabled <br> by "options\{ decayheat=yes \}" | out | text |
| assm.f71 | Output stacked ORIGEN ft71 files for each axial <br> zone | out | binary |
| assembly_restart.f71 | Input stacked ORIGEN ft71 files for each axial <br> zone | in | binary |
| .f71 | Output of stacked ORIGEN ft71 files for each <br> pin and axial zone | out | binary |
| actinideMesh.3dmap | Binary MeshView file of selected actinide <br> masses by depletion cell | out | binary |
| actinideMesh.ASCII.txt | Plaintext MeshView file of selected actinide <br> masses by depletion cell | out | text |
| fpMesh.3dmap | Binary MeshView file of selected fission product <br> masses by depletion cell | out | binary |
| fpMesh.ASCII.txt | Plaintext MeshView file of selected fission <br> product masses by depletion cell | out | text |
| burnupMesh.3dmap | Binary MeshView file of depletion node burnups | out | binary |

(*) Note that all file names are prefixed by an identifier "\$\{OUTBASENAME\}", where \$\{OUTBASENAME\} is a prefix constructed from the input file base name followed by the character string given by input keyword prefix=. For example, the input file named "my.inp" with prefix=sample would give an output prefix "my_sample"; e.g., my_sample.f71, my_sample.assm.f71, my_sample_MCNP_matls.inp, etc.

### 5.4.4.1 Generation of SCALE standard composition data file

If input parameter stdcomp=yes is specified, ORIGAMI produces a text file containing a SCALE standard composition description for each axial interval. The file is written in the form of a stdcomp block that can
be directly used as input to any SCALE module that requires a composition block. If a 1D axial depletion model is used for the assembly, the composition for each axial zone is given a unique mixture number defined for an axial node " $Z$ " as:
(1D axial model)

$$
\begin{equation*}
\operatorname{mix}=1000+(\text { asmid }-1) \times \mathrm{N}_{\mathrm{Z}}+\mathrm{Z} \tag{5.4.13}
\end{equation*}
$$

where $\mathrm{N}_{\mathrm{Z}}$ is the number of axial zones and asmid is the input identifier. For example, if there are 12 axial zones and the input for asmid is 20 , then the mixture number associated with axial zone number 1 is mix $=1229$, and the mixture for zone 12 is mix= 1240. If an assembly is represented by a 3D multiple-pin model, the mixture number is defined,
(3D model) $\quad$ mix $=1000+($ asmid -1$) \times \mathrm{N}_{\mathrm{Z}}+\mathrm{Z}+\mathrm{X} \times 100000+\mathrm{Y} \times 10000000$
where X and Y correspond to the row and column numbers of the pin.
The nuclides components of the mixtures may be specified in the input array compnuc=, or by default the mixture may consist of the nuclides given in Table 5.4.10, which are the nuclides recommended in Ref. 3 for burnup credit analysis, plus ${ }^{16} \mathrm{O}$. The temperatures of the mixtures are set by the value of parameter temper $=$, which defaults to a value of 293 Kelvin. The number densities of the nuclides in the mixtures are calculated using the following expressions:

$$
\begin{align*}
\mathrm{N}_{\mathrm{Z}}^{(\mathrm{i})} & =\rho \frac{\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})}}{\mathrm{M}_{\mathrm{Z}} \cdot 10^{6}} \cdot \frac{N_{A}}{A^{(\mathrm{i})}} \cdot 0.8814 \cdot 10^{-24}  \tag{5.4.15}\\
& =\rho \frac{\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})}}{\mathrm{M}_{\mathrm{Z}} \cdot \mathrm{~A}^{(\mathrm{i})}} \cdot 5.309 \cdot 10^{-7} \tag{5.4.16}
\end{align*}
$$

Where:

| $\mathrm{N}_{\mathrm{Z}}^{(\mathrm{i})}$ | $=$ number density of nuclide "i" in zone Z , in units of atoms of "i" per barn- $\mathrm{cm} \mathrm{of} \mathrm{UO}_{2} ;$ |
| :--- | :--- |
| $\rho$ | $=$ density of $\mathrm{UO}_{2}(\mathrm{~g} / \mathrm{cc})$, defined by the input parameter fdens= (default is $\left.10.4 \mathrm{~g} / \mathrm{cc}\right) ;$ |
| $\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})}$ | $=$ mass $(\mathrm{g})$ of nuclide i in axial zone Z , obtained from ORIGEN calculation; |
| $\mathrm{M}_{\mathrm{Z}} \cdot 10^{6}$ | $=$ mass (g) of uranium in axial zone Z , where $\mathrm{M}_{\mathrm{Z}}$ is given by Eq. (5.4.2); |
| $\mathrm{A}^{\mathrm{i})}$ | $=$ mass (g) of 1 mole of nuclide i ; |
| 0.8814 | $=$ weight fraction of uranium in $\mathrm{UO}_{2} ;$ |
| $10^{-24}$ | $=\mathrm{cm}^{3}$ per barn-cm. |

The definitions of other parameters appearing in this equation are given in Sect. 5.4.2.5. An example of the standard composition file produced by ORIGAMI is given in Sect. 5.4.6, Table 5.4 .15 (illustrated in sample problem 2)

Table 5.4.10. Default Burnup Credit Nuclides in Standard Comp File

| Nuclide | ZAID | Nuclide type |
| :---: | :---: | :---: |
| ${ }^{16} \mathrm{O}$ | 8016 | light element |
| ${ }^{234} \mathrm{U}$ | 92234 | actinide |
| ${ }^{235} \mathrm{U}$ | 92235 | actinide |
| ${ }^{236} \mathrm{U}$ | 92236 | actinide |
| ${ }^{238} \mathrm{U}$ | 92238 | actinide |

| ${ }^{152} \mathrm{Sm}$ | 62152 | fission product |
| ${ }^{151} \mathrm{Eu}$ | 63151 | fission product |
| ${ }^{153} \mathrm{Eu}$ | 63153 | fission product |
| ${ }^{155} \mathrm{Gd}$ | 64155 | fission product |

### 5.4.4.2 MCNP data files

If the input parameter mcnp=yes is set in the options block, the computed weight fractions for the materials in each axial zone also are output in a file in the format of MCNP material cards. These material cards are designed to be coupled to a corresponding MCNP assembly geometry using the same numbering convention for the depletion zones. Sect. 5.4.6 shows an example of the MCNP material information produced by ORIGAMI. The numbering convention of the MCNP materials cards works by combining the axial and pin numbers into a material card, where pins are counted sequentially by row, starting with the bottom-left row of input, counting from left to right across each row to the top-right pin (i.e., the bottom-left pin is pin \#1, etc.). The pin numbers reset with each axial zone, starting from the bottom zone, counting up from 1 . The naming convention for materials cards is thus the pin number ( 1 999) followed by the zone number (1-99); for example, pin \#15 of axial zone \#12 would be $\mathbf{m 1 5 1 2}$. Accompanying each material card is a list of ZAID numbers and final concentrations (following depletion/decay) for the cell expressed in weight fractions. The weight fractions are given as negative values in accordance with MCNP convention. The fuel density, which may be used in the MCNP cell card, is equal to the value of the input parameter fdens=.

When parameter mcnp=yes is set, ORIGAMI also produces output files containing the fuel assembly radiation source magnitude by depletion zone, to support modeling with MCNP. The gamma/neutron source term cards correspond to the total gamma or neutron intensity (particles/s) from each respective depletion region, using the same numbering convention as that for the MCNP material cards. The source magnitude is computed by summing over the MG source spectra defined in Eq. (5.4.12).

$$
\begin{equation*}
S_{\mathrm{Z}}^{(\mathrm{p})}=\sum_{\mathrm{g}} \mathrm{~S}_{\mathrm{Z}, \mathrm{~g}}^{(\mathrm{p})} \tag{5.4.17}
\end{equation*}
$$

Where:
$\mathrm{S}_{\mathrm{Z}}^{(\mathrm{p})} \quad=$ total source magnitude ( $\mathrm{p} / \mathrm{s}$ ) for particles of type $p$;
$\mathrm{S}_{\mathrm{Z}, \mathrm{g}}^{(\mathrm{p})} \quad=$ multigroup source magnitude $(\mathrm{p} / \mathrm{s})$ for energy group $g$, and particles of type $p$
More details on the ORIGEN calculation of the source terms can be found in the ORIGEN section of SCALE documentation.

### 5.4.4.3 Decay heat calculation

When input parameter decayheat=yes is specified in the input, a text file containing the decay heat source by axial zone, summed over all pins, is generated as output. The decay heat in zone $Z$ is given in watts and is computed from the expression

$$
\begin{equation*}
\mathrm{H}_{\mathrm{Z}}=\sum_{\mathrm{i}=1}^{\text {itot }} \mathrm{Q}_{\mathrm{i}} \lambda_{\mathrm{i}} \frac{\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})}}{\mathrm{A}^{(\mathrm{i})}} \cdot 1.602 \cdot 10^{-13} \cdot \mathrm{~N}_{\mathrm{A}}=9.65 \cdot 10^{10} \sum_{\mathrm{i}=1}^{\text {itot }} \mathrm{Q}_{\mathrm{i}} \lambda_{\mathrm{i}} \frac{\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})}}{\mathrm{A}^{(\mathrm{i})}} \tag{5.4.18}
\end{equation*}
$$

where
$\mathrm{Q}_{\mathrm{i}} \quad=$ decay energy in MeV for nuclide $i ;$
$\lambda_{\mathrm{i}} \quad=$ decay constant $\left(\mathrm{s}^{-1}\right)$ for nuclide $i$;
$\mathrm{M}_{\mathrm{Z}}^{(\mathrm{i})} \quad=$ mass $(\mathrm{g})$ of nuclide $i$ in axial zone $Z$, obtained from ORIGEN calculation;
$\mathrm{A}^{(\mathrm{i})} \quad=$ mass $(\mathrm{g})$ of 1 mole of nuclide $i$;
itot $\quad=$ total number of nuclides in burned fuel, and
$1.602 \times 10^{-19}=$ number of joules per MeV .

An example output decay heat file produced by ORIGAMI is shown in Sect. 5.4.6, Table 5.4.16 (from sample problem 2).

### 5.4.4.4 ORIGEN results files

The ORIGEN computation for each depletion region produces an ORIGEN binary concentrations output file, historically called an "ft71" because it was written on "Fortran tape" number 71. The file named "\$\{OUTBASENAME \}.f71" contains the concentrations for all depletion regions, stacked within a single binary file, where " $\$\{O U T B A S E N A M E\}$ " is the base of the output file name, e.g. the "my" in "my.out".

The order of stored cases on the $\mathrm{f71}$ file corresponds to the order in which ORGAMI processes individual depletion cases, starting with the bottom-left row in the user-supplied power map (pin \#1) and looping left to right, progressively up through the series of rows. This process repeats for each axial zone, starting from the bottom of the assembly and working upward (i.e., starting with pin \#1, axial zone \#1, looping through each pin on axial zone \#1, and then proceeding to pin \#1 on axial zone \#2, etc.). This convention is the same as that used for TRITON arrays.

In addition, the compositions are blended over all pins for each axial zone to obtain the axially-dependent compositions for the lumped assembly, stored in a file named "\$\{OUTBASENAME\}.assm.f71". If saved, this file may be input as a restart file, as discussed in Sect. 5.4.2.3.

### 5.4.4.5 Plotting features

ORIGAMI creates three separate mesh summaries of material inventories for individual depletion regions, useful for 3D visualization and inspection. These include maps of (1) depletion region burnups, (2) selected actinide concentrations (including isotopes of $\mathrm{U}, \mathrm{Pu}, \mathrm{A} \mathrm{m}$, and Cm ), and (3) selected fission products typically used for burnup evaluation, including isotopes of Cs, Y, Ag, Rh, Ru, Eu, Sm, Nd, Gd, and others). Additionally, ORIGAMI outputs a separate mesh tally of individual node burnups. These outputs are described in Table 5.4.9. Note: The mesh files are only created if the user specifies the (optional) input arguments for assembly pitch (pitch=) and axial zone locations (meshz array).

These output mesh-dependent maps can be visualized using the Java-based Mesh File Viewer program included with SCALE. An example MeshView visualization of one of these outputs is shown in Figure 5.4.2. MeshView is installed in " $\$\{$ SCALE $\}$ /Meshview", where " $\$\{S C A L E\}$ " is the installation directory. A script to run MeshView is located at "\$\{SCALE\}/cmds/meshview".

Figure 5.4.2. MeshView plots of total plutonium content in the 3D depletion regions (left: XZ plane; right: XY plane).

### 5.4.5 Parallel Execution on Linux Clusters

For large 3D depletion problems it is advantageous to execute the ORIGEN calculations for different depletion regions in parallel. This can be done on Linux clusters using MPI. When parallel execution mode is enabled, ORIGAMI distributes the individual depletion cases across the pin rows, columns, and axial zones across several processors; the depletion calculation is thus split across several processors. ORIGAMI then collects the inventories from each calculation node and concatenates the output.

To execute ORIGAMI in parallel mode, a parallel-enabled MPI build of SCALE must be used and ORIGAMI should be invoked with the percent (\%) prefix:

```
=%origami
<normal ORIGAMI input follows>
```

Additionally, for parallel jobs spanning multiple computational nodes (as opposed to those just using multiple processors on the same node, it is recommended to use the -T option to specify a common temporary directory (such as a network-mounted directory accessible to all nodes). This is due to the way ORIGAMI divides the problem space in parallel mode; each computational node stores its respective binary dump file of the individual pin/zone concentrations. Upon completion of execution, the master node must be able to locate these individual problem node-generated binary dump files; thus, by using a common temporary directory, ORIGAMI can correctly re-assembly the individual pinwise dumpfiles into a single consolidated "master" dump file.

The following is a typical execution command line to execute ORIGAMI in parallel.

```
scalerte -N [number of nodes] -M [machine file] -T [tmpdir]
[input_file.inp]
```

For more information on executing SCALE in parallel, see the SCALE Readme file.

### 5.4.6 Sample Problems

This section shows sample problems for each of the three types of simulated assembly models: 0D fully lumped, 2D lumped axial depletion, and 3D pinwise depletion, and also demonstrates a restart case.

### 5.4.6.1 Sample problem 1: fully lumped assembly model

The first example corresponds to a fully lumped assembly model in which the materials are depleted with a space-independent (i.e., assembly average) flux distribution. The assembly contains 0.38 MTU , and the fuel is $2.8 \mathrm{wt} \%$ enriched. The assembly also includes several non-fuel materials corresponding to cladding and other structural materials. Note that the non-fuel concentrations are specified in $\mathrm{kg} / \mathrm{MTU}$, and thus are not the actual total non-fuel masses in the 0.38 MTU assembly. The assembly is depleted for three cycles with specific powers of $40.0,38.6$, and 25.2 MW/MTU, respectively. The ORIGEN library data are interpolated for eight different burnup steps during the irradiation periods of the first two cycles, and for six burnup steps in the last cycle. Table 5.4 .11 shows the ORIGAMI input for this case, and Table 5.4.12 gives the calculated actinide concentrations at the end of the third cycle.

Table 5.4.11. Input for ORIGAMI Sample Problem 1

```

| ${ }^{242} \mathrm{Cm}$ | $2.663 \mathrm{E}+00$ |
| ${ }^{244} \mathrm{Cm}$ | $5.698 \mathrm{E}+00$ |
| TOTAL | $6.820 \mathrm{E}+01$ |

(*) Actinides with concentrations less than 0.0001 are not shown.

### 5.4.6.2 Sample problem 2: lumped axial depletion assembly model

The second example has the same lumped assembly and power history as sample problem 1, except in this case an axial power distribution is provided for eight zones, so that the fuel burnup will vary axially. Table 5.4.13 shows the ORIGAMI input for this case. Also, the options to generate standard composition and decay output files are requested.

Table 5.4.14 gives the computed actinide concentrations in grams for the first four of the eight axial zones. Since the input axial power distribution is symmetrical about the assembly midplane, the last four zones have identical concentrations as the first four. The last column in the table shows actinide masses for the entire assembly.

Table 5.4.15 is a listing of the contents of the compBlock file, which contains standard composition input for the eight axial zones in the assembly at the end of cycle 3. A complete description of the SCALE standard composition input format is given in the MIPLIB chapter. The first entry on each line in Table 5.4.15 corresponds to the SCALE nuclide identifier. Only the default burnup credit analysis are included. The second entry is the mixture number associated with a particular axial zone. The mixture number for an axial zone is obtained using Eq. (5.4.14). The third entry is always zero in this file, and the fourth entry corresponds to the number density in atoms per barn-cm. The next entry on the line is the temperature, which has the default value of 293.0 since the input parameter temper $=$ was not specified. The final entry is an "end" statement. The information in this file can be used as the read comp input block for any SCALE module.

Table 5.4.16 shows a listing of the file AxialDecayHeat, which contains the heat source at the end of the third cycle. The entries in the file correspond to the decay power in watts for the eight axial zones, which are computed using Eq. (5.4.18).

### 5.4.6.3 Sample problem 3: restart decay calculation for lumped axial depletion assembly model

The third example shows a restart decay-only calculation, using the ORIGEN ft71 binary file obtained from sample problem 2. This case calculates the composition of the burned fuel produced in sample problem 2 after 100,000 additional days of decay. The input this problem is given in Table 5.4.17. Because the input parameter restart=yes is specified, the initial composition of the assembly is obtained
from a file named "assembly_restart.f71". The shell input that precedes the ORIGAMI input in Table 5.4.17 copies the output ft71 file produced in sample problem 2, which was named "assembly_dump.f71", into a file named "assembly_restart.f71" in the temporary directory for SCALE calculations. The restart file contains the complete inventory of nuclide compositions for eight axial zones. Because this restart case is decay only (i.e., power= value is not given in the power-history block), it is necessary to provide the input parameter $n z=8$ because this value is used to determine how many axial zones were used in the previous burnup calculations.

Table 5.4.18 shows the actinide composition of the first four axial of the (symmetrical) eight zones after 100,000 days of decay. The initial masses of these nuclides before decay are the values given in Table 5.4.15. The last column in Table 5.4.18 shows actinide masses for the entire assembly after the decay period.

### 5.4.6.4 Sample problem 4: Simplified 3D multi-pin model

The fourth example is a simulation of a simplified 3D depletion model. The ORIGAMI 3D model normally includes all fuel pins within the assembly, such as a $14 \times 14$ array. However to keep this example case simple and the execution time low, only a $2 \times 2$ array of four individual pins is considered for illustrative purposes. An axial fractional power distribution is also specified for two axial zones. Therefore the total number of depletion regions will be eight - two axial for each of the four pins. Two different ORIGEN libraries are used to obtain cross sections for the four pins. This is done whenever fuel pins in different locations in the assembly have significantly different neutron spectra, such as if some pins are adjacent to a control rod. In this sample problem, ORIGEN libraries for two different types of assembly designs CE (Combustion Engineering) $14 \times 14$ and $16 \times 16$ assembly designs, respectively are used to demonstrate the use of pin-dependent libraries, although in reality the ORIGEN libraries normally would be pre-generated for different pin locations within a single type of assembly configuration. The values specified in libmap = indicate which library is to be used for each pin location. Table 5.4 .19 shows the input for this sample problem.

Table 5.4.19. Input for ORIGAMI Sample Problem 4

```
=origami
    title= 'multi-pin; multi-library pin-deplete model'
    prefix= origam4

        cycle{ power=39.78 burn=284.0 nlib=2 down=54.0 }
    ]
end
```

Table 5.4.20 shows selected actinide compositions for the first row of two pins, that is, locations $(1,1)$ and $(1,2)$, for each of the two axial zones. The blended compositions over all fuel pins, for the two axial zones, are given in Table 5.4.21. The output decay heat file for the assembly is shown in Table 5.4.22, as a function of axial zone, summed over all pins. Note that this file has the prefix "sample4_" appended to the standard file name, since prefix=sample4 is specified in the input.

### 5.4.6.5 Sample problem 5: PWR 3D assembly model

This sample problem shows the input for a simulated full 3D pressurized water reactor (PWR) assemblydepletion model, which corresponds to a $16 \times 16$ lattice with 26 axial zones. Table 5.4 .23 shows the ORIGAMI input for this case. The arrays $p x y=$ and $p z=$ define the $3 \mathrm{D} X \mathrm{XY}$ fractional power distribution. Four different pre-processed ORIGEN libraries are used to describe the pin-averaged ORIGEN cross-sections for the assembly. The array libmap = assigns these libraries to the appropriate pin locations. It can be seen that the libmap= array contains values of zero at 21 locations. These correspond to non-depleting (i.e., zero power) locations. The input includes the information (parameter pitch=, and array $z=$ ) necessary to generate 3D mesh summary maps for subsequent visualization. In this case, the axial mesh is not uniform. Since a total of 6110 ORIGEN cases are executed for the depletable pins, this ORIGAMI calculation was performed in parallel using MPI. Figure 5.4 .3 shows a plot of the axial burnup distribution, summed over all pins.

Table 5.4.23. Input for ORIGAMI Sample Problem 5

$\mathrm{pxy}=\left[\begin{array}{llllllll}{[ } & & & & & & & 0.99 \\ 0.99 & 0.98 & 0.98 & 0.99 & 0.99 & 0.99 & 0.99 & 0.99 \\ 0.99 & 0.99 & 0.99 & 0.99 & 0.98 & 0.98 & 0.97 & 0.98 \\ 0.99 & 0.99 & 0.99 & 1.00 & 1.01 & 1.02 & 1.00 & 1.00 \\ 1.00 & 1.01 & 1.02 & 1.00 & 0.99 & 0.98 & 0.98 & 0.98 \\ 1.00 & 1.00 & 1.01 & 1.03 & 1.03 & 0.00 & 1.03 & 1.01 \\ 1.03 & 1.04 & 0.00 & 1.03 & 1.02 & 1.00 & 0.99 & 0.98 \\ 1.01 & 1.01 & 1.03 & 0.00 & 1.04 & 1.04 & 1.02 & 0.00 \\ 1.03 & 1.04 & 1.04 & 1.04 & 0.00 & 1.02 & 1.00 & 0.99 \\ 1.01 & 1.02 & 1.02 & 1.05 & 0.73 & 1.04 & 1.02 & 1.02 \\ 1.03 & 1.03 & 1.04 & 0.72 & 1.04 & 1.04 & 1.01 & 1.00 \\ 1.02 & 1.04 & 0.00 & 1.05 & 1.04 & 0.00 & 1.03 & 1.01 \\ 1.01 & 1.03 & 0.00 & 1.03 & 1.04 & 0.00 & 1.02 & 1.00 \\ 1.02 & 1.03 & 1.02 & 1.05 & 1.04 & 1.04 & 1.02 & 1.01 \\ 1.01 & 1.02 & 1.03 & 1.02 & 1.02 & 1.03 & 1.01 & 1.00 \\ 1.01 & 1.02 & 1.04 & 0.00 & 1.04 & 1.02 & 1.02 & 1.03 \\ 1.01 & 1.01 & 1.01 & 1.02 & 1.03 & 1.02 & 1.00 & 1.00 \\ 1.00 & 1.01 & 1.02 & 1.03 & 1.02 & 1.02 & 1.03 & 0.00 \\ 1.02 & 1.01 & 1.01 & 1.03 & 0.00 & 1.02 & 0.99 & 0.98 \\ 1.00 & 1.01 & 1.03 & 1.02 & 1.02 & 1.03 & 1.03 & 1.03 \\ 1.01 & 1.01 & 1.03 & 1.02 & 1.03 & 1.03 & 1.00 & 0.99 \\ 1.01 & 1.02 & 0.00 & 1.04 & 1.03 & 0.00 & 1.03 & 1.01 \\ 1.01 & 1.02 & 0.00 & 1.03 & 1.03 & 0.00 & 1.01 & 0.98 \\ 1.00 & 1.01 & 1.04 & 1.04 & 0.72 & 1.04 & 1.03 & 1.03 \\ 1.01 & 1.01 & 1.02 & 0.71 & 1.03 & 1.02 & 0.99 & 0.98 \\ 1.00 & 1.00 & 1.02 & 0.00 & 1.04 & 1.04 & 1.04 & 0.00 \\ 1.02 & 1.01 & 1.03 & 1.03 & 0.00 & 1.01 & 0.98 & 0.97 \\ 0.99 & 0.99 & 1.01 & 1.03 & 1.04 & 0.00 & 1.04 & 1.03 \\ \hline\end{array}\right.$

## 5.A SCALE/ORIGEN LIBRARY GENERATOR (SLIG)

## B. R. Betzler

#### Abstract

This Python script (slig.py) semi-automates the process of generating sets of cross-section libraries for ORIGEN calculations for spent fuel depletion, decay, and source term analysis. SLIG performs several tasks: 1. reads standard-format template files, obtaining information (e.g, enrichments, burnups, moderator densities, etc.) from the file header; 2. generates a set of input files according to this header information; 3. builds a directory tree to house these input files; 4. writes the addition to the arpdata.txt file; 5. moves the final libraries to a new directory; and 6. reads the burnup list for each set of libraries and writes them in the addition to the arpdata.txt file.

This manual is divided into five main sections based on the desired application: (5.A.1) for running SCALE on a local machine or a computing cluster without a queue system, see Quick Start Directions; (5.A.2) for running SCALE on a cluster with a queue system, see Advanced Options; (5.A.3) for editing and writing template files, see Template File Rules and Examples; (5.A.4) for issues running SLIG, see Troubleshooting; and (5.A.5) for making changes to the code, see Code Information.

## 5.A. 1 Quick Start Directions

The SLIG package is located in the SCALE source directory in ./packages/etc/slig/. Because it is necessary to run SCALE to generate the appropriate cross-section libraries, SLIG runs in a disjointed, three-step process:

1. Copy the contents of the ./slig/src/ directory into ./slig/testing/. Move to the ./slig/testing/ directory and use./slig.py -g to perform tasks i through iv. If SLIG returns an error, follow the directions in the error message (see §5.A.4). After a successful run, three new items will appear in the current directory: runSpace/ - the directory tree containing the input files, arpLibList.txt - a list of the locations of the libraries in the directory tree, and addToArpData.txt - additional lines for the arpdata.txt file.
2. Run SCALE with each input within the directory tree (runSpace/). Each input is located within the directory tree in the location ./runSpace/templateName/inputID/, where templateName is the prefix of the template file (i.e., templateName_template.inp) and inputID is a string identifying the enrichment (eNN), moderator density ( wMM , if applicable), and plutonium vector (VPP, if applicable) for the input.
3. After all SCALE calculations are complete, use ./slig.py -f to perform task vand vi. SLIG will identify any missing libraries. After a successful run, two changes will be made in the current directory:
newLibraries/ - this directory containing the new libraries will appear, and addToArpData. txt - the burnup lists will be written on the this file.

The final result is an addition to the arpdata.txt file (addToArpData.txt) and a directory containing all generated libraries (newLibraries/). Do not delete any files associated with slig.py unless it directs you to do so. The following options are available to the user (see §5.A. 2 for more options):
-p PATH or -path=PATH
This specifies the location of the template files. SLIG will search PATH and all its subdirectories for template files. The default path is the current directory.
-x XSLIB or -xsections=XSLIB
This specifies the cross section library used in all calculations. The default is ' $v 7-252$ '.

## 5.A. 2 Advanced Options

The following are more advanced options available to the user:

```
-e EXT or -extension=EXT
```

This specifies the file extension that identifies a template file. By default, SLIG searches for files ending in '_template.inp').
-a or -add

This flag is used with the -g option (./slig.py -ga ) to add input files to the current directory tree (runSpace/). It also adds library information to addToArpData.txt and adds the location of the libraries in the directory tree to arpLibList.txt.
This flag is used with the -f option (./slig.py -fa) to add newly generated libraries to the current library directory (newLibraries/).
-d or -document
This flag turns on documentation routines that automatically generate a $\mathrm{L}^{\mathrm{A}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$ file (libraryInformation.tex) with data about each template file using information on the file header. This also generates a .pdf file (libraryInformation.pdf) using pdflatex (required for this to function properly). Additionally, any figures referenced within the templates must be located within the current directory or any of its subdirectories.
-s or -submit
This flag turns on routines that generate a PBS submit script for each input file for running on clusters with a queue system. It also generates a shell script to submit these jobs (with qsub). The PBS submit script template (run1proc.pbs) must be placed in the current directory. The first two steps of the three-step process for running SLIG (see §5.A.1) change:

1. Use ./slig.py -gs to perform tasks i through iv. After a successful run, four new items will appear in the current directory:
runSpace/ - the directory tree containing the input files, arpLibList.txt - a list of the locations of the libraries in the directory tree, addToArpData. txt - additional lines for the arpdata.txt file, and submitSLIGjobs - a shell script for submitting jobs to the queue.
2. Run the shell script (. /submitSLIGjobs) to submit jobs to the queue. Note that this may submit a very large number of jobs to the queue.
When using ./slig.py -ga, SLIG will check for documentation and submit scripts and will proceed with the same settings that were used for the initial run of SLIG. For example, if the user initially runs ./slig.py -gds to generate documentation and submit scripts then later uses ./slig.py -ga, SLIG will proceed with adding documentation for the additional templates and generating submit scripts. When SLIG generates additional submit scripts, a separate numbered file is generated for each new template (e.g., submitSLIGjobs1).

## 5.A. 3 Template File Rules and Examples

Example templates are provided with the SCALE distribution. For creating new templates, it is best to use these templates as starter files and make incremental changes as necessary for the new
application. The header at the top of each template file contains the information that will be used to generate input files and documentation. Each line of this header must start with an apostrophe; each line is a comment line according to the SCALE standard input. There are two main sections in this header:

1. The template header (see Figure 5.A. 1 and Figure 5.A.2). This header has a parameter list and an option list:
(a) The parameter list identifies the strings within the template file that SLIG will replace as it generates input files. These parameters are found throughout the template file; SLIG will replace these with values as it generates each input files. SLIG identifies the parameter list starting from the first line containing the 'parameter' string and each line thereafter that is indented more than five blank spaces (not including the apostrophe). The following is a list of rules for entering parameters:

- Each parameter is entered on a separate line in the form "parameter description".
- Each parameter must be a unique string of characters.
- Each parameter is a single string without spaces.
- SLIG uses the "description" to characterize the parameter. If these descriptions are changed, SLIG may not be able to properly characterize each parameter. Thus, it is suggested that the descriptions in the following list are not changed.
- There is some flexibility in changing the parameter strings.

```
template to generate libraries for ORIGEN-S
parameters are: u235wt% - wt% U235

    dancoff2 - 0.3103, 0.2316, 0.1823, 0.1484,
                                0.1237
    spec. power - 25.0
    burnups - 0, 1, 2, 3, 4.5, 6, 7.5, 9,
                                10.5, 12, 13.5, 15, 16.5, 18,
                                19.5, 21, 24, 27, 30, 33, 36,
                                39, 42, 45, 48, 51, 54, 57, 60,
                                63, 66, 69, 72
    pin_zone - 11, 20, 16, 12
    pin_gad -4
    avg_pin_dens. - 10.4
```

Figure 5.A.2. A typical BWR MOX template header.

The following is a list of some of the parameters available to the user for working with most PWR and BWR lattices:

```
u235wt% - wt% U235
u234wt% - wt% U234
u236wt% - wt% U236
u238wt% - wt% U238
ddd - coolant density (g/cc)
dancoff1 - dancoff factor 1
dancoff2 - dancoff factor 2
namelibrary - name of generated ORIGEN library
specpow - average specific power
```

```
daystoburn - depletion interval in days
```

For mixed oxide (MOX) PWR and BWR assemblies, there is a different set of parameters available to the user. SLIG will recognize a file as a MOX template by searching for the Pu-239 parameter. SLIG automatically generates a MOX zoning pattern (see Figure 3) for BWR and PWR lattices.

```
IcontentPu - wt% plutonium: inner
```

IcontentU - wt\% uranium: inner
IEcontentPu - wt\% plutonium: inside edge
IEcontentU - wt\% uranium: inside edge
EcontentPu - wt\% plutonium: edge
EcontentU - wt\% uranium: edge
CcontentPu - wt\% plutonium: corner
CcontentU - wt\% uranium: corner
pu238wt\% - wt\% Pu238
pu239wt\% - wt\% Pu239
pu240wt\% - wt\% Pu240
pu241wt\% - wt\% Pu241
pu242wt\% - wt\% Pu242
densityAm - americium density (g/cc)
ddd - coolant density (g/cc)
dancoff1 - dancoff factor 1
dancoff2 - dancoff factor 2
namelibrary - name of generated ORIGEN library
specpow - average specific power
daystoburn - depletion interval in days

Figure 5.A.3. MOX zoning layout for a Westinghouse $14 \times 14$ PWR assembly showing the corner (green), edge (salmon), inside edge (magenta), and inner (red) pin zones.
(b) The option list identifies the quantities or values that SLIG uses to determine the values that will replace the parameters in each input file. SLIG identifies the option list starting from the first line containing the 'option' string and each line thereafter that is indented more than five blank spaces (not including the apostrophe). The following is a list of rules for entering options:

- Each option is entered on a separate line in the form "option - values".
- SLIG uses the "option" to recognize what to do with the values. If this is changed, SLIG may not be able to properly characterize each option. Thus, it is suggested that the options (to the left of the dash) in the following list are not changed.
- For options with multiple values, each value must be separated with a comma.
- For values to continue onto the next line, the last value in a line must end with a comma and the next line must be indented and must begin with the next value.
- The values may be changed.

The following is a list of the options available to the user for working with most PWR and BWR lattices:

```
name - abb_
enrichment - 0.5, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0
cool. density - 0.1, 0.3, 0.5, 0.7, 0.9(ormod. density
    - 1.65)
```

$$
\begin{aligned}
& \text { dancoff1 - 0.4686, 0.3429, 0.2651, 0.2122, } 0.1742 \\
& \text { dancoff2 - 0.3103, 0.2316, 0.1823, 0.1484, 0.1237 } \\
& \text { spec. power - } 25.0 \\
& \text { burnups - 0, 1, 2, 3, 4.5, 6, 7.5, 9, } \\
& \text { 10.5, 12, 13.5, 15, 16.5, 18, } \\
& \text { 19.5, 21, 24, 27, 30, 33, 36, } \\
& \text { 39, 42, 45, 48, 51, 54, 57, 60, } \\
& \text { 63, 66, 69, } 72
\end{aligned}
$$

For mixed oxide (MOX) PWR and BWR assemblies, there is a different set of options available to the user. SLIG automatically generates the MOX zoning pattern according to the values of "pin_zone", "pin_gad", and "avg_pin_dens.".

pin_zone - 11, 20, 16, 12
pin_gad - 4
avg_pin_dens. - 10.4
```

The following is an explanation of each option:

## name

This is the prefix for the name of the final generated libraries. It should be unique to the template (i.e., other templates should have a different name).

## enrichment

This is a list of the ${ }^{235} \mathrm{U}$ enrichments [\%] for which SLIG will create separate inputs.
cool. density or mod. density

This is a list of the coolant or moderator densities $\left[\mathrm{g} / \mathrm{cm}^{3}\right]$ for which SLIG will create separate inputs.
dancoffN
This is a list of dancoff factors that correspond to pin $N$. The length of this list must match the length of the coolant/moderator density list (the dancoff factor varies significantly with this density).
spec. power
This is the specific power [MW/MTU] of the assembly.

## burnups

This is a list of cumulative burnup steps [GWd/MTU] that will be used to create the depletion steps. If a small step is not included, SLIG will print a warning and automatically insert one at the beginning of the calculation (for Xe equilibrium).
pu content
This is a MOX-specific parameter that is a list of the average content of plutonium [\%] in the assembly for which SLIG will create separate inputs. These quantities are calculated as a percentage of the total heavy metal loading in the assembly.
pu vector
This is a MOX-specific parameter that is a list of the enrichments of ${ }^{239} \mathrm{Pu}$ [\%] for which SLIG will create separate inputs. These quantities are calculated as a percentage of the total plutonium in the assembly and are used to calculate the entire plutonium vector ${ }^{1}$.
pin_zone
This is a MOX-specific parameter that lists of the number of pins in the inner, inside edge, edge, and corner zones (see Figure 5.A.3). This varies for each assembly.
pin_gad
This is a MOX-specific parameter that specifies the number of Gd-bearing pins in the assembly. SLIG uses this quantity to calculate ensure that the specified Pu content of the assembly is correctly represented. ${ }^{2}$
avg_pin_dens.
This is a MOX-specific parameter that specifies the average density $\left[\mathrm{g} / \mathrm{cm}^{3}\right]$ of the pins in the assembly. SLIG uses this quantity to calculate ensure that the specified Pu content of the assembly is correctly represented.
2. The documentation header (see Figure 5.A.4). The documentation header has two purposes. First, it is used to track information about the template (e.g., author, date created, and methodology) and the source documents that contributed to the template's creation. This simplifies updating input files for new versions of SCALE. Second, SLIG uses this
header information to generate documentation files. SLIG identifies the documentation header starting from the first line containing 'Documentation’ to the line starting with an apostrophe followed by a space and five dashes (' -----).

        Specific power from Reference 4.
    figure{mox_abb8x8-1.pdf: BWR ABB 8x8-1 fuel assembly.}
```

Figure 5.A.4. A typical BWR MOX documentation header.

The documentation header has a free form-style entry, where sections are specified by "[Section Name]" and the text for each section follows afterward. Figures are referenced as "figure\{figureName.pdf: Figure caption.\}". Any reference to the figure within the header must be in $\mathrm{L}^{\mathrm{A}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$-like form; for this, the figure is labeled as "fi:figureName". The section name keywords "[Data Range]", "[Libraries]", and "[Power ]" are reserved to be auto-populated by SLIG according to information provided within the options list. All information within this header is transferred to the documentation file.
The parameters in the file headers are located within the template file in the appropriate locations. See the example templates for the proper usage. The burndata card in the input file should only be three lines:

```
read burndata
    power=specpow burn=daystoburn down=0 end
end burndata
```

because it will be populated by the burnup points listed in the file header. There should also be a shell command at the end of the input file to save the cross-section library:
=shell
cp ft33f001.cmbined \$RTNDIR/namelibrary

```
end
```

## 5.A. 4 Troubleshooting

If at any time an error occurs, SLIG will exit after printing the reason for the error and offer a possible solution. Following these instructions should resolve most issues with SLIG. The following is a list of factors to consider when having trouble running SLIG.

- SLIG uses the module argparse.py (see https://docs.python.org/3/library/argparse.html) to handle command line arguments; SLIG will crash if it does not have access to it. For versions of Python that do not inherently support this module, download the argparse. py file and include it in the directory with slig.py.
- If SLIG is crashing, there may be an issue with the version of Python. SLIG was developed to be functional with Python 2.7.6.
- After running ./slig.py -g , the addToArpData.txt file will have dummy placeholders instead of the burnup lists. These placeholders are replaced with the burnup lists that are read off of the SCALE output files. The burnup lists in the documentation file are the burnup lists specified in the template files.

## 5.A. 5 Code Information

SLIG consists of a main, one SCALE-specific class (manageTemplate), and three generic classes (messenger, manageDirectory, and manageFile):

- main reads and validates arguments, and contains a loop to make inputs and collect libraries
- manageTemplate manages templates (reads/sorts options, calculates concentrations)
- messenger manages all prints to the screen
- manageDirectory manages external directories (searching, making, etc.)
- manageFile manages external files (reading, writing, searching, copying, etc.)

SLIG calls a separate Python script (collectinfov04.py) to perform documentation functions. This script uses a template (basedoc.v04.tex) to generate the documentation file.

## 5.B UTILITY PROGRAMS

I. C. Gauld, S. M. Bowman, and W. A. Wieselquist

#### Abstract

There are three utility programs that may be of interest to ORIGEN users: PRISM, ARPLIB, and XSECLIST. The traditional use of the PRISM module has been to produce the set of TRITON input files necessary to compile an ORIGEN reactor library, e.g. with varied enrichment and moderator density. For the most part, this capability has been replaced by the SLIG capability described in Appendix 5.A. The ARPLIB utility's main purpose is to remove burnup points from existing ORIGEN libraries, e.g. to reduce the size on disk. The final utility, XSECLIST, provides a simple way to print the burnupdependent cross sections contained in the ORIGEN library.

## 5.B. 1 PRISM

PRISM is a utility that reads a single input template file containing generic parameter flags and replaces them with specific values designated by the user to generate any number of files containing desired combinations of specific parameter values. PRISM provides a procedure to convert a generic input file for a particular fuel assembly design into a large number of input files containing combinations of specific fuel enrichment and moderator densities and/or other parameters for generating basic cross-section libraries. The program was designed in a general manner so PRISM can be used to generate multiple files from any generic file.

The input description for PRISM is presented in Table 5.B.1. The input format is free form. The user input includes the name of the template file to be read; the pattern for the name of the output files to be generated, using the generic parameter flags; the number of generic parameter flags; the number of files to be generated; each generic parameter flag and the specific values to be substituted in each output file.

The template file contains generic parameter flags. PRISM creates copies of the template file and substitutes specific values for the generic flags. Note that the character length of each specific value must be the same as that of the associated generic flag.

An example using PRISM to generate input files for six fuel enrichments is presented in and Figure 5.B.2. In this example a TRITON input file for a Westinghouse $17 \times 17$ fuel assembly (Figure 5.B.2) is processed by PRISM using the input file for PRISM listed in Figure 5.B.1. The case generates 6 specific input files from the template file.

Table 5.B.1. PRISM input description

| Line No. | Parameter | Description | Comments |
| :---: | :---: | :---: | :---: |
| 1 | TEMPLATE | Template file name | 80 characters maximum |
| 2 | OUT_TEMPLATE | Pattern for output file names | 80 characters maximum <br> Must contain enough generic parameter names to create unique filename for each output file |
| 3 | NUMPARMS | Number of generic parameter types |  |
|  | NUMFILES | Number of output files to be generated |  |
|  | NOTE: Repeat the following data for each generic parameter type (i.e., a total of NUMPARMS times). |  |  |
| 4 | PARAM_NAME | Generic parameter name as it appears in template file | 80 characters maximum |
| $5^{a}$ | PARAMETERS | Specific values of generic parameter for each output file | NUMFILES entries required. Length of value must be same as length of PARAM_NAME |

## 5.B.2 ARPLIB

ARPLIB is a utility program designed to read a burnup-dependent binary ORIGEN-ARP cross-section library and copy the cross-section data from only the desired burnup positions to create a new ORIGENARP cross-section library. The default behavior of ARPLIB is to read a library with 21 burnupdependent cross-section sets and reduce it to a 10-burnup-step cross-section library. By default, the ten burnup positions in the library are 1, 2, 3, 4, 5, 6, 7, 12, 17, and 21 (see Table 5.4.A.2). However, any position in the original library may be omitted or retained.

The input for ARPLIB is described in Table 5.B.2. The input is free format. The sign (+/-) of the first input parameter depends upon whether the user wants to select the ten default burnup positions from the multiburnup library, or specify different positions. If the default positions are desired, the first parameter is the total number of multiburnup library files to be converted (NUMLIBS). If the user wants to override the defaults, the NUMLIBS parameter should be any negative integer. If a negative integer is used, it should be followed by the number of burnup positions in each multiburnup library (NL), flags for each burnup position ( $\mathrm{IN}(\mathrm{I}), \mathrm{I}=1, \mathrm{NL}$ ), and the total number of multiburnup libraries to be converted (NUMLIBS). The final portion of the input file in all cases is the filename of each library, followed by the filename of the reduced cross-section library to be created from it.

An example of the input to ARPLIB is given in Figure 5.B.3. Note that the first burnup position is always saved, regardless of the input value for $\operatorname{IN}(1)$. The cross sections in the first burnup position are always assumed to be the fresh fuel cross sections.

Table 5.B.2. ARPLIB input description

| Parameter | Description | Comments |
| :---: | :---: | :---: |
| NUMLIBS | Number of multi-burnup library files ( $>0$ ) or flag to read following optional data ( $<0$ ) | NUMLIBS $<0$ if number of burnups and/or burnup positions to keep differ from default ${ }^{a}$ |
|  | NOTE: The following data are read only if NUMLIBS $<\mathbf{0}$. |  |
| NL | Number of burnup positions on each multiburnup library | Input if NUMLIBS $<0$ Default $=21$. |
| IN | Flag for each burnup position to keep or remove cross sections ${ }^{a}$ | Input if NUMLIBS $<0$ <br> NL entries required <br> = 0 Remove cross sections <br> > 0 Keep cross sections |
| NUMLIBS | Number of multiburnup library files | Input if NUMLIBS <0 |
|  | NOTE: End of optional input for NUMLIBS <0. |  |
|  | NOTE: The following entries are entered in pairs NUMLIB times. |  |
| FILENAME | Input library filename | 80 characters maximum |
| FILENAME2 | Output library filename | 80 characters maximum |
| ${ }^{a}$ Default is to keep cross sections from the following ten burnup positions of a 21-burnup cross-section library: $1,2,3,4,5,6,7,12,17,21$. The first burnup position (i.e., fresh fuel) is always kept, regardless of user input. |  |  |

## 5.B.3 XSECLIST

The XSECLIST program is intended to provide an interpreted listing of any ORIGEN-ARP cross-section library. This utility program allows users to list the absorption and/or fission cross sections of any or all nuclides in the library as a function of burnup. The absorption cross sections are given for light elements, actinides, and fission products. Some of the light-element isotopes in the library may appear also as fission products; therefore, some isotopes may be listed twice. Fission cross sections may be listed for any or all actinides for which nonzero values of the cross sections exist. ORIGEN-S cross sections are typically normalized to thermal flux, rather than the total flux.

The nuclide ID numbers used in the library listings have the form IZ*10000+IA*10+IS,
where
IZ = the atomic number;
IA = the atomic weight;
IS = 0, for ground state;
IS = 1 , for metastable state.
The XSECLIST input is described in Table 5.B.3. The input is free format. The user specifies the library filename, the total number of burnup positions in the library, and the burnup values ( $\mathrm{GWd} / \mathrm{MTU}$ ) corresponding to each burnup position. The user then indicates whether the cross-section data listings are for absorption, fission, or both; and whether the listings are for all nuclides or only certain specified ones.

An example input file for XSECLIST is shown in Figure 5.B.4. This example contains two cases. The first case lists both absorption and fission cross sections for ${ }^{240} \mathrm{Pu}$ in the ORIGEN-ARP $5 \mathrm{wt} \%$ enriched PWR $14 \times 14$ basic cross-section library. The output listing for this case is displayed in Figure 5.B.5. These are microscopic cross sections listed in units of barns. The second case lists the fission cross sections for all nuclides in the ORIGEN-ARP $1.5 \mathrm{wt} \%$ enriched PWR $14 \times 14$ basic cross-section library. The output from this case is not presented here because of its size.

### 6.0. SENSITIVITY AND UNCERTAINTY ANALYSIS

Introduction by B. T. Rearden

SCALE provides a suite of computational tools for sensitivity and uncertainty analysis to (1) identify important processes in safety analysis and design, (2) provide a quantifiable basis for neutronics validation for criticality safety and reactor physics analysis based on similarity assessment, and (3) quantify the effects of uncertainties in nuclear data and physical parameters for safety analysis. ${ }^{1,2}$

## Sensitivity Analysis and Uncertainty Quantification

Sensitivity analysis provides a unique insight into system performance in that the predicted response of the system to a change in some input process is quantified. Important processes can be identified as those that cause the largest changes in the response per unit change in the input. In neutron transport numerical simulations, calculating important responses such as $k_{\text {eff, }}$, reaction rates, and reactivity coefficients requires many input parameters, including material compositions, system geometry, temperatures, and neutron cross section data. Because of the complexity of nuclear data and its evaluation process, the response of neutron transport models to the cross section data can provide valuable information to analysts. The SCALE sensitivity and uncertainty ( $\mathrm{S} / \mathrm{U}$ ) analysis sequences-known as the Tools for Sensitivity and Uncertainty Analysis Methodology Implementation (TSUNAMI)-quantify the predicted change in $k_{e f f}$, reaction rates, or reactivity differences due to changes in the energy-dependent, nuclide-reaction-specific cross section data, whether continuous-energy or multigroup.
Uncertainty quantification is useful for identifying potential sources of computational biases and highlighting parameters important to code validation. When applying uncertainties in the neutron cross section data, the sensitivity of the system to the cross section data can be applied to propagate the uncertainties in the cross section data to an uncertainty in the system response. Additionally, SCALE provides the ability to stochastically sample uncertainties in nuclear data or any other model input parameter (e.g., dimensions, densities, temperatures) and propagate these input uncertainties to uncertainties not only as traditional TSUNAMI responses of $k_{\text {eff, }}$, reaction rates, and reactivity, but also in any general output quantity such as burnup isotopics, dose rates, etc. Additionally, where the same input quantities are used in multiple models, the sampling techniques can be applied to quantify the correlation in uncertainties of multiple systems due to the use of the same uncertain parameters across these systems.

## Validation of Codes and Data

Modern neutron transport codes such as the KENO Monte Carlo codes in the SCALE code system can predict $k_{\text {eff }}$ with a high degree of precision. Still, computational biases of one percent or more are often found when using these codes to model critical benchmark experiments. The primary source of this computational bias is believed to be errors in the cross section data as bounded by their uncertainties. These errors can be tabulated in cross section covariance data. To predict or bound the computational bias for a design system of interest, the American National Standards for Nuclear Criticality Safety in Operations with Fissionable Material Outside Reactors (ANSI/ANS-8.1-1998) ${ }^{3}$ and the American National Standard for Validation of Neutron Transport Methods for Nuclear Criticality Safety Calculations (ANSI/ANS-8.24-2007) ${ }^{4}$ allow calculations to be used to determine subcritical limits for the design of fissionable material systems. The standards require validation of the analytical methods and data used in nuclear criticality safety calculations to quantify any computational bias and the uncertainty in the bias. The validation procedure must be conducted through comparison of computed results with experimental data, and the design system for which the subcritical limit is established must fall within the area of applicability of the experiments chosen for validation. The ANS-8.1 standard defines the area(s) of applicability as "the limiting ranges of material compositions, geometric arrangements, neutron-energy
spectra, and other relevant parameters (e.g., heterogeneity, leakage, interaction, absorption, etc.) within which the bias of a computational method is established."

## TSUNAMI Techniques for Code Validation

The TSUNAMI software provides a unique means to determine the similarity of nuclear criticality experiments to safety applications. ${ }^{5}$ The TSUNAMI validation techniques are based on the assumption that computational biases are primarily caused by errors in cross section data, the potential for which are quantified in cross section covariance data. TSUNAMI provides two methods to establish the computational bias introduced through cross section data.

For the first method, instead of using one or more average physical parameters to characterize a system, TSUNAMI determines the uncertainties in the computed response that are shared between two systems due to cross section uncertainties. These shared uncertainties directly relate to the bias shared by the two systems. To accomplish this, the sensitivity to each group-wise nuclide-reaction-specific cross section is computed for all systems considered in the analysis. Correlation coefficients are developed by propagating the uncertainties in neutron cross section data to uncertainties in the computed response for experiments and safety applications through sensitivity coefficients. The bias in the experiments, as a function of correlated uncertainty with the intended application, is extrapolated to predict the bias and bias uncertainty in the target application. This correlation coefficient extrapolation method is useful where many experiments with uncertainties that are highly correlated to the target application are available.

For the second method, data adjustment or data assimilation techniques are applied to predict computational biases, and more general responses, including but not limited to $k_{\text {eff, }}$ can be addressed simultaneously. ${ }^{5}$ This technique uses $\mathrm{S} / \mathrm{U}$ data to identify a single set of adjustments to nuclear data and experimental responses, taking into account their correlated uncertainties, which would improve the agreement between the response values from the experimental results and computational simulations. The same data adjustments are then used to predict an unbiased response (e.g., $k_{e f f}$ ) value for the application and an uncertainty on the adjusted response value. The difference between the originally calculated response value and the new post-adjustment response value represents the bias in the original calculation, and the uncertainty in the adjusted value represents the uncertainty in this bias. If experiments are available to validate the use of a particular nuclide in the application, the uncertainty of the bias for this nuclide may be reduced. If similar experiments are not available, the uncertainty in the bias for the given nuclide is high. Thus, with a complete set of experiments to validate important components in the application, a precise bias with a small uncertainty can be predicted. Where the experimental coverage is lacking, a bias can be predicted with an appropriately large uncertainty. The data assimilation method presents many advantages over other techniques in that biases can be projected from an agglomeration of benchmark experiments, each of which may represent only a small component of the bias of the target application. Also, contributors to the computational bias can be analyzed on an energy-dependent nuclide-reaction-specific basis. However, this technique requires additional data that are not generally available and must be quantified or approximated by the analyst, specifically the correlation coefficients that quantify the relative independence of experimental measurements that use the same equipment, whether nuclear fuel, reactivity devices, or measurement tools.

## Sensitivity and Uncertainty Analysis Tools in SCALE

The TSUNAMI-1D, TSUNAMI-2D and TSUNAMI-3D analysis sequences compute the sensitivity of $k_{\text {eff }}$ and reaction rates to energy-dependent cross section data for each reaction of each nuclide in a system model. The one-dimensional (1D) transport calculations are performed with XSDRNPM, twodimensional (2D) transport calculations are preformed using NEWT, and the three-dimensional (3D) calculations are performed with KENO V.a or KENO-VI. The Monte Carlo capabilities of TSUNAMI-3D provide for S/U analysis from either continuous-energy or multigroup neutron transport, where the
deterministic capabilities of TSUNAMI-1D and TSUNAMI-2D only operate in multigroup mode. SAMS (Sensitivity Analysis Module for SCALE) is applied within each analysis sequence to provide the requested S/U data. Whether performing a continuous-energy or multigroup calculation, energydependent sensitivity data are stored in multigroup-binned form in a sensitivity data file (SDF) for subsequent analysis. Additionally, these sequences use the energy-dependent cross section-covariance data to compute the uncertainty in the response value due to the cross section-covariance data. As TSUNAMI-2D operates as an extension of the TRITON sequence, it is documented in the "Reactor Physics" section of this document.

TSAR (Tool for Sensitivity Analysis of Reactivity Responses) computes the sensitivity of the reactivity change between two $k_{\text {eff }}$ calculations, using SDFs from TSUNAMI-1D, TSUNAMI-2D, and/or TSUNAMI-3D. TSAR also computes the uncertainty in the reactivity difference due to the cross section covariance data.

TSUNAMI-IP (TSUNAMI Indices and Parameters) uses the SDFs generated from TSUNAMI-1D, TSUNAMI-2D, TSUNAMI-3D, or TSAR for a series of systems to compute correlation coefficients that determine the amount of shared uncertainty between each target application and each benchmark experiment considered in the analysis. TSUNAMI-IP offers a wide range of options for more detailed assessment of system-to-system similarity. Additionally, TSUNAMI-IP can generate input for the USLSTATS (Upper Subcritical Limit Statistical Software) ${ }^{6}$ trending analysis and compute a penalty, or additional margin, needed for the gap analysis. USLSTATS is distributed as a graphical user interface with SCALE, but its use is documented in the TSUNAMI Primer, ${ }^{7}$ not in this documentation chapter.

TSURFER (Tool for S/U Analysis of Response Functions Using Experimental Results) is a bias and bias uncertainty prediction tool that implements the generalized linear least-squares (GLLS) approach to data assimilation and cross section data adjustment that also uses the SDFs generated from TSUNAMI-1D, TSUNAMI-2D, TSUNAMI-3D, or TSAR. The data adjustments produced by TSURFER are not used to produce adjusted cross section data libraries for subsequent use; rather, they are used only to predict biases in application systems.

The TSUNAMI Primer also documents the use of the graphical user interfaces for TSUNAMI, specifically ExSITE (Extensible SCALE Intelligent Text Editor) that facilitates analysis with TSUNAMIIP, TSURFER, TSAR, and USLSTATS as well as VIBE (Validation, Interpretation and Bias Estimation) for examining SDF files, creating sets of benchmark experiments for subsequent analysis, and gathering additional information about each benchmark experiment.
Sampler is a "super-sequence" that performs general uncertainty analysis by stochastically sampling uncertain parameters that can be applied to any type of SCALE calculation, propagating uncertainties throughout a computational sequence. Sampler treats uncertainties from two sources: (1) nuclear data and (2) input parameters. Sampler generates the uncertainty in any result generated by any computational sequence through stochastic means by repeating numerous passes through the computational sequence, each with a randomly perturbed sample of the requested uncertain quantities. The mean value and uncertainty in each parameter is reported, along with the correlation in uncertain parameters where multiple systems are simultaneously sampled with correlated uncertainties.
Used in conjunction with nuclear data covariances available in SCALE, Sampler is a general technique to obtain uncertainties for many types of applications. SCALE includes covariances for multigroup neutron cross section data, as well as for fission product yields, and radioactive decay data, which allow uncertainty calculations to be performed for most MG computational sequences in SCALE. At the present time, nuclear data sampling cannot be applied to SCALE CE Monte Carlo calculations, although the fundamental approach is still valid.
Used in conjunction with uncertainties in input data, Sampler can determine the uncertainties and correlations in computed results due to uncertainties in dimensions, densities, distributions of material
compositions, temperatures, or any quantities that are defined in the user input for any SCALE computational sequence. This methodology was developed to produce uncertainties and correlations in criticality safety benchmark experiments, ${ }^{8}$ but it has a wide range of applications in numerous scenarios in nuclear safety analysis and design. The input sampling capabilities of Sampler also include a parametric capability to determine the response of a system to a systematic variation of an input parameter.

# 6.1 TSUNAMI-1D: CONTROL MODULE FOR ONE-DIMENSIONAL CROSS-SECTION SENSITIVITY AND UNCERTAINTY 

B. T. Rearden, M. A. Jessee, L. M. Petrie, and M. L. Williams

#### Abstract

TSUNAMI-1D (Tools for Sensitivity and Uncertainty Analysis Methodology Implementation in One Dimension) is a SCALE control module that facilitates the application of sensitivity and uncertainty analysis theory to nuclear systems analyses. TSUNAMI-1D was originally developed to provide sensitivity and uncertainty analysis of $k_{\text {eff }}$ for criticality safety applications, and subsequent updates provide for analysis of system responses other than $k_{e f f}$, using generalized perturbation theory. TSUNAMI-1D provides for automated processing of material input, processing of cross-section data, calculation of neutron transport solutions, calculation of sensitivity coefficients, and the calculation of uncertainties in system responses due to cross-section-covariance data. The XSDRNPM module is used for the transport solver. XSDRNPM uses the method of discrete ordinates to calculate $k_{\text {eff }}$ for applications that are appropriate for 1D modeling. The SAMS module is used to determine the sensitivities of the calculated value of $k_{\text {eff }}$ and other system responses to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. The uncertainties in the calculated value of $k_{\text {eff }}$ and other system responses, resulting from uncertainties in the basic nuclear data used in the calculation, are estimated using energy-dependent cross-section-covariance matrices. The implicit effects of the resonance selfshielding calculations are predicted using BONAMIST.

The authors acknowledge Bryan Broadhead of Oak Ridge National Laboratory, and R. L. Childs, formerly of the Oak Ridge National Laboratory, for their assistance with this work. The support and encouragement of Calvin Hopper, Cecil Parks, and Don Mueller of Oak Ridge National Laboratory is also appreciated. Additionally, the authors wish to acknowledge Debbie Weaver and Sheila Walker for their assistance in preparing this document.

### 6.1.1 Introduction

TSUNAMI-1D (Tools for Sensitivity and Uncertainty Analysis Methodology Implementation in One Dimension) is a SCALE control module that facilitates the application of sensitivity and uncertainty theory to nuclear system analyses. The data computed with TSUNAMI-1D are the sensitivity of a system response, such as $k_{\text {eff }}$, to each constituent cross-section data component used in the calculation. The sensitivity data are coupled with cross-section uncertainty data, in the form of multigroup covariance matrices, to produce an uncertainty in the system response due to uncertainties in the underlying nuclear data. The group-wise sensitivity data computed with TSUNAMI-1D are stored in a sensitivity data file (.sdf file) that is suitable for use in assessing system similarity for code validation purposes using TSUNAMI-IP, (see TSUNAMI-IP chapter), and for advanced bias assessment using TSURFER, see the TSURFER chapter.

This manual is intended to provide the user with a detailed reference on code input options and provide some examples of the application of TSUNAMI-1D to generate sensitivity and uncertainty data. A detailed description of code input is provided in Section 6.1.3, three sample problems are given in Section 6.1.4, the techniques used in each computational sequence are described in Section 6.1.2, and additional information is provided in the appendices. A new user may wish to begin by reviewing the sample problems, and then refer to the input details in Section 6.1.3 to customize an input for his specific needs.

TSUNAMI-1D provides automated, problem-dependent cross sections using the same methods and input as the Criticality Safety Analysis Sequences (CSAS). The BONAMIST code computes the sensitivity of resonance self-shielded cross to the input data, the so-called "implicit sensitivities."

After the cross sections are processed, the TSUNAMI-1D sequence performs two XSDRNPM criticality calculations, one forward and one adjoint. Finally, the sequence calls the SAMS module to calculate the sensitivity coefficients that indicate the sensitivity of the calculated values to changes in the cross sections and the uncertainty in the calculated value due to uncertainties in the basic nuclear data. SAMS prints energy-integrated sensitivity coefficients and their statistical uncertainties to the SCALE output file and generates a separate data file containing the energy-dependent sensitivity coefficients.

In addition to the sensitivity and uncertainty analysis sequence, the TSUNAMI-1DC sequence can be used to verify the accuracy of the TSUNAMI-1D calculations with direct perturbation criticality calculations. The verification of computed sensitivity coefficients is imported for systems where the cellweighted material is not the only material used in the model. By default, TSUNAMI-1DC performs the same functions as the TSUNAMI-1D sequence with PARM=CENTRM, except that it does not perform the adjoint XSDRNPM calculation and does not call the SAMS module.

### 6.1.2 TSUNAMI-1D Techniques

TSUNAMI-1D is a SCALE control module. As such, its primary function is to control a sequence of calculations that are performed by other codes. The input for each of the TSUNAMI-1D sequences is very similar to that used for CSAS1, with the addition of the system model description and optional sensitivity calculation data. TSUNAMI-1D uses the same material and cell data input as all other SCALE sequences. The control sequences available in TSUNAMI-1D are summarized in Table 6.1.1, where the functional modules executed by each control sequence are also shown. A general flow diagram of TSUNAMI-1D is shown in Figure 6.1.1.

Table 6.1.1. TSUNAMI-1D control sequences

| Control <br> sequence | Functional modules executed by the control module |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| TSUNAMI-1D | XSProc | XSDRNPM <br> forward | XSDRNPM <br> adjoint* | BONAMIST | SAMS* |
| TSUNAMI-1DC | XSProc | XSDRNPM <br> forward |  |  |  |
| *The XSDRNPM adjoint calculation and SAMS calculation are repeated for each system response defined by the user. |  |  |  |  |  |

TSUNAMI-1D and many other SCALE sequences apply a standardized procedure to provide appropriate cross sections for the calculation. This procedure is carried out by routines of the XSProc that generate number densities and related information, prepare geometry data for resonance self-shielding and fluxweighting cell calculations, and create data input files for the cross-section processing codes.

By default, the TSUNAMI-1D sequence performs cross-section processing with XSProc, exercising all available options there, performs the forward and adjoint XSDRNPM calculations, calls BONAMIST to produce implicit sensitivity coefficients, then calls SAMS to produce sensitivity and uncertainty output and $s d f$ files. Optional sequence level parameters can be used to change methods applied in resonance self-shielding and exclude the implicit sensitivity calculation, which detailed later in this document. If additional system responses are requested in the input, TSUNAMI-1D executes additional generalized adjoint XSDRNPM and SAMS calculations for each system response.

The input requirements for the model description are very similar to those used for multiregion cell descriptions in the cell data section of input. The definition of system responses other than $k_{\text {eff }}$ requires both the DEFINITIONS and SYSTEMRESPONSE block of input data. These blocks of data are described in Section 6.1.3.4. TSUNAMI-1D also reads and prepares inputs for the SAMS calculation. The additional input blocks for the SAMS module are optional. The input format of the SAMS blocks of data are described in the SAMS chapter.

Figure 6.1.1. General flow diagram of TSUNAMI-1D.

### 6.1.3 TSUNAMI-1D Input Description

The input to TSUNAMI-1D consists of a SCALE Analytical Sequence Specification Record, SCALE XSProc data, model problem data, optional sensitivity and uncertainty calculation data, and optional
system response characterization data. The data for each of these segments are entered using the SCALE free-form format, allowing alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. The input is not case sensitive, so either upper- or lowercase letters may be used. A maximum of 252 columns per line may be used for input. Data can usually start or end in any column with a few exceptions. As an example, the word END beginning in column 1 and followed by two blank spaces will end the problem, any data following will be ignored. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating values. For example, 10 will be interpreted as 10.0. Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0E 4 would be correctly interpreted as $1.0 \times 10^{4}$. A comment is initiated with a single quote, ${ }^{\text {' }}$, and continues until the end of the input line.

### 6.1.3.1 Analytical sequence specification record

The analytical sequence specification begins in column 1 of the first line of the input file and must contain one of the following:
=TSUNAMI-1D This sequence is used for sensitivity and uncertainty calculations.
=TSUNAMI-1DC This sequence allows more flexibility than CSAS1 and is used for criticality calculations where the criticality problem description contains more detail than that specified in a single unit cell description.

Optional keyword input may be entered, starting after column 10 of the analytical sequence specification record. These keywords are
PARM=CHECK This option allows the input data to be read and checked without executing any PARM=CHK functional modules.

PARM=SIZE=n The amount of memory requested in four-byte words may be set with this entry. The default value for n is 20000000 . This value only affects calculations in BONAMIST, where this value of the SIZE parameter is used for allocation of storage for the derivatives. Please see the documentation on BONAMIST in the Sensitivity Utility Modules chapter for more details. All other codes use dynamic memory allocation and this value has no effect.

PARM=BONAMIST This is the default configuration for MG TSUNAMI-1D calculations. XSProc with BONAMI and CENTRM is used for cross-section processing, and implicit sensitivities are produced with BONAMIST.

PARM=CENTRM XSProc with BONAMI and CENTRM is used for cross-section processing, but BONAMIST is not run. TSUNAMI-1D sequence with PARM=CENTRM does not produce the implicit portions of the sensitivity coefficients, and should be used with caution.

PARM=BONAMI XSProc with BONAMI is used for cross-section processing, but BONAMIST is not run. TSUNAMI-1D sequence with PARM=BONAMI does not produce the implicit portions of the sensitivity coefficients, and should be used with caution.

## PARM=2REGION

XSProc with BONAMI and CENTRM are run where Dancoff factors are to compute the escape probabilities for an accelerated, yet more approximate, CENTRM calculation. Implicit sensitivities are computed with BONAMIST.

Multiple parameters can be used simultaneously by enclosing them in parentheses and separating them with commas such as PARM=(SIZE=2000000, CHECK).

Multiple parameters can be used simultaneously by enclosing them in parentheses and separating them with commas such as PARM=(SIZE=2000000, CHECK).

### 6.1.3.2 XSProc

XSProc reads the standard composition specification data and the unit cell geometry specifications. It then produces the mixing table and unit cell information necessary for processing the cross sections. The XSProc chapter provides a detailed description of the input data for the Material Information Processor.

### 6.1.3.3 Model problem data

The model problem data are used by the TSUNAMI-1D sequences to prepare input for the XSDRNPM transport calculation. This input section consists of two data blocks, one block contains a geometry description and one contains optional parameters.

### 6.1.3.3.1 Geometry data

The TSUNAMI-1D geometry data block begins with the keywords READ GEOM and ends with the keywords END GEOM. This data block is always required. The following data is contained within this data block:

1. A line containing the geometry and boundary conditions for the XSDRNPM criticality case. The first entry on this line describes the geometry and must be SLAB, CYLINDRICAL, or SPHERICAL. The second entry is optional and describes the right-boundary condition. The default value for the right-boundary condition is VACUUM. The third entry on this line is optional and describes the left-boundary condition. The default value for the left boundary condition is REFLECTED. The last entry on this line is END. Valid entries for the boundary conditions are the following:
```
VACUUM - No return at boundary
REFLECTED - Specular (mirror-like) return at boundary
PERIODIC - Infinite array of cells in slab geometry
WHITE - Isotropic return at boundary
```

2. A line containing the following two entries for each zone of the XSDRNPM case:
a. mixture number in the zone and
b. zone outer dimension (in cm).

Mixture numbers and zone dimensions are entered in pairs until the entire geometry is defined. The mixture numbers must be defined in the material input processor input. Mixture 0 is used for voids, and a mixture number defined with CELLMIX= in the MIP section of the input may be used here. It should be noted that, due to a restriction in XSDRNPM, the mixture number identified with CELLMIX= may not appear in the output file, even though it is input in this section. TSUNAMI-1D automatically renumbers the cell mixed mixture to the next available mixture number for use in XSDRNPM. A message is printed in the output identifying this change. TSUNAMI-1D uses the same techniques as CSAS1X to automatically prepare a spatial mesh appropriate for the input materials and dimensions.

### 6.1.3.3.2 Parameter data

An optional data block may be entered to change parameters of the XSDRNPM forward and adjoint calculations. This data block begins with the keywords READ PARA or READ PARM and must end with either END PARA or END PARM, corresponding to the read keyword. In this data block, the user may enter optional lines that contain entries for selected XSDRNPM input parameters. A list of the parameters and their default values are found in Table 6.1.2.

Table 6.1.2. Optional parameter input for the criticality problem data

| Name | Default | Meaning |
| :---: | :---: | :---: |
| ISN= | 16 | Order of angular quadrature |
| $\mathrm{IIM}=$ | 20 | Inner-iteration maximum |
| $\mathrm{ICM}=$ | 100 | Outer-iteration maximum |
| ID1 $=$ | -1 | Flux-edit option: |
|  |  | -1 no flux print |
|  |  | 0 scalar flux print |
|  |  | 1 scalar and angular flux print |
| $\mathrm{SCT}=$ | 5 | Order of Legendre expansion for cross sections |
| PRT= | -2 | Cross-section print option: |
|  |  | -2 no cross-section print |
|  |  | -1 print 1-D cross sections |
|  |  | 0/N print 2-D cross sections through order N |
| PBT= | 0 | Balance table print option: |
|  |  | -1 no balance table print |
|  |  | 0 fine group balance table print |
| EPS= | 1.E-6 | Outer-iteration convergence criteria |
| PTC= | 1.E-6 | Inner-iteration convergence criteria |
| $\mathrm{DY}=$ | 0 | First-transverse dimension (cm) for buckling correction (i.e., height of cylinder or slab) |
| DZ= | 0 | Second-transverse dimension (cm) for buckling correction (i.e., depth of slab) |
| SZF= | 1.5 | Size factor of spatial computational mesh intervals. Increasing this number will cause the forward and adjoint XSDRNPM calculations to be conducted with larger mesh intervals and fewer mesh points. $0.0<\mathrm{SZF}<1.5$ gives a finer mesh, $\mathrm{SZF}>1.5$ gives a coarser mesh. |

### 6.1.3.4 Sensitivity and uncertainty calculation data

The data blocks for controlling the sensitivity and uncertainty calculation are optional. The optional data blocks include the SAMS block, the HTML block, the COVARIANCE block, the DEFINITIONS block, and the SYSTEMRESPONSES block. These data blocks begin with the keywords READ BLOCKNAME and end with the keywords END BLOCKNAME, where BLOCKNAME is one of SAMS, HTML, COVARIANCE, DEFINITONS, or SYSTEMRESPONSES. These data blocks can be input in any order with the following two exceptions. First, all five data blocks must appear in the input file after the composition and cell data blocks of data. Second, if a SAMS block is specified, the HTML and COVARIANCE data blocks must come after the SAMS block, if they are to be specified. In addition, both the DEFINITONS and SYSTEMRESPONSES data blocks must be present for additional analysis of system responses other than $k_{\text {eff. }}$. If only one or both of the data blocks are omitted, then analysis is only performed for $k_{\text {eff. }}$. The following sub-sections describe these blocks of data in detail.

### 6.1.3.4.1 Response definition data

The DEFINITIONS and SYSTEMRESPONSES blocks are used to define system responses for additional sensitivities and uncertainty analysis in SAMS. For criticality calculations, the sensitivities of system responses other than $k_{\text {eff }}$ are calculated in TSUNAMI-1D using generalized perturbation theory (GPT). The details of the GPT methodology are provided in General Perturbation Theory section of the SAMS chapter. Using GPT, a system response, denoted R , is defined as a ratio such as:

$$
\begin{equation*}
R=\frac{\sum_{g} \int d \bar{r} H_{N, g}(\bar{r}) \phi_{g}(\bar{r})}{\sum_{g} \int d \bar{r} H_{D, g}(\bar{r}) \phi_{g}(\bar{r})} \tag{6.1.1}
\end{equation*}
$$

In this equation, $\phi_{g}(\bar{r})$ is the space-dependent multi-group scalar flux and $H_{N, g}(\bar{r}), H_{D, g}(\bar{r})$ are referred to as the space-dependent, multi-group response functions. In TSUNAMI-1D, the response functions are specified in the DEFINITIONS data block and the system responses are defined in the SYSTEMRESPONSES data block. Responses (other $k_{\text {eff }}$ ) treated in TSUNAMI-1D MUST be ratios.

The DEFINITIONS data block is used by TSUNAMI-1D similarly to that of the MAVRIC and MONACO modules in SCALE. The format of the DEFINITIONS block is as follows:

```
read definitions
    response I I
        (specifications for response I I)
    end response
    response I I2
        (specifications for response I I)
    end response
end definitions
```

The DEFINITIONS block of data begins with READ DEFINITIONS and terminates with END DEFINITIONS. Likewise, each response function definition begins with RESPONSE - followed by a unique, positive integer identifier - and terminates with END RESPONSE. The keyword entries summarized in Table 6.1.3 are allowed for each response specification. Keywords ending with '=' must be followed by the value to be assigned to the corresponding variable. All keywords are optional and can
be entered in any order. However certain keywords are required depending one of the seven basic types of response functions described in the following subsections. The required keywords are summarized for each of the seven basic response function types in Table 6.1.4 at the end of this section.

Table 6.1.3. Response function keywords in DEFINITIONS block

| Keyword | Type | Default value | Description |
| :---: | :---: | :---: | :---: |
| title= | String | " " | Response function title. The title must begin and end with quotes and have a maximum of 256 characters. |
| macro | Logical | F | Macroscopic cross-section flag. If specified, macroscopic cross-sections are used to define the response function. |
| micro | Logical | T | Microscopic cross-section flag. If specified, microscopic cross-sections are used to define the response function. |
| $\begin{gathered} \text { nuclide= } \\ \text { or } \\ \text { zaid= } \end{gathered}$ | Integer or string | Undefined | Nuclide identifier for which cross-sections are used to define the response function. The nuclide can be specified in integer format (92235) or in character string format (u235). |
| $\begin{gathered} \text { reaction= } \\ \text { or } \\ \mathrm{mt}= \end{gathered}$ | Integer or string | Undefined | Reaction identifier for which cross-sections are used to define the response function. The reaction can be specified as an MT number (18) or as a character string (fission). Supported reaction types are listed below. |
| material= <br> or mixture= | Integer | Undefined | Mixture identifier for which cross-sections are used to define the response function. |
| multimix ... end or multimat ... end | Integer array | Undefined | Array of mixture identifiers for which cross-sections are used to define the response function. |
| unity | Logical | F | Flux response function flag. If specified, cross-sections are not used to define the response function. |
| multiplier | Real | 1.0 | Response function multiplier. |
| ehigh= | Real | $10^{25}$ | Upper energy (eV) boundary of the response function. |
| elow= | Real | 0.0 | Lower energy (eV) boundary of the response function. |
| ehightransfer= | Real | $10^{25}$ | Upper energy (eV) boundary used for cross-sections with secondary particle distributions (elastic, inelastic, scatter, and $n, 2 n$ ). |
| elowtransfer= | Real | 0.0 | Lower energy (eV) boundary used for cross-sections with secondary particle distributions (elastic, inelastic, scatter, and $n, 2 n$ ). |

### 6.1.3.4.1.1 Single-mixture flux response function

A single-mixture flux response is simply the integration of the neutron flux wherever a specified mixture is defined in the problem geometry. Therefore, the response function $H_{g}(\bar{r})$ for a single mixture- $j$ is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c * \delta_{g} * \delta_{j}(\bar{r}) \tag{6.1.2}
\end{equation*}
$$

where

$$
\begin{gathered}
\delta_{g}=\left\{\begin{array}{cc}
1.0 & E_{\text {High }}>E_{g}^{\text {Lower }}, E_{\text {Low }}<E_{g}^{\text {Upper }} \\
0 & \text { otherwise }
\end{array}\right. \\
\text { and }
\end{gathered} \quad \begin{aligned}
& \delta_{j}(\bar{r})=\left\{\begin{array}{cc}
1.0 & \text { mixture } j \text { is } \text { used at } \bar{r} \\
0 & \text { otherwise }
\end{array}\right.
\end{aligned}
$$

In this expression, the constant $c$ is the scalar multiplier defined by the multiplier= keyword. For example, the "fast" and "thermal" flux responses for mixture 5 would be:

```
read definitions
    response 1 unity eLow=0.625 mixture=5 end response
    response 2 unity eHigh=0.625 mixture=5 end response
    response 3 unity multiplier=2.0 mixture=5 end response
end definitions
```

In this example, the energy cutoff between the fast group and the thermal group is defined as 0.625 eV . Response 3 reflects the total energy-integrated flux -scaled by a factor of 2.0 -because the default values of eHigh and eLow are used.

For single-mixture flux responses, keywords unity and mixture are required; multiplier, eHigh, and eLow are optional; title, nuclide, reaction, micro, macro, eHighTransfer, and eLowTransfer are optional but are not used; and multimix is not allowed. These keyword dependencies are outlined for each response type in Table 6.1.4.

### 6.1.3.4.1.2 Multiple-mixture flux response

A multiple-mixture flux response is the integration of the neutron flux wherever a set of mixtures are defined in the problem geometry. Therefore, the response function $H_{g}(\bar{r})$ for a set of mixtures " $S$ " is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c^{*} \delta_{g} * \sum_{j \in S} \delta_{j}(\bar{r}) \tag{6.1.3}
\end{equation*}
$$

For example, the following definition is for the energy-integrated flux response, and spatially-integrated wherever mixtures 5,7 , and 9 are used:

```
read definitions
    response 1 unity multimix 5 7 9 end end response
end definitions
```

or alternatively,

```
read definitions
    response 1 multimat 5 7 9 end unity end response
end definitions
```

For multiple-mixture flux responses, keywords unity and multimix are required; multiplier, eHigh, and eLow are optional; title, nuclide, reaction, micro, macro, eHighTransfer, and eLowTransfer are optional but are not used; and mixture is not allowed.

### 6.1.3.4.1.3 Single-mixture, single-nuclide, microscopic cross-section response

A single-mixture, single-nuclide, microscopic cross-section response is the integration of the neutron flux multiplied by a microscopic cross-section. The microscopic cross-section used in the integral is defined by a specific mixture, nuclide, and reaction type. Therefore, the response function $H_{g}(\bar{r})$ is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c * \delta_{g} * \delta_{j}(\bar{r}) * \sigma_{x, g}^{j, n} \tag{6.1.4}
\end{equation*}
$$

In this expression, $\sigma_{x, g}^{j, n}$ is the microscopic cross-section for mixture- $j$, nuclide- $n$, reaction type- $x$, and energy group- $g$. For transfer reaction types-scatter, elastic, inelastic, and n,2n-the expression above is slightly modified so the user can define the energy range of the secondary particles, i.e.,

$$
\begin{equation*}
H_{g}(\bar{r})=c^{*} \delta_{g} * \delta_{j}(\bar{r}) * \sum_{g^{\prime}} \delta_{g^{\prime}}^{\text {Transfer }} \sigma_{x, g \rightarrow g^{\prime}}^{j, n} \tag{6.1.5}
\end{equation*}
$$

where

$$
\delta_{g}^{\text {Transfer }}=\left\{\begin{array}{cc}
1.0 & E_{\text {HighTransfer }}>E_{g}^{\text {Lower }}, E_{\text {LowTransfer }}<E_{g}^{\text {Upper }} \\
0 & \text { otherwise }
\end{array}\right.
$$

Likewise, the expression for $H_{g}(\bar{r})$ is also modified for fission distribution responses (chi), which are usually integrated by the energy-integrated neutron production rate rather than the neutron flux:

$$
\begin{equation*}
H_{g}(\bar{r})=c^{*} \delta_{j}(\bar{r})^{*} \bar{v}_{f, g}^{j, n} * \sigma_{f, g}^{j, n} * \sum_{g^{\prime}} \delta_{g^{\prime}} * \chi_{g^{\prime}}^{j, n} \tag{6.1.6}
\end{equation*}
$$

For examples of this response type, the following DEFINITION block has response definitions for

- total nu-fission rate of U-235 in mixture 1,
- "fast" n,gamma capture rate of U-238 in mixture 1 (energy cutoff is 0.625 eV ),
- downscatter rate of $\mathrm{H}-1$ in mixture 2 , and
- number fission neutrons born from Pu-239 fissions in mixture 1 in the intermediate energy range ( $\mathrm{E}>0.625 \mathrm{eV}$ and $\mathrm{E}<25 \mathrm{keV}$ )

```
read definitions
    response 1
        reaction=nu-fission mixture=1 nuclide=92235
    end response
    response 2
        reaction=n,gamma mixture=1 nuclide=u-238 eLow=0.625
    end response
    response 3
        mt=0 mixture=2 zaid=1001 eLow=0.625 eHighTransfer=0.635
    end response
    response 4
        mt=chi mixture=1 zaid=pu-239 eHigh=25.0e3 eLow=0.625
    end response
end definitions
```

For single-mixture, single-nuclide microscopic cross-section responses, keywords mixture, nuclide, and reaction are required; multiplier, eHigh, eLow, eHighTransfer, eLowTransfer, and micro, are optional; title is optional but not used; and multimix, macro, and unity are not allowed. A list of supported crosssection reaction types is provided at the end of this section in Table 6.1.5.

### 6.1.3.4.1.4 Single-mixture, single-nuclide, macroscopic cross-section response

A single-mixture, single-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section. The macroscopic cross-section used in the integral is defined by a specific mixture, nuclide, and reaction type. The response function $H_{g}(\bar{r})$ is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c * \delta_{g} * \delta_{j}(\bar{r}) * \sum_{x, g}^{j, n} \tag{6.1.7}
\end{equation*}
$$

In this expression, $\Sigma_{x, g}^{j, n}$ is the macroscopic cross-section ( $N^{j, n} * \sigma_{x, g}^{j, n}$ ) for mixture- $j$, nuclide- $n$, reaction type- $x$, and energy group- $g$. The modifications to this expression for transfer reactions and chi are similar to that of single-mixture, single-nuclide, microscopic cross-section responses. Using the same example as above, the single-mixture, single-nuclide, macroscopic cross-section responses are given as:

```
read definitions
    response 1
        reaction=nu-fission mixture=1 nuclide=92235 macro
    end response
    response 2
        reaction=n,gamma mixture=1 nuclide=u-238 eLow=0.625 macro
    end response
    response 3
        mt=0 mixture=2 zaid=1001 eLow=0.625 eHighTransfer=0.635 macro
    end response
    response 4
        mt=chi mixture=1 zaid=pu-239 eHigh=25.0e3 eLow=0.625 macro
    end response
end definitions
```

For single-mixture, single-nuclide macroscopic cross-section responses, keywords mixture, nuclide, macro, and reaction are required; multiplier, eHigh, eLow, eHighTransfer, and eLowTransfer, are optional; title is optional but not used; and multimix, micro, and unity are not allowed.

### 6.1.3.4.1.5 Single-mixture, multiple-nuclide, macroscopic cross-section response

A single-mixture, multiple-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section. The macroscopic cross-section used in the integral is defined by a specific mixture, and reaction type. The response function $H_{g}(\bar{r})$ is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c * \delta_{g} * \delta_{j}(\bar{r}) * \Sigma_{x, g}^{j} \tag{6.1.8}
\end{equation*}
$$

In this expression, $\Sigma_{x, g}^{j}$ is the mixture macroscopic cross-section defined as $\sum_{n} N^{j, n} * \sigma_{x, g}^{j, n}$ for mixture- $j$, reaction type- $x$, and energy group- $g$. The modifications to this expression for transfer reactions is similar to that defined in previous subsections. For mixture chi responses, $H_{g}(\bar{r})$ is rewritten as

$$
\begin{equation*}
H_{g}(\bar{r})=c^{*} \delta_{j}(\bar{r}) * \sum_{n} \bar{v}_{f, g}^{j, n} * \Sigma_{f, g}^{j, n} * \sum_{g^{\prime}} \delta_{g^{\prime}} * \chi_{g^{\prime}}^{j, n} \tag{6.1.9}
\end{equation*}
$$

For examples of this response type, the following DEFINITIONS block has response definitions for

- total nu-fission rate in mixture 1 ,
- "fast" n,gamma capture rate in mixture 1 (energy cutoff is 0.625 eV ),
- downscatter rate in mixture 2, and
- number fission neutrons born in mixture 1 in the intermediate energy range ( $\mathrm{E}>0.625 \mathrm{eV}$ and $\mathrm{E}<25 \mathrm{keV}$ )

```
read definitions
    response 1
        reaction=nu-fission mixture=1 macro
    end response
    response 2
        reaction=n,gamma mixture=1 eLow=0.625 macro
    end response
    response 3
        mt=0 mixture=2 eLow=0.625 eHighTransfer=0.635 macro
    end response
    response 4
        mt=chi mixture=1 eHigh=25.0e3 eLow=0.625 macro
    end response
end definitions
```

For single-mixture, multiple-nuclide macroscopic cross-section responses, keywords mixture, macro, and reaction are required; multiplier, eHigh, eLow, eHighTransfer, and eLowTransfer, are optional; title is optional but not used; and multimix, micro, nuclide, and unity are not allowed.

### 6.1.3.4.1.6 Multiple-mixture, single-nuclide, macroscopic cross-section response

A multiple-mixture, single-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section over a set of mixtures defined in the problem geometry. The macroscopic cross-section used in the integral is defined by a specific mixture, nuclide, and reaction type. The response function $H_{g}(\bar{r})$ is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c^{*} \delta_{g} * \sum_{j \in S} \delta_{j}(\bar{r}) * \sum_{x, g}^{j, n} \tag{6.1.10}
\end{equation*}
$$

In this expression, $\Sigma_{x, g}^{j, n}$ is the macroscopic cross-section ( $N^{j, n} * \sigma_{x, g}^{j, n}$ ) for mixture- $j$, nuclide- $n$, reaction type- $x$, and energy group- $g$. The summation of mixtures in this expression is for a set of user-defined mixtures, denoted $S$. The modifications to this expression for transfer reactions and chi are applied similarly to previously defined response types above.

For examples of this response type, the following DEFINITIONS block has response definitions for

- total nu-fission rate of U-235 in the fuel mixtures (mixtures $1,3,5$ )
- "fast" n,gamma capture rate of U-238 in the fuel mixtures
- downscatter rate of $\mathrm{H}-1$ in the moderator mixtures (mixtures 2,4 )
- number fission neutrons born in the intermediate energy range ( $\mathrm{E}>0.625 \mathrm{eV}$ and $\mathrm{E}<25 \mathrm{keV}$ ) in Pu-239 in the fuel mixtures

```
read definitions
    response 1
            reaction=nu-fission multimix 1 3 5 end macro zaid=92235
        end response
        response 2
            reaction=n,gamma multimix 1 3 5 eLow=0.625 macro zaid=u-238
    end response
    response 3
            mt=0 multimix 2 4 end eLow=0.625 eHighTransfer=0.635 macro zaid=h-1
    end response
    response 4
            mt=chi multimix 1 3 5 end eHigh=25.0e3 eLow=0.625 macro zaid=pu-239
    end response
end definitions
```

For multiple-mixture, single-nuclide macroscopic cross-section responses, keywords multimix, nuclide, macro, and reaction are required; multiplier, eHigh, eLow, eHighTransfer, and eLowTransfer, are optional; title is optional but not used; and mixture, micro, and unity are not allowed.

### 6.1.3.4.1.7 Multiple-mixture, multiple-nuclide, macroscopic cross-section response

A multiple-mixture, multiple-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section over a set of mixtures defined in the problem geometry. The macroscopic cross-section used in the integral is defined by a specific mixture, and reaction type. The response function $H_{g}(\bar{r})$ is defined as:

$$
\begin{equation*}
H_{g}(\bar{r})=c^{*} \delta_{g} * \sum_{j \in S} \delta_{j}(\bar{r}) * \sum_{x, g}^{j} \tag{6.1.11}
\end{equation*}
$$

In this expression, $\Sigma_{x, g}^{j}$ is the mixture macroscopic cross-section for mixture- $j$ and reaction type- $x$, and energy group-g. The summation of mixtures in this expression is for a set of user-defined mixtures, denoted $S$. The modifications to this expression for transfer reactions and chi are applied similarly to the previously defined response types above.

For examples of this response type, the following DEFINITIONS block has response definitions for

- total nu-fission rate in the fuel mixtures (mixtures $1,3,5$ )
- "fast" n,gamma capture rate in the fuel mixtures
- downscatter rate in the moderator mixtures (mixtures 2,4 )
- number fission neutrons born in the intermediate energy range ( $\mathrm{E}>0.625 \mathrm{eV}$ and $\mathrm{E}<25$ keV ) in the fuel mixtures

```
read definitions
    response 1
        reaction=nu-fission multimix 1 3 5 end macro
    end response
    response 2
        reaction=n,gamma multimix 1 3 5 eLow=0.625 macro
    end response
    response 3
        mt=0 multimix 2 4 end eLow=0.625 eHighTransfer=0.635 macro
    end response
    response 4
        mt=chi multimix 1 3 5 end eHigh=25.0e3 eLow=0.625 macro
    end response
end definitions
```

For multiple-mixture, multiple-nuclide macroscopic cross-section responses, keywords multimix, macro, and reaction are required; multiplier, eHigh, eLow, eHighTransfer, and eLowTransfer, are optional; title is optional but not used; and mixture, micro, nuclide, and unity are not allowed.

Table 6.1.4. Keyword dependencies for the DEFINITIONS block

| Response type | Required keywords | Unallowed keywords | Optional keywords | Optional, but not used keywords |
| :---: | :---: | :---: | :---: | :---: |
| Single-mixture flux | unity, mixture | multimix | multiplier, eHigh, eLow | title, $\quad$ nuclide, reaction, $\quad$ micro, macro, eHighTransfer, eLowTransfer |
| Multiple-mixture flux | unity, multimix | mixture | multiplier, eHigh, eLow | title, nuclide, reaction, micro, macro, eHighTransfer, eLowTransfer |
| Single-mixture, single-nuclide, microscopic crosssection | mixture, nuclide, reaction | unity, macro, multimix | multiplier, eHigh, eLow, micro, eHighTransfer ${ }^{\text {a }}$, eLowTransfer ${ }^{\text {a }}$ | title |
| Single-mixture, single-nuclide, macroscopic crosssection | mixture, nuclide, reaction,macro | unity, micro, multimix | multiplier, eHigh, eLow, eHighTransfer ${ }^{\text {a }}$, eLowTransfer ${ }^{\text {a }}$ | title |
| Single-mixture, multiple-nuclide, macroscopic crosssection | mixture, reaction,macro | unity, micro, multimix, nuclide | multiplier, eHigh, eLow, eHighTransfer ${ }^{\text {a }}$, eLowTransfer ${ }^{\text {a }}$ | title |
| Multiple-mixture, single-nuclide, macroscopic crosssection | multimix, <br> nuclide reaction,macro | unity, micro, mixture | multiplier, eHigh, eLow, eHighTransfer ${ }^{\text {a }}$, eLowTransfer ${ }^{\text {a }}$ | title |
| Multiple-mixture, multiple-nuclide, macroscopic crosssection | multimix, reaction,macro | unity, micro, mixture, nuclide | multiplier, eHigh, eLow, eHighTransfer ${ }^{\text {a }}$, eLowTransfer ${ }^{\text {a }}$ | title |

[^15]Table 6.1.5. Supported Reaction Types in DEFINITIONS block

| MT | Reaction | String Identifier |
| :---: | :---: | :---: |
| 1 | total | Total |
| 2 | elastic scattering | Elastic |
| 4 | inelastic scattering | Inelastic |

| 1452 | $\bar{v}$ times fission | nu-fission |
| 1018 | $\chi$ | chi |

${ }^{\mathrm{a}}$ The effective $\mathrm{n}, 2 \mathrm{n}$ is defined by the summation of transfer matrices of the following reaction types: $(\mathrm{n}, 2 \mathrm{n}),(\mathrm{n}, 2 \mathrm{n}+\alpha),(\mathrm{n}, 2 \mathrm{n}+2 \alpha)$, $(\mathrm{n}, 3 \mathrm{n}),(\mathrm{n}, 3 \mathrm{n}+\alpha)$, and $(\mathrm{n}, 4 \mathrm{n})$. The individual transfer matrices are scaled by the number exit channel neutrons, i.e., 2 , 3 , or 4 .

### 6.1.3.4.2 System response definition data

The SYSTEMRESPONSES block is used to define the set of system responses for which TSUNAMI-1D will perform sensitivity and uncertainty analysis additional to $k_{\text {eff. }}$. For SCALE 6.1, only system response ratios are supported in TSUNAMI-1D. The system response ratios are defined from the response function definitions created in the DEFINITIONS block. The format of the SYSTEMRESPONSES block is as follows:

```
read systemresponses
    ratio I I
        (specifications for response ratio I I)
    end ratio
    ratio I I2
        (specifications for response ratio IN)
    end ratio
end systemresponses
```
