Received December 5, 1990

Michael Klemm has recently studied the conditions satisfied by the complete weight enumerator of a self-dual code over $\mathbb{Z}_4$, the ring of integers modulo 4. In the present paper we deduce analogues theorems for the "symmetrized" weight enumerator (which ignores the difference between $+1$ and -1 coordinates) and the Hamming weight enumerator. We give a number of examples of self-dual codes, including codes which realize the basic weight enumerators occurring in all these theorems, and the complete list of self-dual codes of length $n \leqslant 9$. We also classify those self-orthogonal codes that are generated by words of type $\pm 1^4 0^{n-4}$.

1. INTRODUCTION

In recent years, several papers have mentioned (implicitly or explicitly) codes over $\mathbb{Z}_4$ [5–8, 20, 21, 26, 31] without however giving many concrete examples. The main results of the present paper are the following.

The first is a structure theorem (analogous to the result for binary codes stated on p. 35 of [10]) characterizing self-orthogonal[1] codes over $\mathbb{Z}_4$ that are generated by "tetrads," vectors which contain four components congruent to $+1$ or -1 (mod 4), the other components being congruent to 0 (mod 4). As we shall see later, tetrads are the simplest possible vectors in an indecomposable self-orthogonal code over $\mathbb{Z}_4$.

[1] The terms "self-orthogonal," "self-dual," "equivalent," etc., are explained in Section 2.

0097-3165/93 $5.00

THEOREM 1. *Any self-orthogonal code $\mathscr{C}$ over $\mathbb{Z}_4$ generated by tetrads is equivelent to a direct sum of codes from the list*

$$\mathscr{D}_{2m},\ \mathscr{D}_{2m}^{\circ},\ \mathscr{D}_{2m}^{+},\ \mathscr{D}_{2m}^{\oplus}\ (m=1, 2, \ldots),\ \mathscr{E}_7,\ \mathscr{E}_7^{+},\ \mathscr{E}_8. \tag{1}$$

The codes mentioned in (1) are defined in Section 3. They are inequivalent except that $\mathscr{D}_4^{\circ} \cong \mathscr{D}_4^{+}$; the inclusions between these codes are displayed in Fig. 1.

The second theorem classifies self-dual codes of length up to 9. The statement of this result is facilitated by the fact that self-dual codes over $\mathbb{Z}_4$ have

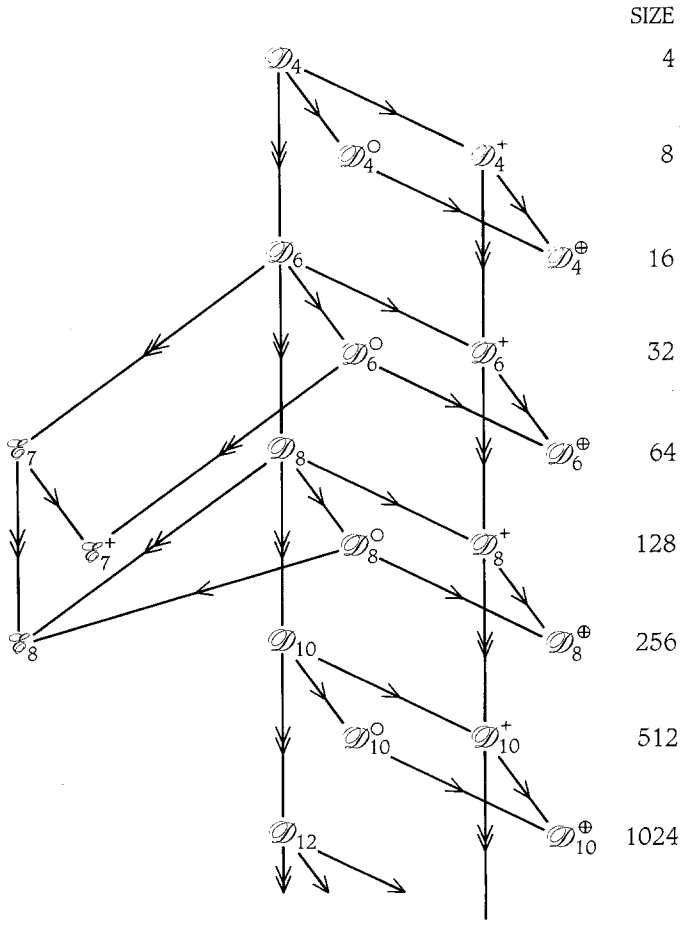

FIG. 1. Indecomposable codes over $\mathbb{Z}_4$ generated by tetrads, ordered by inclusion. An arrow indicates that the lower code can be obtained from the upper code by adjoining a single tetrad. The arrow is single or double according as the number of words increases by a factor of 2 or 4. Note that $\mathscr{D}_4^{\circ} \cong \mathscr{D}_4^{+}$.

TABLE I

All Indecomposable Self-Dual Codes over $\mathbb{Z}_4$ of Length $n \leqslant 9$

$\mathscr{C}$	n	$\lvert\mathscr{C}\rvert$	$\lvert G\rvert$	swe
$\mathscr{A}_1$	1	2^1	2	$1+c$
$\mathscr{D}_4^{\oplus}$	4	$4^1 2^2$	$2^3 \cdot 4!$	$1+6c^2+8b^4+c^4$
$\mathscr{D}_6^{\oplus}$	6	$4^2 2^2$	$2^6 \cdot 6$	$1+3c^2+8c^3+12b^4+3c^4+\cdots$
$\mathscr{E}_7^{+}$	7	$4^3 2^1$	$2 \cdot 168$	$1+7c^3+14b^4+7c^4+\cdots$
$\mathscr{D}_8^{\oplus}$	8	$4^3 2^2$	$2^8 \cdot 8$	$1+4c^2+16b^4+22c^4+\cdots$
$\mathscr{E}_8$	8	4^4	$8 \cdot 2 \cdot 4!$	$1+16b^4+14c^4+48b^4c+\cdots$
$\mathscr{K}_8$	8	$4^1 2^6$	$2^7 \cdot 8!$	$1+28c^2+70c^4+28c^6+\cdots$
$\mathscr{K}'_8$	8	$4^2 2^4$	$2^7(4!)^2$	$1+12c^2+38c^4+64b^4c+\cdots$
$\mathscr{O}_8$	8	4^4	1344	$1+14c^4+112b^4c+112b^4c^3+\cdots$
$\mathscr{Q}_8$	8	$4^3 2^2$	$2^8 \cdot 4!$	$1+4c^2+22c^4+96b^4c+\cdots$

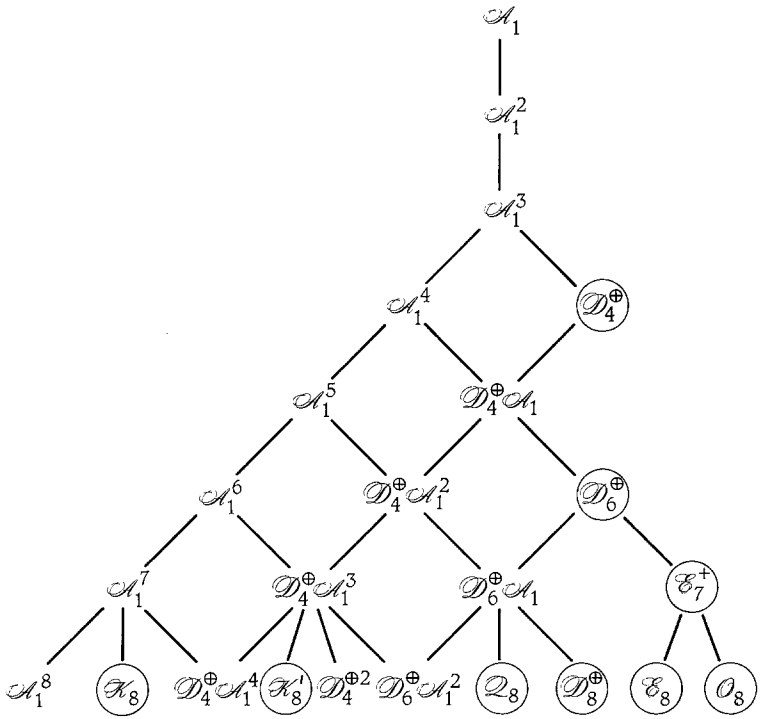

FIG. 2. All self-dual codes of length $n \leqslant 8$. A vertical or sloping line indicates that the upper code can be obtained by shortening the lower code. The indecomposable codes are circled. There are no indecomposable codes of length 9, so that the codes of length 9 are obtainable by adjoining $\mathscr{A}_1$ to the codes of length 8.

a property not shared by self-dual codes over finite fields: a self-dual code $\mathscr{C}$ of length n can be shortened to a self-dual code of length $n-1$ by deleting any one of its coordinates. This is accomplished as follows. If the projection of $\mathscr{C}$ onto the ith coordinate contains all of $\mathbb{Z}_4$, the shortened code is obtained by taking those words of $\mathscr{C}$ that are 0 or 2 in the ith coordinate and omitting that coordinate. If the projection of $\mathscr{C}$ onto the ith coordinate contains only 0 and 2, we take the words of $\mathscr{C}$ that are 0 in the ith coordinate and omit that coordinate.

THEOREM 2. *Any indecomposable self-dual code over $\mathbb{Z}_4$ of length $n \leqslant 9$ is equivalent to one of those shown in Table I. All self-dual codes of length $n \leqslant 8$ are shown in Fig. 2, in which a line indicates that the upper code can be obtained by shortening the lower code.*

For the proofs of Theorems 1 and 2 see Section 3.

In [21], Klemm has studied the conditions satisfied by the complete weight enumerators of self-dual codes over $\mathbb{Z}_4$ (see Theorems 4, 5 below). In Section 2 we deduce analogous theorems for the "symmetrized" and Hamming weight enumerators (see Theorems 6–9), and in Table II we list examples of self-dual codes that realize the basic weight enumerators occurring in all these theorems. The codes themselves are defined in Section 3. Theorem 3 is a general result on obtaining codes over $\mathbb{Z}_4$ from pairs of binary codes.

2. CODES OVER $\mathbb{Z}_4$

We first establish some terminology. By a "code" $\mathscr{C}$ we usually mean an additive subgroup of $\mathbb{Z}_4^n$. We define an inner product on $\mathbb{Z}_4^n$ by $x \cdot y = x_1 y_1 + \cdots + x_n y_n \pmod 4$, and the notions of *dual* code ($\mathscr{C}^*$), *self-orthogonal* code ($\mathscr{C} \subseteq \mathscr{C}^*$) and *self-dual* code ($\mathscr{C} = \mathscr{C}^*$) are then defined in the standard way (cf. [20, 24]). For most applications there is no need to distinguish between $+1$ components of codewords and -1 components, and so we say that two codes are *equivalent* (denoted $\cong$) if one can be obtained from the other by permuting the coordinates and (if necessary) changing the signs of certain coordinates. Codes differing by only a permutation of coordinates are called *permutation-equivalent*. The automorphism group $\mathrm{Aut}(\mathscr{C})$ of $\mathscr{C}$ consists of all permutations and sign-changes of the coordinates that preserve the set of codewords. We denote the order of $\mathrm{Aut}(\mathscr{C})$ by g.

Any code is permutation-equivalent to a code $\mathscr{C}$ with generator matrix of the form

$$\begin{bmatrix} I_{k_1} & A & B \\ 0 & 2I_{k_2} & 2C \end{bmatrix}, \tag{2}$$

where A, B are matrices over $\mathbb{Z}_4$ and C is a $\{0, 1\}$-matrix. The code is then an elementary abelian group of type $4^{k_1}2^{k_2}$, containing $2^{2k_1+k_2}$ codewords. We indicate this by writing $|\mathscr{C}| = 4^{k_1}2^{k_2}$.

The dual code $\mathscr{C}^*$ to (2) has generator matrix

$$\begin{bmatrix} -B^{\mathrm{tr}} - C^{\mathrm{tr}}A^{\mathrm{tr}} & C^{\mathrm{tr}} & I_{n-k_1-k_2} \\ 2A^{\mathrm{tr}} & 2I_{k_2} & 0 \end{bmatrix}, \tag{3}$$

and $|\mathscr{C}^*| = 4^{n-k_1-k_2}2^{k_2}$.

Suppose L (resp. L^*) is the lattice consisting of all integer points congruent modulo 4 to the words of C (resp. C^*). Then the invariant factors of L are

$$4^{k_1}2^{k_2}1^{n-k_1-k_2}$$

and for L^* they are

$$4^{n-k_1-k_2}2^{k_2}1^{k_1}.$$

Let β be the "mod 2" map from $\mathbb{Z}_4$ to $\mathbb{Z}_2$, sending 0 and 2 to 0, 1 and 3 to 1. The kernel $\{0, 2\}$ is isomorphic to $\mathbb{Z}_2$, and we denote this isomorphism by γ, so that $\gamma(0) = 0$, $\gamma(2) = 1$.

There are two binary codes $\mathscr{C}^{(1)}$, $\mathscr{C}^{(2)}$ canonically associated with $\mathscr{C}$:

$$\mathscr{C}^{(1)} = \{\beta(u): u \in \mathscr{C}\},$$
$$\mathscr{C}^{(2)} = \{\gamma(u): u \in \mathscr{C}, \beta(u) = 0\}.$$

$\mathscr{C}^{(1)}$ is an $[n, k_1]$ binary code which (if $\mathscr{C}$ is defined by (2)) has generator matrix

$$[I_{k_1} \quad \beta(A) \quad \beta(B)], \tag{4}$$

while $\mathscr{C}^{(2)} \supseteq \mathscr{C}^{(1)}$ is an $[n, k_1 + k_2]$ binary code with generator matrix

$$\begin{bmatrix} I_{k_1} & \beta(A) & \beta(B) \\ 0 & I_{k_2} & C \end{bmatrix}. \tag{5}$$

If $\mathscr{C}$ is self-orthogonal then $\mathscr{C}^{(1)}$ is a self-orthogonal doubly even binary code and $\mathscr{C}^{(1)} \subseteq \mathscr{C}^{(2)} \subseteq \mathscr{C}^{(1)*}$. Furthermore if $\mathscr{C}$ is self-dual then $\mathscr{C}^{(2)} = \mathscr{C}^{(1)*}$. The next theorem gives the converse assertions.

THEOREM 3. *If $\mathscr{A}$, $\mathscr{B}$ are binary codes with $\mathscr{A} \subseteq \mathscr{B}$ then there is a code $\mathscr{C}$ over $\mathbb{Z}_4$ with $\mathscr{C}^{(1)} = \mathscr{A}$, $\mathscr{C}^{(2)} = \mathscr{B}$. If in addition $\mathscr{A}$ is self-orthogonal and doubly even and $\mathscr{B} \subseteq \mathscr{A}^*$ then there is a self-orthogonal code $\mathscr{C}$ over $\mathbb{Z}_4$ with $\mathscr{C}^{(1)} = \mathscr{A}$, $\mathscr{C}^{(2)} = \mathscr{B}$. Furthermore if $\mathscr{B} = \mathscr{A}^*$ then $\mathscr{C}$ is self-dual.*

Proof. Let $\dim \mathscr{A} = k_1$, $\dim B = k_1 + k_2$. Without loss of generality we may assume that $\mathscr{A}$, $\mathscr{B}$ have generator matrices

$$[I \; X \; Y], \qquad \begin{bmatrix} I & X & Y \\ 0 & I & Z \end{bmatrix}$$

respectively. Then

$$\begin{bmatrix} I & X & Y \\ 0 & 2I & 2Z \end{bmatrix} \tag{6}$$

is a generator matrix for a code $\mathscr{C}$ with $\mathscr{C}^{(1)} = \mathscr{A}$, $\mathscr{C}^{(2)} = \mathscr{B}$. To establish the second assertion we must modify (6) to make $\mathscr{C}$ self-orthogonal. This is accomplished by replacing the (j, i)th entry of (6) by the inner product modulo 4 of rows i and j, for $1 \leqslant i \leqslant k_1$, $1 \leqslant j \leqslant k_1 + k_2$, $i < j$. ∎

In this way every self-*orthogonal* doubly-even binary code corresponds to one or more self-*dual* codes over $\mathbb{Z}_4$. For example the vectors

$$3(200001010011001101011111) \tag{7}$$

—where the parentheses indicate that all cyclic shifts of the parenthesized portion are to be used—generate a self-dual code $\mathscr{G}_{24}$ over $\mathbb{Z}_4$ for which $\mathscr{G}_{24}^{(1)} = \mathscr{G}_{24}^{(2)}$ is the binary Golay code.

The *complete weight enumerator* (or c.w.e.) of $\mathscr{C}$ is

$$\mathrm{cwe}_{\mathscr{C}}(a, b, c, d) = \sum_{u \in \mathscr{C}} a^{n_0(u)} b^{n_1(u)} c^{n_2(u)} d^{n_3(u)}, \tag{8}$$

where $n_i(u)$ is the number of components of u that are congruent to i (mod 4) (cf. [20, 24, p. 141]). Permutation-equivalent codes have the same c.w.e., but equivalent codes may have distinct c.w.e's. The appropriate weight enumerator for an equivalence class of codes is what we call the *symmetrized weight enumerator* (or s.w.e.), obtained by identifying b and d in (8):

$$\mathrm{swe}_{\mathscr{C}}(a, b, c) = \mathrm{cwe}_{\mathscr{C}}(a, b, c, b). \tag{9}$$

This is equivalent to the "weight function" $W(Z_1, Z_2, Z_4)$ of Klemm [20]. The *Hamming weight enumerator* of $\mathscr{C}$ is

$$W_{\mathscr{C}}(a, b) = \mathrm{cwe}_{\mathscr{C}}(a, b, b, b). \tag{10}$$

The theorems stated below require that we work with homogeneous polynomials, but sometimes—as in Table I—it is simpler to set $a = 1$.

There are several other criteria for judging a code $\mathscr{C}$ over $\mathbb{Z}_4$ besides its minimal Hamming weight. One may consider its minimal *Euclidean norm*, defined by $N(0)=0$, $N(\pm 1)=1$, $N(2)=4$ (cf. [4]), which can be found from $\mathrm{swe}_{\mathscr{C}}(1, x, x^4)$. In [13] (see also [9, 14]) the Leech lattice was constructed by combining eight copies of the face-centered cubic lattice using the code $\mathscr{C}=\mathscr{O}_8$. For this type of construction one needs the minimal *A_3-norm* of $\mathscr{C}$, defined by $N(0)=0$, $N(\pm 1)=3/4$, $N(2)=1$, which can be found from $\mathrm{swe}_{\mathscr{C}}(1, x^{3/4}, x)$.

Klemm [21, Theorem 1.5] gives an analog of the MacWilliams identity,

$$\mathrm{cwe}_{\mathscr{C}^*}(a, b, c, d)=\frac{1}{|\mathscr{C}|}\,\mathrm{cwe}_{\mathscr{C}}(a+b+c+d,\ a+ib-c-id,\ a-b+c-d,\ a-ib-c+id), \tag{11}$$

which implies

$$\mathrm{swe}_{\mathscr{C}^*}(a, b, c)=\frac{1}{|\mathscr{C}|}\,\mathrm{swe}_{\mathscr{C}}(a+2b+c,\ a-c,\ a-2b+c) \tag{12}$$

(this is also a special case of Theorem 1.2 of Klemm [20]), and

$$W_{\mathscr{C}^*}(a, b)=\frac{1}{|\mathscr{C}|}\,W_{\mathscr{C}}(a+3b,\ a-b). \tag{13}$$

Klemm observes that (11) is simpler when stated in terms of the variables

$$\bar{a}=\frac{a+c}{\sqrt{2}},\qquad \bar{b}=\frac{b+d}{\sqrt{2}},\qquad \bar{c}=\frac{a-c}{\sqrt{2}},\qquad \bar{d}=\frac{b-d}{\sqrt{2}}. \tag{14}$$

Let $\overline{\mathrm{cwe}}_{\mathscr{C}}$ denote the c.w.e. of $\mathscr{C}$ when written as a function of $\bar{a}$, $\bar{b}$, $\bar{c}$, $\bar{d}$. Then (11) implies [21, Theorem 1.5]

$$\overline{\mathrm{cwe}}_{\mathscr{C}^*}(\bar{a}, \bar{b}, \bar{c}, \bar{d})=\frac{2^n}{|\mathscr{C}|}\,\overline{\mathrm{cwe}}_{\mathscr{C}}(\bar{a}, \bar{c}, \bar{b}, i\bar{d}). \tag{15}$$

The main results of [21] are the following two theorems.

THEOREM 4 (Klemm [21]). *The c.w.e. of a self-dual code over $\mathbb{Z}_4$ belongs to the ring*

$$\mathbb{C}[\theta_1, \theta_{4a}, \theta_{4b}, \theta_8]\oplus\theta_{10}\mathbb{C}[\theta_1, \theta_{4a}, \theta_{4b}, \theta_8], \tag{16}$$

where

$$\begin{aligned}&\theta_1=\bar{a},\qquad \theta_{4a}=(\bar{b}^4+\bar{c}^4),\qquad \theta_{4b}=\bar{d}^4,\\ &\theta_8=\bar{b}^4\bar{c}^4,\qquad \theta_{10}=(\bar{b}\bar{c}\bar{d})^2\,(\bar{b}^4-\bar{c}^4).\end{aligned} \tag{17}$$

This ring has the Molien series (*cf.* [24, 27])

$$\frac{1+\lambda^{10}}{(1-\lambda)(1-\lambda^4)^2(1-\lambda^8)}. \tag{18}$$

THEOREM 5 (Klemm [21]). *The c.w.e. of a self-dual code over* $\mathbb{Z}_4$ *that contains the all-one vector belongs to the ring*

$$R \oplus \sigma_8 R \oplus \sigma_8^2 R \oplus \sigma_{16} R \oplus \sigma_8 \sigma_{16} R \oplus \sigma_8^2 \sigma_{16} R, \tag{19}$$

where R *is the ring of symmetric functions of* $\bar{a}^4$, $\bar{b}^4$, $\bar{c}^4$, *and* $\bar{d}^4$, *and*

$$\begin{aligned} \sigma_8 &= \bar{a}^4\bar{d}^4 + \bar{b}^4\bar{c}^4, \\ \sigma_{16} &= (\bar{a}\bar{b}\bar{c}\bar{d})^2\,(\bar{a}^4\bar{b}^4 + \bar{c}^4\bar{d}^4 - \bar{a}^4\bar{c}^4 - \bar{b}^4\bar{d}^4). \end{aligned} \tag{20}$$

This ring has the Molien series

$$\frac{(1+\lambda^8+\lambda^{16})(1+\lambda^{16})}{(1-\lambda^4)(1-\lambda^8)(1-\lambda^{12})(1-\lambda^{16})}. \tag{21}$$

The analogous theorems for symmetric and Hamming weight enumerators follow easily from Theorems 4 and 5; we omit the proofs.

THEOREM 6. *The s.w.e. of a self-dual code over* $\mathbb{Z}_4$ *belongs to the ring*

$$\mathbb{C}[\tilde{a}, \tilde{b}^4 + \tilde{c}^4, \tilde{b}^4\tilde{c}^4], \tag{22}$$

where

$$\tilde{a} = \frac{a+c}{\sqrt{2}}, \qquad \tilde{b} = \sqrt{2}\,b, \qquad \tilde{c} = \frac{a-c}{\sqrt{2}}. \tag{23}$$

This ring has the Molien series

$$\frac{1}{(1-\lambda)(1-\lambda^4)(1-\lambda^8)}. \tag{24}$$

An alternative basis is given by the polynomials

$$\begin{aligned} \phi_1 &= a + c \\ \phi_4 &= 2b^4 - ac(a^2 + c^2), \\ \phi_8 &= b^4(a-c)^4. \end{aligned} \tag{25}$$

THEOREM 7. *The s.w.e. of a self-dual code of length n over $\mathbb{Z}_4$ containing a vector $\pm 1^n$ belongs to the ring*

$$S \oplus \tilde{b}^4\tilde{c}^4 S \oplus \tilde{b}^8\tilde{c}^8 S, \tag{26}$$

where S is the ring of symmetric functions of $\tilde{a}^4$, $\tilde{b}^4$, $\tilde{c}^4$. This ring has the Molien series

$$\frac{1+\lambda^8+\lambda^{16}}{(1-\lambda^4)(1-\lambda^8)(1-\lambda^{12})}. \tag{27}$$

An explicit basis for S is given by the polynomials

$$\begin{aligned} \Phi_4 &= a^4 + 6a^2c^2 + 8b^4 + c^4, \\ \Phi_8 &= (a^2c^2 - b^4)((a^2+c^2)^2 - 4b^4), \\ \Phi_{12} &= b^4(a^2-c^2)^4, \end{aligned} \tag{28}$$

and then the ring is $S \oplus \Psi_8 S \oplus \Psi_8^2 S$, where

$$\Psi_8 = b^4(a-c)^4, \tag{29}$$

with

$$\Psi_8^3 = \Psi_8^2\left(\frac{1}{16}\Phi_4^2 - \Phi_8\right) - \frac{1}{8}\Psi_8\Phi_4\Phi_{12} + \frac{1}{16}\Phi_{12}^2. \tag{30}$$

THEOREM 8. *The Hamming weight enumerator of a self-dual code over $\mathbb{Z}_4$ belongs to the ring*

$$\mathbb{C}[w_1, w_4] \oplus w_8\mathbb{C}[w_1, w_4], \tag{31}$$

where

$$\begin{aligned} w_1 &= a+b, \\ w_4 &= ab(a^2+b^2) - 2b^4, \\ w_8 &= b^4(a-b)^4, \end{aligned} \tag{32}$$

and

$$w_8^2 = w_8(w_1^8 - 4w_1^4w_4 + 2w_4^2) - w_4^4. \tag{33}$$

This ring has the Molien series

$$\frac{1+\lambda^8}{(1-\lambda)(1-\lambda^4)}. \tag{34}$$

THEOREM 9. *The Hamming weight enumerator of a self-dual code of length n over $\mathbb{Z}_4$ containing a vector $\pm 1^n$ belongs to the ring*

$$\mathbb{C}[W_4, W_8] \oplus X_8\mathbb{C}[W_4, W_8] \oplus X_{12}\mathbb{C}[W_4, W_8] \oplus X_8X_{12}\mathbb{C}[W_4, W_8], \tag{35}$$

where

$$\begin{aligned} W_4 &= (a^2 + 3b^2)^2, \\ W_8 &= b^4(a-b)^4, \\ X_8 &= b^2(a^2 - b^2)^2\,(a^2 + 3b^2), \\ X_{12} &= b^4(a^2 - b^2)^4, \end{aligned} \tag{36}$$

with

$$\begin{aligned} X_8^2 &= W_4X_{12}, \\ X_{12}^2 &= 2X_{12}W_4W_8 + W_8^2(16X_8 - W_4^2) + 16W_8^3. \end{aligned} \tag{37}$$

This ring has the Molien series

$$\frac{(1+\lambda^8)(1+\lambda^{12})}{(1-\lambda^4)(1-\lambda^8)}. \tag{38}$$

A question left unanswered by Klemm in [21] is whether one can find a set of codes with lengths equal to the degrees of the basic polynomials in Theorems 4 and 5 and whose *c.w.e*'s are a polynomial basis for the rings (16) and (19). In other words, are there analogues of Gleason's theorem that says (for example) that the weight enumerator of a self-dual doubly even binary code is a polynomial in the weight enumerators of the Hamming and Golay codes (cf. [3, 16, 23, 24, 27])? Similar questions can be asked about Theorems 6–9.

The affirmative answers to these questions are obtained using the codes listed in Table II.

TABLE II

Theorem	Corresponding Codes
4	$\mathscr{A}_1$, $\mathscr{D}_4^{\oplus}$ in two versions (39a), (39b), $\mathscr{O}_8$ (41); $\mathscr{C}_{10}$ (45)
5	$\mathscr{K}_4$, $\mathscr{K}_8$, $\mathscr{K}_{12}$, $\mathscr{K}_{16}$ (43); $\mathscr{O}_8$ (41), $\mathscr{C}_{16}$ (45)
6	$\mathscr{A}_1$, $\mathscr{D}_4^{\oplus}$, $\mathscr{O}_8$
7	$\mathscr{K}_4$, $\mathscr{K}_8$, $\mathscr{K}_{12}$; $\mathscr{O}_8$
8	$\mathscr{A}_1$, $\mathscr{D}_4^{\oplus}$; $\mathscr{O}_8$
9	$\mathscr{K}_4$, $\mathscr{O}_8$; $\mathscr{K}_8$, $\mathscr{K}_{12}$

The codes mentioned in Table II are defined in Section 3. In general we use the same name for all codes in an equivalence class, but for the first two lines of Table II we include equation numbers to identify particular representatives from the equivalence classes. The codes before the semicolons have algebraically independent weight enumerators, and correspond to the terms in the denominators of the Molien series (18, 21, etc.), while those after the semicolon correspond to the terms in the numerator. We discuss this table further in Section 3.

3. Examples of Self-Orthogonal and Self-Dual Codes over $\mathbb{Z}_4$

The smallest self-dual code is $\mathscr{A}_1 = \{0, 2\}$, with symmetrized weight enumerator $a + c$ and $g = |\mathrm{Aut}(\mathscr{A}_1)| = 2$ (the transformation that negates all coordinates is always in $\mathrm{Aut}(\mathscr{C})$).

If a self-orthogonal code $\mathscr{C}$ contains a vector of type $2^1 0^{n-1}$ then $\mathscr{C} \cong \mathscr{A}_1 \oplus \mathscr{C}'$ is decomposable. The next-simplest possible vectors are "tetrads," of type $\pm 1^4 0^{n-4}$ (see Section 1). We now list a number of self-orthogonal codes that are generated by tetrads; t denotes the total number of tetrads in the code.

The first four codes have the property that the associated binary code $\mathscr{C}^{(1)}$ is the self-dual code d_{2m} of [10, 12].

$\mathscr{D}_{2m}$ ($m \geqslant 2$—the subscript gives the length) is generated by the tetrads 11130...0, 0011130...0, ..., 0...01113; $|\mathscr{D}_{2m}| = 4^{m-1}$, $g = 2 \cdot 4!$ ($m = 2$) or $2^2 \cdot 2^m$ ($m > 2$), $t = 2(m-1)$. $\mathscr{D}_{2m}^*/\mathscr{D}_{2m}$ is a group of type 4^2 with generators $v_1 = 0101...01$, $v_2 = 00...0011$.

$\mathscr{D}_{2m}^{\circ}$ ($m \geqslant 2$) is generated by $\mathscr{D}_{2m}$ and the tetrad 1300...0011 (or equivalently the vector 2020...20); $|\mathscr{D}_{2m}^{\circ}| = 4^{m-1}2$, $g = 2^2 \cdot 8(m=2)$ or $2 \cdot 2^{m-1} \cdot 2m (m > 2)$, $t = 2m$. $(\mathscr{D}_{2m}^{\circ})^*/\mathscr{D}_{2m}^{\circ}$ is a cyclic group of order 4 generated by v_1 (if m is odd), or a 4-group generated by v_1 and $2v_2$ (if m is even).

$\mathscr{D}_{2m}^{+}$ ($m \geqslant 2$, but note that $\mathscr{D}_4^{+} \cong \mathscr{D}_4^{\circ}$) is generated by $\mathscr{D}_{2m}$ and $2v_2$; $|\mathscr{D}_{2m}^{+}| = 4^{m-1}2$, $g = 2^m \cdot 2^{m+1}$, $t = 4(m-1)$. $(\mathscr{D}_{2m}^{+})^*/\mathscr{D}_{2m}^{+}$ is a 4-group generated by $2v_1$ and v_2.

$\mathscr{D}_{2m}^{\oplus}$ ($m \geqslant 2$) is the self-dual code generated by $\mathscr{D}_{2m}^{\circ}$ and $\mathscr{D}_{2m}^{+}$; $|\mathscr{D}_{2m}^{\oplus}| = 4^{m-1}2^2$, $g = 2^3 \cdot 4!$ ($m = 2$) or $2^m \cdot 2^m \cdot 2m$ ($m \geqslant 2$), $t = 4m$. For use in Table II we note that there are two permutation-inequivalent versions of $\mathscr{D}_4^{\oplus}$, with generator matrices

$$\text{(a)} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 2 & 0 & 2 \\ 0 & 0 & 2 & 2 \end{bmatrix}, \qquad \text{(b)} \begin{bmatrix} 1 & 3 & 3 & 3 \\ 0 & 2 & 0 & 2 \\ 0 & 0 & 2 & 2 \end{bmatrix}. \tag{39}$$

$\mathscr{D}_4^{\oplus}$ (in either version) has swe $= a^4 + 6a^2c^2 + c^4 + 8b^4$.

$\mathscr{E}_7$ is generated by 1003110, 1010031, 1101003; $|\mathscr{E}_7| = 4^3$, $g = 2 \cdot 4!$, $t = 8$. $\mathscr{E}_7^*/\mathscr{E}_7$ is a cyclic group of order 4 generated by 3111111.

$\mathscr{E}_7^+$ is the self-dual code generated by $\mathscr{E}_7$ and 2222222 (or equivalently by all cyclic shifts of 3110100); $|\mathscr{E}_7^+| = 4^3 2$, $g = 2 \cdot 168$, $t = 14$, swe $= a^7 + c^7 + 14b^4(a^3 + c^3) + 7a^3c^3(a + c) + 42ab^4c(a + c)$. For both $\mathscr{E}_7$ and $\mathscr{E}_7^+$ the associated binary code $\mathscr{C}^{(1)}$ is the dual Hamming code e_7.

$\mathscr{E}_8$ is the self-dual code generated by $0u$, $u \in \mathscr{E}_7$ and 30001011, or equivalently is the code defined by the generator matrix

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 3 & 0 & 1 & 3 \\ 0 & 0 & 1 & 0 & 3 & 3 & 0 & 1 \\ 0 & 0 & 0 & 1 & 3 & 1 & 3 & 0 \end{bmatrix}; \tag{40}$$

$|\mathscr{E}_8| = 4^4$, $g = 8 \cdot 2 \cdot 4! = 384$, $t = 16$, swe $= a^8 + 16b^8 + c^8 + 16b^4(a^4 + c^4) + 14a^4c^4 + 48ab^4c(a^2 + c^2) + 96a^2b^4c^2$.

Proof of Theorem 1. It is now easy to verify (using Fig. 1 as a guide) that the preceding codes are, up to equivalence, the only ones generated by tetrads; we omit the details. ▮

We next list some further examples of self-dual codes.

The *octacode* $\mathscr{O}_8$ (cf. [9, 13, 14]) is the self-dual code generated by the vectors

$$3(2001011), \tag{41}$$

or equivalently is the code defined by the generator matrix

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 2 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 3 & 2 & 1 & 3 \\ 0 & 0 & 1 & 0 & 3 & 3 & 2 & 1 \\ 0 & 0 & 0 & 1 & 3 & 1 & 3 & 2 \end{bmatrix}; \tag{42}$$

$|\mathscr{O}_8| = 4^4$, $g = 1344$, $t = 0$, swe $= a^8 + 16b^8 + c^8 + 14a^4c^4 + 112ab^4c(a^2 + c^2)$. For both $\mathscr{E}_8$ and $\mathscr{O}_8$ the associated binary code $\mathscr{C}^{(1)}$ is the Hamming code e_8.

The matrices (40) and (42) may be generalized as follows. Let H_n be a skew-type Hadamard matrix of order $n \equiv 0 \pmod 4$ [19, p. 244; 30, pp. 292, 451, 459], with $H_n = I_n + S_n$, $S_n = -S_n^{\mathrm{tr}}$, $S_n S_n^{\mathrm{tr}} = (n-1) I_n$. Then both $[I_n \mid S_n]$ and $[I_n \mid S_n + 2I_n]$ are generator matrices for self-dual codes of length $2n$. Examples are known for $n = 4, 8, 12, \ldots, 112$.

$\mathscr{Q}_8$ is the self-dual code obtained by taking the 16-word code generated

by all even permutations of 0123 and replacing 0 by 00 or 22, 1 by 11 or 33, 2 by 02 or 20, and 3 by 13 or 31. $\mathscr{Q}_8$ has generator matrix

$$\begin{bmatrix} 00 & 11 & 02 & 13 \\ 00 & 02 & 13 & 11 \\ 11 & 02 & 00 & 13 \\ 02 & 02 & 02 & 02 \\ 00 & 00 & 00 & 22 \end{bmatrix};$$

$|\mathscr{Q}_8| = 4^3 2^2$, $g = 2^8 \cdot 4! = 6144$, $t = 0$, swe $= a^8 + 32b^8 + c^8 + 4a^2c^2(a^4 + c^4) + 22a^4c^4 + 96ab^4c(a^2 + c^2)$.

$\mathscr{K}_{4m}$ ($m \geqslant 1$, but note that $\mathscr{K}_4 \cong \mathscr{D}_4^{\oplus}$) is a self-dual code introduced by Klemm [21], having generator matrix

$$\begin{bmatrix} 1 & 1 & 1 & \cdots & 1 & 1 \\ 0 & 2 & 0 & \cdots & 0 & 2 \\ 0 & 0 & 2 & \cdots & 0 & 2 \\ . & . & . & \cdots & . & . \\ 0 & 0 & 0 & \cdots & 2 & 2 \end{bmatrix}; \tag{43}$$

$|\mathscr{K}_{4m}| = 4^1 2^{4m-2}$, $g = 2^{4m-1}(4m)!$, cwe $= 2^{2m-1}(\bar{a}^{4m} + \bar{b}^{4m} + \bar{c}^{4m} + \bar{d}^{4m})$ (see (14)).

More generally, given any graph G with k vertices labeled by positive integers $m_1, \ldots, m_k$ and node-node adjacency matrix $A = (a_{ij})$, there is a self-dual code of length $n = 4m + \cdots + 4m_k$ generated by (i) the vectors

$$v_i = v_{i1} \cdots v_{ik}, \qquad (1 \leqslant i \leqslant k),$$

where $v_{ii} = 1^{4m_i}$, $v_{ij} = 0^{4m_j}$, if $a_{ij} = 0$ or $v_{ij} = 0^{4m_j - 1}2$ if $a_{ij} = 1$, together with (ii) the vectors that have evenly many 2's on each of the k coordinate blocks. $\mathscr{K}_{4m}$ itself is the case where G consists of a single vertex. When G consists of a single edge joining a pair of vertices labeled 1 we obtain a code $\mathscr{K}'_8$ with generator matrix

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 2 & 1 & 1 & 1 & 1 \\ 0 & 2 & 0 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 2 & 0 & 2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 2 & 2 \end{bmatrix}; \tag{44}$$

$|\mathscr{K}'_8| = 4^2 2^4$, $g = 2 \cdot 2^6 \cdot (4!)^2 = 73728$, $t = 0$, swe $= a^8 + 64b^8 + c^8 + 12a^2c^2(a^4 + c^4) + 38a^4c^4 + 64ab^4c(a^2 + c^2)$.

$\mathscr{C}_{10}$ is the self-dual code with generator matrix

$$\begin{bmatrix} 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 3 & 3 & 1 & 0 \\ 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 2 & 2 \end{bmatrix}, \tag{45}$$

and $|\mathscr{C}_{10}| = 4^2 2^6$. This code, used in Table II, was found as a "neighbor" (defined as in [15]) of the direct sum of $d_4^{\oplus}$ and $d_6^{\oplus}$.

Let A be the point-block incidence matrix of a symmetric (v, k, λ)-design for which λ is odd and $k - \lambda \equiv 4 \pmod 8$. Klemm [20, 21] shows that the rows of A span a code $\mathscr{C}$ of length v with $\mathscr{C} = \langle \mathscr{C}^*, 1^v \rangle$, and that $\langle \mathscr{C}^*, 2^v \rangle$ is self-dual. If in addition $\lambda \equiv 3 \pmod 4$ then, by adding an extra coordinate to $\mathscr{C}$ to make the sum of the coordinates zero, we obtain a self-dual code $\mathscr{D}_{v+1}$ containing 1^{v+1}.

For example, any normalized Hadamard matrix H_n of order $n \equiv 16 \pmod{32}$ produces a self-dual code $\mathscr{D}_n$ of length n. $\mathscr{D}_n$ is generated by the vector 1^n and the rows of the matrix obtained from H_n by replacing $+1$ entries by 0 and -1 entries by 1.

There are five distinct Hadamard matrices of order 16 [1, 2, 4, 17, 18, 25, 29], from which we obtain five self-dual codes $\mathscr{D}_{16}$ of length 16. These are inequivalent, since the associated binary codes $\mathscr{D}_{16}^{(1)}$ have been shown by Assmus and Key [2] to be inequivalent. Unfortunately none of the c.w.e.'s of these five codes involves the polynomial σ_{16} of Theorem 5. However, by taking a neighbor of the second code $\mathscr{D}_{16}$ (in the Assmus–Key ordering [2]), we obtain a self-dual code $\mathscr{C}_{16}$ with generator matrix

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 3 & 3 & 1 & 0 & 3 & 2 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 3 & 3 & 1 & 1 & 2 & 3 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 2 & 2 & 0 & 3 & 3 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 3 & 0 & 2 & 3 & 3 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 3 & 2 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 2 & 0 & 2 & 0 & 2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 2 & 2 & 2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 2 & 2 & 2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 2 & 0 & 0 \end{bmatrix}, \tag{46}$$

whose c.w.e. does involve σ_{16}.

Notes on Table II. We illustrate Table II by expressing the symmetrized weight enumerators of the codes in the fourth line of the table in terms of the basic polynomials given in Theorem 7:

$$\begin{aligned}
\mathrm{swe}_{\mathscr{K}_4} &= \Phi_4, \\
\mathrm{swe}_{\mathscr{K}_8} &= \Phi_8 + 16\Phi_4^2, \\
\mathrm{swe}_{\mathscr{K}_{12}} &= 24\Phi_{12} + 48\Phi_4\Phi_8 + \Phi_4^3, \\
\mathrm{swe}_{\mathscr{O}_8} &= -28\Psi_8 - 12\Phi_8 + \Phi_4^2.
\end{aligned}$$

Proof of Theorem 2. Let $\mathscr{C}$ be an indecomposable self-dual code of length $n \geqslant 2$, and let $\mathscr{C}^{(1)}$ be the associated binary code. The projection of $\mathscr{C}$ onto any coordinate must be all of $\mathbb{Z}_4$ (for otherwise $\mathscr{C}^* = \mathscr{C}$ contains a subcode isomorphic to $\mathscr{A}_1$ and is decomposable). $\mathscr{C}^{(1)}$ is therefore a binary self-orthogonal doubly even code in which no coordinate position is identically zero. There are no such codes of lengths 2, 3, 5, or 9.

For length 4 we have $\mathscr{C}^{(1)} = d_4 = \{0^4, 1^4\}$, which forces $\mathscr{C} \cong \mathscr{D}_4^{\oplus} \cong \mathscr{K}_4$. In general, if $\dim \mathscr{C}^{(1)} = 1$, then $\mathscr{C} \cong \mathscr{K}_n$.

For lengths 6, 7, 8 and $\dim \mathscr{C}^{(1)} \geqslant 2$, $\mathscr{C}^{(1)}$ is one of d_6, e_7, d_4^2, d_8 or e_8, and it is not difficult to show that the codes listed in Table I are the only possibilities for $\mathscr{C}$. ∎

We end with a question: is there a "mass formula" for self-dual codes over $\mathbb{Z}_4$, analogous to those for codes over $GF(2)$ [24^2, Chap. 19, Corollaries 19 and 23; 28, (9.1.1) and (9.1.2)], $GF(3)$ [11, p. 313; 28, (9.1.3)], $GF(4)$ [11, p. 313; 28, (9.1.4)] and $GF(5)$ [22]?

Acknowledgments

We thank E. F. Assmus, Jr., T. Etzion, and M. Klemm for helpful comments.

Note added in proof. Mitchell Trott of M.I.T. recently discovered that the Nordstrom–Robinson nonlinear binary code [24, p. 73] can be viewed as a linear code over $\mathbb{Z}_4$. In fact, the octacode $\mathscr{O}_8$ becomes the Nordstrom–Robinson code after the mapping $0 \to 00$, $1 \to 01$, $2 \to 11$, $3 \to 10$. We should have noticed this years ago!
