SERIAL AND PARALLEL BACKPROPAGATION CONVERGENCE VIA NONMONOTONE PERTURBED MINIMIZATION

O. L. Mangasarian[†] and M. V. Solodov[†]

Technical Report # 1149
April 1993

ABSTRACT

A general convergence theorem is proposed for a family of serial and parallel nonmonotone unconstrained minimization methods with perturbations. A principal application of the theorem is to establish convergence of backpropagation (BP), the classical algorithm for training artificial neural networks. Under certain natural assumptions, such as divergence of the sum of the learning rates and convergence of the sum of their squares, it is shown that every accumulation point of the BP iterates is a stationary point of the error function associated with the given set of training examples. The results presented cover serial and parallel BP, as well as modified BP with a momentum term.

1 Introduction

We consider the following unconstrained optimization problem

$$\min_{x \in \mathfrak{R}^n} f(x) \tag{1.1}$$

where $f : \mathfrak{R}^n \rightarrow \mathfrak{R}$ is a continuously differentiable function from the n -dimensional real space \mathfrak{R}^n to the real numbers \mathfrak{R} .

We start with a nonmonotone convergence theorem for unconstrained optimization algorithms (Theorem 2.1 below). This result generalizes the monotone Theorem 2.1 of [11] by adding perturbations to the algorithms that result in a nonmonotone sequence of function values. This is a key generalization that allows the proposed theorems to apply to a wider class of algorithms including backpropagation. We shall establish that every accumulation point of the sequence generated by such perturbed algorithms is a stationary point for the minimization problem (1.1). We further show that algorithms based on appropriately perturbed gradient directions fall within the presented framework (Corollary 2.1).

Of particular interest for us will be the special case when the function $f(x)$ is given by a summation of a finite number of functions $f_j(x), j = 1, \dots, N$ for some $N \geq 1$. That is

$$f(x) = \sum_{j=1}^N f_j(x) \tag{1.2}$$

We note that this is exactly the case for the BP algorithm for training artificial neural networks ([10]), where N is the number of examples in the training set.

Motivated by the parallel BP we present a parallel version of Corollary 2.1 (Theorem 2.2). In particular, we consider the case when the functions $f_j(x), j = 1, \dots, N$ are distributed among k processors. Under the same assumptions as those of Corollary 2.1, convergence of the gradient of the objective function of the problem (1.1) to zero is established (Theorem 2.2).

We note that a primary goal of this paper is the convergence analysis of the classical BP algorithm ([15],[7],[16],[8]). BP has long been successfully used by the artificial intelligence community for training artificial neural networks. Curiously, there seems to be no published *deterministic* convergence results for this method. The primary reason for this seems to be the nonmonotonic nature of the process. Every iteration of on-line BP is a step in the

direction of negative gradient of a partial error function associated with a single training example (e.g. $f_j(x)$ in (1.2)). It is clear that there is no guarantee that such a step will decrease the full objective function $f(x)$, which is the sum of the errors for *all* the training examples . Therefore a single iteration of BP may, in fact, increase rather than decrease the objective function $f(x)$ we are trying to minimize. This difficulty makes convergence analysis of BP a challenging problem that has currently attracted interest of many researchers ([5],[6],[9],[4],[17]).

In [17] White by using *stochastic* approximation ideas ([1],[3]) has shown that, under certain stochastic assumptions, the sequence of weights generated by BP either diverges or converges almost surely to a point that is a stationary point of the error function. More recently, stochastic analysis was also used in [4]. We emphasize that our approach is purely *deterministic*. In fact, we show that BP can be viewed as an ordinary perturbed gradient-type algorithm for unconstrained optimization (Theorem 3.1). We give a convergence result for serial and parallel BP as well as the modified BP with a *momentum term*. There seems to be a consensus in the artificial intelligence community that the use of a momentum term generally yields superior computational results than pure BP ([15],[6]).

The paper is organized as follows. In Section 2 we establish the serial and parallel versions of our nonmonotone convergence theorem for unconstrained optimization. We also show that this theorem can be applied to the analysis of a family of optimization methods with perturbed gradients. In Section 3 we concentrate on the BP algorithm for training neural networks, and apply the results of Section 2 to establish its convergence. Section 4 contains some concluding remarks.

We briefly describe our notation. All the vectors are column-vectors. For x in \mathfrak{R}^n , x^T denotes its transpose. Throughout the paper, $\|\cdot\|$ denotes the two-norm, that is $\|x\| = (x^T x)^{\frac{1}{2}}$ for x in \mathfrak{R}^n . For a differentiable function $f : \mathfrak{R}^n \rightarrow \mathfrak{R}$, ∇f will denote its gradient. If a function f is continuously differentiable on \mathfrak{R}^n , we shall write $f \in C^1(\mathfrak{R}^n)$. If f has Lipschitz continuous partial derivatives on \mathfrak{R}^n with some constant $L > 0$, that is

$$\|\nabla f(y) - \nabla f(x)\| \leq L\|y - x\| \quad \forall x, y \in \mathfrak{R}^n,$$

we write $f \in LC_L^1(\mathfrak{R}^n)$. \mathfrak{R}_+ will denote the nonnegative real line, that is $x \in \mathfrak{R}$ and $x \geq 0$.

2 Convergence of Algorithms with Perturbations

We start with a convergent nonmonotone algorithm theorem for the solution of the unconstrained minimization problem (1.1). Our result is much in the spirit of ([11]), except for the key difference of nonmonotonicity. We first define a forcing function.

Definition 2.1. *A continuous function $\sigma : \mathfrak{R}_+ \rightarrow \mathfrak{R}_+$ such that $\sigma(0) = 0, \sigma(t) > 0$ for $t > 0$, and such that $t^i \geq 0$ and $\{\sigma(t^i)\} \rightarrow 0$ imply that $\{t^i\} \rightarrow 0$, is said to be a forcing function.*

Some typical examples of forcing functions are ct, ct^2 for some $c > 0$.

We now state a classical lemma ([13],p.144, [14],p.6) that will be used later, as well as another lemma used in the proof of Theorem 2.1.

Lemma 2.1. *Let $f \in LC_L^1(\mathfrak{R}^n)$, then*

$$|f(y) - f(x) - \nabla f(x)^T(y - x)| \leq \frac{L}{2} \|y - x\|^2 \quad \forall x, y \in \mathfrak{R}^n$$

Lemma 2.2.([2]) *Let $\{a^i\}$ and $\{\epsilon^i\}$ be two sequences of nonnegative real numbers with $\sum_{i=0}^{\infty} \epsilon^i < \infty$ and $0 \leq a^{i+1} \leq a^i + \epsilon^i$ for $i = 0, 1, \dots$, then the sequence $\{a^i\}$ converges.*

We are now ready to state and prove our first result.

Theorem 2.1. *Let $f \in C^1(\mathfrak{R}^n)$ and let $\inf_{x \in \mathfrak{R}^n} f(x) = \bar{f} > -\infty$. Start with any $x^0 \in \mathfrak{R}^n$. Having x^i stop if $\nabla f(x^i) = 0$, else compute $x^{i+1} = x^i + \eta_i d^i$ according to a direction d^i and stepsize η^i chosen as follows*

Direction d^i :

$$-\nabla f(x^i)^T d^i \geq \sigma(\|\nabla f(x^i)\|) - \lambda_i \tag{2.1}$$

where $\lambda_i \geq 0$ and $\sigma(\cdot)$ is a forcing function .

Stepsize η_i :

$$f(x^i) - f(x^{i+1}) \geq -\eta_i \nabla f(x^i)^T d^i - \nu_i, \quad \eta_i > 0, \nu_i \geq 0 \tag{2.2}$$

If

$$\sum_{i=0}^{\infty} \eta_i = \infty, \quad \sum_{i=0}^{\infty} \lambda_i \eta_i < \infty, \quad \sum_{i=0}^{\infty} \nu_i < \infty \tag{2.3}$$

then the sequence $\{f(x^i)\}$ converges, and $\inf_i \|\nabla f(x^i)\| = 0$. If, in addition, $f \in LC_L^1(\mathfrak{R}^n)$ and $\|d^i\| \leq c, \forall i, c > 0$, it follows that $\{\nabla f(x^i)\} \rightarrow 0$, and for each accumulation point \bar{x} of the sequence $\{x^i\}$, $\nabla f(\bar{x}) = 0$.

Proof. If $\nabla f(x^{\bar{i}}) = 0$ for some \bar{i} , then the algorithm terminates at a stationary point. Suppose now that it does not terminate.

Combining (2.1) and (2.2) we have

$$f(x^i) - f(x^{i+1}) \geq \eta_i \sigma(\|\nabla f(x^i)\|) - \lambda_i \eta_i - \nu_i \quad (2.4)$$

Hence

$$0 \leq f(x^{i+1}) - \bar{f} \leq f(x^i) - \bar{f} + \lambda_i \eta_i + \nu_i$$

By (2.3) and Lemma 2.2, the sequence $\{f(x^i) - \bar{f}\}$ converges, and so does the sequence $\{f(x^i)\}$.

Applying (2.4) to the first summation below we obtain

$$\begin{aligned} f(x^0) - \bar{f} &\geq f(x^0) - f(x^i) = \sum_{j=0}^{i-1} (f(x^j) - f(x^{j+1})) \\ &\geq \sum_{j=0}^{i-1} \eta_j \sigma(\|\nabla f(x^j)\|) - \sum_{j=0}^{i-1} (\lambda_j \eta_j + \nu_j) \\ &\geq \inf_{0 \leq j \leq i-1} \sigma(\|\nabla f(x^j)\|) \sum_{j=0}^{i-1} \eta_j - \sum_{j=0}^{i-1} \lambda_j \eta_j - \sum_{j=0}^{i-1} \nu_j \end{aligned} \quad (2.5)$$

By letting $i \rightarrow \infty$ we obtain

$$f(x^0) - \bar{f} \geq \inf_{j \geq 0} \sigma(\|\nabla f(x^j)\|) \sum_{j=0}^{\infty} \eta_j - \sum_{j=0}^{\infty} \lambda_j \eta_j - \sum_{j=0}^{\infty} \nu_j \quad (2.6)$$

Since the left-hand-side and the last two terms of the right-hand-side in (2.6) are finite numbers, it follows from the divergence of $\sum_{j=0}^{\infty} \eta_j$ that $\inf_j \sigma(\|\nabla f(x^j)\|) = 0$. By Definition 2.1 of the forcing function we immediately have that

$$\inf_i \|\nabla f(x^i)\| = 0 \quad (2.7)$$

Now assume that $f \in LC_L^1(\mathbb{R}^n)$ and $\|d^i\| \leq c$, $\forall i$, $c > 0$. Suppose the sequence $\{\nabla f(x^i)\}$ does not converge to zero. Then there exists some $\epsilon > 0$ and some increasing sequence of integers $\{i_l\}$ such that $\|\nabla f(x^{i_l})\| \geq \epsilon$ for all l . On the other hand, (2.7) guarantees that for every l there exists some $j > i_l$ such that $\|\nabla f(x^j)\| \leq \frac{\epsilon}{2}$. For each l let $j(l)$ denote

the least integer which satisfies these conditions. By the triangle inequality, the fact that $f \in LC_L^1(\mathfrak{R}^n)$ and (2.3), we have

$$\begin{aligned} \frac{\epsilon}{2} &\leq \|\nabla f(x^{i_l})\| - \|\nabla f(x^{j(l)})\| \leq \|\nabla f(x^{i_l}) - \nabla f(x^{j(l)})\| \\ &\leq L\|x^{i_l} - x^{j(l)}\| \leq L \sum_{t=i_l}^{j(l)-1} \eta_t \|d^t\| \leq Lc \sum_{t=i_l}^{j(l)-1} \eta_t \end{aligned}$$

Hence

$$\sum_{t=i_l}^{j(l)-1} \eta_t \geq \frac{\epsilon}{2Lc} = \bar{c} > 0 \quad (2.8)$$

By making use of (2.4) and (2.8), we have

$$\begin{aligned} f(x^{i_l}) - f(x^{j(l)}) &\geq \sum_{t=i_l}^{j(l)-1} \eta_t \sigma(\|\nabla f(x^t)\|) - \sum_{t=i_l}^{j(l)-1} (\lambda_t \eta_t + \nu_t) \\ &\geq \bar{c} \inf_{i_l \leq t \leq j(l)-1} \sigma(\|\nabla f(x^t)\|) - \sum_{t=i_l}^{\infty} (\lambda_t \eta_t + \nu_t) \end{aligned}$$

Since the sequence $\{f(x^i)\}$ converges and the last summation above converges to zero as $l \rightarrow \infty$, it follows that

$$\lim_{l \rightarrow \infty} \inf_{i_l \leq t \leq j(l)-1} \sigma(\|\nabla f(x^t)\|) = 0 \quad (2.9)$$

However, by the choice of i_l and $j(l)$, $\|\nabla f(x^t)\| \geq \frac{\epsilon}{2}$, $\forall t : i_l \leq t < j(l)$. This contradicts (2.9) since $\sigma(\cdot)$ is a forcing function. Hence the assumption that $\nabla f(x^i)$ does not converge to zero is invalid. Taking into account continuity of the gradient of f , we conclude that if \bar{x} is an accumulation point of $\{x^i\}$, then $\nabla f(\bar{x}) = 0$. The proof is complete. \blacksquare

Remark 2.1. Assumptions (2.1),(2.2) and (2.3) can be combined into the following simpler and more general condition, where θ_i replaces $\lambda_i \eta_i + \nu_i$:

$$f(x^i) - f(x^{i+1}) \geq \eta_i \sigma(\|\nabla f(x^i)\|) - \theta_i$$

$$\sum_{i=0}^{\infty} \eta_i = \infty, \quad \sum_{i=0}^{\infty} \theta_i < \infty$$

These new conditions also guarantee that the assertions of Theorem 2.1 hold. However, we have chosen to state Theorem 2.1 in a direction – stepsize form because it is easier to implement. See [11] for specific instances of directions d^i and stepsize η_i choices without perturbation terms.

We now show that Theorem 2.1 can be applied to the analysis of the perturbed gradient-type methods. It is important to point out that the assumptions (2.10) below of Corollary 2.1 of boundedness of f from below, and the Lipschitz continuity and boundedness of ∇f are all satisfied in the context of BP, the convergence of which is established in Section 3.

Corollary 2.1. *Let*

$$f \in LC_L^1(\mathfrak{R}^n), \quad \|\nabla f(x)\| \leq M, \quad f(x) \geq \bar{f} \quad \forall x \in \mathfrak{R}^n \quad (2.10)$$

for some $M > 0$ and some \bar{f} . Start with any $x^0 \in \mathfrak{R}^n$. Having x^i , stop if $\nabla f(x^i) = 0$, else compute

$$x^{i+1} = x^i + \eta_i d^i \quad (2.11)$$

where

$$d^i = -\nabla f(x^i) + e^i \quad (2.12)$$

for some $e^i \in \mathfrak{R}^n$, $\eta_i \in \mathfrak{R}$, $\eta_i > 0$ and such that

$$\sum_{i=0}^{\infty} \eta_i = \infty, \quad \sum_{i=0}^{\infty} \eta_i^2 < \infty, \quad \sum_{i=0}^{\infty} \eta_i \|e^i\| < \infty, \quad \|e^i\| \leq \gamma \quad \forall i, \quad \gamma > 0 \quad (2.13)$$

It follows that $\{f(x^i)\}$ converges, $\nabla f(x^i) \rightarrow 0$ and for each accumulation point \bar{x} of the sequence $\{x^i\}$, $\nabla f(\bar{x}) = 0$.

Proof. It suffices to show that conditions (2.1)–(2.3) of Theorem 2.1 are satisfied. We first note that, by (2.10), (2.12) and (2.13), $\|d^i\| \leq M + \gamma$ for all i .

By the Cauchy-Schwartz inequality, (2.11) and (2.10), we have with $\sigma(s) = s^2$,

$$\begin{aligned} -\nabla f(x^i)^T d^i &= \|\nabla f(x^i)\|^2 - \nabla f(x^i)^T e^i \\ &\geq \sigma(\|\nabla f(x^i)\|) - \|\nabla f(x^i)\| \|e^i\| \\ &\geq \sigma(\|\nabla f(x^i)\|) - M \|e^i\| \end{aligned} \quad (2.14)$$

By Lemma 2.1, (2.11) and (2.12), it follows

$$\begin{aligned}
f(x^i) - f(x^{i+1}) &\geq -\nabla f(x^i)^T(x^{i+1} - x^i) - \frac{L}{2}\|x^{i+1} - x^i\|^2 \\
&= -\eta_i \nabla f(x^i)^T d^i - \frac{L}{2}\eta_i^2 \|d^i\|^2 \\
&\geq -\eta_i \nabla f(x^i)^T d^i - \frac{L}{2}\eta_i^2 (M + \gamma)^2
\end{aligned} \tag{2.15}$$

Relations (2.14), (2.15) and (2.13) establish the assumptions (2.1)–(2.3) of Theorem 2.1 with $\lambda_i = M\|e^i\|$, $\nu_i = \frac{L}{2}(M + \gamma)^2\eta_i^2$. The proof is complete. ■

Remark 2.2. Under appropriate assumptions, other well known direction choices, such as conjugate and quasi-Newton directions ([14]) can also be perturbed similarly as in Corollary 2.1.

Remark 2.3. Similar to [11], a parallel version of Theorem 2.1 can be established where portions of the gradient are distributed among the processors. However, having in mind the analysis of the BP algorithm, we shall instead here concentrate on parallel distribution of the objective function in the form (1.2).

We now turn our attention to the case when the objective function of the problem is represented by the sum of a finite number of functions as in (1.2). Suppose that we have k parallel processors, $k \geq 1$. Let J_l be a partition of $\{1, \dots, N\}$ such that $J_l \subseteq \{1, \dots, N\}$, $\cup_{l=1}^k J_l = \{1, \dots, N\}$, $J_{l_1} \cap J_{l_2} = \emptyset$ for $l_1 \neq l_2$. Let N_l be the number of elements in J_l . We define the function f^l associated with J_l as follows

$$f^l(x) = \sum_{j \in J_l} f_j(x) \tag{2.16}$$

With this definition we have

$$f(x) = \sum_{l=1}^k f^l(x) \tag{2.17}$$

We are now ready to state and prove a parallel version of Corollary 2.1.

Theorem 2.2. Let each f_j , $j = 1, \dots, N$, satisfy the assumptions (2.10) of Corollary 2.1. Start with any $x^0 \in \mathbb{R}^n$. Having x^i , stop if $\nabla f^l(x^i) = 0$ for all $l = 1, \dots, k$. Else compute x^{i+1} as follows:

(i) **Parallelization.** For each processor $l \in \{1, \dots, k\}$ compute

$$y_l^{i+1} = x^i + \eta_l d_l^i \quad (2.18)$$

where

$$d_l^i = -\nabla f^l(x^i) + e_l^i, \quad \eta_l > 0 \quad (2.19)$$

(ii) **Synchronization.** Let

$$x^{i+1} = \frac{1}{k} \sum_{l=1}^k y_l^{i+1} \quad (2.20)$$

If for some $\gamma > 0$

$$\sum_{i=0}^{\infty} \eta_i = \infty, \quad \sum_{i=0}^{\infty} \eta_i^2 < \infty, \quad \sum_{i=0}^{\infty} \eta_i \|e_l^i\| < \infty, \quad \|e_l^i\| \leq \gamma, \quad \forall i, \quad l = 1, \dots, k \quad (2.21)$$

all the conclusions of Corollary 2.1 hold.

Proof. We shall establish assumptions (2.11)–(2.13) of Corollary 2.1.

By (2.17) and (2.18)–(2.20), we have

$$\begin{aligned} x^{i+1} - x^i &= \frac{1}{k} \sum_{l=1}^k y_l^{i+1} - x^i = \frac{1}{k} \sum_{l=1}^k (x^i + \eta_l d_l^i) - x^i \\ &= \frac{1}{k} \sum_{l=1}^k \eta_l d_l^i = \frac{\eta_i}{k} \sum_{l=1}^k (-\nabla f^l(x^i) + e_l^i) \\ &= \frac{\eta_i}{k} \left(-\nabla f(x^i) + \sum_{l=1}^k e_l^i \right) \end{aligned}$$

Now, in view of (2.21), Corollary 2.1 applies with $e^i = \sum_{l=1}^k e_l^i$ and the proof is complete. ■

Remark 2.4. Theorem 2.2 can be easily generalized such that each processor takes an arbitrary but finite number of steps before any synchronization is made. The changes needed to extend Theorem 2.2 to these asynchronous methods are straightforward, and are thus omitted. See [11] for details.

Remark 2.5. A similar parallel version can be stated for Theorem 2.1.

3 Convergence of the Backpropagation Algorithm

We now turn our attention to the classical BP algorithm for training feed-forward artificial neural networks with one layer of hidden units ([15],[7],[16],[8]). The number of hidden units is assumed to be fixed.

Suppose we have N training examples and k processors with $N \geq 1$ and $k \geq 1$. In a manner similar to that of Section 2 we consider a partition of the set $\{1, \dots, N\}$ into the subsets J_l , $l = 1, \dots, k$, so that each example is assigned to at least one processor. The variables of the problem here are the weights associated with the arcs of the neural network and the thresholds of the hidden and output units. The objective is to minimize a certain error function ([10]) which for our purposes here is the same as (2.17), that is

$$\min_{x \in \mathbb{R}^n} f(x) := \sum_{l=1}^k f^l(x) = \sum_{l=1}^k \sum_{j \in J_l} f_j(x)$$

where $J_l \subseteq \{1, \dots, N\}$, $l = 1, \dots, k$, $\cup_{l=1}^k J_l = \{1, \dots, N\}$. We note that this function is the sum of individual error functions each of which is associated with a single training example. Each component f_j of the objective function is a squared composition of the sigmoid and linear functions ([10]), and therefore satisfies the assumptions (2.10) on any bounded set.

Each iteration of the *serial* BP algorithm consists of a step in the direction of negative gradient of an error function associated with a single training example. In the *parallel* BP each processor performs one (or more) cycles of serial BP on its set of training examples. Then a synchronization step is performed that consists of averaging the iterates computed by all the k processors.

Below we state a parallel BP algorithm with an added *momentum term* which consists of the difference between the current and previous iterates. For simplicity and in a similar manner to the method of conjugate gradients ([12]) we reset this term to zero periodically (see Algorithm 3.1). It has been observed that introduction of momentum term usually leads to faster convergence and adds stability to problems with noisy data ([8]).

We now summarize and describe our notation for stating and establishing convergence of the parallel BP algorithm with a momentum term :

$i = \mathbf{1}, \mathbf{2}, \dots$: Index number of major iterations of BP, each of which consists of going through the entire set of error functions $f_1(x), \dots, f_N(x)$. This is achieved serially or in parallel by k processors with processor l handling the error function $f^l(x)$, $l = 1, \dots, k$.

$j = 1, \dots, N_l$: Index of minor iterations performed by parallel processor l , $l = 1, \dots, k$. Each minor iteration j consists of a step in the direction of negative gradient $-\nabla f_{m(j)}^l(z_l^{i,j})$ and a momentum step, where $m(j)$ is an element of the permuted set J_l . Note that in general the map $m(\cdot)$ depends on the index i and processor l . For simplicity, we skip this dependence in our notation. Recall that N_l is the number of elements in the set J_l .

x^i : Iterate in \mathfrak{R}^n of major iteration $i = 1, 2, \dots$

$z_l^{i,j}$: Iterate in \mathfrak{R}^n of minor iteration $j = 1, \dots, N_l$, within major iteration $i = 1, 2, \dots$, computed by processor $l = 1, \dots, k$.

By η_i we shall denote the *learning rate* (the coefficient multiplying the gradient), and by α_i the *momentum rate* (the coefficient multiplying the momentum term). For simplicity we shall assume that the learning and momentum rates remain fixed within each major iteration.

We are now ready to state and prove convergence of the parallel BP algorithm.

Algorithm 3.1. Parallel BP with Momentum Term.

Start with any $x^0 \in \mathfrak{R}^n$. Having x^i , stop if $\nabla f(x^i) = 0$, else compute x^{i+1} as follows :

(i) for each processor $l \in \{1, \dots, k\}$ do

$$z_l^{i,j+1} = z_l^{i,j} - \eta_i \nabla f_{m(j)}^l(z_l^{i,j}) + \alpha_i \Delta z_l^{i,j}, \quad j = 1, \dots, N_l \quad (3.1)$$

$$\text{where } z_l^{i,1} = x^i, \quad 0 < \eta_i < 1, \quad 0 \leq \alpha_i < 1$$

$$\Delta z_l^{i,j} = \begin{cases} 0 & \text{if } j = 1 \\ z_l^{i,j} - z_l^{i,j-1} & \text{otherwise} \end{cases} \quad (3.2)$$

(ii) Synchronization

$$x^{i+1} = \frac{1}{k} \sum_{l=1}^k z_l^{i,N_l+1} \quad (3.3)$$

We note that for $k = 1$, Algorithm 3.1 becomes the serial BP, while the choice of $\alpha_i = 0$ reduces it to the simple BP.

To the best of our knowledge there are no published deterministic convergence proofs for either the parallel or serial BP algorithm. In [17] it is proven that the sequence of weights generated by the serial BP either converges to a point that is almost surely stationary or it

diverges. In contrast, our approach is deterministic. We were largely motivated by [5] where stochastic gradient ideas were used. Our proof which is based on the deterministic results of Section 2, covers both serial and parallel cases as well as the computationally important methods with a momentum term. We point out that the assumptions that we make to prove convergence of the gradient of the error function to zero are weaker than those in [5]. We note the equivalence of BP to a deterministic perturbed gradient algorithm.

We are now ready to apply the analysis of Section 2 to backpropagation.

Theorem 3.1. *Let f_j , $j = 1, \dots, N$ satisfy the assumptions (2.10) on a bounded set. Let*

$$\sum_{i=0}^{\infty} \eta_i = \infty, \quad \sum_{i=0}^{\infty} \eta_i^2 < \infty, \quad \sum_{i=0}^{\infty} \alpha_i \eta_i < \infty \quad (3.4)$$

For any bounded sequence $\{x^i\}$ generated by the BP Algorithm 3.1 it follows that $\{f(x^i)\}$ converges, $\|\nabla f(x^i)\| \rightarrow 0$, and for each accumulation point \bar{x} of the sequence $\{x^i\}$, $\nabla f(\bar{x}) = 0$.

Proof. We shall show that the assumptions of Theorem 2.2 are satisfied.

Using (3.1) and (3.2), for any cycle i , any processor l , and any j such that $2 \leq j \leq N_l + 1$ we obtain

$$\begin{aligned} z_l^{i,j} - x^i &= z_l^{i,j} - z_l^{i,1} = \sum_{t=1}^{j-1} (z_l^{i,t+1} - z_l^{i,t}) \\ &= \sum_{t=1}^{j-1} (-\eta_i \nabla f_{m(t)}^l(z_l^{i,t}) + \alpha_i \Delta z_l^{i,t}) \\ &= -\eta_i \sum_{t=1}^{j-1} \nabla f_{m(t)}^l(z_l^{i,t}) + \alpha_i (z_l^{i,j-1} - x^i) \end{aligned} \quad (3.5)$$

$$= -\eta_i \sum_{t=1}^{j-1} \nabla f_{m(t)}^l(z_l^{i,t}) - \eta_i \sum_{s=1}^{j-2} \left(\alpha_i^{j-1-s} \sum_{t=1}^s \nabla f_{m(t)}^l(z_l^{i,t}) \right) \quad (3.6)$$

where (3.6) is obtained by repeated use of (3.5) with j replaced by $j-1$, $j-2, \dots, 2$. By (3.5) and (2.16), for $j = N_l + 1$ we have

$$\begin{aligned} z_l^{i,N_l+1} - x^i &= -\eta_i \sum_{t=1}^{N_l} \nabla f_{m(t)}^l(z_l^{i,t}) + \alpha_i (z_l^{i,N_l} - x^i) \\ &= -\eta_i (\nabla f^l(x^i) + a_l^i + \frac{\alpha_i}{\eta_i} b_l^i) \end{aligned} \quad (3.7)$$

where

$$a_l^i = \sum_{t=2}^{N_l} (\nabla f_{m(t)}^l(z_l^{i,t}) - \nabla f_{m(t)}^l(x^i)) \quad (3.8)$$

and

$$b_l^i = x^i - z_l^{i,N_l} \quad (3.9)$$

Let

$$e_l^i = -a_l^i - \frac{\alpha_i}{\eta_i} b_l^i \quad (3.10)$$

Now, in view of Theorem 2.2, assumptions (3.4) and (3.7), all we have to do is to verify that

$$\sum_{i=0}^{\infty} \eta_i \|e_l^i\| < \infty, \quad \|e_l^i\| \leq \gamma, \quad \gamma > 0, \quad l = 1, \dots, k \quad (3.11)$$

By (3.8), (3.6), (2.10), the triangle inequality and $\alpha_i \leq 1$ it follows

$$\begin{aligned} \|a_l^i\| &\leq \sum_{t=2}^{N_l} \|\nabla f_{m(t)}^l(z_l^{i,t}) - \nabla f_{m(t)}^l(x^i)\| \leq L \sum_{t=2}^{N_l} \|z_l^{i,t} - x^i\| \\ &\leq L \sum_{t=2}^{N_l} \left(\eta_i \sum_{r=1}^{t-1} \|\nabla f_{m(r)}^l(z_l^{i,r})\| + \eta_i \sum_{s=1}^{t-2} \left(\alpha_i^{t-1-s} \sum_{r=1}^s \|\nabla f_{m(r)}^l(z_l^{i,r})\| \right) \right) \\ &\leq L \eta_i (N_l^2 M + N_l^3 M) = c_1 \eta_i \end{aligned} \quad (3.12)$$

Similarly, by (3.9), (3.6), (2.10), the triangle inequality and $\alpha_i \leq 1$, we have

$$\begin{aligned} \|b_l^i\| &= \|z_l^{i,N_l} - x^i\| \leq \eta_i \left(\sum_{t=1}^{N_l-1} \|\nabla f_{m(t)}^l(z_l^{i,t})\| + \sum_{s=1}^{N_l-2} \left(\alpha_i^{N_l-1-s} \sum_{t=1}^s \|\nabla f_{m(t)}^l(z_l^{i,t})\| \right) \right) \\ &\leq \eta_i \left(\sum_{t=1}^{N_l-1} M + \sum_{s=1}^{N_l-2} M N_l \right) \leq \eta_i (M N_l + M N_l^2) = c_2 \eta_i \end{aligned} \quad (3.13)$$

By (3.10), (3.12), (3.13) and the triangle inequality, we obtain

$$\|e_l^i\| \leq c_1 \eta_i + c_2 \alpha_i$$

The latter combined with (3.4) implies (3.11), and the proof is complete. ■

4 Concluding Remarks

A general theorem for the nonmonotone convergence of a family of unconstrained optimization methods has been presented. It was established that the serial or parallel backpropagation algorithm with or without a momentum term for training feed-forward artificial neural networks with one layer of hidden units can be viewed as a *deterministic* perturbed gradient method. Each accumulation point of the sequence of weights generated by BP is shown to be a stationary point of the error function associated with a given set of training examples.
