Abstract

Neuropathic pain is an important medical problem with few effective treatments. The sigma 1 receptor ($\sigma 1R$) is known to be a potential target for neuropathic pain therapeutics, and antagonists for this receptor are effective in preclinical models and are currently in phase II clinical trials. Conversely, relatively little is known about $\sigma 2R$, which has recently been identified as transmembrane protein 97 (Tmem97). We generated a series of $\sigma 1R$ and $\sigma 2R$ /Tmem97 agonists and antagonists and tested them for efficacy in the mouse spared nerve injury (SNI) model. In agreement with previous reports, we find that $\sigma 1R$ ligands given intrathecally (IT) produce relief of SNI-induced mechanical hypersensitivity. We also find that the putative $\sigma 2R$ /Tmem97 agonists **DKR-1005**, **DKR-1051**, and **UKH-1114** ($K_i \sim 46$ nM) lead to relief of SNI-induced mechanical hypersensitivity, peaking at 48 h after dosing when given IT. This effect is blocked by the putative $\sigma 2R$ /Tmem97 antagonist **SAS-0132**. Systemic administration of **UKH-1114** (10 mg/kg) relieves SNI-induced mechanical hypersensitivity for 48 h with a peak magnitude of effect equivalent to 100 mg/kg gabapentin and without producing any motor impairment. Finally, we find that the *TMEM97* gene is expressed in mouse and human dorsal root ganglion (DRG) including populations of neurons that are involved in pain; however, the gene is also likely expressed in non-neuronal cells that may contribute to the observed behavioral effects. Our results show robust antineuropathic pain effects of $\sigma 1R$ and $\sigma 2R$ /Tmem97 ligands, demonstrate that $\sigma 2R$ /Tmem97 is a novel neuropathic pain target, and identify **UKH-1114** as a lead molecule for further development.

Neuropathic pain; sigma 1 receptor; sigma 2 receptor; Tmem97; dorsal root ganglion; drug discovery

INTRODUCTION

Neuropathic pain is a common medical problem that is very poorly treated by current therapeutics. Recent meta-analyses show that the most widely prescribed drugs for neuropathic pain only achieve 50% pain relief in 1 of 4 patients for the antidepressants (e.g., monoamine oxidase inhibitors) and are effective in as few as 1 in 7 patients for the gabapentinoids.¹ Better therapeutics are clearly needed for neuropathic pain. Sigma receptors (σ Rs) are unique transmembrane proteins expressed throughout the CNS (central nervous system) and in certain peripheral tissues. Consisting of two subtypes, the sigma 1 receptor (σ 1R) and the sigma 2 receptor (σ 2R), these proteins are involved in intracellular ion regulation and neuron survival.² σ 1R has been cloned and a crystal structure of the receptor obtained.³ The involvement of this receptor in pain signaling has been studied extensively, and a variety of compounds that bind to σ 1R demonstrate antinociceptive effects.⁴ E-52862,⁵ a σ 1R antagonist, is currently in phase II clinical trials for the treatment of neuropathic pain as both a monotherapy and in a multidrug cocktail.

Although strong evidence supports a role for σ 1R in neuropathic pain, σ 2R has not been explored as a pain target, and the molecular identity of this receptor has been challenging to pinpoint. Molecular cloning recently confirmed the identity of σ 2R as transmembrane protein 97 (Tmem97),⁶ and this receptor will accordingly be referred to as σ 2R/Tmem97 herein unless we are referring to the Tmem97 mouse or TMEM97 human genes. σ 2R/Tmem97 is a gene product that appears to be involved in cholesterol trafficking and homeostasis and interacts with NPC-1, a protein responsible for shuttling lipids to postlysosomal locations.⁷⁻⁹ σ 2R/Tmem97 is involved in regulating intracellular Ca^{2+} concentration, and certain σ 2R/Tmem97 ligands can induce a transient rise in intracellular Ca^{2+} levels,² while other compounds that bind to σ 2R/Tmem97 suppress Ca^{2+} influx in the presence of an inducer.¹⁰ Some evidence suggests that compounds that bind to σ 2R/Tmem97 modulate a signaling pathway involving progesterone receptor membrane component one (PGRMC1¹¹),¹⁰ a heme binding protein¹² involved in cell survival² and apoptosis.¹³ With respect to medical relevance, it is noteworthy that *TMEM97* has been implicated in the metabolic disorder, Niemann-Pick disease,⁹ as well as in multiple neurodegenerative and neurological conditions.¹⁴ Indeed, small molecules that bind to σ 2R/Tmem97 are emerging as potential therapeutics for a range of CNS disorders, including Alzheimer's disease (AD)¹⁵ and schizophrenia.¹⁶

We have discovered that the chlorinated norbenzomorphan and methanobenzazocine scaffolds **1** and **2** (Figure 1) are excellent templates for preparing both selective and mixed affinity σ 1R and σ 2R/Tmem97 ligands.¹⁷ In the context of CNS lead development, these scaffolds are of particular interest because of their drug-like properties^{18,19} and the ease with which they cross the blood brain barrier, as demonstrated by representative compounds **SAS-0132**¹⁰ and **DKR-1051** (Figure 1). In vivo testing has revealed that some compounds derived from **1** and **2** have promising medicinal properties that may warrant further preclinical development. For example, certain σ 2R/Tmem97 ligands are neuroprotective¹⁰ and also restore cognitive function in transgenic AD mice^{10,20} as well as in aged, nondiseased animals,¹⁰ the latter of which suggests σ 2R/Tmem97 may be a potential target for treating mild cognitive impairment (MCI). Despite this increasing knowledge base and the emergence of tool ligands for probing σ 2R/Tmem97, the involvement of σ 2R/Tmem97 in neuropathic pain has not yet been reported.

Herein we describe the antineuropathic pain properties of a series of σ 1R and σ 2R/Tmem97 ligands in mice. We report that molecules that bind to σ 2R/Tmem97 as putative agonists exert a profound effect on mechanical hypersensitivity in the spared nerve injury (SNI) model with a duration of action and potency that is superior to that of gabapentin. Small molecule modulation of σ 2R/Tmem97 may thus represent a new approach for managing pain by a previously unexplored mechanism of action.

RESULTS

Screening of σ 1R and σ 2R/Tmem97 Ligands for Activity in the Mouse SNI Model

Several previous studies have demonstrated that σ 1R antagonists show efficacy in rodent neuropathic pain models via a spinal mechanism of action,^{21–23} but the possible effect of σ 2R/Tmem97 ligands in this model has not been explored. We screened a series of σ 1R and σ 2R/Tmem97 ligands (Figure 2) for activity in the SNI model via a single IT injection. We chose this route of administration because σ 1R antagonists have been shown to be active in rodent pain models with IT injection,^{21,24} and because we had incomplete knowledge of compound disposition in vivo with systemic dosing.

We first assessed the σ 1R preferring ligands, **JWG-1014**, **JSS-1027**, and **MFG-1046**, all given at 10 μ g doses, and observed antipain effects for all three compounds that were significantly different from vehicle. **JWG-1014** and **JSS-1027** (Figure 8) both demonstrated efficacy 48 h post IT injection, and this effect persisted through 120 h after ligand administration (Figure 3). Faster onset of action was observed with **MFG-1046** (Figure 9), which elicited an antipain effect at 24 h that continued through 72 h after IT injection (Figure 3).

We then tested four σ 2R/Tmem97 preferring ligands of the norbenzomorphan and methanobenzazocine structural class, as well as the known σ 2R/Tmem97 agonist, siramesine.^{25–27} Siramesine induced a small inhibitory effect on mechanical hypersensitivity that was significant at 24 and 48 h (Figure 4A). On the other hand, **DKR-1005**, **DKR-1051**, and **UKH-1114** all produced significant antimechanical hypersensitivity effects at either 24 or 48 h after IT injection (Figure 4B).

Based on the observed in vivo effects of the four σ 2R/Tmem97 preferring ligands examined, tentative functional activity assignments were made. Compounds **DKR-1005**, **DKR-1051**, and **UKH-1114** elicited pronounced and sustained antinociceptive effects. However, when **UKH-1114** was administered with **SAS-0132**, the antinociceptive action of **UKH-1114** was abolished (Figure 5). Because **UKH-1114** elicits a significant antipain effect that is completely blocked by **SAS-0132**, we surmise that **UKH-1114** is a σ 2R/Tmem97 agonist (or partial agonist) and that σ 2R/Tmem97 agonism is responsible for the antimechanical hypersensitivity effects observed with these compounds in SNI mice. On the other hand, **SAS-0132** appears to function as a σ 2R/Tmem97 antagonist by suppressing the action of **UKH-1114**. Indeed, these findings are consistent with our previous work that showed that **SAS-0132** behaves as a σ 2R/Tmem97 antagonist, whereas **DKR-1051** acts as a σ 2R agonist¹⁰ based upon their opposing effects upon Ca²⁺ in SK-N-SH neuroblastoma cells. Namely, treatment of SK-N-SH neuroblastoma cells with **DKR-1051** induces a rapid Ca²⁺ transient, and this effect is attenuated when cells are pretreated with **SAS-0132**.

Systemic Administration of σ 2R/Tmem97 Agonist Alleviates Neuropathic Pain

Of the putative σ 2R/Tmem97 agonists we tested, **UKH-1114** had the largest behavioral effect, and its chemical properties and high selectivity for σ 2R/Tmem97 versus >50 other proteins (See Tables 1 and 2) make it an eligible candidate for systemic dosing.

Therefore, we injected **UKH-1114** IV in mice at 10 mg/kg and compared the effect of the compound to the gold-standard antineuropathic pain treatment, gabapentin (100 mg/kg). Gabapentin completely reversed mechanical hypersensitivity at 1 and 3 h after injection, but animals were fully mechanically hypersensitive again 24 h after IV injection. **UKH-1114** also produced a complete reversal of mechanical hypersensitivity but with a different time course (Figure 6A). A significant effect was observed at both 24 and 48 h after injection indicating that pain relief from this mechanism lasts longer than that produced with a 10-fold larger dose of gabapentin.

Because the mechanism of action of σ 2R/Tmem97 ligands for neuropathic pain relief is not known, we were concerned that this effect could be produced by motor impairment. To test this possibility we used the rotorod test. SNI mice were given IV vehicle or **UKH-1114** and tested at the peak time point for alleviation of neuropathic pain, 48 h after injection. There was no effect of **UKH-1114** on motor performance (Figure 6B) ruling out the possibility of motor impairment.

Tmem97 Gene Expression Analysis in Mouse and Human Tissues

To gain insight into where σ 2R/Tmem97 is expressed, we quantified Tmem97 mRNA relative abundance in mouse DRG as well as additional tissues, and their orthologous tissues in humans, based on publicly available sequencing data (human data sets: GTex project,²⁸ ENCODE project,²⁹ Uhlén et al.,³⁰ Duff et al.,³¹ and the UTD DRG project;³² mouse data sets: mouse ENCODE project,³³ Rakic et al.,³⁴ Gerhold et al.,³⁵ Eipper-Mains et al.,³⁶ and Huan et al.³⁷). We find that *Tmem97* gene expression and its human orthologue (*TMEM97*) are ubiquitously expressed in a wide range of tissues, with higher expression in the human and mouse gastrointestinal (GI) tract commensurate with its role in cholesterol trafficking⁷

(Figure 7A). While expression levels in the human DRG is high, both single cell³⁸ and bulk³⁵ RNA-seq for mouse DRGs identify gene expression, but at lower levels than in human (Figure 7A). *TMEM97/Tmem97* is also relatively highly expressed in human and mouse spinal cord. While the detection rate for *Tmem97* across mouse DRG neuronal subpopulations is relatively low, it is clearly expressed in subpopulations of peptidergic and nonpeptidergic nociceptors (Figure 7B). Given the high TPM levels in mouse and human DRG, *Tmem97* may also be expressed in non-neuronal cells in DRG (e.g., satellite glial cells or Schwann cells). Unfortunately, mouse DRG glial transcriptomes have not been characterized, so we turned to a CNS tissue where these cell populations have available transcriptomes. We find that in adult cerebral cortex,³⁹ *Tmem97* expression in cortical glial cells can be enriched 2-fold or more over neuronal expression levels (Figure 7C), lending credence to the hypothesis of glial expression of *Tmem97* in the DRG and/or spinal cord.

DISCUSSION

Several primary conclusions may be reached based upon the work described herein. First, our results using distinct σ 1R binding ligands are consistent with previous demonstrations that σ 1R antagonists reduce nerve injury-induced mechanical hypersensitivity.^{21,40} This observation suggests that the σ 1R binding ligands described herein might be antagonists. Second, we find that σ 2R/*Tmem97* ligands **DKR-1005**, **DKR-1051**, and **UKH-1114** bind σ 2R/*Tmem97* with high affinity and produce antinociceptive effects when administered IT to SNI mice. **UKH-1114** is the most efficacious of these compounds in vivo, producing a strong antinociceptive effect when administered IV that was longer lasting and equally efficacious at 1/10 the dose of gabapentin. **UKH-1114** is highly selective for σ 2R/*Tmem97* binding with an affinity 28-fold greater at σ 2R/*Tmem97* than at σ 1R, and with negligible affinity for 55 other targets (Table 2). While *TMEM97/Tmem97* is expressed in DRG and spinal cord of humans and mice, the gene is likely expressed in a mix of neuronal and non-neuronal cells that may include key glial and/or immune cells that are thought to play an important role in the pathogenesis of neuropathic pain.⁴¹ Therefore, we conclude the σ 2R/*Tmem97* is a promising target for the generation of neuropathic pain drugs.

An interesting aspect of our behavioral findings is the relatively long onset of action of the compounds that we tested compared to rapid onset actions in previous studies with distinct ligands.^{21,40,42,43} There could be several reasons for this observation. One is that most previous studies have looked at short time points after administration of σ 1R antagonists (30 or 45 min) or at repeated dosing effects^{21,40,42,43} so it is possible that effects with a slower onset are missed by these acute dosing schedules but are part of the sustained efficacy observed with repeated dosing. Another possibility is that while the mechanism of action of σ 1R antagonists in pain was first thought to involve a spinal mechanism of action,²¹⁻²³ more recent studies suggest an action of DRG neurons where σ 1R is also expressed.⁴⁴ It is therefore probable that the time to onset of effects is due to the time that is needed for the drug to diffuse to sites of action that are more distant from the injection site in the intrathecal space. Because σ 1Rs are found on the nuclear envelope of DRG neurons,⁴⁴ yet another possibility is that the effect of these compounds is transcriptional. If this were the case, this would also potentially take longer to manifest as a behavioral change. These considerations aside, our results are consistent with previous studies where σ 1R antagonists produced long

lasting relief of neuropathic mechanical hypersensitivity when given IT.²¹ Another important consideration here is that all of the compounds we examined as σ 1R binding ligands also have affinity at σ 2R/Tmem97 that could alter their behavioral effects, and some of them have affinity in the low nM range (**JSS-1027** and **MFG-1046**).

To our knowledge, σ 2R/Tmem97 ligands have not been previously tested for antinociceptive effects. The σ 2R/Tmem97 ligands described herein have high affinity for σ 2R/Tmem97, have good specificity relative to σ 1R binding, and have little affinity for other targets in a small specificity screen. Indeed, **UKH-1114** displays exceptional selectivity for σ 2R/Tmem97 over >50 other receptors and channels. Although the previously described σ 2R/Tmem97 agonist, siramesine, produced only a small effect in SNI mice, several other putative σ 2R/Tmem97 agonists produced strong effects when given IT in the SNI model. This effect was blocked in the case of **UKH-1114** by the known σ 2R/Tmem97 antagonist, **SAS-0132**, strongly implicating σ 2R/Tmem97 agonism as the mode of action responsible for antinociception. **UKH-1114** was chosen to test via systemic administration in the SNI model. This compound produced a strong antimechanical hypersensitivity effect that was long lasting and devoid of motor impairment. The peak magnitude of effect was equivalent to the standard of care neuropathic pain drug, gabapentin, but it was much longer lasting at 10-fold lower dose. We observed a relatively long onset to antinociceptive action with putative σ 2R/Tmem97 agonists, like σ 1R ligands, although this onset to action was shorter when **UKH-1114** was given IV. This may be explained by the expression of the *Tmem97* gene, which is clearly expressed in structures outside of the intrathecal space and has high expression in the DRG and in non-neuronal cells in the DRG and CNS, suggesting the possibility of immune cell expression. We mined publicly available data sets and found that *Tmem97* mRNA is expressed in many mouse and human tissues, but in the mouse CNS, expression levels are apparently higher in many non-neuronal cells types, including astrocytes and microglia. This is consistent with the known expression of *TMEM97* in human glioma cells.⁴⁵ While beyond the scope of the present experiments, the discovery of tool ligands to manipulate σ 2R/Tmem97 function will allow for testing the role of this receptor in a variety of cell types in the pain pathway.

More work is clearly needed to understand the role of σ 2R/Tmem97 in pain, but these unprecedented results provide compelling support for developing σ 2R/Tmem97 agonists as a novel strategy for the pharmacological management of neuropathic pain, bringing forth the possibility for patients to experience enhanced pain relief and reduced side-effects by modulating a receptor not targeted by currently approved FDA drugs. We are in the process of identifying other σ 2R/Tmem97 agonists to further explore their utility as potential therapeutics for neuropathic pain.

METHODS

Laboratory Animals

All animal procedures were approved by The University of Texas at Dallas Institutional animal care and use committee (IACUC) and were in accordance with National Institutes of Health Guidelines. All of the experiments were performed on male C57B16/J mice obtained from Envigo at 4 weeks of age. Mice were housed in the University of Texas at Dallas

Animal Care Facility for at least 1 week prior to the start of behavior testing and surgery. Animals had ad libitum access to food and water and were on a 12 h noninverted light/dark cycle. Experimenters were blinded to treatment groups in behavioral experiments. Sample size was estimated by performing a power calculation using G*Power (version 3.1.9.2). With 80% power, an expectation of $d = 2.2$ effect size in behavioral experiments, and alpha set to 0.05, the sample size required was calculated as $n = 5$ per group. Standard deviation (set at 0.3) for the power calculation was based on previously published mechanical threshold data.^{46–48}

Behavioral Testing

Mechanical sensitivity was assessed using stimulation of the hindpaw of the mouse with calibrated von Frey filaments from Stoelting. We used the modified up–down method described previously.⁴⁹ Following baseline testing, neuropathic pain was induced in mice using the SNI surgery model. This surgery consists of exposing and cutting the peroneal and tibial branches of the sciatic nerve leaving the sural nerve intact.⁵⁰ Two-weeks postsurgery, mechanical sensitivity testing was repeated to ensure that mechanical hypersensitivity had indeed been produced. Following this test, groups of SNI mice were treated with intrathecal (IT) injections⁵¹ of test compounds given in a volume of 5 μL made up in sterile saline and mechanical sensitivity was assessed at time points indicated in figures. Screening for the effect of IT injection of test compounds on SNI-induced mechanical hypersensitivity was done between 21 and 60 days after SNI. Some groups of mice were tested with multiple compounds to reduce the number of animals that were needed for this study. If mice were given multiple injections they were always spaced by at least 14 days between injections. Some animals received a maximum of 3 IT injections but most received 2. In some experiments drugs were given by intravenous (IV) injection through the tail vein in a volume of 100 μL in sterile saline and mechanical sensitivity was assessed at time points indicated in figures. RotoRod testing was done on an automated rotorod device set to accelerate to a final speed of 40 rotations per minute over a 200 s time course. Mice were trained on the rotorod twice and latency to fall was recorded on the third trial.

Chemical Synthesis and Characterization

Toluene was dried by filtration through one column of activated, neutral alumina followed by one column of Q5 reactant⁵² and was determined to have less than 50 ppm of H_2O by Karl Fischer coulometric moisture analysis. Acetonitrile (CH_3CN), diethyl ether (Et_2O), ethyl acetate (EtOAc), methanol (MeOH), methylene chloride (CH_2Cl_2), 1,2-dichloroethane (DCE), triethylamine (Et_3N), and diisopropylethylamine ($i\text{-Pr}_2\text{NET}$) were used without further purification. All reagents were reagent grade and used without purification unless otherwise noted. All reactions involving air or moisture sensitive reagents or intermediates were performed under an inert atmosphere of nitrogen or argon in glassware that was flame or oven-dried. Reaction temperatures refer to the temperature of the cooling/heating bath. Volatile solvents were removed under reduced pressure using a Buchi rotary evaporator at 20–30 $^\circ\text{C}$ (bath temperature). Thin layer chromatography was run on precoated plates of silica gel with a 0.25 mm thickness containing 60F-254 indicator (EMD Millipore). Chromatography was performed using forced flow (flash chromatography) and the indicated solvent system on 230–400 mesh silica gel (Silicycle flash F60) according to the method of

Still and colleagues⁵³ unless otherwise noted. Radial Preparative Liquid Chromatography (radial plc) was performed on a Chromatotron using glass plates coated with Merck, TLC grade 7749 silica gel with gypsum binder and fluorescent indicator.

Proton nuclear magnetic resonance (¹H NMR) and carbon nuclear magnetic resonance (¹³C NMR) spectra were obtained at the indicated field as solutions in CDCl₃ unless otherwise indicated. Chemical shifts are referenced to the deuterated solvent (*e.g.*, for CDCl₃, $\delta = 7.26$ ppm and 77.0 ppm for ¹H and ¹³C NMR, respectively) and are reported in parts per million (ppm, δ) relative to tetramethylsilane (TMS, $\delta = 0.00$ ppm). Coupling constants (*J*) are reported in Hz and the splitting abbreviations used are s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; comp, overlapping multiplets of magnetically nonequivalent protons; br, broad; app, apparent. Molecular mass was determined using an LCMS system comprised of an Agilent 1200 Series HPLC and an Agilent 6130 single quadrupole mass spectrometer. Samples were injected onto a Phenomenex Gemini C18 column (5 μ m, 2.1 \times 50 mm) and eluted at 0.7 mL/min using a gradient of 10–90% acetonitrile, 0.1% formic acid (11 min linear ramp). Positive mode electrospray ionization ESI was used to verify the identity of the major component. All compounds submitted for in vivo testing were >95% purity as determined by LC via AUC at 214- and 254 nm. Experimental and characterization data for **1**,⁵⁴ **S4**, **S5**, **SAS-0132**,⁵⁵ and **DKR-1005** have been reported previously, and the preparation of the nor-chloro analogue of **2** has been described.⁵⁶

(±)-2-Phenethyl-2,3,4,5-tetrahydro-1H-1,5-methanobenzo[*c*]-azepine (JSS-1027)—

A mixture of **1** (150 mg, 0.45 mmol) and 10% Pd/C (45 wt %, 60 mg) in ethanol (5 mL) was stirred under an atmosphere of H₂ for 6.5 h. The catalyst was removed by filtration through a cotton plug, and the combined filtrates were concentrated under reduced pressure to provide 71 mg of a light brown oil, which was dissolved in CH₃CN (5 mL). (2-Phenyl)ethyl bromide (**S1**, 0.13 mL, 0.90 mmol) and K₂CO₃ (248 mg, 1.8 mmol) were added, and the mixture was heated at 50 °C for 20 h. The reaction was cooled to room temperature and the solids removed by filtration. The combined filtrates were concentrated to give a yellow oil that was purified using radial plc, eluting with 100% hexanes → 20% EtOAc/hexanes, to give 90 mg (76%) of **JSS-1027** as a light-yellow oil: ¹H NMR (500 MHz, CDCl₃) δ 7.36–7.30 (m, 3 H), 7.29–7.16 (comp, 6 H), 4.08 (d, *J* = 5.0 Hz, 1 H), 3.19 (m, 1 H), 2.94 (td, *J* = 12.5, 5.9 Hz, 1 H), 2.84 (td, *J* = 10.0, 5.0 Hz, 1 H), 2.77 (dd, *J* = 15.0, 5.0 Hz, 1 H), 2.65 (td, *J* = 10.0, 5.0 Hz, 1 H), 2.37 (td, *J* = 12.5, 5.9 Hz, 1 H), 2.28 (m, 1 H), 2.07 (td, *J* = 10.0, 5.0 Hz, 1 H), 2.02 (d, *J* = 10.0 Hz, 1 H), 1.59 (m, 1 H), 1.48 (*J* = 10.0, 5.0 Hz, 1 H); ¹³C NMR (125 MHz, CDCl₃) δ 146.4, 140.5, 138.7, 128.8, 128.4, 127.7, 126.2, 126.1, 124.1, 122.5, 63.7, 58.3,

46.9, 44.5, 39.9, 34.4, 30.2; IR (thin film) 2942, 2811, 1472, 1121 cm^{-1} ; HRMS (ESI) m/z calcd for $\text{C}_{19}\text{H}_{22}\text{N}$ ($\text{M}+\text{H}$)⁺, 264.1747; found, 264.1748.

(±)-2-Methyl-2,3,4,5-tetrahydro-1H-1,5-methanobenzo[c]-azepin-8-yl)morpholine (JWG-1014)—

Iodotrimethylsilane (318 mg, 0.226 mL 1.59 mmol) was added in one portion to a solution of carbamate **S4** (300 mg, 0.797 mmol) in CH_2Cl_2 (12 mL) at 0 °C in a flask wrapped in foil. The cooling bath was removed after 1 h, and the reaction was stirred for an additional 4 h, whereupon the mixture was cooled to 0 °C and methanolic HCl (2.0 M, 5 mL) added. After stirring for 5 min, the volatiles were removed under reduced pressure, 2 N $\text{HCl}_{(\text{aq})}$ (20 mL) was added, and the aqueous mixture was extracted with Et_2O (2×15 mL). The pH of the aqueous layer was adjusted to ~9 by the slow addition of 2.2 M $\text{NaOH}_{(\text{aq})}$ and then extracted with CH_2Cl_2 (3×20 mL). The combined organic extracts were dried (Na_2SO_4) and concentrated under reduced pressure to afford 155 mg (79%) of the secondary amine intermediate, which was of sufficient purity (>95% LC and ^1H NMR) to be used in the next step without purification. Paraformaldehyde (**S6**, 66 mg, 2.2 mmol) was added to a solution of secondary amine (28 mg, 0.11 mmol) in DCE (1 mL) followed by the addition of sodium triacetoxyborohydride (117 mg, 0.55 mmol) and acetic acid (10.5 μL , 0.18 mmol). The mixture was stirred for 24 h and then quenched by the addition of 2.2 M $\text{NaOH}_{(\text{aq})}$ (~1 mL) and H_2O (~2 mL). After stirring for 5 more min, the layers were separated, H_2O was added to the aqueous mixture (~2 mL) followed by extraction with CH_2Cl_2 (3×20 mL). Brine was added to the aqueous mixture, which was then extracted with CH_2Cl_2 (2×20 mL). The combined organic extracts were dried (MgSO_4), filtered, and concentrated under reduced pressure to give the *N*-methylamine, which was purified via flash column chromatography (SiO_2), eluting with 100% hexanes \rightarrow 10% EtOAc/hexanes \rightarrow 100% EtOAc \rightarrow 10% MeOH/EtOAc \rightarrow 20% MeOH/EtOAc to give 26 mg (92%; 73% over two steps) of **JWG-1014** as a light yellow oil: ^1H NMR (500 MHz, CDCl_3) δ 7.12 (d, $J = 10.0$ Hz, 1 H), 6.81 (s, 1 H), 6.80 (d, $J = 10.0$ Hz, 1 H), 3.88 (t, $J = 5.0$ Hz, 4 H), 3.83 (d, $J = 5.0$ Hz, 1 H), 3.15 (t, $J = 5.0$ Hz, 4 H), 3.11–3.07 (m, 1 H), 2.61 (dd, $J = 7.5$ Hz, 1 H), 2.22 (s, 3 H), 2.04 (d, $J = 10.0$ Hz, 1 H), 1.98–1.85 (comp, 3 H), 1.54–1.47 (m, 1 H); ^{13}C NMR (125 MHz, CDCl_3) δ 150.3, 138.9, 138.1, 123.0, 115.3, 113.0, 67.0, 66.1, 50.2, 48.4, 44.4, 43.2, 38.4, 29.9; IR (thin film) 2935, 2846, 1492, 1245, 1121 cm^{-1} ; HRMS (ESI) m/z calcd for $\text{C}_{16}\text{H}_{23}\text{N}_2\text{O}$ ($\text{M}+\text{H}$)⁺, 259.1805; found, 259.1803.

(±)-Benzyl-9-chloro-3,4,5,6-tetrahydro-1,6-methanobenzo[c]-azocine-2(1H)-carboxylate (2).⁵⁶—

2

White solid (crystals from CH₃CN); mp 116–119 °C; ¹H NMR (500 MHz, CDCl₃, as a mixture of rotamers) δ 7.53 (br s, 0.4 H), 7.40 (d, *J* = 10.0 Hz, 1 H), 7.34 (t, *J* = 7.5 Hz, 1 H), 7.30–7.15 (comp, 3.6 H), 7.14–7.07 (m, 1 H), 6.99 (t, *J* = 7.5 Hz, 1 H), 5.46 (d, *J* = 7.5 Hz, 0.4 H), 5.29 (d, *J* = 7.5 Hz, 0.6 H), 5.18 (d, *J* = 15.0 Hz, 0.6 H), 5.15–5.08 (m, 1 H), 5.01 (d, *J* = 15.0 Hz, 0.4 H), 4.08 (dd, *J* = 15.0, 8.8 Hz, 0.6 H), 3.83 (dd, *J* = 15.0, 8.8 Hz, 0.4 H), 3.33–3.26 (m, 1 H), 3.20–3.07 (m, 1 H), 2.31–2.17 (m, 1 H), 2.08 (t, *J* = 15.0 Hz, 1 H), 1.78–1.65 (comp, 2 H), 1.53–1.39 (m, 1 H), 0.98–0.85 (m, 1 H); ¹³C NMR (125 MHz, CDCl₃, as a mixture of rotamers) δ 155.6, 155.4, 147.5, 147.3, 145.1, 145.0, 136.8, 136.5, 132.6, 132.4, 128.7, 128.5 (2 C), 128.4, 128.2, 127.9, 127.8, 125.5, 125.1, 124.6, 124.4, 67.5, 67.2, 58.8, 58.2, 44.7, 44.1, 42.9, 42.7, 35.3, 34.9, 34.7, 24.7, 24.5; IR (thin film) 2942, 1705, 1417, 1279 cm⁻¹; HRMS (ESI) *m/z* calcd for C₂₀H₂₀ClNNaO₂ (M+Na)⁺, 364.1080; found, 364.1084.

(±)-9-Chloro-2-(cyclohexylmethyl)-1,2,3,4,5,6-hexahydro-1,6-methanobenzo[c]azocine (MFG-1046)—

Iodotrimethylsilane (384 mg, 0.27 mL 1.92 mmol) was added in one portion to a solution of carbamate **2** (220 mg, 0.64 mmol) in CH₂Cl₂ (10.0 mL) at 0 °C in flask wrapped in foil. The cooling bath was removed after 2 h, and the reaction was stirred for an additional 3.25 h, whereupon the mixture was cooled to 0 °C, and methanolic HCl (2.0 M, 15 mL) was added. After stirring for 5 min, the volatiles were removed under reduced pressure, 2 N HCl_(aq) (30 mL) was added, and the aqueous mixture was extracted with Et₂O (2 × 15 mL). The pH of the aqueous layer was adjusted to ~9 by the slow addition of 2.2 M NaOH_(aq) and then extracted with CH₂Cl₂ (3 × 20 mL). The combined organic extracts were dried (Na₂SO₄), filtered, and concentrated under reduced pressure to afford 120 mg (90%) of the crude secondary amine which was of sufficient purity (>95% LC and ¹H NMR) to be used in the next step without purification. Cyclohexanecarboxaldehyde (**S8**, 47 mg, 50 μL, 0.42 mmol) was added to a solution of secondary amine (30 mg, 0.14 mmol) in DCE (1 mL), followed by the addition of sodium triacetoxymethylborohydride (88 mg, 0.42 mmol). The mixture was stirred for 24 h and then quenched by the addition of saturated sodium bicarbonate solution_(aq). After stirring for 5 min, the layers were separated, and H₂O (~1 mL) was added and the resultant mixture extracted with CH₂Cl₂ (3 × 5 mL). Brine was added to the aqueous mixture, which was then extracted with CH₂Cl₂ (1 × 5 mL). The combined organic extracts

were dried (MgSO_4), filtered, and concentrated under reduced pressure to give the crude product, which was purified via flash column chromatography (SiO_2), eluting with 100% hexanes \rightarrow 10% EtOAc/hexanes to afford 13 mg (30%) **MFG-1046** as a colorless oil: ^1H NMR (500 MHz, CDCl_3) δ 7.36 (d, $J = 10.0$ Hz, 1 H), 7.26 (d, $J = 10.0$ Hz, 1 H), 7.20–7.16 (m, 1 H), 4.76–4.68 (m, 1 H), 3.39–3.34 (m, 1 H), 3.22–3.08 (m, 1 H), 2.83–2.58 (comp, 4 H), 2.41–2.30 (m, 1 H), 2.23–1.89 (comp, 5 H), 1.79–1.69 (comp, 2 H), 1.67–1.49 (comp, 4 H), 1.36–0.99 (comp, 4 H); ^{13}C NMR (125 MHz, CDCl_3) δ 151.9, 153.3, 133.1, 131.5, 126.4, 126.1, 67.1, 61.1, 51.8, 40.7, 34.4, 34.1, 32.3, 32.0, 30.0, 25.8, 25.6; IR (thin film) 2935, 2860, 1458 cm^{-1} ; HRMS (ESI) m/z calcd for $\text{C}_{19}\text{H}_{27}\text{ClN}$ ($\text{M}+\text{H}$) $^+$, 304.18265; found, 304.18300.

(±)-Benzyl-9-(4-(trifluoromethyl)phenyl)-3,4,5,6-tetrahydro-1,6-methanobenzo[c]azocine-2(1H)-carboxylate (S10)—

A solution of carbamate **2** (258 mg, 0.75 mmol), 4-(trifluoromethyl)phenylboronic acid (286 mg, 1.5 mmol), Cs_2CO_3 (489 mg, 1.5 mmol), and palladium(bis)(*tert*-butyl) $_3$ phosphine (19 mg, 37 μmol) in degassed 1,4-dioxane (3.2 mL) was stirred for 1 min at room temperature and then 4 h at 98 $^\circ\text{C}$. The reaction was cooled to room temperature and filtered through a pad of Celite, and the filter pad was rinsed with EtOAc (~30 mL). The combined filtrates were concentrated under reduced pressure, and the crude residue was purified via radial plc (SiO_2), eluting with 100% hexanes \rightarrow 5% EtOAc/hexanes \rightarrow 10% EtOAc/hexanes to give 299 mg **S10** (88%) as a white foam: ^1H NMR (500 MHz, CDCl_3 , as a mixture of rotamers) δ 7.70–7.64 (m, 1 H), 7.61 (d, $J = 10.0$ Hz, 1 H), 7.53 (br s, 1 H), 7.52–7.42 (comp, 2 H), 7.39–7.31 (comp, 4 H), 7.23–7.20 (comp, 3), 5.66 (dd, $J = 7.5$ Hz, 0.4 H), 5.50 (dd, $J = 7.5$ Hz, 0.6 H), 5.37–5.29 (m, 1 H), 5.21–5.08 (m, 1 H), 4.21 (dd, $J = 15.0, 5.0$ Hz, 0.6 H), 3.93 (dd, $J = 15.0, 5.0$ Hz, 0.4 H), 3.50–3.45 (m, 1 H), 3.34–3.22 (m, 1 H), 2.46–2.34 (m, 1 H), 2.25–2.16 (m, 1 H), 1.95–1.85 (comp, 2 H), 1.65–1.55 (m, 1 H), 1.14–1.00 (m, 1 H); ^{13}C NMR (125 MHz, CDCl_3 , mixture of rotamers) δ 155.7, 155.6, 147.1, 146.8, 146.7, 146.5, 144.7, 138.9, 138.7, 136.9, 136.7, 128.6, 128.5, 128.4, 128.2, 127.9, 127.8, 127.4, 127.2, 125.6 (q, $J_{\text{C-F}} = 3.75$ Hz), 124.2, 124.0, 123.8, 123.3, 67.5, 67.2, 59.0, 58.3, 44.8, 44.2, 43.2, 43.0, 35.4, 35.3, 35.0, 34.9, 24.9, 24.7; IR (thin film) 2928, 1698, 1334 cm^{-1} ; HRMS (ESI) m/z calcd for $\text{C}_{27}\text{H}_{24}\text{F}_3\text{NNa}_2\text{O}_2$ ($\text{M}+\text{Na}$) $^+$, 474.1651; found, 474.1657.

(±)-2-Cyclopentyl-9-(4-(trifluoromethyl)phenyl)-1,2,3,4,5,6-hexa-hydro-1,6-methanobenzo[c]azocine (DKR-1051)—

A mixture of **S10** (297 mg, 0.65 mmol) and 10% Pd/C (27 mg) in ethanol (10 mL) was stirred under an atmosphere of H_2 for five h. More 10% Pd/C (44 mg) was added, and the

reaction continued for an additional 3 h. The catalyst was removed by filtration through a cotton plug, and the combined filtrates were concentrated under reduced pressure to provide 208 mg (99%) of crude product, which was of sufficient purity (^1H NMR) to use in the subsequent reaction. Cyclopentanone (**S11**, 36 mg, 40 μL , 0.43 mmol) was added to a solution of secondary amine (69 mg, 0.21 mmol) in DCE (2.0 mL), and sodium triacetoxyborohydride (91 mg, 0.43 mmol) was added. The mixture was stirred for 24 h, and then saturated sodium bicarbonate solution_(aq) (3 mL) was added. After stirring for 5 min, the layers were separated, H₂O was added (~1 mL), and the aqueous mixture was extracted with CH₂Cl₂ (3 \times 5 mL). The combined organic extracts were dried (MgSO₄), filtered, and concentrated under reduced pressure to give the crude product, which was purified via radial plc (SiO₂), eluting with 10% EtOAc/hexanes \rightarrow 15% EtOAc/hexanes to give 66 mg (79%; 78% over two steps) of **DKR-1051** as a colorless oil: ^1H NMR (500 MHz, CDCl₃) δ 7.72–7.65 (comp, 4 H), 7.54–7.45 (m, 1 H), 7.48 (d, J = 7.5 Hz, 1 H), 7.29 (d, J = 7.5 Hz, 1 H), 4.55–4.46 (m, 1 H), 3.37 (app t, J = 5.0 Hz, 1 H), 3.08–3.00 (m, 1 H), 2.82–2.73 (m, 1 H), 2.43–2.23 (comp, 2 H), 2.19–2.06 (comp, 2 H), 2.02–1.90 (comp, 2 H), 1.83–1.71 (comp, 4 H), 1.65–1.57 (comp, 4 H), 1.38–1.27 (m, 1 H); ^{13}C NMR (125 MHz, CDCl₃) δ 149.7, 145.1, 138.6, 129.1, 128.9, 127.4, 125.6 (q, $J_{\text{C-F}}$ = 3.75 Hz), 124.4, 123.9, 123.7, 123.3, 65.0, 63.5, 50.2, 42.3, 34.3, 32.9, 31.9, 30.7, 24.0; IR (thin film) 2963, 2866, 1623, 1327, 1128 cm⁻¹; HRMS (ESI) m/z calcd for C₂₄H₂₇F₃N (M+H)⁺, 386.2090; found 386.2092.

(±)-9-(4-(Trifluoromethyl)phenyl)-3,4,5,6-tetrahydro-1,6-methanobenzo[c]azocin-2(1H)-yl)propan-1-ol (UKH-1114)—

The benzyl carbamate of **S10** was removed with hydrogenolysis conditions as reported for the synthesis of **DKR-1051**. The secondary amine was of sufficient purity (^1H NMR) to use in the subsequent reaction. 3-Bromo-1-propanol (**S12**, 42 mg, 30 μL , 0.30 mmol) and K₂CO₃ (55 mg, 0.40 mmol) were added to a solution of secondary amine (32 mg, 0.10 mmol) in CH₃CN (2.0 mL), and the mixture was heated at 55 °C for 17 h. After cooling to room temperature, the solids were removed by filtration, and the filter cake was rinsed with CH₂Cl₂. The combined filtrates were concentrated under reduced pressure to give the crude product, which was purified via radial plc (SiO₂), eluting with 50% EtOAc/hexanes \rightarrow 100% EtOAc \rightarrow 3% MeOH/EtOAc to give 24 mg (64%; 63% over two steps) of **UKH-1114** as a colorless oil: ^1H NMR (400 MHz, CD₂Cl₂) δ 7.78–7.68 (comp, 4 H), 7.57 (s, 1 H), 7.53 (dd, J = 7.9, 1.8 Hz, 1 H), 7.33 (d, J = 7.9 Hz, 1 H), 4.41 (d, J = 5.6 Hz, 1 H), 3.93–3.82 (comp, 2 H), 3.38 (t, J = 6.2 Hz, 1 H), 3.01–2.92 (m, 1 H), 2.86–2.78 (m, 1 H), 2.63 (dd, J = 12.0, 8.4 Hz, 1 H), 2.24–2.11 (comp, 3 H), 2.04–1.94 (m, 1 H), 1.94–1.82 (m, 1 H), 1.78–1.65 (comp, 3 H), 1.42–1.30 (m, 1 H); ^{13}C NMR (150 MHz, CDCl₃) δ 144.6, 138.8, 129.4, 129.1, 128.3, 127.5, 125.7 (q, $J_{\text{C-F}}$ = 3.3 Hz), 125.2, 124.2, 124.1, 123.4, 66.5, 66.4, 50.3, 45.3, 41.5, 33.3, 27.9, 23.5, 22.3; IR (thin film) 3361, 2935, 2853, 1609, 1334, 1121 cm⁻¹; HRMS (ESI) m/z calcd for C₂₂H₂₅F₃NO (M+H)⁺, 376.1883; found 376.1892.

Sigma Receptor Binding Assay Protocol

Receptor binding assays were performed by the Psychoactive Drug Screening Program (PDSP) at Chapel Hill, North Carolina. The assay protocol book can be accessed free of charge at: <https://pdspdb.unc.edu/pdspWeb/content/PDSP%20Protocols%20II%202013-03-28.pdf>. Briefly, σ 1R were sourced from guinea pig brain and Sig1R binding affinity (K_i) was determined through competition binding assays with [3 H]-(+)-pentazocine. σ 2R were obtained from rat PC12 cells, and the Sig2R ligand binding affinity (K_i) was determined through competition binding assays using the radioligand [3 H]-ditolylguanidine in the presence of (+)-pentazocine to block σ 1R binding sites. K_i values are calculated from best-fit IC_{50} determinations and are the average of two or more independent runs performed in triplicate.

Sample Preparation for in Vivo Use

Dry compounds were reconstituted in dimethyl sulfoxide (DMSO) to a stock concentration between 25 and 100 mM and then diluted down to 10 μ g total drug in a volume of 5 μ L for IT injections. The total amount of DMSO for IT injections was always less than 5%, and the vehicle injections always contained the same amount of DMSO. Siramesine (Tocris) sample was reconstituted and diluted in the same way. Samples were diluted in the same manner for IV injections.

Gene Expression Analysis

Transcripts per million (TPM) was used to quantify relative gene abundance. Fragments per kilobase of transcript per million mapped reads (FPKMs) for coding genes were obtained by running the Tophat/Cuffdiff⁵⁷ pipeline or from published data. These were then normalized to sum to 1 million in order to generate TPMs. For mouse single cell RNA-seq data sets, low sequencing depth makes TPMs inaccurate due to high sampling variation, and the fraction of cells with presence of sequenced reads from genes of interest for different cell types are presented instead.

Statistics

Data are shown as mean \pm standard error of the mean, and the number of animals or samples used in each analysis are shown in figure legends. GraphPad Prism 7 for Mac OSX was used to analyze data. Two-way ANOVAs were used to analyze von Frey data with Bonferroni's multiple comparison post hoc test. Two tailed t tests were used to analyze rotarod data. Significance level was at $\alpha < 0.05$.

Figure 1. Norbenzomorphan and methanobenzazocine scaffolds **1** and **2** and the CNS penetrant σ 2R/Tmem97 ligands **SAS-0132** and **DKR-1051**.

Figure 2.

σ Receptor binding ligands. ^a K_i are shown for each ligand at σ 1R or σ 2R/Tmem97 as the mean of at least two independent experiments \pm standard deviation. Siramesine data is from ref 25. ^aFor all compounds, σ 2R/Tmem97 was sourced from rat PC12 cells, with the exception of siramesine, which utilized rat brain homogenate. See Methods Section for more details.

Figure 3. Effect of IT injection of $\sigma 1R$ ligands in the mouse SNI model. Compounds acting on $\sigma 1R$ were tested in the mouse SNI model. Mechanical sensitivity was measured at the indicated time points after IT injection of 10 μg compound. All vehicle groups, $n = 6$; **JWG-1014**, $n = 5$; **JSS-1027**, $n = 5$; **MFG-1046**, $n = 4$. ** $p < 0.01$, *** $p < 0.001$, and **** $p < 0.0001$.

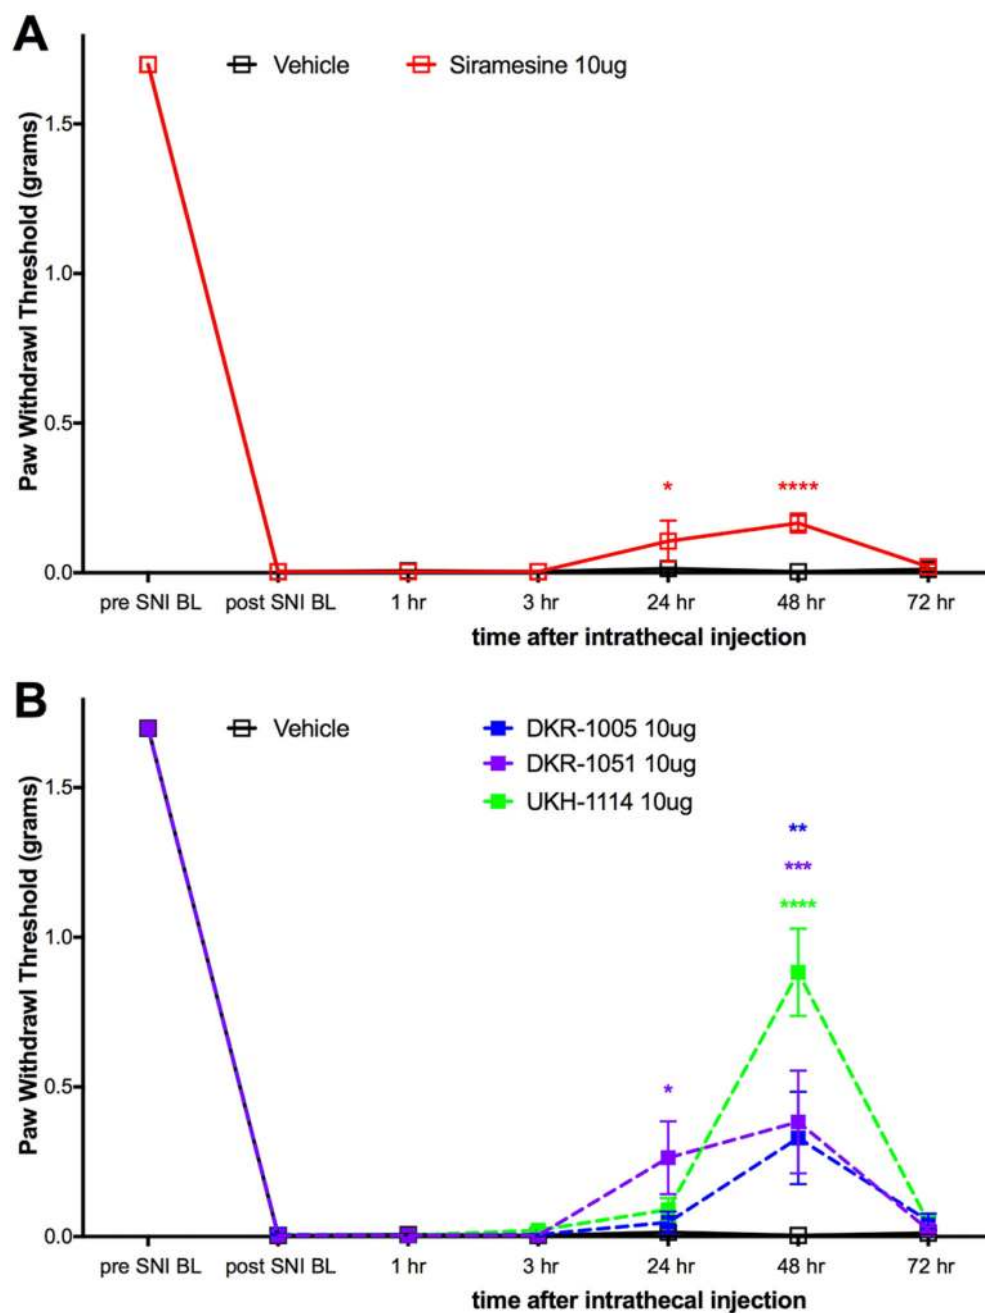

Figure 4. Effect of IT injection of $\sigma_2R/Tmem97$ ligands in the SNI model. Mechanical sensitivity was measured at the indicated time points after IT injection of 10 μg compound. (A) Effect of siramesine ($n = 4$) compared to vehicle ($n = 6$) is shown. (B) Effect of **DKR-1005** ($n = 6$), **DKR-1051** ($n = 5$) and **UKH-1114** ($n = 11$) compared to vehicle ($n = 6$) is shown. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, and **** $p < 0.0001$.

Figure 5. Effect of **UKH-1114** is blocked by the σ_{2R} /Tmem97 antagonist **SAS-0132**. σ_{2R} /Tmem97 antagonist **SAS-0132** at 10 μg dose given at the same time as **UKH-1114**, also at 10 μg dose, completely blocked the effect seen with **UKH-1114** given alone. $n = 6$ per group. **** $p < 0.0001$.

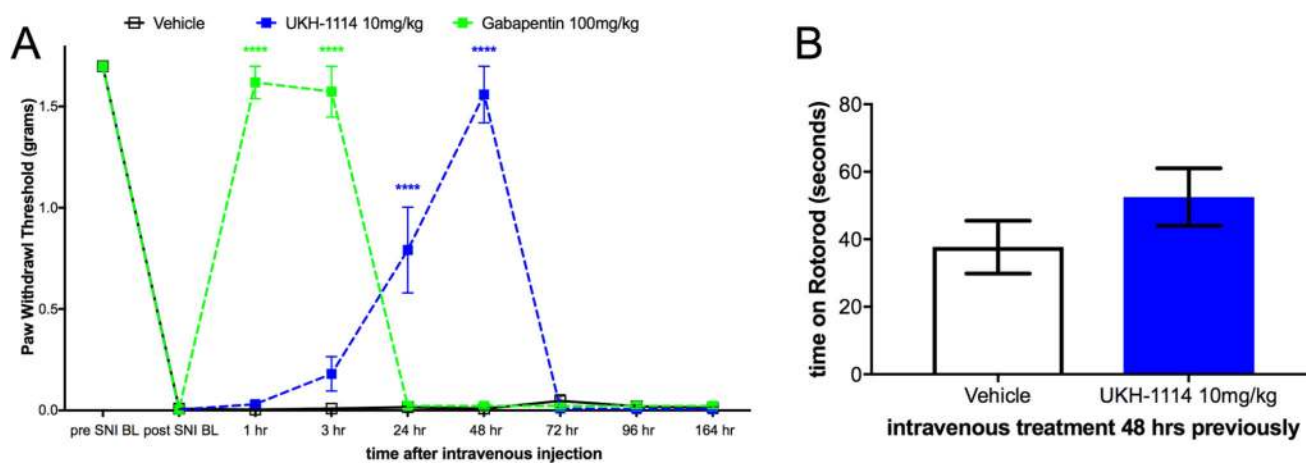

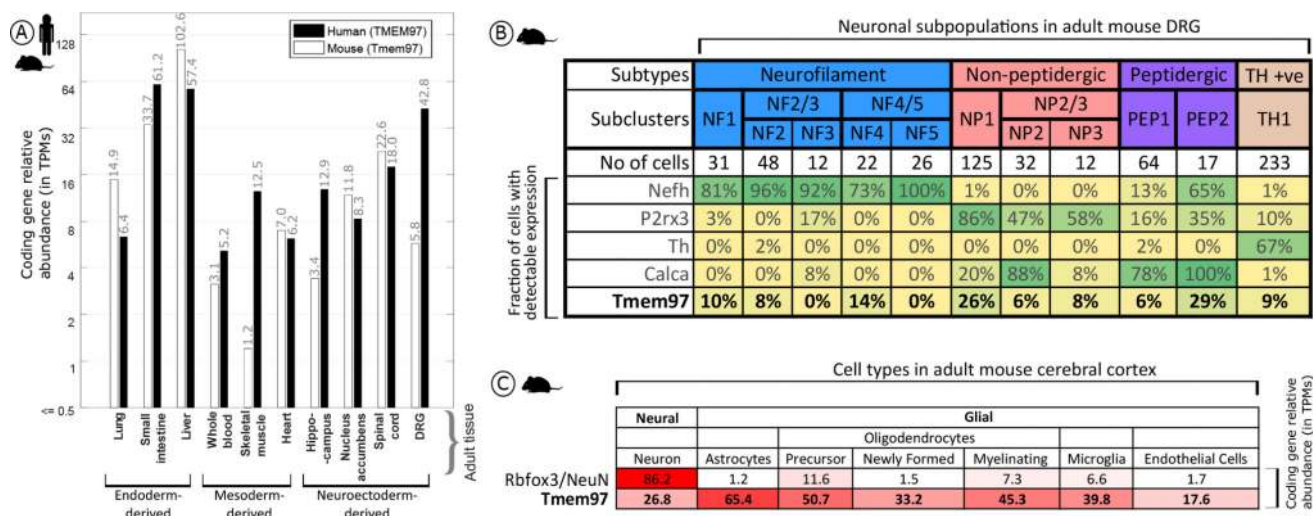

Figure 6.

Systemic dosing with **UKH-1114** leads to alleviation of neuropathic pain without motor effects. (A) Vehicle ($n = 6$), gabapentin (100 mg/kg, $n = 6$), or **UKH-1114** (10 mg/kg, $n = 6$) were given IV and mechanical testing was done at the indicated time points. (B) Rotorod testing was done 48 h after IV injection on an accelerating rotorod reaching a maximum of 40 rotations per minute over 200 s. Latency to fall is shown on the third trial ($n = 6$ per group). **** $p < 0.0001$.

**Figure 7.**

Expression analysis for *Tmem97* (A), *TMEM97* (human), and *Tmem97* (mouse) gene expression across orthologous tissues, with greater expression in the mouse and human GI tract and the human DRG. (B) Analysis of mouse single cell data reveals a maximum detection rate of 29% for *Tmem97* across all sensory neuron subpopulations as contrasted with 67% or more for known subpopulation marker genes. (C) Cortical expression of *Tmem97* as contrasted with the neuronal marker NeuN. *Tmem97* expression spans both neuronal and non-neuronal cells, with ~1.5–2.5-fold higher expression in non-neuronal cells.

**Figure 8.**

Synthesis of norbenzomorphan σ 2R/Tmem97 ligands.

Reagents and conditions (a) 10% Pd/C, H₂, EtOH. (b) K₂CO₃, CH₃CN, 50 °C. (c) Pd(OAc)₂, JohnPhos[®], NaO*t*-Bu, toluene, 100 °C. (d) TMSI, CH₂Cl₂, then HCl. (e) Na(OAc)₃BH, CH₃COOH, 1,2-dichloroethane.

**Figure 9.**

Synthesis of methanobenzazocine σ 2R/Tmem97 ligands.

Reagents and conditions (a) TMSI, CH_2Cl_2 , then HCl. (b) $\text{Na}(\text{OAc})_3\text{BH}$, 1,2-dichloroethane. (c) $\text{Pd}[\text{P}(\text{tBu})_3]_2$, Cs_2CO_3 , 1,4-dioxane, 98 °C. (d) 10% Pd/C, H_2 , EtOH. (e) K_2CO_3 , CH_3CN , 55 °C.
