Interleukin-1 (IL-1) and tumor necrosis factor (TNF- α) stimulate transcription factors AP-1 and NF- κ B through activation of the MAP kinases JNK and p38 and the I κ B kinase (IKK), respectively. The TNF- α and IL-1 signals are transduced through TRAF2 and TRAF6, respectively. Overexpressed TRAF2 or TRAF6 activate JNK, p38, or IKK in the absence of extracellular stimulation. By replacing the carboxy-terminal TRAF domain of TRAF2 and TRAF6 with repeats of the immunophilin FKBP12, we demonstrate that their effector domains are composed of their amino-terminal Zn and RING fingers. Oligomerization of the TRAF2 effector domain results in specific binding to MEKK1, a protein kinase capable of JNK, p38, and IKK activation, and induction of TNF- α and IL-1 responsive genes. TNF- α also enhances the binding of native TRAF2 to MEKK1 and stimulates the kinase activity of the latter. Thus, TNF- α and IL-1 signaling is based on oligomerization of TRAF2 and TRAF6 leading to activation of effector kinases.

[*Key Words*: Signaling; cytokines; protein kinase; effector domain]

Received November 24, 1998; revised version accepted April 1, 1999.

Interleukin-1 (IL-1) and tumor necrosis factor (TNF- α) are proinflammatory cytokines that are key to generation of systemic and local responses to infection, injury, and immunological challenges (Tracey and Cerami 1993; Dinarello 1994). Produced mainly by activated macrophages and monocytes, IL-1 and TNF- α participate in lymphocyte and leukocyte activation and trafficking, fever, acute-phase response, and cartilage remodeling (Tracey and Cerami 1993; Dinarello 1994). The biological functions of IL-1 and TNF- α are very similar, which is quite remarkable given the fact that the two cytokines, as well as their receptors, belong to different structural classes. The effects of IL-1 are mediated by the type-1 IL-1 receptor (IL-1R1) and IL-1R accessory protein (IL-1RAcP) (Dinarello 1994; Greenfeder et al. 1995). TNF- α exerts its effects through type 1 (TNFR1) or type 2 (TNFR2) receptors (Tartaglia and Goeddel 1992). Despite total absence of chemical and structural similarities, occupancy of these receptors leads to activation of two transcription factors, NF- κ B and AP-1, that induce genes involved in acute and chronic inflammatory re-

sponses (Baeuerle and Henkel 1994; Karin 1995; Barnes and Karin 1997). NF- κ B is regulated primarily by phosphorylation of inhibitory proteins, the I κ Bs, which retain it in the cytoplasm of nonstimulated cells (Beg and Baldwin 1993; Verma et al. 1995). Following cell stimulation the I κ Bs are phosphorylated by a cytokine-activated protein kinase complex called I κ B kinase (IKK) (DiDonato et al. 1997; Mercurio et al. 1997; Régnier et al. 1997; Woronicz et al. 1997; Zandi et al. 1997, 1998; Rothwarf et al. 1998; Yamaoka et al. 1998). This results in the ubiquitination and degradation of the I κ Bs and the nuclear translocation of freed NF- κ B. Once in the nucleus, NF- κ B activates transcription of genes whose promoters contain κ B sites. Many of these genes also contain binding sites for AP-1 whose activity is regulated by members of the mitogen-activated protein kinase (MAPK) family, which enter the nucleus upon stimulation to phosphorylate DNA-bound transcription factors (Karin 1995). Most relevant to TNF- α and IL-1 signaling are the so-called stress-activated protein kinases (SAPKs), c-Jun amino (N)-terminal kinases (JNKs), and p38 (Dérjard et al. 1994; Han et al. 1994; Kallunki et al. 1994; Kyriakis et al. 1994; Lee et al. 1994; Rouse et al. 1994). Both the JNKs and the p38s are activated rapidly and potently in response to TNF- α or IL-1, through

Baud et al.

MAPK cascades (Dérjard et al. 1995; Lin et al. 1995). In some cells TNF- α or IL-1 also stimulates ERK activity, which may also contribute to stimulation of AP-1 activity (Westwick et al. 1994).

Unlike growth factor receptors, which contain intrinsic tyrosine kinase domains (Schlessinger and Ullrich 1992), or most other cytokine receptors, which are coupled to Janus kinase (JAK) tyrosine kinases (Ihle 1996), the TNF- α and IL-1 receptors do not appear to function through tyrosine kinases. Instead they operate by recruiting a variety of signal transducers. Binding of TNF- α to TNFR1 or TNFR2 induces receptor trimerization and recruitment of several downstream signaling proteins to their cytoplasmic domains (Hsu et al. 1995, 1996). TNFR1 interacts with the signaling protein TNFR1-associated death domain protein (TRADD), which serves as a platform to recruit at least three additional mediators: TRAF2 (Hsu et al. 1995, 1996), receptor interacting protein (RIP) (Stanger et al. 1995), and Fas-associated protein with death domain (FADD) (Chinnaiyan et al. 1995). TNFR2 activation results in direct recruitment of TRAF2 and its relative TRAF1 (Rothe et al. 1994). Transfection experiments implicated TRAF2 as a critical mediator of NF- κ B (Rothe et al. 1995), JNK, and p38 activation (Liu et al. 1996; Natoli et al. 1997; Reinhard et al. 1997). However, *traf2*^{-/-} cells derived from TRAF2-deficient mice or cells from mice expressing a dominant-negative form of TRAF2 are severely defective in TNF- α -induced JNK activation, whereas they still exhibit considerable, albeit slower, NF- κ B activation (S.Y. Lee et al. 1997; Yeh et al. 1997). The basis for the differential dependence of the AP-1 (JNK and p38) and NF- κ B pathways on TRAF2 is not understood, but it was suggested that TRAF5, may substitute for TRAF2 in NF- κ B activation (S.Y. Lee et al. 1997; Yeh et al. 1997).

Binding of IL-1 to IL-1R1 induces heterodimerization with IL-1RAcP (Greenfeder et al. 1995) and recruitment of the adapter protein MyD88, which mediates the interaction of the IL-1 receptor-associated kinase (IRAK) with the cytoplasmic domain of the receptor (Cao et al. 1996a; Wesche et al. 1997). In turn, IRAK recruits TRAF6 to the activated receptor (Cao et al. 1996b). Thus, despite the lack of structural and chemical similarities between the TNF- α and IL-1 receptors, they both use TRAF proteins as signal transducers.

Like most TRAF proteins, TRAF2 and TRAF6 are composed of a highly conserved carboxy-terminal TRAF domain and a more variable amino-terminal domain, which contains a RING finger and several Zn fingers (Rothe et al. 1994; Cao et al. 1996b; Arch et al. 1998). Overexpression of either TRAF2 or TRAF6 is sufficient to activate signaling pathways leading to NF- κ B and AP-1 in the absence of extracellular stimuli (Rothe et al. 1995; Cao et al. 1996b; Liu et al. 1996; Song et al. 1997). It was found previously that the carboxy-terminal TRAF domains can mediate homotypic and heterotypic TRAF-TRAF interactions, as well as receptor docking (Rothe et al. 1994; Cheng et al. 1995; Cao et al. 1996b). Although these results suggest the carboxy-terminal TRAF domains function mainly as receptor docking and oligo-

merization domains, other experiments implicated them in binding of putative effectors, such as the NF- κ B-inducing kinase NIK (Malinin et al. 1997). Such results, therefore, suggest that the carboxy-terminal TRAF domain may function as an effector domain. On the other hand, the more variable region of TRAF proteins is their amino-terminal half (Cao et al. 1996b), and these regions in TRAF2 and TRAF6 specify their ability to activate NF- κ B (Rothe et al. 1995; Cao et al. 1996b; Takeuchi et al. 1996; Song et al. 1997). However, the amino-terminal halves do not dictate binding of putative effectors such as NIK, which interacts with all TRAFs regardless of their ability to activate NF- κ B (Song et al. 1997). Nevertheless, we postulated that the "signaling end" of TRAF2 and TRAF6 is their amino-terminal domain, whereas the carboxy-terminal TRAF domain may function only as an oligomerization and receptor docking domain. To test this hypothesis, we fused the amino-terminal halves of TRAF2 or TRAF6 to a threefold repeat of the FK506 binding immunophilin FKBP12 (Schreiber 1991) and used the dimeric ligand FK1012 to induce oligomerization of the TRAF-FKBP12 chimeras (Spencer et al. 1993). We provide evidence that the critical event in TRAF-mediated TNF- α and IL-1 signaling is ligand-induced TRAF oligomerization and that once oligomerized the amino-terminal domains of TRAF2 and TRAF6 gain the ability to stably interact with effectors, one of which may be the MAPK kinase (MAPKK) kinase (MAPKKK) MEKK1. Oligomerization of a stably expressed TRAF2-FKBP12 chimera induces the same spectrum of genes, coding for inflammatory mediators, as normally induced by TNF- α or IL-1 themselves.

Results

IRAK and TRAF6 mediate JNK and p38 activation

IRAK and TRAF6 are critical intermediates in the pathway leading from IL-1R1 to NF- κ B (Cao et al. 1996a,b). To examine their involvement in JNK and p38 activation, IRAK or TRAF6 expression vectors were cotransfected into HeLa or HEK 293 cells with expression vectors encoding hemagglutinin (HA)-tagged JNK1 or p38 α . Both IRAK and TRAF6 activated JNK efficiently (Fig. 1A) and p38 (Fig. 1B). IRAK(Δ 218-507), a truncation mutant lacking the protein kinase domain, or TRAF6(289-522), lacking the amino-terminal RING and Zn fingers, did not activate either JNK1 or p38 (Fig. 1C; data not shown). On the contrary, both mutants completely inhibited JNK completely (Fig. 1A) or p38 (Fig. 1B) activation by IL-1. Thus, IRAK and TRAF6 are critical intermediates in the pathway leading from IL-1R1 to JNK or p38.

We addressed the relationship between IRAK and TRAF6 by examining the ability of the truncation mutants described above to interfere with the action of the native proteins. TRAF6(289-522) blocked JNK1 activation by IRAK, but IRAK(Δ 218-507) did not interfere with JNK activation by TRAF6 (Fig. 1C). These results are consistent with those of protein recruitment experiments (Cao et al. 1996b) and indicate that TRAF6 acts

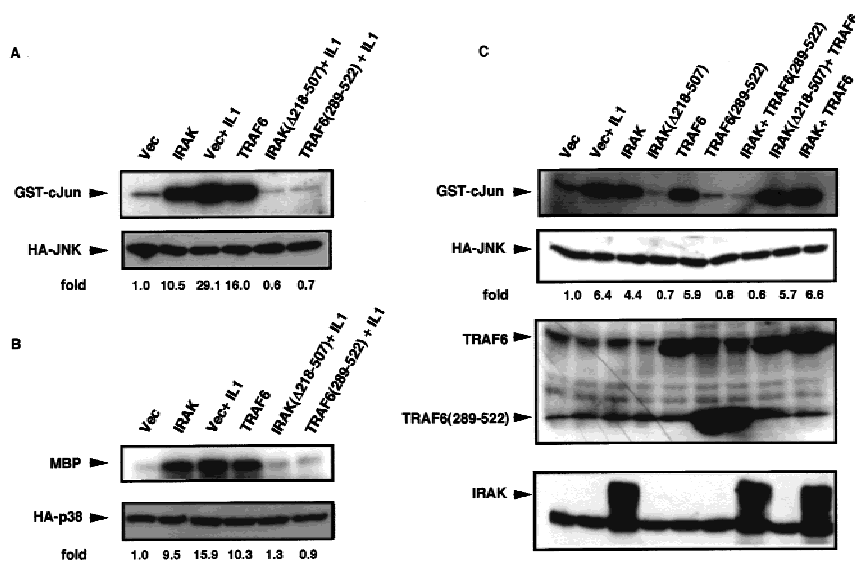

Figure 1. TRAF6 mediates JNK and p38 activation by IL-1. (A) HEK293 cells were cotransfected with HA-JNK1 (0.5 μ g/plate) along with either an empty expression vector (Vec), IRAK or IRAK(Δ 218–507) (100 ng/plate each), or TRAF6 or TRAF6(289–522) (1 μ g/plate each) expression vectors. Total DNA was kept constant (1.5 μ g/plate) using empty expression vector. After 24 hr the transfected cells were treated with IL-1 (10 ng/ml) for 30 min or left untreated. Cells were collected, lysed, and HA-JNK1 activity was determined by immunocomplex kinase assay with GST-cJun(1–79) as a substrate. Fold-increase in HA-JNK1 activity above the basal level in cells cotransfected with empty expression vector was determined by PhosphorImaging and normalized to the level of HA-JNK1 expression, determined by immunoblotting. (B) HEK293 cells were transfected as described above except that an HA-p38 α vector (0.5 μ g/plate)

was used instead of the HA-JNK1 vector. HA-p38 α activity was determined, as above, by immunocomplex kinase assay with myelin basic protein (MBP) as a substrate. (C) HEK293 cells were cotransfected with HA-JNK1 (0.5 μ g/plate), IRAK or IRAK(Δ 218–507) (100 ng/plate each), TRAF6 or TRAF6(289–522) (1 μ g/plate each) expression vectors as indicated. After 24 hr some cultures were treated with IL-1 for 30 min and the rest left untreated. HA-JNK1 activity and expression were determined as described above. Expression of Flag-TRAF6, Flag-TRAF6(289–522), or IRAK was determined by immunoblotting.

downstream of IRAK in the pathway leading from IL-1R to JNK or p38. Accordingly, coexpression of IRAK and TRAF6 did not elicit a greater JNK activation response than either protein alone (Fig. 1C). Essentially identical results were obtained when activation of p38 or NF- κ B were measured as endpoints (data not shown). Immunoblots indicated that the potent inhibitory effect of TRAF6(289–522) on JNK, p38 or NF- κ B activation is not caused by nonspecific interference with IRAK, JNK1, or p38 α expression.

TRAF-FKBP12 chimeras can activate JNK, p38, and IKK

TRAF2 and TRAF6 are recruited to the occupied TNF- α and IL-1 receptors through binding of different adapters, namely TRADD and IRAK, respectively, via their carboxy-terminal TRAF domains (Cao et al. 1996b; Hsu et al. 1996). Overexpression of either TRAF2 or TRAF6 may mimic ligand-induced signaling by causing their aggregation. In addition to mediating recruitment to the receptor complex the carboxy-terminal TRAF domain can engage in homotypic and heterotypic TRAF-TRAF interactions (Rothe et al. 1994; Cheng et al. 1995; Cao et al. 1996b). We therefore hypothesized that the amino-terminal halves of TRAF2 and TRAF6 are their effector domains, whereas the carboxy-terminal TRAF domain serves only as an oligomerization and receptor docking domain. To test this hypothesis we fused amino acids 1–303 of TRAF2 or 1–274 of TRAF6 to a threefold repeat of the immunophilin FKBP12 (Fig. 2A). Upon incubation with dimeric FKBP ligands, such as FK1012, chimeras that contain several FKBP repeats undergo extensive

oligomerization (Spencer et al. 1993). Transient transfection of either TRAF2(1–303)-FKBP12 or TRAF6(1–274)-FKBP12 vectors results in expression of proteins of the expected size at levels similar to those of the native proteins (Fig. 2B,C). In the absence of FK1012 either chimera had little effect on activity of either a coexpressed HA-JNK1 protein (Fig. 2B,C) or a 2 \times NF- κ B-LUC reporter (Fig. 2D,E). However, incubation of cells expressing either TRAF-FKBP12 chimera with FK1012, but not FK506, resulted in large increases in either JNK or NF- κ B activity (Fig. 2B–E). FK1012-induced oligomerization of either TRAF-FKBP12 chimera resulted in activation of IKK (Fig. 2F, data not shown), similar in magnitude to the effects of either wild-type TRAF2 or TRAF6 (data not shown). Oligomerization of a TRAF2-FKBP12 mutant that can not activate NF- κ B (see below) failed to stimulate IKK activity (Fig. 2F, mR1-FKBP).

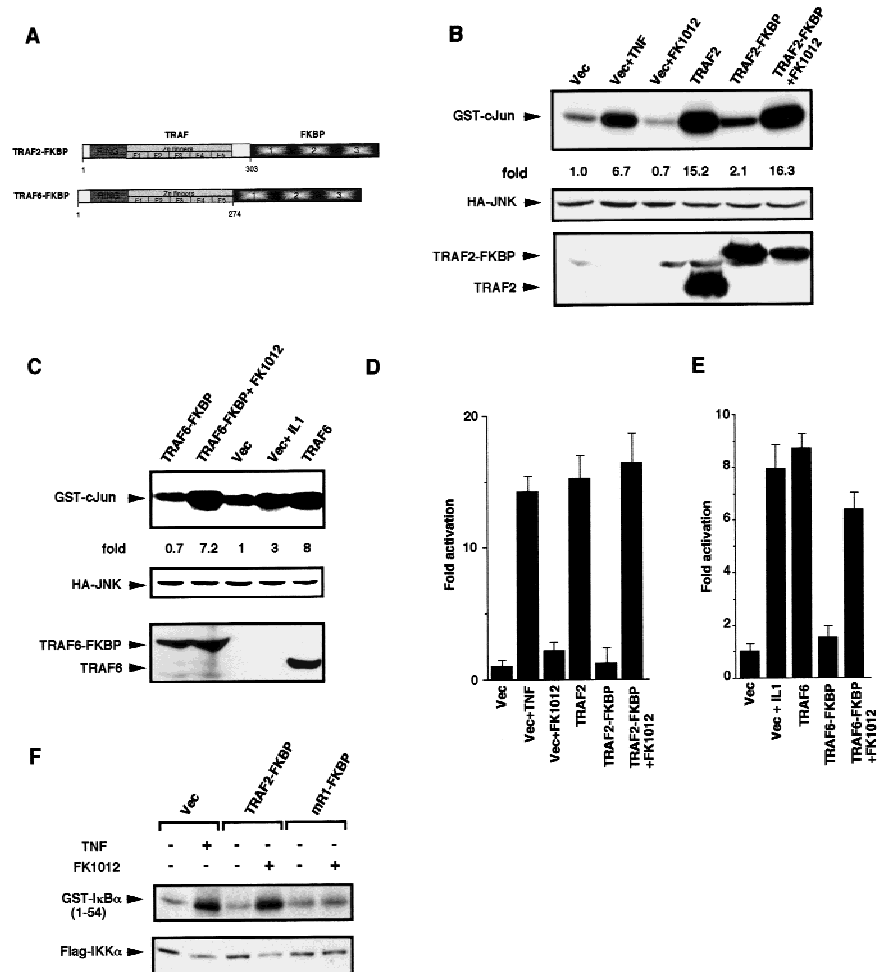

I-TRAF/TANK is a TRAF-interacting protein whose overexpression inhibits TNF- α signaling through binding to the TRAF domain of TRAF2 (Cheng and Baltimore 1996; Rothe et al. 1996). Overexpression of TANK/I-TRAF had little effect on either JNK or NF- κ B activation by TRAF2(1–303)-FKBP12 (Fig. 3) or TRAF6(1–274)-FKBP12 (data not shown), whereas it abolished TRAF2 and strongly reduced TRAF6-induced JNK and NF- κ B activation (Fig. 3; data not shown). Therefore the TRAF-FKBP12 chimeras do not function through an interaction with the endogenous TRAF2 or TRAF6 proteins or through their indirect activation.

Mutations in the amino-terminal RING and Zn fingers attenuate JNK and NF- κ B activation

The results presented above strongly suggested that the

Figure 2. TRAF–FKBP12 chimeras activate JNK and NF- κ B in response to dimerizer-induced oligomerization. (A) A diagram illustrating the domain structure of the two TRAF–FKBP12 fusion proteins. (B) HEK293 cells were transfected with HA–JNK1 (0.5 μ g/plate) along with either empty expression vector or expression vectors for Flag–TRAF2 or Flag–TRAF2(1–303)–FKBP12 (1 μ g/plate each). Some of the transfected cells were treated with either TNF- α (15 ng/ml) for 10 min, or FK506 (0.5 μ M) or FK1012 (0.5 μ M) for 4 hr, as indicated. JNK activity was determined as described above. Expression of HA–JNK1, Flag–TRAF2, or Flag–TRAF2(1–303)–FKBP12 were examined by immunoblotting. Similar results were obtained using HeLa cells as recipients (data not shown). (C) Similar experiments to those described in B were performed using Flag–TRAF6 and Flag–TRAF6(1–274)–FKBP12 expression vectors. Where indicated, transfected cells were treated with IL-1 (4 ng/ml) for 10 min (D, E) NF- κ B activation by TRAF2(1–303)–FKBP12 (D) or TRAF6(1–274)–FKBP12 (E) was measured by transfecting HEK293 cells with a 2 \times NF- κ B–LUC reporter (0.5 μ g/plate) and the indicated TRAF and TRAF–FKBP12 expression vectors (1 μ g/plate). pRSV–*lacZ* (0.1 μ g/plate) was included to normalize transfection efficiency. Cells were collected 6 hr after the indicated treatments (as in B), which were initiated 24 hr after transfection, and luciferase activity was determined. (F) HeLa cells were transfected with Flag–IKK α (0.5 μ g) and the indicated TRAF2–FKBP12 vectors. Where indicated, cells were treated with TNF- α for 5 min or FK1012 for 4 hr before collection and lysis. Immunocomplex kinase assay was performed with GST–IkB α (1–54) as a substrate.

effector domains of TRAF2 and TRAF6 are located in their amino-terminal halves. As a further test of this possibility we generated a set of TRAF2 mutants in which the amino-terminal RING finger and the first three potential Zn fingers were rendered nonfunctional through substitution of cysteines, thought to be involved in metal binding, with serines (Fig. 4A). In mR1 C34 and C37 were replaced with serines, whereas in mF1, mF2, and mF3 C107/C112, C136/C139, and C163/C166, respectively, were substituted with serines.

When examined at low input mR1 and mF1 were defective in JNK activation, whereas mF2 and mF3 had wild-type activity (Fig. 4B, top). However when examined at higher input mR1 and mF1 were only partially defective in JNK activation (Fig. 4B, bottom). A mutant that completely lacks the RING finger, TRAF2(87–501), was inactive at all levels, as described previously (Liu et al. 1996). When examined at either low (data not shown)

or high-input mR1 and mF1 failed to activate NF- κ B, whereas mF2 had wild-type activity (Fig. 4C). Surprisingly, mF3 was 2.5 times more potent than wild-type TRAF2 in NF- κ B activation (Fig. 4C). We also examined the ability of the various TRAF2 mutants to stimulate IKK activity by cotransfecting them with an HA–IKK β vector (Zandi et al. 1997). Whereas neither mR1 nor mF1 activated IKK β , mF2 was as effective as wild-type TRAF2 (Fig. 4D). Consistent with its behavior in the reporter assay, mF3 activates IKK β about twofold better than wild-type TRAF2 (Fig. 4D). mR1 was also inactive as an FKBP fusion protein (Fig. 2F).

Oligomerization of TRAF2–FKBP12 in stably transfected cells activates the program of inflammation-induced genes

To test whether the amino-terminal effector domain of

Figure 3. Activation of JNK and NF- κ B by TRAF2-FKBP12 is insensitive to TANK/I-TRAF. (A) HEK293 cells were cotransfected with HA-JNK1 (0.5 μ g/plate) along with an empty expression vector, Flag-TRAF2 or Flag-TRAF2(1-303)-FKBP12 (500 ng/plate each) and I-TRAF (150 ng/plate) expression vectors as indicated. Cells were treated with either TNF- α for 15 min, or FK506 or FK1012 for 4 hr, as indicated, before being collected to measure HA-JNK1 activity and expression. (B) HEK293 cells were transfected with 2 \times NF- κ B-LUC and RSV-*lacZ* reporters along with the indicated expression vectors and treated as in A. Luciferase activity was determined as described above.

TRAF2 is sufficient for triggering most of the physiological functions of TNF- α at the cellular level, we generated stably transfected clones of HeLa cells that express TRAF2(1-303)-FKBP12 at levels that are not much higher than those of endogenous TRAF2 (data not shown). Treatment of such cells with FK1012, but not FK506 (data not shown), resulted in efficient JNK and IKK activation similar in magnitude to the effects of TNF- α (Fig. 5A) and IL-1 (data not shown). Treatment of nontransfected cells with FK1012 had no effect on either protein kinase (data not shown). To examine whether dimerizer-induced clustering of the TRAF2(1-303)-FKBP12 chimera induced the same gene expression program as induced by TNF- α or IL-1, we extracted total cytoplasmic RNA from cells stably expressing this chimera that were either cultured in growth medium alone or treated with FK1012 (4 hr). We also prepared RNA samples from untreated, TNF- α (7 hr)-, IL-1 (7 hr)-, or FK1012 (4 hr)-treated parental HeLa cells. Poly(A)⁺ RNA was isolated and used to generate total ³²P-labeled cDNA probes that were hybridized to membranes containing 597 spotted DNA fragments derived from different human genes. Exposure to TNF- α or IL-1 induced the expression of five of these genes by more than three- to fourfold (Fig. 5B). These genes code for the chemokines MCP-1, MIP-2a, and IL-8, the cytokine IL-6 and the ad-

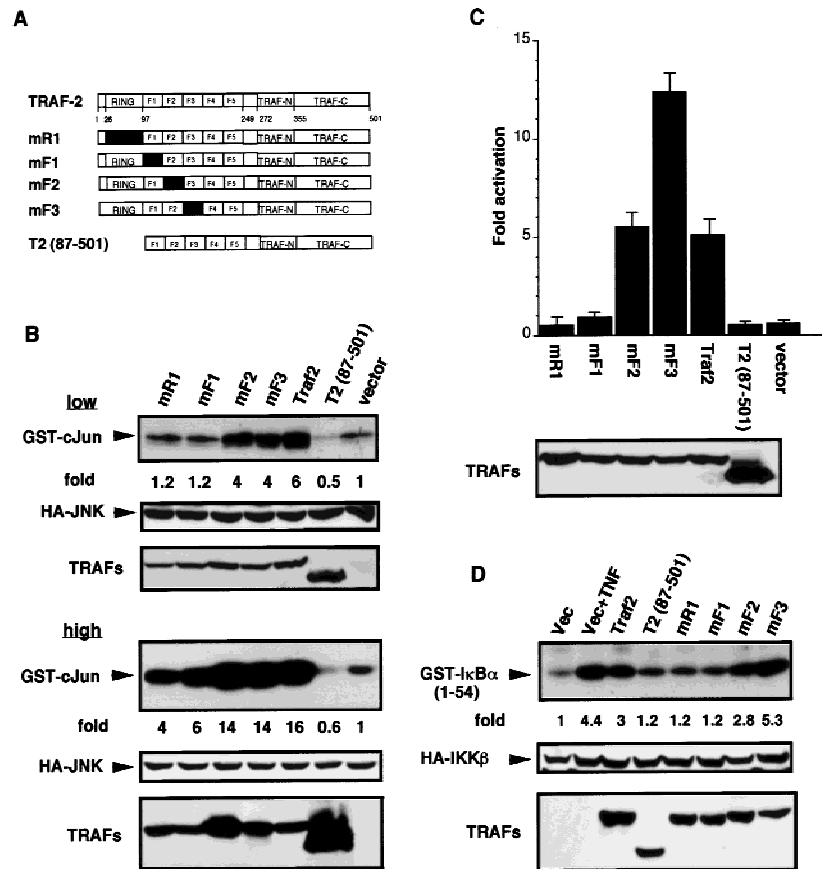

hesion molecule ICAM-1. Treatment of the TRAF2(1-303)-FKBP12-expressing cells with FK1012 induced the same set of genes as induced by TNF- α or IL-1. Moreover, none of the 590 genes (of which only 4 are shown in the Fig. 5B) that were refractory to TNF- α and IL-1 was induced by treatment of TRAF2-FKBP12-expressing cells with FK1012 (Fig. 5B; data not shown). Treatment of nontransfected HeLa cells with FK1012 did not induce any TNF- α - and IL-1-responsive genes (data not shown).

Dimerizer-induced interaction of TRAF-FKBP12 chimeras with MEKK1

A member of the MAPKKK family, NIK, was suggested to mediate TNF- α - and IL-1-induced NF- κ B activation (Malinin et al. 1997). NIK was isolated as a TRAF2-interacting protein. However, NIK interacts with almost all of known TRAF proteins, regardless of their ability to activate NF- κ B (Song et al. 1997; V. Baud, unpubl.). Furthermore, signaling incompetent mutants of TRAF2 or TRAF6 do not exhibit any reduction in their ability to interact with NIK (V. Baud, unpubl.). Yet, overexpressed NIK activates NF- κ B and catalytically inactive NIK(AA) mutant can block TNF- α - and IL-1-induced NF- κ B activation (Malinin et al. 1997). Another MAPKKK, MEKK1 was suggested to transduce the effect of TNF- α and IL-1 to the JNK and p38 cascades (Minden et al. 1995; Liu et al. 1996; Xia et al. 1998). MEKK1 was also suggested to be involved in NF- κ B activation (Lee et al. 1997). Another MAPKKK suggested to be involved in TNF- α -induced JNK activation is ASK1 (Ichijo et al. 1997).

We examined whether the TRAF-FKBP12 chimeras interact with either of these MAPKKKs and other signal-transducing proteins known or thought to be involved in TNF- α or IL-1 signaling. As observed by others (G. Crabtree, pers. comm.) we found that within 1 hr of FK1012 treatment the TRAF-FKBP12 chimeras formed aggregates that could be sedimented from cell lysates by centrifugation. These aggregates were insoluble in nondenaturing buffers and therefore it was impossible to use conventional immunoprecipitation procedures to examine the interaction of any protein with the oligomerized TRAF-FKBP12 chimeras. To circumvent this problem we took advantage of the ability of the oligomerized TRAF-FKBP12 chimeras to form insoluble aggregates and examined whether coexpressed signal transducing proteins cosedimented with TRAF2(1-303)-FKBP12 upon FK1012 addition. Whereas epitope-tagged NIK, ASK1, GCK, and MEKK2 remained soluble after coexpression with TRAF2(1-303)-FKBP12 and FK1012 treatment, full-length MEKK1 was rendered insoluble by this treatment (Fig. 6). If expressed in the absence of TRAF2(1-303)-FKBP12, MEKK1 remained soluble even after incubation with FK1012. Interestingly, truncated MEKK1 polypeptides produced by intracellular proteolysis (Cardone et al. 1997; Widmann et al. 1998) remained soluble and did not cosediment with oligomerized TRAF2(1-303)-FKBP12. To further investigate which region of MEKK1 is involved in the interaction with TRAF2(1-303)-FKBP12, we coexpressed the chimera

Figure 4. Mutations within the amino-terminal effector domain of TRAF2 differentially affect JNK and IKK activation. (A) Schematic representation of TRAF2 mutants. The numbers below the diagram refer to amino acids positions. F1–5 denote the five Zn fingers. The domains in which pairs of cysteine residues were replaced with serines are indicated by black boxes (mR1: S34/37; mF1: S107/112; mF2: S136/139; and mF3: S163/166). (B) JNK activation. HEK293 cells were cotransfected with HA–JNK1 and either an empty vector or expression vectors encoding wild-type or mutant versions of TRAF2, used at either low (0.2 μ g/plate; top two panels) or high (1 μ g/plate; bottom two panels) input levels. After 24 hr cells were collected and HA–JNK1 activity and expression were determined. TRAF expression was also determined. (C) NF- κ B activation. HEK293 cells were cotransfected with 2 \times NF- κ B–LUC and pRSV–*lacZ* reporters and either an empty vector or expression vectors for wild-type and mutant TRAF2 proteins as indicated (1 μ g/plate). Cells were collected, and luciferase activity and TRAF expression were determined. (D) IKK activation. HEK293 cells were cotransfected with HA–IKK β (0.25 μ g/plate) and either an empty vector or expression vectors for wild-type and mutant TRAF2 proteins (1 μ g/plate). Some transfectants were treated with TNF- α (15 ng/ml) for 10 min. Immuno-complex kinase assay was performed with GST–IkB α (1–54) as a substrate. HA–IKK β and TRAF expression were determined by immunoblotting.

with either full-length MEKK1 or two deletion mutants, 70K MEKK1 Δ N and 35K MEKK1 Δ N, which encode the carboxy-terminal 672 and 321 residues of MEKK1, respectively. Whereas full-length MEKK1 cosedimented with TRAF2(1–303)–FKBP12 after FK1012 treatment, the truncation mutants remained soluble (Fig. 6). To further examine the physiological relevance of this interaction we coexpressed MEKK1 with mutant versions of TRAF2(1–303)–FKBP12 that either contain a nonfunctional amino-terminal RING finger (mR1–TRAF2–FKBP12) or completely lack this part of the protein [TRAF2(100–303)–FKBP12; indicated as Δ TRAF2 in the Fig. 6]. Although both mutants were rendered insoluble after FK1012 treatment, mR1–TRAF2–FKBP12 was considerably less effective in coprecipitating MEKK1 in comparison to wild-type TRAF2–FKBP12, whereas a very small fraction of MEKK1, if any, cosedimented with TRAF2(100–303)–FKBP12 (Fig. 6). Interestingly, coexpression of wild-type TRAF2–FKBP12 enhanced MEKK1 proteolysis, whereas coexpression of mR1–TRAF2–FKBP12 or TRAF2(100–303)–FKBP12 decreased the extent of MEKK1 proteolysis. These observations are consistent with previous reports according to which cell stimulation enhanced MEKK1 proteolysis (Cardone et al. 1997; Widmann et al. 1998).

TNF- α activates MEKK1 and enhances its binding to TRAF2

The results described above suggest that MEKK1 is one of the effectors through which TRAF2 activates downstream kinases. To further investigate the role of MEKK1 in TNF- α signaling we examined the effect of TNF- α on the interaction between TRAF2 and MEKK1. HEK293 cells were transfected with either a wild-type TRAF2 or a TRAF2(87–501) expression vector in the absence or presence of an MEKK1 vector. Cells were either left untreated or were stimulated with TNF- α and the interaction between MEKK1 and TRAF2 or TRAF2(87–501) examined by immunoprecipitation. Cell stimulation with TNF- α resulted in a large increase in the interaction between MEKK1 and wild-type TRAF2, whereas no considerable interaction was observed between MEKK1 and TRAF2 (87–501) in the absence or presence of TNF- α (Fig. 7A). In addition, cell stimulation with TNF- α substantially increased the extent of MEKK1 autophosphorylation, only which coexpressed with wild-type TRAF2 (Fig. 7A). In nontransfected cells, stimulation with TNF- α increased both the autokinase activity of MEKK1 and its ability to phosphorylate JNK1 (Fig. 7B). Expression of catalytically inactive MEKK1 inhibited the

Figure 5. Treatment of HeLa cells stably expressing TRAF2-FKBP12 with FK1012 activates the inflammation-induced gene expression program. (A) Treatment of HeLa cells that stably express TRAF2(1-303)-FKBP12 with FK1012 activates JNK and IKK. Endogenous JNK1 (left) or IKK α (right) was immunoprecipitated from untreated or cells treated with either TNF- α (15 ng/ml for 10 min) or FK1012 (0.5 μ M for 4 hr). JNK and IKK activity were determined by immunocomplex kinase assays with GST-cJun(1-79) and GST-I κ B α (1-54) as substrates, respectively. Immunoprecipitated JNK1 and IKK α proteins were detected by immunoblotting. (B) Oligomerization of TRAF2(1-303)-FKBP12 induces the same gene expression program as TNF- α or IL-1. Membranes containing an array of 597 spotted cDNA fragments derived from different human genes were hybridized to 32 P-labeled cDNA probes derived from poly(A)⁺ RNA samples prepared from either parental HeLa cells that were either untreated or treated with either TNF- α (solid bars; 15 ng/ml) or IL-1 (hatched bars; 4 ng/ml) for 7 hr, or from HeLa cells stably expressing TRAF2(1-303)-FKBP12 that were either untreated or treated with FK1012 (open bars; 0.5 μ M for 4 hr). The fold-increase in gene expression above the level in untreated parental or transfected cells was determined by PhosphorImaging and a series of Excel-based macros as described in Materials and Methods. Data are averages of two completely independent experiments. Only 4 of the 590 genes whose expression was not induced by TNF- α , IL-1, or FK1012 are included. Treatment of parental HeLa cells with FK1012 did not result in gene induction (data not shown).

ability of both TRAF2 and TRAF2-FKBP to activate JNK (Fig. 7C). Previously the same mutant was found to inhibit TNF- α -induced JNK activation (Liu et al. 1996). These results strongly implicate MEKK1 as a downstream effector of TRAF2.

Discussion

Although TNF- α and IL-1 or their receptors bear no biochemical and structural resemblance, they elicit similar biological effects (Tracey and Cerami 1993; Dinarello

1994). This is largely because both TNF- α and IL-1 are potent activators of AP-1 and NF- κ B, which mediate many of their effects (Barnes and Karin 1997). Activation of AP-1 and NF- κ B can be attributed to the recruitment of two similar signaling proteins, TRAF2 and TRAF6, respectively, to the TNF- α and IL-1 receptors. TRAF2 and TRAF6 are members of a growing family of signal transducers related by a conserved carboxy-terminal TRAF domain (Cao et al. 1996b). Except for TRAF6, which is exclusively involved in IL-1 signaling (Cao et al. 1996b), most other TRAFs are signal transducers for members of the TNF/TNFR superfamilies (Rothe et al. 1995; Duckett et al. 1997; Arch et al. 1998). The results described above explain how TRAF2 and TRAF6, and by analogy other TRAF proteins, transduce signals generated by receptor occupancy to downstream responses. According to these results the conserved carboxy-terminal TRAF domain is likely to function as an oligomerization domain whose major role is to induce clustering of the more variable amino-terminal effector domain. Regulated clustering of the amino-terminal effector domains of either TRAF2 or TRAF6, through fusion to a threefold FKBP12 repeat and incubation with the dimerizer FK1012 (Spencer et al. 1993), is sufficient for activating all of the downstream protein kinases that transduce the TNF- α and IL-1 signals to AP-1 and NF- κ B and for induction of the same spectrum of target genes normally induced by TNF- α or IL-1.

Overexpressed native TRAF2 or TRAF6 can activate JNK, p38, and IKK, in the absence of extracellular stimuli. We explain these results by postulating that overexpression of TRAF2 or TRAF6 results in their oligomerization, thereby mimicking recruitment to ligand-oligomerized receptors (Heldin 1995). Because the carboxy-terminal TRAF domain is involved in homotypic and heterotypic TRAF-TRAF interactions (Rothe et al. 1994; Cheng et al. 1995), it seemed likely that one of its more important roles is to cause oligomerization of TRAF2 or TRAF6. It therefore followed that the effector functions of TRAF2 or TRAF6 reside within their amino-terminal domains. This hypothesis was tested by fusing these domains to a threefold repeat of the immunophilin FKBP12 and induction of oligomerization with the dimerizer FK1012 (Spencer et al. 1993). Despite the absence of the carboxy-terminal TRAF domain, both TRAF-FKBP12 chimeras were capable of JNK, p38, IKK, and NF- κ B activation after treatment with FK1012. Importantly, FK1012 treatment of HeLa cells that stably express TRAF2(1-303)-FKBP12 induced the same set of target genes whose expression is normally induced by TNF- α or IL-1. These genes code for the chemokines MCP-1, MIP-2a, and IL-8, the cytokine IL-6 and the adhesion molecule ICAM-1. As discussed (Barnes and Karin 1997), these and similar molecules (whose cDNAs were not part of the microarray we used) are instrumental in mediating the proinflammatory activity of TNF- α and IL-1. In addition, MCP-1, IL-8, IL-6, and ICAM-1 promoters contain functional AP-1 and NF- κ B sites (Dendorfer et al. 1994; Chen and Manning 1995; Farina et al. 1997; Martin et al. 1997; Roger et al. 1998). Further

Baud et al.

Figure 6. Oligomerization-induced interaction of TRAF2–FKBP12 with MEKK1. HEK293 cells were transfected with 0.4 μ g of different expression vectors encoding wild-type or mutant versions of TRAF2–FKBP12 chimeras and different MAPKs (MAP3K; MEKK1, MEKK2, ASK1, NIK) or STE20-like kinases (MAP4K; GCK), as indicated. The transfected cultures were left untreated or treated with FK1012 (0.5 μ M for 4 hr) before lysis in nondenaturing buffer. After centrifugation the dissolved insoluble (P) and soluble (S) fractions were separated by 7.5% SDS–polyacrylamide gel. MEKK1, ASK, GCK, and NIK were detected by immunoblotting with antibody to their amino-terminal Xpress tag. The 35K and 70K MEKK1 Δ N truncation mutants and MEKK2 were detected with anti-MEKK1 and MEKK2, respectively. The different TRAF2–FKBP12 chimeras were detected with an antibody to their amino-terminal Flag tag. Equal loading of the lanes was controlled by probing the same blots with an actin antibody.

indication that the amino-terminal halves of TRAF2 and TRAF6 mediate their effector function is provided by mutagenesis experiments. Mutations in the amino-terminal RING finger and several of the putative Zn fingers of TRAF2 had both negative and positive effects on JNK (and p38) and IKK activation.

Why does the amino-terminal effector domain require clustering for its function? We suggest that it may have low intrinsic affinity toward its targets and that clustering stabilizes such interactions. In addition, clustering of the amino-terminal effector domain may cause clustering of its targets, one of which may be MEKK1. Clustering of MEKK1 may facilitate its autophosphorylation, as seen after TNF- α stimulation.

MEKK1 interacts with the amino-terminal effector domain of TRAF2 in an oligomerization-dependent manner. Several pieces of evidence suggest that this interaction is of functional relevance. First, binding of MEKK1 to the amino-terminal effector domain of TRAF2 depends on oligomerization of the latter. Second, the binding is specific and several other MAPKKs, including NIK, or a STE20-like kinase that were examined did not interact with the amino-terminal domain of TRAF2. Third, mutations in the amino-terminal domain of TRAF2 that reduce or abolish its ability to activate JNK and p38 have a corresponding effect on oligomerization-dependent binding to MEKK1. Fourth, cell stimulation with TNF- α greatly enhances the interaction between native TRAF2 and MEKK1. Fifth, deletion of the amino-terminal RING finger of TRAF2 abolishes TNF- α -induced binding to MEKK1. Sixth, TNF- α stimulates MEKK1 kinase activity and the latter is required for JNK activation. Previous experiments have shown that MEKK1 is a potent activator of the JNK cascade (Minden et al. 1994) and provided genetic evidence supporting its involvement in TNF- α -mediated JNK and p38 activation (Minden et al. 1995; Liu et al. 1996; Xia et al. 1998). We

also found that MEKK1 is involved in TNF- α -mediated ERK activation (Y. Xia, unpubl.). More recently, MEKK1 was also proposed to be involved in NF- κ B activation (F.S. Lee et al. 1997; Yin et al. 1998). Although MEKK1 overexpression causes IKK activation (Lee et al. 1998), this effect is weaker than the effect on JNK activity (Karin and Delhase 1998). Also the mR1-TRAF2 mutant which is partly defective in MEKK1 binding has diminished ability to activate JNK but is completely unable to activate IKK or NF- κ B. It is therefore possible that MEKK1 activation can contribute to NF- κ B activation via an IKK-independent mechanism. For instance both p38 and ERK may be involved in stimulation of NF- κ B/p65 transcriptional activity in TNF- α -treated cells (Vanden Berghe et al. 1998). Although MEKK1 is probably not the sole effector that is activated by the TRAF2 amino-terminal domain, these results are consistent with the results of gene targeting experiments. Cells isolated from TRAF2 knockout mice are completely deficient in TNF- α -mediated JNK activation but are compromised only partially in NF- κ B activation (S.Y. Lee et al. 1997; Yeh et al. 1997). One explanation for the partial defect in NF- κ B activation is that another TRAF protein, possibly TRAF5 (Nakano et al. 1996), may compensate for the loss of TRAF2. Alternatively, a weak effect of MEKK1 on IKK may result in nuclear translocation of only a small fraction of NF- κ B complexes, whose transcriptional activity could be enhanced greatly via p38 and ERK. Together, these pathways will cause a large increase in NF- κ B transcriptional activity in TRAF overexpressing cells. Yet, in the absence of TRAF2, TNF- α can activate NF- κ B via MEKK1-independent mechanisms.

TRAF2 was found previously to interact with the germinal center kinase (GCK) and NIK, protein kinases involved in JNK and NF- κ B activation (Malinin et al. 1997; Yuasa et al. 1998). Although catalytically inactive NIK blocks NF- κ B activation (Malinin et al. 1997; Song et al.

Figure 7. TNF- α activates MEKK1 and enhances its binding to TRAF2. (A) TNF- α -dependent association of TRAF2 with MEKK1 and increase of MEKK1 autokinase activity. HEK293 cells were cotransfected with Flag-TRAF2 (50 ng DNA/plate) along with either an empty vector or Xpress-MEKK1 (100 ng DNA/plate). Lysates prepared from untreated or TNF- α -treated cells (10 ng/ml, 4 min) were immunoprecipitated with anti-MEKK1. Coprecipitating Flag-TRAF2 was detected by immunoblot analysis. MEKK1 autophosphorylation was determined by immunocomplex kinase assay without exogenous substrate. Fold increase in TNF- α -induced MEKK1 autophosphorylation was determined by PhosphorImaging. (B) Activation of endogenous MEKK1 by TNF- α . HeLa cells were treated with TNF- α for 30 min, 1 hr, or left untreated. Endogenous MEKK1 was immunoprecipitated from 1 mg of total cell lysates and its autokinase activity and ability to phosphorylate catalytically inactive JNKK1 were determined by immunocomplex kinase assay. (C) Inactive MEKK1 mutant inhibits JNK activation by TRAF2 and TRAF2-FKBP12. HEK293 cells were cotransfected with HA-JNK1 (0.4 μ g DNA/plate), along with an empty expression vector, Flag-TRAF2 (50 ng DNA/plate), or Flag-TRAF2-FKBP12 (100 ng DNA/plate) and MEKK1 (K432M) (2 μ g DNA/plate) expression vectors as indicated. Cells were left untreated or treated with FK1012 for 4 hr, as indicated, before being collected to measure HA-JNK1 activity and expression.

1997), its binding to TRAF2 is mediated by the carboxy-terminal TRAF domain, which is absent from the chimeric protein. Therefore, the ability of NIK to bind to the carboxy-terminal TRAF domains of TRAF2 or TRAF6 (Malinin et al. 1997; Song et al. 1997) is not crucial for their signaling activity. Furthermore, NIK binds indiscriminately to most TRAF proteins regardless of their ability to trigger NF- κ B activation (Song et al. 1997). Importantly, NIK binds to TRAF3 and the mR1 and mF1 mutants of TRAF2 (V. Baud, unpubl.), all of

which cannot activate NF- κ B. Furthermore, binding of NIK to TRAF2 and its catalytic activity are not stimulated by TNF- α (V. Baud, unpubl.). Overexpressed NIK was found to associate with IKK α or IKK β (Régner et al. 1997; Woronicz et al. 1997), but it is not an integral part of the native IKK complex (DiDonato et al. 1997; Rothwarf et al. 1998). Thus, although NIK seems to be involved in NF- κ B activation its exact function and relationship to TNF- α or IL-1 signaling remain enigmatic. GCK binding to TRAF2 is also mediated via the TRAF domain rather than the amino-terminal effector domain (Yuasa et al. 1998). In addition to its role in oligomerization, the carboxy-terminal TRAF domain through interaction with other protein kinases may facilitate the activation of proteins that directly interact with the amino-terminal effector domain of TRAF2, one of which seems to be MEKK1. In this respect, TRAF2 and other family members may be regarded as molecular scaffolds (Faux and Scott 1996).

In summary, binding of TNF- α and IL-1 to their respective receptors induces recruitment of TRAF2 or TRAF6, respectively, to the activated receptors as well as receptor clustering. This results in TRAF oligomerization, which stabilizes or enhances the interaction of the amino-terminal TRAF effector domains with at least two effectors. One effector contributes mostly to MAPK activation, which seems to be MEKK1, and the other contributes mostly to IKK activation. Direct induction of TRAF2 or TRAF6 oligomerization bypasses the initial steps in TNF- α and IL-1 signaling, resulting in effective dimerizer-dependent IKK and MAPK activation and induction of NF- κ B and AP-1 target genes.

Materials and methods

Cell culture and cytokines

HEK293 or HeLa cells were maintained as described (Hsu et al. 1995). Stably transfected HeLa cells expressing TRAF2(1-303)-FKBP12 were established by standard procedures using Neo^r as a selection marker and G418. Positive clones were identified by immunoblot analysis. Human recombinant IL-1 α and TNF- α were provided by Dainippon Pharmaceutical Co. and Chiron, Inc., respectively.

Expression vectors and transfections

HA-JNK1, HA-p38 α , Flag-IKK α , HA-IKK β , and 2 \times NF- κ B-LUC were described (Dérjard et al. 1994; Minden et al. 1994; Liu et al. 1996; DiDonato et al. 1997; Zandi et al. 1997). Expression vectors for IRAK, TRAF6, TRAF6(289-522), I-TRAF, NIK, GCK, ASK1, MEKK1 full-length and deletion mutants and MEKK2 were also described (Lange-Carter et al. 1993; Katz et al. 1994; Blank et al. 1996; Cao et al. 1996a,b; Rothe et al. 1996; Ichijo et al. 1997; Malinin et al. 1997; Natoli et al. 1997; Xia et al. 1998). Kinase-defective IRAK was generated by deleting IRAK coding sequences from amino acid 218 to 507. mR1, mF1, mF2, and mF3 TRAF2 mutants were generated by substituting cysteines 34/37, 107/112, 136/139, and 163/166 in wild-type TRAF2 with serines, respectively, using site-directed mutagenesis. TRAF-FKBP12 expression vectors were generated by standard recombinant DNA procedures and details are available upon request.

Baud et al.

For transfections, 3×10^5 cells in 35-mm dishes were transfected with 1.5–2.0 μg of DNA using lipofectamine (GIBCO BRL) as described (Minden et al. 1994). Luciferase activity was determined as described (Hsu et al. 1995) and normalized for β -galactosidase expression from a cotransfected *lacZ* reporter.

Immunoblotting

Cell lysates (20 μg of protein) were resolved on 7.5%–10% SDS-polyacrylamide gels and transferred to Immobilon P membranes (Millipore). After blocking with 5% skim milk in PBS-T (PBS with 0.1% Tween 20) for 1 hr, the membranes were probed with either HA (Pharmingen), Xpress (Invitrogen), M2 (Sigma), MEKK1 C-22 (Santa Cruz), MEKK2 (gift of B. Su, M.D. Anderson Cancer Center, Houston, TX), JNK1 333.8 (Pharmingen), IKK α (Pharmingen), or IRAK (Santa Cruz) antibodies. Subsequent Western blotting analyses were performed as described (Hsu et al. 1995).

Kinase assays

Transfected cells were collected in 200 μl of M2 lysis buffer 24 hr after transfection (Minden et al. 1994). HA–JNK1, HA–p38 α , Flag–IKK α , or HA–IKK β was immunoprecipitated with HA or M2 antibodies, as required, and their kinase activities determined using 2 μg of GST–cJun(1–79), myelin basic protein (MBP), or GST–IkB α (1–54), as substrates (Dérjard et al. 1994, 1995; DiDonato et al. 1997; Zandi et al. 1997). Fold activation of HA–JNK1, HA–p38 α , HA–IKK β , and Flag–IKK α was determined by PhosphorImaging and normalized to their expression levels.

Gene expression microarray

Total cytoplasmic RNA was prepared (Maniatis et al. 1989). Poly(A)⁺ RNA was isolated using Oligotex resin according to the manufacturer's instructions (Qiagen). Atlas Human cDNA Expression Array (Clontech) containing 597 spotted cDNA fragments derived from different human genes was probed with ³²P-labeled cDNA probes generated from 1.5 μg of poly(A)⁺ RNA, hybridized, and washed as recommended by the manufacturer. Image data were collected by PhosphorImaging. Hit picking and subsequent analysis were performed using a series of Excel-based macros developed at Signal Pharmaceuticals.

Coprecipitation of proteins with TRAF–FKBP12 chimeras

After transfection, HEK293 cells were treated or not with FK1012 (0.5 μM) for 4 hr, collected, and lysed in 200 μl of non-denaturing lysis buffer (25 mM HEPES at pH 7.7, 300 mM NaCl, 1.5 mM MgCl₂, 0.2 mM EDTA, 0.5% Triton X-100, 2 mM DTT, 1 mM PMSF). After centrifugation at 10,000g for 10 min at 4°C, the supernatant was recovered and the pellet was resuspended in 200 μl of 2 \times Laemmli buffer. One-tenth of both soluble and insoluble fractions was fractionated on a 7.5% SDS-polyacrylamide gel, transferred to Immobilon P membrane and Western blotted.

Acknowledgments

We thank Z. Wu and G. Natoli for helpful discussions and various constructs; Z. Cao, M. Rothe, and D.V. Goeddel for IRAK, TRAF6, and I-TRAF plasmids; S.L. Schreiber and G. Crabtree for the generous gifts of the FKBP12 plasmid and FK1012; D. Hecht for developing software for identification and hit-picking from the gene expression microarray. We are grateful to B. Thompson

for excellent manuscript assistance preparation. A banner advertisement for Dharmacon Reagents and Horizon. On the left, the Dharmacon Reagents logo includes the text 'Dharmacon™ Reagents' and 'Custom synthesis, RNAi, and CRISPR solutions'. In the center, the text 'Infinite Reliability' is displayed in a large, white, sans-serif font. To the right, the Horizon logo features the word 'horizon' in a lowercase, white, sans-serif font, with 'a PerkinElmer company' in smaller text below it. A 'More' button is visible in the bottom right corner of the banner. The background of the banner is dark with colorful, abstract, glowing lines.
