# Simultaneous Spectrophotometric Determination of $o$-Aminophenol and $\boldsymbol{p}$-Aminophenol Using H-Point Standard Addition Method -Application to Real Waters 

Theia'a N. Al-Sabha* and Nagham N. Habeb<br>Chemistry Department, College of Education, Mosul University, Mosul, Iraq

Received 12 December 2011, Revised 24 April 2012, Accepted 10 May 2012

#### Abstract

H-point standard addition method (HPSAM) has been applied to the simultaneous determination of $o$-aminophenol ( $o A$ ) and $p$-aminophenol $(p A)$ isomers in binary mixtures. The method is based on the Schiff's base formation of aminophenols with 1,2-naphoquinone sulphonate (NQS) as a chromogenic reagent in the presence of micellar cityltrimethyl ammonium bromide (CTAB) and sodium carbonate. The results showed that simultaneous determinations could be performed with the ratios $0.4: 2.0$ and $4.0: 2.0$ measured at pair of wavelengths ( 480 and 610 ) nm with recovery $\%$ range $94.75-104.37 \%$ and precision better than $4.0 \%$ when $o A$ considered as analyte and $p A$ as interferent, and a ratio $0.4: 0.2$ and $4.0: 2.0$ measured at 455 and 540 nm with recovery $\%$ range $95.37-105.0 \%$ and precision better than $4.0 \%$ when $p A$ considered as analyte and $o A$ as interferent.

Keywords: HPSAM; Aminophenol isomers; NQS; Aqueous solution.

## Introduction

Aminophenol isomers are primarily used as intermediates in the manufacture of dyes and pigments. These are crystalline solids of low volatility and cause contact dermatitis, which appears to be the greatest hazard arising from their use in industry [1]. These compounds are also the main metabolites of aniline both in vivo and in vitro [2].

Voltammetric method has been reported for determination of aminophenols in a mixtures based on the oxidation peak potential difference between $m A$ and $o A$ and $o A$ and $p A$ using singlewall carbon nanotubes modified glassy carbon electrode [3]. Sol-gel technique was used for separation of a mixture of isomeric aminophenols [4]. The only spectrophotometric method reported depends upon the kinetic determinations including the differential reaction-rate method for the
simultaneous determination of aminophenols in a mixtures which is based on its oxidation by octacyanomolybdate(v). The data are evaluated using PLS to resolve binary and tertiary mixtures of the three aminophenols [5].

A number of spectrophotometric methods have been developed to determine the composition of a binary mixture. Most of these are directed at mixtures where one component can be isolated from the other or they require a Beer's law experiment to measure the molar absorptivity of each substance in the mixture.. In 1988, HPSAM was presented based on the principle of dualwavelength spectrophotometry and the standard addition method [6-8]. This method precludes the interference of foreign matter and reagent blank even through the interfering species should be known [9].

[^0]In this work HPSAM was employed for the determination of $o A$ and $p A$ isomers in binary mixtures. The suggested method was successfully applied to the determination of these analytes in real waters.

## Requirements for applying HPSAM

Consider an unknown sample containing an analyte X and an interferent Y . The determination of the concentration of X by HPSAM requires the selection of two wavelengths $\lambda_{1}$ and $\lambda_{2}$, at which the interferent species, Y , has the same absorbance [10]. A known amount of X is successively added to the mixture, and the absorbances are measured at the two wavelengths and expressed by the following equations:
$A_{\lambda I}=b_{0}+b+M_{\lambda I} C_{i}$.
$A_{12}=A_{0}+A^{`}+M_{i 2} C_{i}$.
Where $A_{\lambda 1}$ and $A_{\lambda 2}$ are the analytical signals measured at $\lambda_{1}$ and $\lambda_{2}$, respectively. $b_{0}$ and $A_{0}$ ( $b_{0} \neq A_{0}$ ) are the original analytical signal of X at $A_{\lambda I}$ and $A_{12}$, respectively. $b$ and $A^{\prime}$ are the analytical signals of Y at $A_{\lambda l}$ and $A_{\lambda 2}$, respectively. $M_{\lambda I}$ and $M_{\lambda 2}$ are the slopes of the standard addition calibration lines at $\lambda_{1}$ and $\lambda_{2}$, respectively, and Ci is the added X concentration. The two straight lines obtained intersect at the so-called H-point ($\left.C_{H}, A_{H}\right)$. If the component Y is a known interferent and, the analytical signal corresponding to $\mathrm{Y}, \mathrm{b}$ (at $\lambda_{1}$ or $\lambda_{2}$ ), does not change with the addition of analyte $\mathrm{X}, \mathrm{A}_{\mathrm{H}}$ is only related to the signal of the interferent Y at the two selected wavelengths. To evaluate the interferent concentration from the ordinate value of the H -point $\left(\mathrm{A}_{\mathrm{H}}\right)$, a calibration graph or the absorbance value of an interferent standard is needed. If the component Y is an unknown interferent, the Y analytical signals remain equal with the addition of analyte X . According to the above discussion, at the H-point, $\mathrm{C}_{\mathrm{H}}$ is independent of the concentration of interferent and so $\mathrm{A}_{\mathrm{H}}$ is also independent of the analyte concentration [11].

## Experimental <br> Apparatus

Shimadzu UV-1650 PC UV-Visible spectrophotometer equipped with a $1.0-\mathrm{cm}$ path
length silica cell, Philips PW (9421) pH-meter with a combined glass electrode was used for pH measurements, all calculations in the computing process were done in Microsoft Excel for Windows.

## Reagents

All reagents were of analytical grade (BDH, Fluka and Molekula companies). A standard solutions of $100 \mu \mathrm{~g} \mathrm{ml}^{-1}$ of $o A$ and $p A$ were prepared separately in $100-\mathrm{ml}$ volumetric flask by dissolving 0.01 g in 2.0 ml of ethanol and diluting to the mark with distilled water. They were stored in dark and were found to be stable for at least 4 weeks. $5 \times 10^{-3} \mathrm{M}$ of NQS reagent was prepared by dissolving 0.065 g in distilled water in a 50 ml volumetric flask. 0.1 M sodium bicarbonate was prepared in a 500 ml volumetric flask. 0.1 \% of CTAB was prepared in warm distilled water.

## Procedure

## Individual calibration

Appropriate volumes containing $0.2-10$ and $0.08-18{\mu \mathrm{gml}^{-1}}^{1}$ of $o A$ and $p A$ standard solutions, 0.4 and 0.8 ml of NQS reagent solution, 1.0 and 2.5 ml of sodium bicarbonate were added into 25 ml volumetric flasks, followed by addition of 1.0 and 1.5 ml of CTAB respectively. The solution was made up to the mark with distilled water, and was left for 10 min at room temperature. A portion of the solution was transferred into a 1 cm silica cell to measure the absorbance at 488 and 535 nm against their respective reagent blank for $o A$ and $p A$, respectively.

## H-point standard addition analysis

Standard solutions of synthetic samples containing different concentrations of $o A$ and $p A$ were prepared, and standard addition of $o A$ or $p A$ (up to $4.0 \mu \mathrm{~g} \mathrm{ml}^{-1}$ ) was made followed by addition of 0.6 ml NQS, 1.5 ml sodium bicarbonate and 1.5 ml CTAB. The volume was made up to 25 ml with distilled water in volumetric flask and left for 10 min at room temperature. Simultaneous spectrophotometric determination of $o A$ and $p A$ was made with HPSAM at 480 and 610 nm when
$o A$ was considered as analyte and at 445 and 540 nm when $p A$ was considered as analyte against their reagent blank for each sample solution. $o A$ or $p A$ can be determined simultaneously in the concentration range $0.4-4.8 \mu \mathrm{~g} \mathrm{ml}^{-1}$. The procedure was repeated for some synthetic mixtures to show applicability of the method.

## Results and Discussion

Aminophenol isomers reacted with NQS reagent to give an orange color with $\lambda_{\text {max }}$ at 488 nm for $o A$ and, red color with $\lambda_{\text {max }}$ at 535 nm for $p A$ Schiff base in presence of CTAB (Figure1). Since the absorption maxima of the isomers are nearly identical it is difficult to determine them by classical technique. It is Therefore, necessary to use a chemometric method to solve this problem.

Figure 1. Absorption spectra of NQS product with $4 \mu \mathrm{~g} \mathrm{ml}{ }^{-1}$ (o) $o A$ and (p) $p A$ at the optimum conditions.

## Effect of variables

To take full advantages of the procedures, the reagent concentrations must be optimized. The parameters were optimized by setting all parameters constant and optimizing one at a time.

## Effect of pH

The effect of pH on the absorption spectra for solutions of $o A$ and $p A\left(4 \mu \mathrm{~g} \mathrm{ml}^{-1}\right)$ was studied. To select a suitable pH for this study, a range between 2.0 and 11.0 pH value was examined. It was found that the products were formed in basic
medium with maximum absorption in the ranges of 10.21-11.07 and 10.20-10.50 at 448 and 495 nm , in the absence of surfactant, for $o A$ and $p A$ respectively. A decrease in absorbance occurs above these range was noticed. The pH value of 10.3 was selected in this study.

## Effect of bases and buffer solutions

To obtain high sensitivity for the products, the effect of bases like sodium hydroxide, sodium bicarbonate, sodium carbonate, potassium hydroxide and ammonium hydroxide have been examined. Potassium hydroxide gave maximum absorption at 475 and 525 nm for $o A$ and $p A$ respectively (Table 1), but with unstable color absorbance. Sodium carbonate gave more stable color at 475 and 495 nm for $o A$ and $p A$ respectively. Fig. 2 shows that concentration ranges of $1.0-3.0 \mathrm{ml}$ and $1.5-5.0 \mathrm{ml}$ of 0.1 M sodium carbonate yielded maximum absorption for $o A$ and $p A$ respectively. The effect of ammonium, borate, carbonate and phosphate buffers in above pH ranges were examined but no significant change was observed. Therefore, 1.5 ml of 0.1 M sodium carbonate was selected in the subsequent experiments.

Table 1. Effect of bases on the absorption of $o A$ and $p A$.

Figure 2. Effect of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ concentration on the absorption of reaction mixture of $4 \mu \mathrm{~g} \mathrm{ml}^{-1}$ for each ( $\Delta$ ) $o A$ measured at 475 nm and ( $\square$ ) $p A$ measured at 495 nm in the presence of NQS reagent.

## Effect of NQS reagent

The effect of NQS reagent concentration was studied in the range $0.1-2.4 \mathrm{ml}$ of $5 \times 10^{-3} \mathrm{M}$. As shown in Fig. 3, it was found that the absorbance of both isomers increased by increasing NQS concentration up to 0.4 and 0.6 ml which remained constant at higher concentrations up to 0.6 and 1.2 ml for $o A$ and $p A$, respectively, measured at their respective $\lambda_{\text {max }}$ cited in Table 1, after which the absorbance decreased. Therefore, 0.4 ml of $5 \times 10^{-3} \mathrm{M}$ NQS was selected as optimum concentration.

Figure 3. Effect of NQS reagent concentration on the absorption of reaction mixture of $4 \mu \mathrm{~g} \mathrm{ml}^{-1}$ for each ( $\Delta$ ) oA measured at 475 nm and (■) $p A$ measured at 495 nm in the presence of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution.

## Effect of surfactants

The effect of surfactants, cetyltrimethyl ammonium bromide (CTAB), cetylpyridinium chloride (CPC), Tween-80 (TW-80) and TritonX100 (TX-100), of $0.1 \%$ concentration, on the absorption spectra of products have been investigated. The cationic surfactants CTAB and CPC shift the maximum absorption to longer wavelength (Table 2) and increased the absorbance of both products, but the anionic SDS and nonionic TX-100 and TW-80 surfactants showed no positive effect. CTAB as a cationic surfactant was most effective, and the color was stable and reproducible. The absorbance increases with CTAB concentration up to 1.0 ml and remains constant up to 3.0 ml for both isomers (Fig. 4). Therefore 1.5 ml of $0.1 \%$ CTAB was selected for further investigation.

Table 2. Effect of surfactants on the absorption of $4 \mu \mathrm{~g} \mathrm{ml}^{-1}$ aminophenol isomer products.

| TX-100 | 465 | 0.187 | 500 | 0.259 |
| TW-80 | 465 | 0.176 | 500 | 0.259 |

Figure 4. Effect of CTAB concentration on the absorption of reaction mixture of $4 \mu \mathrm{~g} \mathrm{ml}^{-1}$ for each ( $\Delta$ ) $o \mathrm{~A}$ and (■) pA in the presence of NQS and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution.

## Effect of temperature and developing time

The effect of temperature on the rate of reaction for isomers was studied at 25 and $40^{\circ} \mathrm{C}$. The results indicated that products were formed after addition of reagents immediately at room temperature $\left(25^{\circ} \mathrm{C}\right)$ and reached its maximum absorbance after 5.0 min at 488 and 535 nm for $o A$ and $p A$ respectively. It remains stable for more than 1 h , although a decrease in absorbance with time was noticed at $40^{\circ} \mathrm{C}$. Therefore, 10 min at $25^{\circ} \mathrm{C}$ was used in this work.

## Quantification

The Beer's law limits and molar absorptivity values were evaluated (Table 3). The corresponding correlation coefficient for the aminophenol isomers determined by the proposed method represents excellent linearity. The relative standard deviation (RSD) and accuracy (average recovery \%) for the analysis of six replicates of
each three different concentrations for the isomers indicated that the method is precise and accurate. Limit of quantitation (LOQ) is determined by taking the ratio of standard deviation of the blank with respect to water and the slope of calibration curve multiplied by a factor of 10 . LOQ is approximately 3.3 times greater than LOD. Naturally, the LOQ slightly crosses the lower but LOD is well below the lower limit of Beer's law range.

Table 3. Summary of optical characteristics and statistical data for the proposed method.

| Parameter | $\boldsymbol{o A}$ | $\boldsymbol{p A}$ |
| :--- | :---: | :---: |

H-point standard addition method for simultaneous spectrophotometric determination of oA and $p A$

Based on the optimum conditions obtained above and cited in (Table 4), HPSAM has been
applied for simultaneous determination of $o A$ and $p A$ isomers in binary mixtures.

## Wavelength selection

To select the appropriate wavelength pair for using HPSAM the following principles should be applied. At the selected wavelengths the analyte signals must be linear with concentration and the interferent signal must be equal and remaining unchanged by changing the analyte concentration. The analytical signal obtained from a mixture containing the analyte and the interfering should be equal to the sum of the individual signals of the two components. In addition, the difference in the slopes of the two straight lines measured at two selected wavelengths ( $\lambda_{1}$ and $\lambda_{2}$ ) must be as large as possible in order to get good accuracy and sensitivity [12-15].

For determination of $o A$ and $p A$ in binary mixture, we selected two pairs of wavelengths for above spectra isomers. In this case there were several pairs of wavelengths (Table 5).

Table 5. Amounts found of $o A$ and $p A$ by applying HPSAM at different pairs of wavelengths.

| Wavelengths (nm) | A-C Equation | $\mathbf{R}^{2}$ | Amount present $\left(\mu \mathrm{g} \mathrm{ml}^{-1}\right)$ |  | Amount found $\left(\mu \mathrm{g} \mathrm{ml}^{-1}\right)$ |  |

| 455-540 | $\begin{aligned} & Y_{455}=0.0380 x+0.1383 \\ & Y_{540}=0.0826 x+0.2294 \end{aligned}$ | $\begin{aligned} & 0.9957 \\ & 0.9969 \\ & \hline \end{aligned}$ | 2.0 | 2.0 | 2.18 | 2.04 |

The concentration of interferent was calculated in each sample by the calibration method with a single standard and the ordinate value of the H-point ( $\mathrm{A}_{\mathrm{H}}$ ). As it is shown in Table 5, the best wavelength pairs were 610-480 and $455-540 \mathrm{~nm}$ for $o A$ and $p A$ as analytes, respectively (Fig. 5).

Standard solutions of two species were initially tested to validate the applicability of the chosen wavelengths. (Fig. 6, 7) are H-point
standard addition calibration lines constructed at two selected wavelengths, $610-480 \mathrm{~nm}$ for determination of $o A$ as analyte and $p A$ as interferent and constructed at 455-540 nm for determination of $p A$ as analyte and $o A$ as interferent. According to the characteristics of HPSAM at the H-point, $\mathrm{C}_{\mathrm{H}}$ is independent of interferent concentration, but $\mathrm{A}_{\mathrm{H}}$ is dependent of the interferent. Several synthetic mixtures with different concentration ratios of $o A$ and $p A$ were analyzed by the proposed method (Tables 6,7 ).

Figure 5. Absorption spectra of (o) $o A$ and (p) $p A$ under the compromised conditions and wavelength selection when (a) $o A$ as analyte and (b) $p A$ as analyte.

* Average of three determinations

## Interference study

The influence of the presence of several cations and anions on the determination of $2.0 \mu \mathrm{~g}$ $\mathrm{ml}^{-1}$ of $o A$ and $p A$ have been investigated by HPSAM at wavelengths 480 and 610 nm . The tolerance limit was defined as the concentration of the added ion causing less than a $\pm 3 \%$ relative error. The results showed that $2000 \mu \mathrm{~g} \mathrm{ml}^{-1} \mathrm{Na}^{+}$, $\mathrm{K}^{+}, \mathrm{Mg}^{2+}, \mathrm{SO}_{4}{ }^{2-}, \mathrm{NO}_{3}{ }^{-}, \mathrm{Cl}^{-}$, and 1000,250 and 100 $\mu \mathrm{g} \mathrm{ml}{ }^{-1} \mathrm{Al}^{3+}, \mathrm{Fe}^{2+}$ and $\mathrm{Ca}^{2+}$ respectively did not interfere with the determination of aminophenols. Some aliphatic amines as interferents have been investigated to examine the selectivity of the method. It was found that $40 \mu \mathrm{~g} \mathrm{ml}{ }^{-1}$ dibutylamine and tributylamine and $20 \mu \mathrm{~g} \mathrm{ml}^{-1}$ butylamine did not interfer.

## Application of HPSAM for determination of oA and $p A$ isomers in real water samples

To evaluate the applicability of the proposed method to real samples, simultaneous determination of $o A$ and $p A$ in real water samples was done. The samples tested were found to be free from $o A$ and $p A$. Synthetic samples were prepared by adding known amounts of $o A$ and $p A$ to the water samples. The absorbance was measured at pairs of wavelengths (480-610) and (455-540) nm (Tables 10, 11). Since the recoveries are between 93.5 and $110.0 \%$, there is no serious interference in such water samples. The proposed method is therefore, suitable for simultaneous determination of $o A$ and $p A$ in water samples.

Table 10. Simultaneous determination of $o A$ and $p A$ in water samples considering $o A$ as analyte.

## Conclusion

The HPSAM has been applied for simultaneous determination of $o A$ and $p A$ isomers. The method is based on the color of the product in the reaction with NQS in the presence of sodium carbonate in micellar media. It offers good selectivity, accuracy and precision and has been applied successfully for simultaneous determination of these isomers in real water samples. The proposed method needs no extraction steps. It is simpler than the other spectrophotometric method [5].
