Notes on Contributors:

Professor Fiona Patterson (BSc, MSc, PhD, CPsychol, AcSS, FRSA, FCMI, FRCGP

(Hon)) is a leading expert in the field of selection, assessment, and innovation in organisations with over 20 years' experience working with organisations at a strategic level. Fiona holds a Principal Researcher post at the University of Cambridge and a Visiting Chair at City University, London. Over the past 15 years, her research has had a major impact upon governmental and corporate policy in the UK and abroad.

Dr Lara Zibarras (BSc, MSc, PhD, C.Psychol) is Senior Lecturer in Occupational Psychology at City University, London. Her key research areas are employee selection, particularly the candidate's perspective and new selection methodologies such as situational judgement tests and pro-environmental behaviour in the workplace. She has published widely in academic journals and presented her research at both national and international conferences. lara.zibarras.1@city.ac.uk

Vicki Ashworth (BSc, MSc, CPsychol) is an Associate Director at Work Psychology Group. Vicki specialises in the fields of assessment and selection, evaluation and organisational development, delivering bespoke solutions to public and private sector clients in the UK and internationally.

Acknowledgements:

We especially would like to thank Anna Rosselli and Fran Cousans for their support in preparing the final manuscript.

Abstract

Why use SJTs? Traditionally, selection into medical education professions has focused primarily upon academic ability alone. This approach has been questioned more recently, as although academic attainment predicts performance early in training (McManus et al. 2013, Ferguson et al. 2014), research shows it has less predictive power for demonstrating competence in postgraduate clinical practice (Ferguson et al. 2002, James et al. 2010). Such evidence, coupled with an increasing focus on individuals working in healthcare roles displaying the core values of compassionate care, benevolence and respect, illustrates that individuals should be selected on attributes other than academic ability alone. Moreover, there are mounting calls to widen access to medicine, to ensure that selection methods do not unfairly disadvantage individuals from specific groups (e.g. regarding ethnicity or socio-economic status), so that the future workforce adequately represents society as a whole. These drivers necessitate a method of assessment that allows individuals to be selected on important non-academic attributes that are desirable in healthcare professionals, in a fair, reliable and valid way.

What are SJTs? Situational Judgement Tests (SJTs) are tests used to assess individuals' reactions to a number of hypothetical role-relevant scenarios, which reflect situations candidates are likely to encounter in the target role. These scenarios are based on a detailed analysis of the role and should be developed in collaboration with subject matter experts, in order to accurately assess the key attributes that are associated with competent performance. From a theoretical perspective, SJTs are believed to measure prosocial Implicit Trait Policies (ITPs), which are shaped by socialisation processes that teach the utility of expressing certain traits in different settings such as agreeable expressions (e.g. helping others in need), or disagreeable actions (e.g. advancing ones own interest at others expense).

1
2
3 **Are SJTs reliable, valid, and fair?** Several studies, including good quality meta-analytic
4
5 and longitudinal research, consistently show that SJTs used in many different occupational
6
7 groups are reliable and valid (McDaniel & Nguyen 2001, Lievens et al. 2005a, Patterson et
8
9 al. 2009a, 2013a; Christian et al. 2010, Lievens 2013). Although there is over 40 years of
10
11 research evidence available on SJTs, it is only within the past 10 years that SJTs have been
12
13 used for recruitment into medicine. Specifically, evidence consistently shows that SJTs used
14
15 in medical selection have good reliability (Patterson et al. 2009a,b; Koczwara et al. 2012),
16
17 and predict performance across a range of medical professions, including performance in
18
19 general practice (Patterson et al. 2009a, Lievens & Patterson 2011), in early years (foundation
20
21 training as a junior doctor) and for medical school admissions (Lievens 2013, Patterson et al.
22
23 2016). In addition, SJTs have been found to have significant added value (incremental
24
25 validity) over and above other selection methods such as knowledge tests, measures of
26
27 cognitive ability, personality tests and application forms (Patterson et al. 2009a, Lievens
28
29 2013). Regarding differential attainment, generally SJTs have been found to have lower
30
31 adverse impact compared to other selection methods, such as cognitive ability tests (Oswald
32
33 et al. 2004). SJTs have the benefit of being appropriate both for use in selection where
34
35 candidates are novices (i.e. have no prior role experience or knowledge such as in medical
36
37 school admissions) as well as settings where candidates have substantial job knowledge and
38
39 specific experience (as in postgraduate recruitment for more senior roles) (Motowidlo &
40
41 Beier 2010). An SJT specification (e.g. scenario content, response instructions and format)
42
43 may differ depending on the level of job knowledge required. Research consistently shows
44
45 that SJTs are usually found to be positively received by candidates compared to other
46
47 selection tests such as cognitive ability and personality tests (Hausknecht et al. 2004, Lievens
48
49 & Sackett 2007, Lievens et al. 2008, Patterson et al. 2011). Practically, SJTs are difficult to
50
51 design effectively, and significant expertise is required to build a reliable and valid SJT. Once
52
53
54
55
56
57
58
59
60

1
2
3 designed however, SJTs are cost efficient to administer to large numbers of candidates
4
5 compared to other tests of non-academic attributes (e.g. personal statements, structured
6
7 interviews), as they are standardised and can be computer-delivered and machine-marked.

For Peer-Review Only

Practice Points

- SJTs provide a reliable method for measuring important non-academic attributes (such as empathy, integrity and teamwork) that are important for education, training and practice in medicine and a wide range of healthcare roles.
- SJTs are a measurement methodology rather than a single test per se. As such, SJTs can differ markedly from each other (in scenario content and response formats, for example), and should be designed in collaboration with subject matter experts to ensure their relevance, appropriateness and fairness regarding the target role.
- SJTs measure prosocial Implicit Trait Policies (ITPs), which are beliefs about the cost or benefits of acts expressing compassion, caring, and respect for patients, related to candidates' trait expression and values.
- When designed appropriately, compared to other selection tools, SJTs are generally reliable, valid, fair, and well received by candidates.
- Although good quality SJTs are difficult to design, once developed, SJTs are a cost-effective and an efficient selection tool for non-academic attributes as they can be computer-delivered and machine-marked.

Introduction

Traditionally, students and trainees within medicine have tended to be assessed on academic ability alone. This approach however has a number of limitations, and recently there has been an increasing emphasis in medical education and training on assessing for non-academic and professional attributes that are important for competent performance in clinical practice (Eva et al. 2009, Prideaux et al. 2011). In the UK for example, there are practical limitations of selecting on the basis of academic ability alone, since selecting students on the basis of their A levels is now problematic due to grade inflation (James et al. 2010) with reduced discriminatory power due to a large proportion of medical candidates attaining top grades (McManus et al. 2008).

Although academic attainment has been shown to be a good predictor of early performance in medical school (Ferguson et al. 2002), longitudinal research shows that the predictive power of academic attainment declines as trainees move into clinical practice and beyond (Ferguson et al. 2002, James et al. 2010, McManus et al. 2013). These findings emphasise that academic ability is a necessary, but not sufficient condition to ensure that trainees become competent health professionals, and thus the importance of selecting trainees on a range of non-academic attributes in addition.

Within the UK, although the values and behaviours expected of health and social care professionals are preserved in the National Health Service (NHS) Constitution (2013), recent government enquiries (Cavendish 2013, Francis 2013) have highlighted major concerns about the decline in compassionate care within all healthcare roles, which has global significance. These enquiries, although UK-based, have relevance internationally, as they highlight the critical role that the workforce plays in ensuring the provision of high quality and safe healthcare services and, in particular, the impact of staff values and behaviours on the quality of patient care and thus patient outcomes. Undoubtedly, an important first step is ensuring

1
2
3 that the right individuals with the appropriate values to work in clinical practice are appointed
4
5 to any educational course, training place or healthcare role.
6
7

8 Job analysis research provides supporting evidence for the importance of non-
9
10 academic attributes for successful performance in various healthcare roles. For example,
11
12 attributes such as empathy, resilience, team involvement and integrity are necessary for
13
14 medicine and dental students (Patterson et al. 2012a) and in postgraduate medical training
15
16 (Patterson et al. 2000, 2008). In terms of selection, this presents a challenge regarding how to
17
18 reliably assess values, personal qualities and attributes in an effective and efficient way,
19
20 because many methods that aim to assess non-academic attributes have not been found to be
21
22 robust (Albanese et al. 2003). For example, there is a substantial body of evidence that
23
24 suggests that traditional methods of screening candidates on the basis of non-academic
25
26 attributes, such as personal statements and references, do not provide valid assessments of
27
28 candidates' ability or non-academic attributes (Ferguson et al. 2000, 2003; Poole et al. 2009,
29
30 Kreiter & Axelson 2013, Husbands et al. 2014, Patterson et al. 2016). Regarding personality
31
32 assessments, although evidence suggests that they can provide added value in selection,
33
34 (especially when used to complement structured interviews), some researchers have
35
36 expressed caution in using personality tests as screening tools for high stakes selection (such
37
38 as medicine), due to the risk of faking and susceptibility to coaching (Rankin 2013). By
39
40 contrast, SJTs can be designed to be less susceptible to coaching (Patterson et al. 2013a) and
41
42 recent research suggests that access to coaching does not materially influence the operational
43
44 validity of SJTs in practice (Stemig et al. 2015).
45
46
47
48
49

50
51 A systematic review of the research evidence shows that SJTs are a valid and reliable
52
53 method for assessing non-academic attributes (Patterson et al. 2012b) in the context of
54
55 medical education and training, and the evidence is explored in detail in this Guide.
56
57
58
59
60

Aim/Objective of the Guide

Our aim is to provide an overview of the evidence-base for SJTs, describing how SJTs compare to other assessment tools, and how and where SJTs can be used. Specifically, the evidence for their use in selection will be explored, focusing on reliability, validity, fairness, susceptibility to coaching, and the theory underpinning SJTs. We explore the practical aspects of developing SJTs, including item structure, format, response options and scoring. We also provide several illustrative examples and case studies alongside some comments about future SJT research and implications for practice in medical education and training. Although this Guide frequently references UK practice, other international organisations and institutions can nonetheless use the content and principles.

What are Situational Judgement Tests?

It is important to note that SJTs are a *measurement methodology* rather than a single style of assessment, as the scenario content, response instructions, response formats and approaches to scoring can vary significantly across settings. Typically, candidates sitting an SJT are presented with hypothetical written or video-based scenarios of a situation they are likely to encounter in the given role. Candidates are asked to identify the appropriateness or effectiveness of various response options from a pre-defined list of alternatives (see Boxes 1-3 for examples). These response options are designed in advance with a pre-determined scoring key agreed by subject matter experts. A single SJT is likely to comprise several scenarios so that a broad range of constructs can be measured efficiently.

Box 1:**Example SJT items for postgraduate medical education**

On the morning ward round, your registrar/specialty trainee said that Mrs Anderson is medically fit following her total knee replacement and could be discharged if Occupational Therapy feel it is appropriate. The occupational therapist has assessed Mrs Anderson and believes it is safe for her to go home with a care package that has been arranged. It is now 4pm and the nurse informs you that Mrs Anderson is demanding to see a doctor, as she does not feel that she is ready to go home yet. An elective admission is waiting in the day room for Mrs Anderson's bed.

Rank in order the appropriateness of the following actions in response to this situation (1= Most appropriate; 5= Least appropriate).

- A. Ask Mrs Anderson about her concerns
- B. Ask a senior colleague to speak with Mrs Anderson
- C. Ask the bed manager if he can find another bed for the elective patient
- D. Explain to Mrs Anderson that the bed has already been allocated and she has to go home
- E. Ask the occupational therapist to come and speak to Mrs Anderson with you

You review a patient on the surgical ward who has had an appendicectomy performed earlier in the day. You write a prescription for strong painkillers. The staff nurse challenges your decision and refuses to give the medication to the patient.

Choose the THREE most appropriate actions to take in this situation

- A. Instruct the nurse to give the medication to the patient
- B. Discuss with the nurse why she disagrees with the prescription
- C. Ask a senior colleague for advice
- D. Complete a clinical incident form
- E. Cancel the prescription on the nurse's advice
- F. Arrange to speak to the nurse later to discuss your working relationship
- G. Write in the medical notes that the nurse has declined to give the medication
- H. Review the case again

1
2
3
4
5 An SJT's content, format and test length is designed to fit the role, the selection criteria and
6 specification requirements for the test (Lievens et al. 2008). SJTs have been used in
7
8 assessment for over 40 years across a broad range of occupational contexts in both the public
9
10 and private sectors (Chan et al. 1998, Ployhart et al. 2003, Wyatt et al. 2010), and more
11
12 recently have been applied to roles in medicine and other healthcare professions – see
13
14 Patterson et al (2012a) for a systematic review.
15
16
17

18 ***Role Analysis***

19
20 Whether designed for selection, assessment or development purposes, to follow best
21
22 practice, SJT scenarios should be based on a thorough analysis of the relevant role in order to
23
24 assess the key attributes and competencies that are associated with competent performance in
25
26 the role. This ensures that the content of the SJT reflects work-, education- or training-related
27
28 situations that candidates are likely to encounter in the target role. In addition, the test
29
30 specification should be developed in collaboration with key stakeholders and current role
31
32 incumbents (Motowidlo et al. 1990), and it is important for a thorough design and evaluation
33
34 process to be undertaken to ensure the psychometric quality of an SJT (Patterson et al.
35
36 2009b). A detailed guide to the steps of developing an SJT in line with best practice is
37
38 provided towards the end of this Guide.
39
40
41
42

43 ***Response Instructions and Format***

44
45 Response instructions for SJTs typically fall into one of two categories: knowledge
46
47 based (i.e. 'what is the best option') or behavioural tendency (i.e. 'what would you be most
48
49 likely to do'). A variety of response formats can be used within each of these categories, such
50
51 as *ranking* possible actions in order, *rating* all response options independently, choosing the
52
53 three best answers from a larger number of response options (*multiple choice*), or choosing
54
55 the best and/or worst response options. Some researchers have developed a single-response
56
57
58
59
60

1
2
3 SJT format, whereby only one response option is given as part of the scenario (Motowidlo et
4
5 al. 2009, Martin & Motowidlo 2010).
6

7
8 The type of response format used depends on the test specification and the context or
9
10 level in the education and training pathway that the SJT is targeting, as different response
11
12 formats are differentially related to knowledge, cognitive ability and other constructs. For
13
14 example, for medical school admissions, this is essentially a novice population and we cannot
15
16 (and should not) assume job specific knowledge or experience. By contrast, SJTs for
17
18 postgraduate selection do assume some job experience to retain scenario authenticity and
19
20 validity. Response alternatives can be presented in either a written (low fidelity) or a video-
21
22 based (medium fidelity) format (Lievens et al. 2008, Christian et al. 2010) and each approach
23
24 has both advantages and disadvantages (relating to aspects such as candidate reactions,
25
26 validity and cost, for example). The reliability and effectiveness of different item presentation
27
28 formats and response instructions of SJTs will be explored in this Guide.
29
30

31
32 SJTs are scored by comparing candidates' responses to a pre-determined scoring key,
33
34 which dictates the scores obtained for each answer, and has previously been agreed via an in-
35
36 depth review process by a group of subject matter experts (SMEs). In Box 2 we outline an
37
38 example SJT for the role of junior doctor on the UK Foundation Programme (early
39
40 postgraduate training). Here, the response instructions are knowledge oriented (i.e. what
41
42 should you do/what is the best option) and the response format asks candidates to rank all
43
44 possible responses in order of appropriateness, which represents a relatively complex set of
45
46 judgements.
47
48

54
55
56
57
58
59
60

Box 2: SJT for selection to postgraduate

You are reviewing a routine drug chart for a patient with rheumatoid arthritis during an overnight shift. You notice that your consultant has inappropriately prescribed methotrexate 7.5mg daily instead of weekly.

Rank in order the appropriateness of the following actions in response to this situation.

- A. Ask the nurses if the consultant has made any other drug errors recently
- B. Correct the prescription to 7.5mg weekly
- C. Leave the prescription unchanged until the consultant ward round the following morning
- D. Phone the consultant at home to ask about changing the prescription
- E. Inform the patient of the error

Pre-Review Only

1
2
3 In this scenario you will note that the test taker is already told there has been a
4 prescribing error so the aim is not to test clinical knowledge per se. Instead, the focus of the
5 item relates to a set of interpersonal dilemmas. In this scenario, the most appropriate (first
6 thing to do) is answer B – to correct the prescription. However, there are then a complex set
7 of judgements for a candidate to make regarding how to best deal with some challenging
8 interpersonal dilemmas, i.e. how best to deal with the consultant, the nurses, co-workers and
9 indeed the patient. In this way, by presenting several scenarios in a test, SJTs can measure a
10 range of professional attributes.

16
17
18
19
20
21
22

23 **Theory Behind SJTs – How do they Work?**

24
25 Historically, researchers have engaged in considerable debate regarding the construct
26 validity of SJTs (i.e. what do SJTs measure?), but there is now a relatively clear picture of the
27 theoretical underpinnings of SJTs.
28
29
30
31

32 SJTs are based on two key theoretical propositions. First, SJTs are derived from a
33 long established *behavioural consistency* theory (i.e. that past behaviour is the best predictor
34 of future behaviour), in which the central principle is that eliciting a sample of current
35 behaviour allows the prediction of future (i.e. in-role) behaviour (Wernimont & Campbell
36 1968, Motowidlo et al. 2006).
37
38
39
40
41
42

43 Second, there is a growing consensus in the research literature that SJTs measure
44 prosocial *Implicit Trait Policies* (ITPs), and depending on the job level, specific job
45 knowledge, as in postgraduate selection (Motowidlo & Beier 2010, Patterson et al. 2015b).
46 ITP theory proposes that individuals develop beliefs about the effectiveness of different
47 behaviours – that is, beliefs about the costs and benefits associated with expressing certain
48 traits (which guide behaviours) in particular situations, in relation to individuals' inherent
49 tendencies or traits. As individuals make judgements about how and when to express certain
50
51
52
53
54
55
56
57
58
59
60

1
2
3 traits, ITPs are related to choices about trait *expressions* rather than traits per se (Motowidlo
4 et al. 2006). For example, a doctor dealing with a sensitive situation in the workplace (such
5 as the death of a relative) may have to make a judgement about the utility (cost/benefits) of
6 empathy and agreeableness as a more successful strategy than acting brusquely or being
7 disagreeable (even if the doctor's preference tends towards being generally disagreeable
8 and/or empathetic). As another example, imagine an anaesthetist whose personality profile
9 shows a preference for introversion, but deciding to act in what might be observed as an
10 extraverted manner, as this is most effective for the situation at hand.

11
12 ITPs are thought to be shaped by experiences during socialisation processes, such as
13 through parental modelling throughout childhood (or later during tutoring and role models at
14 medical school). This may teach individuals the utility of, for example; agreeable
15 expressions, that is, helping others in need, or turning the other cheek; or disagreeable
16 expressions, that is, showing selfish preoccupation with one's own interests, holding a
17 grudge/"getting even" or advancing ones own interests at another person's expense. As
18 such, SJTs may also represent a promising tool for assessing individuals' values, as the
19 element of personal choice involved when behaving consistently with one's values can be
20 measured by an SJT (i.e. candidates must make a choice about which response options are the
21 most appropriate or important) (Parks & Guay 2009, Patterson et al. 2015b).

22
23 Research evidence suggests that SJTs are effective predictors of job performance
24 because SJTs measure procedural awareness about effective behaviour in a given situation
25 (including domain-based knowledge where appropriate), and, relatedly, individuals' beliefs
26 about the costs/benefits of expressing personality traits in role-related situations (Motowidlo
27 et al. 2006, Lievens & Patterson 2011).

What is the Research Evidence for SJTs?

Any selection method in operational use must meet exacting standards relating to the psychometric properties (i.e. reliability, validity, accuracy), in addition to being acceptable to stakeholders, in that particular context (Schmidt & Hunter 1998, Arnold et al. 2010, Patterson et al. 2012c). These standards ensure a method provides an effective, acceptable and legally defensible means of selection, which is arguably especially important within high-stakes, high-volume selection contexts such as in medicine. As such, when SJTs are used in medicine (and in other settings), they should be regularly reviewed and evaluated to ensure that they meet these psychometric and acceptability requirements. The research evidence for SJTs relating to these issues is reviewed in the following sections.

How and when can SJTs be used?

SJTs may be used for selection, assessment or development, and have the benefit of being designed in a way that is tailored to fit the specific purpose and needs of the target role. In medicine, SJTs are often used as a screening tool during selection as they enable the assessment of the non-academic abilities and attributes of large numbers of candidates in a standardised and cost-efficient way (Koczwara & Ashworth 2013). Those who successfully complete an SJT are then typically shortlisted to the next stage of the selection process, such as a structured interview.

SJTs can also be used effectively at the interview stage, as one of several stations of a multiple mini-interview, for example. As such, SJTs tend to form one part of a multi-method selection process, whereby candidates are assessed across a range of attributes and skills, as identified by the role analysis. A large number of scenarios can be measured in an SJT, whereas in interviews, a small number of scenarios can be discussed and probed, such that SJTs and structured interviews are complementary.

1
2
3 In the UK, SJTs are increasingly being incorporated into healthcare selection, with
4 many recent examples in medical education and training. For example, an SJT is being used
5 alongside a battery of cognitive ability tests for UK medical schools admissions,
6 demonstrating promising evidence of reliability and validity (Patterson & Martin 2014,
7 Patterson et al. 2014, Sartania et al. 2014).

8
9
10
11
12
13
14 Alongside other methods, an SJT measuring empathy, integrity and resilience has
15 been used successfully for selection into training into UK general practice for over 10 years,
16 which has also demonstrated good predictive validity, positive candidate reactions and
17 significant cost savings regarding the resources required for hand-marking personal
18 statements, for example (Patterson et al. 2009a, Plint & Patterson 2010, Lievens & Patterson
19 2011).

20
21
22
23
24
25
26
27 An SJT has been used alongside an educational performance measure to select all
28 doctors applying for UK Foundation training since 2013, also demonstrating predictive
29 validity with subsequent training outcomes and job performance. This SJT is designed to
30 assess for the key attributes identified in a role analysis (including commitment to
31 professionalism, coping with pressure, effective communication, patient focus, working
32 effectively as part of a team), and has performed well psychometrically year on year.

33
34
35
36
37
38
39
40 In the UK, SJTs are used for postgraduate training selection for a variety of roles
41 including Public Health (Kerrin et al. 2014), Psychiatry (Lopes et al. 2015a) and
42 Ophthalmology (Lopes et al. 2015b). SJTs are also used for a variety of other healthcare
43 professions including dental foundation training (Patterson et al. 2012a) and veterinary
44 science (Kerrin et al. 2015).

45
46
47
48
49
50
51
52 The use of SJTs in healthcare selection is expanding globally. Internationally, SJTs
53 have been used in medical school admissions in Belgium (Lievens et al. 2005a), Singapore
54 (Ashworth et al. 2014), Canada (Dore et al. 2009) and in postgraduate recruitment in
55
56
57
58
59
60

1
2
3 Australia to select trainees for entry to training in general practice (Roberts & Togno 2011,
4
5 Roberts et al. 2014). Many other countries are piloting the use of SJTs in admissions; for
6
7 example, an SJT is being piloted at the American Association of Medical Colleges (AAMC –
8
9 <https://www.aamc.org/initiatives/admissionsinitiative/sjt/>), alongside the MCAT.
10
11

12 ***How reliable are SJTs?***

14 There are a number of ways to ensure that an SJT is *reliable* in measuring the
15
16 constructs it aims to assess (based on the role analysis) in a consistent way. This includes
17
18 measuring *internal consistency*, which assesses whether several items that should measure the
19
20 same construct produce similar scores; *test-retest reliability* which indicates whether a
21
22 measure is stable over a given time period; and *parallel forms reliability* where two versions
23
24 of the same test correlate sufficiently (Rust & Golombok 1999).
25
26

27
28 SJTs have been described as “*construct heterogeneous*” at the item level (McDaniel &
29
30 Whetzel 2007) since any one item may target several performance dimensions or constructs
31
32 (in others words, SJTs rarely measure one single dimension), which implies an inherent
33
34 difficulty in accurately estimating the internal consistency of an SJT, and a risk of
35
36 underestimating their reliability (McDaniel & Whetzel 2007, Catano et al. 2012). Indeed, a
37
38 meta-analysis of 39 different studies, found Cronbach’s alpha coefficients ranging from
39
40 $\alpha=.43$ to $.94$ (McDaniel et al. 2001). However, internal consistency of SJTs used in medical
41
42 and dental contexts (Koczwara et al. 2012, Patterson et al. 2012a, 2014, 2015a) have been
43
44 found to consistently approach or exceed $\alpha=.70$; the accepted value indicating good internal
45
46 consistency (Kline 2000).
47
48

49
50 Some researchers argue that *test-retest* or *parallel forms reliability* may be a more
51
52 accurate approach to examining the reliability of an SJT since internal consistency is more
53
54 appropriate for uni-dimensional (*construct homogenous*) tests (McDaniel & Nguyen 2001,
55
56 Lievens et al. 2008, Catano et al. 2012). Research shows a range of values for test-retest
57
58
59
60

1
2
3 reliability of SJTs, from $r=.20$ to $r=.92$ (Ployhart & Ehrhart 2003, Ployhart et al. 2003),
4
5 dependent upon the quality of the test construction.
6

7 *Parallel forms* reliability is measured by the correlation of two tests that are assessing
8
9 the same construct (Rust & Golombok 1999). Kline (2000) recommends that parallel forms
10
11 reliability should be above $r=.70$. On balance, the research evidence shows good levels of
12
13 parallel forms reliability for SJTs, for example: $r=.76$ (Chan & Schmitt 2002) and $r=.66$
14
15 (Lievens et al. 2005b).
16

17
18 In summary, the research broadly shows that SJTs have moderate to good levels of
19
20 reliability, regardless of the type of method used to assess reliability. Since SJTs are a
21
22 measurement method and there is no one single type of SJT, it is important to evaluate each
23
24 test independently to judge reliability. When evaluating reliability, internal consistency may
25
26 sometimes be a less appropriate measurement of SJT consistency than other measures of
27
28 reliability, due to the usually heterogeneous nature of SJT items.
29
30
31

32 33 34 ***How valid are SJTs?*** 35

36
37 As with all other assessment tools, there are multiple approaches to evaluate the
38
39 *validity* of an SJT (i.e. is the tool measuring the criteria that it purports to measure). To
40
41 establish the validity of a tool this includes measuring *criterion-related validity* (i.e.
42
43 evaluating the extent to which scores on an SJT can predict subsequent performance or work
44
45 behaviour); *incremental validity* (i.e. does the tool add value and predict variance in outcome
46
47 criteria beyond other tools); and *construct validity* (i.e. evaluating the extent to which a tool is
48
49 measuring what it is supposed to measure, where comparisons are made with measures of
50
51 similar constructs).
52
53
54
55
56
57
58
59
60

Criterion-Related Validity

A central consideration when assessing the criterion-related validity of any selection method is to consider precisely *what the method is intended to measure*. For example, Lievens et al. (2005a) acknowledged the need to attend to the constructs underlying both predictors and criterion (outcome) measures when assessing relationships between the two. Considering this in the context of SJTs, which are designed to assess non-academic constructs and interpersonal skills, we would not theoretically expect an SJT to predict performance on a highly cognitively loaded criterion. We would, however, expect them to predict performance on criterion-matched outcomes, such as interpersonal skills courses, educational supervisor ratings of empathy and integrity, or communication stations in an OSCE.

The literature regarding the criterion-related validity of SJTs in healthcare and other professions supports this proposition. For example, Lievens et al. (2005a) examined the criterion-related validity of an SJT for medical college admissions in Belgium, and found that the SJT showed incremental validity over cognitively-oriented measures for curricula that included interpersonal courses, but not for other, academic curricula. Similarly, Oswald et al. (2004) found that an SJT predicted performance on dimensions such as leadership and perseverance, but did not predict grade point average, and Libbrecht et al. (2014) found that an SJT measuring emotional intelligence predicted performance in courses on communication and interpersonal sensitivity in medical school, beyond cognitive ability and conscientiousness.

Meta-analyses have found favourable criterion-related validity of SJTs compared to other selection methods. For example, Christian et al. (2010) found corrected operational validity coefficients of .25 to .47, and McDaniel et al. (2001) estimated a criterion-related validity of $r=.34$ across multiple occupational groups. Additionally, SJTs have been shown to

1
2
3 have comparable or increased predictive validity over structured interviews (McDaniel et al.
4
5 1994), selection centres (Gaugler et al. 1987) and cognitive ability tests (Clevenger et al.
6
7 2001).

8
9
10 Regarding medical education specifically, on-going evaluation has shown that an SJT
11
12 used in selection for postgraduate training in the UK predicts subsequent in-training
13
14 performance and end-of-training competence after three years, with large effect sizes
15
16 (Patterson et al. 2013b). Longer-term studies also show that the SJT predicts performance in
17
18 training in relation to educational supervisors' ratings (Lievens & Patterson 2011) and
19
20 performance in clinical skills licensing OSCEs (Patterson et al. 2012c).

21
22
23 Two longitudinal, multiple cohort studies in Belgium found an SJT used within
24
25 medical school admissions predicted a number of assessments at different points throughout
26
27 training, in addition to job performance nine years later in both studies: $r=.22$ (Lievens &
28
29 Sackett 2012) and $r=.15$ (Lievens 2013).

30
31
32 In summary, SJTs have been found to have good levels of predictive validity across a
33
34 wide range of different occupations, including in healthcare education and training.
35
36 Methodologically, it is important to ensure that appropriate outcome criteria and measures are
37
38 identified in order to meaningfully assess the validity of SJTs.

39 40 41 *Incremental Validity*

42
43 It is important to establish whether an SJT has predictive validity over and above
44
45 other selection methods, such as cognitive ability, personality and job knowledge tests, to
46
47 assess the value added by an SJT in a selection system (i.e. what is the added benefit of using
48
49 an SJT?). The presence or absence of such added (incremental) validity can provide evidence
50
51 for the cost-effectiveness and efficiency of SJTs, as well as to support their theoretical
52
53 rationale.
54
55
56
57
58
59
60

1
2
3 The incremental validity of SJTs has been widely demonstrated in the literature across
4 numerous operational groups, including healthcare. SJTs explained an additional 2.6% of
5 variance over the combined predictive validity of conscientiousness, job experience and job
6 knowledge in federal investigator officers' job performance (Clevenger et al. 2001). In
7 numerous manufacturing organisations, an SJT showed incremental validity over cognitive
8 (3%) and personality (4%) measures for the prediction of task performance, and over
9 cognitive ability (4%) when predicting contextual performance (O'Connell et al. 2007).

10
11 In the context of medicine specifically, Lievens et al. (2005a) found that an SJT
12 assessing interpersonal awareness for entry into medical schools in Belgium had incremental
13 validity over the cognitive measures for components of the curricula that had an interpersonal
14 skills component. Patterson and colleagues (2009a) showed that an SJT used for selection in
15 postgraduate GP training had substantial incremental validity over scores from an application
16 form (17%) and a job-knowledge test (14%). Similar findings have been demonstrated for an
17 SJT into Core Medical Training in the UK (Patterson et al. 2009b).

18
19 In summary, there is a wealth of evidence in healthcare and beyond that SJTs provide
20 added value over other selection methods for predicting job performance.

21 22 *Considerations in Assessing the Predictive Validity of SJTs*

23
24 Research suggests that the predictive validity of measures of non-academic attributes
25 differs over time in the context of medical education and training (i.e. predictive validity is
26 higher when students enter clinical practice). We propose that this is because during the
27 classroom-based, didactic setting in which learning takes place during the early years of a
28 medical degree, the focus is more on cognitive indicators and academic attainment. However,
29 as students move into clinical practice and beyond, the necessity for interpersonal skills
30 comes to the fore because the team-based working and patient contact are key measures of
31 competence (Ferguson et al. 2014). This proposition is supported by other researchers
32
33
34
35
36
37
38
39
40
41
42
43

57
58
59
60

1
2
3 (McDaniel et al. 2007, Lievens et al. 2008), and reiterates the importance of choosing not
4 only appropriate outcome criteria to assess the validity of SJTs, but also of collecting
5 outcome data at the appropriate time.
6
7
8

9
10 Emerging evidence from the medical education literature in the UK indicates that
11 SJTs may have greater predictive validity at the lower end of performers (as yet unpublished
12 research by the present authors across a number of SJTs for medical admissions in the UK).
13 For example, applicants lacking prosocial ITPs are less likely to perform well on an SJT.
14 Further research both internally and in broader healthcare contexts is required to replicate and
15 extend these findings.
16
17
18
19
20
21
22

23 In summary, it is important to take into consideration the point in a healthcare
24 education or training pathway that outcome data is collected, in order to most accurately
25 assess the validity of an SJT. Emerging evidence suggests SJTs may be best used to ‘select
26 out’ candidates as they are potentially better predictors at the lower end of the distribution of
27 scores, however evidence for this is in its infancy.
28
29
30
31
32
33

34 *Construct Validity*

35
36 As outlined previously, SJTs represent a methodology rather than a specific test. As
37 such, scenarios are context-specific and responses can be designed to assess a range of
38 different attributes or constructs. Consequently, SJTs are designed to measure a wide range of
39 different attributes, and a candidate’s response may represent a combination of their ability,
40 personality and experience (Lievens et al. 2008). Therefore, due to the heterogeneous nature
41 of different SJTs, with a broad range of different test specifications available, it is challenging
42 for researchers to describe specifically what SJTs as a methodology measure (i.e. their
43 construct validity), and a range of constructs have been identified as being associated with
44 scores on SJTs.
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 McDaniel et al.'s (2001) review shows that SJTs correlate with cognitive ability,
4 although the magnitude of the relationship depended on several factors. SJTs based on a job
5 analysis correlated more highly with cognitive ability ($r=.50$) than those that were not
6 ($r=.38$), and SJTs which contained more detailed questions were more highly correlated with
7 cognitive ability ($r=.56$) than those less detailed ($r=.47$). It is suggested that SJTs that are
8 cognitively-oriented (such as those involving planning, organising and problem-solving) tend
9 to correlate higher with cognitive ability than those oriented solely on interpersonal issues
10 such as empathy. In postgraduate medical selection, Koczwara and colleagues (2012) found
11 that an SJT correlated significantly with cognitive ability tests, suggesting that they measure
12 overlapping constructs. By contrast, Clevenger et al. (2001) found SJT scores were not
13 correlated with cognitive ability, and an SJT used for assessment of professionalism in dental
14 school based on a role analysis did not correlate with a test of clinical knowledge (Escudier et
15 al. 2015). As such, the evidence indicates that the extent to which SJTs measures cognitive
16 ability varies, depending on the specific design of each individual SJT.

17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34 In relation to personality, Mullins and Schmitt (1998) found that an SJT was most
35 strongly correlated with the personality traits of Conscientiousness ($r=.26$) and Agreeableness
36 ($r=.22$). A meta-analysis found SJT scores had a corrected correlation of $r=.25$ with
37 Agreeableness; $r=.31$ with Emotional Stability, $r=.26$ with Conscientiousness, $r=.06$ with
38 Extraversion, and $r=.09$ with Openness (McDaniel & Nguyen 2001). McDaniel et al. (2007)
39 found similar results, indicating that SJTs correlate most highly with the personality trait of
40 Agreeableness and Conscientiousness, i.e. cooperation, forgiveness and a tendency to defer to
41 others in interpersonal conflict; and achievement striving, leadership skills and organisation,
42 respectively (McCrae & Costa 2008).

43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
Motowidlo (2003) suggests the relationship between personality and ITPs (described
earlier) can be explained via the notion of '*dispositional fit*'; that is, some individuals'

1
2
3 dispositions (i.e. their personalities) are more appropriate for handling challenging social
4
5 situations than others' dispositions. Dispositional fit specifies that people develop beliefs
6
7 consistent with their personality traits about how best to handle difficult situations. Situations
8
9 encountered in any given role are believed to vary in the extent to which they require
10
11 behavioural responses that are expressive of a given trait. When individuals' beliefs about the
12
13 appropriate behavioural responses to a situation correspond to the type of response actually
14
15 required by the situation, those individuals possess greater knowledge because their beliefs
16
17 are correct (Campbell et al. 1996). Because people often believe that actions expressive of
18
19 their own personalities are most effective, people whose traits match those demanded by the
20
21 situation will be most likely to possess knowledge of how to effectively behave in that
22
23 situation.
24
25
26

27 Considering the relationship between SJT scores and agreeableness, for example,
28
29 because agreeable people should have ITPs that weigh agreeableness more strongly, they are
30
31 more likely to discriminate accurately between SJT response options, according to the level
32
33 of agreeableness expressed by each response option; thereby achieving higher scores on an
34
35 SJT.
36
37

38 The literature has not yet fully converged on the association between SJTs and role
39
40 knowledge. Earlier research has suggested that SJTs may simply be tests of role-specific
41
42 knowledge (Schmidt 1994), whilst others suggest that since "*experience*" is multifaceted,
43
44 different operationalisations of experience will result in different relationships between
45
46 experience in a role and performance on an SJT. Indeed, Motowidlo and Beier (2010) posit
47
48 that the type of experience that leads to the development of ITPs (i.e. general experience), is
49
50 different to the type of experience that allows individuals to develop specific knowledge
51
52 about a particular role. They conclude that the ITPs and specific role knowledge combine to
53
54 produce the procedural knowledge measured by an SJT, but they have independent effects on
55
56
57
58
59
60

1
2
3 role performance. Moreover, some SJTs are more strongly related to general experience
4
5 (ITPs) than to highly role-specific experience.
6

7
8 In summary, since SJTs can be designed to assess a range of different attributes,
9
10 research regarding their construct validity has been mixed. Research identifies that SJTs can
11
12 correlate with cognitive ability, personality and knowledge, depending on the specification of
13
14 the SJT.
15

16 17 18 19 ***What is the Reliability and Validity of Different SJT Formats, Response Formats and*** 20 21 ***Instructions?*** 22

23 24 *Response Formats*

25
26 Research has focused on the relative benefits of response formats based on knowledge
27
28 based (i.e. *what is the best option*) or behavioural tendency (i.e. *what would you be most*
29
30 *likely to do*) formats (McDaniel & Nguyen 2001, McDaniel et al. 2003, 2007). St-Sauveur et
31
32 al. (2014) posit that an argument in favour of a knowledge based format, is that regardless of
33
34 whether an SJT uses a knowledge based or behavioural tendency format, it will still measure
35
36 the extent to which candidates know what the “correct” behaviour is in a given situation (i.e.
37
38 knowing ‘*what you should do*’). Additionally, they argue that knowledge based response
39
40 formats lead to greater certainty as to what the test measures (i.e. clearer construct validity).
41
42 A meta-analysis (McDaniel et al. 2007) also found a better correlation with work
43
44 performance for knowledge based response formats.
45
46

47
48 A key design consideration regarding response formats is the extent to which an SJT
49
50 is required to be cognitively loaded, which will depend on its intended use and target
51
52 candidate population. For example, it would be more appropriate for an SJT used for
53
54 selection into a highly specialised trainee post (where specialist and clinical detail may be
55
56 required to contextualise the scenarios) to have a greater degree of cognitive loading than an
57
58
59
60

1
2
3 SJT for entry into an undergraduate healthcare degree. Whetzel and McDaniel (2009)
4
5 conclude that SJTs with knowledge based instructions correlate more highly with cognitive
6
7 ability than SJTs with behavioural tendency instructions. As such, test developers who wish
8
9 to emphasise the assessment of personality constructs in an SJT may wish to use behavioural
10
11 tendency instructions. On the other hand, if a selector wishes to maximise the variability in
12
13 SJTs scores on the basis of cognitive ability within an SJT, a test with knowledge based
14
15 instructions may be more appropriate (Whetzel & McDaniel 2009). Arguably, since medicine
16
17 is a cognitively demanding profession, more cognitively loaded SJTs are more relevant.
18
19

20
21 Regarding construct validity and response instructions, Weekley et al. (2006) and
22
23 McDaniel and colleagues (2007) found that SJT *format* may also influence construct validity:
24
25 SJTs with knowledge-based instructions have higher correlations with cognitive ability than
26
27 those with behavioural tendency instructions. Conversely, the researchers found that SJTs
28
29 with behavioural tendency instructions correlated more strongly with the Big Five personality
30
31 traits. As such, SJTs with knowledge instructions may be considered measures of maximal
32
33 performance, whilst behavioural tendency instructions may be measures of typical
34
35 performance (Lievens et al. 2008).
36
37

38
39 Knowledge based SJTs however, if more cognitively loaded than behavioural
40
41 tendency SJTs, are more likely to result in greater subgroup differences (Whetzel et al. 2008,
42
43 Roth et al. 2013, St-Sauveur et al. 2014). Given that the reduction in subgroup differences is
44
45 considered to be one of the key benefits of SJTs over other selection methods (compared to
46
47 academic attainment), this may pose a significant challenge to test developers. Conversely,
48
49 research shows behavioural tendency instructions are more susceptible to ‘faking’, similar to
50
51 personality tests (Nguyen et al. 2005, Birkeland et al. 2006); and thus the balance of the costs
52
53 and benefits of each response format must be considered when defining the specification of
54
55 an SJT. Given that medical selection is competitive, it could be argued that knowledge based
56
57
58
59
60

1
2
3 formats may be more appropriate for this high-stakes selection context, since SJTs are a
4
5 measure of maximal performance (i.e. how a candidate performs at their peak), whereas
6
7 behavioural tendency formats measure typical performance (i.e. how one typically behaves)
8
9 (McDaniel et al. 2007). When knowledge based formats are used, evidence shows candidates
10
11 are less able to 'fake' the answer by attempting to give an answer that the candidate thinks
12
13 the recruiter wants to hear. Similarly, research shows also that knowledge based formats are
14
15 less susceptible to coaching than behavioural tendency formats (McDaniel et al. 2007), which
16
17 is an important consideration in high completion selection, such as medicine.
18
19

20 21 *Response Instructions*

22
23 Research shows that the type of response *instructions* can influence the reliability of
24
25 an SJT. For example, Ployhart and Ehrhart (2003) found that *rating the effectiveness of each*
26
27 *response* results in the highest internal consistency ($\alpha=.73$), whilst *choosing the most*
28
29 *effective response* results in the lowest internal consistency ($\alpha=.24$). St-Sauveur et al. (2014)
30
31 found that a single best answer response format had the lowest internal consistency of SJT
32
33 response formats, compared to rank-order and choosing the 'best and worst' responses.
34
35 Similarly, Ployhart and Ehrhart (2003) found that test-retest stability depends on the type of
36
37 response instructions used, with higher reliabilities when candidates are asked to rate the
38
39 likelihood that they would perform each response option.
40
41

42
43 Outside of medicine, emerging evidence indicates promising validity of the single-
44
45 response response SJT format as a measure of procedural knowledge and as a predictor of job
46
47 performance (Motowidlo et al. 2009, Martin & Motowidlo 2010, Crook et al. 2011), however
48
49 further research is required to ascertain the reliability and long-term validity of this response
50
51 format.
52

53
54 In summary, there are advantages and disadvantages of all possible SJT response
55
56 formats and instructions, which may significantly impact the reliability, and validity of an
57
58
59
60

1
2
3 SJT; these are important considerations when defining the specifications and purpose of an
4
5 SJT.
6

7 Box 3 shows three examples of SJT items using different types of response
8 instructions. The choice of response instructions during test design reflects a number of
9 considerations: the scenario content, the ability to provide and elicit the information needed,
10 the target population (i.e. how cognitively loaded a response instruction should be), and the
11 level of discrimination required between candidates. For example, the nature of some
12 scenarios and the possible responses to them lend themselves to ranking items (requiring the
13 ability to differentiate between singular responses to a scenario), whereas other scenarios lend
14 themselves to multiple choice items (where it is necessary to do more than one thing, or
15 tackle more than one aspect, in response to a scenario).

For Peer-Review Only

Format

Mostly, SJTs are delivered either as a written/text-based paper and pencil format or delivered online (Weekley & Ployhart 2005). It is also possible to deliver an SJT in a video-based format, which has the benefit of providing candidates with a more realistic, medium fidelity example of a role-related scenario (Sharma & Nagle 2015). Text based SJTs are significantly more cost effective to develop and maintain compared to video-based SJTs, and some evidence suggests that written SJTs have higher correlations with cognitive ability, due to the reading skills required (Chan & Schmitt 1997, Lievens & Sackett 2006). It could be argued that text based SJTs may be more appropriate in job roles that require advanced cognitive processing skills, such as medicine and other complex healthcare roles. Recent research has also investigated the possible utility of a pictorial SJT to measure affect (Sharma & Nagle 2015), although research regarding the validity and reliability of this format of SJT delivery is in its infancy, it offers a fruitful avenue for future research.

Are SJTs Fair?

Fairness issues in selection for medical education and training represents a challenge globally, and it is becoming an increasingly important consideration (Patterson et al. 2016). Regarding widening access, medical education and training providers face the challenge of identifying selection methods that both select individuals with the required skills, attributes and abilities, and also admit a diverse pool of individuals into healthcare education and training positions, to ensure that the healthcare workforce is representative of society (BMA 2009, Patterson et al. 2012c, Lievens 2014). Research allows only tentative conclusions to be drawn about the relative costs and benefits of different selection methods regarding their impact on widening access (O'Neill et al. 2013, Patterson et al. 2016), however emerging evidence suggests that SJTs may not follow socio-economic trends often observed in aptitude test scores and measures of academic attainment (Whetzel et al. 2008, Woolf et al. 2011,

1
2
3 Wakeford et al. 2015) (i.e. in the UK, White candidates from the higher socioeconomic
4
5 classes tend to outperform BMEs and those from lower socioeconomic backgrounds, and
6
7 males tend to perform better than females, on aptitude tests and measures of academic
8
9 attainment).

10
11 A meta-analysis by Whetzel and colleagues (2008) reported that White test takers did
12
13 marginally better than other ethnic groups, with a small effect size. Regarding gender, the
14
15 research generally suggest that females tend to score marginally higher on SJTs than males
16
17 (O'Connell et al. 2007, Whetzel et al. 2008, Lievens 2013, Luschin-Ebengreuth et al. 2015),
18
19 which is consistent with other forms of non-academic assessment (Anderson et al. 2006).
20
21

22
23 In summary, research suggests that SJTs have less adverse impact regarding ethnicity
24
25 and gender compared to other selection tools (such as cognitive ability tests). Recent research
26
27 also suggests that SJTs can promote widening access compared to indicators of academic
28
29 attainment.
30
31

32 33 34 ***How do Candidates React When Sitting SJTs?*** 35

36
37 It is important to consider candidates' reactions to selection tools because negative
38
39 experiences can result in the loss of good candidates from the selection process and increase
40
41 the likelihood of legal challenge (Chambers 2002, Hülshager & Anderson 2009).
42
43 Consequently, selection processes require on-going evaluation and monitoring regarding
44
45 candidates' perceptions (Cascio & Aguinis 2008). Research shows fair selection processes
46
47 positively influence an organisation's continued ability to attract the best candidates and
48
49 recruit effectively within a given job market (Schmitt & Chan 1999). Chan and Schmitt
50
51 (1997) found evidence to suggest that *face validity* perceptions (the extent to which
52
53 candidates perceive a test to be relevant to the role they are applying) to significantly
54
55
56
57
58
59
60

1
2
3 influence test-taking motivation. It is important therefore that candidates perceive selection
4
5 methods to be relevant, face valid and fair (Gray 1997).
6

7 Focusing on SJTs more specifically, research shows that candidates have a preference
8
9 for job-relevant selection methods (Gilliland 1993, Bauer et al. 2001), with work sample
10
11 simulations used in selection receiving the most positive ratings from candidates alongside
12
13 interviews (Hausknecht et al. 2004). Research evidence consistently shows that SJTs are
14
15 positively perceived by candidates (Chan & Schmitt 2002, Lievens & Sackett 2007, Lievens
16
17 et al. 2008, Plint & Patterson 2010, Patterson et al. 2011, Koczwara et al. 2012, Roberts et al.
18
19 2014, Luschin-Ebengreuth et al. 2015), due to the highly role-specific, contextualised
20
21 scenarios presented in SJTs (i.e. they are more *face valid* to candidates).
22
23

24
25 Video-based SJTs represent a medium fidelity SJT format (compared to text based
26
27 SJTs which are low fidelity assessment modalities). As expected, video-based SJTs tend to
28
29 have more favourable candidate reactions than text based SJTs, as candidates perceive them
30
31 to have higher face validity (Chan & Schmitt 1997). However, Hausknecht et al. (2004) and
32
33 Lievens and Sackett (2006) found no difference in candidate reactions to SJTs in healthcare
34
35 settings, based on their method of delivery. In a recent study in which SJTs were used as an
36
37 in-training assessment for junior doctors, results indicated that candidates felt that a video as
38
39 an SJT delivery method was a more engaging way to view the training material compared to
40
41 text based SJTs (Kerrin et al. 2014), although the SJT was used more for developmental
42
43 purposes rather than selection in this context.
44
45

46
47 In summary, candidate reactions in any selection context are an important
48
49 consideration to ensure that perceptions of the organisation remain favourable, and especially
50
51 when considering attraction in recruitment. Candidate reactions towards SJTs used in
52
53 selection for medical education and training have been found to be favourable. Although the
54
55 face validity of video-based SJTs is high, they are significantly more expensive to develop
56
57
58
59
60

1
2
3 and maintain compared to text-based SJTs. Research does not currently support the
4
5 supposition that high-fidelity video-based SJTs would be more favourably received than text
6
7 based SJTs in medical selection, although further research is required to explore the issues.
8
9

10 *Are SJTs Susceptible to Coaching?*

11
12 The high-stakes nature of selection into medical education and training internationally
13
14 demands consideration of whether candidates' performance on SJTs can be significantly
15
16 influenced by access to coaching. In overview, although early research evidence has offered
17
18 mixed findings, there is now a consensus emerging.
19
20

21
22 Cullen et al. (2006) examined the coaching susceptibility of two SJTs (the College
23
24 Student Questionnaire; CSQ; and the Situational Judgement Inventory; SJI). Coaching
25
26 courses were developed for the two SJTs and findings showed that scores increased for the
27
28 CSQ but decreased for the SJI, compared to un-coached controls. The study authors
29
30 concluded that SJTs constructed from subject matter expert judgements are less susceptible to
31
32 coaching effects. Similarly, Lievens and colleagues (2012) found that coaching effects were
33
34 estimated to be 0.5 standard deviation difference in favour of coached candidates for an SJT
35
36 for admission to medical school in Belgium.
37
38
39

40
41 Other researchers however have identified that knowledge based response formats are
42
43 significantly less susceptible to coaching than behavioural tendency formats (McDaniel et al.
44
45 2007, Patterson et al. 2013a). Moreover, the literature suggests that building complexity into
46
47 SJT scenarios can reduce susceptibility to coaching effects, as this requires candidates to
48
49 engage with the scenario rather than employing a simple response strategy (Patterson et al.
50
51 2013a). Research suggests it is possible to reduce coaching effects by using an item banking
52
53 approach which creates repository of test items that belong to the SJT, as well as having
54
55 multiple test forms which are equated for difficulty (Patterson et al. 2013a). Many of these
56
57
58
59
60

1
2
3 approaches have been used in selection for medical education and training to reduce
4
5 susceptibility to coaching (Koczwara et al. 2012). A recent study concludes that coaching and
6
7 revising for an SJT to select junior doctors in the UK has no effect on the operational validity
8
9 the SJTs (Simon et al. 2015).
10

11
12 In summary, despite researchers raising concerns regarding SJTs' potential
13
14 susceptibility to coaching effects, several design strategies may be adopted to minimise the
15
16 potential effects of coaching where the operational validity of SJTs remains unaffected. Other
17
18 research has identified that commercial coaching techniques are not as effective as previously
19
20 thought (Stemig et al. 2015).
21
22
23
24

25 **SJT in Practice – How are SJTs Designed and Developed?**

26
27 Designing an SJT requires a thorough development and validation process in line with
28
29 best practice. The key steps to the best practice design of an SJT are described below. Each
30
31 step ensures an SJT is relevant to the specific role for which it has been developed, and
32
33 optimises the likelihood that an SJT is reliable, valid and fair.
34
35
36
37

38 ***Step 1 Role Analysis and Test Specification***

39
40 The first step in designing an SJT involves conducting a role analysis and determining
41
42 the test specification. A role (job) analysis is a systematic way of collecting and analysing
43
44 role-related information: typical role analysis information includes responsibilities, tasks,
45
46 knowledge, skills and abilities relevant to any given role, including work-based roles and
47
48 positions on educational or training courses. Not only does a role analysis contribute crucial
49
50 information required for the specification of a particular selection method, such as an SJT,
51
52 but it also increases the likelihood that the SJT is an accurate measurement tool.
53
54
55
56
57
58
59
60

1
2
3 In designing an SJT, the role analysis often includes conducting interviews with
4
5 current role incumbents and collecting “critical incidents” (challenging or salient situations
6
7 that are likely to occur in the target role), which are later used to develop the item content in
8
9 Step 2. By conducting a role analysis in this first step, it is possible to ensure that the SJT
10
11 content is relevant to the particular role and increase fairness across candidates (Lievens et al.
12
13 2008). See Box 4

For Peer-Review Only

1
2
3
4
5 Following the role analysis, the information collected is used to determine the *test*
6
7 *specification*. This includes a description of the actual test content of the SJT, the types of
8
9 items and response instructions, response instructions, formats used (e.g. knowledge based/
10
11 behavioural tendency; multiple choice/ rank order/ rating/ best and worst/ pencil and paper;
12
13 online/ video-based, respectively), a description of the length of the test, the scoring
14
15 convention to be used and how the test will be administered. Significant expertise is required
16
17 in SJT design to design the test specification.
18
19

20 21 22 23 24 25 ***Step 2 Item Development and Initial Reviews*** 26

27 Having documented a test specification and collected role analysis information, SJT
28
29 scenarios and response options are developed in collaboration with individuals who are
30
31 familiar with the target role (subject matter experts - SMEs). These may include role
32
33 incumbents and supervisors, or any other staff familiar with the target role. Working with
34
35 these SMEs is essential for item development in order to ensure that SJT scenarios and
36
37 responses are developed based on realistic, appropriate and plausible scenarios. The “critical
38
39 incidents” identified in Step 1 can be used to develop different role-related scenarios where
40
41 the candidate would need to make a decision regarding the best course of action, given the
42
43 situation. Different responses to these scenarios are also developed in conjunction with
44
45 SMEs, who advise the item writer regarding the appropriateness or importance of various
46
47 response options (i.e. what the scoring key should be for each response). A thorough and
48
49 systematic review of these scenarios and responses is then undertaken by a different set of
50
51 SMEs to ensure that each item is fair, relevant to the role and realistic.
52
53
54
55
56
57
58
59
60

Step 3 Scoring Key Agreed by Subject Matter Experts

Once item content has been developed, agreement between SMEs is required on the scoring key (i.e. how the response should be scored) for each of the possible responses to the given scenario. This is typically achieved through a *concordance panel* with SMEs. Generally this conducted with a different group of SMEs to those during Step 2, who score each response option based on how appropriate or important they consider each response to be. This process is used for the various response options available in an SJT, including ranking responses from most to least appropriate, choosing the single best answer or the three best answers (multiple choice), or rating each response independently of each other. This is often an iterative process, but results in a final scoring key being developed.

Step 4 Test Construction

In Step 4, the test is constructed. It may be in a written (paper and pencil, or electronic) format, or in some situations, the scenario may be presented in a video or interactive format.

Step 5 Piloting

Once the SJT has been constructed, the next step is piloting to ensure that it is fair and measures what it is intended to measure (i.e. has construct validity). Piloting also provides an opportunity to gain candidate reactions to the SJT, for example whether candidates perceive it to be fair and relevant to the target role. This minimises the risk of potential legal action against the organisation in operational selection settings due to a perceived lack of fairness or robustness (Patterson et al. 2011).

Step 6 Psychometric Analysis and Quality Assurance

After an SJT has been piloted, psychometric analysis of the pilot data can be conducted. At this stage it is possible to examine the reliability and validity of the test, and to ensure that each SJT item is performing well psychometrically. In addition, a fairness

1
2
3 analysis can be conducted to identify whether there are any performance differences on the
4
5 SJT as a whole, and for specific scenarios, based on demographic group differences such as
6
7 ethnicity or gender. If performance differences do exist, it is possible that an item is
8
9 discriminating against a particular sub-group (“differential item functioning”) and
10
11 consideration should be given to whether it is fair and appropriate for the scenario to remain
12
13 in the test.
14

15 16 ***Step 7 Development of an Item Bank***

17
18 Finally, there will be further development of the item bank through ongoing
19
20 development, review and validation of the scenarios and responses as more candidate score
21
22 data is collected.
23
24

25 26 27 28 ***Approaches to Scoring SJTs***

29
30 There are various scoring methods for multiple choice SJTs. They are typically
31
32 broken down into ‘*rational*’ and ‘*empirical*’. Rational scoring of items is based on experts’
33
34 judgement concerning the effectiveness of responses or best/worst options. When items are
35
36 empirically scored, they are administered to a large pilot sample. Items are selected and/or
37
38 weighted according to evidence that they differentiate between individuals who score at
39
40 different levels on a criterion variable (e.g. job performance).
41
42
43
44
45
46

47 48 **Conclusions and Future Directions for Research and Practice**

49
50 SJTs represent a measurement methodology, rather than a specific measure per se, as
51
52 each SJT may be constructed differently; and so have the potential to vary significantly in
53
54 terms of their robustness, reliability and validity. Crucially therefore, evidence suggests that
55
56 good quality SJTs require significant expertise to design and develop appropriately. Best
57
58
59
60

1
2
3 practice design of SJTs begins with a thorough role analysis, constructed in consultation with
4
5 subject matter experts. Design issues should also consider susceptibility to coaching,
6
7 especially in selection for medical education and training.
8

9
10 On balance, the evidence to date demonstrates that SJTs are a valid, reliable and well-
11
12 received method for measuring important non-academic attributes, such as empathy, integrity
13
14 and teamwork. SJTs have been successfully implemented for use in selection across a range
15
16 of healthcare professions, especially within medical education and training. SJTs have the
17
18 benefit of having reduced sub-group differences compared to other selection methods, and
19
20 are well received by candidates. The theoretical basis underpinning SJTs shows they assess
21
22 individuals' beliefs about the costs and benefits of expressing certain traits via behaviours in
23
24 given situations. Future research could extend the emerging evidence relating to the construct
25
26 validity of SJTs, for example, exploring why there is little effect of socio-economic status and
27
28 SJT performance (unlike indicators of academic attainment).
29
30

31
32 Despite a plethora of research evidence supporting the use of SJTs in the context of
33
34 medical education and training, a number of possible areas of exploration remain. Further
35
36 research could systematically compare video-based and text based SJTs to more adequately
37
38 explain the advantages and disadvantages of each approach, where potentially researchers are
39
40 able to comment on what each mode of item presentation offers more fully.
41
42

43
44 Future areas of enquiry may include the use of SJTs as a diagnostic tool to identify
45
46 individuals' training needs. This has the potential to be supplemented by education
47
48 interventions to provide training in the non-academic skills required for the target role, and so
49
50 accelerate time to competence in preparation for entry into clinical practice. Although more
51
52 traditionally used in selection contexts, extending the application of SJTs to training and
53
54 development may provide a beneficial resource in monitoring and training relevant non-
55
56 academic attributes as individuals progress through a given role or training programme.
57
58
59
60

1
2
3 Further longitudinal research studies are required to evaluate the extent to which SJTs
4
5 effectively predict performance throughout the medical education pathway, from medical
6
7 school admissions through to independent clinical practice, and beyond. This is especially
8
9 relevant given the emerging evidence that SJTs have different predictive validity at different
10
11 stages during medical education, training and practice. More research is also required to
12
13 confirm initial findings that SJTs are more predictive of performance at the lower end of
14
15 score distributions than at the top end (i.e. in identifying individuals who lack the appropriate
16
17 values and attributes to be suited to a career in healthcare). This, in turn, would help
18
19 researchers develop the theory underpinning SJTs as a measurement method.
20
21

22
23 To conclude, SJTs represent a reliable, valid, well-received and fair selection method
24
25 when designed appropriately. Future research should investigate the use of SJTs for
26
27 development, focus on gathering longitudinal data, and assess the differential predictive
28
29 validity of SJTs at different points during education and training pathways in healthcare and
30
31 at different ends of score distributions.

Box 3.

Example items of Situational Judgement Tests showing different response formats (Patterson et al., 2012).

Choose most likely & least likely response	Ranking response format	Best single response format
<p>You are shopping when you notice a man robbing the store. What would you do?</p> <p><i>Choose most likely & least likely response</i></p>	<p>You are looking after Mr Kucera who has previously been treated for prostate cancer. Preliminary investigations are strongly suggestive of a recurrence. As you finish taking blood from a neighbouring patient, Mr Kucera leans across and says “tell me honestly, is my cancer back?”</p>	<p><u>Patient:</u> <i>So, this physiotherapy is really going to help me?</i></p> <p><u>Physician:</u> <i>Absolutely, even though the first days it might still be painful.</i></p> <p><u>Patient:</u> <i>Yes, I suppose it will take a while before it starts working.</i></p> <p><u>Physician:</u> <i>That is why I am going to prescribe a</i></p>

painkiller. You should take 3 painkillers per day.

- A. Leave the store as quickly as possible and call the police.
- Rank in order the appropriateness of the following actions in response to this situation (1= Most appropriate; 5= Least appropriate).*
- B. Try to apprehend the robber yourself.
- C. Follow the man and call the police as soon as he appears settled somewhere.
- D. Nothing, as you do not wish to get involved in the matter.
- A. Explain to Mr Kucera that it is likely that his cancer has come back.
- B. Reassure Mr Kucera that he will be fine.
- C. Explain to Mr Kucera that you do not have all the test results, but you will speak to him as soon as you do.
- D. Inform Mr Kucera that you will chase up the results of his tests and ask one of your senior colleagues to discuss them with him.
- E. Invite Mr Kucera to join you and a senior
- Patient: *Do I really have to take them? I have already tried a few things. First, they didn't help me. And second, I'm actually opposed to taking any medication. I'd rather not take them. They are not good for my health.*
- What is the best way for you (as a physician) to react to this patient's refusal to take the prescribed medication?*
- A. Ask her if she knows something else to relieve the pain.
- B. Give her the scientific evidence as to why

nurse in a quiet room, get a colleague to hold

painkillers will help.

your 'bleep' then explore his fears.

C. Agree not to take them now, but also stress the importance of the physiotherapy

D. Tell her that, in her own interests, she will have to start changing her attitude.

Box 4:**Case Study: Designing an SJT to target specific attributes in postgraduate training**

Each year approximately 8,000 final year medical students apply for posts as junior doctors in the UK's foundation programme (Patterson et al. 2013a). Medical graduates are required to complete this two-year programme if they wish to work as doctors in the UK, and competition has increased due to the expansion of UK medical schools and the increasing number of applications from overseas.

An SJT was recently designed to be used as part of the selection process for these medical students. In order to define the professional attributes required to be successful in the Foundation Year 1 (FY1) role, a role analysis of the doctor role was performed with a person specification based on this analysis. Educational supervisors, clinical supervisors and other subject matter experts involved in the Foundation Programme contributed to the development of new test questions based on the test specification.

The results of the job analysis indicated that five professional attributes should be targeted by the SJT. These are:

- Commitment to Professionalism
- Coping with Pressure
- Effective Communication
- Patient Focus
- Working Effectively as Part of a Team

The list below shows each of the target attribute domains and includes possible SJT scenarios associated with them.

Matrix of SJT Target Attribute Domains (Patterson et al. 2013a)

Commitment to	<ul style="list-style-type: none"> Dealing with issues of confidentiality, e.g. hearing a colleague talking about a patient outside of work
Professionalism	<ul style="list-style-type: none"> Challenging inappropriate behaviour, e.g. consultant speaking to a colleague/patient in an inappropriate way Commitment to learning, e.g. need to go to teaching while also being needed on the ward
Coping with Pressure	<ul style="list-style-type: none"> Knowing how to respond when you make a mistake, e.g. providing wrong medication to patient Dealing with confrontation, e.g. with an angry relative Seeking help when not sure of the correct procedure / best way of doing things
Effective Communication	<ul style="list-style-type: none"> Gathering information and communicating your intentions to nursing staff or other colleagues Negotiating, e.g. for a scan from radiology Listening and effectively communicating, e.g. with an unhappy patient or relative
Patient Focus	<ul style="list-style-type: none"> Identifying that a patient's views and concerns are important and

they should have input into their care

- Considering that a patient may have different needs from others around them
- Spending time trying to understand a patient's concerns and empathising with them

Working

Effectively as Part

of a Team

- Recognising and valuing the skills and knowledge of nursing staff, when faced with a disagreement about a patient's care
- Consulting with colleagues about how to share workload fairly
- Offering assistance and support to colleagues when they are not able to handle their workload
