33 Long-term potentiation, PDE, PDE4A5, phosphodiesterase

34

35

36 **Summary**

37 Brief periods of sleep loss have long-lasting consequences such as impaired memory consolidation.
38 Structural changes in synaptic connectivity have been proposed as a substrate of memory storage.
39 Here, we examine the impact of brief periods of sleep deprivation on dendritic structure. In mice, we
40 find that five hours of sleep deprivation decreases dendritic spine numbers selectively in hippocampal
41 area CA1 and increased activity of the filamentous actin severing protein cofilin. Recovery sleep
42 normalizes these structural alterations. Suppression of cofilin function prevents spine loss, deficits in
43 hippocampal synaptic plasticity, and impairments in long-term memory caused by sleep deprivation.
44 The elevated cofilin activity is caused by cAMP-degrading phosphodiesterase-4A5 (PDE4A5), which
45 hampers cAMP-PKA-LIMK signaling. Attenuating PDE4A5 function prevents changes in cAMP-
46 PKA-LIMK-cofilin signaling and cognitive deficits associated with sleep deprivation. Our work
47 demonstrates the necessity of an intact cAMP-PDE4-PKA-LIMK-cofilin activation-signaling pathway
48 for sleep deprivation-induced memory disruption and reduction in hippocampal spine density.

58 **Introduction**

59 Sleep is a ubiquitous phenomenon and most species, including humans, spend a significant time
60 asleep. Although the function of sleep remains unknown, it is widely acknowledged that sleep is
61 crucial for proper brain function. Indeed, learning and memory, particularly those types mediated by
62 the hippocampus, are promoted by sleep and disrupted by sleep deprivation (1-3). Despite the general
63 consensus that sleep deprivation impairs hippocampal function, the molecular signaling complexes
64 and cellular circuits by which sleep deprivation leads to cognitive deficits remain to be defined.

65 The alternation of wakefulness and sleep has a profound impact on synaptic function, with
66 changes observed in synaptic plasticity and transmission (1, 2, 4). This relationship has led to the
67 development of influential theories on the function of sleep (5, 6). Recent imaging suggests that
68 dendritic structure is dynamic, especially during development, with alterations in spine numbers
69 correlating with changes in sleep/wake state (7, 8). However, the impact of sleep deprivation or sleep
70 on synaptic structure in the hippocampus in the context of memory storage or synaptic plasticity has
71 not been examined. This is an important issue, as such structural changes in ensembles of synapses
72 have been shown to play a critical role in memory storage (9, 10).

73 The formation of associative memories increases the number of dendritic spines in area CA1
74 of the hippocampus (11). Also, the induction of long-term potentiation (LTP), a cellular correlate of
75 memory storage (12), is associated with an increase in spine density in cultured hippocampal neurons
76 (13). In addition to a critical function during development (14), cofilin plays an essential role in
77 synapse structure by mediating both the enlargement and pruning of dendritic spines (15-17). The
78 activity of cofilin is negatively regulated by phosphorylation. Specifically, phosphorylation of serine 3
79 of cofilin suppresses its depolymerizing and F-actin severing activity (16). Importantly, increased
80 cofilin activity can lead to the depolymerization and severing of F-actin, which in turn results in the
81 shrinkage and loss of spines (15, 18-20). Hippocampal cofilin phosphorylation levels are increased

82 after the induction of long-term potentiation (LTP) (21-23), and during memory consolidation (24,
83 25). Additionally, elevated cofilin activity in the hippocampus was recently implicated in abnormal
84 spine structure and function in mutant mice with altered chromatin remodeling (10).

85 Here we show for the first time that 5 hours of sleep deprivation leads to the loss of dendritic
86 spines of CA1, but not CA3, neurons in the dorsal hippocampus. The spine loss in CA1 neurons was
87 accompanied by reductions in dendrite length. This process was readily reversed by sleep, with just 3
88 hours of recovery sleep normalizing this spine loss and dendrite length. The molecular mechanisms
89 underlying these negative effects of sleep deprivation were shown to target cofilin, whose elevated
90 activity could contribute to spine loss. Indeed, suppression of cofilin activity in hippocampal neurons
91 prevented the structural, biochemical, and electrophysiological changes as well as the cognitive
92 impairments associated with sleep loss. The elevated cofilin activity is caused by the activity of the
93 cAMP degrading phosphodiesterase-4A5 isoform (PDE4A5), which suppresses activity of the cAMP-
94 PKA-LIMK pathway. Genetic inhibition of the PDE4A5 isoform in hippocampal neurons restores
95 LIMK and cofilin phosphorylation levels and prevents the cognitive impairments associated with
96 sleep loss. Thus changes in the [cAMP-PDE4-PKA-LIMK-cofilin signaling pathway](#) in the adult
97 hippocampus underlie the cognitive deficits associated with sleep loss. These observations provide a
98 molecular model for the notion that prolonged wakefulness reduces structural signaling and
99 negatively impacts dendritic structure, which is then restored with sleep.

100

102

103

104 **Results**

105 **Sleep deprivation causes a robust reduction in apical and basal CA1 spine numbers and**
106 **dendrite length**

107 To determine whether short periods of sleep loss affect dendritic structure in the hippocampus,
108 we used Golgi staining to examine the length of dendrites and number of dendritic spines in the
109 mouse hippocampus following 5 hours of sleep deprivation, a period of sleep loss that is known to
110 impair selectively hippocampus-dependent memory consolidation and synaptic plasticity (1, 2, 26-28).
111 Analyses of Golgi-impregnated CA1 neurons (Figure 1A) indicated that sleep deprivation
112 significantly reduced the apical/basal spine density (Figure 1B; spine numbers per dendrite, NSD:
113 1.42 ± 0.03 , SD: 1.17 ± 0.02 ; Student's t-test, $p = 0.0002$) and dendrite length (Figure 1C; NSD:
114 1198.4 ± 31.6 , SD: $984.2 \pm 29.8 \mu\text{m}$; Student's t-test, $p = 0.0012$). This decrease in spine density and
115 dendrite length was observed in both apical and basal dendrites (Figure 1, Figure Supplement 1A, B).
116 To complement our Golgi studies, we conducted an additional experiment in which individual CA1
117 neurons in hippocampal slices from sleep deprived and non-sleep deprived mice were labeled using
118 the DiI method as described (29). In line with our Golgi studies, we found that sleep deprivation
119 significantly reduced the total number of spines on apical dendrites of CA1 neurons (Figure 1D; NSD:
120 1.0 ± 0.03 , SD: 0.84 ± 0.04 Student's t-test, $p = 0.033$; Figure 1E; NSD: 1.0 ± 0.06 , SD: 0.86 ± 0.02
121 Student's t-test, $p = 0.03$).

122 Subtype-specific apical/basal spine analyses of the Golgi impregnated neurons revealed a
123 significant decrease for all spine subtypes in sleep-deprived mice (Figure 1F, for all spine types,
124 Student's t-tests $p < 0.005$, for separate apical and basal spine analyses see Supplementary Figure 1C,
125 1D). Sleep deprivation causes the greatest reduction in apical/basal spine density between $60 \mu\text{m}$ and
126 $150 \mu\text{m}$ from the soma (Figure 1G, for separate apical and basal spine analyses see Figure 1, Figure

127 Supplement 1E, F). This region corresponds to the middle range of the dendritic branch (3rd to 9th
128 branch orders, Figure 1H) where the primary input from CA3 is located (30), suggesting that the
129 hippocampal Schaffer collateral pathway is particularly vulnerable to sleep loss.

130 We next assessed whether sleep deprivation also impacted spine numbers and dendrite length
131 of CA3 neurons. Surprisingly, in contrast to CA1 neurons, CA3 neurons were unaffected by sleep
132 deprivation. We did not observe reductions in spine density or dendrite length of either basal or apical
133 dendrites of any type (Figure 1, Figure Supplement 2). Together, these data suggest that CA1 neurons
134 at the level of dendritic structure seem particularly vulnerable to sleep deprivation.

135 To determine whether recovery sleep would reverse spine loss in CA1 neurons, we repeated
136 the sleep deprivation experiment but then left the sleep-deprived mice undisturbed for three hours
137 afterwards. This period was chosen as our previous work indicated that three hours of recovery sleep
138 is sufficient to restore deficits in LTP caused by sleep deprivation (27). In line with the
139 electrophysiological studies, recovery sleep restored apical/basal spine numbers and dendrite length in
140 CA1 neurons to those observed in non-sleep deprived mice (Figure 2A, spine density of apical/basal
141 dendrites, NSD: 1.23 ± 0.02 , RS: 1.29 ± 0.02 ; Student's t-test, $p > 0.05$; Figure 2B, dendrite length in
142 μm , NSD: 1817.0 ± 64.6 , RS: 1741.6 ± 55.57 ; Student's t-test, $p = 0.1721$; Figure 2C, Student's t-test,
143 $p > 0.05$ for each distance from soma; Figure 2D, Student's t-test, $p > 0.05$ for each branch number;
144 for separate apical and basal spine analyses see Figure 2, Figure Supplement 1) with the exception of
145 branched spines in the basal dendrites (Figure 2, Figure Supplement 1C). Recovery sleep slightly but
146 significantly elevated the number of filopodia spines of the apical CA1 dendrites and total spine
147 numbers of the 7th and 8th branch of the apical and basal dendrites respectively (Figure 2, Figure
148 Supplement 1).

149 **Sleep deprivation increases hippocampal cofilin activity and suppression of cofilin function**

150 **prevents spine loss in CA1 neurons associated with the loss of sleep**

151 We hypothesized that the structural changes in the hippocampus following sleep deprivation might be
152 related to increased activity of the actin-binding protein cofilin because increased cofilin activity can
153 cause shrinkage and loss of dendritic spines through the depolymerization and severing of actin
154 filaments (18-20). The ability of cofilin to bind and depolymerize and sever F-actin is inhibited by
155 phosphorylation at serine 3 (15-17). We therefore assessed whether sleep deprivation alters cofilin
156 phosphorylation by Western blot analysis of hippocampus homogenates collected after 5 hours of
157 sleep deprivation. Indeed, 5h of sleep deprivation reduced cofilin Ser-3 phosphorylation, suggesting
158 an increase in cofilin activity in the hippocampus (NSD: 100.0 ± 6.9 %; SD: 67.7 ± 9.2 %; Student t-
159 test $p = 0.0090$; Figure 3A). A similar effect was not evident in the prefrontal cortex (NSD, n=5:
160 100.0 ± 1.84 %; SD, n=5: 101.92 ± 2.41 %; Student t-test $p = 0.54$; Figure 3, Figure Supplement 1),
161 indicating sleep deprivation affects cofilin phosphorylation in a brain region-specific fashion. In line
162 with the observation that 3 hours of recovery sleep reversed the reduction in dendritic spines of CA1
163 neurons, we found that recovery sleep restored hippocampal cofilin phosphorylation levels to the
164 levels observed in non-sleep deprived mice (NSD, n=8: 100.0 ± 3.37 %; SD, n=7: 103.23 ± 2.42 %;
165 Student t-test $p = 0.46$; Figure 3, Figure Supplement 2).

166 Based on these findings, we hypothesized that suppressing cofilin activity would prevent the
167 sleep deprivation-induced changes in spine numbers of CA1 neurons. To test this hypothesis, we used
168 a phosphomimetic form of cofilin that renders it inactive, namely cofilin^{S3D} (31-33). Previous work
169 suggested that cofilin^{S3D} expression can inhibit endogenous cofilin activity (34, 35), through
170 competition with endogenous cofilin for signalosomes where cofilin is activated by means of
171 dephosphorylation (36, 37). For example, cofilin^{S3D} may compete with endogenous cofilin for binding
172 to the cofilin-dephosphorylating phosphatase slingshot (37). Importantly, cofilin^{S3D} expression does
173 not alter spine density under baseline conditions (31, 35). We expressed either the phosphomimetic

174 cofilin^{S3D} or enhanced green fluorescent protein (eGFP), which served as a control, in hippocampal
175 excitatory neurons of adult male C57BL/6J mice using Adeno-Associated Viruses (AAVs) (Figure
176 3B, C). A 0.4kb CaMKII α promoter fragment was used to restrict expression to excitatory neurons
177 (38). Virally mediated expression of cofilin^{S3D} was observed in excitatory neurons in all 3 major sub-
178 regions of the hippocampus three weeks after viral injection (Figure 3D-F). Western blot analyses of
179 hippocampal lysates 3 weeks after injection showed that the level of virally delivered cofilin was
180 roughly estimated 75% of the amount of endogenous wild-type cofilin and that the amount of wild-
181 type cofilin *per se* was not substantially affected by expression of the mutant form (Figure 3G).

182 We subsequently determined whether expression of the inactive cofilin^{S3D} prevented the loss
183 of dendritic spines in hippocampal area CA1 caused by sleep deprivation. Analyses of Golgi-
184 impregnated hippocampal neurons in area CA1 indicated that in cofilin^{S3D} expressing mice sleep
185 deprivation no longer reduced the spine density of apical/basal dendrites (NSD: 1.42 ± 0.03 ; SD: 1.34
186 ± 0.03 ; Student's t-test, $p > 0.05$ Figure 3H, J, K; for separate apical and basal spine analyses see
187 Figure 3, Figure Supplement 2) with the exception of a small but statistically significant reduction in
188 branched spines of apical and basal dendrites (Figure 3, Figure Supplement C, D) and a decrease in
189 number of spines on apical dendrites about 180 μm away from the soma (Figure 3, Figure Supplement
190 2E, F). Likewise, sleep deprivation no longer affected dendrite length (NSD: $1283.0 \pm 35.95 \mu\text{m}$, SD:
191 $1250.1 \pm 41.19 \mu\text{m}$; Student's t-test, $p = 0.5612$; Figure 3I, for separate apical and basal spine
192 analyses see Figure 3, Figure Supplement 2B). Together these data suggest that suppressing cofilin
193 function in hippocampal neurons prevents the negative impact of sleep deprivation on spine loss and
194 dendrite length of CA1 neurons.

195

196 **Suppressing cofilin function in hippocampal neurons prevents the impairments in memory and**
197 **synaptic plasticity caused by brief periods of sleep deprivation**

198 As a next step, we sought to determine whether prevention of the increase in cofilin activity in sleep-
199 deprived mice would not only protect against the reduction in spine numbers on CA1 dendrites but
200 also the functional impairment at the behavioral level. The consolidation of object-place memory
201 requires the hippocampus (39, 40) and is sensitive to sleep deprivation (28, 40, 41). Therefore, we
202 assessed whether cofilin^{S3D} expression would prevent cognitive deficits caused by sleep deprivation in
203 this task. Mice virally expressing eGFP or cofilin^{S3D} were trained in this task 3 weeks after viral
204 infection and sleep deprived for 5 hours immediately after training or left undisturbed in the home
205 cage. Upon testing for memory the next day, sleep-deprived mice expressing eGFP showed no
206 preference for the relocated object indicating that brief sleep deprivation impaired the consolidation of
207 object-place memory. In contrast, mice expressing cofilin^{S3D} showed a strong preference for the
208 displaced object despite sleep deprivation (eGFP NSD: $45.2 \pm 6.4\%$, eGFP SD: $33.4 \pm 2.0\%$,
209 cofilin^{S3D} NSD: $51.9 \pm 2.9\%$, cofilin^{S3D} SD: $53.2 \pm 4.6\%$; Figure 4A).

210 Expression of the mutant form of cofilin did not affect object exploration during training,
211 exploration of an open field or zero maze indicating that anxiety levels were unaffected by expression
212 of cofilin^{S3D} in the hippocampus (Figure 4, Figure Supplement 1A-C). Moreover, using a behaviorally
213 naïve cohort of mice, we found that cofilin^{S3D} expression did not alter short-term object-place memory
214 in the same task (Figure 4, Figure Supplement 1D). Together, these findings demonstrate that
215 cofilin^{S3D} expression specifically prevents the cognitive deficits caused by sleep deprivation.
216 Although we can not rule out the possibility of off-target effects of the cofilinS3D mutant, we think
217 that these are unlikely as expression of this mutant form of cofilin reversed the effects of sleep
218 deprivation, restoring spine loss, LTP and memory to non-sleep deprived levels while not having an
219 effect in non-sleep deprived mice.

220 To further define the role of cofilin in impairments in hippocampal function caused by sleep
221 deprivation, we next determined if suppression of cofilin activity would prevent the deficits in

222 hippocampal LTP caused by brief periods of sleep deprivation (1, 2, 27, 41). Five hours of sleep
223 deprivation significantly impaired long-lasting LTP induced by 4 high-frequency trains of electrical
224 stimuli applied at 5-minute intervals (spaced 4-train stimulation) in hippocampal slices from mice
225 expressing eGFP (Figure 4B), confirming our previously published findings with non-injected wild-
226 type mice (27). In contrast, spaced 4-train LTP was unaffected by sleep deprivation in hippocampal
227 slices from mice expressing the inactive cofilin^{S3D} (Figure 4C). The expression of cofilin^{S3D} or sleep
228 deprivation did not alter basal synaptic properties or paired-pulse facilitation (Figure 5, Figure
229 Supplement 1E-H) suggesting that the spine loss caused by sleep deprivation specifically impairs
230 long-lasting forms of synaptic plasticity.

231 As a next step, we wanted to assess whether expression of a catalytically active version of
232 cofilin (cofilin^{S3A}) mimics the behavioral and synaptic plasticity phenotypes associated with sleep
233 deprivation. Mice virally expressing eGFP or cofilin^{S3A} were trained in the object-place memory task
234 3 weeks after viral infection and tested 24 hours after training. Mice expressing eGFP showed a strong
235 preference for the relocated object while mice expressing cofilin^{S3A} showed no preference for the
236 object that was moved to a novel location (eGFP: $46.9 \pm 6.4\%$, cofilin^{S3A}: $34.9 \pm 2.1\%$, cofilin^{S3D} SD:
237 $53.2 \pm 4.6\%$; Figure 4, Figure supplement 2B). The observed memory deficit could not be explained
238 by a reduction in object exploration during the training as the total object exploration time was similar
239 for both groups during training (Figure 4, Figure supplement 2A).

240 Based on these findings, we conducted a set of electrophysiological experiments to determine
241 whether expression of cofilin^{S3A} is also sufficient to induce impairments in spaced 4-train LTP.
242 Cofilin^{S3A} expression did not affect this form of L-LTP (Figure 4, Figure supplement 2E). The
243 expression of cofilin^{S3D} or sleep deprivation did not alter basal synaptic properties or paired-pulse
244 facilitation (Figure 4, Figure Supplement 2C-D).

245 In summary, these data show that phosphorylation-dependent reductions in cofilin activity in

246 hippocampal excitatory neurons prevent the decrease in hippocampal spine numbers, and also prevent
247 the functional impairments in synaptic plasticity and behavior caused by a brief period of sleep
248 deprivation. Furthermore, expression of constitutively active cofilin in hippocampal neurons is
249 sufficient to mimic the memory deficits but not the synaptic plasticity impairment associated with a
250 brief period of sleep deprivation.

251

cAMP phosphodiesterase-4A5 (PDE4A5) causes the increase in cofilin activity associated with sleep deprivation through inhibition of the cAMP-PKA-LIMK pathway

Sleep deprivation attenuates cAMP signaling in the hippocampus through increased levels and cAMP hydrolyzing activity of PDE4A5 (27). Cofilin activity is known to be suppressed by the PKA-LIMK signaling pathway through the LIMK-mediated phosphorylation of cofilin at Ser-3 (42, 43). We hypothesized that the elevation in PDE4A5 activity, associated with sleep loss, could negatively impact the cAMP-PKA-LIMK signaling pathway by enhancing cAMP degradation, thereby leading to increased cofilin activity. Based on this hypothesis, we also anticipated that blocking PDE4A5 function in hippocampal neurons would make the cAMP-PKA-LIMK pathway, which controls cofilin activity, resistant to the effects of sleep deprivation. To test this hypothesis, we engineered a catalytically inactive form of PDE4A5 (referred to as PDE4A5^{catnull}) in which an aspartate group located deep within the cAMP binding pocket of PDE4A5 (PDE4A5^{D577A}), that is critical for catalytic activity, is replaced with an alanine group (44, 45). Expression of PDE4A5^{catnull} outcompetes the low levels of active, endogenous PDE4A5 from PDE4A5-containing signalosome complexes that specifically sequester it (46), thereby preventing the breakdown of cAMP in the vicinity of those complexes. We used the viral approach (28) to express PDE4A5^{catnull} selectively in hippocampal neurons (Figure 5A,B). Four weeks after viral injections, expression of PDE4A5^{catnull} was observed in all major hippocampal subregions (Figure 5C-E), and expression was excluded from astrocytes

(Figure 5F-H). Expression of PDE4A5^{catnull} did not alter PDE4 activity in the hippocampus, prefrontal cortex or cerebellum (Figure 5, Figure Supplement 1A-C). Next, we sleep deprived mice for 5 hours and assessed whether the phosphorylation of LIMK and cofilin was altered in the hippocampus. In agreement with our hypothesis, we observed that 5 hours of sleep deprivation reduced both LIMK and cofilin phosphorylation in hippocampal lysates from eGFP mice (Figure 5I,J). PDE4A5^{catnull} expression prevented the sleep deprivation-induced decreases in LIMK and cofilin phosphorylation (Figure 5I,J). While expression of PDE4A5^{catnull} fully restored the pcofilin/cofilin ratio in the hippocampus of sleep deprived mice to the levels observed under non-sleep deprivation conditions, it should be noted that phosphatases such as slingshot (36) may also contribute to the reduction in cofilin phosphorylation levels under conditions of sleep deprivation. Three hours of recovery sleep was sufficient to restore both LIMK and cofilin phosphorylation levels in the hippocampus (Figure 5K,L). The latter observation is in line with our previous observations that a few hours of recovery sleep is sufficient to restore hippocampal synaptic plasticity (27).

252 **Blocking PDE4A5 function in hippocampal neurons prevents memory deficits caused by sleep**
253 **deprivation**

254 Because PDE4A5^{catnull} expression in hippocampal neurons prevents changes in the cAMP-PKA-
255 LIMK-cofilin pathway caused by sleep deprivation, we hypothesized that expression of PDE4A5^{catnull}
256 in hippocampal excitatory neurons would also prevent the memory deficits induced by 5 hours of
257 sleep deprivation. Mice expressing eGFP showed a clear preference for the displaced object 24 hours
258 after training, which was lost in animals that were deprived of sleep for 5 hours immediately after
259 training (Figure 5M). In contrast, mice expressing PDE4A5^{catnull} showed a strong preference for the
260 displaced object despite sleep deprivation (Figure 5M). The memory rescue was not a result of altered
261 exploratory behavior during training in the object-place recognition task (Figure 5, Figure Supplement
262 1D). Furthermore, PDE4A5^{catnull} expression did not alter anxiety levels and exploratory behavior in

263 the open field (Figure 5, Figure Supplement 1E).

264 Although the catalytic unit of the 25 distinct PDE4 isoforms is highly conserved, each has a
265 unique N-terminal localization sequence that directs isoform targeting to a specific and unique set of
266 protein complexes (signalosomes) (46). This allows for a highly orchestrated sequestering of cAMP
267 signaling in specific intracellular domains rather than a general, global degradation of cAMP
268 throughout the cell (46). We therefore aimed to determine whether the rescue of memory impairments
269 by expression of PDE4A5^{catnull} requires the unique N-terminal domain of PDE4A5. To answer this
270 question, we engineered a truncated version of PDE4A5^{catnull} that lacks the first 303 base pairs
271 encoding the isoform unique N-terminal domain (47) (referred to as PDE4A5^{catnullΔ4}, Figure 5, Figure
272 Supplement 1F) and expressed this mutant in excitatory neurons in the hippocampus using a viral
273 approach. As this species has no targeting N-terminus then, unlike the full length inactive PDE4A5
274 that displaces endogenous active PDE4A5 from its functionally relevant location in the cell and
275 thereby increase cAMP levels localized to the sequestering signaling complex, this engineered 5'
276 truncated complex would simply lead to the expression of an inactive PDE4A catalytic unit unable to
277 be targeted like the native enzyme and so unable to exert an effect on localized cAMP degradation in
278 the functionally relevant compartment.

279 Western blot analyses of hippocampal tissue 4 weeks after viral injection confirmed the
280 presence of the truncated PDE4A5^{catnullΔ4} at the protein level using an antibody that detects all PDE4A
281 isoforms and an antibody against the HA-tag (Figure 5, Figure Supplement 1F, G). With a
282 behaviorally naïve cohort of mice now expressing eGFP or PDE4A5^{catnullΔ4} we repeated the object-
283 place recognition task. Brief sleep deprivation after training in the object-place recognition task
284 resulted in a loss of preference for the displaced object in mice expressing PDE4A5^{catnullΔ4} (Figure 5,
285 Figure Supplement 1I). The inability of PDE4A5^{catnullΔ4} to prevent the memory deficit caused by sleep
286 deprivation was not a consequence of altered exploration levels during training (Supplementary

287 Figure 7H). This finding indicates that the memory rescue in the previous experiment was a result of
288 the full length PDE4A5^{catnull} being sequestered to specific signalosomes through the isoform-unique
289 N-terminal region rather than a consequence of PDE4A5^{catnull} being unable to target the functionally
290 relevant complexes sequestering full length PDE4A5. It also indicates that displacing sequestered,
291 active endogenous PDE4A5 in hippocampal excitatory neurons is sufficient to prevent memory
292 deficits induced by 5 hours of sleep deprivation. Overall, these data suggest that sleep deprivation
293 negatively impacts spine numbers by targeting the PKA-LIMK-cofilin pathway through the
294 alterations in activity of PDE4A5 (Figure 6).

305

306 **Discussion**

307 One of the major challenges in sleep research is the elucidation of molecular mechanisms and cellular
308 circuits underlying the adverse consequences of sleep loss. Here, we use *in vivo* rescue experiments to
309 define a critical molecular mechanism by which brief sleep deprivation leads to cognitive
310 impairments. First, we show that sleep deprivation dramatically reduces spine number and dendrite
311 length of hippocampal CA1 neurons without affecting dendritic structure of CA3 neurons. Second, we
312 demonstrate that sleep deprivation increases cofilin activity in the hippocampus, but not the prefrontal
313 cortex, which is a likely explanation for the reductions in CA1 spine numbers and dendrite length.
314 Third, we find that three hours of recovery sleep restores spine number, dendrite length and cofilin
315 phosphorylation levels to those observed in non-sleep deprived mice. Fourth, we show that
316 suppression of cofilin activity in hippocampal excitatory neurons is sufficient to prevent sleep-
317 deprivation-induced decreases in dendritic spines number, LTP impairments, and memory. Fifth, we
318 demonstrate that hippocampal expression of constitutively active cofilin is sufficient to cause long-
319 term memory deficits but not LTP impairments. Sixth, we find that suppression of PDE4A5 function
320 through overexpression of a catalytically inactive mutant version of PDE4A5 changes LIMK and
321 cofilin phosphorylation levels caused by sleep deprivation. Finally, we show that hippocampal
322 suppression of PDE4A5 function prevents the negative impact of sleep deprivation on memory
323 consolidation. Thus, our studies demonstrate that changes in the cAMP/PKA/LIMK/cofilin pathway
324 are necessary to cause memory deficits under conditions of sleep deprivation.

325 In light of the fact that elevated cofilin activity can lead to spine shrinkage and spine loss (18,
326 31), our genetic manipulations of cofilin and PDE4A5 signaling independently link impairments in
327 synaptic plasticity and memory caused by brief sleep deprivation with the loss of dendritic spines in
328 the hippocampus. Deficits in synaptic plasticity and memory both represent read outs of the impact of
329 sleep deprivation on hippocampal function, but our work does not directly examine the direct

330 relationship between synaptic plasticity and memory, a topic that has been the subject of extensive
331 study and discussion in the literature (48, 49). That care should be taken to directly relate LTP deficits
332 with memory impairments is emphasized by our findings that expression of constitutively active
333 cofilin is sufficient to cause memory deficits while it does not impact at least one form of L-LTP that
334 is disrupted by sleep deprivation (27).

We observed a significant reduction in the total number of dendritic spines of excitatory CA1 neurons after 5 hours of sleep deprivation. This substantial decrease in dendritic spine number occurs rapidly and exceeds the fluctuations in hippocampal spine number observed across the estrus cycle (50), or the changes in spine number caused by stress (51, 52). In contrast to sleep deprivation, acute stress results in an increase rather than a decrease in CA1 spine number in male rats (52). Even 3 to 4 weeks of chronic stress or systemic delivery of corticosterone does not alter dendritic arborization of CA1 neurons (51). It is also unlikely that other factors associated with the procedure to keep animals awake rather than sleep deprivation per se causes the spine loss as our previous work indicated that applying the exact same amount of stimulation in the waking phase (*i.e.* the dark phase) does not lead to memory impairments (53).

In line with our finding of reductions in spines during sleep deprivation, work by Yang and colleagues revealed that sleep promotes dendritic spine formation in neurons activated by learning (54). Combined with our work, these experiments suggest that sleep deprivation disrupts learning-induced changes in spines that occur during sleep. Importantly, our structural studies reveal that spine loss is reversed by recovery sleep, consistent with this idea. Thus, our work reveals a distinct, selective, and rapid effect of brief periods of sleep loss on synaptic structure. It is noteworthy that even a short period of sleep deprivation acts to trigger such a dramatic effect on neuronal structure, which is reversed by recovery sleep.

Studies assessing the impact of sleep deprivation on electrophysiological properties of excitatory hippocampal neurons suggest that sleep deprivation negatively impacts long-lasting forms of LTP (1, 2). In this study and our previous work (27, 41), we showed that 5 hours of sleep deprivation attenuates long-lasting forms of LTP in the hippocampus. We observed that expression of an inactive mutant form of cofilin prevented the reductions in CA1 spine number, the impairment in a long-lasting form of LTP caused by sleep loss. It is interesting to note that three hours of recovery sleep not only restores spine numbers in CA1 neurons, but also hippocampal LIMK and cofilin phosphorylation levels. These findings complement our previous electrophysiological studies, in which we showed that such a short period of recovery sleep also restores deficits in LTP caused by 5 hours of sleep deprivation (27).

Our work reveals that PDE4A5 is a critical mediator of the impact of sleep deprivation on memory consolidation. Indeed, one reason why hippocampal area CA1 is specifically vulnerable to sleep deprivation may be the high level of PDE4A5 expression in this region (55). Specific PDE4 isoforms are sequestered by distinct signalosome complexes that regulate localized cAMP signaling and impart functionally distinct roles (46). Impairing the function of PDE4A5 signalosomes through expression of a full length catalytically inactive form of PDE4A5 exerts a dominant negative action, phenotypically identified here as preventing the alterations in LIMK and cofilin signaling caused by sleep deprivation. This makes memory consolidation resistant to the negative impact of sleep loss. Consistent with notion that a key functional role of the isoform-unique N-terminal region of PDE4 isoforms is in targeting to signalosomes so as to exert functionally distinct actions (46) the hippocampal expression of a catalytically inactive version of PDE4A5 lacking the isoform unique N-terminal domain fails to rescue the cognitive deficits associated with sleep loss. The latter observation suggests that the isoform-specific N-terminal domain of PDE4A5 targets this specific PDE isoform to signalosomes that degrade cAMP in the vicinity of complexes that are particularly sensitive to sleep

deprivation such as the complexes that contain LIMK and cofilin. Consistent with this, no such dominant negative phenotype is evident in a catalytically inactive PDE4A construct engineered to lack such an N-terminal targeting region.

Our data contradict the synaptic homeostasis hypothesis for sleep function. This hypothesis proposes that sleep functions to downscale synaptic strength that has increased as a result of neuronal activity and experiences during wakefulness (5). This hypothesis has focused on explaining data from the cortex rather than the hippocampus, but one previously published study has suggested that the synaptic homeostasis hypothesis applies to the hippocampus as well (56). However, the hippocampus may be unique from the cortex as the hippocampus is involved in episodic memory and in much greater experience-dependent plasticity than anywhere else in the brain and thus our findings may not extend to other areas where synaptic plasticity is not as prominent. Further, the hippocampus also exhibits many distinct forms of synaptic plasticity. Here, we examine structural changes in hippocampal neurons and find that extended wakefulness leads to a loss of synaptic spines mediated by a signaling pathway involving cofilin. This suggests that prolonged wakefulness down-regulates synaptic connectivity in the hippocampus. As little as 3 hours of recovery sleep is sufficient to restore signaling through these complexes, suggesting that sleep functions to restore synaptic connectivity. Thus, the signaling pathways that mediate changes in dendritic structure are rapidly impaired by sleep loss and then can be quickly restored during recovery sleep.

Lack of sleep is a common problem in our 24/7 modern society and it has severe consequences for health, overall wellbeing, and brain function (57, 58). Despite decades of research, the mechanisms by which sleep loss negatively impacts brain function have remained unknown. Our findings suggest that the cognitive impairments caused by brief sleep deprivation are a result of altered spine dynamics leading to a reduction in spine numbers. Our findings may also explain the reduction in hippocampal volume observed in an animal model of more chronic sleep restriction (59)

and sleep disorders, such as primary insomnia (60) as well as sleep apnea (61). Our work defining the molecular pathway through which sleep deprivation impacts memory consolidation underscores the importance of the plasticity of the neuronal cytoskeleton and reveals that rapid synaptic remodeling occurs with changes in behavioral state.

Materials and Methods

335 **Subjects**

336 Experimentally naïve C57BL/6J male mice (2-3 months of age; IMSR_JAX:000664) were obtained
337 from Jackson laboratories at an age of 6 weeks and housed in groups of 4 with littermates on a 12
338 hr/12 hr light/dark schedule with lights on at 7 am (ZT0). Mice had food and water available *ad*
339 *libitum*. In case of the viral studies, mice underwent surgery at an age of 8-12 weeks, were single
340 housed for 5 days and then pair-housed with a littermate throughout the experiment. For the perfusion
341 experiments, mice were single housed 1 week prior to the start of the experiment. For all experiments,
342 mice were randomly assigned to groups and were handled for 5 days for 2 minutes per day. All
343 experiments were conducted according to National Institutes of Health guidelines for animal care and
344 use and were approved by the Institutional Animal Care and Use Committee of the University of
345 Pennsylvania (IACUC protocols 804240, 804407, 802784).

346 **Sleep deprivation**

347 Mice were sleep deprived using the gentle stimulation method (27, 53, 62-64). In short, animals were
348 kept awake by gentle tapping the cage, gently shaking the cage and/or removing the wire cage top.
349 Their bedding was disturbed in cases when mice did not respond to tapping or shaking the cage. This
350 method of sleep deprivation has been validated by our laboratory using EEG recordings (65).

351 **Behavioral assays**

352 In the object-place recognition task, mice learn the location of 3 distinct objects and were tested for
353 memory of the object locations 24 hours after training by displacing one of the objects. Training
354 commenced at ZT0 or 45 min after lights on using the previously described training protocol (39, 66).
355 Mice were trained 3 or 4 weeks after viral surgery. Object exploration levels were scored manually by

356 the experimenter blind to treatment conditions. The zero maze and open field studies were conducted
357 as previously described (66, 67).

358 **Viral surgeries**

359 Mice were anaesthetized using isoflurane and remained on a heating pad throughout the surgery and
360 kept warm using a heating lamp for 5-10 minutes during the recovery from the anesthesia until the
361 mouse was awake. Mice received metacam and buprenol as analgesics during and post-surgery and
362 artificial tears (Puralube) were used to prevent the eyes from drying out during surgery. Two small
363 holes were drilled in the skull at the appropriate locations using a microdrill. The virus was injected
364 using a nanofil 33G beveled needles (WPI) attached to a 10 µl Hamilton syringe. A microsyringe
365 pump (UMP3; WPI) connected to a mouse stereotax and controller (Micro4; WPI) were used to
366 control the speed of the injections. The needle was slowly lowered to the target site over the course of
367 3 minutes and remained at the target site for 1 minute before beginning of the injection (0.2 µl per
368 minute). After the injection, the needle remained at the target site for 1 minute and then was slowly
369 gradually removed over a 5 minute period. The coordinates for the bilateral injections are (A/P -1.9
370 mm, L/M +/- 1.5 mm, and 1.5 mm below bregma). After removal of the needle, a small amount of
371 bone wax (Lukens) was used to close the drill holes and the incision was closed with sutures.

372 **DNA manipulation and Virus constructs**

373 Site-directed mutagenesis of plasmid DNA was carried out to generate PDE4A5^{catnull} using the
374 Stratagene QuikChange® Site-Directed Mutagenesis kit, using the method in the manufacturer's
375 instructions. N-terminal lacking PDE4A5^{catnull} was generated using standard PCR cloning procedures
376 and the Stratagene PfuUltra High-Fidelity DNA polymerase. Purified plasmid DNA was produced
377 using Qiagen QIAprep® kits and stored at 4 °C. The pAAV₉-CaMKIIα0.4-PDE4A5^{catnull}-VSV,
378 pAAV₉-CaMKIIα0.4-PDE4A5^{catnullΔ4}-HA, pAAV₉-CaMKIIα0.4-Cofilin^{S3D}-HA, pAAV₉-

379 CaMKII α 0.4-Cofilin^{S3A}-HA and pAAV₉-CaMKII α 0.4-eGFP were constructed by standard methods
380 and packaged by the University of Pennsylvania viral core. Transduced cofilin^{S3D} may compete with
381 endogenous cofilin for binding to the cofilin-specific phosphatase slingshot, thereby leading to
382 inactivation of the endogenous protein (36, 37). Titers ranged from 2.4 x 10¹² to 4.91 x 10¹³ genome
383 copy numbers. A 0.4kb CaMKII α promoter fragment (38) was used to restrict expression to excitatory
384 neurons. An HA-tag was included to discriminate endogenous from virally expressed proteins.
385 Approximately 1 μ l, (corrected for genome copy number between constructs) was injected per
386 hippocampus.

387 **Biochemistry**

388 The cAMP-specific PDE activity assays and western blots to assess sleep deprivation-induced
389 changes in PDE4A5 levels were conducted as described (27). Hippocampal tissue was lysed using a
390 tissue ruptor (Qiagen) in lysis buffer (Tris 50 mM, pH: 9, sodium deoxycholate 1 %, Sodium fluoride
391 50 mM, activated sodium vanadate 20 μ M, EDTA 20 μ M, and beta-glycerophosphate 40 μ M.
392 Additional phosphatase inhibitor cocktail (Thermo scientific) and protease inhibitors (Roche) were
393 added to the freshly prepared buffer just prior to tissue lysis. Samples were centrifuged for 10 minutes
394 at 13000 x g at 4°C and supernatant was collected. Protein concentration of the samples was measured
395 using the Bradford method (Biorad) and sample concentration was corrected using additional lysis
396 buffer. Afterwards LDS sample buffer (Nupage, Invitrogen) including 2-mercaptoethanol was added
397 and samples were for boiled for 5 minutes prior to loading on Criterion TGX 18-well 4-20 % gels.
398 After electrophoreses, proteins were transferred to PVDF membrane followed by blocking for 1 hr in
399 5% milk in TBST or 5% BSA in TBST (in case of cofilin antibodies). After blocking, the following
400 antibodies were used GAPDH (1:1000, Santa Cruz, RRID:AB_10167668), PDE4A (1:1000(27)),
401 PDE4A5 (1:1000(27)), pCofilin (1:1000, Cell signaling, RRID:AB_2080597), Cofilin (1:3000 BD
402 Transduction Laboratories, RRID:AB_399515), HA-tag (1:1000, Roche, RRID:AB_390918), VSV-G

403 tag (1:1000, Abcam, RRID:AB_302646), LIMK (1:2000, Millipore, RRID:AB_1977324). Polyclonal
404 phospho-serine 596 LIMK antibody was generated by New England Biopeptides using
405 CDPEKRP(pS)FVKLEQ peptide. After incubation with the primary antibodies, membranes were
406 incubated in HRP-conjugated secondary antibodies for 1 hr at room temperature (Santa Cruz, mouse
407 secondary antibody 1:1000, RRID:AB_641170; Santa Cruz, rabbit secondary antibody,
408 RRID:AB_631746). The immunoreactive bands were captured on autoradiography film (Kodak) and
409 analyzed using ImageJ (NIH).

410 **Immunohistochemistry**

411 Immunohistochemistry was conducted as described previously (67, 68). In short, animals were
412 transcardially perfused with ice cold 4% paraformaldehyde in PBS followed by a 48 hr post fixation
413 in 4% PFA. Coronal brain sections were cut at a thickness of 25 microns. Sections were rinsed in
414 PBS, blocked with 5% normal serum and incubated in PBS with 0.1% triton and 2% normal serum
415 with either of the following antibodies or combinations of antibodies PDE4A5 (1:200, (27)), HA-tag
416 (1:200, Roche, RRID:AB_390918), VSV-G tag (1:2000, Abcam, RRID:AB_302646), GFAP-alexa
417 488 (1:200, Invitrogen, RRID:AB_143165) followed by the appropriate Alexa fluor-conjugated
418 secondary antibodies (1:1000 Invitrogen, RRID:AB_141459, RRID:AB_10562718,
419 RRID:AB_10564074). Fluorescent images were analyzed using a Leica confocal microscope.

420 **Diolistic staining.**

421 After sleep deprivation mice were injected (i.p.) with a lethal dose of morbital and perfused with
422 phosphate-buffered saline (PBS, 3 min at RT), followed by 1.5 % PFA (20 min at RT). Brains were
423 then removed and post-fixed in 1.5 % PFA (40 min at RT). After post perfusion incubation in 1.5 %
424 PFA, each hemisphere was cut in 130 μ m slices using a vibratome. Slices were collected to multiwell
425 plates filled with PBS. After one hour incubation in room temperature, PBS was removed and slices
426 were stained with a GeneGun (Biorad, pressure: 100-120 psi) using nylon filter (Merc Millipore, 10

427 μm , cat. No. NY1004700). DiI bullets were prepared as described (29). After staining, slices were
428 incubated over night at RT in PBS. The next day slices were incubated for one hour in 4% PFA and
429 mounted with DapiFluoromount G (SouthernBiotech). Microphotographs of DiI stained apical
430 dendrites in the stratum radiatum of CA1 area (approx. 100 μm from cell bodies) were performed in
431 z-stacks using Zeiss LSM 780 (step 0.3 μm , objective 63x, digital magnifications 5x, resolution 1024
432 x 1024). Linear density (per mm of dendrite) and size of spines were counted using SpineMagick
433 software. On average 155 spines were analyzed per an animal. Importantly, for the comparison of the
434 spine numbers using golgi and diolistic staining methods we focused *specifically* on the 2nd and 3rd
435 branch of the apical dendrites as the diolistic staining technique is suboptimal to label and analyze
436 branches farther away from the soma.

437 **Electrophysiology**

438 Experiments were performed in the hippocampal Schaffer collateral pathway as previously described
439 (27, 67). Briefly, male mice injected with eGFP or cofilin^{S3D} virus were sacrificed by cervical
440 dislocation, and hippocampi were quickly collected in chilled, oxygenated aCSF containing 124 mM
441 NaCl, 4.4 mM KCl, 1.3 mM MgSO₄×7H₂O, 1 mM NaH₂PO₄×H₂O, 26.2 mM NaHCO₃, 2.5 mM
442 CaCl₂×2H₂O, and 10 mM D-glucose bubbled with 95% O₂ / 5% CO₂. 400 μm thick transverse
443 hippocampal slices were placed in an interface recording chamber at 28°C (Fine Science Tools, Foster
444 City, CA). Slices were equilibrated for at least 2 hours in aCSF (pH 7.4). The stimulus strength was
445 set to elicit 40% of the maximum field excitatory postsynaptic potential (fEPSP) amplitude. The
446 average of the baseline initial fEPSP slope values over the first 20 min was used to normalize each
447 initial fEPSP slope.

448 **Golgi Analyses**

449 Brains were impregnated using the Rapid Golgi stain kit (FD Neurotechnologies Inc.) according to the

450 instructions. Coronal sections (80-*um* thickness) that covered the rostro-caudal axis of CA1 of the
451 hippocampus were analyzed. The serial sections were then chosen and analyzed using a stereology-
452 based software (Neurolucida, v10, Microbrightfield, VT), and Zeiss Axioplan 2 image microscope
453 with Optronics MicroFire CCD camera (1600 x 1200) digital camera, motorized X, Y, and Z-focus
454 for high-resolution image acquisition and digital quantitation in combination with a 100x objective
455 using a sophisticated and well established method that should represent a 3D quantitative profile of
456 the neurons sampled and prevents a failure to detect less prominent spines.

457 Our sampling strategy is to prescreen the impregnated neurons along the anterior/posterior
458 axis of the region of interest to see if they were qualified for analysis. Neurons with incomplete
459 impregnation or neurons with truncations due to the plane of sectioning were not collected. Moreover,
460 cells with dendrites labeled retrogradely by impregnation in the surrounding neuropil were excluded.
461 We also made sure there was a minimal level of truncation at the most distal part of the dendrites; this
462 often happens in most of the Golgi studies, likely due to the plane of sectioning at top and bottom
463 parts of the section. The brains were cut at a 80 μ m thickness. With consideration of the shrinkage
464 factor after processing (generally 10-25% shrinkage), the thickness of the section is even less, so the
465 visualization of the spine subclass is no issue as we used a 100x Zeiss objective lens with immersion
466 oil, which is sufficient to resolve the details or subtype of the spines for laborious counting. All
467 analyses were conducted by an experimenter blind to treatment.

468 **Statistics**

469 Behavioral and electrophysiological data were analyzed using Student's t-tests or two-way ANOVAs
470 (in some cases with repeated measures as the within subject variable). Dunnett's tests were used for
471 post-hoc analyses where needed. Biochemical data was analyzed using independent samples t-tests.
472 The experimenter was blind to group treatment in all studies. Differences were considered statistically
473 significant when $p < 0.05$. All data are plotted as mean \pm s.e.m.

Acknowledgements

474 We thank Abel lab members for their help with these experiments and for their comments on the
475 manuscript. We thank James Bamberg (Colorado State University) for providing cofilin antibodies.
476 We thank Amita Sehgal (University of Pennsylvania), Tom Jongens (University of Pennsylvania) and
477 Noreen O'Connor-Abel (University of Pennsylvania) for input on a previous version of the
478 manuscript. We thank Paul Schiffmacher for assistance with the illustrations.

479 Author Contributions

480 Experiments were conceived and designed by R.H and T.A. with input from G.S.B., M.D.H., P.M.,
481 S.J.A., and K.R. Behavioral experiments were carried out by R.H. with help from J.C.T., R.T.H.,

495 **hippocampus**

496 (A) Representative images of Golgi-impregnated dendritic spines of CA1 pyramidal neurons from
497 sleep deprived (SD) and non-sleep deprived (NSD) mice. Scale bar, 5 μ m. (B) Sleep deprivation
498 reduces the spine density of apical/basal dendrites of CA1 neurons (n = 5-6, Student's t-test, p =
499 0.0002). (C) Sleep deprivation decreases apical/basal dendrite length of CA1 neurons (n = 5-6,
500 Student's t-test, p = 0.0012). (D, E) Comparative analyses of spine numbers in the 2nd-3rd branch of
501 apical dendrites of CA1 neurons reveal a significant reduction as a result of sleep deprivation using
502 either the DiI labeling method (n = 3-4, Student's t-test, p = 0.03) or Golgi analyses (n = 5, Student's
503 t-test, p = 0.03). Importantly, for the comparison of the two methods we focused on the 2nd and 3rd
504 branch of the apical dendrites. See also the methods section. (F) Sleep deprivation reduces the number
505 of all spine types in apical/basal dendrites of CA1 neurons (n = 5-6, Student's t-test, p < 0.005). (G)
506 Sleep deprivation reduces spine density of apical/basal dendrites between 60 and 150 μ m away from
507 the soma of CA1 neurons (n = 5-6, Student's t-test, p < 0.005). (H) Sleep deprivation reduces
508 apical/basal spine density in branch 3-9 of CA1 neurons (n = 5-6, Student's t-test, p < 0.005). NSD:
509 non-sleep deprived, SD: sleep deprived, Values represent the mean \pm SEM. * p<0.05, ***p < 0.005,
510 by Student's t test. See also Figure 1 Figure Supplement 1 and 2 for separate Golgi analyses of apical
511 and basal spine numbers.

512

513 **Figure 2. Three hours of recovery sleep restores spine numbers and dendrite length of CA1**
514 **neurons in the hippocampus**

515 (A) Golgi analyses indicated that three hours of recovery sleep after 5 hours of sleep deprivation
516 restores the total number of spines per apical/basal dendrite of CA1 neurons (n = 6, Student's t-test, p
517 > 0.05). (B) Three hours of recovery sleep after 5 hours of sleep deprivation restores apical/basal
518 dendrite length of CA1 neurons (n = 6, Student's t-test, p = 0.173). (C, D) Three hours of recovery
519 sleep restores apical/basal spine numbers at all distances from the soma (Student's t-test, p > 0.05 for
520 each distance from soma, C) and at each branch number (Student's t-test, p > 0.05 for each branch
521 number, C). NSD: non-sleep deprived, RS: Sleep deprivation + recovery sleep. Values represent the
522 mean ± SEM. See also Figure 2 Figure Supplement 1 for separate Golgi analyses of apical and basal
523 spine numbers.

524

525 **Figure 3. Increased cofilin activity in the hippocampus mediates the spine loss associated with**
526 **sleep deprivation.**

527 (A) Five hours of sleep deprivation leads to a reduction in cofilin phosphorylation at serine 3 in the
528 hippocampus. A representative blot is shown. Each band represents an individual animal. (n = 13-14,
529 Student's t-test p = 0.0090). (B) Mice were injected with pAAV₉-CaMKII α 0.4-eGFP or pAAV₉-
530 CaMKII α 0.4-cofilin^{S3D}-HA into the hippocampus to drive expression of eGFP or the mutant inactive
531 form of cofilin (cofilin^{S3D}) in excitatory neurons. This inactive mutant form of cofilin was made by
532 substituting serine 3 for aspartic acid, which mimics a phosphoserine residue. An HA-tag was
533 included to discriminate between mutant and endogenous cofilin. (C) A representative image showing
534 that viral eGFP expression was restricted to the hippocampus. (D-F) Cofilin^{S3D} expression was
535 excluded from astrocytes in area CA1 as indicated by a lack of co-labeling (F) between viral cofilin
536 (D) and GFAP expression (E). Scale bar, 100 μ M. (G) Virally delivered cofilin^{S3D} protein levels were
537 approximately 75% (blue bar) of wild-type cofilin levels (green bar). Wild-type cofilin levels were not
538 significantly affected by expression of cofilin^{S3D}. An HA-tag antibody was used to detect the mutant

539 inactive form of cofilin. (n = 4). (H) Hippocampal cofilin^{S3D} expression prevents spine loss in
540 apical/basal dendrites of CA1 neurons that is associated with sleep deprivation (n = 6, Student's t-test,
541 $p > 0.05$). (I) Hippocampal cofilin^{S3D} expression prevents the decrease in apical/basal dendritic spine
542 length in neurons of hippocampal that is caused by sleep deprivation (n = 6, Student's t-test, $p > 0.05$).
543 (J) Sleep deprivation does not alter the number of any spine type in apical/basal dendrites of CA1
544 neurons in the hippocampus of mice expressing cofilin^{S3D} (n = 6, Student's t-test, $p > 0.05$). (K) Sleep
545 deprivation does not attenuate apical/basal spine density at any distance from the soma in mice
546 expressing cofilin^{S3D} (n = 6, Student's t-test, $p > 0.05$). NSD: non-sleep deprived, SD: sleep deprived.
547 Values represent the mean \pm SEM. ** $p = 0.0090$. Student's t test. See also Figure 3, Figure
548 Supplement 1. For separate analyses of apical and basal spine numbers see Figure 3, Figure
549 Supplement 2.

550

551 **Figure 4. Increased cofilin activity in the hippocampus mediates the memory and synaptic**
552 **plasticity deficits associated with sleep deprivation.**

553 (A) Mice expressing eGFP or cofilin^{S3D} were trained in the hippocampus-dependent object-place
554 recognition task. Half of the groups were sleep deprived for 5 hours and all mice were tested 24 hours
555 later. Hippocampal cofilin^{S3D} expression prevents memory deficits caused by sleep deprivation (n = 9-
556 10, two-way ANOVA, effect of virus $F_{1,35} = 18.567$, $p = 0.0001$; effect of sleep deprivation $F_{1,35} =$
557 2.975 , $p = 0.093$; interaction effect $F_{1,35} = 4.567$, $p = 0.040$; eGFP SD group versus other groups, $p <$
558 0.05). The dotted line indicates chance performance (33.3%). (B, C) Following 5 hours of sleep
559 deprivation, long-lasting LTP was induced in hippocampal slices by application of four 100 Hz trains,
560 1s each, spaced 5 minutes apart to the Schaffer collateral pathway. Five hours of sleep deprivation
561 impairs long-lasting LTP in slices from mice expressing eGFP (n = 6-7, two-way ANOVA, effect of

562 virus $F_{1,10} = 21.685$, $p < 0.001$). In contrast, virally delivered cofilin^{S3D} prevents sleep deprivation-
563 induced deficits ($n = 5$, two-way ANOVA, effect of virus $F_{1,8} = 0.016$, $p > 0.902$).

564 NSD: non-sleep deprived, SD: sleep deprived. Values represent the mean \pm SEM. * $p < 0.05$ by
565 posthoc Dunnett's test, ** $p < 0.01$ by Student's t test. See also Figure 4 Figure Supplement 1.

566

567 **Figure 5. Expression of catalytically inactive PDE4A5 in hippocampal neurons prevents**
568 **memory deficits and alterations in the cAMP-PKA-LIMK-cofilin signaling pathway associated**
569 **with sleep deprivation.**

570 (A) Mice were injected with pAAV₉-CaMKII α 0.4-eGFP or pAAV₉-CaMKII α 0.4-PDE4A5^{catnull}-VSV
571 into the hippocampus to drive neuronal expression of eGFP or catalytically inactive full-length
572 PDE4A5 (PDE4A5^{catnull}). (B) Robust PDE4A5^{catnull} expression was observed at the expected
573 molecular weight, 108 kDa, in hippocampal lysates. (C-E) PDE4A5^{catnull} expression was observed in
574 all 3 subregions of the hippocampus. (F-H) PDE4A5^{catnull} was not expressed in astrocytes reflected by
575 a lack of co-labeling between PDE4A5^{catnull} and GFAP expression. (I) Sleep deprivation causes a
576 reduction in LIMK serine 596 phosphorylation in the hippocampus that is prevented by PDE4A5^{catnull}
577 expression ($n = 7-8$; two-way ANOVA, effect of virus $F_{1,27} = 3.299$, $p = 0.08$; effect of sleep
578 deprivation $F_{1,27} = 6.124$, $p = 0.02$; interaction effect $F_{1,27} = 11.336$, $p = 0.002$; eGFP SD group versus
579 other groups $p < 0.05$). (J) Sleep deprivation causes a reduction in cofilin phosphorylation in the
580 hippocampus that is prevented by PDE4A5^{catnull} expression ($n = 9-10$; two-way ANOVA, effect of
581 virus $F_{1,35} = 4.122$, $p = 0.05$; effect of sleep deprivation $F_{1,35} = 2.885$, $p = 0.1$; interaction effect $F_{1,35} =$
582 9.416 , $p = 0.004$; eGFP SD group versus other groups $p < 0.05$). (K, L) Three hours of recovery sleep
583 after five hours of sleep deprivation restores hippocampal LIMK phosphorylation at serine 596 and
584 cofilin phosphorylation at serine 3 to those observed in non-sleep deprived controls ($p > 0.45$ for both
585 comparisons). (M) Mice expressing eGFP or PDE4A5^{catnull} were trained in the hippocampus-

586 dependent object-place recognition task and immediately sleep deprived for 5 hrs after training (SD)
587 or left undisturbed (NSD). Hippocampal PDE4A5^{catnull} expression prevents memory deficits caused by
588 sleep deprivation (n = 8-10; two-way ANOVA, effect of virus $F_{1,33} = 2.626$, $p = 0.115$; effect of sleep
589 deprivation $F_{1,33} = 2.311$, $p = 0.138$; interaction effect $F_{1,33} = 7.485$, $p = 0.01$; posthoc Dunnet test
590 eGFP SD group versus other groups $p < 0.05$). In all blots, each lane represents one individual animal.
591 NSD: non-sleep deprived, SD: sleep deprived, SD+RS: sleep deprived plus recovery sleep. Scale bar,
592 100 μm . Values represent the mean \pm SEM. * $p < 0.05$ by posthoc Dunnet's posthoc test. See also
593 Figure 5 Figure Supplement 1.

594

595 **Figure 6. The impact of sleep deprivation on hippocampal spine dynamics.** Sleep deprivation
596 increases PDE4A5 protein levels that cause a reduction in cAMP levels and attenuation of the PKA-
597 LIMK signaling pathway, which results in a reduction in the phosphorylation of cofilin. De-
598 phosphorylated cofilin can lead to spine loss. Suppressing PDE4A5 function through viral expression
599 of a catalytically inactive PDE4A5 prevents alterations in LIMK and cofilin signaling as well as the
600 cognitive impairments caused by sleep deprivation. Likewise, attenuating cofilin activity through viral
601 expression of a catalytically inactive form of cofilin prevents the loss of dendritic spines, impairments
602 in synaptic plasticity, and memory deficits associated with sleep loss. Proteins whose function is
603 reduced after sleep deprivation are shown in blue. Proteins whose function is promoted by sleep
604 deprivation are shown in red.

611 **Supplementary Figure legends**

612 **Figure 1-figure supplement 1. Sleep deprivation decreases spine density and dendrite length in**
613 **both basal and apical dendrites of CA1 neurons.**

614 (A) Sleep deprivation reduces the spine density of both basal and apical dendrites in CA1 neurons (5-
615 6 animals per group, 5 neurons per animal). (B) Sleep deprivation decreases basal and apical dendrite
616 length of CA1 neurons (5-6 animals per group, 5 neurons per animal). (C) Sleep deprivation reduces
617 the number of all spine types in basal dendrites in CA1 neurons (5-6 animals per group, 5 neurons per
618 animal). (D) Sleep deprivation reduces the number of all spine types with exception of filopodia
619 spines in apical dendrites of CA1 neurons (5-6 animals per group, 5 neurons per animal).

620 (E) Sleep deprivation reduces spine density of basal dendrites between 60 and 150 μm away from the
621 soma (5-6 animals per group, 5 neurons per animal). (F) Sleep deprivation reduces spine density of
622 apical dendrites between 60 and 150 μm away from the soma (5-6 animals per group, 5 neurons per
623 animal). (G) Sleep deprivation decreases spine density in the 3rd to 6th branch of basal dendrites of
624 hippocampal CA1 neurons (5-6 animals per group, 5 neurons per animal). (H) Sleep deprivation
625 decreases spine density in the 3rd to 9th branch of apical dendrites in hippocampal CA1 neurons (5-6
626 animals per group, 5 neurons per animal). NSD: non-sleep deprived, SD: sleep deprived. Values
627 represent the mean \pm SEM. * $p < 0.05$, ** $p < 0.01$, **** $p < 0.0001$ by Student's t test.

628

629 **Figure 1-figure supplement 2. Sleep deprivation does not reduce spine density and dendrite**
630 **length in both basal and apical dendrites of CA3 neurons.**

631 (A) Sleep deprivation does not alter the spine density of basal and apical dendrites in CA3 neurons (6
632 animals per group, 4 neurons per animal, Student's t test $p > 0.28$). (B) Sleep deprivation does not
633 alter basal and apical dendrite length of CA3 neurons (6 animals per group, 4 neurons per animal,
634 Student's t test, $p > 0.37$). (C) Sleep deprivation does not change the number of any spine type in

635 basal dendrites of CA3 neurons (6 animals per group, 4 neurons per animal, Student's t test, $p > 0.31$).
636 (D) Sleep deprivation does not affect the number of any spine type in apical dendrites of CA3 neurons
637 (6 animals per group, 4 neurons per animal, Student's t test, $p > 0.31$). (E) Sleep deprivation does not
638 alter the spine density of basal dendrites at any distance from the soma (6 animals per group, 4
639 neurons per animal, Student's t test, $p > 0.05$). (F) Sleep deprivation does not impact spine density of
640 apical dendrites at any distance from the soma (6 animals per group, 4 neurons per animal). (G) Sleep
641 deprivation does not affect the number of spines of basal dendrites at any branch number (6 animals
642 per group, 4 neurons per animal, Student's t test, $p > 0.05$). (H) Sleep deprivation does not affect the
643 number of spines of apical dendrites at any branch number with exception of the 1st apical branch (6
644 animals per group, 4 neurons per animal, Student's t test, $p > 0.05$; branch 1 Student's t test, $p < 0.05$).
645 NSD: non-sleep deprived, SD: sleep deprived. Values represent the mean \pm SEM. * $p < 0.05$, by
646 Student's t test.

647

648 **Figure 2-figure supplement 1. Three hours of recovery sleep after 5 hours of sleep deprivation is**
649 **sufficient to restore spine numbers and dendrite length in both basal and apical dendrites of**
650 **CA1 neurons.**

651 (A) Recovery sleep leads to increased spine density in apical dendrite of CA1 neurons (6 animals per
652 group, 4 neurons per animal, Student's t test $p < 0.05$). (B) Recovery sleep restores basal and apical
653 dendrite length of CA1 neurons (6 animals per group, 4 neurons per animal, Student's t test $p > 0.16$).
654 (C) Recovery sleep restores the number of all spine types in basal dendrites of CA1 neurons with the
655 exception of branched spines (6 animals per group, 4 neurons per animal, Student's t test $p > 0.15$;
656 branched spines Student's t test $p < 0.05$). (D) Recovery sleep restores the number of all spine types in
657 apical dendrites of CA1 neurons with the exception of branched spines which are increased by
658 recovery sleep (6 animals per group, 4 neurons per animal, Student's t test $p > 0.4$; filopodia spines

659 Student's t test $p < 0.05$). (E) Recovery sleep restores the spine density of basal dendrites at all
660 distances of the soma (6 animals per group, 4 neurons per animal, Student's t test $p > 0.05$). (F)
661 Recovery sleep restores the spine density of apical dendrites between at all distances from the soma (6
662 animals per group, 4 neurons per animal, Student's t test $p > 0.05$). (G) Recovery sleep restores the
663 spine density of basal dendrites of hippocampal CA1 neurons at all branch numbers (6 animals per
664 group, 4 neurons per animal, Student's t test $p > 0.05$). (H) Recovery sleep restores the spine density
665 of apical dendrites of hippocampal CA1 neurons at all branch numbers with exception of the 7th
666 branch (6 animals per group, 4 neurons per animal, Student's t test $p > 0.05$; branch 7 Student's t test
667 $p < 0.05$). NSD: non-sleep deprived, RS: recovery sleep. Values represent the mean \pm SEM. * $p <$
668 0.05, by Student's t test.

669

670 **Figure 3-figure supplement 1. Sleep deprivation does not alter cofilin phosphorylation in the**
671 **prefrontal cortex.** Five hours of sleep deprivation does not lead to a reduction in cofilin
672 phosphorylation at serine 3 in the prefrontal cortex. A representative blot is shown. Each band
673 represents an individual animal. (Student's t test $p > 0.5$).

674

675 **Figure 3-figure supplement 2. Cofilin^{S3D} expression prevents sleep deprivation-induced**
676 **reductions in spine numbers and dendrite length in both basal and apical dendrites of CA1**
677 **neurons.**

678 (A) In mice expressing cofilin^{S3D}, sleep deprivation does not decrease the spine density of basal and
679 apical dendrite of CA1 neurons (6 animals per group, 4 neurons per animal). (B) In mice expressing
680 cofilin^{S3D}, sleep deprivation does not cause a decrease in the length of basal and apical dendrite length
681 of CA1 neurons (6 animals per group, 4 neurons per animal). (C) In mice expressing cofilin^{S3D}, sleep
682 deprivation does not cause a reduction in the total number of spines for each subtype in basal

683 dendrites of CA1 neurons with exception of the branched spines (6 animals per group, 4 neurons per
684 animal, Student's t test $p > 0.5$, branched spines Student's t test $p < 0.05$). (D) In mice expressing
685 cofilin^{S3D}, sleep deprivation does not cause a decrease in the total number of spines for each subtype
686 in apical dendrites of CA1 neurons with exception of the branched spines (6 animals per group, 4
687 neurons per animal, Student's t test $p > 0.5$, branched spines Student's t test $p < 0.05$).
688 (E) In mice expressing cofilin^{S3D}, sleep deprivation does not reduce the spine density of basal
689 dendrites at any distance from the soma (6 animals per group, 4 neurons per animal, Student's t test p
690 > 0.05). (F) In mice expressing cofilin^{S3D}, sleep deprivation reduces spine density of apical dendrites
691 only at a 180 μm distance from the soma (6 animals per group, 4 neurons per animal, Student's t test p
692 > 0.05). (G) In mice expressing cofilin^{S3D}, sleep deprivation does not decrease the spine density in any
693 dendritic branch of the basal dendrites of CA1 neurons (6 animals per group, 4 neurons per animal,
694 Student's t test $p > 0.05$). (H) In mice expressing cofilin^{S3D}, sleep deprivation does not reduce the
695 spine density in any dendritic branch of apical dendrites of hippocampal CA1 neurons (6 animals per
696 group, 4 neurons per animal, Student's t test $p > 0.05$). NSD: non-sleep deprived, SD: sleep deprived.
697 Values represent the mean \pm SEM. * $p < 0.05$ by Student's t test.

698

699 **Figure 4-figure supplement 1. Cofilin^{S3D} expression in hippocampal neurons does not affect**
700 **exploratory activity, anxiety levels, or basal synaptic transmission**

701 (A) Expression of the catalytically inactive cofilin^{S3D} in hippocampal neurons does not affect the total
702 time spent exploring objects during training in the object place recognition task (ANOVA $F_{1,35} =$
703 1.026 , $p = 0.318$). All groups show a decrease in the total object exploration time during the training
704 sessions ($n = 9-10$, two-way ANOVA, effect of session $F_{2,70} = 54.060$, $p = 0.0001$; interaction effect
705 $F_{2,70} = 0.880$, $p = 0.419$). (B) Mice expressing cofilin^{S3D} in hippocampal neurons spent a similar
706 amount of time in the enclosed arm of the zero maze as eGFP expressing mice indicating normal

707 anxiety-related behavior ($n = 7$, Student's t test, $p = 0.632$). (C) Mice expressing $\text{cofilin}^{\text{S3D}}$ in
708 hippocampal neurons had a similar number of transitions in the zero maze as eGFP expressing mice
709 indicating normal locomotor activity ($n = 7$, Student's t test, $p = 0.849$). (D) $\text{Cofilin}^{\text{S3D}}$ expression did
710 not alter the formation of short-term object location memories measured one hour after training ($n =$
711 $7-8$, Student's t test, $p = 0.42$). (E, F) Input-output curves relating the amplitude of the presynaptic
712 fiber volley to the initial slope of the corresponding fEPSP at various stimulus intensities are similar
713 in slices from eGFP and $\text{cofilin}^{\text{S3D}}$ in slices from sleep deprived and non-sleep deprived mice ($n = 5$,
714 eGFP NSD vs SD group, Student's t test $p = 0.75$; $\text{cofilin}^{\text{S3D}}$, NSD vs SD group, Student's t test $p =$
715 0.17). (G, H) Paired-pulse facilitation, a short-term form of synaptic plasticity, was not changed in
716 slices from eGFP and $\text{cofilin}^{\text{S3D}}$ in slices from sleep deprived and non-sleep deprived mice ($n = 5$,
717 eGFP NSD vs SD group two-way repeated-measures ANOVA, $F_{1,8} = 0.393$, $p = 0.545$) ($\text{cofilin}^{\text{S3D}}$
718 NSD vs SD group two-way repeated-measures ANOVA, $F_{1,8} = 3.056$, $p = 0.114$). NSD: non-sleep
719 deprived, SD: sleep deprived. Values represent the mean \pm SEM.

720

721

722 **Figure 4-figure supplement 2. Cofilin^{S3A} expression in hippocampal neurons attenuates the**
723 **formation of long-term object-location memories but not long-term potentiation induced by**

724 **spaced-four train LTP.** (A) Mice expressing eGFP or the catalytically active $\text{cofilin}^{\text{S3A}}$ in

725 hippocampal neurons were trained in the hippocampus-dependent object-place recognition task.

726 Expression of the $\text{cofilin}^{\text{S3A}}$ does not affect the total time spent exploring objects during training in the

727 object place recognition task (ANOVA $F_{1,18} = 1.919$, $p = 0.183$). Both groups show a decrease in the

728 total object exploration time during the training sessions ($n = 10$, two-way ANOVA, effect of session

729 $F_{2,36} = 11.696$, $p = 0.0001$; interaction effect $F_{2,36} = 1.85$, $p = 0.172$). (B) During the test session 24

730 hours after training, eGFP mice preferentially explored the displaced object indicating that they

731 successfully remembered the previous location of the individual objects. In contrast, mice expressing
732 cofilin^{S3A} explored all objects to a similar extent, indicative of a poor memory for the original object
733 locations (eGFP, $46.9 \pm 4.2\%$; cofilin^{S3A}, $34.9 \pm 2.1\%$; Student's t test, $p = 0.025$). (C) Input-output
734 curves relating the amplitude of the presynaptic fiber volley to the initial slope of the corresponding
735 fEPSP at various stimulus intensities are similar in slices from eGFP and cofilin^{S3A} in slices from non-
736 sleep deprived mice (eGFP $n = 6$, cofilin^{S3A} $n=8$, Student's t test $p = 0.857$). (D) Paired-pulse
737 facilitation, a short-term form of synaptic plasticity, was not changed in slices from eGFP and
738 cofilin^{S3A} in slices from non-sleep deprived mice ($n = 5-6$, eGFP vs cofilin^{S3A} group two-way
739 repeated-measures ANOVA, $F_{1,12} = 0.218$, $p = 0.649$). (E) Long-lasting LTP was induced in
740 hippocampal slices by application of four 100 Hz trains, 1 s each, spaced 5 minutes apart to the
741 Schaffer collateral pathway. Virally delivered Cofilin^{S3A} expression did not alter LTP expression ($n =$
742 5 , two-way ANOVA, effect of virus $F_{1,8} = 1.102$, $p = 0.0325$). Dotted line indicates chance level
743 performance. Values represent the mean \pm SEM. * $p < 0.05$ by Student's t test.

744

745 **Figure 5-figure supplement 1. Expression of catalytically null PDE4A5 in the hippocampus:**
746 **Catalytically inactive PDE4A5 without the unique N-terminal localization domain fails to**
747 **prevent memory deficits associated with sleep loss.**

748 (A) PDE4A5^{catnull} expression in hippocampal neurons did not significantly affect PDE4 activity in the
749 hippocampus ($n = 7$, Student's t test $p = 0.097$). (B) PDE4 activity in the prefrontal cortex was not
750 altered by expression of the catalytically inactive PDE4A5^{catnull} in the hippocampus ($n = 7-8$,
751 Student's t test $p = 0.162$). (C) PDE4 activity in the cerebellum was not changed by expression of the
752 catalytically inactive PDE4A5^{catnull} in the hippocampus ($n = 7-8$, Student's t test $p = 0.293$).
753 (D) Expression of the catalytically inactive PDE4A5^{catnull} in hippocampal neurons did not alter the
754 total time spent exploring objects during training in the object-place recognition task ($n = 8-10$, two-

755 way ANOVA, effect of virus $F_{1,33} = 0.043$, $p = 0.873$). All groups show a decrease in the total object
756 exploration time during consecutive training sessions (two-way ANOVA effect of session $F_{2,66} =$
757 32.777 , $p = 0.0001$). Mice expressing PDE4A5^{catnull} had a slightly but non-significantly lower object
758 exploration time during the first training session, and a slightly but non-significantly higher object
759 exploration time during the last training session (interaction effect $F_{2,66} = 4.875$, $p = 0.011$, one way
760 ANOVAs per session, $p > 0.05$). (E) Mice expressing PDE4A5^{catnull} spend a similar time in the
761 periphery of the open field as mice expressing eGFP in hippocampal neurons ($n = 8$, Student's t test, p
762 $= 0.292$). (F) Mice were injected with pAAV₉-CaMKII α 0.4-eGFP or pAAV₉-CaMKII α 0.4-
763 PDE4A5^{catnull Δ 4}-VSV into the hippocampus to drive neuronal expression of eGFP or catalytically
764 inactive full-length PDE4A5 which lacked the N-terminal domain unique for PDE4A5 (PDE4A5^{catnull}
765 Δ 4). A VSV-tag was included to discriminate between endogenous PDE4A5 and the truncated
766 PDE4A5^{catnull Δ 4}. (G) PDE4A5^{catnull Δ 4} protein levels in the hippocampus 4 weeks after viral injection.
767 A sample blot probed with an isoform-nonspecific PDE4A antibody revealed the presence of both
768 wild-type PDE4A5 protein and truncated PDE4A5^{catnull Δ 4} protein. Probing the blot with an antibody
769 for the HA-tag confirmed that the truncated protein is indeed the N-terminal lacking catalytically
770 inactive PDE4A5^{catnull Δ 4}. Each band represents an individual animal (H) Expression of the
771 catalytically inactive PDE4A5^{catnull Δ 4} lacking the N-terminal domain in hippocampal neurons did not
772 affect total object exploration time during training in the object-place recognition task ($n = 7-9$, two-
773 way ANOVA effect of virus $F_{1,29} = 0.470$, $p = 0.498$). All groups show decreased total object
774 exploration times during consecutive training sessions (two-way ANOVA effect of session $F_{2,58} =$
775 13.597 , $p = 0.0001$; interaction effect $F_{2,58} = 0.555$, $p = 0.557$). (I) Mice expressing eGFP or the N-
776 terminal domain lacking inactive form of PDE4A5^{catnull Δ 4} were trained in the hippocampus-dependent
777 object-place recognition task. Sleep deprivation causes memory deficits in both eGFP and
778 PDE4A5^{catnull Δ 4} mice ($n = 7-9$; two-way ANOVA effect of sleep deprivation $F_{1,29} = 18.131$, $p =$

779 0.0001; effect of virus $F_{1,29} = 1.064$, $p = 0.311$; interaction effect $F_{1,29} = 0.001$, $p = 0.986$; eGFP NSD
780 versus EGFP SD, posthoc Tukey' t test $p = 0.0054$; PDE4A5^{catnullΔ4} NSD versus PDE4A5^{catnullΔ4} SD,
781 posthoc Tukey' t test $p = 0.0037$). Dotted line indicates chance level performance. NSD: non-sleep
782 deprived, SD: sleep deprived. Values represent the mean \pm SEM. # $p < 0.01$ by Tukeys t test.
