#### **Abstract**

The notion of statistical convergence was defined by Fast (Colloq. Math. 2:241-244, 1951) and over the years was further studied by many authors in different setups. In this paper, we define and study statistical  $\tau$ -convergence, statistically  $\tau$ -Cauchy and  $S^*(\tau)$ -convergence through de la Vallée-Poussin mean in a locally solid Riesz space. **MSC:** 40A35; 40G15; 46A40

**Keywords:** statistical convergence; statistical Cauchy; de la Vallée-Poussin mean; locally solid Riesz space

# 1 Introduction and preliminaries

Since 1951, when Steinhaus [1] and Fast [2] defined statistical convergence for sequences of real numbers, several generalizations and applications of this notion have been investigated. For more detail and related concepts, we refer to [3–29] and references therein. Quite recently, Di Maio and Kŏcinac [30] studied this notion in topological and uniform spaces and Albayrak and Pehlivan [31], and Mohiuddine and Alghamdi [32] for real and lacunary sequences, respectively, in locally solid Riesz spaces. Afterward, the idea was extended to double sequences by Mohiuddine *et al.* [33] in the framework of locally solid Riesz spaces.

Let K be a subset of  $\mathbb{N}$ , the set of natural numbers. Then the *asymptotic density* of K denoted by  $\delta(K)$  is defined as

$$\delta(K) = \lim_{n \to \infty} \frac{1}{n} |\{k \le n : k \in K\}|,$$

where the vertical bars denote the cardinality of the enclosed set.

The number sequence  $x = (x_j)$  is said to be *statistically convergent* to the number  $\ell$  if for each  $\epsilon > 0$ ,

$$\lim_{n\to\infty} \frac{1}{n} \left| \left\{ j \le n : |x_j - \ell| \ge \epsilon \right\} \right| = 0.$$

In this case, we write st- $\lim x_i = \ell$ .

**Remark 1.1** It is well known that every statistically convergent sequence is convergent, but the converse is not true. For example, suppose that the sequence  $x = (x_n)$  is defined as

$$x = (x_n) = \begin{cases} \sqrt{n} & \text{if } n \text{ is a square,} \\ 0 & \text{otherwise.} \end{cases}$$

It is clear that the sequence  $x = (x_n)$  is statistically convergent to 0, but it is not convergent.

Now we recall some definitions related to the notion of a locally solid Riesz space. Let X be a real vector space and  $\leq$  be a partial order on this space. Then X is said to be an *ordered vector space* if it satisfies the following properties:

- (i) If  $x, y \in X$  and y < x, then y + z < x + z for each  $z \in X$ .
- (ii) If  $x, y \in X$  and  $y \le x$ , then  $\lambda y \le \lambda x$  for each  $\lambda \ge 0$ .

If in addition X is a lattice with respect to the partial order  $\leq$ , then X is said to be a *Riesz space* (or a *vector lattice*) [34].

For an element x of a Riesz space X, the positive part of x is defined by  $x^+ = x \vee \theta = \sup\{x, \theta\}$ , the negative part of x by  $x^- = (-x) \vee \theta$  and the absolute value of x by  $|x| = x \vee (-x)$ , where  $\theta$  is the zero element of X.

A subset *S* of a Riesz space *X* is said to be *solid* if  $y \in S$  and  $|x| \le |y|$  imply  $x \in S$ .

A topological vector space  $(X,\tau)$  is a vector space X which has a (linear) topology  $\tau$  such that the algebraic operations of addition and scalar multiplication in X are continuous. The continuity of addition means that the function  $f: X \times X \to X$  defined by f(x,y) = x+y is continuous on  $X \times X$ , and the continuity of scalar multiplication means that the function  $f: \mathbb{R} \times X \to X$  defined by  $f(\lambda, x) = \lambda x$  is continuous on  $\mathbb{R} \times X$ .

Every linear topology  $\tau$  on a vector space X has a base  $\mathcal N$  for the neighborhoods of  $\theta$  satisfying the following properties:

- (C<sub>1</sub>) Each  $Y \in \mathcal{N}$  is a *balanced set*, that is,  $\lambda x \in Y$  holds for all  $x \in Y$  and every  $\lambda \in \mathbb{R}$  with  $|\lambda| < 1$ .
- (C<sub>2</sub>) Each  $Y \in \mathcal{N}$  is an *absorbing set*, that is, for every  $x \in X$ , there exists  $\lambda > 0$  such that  $\lambda x \in Y$ .
- $(C_3)$  For each  $Y \in \mathcal{N}$ , there exists some  $E \in \mathcal{N}$  with  $E + E \subseteq Y$ .

A linear topology  $\tau$  on a Riesz space X is said to be *locally solid* (cf. [35, 36]) if  $\tau$  has a base at zero consisting of solid sets. A *locally solid Riesz space*  $(X, \tau)$  is a Riesz space equipped with a locally solid topology  $\tau$ .

In this paper, we define and study statistical  $\tau$ -convergence, statistically  $\tau$ -Cauchy and  $S^*(\tau)$ -convergence through de la Vallée-Poussin mean in a locally solid Riesz space.

# 2 Generalized statistical $\tau$ -convergence

Throughout the text, we write  $\mathcal{N}_{sol}$  for any base at zero consisting of solid sets and satisfying the conditions  $(C_1)$ ,  $(C_2)$  and  $(C_3)$  in a locally solid topology. The following idea of  $\lambda$ -statistical convergence was introduced in [37] and further studied in [38–40].

Let  $\lambda = (\lambda_n)$  be a non-decreasing sequence of positive numbers tending to  $\infty$  such that

$$\lambda_{n+1} \leq \lambda_n + 1, \qquad \lambda_1 = 0.$$

The generalized de la Vallée-Poussin mean is defined by

$$t_n(x) =: \frac{1}{\lambda_n} \sum_{j \in I_n} x_j,$$

where  $I_n = [n - \lambda_n + 1, n]$ .

A sequence  $x = (x_i)$  is said to be  $(V, \lambda)$ -summable to a number  $\ell$  if

$$t_n(x) \to \ell$$
 as  $n \to \infty$ .

A sequence  $x = (x_i)$  is said to be *strongly*  $(V, \lambda)$ -summable to a number  $\ell$  if

$$\frac{1}{\lambda_n} \sum_{j \in I_n} |x_j - \ell| \to 0 \quad \text{as } n \to \infty.$$

We denote it by  $x_i \to \ell[V, \lambda]$  as  $j \to \infty$ .

Let  $K \subseteq \mathbb{N}$  be a set of positive integers, then

$$\delta_{\lambda}(K) = \lim_{n \to \infty} \frac{1}{\lambda_n} \left| \{ n - \lambda_n + 1 \le j \le n : j \in K \} \right|$$

is said to be the  $\lambda$ -density of K.

In case  $\lambda_n = n$ , the  $\lambda$ -density reduces to the natural density.

The number sequence  $x = (x_j)$  is said to be  $\lambda$ -statistically convergent to the number  $\ell$  if for each  $\epsilon > 0$ ,  $\delta_{\lambda}(K_{\epsilon}) = 0$ , where  $K_{\epsilon} = \{j \in \mathbb{N} : |x_j - \ell| > \epsilon\}$ , *i.e.*,

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\left|\left\{j\in I_n:|x_j-\ell|>\epsilon\right\}\right|=0.$$

In this case, we write  $st_{\lambda}$ - $\lim_{j} x_{j} = \ell$  and we denote the set of all  $\lambda$ -statistically convergent sequences by  $S_{\lambda}$ . This notion was extended to double sequences in [41, 42].

**Remark 2.1** As in Remark 1.1, we observe that if a sequence is  $(V, \lambda)$ -summable to a number  $\ell$ , then it is also  $\lambda$ -statistically convergent to the same number  $\ell$ , but the converse need not be true. For example, let the sequence  $z = (z_k)$  be defined by

$$z_k = \begin{cases} k & \text{if } n - [\sqrt{\lambda_n}] + 1 \le k \le n, \\ 0 & \text{otherwise,} \end{cases}$$

where [a] denotes the integer part of  $a \in \mathbb{R}$ . Then x is  $\lambda$ -statistically convergent to 0 but not  $(V, \lambda)$ -summable.

**Definition 2.1** Let  $(X, \tau)$  be a locally solid Riesz space. Then a sequence  $x = (x_j)$  in X is said to be *generalized statistically*  $\tau$ -convergent (or  $S_{\lambda}(\tau)$ -convergent) to the number  $\xi \in X$  if for every  $\tau$ -neighborhood U of zero,

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\big|\{j\in I_n:x_j-\xi\notin U\}\big|=0.$$

In this case, we write  $S_{\lambda}(\tau)$ -lim  $x = \xi$  or  $x_j \xrightarrow{S_{\lambda}(\tau)} \xi$ .

**Definition 2.2** Let  $(X, \tau)$  be a locally solid Riesz space. We say that a sequence  $x = (x_j)$  in X is *generalized statistically*  $\tau$ -bounded if for every  $\tau$ -neighborhood U of zero, there exists some  $\lambda > 0$  such that the set

$$\{j \in \mathbb{N} : \lambda x_i \notin U\}$$

has  $\lambda$ -density zero.

**Theorem 2.1** Let  $(X, \tau)$  be a Hausdorff locally solid Riesz space and  $x = (x_j)$  and  $y = (y_k)$  be two sequences in X. Then the following hold:

- (i) If  $S_{\lambda}(\tau)$ - $\lim_{j} x_{j} = \xi_{1}$  and  $S_{\lambda}(\tau)$ - $\lim_{j} x_{j} = \xi_{2}$ , then  $\xi_{1} = \xi_{2}$ .
- (ii) If  $S_{\lambda}(\tau)$ - $\lim_{i} x_{i} = \xi$ , then  $S_{\lambda}(\tau)$ - $\lim_{i} \alpha x_{i} = \alpha \xi$ ,  $\alpha \in \mathbb{R}$ .
- (iii) If  $S_{\lambda}(\tau)$ - $\lim_{j} x_{j} = \xi$  and  $S_{\lambda}(\tau)$ - $\lim_{j} y_{j} = \eta$ , then  $S_{\lambda}(\tau)$ - $\lim_{j} (x_{j} + y_{j}) = \xi + \eta$ .

*Proof* (i) Suppose that  $S_{\lambda}(\tau)$ - $\lim_{j} x_{j} = \xi_{1}$  and  $S_{\lambda}(\tau)$ - $\lim_{j} x_{j} = \xi_{2}$ . Let U be any  $\tau$ -neighborhood of zero. Then there exists  $Y \in \mathcal{N}_{sol}$  such that  $Y \subseteq U$ . Choose any  $E \in \mathcal{N}_{sol}$  such that  $E + E \subseteq Y$ . We define the following sets:

$$K_1 = \{j \in \mathbb{N} : x_j - \xi_1 \in E\},\,$$

$$K_2 = \{ j \in \mathbb{N} : x_i - \xi_2 \in E \}.$$

Since  $S_{\lambda}(\tau)$ -lim $_{j}x_{j}=\xi_{1}$  and  $S_{\lambda}(\tau)$ -lim $_{j}x_{j}=\xi_{2}$ , we have  $\delta_{\lambda}(K_{1})=\delta_{\lambda}(K_{2})=1$ . Thus  $\delta(K_{1}\cap K_{2})=1$  and, in particular,  $K_{1}\cap K_{2}\neq\emptyset$ . Now, let  $j\in K_{1}\cap K_{2}$ . Then

$$\xi_1 - \xi_2 = \xi_1 - x_i + x_i - \xi_2 \in E + E \subseteq Y \subseteq U.$$

Hence, for every  $\tau$ -neighborhood U of zero, we have  $\xi_1 - \xi_2 \in U$ . Since  $(X, \tau)$  is Hausdorff, the intersection of all  $\tau$ -neighborhoods U of zero is the singleton set  $\{\theta\}$ . Thus, we get  $\xi_1 - \xi_2 = \theta$ , *i.e.*,  $\xi_1 = \xi_2$ .

(ii) Let U be an arbitrary  $\tau$ -neighborhood of zero and  $S_{\lambda}(\tau)$ -lim<sub>j</sub>  $x_j = \xi$ . Then there exists  $Y \in \mathcal{N}_{sol}$  such that  $Y \subseteq U$  and also

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\big|\{j\in I_n:x_j-\xi\in Y\}\big|=1.$$

Since *Y* is balanced,  $x_j - \xi \in Y$  implies  $\alpha(x_j - \xi) \in Y$  for every  $\alpha \in \mathbb{R}$  with  $|\alpha| \le 1$ . Hence, for every  $n \in \mathbb{N}$ , we get

$$\{j \in I_n : x_j - \xi \in Y\} \subseteq \{j \in I_n : \alpha x_j - \alpha \xi \in Y\}$$
$$\subseteq \{j \in I_n : \alpha x_j - \alpha \xi \in U\}.$$

Thus, we obtain

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\left|\{j\in I_n:\alpha x_j-\alpha\xi\in U\}\right|=1$$

for each  $\tau$ -neighborhood U of zero. Now let  $|\alpha| > 1$  and  $[|\alpha|]$  be the smallest integer greater than or equal to  $|\alpha|$ . There exists  $E \in \mathcal{N}_{sol}$  such that  $[|\alpha|]E \subseteq Y$ . Since  $S_{\lambda}(\tau)$ -lim<sub>j</sub>  $x_j = \xi$ , the

set

$$K = \{ j \in \mathbb{N} : x_i - \xi \in E \}$$

has  $\lambda$ -density zero. Therefore, for all  $n \in \mathbb{N}$  and  $j \in K \cap I_n$ , we have

$$|\alpha \xi - \alpha x_i| = |\alpha| |\xi - x_i| \le \lceil |\alpha| \rceil |\xi - x_i| \in \lceil |\alpha| \rceil E \subseteq Y \subseteq U.$$

Since the set *Y* is solid, we have  $\alpha \xi - \alpha x_i \in Y$ . This implies that  $\alpha \xi - \alpha x_i \in U$ . Thus,

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\big|\{j\in I_n:\alpha x_j-\alpha\xi\in U\}\big|=1$$

for each  $\tau$ -neighborhood U of zero. Hence  $S_{\lambda}(\tau)$ - $\lim_{i} \alpha x_{i} = \alpha \xi$ .

(iii) Let U be an arbitrary  $\tau$ -neighborhood of zero. Then there exists  $Y \in \mathcal{N}_{sol}$  such that  $Y \subseteq U$ . Choose E in  $\mathcal{N}_{sol}$  such that  $E + E \subseteq Y$ . Since  $S_{\lambda}(\tau)$ - $\lim_{j} x_{j} = \xi$  and  $S_{\lambda}(\tau)$ - $\lim_{j} y_{j} = \eta$ , we have  $\delta_{\lambda}(H_{1}) = 1 = \delta_{\lambda}(H_{2})$ , where

$$H_1 = \{j \in \mathbb{N} : x_i - \xi \in E\},$$

$$H_2 = \{j \in \mathbb{N} : \gamma_i - \eta \in E\}.$$

Let  $H = H_1 \cap H_2$ . Hence, we have  $\delta_{\lambda}(H) = 1$ . For all  $n \in \mathbb{N}$  and  $j \in H \cap I_n$ , we get

$$(x_i + y_i) - (\xi + \eta) = (x_i - \xi) + (y_i - \eta) \in E + E \subset Y \subset U.$$

Therefore,

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\Big|\Big\{j\in I_n:(x_j+y_j)-(\xi+\eta)\in U\Big\}\Big|=1.$$

Since *U* is arbitrary, we have  $S_{\lambda}(\tau)$ - $\lim_{j}(x_{j}+y_{j})=\xi+\eta$ .

**Theorem 2.2** Let  $(X, \tau)$  be a locally solid Riesz space. If a sequence  $x = (x_j)$  is generalized statistically  $\tau$ -convergent, then it is generalized statistically  $\tau$ -bounded.

*Proof* Suppose  $x=(x_j)$  is generalized statistically  $\tau$ -convergent to the point  $\xi \in X$  and let U be an arbitrary  $\tau$ -neighborhood of zero. Then there exists  $Y \in \mathcal{N}_{sol}$  such that  $Y \subseteq U$ . Let us choose  $E \in \mathcal{N}_{sol}$  such that  $E + E \subseteq Y$ . Since  $S_{\lambda}(\tau)$ - $\lim_{j \to \infty} x_j = \xi$ , the set

$$K = \{ j \in \mathbb{N} : x_i - \xi \notin E \}$$

has  $\lambda$ -density zero. Since E is absorbing, there exists  $\lambda > 0$  such that  $\lambda \xi \in E$ . Let  $\alpha \in (0, \min\{1, \lambda\})$ . Since E is solid and  $|\alpha \xi| \le |\lambda x|$ , we have  $\alpha \xi \in E$ . Since E is balanced,  $x_j - \xi \in E$  implies  $\alpha(x_j - \xi) \in E$ . Then, for each  $n \in \mathbb{N}$  and  $j \in (\mathbb{N} \setminus K) \cap I_n$ , we have

$$\alpha x_i = \alpha(x_i - \xi) + \alpha \xi \in E + E \subseteq Y \subseteq U.$$

Thus

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\big|\{j\in I_n:\alpha x_j\notin U\}\big|=0.$$

Hence,  $(x_i)$  is generalized statistically  $\tau$ -bounded.

**Theorem 2.3** Let  $(X, \tau)$  be a locally solid Riesz space. If  $(x_j)$ ,  $(y_j)$  and  $(z_j)$  are three sequences such that

- (i)  $x_i \le y_i \le z_i$  for all  $j \in \mathbb{N}$ ,
- (ii)  $S_{\lambda}(\tau)$ - $\lim_{i} x_{i} = \xi = S_{\lambda}(\tau)$ - $\lim_{i} z_{i}$ ,

then  $S_{\lambda}(\tau)$ - $\lim_{j} y_{j} = \xi$ .

*Proof* Let U be an arbitrary  $\tau$ -neighborhood of zero, there exists  $Y \in \mathcal{N}_{sol}$  such that  $Y \subseteq U$ . Choose  $E \in \mathcal{N}_{sol}$  such that  $E + E \subseteq Y$ . From condition (ii), we have  $\delta_{\lambda}(A) = 1 = \delta_{\lambda}(B)$ , where

$$A = \{j \in \mathbb{N} : x_j - \xi \in E\},\$$

$$B = \{ j \in \mathbb{N} : x_i - \xi \in E \}.$$

Also, we get  $\delta_{\lambda}(A \cap B) = 1$ , and from (i) we have

$$x_j - \xi \le y_j - \xi \le z_j - \xi$$

for all  $j \in \mathbb{N}$ . This implies that for all  $n \in \mathbb{N}$  and  $j \in A \cap B \cap I_n$ , we get

$$|y_i - \xi| \le |x_i - \xi| + |z_i - \xi| \in E + E \subseteq Y$$
.

Since *Y* is solid, we have  $y_i - \xi \in Y \subseteq U$ . Thus,

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\left|\{j\in I_n:y_j-\xi\in U\}\right|=1$$

for each  $\tau$ -neighborhood U of zero. Hence  $S_{\lambda}(\tau)$ - $\lim_{j} y_{j} = \xi$ .

# 3 Generalized statistically $\tau$ -Cauchy and $S_1^*(\tau)$ -convergence

**Definition 3.1** Let  $(X, \tau)$  be a locally solid Riesz space. A sequence  $x = (x_j)$  in X is *generalized statistically*  $\tau$ -Cauchy if for every  $\tau$ -neighborhood U of zero there exists  $p \in \mathbb{N}$  such that the set

$$\{j \in \mathbb{N} : x_j - x_p \notin U\}$$

has  $\lambda$ -density zero.

**Theorem 3.1** Let  $(X, \tau)$  be a locally solid Riesz space. If a sequence  $x = (x_j)$  is generalized statistically  $\tau$ -convergent, then it is generalized statistically  $\tau$ -Cauchy.

*Proof* Suppose that  $S_{\lambda}(\tau)$ -lim<sub>j</sub>  $x_j = \xi$ . Let U be an arbitrary  $\tau$ -neighborhood of zero, there exists  $Y \in \mathcal{N}_{sol}$  such that  $Y \subseteq U$ . Choose  $E \in \mathcal{N}_{sol}$  such that  $E + E \subseteq Y$ . By generalized statistical  $\tau$ -convergence to  $\xi$ , there is  $p \in \mathbb{N}$  with  $\xi - x_p \in E$  and

$$\lim_{n\to\infty}\frac{1}{\lambda_n}\left|\{j\in I_n:x_j-\xi\notin E\}\right|=0.$$

Also, for all  $n \in \mathbb{N}$  and  $j \in (\mathbb{N} \setminus K) \cap I_n$ , where

$$K = \{j \in \mathbb{N} : x_i - \xi \notin E\},\$$

we have

$$x_i - x_p = x_i - \xi + \xi - x_p \in E + E \subseteq Y \subseteq U$$

and  $\delta_{\lambda}(K) = 0$ . Therefore the set

$$\{j \in \mathbb{N} : x_j - x_p \notin U\} \subseteq K \cap I_n$$

for all  $n \in \mathbb{N}$ . For every  $\tau$ -neighborhood U of zero there exists  $p \in \mathbb{N}$  such that the set  $\{j \in \mathbb{N} : x_j - x_p \notin U\}$  has  $\lambda$ -density zero. Hence  $(x_j)$  is generalized statistically  $\tau$ -Cauchy.

Now we define another type of convergence in locally solid Riesz spaces.

**Definition 3.2** A sequence  $(x_j)$  in a locally solid Riesz space  $(X, \tau)$  is said to be  $S^*_{\lambda}(\tau)$ convergent to  $\xi \in X$  if there exists an index set  $K = \{j_n\} \subseteq \mathbb{N}$ ,  $n = 1, 2, \ldots$ , with  $\delta_{\lambda}(K) = 1$  such that  $\lim_{n \to \infty} x_{j_n} = \xi$ . In this case, we write  $\xi = S^*_{\lambda}(\tau)$ - $\lim x$ .

**Theorem 3.2** A sequence  $x = (x_j)$  in a locally solid Riesz space  $(X, \tau)$  is generalized statistically  $\tau$ -convergent to a number  $\xi$  if it is  $S^*_{\lambda}(\tau)$ -convergent to  $\xi$ .

*Proof* Let U be an arbitrary  $\tau$ -neighborhood of  $\xi$ . Since  $x=(x_j)$  is  $S^*_{\lambda}(\tau)$ -convergent to  $\xi$ , there is an index set  $K=\{j_n\}\subseteq\mathbb{N},\, n=1,2,\ldots$ , with  $\delta_{\lambda}(K)=1$  and  $j_0=j_0(U)$ , such that  $j\geq j_0$  and  $j\in K$  imply  $x_j-\xi\in U$ . Then

$$K_U = \{j \in \mathbb{N} : x_j - \xi \notin U\} \subseteq \mathbb{N} - \{j_{N+1}, j_{N+2}, \ldots\}.$$

Therefore  $\delta_{\lambda}(K_U) = 0$ . Hence x is generalized statistically  $\tau$ -convergent to  $\xi$ .

Note that the converse holds for a first countable space.

Recall that a topological space is first countable if each point has a countable (decreasing) local base.

**Theorem 3.3** Let  $(X, \tau)$  be a first countable locally solid Riesz space. If a sequence  $x = (x_j)$  is generalized statistically  $\tau$ -convergent to a number  $\xi$ , then it is  $S^*_{\lambda}(\tau)$ -convergent to  $\xi$ .

*Proof* Let x be generalized statistically  $\tau$ -convergent to a number  $\xi$ . Fix a countable local base  $U_1 \supset U_2 \supset U_3 \supset \cdots$  at  $\xi$ . For each  $i \in \mathbb{N}$ , put

$$K_i = \{j \in \mathbb{N} : x_i - \xi \notin U_i\}.$$

By hypothesis,  $\delta_{\lambda}(K_i) = 0$  for each i. Since the ideal  $\mathcal{I}$  of all subsets of  $\mathbb{N}$  having  $\lambda$ -density zero is a P-ideal (see, for instance, [43]), then there exists a sequence of sets  $(J_i)_i$  such that the symmetric difference  $K_i \Delta J_i$  is a finite set for any  $i \in \mathbb{N}$  and  $J := \bigcup_{i=1}^{\infty} J_i \in \mathcal{I}$ .

Let  $K = \mathbb{N} \setminus J$ , then  $\delta_{\lambda}(K) = 1$ . In order to prove the theorem, it is enough to check that  $\lim_{i \in K} x_i = \xi$ .

Let  $i \in \mathbb{N}$ . Since  $K_i \Delta J_i$  is finite, there is  $j_i \in \mathbb{N}$ , without loss of generality, with  $j_i \in K$ ,  $j_i > i$ , such that

$$(\mathbb{N} \setminus J_i) \cap \{j \in \mathbb{N} : j \ge j_i\} = (\mathbb{N} \setminus K_i) \cap \{j \in \mathbb{N} : j \ge j_i\}. \tag{1}$$

If  $j \in K$  and  $j \ge j_i$ , then  $j \notin J_i$ , and by (1),  $j \notin K_i$ . Thus  $x_j - \xi \in U_i$ . So, we have proved that for all  $i \in \mathbb{N}$ , there is  $j_i \in K$ ,  $j_i > i$ , with  $x_j - \xi \in U_i$  for every  $j \ge j_i$ : without loss of generality, we can suppose  $j_{i+1} > j_i$  for every  $i \in \mathbb{N}$ . The assertion follows taking into account that the  $U_i$ 's form a countable local base at  $\xi$ .

## 4 Conclusion

Recently, statistical convergence has been established as a better option than ordinary convergence. It is found very interesting that some results on sequences, series and summability can be proved by replacing the ordinary convergence by statistical convergence; and further, through some examples, where some efforts are required, we can show that the results for statistical convergence happen to be stronger than those proved for ordinary convergence (e.g., [44–49]). This notion has also been defined and studied in different setups. In this paper, we have studied this notion through de la Vallée-Poussin mean in a locally solid Riesz space to deal with the convergence problems in a broader sense.

# Submit your manuscript to a SpringerOpen journal and benefit from:

- ► Convenient online submission
- ► Rigorous peer review
- ► Immediate publication on acceptance
- ► Open access: articles freely available online
- ► High visibility within the field
- ► Retaining the copyright to your article
