Abstract—The strategic communication problem consists of a joint source-channel coding problem in which the encoder and the decoder optimize two arbitrary distinct distortion functions. This problem lies on the bridge between Information Theory and Game Theory. As in the persuasion game of Kamenica and Gentzkow, we consider that the encoder commits to an encoding strategy, then the decoder selects the optimal output symbol based on its Bayesian posterior belief. The informational content of the source affects differently the two distinct distortion functions, therefore each symbol is encoded in a specific way. In this work, we consider that the decoder has side information. Accordingly, we reformulate the Bayesian update of the decoder posterior beliefs and the optimal information disclosure policy of the encoder. We provide four different expressions of the solution, in terms of the expected encoder distortion optimized under an information constraint, and it in terms of convex closures of auxiliary distortion functions. We compute the encoder optimal distortion for the doubly symmetric binary source example.

I. INTRODUCTION

Communication between autonomous devices that have distinct objectives is under study. This problem, referred to as the strategic communication problem, is at the crossroads of different disciplines such as Control Theory [1], [2], Computer Science [3] and Information Theory [4], [7], [8], [9], [10], [11], [12], where it was introduced by Akyol et al. in [5], [6].

Three different formulations of the strategic communication problem are originally proposed in the Game Theory literature, see [13]. The cheap talk game of Crawford and Sobel [14] relies on the Nash equilibrium solution. In the mechanism design problem of Jackson and Sonnenschein [15] the receiver commits to a prescribed decoding strategy, as the leader of a Stackelberg game. The hypothesis of decoder commitment is also considered in the mismatched rate-distortion problem in [16], [17]. In the persuasion game of Kamenica and Gentzkow [18] it is the sender who commits to a strategy whereas the decoder computes its Bayesian posterior belief and selects the optimal output symbol. In [19], we characterize the impact of the channel noise in the solution to the persuasion problem.

In this article, we extend these previous results with encoder commitment by considering that the decoder has side information. More specifically, we formulate a joint source-channel coding problem with decoder side information in which the encoder and the decoder are endowed with distinct distortion functions. Given an encoder strategy, the decoder selects an optimal strategy for its distortion function. The encoder anticipates the mismatch of the distortion functions and commits to implement the encoding strategy that minimizes its distortion.

The technical novelty consists in controlling the distance of the posterior beliefs induced by Wyner-Ziv’s coding to the target posterior beliefs. This demonstrates that the Wyner-Ziv’s encoding reveals nothing but the exact amount of information needed to implement the optimal decoding strategy. Consequently at the optimum the decoder produces a sequence of outputs which is almost the same as the one generated by the Wyner-Ziv’s coding [20], for a specific probability distribution.

![Fig. 1. The source $P_{UZ}$ is i.i.d., the channel $T_{V|X}$ is memoryless. The encoder and the decoder have arbitrary mismatched distortion functions $d_{e}(u,v) \neq d_{d}(u,v)$.

$$P_{UZ} \xrightarrow{\sigma} X^n \xrightarrow{T_{V|X}} Y^n \xrightarrow{\tau} V^n$$

II. SYSTEM MODEL

We denote by $U$, $Z$, $X$, $Y$, $V$, the finite sets of information source, side information, channel inputs, channel outputs and decoder’s outputs. Uppercase letters $U^n = (U_1, \ldots, U_n) \in U^n$ and $Z^n$, $X^n$, $Y^n$, $V^n$ stand for $n$-length sequences of random variables with $n \in \mathbb{N}^* = \mathbb{N} \setminus \{0\}$, whereas lowercase letters $u^n = (u_1, \ldots, u_n) \in U^n$ and $z^n$, $x^n$, $y^n$, $v^n$, stand for sequences of realizations. We denote by $\Delta(X)$ the set of probability distributions $Q_X$ over $X$. The support of $Q_X$ is denoted by $\text{supp} \ Q_X = \{x \in X, \ Q(x) > 0\}$.

We consider an i.i.d. information source and a memoryless channel distributed according to $P_{UZ} \in \Delta(U \times Z)$ and $T_{V|X} : X \rightarrow \Delta(Y)$, as depicted in Fig. 1.

Definition 1 We define the encoding strategy by $\sigma : U^n \rightarrow \Delta(X^n)$ and the decoding strategy by $\tau : Y^n \times Z^n \rightarrow \Delta(Y^n)$, and we denote by $P^{\sigma,\tau}$ the distribution defined by

$$P^{\sigma,\tau} = \left(\prod_{t=1}^{n} P_{U_t}\right) \sigma_{X^n|U^n} \left(\prod_{t=1}^{n} T_{V_t|X_t}\right) \tau_{V^n|Y^n Z^n}, \quad (1)$$

where $\sigma_{X^n|U^n}$, $\tau_{V^n|Y^n Z^n}$ denote the distributions of $\sigma$, $\tau$. 

Definition 2 The encoder and decoder distortion functions $d_e : \mathcal{U} \times \mathcal{V} \rightarrow \mathbb{R}$ and $d_d : \mathcal{U} \times \mathcal{V} \rightarrow \mathbb{R}$ are arbitrary and distinct, i.e. we consider any pair of functions. The long-run distortion functions $d_n^e(\sigma, \tau), d_n^d(\sigma, \tau)$ are given by

$$d_n^e(\sigma, \tau) = \min_{u^n, v^n} \mathcal{P}^\sigma( u^n, v^n) \cdot \left( \frac{1}{n} \sum_{t=1}^n d_d(u_t, v_t) \right).$$

Definition 3 Given $n \in \mathbb{N}^*$, we define:

1. the set of decoder best responses to strategy $\sigma$ by

$$\text{BR}_d(\sigma) = \arg\min_{\tau \in \text{BR}_d(\sigma)} d_n^d(\sigma, \tau).$$

2. the long-run encoder distortion value by

$$D^*_n = \inf_{\sigma} \max_{\tau \in \text{BR}_d(\sigma)} d_n^e(\sigma, \tau).$$

In case $\text{BR}_d(\sigma)$ is not a singleton, we assume that the decoder selects the worst strategy for the encoder distortion $\max_{\tau \in \text{BR}_d(\sigma)} d_n^e(\sigma, \tau)$, so that the solution is robust to the exact specification of the decoding strategy.

We aim at characterizing the asymptotic behavior of $D^*_n$.

Definition 4 We consider an auxiliary random variable $W \in \mathcal{W}$ with $|\mathcal{W}| = \min((|\mathcal{U}| + 1, |\mathcal{V}|/2)$ and we define

$$Q = \left\{ \mathcal{P}_{UZ} \mathcal{Q}_{W|U} \bigg| \max_{\mathcal{P}_X} I(X; Y) - I(U; W|Z) \geq 0 \right\}. \quad (4)$$

Given $\mathcal{Q}_{UZW}$, we define the single-letter best responses

$$\Lambda_d(\mathcal{Q}_{UZW}) = \arg\min_{\mathcal{Q}_{V|ZW}} \mathbb{E}_{\mathcal{Q}_{UZW}} \left[ d_e(U, V) \right]. \quad (5)$$

The encoder optimal distortion $D^*_e$ is given by

$$D^*_e = \inf_{\mathcal{Q}_{UZW} \in Q} \max_{\Lambda_d(\mathcal{Q}_{UZW})} \mathbb{E}_{\mathcal{Q}_{UZW}} \left[ d_e(U, V) \right]. \quad (6)$$

If $\Lambda_d(\mathcal{Q}_{UZW})$ is not a singleton, the decoder selects the worst distribution $\mathcal{Q}_{V|ZW}$ from the encoder perspective.

Theorem 1

$$\forall n \in \mathbb{N}^*, \quad D_n^e \geq D_n^*, \quad (7)$$

$$\forall \varepsilon > 0, \exists n \in \mathbb{N}^*, \forall n \geq \bar{n}, \quad D_n^e \leq D_n^* + \varepsilon. \quad (8)$$

The proof of Theorem 1 is stated in [22, App. B and C].

Sketch of proof of (7). For all $n \in \mathbb{N}^*$, the converse result relies on the identification of the auxiliary random variables $W = (Y^n, Z^nT^{-1}, Z^nT^{-1}T)$ and $(U, Z, V) = (U_T, Z_T, V_T)$, where $T$ is uniformly distributed over $\{1, \ldots, n\}$. We denote by $\mathcal{Q}^e_{UZW}, \mathcal{Q}^d_{V|ZW}$ the distributions induced by $(\sigma, \tau)$ over $(U, Z, W, V)$. In [21], it is proved that the Markov chain $Z \Rightarrow U \Rightarrow W$ holds and that $I(U; W|Z) \leq \max_{\mathcal{P}_X} I(X; Y)$, hence $\mathcal{Q}^e_{UZW} \in Q$. We show that $d_n^e(\sigma, \tau) = \mathbb{E}_{\mathcal{Q}^e_{UZW}} \left[ d_e(U, V) \right]$ and $\{ \mathcal{P}_{V|ZW}, \exists \tau \in \text{BR}_d(\sigma), \mathcal{Q}^d_{V|ZW} = \mathcal{P}_{V|ZW} \} = \Lambda_d(\mathcal{Q}^e_{UZW})$. Then for any $\bar{\sigma}$, we have

$$\max_{\tau \in \text{BR}_d(\bar{\sigma})} d_n^e(\bar{\sigma}, \tau) = \max_{\mathcal{Q}_{V|ZW} \in \Lambda_d(\mathcal{Q}^e_{UZW})} \mathbb{E}_{\mathcal{Q}_{V|ZW}} \left[ d_e(U, V) \right]$$

$$= \max_{\mathcal{Q}_{V|ZW} \in Q} \mathbb{E}_{\mathcal{Q}_{V|ZW}} \left[ d_e(U, V) \right] \geq \inf_{\mathcal{Q}_{UZW} \in Q} \max_{\Lambda_d(\mathcal{Q}_{UZW})} \mathbb{E}_{\mathcal{Q}_{UZW}} \left[ d_e(U, V) \right] = D_n^e, \quad (11)$$

which implies (7).

Note that the sequence $(nD_n^e)_{n \in \mathbb{N}^*}$ is sub-additive. Indeed, when $\sigma$ is the concatenation of several encoding strategies, the optimal $\tau$ in (3) is the concatenation of the optimal decoding strategies. Theorem 1 and Feke’s lemma, show that

$$D_n^* = \lim_{n \rightarrow +\infty} D_n^e = \inf_{n \in \mathbb{N}^*} D_n^e. \quad (12)$$

III. Convex Closure Formulation

We denote by $\text{vex} f : \mathcal{X} \rightarrow \mathbb{R} \cup \{-\infty\}$ the convex closure of a function $f$, i.e. the largest convex function everywhere smaller than $f$ on $X$. We reformulate $D^*_n$ in terms of a convex closure, similarly to [18, Corollary 1].

Lemma 1 For all $\mathcal{Q}_{W|U} \in \Delta(\mathcal{W})^{U|D}$, for all $(u, z, w) \in \text{supp}(\mathcal{P}_{UZ} \mathcal{Q}_{W|U})$ we have

$$Q(u|w, z) = \frac{\mathbb{Q}(u|w)\mathbb{P}(z|u)}{\sum_{u'} \mathbb{Q}(u'|w)\mathbb{P}(z|u')}.$$

The proof is direct. The conditional distribution $\mathcal{Q}_{U|WZ} \in \Delta(\mathcal{U})^{W \times \mathcal{Z} \mid \mathcal{W}}$ reformulates in terms of $\mathcal{Q}_{U|W} \in \Delta(\mathcal{U})^{W \mid \mathcal{V}}$.

Definition 5 For $p \in \Delta(U)$, the decoder selects $v^*(p)$ in

$$V^*(p) = \arg\max_{v^*} \mathbb{E}_p \left[ d_e(U, v) \right]. \quad (14)$$

and the robust distortion function writes

$$\psi_p(v^*(p)) = \mathbb{E}_p \left[ d_e(U, v^*(p)) \right], \quad v^*(p) \in V^*(p). \quad (15)$$

Definition 6 For $p \in \Delta(U)$, the average distortion function $\Psi_e(p)$ and the average entropy function $h(p)$ are defined by

$$\Psi_e(p) = \sum_{u, z} p(u) \mathbb{P}(z|u) \psi_p \left( \frac{p(\cdot) \mathbb{P}(\cdot|z) \psi_p}{\sum_{u'} p(u') \mathbb{P}(z|u')} \right), \quad (16)$$

$$h(p) = \sum_{u} p(u) \mathbb{P}(u') \log_2 \left( \frac{\sum_{u'} p(u') \mathbb{P}(z|u')}{p(u) \mathbb{P}(z|u)} \right). \quad (17)$$

The function $h(p)$ is the conditional entropy $H(U|Z)$ evaluated with respect to $p \cdot \mathcal{P}_{Z|U}$ instead of $\mathcal{P}_{UZ}$.

Lemma 2 The function $h(p)$ is concave in $p \in \Delta(U)$.
Proof. [Lemma 2] The entropy $H(U)$ is concave in $p \in \Delta(U)$, the mutual information $I(U;Z)$ is convex in $p \in \Delta(U)$ for fixed $P_{Z|U}$ and moreover $H(U|Z) = H(U) - I(U;Z)$.

Theorem 2

$$D^*_\psi = \inf \left\{ \sum_{w \in W} \lambda_w \Psi(p_w), \quad \sum_{w \in W} \lambda_w p_w = P_U, \quad \sum_{w \in W} \lambda_w h(p_w) \geq H(U|Z) - \max_{P_X} I(X;Y) \right\}, \quad (18)$$

where the infimum is taken over $(\lambda_w, p_w)_{w \in W}$ with $|W| = \min \left(|U| + 1, |V||Z|\right)$, such that for each $w \in W$, $p_w \in \Delta(U)$, $\lambda_w \in [0,1]$, and $\sum_{w \in W} \lambda_w = 1$.

The proof of Theorem 2 is stated in [22, App. A]. It is a consequence of the Markov chain property $Z \leftrightarrow U \leftrightarrow W$. Note that all the channels such that $\max_{P_{Z|U}} I(X;Y) \geq H(U|Z)$ lead to the same value for $D^*_\psi$. The optimal parameters $(\lambda^*_w, p^*_w)_{w \in W}$ in (18) are referred to as the optimal splitting of the prior distribution $P_U$, see [24]. When removing the decoder side information, e.g. $|Z| = 1$, and changing the infimum into a supremum, we recover the value of the optimal splitting problem of [19, Definition 2.4].

- Since $\sum_{w \in W} \lambda_w h(p_w) = H(U|Z,W)$, the information constraint in (18) is a reformulation of $I(U;W|Z) \leq \max_{P_X} I(X;Y)$.
- The dimension of the problem (18) is $|U| + 1$. Caratheodory’s Lemma [23, Corollary 17.1.5, pp. 157] induces the cardinality bound $|W| \leq |U| + 1$.
- The cardinality of $W$ is also restricted by the vector of recommended symbols $|W| \leq |V|^{|Z|}$, telling to the decoder which symbol $v \in V$ to select when the side information is $z \in Z$.

The encoder optimal distortion $D^*_\psi$ can be reformulated in terms of Lagrangian and in terms of the convex closure of

$$\Psi(p, \nu) = \begin{cases} \Psi(p), & \text{if } \nu \leq h(p), \\ +\infty, & \text{otherwise.} \end{cases} \quad (19)$$

Theorem 3

$$D^*_\psi = \sup_{t \geq 0} \left\{ \text{vex} \left[ \Psi + t \cdot h \right](P_U) - t \cdot \left( H(U|Z) - \max_{P_X} I(X;Y) \right) \right\} \quad (20)$$

$$= \text{vex} \left[ \Psi_{\psi}(P_U, H(U|Z) - \max_{P_X} I(X;Y)) \right]. \quad (21)$$

Equation (20) is the convex closure of a Lagrangian with the information constraint. Equation (21) corresponds to the convex closure of a bi-variate function where the information constraint requires an additional dimension. The proof follows directly from [19, Theorem 3.3, pp. 37] by replacing concave closure by convex closure.

Remark 1 When $d_\psi = d_{\tilde{\psi}}$, then $\psi(p) = \min_{v} \mathbb{E}_p \left[d_{\tilde{\psi}}(U, v)\right]$ and we obtain a reformulation of the Wyner-Ziv’s solution [20]

$$D_{\tilde{\psi}} = \inf_{(\lambda_w, p_w)_{w \in W}} \left\{ \sum_{w \in W} \lambda_w \sum_{u,z} p_w(u) \lambda_z \left[ d_{\tilde{\psi}}(U, v) \right] \right\}, \quad \sum_{w \in W} \lambda_w h(p_w) \geq H(U|Z) - \max_{P_X} I(X;Y) \right\}. \quad (22)$$

When $d_\psi = -d_{\tilde{\psi}}$, then $V^*(p) = \arg\max_{v} \mathbb{E}_p \left[d_{\tilde{\psi}}(U, v)\right]$ and both functions $\psi(p)$, $\tilde{\psi}(p)$ are convex in $p \in \Delta(U)$. By Jensen’s inequality, the infimum in (18) is achieved by $p^*_w = P_U$, $\forall w \in W$. i.e. no information is transmitted and $D^*_\psi$ is convex.

IV. DOUBLY SYMMETRIC BINARY SOURCE

We consider the doubly symmetric binary source (DSBS) example introduced by Wyner-Ziv in [20, Sec. II], depicted in Fig. 2 with parameters $|p_0, \delta_0, \delta_1| \in [0,1]^3$. The cardinality bound is $|W| = \min \left(|U| + 1, |V||Z|\right) = 3$, hence the random variable $W$ is drawn according to the conditional probability distribution $Q_{W|U}$ with parameters $(\alpha_k, \beta_k)_{k \in {1,2,3}} \in [0,1]^6$ such that $\sum_{k} \alpha_k = \sum_{k} \beta_k = 1$.

![Fig. 2. Joint probability distribution $P(u,v)Q(w|u)$ with $|W| = 3$ depending on parameters $p_0, \delta_0, \delta_1, (\alpha_k, \beta_k)_{k \in {1,2,3}}$ that belong to $[0,1]$.](image)

![Fig. 3. Encoder distortion $d_{\psi}(u,v)$.](image)

![Fig. 4. Decoder distortion $d_{\tilde{\psi}}(u,v)$.](image)

![Fig. 5. Decoder’s expected distortion $\mathbb{E}_p \left[d_{\tilde{\psi}}(U, v)\right] = (1-p) \cdot d_{\tilde{\psi}}(u_0, v_1) + p \cdot d_{\tilde{\psi}}(u_1, v_1)$ for $v \in \{v_0, v_1\}$ depending on the belief $Q(u_1|w,z) \in [0,1]$.](image)
The optimal decision for the decoder depends on the posterior belief \( Q_U(w, z) \in \Delta(H) \) after observing the symbols \((w, z)\). We denote by \( \gamma = \frac{1 + \kappa}{2} = \frac{7}{8} \) the belief threshold at which the decoder changes from symbol \( v_0 \) to \( v_1 \), as in Fig. 5. The decoder chooses \( \psi_0^* \) (resp. \( \psi_1^* \)) when the posterior belief belongs to \([0, \gamma]\) (resp. \([\gamma, 1]\)).

The correlation of \((U, Z)\) is fixed whereas the correlation of \((U, W)\) is selected by the encoder. Lemma 1 formulates the posterior belief \( Q_U|W,Z \) in terms of the interim belief \( Q_U|W\).

For the symbols \( w \in \mathcal{W}, z_0 \in \mathcal{Z}, z_1 \in \mathcal{Z} \) we have

\[
Q(u_1 | w, z_0) = \frac{q \delta_1}{(1 - q)(1 - \delta_0) + q \delta_1} =: p_0(q),
\]

\[
Q(u_1 | w, z_1) = \frac{q(1 - \delta_1)}{(1 - q)\delta_0 + q(1 - \delta_1)} =: p_1(q).
\]

Equations (23) and (24) are depicted on Fig. 6. Given the belief threshold \( \gamma = \frac{7}{8} \), we define \( \nu_0 \) and \( \nu_1 \) such that

\[
\gamma = p_0(\nu_0) \iff \nu_0 = \frac{\gamma(1 - \delta_0)}{\delta_1(1 - \gamma) + \gamma(1 - \delta_0)},
\]

\[
\gamma = p_1(\nu_1) \iff \nu_1 = \frac{\gamma \delta_0}{\gamma \delta_0 + (1 - \delta_1)(1 - \gamma)}.
\]

Without loss of generality, we assume that \( \delta_0 + \delta_1 < 1 \iff \nu_1 < \nu_0 \). The robust and average distortion functions writes

\[
\psi(p) = p \cdot \mathbb{1}(p \leq \gamma) + (1 - p) \cdot \mathbb{1}(p > \gamma),
\]

\[
\Psi(q) = \Pr_q(z_0) \cdot \psi(p_0(q)) + \Pr_q(z_1) \cdot \psi(p_1(q))
\]

\[
= q \cdot \mathbb{1}(q \leq \nu_1) + (1 - q) \cdot \mathbb{1}(q > \nu_0) + (q \delta_1 + (1 - q) \delta_0) \cdot \mathbb{1}(\nu_1 < q \leq \nu_0).
\]

The average distortion function \( \Psi(q) \) is depicted by the orange lines in Fig. 7, Fig. 8 and Fig. 11, where the black curve is the average entropy \( h(q) = H_b(q) + (1 - q) \cdot H_b(\delta_0) + q \cdot H_b(\delta_1) - H_b((1 - q) \delta_0 + q(1 - \delta_1)) \) and \( H_b \) denotes the binary entropy.

The optimal splitting has posterior \((q_1, q_2, q_3) \in [0, 1]^3\) with respective weights \((\lambda_1, \lambda_2, \lambda_3) \in [0, 1]^3\) that satisfy

\[
1 = \lambda_1 + \lambda_2 + \lambda_3,
\]

\[
p_0 = \lambda_1 q_1 + \lambda_2 q_2 + \lambda_3 q_3,
\]

\[
H(U|Z) - C = \lambda_1 \cdot h(q_1) + \lambda_2 \cdot h(q_2) + \lambda_3 \cdot h(q_3).
\]

Equation (32) is satisfied when the information constraint is binding, therefore we obtain [19, Equations (58) - (60)]. Without loss of generality, we assume that \( q_1 \in [\nu_1, \nu_2], q_2 \in [\nu_1, \nu_2], q_3 \in [\nu_2, 1] \) and characterize the optimal solution in three different scenarios. According to the Splitting Lemma [24], we have for \( k \in \{1, 2, 3\} \),

\[
Q(w_k | u_0) = \frac{Q(w_k) - Q(u_1 | w_k)}{1 - P(u_1)} = \lambda_k \cdot \frac{1 - q_k}{1 - p_0} = \alpha_k,
\]

\[Q(w_k | u_1) = \frac{Q(w_k) - Q(w_k | u_1)}{P(u_1)} = \lambda_k \cdot \frac{q_k}{p_0} = \beta_k.
\]

A. Wyner-Ziv’s Example With Equal Distortions

We consider \( p_0 = 0.5, \delta_0 = \delta_1 = 0.3, \kappa = 0 \), hence both encoder and decoder minimize the Hamming distortion and hence \( \gamma = \frac{1}{2} \). The average distortion and average entropy write

\[
\Psi(q) = q \cdot \mathbb{1}(q \leq \delta) + \delta \cdot \mathbb{1}(\delta < q \leq 1 - \delta)
\]

\[
+ (1 - q) \cdot \mathbb{1}(q > 1 - \delta),
\]

\[
h(q) = H(U|Z) + H_b(q) - H_b(q + \delta),
\]

Fig. 7. The optimal splitting has three posteriors when \( C \in [H(U|Z) - h(q^*), H(U|Z)] \), with \( p_0 = 0.5, \delta_0 = \delta_1 = 0.3, C = 0.2, \kappa = 0 \), then \( D^*_0 = 0.2098 \).
Proposition 1 We denote by $q^*$ the unique solution to

$$h'(q) = \frac{H(U|Z) - h(q)}{\delta - q}. \quad (37)$$

1) If $C \in [0, H(U|Z) - h(q^*)]$ then at the optimum (Fig. 7) $q_1 = q^* = 1 - q$, $q_2 = \frac{1}{2}$, $\lambda_1 = \frac{1}{2} \frac{C}{H(U|Z) - h(q^*)} = \lambda_3 = \frac{1 - \lambda_2}{2}$, (38)

which correspond to the distribution parameters $\alpha_1 = (1 - q^*) \frac{C}{H(U|Z) - h(q^*)} = \beta_3$, $\alpha_2 = 1 - \frac{C}{H(U|Z) - h(q^*)} = \beta_2$, $\alpha_3 = q^* \frac{C}{H(U|Z) - h(q^*)} = \beta_1$, and to the optimal distortion

$$D^*_c = \delta - C \cdot \frac{\delta - q^*}{H(U|Z) - h(q^*)}. \quad (40)$$

2) If $C \in [H(U|Z) - h(q^*), H(U|Z)]$ then at the optimum (Fig. 8) $q_1 = h^{-1}(H(U|Z) - C) = 1 - q_3$, $q_2 = \frac{1}{2}$, $\lambda_1 = \frac{1}{2} = \lambda_3$, $\lambda_2 = 0$, which correspond to the distribution parameters $\alpha_1 = 1 - h^{-1}(H(U|Z) - C) = 1 - \alpha_3 = \beta_3 = 1 - \beta_1$ and $\alpha_2 = \beta_2 = 0$ and to the optimal distortion

$$D^*_c = h^{-1}(H(U|Z) - C), \quad (41)$$

where the notation $h^{-1}(H(U|Z) - C)$ stands for the unique solution $q \in [0, 1]$ of the equation $h(q) = H(U|Z) - C$.

3) If $C > H(U|Z)$, then the optimal splitting rely on the two extreme posterior beliefs ($0, 1$) and $D^*_c = 0$.

The proof of Proposition 1 is provided in [22, App. D]. When $C \leq H(U|Z) - h(q^*)$, the optimal strategy consists of a time-sharing between $(D^*_c, C) = (q^*, H(U|Z) - h(q^*))$ and the zero rate point $(0, 0)$, as depicted in Fig. 9.

B. Mismatched Distortions Without Side Information

We consider $p_0 = 0.5$, $C = 0.2$, $\kappa = \frac{3}{2}$ and $\delta_0 = \delta_1 = 0.5$ so that $Z$ is independent of $U$, as in [19]. We have $H_b(\delta_1) = H_b(1 - \delta_0 + q_1(1 - \delta_1)) = 1$ and $\nu_1 = \nu_2 = \gamma = \frac{2}{3}$. The average entropy and average distortion write

$$h(q) = H_b(q), \quad (42)$$

$$\Psi_\delta(q) = \psi_\delta(q) = p \cdot 1 \{p \leq \gamma\} + (1 - p) \cdot 1 \{p > \gamma\}, \quad (43)$$

and are depicted in Fig. 10. Applying [19, Corollary 3.5], the optimal splitting has two posteriors, i.e. $|W| = 2$, and satisfy

$$\frac{p_0 - q_3}{q_1 - q_2}, H_b(q_1) + \frac{q_1 - p_0}{q_1 - q_2} \cdot H_b(q_2) \geq H(U) - C. \quad (44)$$

By numerical optimization, the above inequality is satisfied for $p_0 = 0.5$, $\delta_0 = \delta_1 = 0.5$, $C = 0.2$, $\kappa = \frac{3}{2}$, hence the optimal distortion is achieved by using $q_2 = \gamma$, as in Fig. 10.

C. Mismatched Distortions With Side Information

We consider $p_0 = 0.5$, $\delta_0 = 0.05$, $\delta_1 = 0.5$, $C = 0.2$, $\kappa = \frac{3}{2}$. By numerical simulation, we determine the optimal triple of posteriors $(q_1, q_2, q_3)$ represented by the red dots in Fig. 11, corresponding to $D^*_c = 0.1721$. The parameters of the optimal strategy in Fig. 2, are given by the following table.

<table>
<thead>
<tr>
<th>$q_1$</th>
<th>$q_2$</th>
<th>$q_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0715</td>
<td>0.4118</td>
<td>0.9301</td>
</tr>
<tr>
<td>$\lambda_1$</td>
<td>$\lambda_2$</td>
<td>$\lambda_3$</td>
</tr>
<tr>
<td>0.1288</td>
<td>0.6165</td>
<td>0.2548</td>
</tr>
<tr>
<td>$\alpha_1$</td>
<td>$\alpha_2$</td>
<td>$\alpha_3$</td>
</tr>
<tr>
<td>0.2392</td>
<td>0.7252</td>
<td>0.0356</td>
</tr>
<tr>
<td>$\beta_1$</td>
<td>$\beta_2$</td>
<td>$\beta_3$</td>
</tr>
<tr>
<td>0.0184</td>
<td>0.5077</td>
<td>0.4739</td>
</tr>
</tbody>
</table>
