Department of Chemistry, Room 18-490 Massachusetts Institute of Technology Cambridge, MA 02139 (USA)

Abstract

Hypervalent iodine λ^3 -benziodoxoles are common electrophilic transfer reagents known for their enhanced stability compared to their non-cyclic analogues. Herein we present data showing that chlorobenziodoxole reacts with two different thiolate nucleophiles (thiocyanate and trifluoromethylthiolate), resulting in the formation of stable thioperoxy complexes rather than the expected benziodoxole derivatives. We further report a revised structure for the earlier described electrophilic trifluoromethylthiolation reagent (1), which was previously believed to contain the benziodoxole framework. Our findings, which are based on a combination of analytical techniques, including the recently introduced crystalline sponge method for X-ray analysis, unambiguously demonstrate that 1 is a thioperoxy compound both in solution and the solid state.

Keywords

crystalline sponge crystallography; host-guest systems; hypervalent compounds; thioperoxides; trifluoromethylthiolation

Recently, Shen et al. introduced a new hypervalent iodine reagent for the transfer of an electrophilic trifluoromethylsulfur group (Figure 1, 1).^[1] Compound 1 was isolated as a colorless liquid and characterized by ¹H, ¹³C, and ¹⁹F NMR spectroscopy, as well as elemental analysis. Based on these data, Shen proposed that 1 contains the sulfur-bound hypervalent iodine motif, similar to all previously reported benziodoxole and benziodoxolone transfer reagents (Figure 1).^[2-9]

As part of our work on the synthesis of aryl isocyanates,^[10] we were interested in developing new reagents based on the benziodoxole motif for isocyanate and isothiocyanate group transfer chemistry. We anticipated that the ambidentate cyanate and thiocyanate nucleophiles could potentially react with reagent **3** at either the nitrogen or group 16 element (oxygen or sulfur) nucleophilic sites. Indeed, when **3** was treated with silver cyanate, a mixure of isomeric 1-cyanatobenziodoxoles was obtained, with the major product arising from reaction at the nitrogen atom (**4**, Scheme 1a). In contrast, the reaction of **3** with silver thiocyanate yielded a single compound that did not contain the expected benziodoxole

scaffold (**5**, Scheme 1b). As shown in Scheme 1, the single crystal X-ray analysis of compound **5** revealed that the thiocyanate-group was S-bound to the oxygen atom of **2** rather than to the iodine.^[11,12]

Intrigued by this result, we conducted a brief comparison of the ¹H NMR spectra of the benziodoxoles and 2- iodobenzyl alcohol-derivatives that are shown in Figure 2. We found that the two compound classes (closed benziodoxole vs. open benzyl alcohol) generally display different characteristic signals in the aromatic region. Most notably, the aromatic protons that are *para* to the alkyl group (H_b) exhibited significant (0.5 ppm or greater) downfield shifts in the closed compounds (Figure 2a,b) when compared to the open ones (Figure 2c,d). As described above, the sulfur-based nucleophile afforded the corresponding open compound (Figure 2d) with complete selectivity, which is in contrast to the reported benziodoxole structure of the related trifluoromethylthiolation reagent 1. Compound 1 was synthesized according to literature procedure^[1a] and exhibited identical spectral properties as reported. To our surprise, the ¹H NMR spectrum of 1 (Figure 2e) resembles those of the open-form compounds more closely than the spectra of the closed-form ones, suggesting that 1 could potentially exist as the open thioperoxy compound rather than the benziodoxole. The oxidation state of iodine in 1, 5 and 6 as I^I in solution was further corroborated by ¹³C NMR spectroscopy, as outlined previously by Katritzky et al.^[13]

To further evaluate the structure of the Shen reagent, we undertook two parallel studies that would allow us to obtain X-ray crystallographic structural data.^[14,15] We first sought to prepare a solid analogue of the trifluoromethylthio-transfer reagent. According to the route outlined in Scheme 2, we were able to construct a modified reagent **6** that contained the dichlorotrimethoxyphenyl substituent at C4 of the phenyl ring. This new reagent displayed the characteristic aromatic ¹H NMR signal that indicated a compound that did not contain the benziodoxole scaffold (Figure 2f). X-ray diffraction analysis of single crystals of **6** provided unequivocal structural evidence that the SCF₃ group is bound to oxygen rather than to iodine (Scheme 2).

To evaluate the potential steric and electronic effects that installation of the functionalized aromatic substituent could impart to the reagent, we compared the reactivity of **6** and **1** in previously reported SCF₃–transfer reactions. Under the optimized conditions reported by Shen et al. for β -ketoester- (Scheme 3a) or Cu-catalyzed arylboronic acid-trifluoromethylthiolation (Scheme 3b),^[1a] the two reagents displayed nearly identical reactivity profiles (Scheme 3).

Although it is possible that there exists a Curtin-Hammet scenario where both forms of the reagent exist in equilibrium in solution and the reactivity arises from the hypervalent iodine structure, no evidence for such an equilibrium was observed by ¹H or ¹⁹F NMR spectroscopy, even at low temperatures (-80 °C). Furthermore, the similarity of the thioperoxide structure to the previously reported nitrogen-based electrophilic trifluoromethylthiolation reagents by the groups of Billard^[16] and Rueping^[17] (Scheme 4a and b), as well as the disulfide reagents used for directed Cu-promoted sulfenylation of sp² C–H bonds by Daugulis et al.^[18] (Scheme 4c) supports the hypothesis that the observed reactivity^[1a,c] could arise from the thioperoxide fragment itself.

Fujita recently introduced a new method for the structure determination of liquid compounds trapped in the pores of a host Metal Organic Framework (MOF).^[19] We were interested in applying this methodology to gain access to the X-ray structure of the parent reagent **1**. The MOF material was prepared by slow diffusion of the solution of ZnI_2 in methanol into the solution of 2,4,6-Tri(4-pyridyl)-1,3,5-triazine in a mixture of nitrobenzene and methanol. Soaking the resulting crystals in cyclohexane at 50 °C for 2 weeks (used solvent was replaced by fresh solvent each day) allowed for the majority of nitrobenzene in the pores of the MOF to be exchanged with more labile cyclohexane molecules.^[20] A consecutive soak of the crystals in the analyte provided X-ray quality crystals of the host-guest complex **1**@MOF. Subsequent structure determination using a variety of advanced refinement techniques^[21] revealed the presence of 92% of reagent **1** per asymmetric unit of the crystal structure of **1**@MOF, disordered over three crystallographically independent sites (see Supporting Information for details). As shown in Scheme 5, the crystallographically-derived structure of **1** does not contain the benziodoxole fragment, and the SCF₃-group is bound to the oxygen atom.

In summary, we have discovered that the reaction of chlorobenziodoxole with two sulfurcontaining nucleophiles leads to the formation of rearranged products containing stable thioperoxy groups. A combination of spectroscopic techniques, derivatization experiments and the crystalline sponge method recently introduced by Fujita,^[19] allowed for unambiguous confirmation of the open form thioperoxide structure of the recently reported trifluoromethylthiolation reagent **1** both in solution and in solid state at room temperature. Importantly, while these results do not affect the chemical reactivity studies utilizing reagent **1** as recently reported by Shen,^[1a] they do suggest that other mechanistic pathways for electrophilic trifluoromethylthiolation are possible.^[1c]

- [11]. Although an exact mechanism for the formation of thioperoxide species is not known, a plausible mechanism involves reductive elimination from the intermediate hypervalent iodine species facilitated by the strongly electron-withdrawing substituent on the sulfur. Similar reactivity has been observed in reactions with Togni reagents, where unreactive trifluoromethyl ethers and esters were obtained as byproducts in the trifluoromethylations: Niedermann K, Früh N, Senn R, Czarniecki B, Verel R, Togni A. Angew. Chem. 2012; 124:6617–6621. Angew. Chem. Int. Ed. 2012; 51:6511–6515. This process has been shown to be accelerated by strongly Lewis and Brønsted acidic catalysts in the case of benziodoxolone reagents: Fantasia S, Welch JM, Togni A. J. Org. Chem. 2009; 75:1779–1782.
