Abstract. The new organic–inorganic hybrid compound $[C_6H_6NO_2]_2CuCl_4\cdot H_2O$ has been grown from an aqueous mixture by the solvent evaporation method. X-ray diffraction, Hirshfeld surface analysis, FT-IR and FT-Raman spectroscopy were applied to characterize the composition and crystal structure of the complex. It is crystallized in a triclinic system (PI space group). The structure of this compound might be described as layered with two parallel anionic and cationic layers. The first layer is composed of isolated square planar $[CuCl_4]^{2-}$ and the second layer of $[C_6H_6NO_2]^{2+}$. The water molecule is placed between the layers formed by organic cations along the *b* axis. Network hydrogen-bonding and $\pi - \pi$ interactions lead to the formation of a three-dimensional architecture. Hirshfeld surface analysis for visually analysing intermolecular interactions in crystal structures employing molecular surface contours and 2D fingerprint plots has been used to scrutinize molecular shapes. The vibration properties of this structure were studied by IR spectroscopy and Raman scattering. Vibration spectra were also calculated theoretically by means of Gaussian 03 package of programs within the density functional theory (DFT) framework using the B3LYP/LanL2DZ level of theory. To sum up, good consistency is found between the calculated results on one hand and the IR and Raman spectra and experimental structure on the other. This study confirms the presence of the organic cations $[C_6H_6NO_2]^{2+}$, the inorganic anions $[CuCl_4]^{2-}$ and H₂O.

Keywords. Crystal structure; Hirshfeld surface; FT-IR; Raman; DFT/B3LYP/LanL2DZ.

1. Introduction

In recent years, layered hybrid organic-inorganic compounds based on metal halide units have attracted much attention due to their possibility to combine the properties of organic and inorganic materials at the molecular level [1]. In fact, organic compounds offer a number of useful properties, including structural diversity, mechanical plasticity and ease of processing [2]. Inorganic materials have a distinct set of advantages, including good electric mobility, tunable band gap property, magnetic property and thermal stability [3,4]. In these materials, the structural arrangement can be described as an alternation of inorganic sheets and layers of the organic molecules. The nature of the interface has been used to grossly divide these materials into two distinct classes. In class I, organic and inorganic compounds are embedded and only weak bonds (hydrogen, van der Waals or ionic bonds) give the cohesion to the whole structure. In class II materials, the two phases are linked together through strong chemical bonds (covalent or iono-covalent bonds). Much of the recent research has focused on the synthesis of crystalline organicinorganic halogenocuprates (II) due to the fact that they show a high variety of coordination numbers and geometries (tetrahedral [5], trigonal bi-pyramidal [6] square pyramidal and octahedral [7]). This large structural variability of Cu (II) is due to the presence of an active Jahn–Teller effect in the d⁹ electronic system [8].

In this work, we focused our attention on the synthesis and characterization of a new hybrid material $[C_6H_6NO_2]CuCl_4 \cdot H_2O$, which is crystallized in space group $P\bar{1}$. We have used X-ray diffraction measurements, which provided us with information about the complete crystal structure at room temperature. An investigation of close intermolecular interactions in this compound via Hirshfeld surface analysis is also reported. Besides, the geometric parameters and vibrational frequencies of (4-pyridine carboxylic acid) tetrachlorocuprate (II) monohydrate have been investigated by the DFT/B3LYP/LanL2DZ method. Moreover, the FT-IR and FT-Raman spectra have been recorded in the range of 400–4000 and 50–4000 cm⁻¹, respectively.

2. Experimental

2.1 Synthesis of $[C_6H_6NO_2]CuCl_4 \cdot H_2O$

The (4-pyridine carboxylic acid) tetrachlorocuprate (II) monohydrate crystals were prepared by dissolving $CuCl_2 \cdot 6H_2O$ in a minimum volume of water and $[C_6H_6NO_2]$ in concentrated HCl. After the solutions were mixed, it remained clear

CrossMark

^{*}Author for correspondence (azouzi.khaoula@yahoo.fr)

without any precipitate. The resulting aqueous solution was left to evaporate slowly at room temperature. After 2 weeks, high-quality yellow crystals appeared in the solution and became stable under normal conditions of temperature and humidity. The average value of density, $D = 2.601 \text{ mg m}^{-3}$, is in agreement with that calculated, $D = 2.649 \text{ mg m}^{-3}$.

2.2 Crystal data and structure determination

For the structural study we chose a crystal with the dimensions of $0.31 \times 0.28 \times 0.19 \text{ mm}^3$. The single crystal was fixed on a Bruker APEXII CCD four-circle diffractometer; MoK α radiation ($\lambda = 0.71073$ Å) was used in order to study its structural analysis. The crystal structure has been solved in the triclinic system, space group $P\bar{1}$ according to the automated search for space group available in WINGX [9]. The crystal structure has been solved using the classical method: interpretation of the three-dimensional Patterson function followed by successive difference Fourier maps after introducing anisotropic thermal factors for the non-hydrogen atoms and isotropic thermal factors for H atoms. The structure was solved and refined using SHELXS-97 and SHELXL-97 programs [10,11] respectively, down to R = 0.04 and wR2 = 0.10. The structural graphics were created with ORTEP [12] and DIAMOND [13]. The crystallographic data and some details of the structural refinement are summarized in table 1. The atomic coordinates and equivalent isotropic and anisotropic thermal agitation factors are listed in tables 2 and 3, respectively.

2.3 Hirshfeld surfaces computational method

The Hirshfeld surfaces and the associated 2D fingerprint plots were calculated using the Crystal Explorer [14] program, which accepts a structure input file in the CIF format. A Hirshfeld surface is the outer contour of the space which a molecule or an atom consumes in a crystalline environment. The normalized contact distance d_{norm} based on both d_e (distance from the point to the nearest nucleus external to the surface) and d_i (distance to the nearest nucleus internal to the surface) and the van der Waals (vdW) radii of the atom, given by equation (1), enables identification of the regions of particular importance to intermolecular interactions [15]:

$$d_{\rm norm} = \frac{(d_{\rm i} - r_{\rm i}^{\rm vdw})}{r_{\rm i}^{\rm vdw}} + \frac{(d_{\rm e} - r_{\rm e}^{\rm vdw})}{r_{\rm e}}.$$
 (1)

The value of the d_{norm} is negative or positive when intermolecular contacts are, respectively, shorter or longer than vdW separations. Because of the symmetry between d_e and d_i in the expression for d_{norm} , where two Hirshfeld surfaces

touch, both will display a red spot identical in colour intensity as well as size and shape. The d_{norm} values are mapped onto the Hirshfeld surface using a red-blue-white colour scheme: red regions correspond to closer contacts and negative d_{norm} value, the blue regions correspond to longer contacts and positive d_{norm} value and the white regions are those where the distance of contacts is exactly the vdW separation and with a d_{norm} value of zero. The combination of d_e and d_i in the form of a 2D fingerprint plot provides summary of intermolecular contacts in the crystal.

2.4 Spectroscopic measurements

The vibrational measurements were carried out at room temperature. The infrared spectrum was taken on a 'Nicole Impact 410 FT-IR' spectrophotometer in the region 400– 4000 cm⁻¹. The sample for this measurement was finely ground and mixed with KBr. This mixture was then pressed under vacuum at high pressure to obtain a transparent disc, which was then placed in the sample compartment. The Raman spectrum of polycrystalline sample was performed in the 50–4000 cm⁻¹ range employing a LABRAMHR 800 triple monochromatic instrument using the 514.5 nm line spectra-physics argon ion lasers.

2.5 Computational details

The density functional theory (DFT) approaches, especially those using hybrid functionals, have evolved to a powerful and very reliable tool, being commonly used for the determination of various properties of molecules. Within the framework of the DFT approach, the B3LYP hybrid functional has often been preferred since it proved efficient in reproducing various molecular properties. The combined use of B3LYP functional with the LanL2DZ basis set has previously been shown to provide an excellent compromise between accuracy and computational efficiency of vibrational spectra for large and medium size molecules.

The geometry and frequencies were fully optimized at the density functional level of theory with the Becke 3 parameter hybrid functional combined with the Lee–Yang–Parr correlation functional (B3LYP), implemented with Gaussian 03 program [16]. LanL2DZ was used as the basis set. The atomic coordinates for calculations were obtained from the X-ray data. First, the geometry optimization was performed using DFT with the B3LYP correlation functional. It is to be noted that LanL2DZ was used as the basis for all atoms. Therefore, the calculations converged to optimized geometries that corresponded to true energy minima, as revealed by the lack of imaginary values in the vibrational mode calculations. Besides, the vibrational frequencies calculations were performed at the DFT/LanL2Dz level.

The calculated geometrical parameters of the title compound are reported and compared to the experimental ones in table 4.

3. Results and discussion

3.1 Structure description

The (4-aminopyridinium) tetrachlorocuprate (II) monohydrate compound crystallizes in the triclinic system $P\bar{1}$ at room temperature with the following parameters: a = 7.0791(10) Å,

b = 8.5514(13) Å, c = 8.9031(13) Å, $\alpha = 81.237(4)^{\circ}$, $\beta = 74.171(4)^{\circ}$, $\gamma = 65.686(4)^{\circ}$ and Z = 1. The formula unit of the title compound (shown in figure 1a), drawn with 50% probability thermal ellipsoids shows the presence of one anionic entity $[CuCl_4]^{2-}$, one molecule of water and one cation $[C_6H_6NO_2]^{2+}$.

The examination of the structure has clearly shown an alternation of organic–inorganic layers that run parallel to the *a* axis. The first layer is composed of isolated square planar $[CuCl_4]^{2-}$ and the second layer of $[C_6H_6NO_2]^{2+}$. The water molecules are sandwiched between the $[CuCl_4]^{2-}$ anion and the $[C_6H_6NO_2]^{2+}$ cation on both sides of the layer (figure 2).

Inorganic layers are extended as zero-dimensional (0D) network by isolated square planar $[CuCl_4]^{2-}$ (figure 3), forming chains running along the axis *b*. The $[CuCl_4]^{2-}$ anions are located in the [110] plane at x = 1/2. The copper (II) ion is coordinated by four chlorine atoms, with Cu–Cl distances ranging from 2.2601(14) to 2.2703(12) Å and Cl–Cu–Cl angles varying from 90.50(4) to 390.50(4)°. The distortion of the $[CuCl_4]^{2-}$ square planar is correlated to the deformations resulting from hydrogen bond interactions [17,18]. The two negative charges of the anionic species are contra-balanced by the two positive charges of the organic cation.

The organic part consists of one organic cation type, which orients its nitrogen towards the neighbouring anion. Table 4 reports the main geometrical features of $[C_6H_6NO_2]^{2+}$ entities. The C–C bond lengths vary from 1.364(4) to 1.502(8) Å; the C–O bond lengths vary from 1.283(3) to 1.211(4) Å and the mean value of the N–C bond lengths is 1.325(3) Å.

The compound has an extensive network of hydrogen bonding due to numerous acceptor and donor atoms. In the crystal structure the 4-cyanopyridine cations are linked to $[CuCl_4]^{2-}$ by C–H....Cl and N–H....Cl hydrogen bond, forming infinite chains. At the same time the components of the structure are linked to molecule of water in

Bond length (Å)	Experimental	Theoretical	Bond angle (°)	Experimental	Theoretical

the crystallographic *c* direction by O–H....O and O–H....Cl hydrogen bond to form a second set of infinite chains (figure 4a). In addition to these hydrogen interactions, we also note that the cohesion in the crystal is ensured by weak interactions type π – π stacking observed between the planes containing the fused aromatic rings. The interstacking distances are equal to 3.210 Å, which is comparable to interplanar distances found in the aromatic π -system (figure 4b) [19].

Both hydrogen bond and $\pi - \pi$ stacking interactions cause the formation of a three-dimensional architecture.

According to the charge compensation hypothesis, the observed structure of copper (II) halides salts can be visualized as a balance between crystal field stabilization effects and an electrostatic ligand–ligand repulsion effect. In fourcoordinate compounds, the former favours a square-planar and the latter a tetrahedral geometry. As long as hydrogen bonds tend to remove charge from the Cl atoms they will promote the $[CuCl_4]^{2-}$ ion to move towards a square-planar geometry.

DFT is developing rapidly as a cost-effective general procedure for studying vibrational properties of molecules. Optimized geometry of the title compound model is presented in figure 1b. Selected measured bond lengths and bond angles together with the calculated ones are presented in table 4 in accordance with the atom numbering scheme given in figure 1a. After careful comparison, we find that most of the optimized bond lengths are slightly larger than

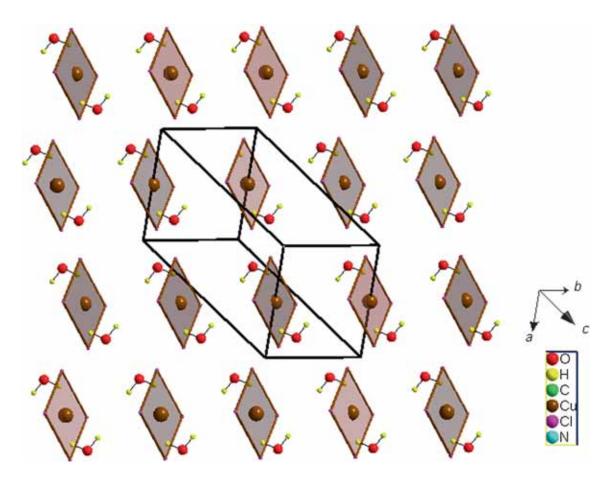

Figure 3. Drawing showing the arrangement of the square plane $[CuCl_4]^{2-}$.

the experimental values, which is not surprising given that theoretical calculation belongs to the isolated molecule in the gaseous phase at 0 K and the experimental result belongs to the molecule in the solid state with intermolecular interactions and crystal packing effect. As shown in table 4, the optimized parameters are in good agreement with the experimental data.

C5-H5Cl2	0.9300	2.8200	3.674(4)	153.00

Symmetry codes: -x, 1-y, -z.

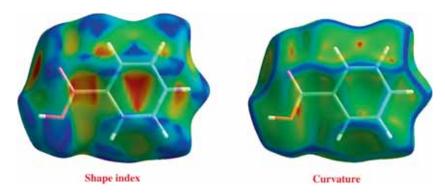

Figure 6. Hirshfeld surfaces mapped for shape index and curvature of $[C_6H_6NO_2]$ CuCl₄·H₂O.

The difference between the calculated and experimental bond lengths and bond angles of the title compound is very small. This indicates that the calculation precision is satisfactory and the DFT/B3LYP/LanL2DZ level is suitable for the complex system studied here.

3.2 Hirshfeld surface analysis

In order to profoundly examine the strength and role of the hydrogen bonds and other intermolecular contacts, and to estimate their importance for the crystal lattice stability, Hirshfeld surface analysis has been conducted. The Hirshfeld surface of the title compound is illustrated in figure 5a, showing surfaces that have been mapped over a d_{norm} range of -0.5 to 1.5 Å. The surfaces are shown as transparent to allow visualization of the molecular moiety, in a similar orientation for all of the structures. It is clear that the information presented in table 5 is summarized effectively in these spots, with the large circular depressions (deep red) visible on the surfaces indicative of hydrogen-bonding contacts.

The 2D fingerprint plots, which are used to analyse all of the intermolecular contacts at the same time, revealed that the main intermolecular interactions in the compound were H...Cl, H...O and H...H (figure 5b).

The Hirshfeld surfaces of (4-aminopyridinium) tetrachlorocuprate (II) monohydrate are illustrated in figure 6, showing surfaces that have been mapped for shape index and curvature.

Curvature conveys similar information as that of shape index. In fact, the π - π stacking is shown by the pattern of red and blue triangles on the same region of the shape index surfaces. It is shown by the large flat region delineated by a blue outline on the curvature surfaces.

In order to find out directional interactions, the characteristic features in the fingerprint plots obtained from the Hirshfeld surface were further analysed. This analysis shows the relative contribution of each contact present in the title compound (figure 7). As previously observed, the highest contribution occurs due to Cl...H and H...Cl contacts (46%). The O...H interactions are represented by a spike in the bottom left (donor) area of the fingerprint plot, which represents the water oxygen interacting with acid oxygen, forming a 2D network of hydrogen bonds. The H...O interactions are represented by a spike in the bottom right region of fingerprint plot (acceptor). The proportion of H...H interactions comprises 18.6% of the total Hirshfeld surfaces. Lower percentages

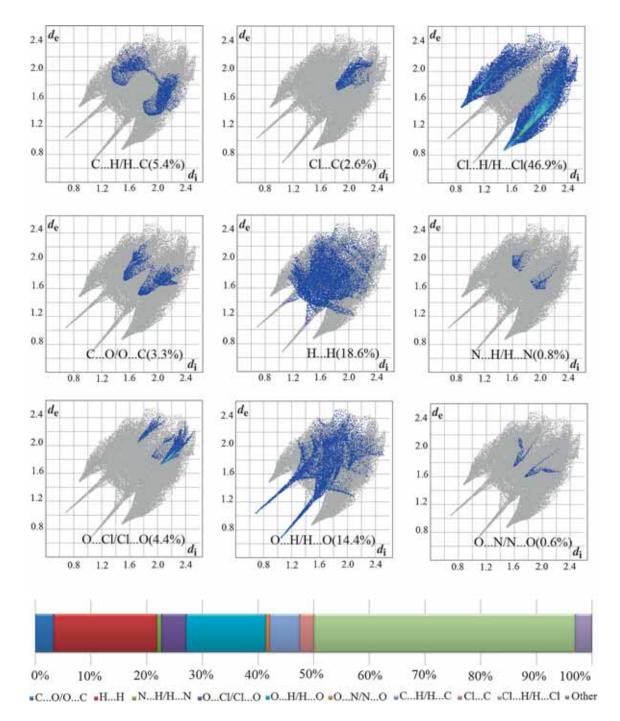

Figure 7. Relative contributions to the percentage of Hirshfeld surface area for the various intermolecular contacts in the title compounds.

are observed for the C...H/H...C (5.4%) and O...Cl/Cl...O (4.4%) contacts, with the last contact contribution corresponding largely to other interactions. The relative contribution of the different interactions to the Hirshfeld surface is presented in figure 7; the Cl...H/H...Cl interactions have the most participations in crystal structures.

3.3 Vibrational studies

To gain more information on the crystal structure, we have undertaken a vibrational study using infrared spectroscopy and Raman scattering. The FT-infrared and the FT-Raman spectra of the title compound are shown in figures 8 and 9,

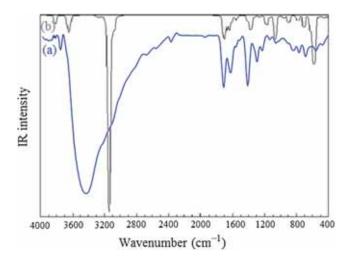

Figure 8. (a) Experimental and (b) simulated FT-IR spectra of the title compound in the region $400-4000 \text{ cm}^{-1}$ recorded at room temperature.

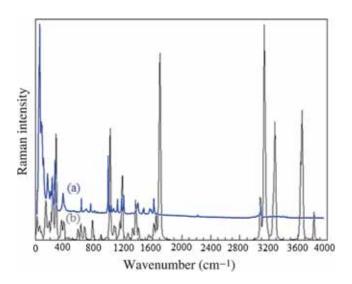

Figure 9. (a) Experimental and (b) simulated FT-Raman spectra of the title compound in the region $50-4000 \text{ cm}^{-1}$ recorded at room temperature.

respectively. Although a detailed assignment of all the bands is difficult, the most important attribution mode is realized by comparison with similar compounds [20,21]. The observed and computed wavenumbers and detailed assignments are summarized in table 6.

3.3a [*CuCl₄*] anion mode: The bands observed at 92 and 84 cm⁻¹ are assigned to Cl–Cu–Cl bending and the DFT calculations give this mode at 107 and 84 cm⁻¹. The Cl–Cu–Cl deformation mode is found at 145 and 116 cm⁻¹ and it is predicted at 154 and 130 cm⁻¹ according to DFT/B3LYP/LanL2DZ calculations. The observed large bands at 296 and 255 cm⁻¹ are assigned to the asymmetric and symmetric Cl–Cu–Cl stretching, respectively, and are predicted at 322 and 261 cm⁻¹ according to DFT/B3LYP/LanL2DZ calculations. It is obvious that the agreement between the observed and calculated frequencies is reasonable, showing that the DFT/B3LYP/LanL2DZ performed for the system presented in figure 1b has accurately modelled the system.

3.3b [H_2O] molecule mode: When the water molecule is in isolated state, it has the C2v symmetry and 3N-6 internal vibrations are presented where N = 3 is the number of atoms. The H₂O deformation mode is observed at 1595 cm⁻¹. This value will shift towards higher ones if at least one of the H atoms is involved in a hydrogen bond.

The bands, observed at 3450 cm⁻¹ and calculated at 3525 cm⁻¹ in FT-IR, are ascribed to stretching vibration of O–H. The asymmetric and symmetric stretching vibrations of H₂O group are not observed in the FT-IR and FT-Raman spectra but predicted at 3675 and 3502 cm⁻¹ according to DFT/B3LYP/LanL2DZ calculations, respectively.

3.3c $[C_6H_6NO_2]$ cation mode: In our present work, the C–H stretching vibrations are observed at 3113 cm⁻¹ as weak bands in Raman spectrum. The C–H ring stretching modes are found to be weak, which is due to the charge transfer between the hydrogen atoms and carbon atoms. The scaled vibrations by the B3LYP/LanL2DZ method predicted at 3163 cm⁻¹ show good agreement with recorded spectral data.

The weak bands at 1710 cm^{-1} in the infrared are assigned to the COOH bending modes. The corresponding vibrations in the FT-Raman spectrum appear at 1730 cm^{-1} . As seen from table 6, the calculated COOH vibration wavenumbers show good agreement with experimental data. Besides, the band located at 1620 and 1600 cm⁻¹ in the FT-IR and FT-Raman spectra, respectively, corresponds to the CH rocking; the corresponding calculated value is 1624 cm^{-1} .

The O–H stretching mode is located experimentally at 1060 cm^{-1} in infrared spectrum, at 1065 cm^{-1} in FT-Raman spectrum and predicted theoretically at 1069 cm^{-1} . Concerning the wavenumbers found between 770 and 782 cm⁻¹ in FT-IR and FT-Raman spectra, they are attributed to C–N–C

Table 6. Wavenumbers (cm^{-1}) and relative assignments of the observed and calculated bands in the FT-infrared and FT-Raman spectrum of $[C_6H_6NO_2]_2CuCl_4 \cdot H_2O$.

_	255	26	Cl–Cu–Cl symmetric stretching		
_	190	22	H ₂ O scissoring		
_	145-116	15-13	Cl–Cu–Cl deformation		
_	92-84	10-84	Cl–Cu–Cl bending		

deformation. Our DFT calculations give these modes at 777 cm^{-1} .

The bands in FT-IR spectrum and in FT-Raman spectrum, located at 680 and 650 cm⁻¹, respectively, are assigned to the mode stretching of C–H. The computed wavenumber is 680 cm⁻¹.

Finally, as table 6 shows, the experimental wavenumbers of the title compound are found to compare well with the data obtained by DFT/B3LYP/LanL2DZ method.

4. Conclusion

In summary, a novel organic–inorganic hybrid compound, $[C_6H_6NO_2]CuCl_4\cdot H_2O$, has been successfully synthesized at room temperature by slow evaporation. The structure consists of alternation of organic and inorganic layers. Hirshfeld surfaces display all of the intermolecular interactions within the crystal at once and are therefore ideal for analysing the crystal packing. The vibrational properties of this structure were studied by FT-infrared spectroscopy and FT-Raman scattering. The assignment of the vibrational bands was based on comparisons with vibrational mode frequencies of homologous compounds and theoretical vibrational mode calculated by DFT/B3LYP/LanL2DZ.

Acknowledgements

We would like to thank the members of units of common services, in particular Mr Tarek Gargouri, at the University of Sfax for their assistance in the measurements of X-ray diffraction. We are also thankful to Prof Hamadi Khemakhem for co-operating in the Raman spectroscopy measurement.

Electronic Supplementary Material

Crystallographic data for the title compound, have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication CCDC 1046854. Copies of these data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK (fax: +44(0)-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk).
