TABLES FOR THE TWO-SAMPLE MEDIAN TEST

ZBYNĚK ŠIDÁK

(Received April 4, 1975)

Summary. The paper contains tables for the non-parametric median test for two samples whose sizes m, n satisfy $3 \leqq m \leqq n$, $m + n \leqq 41$. We tabulate the probabilities of the upper tail of the distribution up to the point where 10% is exceeded for the first time.

Description of the test. Let us have two random samples $X_1, \ldots, X_m$ and $Y_1, \ldots, Y_n$ with densities f_1 and f_2, respectively, and suppose that the notation is chosen so that $m \leqq n$. Our aim is to test the hypothesis H_0 that f_1 and f_2 are identical but otherwise arbitrary against the alternatives of shift in location expressed by $f_1(x) = f(x - \Delta)$, $f_2(x) = f(x)$, where $\Delta > 0$, or $\Delta < 0$ (one-sided alternatives), or $\Delta \neq 0$ (two-sided alternative).

The median test is performed very easily. First, we pool both samples and find the median of this pooled sample. (Since we assume the existence of densities, with probability 1 all the sample values are distinct and the median is defined uniquely.) More formally, if we put $X_{m+1} = Y_1, \ldots, X_{m+n} = Y_n$, and if $X^{(1)} < X^{(2)} < \ldots < X^{(m+n)}$ are the values of the pooled sample $X_1, \ldots, X_m, X_{m+1}, \ldots, X_{m+n}$ arranged in the order of their magnitude, then the median is $X^{((m+n+1)/2)}$ for $m + n$ odd, and $\frac{1}{2}[X^{((m+n)/2)} + X^{((m+n)/2+1)}]$ for $m + n$ even. The test statistic S of our median test is then equal to the number of the values X_i, $i = 1, \ldots, m$, exceeding this median, increased in addition by 0·5 if and only if $m + n$ is odd and the median coincides with some value X_i, $i = 1, \ldots, m$.

In a concise mathematical formula, we can write $S = \sum_{i=1}^{m} a_{m+n}(R_i)$, where R_i is the rank of X_i in the pooled sample $X_1, \ldots, X_m, X_{m+1}, \ldots, X_{m+n}$, and the scores a_{m+n} are given by $a_{m+n}(j) = \frac{1}{2}[\operatorname{sign}(j - \frac{1}{2}(m + n + 1)) + 1]$ for $j = 1, \ldots, m + n$.

We may note that the median test is asymptotically optimum (in the class of all tests) for the above-mentioned two-sample problem of shift in location, if f is of the double-exponential type, i.e. if $f(x) = (2\sigma)^{-1} e^{-|x-\mu|/\sigma}$ (cf. Hájek-Šidák [1], Section III.1.1).

Description of the table. Table 1 should be read one double-column after the other, and we tabulate here the upper tails of the distribution of the statistic S, under H_0, for all pairs m, n such that $3 \leqq m \leqq n$, $m + n \leqq 41$. In each double-column, following the heading m, n, the left column shows possible critical values c_α of S, while the right column shows the corresponding one-sided significance levels $\alpha = 100P\{S \geqq c_\alpha\}$ (i.e. in per cents) rounded off to three decimal places. The tabulation begins by the largest c_α for which the corresponding α (rounded off to three decimal places) is $> 0{\cdot}000$, and continues with all possible consecutive values c_α of S until such c_α is reached for which the corresponding α exceeds for the first time 10.000%.

For the computation of Table 1 we used the formula

$$P\{S = k\} = \binom{[\frac{1}{2}(m + n)]}{[k]}\binom{[\frac{1}{2}(m + n)]}{[m - k]}\binom{m + n}{m}^{-1}$$

(where $[x]$ denotes the largest integer not exceeding x), valid for $k = 0, 1, \ldots, m$ whenever $m + n$ is even) and for $k = 0, \frac{1}{2}, \ldots, m - \frac{1}{2}, m$ whenever $m + n$ is odd. (Cf. Hájek-Šidák [1], Theorem IV. 2.1.a.) The present author is deeply indebted to M. Nosál for programming the computation.

It may be observed further, that the distribution (under H_0) of S is symmetric about its mean value $\mathsf{E}S = \frac{1}{2}m$, and its variance is

$$\operatorname{var} S = mn/[4(m + n - 1)] \quad \text{for} \quad m + n \quad \text{even},$$
$$= mn/[4(m + n)] \quad \text{for} \quad m + n \quad \text{odd}.$$

If we are testing H_0 against the one-sided alternative $\Delta > 0$ (i.e. f_1 is shifted to the right with respect to f_2), we use the critical region $\{S \geqq c_\alpha\}$ and the corresponding significance level is the tabulated α. If we are testing against $\Delta < 0$ (i.e. f_1 is shifted to the left), we use the critical region $\{S \leqq m - c_\alpha\}$ whose significance level is again α. If we are testing against the two-sided alternative $\Delta \neq 0$, we use the critical region $\{S \geqq c_\alpha \text{ or } S \leqq m - c_\alpha\}$ whose significance level is equal to 2α.

Example. Let one sample contain the values 81; 105; 33; 78; 126; 61; 88, the other sample the values 32; 83; 50; 59; 10; 45. For the application of our table we must have $m \leqq n$, therefore the latter sample must be denoted as $X_1, \ldots, X_6$, and the former sample as $Y_1, \ldots, Y_7$. The median of the pooled sample is 61. The number of the values X_i exceeding 61 is 1; $m + n$ is odd but the median is one of the values Y_j, so that we shall not add the number 0·5. Therefore $S = 1$. In Table 1 we find for $m = 6$, $n = 7$, $c_\alpha = 5{\cdot}0$ the one-sided significance level $\alpha = 2{\cdot}506\%$. If we are testing against the one-sided alternative $\Delta < 0$, we use the critical region $\{S \leqq 6 - 5\} = \{S \leqq 1\}$ so that H_0 may be rejected at the level $\alpha = 2{\cdot}506\%$. If we are testing against the two-sided alternative $\Delta \neq 0$, we use the critical region $\{S \geqq 5 \text{ or } S \leqq 1\}$ so that H_0 may be rejected at the level $2\alpha = 5{\cdot}012\%$.

Remark on asymptotic normality. For large sizes m, n we may use the normal approximation, since the standardized test statistic $(S - \mathsf{E}S)/(\mathsf{var}\ S)^{1/2}$ has (under H_0) asymptotically the standardized normal distribution whenever $m \to \infty$, $n \to \infty$ in an arbitrary manner (cf. Hájek-Šidák [1], Section III.1.1).

Remark on ties. In practice, equal observations sometimes occur in the samples. In this case, we may use e.g. the following "method of average scores" (cf. Hájek-Šidák [1], Section III.8.1). First, in each group of equal observations, the observations are arranged in some auxiliary ordering, and the median is then found as usually. The only trouble in calculating the value of S arises with the group of observations that are equal to the median; this group will be called the median group, and let it contain a values X_i, and b values Y_j. Further, in our auxiliary ordering, let the median group contain r values preceding the median, and s values exceeding the median.

If $m + n$ is even, the median group has $a + b = r + s$ values, and the average score in it is $(r \cdot 0 + s \cdot 1)/(r + s)$; hence S equals the number of X_i's larger than the median, plus $as/(r + s)$.

If $m + n$ is odd, the median group has $a + b = r + s + 1$ values, and the average score in it is $(r \cdot 0 + \frac{1}{2} + s \cdot 1)/(r + s + 1)$; hence S equals the number of X_i's larger than the median, plus $a(s + \frac{1}{2})/(r + s + 1)$.

If the median group does not contain too many observations, we can still use our Table 1 as an approximation.

Remark on related tests. Several closely related tests have been introduced in the past under the name "median test". E.g. many authors define the "median test" statistic S_0 simply as the number of X_i's larger than the median of the pooled sample (without possible adding $\frac{1}{2}$); however, the distribution of S_0 for $m + n$ odd is not symmetric. In the book [1] and in the present tables we have preferred the statistic S defined above, because the calculation of S is practically not more difficult than that of S_0 but S has two advantages: its distribution is always symmetric, and it offers, for $m + n$ odd, a richer choice of possible significance levels.

Still some other forms of the "median test" statistic have been employed, e.g. those arising from the expression of the problem as a 2×2 contingency table, or the statistic being equal to the number of X_i's exceeding the median of Y_j's (cf. Hájek-Šidák [1], Section III.1.1).

Souhrn

TABULKY PRO DVOUVÝBĚROVÝ MEDIÁNOVÝ TEST

ZBYNĚK ŠIDÁK

Pro neparametrický mediánový test pro dva výběry, jejichž rozsahy m, n splňují $3 \leqq m \leqq n$, $m + n \leqq 41$, se tabelují pravděpodobnosti horních konců rozložení až do bodu, kde je po prvé překročeno 10%.
