#### Abstract

In this paper, we prove that a real tensor is strictly semi-positive if and only if the corresponding tensor complementarity problem has a unique solution for any nonnegative vector and a real tensor is semi-positive if and only if the corresponding tensor complementarity problem has a unique solution for any positive vector. It is showed that a real symmetric tensor is a (strictly) semi-positive tensor if and only if it is (strictly) copositive.

Keywords Tensor complementarity • strictly semi-positive • strictly
copositive • unique solution

## 1 Introduction

It is well-known that the linear complementarity problem (LCP) is the firstorder optimality conditions of quadratic programming, which has wide applications in applied science and technology such as optimization and physical or economic equilibrium problems. By means of the linear complementarity problem, properties of (strictly) semi-monotone matrices were considered by Cottle and Dantzig [1], Eaves [2] and Karamardian [3], see also Han, Xiu and Qi [4], Facchinei and Pang [5] and Cottle, Pang and Stone [6].

Pang [7,8] and Gowda [9] presented that some relations between the solution of the LCP $(\mathbf{q}, A)$ and (strictly) semi-monotone. Cottle [10] showed that each completely Q-matrix is a strictly semi-monotone matrix. Eaves [2] gave an equivalent definition of strictly semi-monotone matrices using the linear complementarity problem. The concept of (strictly) copositive matrices is one of the most important concept in applied mathematics and graph theory, which was introduced by Motzkin [11] in 1952. In the literature, there are extensive discussions on such matrices [12-14].

The nonlinear complementarity problem has been systematically studied in the mid-1960s and has developed into a very fruitful discipline in the field of mathematical programming, that included a multitude of interesting connections to numerous disciplines and a widely important applications in engi-
neering and economics. The notion of the tensor complementarity problem, a special structured nonlinear complementarity problem, is used firstly by Song and Qi [15], and they studied the existence of solution for the tensor complementarity problem with some classes of structured tensors. In particular, they showed that the tensor complementarity problem with a nonnegative tensor has a solution if and only if all principal diagonal entries of such a tensor are positive. Che, Qi, Wei [16] showed the existence of solution for the tensor complementarity problem with symmetric positive definite tensors and copositive tensors. Luo, Qi, Xiu [17] studied the sparsest solutions to $Z$-tensor complementarity problems.

In this paper, we will study some relationships between the unique solution of the tensor complementarity problem and (strictly) semi-positive tensors. We will prove that a symmetric m-order n -dimensional tensor is (strictly) semipositive if and only if it is (strictly) copositive.

In Section 2, we will give some definitions and basic conclusions. We will show that all diagonal entries of a semi-positive tensor are nonnegative, and all diagonal entries of a strictly semi-positive tensor are positive.

In Section 3, we will prove that a real tensor is a semi-positive tensor if and only if the corresponding tensor complementarity problem has no nonzero vector solution for any positive vector and a real tensor is a strictly semi-positive tensor if and only if the corresponding tensor complementarity problem has no non-zero vector solution for any nonnegative vector. We show that a symmetric real tensor is semi-positive if and only if it is copositive and
a symmetric real tensor is a strictly semi-positive if and only if it is strictly copositive.

## 2 Preliminaries

Throughout this paper, we use small letters $x, y, v, \alpha, \cdots$, for scalars, small bold letters $\mathbf{x}, \mathbf{y}, \cdots$, for vectors, capital letters $A, B, \cdots$, for matrices, calligraphic letters $\mathcal{A}, \mathcal{B}, \cdots$, for tensors. All the tensors discussed in this paper are real. Let $I_{n}:=\{1,2, \cdots, n\}$, and $\mathbb{R}^{n}:=\left\{\left(x_{1}, x_{2}, \cdots, x_{n}\right)^{\top} ; x_{i} \in \mathbb{R}, i \in I_{n}\right\}$, $\mathbb{R}_{+}^{n}:=\left\{x \in \mathbb{R}^{n} ; x \geq \mathbf{0}\right\}, \mathbb{R}_{-}^{n}:=\left\{\mathbf{x} \in \mathbb{R}^{n} ; x \leq \mathbf{0}\right\}, \mathbb{R}_{++}^{n}:=\left\{\mathbf{x} \in \mathbb{R}^{n} ; x>\mathbf{0}\right\}$, where $\mathbb{R}$ is the set of real numbers, $\mathbf{x}^{\top}$ is the transposition of a vector $\mathbf{x}$, and $\mathbf{x} \geq \mathbf{0}(\mathbf{x}>\mathbf{0})$ means $x_{i} \geq 0\left(x_{i}>0\right)$ for all $i \in I_{n}$.

Let $A=\left(a_{i j}\right)$ be an $n \times n$ real matrix. The linear complementarity problem, denoted by LCP $(\mathbf{q}, A)$, is to find $\mathbf{z} \in \mathbb{R}^{n}$ such that

$$
\begin{equation*}
\mathbf{z} \geq \mathbf{0}, \mathbf{q}+A \mathbf{z} \geq \mathbf{0}, \text { and } \mathbf{z}^{\top}(\mathbf{q}+A \mathbf{z})=0 \tag{1}
\end{equation*}
$$

or to show that no such vector exists. A real matrix $A$ is said to be
(i) semi-monotone (or semi-positive) iff for each $\mathbf{x} \geq 0$ and $\mathbf{x} \neq \mathbf{0}$, there exists an index $k \in I_{n}$ such that $x_{k}>0$ and $(A \mathbf{x})_{k} \geq 0$;
(ii) strictly semi-monotone (or strictly semi-positive) iff for each $\mathbf{x} \geq \mathbf{0}$ and $\mathbf{x} \neq \mathbf{0}$, there exists an index $k \in I_{n}$ such that $x_{k}>0$ and $(A \mathbf{x})_{k}>0$;
(iii) copositive iff $\mathbf{x}^{\top} A \mathbf{x} \geq 0$ for all $\mathbf{x} \in \mathbb{R}_{+}^{n}$;
(iv) strictly copositive iff $\mathbf{x}^{\top} A \mathbf{x}>0$ for all $\mathbf{x} \in \mathbb{R}_{+}^{n} \backslash\{\mathbf{0}\}$;
(v) $\mathbf{Q}$-matrix iff $\operatorname{LCP}(A, \mathbf{q})$ has a solution for all $\mathbf{q} \in \mathbb{R}^{n}$;
(vi) completely Q-matrix iff $A$ and all its principal sub-matrices are Q matrices.

In 2005, Qi [18] introduced the concept of positive (semi-)definite symmetric tensors. A real $m$ th order $n$-dimensional tensor (hypermatrix) $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right)$ is a multi-array of real entries $a_{i_{1} \cdots i_{m}}$, where $i_{j} \in I_{n}$ for $j \in I_{m}$. Denote the set of all real $m$ th order $n$-dimensional tensors by $T_{m, n}$. Then $T_{m, n}$ is a linear space of dimension $n^{m}$. Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$. If the entries $a_{i_{1} \cdots i_{m}}$ are invariant under any permutation of their indices, then $\mathcal{A}$ is called a symmetric tensor. Denote the set of all real $m$ th order $n$-dimensional symmetric tensors by $S_{m, n}$. Then $S_{m, n}$ is a linear subspace of $T_{m, n}$. We denote the zero tensor in $T_{m, n}$ by $\mathcal{O}$. Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$ and $\mathbf{x} \in \mathbb{R}^{n}$. Then $\mathcal{A} \mathbf{x}^{m-1}$ is a vector in $\mathbb{R}^{n}$ with its $i$ th component as

$$
\left(\mathcal{A} \mathbf{x}^{m-1}\right)_{i}:=\sum_{i_{2}, \cdots, i_{m}=1}^{n} a_{i i_{2} \cdots i_{m}} x_{i_{2}} \cdots x_{i_{m}}
$$

for $i \in I_{n}$. Then $\mathcal{A} \mathbf{x}^{m}$ is a homogeneous polynomial of degree $m$, defined by

$$
\mathcal{A} \mathbf{x}^{m}:=\mathbf{x}^{\top}\left(\mathcal{A} \mathbf{x}^{m-1}\right)=\sum_{i_{1}, \cdots, i_{m}=1}^{n} a_{i_{1} \cdots i_{m}} x_{i_{1}} \cdots x_{i_{m}}
$$

A tensor $\mathcal{A} \in T_{m, n}$ is called positive semi-definite if for any vector $\mathbf{x} \in \mathbb{R}^{n}$, $\mathcal{A} \mathbf{x}^{m} \geq 0$, and is called positive definite if for any nonzero vector $\mathbf{x} \in \mathbb{R}^{n}$, $\mathcal{A} \mathbf{x}^{m}>0$. Recently, miscellaneous structured tensors are widely studied, for example, Zhang, Qi and Zhou [19] and Ding, Qi and Wei [20] for M-tensors, Song and Qi [21] for $\mathrm{P}-\left(\mathrm{P}_{0}\right)$ tensors and $\mathrm{B}-\left(\mathrm{B}_{0}\right)$ tensors, Qi and Song [22] for B- $\left(\mathrm{B}_{0}\right)$ tensors, Song and Qi [23] for infinite and finite dimensional Hilbert
tensors, Song and Qi [24] for E-eigenvalues of weakly symmetric nonnegative tensors and so on.

Recently, Song and Qi [15] extended the concepts of (strictly) semi-positive matrices and the linear complementarity problem to (strictly) semi-positive tensors and the tensor complementarity problem, respectively. Moreover, some nice properties of those concepts were obtained.

Definition 2.1 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$. The tensor complementarity problem, denoted by $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$, is to find $\mathbf{x} \in \mathbb{R}^{n}$ such that

$$
\begin{equation*}
\mathbf{x} \geq \mathbf{0}, \mathbf{q}+\mathcal{A} \mathbf{x}^{m-1} \geq \mathbf{0}, \text { and } \mathbf{x}^{\top}\left(\mathbf{q}+\mathcal{A} \mathbf{x}^{m-1}\right)=0 \tag{2}
\end{equation*}
$$

or to show that no such vector exists.

Clearly, the tensor complementarity problem is the first-order optimality conditions of the homogeneous polynomial optimization problem, which may be referred to as a direct and natural extension of the linear complementarity problem. The tensor complementarity problem $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$ is a specially structured nonlinear complementarity problem, and so, the $\mathrm{TCP}(\mathbf{q}, \mathcal{A})$ has its particular and nice properties other than ones of the classical nonlinear complementarity problem.

Definition 2.2 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n} . \mathcal{A}$ is said to be
(i) semi-positive iff for each $\mathbf{x} \geq 0$ and $\mathbf{x} \neq \mathbf{0}$, there exists an index $k \in I_{n}$ such that

$$
x_{k}>0 \text { and }\left(\mathcal{A} \mathbf{x}^{m-1}\right)_{k} \geq 0
$$

(ii) strictly semi-positive iff for each $\mathbf{x} \geq \mathbf{0}$ and $\mathbf{x} \neq \mathbf{0}$, there exists an index $k \in I_{n}$ such that

$$
x_{k}>0 \text { and }\left(\mathcal{A} \mathbf{x}^{m-1}\right)_{k}>0
$$

(iii) $\mathbf{Q}$-tensor iff the $T C P(\mathbf{q}, \mathcal{A})$ has a solution for all $\mathbf{q} \in \mathbb{R}^{n}$.

Lemma 2.1 (Song and Qi [15, Corollary 3.3, Theorem 3.4]) Each strictly semi-positive tensor must be a Q-tensor.

Proposition 2.1 Let $\mathcal{A} \in T_{m, n}$. Then
(i) $a_{i i \cdots i} \geq 0$ for all $i \in I_{n}$ if $\mathcal{A}$ is semi-positive;
(ii) $a_{i i \cdots i}>0$ for all $i \in I_{n}$ if $\mathcal{A}$ is strictly semi-positive;
(iii) there exists $k \in I_{n}$ such that $\sum_{i_{2}, \cdots, i_{m}=1}^{n} a_{k i_{2} \cdots i_{m}} \geq 0$ if $\mathcal{A}$ is semi-positive;
(iv) there exists $k \in I_{n}$ such that $\sum_{i_{2}, \cdots, i_{m}=1}^{\substack{i_{2}, \cdots, i_{m}=1 \\ n}} a_{k i_{2} \cdots i_{m}}>0$ if $\mathcal{A}$ is strictly semipositive.

Proof It follows from Definition 2.2 that we can obtain (i) and (ii) by taking

$$
\mathbf{x}^{(i)}=(0, \cdots, 1, \cdots, 0)^{\top}, i \in I_{n}
$$

where 1 is the ith component $x_{i}$. Similarly, choose $\mathbf{x}=\mathbf{e}=(1,1, \cdots, 1)^{\top}$, then we obtain (iii) and (vi) by Definition 2.2.

Definition 2.3 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n} . \mathcal{A}$ is said to be
(i) copositive if $\mathcal{A} \mathbf{x}^{m} \geq 0$ for all $\mathbf{x} \in \mathbb{R}_{+}^{n}$;
(ii) strictly copositive if $\mathcal{A} \mathbf{x}^{m}>0$ for all $\mathbf{x} \in \mathbb{R}_{+}^{n} \backslash\{\mathbf{0}\}$.

The concept of (strictly) copositive tensors was first introduced and used by Qi in [25]. Song and Qi [26] showed their equivalent definition and some special structures. The following lemma is one of the structure conclusions of (strictly) copositive tensors in [26].

Lemma 2.2 ([26, Proposition 3.1]) Let $\mathcal{A}$ be a symmetric tensor of order $m$ and dimension $n$. Then
(i) $\mathcal{A}$ is copositive if and only if $\mathcal{A} x^{m} \geq 0$ for all $x \in \mathbb{R}_{+}^{n}$ with $\|x\|=1$;
(ii) $\mathcal{A}$ is strictly copositive if and only if $\mathcal{A} x^{m}>0$ for all $x \in \mathbb{R}_{+}^{n}$ with $\|x\|=1$.

Definition 2.4 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$. In homogeneous polynomial $\mathcal{A} \mathbf{x}^{m}$, if we let some (but not all) $x_{i}$ be zero, then we have a less variable homogeneous polynomial, which defines a lower dimensional tensor. We call such a lower dimensional tensor a principal sub-tensor of $\mathcal{A}$, i.e., an $m$-order $r$-dimensional principal sub-tensor $\mathcal{B}$ of an $m$-order $n$-dimensional tensor $\mathcal{A}$ consists of $r^{m}$ entries in $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right)$ : for any set $\mathcal{N}$ that composed of $r$ elements in $\{1,2, \cdots, n\}$,

$$
\mathcal{B}=\left(a_{i_{1} \cdots i_{m}}\right), \text { for all } i_{1}, i_{2}, \cdots, i_{m} \in \mathcal{N}
$$

The concept were first introduced and used by Qi [18] to the higher order symmetric tensor. It follows from Definition 2.2 that the following Proposition is obvious.

Proposition 2.2 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$. Then
(i) each principal sub-tensor of a semi-positive tensor is semi-positive;
(ii) each principal sub-tensor of a strictly semi-positive tensor is strictly semipositive.

Let $N \subset I_{n}=\{1,2, \cdots, n\}$. We denote the principal sub-tensor of $\mathcal{A}$ by $\mathcal{A}^{|N|}$, where $|N|$ is the cardinality of $N$. So, $\mathcal{A}^{|N|}$ is a tensor of order $m$ and dimension $|N|$ and the principal sub-tensor $\mathcal{A}^{|N|}$ is just $\mathcal{A}$ itself when $N=I_{n}=\{1,2, \cdots, n\}$.

## 3 Main results

In this section, we will prove that a real tensor $\mathcal{A}$ is a (strictly) semi-positive tensor if and only if the tensor complementarity $\operatorname{problem}(\mathbf{q}, \mathcal{A})$ has a unique solution for $\mathbf{q}>\mathbf{0}(\mathbf{q} \geq \mathbf{0})$.

Theorem 3.1 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$. The following statements are equivalent:
(i) $\mathcal{A}$ is semi-positive.
(ii) The $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$ has a unique solution for every $\mathbf{q}>\mathbf{0}$.
(iii) For every index set $N \subset I_{n}$, the system

$$
\begin{equation*}
\mathcal{A}^{|N|}\left(\mathbf{x}^{N}\right)^{m-1}<\mathbf{0}, \mathbf{x}^{N} \geq \mathbf{0} \tag{3}
\end{equation*}
$$

has no solution, where $\mathbf{x}^{N} \in \mathbb{R}^{|N|}$.

Proof (i) $\Rightarrow$ (ii). Since $\mathbf{q}>\mathbf{0}$, it is obvious that $\mathbf{0}$ is a solution of TCP $(\mathbf{q}, \mathcal{A})$. Suppose that there exists a vector $\mathbf{q}^{\prime}>\mathbf{0}$ such that $\operatorname{TCP}\left(\mathbf{q}^{\prime}, \mathcal{A}\right)$ has non-zero vector solution $\mathbf{x}$. Since $\mathcal{A}$ is semi-positive, there is an index $k \in I_{n}$ such that

$$
x_{k}>0 \text { and }\left(\mathcal{A} \mathbf{x}^{m-1}\right)_{k} \geq 0
$$

Then $q_{k}^{\prime}+\left(\mathcal{A} \mathrm{x}^{m-1}\right)_{k}>0$, and so

$$
\mathbf{x}^{\top}\left(\mathbf{q}^{\prime}+\mathcal{A} \mathbf{x}^{m-1}\right)>0
$$

This contradicts the assumption that $\mathbf{x}$ solves $\operatorname{TCP}\left(\mathbf{q}^{\prime}, \mathcal{A}\right)$. So the $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$ has a unique solution $\mathbf{0}$ for every $\mathbf{q}>\mathbf{0}$.
(ii) $\Rightarrow$ (iii). Suppose that there is an index set $N$ such that the system (3) has a solution $\overline{\mathbf{x}}^{N}$. Clearly, $\overline{\mathbf{x}}^{N} \neq \mathbf{0}$. Let $\overline{\mathbf{x}}=\left(\bar{x}_{1}, \bar{x}_{2}, \cdots, \bar{x}_{n}\right)^{\top}$ with

$$
\bar{x}_{i}=\left\{\begin{array}{l}
\overline{\mathbf{x}}_{i}^{N}, i \in N \\
0, \quad i \in I_{n} \backslash N .
\end{array}\right.
$$

Choose $\mathbf{q}=\left(q_{1}, q_{2}, \cdots, q_{n}\right)^{\top}$ with

$$
\left\{\begin{array}{l}
q_{i}=-\left(\mathcal{A}^{|N|}\left(\overline{\mathbf{x}}^{N}\right)^{m-1}\right)_{i}=-\left(\mathcal{A} \overline{\mathbf{x}}^{m-1}\right)_{i}, i \in N \\
q_{i}>\max \left\{0,-\left(\mathcal{A} \overline{\mathbf{x}}^{m-1}\right)_{i}\right\} \quad i \in I_{n} \backslash N
\end{array}\right.
$$

So, $\mathbf{q}>\mathbf{0}$ and $\overline{\mathbf{x}} \neq \mathbf{0}$. Then $\overline{\mathbf{x}}$ solves the $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$. This contradicts (ii).
(iii) $\Rightarrow$ (i). For each $\mathbf{x} \in \mathbb{R}_{+}^{n}$ and $\mathbf{x} \neq \mathbf{0}$, we may assume that $\mathbf{x}=$ $\left(x_{1}, x_{2}, \cdots, x_{n}\right)^{\top}$ with for some $N \subset I_{n}$,

$$
\left\{\begin{array}{l}
x_{i}>0, i \in N \\
x_{i}=0, i \in I_{n} \backslash N
\end{array}\right.
$$

Since the system (3) has no solution, there exists an index $k \in N \subset I_{n}$ such that

$$
x_{k}>0 \text { and }\left(\mathcal{A} \mathrm{x}^{m-1}\right)_{k} \geq 0
$$

and hence $\mathcal{A}$ is semi-positive.
Using the same proof as that of Theorem 3.1 with appropriate changes in the inequalities. We can obtain the following conclusions about the strictly semi-positive tensor.

Theorem 3.2 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in T_{m, n}$. The following statements are equivalent:
(i) $\mathcal{A}$ is strictly semi-positive.
(ii) The $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$ has a unique solution for every $\mathbf{q} \geq \mathbf{0}$.
(iii) For every index set $N \subset I_{n}$, the system

$$
\begin{equation*}
\mathcal{A}^{|N|}\left(\mathbf{x}^{N}\right)^{m-1} \leq \mathbf{0}, \quad \mathbf{x}^{N} \geq \mathbf{0}, \quad \mathbf{x}^{N} \neq \mathbf{0} \tag{4}
\end{equation*}
$$

has no solution.

Now we give the following main results by means of the concept of principal sub-tensor.

Theorem 3.3 Let $\mathcal{A}$ be a symmetric tensor of order $m$ and dimension $n$. Then $\mathcal{A}$ is semi-positive if and only if it copositive.

Proof If $\mathcal{A}$ is copositive, then

$$
\begin{equation*}
\mathcal{A} \mathbf{x}^{m}=\mathbf{x}^{\top} \mathcal{A} \mathbf{x}^{m-1} \geq 0 \text { for all } \mathbf{x} \in \mathbb{R}_{+}^{n} . \tag{5}
\end{equation*}
$$

So $\mathcal{A}$ must be semi-positive. In fact, suppose not. Then there is a vector $\mathbf{x} \in \mathbb{R}^{n}$ such that for all $k \in I_{n}$

$$
\left(\mathcal{A} \mathbf{x}^{m-1}\right)_{k}<0 \text { when } x_{k}>0 .
$$

Then we have

$$
\mathcal{A} \mathbf{x}^{m}=\mathbf{x}^{\top} \mathcal{A} \mathbf{x}^{m-1}=\sum_{k=1}^{n} x_{k}\left(\mathcal{A} \mathbf{x}^{m-1}\right)_{k}<0
$$

which contradicts (5).

Now we show the necessity. Let

$$
S=\left\{\mathbf{x} \in \mathbb{R}_{+}^{n} ; \sum_{i=1}^{n} x_{i}=1\right\} \text { and } F(\mathbf{x})=\mathcal{A} \mathbf{x}^{m}=\mathbf{x}^{\top} \mathcal{A} \mathbf{x}^{m-1}
$$

Obviously, $F: S \rightarrow \mathbb{R}$ is continuous on the set $S$. Then there exists $\tilde{\mathbf{y}} \in S$ such that

$$
\begin{equation*}
\mathcal{A} \tilde{\mathbf{y}}^{m}=\tilde{\mathbf{y}}^{\top} \mathcal{A} \tilde{\mathbf{y}}^{m-1}=F(\tilde{\mathbf{y}})=\min _{\mathbf{x} \in S} F(\mathbf{x})=\min _{\mathbf{x} \in S} \mathbf{x}^{\top} \mathcal{A} \mathbf{x}^{m-1}=\min _{\mathbf{x} \in S} \mathcal{A} \mathbf{x}^{m} \tag{6}
\end{equation*}
$$

Since $\tilde{\mathbf{y}} \geq 0$ with $\tilde{\mathbf{y}} \neq 0$, we may assume that

$$
\tilde{\mathbf{y}}=\left(\tilde{y}_{1}, \tilde{y}_{2}, \cdots, \tilde{y}_{l}, 0, \cdots, 0\right)^{T}\left(\tilde{y}_{i}>0 \text { for } i=1, \cdots, l, 1 \leq l \leq n\right) .
$$

Let $\tilde{\mathbf{w}}=\left(\tilde{y}_{1}, \tilde{y}_{2}, \cdots, \tilde{y}_{l}\right)^{T}$ and let $\mathcal{B}$ be a principal sub-tensor that obtained from $\mathcal{A}$ by the polynomial $\mathcal{A} x^{m}$ for $\mathbf{x}=\left(x_{1}, x_{2}, \cdots, x_{l}, 0, \cdots, 0\right)^{T}$. Then

$$
\begin{equation*}
\tilde{\mathbf{w}} \in \mathbb{R}_{++}^{l}, \sum_{i=1}^{l} \tilde{y}_{i}=1 \text { and } F(\tilde{\mathbf{y}})=\mathcal{A} \tilde{\mathbf{y}}^{m}=\mathcal{B} \tilde{\mathbf{w}}^{m}=\min _{\mathbf{x} \in S} \mathcal{A} \mathbf{x}^{m} \tag{7}
\end{equation*}
$$

Let $\mathbf{x}=\left(z_{1}, z_{2}, \cdots, z_{l}, 0, \cdots, 0\right)^{T} \in \mathbb{R}_{+}^{n}$ for all $\mathbf{z}=\left(z_{1}, z_{2}, \cdots, z_{l}\right)^{T} \in \mathbb{R}_{+}^{l}$ with $\sum_{i=1}^{l} z_{i}=1$. Clearly, $\mathbf{x} \in S$, and hence, by (7), we have

$$
F(x)=\mathcal{A} \mathbf{x}^{m}=\mathcal{B} \mathbf{z}^{m} \geq F(\tilde{\mathbf{y}})=\mathcal{A} \tilde{\mathbf{y}}^{m}=\mathcal{B} \tilde{\mathbf{w}}^{m}
$$

Since $\tilde{\mathbf{w}} \in \mathbb{R}_{++}^{l}, \tilde{\mathbf{w}}$ is a local minimizer of the following optimization problem

$$
\min _{\mathbf{z} \in \mathbb{R}^{l}} \mathcal{B} \mathbf{z}^{m} \text { s.t. } \sum_{i=1}^{l} z_{i}=1 .
$$

So, the standard KKT conditions implies that there exists $\mu \in \mathbb{R}$ such that

$$
\left.\nabla\left(\mathcal{B} \mathbf{z}^{m}-\mu\left(\sum_{i=1}^{l} z_{i}-1\right)\right)\right|_{\mathbf{z}=\tilde{\mathbf{w}}}=m \mathcal{B} \tilde{\mathbf{w}}^{m-1}-\mu \mathbf{e}=0
$$

where $\mathbf{e}=(1,1, \cdots, 1)^{\top}$, and hence

$$
\mathcal{B} \tilde{\mathbf{w}}^{m-1}=\frac{\mu}{m} \mathbf{e}
$$

Let $\lambda=\frac{\mu}{m}$. Then

$$
\mathcal{B} \tilde{\mathbf{w}}^{m-1}=(\lambda, \lambda, \cdots, \lambda)^{\top} \in \mathbb{R}^{l}
$$

and so

$$
\mathcal{B} \tilde{\mathbf{w}}^{m}=\tilde{\mathbf{w}}^{\top} \mathcal{B} \tilde{\mathbf{w}}^{m-1}=\lambda \sum_{i=1}^{l} \tilde{y}_{i}=\lambda .
$$

It follows from (7) that

$$
\mathcal{A} \tilde{\mathbf{y}}^{m}=\tilde{\mathbf{y}}^{\top} \mathcal{A} \tilde{\mathbf{y}}^{m-1}=\mathcal{B} \tilde{\mathbf{w}}^{m}=\min _{\mathbf{x} \in S} \mathcal{A} \mathbf{x}^{m}=\lambda
$$

Thus, for all $\tilde{y}_{k}>0$, we have

$$
\left(\mathcal{A} \tilde{\mathbf{y}}^{m-1}\right)_{k}=\left(\mathcal{B} \tilde{\mathbf{w}}^{m-1}\right)_{k}=\lambda
$$

Since $\mathcal{A}$ is semi-positive, for $\tilde{\mathbf{y}} \geq \mathbf{0}$ and $\tilde{\mathbf{y}} \neq \mathbf{0}$, there exists an index $k \in I_{n}$ such that

$$
\tilde{\mathbf{y}}_{k}>0 \text { and }\left(\mathcal{A} \tilde{\mathbf{y}}^{m-1}\right)_{k} \geq 0
$$

and hence, $\lambda \geq 0$. Consequently, we have

$$
\min _{\mathbf{x} \in S} \mathcal{A} \mathbf{x}^{m}=\mathcal{A} \tilde{\mathbf{y}}^{m}=\lambda \geq 0
$$

It follows from Lemma 2.2 that $\mathcal{A}$ is copositive. The theorem is proved.

Using the same proof as that of Theorem 3.3 with appropriate changes in the inequalities, we can obtain the following conclusions about the strictly copositive tensor.

Theorem 3.4 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in S_{m, n}$. Then $\mathcal{A}$ is strictly semi-positive if and only if it is strictly copositive.

By Lemma 2.1 and Theorem 3.4, the following conclusion is obvious.

Corollary 3.1 Let $\mathcal{A}=\left(a_{i_{1} \cdots i_{m}}\right) \in S_{m, n}$ be strictly copositive. Then the tensor complementarity problem $\operatorname{TCP}(\mathbf{q}, \mathcal{A})$,
finding $\mathbf{x} \in \mathbb{R}^{n}$ such that $\mathbf{x} \geq \mathbf{0}, \mathbf{q}+\mathcal{A} \mathbf{x}^{m-1} \geq \mathbf{0}$, and $\mathbf{x}^{\top}\left(\mathbf{q}+\mathcal{A} \mathbf{x}^{m-1}\right)=0$ has a solution for all $\mathbf{q} \in \mathbb{R}^{n}$.

## 4 Perspectives

There are more research topics on the tensor complementarity problem for further research.

It is known that there are many efficient algorithms for computing a solution of (non-) linear complementarity problem. Then, whether or not may these algorithms be applied to tensor complementarity problem? If not, can one construct an efficient algorithm to compute the solution of the tensor complementarity problem with a special structured tensor?

A real m-order n-dimensional tensor is said to be completely Q-tensor iff it and all its principal sub-tensors are Q-tensors. Clearly, each strictly semi-
positive tensor must be a completely Q-tensor. Naturally, we would like to ask whether each completely Q-tensor is strictly semi-positive or not.

## 5 Conclusions

In this paper, we discuss some relationships between the unique solution of the tensor complementarity problem and (strictly) semi-positive tensors. Furthermore, we establish the equivalence between (strictly) symmetric semi-positive tensors and (strictly) copositive tensors.
