The \mathcal{A} -hypergeometric System

Associated with a Monomial Curve

Eduardo Cattani, Carlos D'Andrea, and Alicia Dickenstein

Introduction

In this paper we make a detailed analysis of the \mathcal{A} -hypergeometric system (or GKZ system) associated with a monomial curve and integral, hence resonant, exponents. We describe all rational solutions and show in Theorem 1.10 that they are, in fact, Laurent polynomials. We also show that for any exponent, there are at most two linearly independent Laurent solutions, and that the upper bound is reached if and only if the curve is not arithmetically Cohen–Macaulay. We then construct, for all integral parameters, a basis of local solutions in terms of the roots of the generic univariate polynomial (0.5) associated with \mathcal{A} . We also determine in Theorem 3.7 the holonomic rank $r(\alpha)$ for all $\alpha \in \mathbb{Z}^2$ and show that $d \leq r(\alpha) \leq d + 1$, where d is the degree of the curve. Moreover, the value $d + 1$ is attained only for those exponents α for which there are two linearly independent rational solutions and, therefore, $r(\alpha) = d$ for all α if and only if the curve is arithmetically Cohen-Macaulay.

In order to place these results in their appropriate context, we recall the definition of the \mathcal{A} -hypergeometric systems. These were introduced in a series of papers in the mid 1980's by the Gel'fand school, particularly Gel'fand, Kapranov, and Zelevinsky (see [7, 9], and the references therein). Let $\mathcal{A} = \{\nu_1, \dots, \nu_r\} \subset \mathbb{Z}^{n+1}$ be a finite subset which spans the lattice \mathbb{Z}^{n+1} . Suppose, moreover, that there exists a vector $\lambda = (\lambda_0, \dots, \lambda_n) \in \mathbb{Q}^{n+1}$ such that $\langle \lambda, \nu_j \rangle = 1$ for all $j = 1, \dots, r$, i.e. the set \mathcal{A} lies in a rational hyperplane. Let \mathcal{A} also denote the $(n + 1) \times r$ matrix whose columns are the vectors ν_j . Let $\mathcal{L} \subset \mathbb{Z}^r$ be the sublattice of elements $v \in \mathbb{Z}^r$ such that $\mathcal{A} \cdot v = 0$. Given $\alpha \in \mathbb{C}^{n+1}$, the *\mathcal{A} -hypergeometric system with exponent (or parameter) α* is:

$$\mathcal{D}_v \varphi = 0 \quad ; \quad v \in \mathcal{L} \tag{0.1}$$

$$\sum_{j=1}^r \nu_{ji} x_j \frac{\partial \varphi}{\partial x_j} = \alpha_i \varphi \quad ; \quad i = 1, \dots, n + 1 \tag{0.2}$$

where \mathcal{D}_v is the differential operator in \mathbb{C}^r :

$$\mathcal{D}_v := \prod_{v_j > 0} \left(\frac{\partial}{\partial x_j} \right)^{v_j} - \prod_{v_k < 0} \left(\frac{\partial}{\partial x_k} \right)^{-v_k} .$$

1991 AMS Subject Classification: Primary 33C70, Secondary 14M05, 33D20.

The \mathcal{A} -hypergeometric system is holonomic (with regular singularities) and, consequently, the number of linearly independent solutions at a generic point is finite [7]. Let $r(\alpha)$ denote the holonomic rank of the system, i.e. the dimension of the space of local solutions at a generic point in \mathbb{C}^r . If we drop the assumption that \mathcal{A} lies in a hyperplane, then the regular singularities property is lost but, as Adolphson [2] has shown, the system remains holonomic. The singular locus is described by the zeroes of the principal \mathcal{A} -determinant ([11]). We set $R := \mathbb{C}[\xi_1, \dots, \xi_r]/\mathcal{I}_{\mathcal{A}}$, where $\mathcal{I}_{\mathcal{A}}$ is the toric ideal

$$\mathcal{I}_{\mathcal{A}} := \langle \xi^u - \xi^v : u, v \in \mathbb{N}^r; \mathcal{A} \cdot u = \mathcal{A} \cdot v \rangle. \quad (0.3)$$

When $n = 1$, we can assume without loss of generality that

$$\mathcal{A} = \begin{pmatrix} 1 & 1 & \cdots & 1 & 1 \\ 0 & k_1 & \cdots & k_m & d \end{pmatrix}, \quad (0.4)$$

where $0 < k_1 < \cdots < k_m < d$. Note that the condition that the columns of \mathcal{A} generate the lattice \mathbb{Z}^2 is equivalent to $\gcd(k_1, \dots, k_m, d) = 1$. The homogeneous ideal $\mathcal{I}_{\mathcal{A}}$ defines a monomial curve $X_{\mathcal{A}} \subset \mathbb{P}^{m+1}$ of degree d whose homogeneous coordinate ring is R . $X_{\mathcal{A}}$ is *normal* if and only if $d = m + 1$. Recall that $X_{\mathcal{A}}$ is said to be arithmetically Cohen-Macaulay if and only if the ring R is Cohen-Macaulay.

The system associated with (0.4) admits very interesting solutions. Let

$$f(x; t) := x_0 + x_{k_1} t^{k_1} + \cdots + x_{k_m} t^{k_m} + x_d t^d, \quad (0.5)$$

denote the generic polynomial with exponents $0, k_1, \dots, k_m, d$. It is not hard to see that the powers $\rho^s(x)$, $s \in \mathbb{Z}$, of the roots of $f(x; t)$, viewed as functions of the coefficients, are algebraic solutions of the \mathcal{A} -hypergeometric system with exponent $(0, -s)$. This fact was observed by Mayr [17] who constructed series expansions for these functions. These have more recently been refined by Sturmfels [22]. The total sum

$$p_s(x) := \rho_1^s(x) + \cdots + \rho_d^s(x) \quad (0.6)$$

will then be a rational solution with the same exponent. Similarly, one can show that the local residues

$$\operatorname{Res}_{\rho(x)} \left(\frac{t^b}{f^a(x; t)} \frac{dt}{t} \right); \quad a, b \in \mathbb{Z}, \quad a \geq 1 \quad (0.7)$$

give algebraic solutions with exponent $(-a, -b)$ and, again, the total sum of residues will be a rational solution.

In §1 we describe explicitly all rational solutions of the \mathcal{A} -hypergeometric system associated with a monomial curve. Since for \mathcal{A} as in (0.4), the principal \mathcal{A} -determinant factors into powers of x_0 , x_d , and the discriminant $\Delta(f)$, we know a priori what the possible denominators of a rational solution may be. However, we show in Theorem 1.10 that there are no rational solutions whose denominator involves $\Delta(f)$ and therefore, every rational solution must be a Laurent polynomial. This is a somewhat surprising result which is peculiar to the case $n = 1$ (see Example 1.11). One may give explicit formulas for these

Laurent polynomials in terms of hypergeometric polynomials in fewer variables. When applied to the sum of powers of roots one recovers the classical Girard formulas. One also obtains similar expressions for total residues in terms of hypergeometric polynomials.

We show that for any $\alpha \in \mathbb{Z}^2$ the dimension of the space of rational \mathcal{A} -hypergeometric functions with parameter α is at most 2. Moreover, the value 2 may be reached for only finitely many values of α and this happens if and only if the ring R is not Cohen-Macaulay.

In §2 we exhibit a family of algebraic \mathcal{A} -hypergeometric functions defined in terms of the roots of the polynomial $f(x; t)$. These are the building blocks for the construction, in §3, of local bases of solutions and the determination of the holonomic rank for all integral exponents. It becomes necessary to consider four possibilities for the exponent α . These cases admit combinatorial descriptions (see (1.9)) and correspond to the existence of a polynomial solution; a one-dimensional space of rational -non-polynomial- solutions; a two-dimensional space of rational solutions; or no rational solution for the given exponent. For $u \in \mathbb{N}^{m+2}$, the derivative D_u maps \mathcal{A} -hypergeometric functions to \mathcal{A} -hypergeometric functions while changing the exponent from α to $\alpha - \mathcal{A} \cdot u$. A careful analysis of the kernel and image of this operator together with Corollary 5.20 of [2] leads to the determination of the holonomic rank for all values of α . We show, in particular, that

$$d \leq r(\alpha) \leq d + 1 \tag{0.8}$$

and that $r(\alpha) = d + 1$ exactly for those parameters $\alpha \in \mathbb{Z}^2$ for which the dimension of the space of rational solutions is 2. Hence, $r(\alpha) = d$ for all $\alpha \in \mathbb{Z}^2$ if and only if the curve $X_{\mathcal{A}}$ is arithmetically Cohen-Macaulay.

These results allow us to clarify the relationship between the holonomic rank and $\text{vol}(P)$, the normalized volume of the convex hull $P \subset \mathbb{R}^{n+1}$ of \mathcal{A} and the origin (which equals the degree d in the case of curves). It was originally claimed in [9, Theorem 2] that $r(\alpha) = \text{vol}(P)$ in all cases, but it was pointed out by Adolphson that, for resonant exponents, the proof required the assumption that the ring R be Cohen-Macaulay (see [10]). In [2, Corollary 5.20], Adolphson showed that $r(\alpha) = \text{vol}(P)$, for α a semi-nonresonant exponent, without any additional assumptions on R . The first explicit example where the equality fails is given in [23] and described in Example 1.8.i). In the forthcoming monograph [19], Saito, Sturmfels and Takayama prove (0.8) using Gröbner deformation methods and show that the inequality $r(\alpha) \geq \text{vol}(P)$ holds without restrictions on n .

Very little seems to be known about the problem of finding rational solutions of differential equations beyond the case of linear differential operators in one variable. In this case, Singer [20] has shown that one can determine in a finite number of steps whether a given equation has a rational solution and find a basis for the space of such solutions. Abramov and Kvasenko ([1]) have further studied the problem of effectively finding rational solutions for such operators. In our case one could, in principle, use non-commutative elimination to obtain linear operators in one variable with coefficients that depend rationally on the other variables and apply Singer's decision procedure to characterize the rational solutions. This can be done in small examples using non-commutative Gröbner bases packages such as `kan` ([24]) but we have not been able to obtain any general results in this manner.

Gel'fand, Zelevinsky, and Kapranov have constructed series solutions for (0.1)-(0.2), associated with regular triangulations of the polytope P . When the exponent α is non-

resonant for the triangulation, it is possible to obtain in this manner $\text{vol}(P)$ -many independent solutions. There are, however, very interesting cases in which the exponents are integral and, therefore, automatically resonant. For example, it has been observed by Batyrev in [4] that the period integrals of Calabi-Yau hypersurfaces in toric varieties satisfy an \mathcal{A} -hypergeometric system with exponents $\alpha = (-1, 0, \dots, 0)$. In this case, series solutions have been obtained by Hosono, Lian, and Yau in [14, 15] (see also [3, 5, 13]). Very recently, Stienstra [21] has generalized the Γ -series construction of Gel'fand, Zelevinsky, and Kapranov to obtain series solutions in the case of resonant exponents under a maximal-degeneracy assumption. In particular, if $\alpha = 0$ and P admits a unimodular triangulation –which implies that R is Cohen-Macaulay– all solutions of (0.1)-(0.2) may be obtained in this manner. This method also yields all solutions of interest in the context of toric mirror symmetry.

A key result, in the curve case, is Theorem 1.9 which asserts that for $m \geq 1$, there are no rational solutions with integral exponents in the Euler-Jacobi cone. This corresponds to the classical vanishing theorem for the total sum of residues, a statement which has a generalization as the Euler-Jacobi theorem (see [16] for the most general form of this result). It is interesting to note then that Euler-Jacobi vanishing is a consequence of the fact that residues satisfy the \mathcal{A} -hypergeometric system. We also point out that while the characterization of Laurent solutions follows from formal arguments, the proof of the Euler-Jacobi vanishing involves transcendental methods.

Acknowledgments: We are grateful to B. Sturmfels for many helpful comments and, particularly, for the statement and proof of Proposition 1.6. We also thank A. Zelevinsky for useful suggestions and the two referees for their careful reading of the manuscript and very thoughtful suggestions for improvement. E. Cattani was supported by NSF Grant DMS-9406462. C. D'Andrea was supported by a Doctoral Fellowship from FOMEC, Argentina. A. Dickenstein was supported by UBACYT and CONICET, Argentina.

1. Rational solutions

The polynomial solutions of a general \mathcal{A} -hypergeometric system admit a very simple description. Given $\alpha \in \mathbb{Z}^r$, we define the *hypergeometric polynomial*

$$\Phi^{\mathcal{A}}(\alpha; x) := \sum_{\substack{u \in \mathbb{N}^r \\ \mathcal{A} \cdot u = \alpha}} \frac{x^u}{u!} = \sum_{\substack{u \in \mathbb{N}^r \\ \mathcal{A} \cdot u = \alpha}} \frac{x_1^{u_1} x_2^{u_2} \cdots x_r^{u_r}}{u_1! u_2! \cdots u_r!}. \quad (1.1)$$

As usual, we set $\Phi^{\mathcal{A}}(\alpha; x) := 0$ if $\alpha \notin \mathcal{A} \cdot \mathbb{N}^r$. The following result, whose verification is left to the reader, is Proposition 2.1 in [18]:

Proposition 1.1. $\Phi^{\mathcal{A}}(\alpha; x)$ is the unique, up to scaling, polynomial solution of the \mathcal{A} -hypergeometric system with exponent α . Moreover, for any $u \in \mathbb{N}^r$,

$$D_u(\Phi^{\mathcal{A}}(\alpha; x)) = \Phi^{\mathcal{A}}(\alpha - \mathcal{A} \cdot u; x) \quad (1.2)$$

where D_u stands for the partial derivative $\partial^{|u|}/\partial x^u$.

The purpose of this section is to describe the rational solutions of the \mathcal{A} -hypergeometric system associated with a matrix \mathcal{A} as in (0.4). Note that for $m = 0$ the system restricts to the homogeneity equations (0.2). Therefore we may assume throughout that $m \geq 1$. To simplify our notation, we will index all $(m+2)$ -tuples by $0, k_1, \dots, k_m, d$. Let e_0, e_{k_1}, \dots, e_d denote the standard basis of \mathbb{Z}^{m+2} . For $i = 1, \dots, m$ we have

$$\omega_{k_i} := (d - k_i) e_0 - d e_{k_i} + k_i e_d \in \mathcal{L}. \quad (1.3)$$

The following observation will be useful in the sequel:

Proposition 1.2. Suppose φ is a local holomorphic solution of (0.1)-(0.2), polynomial with respect to any of the variables x_0, x_{k_1}, \dots, x_d . Then φ is a Laurent polynomial.

Proof: Since φ satisfies the equations (0.1), it follows from (1.3) that for all $\ell \in \mathbb{N}$,

$$D_{k_i}^{\ell d} \varphi = D_0^{\ell(d-k_i)} D_d^{\ell k_i} \varphi \quad (1.4)$$

and, consequently, if φ is polynomial in any of the variables, it must be so in all of the variables x_{k_i} , $i = 1, \dots, m$, and we may write:

$$\varphi(x) = \sum_u \varphi_u(x_0, x_d) \tilde{x}^u \quad ; \quad \tilde{x} = (x_{k_1}, \dots, x_{k_m})$$

where u varies in a finite subset of \mathbb{N}^m and each $\varphi_u(x_0, x_d)$ is homogeneous in each variable with respective degrees β_0, β_d satisfying $d\beta_d \in \mathbb{Z}$, $\beta_0 + \beta_d \in \mathbb{Z}$. Thus, $\varphi_u(x_0, x_d) = c_u x_0^{\beta_0} x_d^{\beta_d}$, $c_u \in \mathbb{C}$. But, because of (1.4), for $r, s \in \mathbb{N}$ sufficiently large, $D_0^r D_d^s \varphi = 0$, and consequently one, and therefore both, of β_0, β_d must be an integer. Hence φ is a Laurent polynomial. \diamond

Note that in the one-dimensional case, an \mathcal{A} -hypergeometric Laurent polynomial may not contain a non-zero term of the form $c_u x^u$ with $u_{k_i} < 0$. This follows from the fact that the singular locus Σ of the hypergeometric system is given by the zeroes of the principal \mathcal{A} -determinant, i.e.

$$\Sigma = \{x_0 = 0\} \cup \{x_d = 0\} \cup \{\Delta(f) = 0\}$$

where $\Delta(f)$ is the discriminant of the generic polynomial (0.5). Alternatively, if a solution contains a non-zero term $c_u x^u$ with $u_{k_i} < 0$, being in the kernel of the differential operator $D_{k_i}^d - D_0^{d-k_i} D_d^{k_i}$, it must also contain non-trivial terms of the form $c_v x^v$ with $v_{k_i} = u_{k_i} - j d$ for all positive integers j and this is clearly impossible. A similar argument shows that a Laurent solution may not contain terms of the form: $c_u x^u$ with both $u_0 < 0$ and $u_d < 0$.

Thus, any Laurent solution must be of the form

$$L_0(x) + L_d(x)$$

where $L_0(x)$ has as denominators only powers of x_0 and $L_d(x)$ has as denominators only powers of x_d . We note that the study of $L_0(x)$ and $L_d(x)$ is completely symmetric. Indeed, let $\ell_j = d - k_{m-j+1}$, $j = 1, \dots, m$, and

$$\hat{\mathcal{A}} = \begin{pmatrix} 1 & 1 & \cdots & 1 & 1 \\ 0 & \ell_1 & \cdots & \ell_m & d \end{pmatrix} \quad (1.5)$$

Then, if $R(x)$ is a Laurent solution of the \mathcal{A} -hypergeometric system and exponent $\alpha = (\alpha_1, \alpha_2)$ (although α should be viewed as a column vector we will, for simplicity of notation, always write exponents as row vectors), the function $\hat{R}(y_0, y_{\ell_1}, \dots, y_{\ell_m}, y_d)$ obtained from R by substituting:

$$x_0 \mapsto y_d, \quad x_{k_j} \mapsto y_{\ell_j}, \quad x_d \mapsto y_0, \quad (1.6)$$

is a solution of the $\hat{\mathcal{A}}$ -hypergeometric system and exponents $\hat{\alpha} = (\alpha_1, d\alpha_1 - \alpha_2)$.

Lemma 1.3. *For $\alpha \in \mathcal{A} \cdot \mathbb{N}^{m+2}$, the only Laurent solutions of the \mathcal{A} -hypergeometric system are the constant multiples of the hypergeometric polynomial (1.1).*

Proof: Suppose there is a Laurent solution $L(x)$ of exponent α containing a term of the form x^u/x_d^r , with $u \in \mathbb{N}^{m+2}$, $u_d = 0$ and $r > 0$ (we will always assume that monomials are written in reduced form). Then $\mathcal{A} \cdot (u - r e_d) = \alpha$. Let $v \in \mathbb{N}^{m+2}$ be such that $\mathcal{A} \cdot v = \alpha$, then $\mathcal{A} \cdot u = \mathcal{A} \cdot (v + r e_d)$, and the operator $D_u - D_d^r D_v$ being in the hypergeometric system, must vanish on L . This means that L must also contain a term x^w whose derivative $D_d^r D_v(x^w)$ is a non-zero multiple of $1/x_d^r$. Since $v_d \geq 0$, this is clearly impossible. Arguing by symmetry, we see that there cannot be a solution containing a term of the form x^u/x_0^r , with $u_0 = 0$ and $r > 0$. \diamond

We will denote by \mathcal{B} the matrix

$$\mathcal{B} = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ 0 & k_1 & \cdots & k_m \end{pmatrix}$$

and x' the vector consisting of the first $m + 1$ variables $(x_0, x_{k_1}, \dots, x_{k_m})$. Similarly, let \mathcal{C} be the matrix

$$\mathcal{C} = \begin{pmatrix} 1 & \cdots & 1 & 1 \\ k_1 & \cdots & k_m & d \end{pmatrix}$$

and \tilde{x} the vector $(x_{k_1}, \dots, x_{k_m}, x_d)$.

Given $\alpha \in \mathbb{Z}^2$ we define

$$\Psi_d^{\mathcal{A}}(\alpha; x) := \sum_{r \geq 1} (-1)^r (r-1)! \frac{\Phi^{\mathcal{B}}(\alpha'(r); x')}{x_d^r}, \quad (1.7)$$

where $\alpha'(r) = \alpha + r(1, d)$, and

$$\Psi_0^{\mathcal{A}}(\alpha; x) := \sum_{r \geq 1} (-1)^r (r-1)! \frac{\Phi^{\mathcal{C}}(\tilde{\alpha}(r); \tilde{x})}{x_0^r}, \quad (1.8)$$

where $\tilde{\alpha}(r) = \alpha + r(1, 0)$.

Note that both sums are finite. This follows from the fact that $\Phi^{\mathcal{B}}(\alpha'(r); x') = 0$ unless $\alpha'(r) \in \mathcal{B} \cdot \mathbb{N}^{m+1}$, but then $\alpha_2 + dr \leq k_m(\alpha_1 + r)$ and, therefore, $(d - k_m)r \leq k_m\alpha_1 - \alpha_2$. This means that the possible values of r in (1.7) are bounded by $(k_m\alpha_1 - \alpha_2)/(d - k_m)$. The statement for (1.8) follows by symmetry. In fact, we should observe that the change of variables (1.6) transforms $\Psi_d^{\mathcal{A}}(\alpha; x)$ into $\Psi_0^{\hat{\mathcal{A}}}(\hat{\alpha}; x)$.

The following subsets of \mathbb{Z}^2 will play an important role in the description of \mathcal{A} -hypergeometric functions:

$$\begin{aligned} I(\mathcal{A}) &:= \mathcal{A} \cdot \mathbb{N}^{m+2}; \\ F_0(\mathcal{A}) &:= \mathcal{C} \cdot \mathbb{N}^{m+1} - \mathbb{N}(1, 0); \quad E_0(\mathcal{A}) := F_0(\mathcal{A}) \setminus I(\mathcal{A}); \\ F_d(\mathcal{A}) &:= \mathcal{B} \cdot \mathbb{N}^{m+1} - \mathbb{N}(1, d); \quad E_d(\mathcal{A}) := F_d(\mathcal{A}) \setminus I(\mathcal{A}); \\ E(\mathcal{A}) &:= E_0(\mathcal{A}) \cap E_d(\mathcal{A}); \quad J(\mathcal{A}) := \mathbb{Z}^2 \setminus (I(\mathcal{A}) \cup F_0(\mathcal{A}) \cup F_d(\mathcal{A})). \end{aligned} \quad (1.9)$$

Note that via the change of variables (1.6), and denoting for $\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}^2$, $\hat{\alpha} = (\alpha_1, d\alpha_1 - \alpha_2)$, we have for $\hat{\mathcal{A}}$ as in (1.5):

$$I(\hat{\mathcal{A}}) = \widehat{I(\mathcal{A})}; \quad F_0(\hat{\mathcal{A}}) = \widehat{F_0(\mathcal{A})}; \quad F_d(\hat{\mathcal{A}}) = \widehat{F_d(\mathcal{A})}.$$

It is clear from the definitions (1.7) and (1.8) that $\Psi_0^{\mathcal{A}}(\alpha; x) \neq 0$ if and only if $\alpha \in F_0(\mathcal{A})$ and, similarly, $\Psi_d^{\mathcal{A}}(\alpha; x) \neq 0$ if and only if $\alpha \in F_d(\mathcal{A})$. In particular,

$$\Psi_d^{\mathcal{A}}(\alpha; x) = 0 \quad \text{if} \quad d\alpha_1 < \alpha_2, \quad (1.10)$$

and,

$$\Psi_0^{\mathcal{A}}(\alpha; x) = 0 \quad \text{if} \quad \alpha_2 < 0. \quad (1.11)$$

On the other hand, the importance of the sets $E_0(\mathcal{A})$ and $E_d(\mathcal{A})$ stems from the fact that according to Lemma 1.3, it is only for $\alpha \in E_0(\mathcal{A})$ (respectively $\alpha \in E_d(\mathcal{A})$) that

the Laurent polynomial $\Psi_0^{\mathcal{A}}(\alpha; x)$ (respectively $\Psi_d^{\mathcal{A}}(\alpha; x)$) may be -and as the following result shows is- \mathcal{A} -hypergeometric. Note also that there are no \mathcal{A} -hypergeometric Laurent polynomials with exponent $\alpha \in J(\mathcal{A})$ and it will be a consequence of Theorem 1.10 that there are no rational \mathcal{A} -hypergeometric functions with exponent $\alpha \in J(\mathcal{A})$.

Theorem 1.4. *Let \mathcal{A} be as in (0.4) and $\alpha \in \mathbb{Z}^2 \setminus I(\mathcal{A})$. Then:*

i) $\Psi_d^{\mathcal{A}}(\alpha; x)$ and $\Psi_0^{\mathcal{A}}(\alpha; x)$ are solutions (possibly trivial) of the \mathcal{A} -hypergeometric system with parameter α .

ii) For any $u \in \mathbb{N}^{m+2}$,

$$D_u(\Psi_d^{\mathcal{A}}(\alpha; x)) = \Psi_d^{\mathcal{A}}(\alpha - \mathcal{A} \cdot u; x); \quad D_u(\Psi_0^{\mathcal{A}}(\alpha; x)) = \Psi_0^{\mathcal{A}}(\alpha - \mathcal{A} \cdot u; x) \quad (1.12)$$

iii) The functions $\Psi_d^{\mathcal{A}}(\alpha; x)$ and $\Psi_0^{\mathcal{A}}(\alpha; x)$ span the space of Laurent solutions of the \mathcal{A} -hypergeometric system with parameter α .

Proof: Clearly, i) is an immediate consequence of ii) and, because of symmetry, it suffices to show (1.12) for $\Psi_d^{\mathcal{A}}(\alpha; x)$. Suppose $u \in \mathbb{N}^{m+2}$ is such that $u_d = 0$, then

$$\begin{aligned} D_u(\Psi_d^{\mathcal{A}}(\alpha; x)) &= \sum_{r \geq 1} (-1)^r (r-1)! \frac{D_u(\Phi^{\mathcal{B}}(\alpha'(r); x'))}{x_d^r} \\ &= \sum_{r \geq 1} (-1)^r (r-1)! \frac{\Phi^{\mathcal{B}}(\alpha'(r) - \mathcal{B} \cdot u; x')}{x_d^r} = \Psi_d^{\mathcal{A}}(\alpha - \mathcal{A} \cdot u; x). \end{aligned}$$

Thus, it remains to prove (1.12) for the partial derivative D_d . We have

$$\begin{aligned} D_d \Psi_d^{\mathcal{A}}(\alpha; x) &= \sum_{r \geq 1} (-1)^{r+1} r! \frac{\Phi^{\mathcal{B}}(\alpha'(r); x')}{x_d^{r+1}} \\ &= \sum_{r \geq 1} (-1)^{r+1} r! \frac{\Phi^{\mathcal{B}}((\alpha - \mathcal{A} \cdot e_d)'(r+1); x')}{x_d^{r+1}} \\ &= \Psi_d^{\mathcal{A}}(\alpha - \mathcal{A} \cdot e_d; x). \end{aligned}$$

The last equality follows since $\alpha \notin \mathcal{A} \cdot \mathbb{N}^{m+2}$ implies that

$$\Phi^{\mathcal{B}}((\alpha - \mathcal{A} \cdot e_d)'(1); x') = \Phi^{\mathcal{B}}(\alpha; x') = 0.$$

Suppose now that $L(x)$ is a Laurent solution with exponent α and write $L(x) = L_d(x) + L_0(x)$. If we decompose further:

$$L_d(x) = \sum_{r \geq 1} \frac{A_r(x')}{x_d^r}$$

then, the polynomials $A_r(x')$ must be solutions of the \mathcal{B} -hypergeometric system and exponent $\alpha'(r)$. Thus, $A_r(x') = c_r \Phi^{\mathcal{B}}(\alpha'(r); x')$. Assume now that for $r, s \geq 1$, $r \neq s$, we have $\alpha'(r), \alpha'(s) \in I(\mathcal{B})$ and let $v, w \in \mathbb{N}^{m+1}$ be such that $\mathcal{B} \cdot v = \alpha'(r)$ and $\mathcal{B} \cdot w = \alpha'(s)$. Then, since $\mathcal{A} \cdot (v + se_d) = \mathcal{A} \cdot (w + re_d)$, the operator

$$\frac{\partial^{|v|+s}}{\partial x^v x_d^s} - \frac{\partial^{|w|+r}}{\partial x^w x_d^r}$$

is in the hypergeometric system and must vanish on L . This means that

$$\frac{(-1)^s (r+s-1)!}{(r-1)! x_d^{r+s}} \frac{\partial^{|v|}(A_r(x'))}{\partial x^v} = \frac{(-1)^r (r+s-1)!}{(s-1)! x_d^{r+s}} \frac{\partial^{|w|}(A_s(x'))}{\partial x^w}$$

which implies that

$$\frac{(-1)^s}{(r-1)!} c_r = \frac{(-1)^r}{(s-1)!} c_s$$

and, consequently,

$$c_r = c (-1)^r (r-1)!.$$

A symmetric argument shows that if the component $L_0(x)$ is non-trivial then it must be a constant multiple of $\Psi_0^{\mathcal{A}}(\alpha; x)$, which proves part iii). \diamond

We state for emphasis:

Corollary 1.5. *Let \mathcal{A} be as in (0.4) and let $\mathcal{L}(\alpha)$ denote the vector space of \mathcal{A} -hypergeometric Laurent polynomials of exponent α . Then $\dim \mathcal{L}(\alpha) \leq 2$. Moreover, $\dim \mathcal{L}(\alpha) \geq 1$ if and only if $\alpha \in I(\mathcal{A}) \cup E_0(\mathcal{A}) \cup E_d(\mathcal{A})$, and $\dim \mathcal{L}(\alpha) = 2$ if and only if $\alpha \in E(\mathcal{A})$.*

The following result was brought to our attention by Bernd Sturmfels:

Proposition 1.6. *Given \mathcal{A} as in (0.4), the ring $R = \mathbb{C}[\xi_0, \dots, \xi_d]/\mathcal{I}_{\mathcal{A}}$ is Cohen-Macaulay if and only if $E(\alpha) = \emptyset$.*

Proof: The ring R is a particularly simple example of an affine semigroup ring whose properties have been extensively studied (see for example [6, Chapter 6], [12], [25]). In fact, Proposition 1.6 is a special case of Theorem 2.6 in [12] which gives necessary and sufficient conditions for an affine semigroup ring which, like R does, admits a system of monomial parameters. Their condition (ii) is easily seen to be equivalent, in our notation, to $E(\alpha) = \emptyset$. \diamond

1.7. Remarks: i) When the curve $X_{\mathcal{A}}$ is normal, i.e. $d = m + 1$, the sets defined in (1.9) have a very simple description: the image $I(\mathcal{A})$ coincides with the ‘‘cone’’ (properly speaking semigroup)

$$\mathcal{C} := \{\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}^2 : 0 \leq \alpha_2 \leq d\alpha_1\},$$

while $E_0(\mathcal{A}) = \{\alpha \in \mathbb{Z}^2 : \alpha_2 \geq 0, d\alpha_1 < \alpha_2\}$, and $E_d(\mathcal{A}) = \{\alpha \in \mathbb{Z}^2 : \alpha_2 < 0, d\alpha_1 \geq \alpha_2\}$. The complement $J(\mathcal{A})$ of these three sets, i.e. the set of $\alpha \in \mathbb{Z}^2$ for which there are no \mathcal{A} -hypergeometric Laurent polynomials of exponent α is the *Euler-Jacobi cone*:

$$\mathcal{EJ} := \{(\alpha_1, \alpha_2) \in \mathbb{Z}^2 : d\alpha_1 < \alpha_2 < 0\}. \quad (1.13)$$

ii) For arbitrary \mathcal{A} as in (0.4) we have $I(\mathcal{A}) \subset \mathcal{C}$, $E(\mathcal{A}) \subset \mathcal{C}$, and $\mathcal{EJ} \subset J(\mathcal{A})$.

iii) The conditions (1.10) and (1.11) are far from being sharp. It is easy to see, for example, that for $\alpha \in \mathcal{C}$, $\Psi_0^{\mathcal{A}}(\alpha; x) \neq 0$ and $\Psi_d^{\mathcal{A}}(\alpha; x) \neq 0$, imply that $k_1 \alpha_1 < \alpha_2 < k_m \alpha_1$. In particular, if $m = 1$, $k_1 = k_m$ and there is no $\alpha \in \mathcal{C}$ for which both $\Psi_0^{\mathcal{A}}(\alpha; x)$ and $\Psi_d^{\mathcal{A}}(\alpha; x)$ are non-trivial. Hence, there is for each α at most one, up to constant multiple, Laurent solution of exponent α . Note also that the toric ring R is always Cohen-Macaulay but it is normal if and only if $d = 2$.

iv) It is not hard to prove (see for example [2, Lemma 3.12]) that there exists $v \in \mathcal{A} \cdot \mathbb{N}^{m+2}$ such that $v + \mathcal{C} \subset I(\mathcal{A})$. Thus, for $\alpha \in v + \mathcal{C}$, there is a unique \mathcal{A} -hypergeometric Laurent polynomial and it is given by (1.1). Moreover, when this observation is combined with the inequalities in iii), it follows that the set $E(\mathcal{A})$ is finite.

1.8. Examples: We exhibit two examples where $E(\mathcal{A}) \neq \emptyset$ and, consequently, the associated toric ring R is not Cohen-Macaulay.

i) This is the “running example” in [23]. Let

$$\mathcal{A} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 3 & 4 \end{pmatrix}$$

The exponent $\alpha = (1, 2)$ is the unique element in \mathcal{C} such that $\alpha \notin I(\mathcal{A})$ and $\alpha_1 < \alpha_2 < 3\alpha_1$. Both $\Psi_0^{\mathcal{A}}((1, 2); x) = (-1/2) (x_1^2/x_0)$ and $\Psi_4^{\mathcal{A}}((1, 2); x) = (-1/2) (x_3^2/x_4)$ are non-trivial. The element $\beta = (2, 3) \in F_0(\mathcal{A}) \cap F_4(\mathcal{A})$ and therefore both $\Psi_0^{\mathcal{A}}(\beta; x) = (-1/6) x_1^3/x_0$ and $\Psi_4^{\mathcal{A}}(\beta; x) = (-1/2) x_1 x_3^2/x_4$ are non-trivial. However, since $\beta = \mathcal{A} \cdot (e_0 + e_3) \in I(\mathcal{A})$, it follows from Lemma 1.3 that neither $\Psi_0^{\mathcal{A}}(\beta; x)$, nor $\Psi_d^{\mathcal{A}}(\beta; x)$, is \mathcal{A} -hypergeometric and the only \mathcal{A} -hypergeometric Laurent polynomials of exponent β are the multiples of the polynomial $\Phi^{\mathcal{A}}(\beta; x) = x_0 x_3$.

ii) Consider the system associated with the matrix

$$\mathcal{A} = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 6 & 7 & 13 & 14 \end{pmatrix}$$

and $\alpha = (2, 18) \notin I(\mathcal{A})$. We have

$$\Psi_0^{\mathcal{A}}((2, 18); x) = -\frac{1}{6} \frac{x_6^3}{x_0} \quad ; \quad \Psi_{14}^{\mathcal{A}}((2, 18); x) = -\frac{1}{2} \frac{x_6 x_{13}^2}{x_{14}} + \frac{1}{6} \frac{x_7 x_{13}^3}{x_{14}^2}.$$

It follows from (1.10) and (1.11) that there are no \mathcal{A} -hypergeometric Laurent polynomials whose exponent α is in the Euler-Jacobi cone (1.13). In fact, as the following result shows, there are no *rational* solutions with exponent in that region.

Theorem 1.9. *The \mathcal{A} -hypergeometric system associated with the matrix (0.4) has no rational solutions whose exponent α lies in the Euler-Jacobi cone.*

Given $\alpha \in \mathbb{Z}^2$, we will denote by $\mathcal{R}(\alpha)$ the vector space of rational \mathcal{A} -hypergeometric functions of exponent α . Before proving Theorem 1.9 we note the following consequence.

Theorem 1.10. *The only rational solutions of the \mathcal{A} -hypergeometric system associated with the matrix (0.4) are the Laurent polynomial solutions described by Proposition 1.1 and Theorem 1.4.*

Proof: Suppose $\varphi \in \mathcal{R}(\alpha)$. For $\ell \in \mathbb{N}$ sufficiently large, $\beta = \alpha - \ell(1, k_1)$ lies in the Euler-Jacobi cone. Then, $D_{k_1}^\ell \varphi$ is a rational solution in $\mathcal{H}(\beta)$, and thus it is identically zero by Theorem 1.9. Hence, φ is polynomial in x_{k_1} and by Proposition 1.2 it must be a Laurent polynomial. \diamond

1.11. Example: Theorem 1.10 is not true for $n > 1$. It fails already in the simplest two-dimensional situation: Consider the hypergeometric system associated with the matrix

$$\mathcal{A} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix}.$$

The lattice \mathcal{L} has rank one; in fact $\mathcal{L} = \mathbb{Z} \cdot (1, -1, -1, 1)^T$, and the system (0.1)-(0.2) is equivalent to Gauss' classical hypergeometric equation. The function $1/(x_1 x_4 - x_2 x_3)$ is a solution with parameters $(-2, -1, -1)$.

Proof of Theorem 1.9: The proof will be by induction on m . We begin by considering the case $m = 1$ and write, for simplicity, $k_1 = k$. Note that in this case the lattice \mathcal{L} has rank 1 and is generated by $\omega := (d-k)e_0 - de_k + ke_d$. In particular, for appropriate values of α , we can write the \mathcal{A} -hypergeometric functions in terms of classical hypergeometric functions (see [9, §3.1]).

The discriminant of the generic polynomial $x_0 + x_k t^k + x_d t^d$ is, up to factors which are powers of x_0 and x_d ,

$$\Delta(x) = d^d x_0^{d-k} x_d^k + (-1)^{d-1} k^k (d-k)^{d-k} x_k^d = c x_k^d (1 - \lambda z)$$

where $c = (-1)^{d-1} k^k (d-k)^{d-k}$, $z = x^\omega = x_0^{d-k} x_k^{-d} x_d^k$, and

$$\lambda = \frac{(-1)^d d^d}{k^k (d-k)^{d-k}}$$

Suppose now that $R(x) = P(x)/Q(x) \in \mathcal{R}(\alpha)$ with $\alpha \in \mathcal{E}\mathcal{J}$, i.e. $d\alpha_1 < \alpha_2 < 0$. Note that both P and Q are bihomogeneous relative to the \mathbb{Z}^2 -degree defined by \mathcal{A} . We can then write $P(x) = x^v P_1(z)$, where P_1 is a polynomial and $P_1(0) \neq 0$. Thus, up to a constant,

$$R(x) = x^u \frac{P_1(z)}{(1 - \lambda z)^r} = x^u \sum_{j \geq 0} c_j z^j = x^u \sum_{j \geq 0} c_j x^{j\omega}, \quad (1.14)$$

with $c_0 \neq 0$, and $\mathcal{A} \cdot u = \alpha$.

Since R is in the kernel of the differential operator

$$\mathcal{D}_\omega = D_0^{d-k} D_d^k - D_k^d, \quad (1.15)$$

the coefficients in (1.14) satisfy the relation:

$$c_j \prod_{\ell=0}^{d-1} (u_k - jd - \ell) = c_{j+1} \prod_{\ell'=0}^{d-k-1} (u_0 + (j+1)(d-k) - \ell') \prod_{\ell''=0}^{k-1} (u_d + (j+1)k - \ell''), \quad (1.16)$$

for all $j \in \mathbb{Z}$. Setting $j = -1$ we get

$$0 = c_0 \prod_{\ell'=0}^{d-k-1} (u_0 - \ell') \prod_{\ell''=0}^{k-1} (u_d - \ell''),$$

which implies that either $0 \leq u_0 \leq d - k - 1$, or $0 \leq u_d \leq k - 1$. On the other hand, $ku_k + du_d = \alpha_2 < 0$ and $du_0 + (d - k)u_k = d\alpha_1 - \alpha_2 < 0$, which means that in either case, $u_k < 0$. Therefore the left-hand side of (1.16) is never zero and, consequently neither is the right-hand side. This implies that $u_0 \geq 0$ and $u_d \geq 0$ and for all $j \geq 0$

$$c_j = c (-1)^{jd} \frac{(-u_k + jd)!}{(u_0 + j(d - k))! (u_d + jk)!},$$

for some constant c .

But a function with such an expansion may not be rational. Indeed, Stirling's formula implies that, asymptotically, $c_j \sim \mu j^{-\alpha_1} \lambda^j / \sqrt{j}$, for some constant μ . On the other hand, for a rational function R whose denominator is a power of $(1 - \lambda z)$, we would have $c_j \sim p(j) \lambda^j$ with p a polynomial. This completes the proof of Theorem 1.9 in the case $m = 1$.

Assume now that Theorem 1.9, and its consequence Theorem 1.10, are valid for $m - 1$, $m \geq 2$, and consider the \mathcal{A} -hypergeometric system associated with the matrix \mathcal{A} in (0.4).

Let $R(x)$ be a rational solution with parameter α in the Euler-Jacobi cone; that is, $\alpha = (\alpha_1, \alpha_2)$ with $d\alpha_1 < \alpha_2 < 0$. Suppose we can write $R(x) = P(x)/(x_d^r Q(x))$; $r > 0$ and assume that x_d does not divide $P(x)$ or $Q(x)$. Let again $x' = (x_0, x_{k_1}, \dots, x_{k_m})$ and write $Q(x) = \sum_{k=0}^r q_k(x') x_d^k$ with $q_0(x') \neq 0$, and set $c_k(x') = -q_k(x')/q_0(x')$. Then

$$R(x) = \frac{P(x)}{x_d^r \cdot q_0(x')} \left(1 + \sum_{m=1}^{\infty} \left(\sum_{k=1}^r c_k(x') x_d^k \right)^m \right) = \sum_{\ell \geq -r} A_\ell(x') x_d^\ell. \quad (1.17)$$

By inductive assumption, since $A_\ell(x')$ is a rational \mathcal{B} -hypergeometric function, it must be a Laurent polynomial as described by Theorem 1.4. (Note that even though we may have $\ell = \gcd(k_1, \dots, k_m) > 1$ we may easily reduce to the system associated with a matrix where k_i has been replaced by k_i/ℓ .) Set $x_d = 0$ and consider the non-trivial rational function $A_{-r}(x') = P(x', 0)/Q(x', 0)$ which has \mathcal{B} -exponent $\alpha'(r) = (\alpha_1 + r, \alpha_2 + dr)$. It

is clear that $\alpha'(r) \notin E(\mathcal{B})$ and hence there may be, up to constant, at most one Laurent solution with exponent $\alpha'(r)$. We distinguish the two possible cases.

i) Suppose $A_{-r}(x')$ is a non-zero multiple of $\Psi_{k_m}^{\mathcal{B}}(\alpha'(r), x')$. Then it contains a non-zero term of the form

$$\frac{\hat{x}^u}{x_{k_m}^s}; \quad s > 0$$

where \hat{x}^u is a monomial with positive exponents involving only the variables $x_0, x_{k_1}, \dots, x_{k_{m-1}}$. Thus a Laurent series expansion of $R(x)$, as a function of x_d , has a non-zero term of the form

$$\frac{\hat{x}^u}{x_{k_m}^s x_d^r}; \quad r > 0, s > 0$$

Successive applications of the fact that R is in the kernel of the operator (1.15), with k_m in the place of k , yields that R must also contain a non-zero term whose derivative $D_0^{j(d-k_m)} D_d^{jk_m}$ is a multiple of

$$\frac{\hat{x}^u}{x_{k_m}^{s+dj} x_d^r}; \quad r > 0, s > 0$$

for all $j \geq 0$ which is impossible as soon as $jk_m \geq r$.

ii) Suppose $A_{-r}(x')$ is a non-zero multiple of $\Psi_0^{\mathcal{B}}(\alpha'(r), x')$. Then it contains a non-zero term of the form

$$\frac{\check{x}^u}{x_0^s}; \quad s > 0$$

where \check{x}^u is a monomial with positive exponents involving only the variables x_{k_1}, \dots, x_{k_m} . which implies that a Laurent series expansion of $R(x)$, as a function of x_d , has a non-zero term of the form

$$\frac{\check{x}^u}{x_0^s x_d^r}; \quad r > 0, s > 0$$

But, since the operator (1.15), with k_m in the place of k must vanish on R , there must also be a non-zero term of the form:

$$\frac{\check{x}^u x_{k_m}^d}{x_0^{s+d-k_m} x_d^{r+k_m}}$$

which contradicts the index bound in (1.17).

By symmetry we can then assume that $R(x) = P(x)/Q(x)$ and neither x_d nor x_0 divide Q . Thus $R(x)$ is written as in (1.17) with $r = 0$. For each $\ell \geq 0$, $A_\ell(x')$ is a solution of the \mathcal{B} -hypergeometric system with exponent $(\alpha_1 - \ell, \alpha_2 - d\ell)$. By inductive hypothesis, these must be Laurent polynomials and it is easy to check that the only possible denominators are powers of x_{k_m} . Thus, only powers of x_{k_m} may appear in the denominator of the above expansion for R , which implies that $q_0(x')$ must be of the form $x_{k_m}^d$ and, therefore, $Q(x)$ has bidegree $(d, k_m d)$. On the other hand, a symmetric argument would imply that $Q(x)$

must contain a term of the form $x_{k_1}^e$ and hence $Q(x)$ should have bidegree $(e, k_1 e)$. Since $m > 1$, this implies that $Q(x)$ has degree 0, but then $R(x)$ is a polynomial solution which is impossible since, being in the Euler-Jacobi cone, $\alpha \notin \mathcal{A} \cdot \mathbb{N}^{m+2}$. \diamond

As we have noted before, given $s \in \mathbb{Z}$, the sum (0.6) $p_s(x) = \rho_1^s(x) + \dots + \rho_d^s(x)$, of the powers of the roots of the generic polynomial (0.5) is a rational \mathcal{A} -hypergeometric function with exponent $(0, -s)$. By Theorem 1.10 it must be a Laurent polynomial and, therefore expressible in terms of $\Psi_0^{\mathcal{A}}$ and $\Psi_d^{\mathcal{A}}$. In fact,

Corollary 1.12. *For $s > 0$,*

$$p_s(x) = s \cdot \Psi_d^{\mathcal{A}}((0, -s); x) = s \cdot \sum_{r=1}^s (-1)^r (r-1)! \frac{\Phi^{\mathcal{B}}((r, r d - s); x')}{x_d^r}, \quad (1.18)$$

while for $s < 0$,

$$p_s(x) = s \cdot \Psi_0^{\mathcal{A}}((0, -s); x) = s \cdot \sum_{r=1}^s (-1)^r (r-1)! \frac{\Phi^{\mathcal{C}}((r, -s); \tilde{x})}{x_0^r}. \quad (1.19)$$

Proof: It suffices to consider the normal case, $d = m + 1$, and then set the appropriate variables equal to zero. For $s > 0$, it follows from (1.11), that $p_s(x)$ must be a multiple of $\Psi_d^{\mathcal{A}}((0, -s); x)$. It is easy to see that the value of the multiple must be s by specialization to the case when $f(x; t) = t^d + t^{d-1}$. The statement for $s < 0$ follows by symmetry after observing that with the change of variables (1.6), the polynomial $\hat{f}(y; \tau)$ associated with the matrix $\hat{\mathcal{A}}$ in (1.5) is given by $\hat{f}(y; \tau) = \tau^d \cdot f(x; \tau^{-1})$ and, consequently, its roots are the inverse of those of f . \diamond

1.13. Remarks: i) Note that each term in the right hand side of (1.18) is of total degree zero and, therefore, we may express $p_s(x)$ as a polynomial in $x_{d-j}/x_d = (-1)^j \sigma_j(\rho_1, \dots, \rho_d)$, $j = 1, \dots, d$, where σ_j is the j -th elementary symmetric polynomial. This yields the classical Girard formulas.

ii) As we have also noted in the introduction, the total sum of the local residues (0.7) gives a rational \mathcal{A} -hypergeometric function with exponent $(-a, -b)$ and hence, as in Corollary 1.12, it must be a multiple of $\Psi_d^{\mathcal{A}}((-a, -b); x)$ if $b > 0$ and of $\Psi_0^{\mathcal{A}}((-a, -b); x)$ if $b \leq 0$. In particular, for $a = 1$, $b > 0$ we have

$$\sum_{\rho} \text{Res}_{\rho(x)} \left(\frac{t^b}{f(x; t)} \frac{dt}{t} \right) = \begin{cases} 0, & \text{if } 0 < b < d; \\ -\Psi_d^{\mathcal{A}}((-1, -b); x), & \text{if } b \geq d. \end{cases}$$

We end this section with a result that should be seen as a complement to (1.10) and (1.11) and which will be of use in §2.

Proposition 1.14. *Let $\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}^2 \setminus I(\mathcal{A})$ and set $s = s(\alpha) := d\alpha_1 - \alpha_2$.*

i) If $s > 0$, then $\Psi_d^{\mathcal{A}}(\alpha; x) = 0$ if and only if $p_s(x) = 0$.

ii) If $\alpha_2 > 0$, then $\Psi_0^A(\alpha; x) = 0$ if and only if $p_{-\alpha_2}(x) = 0$.

Proof: It suffices to prove the first statement and then deduce ii) by symmetry. Suppose $\beta \in \mathbb{Z}^2$ with $\beta_1 = \alpha_1 - r$, $r > 0$ and $s(\beta) = s(\alpha)$ then, if $\Psi_d^A(\alpha; x) = 0$ we have by (1.12): $\Psi_d^A(\beta; x) = D_d^r \Psi_d^A(\alpha; x) = 0$. But, if $\Psi_d^A(\alpha; x) \neq 0$, then the same argument implies that $\Psi_d^A(\beta; x) \neq 0$ since the dependence of $\Psi_d^A(\alpha; x)$ on x_d is not polynomial. Hence, given $\alpha, \beta \in \mathbb{Z}^2 \setminus \mathcal{A} \cdot \mathbb{N}^{m+2}$ such that $s(\alpha) = s(\beta)$, $\Psi_d^A(\alpha; x) = 0$ if and only if $\Psi_d^A(\beta; x) = 0$. The result now follows from the fact that $\Psi_d^A((0, -s); x) = s p_s(x)$. \diamond

2. Algebraic solutions

In this section we introduce a family ψ_ρ of local algebraic solutions of the \mathcal{A} -hypergeometric system associated with a monomial curve. These solutions, which are given in terms of the roots $\rho(x)$ of the generic polynomial (0.5), will play a central role in §3 when we compute the holonomic rank and construct a basis of local solutions for all exponents $\alpha \in \mathbb{Z}^2$.

Let \mathcal{A} be as in (0.4). Given an open set $\mathcal{U} \subseteq \mathbb{C}^{m+2}$, let $\mathcal{H}(\alpha)(\mathcal{U})$ denote the space of solutions, holomorphic on \mathcal{U} , of the \mathcal{A} -hypergeometric system with exponent α , and $\mathcal{H}_{alg}(\alpha)(\mathcal{U})$ the subspace of algebraic solutions. We will drop the reference to the open set \mathcal{U} whenever we are only interested in the space of local solutions around a generic point. Let $\rho(x)$ be a root of the polynomial $f(x; t)$ defined by (0.5), holomorphic for x in some simply-connected open subset $\mathcal{U} \subset \mathbb{C}^{m+2} \setminus \Sigma$.

Given $\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}^2$, $\alpha_1 \geq 0$ we define:

$$\psi_\rho(\alpha; x) := \sum_{\substack{i=0 \\ i \neq \alpha_2}}^{d\alpha_1} \Phi^A((\alpha_1, i); x) \frac{\rho^{i-\alpha_2}(x)}{i - \alpha_2} + \Phi^A(\alpha; x) \log(\rho(x)). \quad (2.1)$$

Note that the condition $i \neq \alpha_2$ is automatically satisfied when $\alpha_2 < 0$ or $\alpha_2 > d\alpha_1$, and that for $\alpha_1 = 0$, $\alpha_2 \neq 0$, $\psi_\rho(\alpha)$ is just $\rho^{-\alpha_2}/(-\alpha_2)$. (If there is no ambiguity we will drop any reference to the variable x .)

For $\alpha \notin I(\mathcal{A})$, the hypergeometric polynomial $\Phi^A(\alpha; x)$ vanishes and $\psi_\rho(\alpha)$ is an algebraic function. This is the case which will be of interest in this section; however, in §3 we will need (2.1) for arbitrary $\alpha \in \mathbb{Z}^2$ and is, therefore, more economical to work in this slightly more general setting. We will extend the definition of $\psi_\rho(\alpha)$ to the case $\alpha_1 < 0$ in (2.6).

Proposition 2.1. *Let $\alpha, \alpha' \in \mathbb{Z}^2$ and assume that $\alpha_1, \alpha'_1 \geq 0$. Let $u, u' \in \mathbb{N}^{m+2}$ be such that $\alpha - \mathcal{A} \cdot u = \alpha' - \mathcal{A} \cdot u'$. Then*

$$D_u \psi_\rho(\alpha) = D_{u'} \psi_\rho(\alpha'). \quad (2.2)$$

Proof: In order to prove (2.2) we show, as a first step, that if $\alpha = (\alpha_1, \alpha_2)$ and $\alpha_1 > 0$, then

$$\frac{\partial}{\partial x_\ell}(\psi_\rho(\alpha)) = \psi_\rho(\alpha - \mathcal{A} \cdot e_\ell). \quad (2.3)$$

Since, by (1.2), $\partial(\Phi^{\mathcal{A}}(\alpha))/\partial x_\ell = \Phi^{\mathcal{A}}(\alpha - \mathcal{A} \cdot e_\ell)$, we have

$$\begin{aligned} \frac{\partial}{\partial x_\ell}(\psi_\rho(\alpha)) &= \sum_{\substack{i=0 \\ i \neq \alpha_2}}^{d\alpha_1} \Phi^{\mathcal{A}}((\alpha_1 - 1, i - \ell)) \frac{\rho^{i-\alpha_2}}{i - \alpha_2} + \Phi^{\mathcal{A}}(\alpha - \mathcal{A} \cdot e_\ell) \log(\rho) \\ &+ \sum_{\substack{i=0 \\ i \neq \alpha_2}}^{d\alpha_1} \Phi^{\mathcal{A}}((\alpha_1, i)) \rho^{i-\alpha_2-1} \frac{\partial \rho}{\partial x_\ell} + \Phi^{\mathcal{A}}(\alpha) \rho^{-1} \frac{\partial \rho}{\partial x_\ell} \end{aligned} \quad (2.4)$$

Note that the last two terms in the expression above cancel since $f^{\alpha_1}(x; \rho(x)) = 0$ implies that:

$$\sum_{\substack{i=0 \\ i \neq \alpha_2}}^{d\alpha_1} \Phi^{\mathcal{A}}(\alpha_1, i) \rho^i = -\Phi^{\mathcal{A}}(\alpha) \rho^{\alpha_2}.$$

On the other hand, setting $j = i - \ell$, the right-hand side of (2.4) becomes

$$\sum_{\substack{j=0 \\ j \neq \alpha_2 - \ell}}^{d(\alpha_1 - 1)} \Phi^{\mathcal{A}}((\alpha_1 - 1, j)) \frac{\rho^{j - (\alpha_2 - \ell)}}{j - (\alpha_2 - \ell)} + \Phi^{\mathcal{A}}(\alpha - \mathcal{A} \cdot e_\ell) \log(\rho) = \psi_\rho(\alpha - \mathcal{A} \cdot e_\ell)$$

where we have used that the hypergeometric polynomial $\Phi^{\mathcal{A}}((\alpha_1 - 1, j))$ vanishes for $j < 0$ or $j > d(\alpha_1 - 1)$. This proves (2.3).

Applying (2.3) successively we may assume that $\alpha_1 = \alpha'_1 = 0$. Suppose $\alpha = (0, -s)$, $s \neq 0$, so that $\Phi^{\mathcal{A}}(\alpha) = 0$ and $\psi_\rho(\alpha) = \rho^s/s$. Given $u \in \mathbb{N}^{m+2}$ we want to compute $D_u(\psi_\rho(\alpha))$. Locally on x we can write

$$\begin{aligned} D_u\left(\frac{2\pi i}{s} \rho^s\right) &= \int_\Gamma \frac{t^s}{s} D_u\left(\frac{f'(x; t)}{f(x; t)}\right) dt \\ &= \int_\Gamma \frac{d}{dt} \left(\frac{t^s}{s} D_u(\log f(x; t))\right) dt - \int_\Gamma t^{s-1} D_u(\log f(x; t)) dt \\ &= (-1)^{\beta_1-1} (\beta_1 - 1)! \int_\Gamma t^{s-1} \frac{t^{\beta_2}}{f^{\beta_1}} dt, \end{aligned} \quad (2.5)$$

where $\mathcal{A} \cdot u = (\beta_1, \beta_2)$ and Γ is a sufficiently small loop in the complex plane. Thus $D_u(\psi_\rho(\alpha))$ depends only on the pair $(\beta_1, \beta_2 + s) = -(\alpha - \mathcal{A} \cdot u)$.

If $\alpha = (0, 0)$, $\psi_\rho((0, 0)) = \log(\rho)$ and we can show that $D_u(\log(\rho))$ depends only on $\mathcal{A} \cdot u$ arguing as above with $\log(t)$ taking the place of t^s/s . This completes the proof. \diamond

Proposition 2.1 now allows us to extend the definition of $\psi_\rho(\alpha)$ to the case $\alpha_1 < 0$. Indeed, let $u \in \mathbb{N}^{m+2}$ be such that $\mathcal{A} \cdot u = (\beta_1, \beta_2)$ with $\beta_1 \geq -\alpha_1$ and set:

$$\psi_\rho(\alpha) := D_u(\psi_\rho(\alpha + \mathcal{A} \cdot u)) \quad (2.6)$$

Clearly, this definition does not depend on the choice of u and for any $\alpha \in \mathbb{Z}^2$, $u \in \mathbb{N}^{m+2}$:

$$D_u(\psi_\rho(\alpha)) = \psi_\rho(\alpha - \mathcal{A} \cdot u). \quad (2.7)$$

If $\alpha \notin I(\mathcal{A})$ we can choose u so that $\alpha + \mathcal{A} \cdot u \notin I(\mathcal{A})$ either, and hence $\psi_\rho(\alpha)$ is an algebraic function.

Theorem 2.2. *For $\alpha \in \mathbb{Z}^2 \setminus I(\mathcal{A})$ the algebraic functions $\psi_\rho(\alpha)$ are \mathcal{A} -hypergeometric.*

Proof: Given (2.6), it suffices to consider the case $\alpha_1 \geq 0$. The hypergeometric polynomials $\Phi^{\mathcal{A}}((\alpha_1, i); x)$ are \mathcal{A} -bihomogeneous of bidegree (α_1, i) while the powers $\rho^{i-\alpha_2}(x)$ have bidegree $(0, \alpha_2 - i)$. Hence, $\psi_\rho(\alpha)$ satisfies the homogeneity equations (0.2) with exponent α . On the other hand, it is an immediate consequence of Proposition 2.1 that $\psi_\rho(\alpha)$ satisfies the higher-order equations (0.1). \diamond

Let now $\mathcal{U} \subset \mathbb{C}^{m+2} \setminus \Sigma$ be a simply-connected open set and let $\rho_1(x), \dots, \rho_d(x)$ be distinct roots of the polynomial $f(x; t)$, holomorphic for $x \in \mathcal{U}$. Let $\alpha \in \mathbb{Z}^2 \setminus I(\mathcal{A})$ and set $\psi_j(\alpha) := \psi_{\rho_j}(\alpha) \in \mathcal{H}_{alg}(\alpha)(\mathcal{U})$. The function

$$\Psi^{\mathcal{A}}(\alpha) := \psi_1(\alpha) + \dots + \psi_d(\alpha)$$

is then a rational solution of the \mathcal{A} -hypergeometric system with parameters α . It follows from (2.7) that, for any $u \in \mathbb{N}^{m+2}$,

$$D_u(\Psi^{\mathcal{A}}(\alpha)) = \Psi^{\mathcal{A}}(\alpha - \mathcal{A} \cdot u). \quad (2.8)$$

Proposition 2.3. *Let $\alpha \in \mathbb{Z}^2 \setminus I(\mathcal{A})$. Then,*

- i) $\Psi^{\mathcal{A}}(\alpha; x) = \Psi_d^{\mathcal{A}}(\alpha; x) + \Psi_0^{\mathcal{A}}(\alpha; x)$, defined as in (1.7) and (1.8).
- ii) $\Psi^{\mathcal{A}}(\alpha) = 0$ if and only if there exist no non-trivial rational \mathcal{A} -hypergeometric functions with parameter α .
- iii) If $\alpha = (\alpha_1, \alpha_2)$ and $\alpha_1 > 0$, then

$$\Psi_0^{\mathcal{A}}(\alpha; x) = \sum_{\substack{i=0 \\ i < \alpha_2}}^{d\alpha_1} \Phi^{\mathcal{A}}((\alpha_1, i); x) \Psi_0^{\mathcal{A}}((0, \alpha_2 - i); x), \text{ and} \quad (2.9)$$

$$\Psi_d^{\mathcal{A}}(\alpha; x) = \sum_{\substack{i=0 \\ i > \alpha_2}}^{d\alpha_1} \Phi^{\mathcal{A}}((\alpha_1, i); x) \Psi_d^{\mathcal{A}}((0, \alpha_2 - i); x). \quad (2.10)$$

Proof: By Theorem 1.4 iii), $\Psi^{\mathcal{A}}(\alpha)$ is a linear combination $\lambda\Psi_d^{\mathcal{A}}(\alpha; x) + \mu\Psi_0^{\mathcal{A}}(\alpha; x)$. Moreover, if $\alpha_1 = 0$ the result follows from (1.18) and (1.19). Therefore, computing derivatives with respect to x_d , the result follows for $s(\alpha) = d\alpha_1 - \alpha_2 > 0$, $\alpha_1 < 0$ where $\Psi_0^{\mathcal{A}}(\alpha; x) = 0$. By symmetry i) also holds for $\alpha_2 > 0$, $\alpha_1 < 0$.

If $\alpha \in \mathbb{Z}^2 \setminus I(\mathcal{A})$ is such that $\Psi_d^{\mathcal{A}}(\alpha; x) \neq 0$ then,

$$\Psi^{\mathcal{A}}((0, -s(\alpha))) = \frac{\partial^{\alpha_1} \Psi^{\mathcal{A}}(\alpha)}{\partial x_d^{\alpha_1}} = \lambda \frac{\partial^{\alpha_1} \Psi_d^{\mathcal{A}}(\alpha)}{\partial x_d^{\alpha_1}} = \lambda \Psi_d^{\mathcal{A}}((0, -s(\alpha)))$$

which implies $\lambda = 1$ since, because of Proposition 1.14, $\Psi_d^{\mathcal{A}}((0, -s(\alpha))) \neq 0$. A similar argument shows that if $\Psi_0^{\mathcal{A}}(\alpha; x) \neq 0$ then $\mu = 1$.

The second assertion is an immediate consequence of i) and iii) in Theorem 1.4. The identities (2.9) and (2.10) follow from part i), together with (1.18) and (1.19). \diamond

We now determine the dimension of the subspace of algebraic hypergeometric functions over \mathcal{U} spanned by $\psi_1(\alpha), \dots, \psi_d(\alpha)$, $\alpha \notin I(\mathcal{A})$.

Theorem 2.4. *For $\alpha \in \mathbb{Z}^2 \setminus I(\mathcal{A})$, the \mathcal{A} -hypergeometric functions $\psi_1(\alpha), \dots, \psi_d(\alpha)$ span a linear space of dimension at least $d - 1$. Moreover, they are linearly dependent if and only if $\Psi^{\mathcal{A}}(\alpha) = 0$.*

Before giving the proof of Theorem 2.4, we first recall the construction by Gel'fand, Zelevinsky, and Kapranov [9] of Γ -series solutions for the \mathcal{A} -hypergeometric system and the expressions obtained by Sturmfels [22] for the roots of $f(x; t)$ in terms of them. We will begin by considering the normal case, and eventually we will specialize coefficients to study the general case. We only need to consider the coarsest triangulation of the polytope P , the convex hull of \mathcal{A} and the origin, i.e. the one consisting of the single simplex P . As before, we let \mathcal{L} stand for the integral kernel of \mathcal{A} , that is, the sublattice of elements $v \in \mathbb{Z}^{d+1}$ such that $\mathcal{A} \cdot v = 0$. Given $u \in \mathbb{Q}^{d+1}$ we define the formal power series

$$[x_0^{u_0} x_1^{u_1} \cdots x_d^{u_d}] := \sum_{v \in \mathcal{L}} \prod_{i=0}^d (\gamma(u_i, v_i) x_i^{u_i + v_i}), \quad (2.11)$$

where, for any rational number u and any integer v , we write

$$\gamma(u, v) := \begin{cases} 1 & \text{if } v = 0, \\ u(u-1)(u-2) \cdots (u+v+1) & \text{if } v < 0, \\ 0 & \text{if } u \text{ is a negative integer and } u \geq -v, \\ \frac{1}{(u+1)(u+2) \cdots (u+v)} & \text{otherwise.} \end{cases}$$

If u has no negative integer coordinates, or is of the form $(0, \dots, 0, 1, -1, 0, \dots, 0)$, the series $[x_0^{u_0} \cdots x_d^{u_d}]$ is a formal solution of the \mathcal{A} -hypergeometric system with parameters $\mathcal{A} \cdot u \in \mathbb{Q}^2$ (see [9, Lemma 1], [22, Lemma 3.1]). Moreover, if at most two of the exponents u_i are non-integers, the series (2.11) converges in a suitable open subset of $\mathbb{C}^{d+1} \setminus \Sigma$ ([9]).

Let ξ_1, \dots, ξ_d be the d -th roots of -1 and consider the series $\rho_i(x) := \sum_{a=1}^d \xi_i^a \cdot \sigma_a(x)$, where

$$\sigma_1(x) := \left[x_0^{\frac{1}{d}} x_d^{-\frac{1}{d}} \right]; \quad \sigma_a(x) := \frac{1}{d} \cdot \left[x_{a-1} x_0^{\frac{a-d}{d}} x_d^{-\frac{a}{d}} \right], \quad a = 2, \dots, d.$$

It follows from [9, Proposition 2] that there exists an open set $\mathcal{V} \subset \mathbb{C}^{d+1} \setminus \Sigma$ of the form

$$\mathcal{V} := \{x \in \mathbb{C}^{d+1} : |x_0|^{d-j} |x_d|^j > M |x_j|^d ; j \neq 0, d\},$$

for some positive real constant M , where all these series converge, and, according to [22, Theorem 3.2], locally on \mathcal{V} , they define the holomorphic d roots of the generic polynomial $\sum_{j=0}^d x_j \cdot t^j$. Given a positive integer s we consider the powers $\rho_i^s(x)$ and write

$$\rho_i^s(x) = \sum_{b=1}^d \xi_i^b \cdot \theta_b(x) \quad \text{where} \quad \theta_b(x) = \sum_{a_1 + \dots + a_s = b + \ell d} (-1)^\ell \prod_{j=1}^s \sigma_{a_j}(x)$$

We now consider the \mathcal{A} -hypergeometric system associated with the matrix (0.4) and recall that we are assuming that $\gcd(k_1, \dots, k_m, d) = 1$. Let J denote the complement of $\{0, k_1, \dots, k_m, d\}$ in $\{0, 1, \dots, d\}$, and V_J the $(m+2)$ -dimensional subspace of \mathbb{C}^{d+1} obtained by setting $x_j = 0$, $j \in J$. Note that $\mathcal{V} \cap V_J$ is non-empty.

Lemma 2.5. *For $b = 1, \dots, d-1$, the restriction of $\theta_b(x)$ to V_J is non-trivial. The same is true of any of its derivatives $D_u \theta_b$, $u \in \mathbb{N}^{m+2}$, with respect to variables x_i , $i \notin J$.*

Proof: Note that if $\rho^s = (\rho_1^s, \dots, \rho_d^s)^T$ and $\theta = (\theta_1, \dots, \theta_d)^T$, then $\theta = M^{-1} \cdot \rho^s$ where M is the non-singular matrix $M = (\xi_i^a)$, $i, a = 1, \dots, d$. In particular, $\theta_b(x) \in \mathcal{H}((0, -s))(\mathcal{U})$.

We now claim that for any set of indices a_1, \dots, a_s such that $a_1 + \dots + a_s = b + \ell d$, for some $\ell \in \mathbb{N}$,

$$\theta_b(x) = \lambda \cdot \left[x_{a_1-1} \cdots x_{a_s-1} x_0^{\frac{b+(\ell-s)d}{d}} x_d^{-\frac{b+\ell d}{d}} \right], \quad (2.12)$$

for some non-zero constant λ . Indeed, forgetting for the moment the coefficients, suppose that $x^w = x^{w^{(1)}} \cdots x^{w^{(s)}}$ is a monomial appearing in the product $\prod_{j=1}^s \sigma_{a'_j}(x)$ where $a'_1 + \dots + a'_s = b + \ell' d$. Then $\mathcal{A} \cdot w = (0, -s)^T$ and therefore, x^w must differ from the monomial inside the bracket (2.12) by a monomial of the form x^v with $v \in \mathcal{L}$. This means that all the monomials in the power series of $\theta_b(x)$ appear in the Γ -series of (2.12). But, on the other hand, since we already know that $\theta_b(x)$ is \mathcal{A} -hypergeometric, if a monomial, such as the one in (2.12), appears in its expansion then the whole Γ -series must appear and with the appropriate coefficients.

Suppose now that we set the variables x_j , $j \in J$, equal to zero. We may assume without loss of generality that in the bracket in (2.12), $a_1 - 1, \dots, a_r - 1$ are the only indices in J . Since $\gcd(k_1, \dots, k_m, d) = 1$, there exist positive integers $p'_d, p''_d, p_1, \dots, p_m$ such that

$$(a_1 - 1) + \dots + (a_r - 1) + p'_d d = p_1 k_1 + \dots + p_m k_m + p''_d d$$

Setting $p_d = p_d'' - p_d'$, there exists $p_0 \in \mathbb{Z}$ such that

$$v := p_0 e_0 + p_1 e_{k_1} + \cdots + p_m e_{k_m} + p_d e_d - e_{a_1-1} - \cdots - e_{a_r-1} \in \mathcal{L}.$$

Consequently, multiplication of the monomial in the bracket (2.12) by x^v yields a term in the Γ -series which does not involve any variables from the index set J . On the other hand, it is easy to check that all coefficients $\gamma(u_i, v_i)$ are non-zero and therefore the restriction of $\theta_b(x)$ is non-trivial.

The statement about the derivatives of $\theta_b(x)$ follows from the fact that for $b < d$, the exponents of x_0 and x_n in the bracket in (2.12) are not integers, while the exponents with which any of the other variables x_{k_i} appears in the Γ -series cannot be bounded since for any $\ell \in \mathbb{N}$, the element

$$\ell \cdot (d e_{k_i} - (d - k_i) e_0 - k_i e_d) \in \mathcal{L}. \quad \diamond$$

Proof of Theorem 2.4: We consider, first of all, the case $\alpha = (0, -s)$ with s a positive integer. Then $\psi_j(\alpha) = \rho_j^s/s$ and, since $\rho^s = M \cdot \theta$ with M non singular, $\rho_1^s, \dots, \rho_d^s$ are linearly independent if and only if $\theta_1(x), \dots, \theta_d(x)$ are so. But comparing the exponents of x_d in the corresponding Γ -series it is clear that $\theta_1(x), \dots, \theta_d(x)$ will be linearly independent unless their restriction to V_J vanishes. On the other hand, Lemma 2.5 asserts that only $\theta_d(x)$ may be identically zero when restricted to V_J . Hence, the dimension of the linear span of $\rho_1^s(x), \dots, \rho_d^s(x)$ is at least $d - 1$ and will be exactly $d - 1$ if and only if $\theta_d(x) = 0$. But,

$$\sum_{i=1}^d \rho_i^s(x) = \sum_{b=1}^d \left(\sum_{i=1}^d \xi_i^b \right) \cdot \theta_b(x) = -d \theta_d(x).$$

Thus, $\theta_d(x) = 0$ if and only if $\rho_1^s(x) + \cdots + \rho_d^s(x) = 0$.

The assertion for $\alpha = (0, s)$ with s a positive integer follows from symmetry. In view of the definition (2.6), the statement for $\alpha_1 < 0$ follows from that for $\alpha_1 = 0$ using the assertion in Lemma 2.5 about the derivatives of the Γ -series $\theta_b(x)$.

It remains to consider the case $\alpha_1 > 0$. Suppose there is a non-trivial linear relation $\sum_{i=1}^d \lambda_i \cdot \psi_i(\alpha) = 0$; because of (2.7), applying the derivative $\partial^{\alpha_1}/\partial x_0^{\alpha_1}$ we obtain

$$\sum_{i=1}^d \lambda_i \cdot \psi_i((0, \alpha_2)) = 0.$$

But $\alpha \notin I(\mathcal{A})$ implies that $(0, \alpha_2) \notin I(\mathcal{A})$, and therefore, $\lambda_1 = \cdots = \lambda_d$, and the proof is complete. \diamond

The following result implies that the holonomic rank of the \mathcal{A} -hypergeometric system is at least $d + 1$ for all exponents $\alpha \in E(\mathcal{A})$.

Theorem 2.6. For any $\alpha \in E(\mathcal{A})$, $\dim(\mathcal{H}_{alg}(\alpha)(\mathcal{U})) \geq d + 1$.

Proof: For any $\alpha \in E(\mathcal{A})$ the \mathcal{A} -hypergeometric Laurent polynomials $\Psi_0^{\mathcal{A}}(x)$ and $\Psi_d^{\mathcal{A}}(x)$ are both non-trivial. In particular, $0 < \alpha_2 < d\alpha_1$. From i) in Proposition 2.3 we have that

$$\psi_1(\alpha) + \cdots + \psi_d(\alpha) \neq 0,$$

and Theorem 2.4 implies that $\psi_1(\alpha), \dots, \psi_d(\alpha)$ are linearly independent. Moreover, we will show next that so are the functions $\psi_1(\alpha), \dots, \psi_d(\alpha), \Psi_0^{\mathcal{A}}(\alpha)$. Suppose there is a non-trivial linear combination $\Psi_0^{\mathcal{A}}(\alpha) = \sum_{i=1}^d \lambda_i \cdot \psi_i(\alpha)$, $\lambda_i \in \mathbb{C}$. By differentiation we obtain a similar relation

$$\Psi_0^{\mathcal{A}}((0, \alpha_2)) = \frac{\partial^{\alpha_1} \Psi_0^{\mathcal{A}}(\alpha)}{\partial x_0^{\alpha_1}} = \sum_{i=1}^d \lambda_i \cdot \frac{\partial^{\alpha_1} \psi_i(\alpha)}{\partial x_0^{\alpha_1}} = \sum_{i=1}^d \lambda_i \cdot \psi_i((0, \alpha_2)).$$

But (1.10) implies that $\Psi_d^{\mathcal{A}}((0, \alpha_2)) = 0$ and therefore $\Psi_0^{\mathcal{A}}((0, \alpha_2)) = \sum_{i=1}^d \psi_i((0, \alpha_2))$. Since according to ii) in Proposition 1.14, $\Psi_0^{\mathcal{A}}((0, \alpha_2)) \neq 0$, we have that all $\lambda_i = 1$. This implies that $\Psi_0^{\mathcal{A}}(\alpha) = \sum_{i=1}^d \psi_i(\alpha) = \Psi_0^{\mathcal{A}}(\alpha) + \Psi_d^{\mathcal{A}}(\alpha)$, i.e. $\Psi_d^{\mathcal{A}}(\alpha) = 0$, which contradicts our assumption. \diamond

Corollary 2.7. The toric ring $R = \mathbb{C}[\xi_0, \dots, \xi_d]/\mathcal{I}_{\mathcal{A}}$ is Cohen-Macaulay if and only if, for every $\alpha \in \mathbb{C}^2$ the dimension of the space of \mathcal{A} -hypergeometric functions of exponent α , at a generic point, is equal to d .

Proof: The only if direction is Theorem 2 in [9] (see also [10] and [2]). To prove the converse we note that, because of Proposition 1.6, if R is not Cohen-Macaulay then $E(\mathcal{A}) \neq \emptyset$, and the result follows from Theorem 2.6.

3. Bases of solutions and holonomic rank

In this section we will determine the holonomic rank of the \mathcal{A} -hypergeometric system associated with a monomial curve for all integral exponents and exhibit explicit bases of local solutions constructed in terms of the roots of the generic polynomial (0.5).

Four different scenarios need to be considered:

- The exponent $\alpha \in I(\mathcal{A})$: In this case $r(\alpha) = d$ and we construct in Theorem 3.1, $d - 1$ local solutions which, together with the hypergeometric polynomial $\Phi^{\mathcal{A}}(\alpha)$ define a basis of solutions.
- $\alpha \in E(\mathcal{A})$: We now have $r(\alpha) = d + 1$ and we have constructed $d + 1$ (algebraic) local solutions in Theorem 2.6.
- $\alpha \in (E_0(\mathcal{A}) \cup E_d(\mathcal{A})) \setminus E(\mathcal{A})$: The holonomic rank equals d and we have from Theorem 2.4 a basis of algebraic solutions.
- $\alpha \in J(\mathcal{A})$: Then $\mathcal{R}(\alpha) = \{0\}$, $r(\alpha) = d$, and we construct a basis of local solutions in Theorem 3.5.

In Theorem 3.7 we determine the holonomic rank $r(\alpha)$ for all $\alpha \in \mathbb{Z}^2$. Our starting point is a result of Adolphson ([2, Corollary 5.20]) which states that even without assuming that the ring R is Cohen-Macaulay, the equality $r(\alpha) = \text{vol}(P)$ holds for so-called *semi-nonresonant* exponents α . In our particular case, this condition is equivalent to α being in the Euler-Jacobi cone (1.13).

We consider first the case when $\alpha \in I(\mathcal{A})$, i.e. when the \mathcal{A} -hypergeometric polynomial $\Phi^{\mathcal{A}}(\alpha; x) \neq 0$. By Proposition 2.1, given a root $\rho(x)$, the function $\psi_{\rho}(\alpha; x)$ satisfies the higher-order equations (0.1) but, clearly, not the homogeneity equations (0.2). However, if we fix a choice of a root $\hat{\rho}$ then, for any other root ρ , the function

$$\tau_{\rho}(\alpha) := \sum_{\substack{i=0 \\ i \neq \alpha_2}}^{d\alpha_1} \Phi^{\mathcal{A}}(\alpha_1, i) \frac{\rho^{i-\alpha_2} - \hat{\rho}^{i-\alpha_2}}{i - \alpha_2} + \Phi^{\mathcal{A}}(\alpha) \log(\rho/\hat{\rho}). \quad (3.1)$$

is \mathcal{A} -hypergeometric with exponent α . Indeed, it differs from $\psi_{\rho}(\alpha) - \psi_{\hat{\rho}}(\alpha)$ by a constant multiple of $\Phi^{\mathcal{A}}(\alpha)$.

Theorem 3.1. *Given $\alpha \in I(\mathcal{A})$ and a choice of a root $\hat{\rho}$ of $f(x; t)$ on \mathcal{U} , the functions $\Phi^{\mathcal{A}}(\alpha)$ and $\tau_{\rho}(\alpha)$ where ρ runs over all roots of $f(x; t)$ on \mathcal{U} different from $\hat{\rho}$, are linearly independent \mathcal{A} -hypergeometric functions.*

Proof: Suppose $\alpha = \mathcal{A} \cdot u$, $u \in \mathbb{N}^{m+2}$, and suppose there is a non-trivial linear combination

$$\lambda \Phi^{\mathcal{A}}(\alpha) + \sum_{\rho \neq \hat{\rho}} \lambda_{\rho} \tau_{\rho}(\alpha) = 0.$$

Applying the operator D_u and using (1.2) and (2.7), we may assume that $\alpha = (0, 0)$ and, consequently, $\Phi^{\mathcal{A}}(\alpha) = 1$, $\tau_\rho(\alpha) = \log(\rho/\hat{\rho})$, and

$$\lambda + \sum_{\rho \neq \hat{\rho}} \lambda_\rho \log(\rho/\hat{\rho}) = 0. \quad (3.2)$$

Implicit differentiation of the equation $f(x; \rho(x)) = 0$ yields $\partial\rho/\partial x_\ell = -\rho^\ell/f'(\rho)$, $\ell \geq 0$ and, consequently,

$$\frac{\partial \log \rho}{\partial x_d} = \frac{1}{d} \frac{\partial \rho^d}{\partial x_0} = \psi_\rho((-1, -d)).$$

Hence, derivating (3.2), we obtain

$$\sum_{\rho \neq \hat{\rho}} \lambda_\rho (\psi_\rho((-1, -d)) - \psi_{\hat{\rho}}((-1, -d))) = 0,$$

which, in view of Theorem 2.4, implies $\lambda_\rho = 0$ for all $\rho \neq \hat{\rho}$. \diamond

Suppose now that $\alpha \in J(\mathcal{A})$. In particular, $\alpha \notin I(\mathcal{A})$, and, by ii) in Proposition 2.3, $\Psi^{\mathcal{A}}(\alpha) = 0$. Recall also that this case includes all integral exponents lying in the Euler-Jacobi cone.

As before, we let \mathcal{U} denote a simply-connected open set in $\mathbb{C}^{m+2} \setminus \Sigma$ and let ρ_1, \dots, ρ_d denote the roots of $f(x; t)$ for $x \in \mathcal{U}$. Given $\alpha \in \mathbb{Z}^2$ such that $\alpha_1 \geq 0$, we define

$$\chi(\alpha) := \sum_{j=1}^d \psi_j(\alpha) \log(\rho_j). \quad (3.3)$$

Proposition 3.2. *Suppose $\alpha \in J(\mathcal{A})$ is such that $\alpha_1 \geq 0$. Then the function $\chi(\alpha)$ is \mathcal{A} -hypergeometric with exponent α .*

Proof: Since $\Psi^{\mathcal{A}}(\alpha) = \sum_{j=1}^d \psi_j(\alpha) = 0$ it follows that $\chi(\alpha)$ satisfies the equations (0.2) with exponent α . In order to check that the higher-order equations (0.1) are satisfied as well we show, first of all, that if $\alpha_1 > 0$, then

$$\frac{\partial \chi(\alpha)}{\partial x_\ell} = \chi(\alpha - \mathcal{A} \cdot e_\ell). \quad (3.4)$$

Indeed,

$$\begin{aligned} \frac{\partial \chi(\alpha)}{\partial x_\ell} &= \sum_{j=1}^d \psi_j(\alpha - \mathcal{A} \cdot e_\ell) \log(\rho_j) + \sum_{j=1}^d \psi_j(\alpha) \rho_j^{-1} \frac{\partial \rho_j}{\partial x_\ell} \\ &= \chi(\alpha - \mathcal{A} \cdot e_\ell) + \sum_{i=0}^{d\alpha_1} \frac{\Phi^{\mathcal{A}}((\alpha_1, i))}{i - \alpha_2} \left(\sum_{j=1}^d \rho_j^{i - \alpha_2 - 1} \frac{\partial \rho_j}{\partial x_\ell} \right). \end{aligned}$$

We claim that the second summand is identically zero. In fact,

$$\sum_{j=1}^d \rho_j^{i-\alpha_2-1} \frac{\partial \rho_j}{\partial x_\ell} = \frac{\partial}{\partial x_\ell} \left(\sum_{j=1}^d \frac{\rho_j^{i-\alpha_2}}{i-\alpha_2} \right).$$

Assume $\Phi^{\mathcal{A}}(\alpha_1, i) \neq 0$, i.e., there exists $w \in \mathbb{N}^{m+2}$ such that $\mathcal{A} \cdot w = (\alpha_1, i)$. If $\sum_{j=1}^d \rho_j^{i-\alpha_2}$ does not vanish identically, there exists $v \in \mathbb{Z}^{m+2}$ such that $v_{k_i} \geq 0$ for all $i = 1, \dots, m$, and either $v_0 \geq 0$ or $v_d \geq 0$, verifying $\mathcal{A} \cdot v = (0, \alpha_2 - i)$. But then $\mathcal{A} \cdot (v + w) = \alpha$, which contradicts the fact that $\Psi^{\mathcal{A}}(\alpha) = 0$. This proves (3.4).

Arguing as in the proof of Proposition 2.1, the proof of Proposition 3.2 now reduces to the following:

Lemma 3.3. *Given $s \in \mathbb{Z}$, $s \neq 0$, and $u \in \mathbb{N}^{m+2}$, let $\beta = \mathcal{A} \cdot u$ and $\gamma = (0, -s) - \beta$. Then, if $\Psi^{\mathcal{A}}(\gamma) = 0$, the derivative*

$$D_u \left(\sum_{j=1}^d \frac{\rho_j^s}{s} \log \rho_j \right)$$

depends only on γ .

Proof: We argue as in (2.5); locally on x ,

$$\begin{aligned} 2\pi i D_u \left(\sum_{j=1}^d \frac{\rho_j^s}{s} \log \rho_j \right) &= \sum_{j=1}^d \int_{\Gamma_j} \frac{t^s}{s} \log t D_u \left(\frac{f'(x; t)}{f(x; t)} \right) dt \\ &= - \sum_{j=1}^d \int_{\Gamma_j} \frac{d}{dt} \left(\frac{t^s}{s} \log t \right) D_u(\log f(x; t)) dt \\ &= c \cdot \left[\sum_{j=1}^d \int_{\Gamma_j} \log t \frac{t^{\beta_2+s-1}}{f^{\beta_1}} dt + \sum_{j=1}^d \int_{\Gamma_j} \frac{t^{s-1}}{s} \frac{t^{\beta_2}}{f^{\beta_1}} dt \right], \end{aligned} \quad (3.5)$$

where Γ_j is a sufficiently small loop in the complex plane enclosing only the root ρ_j and $c = (-1)^{\beta_1-1}(\beta_1 - 1)!$. Now, according to (2.5), the last sum in (3.5), agrees, up to constant, with

$$\sum_{j=1}^d D_u(\rho_j^s/s) = \sum_{j=1}^d D_u(\psi_j((0, -s))) = \sum_{j=1}^d \psi_j(\gamma) = \Psi^{\mathcal{A}}(\gamma) = 0.$$

Hence the Lemma, and Proposition 3.2, follow. \diamond

We now extend the definition (3.3) of $\chi(\alpha)$ to the case $\alpha \in \mathbb{Z}^2$, $\alpha_1 < 0$, by setting:

$$\chi(\alpha) = \begin{cases} D_0^{-\alpha_1} \chi((0, \alpha_2)), & \text{if } \alpha_2 \neq 0 \\ D_{k_1} D_0^{-\alpha_1-1} \chi((0, k_1)), & \text{if } \alpha_2 = 0, \end{cases} \quad (3.6)$$

where, we recall

$$\chi((0, s)) = \sum_{j=1}^d \frac{\rho_j^{-s}}{-s} \log \rho_j ; \quad s \neq 0. \quad (3.7)$$

Proposition 3.4. *Let $\alpha \in \mathbb{Z}^2$, $\alpha_1 < 0$. Then*

i) $\chi(\alpha)(t * x) = t^{\alpha_2} \chi(\alpha)(x) - t^{\alpha_2} \log t \Psi^{\mathcal{A}}(\alpha; x)$, where $t \in \mathbb{C}^*$, and

$$t * x = (x_0, t^{k_1} x_{k_1}, \dots, t^d x_d).$$

ii) If $\alpha \in J(\mathcal{A})$, $\chi(\alpha)$ is \mathcal{A} -hypergeometric with exponent α .

iii) For M sufficiently large and $j = 1, \dots, m$,

$$D_0^{M(d-k_j)} D_d^{Mk_j} (\chi(\alpha)) = D_{k_j}^{Md} (\chi(\alpha)).$$

Proof: In view of (3.7), the first assertion follows from (3.6) together with the fact that $\rho_j(t * x) = t^{-1} \rho_j(x)$, $j = 1, \dots, d$.

If $\alpha \in J(\mathcal{A})$, $\Psi^{\mathcal{A}}(\alpha; x) = 0$ and it follows from i) that $\chi(\alpha)$ satisfies the homogeneity equations (0.2). On the other hand, if $\alpha \in J(\mathcal{A})$, the same is true of $\alpha - \mathcal{A} \cdot u$ for every $u \in \mathbb{N}^{m+2}$. Hence it follows from Lemma 3.3 that $\chi(\alpha)$ satisfies the equations (0.1).

The last assertion follows again from Lemma 3.3 for M so that $\alpha - (M d, M d k_j) \in \mathcal{EJ} \subset J(\mathcal{A})$. \diamond

Theorem 3.5. *Let $\alpha \in J(\mathcal{A})$. Let \mathcal{U} , ρ_1, \dots, ρ_d , be as above. Then the functions $\psi_1(\alpha), \dots, \psi_{d-1}(\alpha), \chi(\alpha) \in \mathcal{H}(\alpha)(\mathcal{U})$ are linearly independent.*

Proof: In view of Theorem 2.4, it will be enough to show that $\chi(\alpha)$ is not an algebraic function. In fact, we will show that its orbit under the monodromy action of $\pi_1(\mathbb{C}^{m+2} \setminus \Sigma)$ is infinite.

For generic values a_{k_1}, \dots, a_d the polynomial $f((0, a_{k_1}, \dots, a_d); t)$ will have a root of multiplicity k_1 at the origin and $d - k_1$ simple, non-zero roots. Thus, for $|a_0|$ small, relative to $|a_{k_1}|, \dots, |a_d|$, the polynomial $f(a; t)$ will have simple roots and k_1 of them, say $\rho_1, \dots, \rho_{k_1}$, will be very close to the k_1 -th roots of $-a_0/a_{k_1}$. This means that analytic continuation of the roots along the loop

$$\gamma(\theta) := (\exp(2\pi i k_1 \theta) a_0, a_{k_1}, \dots, a_d) ; \quad \theta \in [0, 1]$$

returns the roots to their original values, but, for any choice of logarithm for all roots of f near a :

$$\gamma^*(\log(\rho_j)) = \begin{cases} \log(\rho_j) + 2\pi i, & \text{if } j = 1, \dots, k_1; \\ \log(\rho_j), & \text{otherwise.} \end{cases}$$

Since $\alpha \notin I(\mathcal{A})$, it follows from (2.1) and (2.6) that $\gamma^*(\psi_j(\alpha)) = \psi_j(\alpha)$ for any $j = 1, \dots, d$. Therefore, for $\alpha_1 \geq 0$,

$$\gamma^*(\chi(\alpha)) = \gamma^* \left(\sum_{j=1}^d \psi_j(\alpha) \log(\rho_j) \right) = \chi(\alpha) + 2\pi i \sum_{j=1}^{k_1} \psi_j.$$

Since $0 < k_1 < d$, by Theorem 2.4 $\psi_1 + \dots + \psi_{k_1} \neq 0$, and therefore the orbit of $\chi(\alpha)$ under successive powers of γ is infinite.

Suppose now that $\alpha_1 < 0$. Then,

$$\chi(\alpha) = \frac{\partial^{-\alpha_1}}{\partial x_0^{-\alpha_1}} \left(\sum_{j=1}^d \psi_j((0, \alpha_2)) \log \rho_j \right) = \sum_{j=1}^d \psi_j(\alpha) \log \rho_j + R(\alpha).$$

It is straightforward to check that $R(\alpha)$ is algebraic and invariant under the monodromy action, i.e. $R(\alpha)$ is a rational function. Since we have just shown that the function $\sum_{j=1}^d \psi_j(\alpha) \log \rho_j$ is not algebraic, the proof is complete. \diamond

3.6. Remark: Note that since the function $\chi(\alpha)$ is not algebraic, any rational \mathcal{A} -hypergeometric function R with exponent α in the Euler–Jacobi cone must be a linear combination of $\psi_1(\alpha), \dots, \psi_d(\alpha)$. On the other hand, with similar arguments as in the proof of Theorem 3.5, it is possible to show the existence of a loop γ whose action on the roots is a cyclic permutation. It is then easy to see that R must be a constant multiple of $\sum_{j=1}^d \psi_j(\alpha)$, and therefore it must vanish. This gives an alternative proof of Theorem 1.9.

Theorem 3.7. *For every $\alpha \in \mathbb{Z}^2$,*

$$d \leq r(\alpha) \leq d + 1.$$

Moreover, $r(\alpha) = d + 1$ if and only if $\alpha \in E(\mathcal{A})$.

Proof: Note, first of all, that the lower bound follows from Theorem 2.4 (for $\alpha \in E_0(\mathcal{A}) \cup E_d(\mathcal{A})$), Theorem 3.1 (for $\alpha \in I(\mathcal{A})$), and Theorem 3.5 (for $\alpha \in J(\mathcal{A})$).

Suppose now that α is in the Euler-Jacobi cone $\mathcal{E}\mathcal{J}$. Then, as we observed before, α is semi-nonresonant in the sense of Adolphson and it follows from [2, Corollary 5.20] that $r(\alpha) = d$. For any $\alpha \in \mathbb{Z}^2$, there exist $u \in \mathbb{N}^{m+2}$ such that $\alpha - \mathcal{A}.u$ lies in $\mathcal{E}\mathcal{J}$, and, because of Theorem 1.9, for any such u the kernel of the linear map

$$D_u : \mathcal{H}(\alpha) \rightarrow \mathcal{H}(\alpha - \mathcal{A}.u),$$

contains $\mathcal{R}(\alpha)$. We will determine the dimension of $\mathcal{H}(\alpha)$ by computing the kernel and the image of D_u for suitable u .

Suppose first that $\alpha \in J(\mathcal{A})$. For $u = \ell e_{k_1}$, $\ell \gg 0$, we have $\alpha - \mathcal{A}.u \in \mathcal{E}\mathcal{J}$ and, it follows from Proposition 1.2 and Corollary 1.5 that $\ker(D_u) = \mathcal{R}(\alpha) = \{0\}$. Therefore, D_u

is a monomorphism, which implies that $\dim \mathcal{H}(\alpha) \leq d$. Since it is at least d , we deduce $\dim \mathcal{H}(\alpha) = d$.

Suppose now that $\alpha \notin J(\mathcal{A})$, then $\dim(\mathcal{R}(\alpha)) = 1$ or 2 . We can again choose $u = \ell e_{k_1}$, $\ell \gg 0$, so that $\beta := \alpha - \mathcal{A} \cdot u \in \mathcal{EJ}$. As the kernel of D_u is precisely $\mathcal{R}(\alpha)$ it will be enough to show that, for some ℓ sufficiently large, the dimension of the image of D_u is $d - 1$.

From (2.6) and Theorem 3.5, we deduce that the functions $\psi_j(\beta)$ generate a subspace of the image of dimension at least $d - 1$. The proof will be completed by showing that the function $\chi(\beta)$ defined in (3.6) is not in the image $D_u(\mathcal{H}(\alpha))$.

Consider first the case $\alpha \in E_0(\mathcal{A})$. Choosing $\ell = sd$, we factor $D_u = D_{k_1}^{sd} = D_d^{k_1 s} D_0^{(d-k_1)s}$. Set $\alpha' := \alpha - ((d - k_1)s, 0)$. It is enough to show that $\chi(\beta) \notin D_d^{k_1 s}(\mathcal{H}(\alpha'))$. Note that $\alpha' \in E_0(\mathcal{A})$ as well and, therefore, we may assume without loss of generality that $\alpha_1 < 0$ and $\beta = \alpha - \ell e_d \in \mathcal{EJ}$ for some sufficiently big ℓ .

Let $\chi(\alpha)$ be as in (3.6). Since $\beta \in \mathcal{EJ}$, it follows from Lemma 3.3 that $D_d^\ell(\chi(\alpha)) = \chi(\beta)$. Therefore, if $\phi \in \mathcal{H}(\alpha)$ is such that $D_d^\ell(\phi) = \chi(\beta)$ we must have

$$\phi = \chi(\alpha) + F$$

where F depends polynomially on x_d . On the other hand, because of iii) in Proposition 3.4 and the fact that ϕ is hypergeometric, we have

$$D_{k_j}^{Md}(F) = D_0^{M(d-k_j)} D_d^{Mk_j}(F)$$

for all M large enough. This implies that F is polynomial on x_{k_1}, \dots, x_{k_m} as well.

But, it follows from i) in Proposition 3.4 that

$$F(t * x) = t^{\alpha_2} F(x) + t^{\alpha_2} \log t \Psi(\alpha)(x)$$

which is impossible since the fact that the action of t does not affect x_0 implies that $F(t * x)$ is polynomial in t .

By symmetry, the result also holds for $\alpha \in E_d(\mathcal{A})$. Thus, it remains to consider the case $\alpha \in I(\mathcal{A})$. For ℓ large enough, so that $\alpha'_1 = \alpha_1 - \ell(d - k_1) < 0$, we have $\alpha' = (\alpha'_1, \alpha_2) \in E_0(\mathcal{A})$ and an argument similar to the one above yields the result. \diamond

3.8. Remark: In [19, Theorem 12.2], M. Saito, B. Sturmfels and N. Takayama prove Theorem 3.7 by the method of Gröbner deformations. They also show ([19, Theorem 11.1]) that the lower bound $\text{vol}(P) \leq r(\alpha)$ holds for arbitrary \mathcal{A} .

Given $\alpha \in \mathbb{Z}^2$, define $\hat{\mathcal{H}}(\alpha) := \mathcal{H}(\alpha)/\mathcal{R}(\alpha)$ if $\mathcal{R}(\alpha) \neq \{0\}$ and $\hat{\mathcal{H}}(\alpha) := \mathcal{H}(\alpha)/\mathbb{C} \cdot \chi(\alpha)$ if $\mathcal{R}(\alpha) = \{0\}$.

Corollary 3.9. For every $\alpha \in \mathbb{Z}^2$,

- i) $\dim(\hat{\mathcal{H}}(\alpha)) = d - 1$.
- ii) For every $u \in \mathbb{N}^{m+2}$ the operator

$$D_u : \hat{\mathcal{H}}(\alpha) \rightarrow \hat{\mathcal{H}}(\alpha - \mathcal{A} \cdot u)$$

is an isomorphism. \diamond
