Abstract

We examine the characteristics of accounting amounts using a sample of German companies reporting under IAS during 2000-2002 (IAS period), and IFRS during 2003-2004 (IFRS$_{voluntary}$ period) and 2005-2006 (IFRS$_{mandatory}$ period). We find a decrease in accounting quality after the mandatory EU adoption in 2005. Our findings on earnings smoothing and timely loss recognition corroborates largely our findings related to value relevance of accounting information. Our results indicate that accounting quality has not improved but worsened over time. Further analysis shows that this development is less likely be driven by new adopters of IFRS but is driven by the changes of the standards. Contrary to the intention with the adoption of the European adoption of IFRS, this makes it harder for investors to base their decisions on the IFRS financial reporting.

I. Introduction

The main objective of this study is to examine and compare the quality of accounting numbers under International Accounting Standards (IAS) during 2000-2002 with those under International Financial Reporting Standards (IFRS) during 2003-2006[3]. Accordingly, we compare the characteristics of accounting amounts using a sample of German companies reporting under IAS during 2000-2002 (IAS period), and IFRS during 2003-2004 (IFRS$_{voluntary}$ period) and 2005-2006 (IFRS$_{mandatory}$ period). Specifically, we investigate whether there is a change in accounting quality during these three time periods. We limit our investigation to German companies to hold constant certain institutional factors such as stock listing requirements, accounting disclosure requirements, market microstructures and regulatory environments that may confound the results, thereby strengthening the reliability of our findings.

Our inquiry is mainly motivated by the major revisions of IASs and the development of new IFRSs since the implementation of the new structure with IASB taking over the standard setting responsibilities from IASC in April 2001. The IASB has focused on developing a set of high quality standards to promote global accounting harmonization. This has led to significant changes in standards; only 31 of the 41 IASs remained in effect as of January 2005. In addition, by this time, IASB has issued eight new IFRSs (IASB). Many of these revisions and new additions of accounting standards reflect IASB's preference for fair value measurement of assets and liabilities (Alexander and Jermakowicz 2006; Hung and Subramanyam 2007; Schipper 2005; Whittington 2005). Considering the developments in the international standards, we predict that these

---

[3] Beginning in 2005, all listed companies in the European Union (EU) are required to prepare their consolidated financial statements in accordance with IFRS. Prior to that, using IAS/IFRS was voluntary in many European countries.

changes are likely to affect the quality of accounting amounts as a result of IASB's increased orientation towards fair value accounting.

The European Union's (EU) adoption has made IFRS the most widely accepted financial accounting model in the world. It is very important that current and potential investors as well as the standard setters understand the implication of IFRS on accounting variables. Hence, we also examine the effect of the EU's mandatory adoption of IFRS in 2005 and 2006 on the quality of accounting. Specifically, we examine whether the mandatory adoption of IFRS in the EU may have changed the structure of the set of companies reporting under IFRS and how this may have impacted the overall accounting quality.

Prior research has compared properties of accounting numbers using samples of German companies (e.g., Hung and Subramanyam 2007; Bartov and Kim 2005; Barth et al. 2008, Barth et al. 2006). Our study differs from prior research on quality of IAS and IFRS accounting measures in that we examine the change in quality of accounting caused by the revisions made to IASs and the development of new IFRSs. This study compares the characteristics of accounting amounts using a sample of German companies reporting under IAS during 2000-2002, and IFRS during 2003-2004 and 2005-2006. Specifically, we investigate whether there is a change in accounting quality during these three time periods as IASB revises existing IAS and issues new IFRS to formulate a set of high quality international accounting standards for global financial reporting purpose. Contrary to our expectations, our results suggest a decrease in accounting quality after the mandatory EU adoption of IFRS. We find that earnings and book value of equity are becoming less value relevant during the IFRS periods compared to the IAS period. Our

4

findings on earnings smoothing and timely loss recognition largely corroborates our findings with respect to the value relevance of accounting information. Our results indicate that accounting quality has not improved but worsened over time. Further analysis shows that this is less likely to be driven by new adopters of IFRS in 2005 and more by the change in international accounting standards. When using a matched sample we cannot find any clear indication of either an improved or a worsened quality of financial reporting. We also analyzed the voluntary and the mandatory adopters in the period 2005 to 2006. We found only weak indications that the decrease in quality was caused by the mandatory adopters. Furthermore, we also investigated whether our results were driven by a new dominating industry group, Financials. We find nothing supporting that this is the case and our interpretation is that the decrease in accounting quality is driven by the revisions of IASs and the addition of new of IFRSs around the time of the European mandatory adoption. Contrary to the intention with the European adoption of IFRS, this might make it harder for investors to base their decisions on the accounting information.

Our primary contribution is that we exclusively examine the impact of international standards over *time* on accounting quality and value relevance of accounting measures as these standards go through revisions and new standards are issued. No study, to our knowledge, has empirically examined this issue. Our second contribution is that we include more recent data and investigate the effects of the mandatory EU adoption of IFRS since 2005 on accounting quality.

The remainder of our paper is organized as follows. The next section describes the development of international accounting standards over time. Section III briefly

discusses prior research and develops hypotheses. Section IV discusses the research design and how we examine earnings smoothing, timely loss recognition and value relevance over time. Section V describes the sample, and the sample selection criteria. Section VI presents our findings while Section VII concludes.

II. The Development of International Accounting Standards over Time

During the period of our investigation, a number of revisions to International Accounting Standards took place. These changes are summarized in Table 1, which outlines the revisions of existing IASs and the issuance of new IFRSs in the chronological order these changes went into effect. Of these changes, we consider three to have had a major impact on companies' financial reporting and thereby the possibility of a major impact on the value relevance on book value of equity and earnings. Theses changes are related to IAS 36, *Impairment of assets*, IAS 38, *Intangible assets*, and IFRS 3, *Business combinations*. IAS 36 requires a review of assets including intangible assets with an indefinite useful life for impairment, and measurement of recoverable amounts on an annual basis. Any impairment loss is recorded as an expense in the income statement. IAS 38 requires the recognition of an intangible asset when it is probable that future benefits of an intangible asset will benefit the company, and the cost of the intangible asset can be measured reliably. In addition, intangible assets should also be assessed for impairment in accordance with IAS 36. IFRS 3 allows only the purchase method for business combinations. All identifiable assets and liabilities are valued at fair value. Goodwill is not amortized, but subject to an impairment test annually. Negative goodwill is recognized immediately in the income statement. Since the changes in these

accounting standards are all fair-value oriented, we expect the informativeness of IFRS earnings and book values to increase compared to that of IAS earnings and book values.

<Table 1 about here>

II. Prior Research and Hypotheses Development

As noted earlier, some recent studies compare IAS accounting measures to those under other GAAPs. Hung and Subramanyam (2007) compare the financial statement effects of using IAS to those using German GAAP for a sample of German companies that elected to adopt IAS by examining these companies' restatements of prior years accounting numbers in the adoption year. They find that the adjustments between the two reporting systems are value relevant for book values of equity, but not for earnings. But they do not find any difference in value relevance of book value of equity and earnings under IAS and German GAAP. They also find that total assets and book value of equity are significantly higher under IAS and that there is a higher variability in book value of equity and earnings under IAS. Finally, they find that IAS adopters exhibit larger loss provisions. Bartov et al. (2005) also examine and compare the value relevance of earnings based US GAAP, IAS and German GAAP. They, on the other hand, find that IAS earnings are more value relevant than those based on German GAAP. The difference in the results of these two studies may be found in that Bartov et al. (2005) exclude loss-firm observations in their estimations while these are included in the Hung Subramanyam (2007) study.

Jermakowicz et al. (2007) examine German companies' adoption of IFRS and US GAAP over the period 1995 to 2004. Specifically, they investigate the usefulness, proxied as value relevance, before and after the adoption of these GAAPs and the

perceived benefits and costs related to the process of implementing IFRS among the

DAX-30 companies.[4] They find a significant increase in the value relevance of earnings

after the adoption of these GAAPs. They also find that the key challenges related to the

adoption of IFRS are the complexity of IFRS, the costs involved, and the lack of

implementation guidance. The challenges related to the adoption of IFRS documented by

Jermakowicz et al. (2007) and Soderstrom and Sun (2007) may explain the findings of

Christensen et al. (2007). Christensen et al. (2007) investigate the change in earnings

management and timely loss recognition among German firms that voluntarily adopt

IFRS and those who wait until the adoption of IFRS is mandatory. They find that

companies that voluntarily adopt are less prone to earnings management and recognize

losses more timely compared to those that resist and wait until the adoption of IFRS

becomes mandatory. They interpret their findings as a sign of how certain companies (i.e.

insider oriented companies) have less incentive to adopt IFRS since they will not benefit

and the challenges involved are considerable.

Finally, Barth et al. (2008) also study IAS adopters from a number of countries,

whereof Germany is one of the countries with greatest representation in the sample.

They find that firms that adopt IAS are less prone to engage in earnings smoothing and

recognize losses more timely.

There are also other recent studies on the effect of German and other GAAPs' on

accounting quality and cost of capital. Leuz and Verrecchia (2000) investigate the bid-

ask spreads, trading volume, and stock return volatility as proxies for the information

asymmetry part of cost of capital. Comparing the above proxies for German companies

---

[4] DAX-30 (Deutscher Aktien IndeX 30 (formerly Deutscher Aktien-Index-30) is a Blue Chip stock market index consisting of the 30 major German companies trading on the Frankfurt Stock Exchange.

which switch from German GAAP to either IAS or US GAAP, as they predict, they find that the bid-asked spread decreases, and the trading volume increases, however they find no reduction in stock return volatility. Daske (2006) builds on Leuz and Verrecchia's (2000) study using data from 1993 and 2002. He, on the other hand, does not find any sign of a lower cost of capital for companies that switch to IAS or US GAAP. On the contrary, Daske (2006) finds an increase in cost of capital for these companies. Finally, Platikanova and Nobes (2006) compare the information asymmetry component of the bid-ask spread among companies before and after EU's adoption of IFRS in 2005. They find a larger volatility in the information asymmetry for UK and German companies. Contrary to expectations, they also find that companies from countries where earnings management is more common exhibit a *lower* information asymmetry component compared to other groups of countries. They interpret this result as income smoothing reduces information asymmetry.

Overall, the results of these studies do not provide clear evidence on how the recent development in the global accounting standards impacts the quality of the accounting amounts. For instance, Barth et al. (2008) and Jermakowicz et al. (2007) cover a period including both IAS and IFRS data, which makes it difficult to interpret their results regarding the impact on accounting quality as the international accounting standards go through changes over time. In addition, the fact that Bartov et al. (2005) exclude loss-firm observations and obtain a result different from Hung and Subramanyam (2005) suggests that certain characteristics of the companies reporting under international accounting standards may drive the results. This notion is supported by the findings of both Jermakowicz et al. (2007) and Christensen et al. (2007). Jermakowicz et al. (2007)

results suggests that the value relevance of earnings increases after companies adopt IFRS or US GAAP, a notion that make sense considering the sample used in the study (DAX-30 companies), a set of companies that are most likely to be able to cope with the complexity of implementing these GAAPs. They also find that, in spite of these companies' ability to cope with an adoption to a more complex GAAP, they still find the adoption of IFRS to be a major challenge due to its complexity, high cost, and the lack of implementation guidance. Christensen et al.'s (2007) results suggests that companies that have an incentive to implement a more challenging GAAP are more likely to maintain a higher accounting quality (proxied as earnings management and timely loss recognition) compared to those who do not.

We assume that the recent developments in the international accounting standards have led to changes in the quality of financial reporting over time. Therefore, the question remains whether the accounting quality is higher as a result of the IASB's initiatives and actions. As the IASB reduces the allowable alternative accounting methods and choices and provides a more consistent approach to accounting measurement for the goal of developing a single set of high quality international accounting standards, we predict that these changes in recent years improve the quality of accounting as evidenced by higher value relevance of earnings and book value of equity, less earnings smoothing, and more timely recognition of losses.

With respect to value relevance, we expect to see higher association between stock prices and earnings and book value of equity for firms with higher quality of reported accounting numbers. Moreover, we expect that firms with less earnings smoothing will exhibit more variability in change in net income, a higher ratio of the

variability of change in net income to variability of change in cash flow, a less negative

correlation between accruals and cash flows and less frequency of reporting small

positive earnings as the accounting quality improves. With respect to timely loss

recognition, we predict that firms with higher accounting quality show a larger frequency

of large losses.

III. Research Design

We follow Barth et al. (2008) and Lang et al. 2005) when testing our predictions

of higher quality of accounting as the IASB revises IAS and issues new IFRS in the

recent years, we divide our study period (2000-2006) to three time periods: the IAS

period ranging from 2000-2002; the IFRS$_{voluntary}$ period ranging from 2003-2004 and the

IFRS$_{mandatory}$ period ranging from 2005-2006. Following prior research, we

operationalize quality of accounting using earnings smoothing, timely recognition of

losses measures, and value relevance.

Four measures of earnings smoothing are used in this study. They are the

variability of the change in net income, the ratio of the variability of the change in net

income to the variability of the change in operating cash flows, the correlation between

accruals and cash flows and the frequency of small positive net income (Lang et al. 2005;

Barth et al. 2006, 2008). Our first earnings smoothing metric is the variability of the

change in net income scaled by total assets, ΔNI (Barth et al. 2006, 2008; Lang et al.

2006). To control for other economic factors that affect earnings variability unrelated to

the financial reporting system, we regress ΔNI on a number of control variables identified

in prior literature (Ashbaugh 2001; Pagano et al., 2002; Lang et al., 2003; Tarca 2004;

Lang et al. 2006; Barth et al., 2006, 2008), and the variances of the residuals of the regression is our measure of the earnings variability. The ΔNI is estimated as follows:

$$\Delta NI_{it} = \beta_0 + \beta_1 LEV1_{it} + \beta_2 Growth_{it} + \beta_3 Eissue_{it} + \beta_4 Dissue_{it} + \beta_5 Turn_{it} + \beta_6 Size_{it} + \beta_7 CFO_{it} + \beta_8 AUD_{it} + \beta_9 NUMEX_{it} + \beta_{10} XLIST_{it} + \beta_{11} FF_{it} + \varepsilon_{it}. \tag{1}$$

where:

LEV = the total liabilities divided by shareholders' equity;

$GROWTH$ = the percentage of change in sales;

$Eissue$ = the percentage change in common shareholders' equity;

$Dissue$ = the percentage change in total liabilities;

$Turn$ = sales divided by total assets;

$Size$ = the natural log of total assets;

CFO = the cash flow from operating activities scaled by total assets

AUD= a dummy variable taking the value one if the firm's auditor is PwC, KPMG, Arthur Andersen, E&Y, or D&T and zero otherwise;

$NUMEX$ = the number of stock exchanges on which a firm's stock is listed;

$XLIST$ = a dummy variable taking the value one if the firm is listed on a U.S. stock exchange (the U.S. not being the primary exchange) and zero otherwise.

FF = the average number of shares traded the last day of the month during the fiscal year divided by number of common shares outstanding at the fiscal year end.

We estimate equation (1) pooling observations in each of the three time periods examined and compare the variances of the residuals of the regression for each time period using a two-tailed variance ratio F-test.

Our second measure of earnings smoothing is the ratio of the variability of the change in net income, ΔNI, to the variability of the change in operating cash flows,

ΔCFO (Barth et al., 2006; Lang et al., 2006). ΔCFO is the change in cash flows scaled by total assets. As with ΔNI, to control for other economic factors that affect cash flows variability unrelated to financial reporting system, we regress ΔCFO on a number of control variables similar to equation (1), but with ΔCFO as the dependent variable.

$$\Delta CFO_{it} = \beta_0 + \beta_1 LEV1_{it} + \beta_2 Growth_{it} + \beta_3 Eissue_{it} + \beta_4 Dissue_{it} + \beta_5 Turn_{it} + \beta_6 Size_{it} + \beta_7 CFO_{it} + \beta_8 AUD_{it} + \beta_9 NUMEX_{it} + \beta_{10} XLIST_{it} + \beta_{11} FF_{it} + \varepsilon_{it}.$$ (2),

The variability of the change in cash flows is the variance of residuals from equation (2). Then the second measure of earnings smoothing is the ratio of the variability of ΔNI to the variability of ΔCFO. The rationale for using this ratio is that it is plausible that the variability of net income is affected by the firm-specific volatility of cash flows and by using the ratio we control for this (Barth et al. 2006, 2008; Lang et al. 2006). We measure the difference between these ratios across time periods using ranksum test of the permuted dataset.

The third measure of earnings smoothing is the spearman correlation between accruals and cash flows. As with the previous tests, to control for economic factors unrelated to earnings smoothing, we run separate regressions of accruals and cash flows on the control variables as included in Equations 1 and 2, except *CFO*.

$$CFO_{it} = \beta_0 + \beta_1 LEV1_{it} + \beta_2 Growth_{it} + \beta_3 Eissue_{it} + \beta_4 Dissue_{it} + \beta_5 Turn_{it} + \beta_6 Size_{it} + \beta_7 AUD_{it} + \beta_8 NUMEX_{it} + \beta_9 XLIST_{it} + \beta_{10} FF_{it} + \varepsilon_{it}.$$ (3)

$$ACC_{it} = \beta_0 + \beta_1 LEV1_{it} + \beta_2 Growth_{it} + \beta_3 Eissue_{it} + \beta_4 Dissue_{it} + \beta_5 Turn_{it} + \beta_6 Size_{it} + \beta_7 AUD_{it} + \beta_8 NUMEX_{it} + \beta_9 XLIST_{it} + \beta_{10} FF_{it} + \varepsilon_{it}.$$ (4)

We then compare and test the correlation of the residuals from equations (3) and (4) between the three time periods based on Cramer's (1987) squared correlation test.

To test managing towards positive earnings, we run the following model including two periods (IAS vs. IFRS$_{voluntary}$ and IFRS$_{voluntary}$ vs. IFRS$_{mandatory}$) at a time to examine if firms in one period are more likely to manage towards positive earnings (Barth et al., 2006; Lang et al., 2006) than the other. The coefficient on the small positive net income is our measure of managing towards positive earnings.

$$IAS(0,1)_{it} = \beta_0 + \beta_1 SPO_{it} + \beta_2 LEV_{it} + \beta_3 Growth_{it} + \beta_4 Eissue_{it} + \beta_5 Dissue_{it} + \\ \beta_6 Turn_{it} + \beta_7 Size_{it} + \beta_8 CFO_{it} + \beta_9 AUD_{it} + \beta_{10} NUMEX_{it} + \beta_{11} XLIST_{it} + \qquad (5) \\ \beta_{12} FF_{it} + \varepsilon_{it}.$$

and

$$IFRS(0,1)_{it} = \beta_0 + \beta_1 SPO_{it} + \beta_2 LEV_{it} + \beta_3 Growth_{it} + \beta_4 Eissue_{it} + \beta_5 Dissue_{it} + \\ \beta_6 Turn_{it} + \beta_7 Size_{it} + \beta_8 CFO_{it} + \beta_9 AUD_{it} + \beta_{10} NUMEX_{it} + \beta_{11} XLIST_{it} + \qquad (6) \\ \beta_{12} FF_{it} + \varepsilon_{it}.$$

IAS(0,1) in the first estimation is equal to 1 for the IAS period and zero for the IFRS$_{voluntary}$ period and in the second estimation, the IAS(0,1) is equal to 1 for the IFRS$_{voluntary}$ and zero for the IFRS$_{mandatory}$ period. SPO is a binary variable equal to 1 if net income scaled by total assets is between 0 and 0.01 (Barth et al., 2006; Lang et al., 2006; Lang et al., 2003). A positive coefficient on SPO in the estimation covering the IAS (IFRS$_{voluntary}$) period and the IFRS$_{voluntary}$ (IFRS$_{mandatory}$) period indicates that firms in the IAS (IFRS$_{voluntary}$) period manage earnings toward small positive amounts more frequently than firms in the IFRS$_{voluntary}$(IFRS$_{mandatory)}$ period.

For the measure of timely recognition of losses, we also estimate an equation similar to equation (5) and (6), but replacing SPO with LNEG.

$$IAS(0,1)_{it} = \beta_0 + \beta_1 LNEG_{it} + \beta_2 LEV_{it} + \beta_3 Growth_{it} + \beta_4 Eissue_{it} + \beta_5 Dissue_{it} + \\ \beta_6 Turn_{it} + \beta_7 Size_{it} + \beta_8 CFO_{it} + \beta_9 AUD_{it} + \beta_{10} NUMEX_{it} + \beta_{11} XLIST_{it} + \qquad (7) \\ \beta_{12} FF_{it} + \varepsilon_{it}.$$

and

$$IFRS(0,1)_{it} = \beta_0 + \beta_1 LNEG_{it} + \beta_2 LEV_{it} + \beta_3 Growth_{it} + \beta_4 Eissue_{it} + \beta_5 Dissue_{it} +$$
$$\beta_6 Turn_{it} + \beta_7 Size_{it} + \beta_8 CFO_{it} + \beta_9 AUD_{it} + \beta_{10} NUMEX_{it} + \beta_{11} XLIST_{it} + \qquad (8)$$
$$\beta_{12} FF_{it} + \varepsilon_{it}.$$

LNEG is a binary variable taking on the value of 1 for observations with annual earnings

scaled by total assets less than negative 0.2, and zero otherwise. The coefficient on

LNEG is our measure of timely loss recognition. A positive coefficient on LNEG

indicates that firms in the IAS (IFRS$_{voluntary}$) period recognize large losses more

frequently than those in IFRS$_{voluntary}$ (IFRS$_{mandatory}$).

In addition, we also use Basu's (1997) reverse regressions of earnings on a

dummy variable for bad news (negative returns), annual return, and an interaction

variable of return and the dummy variable for bad news. We expect that more timely loss

recognition will result in a larger coefficient on bad news earnings. We compare the

magnitude of the interaction coefficient across the three periods to evaluate the timeliness

of bad news reflected in earnings. A larger coefficient indicates more timely loss

recognition.

The test of relative value relevance is based on a valuation framework provided

by Ohlson (1995) where a firm's share price is a function of both earnings and book

value of equity.

$$P_{it} = \beta_0 + \beta_1 E_{it} + \beta_2 BVE + \varepsilon_{it} \qquad (9),$$

where P$_{it}$ is the market price per share three months after fiscal year end in year t of

company$_i$, and E$_{it}$, and BVE$_{it}$ are earnings before extraordinary items, and book value of

stockholders' equity per share, respectively, and ε_{it} is the other value-relevant information

of company i in year t. The regression model's R^2 indicates the strength of the association between the respective accounting variable(s) and stock price.

We also use a reverse regression with earnings as the dependent variable and returns as the independent variable. We expect that if losses are recognized in a timely manner, the association between returns and earnings is stronger, mirroring that more information about earnings reaches the equity market on in the period the loss occurs and not later (Basu 1997). Hence, we predict an increase in the association between earnings and return over the three time periods under investigation.

IV. Sample Selection and Descriptive Statistics

The initial sample consists of all industrial German listed companies found in the Datastream database in the years 2000 – 2002, 2003 – 2004 and 2005-2006, indicating IAS/IFRS as their primary accounting standards.[5] German companies often are traded on more than one domestic stock exchange; we choose the common stock issue of the highest market value as the company's primary stock issue, and use the stock price of that issue when a company has multiple issues of common stocks. For the value relevance test, the sample selection process yields a German IAS sample of 187 firm-year observations for 107 companies, a German IFRS$_{voluntary}$ sample of 204 firm-year observations and companies, and a German IFRS$_{mandatory}$ sample of 448 firm-year observations and companies. Table 2 outlines our sample selection procedures for the value relevance tests.

In addition, to mitigate the effect of different firms in each period on the regression estimations, we match the sample firms in one period with the same firms in

---

[5] We include all firms where the applied accounting standards are either international accounting standards or IFRS.

the next period, and re-run all equations with the matched sample. This procedure yields 159 observations (92 companies) under the IAS period, 92 observations (92 companies) for the IFRS$_{voluntary}$ period, and 90 observations (90 companies) under the IFRS$_{mandatory}$ period.

    <Table 2 about here>

As shown in Table 3 below, the Electronic industry is the largest industry cluster in the IAS and the IFRS$_{voluntary}$ periods, and Financials is the largest in the IFRS$_{mandatory}$ period. The Financials industry is the second largest industry during the IAS period, and the Financials and Machinery and Equipment firms are both the second largest industries during the IFRS$_{voluntary}$ period and Financials during the IFRS$_{mandatory}$ period. One of the most notable change in industry specialization is an increase in number of Financial firms in the IFRS$_{mandatory}$ period. It seems that most of the Financials firms were not using the IAS/IFRS until the mandatory adoption of IFRS in 2005. Another change is the steady relative decrease of firms within the Recreation industry.

    <Table 3 about here>

Table 4 presents the descriptive statistics of earnings smoothing, timely loss recognition metrics, and value relevance, followed by the control variables.[6] The earnings per share (EPS) increases significantly across the periods, which is plausible considering the economic upturn between 2003 and 2006. There is a significant increase in book value of shareholders' equity per share (BVPS) between the IFRS$_{voluntary}$ period and the IFRS$_{mandatory}$ period. The change in net income (ΔNI) increases significantly from the IAS period to the IFRS$_{voluntary}$ periods. The ΔNI then decreases between the IFRS$_{voluntary}$ period and the IFRS$_{mandatory}$ period. There is no significant difference in change in cash flows

---

[6] Variables in all our analyzes are winsorized at the 1st and 99th percentiles to control for outliers.

from operations (ΔCFO) between the IAS and the IFRS$_{voluntary}$ periods, while there is a significant decrease between the the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods. There is a significant increase in accruals (ACC), measured as net income minus cash flow from operations scaled by total assets, between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods, which could possibly be related to a buildup of accruals caused by the abolishment of amortization of acquired goodwill. There is no significant difference in the prevalence of reporting of small positive earnings (SPOS) across the three periods. There is a significant decrease in the reporting of large negative earnings (Lneg) across the IAS and the IFRS$_{voluntary}$ periods. This could be a sign of an increase in income smoothing behavior; however, this development could also be driven by the economic situation during the IAS period and the ongoing upturn during the two following period. The descriptive statistics on the control variables suggests that there is a decrease in growth between the IAS and the IFRS$_{voluntary}$ periods but an increase in growth between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods (measured as change in sales). The latter increase could be related to the new companies adopting IFRS in 2005. There is no statistically significant difference in change in common stock over the three periods. There is no significant difference in changes in total liabilities (Dissue) between the IAS and the IFRS$_{voluntary}$ periods but there is significant increase between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods. The significant increase in the IFRS$_{mandatory}$ period could be driven by the fact that many more companies now must adopt IFRS and this result in the inclusion of companies that are less capital market oriented and more reliant on debt in the IFRS$_{mandatory}$ sample. However, it should be noted that there is no significant difference in leverage (measured as total liabilities to total shareholders' equity) across

18

the three periods. There is a statistically significant increase in the asset turnover rate between the IAS and the IFRS$_{voluntary}$ periods. Although, this is development is reversed between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods. The latter is most likely a consequence of the inclusion of a large number of new IFRS adopters in the sample group. The size of the sample companies (measured as the natural log of total assets) decreases significantly between the IAS period and the IFRS$_{voluntary}$ period. This could be driven by a lot of write downs during the IAS period due to the economic situation at that time, which is corroborated by the fact that in this period there was a significantly higher prevalence of reporting of large negative earnings. Finally, the cash flow from operations increased significantly between the IAS period and the IFRS$_{voluntary}$ period, this may also be explained by the improved economic conditions in the following periods. However, the cash flow from operations decreased significantly between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods, which could be related to the inclusion of a large number of new IFRS adopters in the sample group. Finally, there is a significant decrease in the free float between the IAS period and the IFRS$_{voluntary}$ period.

<Table 4 about here>

V. Results

Earnings Smoothing

As reported in Table 5, Panel A, the results of the tests of earnings smoothing are contrary to our expectations in some instances. The variability in the change in net income, ΔNI^*, does increase significantly between the IAS and the IFRS$_{voluntary}$ periods, however, there is a significant decrease between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods, suggesting an increase in income smoothing behavior. We also control for the

firm-specific volatility in cash flow from operations by using the ratio of income variability and cash flow from operations variability. As predicted, the variability increases significantly between the IAS and the IFRS$_{voluntary}$ periods but decrease sharply and end up below the IAS level in the IFRS$_{mandatory}$ period, however, in this test the difference is statistically significant on the 5% level. Once again, this suggests an increase in income smoothing behavior. The correlation between the residuals from the regression on accruals (ACC) and cash flow from operations CFO shows an increase in the magnitude of the negative correlation indicating a significant increase in earnings management across the three periods. It should be noted that the correlation between ACC and CFO is positive in the IAS period. We interpret this as a sign that companies are growing and the growth is driving both an increase in CFO and a buildup of accruals. This notion is also confirmed by the measure of growth that was significantly larger in this period compared to the later two. Finally, there is no significant difference between the small positive income variable (SPOS) across the three periods.

Timely Loss Recognition Tests

Table 5, Panel B shows a significant decrease in the reporting of large negative earnings. As previously pointed out, the change in reporting of large negative earnings may be the result of an improvement of the economic conditions since the IAS period. However, most of our tests support the notion that the quality of accounting has decreased among German companies reporting under IAS and IFRS over time. Furthermore, the coefficient of the interaction variable of return and bad news shows a significant increase between the IAS period and the IFRS$_{voluntary}$ period, as predicted. However, there is a significant decrease between the IFRS$_{voluntary}$ period and the

IFRS$_{mandatory}$ period indicating less timely loss recognition. This also may have something to do with the number of new adopters in the IFRSmandatory period.

Value Relevance Test

We measure value relevance in terms of the ability of accounting measures to explain stock prices. As shown in Table 5, Panel C, the overall R^2 of the regression models for each of the time period examined was 0.44 in the IAS period, 0.09 in the IFRS$_{voluntary}$ period, and 0.19 in the IFRS$_{mandatory}$ period. Cramer's (1987) test indicates a significant difference in R^2 between all three periods. Contrary to our expectations, the R^2s of both the IFRS periods are lower than the R^2 of the IAS period, indicating a lower usefulness of financial reporting under IFRS compared to IAS.

We also measure the R^2 of a reverse regression where earnings is dependent variable and returns as the independent variable (Basu 1997). As predicted, there seem to be an increase in the association between earnings and returns between the IAS and the IFRS$_{voluntary}$ periods (from 0.19 to 0.28). However, this development is once again reversed between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods (from 0.28 to 0.16). However, only the increase between the the IAS and the IFRS$_{voluntary}$ periods is statistically significant. Turning to the bad news observations only, once again, we find an expected increase in the association between the IAS and the IFRS$_{voluntary}$ period. However, contrary to expectations, this turns into a significant decrease from 0.35 to 0.11 between the IFRS$_{voluntary}$ period and the IFRS$_{mandatory}$ period.

<Table 5 about here>

In summary, our tests show consistent evidence that the quality of accounting increased between the IAS period and the IFRS$_{voluntary}$ but that this development reverses between the IFRS$_{voluntary}$ period and the IFRS$_{mandatory}$ period.

Sensitivity Analysis

Our findings in the main analysis may be a result of a structural change in the type of companies that report under IFRS since it became mandatory for most public companies in Germany. When IFRS was a choice, certain types of firms may have had more incentives to opt to report under IFRS than others. Germany has a large and liquid capital market, which means that large and well established companies have relatively less incentive to switch to IAS/IFRS to attract foreign investors since they can raise capital reporting under German GAAP. However, small information technology and less well established companies may not have the same access to the German capital market, and therefore, have reasons to switch to IAS/IFRS to be able to raise capital. Also, as shown in Table 4, the distribution of companies in different industries changed between the IFRS$_{voluntary}$ periods when the Electronics industry dominated and the IFRS$_{mandatory}$ period when the financial sector became dominating.

In order to examine whether a self-selection bias in our pre-2005 sample drives the results we also rerun all tests using a sub-sample consisting of companies with firm-year observations in both the IAS and the IFRS period. This sample has 159 observations (92 companies) for the IAS period and 92 observations (92 companies) for the IFRS$_{voluntary}$ period and 90 observations (90 companies) for the IFRS$_{mandatory}$ period.

As shown in Table 6 Panel A, the results for tests of earnings smoothing and timely loss recognition to some extent support the findings in the analysis using the

22

whole sample, although the reduction in accounting quality seems to be considerably lesser. The variability in the change in net income, ΔNI^*, increases significantly between the IAS and the IFRS$_{voluntary}$ periods but, as in the case with the whole sample, decreases significantly compared to the IFRS$_{mandatory}$ period. When controlling for the volatility in cash flow from operating activities, by using the ratio of net income variability and cash flow from operations variability, we find the same pattern, a significant increase between the IAS and the IFRS$_{voluntary}$ periods followed by a significant between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods. The correlation between accruals and cash flow from operations shows a significant decrease between the IAS and the IFRS$_{voluntary}$ periods. The correlation is positive in both of these periods, although it becomes negative in the IFRS$_{mandatory}$, however, the change is not statistically significant. We find no significant difference in the frequency of reporting small positive earnings across the two periods. Finally, as shown in Table 6 Panel B, we find no significant change in reporting of large negative earnings, indicative for less timely loss recognition. However, contrary to the previous measure, the coefficient of the interaction variable of annual return and negative return is significantly larger for the IFRS$_{voluntary}$ period compared to the IAS period. There is no significant difference between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods. Furthermore, as shown in Table 6 Panel C, the value relevance measures are also contradicting. The overall R^2 of the regression models for time periods examined was 0.47 in the IAS period and 0.15 in the IFRS$_{voluntary}$ period. Cramer's (1987) test indicates a significant difference in R^2 between the two periods on the 1% level. This is partially reversed between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods (from 0.15 to 0.38, significant on the 5% level). The analysis of the earnings on returns regressions shows a

significant increase between IAS period and the IFRS$_{voluntary}$ periods and a decrease

between the IFRS$_{voluntary}$ and the IFRS$_{mandatory}$ periods (though this is not significant).

When we analyze the earnings on returns regressions using bad news observations only

we find an incremental increase in the value relevance across all three periods.

<Table 6 about here>

We conclude that our measures of earnings management, timely loss recognition,

and value relevance using a matched sample are neither providing evidence of an

increase nor a decrease in accounting quality between the IAS and the IFRS period.

At the time of the mandatory adoption of IFRS, there is a shift in the structure of

the sample, the largest industry group was Electronics up to the end of 2004 after the

mandatory adoption in 2005 the largest industry group is now the Financial. We,

therefore, rerun our tests excluding financial observations in order to investigate whether

the results of our main analysis is driven by companies in the financial sector. As shown

in Table 7, there is no qualitative difference in our results from these tests compared to

the main analysis using the full sample.

<Table 7 about here>

In order to analyze whether our results are driven by the new adopters in 2005, we

also split the sample used in the IFRS$_{mandatory}$ period into a mandatory and a voluntary

adopter group. Where the mandatory adopters are those who waited to adopt IFRS until it

was made mandatory in 2005 and those who adopted IFRS before are classified as

voluntary adopters. In addition, when doing this we also excluded all adopters of U.S.

GAAP who waited to adopt IFRS until it was made mandatory. The reason for this is that

we do not consider these companies as resisting the use of international accounting

standards, and therefore, they are different from those companies who resist switching from German GAAP to IFRS. As shown in Table 8, we find that there is slightly less variability in residuals of change of net income and the variability of the ratio of the variability of change in residuals of net income and cash flow from operations; however, the differences are not statistically significant. There seem to be more large negative earnings reported by the voluntary adopters but once again, the difference is not statistically significant. The only significant difference between the two groups is found in the value relevance tests, the resisters are consistently showing significantly lower value relevance in all such tests.

<Table 8 about here>

In order to establish that the any decrease in the quality of financial reporting is driven by the excluded set of U.S, GAAP adopters; we also compared these observations to the voluntary adopters. As expected, we did not find any evidence of this. On the contrary, the U.S. GAAP adopters show a significantly higher variability in change in residuals of net income (also when controlling for variability in change in residuals of cash flow from operations), a positive correlation between accruals and cash flow, a significantly lower frequency in reporting small positive incomes. However, the value relevance among these companies was lower than that of the voluntary adopters.

<Table 9 about here>

VI. Conclusion

This study compares the characteristics of accounting amounts using a sample of German companies reporting under IAS during 2000-2002, and IFRS during 2003-2004 and 2005-2006. Specifically, we investigate whether there is a change in accounting

quality during these three time periods as IASB revises existing IAS and issues new IFRS to formulate a set of high quality international accounting standards for global financial reporting purpose. Following prior research, we operationalize accounting quality with earnings smoothing, timely loss recognition, and value relevance metrics. Contrary to our expectations, our results suggest a decrease in accounting quality over the last years. We find that earnings and book value of equity are becoming less value relevant during the IFRS$_{mandatory}$ period compared to both the IAS and the IFRS$_{voluntary}$ period. The findings on earnings smoothing and timely loss recognition corroborate largely our findings with respect to the value relevance of accounting information. Our results consistently indicate that accounting quality has worsened over time. When using a matched sample we cannot find any clear indication of either an improved or a worsened quality of financial reporting. Further analysis of the 2005 to 2006 period provides some weak indications that this might have been partly driven by new adopters of IFRS in 2005, however, only the difference in value relevance is statistically significant. We also investigated whether our results were driven by a new dominating industry group, Financials. We find nothing suggesting that this is the case. In sum, it seems that the decrease in accounting quality is mainly driven by changes in accounting standards, not the new adopters in 2005. The implication of this is that the last revisions of IASs and the addition of new IFRSs have caused a decrease the quality of financial reporting in Germany and future research needs to establish which standards drive this development.

Table 1: Summary of Revisions of IAS and IFRS over Time

Panel A: Revisions During the IAS period

Standard	Issued/ revised Year	In effect	Focus	Revision Made
IAS 12	2000	2001	Income Taxes	The standard was amended to include guidance on accounting for tax consequences of dividends and other distributions made by the reporting parent company.
IAS 19	2000	2001	Employee benefits	Revised to include and regulate more the retirement benefit costs only.
IAS 40	2000	2001	Investment property	Was an attempt to impose fair value measurement of investment property, ended up allowing it as an alternative to historical cost accounting.

Panel B: Revisions During the IFRS voluntary period

Standard	Issued/ revised Year	In effect	Focus	Revision Made
IAS 10	2003	2004	Events after the reporting period	Regulates the reporting of events after the reporting period.
IAS 17	2003	2004	Leases	Initial direct and incremental costs by lessors in negotiating leases must be recognized over the lease term.
IAS 32	2003	2005*	Presentation of financial instruments	Additional guidance on measurement of the components of compound instruments on initial recognition and to group all guidance on financial instruments in one standard
IAS 33	2003	2005*	Earnings per share	Clarifying the standard and eliminate alternatives allowed by the standard.
IAS 41	2001	2003	Agriculture	Regulates accounting for agricultural assets. These types of assets were previously not covered by other IASs.
IAS 36	2004	2004	Impairment of assets	Requires measurement of recoverable amount of intangible assets with an indefinite useful life on an annual basis (including goodwill and intangible assets not yet available for use).
IAS 38	2004	2004	Intangible assets	The assumption that all assets' useful life is finite is abolished. In addition, intangible assets with infinite useful life should not be amortized.
IFRS 1	2003	2004	First-time adoption of IFRS	Sets out the procedures for first-time Adoption.
IFRS 3	2004	2004	Business combinations	Prohibits the use of the pooling of interests method for business combinations. Goodwill is initially defined as the net fair value of acquired assets and liabilities. Goodwill etc. with infinite lives are mot amortized. Also see IAS 36 and IAS 38.
IAS 1	2003	2005*	Presentation of Financial Statements	Mostly transferring the policies application related to changes in accounting estimates and errors to IAS 8 while the presentation issues is transferred to IAS 1.

Panel B: Revisions During the IFRS voluntary period cont.

Standard	Issued/ revised Year	In effect	Focus	Revision Made
IAS 2	2003	2005[*]	Inventories	The main change is the prohibition of LIFO as a cost formula.
IAS 8	2003	2005[*]	Accounting policies, changes in accounting estimates and errors	Please refer to revisions described for IAS 1.
IAS 16	2004	2005[*]	Property, plant, and equipment	Costs of dismantlement, removal or restoration are included in capitalized amounts. Fair value revaluation only if this is reliably measurable. Depreciation must start when the asset is available for use and continues regardless if the asset is idle or not.
IAS 19	2004	2006[*]	Employee benefits	Revised to permit recognition of actuarial gain and losses in equity and to require additional disclosure.
IAS 21	2003	2005[*]	Changes in foreign exchange rates	Removal of a limited option to capitalize exchange rate differences resulting from severe devaluation or depreciation of a currency against which there is no means of hedging.
IAS 24	2003	2005[*]	Related party disclosures	Requires disclosure of compensation to key management employees and expands the definition of "related party" by adding joint ventures, etc.
IAS 27	2003	2005[*]	Consolidated and separate financial statements	Minority interests are now presented within the equity as a separate line item.
IAS 28	2003	2005[*]	Investments in associates	Investors must not only consider the carrying amount the investment but also other long-term interests in the associate when recognizing its share of losses of the associate.
IAS 31	2003	2005[*]	Interests in joint ventures	Investors must disclose the method used to recognize its interest in jointly controlled entities (proportional consolidation or the equity method).
IAS 39	2004	2005[*]	Financial instruments: recognition and measurement	Added fair value accounting for a hedge of the interest rate exposure of a portfolio of financial assets and liabilities.
IAS 40	2004	2005[*]	Investment property	Defining the concept "investment property" and impose a consistent use of the fair value or the cost model.
IFRS 2	2004	2005[*]	Share-based payment	Require recognition of all share-based payment transactions using a fair value measurement basis.

Panel B: Revisions During the IFRS voluntary period cont.

Standard	Issued/ revised Year	In effect	Focus	Revision Made
IFRS 4	2004	2005[*]	Insurance contracts	Prohibits catastrophe and equalization reserves. Requires testing of the adequacy of recognized insurance liabilities and impairment tests of reinsurance assets.
IFRS 5	2004	2005[*]	Non-current assets held for sale and discontinued operations	Prescribes accounting for assets held for sale and the presentation and disclosure of discontinued operations.

Panel C: Revisions During the IFRS mandatory period

Standard	Issued/ revised Year	In effect	Focus	Revision Made
IAS 39	2005	2006	Financial instruments: recognition and measurement	Restricted the use of the "fair value option" to eliminate accounting or economic mismatches.
IFRS 6	2005	2006	Exploration for and evaluation of mineral resources	Regulates the financial reporting of mineral resources until IASB has completed a comprehensive project of this.
IFRS 7	2006	2007	Financial instruments disclosure	Require disclosure of information on the significance of financial instruments for a company's financial position and profitability.
IFRS 8	2006	2009[*]	Operating Segments	Extends and change the scope of segment reporting.

[*]Earlier application is encouraged.

[1] EPS is earnings per share at year end of the fiscal year deflated by the share price 6 months after the preceding fiscal year end.

[2] BVPS is the book value of shareholders' equity per share at the end of the fiscal year deflated by the share price 6 months after the preceding fiscal year end.

[3] Return is the annual return of company i at time t.

[4] ΔNI is the change in annual earnings scaled by total assets.

[5] ΔCF is the change in cash flow from operating activities scaled by total assets.

[6] ACC is earnings less cash flow from operating activities scaled by total assets.

[7] SPOS is a dummy variable taking on the value 1 for observations for which the annual earnings scaled by total assets is between 0 and 0.01, and 0 otherwise.

[8] Lneg is a dummy variable taking on the value 1 for observations for which the annual earnings scaled by total assets is less than -0.20, and 0 otherwise.

[9] LEV is total liabilities divided by shareholders' equity.

[10] Growth is the percentage change in sales.

[11] Eissue is the percentage change in common shareholders' stock.

[12] Dissue is the percentage change in total liabilities.

[13] Turn is sales divided by total assets.

[14] Size is the natural log of total assets.

[15] CFO is the cash flow from operating activities scaled by total assets.

[16] NUMEX is the number of stock exchange listings.

[17] AUD is an indicator taking on the value of 1 if the firm's auditor is PwC, KPMG, Arthur Andersen, E&Y, or D&T, and 0 otherwise.

[18] XLIST is an indicator taking on the value of 1 if the firm is listed on any U.S. stock exchange and 0 otherwise.

[19] FF is the free float measured as the average number of shares traded the last day of the month during the fiscal year divided by number of common shares outstanding at the fiscal year end, divided by 1,000.

Asterisks indicate that there is significantly different from the previous time period using a two-tailed t-test: [*] $p < 0.1$, [**] $p < 0.05$, and [***] $p < 0.01$.

Table 5: Analysis of Accounting Quality

Panel A: Earnings Management	IAS N=187	IFRS$_V$ N=204	IFRS$_M$ N=448

*, **, *** Significantly different between each category at the 0.01, 0.05, and the 0.10 respectively (two-tailed)

#, ##, ### Significantly different from zero at the 0.01, 0.05, and the 0.10 respectively (two-tailed)

[1] ΔNI* is the variance of residuals from a regression of the ΔNI on the control variables.

[2] ΔCFO* is the variance of residuals from a regression of the ΔNI on the control variables.

[3] Variability of ΔNI* over ΔCFO* is the ratio of ΔNI* divided by ΔCFO*.

[4] Correlation of ACC* and CFO* is the partial Spearman correlation between the residuals from the ACC and CFO regression.

[5] SPOS is a dummy variable taking on the value 1 for observations for which the annual earnings scaled by total assets is between 0 and 0.01, and 0 otherwise.

[6] Lneg is a dummy variable taking on the value 1 for observations for which the annual earnings scaled by total assets is less than -0.20, and 0 otherwise.

[7] The regression is $EPS = \beta_0 + \beta_1 R + \beta_2 DUM + \beta_3 R * DUM + \varepsilon$ where EPS is annual earnings per share deflated by share price at the beginning of the period, R is annual return, and DUM takes on the value 1 if the return is negative and 0 otherwise.

[8] The regression is $P = \beta_0 + \beta_1 EPS + \beta_2 BVPS + \varepsilon$ where P is price as of three months after the fiscal year – end, EPS is earnings per share and $BVPS$ is the book value of shareholders' equity per share. All variables are scaled by share price six months after the preceding year-end.

[9] The Basu good and bad news regression is $EPS = \beta_0 + \beta_1 R + \varepsilon$, where EPS is earnings per share deflated by price at the beginning of the year and R is the annual return. Good news observations are those for which R is positive and bad news are those for which return is negative. We winsorize all continuous variables at the 1% level to control for outliers.

Table 6: Analysis of Accounting Quality Using a Sub-Sample of voluntary IFRS adopters.
