The Frankel property for self-shrinkers from the viewpoint of elliptic PDEs

By *Debora Impera* at Torino, *Stefano Pigola* at Milano and *Michele Rimoldi* at Torino

————————

Abstract. We show that two properly embedded self-shrinkers in Euclidean space that are sufficiently separated at infinity must intersect at a finite point. The proof is based on a localized version of the Reilly formula applied to a suitable f-harmonic function with controlled gradient. In the immersed case, a new direct proof of the generalized half-space property is also presented.

1. Basic notation and purpose of the paper

1.1. Weighted manifolds. By a *weighted manifold* (also called *manifold with density*, or *smooth metric measure space*) we mean a triad

$$M_f = (M, g, dv_f),$$

where (M, g) is an m-dimensional Riemannian manifold with volume element dv,

$$dv_f = e^{-f} \, dv$$

and $f : M \to \mathbb{R}$ is a smooth weight function. The (obviously intrinsic) geometric analysis of M_f is related to bounds on its *Bakry–Émery Ricci curvature*

$$\mathrm{Ric}_f := \mathrm{Ric} + \mathrm{Hess}(f)$$

combined with the analysis of its *weighted Laplacian*

$$\Delta_f u = \mathrm{div}_f \nabla u = \Delta u - g(\nabla f, \nabla u),$$

where the *weighted divergence* is the operator

$$\mathrm{div}_f X = e^f \, \mathrm{div}(e^{-f} X).$$

————————

An important example of weighted manifold is represented by the *Gaussian space*

$$\mathbb{R}^{m+1}_f = (\mathbb{R}^{m+1}, \langle \cdot, \cdot \rangle, e^{-\frac{1}{2}|x|^2} dx).$$

Since the weight function is $f(x) = \frac{1}{2}|x|^2$, we have that the Bakry–Émery Ricci curvature is

$$\mathrm{Ric}_f^{\mathbb{R}^{m+1}} \equiv 1,$$

hence $\mathbb{R}^{m+1}_f$ is called a *shrinking Ricci soliton.* Moreover, the weighted Laplacian is the *Ornstein–Uhlenbeck* operator

$$\Delta_f u = \Delta u - \langle \nabla u, x \rangle.$$

1.2. Self shrinkers of the MCF.   Given an isometrically immersed hypersurface in the weighted manifold M_f^{m+1}

$$x : \Sigma^m \to M_f^{m+1},$$

we introduce the corresponding *weighted mean curvature vector field* of the immersion as

$$\mathbf{H}_f := \mathbf{H} + (\nabla f)^\perp,$$

where we are using the convention $\mathbf{H} = \mathrm{tr}_\Sigma \mathbf{A}$, $\mathbf{A}$ being the vector-valued second fundamental form. Here $(\cdot)^\perp$ denotes the orthogonal projection on the normal bundle of Σ. We say that $x : \Sigma^m \to M_f^{m+1}$ is f-*minimal* if $\mathbf{H}_f \equiv 0$.

   A *self-shrinker* of the mean curvature flow (MCF) in the Euclidean space $\mathbb{R}^{m+1}$ is an f-minimal hypersurface of the Gaussian space $\mathbb{R}^{m+1}_f$. This is completely equivalent to require that the mean curvature vector field satisfies the equation

$$x^\perp = -\mathbf{H}.$$

1.3. Intrinsic vs. extrinsic weighted structure.   Clearly, the self-shrinker Σ^m inherits the weighted structure of the ambient space. Thus, intrinsically, we can consider the manifold with density

$$\Sigma_{\tilde{f}}^m = (\Sigma^m, g = x^*\langle \cdot, \cdot \rangle, dv_{\tilde{f}}),$$

where $\tilde{f} = f \circ x$. It is customary to drop the "tilde" in the weight function and to write Σ_f^m. An important relation between the (intrinsic) Bakry–Émery Ricci tensor of Σ_f^m and the extrinsic geometry of the f-minimal hypersurface Σ^m comes from the Gauss equations. Indeed, it was observed in [22] that

$$\mathrm{Ric}_f^\Sigma \geq 1 - |\mathbf{A}|^2.$$

As in the usual minimal surface theory, another important link between the intrinsic weighted geometry and the extrinsic properties of the self-shrinker comes from the f-Laplacian of the immersion. We have the following identity (see e.g. [4])

(1.1) $$\Delta_f^\Sigma x = -x$$

and its direct consequence

$$\Delta_f^\Sigma |x|^2 = 2(m - |x|^2).$$

1.4. Properly immersed self-shrinkers.   In this paper, we are mainly interested in *properly immersed* self-shrinkers. A remarkable result by Q. Ding and Y. L. Xin [5] states that a properly immersed self-shrinker $x : \Sigma^m \to \mathbb{R}^{m+1}_f$ has extrinsic Euclidean volume growth

(1.2) $$|\Sigma^m \cap \mathbb{B}_R^{m+1}| = \mathcal{O}(R^m)$$

and, hence, finite weighted volume

$$\mathrm{vol}_f(\Sigma^m) < +\infty.$$

This latter condition implies that the complete weighted manifold Σ_f^m is f-*parabolic*, i.e., for any $u \in \mathscr{C}^0(\Sigma) \cap \mathscr{W}^{1,2}_{\mathrm{loc}}(\Sigma)$,

$$\begin{cases} \Delta_f^\Sigma u \geq 0, \\ \sup_\Sigma u < +\infty, \end{cases} \implies u \equiv \mathrm{const.}$$

It is well known that parabolicity is a kind of compactness from several viewpoints, including global Stokes theorems and maximum principles, as it is already visible from the above definition.

1.5. The Frankel property. In many instances, properly immersed self-shrinkers behave like compact minimal hypersurfaces of the standard sphere. In this latter setting, it is well known that any two closed minimal immersed hypersurfaces must intersect. Actually, the ambient space can be generalized to a compact Riemannian manifold with strictly positive Ricci curvature. This is called the *Frankel property* after the celebrated paper by T. Frankel [6]. The original proof gives an estimate of the (positive) distance between non-intersecting compact hypersurfaces in terms of their mean curvatures and it is based on the second variation of length along a geodesic realizing the distance. New arguments and further extensions of the Frankel property to other geometric contexts are now available. Most notably, and relevantly for the development of the present paper, we mention [18] by P. Petersen and F. Wilhelm, where the maximum principle for the hypersurface-distance function is used, and [7] by A. Fraser and M. M.-C. Li, where the Frankel property is investigated in the setting of compact embedded free boundary minimal surfaces in a manifold with non-negative Ricci curvature. We shall comment on these works later on, in Section 3. It is natural to ask:

Problem. Let $x_j : \Sigma_j^m \to \mathbb{R}_f^{m+1}$ for $j = 1, 2$ be complete, properly immersed self-shrinkers. To what extent is it true that $x_1(\Sigma_1^m) \cap x_2(\Sigma_2^m) \neq \emptyset$?

Starting from the work by G. Wei and W. Wylie, [26], where the case of compact hypersurfaces is considered (actually what is really needed is that the positive distance between the hypersurfaces is realized at finite points), few partial positive answers to this question appeared in the literature. They are mostly related to (generalized) half-space properties of the shrinkers; see Section 2.

During the summer school "Geometric Analysis on Riemannian and Singular Metric Measure Spaces", held in Como in July 2016, `http://arms.lakecomoschool.org`, Professor Tom Ilmanen suggested (and kindly outlined the main steps of the parabolic proof) that the Frankel property can be proved in the general framework of the motion by level-sets in Euclidean space.

1.6. Purpose of the paper. In the present paper, by taking the purely elliptic viewpoint, we give the first general result in the literature about the validity of the (smooth) properly embedded Frankel property for self-shrinkers of the MCF. To this end, we shall collect results

and techniques that, we feel, will be interesting also in other settings. The main contributions are the following:

- With a new direct argument, based on the potential theory of weighted manifolds, we recover the main result of [1], namely we show that a properly immersed self-shrinker cannot be located neither inside nor outside a self-shrinker cylinder; see Theorem A in Section 2.

- We apply a localized version of the Reilly formula to a suitable f-harmonic function with controlled gradient in order to show that two properly embedded self-shrinkers that are sufficiently separated at infinity must intersect at a finite point; see Theorem B and Theorem C in Section 3.

2. Immersed shrinkers: Half-space-type properties

After the celebrated paper by D. Hoffman and W. Meeks, [10], one says that the *(weak) half-space property* holds for a certain family $\mathscr{F}$ of immersed hypersurfaces if any $\Sigma \in \mathscr{F}$ cannot be confined in certain half-spaces unless it is a totally geodesic hyperplane.

The first half-space property for Euclidean properly immersed self-shrinkers of the MCF was observed in [20, Theorem 3].

Theorem. *Let $x : \Sigma^m \to \mathbb{R}^{m+1}$ be a properly immersed self-shrinker. If $x(\Sigma)$ is contained in a closed half-space of $\mathbb{R}^{m+1}$ determined by a hyperplane Π passing through the origin, then $x(\Sigma) = \Pi$.*

In the same paper, the authors started the investigation on the possible regions where a properly immersed self-shrinker (with various geometric assumptions) can be located. The proof of the half-space property proposed in [20] is a simple application of the f-parabolicity of the self-shrinkers. Soon after, P. Cavalcante and J. Espinar, [1, Theorem 1.1], obtained the same result using the touching principle, following closely the original proof by Hoffman and Meeks. The role of the catenoid is now played by a rotational self-shrinker discovered by S. Kleene and N. Møller [14]. With a different analytic technique, based on a perturbation argument that exploits the instability of the Jacobi operator associated to a cylinder, they were also able to replace the half-space by the interior or the exterior region of a cylindrical self-shrinker; [1, Theorem 1.2 and Theorem 1.3]

In the next result we use potential theoretic arguments to recover [1, Theorem 1.2 and Theorem 1.3] in a very succinct way.

Theorem A. *Let $x : \Sigma^m \to \mathbb{R}^{m+1}$ be a complete properly immersed self-shrinker. If $x(\Sigma)$ is confined inside either one of the connected regions of $\mathbb{R}^{m+1}$ determined by the self-shrinker cylinder $\mathbb{S}^k_{\sqrt{k}} \times \mathbb{R}^{m-k} \subset \mathbb{R}^{m+1}$, $1 \le k \le m-1$, then $x(\Sigma) = \mathbb{S}^k_{\sqrt{k}} \times \mathbb{R}^{m-k}$.*

Proof. Letting $\{e_A\}_{A=1}^{m+1}$ be an orthonormal frame of $\mathbb{R}^{m+1}$, we will denote the coordinate functions of x by $x_A := \langle x, e_A \rangle$ and by $\mathcal{N}$ the chosen (local) Gauss map of the immersion. Fix $1 \le k \le m-1$ and consider a self-shrinker cylinder

$$\mathcal{C}^k_{\sqrt{k}} := \mathbb{S}^k_{\sqrt{k}} \times \mathbb{R}^{m-k} \subset \mathbb{R}^{m+1}.$$

Let $u : \Sigma \to \mathbb{R}$ be the smooth function defined by

$$u = \sum_{A=1}^{k+1} x_A^2.$$

Clearly, for every $p \in \Sigma$,

$$u(p) = \left(\overline{\text{dist}}_{\mathbb{R}^{m+1}}(x(p), \mathcal{C}_{\sqrt{k}}^k) + \sqrt{k}\right)^2,$$

where $\overline{\text{dist}}_{\mathbb{R}^{m+1}}(x(p), \mathcal{C}_{\sqrt{k}}^k)$ denotes the signed distance. Here, we are using the convention that such a distance is negative inside $\mathcal{C}_{\sqrt{k}}^k$. Note that

$$\begin{aligned}
(2.1) \qquad \frac{1}{4}|\nabla^\Sigma u|^2 &= u - \left(\sum_{A=1}^{k+1} x_A \langle e_A, \mathcal{N}\rangle\right)^2 \\
&= u - \langle \overline{x}, \overline{\mathcal{N}}\rangle^2 \\
&= u\left(1 - \left\langle \frac{\overline{x}}{|\overline{x}|}, \overline{\mathcal{N}}\right\rangle^2\right),
\end{aligned}$$

where we are using the notation

$$\overline{x} = \sum_{A=1}^{k+1} x_A e_A \quad \text{and} \quad \overline{\mathcal{N}} = \sum_{A=1}^{k+1} \langle e_A, \mathcal{N}\rangle e_A.$$

By equation (1.1), we have that

$$\frac{1}{2}\Delta_f^\Sigma x_A^2 = x_A \Delta_f^\Sigma x_A + |\nabla^\Sigma x_A|^2 = -x_A^2 + |e_A^T|^2.$$

Hence,

$$\begin{aligned}
(2.2) \qquad \frac{1}{2}\Delta_f^\Sigma u &= \sum_{A=1}^{k+1} |e_A^T|^2 - u \\
&= k + 1 - \sum_{A=1}^{k+1} \langle e_A, \mathcal{N}\rangle^2 - u \\
&= k + 1 - |\overline{\mathcal{N}}|^2 - u.
\end{aligned}$$

A direct consequence of (2.2) is that

$$(2.3) \qquad \frac{1}{2}\Delta_f^\Sigma u \geq k - u.$$

On the other hand, using (2.1) and (2.2), we deduce the estimate

$$(2.4) \qquad \Delta_f^\Sigma \sqrt{u} = \frac{\Delta_f^\Sigma u}{2\sqrt{u}} - \frac{|\nabla^\Sigma u|^2}{4u^{\frac{3}{2}}} = \frac{k - u}{\sqrt{u}} + \frac{\left\langle \frac{\overline{x}}{|\overline{x}|}, \overline{\mathcal{N}}\right\rangle^2 - |\overline{\mathcal{N}}|^2}{\sqrt{u}} \leq \frac{k - u}{\sqrt{u}}.$$

Assume now that $x(\Sigma)$ is confined in the closed exterior region determined by the self-shrinker cylinder $\mathcal{C}_{\sqrt{k}}^k \subset \mathbb{R}^{m+1}$. Thus, $u \geq k$ and, by inequality (2.4), $\sqrt{u}$ is f-superharmonic. On the other hand, since Σ is properly immersed, Σ_f is parabolic in the sense of (1.4). It follows that $\sqrt{u} \equiv C$ for some constant $C \geq \sqrt{k}$ and using this information into (2.4) yields that, in fact, $u \equiv k$, i.e., $x(\Sigma) \subseteq \mathcal{C}_{\sqrt{k}}^k$. The desired equality now follows by geodesic completeness.

Similarly, suppose that $x(\Sigma)$ is confined inside the solid cylinder bounded by the self-shrinker $\mathcal{C}^k_{\sqrt{k}} \subseteq \mathbb{R}^{m+1}$. Then, we see from (2.3) that the function u is f-subharmonic. Since $u \leq k$ it follows that u must be constant by f-parabolicity. Whence, reasoning as in the previous case, we reach once more the conclusion that $x(\Sigma) = \mathcal{C}^k_{\sqrt{k}}$.   □

3. Embedded shrinkers with controlled asymptotic distance: Main results

As we have alluded to in the introduction, a new approach to the traditional Frankel property that could be relevant in our setting was proposed by Petersen-Wilhelm in [18]. As all of the other proofs of Frankel-type properties, it proceeds by contradiction, assuming that two properly embedded minimal hypersurfaces Σ_1, Σ_2 do not intersect. Then one considers the function $u = r_1 + r_2$ on the open set Ω bounded by Σ_1 and Σ_2, where $r_j(x) = \mathrm{dist}(x, \Sigma_j)$, $j = 1, 2$. At points x where the normal exponential map $\exp^{\perp}_{\Sigma_j}$ is a diffeomorphism onto its image, and denoting with γ_j the geodesic segment connecting Σ_j with x, from the Riccati equation one obtains

$$\frac{d}{dt}(\Delta r_j \circ \gamma_j(t)) = -1 - |\mathrm{Hess}(r_j)|_{\gamma_j(t)}|^2 \leq -1,$$

which, once integrated, gives that u satisfies, in the barrier sense of Calabi,

$$\Delta u \leq -u \quad \text{on } \Omega.$$

Now, if $\mathrm{dist}(\Sigma_1, \Sigma_2) > 0$ is attained at some pair of points $(p, q) \in \Sigma_1 \times \Sigma_2$ a segment $\gamma_1 = \gamma_2$ connecting p and q is a curve of interior minima for u, contradicting the maximum principle. Similar arguments can be used when Σ_1, Σ_2 are compact f-minimal hypersurfaces in the Gaussian space up to replacing the Laplace–Beltrami operator with the corresponding weighted Laplacian Δ_f; see [26, Theorem 7.3, Theorem 7.4]. However, if $\inf u$ is not achieved, i.e., $\mathrm{dist}(\Sigma_1, \Sigma_2)$ is either zero or realized at infinity, things are much more subtle. Since Ω is an f-parabolic manifold with boundary, a natural attempt is to apply global forms of the maximum principle. Unfortunately, a formal computation suggests that the normal derivative of u in the exterior direction η satisfies, in a suitable weak sense, $\partial_\eta u \leq 0$ on $\partial\Omega$. Thus, it is unlikely that the potential theory for parabolic manifolds with boundary developed in [12] could be applicable directly to u or to variants thereof.

In the recent paper [7], A. Fraser and M. Li proved that the Frankel property holds for compact embedded free boundary minimal surfaces in a compact manifold with non-negative Ricci curvature. They supplied two different arguments: the first one is a small variation of the original proof by Frankel whereas the second one, to the best of our knowledge, is completely new. It relies on the Reilly's formula applied to a harmonic function that separates the two surfaces. Inspired by this latter proof we shall obtain that if two properly embedded self-shrinkers are separated enough at infinity then they must intersect at some finite point. To make this claim more precise, we first observe that two properly embedded shrinkers cannot be a positive distance apart.

Theorem B. *Let* Σ_1^m, Σ_2^m *be properly embedded* f-*minimal hypersurfaces inside the complete weighted manifold* M_f^{m+1} *with* $\mathrm{Ric}_f \geq K^2 > 0$. *Assume that each of* Σ_1 *and* Σ_2 *separates* M_f. *Then* Σ_1^m *cannot be a positive distance apart from* Σ_2^m.

We note that this result, in the setting of embedded hypersurfaces, extends [26, Theorem 7.4] since it covers also the case where the two hypersurfaces realize their positive distance at infinity. It remains to rule out the situation where Σ_1 and Σ_2 intersect at infinity. We achieve the goal in the following assumptions:

Asymptotic Distance Condition. The two hypersurfaces Σ_1 and Σ_2 are separated "enough" at infinity.

Tubular Neighborhood Condition. One of the hypersurfaces, say Σ_2, is separated "enough" from itself at infinity.

In both cases, "enough" is quantified in exponential terms. More precisely:

Theorem C. *Let Σ_1^m and Σ_2^m be properly embedded connected self-shrinkers in the Euclidean space $\mathbb{R}^{m+1}$. Assume that*

$$(3.1) \qquad \liminf_{\substack{|z| \to +\infty \\ z \in \Sigma_2}} \frac{\mathrm{dist}_{\mathbb{R}^{m+1}}(z, \Sigma_1)}{e^{-b|z|^2} \mathscr{P}(|z|)^{-1}} > 0,$$

and that the ray $R(z) > 0$ of a regular normal tubular neighborhood $\mathcal{T}(\Sigma_2)$ at a point $z \in \Sigma_2$ decays in the following controlled way:

$$(3.2) \qquad \liminf_{\substack{|z| \to +\infty \\ z \in \Sigma_2}} \frac{R(z)}{e^{-c|z|^2} \mathscr{P}(|z|)^{-1}} > 0$$

for some polynomial $\mathscr{P} \in \mathbb{R}[t]$ and some constants $b, c > 0$ satisfying $0 < mc + b < \frac{1}{2}$. Then

$$\Sigma_1 \cap \Sigma_2 \neq \emptyset.$$

Example 1 (2-dimensional). Let us briefly illustrate a concrete situation where our results could be applied. Let $\Sigma_1, \Sigma_2 \hookrightarrow \mathbb{R}^3$ be properly embedded self-shrinkers with finite topology.

By [25], the ends of each surface Σ_j are smoothly asymptotic either to a cylinder or to a cone over a link in $\mathbb{S}^2$. Examples with exactly one conical end are constructed in [13].

Assume that each surface Σ_j has only one end $\mathcal{E}_j$, asymptotic to the cone $\mathcal{C}_j$, $j = 1, 2$. Then, by [2, 24], we know that $\mathcal{E}_j$ has a uniform normal tubular neighborhood. Indeed:

(i) $\mathcal{E}_j = \mathrm{Graph}_{\mathcal{C}_j}(w_j)$ is a normal graph over $\mathcal{C}_j$ with $|\nabla^k w_j| \to 0$ at ∞, for all $k \geq 0$.

(ii) $\mathcal{E}_j$ has unit normal ν_j asymptotic to the unit normal $\nu_{\mathcal{C}_j}$ of $\mathcal{C}_j$ at ∞.

Now, the following possibilities can occur:

(a) If $\mathcal{C}_1 = \mathcal{C}_2$, then, by [24], $\mathcal{E}_1 = \mathcal{E}_2$ and in particular $\Sigma_1 \cap \Sigma_2 \neq \emptyset$.

(b) If $\mathcal{C}_1 \cap \mathcal{C}_2 = \{0\}$, i.e., the links of $\mathcal{C}_1$ and $\mathcal{C}_2$ are disjoint, then $\mathcal{E}_1$ and $\mathcal{E}_2$ are very much separated and, hence, $\Sigma_1 \cap \Sigma_2 \neq \emptyset$.

(c) If $\mathcal{C}_1$ intersects transversally $\mathcal{C}_2$ outside $\{0\}$, i.e. the links of $\mathcal{C}_1$ and $\mathcal{C}_2$ intersects transversally, then $\mathcal{E}_1 \cap \mathcal{E}_2 \neq \emptyset$ and in particular $\Sigma_1 \cap \Sigma_2 \neq \emptyset$.

(d) If $\mathcal{C}_1$ intersects $\mathcal{C}_2$ tangentially, i.e. the links of $\mathcal{C}_1$ and $\mathcal{C}_2$ are tangential, then we can still conclude that $\Sigma_1 \cap \Sigma_2 \neq \emptyset$ provided that $\mathcal{E}_1, \mathcal{E}_2$ are $e^{-b|z|^2}$-separated at ∞.

Both Theorem C and Theorem B, can be considered as concrete realizations of the following abstract result.

Theorem D.   *Let Σ_1^m, Σ_2^m be properly embedded f-minimal hypersurfaces inside the complete weighted manifold M_f^{m+1} with $\mathrm{Ric}_f \geq K^2 > 0$. Assume that $\Sigma_1 \cap \Sigma_2 = \emptyset$ and that each of Σ_1 and Σ_2 separates M_f. The domain enclosed by the two hypersurfaces is denoted by Ω. If $u \in \mathscr{C}^\infty(\overline{\Omega})$ is a solution of the following problem:*

$$(3.3) \qquad \begin{cases} \Delta_f u = 0 & in\ \Omega, \\ \quad u = 0 & on\ \Sigma_1, \\ \quad u = 1 & on\ \Sigma_2, \end{cases}$$

then

$$\lim_{R \to +\infty} \frac{\int_{B_R^M \cap \Omega} |\nabla u|^2\, dv_f}{R^2} = +\infty.$$

The rest of the paper is organized as follows:

- First, in Section 4, we prove the abstract Theorem D using a localized version of the Reilly's formula that, we feel, is of independent interest.

- Next, in Section 5, we assume by contradiction that the two self-shrinkers do not intersect and we prove that a bounded solution of (3.3), with finite Dirichlet f-energy, exists provided the assumptions of Theorem C are met. This contradicts Theorem D.

- Finally, in Section 6, using a variational viewpoint, we still assume by contradiction that the two self-shrinkers do not intersect and we show that a bounded solution of (3.3), with finite Dirichlet f-energy, exists without any restriction on the extrinsic geometry of Σ_2, provided the distance between the two self-shrinkers is strictly positive. This, again, contradicts Theorem D.

4. Localized Reilly's formula and a proof of Theorem D

Reilly's formula is a celebrated integral formula first introduced in [21] to study isometric immersions and geometric bounds on the first Neumann eigenvalue of a compact manifold with boundary; see also [3] and the survey paper [19] for more applications. A version of this formula for the weighted Laplacian is obtained in [16] following the arguments in [3]. We are going to prove a localized version of the Reilly's formula that holds in the non-compact weighted setting.

Lemma 2.   *Let Ω be a domain with smooth boundary $\Sigma = \partial\Omega$ in the (possibly incomplete) smooth metric measure space M_f^{m+1} and let $\phi \in \mathscr{C}_c^\infty(M)$. Then, for any $u \in \mathscr{C}^2(\overline{\Omega})$,*

$$(4.1) \qquad \int_\Omega \phi^2 \big(|\mathrm{Hess}\, u|^2 - (\Delta_f u)^2 + \mathrm{Ric}_f(\nabla u, \nabla u) \big)\, dv_f$$

$$+ \int_\Omega \langle \nabla\phi^2, \tfrac{1}{2}\nabla|\nabla u|^2 - \Delta_f u \nabla u \rangle\, dv_f$$

$$= \int_\Sigma \phi^2 \left(\mathbf{A}_\Sigma(\nabla^\Sigma u, \nabla^\Sigma u) + \nabla^\Sigma u \left(\frac{\partial u}{\partial \nu} \right) - \left(\Delta_f^\Sigma u - H_f \frac{\partial u}{\partial \nu} \right) \frac{\partial u}{\partial \nu} \right) dv_f^\Sigma,$$

where v is the exterior unit normal to Σ and $\mathbf{A}_\Sigma$ is the corresponding second fundamental form, and dv_f^Σ is the weighted measure of the boundary Σ.

Proof. Let $\phi \in C_c^\infty(M_f)$ and let $Z = \nabla \frac{|\nabla u|^2}{2} - \Delta_f u \, \nabla u$. Then, using the f-Bochner formula, we get

$$\operatorname{div}_f(\phi^2 Z) = \phi^2 \left[\operatorname{div}_f \left(\nabla \frac{|\nabla u|^2}{2} \right) - \Delta_f u \operatorname{div}_f(\nabla u) - \langle \nabla \Delta_f u, \nabla u \rangle \right]$$
$$+ \left\langle \nabla \phi^2, \nabla \frac{|\nabla u|^2}{2} - \Delta_f u \nabla u \right\rangle$$
$$= \phi^2 \left[\Delta_f \frac{|\nabla u|^2}{2} - (\Delta_f u)^2 - \langle \nabla \Delta_f u, \nabla u \rangle \right] + \left\langle \nabla \phi^2, \nabla \frac{|\nabla u|^2}{2} - \Delta_f u \nabla u \right\rangle$$
$$= \phi^2 \left[|\operatorname{Hess} u|^2 + \langle \nabla \Delta_f u, \nabla u \rangle + \operatorname{Ric}_f(\nabla u, \nabla u) - (\Delta_f u)^2 - \langle \nabla \Delta_f u, \nabla u \rangle \right]$$
$$+ \left\langle \nabla \phi^2, \nabla \frac{|\nabla u|^2}{2} - \Delta_f u \nabla u \right\rangle$$
$$= \phi^2 \left[|\operatorname{Hess} u|^2 + \operatorname{Ric}_f(\nabla u, \nabla u) - (\Delta_f u)^2 \right] + \left\langle \nabla \phi^2, \nabla \frac{|\nabla u|^2}{2} - \Delta_f u \nabla u \right\rangle.$$

Applying the f-divergence theorem, we get

$$(4.2) \qquad \int_\Sigma \phi^2 \langle Z, v \rangle \, dv_f^\Sigma = \int_\Omega \operatorname{div}_f(\phi^2 Z) \, dv_f$$
$$= \int_\Omega \phi^2 \left[|\operatorname{Hess} u|^2 + \operatorname{Ric}_f(\nabla u, \nabla u) - (\Delta_f u)^2 \right] dv_f$$
$$+ \int_\Omega \left\langle \nabla \phi^2, \nabla \frac{|\nabla u|^2}{2} - \Delta_f u \nabla u \right\rangle dv_f.$$

Let $\{E_i\}_{i=1}^m$ be a local orthonormal frame on Σ. Letting $H_f := H + \langle \nabla f, v \rangle$ and using the identity

$$\nabla u = \nabla^\Sigma u + \frac{\partial u}{\partial v} v,$$

one gets that

$$\Delta_f u = \sum_{i=1}^m \operatorname{Hess} u(E_i, E_i) + \operatorname{Hess} u(v, v) - \langle \nabla f, \nabla u \rangle$$
$$= \Delta_f^\Sigma u + \operatorname{Hess} u(v, v) - H_f \frac{\partial u}{\partial v}$$

and

$$\left\langle \nabla \frac{|\nabla u|^2}{2}, v \right\rangle = \operatorname{Hess} u(\nabla^\Sigma u, v) + \frac{\partial u}{\partial v} \operatorname{Hess} u(v, v)$$
$$= -\langle \nabla_{\nabla^\Sigma u} v, \nabla^\Sigma u \rangle + \left\langle \nabla_{\nabla^\Sigma u} \left(\frac{\partial u}{\partial v} v \right), v \right\rangle + \frac{\partial u}{\partial v} \operatorname{Hess} u(v, v)$$
$$= \mathbf{A}_\Sigma(\nabla^\Sigma u, \nabla^\Sigma u) + \nabla^\Sigma u \left(\frac{\partial u}{\partial v} \right) + \frac{\partial u}{\partial v} \operatorname{Hess} u(v, v).$$

Inserting these two relations in (4.2), we obtain the desired conclusion. □

Theorem D is a direct consequence of the localized Reilly's formula.

Proof of Theorem D.   Let $u \in \mathscr{C}^\infty(\overline{\Omega})$ be a solution of

$$
\begin{cases}
\Delta_f u = 0 & \text{in } \Omega, \\
\quad u = 0 & \text{on } \Sigma_1, \\
\quad u = 1 & \text{on } \Sigma_2.
\end{cases}
$$

Applying (4.1) to u and using Young's and Kato's inequalities, we get that for any $\varepsilon > 0$,

$$
\begin{aligned}
0 &\geq \int_\Omega \phi^2(|\mathrm{Hess}\, u|^2 + K^2|\nabla u|^2) + \left\langle \nabla \phi^2, \frac{\nabla |\nabla u|^2}{2} \right\rangle dv_f \\
&= \int_\Omega \phi^2(|\mathrm{Hess}\, u|^2 + K^2|\nabla u|^2) + 2\phi|\nabla u|\langle \nabla \phi, \nabla|\nabla u|\rangle \, dv_f \\
&\geq \int_\Omega \phi^2(|\mathrm{Hess}\, u|^2 + K^2|\nabla u|^2) - \frac{\phi^2}{\varepsilon}\big|\nabla|\nabla u|\big|^2 - \varepsilon|\nabla\phi|^2|\nabla u|^2 \, dv_f \\
&\geq \int_\Omega \phi^2\left(1 - \frac{1}{\varepsilon}\right)\big|\nabla|\nabla u|\big|^2 \, dv_f + \int_\Omega (K^2\phi^2 - \varepsilon|\nabla\phi|^2)|\nabla u|^2 \, dv_f.
\end{aligned}
$$

Choose now $\varepsilon > 1$ and let ϕ_R be smooth cut-offs such that $\phi_R = 1$ on B_R^M, $\mathrm{supp}(\phi_R) \subset B_{2R}^M$ and $|\nabla\phi|^2 \leq \frac{4}{R^2}$. Then we get

$$
\begin{aligned}
K^2 \int_{\Omega \cap B_R^M} |\nabla u|^2 \, dv_f &\leq K^2 \int_{\Omega \cap B_{2R}^M} \phi^2 |\nabla u|^2 \, dv_f \leq \varepsilon \int_{\Omega \cap B_{2R}^M} |\nabla\phi|^2 |\nabla u|^2 dv_f \\
&\leq \frac{4\varepsilon}{R^2} \int_{\Omega \cap B_{2R}^M} |\nabla u|^2 \, dv_f.
\end{aligned}
$$

By taking the limit as $R \to +\infty$, this yields that

$$
(4.3) \qquad\qquad \int_\Omega |\nabla u|^2 \, dv_f \leq \frac{4\varepsilon}{K^2} \liminf_{R \to +\infty} \frac{1}{R^2} \int_{\Omega \cap B_{2R}^M} |\nabla u|^2 \, dv_f.
$$

Since, obviously, u is non-constant, we must have

$$
\liminf_{R \to +\infty} \frac{1}{R^2} \int_{\Omega \cap B_{2R}^M} |\nabla u|^2 \, dv_f > 0.
$$

In particular, $|\nabla u| \notin \mathscr{L}^2(\Omega, dv_f)$ and from inequality (4.3) we conclude

$$
\lim_{R \to +\infty} \frac{1}{R^2} \int_{\Omega \cap B_{2R}^M} |\nabla u|^2 \, dv_f = +\infty,
$$

thus completing the proof. $\square$

5. Construction of special f-harmonic functions and proof of Theorem C

The strategy of the proof of Theorem C goes as follows:

- By contradiction we assume that the hypersurfaces Σ_1 and Σ_2 are disjoint. Recall that, by the Jordan–Brouwer Separation Theorem, each hypersurface Σ_j separates $\mathbb{R}^{m+1}$; see [9]. Therefore it is well defined the region Ω of $\mathbb{R}^{m+1}$ in between Σ_1 and Σ_2.

- We construct on Ω a (unique) bounded positive f-harmonic function u with Dirichlet boundary conditions 0 and 1, respectively, on Σ_1 and Σ_2. To construct u, we solve a mixed boundary value problem along an exhaustion of Ω where a Neumann condition is imposed on the "free" part of the boundary. An application of interior and boundary Schauder estimates enables us to extract a subsequence converging in $\mathscr{C}^2$ on every compact set to the desired global solution.

- We use the asymptotic distance assumption (3.1) and the condition on the extrinsic geometry of Σ_2 to obtain that, in fact, $|\nabla u| \in \mathscr{L}^2(\Omega, dv_f)$. To this end, a Caccioppoli inequality up to the boundary reduces the problem to an estimate of $|\nabla u|$ on the hypersurface Σ_2. Thanks to the control on the extrinsic geometry of Σ_2, a pointwise estimate of $|\nabla u|$ on Σ_2 is obtained using maximum principle arguments.

- We use Theorem D to get a contradiction.

Accordingly, the main purpose of the present section is to prove the following.

Lemma E. *Let Σ_1^m and Σ_2^m be disjoint, properly embedded hypersurfaces in the complete weighted manifold M_f^{m+1} satisfying $\mathrm{Ric}_f \geq K^2 > 0$. Assume that Σ_1, Σ_2 separate M and let $\Omega \subset M$ be the domain enclosed between these hypersurfaces so that $\partial\Omega = \Sigma_1 \cup \Sigma_2$. Then there exists a unique bounded solution $u \in \mathscr{C}^\infty(\overline{\Omega})$ of the problem*

$$(5.1) \qquad \begin{cases} \Delta_f u = 0 & \text{in } \Omega, \\ u = 0 & \text{on } \Sigma_1, \\ u = 1 & \text{on } \Sigma_2, \end{cases}$$

satisfying

$$0 < u < 1 \quad \text{on } \Omega.$$

Moreover, assume that $M_f^{m+1} = \mathbb{R}_f^{m+1}$ is the Gaussian space and that Σ_2 satisfies the asymptotic distance condition (3.1) and the normal neighborhood condition (3.2). Then u has finite f-energy:

$$(5.2) \qquad |\nabla u| \in \mathscr{L}^2(\Omega, dv_f).$$

As we have outlined above, we split the proof in several steps.

5.1. Uniqueness of the solution. Following [12], it is convenient to set the following:

Definition 3. Let M_f be a smooth metric measure space with boundary $\partial M \neq \emptyset$. Say that M_f is f-parabolic in the sense of Dirichlet if every bounded f-harmonic function $u \in \mathscr{C}^\infty(\mathrm{int}M) \cap \mathscr{C}^0(M)$ is uniquely determined by its boundary values.

Adapting to the framework of manifolds with density what is known from [12] (see also [11]), we have the following:

Lemma 4. *Let M_f be a complete weighted manifold with boundary such that, for some origin $o \in \mathrm{int}M$,*

$$\mathrm{vol}_f(B_R(o)) = \mathcal{O}(R^2).$$

Then M_f is f-parabolic in the sense of Dirichlet.

Since, in the setting of Lemma E, $\mathrm{vol}_f(\Omega) \leq \mathrm{vol}_f(M) < +\infty$, the complete manifold $\overline{\Omega}$ with boundary $\partial\Omega \neq \emptyset$ is f-parabolic in the sense of Dirichlet. Hence a bounded solution of (5.1), if any, must be unique.

5.2. Existence of the solution by exhaustion. As in the statement of Lemma E, let M_f^{m+1} be a complete smooth metric measure space and let $\overline{\Omega} \subset M$ be the domain whose boundary is given by $\partial\Omega = \Sigma_1 \cup \Sigma_2$. Let $D_k \nearrow M$ be an exhaustion of M by relatively compact domains with smooth boundary ∂D_k intersecting transversally Σ_1 and Σ_2; see e.g. [17]. Let $\Omega_k \nearrow \Omega$ be the Lipschitz domains defined by $\Omega_k = D_k \cap \Omega$. Note that

$$\partial\Omega_k = \Sigma_{1,k} \cup \Sigma_{2,k} \cup \Gamma_k,$$

where $\Sigma_{i,k} \subset \Sigma_i$, $i = 1, 2$, and $\Gamma_k \subset \partial D_k$. The singular set of Ω_k is denoted by $\mathscr{S}_k$. Then $\{\Omega_k\}$ is a "good" exhaustion of Ω with respect to mixed boundary value problems. Consider the solution u_k to the problem

$$(5.3) \qquad \begin{cases} \Delta_f u_k = 0 & \text{in } \Omega_k, \\ u_k = 0 & \text{on } \Sigma_{1,k}, \\ u_k = 1 & \text{on } \Sigma_{2,k}, \\ \dfrac{\partial u_k}{\partial \nu_k} = 0 & \text{on } \Gamma_k, \end{cases}$$

where ν_k is the outward unit normal to Γ_k. It follows from the Perron construction in [15], and the well-known local regularity theory, that $u_k \in \mathscr{C}^0(\overline{\Omega}_k) \cap \mathscr{C}^\infty(\overline{\Omega}_k \setminus \mathscr{S}_k)$. Furthermore, by the strong maximum principle and the boundary point lemma,

$$0 < u_k < 1 \quad \text{on } \Omega_k.$$

For any fixed $k_0 \in \mathbb{N}$, let us consider the sequence of solutions of (5.3):

$$\mathscr{U}_{k_0+2} = \{u_k : k \geq k_0 + 2\} \subset \mathscr{C}^\infty(\overline{\Omega}_{k_0+1}).$$

We claim that, given $\alpha > 0$, there exists a constant $C_{k_0} > 0$ such that

$$(5.4) \qquad \sup_{u_k \in \mathscr{U}_{k_0+2}} \|u_k\|_{\mathscr{C}^{2,\alpha}(\overline{\Omega}_{k_0})} \leq C_{k_0}.$$

To this end:

- We apply [8, Corollary 6.7] with the choices $\Omega := \Omega_{k_0+1}$, $T := \Sigma_{1,k_0+1}$, $L := \Delta_f$, $\varphi := 0$, $f := 0$ and we obtain that there exist a ray $\delta_{1,k_0} > 0$ and a constant $C_{1,k_0} > 0$ such that, having defined the δ_{k_0}-neighborhood of Σ_{1,k_0} as

$$\mathscr{T}_{\delta_{1,k_0}}(\Sigma_{1,k_0}) = \bigcup_{p \in \Sigma_{1,k_0}} B_{\delta_{1,k_0}}^M(p) \cap \Omega_{k_0+1},$$

  it holds

$$\|u_k\|_{\mathscr{C}^{2,\alpha}(\mathscr{T}_{\delta_{1,k_0}}(\Sigma_{1,k_0}))} \leq C_{1,k_0}$$

  for every $u_k \in \mathscr{U}_{k_0+2}$.

- Similarly, we apply [8, Corollary 6.7] with the choices $\Omega := \Omega_{k_0+1}$, $T := \Sigma_{2,k_0+1}$, $L := \Delta_f$, $\varphi := 1$, $f := 0$ and we obtain that there exist a ray $\delta_{2,k_0} > 0$ and a constant $C_{2,k_0} > 0$ such that

$$\|u_k\|_{\mathscr{C}^{2,\alpha}(\mathcal{T}_{\delta_{2,k_0}}(\Sigma_{2,k_0}))} \le C_{2,k_0}$$

for every $u_k \in \mathscr{U}_{k_0+2}$.

- Set

$$\delta_{k_0} = \min(\delta_{1,k_0}, \delta_{2,k_0}) > 0$$

and define the compact set

$$\mathcal{K}_{k_0} = \overline{\Omega}_{k_0} \setminus \left(\mathcal{T}_{\frac{\delta_{k_0}}{2}}(\Sigma_{1,k_0}) \cup \mathcal{T}_{\frac{\delta_{k_0}}{2}}(\Sigma_{2,k_0}) \right) \subset \Omega_{k_0+1}.$$

By [8, Theorem 6.2] with $\Omega := \Omega_{k_0+1}$ and $L := \Delta_f$, there exists a constant $C_{3,k_0} > 0$ such that

$$\|u_k\|_{\mathscr{C}^{2,\alpha}(\mathcal{K}_{k_0})} \le C_{3,k_0}$$

for every $u_k \in \mathscr{U}_{k_0+2}$.

- Since

$$\Omega_{k_0} \subset \mathcal{T}_{\delta_{k_0}}(\Sigma_{1,k_0}) \cup \mathcal{T}_{\delta_{k_0}}(\Sigma_{2,k_0}) \cup \mathcal{K}_{k_0} \quad \text{and} \quad \mathscr{U}_{k_0+2} \subset \mathscr{C}^\infty(\overline{\Omega}_{k_0+1}),$$

the claimed estimate (5.4) follows by taking $C_{k_0} = \max(C_{1,k_0}, C_{2,k_0}, C_{3,k_0})$.

Now, for $0 < \alpha_1 < \alpha_2$, the embedding $\mathscr{C}^{2,\alpha_2}(\overline{\Omega}_{k_0}) \hookrightarrow \mathscr{C}^{2,\alpha_1}(\overline{\Omega}_{k_0})$ is compact. Therefore, possibly passing to a subsequence, we obtain that $\mathscr{U}_{k_0+2}$ converges in $\mathscr{C}^2(\overline{\Omega}_{k_0})$ to a solution $u_{k_0} \in \mathscr{C}^2(\overline{\Omega}_{k_0})$ (actually $u_{k_0} \in \mathscr{C}^\infty(\overline{\Omega}_{k_0})$ by higher elliptic regularity) of the problem

$$\begin{cases} \Delta_f u_{k_0} = 0 & \text{in } \Omega_{k_0}, \\ u_{k_0} = 0 & \text{on } \Sigma_{1,k_0}, \\ u_{k_0} = 1 & \text{on } \Sigma_{2,k_1}. \end{cases}$$

Moreover,

$$0 \le u_{k_0} \le 1.$$

To conclude the construction, we let k_0 increase to $+\infty$ and we use a classical diagonal argument. This yields the desired solution $u \in \mathscr{C}^\infty(\overline{\Omega})$ of

$$\begin{cases} \Delta_f u = 0 & \text{in } \Omega, \\ u = 0 & \text{on } \Sigma_1, \\ u = 1 & \text{on } \Sigma_2, \end{cases}$$

satisfying

$$0 \le u \le 1.$$

5.3. The finite f-energy condition. From now on, unless otherwise specified, we assume that M_f is the Gaussian space $\mathbb{R}^{m+1}_f$. We want to obtain the finiteness of the Dirichlet f-energy of the solution u of (5.1): $\|\nabla u\|_{\mathscr{L}^2(\Omega, dv_f)} < +\infty$. A standard Caccioppoli inequality up to the boundary reduces the problem to an estimate of $|\nabla u|$ along Σ_2 (the boundary hypersurface where the datum 1 is imposed). This latter, in turn, can be carried out by maximum principle considerations.

5.3.1. A Caccioppoli inequality up to the boundary.   We prove the following:

Lemma 5.   *Let $u : \Omega \to \mathbb{R}$ be a solution of* (5.1). *Then*

$$(5.5) \qquad \int_\Omega |\nabla u|^2 \, dv_f \le 2 \int_{\Sigma_2} |\nabla u| \, dv_{2;f_2},$$

where $dv_{i;f_i}$ is the weighted measure of the boundary hypersurface Σ_{i,f_i} and $f_i = f|_{\Sigma_i}$, $i = 1, 2$.

Proof.   Let $\varphi = \varphi_R \in \mathscr{C}_c^\infty(\mathbb{R}^{m+1})$ be a family of standard cut-off functions satisfying the following conditions:

(i) $0 \le \varphi \le 1$,

(ii) $\varphi = 1$ on $\mathbb{B}_{R/4}^{m+1}(\overline{x})$,

(iii) $\varphi = 0$ on $\mathbb{R}^{m+1} \setminus \mathbb{B}_{R/2}^{m+1}(\overline{x})$,

(iv) $\|\nabla \varphi\|_\infty \le \frac{2}{R}$.

Consider the vector field

$$X = \varphi^2 u \nabla u.$$

Observe that the f-divergence of X is given by

$$\operatorname{div}_f X = 2u\varphi \langle \nabla u, \nabla \varphi \rangle + \varphi^2 |\nabla u|^2.$$

Integrating X on Ω, using the f-divergence theorem, the Young inequality and recalling the (Dirichlet) boundary conditions satisfied by u, we get

$$\int_\Omega \varphi^2 |\nabla u|^2 \, dv_f = -\int_\Omega 2u\varphi \langle \nabla u, \nabla \varphi \rangle \, dv_f + \int_{\Sigma_2} \varphi^2 \frac{\partial u}{\partial v_2} \, dv_{2;f_2}$$

$$\le \varepsilon \int_\Omega u^2 |\nabla \varphi|^2 \, dv_f + \varepsilon^{-1} \int_\Omega \varphi^2 |\nabla u|^2 \, dv_f + \int_{\Sigma_2} \varphi^2 \frac{\partial u}{\partial v_2} \, dv_{2;f_2},$$

where $\varepsilon > 0$ is any fixed constant. Whence, if $\varepsilon = 2$, we deduce

$$\int_\Omega \varphi^2 |\nabla u|^2 \, dv_f \le 2 \left\{ 2 \int_\Omega u^2 |\nabla \varphi|^2 \, dv_f + \int_{\Sigma_2} \varphi^2 \frac{\partial u}{\partial v_2} \, dv_{2;f_2} \right\}.$$

Now, by the boundary point lemma and the maximum principle we have

$$\Sigma_2 = \{u = 1\}, \quad \nabla u \ne 0 \text{ on } \Sigma_2$$

and the outward unit normal to the hypersurface Σ_2 is given by

$$v_2 = \frac{\nabla u}{|\nabla u|}.$$

Inserting this information into the above integral inequality, and recalling property (iv) of φ, we deduce

$$\int_\Omega \varphi^2 |\nabla u|^2 \, dv_f \le \frac{16}{R^2} \int_{\Omega \cap \mathbb{B}_{2R}^{m+1}} u^2 \, dv_f + 2 \int_{\Sigma_2} \varphi^2 |\nabla u| \, dv_{2;f_2}.$$

Whence, using once again the properties of $\varphi = \varphi_R$, the fact that the function u is bounded, hence $\mathscr{L}^2(\Omega, dv_f)$, on the finite f-measure domain Ω, and letting $R \to +\infty$ we conclude the validity of (5.5). $\square$

5.3.2. Pointwise gradient estimates at the boundary.   It remains to estimate the integral $\int_{\Sigma_2} |\nabla u| \, dv_{2;f_2}$. Since the self-shrinker Σ_2 is properly embedded, it has polynomial (actually Euclidean) extrinsic volume growth. Assuming that Σ_2 has bounded extrinsic geometry, we can estimate $|\nabla u|$ pointwise along Σ_2 by maximum principle arguments. This is done in the next Lemma. Whence, using (3.1) we shall deduce immediately the desired $\mathscr{L}^1$ integrability of $|\nabla u|$ on Σ_2, thus completing the proof of Lemma E.

Lemma 6.   *Let $u \in \mathscr{C}^\infty(\overline{\Omega})$ be a solution of (5.1). Assume that Σ_2 satisfies an exterior R-sphere condition at some point $z \in \Sigma_2$. Then*

$$(5.6) \qquad |\nabla u|(z) \leq \frac{(R+1)^m}{R^m} \frac{e^{|z|}}{\mathrm{dist}_{\mathbb{R}^{m+1}}(z, \Sigma_1)}.$$

Recall that a connected component Σ of the boundary $\partial\Omega$ of a domain $\Omega \subset \mathbb{R}^{m+1}$ is said to satisfy the *exterior R-sphere condition* at $z \in \Omega$ if there exists a ball $\mathbb{B}_R^{m+1}(y) \subset \mathbb{R}^{m+1} \setminus \overline{\Omega}$ such that $\overline{\mathbb{B}}_R^{m+1}(y)$ is tangent to Σ at z. Clearly the exterior R-sphere condition at z implies that the (scalar) second fundamental form $A_\Sigma = \langle \mathbf{A}_\Sigma, \nu \rangle$ of Σ, with respect to the exterior unit normal ν, satisfies $A_\Sigma(z) \leq \frac{1}{R}$ in the sense of quadratic forms. More importantly, we point out the following simple fact that gives the link between the exterior sphere condition and the tubular neighborhood assumption in Lemma E.

Fact.   *The exterior R-sphere condition at $z \in \Sigma$ is implied by the existence of a regular normal neighborhood of Σ whose width at z is at least R.*

Proof.   Indeed, start with a small ball $\mathbb{B}_a^{m+1}(y)$ touching Σ only at z and let the ray $a > 0$ increase by keeping the same tangent property. The corresponding balls are all centered along the normal line to Σ passing through z. Let $T(z) \in \mathbb{R}_{>0} \cup \{+\infty\}$ denote the supremum of such rays and assume $T(z) < +\infty$, for otherwise there is nothing to prove. Then $\mathbb{B}_{T(z)}^{m+1}(y')$ is tangent to Σ at two distinct points $z, z' \in \Sigma$. The (closed) segments normal to Σ, of length $2T(z)$ and centered respectively in z and z' meet precisely at the center y' of the ball. Therefore, by definition, the ray $R(z)$ of the normal regular tubular neighborhood of Σ at z must satisfy $R(z) \leq T(z)$. The conclusion now follows trivially.   □

Proof (of Lemma 6).   We use the technique developed in [23] (see also [8, Chapter 14]). Keeping the notation introduced in the previous section, we let

$$v = u - 1.$$

Thus, v is a smooth solution of

$$(5.7) \qquad \begin{cases} \Delta_f v = 0 & \text{in } \Omega, \\ \quad v = -1 & \text{on } \Sigma_1, \\ \quad v = 0 & \text{on } \Sigma_2, \\ -1 < v < 0 & \text{in } \Omega. \end{cases}$$

Fix $z \in \Sigma_2$. Let $\mathbb{B}_R^{m+1}(y) \subset \mathbb{R}^{m+1} \setminus \overline{\Omega}$ be an exterior ball tangent to Σ_2 at z. We assume that

$$\partial\mathbb{B}_{R+a}^{m+1}(y) \cap \Sigma_1 = \emptyset,$$

for a suitable $a > 0$. Namely, we choose

$$0 < a < \operatorname{dist}_{\mathbb{R}^{m+1}}(z, \Sigma_1).$$

Define the domain

$$W_{R,a} = \left(\mathbb{B}^{m+1}_{R+a}(y) \setminus \overline{\mathbb{B}}^{m+1}_R(y) \right) \cap \Omega.$$

Let

$$r(x) = |x - y| \quad \text{and} \quad d(x) = r(x) - R$$

so that

$$d(x) = \operatorname{dist}_{\mathbb{R}^{m+1}}(x, \partial \mathbb{B}^{m+1}_R(y)).$$

We construct a smooth function

$$\psi(d) : [0, a] \rightarrow [0, +\infty)$$

satisfying the following conditions:

  (i) $\Delta_f \psi(d(x)) \leq 0$ on $W_{R,a}$,

  (ii) $\psi(0) = 0$,

  (iii) $\psi(a) = 1$,

  (iv) $\psi' > 0$.

To this end, note that, if (iv) is satisfied, then

$$\Delta_f \psi = \psi'' + \psi' \left\{ \frac{m}{d + R} - \langle x, \nabla r \rangle \right\}$$

$$\leq \psi'' + \psi' \left\{ \frac{m}{d + R} - |x - y| + |y - z| + |z| \right\}$$

$$= \psi'' + \psi' \left\{ \frac{m}{d + R} - d + |z| \right\}.$$

Therefore, we are led to impose

$$\psi'' + \psi' \left\{ \frac{m}{d + R} - d + |z| \right\} = 0.$$

Integrating on $[0, d] \subseteq [0, a]$ and recalling (ii), we get

$$\psi(d) = R^m \psi'(0) \int_0^d \frac{e^{\frac{t^2}{2}} \, dt}{(t + R)^m e^{|z| t}}.$$

This definition satisfies (i), (ii) and (iv) provided $\psi'(0) > 0$. Finally, we impose the validity of (iii). This implies the choice

$$(5.8) \qquad \psi'(0) = \frac{1}{R^m \int_0^a \frac{e^{t^2/2} \, dt}{(t+R)^m e^{|z| t}}}$$

and we conclude that, the desired function ψ has the expression

$$\psi(d) = \frac{\int_0^d \frac{e^{t^2/2} \, dt}{(t+R)^m e^{|z| t}}}{\int_0^a \frac{e^{t^2/2} \, dt}{(t+R)^m e^{|z| t}}}.$$

We observe explicitly from (5.8) that the following rough estimate holds:

$$(5.9) \qquad\qquad 0 < \psi'(0) \leq C(R, a)e^{a|z|},$$

where

$$C(R, a) = \frac{(R + a)^m}{R^m a}.$$

Summarizing we have obtained that

$$\begin{cases} \Delta_f \psi(d(x)) \leq 0 & \text{in } W_{R,a}, \\ \psi = 0 = v & \text{at } z, \\ \psi = 1 > 0 \geq v & \text{on } \partial W_{R,a} \cap \Omega, \\ \psi \geq 0 = v & \text{on } \partial\Omega \cap \overline{W}_{R,a} = \Sigma_2 \cap \overline{W}_{R,a}, \end{cases}$$

and, similarly,

$$\begin{cases} \Delta_f(-\psi(d(x))) \geq 0 & \text{in } W_{R,a}, \\ (-\psi) = 0 = v & \text{at } z, \\ (-\psi) = -1 \leq v & \text{on } \partial W_{R,a} \cap \Omega, \\ (-\psi) \leq 0 = v & \text{on } \partial\Omega \cap \overline{W}_{R,a} = \Sigma_2 \cap \overline{W}_{R,a}. \end{cases}$$

In view of (5.7), (5.9) and the fact that $\frac{\partial v}{\partial v} = |\nabla u|$ on Σ_2, arguing as in [23] we conclude that

$$|\nabla u|(z) \leq \psi'(0) \leq C(R, a)e^{a|z|}.$$

This latter implies the validity of (5.6) by choosing $a = \min(1, \text{dist}_{\mathbb{R}^{m+1}}(z, \Sigma_1) - \epsilon)$ and letting $\epsilon \searrow 0$. $\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \square$

5.4. Proof of Lemma E.   Recall from Section 5.1 and Section 5.2 that, in any complete weighted manifold M_f^{m+1} with

$$\text{Ric}_f \geq K^2 > 0,$$

the Dirichlet problem (5.1) has a unique solution $u \in \mathscr{C}^\infty(\overline{\Omega})$ satisfying $0 \leq u \leq 1$. Assume now that $M_f^{m+1} = \mathbb{R}_f^{m+1}$ is the Gaussian soliton and that $\Sigma_1^m, \Sigma_2^m \hookrightarrow \mathbb{R}_f^{m+1}$ are f-minimal. Then, by Lemma 5,

$$\int_\Omega |\nabla u|^2 \, dv_f \leq C_1 \int_{\Sigma_2} |\nabla u| \, dv_{2;f_2}.$$

On the other hand, in view of the asymptotic distance condition (3.1) and the normal neighborhood condition (3.2), from (5.6) of Lemma 6 we know that

$$|\nabla u(z)| \leq C_2 e^{\tilde{b}|z|^2} \quad \text{on } \Sigma_2$$

for some constants $C_2 > 0$ and $0 < \tilde{b} < \frac{1}{2}$. Since Σ_2 is properly immersed, it has a polynomial extrinsic volume growth; see (1.2). Recalling e.g. [20, Lemma 25], we deduce that

$$|\nabla u| \in \mathscr{L}^1(\Sigma_2, dv_{2;f_2})$$

and, therefore, $|\nabla u| \in \mathscr{L}^2(\Omega, dv_f)$, as required. The proof of Lemma E is completed.

6. Variational considerations and proof of Theorem B

6.1. The finite f-energy condition from a variational viewpoint.　There is (at least) an alternative way to deduce the finiteness condition of the f-energy (5.2) for the bounded solution of (5.1). It relies on a variational argument that however seems to need the validity of the asymptotic distance assumption (3.1) with the more demanding condition

$$(6.1) \qquad\qquad 0 \le b < \frac{1}{4}.$$

We briefly outline the argument.

Let $\Sigma_1 \cap \Sigma_2 = \emptyset$ be properly embedded hypersurfaces that separate the complete ambient space $(M^{m+1}, \langle \cdot, \cdot \rangle)$ and let Ω be the enclosed region of M so that $\partial\Omega = \Sigma_1 \cup \Sigma_2$. Consider the orthogonal projection $\Pi_1 : \overline{\Omega} \to \Sigma_1$ and note that

$$\operatorname{dist}_M(z, \Pi_1(z)) = \operatorname{dist}_M(z, \Sigma_1).$$

Now, let $\psi : \mathbb{R} \to [0, 1]$ be the Lipschitz function

$$(6.2) \qquad\qquad \psi(t) = \begin{cases} 0, & t \le 0, \\ t, & 0 < t < 1, \\ 1, & t \ge 1. \end{cases}$$

Define a locally Lipschitz function $\Psi : \overline{\Omega} \to [0, 1]$ by

$$(6.3) \qquad\qquad \Psi(z) = \psi\left(\frac{\operatorname{dist}_M(z, \Sigma_1)}{\operatorname{dist}_M(\Pi_1(z), \Sigma_2)} \right).$$

Obviously,

$$(6.4) \qquad\qquad \Psi \equiv 0 \quad \text{on } \Sigma_1.$$

Moreover, since

$$\operatorname{dist}_M(z, \Sigma_1) = \operatorname{dist}_M(\Pi_1(z), z) \ge \operatorname{dist}_M(\Pi_1(z), \Sigma_2) \quad \text{for all } z \in \Sigma_2,$$

we have

$$(6.5) \qquad\qquad \Psi \equiv 1 \quad \text{on } \Sigma_2.$$

Finally,

$$\operatorname{Lip}[\Psi](z) \le C \frac{1 + \operatorname{Lip}[\Pi_1](z)}{\operatorname{dist}_M(\Pi_1(z), \Sigma_2)}$$

for some constant $C > 0$. This follows from the fact that distances are globally Lipschitz functions and, furthermore,

$$\frac{\operatorname{dist}_M(z, \Sigma_1)}{\operatorname{dist}_M(\Pi_1(z), \Sigma_2)} > 1 \implies \operatorname{Lip}[\Psi](z) = 0.$$

Thus, if we now specify the situation to properly embedded self-shrinkers in $\mathbb{R}_f^{m+1}$ and assume the validity of the asymptotic distance condition (3.1) with b satisfying (6.1), then

(a) $\Psi \in \mathscr{W}^{1,2}(\Omega, dv_f)$,

(b) $\Psi \equiv 0$ on Σ_1,

(c) $\Psi \equiv 1$ on Σ_2.

Note now that the solutions u_k to (5.3) over the exhaustion $\Omega_k \nearrow \Omega$ and constructed using Lieberman approach coincide with those obtained by applying the direct calculus of variations

to the weighted energy functional

$$E_{k,f}(v) = \tfrac{1}{2} \int_{\Omega_k} |\nabla v|^2 \, dv_f$$

on the closed convex space

$$\mathscr{W}_{\mathcal{D}}^{1,2}(\overline{\Omega}_k, dv_f) = \{v \in \mathscr{W}^{1,2}(\Omega_k, dv_f) : v|_{\Sigma_1} \equiv 0 \text{ and } v|_{\Sigma_2} \equiv 1\}.$$

Here, Dirichlet data are understood in the trace sense. Thus, each u_k is a minimizer of $E_{k,f}$ over $\mathscr{W}_{\mathcal{D}}^{1,2}(\overline{\Omega}_k, dv_f)$. Thanks to the global $\mathscr{W}^{1,2}$-regularity established in [12, Proposition 1.2], this follows from [12, Remark 1.3] by a suitable choice of the domains Ω and $D \Subset \Omega$.

With this preparation, let $\Psi_k = \Psi|_{\Omega_k}$ be the restriction to $\Omega_k \nearrow \Omega_\infty = \Omega$ of the barrier function (6.3) and let u_k be the solution of problem (5.3). Recall that, up to subsequences, u_k $\mathscr{C}^2$-converges on compact subsets of Ω to the bounded solution u of problem (5.1). Since $\Psi_k \in \mathscr{W}_{\mathcal{D}}^{1,2}(\overline{\Omega}_k, dv_f)$, we deduce

$$E_{k_0,f}(u_k) \leq E_{k,f}(u_k) \leq E_{k,f}(\Psi_k) \leq E_{\infty,f}(\Psi) < +\infty$$

for every $k_0 < k$. Whence, recalling that $\nabla u_k \to \nabla u$ uniformly on compact subsets of $\overline{\Omega}$ and using the Fatou lemma, we conclude that $|\nabla u| \in \mathscr{L}^2(\Omega, dv_f)$.

6.2. Proof of Theorem B. If on the one hand the previous arguments require a more stringent condition on the asymptotic behavior of Σ_1 and Σ_2 and, thus, cannot be used to recover Theorem C, on the other hand they suggest a way to obtain the intersection property when no extrinsic condition on Σ_2 is imposed. Indeed, note that if the two f-minimal hypersurfaces Σ_1^m, Σ_2^m of M_f^{m+1} are a positive distance apart (but their positive distance could be realized at infinity), then we can consider the function defined by

$$\Psi(z) = \psi\left(\frac{\mathrm{dist}_M(z, \Sigma_1) - \mathrm{dist}_M(z, \Sigma_2) + \mathrm{dist}_M(\Sigma_1, \Sigma_2)}{2\mathrm{dist}_M(\Sigma_1, \Sigma_2)}\right),$$

with ψ as in (6.2). It is easy to check that Ψ is a Lipschitz function satisfying conditions (6.4) and (6.5). In particular, Ψ can be used as a global barrier function and reasoning as in the previous subsection we deduce that, without any assumption on the extrinsic geometry of the hypersurfaces, the bounded solution u of (5.1) satisfies $|\nabla u| \in \mathscr{L}^2(\Omega, dv_f)$. When combined with Theorem D and Lemma E, this fact proves Theorem B.
