ABSTRACT

This study reports a portion of a series of investigations designed to determine to what extent credibility scales can be generalized. The investigation data was collected in six phases, representing six subject populations. All of the subjects were either college students or non-student adults. Subjects were asked to respond to one of four political figures, each representing a wide range of political viewpoints. Semantic differential-type scales, representing dimensions of source credibility reported by various researchers, and Likert-type statements on an eleven-step continuum bound by bipolar adjectives were used to measure potential communication behavior and response to communication behavior. The results suggested that researchers should not expect exactly the same dimensionality of source credibility for all subject populations. (Author/LG)

ABSTRACT

This paper reports a portion of a series of investigations designed to determine generalizability of source credibility scales across various types of sources and various types of subjects. Semantic differential-scales that have been found to load on factors of source credibility in previous investigations were combined to provide an item pool for this study. Six groups of subjects were asked to respond to public figures on the scales. Subjects included a random sample of adults in Bloomington-Normal, Illinois, a random sample of adults in Peoria, Illinois, college students in basic communication and speech classes at Illinois State University, the University of Southern California, Hampton Institute, and Nihon University in Tokyo, Japan. Results of the investigation indicate that the factor structure for source credibility for public figures varies from one subject sample to another. The implications of this variability for research on source credibility are discussed and suggestions are provided for researchers concerned with this variable.

Paper presented at Speech Communication Association Convention
Chicago, Illinois
December, 1972

Acknowledgments

The authors wish to express their appreciation to several colleagues who provided invaluable assistance in the collection of the data for this study: To Michael Scott (USC) who collected the Southern California data, to Jeff Nutnick (Hampton Institute) who collected the Hampton Institute data, to Donald Klopff (University of Hawaii) and Takehide Kawashima (Nihon University) who collected the Japanese data, and to 30 graduate assistants at Illinois State University from 1970 to 1972 who interviewed the subjects in the Bloomington-Normal and Peoria samples. Without the many hours of effort expended by these people, this study would have been impossible.

ED 074560

GENERALIZABILITY OF SOURCE CREDIBILITY SCALES FOR PUBLIC FIGURES

Whether source credibility is an important variable in persuasion is no longer a real question. An extensive body of literature has developed over the past two decades indicating that source credibility may be the single most important variable in determining persuasive effects of communication. Researchers in the area of persuasion have become increasingly aware that source credibility must be controlled and/or measured in persuasion studies in order to account for either main effects of credibility, interaction effects of credibility, or contamination due to the credibility variable. Similarly, source credibility as a terminal effect of persuasion has received increasing attention from researchers in the field.

This increased recognition of the importance of source credibility in research on persuasive communication has created a demand for measuring instruments which can reliably tap the credibility variable. Two sets of scales have been the predominate choice of researchers in the field of speech communication. These are the scales developed by McCroskey (1966) and by Berlo, Lemert, and Mertz, (1969). Use of either of these scales presumes the multi-dimensionality of the source credibility construct. Both sets were developed utilizing the methodology of factor analysis. Both include dimensions concerning the competence and the character of the communication source. In addition, the Berlo instrument includes scales to measure the dynamism of the source. The Berlo instrument employs the semantic differential approach to measurement. While McCroskey reports both Likert-type and semantic differential-type scales, the semantic differential-type scales are the ones which have been predominantly chosen for use.

These two sets of scales are virtually identical both in the method of their development and in the scales themselves with the exception of the dynamism dimension being present in the Berlo instrument. The only important difference in the development of the scales is that one (McCroskey) was based on research with undergraduate students while the other (Berlo) was based on the sample of adults in the Lansing, Michigan area. The development of both sets of scales was predicated upon subjects' responses to public figures. Since the scales are so similar and were based on two different subject populations, many people have assumed that these scales are highly generalizable and, as a result, have used them to measure many types of communication sources.

Tucker (1971) has noted the error in assuming that these scales are universal. He notes that varying subject-type or source-type may cause the dimensionality of source credibility scales to change. McCroskey, Scott, and Young (1971) provided a direct test of the generalizability of these scales. Their results indicated that the use of either of these sets of scales to measure the credibility of sources who were either spouses or peers, when the research subjects were adults, would be undefendable. They also found that scales developed by Norman (1963), Harkham (1968), and Whitehead (1968) did not generalize to sources of this type. It is clear from the Tucker critique and the McCroskey, Scott, and Young research that researchers concerned with source credibility should be advised to factor analyze their source credibility scales prior to their use as either

dependent or independent variables. Unfortunately, that advice is much easier to give, under some circumstances, than it is to follow. Some writers concerned with factor analysis suggest that there is a need for at least 200 subjects for a factor analysis to be justified (e.g., Guilford, 1954). It is very common to find studies concerned with source credibility that do not have this size of sample. In addition, many studies include only a single source. Factor analysis of data provided by subjects all responding to the same source is of very questionable value. Unless there is considerable variability in the subject population, the resulting factor structure may be meaningless, as in the case of the Whitehead (1968) study.

An alternative to the "factor analyze everytime" advice is a series of investigations designed to determine just how far credibility scales can be generalized. The current paper is a report of a portion of such a series of investigations. This series of studies assumes that three elements may contribute to a lack of generalizability of factor structures and source credibility measuring instruments. The first, and most obvious element which may contribute to the lack of generalizability, is in the scales employed. The major factor analytic studies concerning credibility have all used different item pools. Consequently, the obtained differences in factor structures could be simply a function of the difference in items employed. The second element that may contribute to the lack of generalizability is differences in research subjects. With the exception of the research by Berlo (1969), the research subjects in all of the factor analytic investigations have been college students, more specifically, white college students. Even the novice behaviorist in communication soon learns how questionable it is to generalize from college students to an adult population. But beyond that, within either a student population or an adult population there are many sub-cultural groupings. To employ predominantly white college students as subjects and then to generalize even to college students as a whole is dangerous. There has been no research examining non-white groups within our society and their responses in terms of source credibility dimensions.

The third and possibly the most important element which may contribute to the lack of generalizability of source credibility instruments is differences in source-type. Do we respond on the same psychological dimensions to all types of sources? The research reported by McCroskey, Scott, and Young (1971) indicates that we may not. The subjects in their study responded to peers on four dimensions while responding to spouses on six dimensions. It would appear, therefore, that if we are to obtain source credibility measuring instruments which have any generalizability at all, these instruments must be based upon specific source-types. The current series of investigations is involved with the following categories of source-type; public figures, peers, spouses, mass media, organization sources, teachers, superiors in an organization, subordinates in an organization, and members of a small group communication task-group. Other categories of source-type may be added later as the need becomes apparent. The present report is concerned with the source-type most often considered in previous investigations--public figures.

Of equal and possibly greater importance than the question of factor structure is the question of factor importance. Just because a given dimension appears in a number of factor analytic studies, this does not mean that that dimension has any social utility. The primary reason for

the development of measures of source credibility is so that researchers may use measures of credibility to predict variance in communication or other behavior. Consequently, the current series of investigations took additional measures relating to potential communication behavior and responses to communication behavior from each subject for each source. The data were then analyzed to determine the ability of obtained credibility dimensions to predict these variables.

METHOD

The current investigation employed as its initial item pool 53 semantic differential-type scales representing the dimensions of source credibility reported by Norman (1963), McCroskey (1966), Markham (1968), Whitehead (1968), and Berlo, Lemert, and Hertz (1969). All of the scales with high loadings on given factors in these studies were included, but because of several duplications of items, the item pool was reduced to 53. After the first (pilot) phase of this study, 11 items in the original data pool were omitted. The first phase of the study involved four source-types. The 11 items omitted failed to have satisfactory factor loadings on any factor for any source-type. Four additional items were added to the item pool after this investigation. These items were added for the purpose of strengthening obtained factors in the first investigation that appeared to be clear dimensions of response but which had only 2 or 3 items with satisfactory loadings. For phases 2 thru 6, therefore, the item pool was composed of 46 semantic differential-type scales. (See Appendix A).

Measures of potential communication behavior and response to communication behavior were Likert-type statements with response options falling on an eleven-step continuum bound by bipolar adjectives. In the first (pilot) phase of the investigation only four of these items were included. This number was expanded to nine in the subsequent phases. (See Appendix A.)

SOURCES

The public figures employed with the American subjects in this investigation were President Richard Nixon, Vice President Spiro Agnew, Senator Ted Kennedy, Senator George McGovern, Mayor John Lindsey, Governor George Wallace, Governor Ronald Reagan, and Senator Edmund Muskie. These sources were selected because it was believed that the overwhelming majority of the subjects in the study would be familiar with the sources and because these individuals represent a wide range of political viewpoints which should insure considerable variability in subject response. Each subject was asked to respond to only one public figure. Which public figure the individual was asked to evaluate was determined randomly.

In the phase of this investigation which employed Japanese college students, the American sources were not included. Rather, the subjects were asked to select a public figure well known in Japan (of their choice) and then respond to that individual. As in the other phases of the study, each subject responded to only one public figure.

SUBJECT TYPE

The data for this investigation were collected in six phases, representing six subject populations. All of the subjects were either college students or a random sample of non-student adults. Phase one of the investigation (the pilot study) involved 212 randomly selected adults living in either Bloomington or Normal, Illinois. These individuals were contacted directly by 12 graduate student interviewers. This phase of the study was completed during the spring of 1971. Phase 2 of this investigation involved 558 randomly selected adults in Peoria, Illinois. These individuals were contacted directly by 18 graduate student interviewers. Phase 3 and 4 of the investigation involved predominately white college students. Phase 3 was composed of 434 undergraduate students at Illinois State University. Phase 4 involved 130 undergraduate students at the University of Southern California. Phase 5 of the investigation involved 107 black undergraduate students from Hampton Institute. Phase 6 of the investigation involved 54 undergraduate students from Nippon University in Tokyo, Japan. All of the student samples were composed of undergraduates enrolled in basic speech or communication classes. The instruments were administered during regular class time.

DATA ANALYSIS

The data from the six phases of this investigation were analyzed separately. The data were subjected to principal components factor analysis and varimax rotation. Unity was inserted in the diagonals. An eigenvalue of 1.0 was established as the criterion for termination of factor extraction. For an item to be considered loaded on a resulting factor, a loading of .60 or higher was required with no loading of .40 or higher on any other factor. For a factor to be considered meaningful, the a priori requirement was set that at least two scales must be loaded on that factor. All data analyses were performed with the cooperation of the computation center at Illinois State University.

Where sample size permitted (in excess of 400) the data were divided into 2 sub-sets and analyzed to determine whether internal replication was possible. In phase 2, the Peoria adults, subjects were randomly assigned to the two sub-sets. In phase 3, the Illinois State University students, the data were divided by the sex of the respondent.

The second phase of the data analysis employed step-wise multiple regression analyses. Scores were computed for each obtained dimension of credibility for each subject sample based on all of the items with satisfactory factor loadings on the given dimensions. So that the scores on the various dimensions could be placed on the same continuum for comparison, the obtained score for each dimension was divided by the number of items loading on that dimension. These scores were then employed as predictor variables in multiple regression analyses. The criterion variables for the analyses were the measures of potential communication behavior and responses to communication behavior. Each criterion measure was analyzed separately.

The criterion established for termination of the step-wise multiple regression and analyses was when an entering variable in the analysis had

a nonsignificant ($p < .05$) partial correlation with the criterion variable or when extraction of an additional step would account for less than a one per cent increase in variance accounted for from the analysis.

The first multiple regression analyses conducted were based on the factor structure for the data sample under consideration (e.g. the Peoria factor structure for the Peoria data). Subsequently, analyses were conducted employing the factor structure for other data samples on the data under consideration (e.g., the Japan factor structure on the Peoria data.) The data from phases 2-6 were examined in this manner.

RESULTS

Factor Analyses

Factor analysis of the data from phase 1 of the investigation (Bloomington-normal) indicated a four-factor solution which accounted for 70 per cent of the total variance of the satisfactory scales. These four factors were labeled "competence," "extroversion," "sociability," and "composure." Table 1 reports the factor loadings for the prominent items for each factor.

The results of the analysis for phase 2 of the investigation (Peoria) indicate the presence of five factors in each sub-set of the data. These 5 factors were labeled "competence," "extroversion," "sociability," "composure," and "character." These factors accounted for 72 per cent of the total variance of the satisfactory scales in one sub-sample and 69 per cent of the total variance in the other sub-sample. As is noted in Table 2, almost perfect replication between the two sub-samples was obtained.

Phase 3 (Illinois State) analyses indicated four factors for both male and female subjects. These four factors were labeled "competence," "composure," "extroversion," and "character." These factors accounted for 64 per cent of the total variance of the satisfactory scales for male subjects and 63 per cent of total variance for female subjects. Again, as was found in phase 2, almost perfect replication was obtained between the two sub-sets of the sample. Sex did not have an observable impact of the factor structures.

The analyses of the phase 4 (Southern California) data indicated the presence of only three credibility dimensions. The three factors obtained were labeled "General Evaluation," "Extroversion," and "Composure." These factors accounted for 63 per cent of the total variance of the satisfactory scales. (See Table 4).

The data for phase 5 (Hampton Institute) indicated the presence of five credibility dimensions. The five factors were labeled "General Evaluation," "Extroversion," "Composure," "Dynamism," and "Sociability." These factors accounted for 67 per cent of the total variance of the satisfactory scales. (See Table 5).

The final factor analysis, that for phase 6 (Japan), resulted in a four-factor solution which accounted for 64 per cent of the total variance of the satisfactory scales. (See Table 6). The four factors were labeled "Character-Sociability," "Composure," "Competence," and "Extroversion."

Taken as a group the results of the factor analyses suggest the presence of different factor structures for the populations in the samples employed in this study. However, it would appear that approximately five essentially similar dimensions of response are associated with the source credibility of public figures across several populations. The "Competence" dimension is similar to factors found in a number of previous studies. This dimension has to do with the expertness or qualifications of the individual. The "Character" dimension obtained in these analyses is similar to the "Character" and "Trustworthiness" dimensions observed in previous research. This dimension appears to relate to the honesty and essential goodness of the public figure. The "Sociability" dimension, which was observed as an individual factor in three phases of the study, should be considered a "new dimension." It is principally composed of scales relating to the personality of the public figure. When this dimension did not appear as a separate factor, these items tended to combine with either "Character" or "General Evaluation." The fourth consistent factor observed in this investigation was "Composure." This factor appeared in all six phases of the study. The scales representing this dimension appeared to tap a response to a public figure's exhibited anxiety level. The final factor observed was "Extroversion," which appeared in all six phases of the investigation. This factor seems to represent the aggressiveness or talkativeness of the public figure.

In two of the analyses "Competence" and "Character" combined to form a "General Evaluation" factor. In the Hampton Institute sample "Extroversion" divided into two factors which were labeled "Extroversion" and "Dynamism." The reasons for these differences in factor structure are not clear. However, the comparatively small samples in phases 4, 5, and 6 may be important. There was considerably more consistency among the results from the samples in the first three phases of the study. In each of these samples, the sample size was substantially larger.

Regression Analyses

The regression analyses provided data with regard to three important questions. The first of these was "Can the dimensions of credibility predict substantial variance in potential communication-related behavior?" The second question was "Do differences in factor structure among six populations affect the ability of source credibility dimensions to predict communication-related behavior?" The final question was "What is the comparative importance of observed credibility dimensions in the prediction of potential communication-related behavior?"

Table 7 reports the multiple correlations obtained for the regression analyses that were based on the individual samples own factor structures. As is indicated in Table 7, it was possible to predict substantial variance on the nine criterion variables on the basis of the scores on the credibility dimensions. For most of the samples on most of the criterion variables the obtained multiple correlations ranged from .5 to .7. The main exception was observed with the Japan sample, where substantially less variance was predictable. This is suggestive of a cultural difference between Japan and the U.S. The other exception related to the ability of source credibility to predict the fourth criterion variable for all samples. This criterion variable was concerned with the subjects' behavior in seeking communication with the public

figure. A comparatively small portion of the variance in this behavior was found to be predictable. A possible reason for this relatively poor predictability is that most of the subjects in all of the samples would never have direct interpersonal communication with any of the public figures studied. Rather, the subjects would probably only be receivers of mediated communication from these sources. Consequently, responses to this criterion variable may have had substantially higher error variance associated with them than responses to the other criterion variables.

The answer to our first question, therefore, is a qualified "yes." Dimensions of credibility can predict substantial variance in potential communication-related behavior.

Tables 8 - 12 report the multiple correlations obtained from both the primary and supplementary regression analyses. The primary analyses employed the factor structure for the predictor variables that was generated by the same subjects who provided the responses representing the criterion variables. The supplementary analyses used factor structures based on the other data samples. These results give some indication of the relative importance of using a population's own factor structure for the prediction of their communication-related behavior as opposed to using a factor structure generated for another population. An examination of the results reported in Tables 8 - 12 strongly suggests that the source of the factor structure is relatively unimportant. Roughly equivalent multiple correlations were obtained on all of the criterion variables regardless of which factor structure served as the basis of the predictor variable. The only exception to this was the comparatively lower multiple correlations generated when the Southern California factor structure was used to predict the criterion variable data supplied by the Peoria and Illinois State samples. The reason for this deviation is unclear.

The answer to our second question, therefore, appears to be "no." Differences in factor structure among the six populations investigated in this study did not substantially affect the ability of credibility dimensions to predict communication-related behavior.

The third important question to which the regression analyses were directed was concerned with the comparative importance of obtained credibility dimensions in the prediction of potential communication-related behavior. Tables 13 - 21 report the regression equations obtained for the criterion variables for each sample. An examination of these equations indicates that all of the dimensions of credibility obtained in this study contributed, under certain conditions, to the prediction of potential communication-related behavior. However, the two dimensions which regularly accounted for the most variance were "Competence" and "Character." In several instances, these were the only two credibility dimensions indicating significant predictive power.

Conclusions:

The current investigation was designed to test the generalizability of source credibility factors and scales for public figures across diverse subject populations. In addition, the study was designed to generate information concerning the importance of any observed lack of generalizability.

The results of this investigation suggest that researchers should not expect exactly the same dimensionality of source credibility for all subject populations.

Substantial differences in factor structure were observed. Not only were different numbers of dimensions obtained from different populations, but even when the same dimension appeared for more than one subject population the scales representing that dimension were not always identical. On the surface these results suggest a severe problem for the development of measures of source credibility of public figures that can be used across a variety of subject populations. However, further examination of the data suggests that such a conclusion is probably unwarranted. The results of the regression analyses indicated that the observed variability in factor structure does not seriously affect the ability of those factor structures to predict the same potential communication-related behavior. Consequently, the scales reported in Table 22 are suggested for use across populations. These scales can be expected to tap all of the dimensions observed in the six phases of this study. While in some instances an investigator may obtain more information from these scales than he needs (the behavior which he may wish to predict may not be related to one or more dimensions being measured), the use of these scales ought to provide reasonable assurance that necessary information will be available.

It should be stressed that the scales recommended in Table 22 are recommended only for the measurement of the credibility of public figures. Their use for other types of sources may be totally inappropriate. It should also be stressed that as extensive as the current investigation was, these results should not be considered representative of all potential subject populations. While there may be comparatively less need for replication research with general American populations, there is clearly a need for research with other sub-cultural populations within the United States and cultures represented in other nations. In addition, there is need for research which employs these or similar credibility scales and obtains more direct measures of actual (rather than potential) communication-related behavior. This and previous research strongly suggests that source credibility plays a major role in communication behavior. The need now is for research that can specify quantitatively the degree of that relationship.

TABLE 13

Regression Equations for Criterion Variable 1:
 "When I need information on an issue, I consider
 this person as a source of information, to be"

Sample	Equation
Bloomington-Normal	$Y = 1.30 + 1.44$ (Competence)
Peoria	$Y = .10 + 1.18$ (Character) $- .24$ (Extroversion) $+ .38$ (Competence)
ISU	$Y = .06 + .25$ (Competence) $- .19$ (Composure) $+ 1.29$ (Character)
USC	$Y = -.79 + 1.57$ (General Evaluation)
Hampton	$Y = -2.78 + 1.76$ (General Evaluation) $+ .38$ (Extroversion) $- .30$ (Sociability)
Japan	$Y = 3.05 + .54$ (Character/Sociability) $+ .36$ (Competence)

TABLE 14

Regression Equations for Criterion Variable 2:
 "When I am faced with making a decision, I
 consider this person's opinions to be"

Sample	Equation
Bloomington-Normal	$Y = 4.64 + 1.38$ (Competence) $+ .47$ (Sociability) $+ .41$ (Composure)
Peoria	$Y = -0.73 + 1.27$ (Character) $+ .15$ (Competence)
ISU	$Y = .17 - .24$ (Competence) $+ 1.46$ (Character)
USC	$Y = 0.37 + 1.48$ (General Evaluation) $- .29$ (Composure)
Hampton	$Y = -2.74 + 1.50$ (General Evaluation) $+ .22$ (Dynamism)
Japan	$Y = 5.47 + .52$ (Character/Sociability) $- .18$ (Composure)

TABLE 15

Regression Equations for Criterion Variable 3:
"As a communicator, I consider this person to
be"

Sample	Equation
Bloomington-Normal	$Y = -1.60 + 1.27 (\text{Competence}) + .39 (\text{Sociability})$
Peoria	$Y = .05 + 1.09 (\text{Character}) + .28 (\text{Competence})$
ISU	$Y = -1.23 + .32 (\text{Competence}) + .27 (\text{Extroversion}) + 1.07 (\text{Character})$
USC	$Y = -2.83 + 1.20 (\text{General Evaluation}) + .55 (\text{Extroversion}) + .22 (\text{Composure})$
Hampton	$Y = .97 + 1.32 (\text{General Evaluation})$
Japan	$Y = .67 + .23 (\text{Character/Sociability}) + .42 (\text{Competence}) + .61 (\text{Extroversion})$

TABLE 16

Regression Equations for Criterion Variable 4:
"I seek opportunities to communicate with
this person"

Sample	Equation
Bloomington-Normal	$Y = -1.87 + .63 (\text{Competence}) + .68 (\text{Sociability})$
Peoria	$Y = 2.10 + .88 (\text{Character}) - .29 (\text{Extroversion})$
ISU	$Y = -.38 + .45 (\text{Competence}) - .22 (\text{Composure}) + .70 (\text{Character})$
USC	$Y = 2.93 + .25 (\text{General Evaluation}) - .35 (\text{Composure})$
Hampton	$Y = -2.6 + .66 (\text{General Evaluation}) + .20 (\text{Composure}) + .38 (\text{Dynamism})$
Japan	$Y = 6.10 + .45 (\text{Character/Sociability}) - .18 (\text{Competence}) - .31 (\text{Extroversion})$

TABLE 17

Regression Equations for Criterion Variable 5:
 "If this person asked you to change your opinion
 on something, how likely would you be to do so?"

Sample	Equation
Peoria	$Y = .80 + 1.06 (\text{Character}) - .21 (\text{Extroversion})$
ISU	$Y = -.31 - .18 (\text{Competence}) + 1.25 (\text{Character})$
USC	$Y = 1.10 + 1.41 (\text{General Evaluation})$ $+ .29 (\text{Extroversion}) - .57 (\text{Composure})$
Hampton	$Y = -2.96 + 1.06 (\text{General Evaluation})$ $+ .39 (\text{Dynamism})$
Japan	$Y = .51 + .61 (\text{Character/Sociability})$ $+ .24 (\text{Composure}) + .23 (\text{Competence})$

TABLE 18

Regression Equations for Criterion Variable 6:
 "If this person asked you to do something you
 had not done before, how likely would you be
 to do so?"

Sample	Equation
Peoria	$Y = .81 + 1.06 (\text{Character}) - .23 (\text{Extroversion})$
ISU	$Y = .13 - .22 (\text{Competence}) + 1.12 (\text{Character})$
USC	$Y = -.02 + 1.28 (\text{General Evaluation})$ $- .33 (\text{Composure})$
Hampton	$Y = -2.58 + .96 (\text{General Evaluation})$ $+ .38 (\text{Dynamism})$
Japan	$Y = 2.04 - .26 (\text{Composure}) + .60 (\text{Competence})$ $+ .20 (\text{Extroversion})$

TABLE 19

Regression Equations for Criterion Variable 7:
 "If this person said something was false that
 you believed was true, how likely would you be
 to change your mind?"

Sample	Equation
Peoria	$Y = -0.38 + .94$ (Character)
ISU	$Y = -.31 - .26$ (Competence) + 1.24 (Character)
USC	$Y = -.66 + 1.05$ (General Evaluation)
Hampton	$Y = -1.55 + 1.02$ (General Evaluation) $-.27$ (Sociability) + .45 (Dynamism)
Japan	$Y = 4.69 + .75$ (Character/sociability) $-.75$ (Composure) + .19 (Competence)

TABLE 20

Regression Equations for Criterion Variable 8:
 "How well do I like this person?"

Sample	Equation
Peoria	$Y = -1.51 + 1.48$ (Character)
ISU	$Y = -.63 - .21$ (Competence) + 1.53 (Character)
USC	$Y = -1.01 + 1.53$ (General Evaluation) $-.25$ (Composure)
Hampton	$Y = -4.35 + 1.33$ (General Evaluation) $+ .30$ (Extroversion) + .34 (Dynamism)
Japan	$Y = 1.92 + .39$ (Character/Sociability)

TABLE 21

Regression Equations for Criterion Variable 9:
 "How well would you like to work with this person?"

Sample	Equation
Peoria	$Y = 2.07 + 1.36 (\text{Character}) + .19 (\text{Composure})$
ISU	$Y = -.65 -.23 (\text{Composure}) + 1.56 (\text{Character})$
USC	$Y = -.79 + 1.24 (\text{General Evaluation})$ $+ .31 (\text{Extroversion}) -.32 (\text{Composure})$
Hampton	$Y = -4.15 + 1.50 (\text{General Evaluation})$ $+ .37 (\text{Extroversion})$
Japan	$Y = .43 + .73 (\text{Character/Sociability})$ $+ .38 (\text{Competence})$

TABLE 22

Suggested Scales For the Measurement of the Source Credibility of Public Figures

Dimension	Scales
Competence	expert-inexpert competent-incompetent responsible-undependable qualified-unqualified experienced-inexperienced trained-untrained intelligent-unintelligent intellectual-narrow
Character	honest-dishonest nice-awful just-unjust good-bad kind-cruel reliable-unreliable believable-unbelievable admirable-contemptible
Composure	calm-anxious poised-nervous relaxed-tense
Extroversion	talkative-silent extroverted-introverted verbal-quiet aggressive-mEEK bold-timid adventurous-cautious energetic-tired
Sociability	attractive-unattractive good-natured-irritable cheerful-gloomy sociable-unsociable

APPENDIX A

Semantic Differential Scales

Intelligent-Unintelligent	Untrained-Trained
Sociable-Unsociable	Unsympathetic-Sympathetic
Nervous-Poised	Admirable-Contemptible
Cheerful-Gloomy	Awful-nice
Tense-Relaxed	Qualified-Unqualified
Sinful-Virtuous	Extroverted-Introverted
Believable-Unbelievable	Just-Unjust
Good-natured-Irritable	Unpleasant-Pleasant
Intellectual-Narrow	Timid-Bold
Cooperative-Negativistic	Energetic-Tired
Outgoing-Withdrawn	Good-Bad
Dishonest-Honest	Repulsive-Attractive
Weak-Aggressive	Uninformed-Informed
Valuable-Worthless	Composed-Excitable
Selfish-Unselfish	Incompetent-Competent
Calm-Anxious	Cruel-Kind
Inexperienced-Experienced	Talkative-Silent
Verbal-Quiet	Expert-Inexpert
Logical-Illogical	Passive-Active
Undependable-Responsible	Impressive-Unimpressive
Headstrong-mild	Adventurous-Cautious
Friendly-Unfriendly	Crude-Refined
Confident-Lacks confidence	Reliable-Unreliable

Potential Communication-Related Behavior Scales

1. When I need information on an issue, I consider this person as a source of information, to be:
Worthless - Extremely Valuable
2. When I am faced with making a decision, I consider this person's opinions to be:
Worthless - Extremely Valuable
3. As a communicator, I consider this person to be:
Inferior - Superior
4. I seek opportunities to communicate with this person
Not at all - Very often
5. If this person asked you to change your opinion on something, how likely would you be to do so? Very Unlikely - Very Likely
6. If this person asked you to do something you had not done before, how likely would you be to do so? Very Unlikely - Very Likely
7. If this person said something was false that you believed was true, how likely would you be to change your mind?
Very Unlikely - Very Likely
8. How well do you like this person? Very Little - Very much
9. How well would you like to work with this person?
Very Little - Very much
