Abstract. The nondeterministic information logic NIL has been introduced by Orłowska and Pawlak in 1984 as a logic for reasoning about total information systems with the similarity, the forward inclusion and the backward inclusion relations. In 1987, Vakarelov provides the first first-order characterization of structures derived from information systems and this has been done with the semantical structures of NIL. Since then, various extensions of NIL have been introduced and many issues for information logics about decidability and Hilbert-style proof systems have been solved. However, computational complexity issues have been seldom attacked in the literature mainly because the information logics are propositional polymodal logics with interdependent modal connectives. We show that NIL satisfiability is a PSPACE-complete problem. PSPACE-hardness is shown to be an easy consequence of PSPACE-hardness of the well-known modal logic S4. The main difficulty is to show that NIL satisfiability is in PSPACE. To do so we present an original construction that extends various previous works by Ladner (1977), Halpern and Moses (1992) and Spaan (1993).

Keywords: information system, multimodal logic, computational complexity, Ladner-like algorithm.

1. Introduction

Information systems. The information logics derived from Pawlak's *information systems* [28] are intended to be able to reason about information systems. An *information system* can be seen as a structure $\langle OB, AT \rangle$ such that OB is a nonempty set of *objects*, AT is a nonempty set of *attributes* and each attribute $a \in AT$, is a mapping $a : OB \rightarrow \mathcal{P}(Val_a) \setminus \{\emptyset\}$ where Val_a is a nonempty set of *values*. For each object x and for each attribute a , $a(x)$ can be read as

the set of possible values of the attribute a for the object x . In that setting, various derived relations between objects can be defined. We recall some of them below from the literature (see e.g. [23]). For any $x_1, x_2 \in OB$, $A \subseteq AT$,

- $x_1 \mathit{ind}(A) x_2 \stackrel{\text{def}}{\Leftrightarrow}$ for any $a \in A$, $a(x_1) = a(x_2)$ (indiscernibility) ;
- $x_1 \mathit{comp}(A) x_2 \stackrel{\text{def}}{\Leftrightarrow}$ for any $a \in A$, $a(x_1) = \text{Val}_a \setminus a(x_2)$ (complementarity);
- $x_1 \mathit{fin}(A) x_2 \stackrel{\text{def}}{\Leftrightarrow}$ for any $a \in A$, $a(x_1) \subseteq a(x_2)$ (forward inclusion);
- $x_1 \mathit{bin}(A) x_2 \stackrel{\text{def}}{\Leftrightarrow}$ for any $a \in A$, $a(x_2) \subseteq a(x_1)$ (backward inclusion);
- $x_1 \mathit{sim}(A) x_2 \stackrel{\text{def}}{\Leftrightarrow}$ for any $a \in A$, $a(x_1) \cap a(x_2) \neq \emptyset$ (similarity).

$x_1 \mathit{ind}(A) x_2$ can be read as follows: the objects x_1 and x_2 cannot be distinguished modulo the set of attributes A . Similarly, $x_1 \mathit{sim}(A) x_2$ iff x_1 and x_2 are similar modulo A . The other relations $\mathit{comp}(A)$, $\mathit{fin}(A)$ and $\mathit{bin}(A)$ admit a reading in the same vein. The polymodal logics obtained from the information systems are multimodal logics such that the relations in the Kripke-style semantical structures correspond to relations between objects in the underlying information systems. The first information logic has been introduced in [24] and many others appeared later (see e.g. [11, 33, 1, 18, 34, 8]). The information logic NIL (introduced in [25]) is remarkable among the class of information logics. Indeed, in 1987, Vakarelov [32] provides the first first-order characterization of structures derived from information systems and this has been done with the semantical structures of NIL. The NIL semantical structures contain not only forward and backward inclusions derived relations but also the similarity relation. More precisely, the NIL frames are all the structures $\langle OB, \mathit{fin}(AT), \mathit{bin}(AT), \mathit{sim}(AT) \rangle$ derived from some information system $\langle OB, AT \rangle$. Actually, in [32], it has been shown that in order to define NIL an additional condition (not present in [25]) between forward inclusion and similarity needs to be taken into account (the forthcoming condition (N4)).

Our contribution. The main contribution of the paper is to fully characterize the computational complexity of NIL satisfiability. Actually, we show that NIL satisfiability is a **PSPACE**-complete problem (see e.g. [27] for a thorough introduction to complexity theory). So, NIL satisfiability captures the difficulty of the whole complexity class **PSPACE** that is the class of (decision) problems that can be solved by a deterministic Turing machine in polynomial space in the length of the input string. **PSPACE**-hardness with respect to logarithmic space transformations is shown to be an easy consequence of **PSPACE**-hardness of the well-known modal logic S4 [20]. The main difficulty is to show that NIL satisfiability is in **PSPACE**. To do so we present an original construction that extends various previous works in [20, 15, 31]. The technique can be extended to other information logics (and polymodal logics with interdependent modal connectives) and this shall be the topic of forthcoming papers. Moreover, the analysis developed in the paper could be easily plug into a labelled tableaux calculus for NIL. Such a calculus is not difficult to define following for instance [2, 7, 35].

Related work. The procedure designed in this paper has a direct filiation with the works of Ladner [20], Halpern and Moses [15] and Spaan [31]. Indeed, we shall use a tableau-based procedure to show that we do not need more than polynomial space to check NIL satisfiability. We cannot take advantage of [16] where the complexity of join modal logics is characterized (NIL contains interdependent modal connectives). The detection of cycles for S4 modalities in NIL is similar to the proof-theoretical results from [5] that is related to the techniques from [20, 14]. Other proof-theoretical analysis about complexity issues for modal logics can be found in [22, 35].

2. Definition of NIL and PSPACE-hardness

For any set X , we write X^* [resp. X^+] to denote the set of [resp. nonempty] finite strings built from elements of X . For any finite string s , we write $|s|$ [resp. $last(s)$] to denote its length [resp. the last element of s , if any]. For any $s \in X^*$, we write s^k to denote the string composed of k copies of s . For instance, $(bin \cdot fin)^2 = bin \cdot fin \cdot bin \cdot fin$ and $|(bin \cdot fin)^2| = 4$.

Given a countably infinite set $\text{For}_0 = \{p_0, p_1, p_2, \dots\}$ of *propositional variables* the NIL-formulae ϕ are inductively defined as follows:

$$\phi ::= p_k \mid \phi_1 \wedge \phi_2 \mid \neg\phi \mid [\leq]\phi \mid [\geq]\phi \mid [\sigma]\phi$$

for $p_k \in \text{For}_0$. We write $|\phi|$ to denote the *length* of the formula ϕ , that is the length of the string ϕ ($[\geq]$, $[\leq]$ and $[\sigma]$ count here for one symbol). We write $md(\phi)$ to denote the modal degree of ϕ , that is the modal depth of ϕ . md is naturally extended to finite sets of formulae, understood as conjunctions and by convention $md(\emptyset) = 0$. For $\mathbf{R} \in \{\sigma, \leq, \geq\}$, $[\mathbf{R}]^i\phi$ is inductively defined as follows: $[\mathbf{R}]^0\phi = \phi$ and $[\mathbf{R}]^{i+1}\phi = [\mathbf{R}][\mathbf{R}]^i\phi$ for $i \geq 1$. For $s \in \{[\leq], [\geq], [\sigma]\}^*$, an s -formula is defined as a formula prefixed by s . For instance, $[\sigma][\leq][\geq]p_0$ is a $[\sigma][\leq]$ -formula. A *NIL-model* \mathcal{M} is a structure $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ such that W is a nonempty set, m assigns to each propositional variable a subset of W and $R_{\leq}, R_{\geq}, R_{\sigma}$ are binary relations on W such that

- (N1) $R_{\leq} = (R_{\geq})^{-1}$, that is R_{\leq} is the converse of R_{\geq} ;
- (N2) R_{\leq} is reflexive and transitive;
- (N3) R_{σ} is reflexive and symmetric;
- (N4) If $\langle x, y \rangle \in R_{\sigma}$, $\langle x, x' \rangle \in R_{\leq}$ and $\langle y, y' \rangle \in R_{\leq}$, then $\langle x', y' \rangle \in R_{\sigma}$.

Observe that in any NIL-model, we have $(R_{\leq} \cup R_{\geq}) \subseteq R_{\sigma}$. The condition (N4) was not originally in the logic NIL defined in [25] but it appeared in [32] for the first-order characterization of the structures

$$\langle OB, fin(AT), bin(AT), sim(AT) \rangle$$

where $\langle OB, AT \rangle$ is an information system. The condition (N4) is mainly responsible for the difficulty in showing that NIL satisfiability is in **PSPACE**. Conditions (N2) and (N4) can be equivalently replaced by

- (N2') R_{\geq} is reflexive and transitive;

(N4') If $\langle x, y \rangle \in R_\sigma$ and $\langle y, y' \rangle \in R_{\leq}$, then $\langle x, y' \rangle \in R_\sigma$.

The condition (N4') can be read as a pseudo transitivity condition involving two binary relations. Transitivity of R_{\leq} and R_{\geq} requires a specific treatment in order to show that NIL-satisfiability is in **PSPACE**. We apply a method of detection of cycles known in the literature (see [20, 31]).

As is usual for modal logics, the formula ϕ is *satisfied by the world* $w \in W$ in $\mathcal{M} \stackrel{\text{def}}{\Leftrightarrow} \mathcal{M}, w \models \phi$ where the satisfaction relation \models is inductively defined as follows:

- $\mathcal{M}, w \models \mathbf{p} \stackrel{\text{def}}{\Leftrightarrow} w \in m(\mathbf{p})$, for every propositional variable \mathbf{p} ;
- $\mathcal{M}, w \models [\leq]\phi \stackrel{\text{def}}{\Leftrightarrow}$ for every $w' \in R_{\leq}(w)$, $\mathcal{M}, w' \models \phi$;
- $\mathcal{M}, w \models [\geq]\phi \stackrel{\text{def}}{\Leftrightarrow}$ for every $w' \in R_{\geq}(w)$, $\mathcal{M}, w' \models \phi$;
- $\mathcal{M}, w \models [\sigma]\phi \stackrel{\text{def}}{\Leftrightarrow}$ for every $w' \in R_\sigma(w)$, $\mathcal{M}, w' \models \phi$.

We omit the standard conditions for the propositional connectives. A formula ϕ is said to be *NIL-satisfiable* $\stackrel{\text{def}}{\Leftrightarrow}$ there is a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_\sigma, m \rangle$ and $w \in W$ such that $\mathcal{M}, w \models \phi$. An Hilbert-style system can be easily designed for NIL in which all the modal axiom schemes are Sahlqvist formulae (see e.g. [30]). Similarly, prefixed tableaux calculi and cut-free display calculi can be defined for NIL using the general results from [19, 2]. Moreover, a linear-time transformation from NIL satisfiability problem into the fragment of first-order logic with three individual variables can be given by using the standard translation from modal logics into classical logic (see e.g. [3]). Although this fragment of classical logic is known to be undecidable, the results in the paper can be viewed as an explanation for the decidability (and indeed **PSPACE**-completeness) of the exact fragment of first-order logic with three individual variables delineated by the translation from NIL. However, the complexity of NIL satisfiability is really a problematic issue since NIL contains interdependent modal connectives. A complexity lower bound can be easily established since NIL can be viewed as an extension of S4.

Theorem 2.1. *NIL satisfiability is logarithmic space hard in PSPACE.*

Proof:

Let X be the set of NIL satisfiable formulae ϕ such that neither $[\sigma]$ nor $[\geq]$ occurs in ϕ . We shall show that X is the set of S4 satisfiable formulae modulo the replacement of $[\leq]$ by the standard modal connective $[\]$. Since S4 satisfiability is logarithmic space hard in **PSPACE** [20], so is NIL satisfiability. If $\phi \in X$, then ϕ is S4 satisfiable since by removing from a NIL-model for ϕ the components R_σ and R_{\geq} we get an S4-model. Moreover, if ϕ is S4 satisfiable, then there exist an S4-model $\mathcal{M} = \langle W, R, m \rangle$ and $w \in W$ verifying $\mathcal{M}, w \models \phi$. Let $\mathcal{M}' = \langle W, R_{\leq}, R_{\geq}, R_\sigma, m \rangle$ be the NIL-model such that $R_{\leq} \stackrel{\text{def}}{=} R$, $R_{\geq} \stackrel{\text{def}}{=} R^{-1}$ (the converse of R) and $R_\sigma \stackrel{\text{def}}{=} W \times W$. Obviously $\mathcal{M}', w \models \phi$ (modulo the replacement of $[\leq]$ by $[\]$) and \mathcal{M}' is indeed a NIL-model. \square

What is done in the proof of Theorem 2.1 at the level of Kripke-style structures can be also interpreted at the level of information systems. Indeed, let $S = \langle OB, AT \rangle$ and $S' = \langle OB, AT' \rangle$ be information systems such that

- $AT' \stackrel{\text{def}}{=} \{a' : a \in AT\}$;

- for $a' \in AT'$, $Val_{a'} \stackrel{\text{def}}{=} Val_a \cup \{Dummy\}$ with $Dummy \notin \bigcup\{Val_a : a \in AT\}$;
- for $a' \in AT'$ and $x \in OB$, $a'(x) \stackrel{\text{def}}{=} a(x) \cup \{Dummy\}$.

One can easily check that $fin(AT) = fin(AT')$ and $sim(AT') = OB \times OB$, that is the S4-frame $\langle OB, fin(AT) \rangle$ can be extended to the NIL-frame

$$\langle OB, fin(AT'), bin(AT'), sim(AT') \rangle$$

where $sim(AT')$ is the universal relation $OB \times OB$.

Results from [20, 31, 6, 21] easily entail the following:

Theorem 2.2. (I) Any fragment of NIL with a single modal connective $[R]$ where $R \in \{\leq, \geq, \sigma\}$ has a **PSPACE**-complete satisfiability problem;

(II) The fragment of NIL without the modal connective $[\sigma]$ has a **PSPACE**-complete satisfiability problem.

It remains to show that NIL satisfiability with the three modal connectives $[\leq]$, $[\geq]$ and $[\sigma]$ living together and interacting, is also in **PSPACE**. To do so, we shall follow the proof technique from [31] and we propose substantial modifications in order to cope with the much more difficult NIL case. It is worth mentioning that interactions between modal connectives can lead to an increase of computational complexity. K-satisfiability and S5-satisfiability are in **PSPACE** and in **NP**, respectively [20]. However, the bimodal logic with an S5 modal connective $[1]$ and with a K modal connective $[2]$ such that $[1]\phi \Rightarrow [2]\phi$ is an additional axiom has an **EXPTIME**-hard satisfiability problem [17]. This is well-known that the axiom schema $[1]\phi \Rightarrow [2]\phi$ corresponds to the semantical condition $R_2 \subseteq R_1$ where R_i is the accessibility relation associated to the modal operator $[i]$ ($i = 1, 2$).

3. Preliminary results

In Definition 3.1 below, we introduce a closure operator for sets of NIL-formulae as it is done for Propositional Dynamic Logic PDL by Fischer and Ladner in [12].

Definition 3.1. Let X be a set of NIL-formulae. Let $cl(X)$ be the smallest set of formulae such that:

- $X \subseteq cl(X)$;
- if $\neg\phi \in cl(X)$, then $\phi \in cl(X)$;
- if $\phi_1 \wedge \phi_2 \in cl(X)$, then $\phi_1, \phi_2 \in cl(X)$;
- if $[\leq]\phi \in cl(X)$, then $\phi \in cl(X)$;
- if $[\geq]\phi \in cl(X)$, then $\phi \in cl(X)$;
- if $[\sigma]\phi \in cl(X)$, then $[\geq]\phi \in cl(X)$;

- if $[\sigma]\phi \in \text{cl}(X)$ and ϕ is not a $[\leq]$ -formula, then $[\sigma][\leq]\phi \in \text{cl}(X)$;
- if $[\sigma][\leq]\phi \in \text{cl}(X)$, then $[\sigma]\phi \in \text{cl}(X)$.

Consequently, if $[\sigma]\phi \in \text{cl}(X)$ and ϕ is not a $[\leq]$ -formula, then $[\leq]\phi \in \text{cl}(X)$ and if $[\sigma]\phi \in \text{cl}(X)$, then $\phi \in \text{cl}(X)$. A set X of formulae is said to be *closed* $\stackrel{\text{def}}{\iff} \text{cl}(X) = X$. For any finite set X of formulae, we have $\text{md}(\text{cl}(X)) \leq \text{md}(X) + 1$. Moreover, for any formula ψ , $\text{md}([\leq]\psi) = \text{md}([\geq]\psi) = \text{md}(\text{cl}(\{[\leq]\psi\})) = \text{md}(\text{cl}(\{[\geq]\psi\}))$.

Lemma 3.1. *Let ϕ be a formula. Then, $\text{card}(\text{cl}(\{\phi\})) < 5 \times |\phi|$.*

Proof:

Let $\text{sub}(\phi)$ be the set of subformulae of the formula ϕ . Obviously, $\text{sub}(\phi) \subseteq \text{cl}(\{\phi\})$. Moreover, $\text{cl}(\{\phi\})$ is the union of the following sets:

1. $\text{sub}(\phi)$;
2. $\{[\geq]\psi : [\sigma]\psi \in \text{sub}(\phi)\}$;
3. $\{[\geq]\psi : [\sigma][\leq]^n\psi \in \text{sub}(\phi), n \geq 1\}$;
4. $\{[\geq][\leq]\psi : [\sigma]\psi \in \text{sub}(\phi), \psi \neq [\leq]\psi'\}$;
5. $\{[\sigma][\leq]\psi : [\sigma]\psi \in \text{sub}(\phi), \psi \neq [\leq]\psi'\}$;
6. $\{[\sigma]\psi : [\sigma][\leq]^n\psi \in \text{sub}(\phi), n \geq 1\}$;
7. $\{[\leq]\psi : [\sigma]\psi \in \text{sub}(\phi), \psi \neq [\leq]\psi'\}$.

Each set above is of the cardinality at most $\text{card}(\text{sub}(\phi))$ and a formula in $\text{sub}(\phi)$ can generate at most four formulae in $\text{cl}(\{\phi\})$. So $\text{card}(\text{cl}(\{\phi\})) < 5 \times |\phi|$, since $\text{card}(\text{sub}(\phi)) < |\phi|$. \square

In order to determine the NIL satisfiability of some formula ϕ , we need to handle sets of formulae. All those sets shall be subsets of $\text{cl}(\{\phi\})$. In establishing the **PSPACE** complexity upper bound, the fact that $\text{cl}(\{\phi\})$ is finite and its cardinality is linear in the size of ϕ plays an important role.

In order to check whether ϕ is NIL-satisfiable, we build sequences of the form

$$X_0 \ x_0 \ X_1 \ x_1 \ X_2 \ x_2 \ \dots$$

where $\phi \in X_0 \subseteq \text{cl}(\{\phi\})$ and for $i \in \omega$, X_i is a *consistent* subset of $\text{cl}(\{\phi\})$ and $x_i \in \{\sigma, \leq, \geq\}$. We extend a finite sequence $X_0 \ x_0 \ X_1 \ x_1 \ \dots \ x_{i-1} \ X_i$ with $x_i X_{i+1}$ whenever we need a witness of $[x_i]\psi \notin X_i$ for some formula ψ (and $\psi \notin X_{i+1}$). The intention is to build paths in some NIL model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ such that for $i \in \omega$, there is $w_i \in W$ such that $\mathcal{M}, w_i \models \psi$ iff $\psi \in X_i$ and $\langle w_i, w_{i+1} \rangle \in R_{x_i}$. This roughly corresponds to the exploration of a branch in the depth-first proof search for a tableaux-style calculus. In order to avoid confusion, σ [resp. \leq, \geq] shall be written *sim* [resp. *fin, bin*].

In order to establish termination of the proof of building sequences, which is a necessary step to obtain the **PSPACE** complexity upper bound, we define subsets $\text{cl}(s, \phi) \subseteq \text{cl}(\{\phi\})$ for $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ such that for $i \in \omega$,

$$X_i \subseteq \text{cl}(x_0 \dots x_{i-1}, \phi)$$

For $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ and $x \in \{\text{sim}, \text{fin}, \text{bin}\}$ $\text{cl}(s \cdot x, \phi)$ contains all the formulae ψ which we could possibly be put in X_{i+1} for $\psi \in \text{cl}(x_0 \dots x_{i-1}, \phi)$.

We will get termination if there is some computable map $f : \omega \rightarrow \omega$ such that for $|s| \geq f(|\phi|)$, $\text{cl}(s, \phi) = \emptyset$. To establish the **PSPACE** complexity upper bound, f should preferably be bounded by a polynomial. Those general principles may look quite attractive but in concrete examples of modal logics they are seldom sufficient to show that the satisfiability problem is in **PSPACE**. Since transitivity of R_{\leq} is required, if $[\leq]\psi \in X_i$, then $\mathcal{M}, w_i \models [\leq]\psi$, $\mathcal{M}, w_i \models [\leq][\leq]\psi$ and therefore one can expect that $[\leq]\psi \in X_{i+1}$ if $x_i = \text{fin}$. So the formula $[\leq]\psi \in X_i$ should be propagated for any “fin” transition. However, this does not guarantee termination. Actually, as already known from [20, 31, 5], duplicates can be identified in $X_0 x_0 X_1 x_1 X_2 x_2 \dots$ which corresponds to a cycle detection (see also [13]). Since $\text{card}(\mathcal{P}(\text{cl}(\{\phi\})))$ is in $\mathcal{O}(2^{|\phi|})$, a finer analysis is necessary to establish the **PSPACE** complexity upper bound as done in [20] (see also [31] for the tense extension of Ladner’s solution). Things are even worse. since by (N4), if $[\sigma]\psi \in X_i$, then $\mathcal{M}, w_i \models [\sigma]\psi$ and $\mathcal{M}, w_i \models [\geq]^n[\sigma][\leq]^{n'}\psi$ for $n, n' \geq 0$. One can expect that $[\geq]^{n-1}[\sigma][\leq]^{n'}\psi \in X_{i+1}$ if $x_i = \text{bin}$ and $n \geq 1$. This is not a good perspective for termination and in this paper we shall also provide a technical answer to this problem. We omit at this stage of the paper, the complications caused by having a symmetric relation in the NIL models.

In order to conclude this introductory part that motivates the existence of the sets of the form $\text{cl}(s, \phi)$, let us say that once the set X_i of formulae is built and x_i is chosen, the set X_{i+1} satisfies:

1. X_{i+1} is a consistent subset of $\text{cl}(x_0 \dots x_i, \phi)$;
2. $\langle X_i, X_{i+1} \rangle$ satisfies a certain condition (to be specified in the sequel) that shall guarantee that \mathcal{M} is a NIL model and $\langle w_i, w_{i+1} \rangle \in R_{x_i}$.

Definition 3.2. Let ϕ be a formula. For $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$, let $\text{cl}(s, \phi)$ be the smallest set such that:

1. $\text{cl}(\lambda, \phi) = \text{cl}(\{\phi\})$;
2. $\text{cl}(s, \phi)$ is closed;
3. if $[\sigma][\leq]\psi \in \text{cl}(s, \phi)$, then $[\leq]\psi \in \text{cl}(s \cdot \text{sim}, \phi)$;
4. if $[\leq]\psi \in \text{cl}(s, \phi)$, then $[\leq]\psi \in \text{cl}(s \cdot \text{fin}, \phi)$;
5. if $[\geq]\psi \in \text{cl}(s, \phi)$, then $[\geq]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$;
6. if $[\sigma][\leq]\psi \in \text{cl}(s, \phi)$, then $[\sigma][\leq]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$.

Example 3.1. Let ϕ be the formula $[\sigma]\mathbf{p}_0$. We have

$$\text{cl}(\lambda, \phi) = \text{cl}(\{\phi\}) = \{[\sigma]\mathbf{p}_0, \mathbf{p}_0, [\geq]\mathbf{p}_0, [\sigma][\leq]\mathbf{p}_0, [\geq][\leq]\mathbf{p}_0, [\leq]\mathbf{p}_0\}$$

Below are some examples of sets of the form $\text{cl}(s, \phi)$:

- $\text{cl}(\text{bin}, \phi) = \text{cl}(\{\phi\})$;
- $\text{cl}(\text{bin} \cdot \text{sim}, \phi) = \{\mathbf{p}_0, [\leq]\mathbf{p}_0\}$;
- $\text{cl}(\text{bin} \cdot \text{sim} \cdot \text{fin}, \phi) = \{\mathbf{p}_0, [\leq]\mathbf{p}_0\}$;
- $\text{cl}(\text{bin} \cdot \text{sim} \cdot \text{fin} \cdot \text{bin}, \phi) = \emptyset$.

One can check that for any $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ such that $|s| \geq 4$, we have $\text{cl}(s, \phi) = \emptyset$.

Lemma 3.2 contains some basic properties of the sets $\text{cl}(s, \phi)$.

Lemma 3.2. *Let ϕ be a formula and $s, s' \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ such that s is a prefix of s' . Then,*

- (I) $\text{cl}(s', \phi) \subseteq \text{cl}(s, \phi)$;
- (II) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s \cdot \text{sim}, \phi)$;
- (III) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $[\sigma]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$;
- (IV) if $[\leq]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$, then $\text{md}([\leq]\psi) < \text{md}(\text{cl}(s \cdot \text{bin}, \phi))$.

Proof:

(I) This is immediate by Definition 3.2, since both $\text{cl}(s, \phi)$ and $\text{cl}(s', \phi)$ are closed.

(II) Let $[\sigma]\psi \in \text{cl}(s, \phi)$. If $\psi = [\leq]\psi'$, then by definition $\psi \in \text{cl}(s \cdot \text{sim}, \phi)$. If $\psi \neq [\leq]\psi'$, then since $\text{cl}(s, \phi)$ is closed, $[\sigma][\leq]\psi \in \text{cl}(s, \phi)$. By definition, $[\leq]\psi \in \text{cl}(s \cdot \text{sim}, \phi)$. Since $\text{cl}(s \cdot \text{sim}, \phi)$ is closed, $\psi \in \text{cl}(s \cdot \text{sim}, \phi)$.

(III) Similar to (II).

(IV) Let $[\leq]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$. Two cases are distinguished according to the way the formula $[\leq]\psi$ can appear in $\text{cl}(s \cdot \text{bin}, \phi)$.

Case 1: $[\leq]\psi \in \text{cl}(\{[\geq]\psi'\})$ for some $[\geq]\psi' \in \text{cl}(s, \phi)$ (see Definition 3.2(5)).

We distinguish two cases according to the way $[\leq]\psi$ belongs to $\text{cl}(\{[\geq]\psi'\})$. If $[\leq]\psi$ is a subformula of $[\geq]\psi'$ (see the point 1. in the proof of Lemma 3.1), then $\text{md}([\leq]\psi) < \text{md}([\geq]\psi')$ since $[\leq]\psi \neq [\geq]\psi'$ and $[\geq]\psi' \in \text{cl}(s \cdot \text{bin}, \phi)$. So $\text{md}([\leq]\psi) < \text{md}(\text{cl}(s \cdot \text{bin}, \phi))$. If $[\sigma]\psi$ is a subformula of $[\geq]\psi'$ and ψ is not a $[\leq]$ -formula (see the point 7. in the proof of Lemma 3.1), then $[\sigma][\leq]\psi \in \text{cl}(\{[\geq]\psi'\}) \subseteq \text{cl}(s \cdot \text{bin}, \phi)$. Hence, $\text{md}([\leq]\psi) < \text{md}(\text{cl}(s \cdot \text{bin}, \phi))$.

Case 2: $[\leq]\psi \in \text{cl}(\{[\sigma][\leq]\psi'\})$ for some $[\sigma][\leq]\psi' \in \text{cl}(s, \phi)$ (see Definition 3.2(6)).

Thus,

- $[\leq]\psi \in \text{cl}(\{[\leq]\psi'\})$; and
- $\text{md}([\leq]\psi) \leq \text{md}([\leq]\psi') = \text{md}(\text{cl}(\{[\leq]\psi'\}))$.

Hence, $\text{md}([\leq]\psi) \leq \text{md}([\leq]\psi') < \text{md}([\sigma][\leq]\psi') \leq \text{md}(\text{cl}(s \cdot \text{bin}, \phi))$. □

Lemma 3.3 below is crucial to prove forthcoming Theorem 3.1 and this is the cornerstone for termination of the procedure defined in Section 4.1. It states sufficient conditions on the string s' to guarantee that the modal degree of $\text{cl}(s \cdot s', \phi)$ is strictly less than the modal degree of $\text{cl}(s, \phi)$.

Lemma 3.3. *Let ϕ be a formula, $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ and $s' \in \{\text{bin} \cdot \text{fin} \cdot \text{bin}, \text{fin} \cdot \text{bin} \cdot \text{fin}, \text{sim}\}$. Then, $\text{md}(\text{cl}(s \cdot s', \phi)) \leq \max(0, \text{md}(\text{cl}(s, \phi)) - 1)$.*

Proof:

Assume that $\text{md}(\text{cl}(s, \phi)) \geq 1$, otherwise the proof is immediate by Lemma 3.2(I). Let $\varphi \in \text{cl}(s, \phi)$ be such that $\text{md}(\varphi) = \text{md}(\text{cl}(s, \phi))$. Let us show that $\varphi \notin \text{cl}(s \cdot s', \phi)$. By Lemma 3.2(I) we are done. We distinguish cases according to the value of s' .

Case 1: $s' = \text{fin} \cdot \text{bin} \cdot \text{fin}$

Case 1.1: the outermost connective of φ is in $\{\wedge, \neg\}$.

By Definition 3.2, we have $\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$ iff there is $[\leq]\psi \in \text{cl}(s, \phi)$ such that $\varphi \in \text{cl}(\{[\leq]\psi\})$. Suppose $\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$. φ can only be a proper subformula of $[\leq]\psi$. But then $\text{md}(\varphi) < \text{md}([\leq]\psi)$, a contradiction. Hence, $\varphi \notin \text{cl}(s \cdot \text{fin}, \phi)$ and therefore $\varphi \notin \text{cl}(s \cdot s', \phi)$.

Case 1.2: $\varphi = [\sigma][\leq]\varphi'$.

Suppose $\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$ (otherwise $\varphi \notin \text{cl}(s \cdot s', \phi)$ by Lemma 3.2(I)). By Definition 3.2(4), there is $[\leq]\psi \in \text{cl}(s, \phi)$ such that $\varphi \in \text{cl}(\{[\leq]\psi\})$. $[\sigma][\leq]\varphi'$ cannot be a subformula of $[\leq]\psi$, otherwise $\text{md}([\sigma][\leq]\varphi') < \text{md}([\leq]\psi)$ (see the point 1. in the proof of Lemma 3.1). Similarly, $[\sigma][\leq]^{n+1}\varphi'$ is not a subformula of $[\leq]\psi$ with $n \geq 1$ (see the point 3. in the proof of Lemma 3.2) by maximality of $\text{md}(\varphi)$. The only remaining possibility is that $[\sigma]\varphi'$ is a subformula of $[\leq]\psi$ and φ' is not a $[\leq]$ -formula. Hence, $\text{md}([\leq]\psi) = \text{md}(\varphi)$. Now since $\varphi \in \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$, $\text{md}(\varphi) = \text{md}(\text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi))$. By Lemma 3.2(IV), for any $[\leq]\psi'$ in $\text{cl}(s, \phi)$ such that $\text{md}([\leq]\psi') = \text{md}(\text{cl}(s, \phi))$, we have $[\leq]\psi' \notin \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$. In particular, $[\leq]\psi \notin \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$. We can now in position to conclude the present case. $[\sigma][\leq]\varphi' \in \text{cl}(s \cdot s', \phi)$ iff there is $[\leq]\psi' \in \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$ such that $[\sigma][\leq]\varphi' \in \text{cl}(\{[\leq]\psi'\})$ (see Definition 3.2(4)). Suppose $[\sigma][\leq]\varphi' \in \text{cl}(s \cdot s', \phi)$. So $\text{md}([\sigma][\leq]\varphi') = \text{md}([\leq]\psi')$ and from the above developments, we can conclude that $[\leq]\psi' \notin \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$, a contradiction.

Case 1.3: $\varphi = [\leq]\varphi'$.

So $\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$. Now suppose $\varphi \in \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$. By Lemma 3.2(IV), $\text{md}(\varphi) < \text{md}(\text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi))$. By Lemma 3.2(I),

$$\text{md}(\text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)) \leq \text{md}(\text{cl}(s, \phi))$$

So, $\text{md}(\varphi) < \text{md}(\text{cl}(s, \phi))$, a contradiction.

Case 1.4: $\varphi = [\geq]\varphi'$.

Assume $\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$ (otherwise $\varphi \notin \text{cl}(s \cdot s', \phi)$ by Lemma 3.2(I)). So, there is $[\leq]\psi \in \text{cl}(s, \phi)$ such that $\varphi \in \text{cl}(\{[\leq]\psi\})$. So $\text{md}([\leq]\psi) = \text{md}(\varphi)$. Since $\text{md}(\varphi) = \text{md}(\text{cl}(s, \phi))$, φ cannot be a subformula of $[\leq]\psi$ (see the point 1. in the proof of Lemma 3.1). Similarly, there is no subformula $[\sigma][\leq]^n\varphi'$ of $[\leq]\psi$ for some $n \geq 1$ (see the point 3. in the proof of Lemma 3.1) by maximality

of $\text{md}(\varphi)$. φ can only be of the form $[\geq][\leq]\varphi''$ for some subformula $[\sigma]\varphi''$ of $[\leq]\psi$ such that φ'' is not a $[\leq]$ -formula. So $\varphi \in \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$. By Lemma 3.2(IV), $[\leq]\psi \notin \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$. Otherwise, we have

$$\text{md}(\varphi) = \text{md}([\leq]\psi) = \text{md}(\text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi))$$

Actually, for any formula $[\leq]\psi' \in \text{cl}(s, \phi)$ such that $\text{md}([\leq]\psi') = \text{md}(\text{cl}(s, \phi))$, we have $[\leq]\psi' \notin \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$.

Now, $[\geq][\leq]\varphi'' \in \text{cl}(s \cdot \text{fin} \cdot \text{bin} \cdot \text{fin}, \phi)$ iff there is $[\leq]\psi' \in \text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi)$ such that $[\geq][\leq]\varphi'' \in \text{cl}(\{[\leq]\psi'\})$ (see Definition 3.2(4)). Analogously, we can conclude that $[\sigma]\varphi''$ is a subformula of $[\leq]\psi'$. Suppose $[\geq][\leq]\varphi'' \in \text{cl}(s \cdot \text{fin} \cdot \text{bin} \cdot \text{fin}, \phi)$. By Lemma 3.2(I), we have $\text{cl}(s \cdot \text{fin} \cdot \text{bin}, \phi) \subseteq \text{cl}(s, \phi)$ and therefore $[\leq]\psi' \in \text{cl}(s, \phi)$ and $\text{md}([\leq]\psi') = \text{md}(\varphi)$ which leads to a contradiction from the above developments. Thus, $[\geq][\leq]\varphi'' \notin \text{cl}(s \cdot \text{fin} \cdot \text{bin} \cdot \text{fin}, \phi)$.

Case 2: $s' = \text{bin} \cdot \text{fin} \cdot \text{bin}$

Case 2.1: the outermost connective of φ is in $\{\wedge, \neg\}$.

See the Case 1.1.

Case 2.2: either $\varphi = [\sigma][\leq]\varphi'$ or $\varphi = [\geq]\varphi'$ (see Definition 3.2(5-6)).

So $\varphi \in \text{cl}(s \cdot \text{bin}, \phi)$. Suppose $\varphi \in \text{cl}(s \cdot \text{bin} \cdot \text{fin}, \phi)$ (otherwise $\varphi \notin \text{cl}(s \cdot s', \phi)$). So there is $[\leq]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$ such that $\varphi \in \text{cl}(\{[\leq]\psi\})$ (see Definition 3.2(4)). Since $\text{md}(\varphi) = \text{md}(\text{cl}(s, \phi))$, $\text{md}([\leq]\psi) = \text{md}(\varphi)$. By Lemma 3.2(IV), $\text{md}(\varphi) < \text{md}(\text{cl}(s \cdot \text{bin}, \phi))$, a contradiction.

Case 2.3: $\varphi = [\leq]\varphi'$.

Suppose $\varphi \in \text{cl}(s \cdot \text{bin}, \phi)$. By Lemma 3.2(IV), $\text{md}(\varphi) < \text{md}(\text{cl}(s \cdot \text{bin}, \phi)) \leq \text{md}(\text{cl}(s, \phi))$, a contradiction.

Case 3: $s' = \text{sim}$

Suppose $\varphi \in \text{cl}(s \cdot \text{sim}, \phi)$. By Definition 3.2(3), $\varphi \in \text{cl}(s \cdot \text{sim}, \phi)$ iff there is $[\sigma][\leq]\psi \in \text{cl}(s, \phi)$ such that $\varphi \in \text{cl}(\{[\leq]\psi\})$. Observe that $\text{md}([\leq]\psi) = \text{md}(\text{cl}(\{[\leq]\psi\})) < \text{md}([\sigma][\leq]\psi)$. Hence $\text{md}(\varphi) < \text{md}(\text{cl}(\{[\leq]\psi\}))$, a contradiction. \square

Theorem 3.1. *Let ϕ be a formula and $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ be such that neither $\text{bin} \cdot \text{bin}$ nor $\text{fin} \cdot \text{fin}$ is a substring of s and $|s| \geq 3 \times |\phi|$. Then $\text{cl}(s, \phi) = \emptyset$.*

Proof:

First observe that for any substring s' of length 3 in s , either sim occurs in s' or $s' \in \{\text{fin} \cdot \text{bin} \cdot \text{fin}, \text{bin} \cdot \text{bin} \cdot \text{bin}\}$. Since $\text{md}(\phi) + 1 \leq |\phi|$, let s'' be the prefix of s of length $3 \times \text{md}(\phi)$. By Lemma 3.3, $\text{md}(\text{cl}(s'', \phi)) = 0$ and therefore $\text{cl}(s', \phi) = \emptyset$. \square

What is really important in Theorem 3.1 is that for certain elements s of $\{\text{sim}, \text{fin}, \text{bin}\}^*$ of polynomial length in $|\phi|$, $\text{cl}(s, \phi)$ is empty. The strings $\text{bin} \cdot \text{bin}$ and $\text{fin} \cdot \text{fin}$ do not occur in s , since by (N1) and (N2) we shall identify any element of $\{\text{bin}\}^+$ [resp. $\{\text{fin}\}^+$] with bin [resp. fin]. Theorem 3.1 can be extended in the following way.

Theorem 3.2. *Let $f : \omega \rightarrow \omega$ be a computable map, ϕ be a formula and $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ be such that neither bin^{k+1} nor fin^{k+1} is a substring of s for $k \geq f(|\phi|)$ and $|s| \geq 3 \times |\phi| \times f(|\phi|)$. Then $\text{cl}(s, \phi) = \emptyset$.*

Theorem 3.1 is a particular case of Theorem 3.2 where f is the constant map 1. The proof of Theorem 3.2 also uses the property that $\text{cl}(s \cdot \text{bin}^k, \phi) = \text{cl}(s \cdot \text{bin}, \phi)$ [resp. $\text{cl}(s \cdot \text{fin}^k, \phi) = \text{cl}(s \cdot \text{fin}, \phi)$] for $k \geq 1$.

It is legitimate to wonder whether Theorem 3.1 is optimal. We show that we can hardly do better: the factor 3 cannot be replaced by the factor 2.

Lemma 3.4. *For $n \in \omega$, there exist a formula ϕ_n and $s_n \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ such that*

- $\text{md}(\phi_n) = n + 1$ and $|\phi_n| = n + 3$;
- neither $\text{bin} \cdot \text{bin}$ nor $\text{fin} \cdot \text{fin}$ occurs in s_n ;
- $|s_n| = 3 \times n + 1$;
- $\text{cl}(s_n, \phi_n) \neq \emptyset$.

Proof:

Let us define $\phi_n \stackrel{\text{def}}{=} [\leq][\sigma]^n \mathbf{p}_0$ and $s_n \stackrel{\text{def}}{=} (\text{fin} \cdot \text{bin} \cdot \text{sim})^n \cdot \text{fin}$. Let us show that $\text{cl}(s_n, \phi_n) \neq \emptyset$. To do so, we prove that for $i \in \{0, \dots, n\}$, $[\leq][\sigma]^i \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i}, \phi_n)$.

Base case: $i = n$. $[\leq][\sigma]^n \mathbf{p}_0 \in \text{cl}(\lambda, \phi_n)$.

Induction step: Let us take as an induction hypothesis that $[\leq][\sigma]^{i+1} \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i-1}, \phi_n)$ for some $i \geq 0$. It follows that

- $[\leq][\sigma]^{i+1} \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i-1} \cdot \text{fin}, \phi_n)$;
- $[\sigma]^{i+1} \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i-1} \cdot \text{fin}, \phi_n)$;
- $[\sigma][\leq][\sigma]^i \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i-1} \cdot \text{fin}, \phi_n)$;
- $[\sigma][\leq][\sigma]^i \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i-1} \cdot \text{fin} \cdot \text{bin}, \phi_n)$;
- $[\leq][\sigma]^i \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^{n-i-1} \cdot \text{fin} \cdot \text{bin} \cdot \text{sim}, \phi_n)$.

Hence, $[\leq] \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^n, \phi_n)$ and $[\leq] \mathbf{p}_0 \in \text{cl}((\text{fin} \cdot \text{bin} \cdot \text{sim})^n \cdot \text{fin}, \phi_n)$. \square

Definition 3.3. The binary relation \approx on sets of NIL-formulae is defined as follows: $X \approx Y \stackrel{\text{def}}{\iff}$

1. for all $[\sigma]\psi \in X$, $\psi \in Y$;
2. for all $[\sigma]\psi \in Y$, $\psi \in X$.

The binary relation \preceq is defined as follows: $X \preceq Y \stackrel{\text{def}}{\iff}$

1. for all $[\leq]\psi \in X$, $[\leq]\psi, \psi \in Y$;
2. for all $[\geq]\psi \in Y$, $[\geq]\psi, \psi \in X$;
3. for all $[\sigma]\psi \in Y$, $[\sigma]\psi \in X$.

Let \mathbf{clos} be the set of subsets Y of $\text{cl}(\{\phi\})$ such that for $\mathbf{R} \in \{\sigma, \geq, \leq\}$, $[\mathbf{R}]\psi \in Y$ implies $\psi \in Y$. The binary relation \approx is a reflexive and symmetric relation on \mathbf{clos} and \preceq is a reflexive and transitive relation on \mathbf{clos} . In Definition 3.4 below, for $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$, we define the set of s -consistent sets which is a subset of \mathbf{clos} .

Definition 3.4. Let X be a subset of $\text{cl}(s, \phi)$ for some $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ and for some formula ϕ . The set X is said to be s -consistent $\stackrel{\text{def}}{\iff}$ for $\psi \in \text{cl}(s, \phi)$:

1. if $\psi = \neg\varphi$, then $\varphi \in X$ iff not $\psi \in X$;
2. if $\psi = \varphi_1 \wedge \varphi_2$, then $\{\varphi_1, \varphi_2\} \subseteq X$ iff $\psi \in X$;
3. if $\psi = [\mathbf{R}]\varphi$ for some $\mathbf{R} \in \{\sigma, \leq, \geq\}$ and $\psi \in X$, then $\varphi \in X$;
4. if $\psi = [\sigma]\varphi$, $\varphi \neq [\leq]\varphi'$ and $\psi \in X$, then $[\sigma][\leq]\varphi \in X$;
5. if $\psi = [\sigma][\leq]\varphi$ and $\psi \in X$, then $[\sigma]\varphi \in X$;
6. if $\psi = [\sigma]\varphi$ and $\psi \in X$, then $[\geq]\varphi \in X$.

Roughly speaking, the s -consistency entails the maximal propositional consistency with respect to the set $\text{cl}(s, \phi)$ of formulae. Furthermore, the modal conditions 3.-6. in Definition 3.4 are added in order to take into account the reflexivity of the relations in the NIL models and the inclusion $R_{\leq} \cup R_{\geq} \subseteq R_{\sigma}$. For instance, if X is s -consistent and $[\sigma]\psi \in X$, then $\{[\leq]\psi, [\geq]\psi\} \subseteq X$.

Lemma 3.5. Let $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ be a NIL model, $w \in W$, $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$, ϕ be a NIL formula. Then, $\{\psi \in \text{cl}(s, \phi) : \mathcal{M}, w \models \psi\}$ is s -consistent.

The proof of the above lemma is by an easy verification using that $\text{cl}(s, \phi)$ is closed. Lemma 3.6(II) below roughly states that $\leq \subseteq \approx$ which is the syntactic version of $R_{\leq} \subseteq R_{\sigma}$ in the NIL models. Similarly, Lemma 3.6(I) below states a syntactic version of $R_{\geq} \circ R_{\sigma} \circ R_{\leq} \subseteq R_{\sigma}$ in the NIL models. \circ denote the composition operation for binary relations.

Lemma 3.6. Let X_i be an s_i -consistent set, $i = 1, \dots, 4$, such that $X_1 \succeq X_2 \approx X_3 \preceq X_4$. Then,

- (I) if $[\sigma]\psi \in X_1$, $\psi \in X_4$.
- (II) $X_1 \approx X_2$.

Proof:

(I) Let $[\sigma]\psi \in X_1$. Since $X_1 \succeq X_2$, we have $[\sigma]\psi \in X_2$ and $\psi \in X_2$ by Definition 3.4(3). If $\psi = [\leq]\varphi$, then by $X_2 \approx X_3$, $[\leq]\varphi \in X_3$ and by $X_3 \preceq X_4$, $[\leq]\varphi \in X_4$. Otherwise, if $\psi \neq [\leq]\varphi$, then by s_2 -consistency, we have $[\sigma][\leq]\psi \in X_2$. By $X_2 \approx X_3$, $[\leq]\psi \in X_3$. By $X_3 \preceq X_4$, $\psi \in X_4$.

(II) Let $[\sigma]\psi \in X_2$. If $\psi \neq [\leq]\varphi$, then $[\sigma][\leq]\psi \in X_2$ by s_2 -consistency. Moreover, by s_2 -consistency, $[\leq]\psi \in X_2$. Now since $X_2 \preceq X_1$, $\psi \in X_1$. In the case $\psi = [\leq]\varphi$, by s_2 -consistency, $\psi \in X_2$. Now since $X_2 \preceq X_1$, $[\leq]\varphi \in X_1$.

Let $[\sigma]\psi \in X_1$. If $\psi \neq [\leq]\varphi$, then $[\sigma][\leq]\psi \in X_1$ by s_1 -consistency. By s_1 -consistency, $[\geq][\leq]\psi \in X_1$. Now since $X_2 \preceq X_1$, $[\leq]\psi \in X_2$. By s_2 -consistency of X_2 , $\psi \in X_2$. In the case $\psi = [\leq]\varphi$, by s_1 -consistency, $[\geq]\psi \in X_1$. Now since $X_2 \preceq X_1$, $\psi \in X_2$. \square

In the forthcoming Lemma 3.7, Lemma 3.8, Lemma 3.9, Lemma 3.10 and Lemma 3.11 we state some basic facts about the sets $\text{cl}(s, \phi)$.

Lemma 3.7. Let $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ and ϕ be a formula.

- (I) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s \cdot \text{sim}, \phi)$;
- (II) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s \cdot \text{fin}, \phi)$;
- (III) if $[\sigma]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$, then $\psi \in \text{cl}(s, \phi)$;
- (IV) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s, \phi)$.

Proof:

(I) By Lemma 3.2(II).

(II) Assume $[\sigma]\psi \in \text{cl}(s, \phi)$. If $\psi \neq [\leq]\varphi$, then $[\sigma][\leq]\psi \in \text{cl}(s, \phi)$ and $[\leq]\psi \in \text{cl}(s, \phi)$. By definition of $\text{cl}(s \cdot \text{fin}, \phi)$, we get that both $[\leq]\psi$ and ψ are in $\text{cl}(s \cdot \text{fin}, \phi)$. If $\psi = [\leq]\varphi$, then $[\leq]\varphi \in \text{cl}(s, \phi)$ and by definition of $\text{cl}(s \cdot \text{fin}, \phi)$, $[\leq]\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$.

(III) Assume $[\sigma]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$. So $[\sigma]\psi \in \text{cl}(s, \phi)$ by Lemma 3.2(I) and therefore $\psi \in \text{cl}(s, \phi)$.

(IV) This is immediate since $\text{cl}(s, \phi)$ is closed. \square

Lemma 3.8. *Let $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ and ϕ be a formula.*

- (I) if $[\sigma]\psi \in \text{cl}(s \cdot \text{sim}, \phi)$, then $\psi \in \text{cl}(s, \phi)$;
- (II) if $[\sigma]\psi \in \text{cl}(s \cdot \text{fin}, \phi)$, then $\psi \in \text{cl}(s, \phi)$;
- (III) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s \cdot \text{bin}, \phi)$;
- (IV) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s, \phi)$;

Proof:

(I) This is immediate since $\text{cl}(s \cdot \text{sim}, \phi) \subseteq \text{cl}(s, \phi)$ and $\text{cl}(s, \phi)$ is closed.

(II) This is immediate since $\text{cl}(s \cdot \text{fin}, \phi) \subseteq \text{cl}(s, \phi)$ and $\text{cl}(s, \phi)$ is closed.

(III) Assume $[\sigma]\psi \in \text{cl}(s, \phi)$. If $\psi = [\leq]\psi'$, $[\sigma]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$ and $\psi \in \text{cl}(s \cdot \text{bin}, \phi)$ since $\text{cl}(s \cdot \text{bin}, \phi)$ is closed. Otherwise ($\psi \neq [\leq]\psi'$), $[\sigma][\leq]\psi \in \text{cl}(s, \phi)$ since $\text{cl}(s, \phi)$ is closed and $[\sigma][\leq]\psi, [\leq]\psi, [\sigma]\psi, \psi \in \text{cl}(s \cdot \text{bin}, \phi)$.

(IV) By Lemma 3.7(IV). \square

Lemma 3.9. *Let $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ and ϕ be a formula.*

- (I) if $[\leq]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s \cdot \text{fin}, \phi)$;
- (II) if $[\leq]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$, then $\psi \in \text{cl}(s, \phi)$;
- (III) if $[\leq]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s, \phi)$;

Proof:

(I) By definition since $\text{cl}(s \cdot \text{fin}, \phi)$ is closed.

(II) This is immediate since $\text{cl}(s \cdot \text{bin}, \phi) \subseteq \text{cl}(s, \phi)$ and $\text{cl}(s, \phi)$ is closed.

(III) This is immediate since $\text{cl}(s, \phi)$ is closed. \square

Lemma 3.10. *Let $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ and ϕ be a formula.*

- (I) if $[\geq]\psi \in \text{cl}(s \cdot \text{fin}, \phi)$, then $\psi \in \text{cl}(s, \phi)$;

(II) if $[\geq]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s \cdot \text{bin}, \phi)$;

(III) if $[\geq]\psi \in \text{cl}(s, \phi)$, then $\psi \in \text{cl}(s, \phi)$.

Proof:

(I) This is immediate since $\text{cl}(s \cdot \text{fin}, \phi) \subseteq \text{cl}(s, \phi)$ and $\text{cl}(s, \phi)$ is closed.

(II) This is immediate since $\text{cl}(s \cdot \text{fin}, \phi)$ is closed.

(III) This is obvious since $\text{cl}(s, \phi)$ is closed. □

Lemma 3.11. *Let $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$ and ϕ be a formula.*

(I) if $[\sigma]\psi \in \text{cl}(s \cdot \text{fin}, \phi)$, then $[\sigma]\psi \in \text{cl}(s, \phi)$;

(II) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $[\sigma]\psi \in \text{cl}(s \cdot \text{bin}, \phi)$;

(III) if $[\sigma]\psi \in \text{cl}(s, \phi)$, then $[\sigma]\psi \in \text{cl}(s, \phi)$.

Proof:

(I) This is immediate since $\text{cl}(s \cdot \text{fin}, \phi) \subseteq \text{cl}(s, \phi)$.

(II) See the proof of Lemma 3.8(III).

(III) Obvious. □

Before defining the main algorithm of the paper, let us conclude by presenting some relationships between the relations \preceq and \approx and the relations from the NIL-models.

Lemma 3.12. *Let $\mathcal{M} = \langle W, R_\sigma, R_\leq, R_\geq, m \rangle$ be a NIL-model and $w, w' \in W$. Let $s \in \{\text{sim}, \text{bin}, \text{fin}\}^*$, $s', s'' \in \{\lambda, \text{sim}, \text{fin}, \text{bin}\}$ and ϕ be a formula. Let*

$$X_w \stackrel{\text{def}}{=} \{\psi \in \text{cl}(s \cdot s', \phi) : \mathcal{M}, w \models \psi\} \quad X_{w'} \stackrel{\text{def}}{=} \{\psi \in \text{cl}(s \cdot s'', \phi) : \mathcal{M}, w' \models \psi\}$$

Then,

(I) X_w is $s \cdot s'$ -consistent and $X_{w'}$ is $s \cdot s''$ -consistent;

(II) if $\langle s', s'' \rangle \in \{\langle \lambda, \text{sim} \rangle, \langle \text{sim}, \lambda \rangle, \langle \lambda, \lambda \rangle\}$ and $\langle w, w' \rangle \in R_\sigma$, then $X_w \approx X_{w'}$;

(III) if $\langle s', s'' \rangle \in \{\langle \lambda, \text{fin} \rangle, \langle \text{bin}, \lambda \rangle, \langle \lambda, \lambda \rangle\}$ and $\langle w, w' \rangle \in R_\leq$, then $X_w \preceq X_{w'}$.

The proof is by an easy verification using the previous lemmas.

4. NIL is in PSPACE

4.1. The algorithm

In Figure 1, the function NIL-WORLD(Σ, s, ϕ) returning a Boolean is defined. Σ is a nonempty finite sequence of subsets of $\text{cl}(\{\phi\})$ and $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$. For any $X \subseteq \text{cl}(\{\phi\})$ and for any call NIL-WORLD(Σ, s, ϕ) in NIL-WORLD(X, λ, ϕ) (at any recursion depth), we have $\text{last}(\Sigma) \subseteq \text{cl}(s, \phi)$. In the next section we shall show that

- $|\Sigma| \leq 25 \times |\phi|^2$;

```

function NIL-WORLD( $\Sigma, s, \phi$ )
  if  $last(\Sigma)$  is not  $s$ -consistent, then return false;
  for  $[\sigma]\psi \in cl(s, \phi) \setminus last(\Sigma)$  do
    for each  $X_\psi \subseteq cl(s \cdot sim, \phi) \setminus \{\psi\}$  such that  $last(\Sigma) \approx X_\psi$ , call NIL-WORLD( $X_\psi, s \cdot sim, \phi$ ). If all these calls return false, then return false;

  for  $[\leq]\psi \in cl(s, \phi) \setminus last(\Sigma)$  do
    if there is no  $X \in \Sigma$  such that  $\psi \notin X$ ,  $last(\Sigma) \preceq X$ , and  $last(s) = fin$ , then
    for each  $X_\psi \subseteq cl(s \cdot fin, \phi) \setminus \{\psi\}$  such that  $last(\Sigma) \preceq X_\psi$ , if  $last(s) = fin$ , then call
    NIL-WORLD( $\Sigma \cdot X_\psi, s, \phi$ ), otherwise call NIL-WORLD( $X_\psi, s \cdot fin, \phi$ ). If all these calls
    return false, then return false;

  for  $[\geq]\psi \in cl(s, \phi) \setminus last(\Sigma)$  do
    if there is no  $X \in \Sigma$  such that  $\psi \notin X$ ,  $last(\Sigma) \succeq X$ , and  $last(s) = bin$ , then
    for each  $X_\psi \subseteq cl(s \cdot bin, \phi) \setminus \{\psi\}$  such that  $X_\psi \preceq last(\Sigma)$ , if  $last(s) = bin$ , then call
    NIL-WORLD( $\Sigma \cdot X_\psi, s, \phi$ ), otherwise call NIL-WORLD( $X_\psi, s \cdot bin, \phi$ ). If all these calls
    return false, then return false;

  Return true.

```

Figure 1. Algorithm NIL-WORLD

-
- $|s| \leq 3 \times |\phi|$.

The function NIL-WORLD is actually defined on the model of the function K-WORLD in [20] and it is an extension of the function $S4_t$ -WORLD defined in [31] (see also [10, 22, 35]). The results given in Section 3 are crucial to guarantee that NIL-WORLD is *correct* and *terminates*. By a *successful call* of NIL-WORLD(Σ, s, ϕ) we mean that it returns true.

4.2. Termination and complexity upper bounds

If NIL-WORLD is correct, then for any formula ϕ , ϕ is NIL satisfiable iff there is $X \subseteq cl(\{\phi\})$ such that $\phi \in X$ and NIL-WORLD(X, λ, ϕ) returns true. Each subset $X \subseteq cl(\{\phi\})$ can be represented as a bitstring of length $5 \times |\phi|$ since $card(cl(\phi)) < 5 \times |\phi|$. At each level of the recursion, we use space in $\mathcal{O}(|\phi|)$ by implementing Σ as a global stack. For instance, in the parts of NIL-WORLD of the form “for each $X_\psi \dots$ then return false”, the implementation uses a bitstring of length $5 \times |\phi|$ to encode X_ψ and a Boolean indicating whether a call has returned true.

Suppose that in the call of NIL-WORLD(X, λ, ϕ) at some recursion depth, NIL-WORLD(Σ, s, ϕ) is called with $\Sigma = X_1 \cdot \dots \cdot X_n$, $n \geq 2$. We treat the case $s = s' \cdot fin$ and the case $s = s' \cdot bin$

is omitted because it is very similar. Moreover, if $s = s' \cdot sim$, then $|\Sigma| = 1$ and hence this case is not relevant, since we assume $n \geq 2$. For $i \in \{1, \dots, n-1\}$, $[\leq]\psi \in X_i$ implies $[\leq]\psi \in X_{i+1}$. Thus, Σ can be written as $\Sigma = \Sigma_1 \cdot \dots \cdot \Sigma_{n'}$ where for $i, i' \in \{1, \dots, n'\}$

- the elements of Σ_i contain the same $[\leq]$ -formulae;
- $i < i'$ implies the set of $[\leq]$ -formulae of Σ_i is a proper subset of the set of $[\leq]$ -formulae of $\Sigma_{i'}$.

Since there are less than $5 \times |\phi|$ $[\leq]$ -formulae in $\text{cl}(\{\phi\})$, $n' \leq 5 \times |\phi|$.

Let $i \in \{1, \dots, n'\}$. Σ_i can be written as $\Sigma_i = \Sigma_i^1 \cdot \dots \cdot \Sigma_i^{l(i)}$ where for $j, j' \in \{1, \dots, l(i)\}$, the elements of Σ_i^j contains the same $[\geq]$ -formulae and $[\sigma]$ -formulae and $j < j'$ implies the set of $[\geq]$ -formulae and $[\sigma]$ -formulae of Σ_i^j is a proper subset of the set of $[\geq]$ -formulae and $[\sigma]$ -formulae of $\Sigma_i^{j'}$.

For $i \in \{1, \dots, n\}$, let $Z_i^1 \stackrel{\text{def}}{=} \{[\geq]\psi : [\geq]\psi \in X_i\}$ and $Z_i^2 \stackrel{\text{def}}{=} \{[\sigma]\psi : [\sigma]\psi \in X_i\}$. We have

$$(Z_n^1 \cup Z_n^2) \subseteq \dots \subseteq (Z_1^1 \cup Z_1^2)$$

One can see that $l(1) + \dots + l(n')$ is in $\mathcal{O}(|\phi|)$, since the above sequence contains at most $\mathcal{O}(|\phi|)$ proper inclusions. Actually, $l(1) + \dots + l(n') < 5 \times |\phi|$.

Now let us estimate the maximal length $|\Sigma_i^j|$ for $i \in \{1, \dots, n'\}$ and $j \in \{1, \dots, l(i)\}$. Suppose $\Sigma_i^j = Y_1 \cdot \dots \cdot Y_k$. If $1 \leq u < u' \leq k$, then for $[\leq]\psi \in Y_u$, we have $[\leq]\psi \in Y_{u'}$. Since for $2 \leq \alpha < k$, $\text{NIL-WORLD}(\Sigma_1 \dots \Sigma_{i-1} Y_1 \cdot \dots \cdot Y_\alpha, s, \phi)$ calls $\text{NIL-WORLD}(\Sigma_1 \dots \Sigma_{i-1} Y_1 \cdot \dots \cdot Y_{\alpha+1}, s, \phi)$, there are formulae ψ_2, \dots, ψ_k in $\text{cl}(\{\phi\})$ such that $\psi_\alpha \notin Y_\alpha$ and for $1 \leq \alpha' < \alpha$, $\psi_\alpha \in Y_{\alpha'}$. Hence ψ_2, \dots, ψ_k are $(k-1)$ different formulae in $\text{cl}(\{\phi\})$. Hence k is in $\mathcal{O}(|\phi|)$. More precisely, $k < 5 \times |\phi|$. So the maximal length of Σ is in $\mathcal{O}(|\phi|^2)$. More precisely, $|\Sigma| \leq 25 \times |\phi|^2$. Termination is not yet proved since there are moments in the computation where the length of Σ strictly decreases. However, the following observations will help finishing the proof of termination of $\text{NIL-WORLD}(X, \lambda, \phi)$:

- If $\text{NIL-WORLD}(\Sigma, s, \phi)$ calls $\text{NIL-WORLD}(\Sigma', s', \phi)$ (not at any recursion depth), then either $|\Sigma| < |\Sigma'|$ or $|s| < |s'|$;
- Any call $\text{NIL-WORLD}(\Sigma, s, \phi)$ from $\text{NIL-WORLD}(X, \lambda, \phi)$ satisfies that neither $bin \cdot bin$ nor $fin \cdot fin$ is a substring of s ;
- Any call $\text{NIL-WORLD}(\Sigma, s, \phi)$ with $|s| \geq 3 \times |\phi|$ does not call recursively NIL-WORLD . This means that no more recursive calls to NIL-WORLD is executed (see Theorem 3.1).

Consequently, the depth of the recursion is in $\mathcal{O}(|\phi|^3)$. More precisely, the depth is bounded by $75 \times |\phi|^3$. Since we need space in $\mathcal{O}(|\phi|)$ at each level of the recursion, the total space to compute $\text{NIL-WORLD}(X, \lambda, \phi)$ for $X \subseteq \text{cl}(\{\phi\})$ is in $\mathcal{O}(|\phi|^4)$. As a consequence we have,

Theorem 4.1. *Let $X \subseteq \text{cl}(\{\phi\})$.*

(I) *$\text{NIL-WORLD}(X, \lambda, \phi)$ terminates and requires space in $\mathcal{O}(|\phi|^4)$;*

(II) *Let $\text{NIL-WORLD}(\Sigma, s, \phi)$ be a call in the computation of $\text{NIL-WORLD}(X, \lambda, \phi)$. Then, $|\Sigma| \leq 25 \times |\phi|^2$ and $|s| \leq 3 \times |\phi|$;*

(III) Let a call $\text{NIL-WORLD}(\Sigma', s', \phi)$ be made in $\text{NIL-WORLD}(\Sigma, s, \phi)$ in the computation of $\text{NIL-WORLD}(X, \lambda, \phi)$. Then,

$$\langle 3 \times |\phi| - |s'|, 25 \times |\phi|^2 - |\Sigma'| \rangle < \langle 3 \times |\phi| - |s|, 25 \times |\phi|^2 - |\Sigma| \rangle$$

where $<$ is the standard (well-founded) lexicographical ordering on ω^2 .

4.3. Correction

Theorem 4.1 is an important step to prove that NIL satisfiability is in **PSPACE** but it is not sufficient. Indeed, up to now we have no guarantee that the function NIL-WORLD is correct. This is shown in the next two lemmas.

Lemma 4.1. *Let ϕ be a NIL-formula and let $Y \subseteq \text{cl}(\{\phi\})$ satisfy $\phi \in Y$. If $\text{NIL-WORLD}(Y, \lambda, \phi)$ returns true, then ϕ is NIL-satisfiable.*

Proof:

Assume that $\text{NIL-WORLD}(Y, \lambda, \phi)$ returns true. Let us build a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ for which there is $w \in W$ such that for all $\psi \in \text{cl}(\{\phi\})$, $\mathcal{M}, w \models \psi$ iff $\psi \in Y$.

Let S be the set of strings s over $\{\text{sim}, \text{bin}, \text{fin}\}$ such that $|s| \leq 3 \times |\phi|$. We define W as the set of pairs $\langle X, s \rangle$ for which there is a finite sequence $\langle \Sigma_1, s_1 \rangle, \dots, \langle \Sigma_k, s_k \rangle$ ($k \geq 1$) such that

1. for $i \in \{1, \dots, k\}$, $\text{NIL-WORLD}(\Sigma_i, s_i, \phi)$ is called in $\text{NIL-WORLD}(Y, \lambda, \phi)$ (at any depth of the recursion);
2. $\Sigma_1 = Y$; $s_1 = \lambda$; $\text{last}(\Sigma_k) = X$; $s_k = s$;
3. for $i \in \{1, \dots, k\}$, $\text{NIL-WORLD}(\Sigma_i, s_i, \phi)$ returns true;
4. for $i \in \{1, \dots, k-1\}$, $\text{NIL-WORLD}(\Sigma_i, s_i, \phi)$ calls directly $\text{NIL-WORLD}(\Sigma_{i+1}, s_{i+1}, \phi)$.

The conditions 3. and 4. state that we only want to record those pairs $\langle X, s \rangle \in \text{clos} \times S$ that contribute to making $\text{NIL-WORLD}(Y, \lambda, \phi)$ true. $\langle Y, \lambda \rangle \in W$ by assumption. Furthermore, for all $\langle X, s \rangle \in W$, X is s -consistent.

Let us define the binary relation R_{sim} on W as follows: $\langle X, s \rangle R_{\text{sim}} \langle X', s' \rangle \stackrel{\text{def}}{\iff}$ there is a successful call $\text{NIL-WORLD}(\Sigma, s, \phi)$ in $\text{NIL-WORLD}(Y, \lambda, \phi)$ (at any depth of the recursion) such that

1. $\text{last}(\Sigma) = X$;
2. $\text{NIL-WORLD}(\Sigma, s, \phi)$ calls $\text{NIL-WORLD}(\Sigma', s', \phi)$ successfully in the “sim” segment of $\text{NIL-WORLD}(\Sigma, s, \phi)$;
3. $\text{last}(\Sigma') = X'$.

If $\langle X, s \rangle R_{\text{sim}} \langle X', s' \rangle$, then $s' = s \cdot \text{sim}$, $\Sigma' = X'$ and $X \approx X'$.

In a similar way, let us define the binary relation R_{fin} [resp. R_{bin}] on W as follows: $\langle X, s \rangle R_{\text{fin}} \langle X', s' \rangle$ [resp. $\langle X, s \rangle R_{\text{bin}} \langle X', s' \rangle$] $\stackrel{\text{def}}{\iff}$ there is a successful call of $\text{NIL-WORLD}(\Sigma, s, \phi)$ in $\text{NIL-WORLD}(Y, \lambda, \phi)$ (at any depth of the recursion) such that

1. either

- (a) $last(\Sigma) = X$;
- (b) $NIL\text{-}WORLD(\Sigma, s, \phi)$ calls $NIL\text{-}WORLD(\Sigma', s', \phi)$ successfully in the “fin” [resp. “bin”] segment of $NIL\text{-}WORLD(\Sigma, s, \phi)$;
- (c) $last(\Sigma') = X'$.

2. or there is a finite sequence $\langle \Sigma_1, s_1 \rangle, \dots, \langle \Sigma_k, s_k \rangle$ such that:

- (a) $last(\Sigma_k) = X$; $last(\Sigma_1) = X'$;
- (b) $\Sigma_k = \Sigma$; $s_k = s$; $s_1 = s'$;
- (c) for $i \in \{1, \dots, k\}$, $\langle last(\Sigma_i), s_i \rangle \in W$;
- (d) for $i \in \{1, \dots, k-1\}$, $NIL\text{-}WORLD(\Sigma_i, s_i, \phi)$ calls $NIL\text{-}WORLD(\Sigma_{i+1}, s_{i+1}, \phi)$ in the “fin” [resp. “bin”] segment of $NIL\text{-}WORLD$ and both $NIL\text{-}WORLD(\Sigma_i, s_i, \phi)$ and $NIL\text{-}WORLD(\Sigma_{i+1}, s_{i+1}, \phi)$ return true;
- (e) the call $NIL\text{-}WORLD(\Sigma_k, s_k, \phi)$ enters in the “fin” [resp. “bin”] segment of $NIL\text{-}WORLD$, $last(s_k) = fin$ [resp. $last(s_k) = bin$], and for some formula $[\leq]\psi \in cl(s, \phi) \setminus X$ [resp. $[\geq]\psi \in cl(s, \phi) \setminus X$], $\psi \notin X'$ and $X \preceq X'$ [resp. $X \succeq X'$].

The definition of \mathcal{M} can be now completed:

- $R_{\leq} \stackrel{\text{def}}{=} (R_{fin} \cup R_{bin}^{-1})^*$;
- $R_{\geq} \stackrel{\text{def}}{=} (R_{bin} \cup R_{fin}^{-1})^*$;
- $R_{\sigma} \stackrel{\text{def}}{=} R_{\geq} \circ (R_{sim} \cup R_{sim}^{-1} \cup \{\langle \langle X, s \rangle, \langle X, s \rangle \rangle : \langle X, s \rangle \in W\}) \circ R_{\leq}$;
- for $\mathbf{p} \in \text{For}_0$, $m(\mathbf{p}) \stackrel{\text{def}}{=} \{\langle X, s \rangle \in W : \mathbf{p} \in X\}$.

It is easy to see that R_{\leq} and R_{\geq} are reflexive and transitive relations and R_{\geq} is the converse of R_{\leq} . Moreover, it is easy to show that R_{σ} is reflexive and symmetric and $R_{\geq} \circ R_{\sigma} \circ R_{\leq} \subseteq R_{\sigma}$. So, \mathcal{M} is NIL-model and W is of cardinality $2^{\mathcal{O}(|\phi|)}$. One can show:

- (i) $\langle X, s \rangle (R_{fin} \cup R_{bin}^{-1}) \langle X', s' \rangle$ implies $X \preceq X'$;
- (ii) $\langle X, s \rangle (R_{bin} \cup R_{fin}^{-1}) \langle X', s' \rangle$ implies $X' \preceq X$;
- (iii) $\langle X, s \rangle (R_{sim} \cup R_{sim}^{-1} \cup \{\langle \langle X, s \rangle, \langle X, s \rangle \rangle : \langle X, s \rangle \in W\}) \langle X', s' \rangle$ implies $X \approx X'$.

So,

- (iv) $\langle X, s \rangle R_{\leq} \langle X', s' \rangle$ implies for all $[\leq]\psi \in X$, $\psi \in X'$ (by definition of \preceq);
- (v) $\langle X, s \rangle R_{\geq} \langle X', s' \rangle$ implies for all $[\geq]\psi \in X$, $\psi \in X'$ (by definition of \preceq);
- (vi) $\langle X, s \rangle R_{\sigma} \langle X', s' \rangle$ implies for all $[\sigma]\psi \in X$, $\psi \in X'$ (by definition of \approx and by Lemma 3.6(I)).

By induction on the structure of ψ we shall show that for all $\langle X, s \rangle \in W$, for all $\psi \in \text{cl}(s, \phi)$, $\psi \in X$ iff $\mathcal{M}, \langle X, s \rangle \models \psi$. The case when ψ is a propositional variable is by definition of m .

Induction hypothesis: for all $\psi \in \text{cl}(\{\phi\})$ such that $|\psi| \leq n$, for all $\langle X, s \rangle \in W$, if $\psi \in \text{cl}(s, \phi)$, then $\psi \in X$ iff $\mathcal{M}, \langle X, s \rangle \models \psi$.

Let ψ be a formula in $\text{cl}(\{\phi\})$ such that $|\psi| \leq n + 1$. The cases when the outermost connective of ψ is Boolean is a consequence of the s -consistency of X and the induction hypothesis. Let us treat the other cases.

Case 1: $\psi = [\leq]\psi'$.

Let $\langle X, s \rangle \in W$ such that $\psi \in \text{cl}(s, \phi)$. By definition of W , there is a sequence Σ such that $\text{last}(\Sigma) = X$ and $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true. If $\psi \notin X$ one of the following two cases occurs.

Case 1.1: there is X' in Σ such that $X \preceq X'$, $\psi' \notin X'$ and $\text{last}(s) = \text{fin}$. By definition of W , there is a subsequence Σ' of Σ and s' such that $\text{last}(\Sigma') = X'$ and $\text{NIL-WORLD}(\Sigma', s', \phi)$ returns true (see the conditions 3. and 4. defining W). Hence, we have $\langle X, s \rangle R_{\text{fin}} \langle X', s' \rangle$ and therefore $\langle X, s \rangle R_{\leq} \langle X', s' \rangle$. Observe that either $s' = s$ or $s = s' \cdot \text{fin}$. By Lemma 3.9, $\psi' \in \text{cl}(s', \phi)$. By induction hypothesis, $\mathcal{M}, \langle X', s' \rangle \not\models \psi'$ and therefore $\mathcal{M}, \langle X, s \rangle \not\models \psi$.

Case 1.2: $\text{NIL-WORLD}(\Sigma, s, \phi)$ calls successfully $\text{NIL-WORLD}(\Sigma', s', \phi)$ in the “fin” segment of NIL-WORLD , $\text{last}(\Sigma') = X'$, $\psi' \notin \text{last}(\Sigma')$, $X \preceq X'$ and $X' \subseteq \text{cl}(s', \phi)$. Moreover, we have either $s' = s$ or $s' = s \cdot \text{fin}$. This is so since $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true. By definition of R_{fin} , $\langle X, s \rangle R_{\text{fin}} \langle X', s' \rangle$. Furthermore, $\psi' \in \text{cl}(s', \phi)$ by Lemma 3.9. By the induction hypothesis, $\mathcal{M}, \langle X', s' \rangle \not\models \psi'$ and therefore $\mathcal{M}, \langle X, s \rangle \not\models \psi$.

If $\psi \in X$, then by (iv), for all $\langle X', s' \rangle \in R_{\leq}(\langle X, s \rangle)$, $\psi' \in X'$ (and $\psi' \in \text{cl}(s', \phi)$ by Lemma 3.9). By the induction hypothesis, $\mathcal{M}, \langle X', s' \rangle \models \psi'$ and therefore $\mathcal{M}, \langle X, s \rangle \models \psi$.

Case 2: $\psi = [\geq]\psi'$.

This is analogous to the Case 1 and can be proved by using (v) above and Lemma 3.10.

Case 3: $\psi = [\sigma]\psi'$.

By definition of W , there is a sequence Σ such that $\text{last}(\Sigma) = X$ and $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true. If $\psi \notin X$, then $\text{NIL-WORLD}(\Sigma, s, \phi)$ calls $\text{NIL-WORLD}(X', s \cdot \text{sim}, \phi)$ in its “sim” segment, $\psi' \notin \text{last}(X')$, $X \approx X'$ and $X' \subseteq \text{cl}(s', \phi)$. This is so since $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true. By definition of R_{sim} , $\langle X, s \rangle R_{\text{sim}} \langle X', s \cdot \text{sim} \rangle$. By Lemma 3.7, $\psi' \in \text{cl}(s \cdot \text{sim}, \phi)$. By the induction hypothesis, $\mathcal{M}, \langle X', s \cdot \text{sim} \rangle \not\models \psi'$ and therefore $\mathcal{M}, \langle X, s \rangle \not\models \psi$.

If $\psi \in X$, by (vi), for all $\langle X', s' \rangle \in R_{\sigma}(\langle X, s \rangle)$, $\psi' \in X'$ (and $\psi' \in \text{cl}(s', \phi)$ by Lemma 3.7 and Lemma 3.8). By the induction hypothesis, $\mathcal{M}, \langle X', s' \rangle \models \psi'$ and therefore $\mathcal{M}, \langle X, s \rangle \models \psi$.

As a conclusion, since $\phi \in Y$ and $\text{NIL-WORLD}(Y, \lambda, \phi)$ returns true, $\mathcal{M}, \langle Y, \lambda \rangle \models \phi$ and therefore ϕ is NIL-satisfiable. \square

The proof of Lemma 4.1 can be viewed as a way to transform a successful call of $\text{NIL-WORLD}(Y, \lambda, \phi)$ into a *quasi* NIL-model by analyzing the computation tree of $\text{NIL-WORLD}(Y, \lambda, \phi)$. Then, this quasi NIL-model is appropriately completed in order to get a NIL-model. The idea to construct a (standard) model from different *coherent* pieces is very common to establish decidability and complexity results for modal logics (see e.g. [20, 29, 21, 4]).

Lemma 4.2. *Let ϕ be a NIL-formula. If ϕ is NIL-satisfiable, then there is $Y \subseteq \text{cl}(\{\phi\})$ such that $\phi \in Y$ and $\text{NIL-WORLD}(Y, \lambda, \phi)$ returns true.*

Proof:

Assume ϕ is NIL-satisfiable. So, there is a NIL-model $\mathcal{M}^0 = \langle W^0, R_{\leq}^0, R_{\geq}^0, R_{\sigma}^0, m^0 \rangle$ and $w^0 \in W^0$ such that $\mathcal{M}^0, w^0 \models \phi$. We shall show that

- (i) for any $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ such that neither $\text{bin} \cdot \text{bin}$ nor $\text{fin} \cdot \text{fin}$ occurs in s , if Σ is a finite nonempty sequence of subsets of $\text{cl}(s, \phi)$ that contains no duplicates, $\text{last}(\Sigma) = X$ and there is a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ and $w \in W$ satisfying for all $\psi \in \text{cl}(s, \phi)$, $\mathcal{M}, w \models \psi$ iff $\psi \in X$, then $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true.

Consequently, by taking $s = \lambda$, $X = \{\psi \in \text{cl}(\{\phi\}) : \mathcal{M}^0, w^0 \models \psi\}$ and $\Sigma = X$ we get that $\text{NIL-WORLD}(X, \lambda, \phi)$ returns true.

The proof of (i) is by double induction on the length of s and on the length of Σ .

Base case 1: $|s| > 3 \times |\phi|$.

Then $\text{cl}(s, \phi) = \emptyset$ and therefore (i) holds.

Induction hypothesis 1: for any $s' \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ such that neither $\text{bin} \cdot \text{bin}$ nor $\text{fin} \cdot \text{fin}$ occurs in s' , $|s'| \geq n$ for some $n \geq 1$, if Σ is a finite nonempty sequence of subsets of $\text{cl}(s', \phi)$ that contains no duplicates, $\text{last}(\Sigma) = X$ and there is a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ and $w \in W$ satisfying for all $\psi \in \text{cl}(s', \phi)$, $\mathcal{M}, w \models \psi$ iff $\psi \in X$, then $\text{NIL-WORLD}(\Sigma, s', \phi)$ returns true.

Let $s \in \{\text{sim}, \text{fin}, \text{bin}\}^*$ such that neither $\text{bin} \cdot \text{bin}$ nor $\text{fin} \cdot \text{fin}$ occurs in s , $|s| = n - 1$. Let Σ be a finite nonempty sequence of subsets of $\text{cl}(s, \phi)$ that contains no duplicates with $\text{last}(\Sigma) = X$. and \mathcal{M} be a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ with $w \in W$ satisfying for all $\psi \in \text{cl}(s, \phi)$, $\mathcal{M}, w \models \psi$ iff $\psi \in X$. Now we use a second induction on the length of Σ .

Base case 2: $|\Sigma| > 2^{\text{card}(\text{cl}(s, \phi))}$.

Σ contains duplicates and (i) holds.

Induction hypothesis 2: for all finite nonempty sequence Σ of subsets of $\text{cl}(s, \phi)$ that contains no duplicates with $\text{last}(\Sigma) = X$, $|\Sigma| \geq n'$ for some $n' \geq 1$ and there is a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ and $w \in W$ satisfying for all $\psi \in \text{cl}(s, \phi)$, $\mathcal{M}, w \models \psi$ iff $\psi \in X$, then $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true.

Assume Σ is a sequence of subsets of $\text{cl}(s, \phi)$ that contains no duplicates, $\text{last}(\Sigma) = X$, $|\Sigma| = n' - 1$ and there is a NIL-model $\mathcal{M} = \langle W, R_{\leq}, R_{\geq}, R_{\sigma}, m \rangle$ and $w \in W$ satisfying for all $\psi \in \text{cl}(s, \phi)$, $\mathcal{M}, w \models \psi$ iff $\psi \in X$. Consequently, X is s -consistent by Lemma 3.5. So $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns false only because either the segment “sim” or the segment “bin” or the segment “fin” returns false.

Case 1: Consider $[\leq]\psi \in \text{cl}(s, \phi) \setminus X$ such that $\mathcal{M}, w \not\models [\leq]\psi$.

There is $w' \in W$ such that $\langle w, w' \rangle \in R_{\leq}$ and $\mathcal{M}, w' \not\models \psi$. Let Y be the subset of $\text{cl}(s \cdot \text{fin}, \phi)$ such that for $\varphi \in \text{cl}(s \cdot \text{fin}, \phi)$, $\varphi \in Y \stackrel{\text{def}}{\iff} \mathcal{M}, w' \models \varphi$. So, $\psi \notin Y$ and $X \preceq Y$ by Lemma 3.12(III).

If $Y \in \Sigma$ and $\text{last}(s) = \text{fin}$, then no recursive call to NIL-WORLD is needed by definition of NIL-WORLD . In the case when either $Y \notin \Sigma$ or $\text{last}(s) \neq \text{fin}$, by induction hypothesis, either

$\text{NIL-WORLD}(\Sigma \cdot Y, s, \phi)$ returns true (by the induction hypothesis 2) or $\text{NIL-WORLD}(Y, s \cdot \text{fin}, \phi)$ returns true (by the induction hypothesis 1). Therefore, $\text{NIL-WORLD}(\Sigma, s, \phi)$ does not return false in the “fin” segment of NIL-WORLD . Similarly, we can show that $\text{NIL-WORLD}(\Sigma, s, \phi)$ does not return false in the “bin” segment of NIL-WORLD .

Case 2: consider $[\sigma]\psi \in \text{cl}(s, \phi) \setminus X$ such that $\mathcal{M}, w \not\models [\sigma]\psi$.

There is $w' \in W$ such that $\langle w, w' \rangle \in R_\sigma$ and $\mathcal{M}, w' \not\models \psi$. Let Y be the subset of $\text{cl}(s \cdot \text{sim}, \phi)$ such that for $\varphi \in \text{cl}(s \cdot \text{sim}, \phi)$, $\varphi \in Y \stackrel{\text{def}}{\iff} \mathcal{M}, w' \models \varphi$. So, $\psi \notin Y$ and $X \approx Y$ by Lemma 3.12(II). By the induction hypothesis 1 (remember $\psi \in \text{cl}(s \cdot \text{sim}, \phi)$), $\text{NIL-WORLD}(Y, s \cdot \text{sim}, \phi)$ returns true. Therefore, $\text{NIL-WORLD}(\Sigma, s, \phi)$ does not return false in the “sim” segment of NIL-WORLD . The fact that the induction hypothesis 2 is not used in this case should not come as a surprise. Indeed, $\text{NIL-WORLD}(\Sigma'', s'' \cdot \text{sim}, \phi) = \text{NIL-WORLD}(\text{last}(\Sigma''), s'' \cdot \text{sim}, \phi)$ for any nonempty finite sequence Σ'' of elements of $\mathcal{P}(\text{cl}(s'' \cdot \text{sim}, \phi))$ and $s'' \in \{\text{sim}, \text{fin}, \text{bin}\}^*$. In other words, for a ‘sim’ transition, we do not need to keep track of the history of the path. Actually, we only need to check the predecessor which is done with the syntactic relation \approx .

Consequently, since neither the segment “sim” nor the segment “bin” nor the segment “fin” returns false, $\text{NIL-WORLD}(\Sigma, s, \phi)$ returns true and this completes the proof. \square

Since NIL-WORLD is correct, the proof of Lemma 4.1 provides the finite model property for NIL and an exponential bound for the size of the models exists. These results could be also obtained via a filtration construction but here we get them as a by-product of the complexity result.

Finally,

Theorem 4.2. *NIL satisfiability is in PSPACE.*

Proof:

By Lemma 4.1 and Lemma 4.2, for any formula ϕ , ϕ is NIL -satisfiable iff there is $X \subseteq \text{cl}(\{\phi\})$ such that $\text{NIL-WORLD}(X, \lambda, \phi)$ returns true. By Theorem 4.1, $\text{NIL-WORLD}(X, \lambda, \phi)$ requires space in $\mathcal{O}(|\phi|^4)$ and the index necessary to remember which $X \subseteq \text{cl}(\{\phi\})$ have been already treated, is in space $\mathcal{O}(\log \text{card}(\mathcal{P}(\text{cl}(\{\phi\}))))$, that is in space $\mathcal{O}(|\phi|)$. \square

5. Concluding remarks

We have shown that the information logic NIL introduced in [25] and further studied in [32] has a **PSPACE**-complete satisfiability problem. This should not come as a real surprise since **PSPACE** is known to be the complexity class for modal logics. However, it is also known that the satisfiability of polymodal logics can be **EXPTIME**-hard as soon as the universal modality or the reflexive transitive modality is added to appropriate modal logics [17]. For instance, the bimodal logic (say, with modal operators [1] and [2]) characterized by the class of frames $\langle W, R_1, R_2 \rangle$ such that $R_1 \subseteq R_2 \subseteq W \times W$ and R_2 is an equivalence relation is **EXPTIME**-hard [17]. Remember that in a NIL model we also have $R_{\leq} \subseteq R_\sigma$ and $R_{\geq} \subseteq R_\sigma$. Furthermore, **PSPACE**-hardness for satisfiability is not a systematic feature of polymodal information

logics (assuming $\mathbf{NP} \neq \mathbf{PSPACE}$). For instance, the bimodal information logic containing a modal operator for indiscernibility and a modal operator for complementarity (see Section 1) has an \mathbf{NP} -complete satisfiability problem [9]. Hence, a further analysis about the \mathbf{PSPACE} -completeness of NIL satisfiability shall certainly help understanding the complexity of other information logics and in a more general setting the computational complexity of numerous polymodal logics with interdependent modal connectives.
