(Received 20 February 2002; revised 27 February 2003)

Two nonlinear diffusion equations for thin film epitaxy, with or without slope selection, are studied in this work. The nonlinearity models the Ehrlich–Schwoebel effect – the kinetic asymmetry in attachment and detachment of adatoms to and from terrace boundaries. Both perturbation analysis and numerical simulation are presented to show that such an atomistic effect is the origin of a nonlinear morphological instability, in a rough-smooth-rough pattern, that has been experimentally observed as transient in an early stage of epitaxial growth on rough surfaces. Initial-boundary-value problems for both equations are proven to be well-posed, and the solution regularity is also obtained. Galerkin spectral approximations are studied to provide both *a priori* bounds for proving the well-posedness and numerical schemes for simulation. Numerical results are presented to confirm part of the analysis and to explore the difference between the two models on coarsening dynamics.

1 Introduction

We consider the following two nonlinear diffusion equations:

$$\partial_t h = -\nabla \cdot \left(\frac{\nabla h}{1 + |\nabla h|^2} + \delta \nabla \Delta h \right) \quad (1.1)$$

and

$$\partial_t h = -\nabla \cdot [(1 - |\nabla h|^2) \nabla h + \delta \nabla \Delta h] \quad (1.2)$$

that model epitaxial growth of thin films, where $h = h(x, t)$, $x = (x_1, x_2)$, is a scaled height function of a thin film in a co-moving frame and δ is a positive constant. If the surface gradient $|\nabla h|$ is small, then $1/(1 + |\nabla h|^2) \approx 1 - |\nabla h|^2$, and (1.2) can be formally derived from (1.1). With suitable boundary conditions, solutions of these equations satisfy

$$\frac{d}{dt} \int h \, dx = 0,$$

i.e. the mass is conserved.

In (1.1) and (1.2), the fourth-order term models surface diffusion, and the nonlinear second-order term models the Ehrlich–Schwoebel effect. In a typical step-flow or

FIGURE 1. The Ehrlich–Schwoebel barrier.

layer-by-layer epitaxial growth of thin films, adatoms – atoms that are adsorbed onto the surface but have not yet become part of the crystal – diffuse on a terrace and likely hit a terrace boundary. In order to stick to the boundary from an upper terrace, an adatom must overcome a higher energy barrier – the Ehrlich–Schwoebel barrier [7, 31, 30] (cf. Figure 1). This asymmetry in attachment and detachment of adatoms to and from terrace boundaries has many important consequences: it induces an uphill current which in general destabilizes nominal surfaces (high symmetry surfaces) [7, 30, 31], but stabilizes vicinal surfaces (surfaces that are in the vicinity of high symmetry surfaces) with large slope, preventing step bunching [35]; it also leads to the Bales–Zangwill morphological instability of atomic steps [2, 29]; Finally, it contributes to the kinetic roughening of film surfaces [17, 27, 35].

The growth equations (1.1) and (1.2) are the gradient flow with respect to the $L^2(\Omega)$ inner product of energy functionals

$$E_1(h) = \int_{\Omega} \left[-\frac{1}{2} \ln(1 + |\nabla h|^2) + \frac{\delta}{2} |\Delta h|^2 \right] dx \quad (1.3)$$

and

$$E_2(h) = \int_{\Omega} \left[\frac{1}{4} (|\nabla h|^2 - 1)^2 + \frac{\delta}{2} |\Delta h|^2 \right] dx, \quad (1.4)$$

respectively. Due to the presence of the negative term, the energy $E_1(h)$ is expected to behave badly, and is in fact poorly understood mathematically. The second energy $E_2(h)$ appears in several areas of material modeling. For instance, it serves as a variational model in the theory of liquid crystals [1]. It is an example of elastic energy functional of scalar deformations h in the strain-gradient theory for structural phase transitions in solids [3, 19]. It is also a simplified and rescaled folding energy for an out-of-plane displacement h modelling the folding pattern of a blister formed in the buckling-driven delamination of thin films [9, 14]. In the context of thin film epitaxy, the first term in $E_2(h)$ selects the slope of the film surface. For this reason, we call the associated equation

(1.2) the growth equation with slope selection, and correspondingly the equation (1.1) the growth equation without slope selection.

The interfacial dynamics governed by (1.1) and (1.2) are different. With slope selection, (1.2) predicts that mound-like or pyramid structures in the surface profile tend to have a uniform, constant mound slope [23, 25]. However, without slope selection, (1.1) predicts an unbounded mound slope $M(t) = O(t^{1/4})$ [10]. Experiments and simulations predict that the roughness – the standard deviation of the height profile $w(t)$ and the characteristic lateral size $\lambda(t)$ of pyramids obey the scaling laws $w(t) \sim t^\beta$ and $\lambda(t) \sim t^n$ before the finite size effect kicks in. These exponents β and n are called the *roughness exponent* and the *coarsening exponent*, respectively. With slope selection, (1.2) predicts $\beta = n = 1/3$; without slope selection, (1.1) predicts $\beta = 1/2$ and $n = 1/4$ [10, 15, 21, 23, 25, 32]. We refer to recent work [20] for a discussion on mathematical justification of such predictions.

Both the growth equation (1.2) for thin film epitaxy and the Cahn–Hilliard equation [5] for phase separation in a binary alloy model mass-conserved systems, and have variational structures though with different topologies. For one-dimensional space, the derivative of the solution to the growth equation (1.2) solves the Cahn–Hilliard equation. However, for two-dimensional space, the Cahn–Hilliard equation is not suitable for modeling the epitaxial growth of thin films, cf. the argument in Politi *et al.* [28, §4.6.2]. The geometry in the epitaxial dynamics (1.2) seems to be more complicated than that in the Cahn–Hilliard dynamics.

In this work, we attempt to understand continuum consequences of the Ehrlich–Schwoebel effect and differences between the two models with regards to solution properties and coarsening dynamics. Our main contributions are as follows:

- (1) We show by a high-order perturbation analysis and numerical simulation for both equations that the Ehrlich–Schwoebel effect is the origin of a nonlinear morphological instability, in a rough-smooth-rough pattern, that has been experimentally observed in epitaxial growth of thin film on rough surfaces [11]. This is a typical transient phenomenon in an early stage of thin film epitaxy.
- (2) We prove that the initial-boundary-value problem for both of the growth equations is well-posed. We also obtain the solution regularity.
- (3) We prove various kinds of bounds and error estimates for Galerkin spectral approximations of the weak solution for both equations. These bounds and estimates are used to prove the well-posedness and justify our numerical computation.
- (4) We develop a spectral method for solving numerically the growth equations, and present numerical results that confirm part of our analysis and show differences between the two models in terms of solution behavior and coarsening dynamics.

The well-posedness for the growth equation with slope selection for different boundary conditions is also studied in King *et al.* [18] using a different approach.

We now recall briefly the derivation of the growth equation (1.1) under the following assumptions: (1) a thin film is growing due to an incoming atomic or molecular beam with a constant deposition flux rate F ; (2) the main mechanism of mass transport of the film is the geometrically controlled, isotropic surface diffusion; and (3) the Ehrlich–Schwoebel effect is significant. All other effects such as the beam fluctuation, adatom desorption,

diffusion anisotropy, and island nucleation are neglected. For a growing high-symmetry surface in molecular-beam epitaxy with relatively low temperature and large average size of adatom islands, these assumptions are reasonable [29].

In a fixed Cartesian coordinate system $Ox_1x_2x_3$, we represent the macroscopic height of the film surface at time t in a co-moving frame by a height function $x_3 = h(x_1, x_2, t)$. Thus, $h = h_{real} - Ft$, where h_{real} is the real height of the film surface at time t . Conservation of mass leads to

$$\partial_t h = -\nabla \cdot \mathbf{j}, \quad (1.5)$$

where $\mathbf{j} = \mathbf{j}(\nabla h)$ is the surface current depending on the macroscopic gradient ∇h of the film surface. Following our assumptions, we have

$$\mathbf{j} = \mathbf{j}_{SD} + \mathbf{j}_{ES}, \quad (1.6)$$

where \mathbf{j}_{SD} is the equilibrium surface current due to the adatom surface diffusion and \mathbf{j}_{ES} the kinetic surface current due to the Ehrlich–Schwoebel effect.

It follows from Fick's law [16, 26] that $\mathbf{j}_{SD} = -K_s \nabla_s \mu_c$, where $K_s > 0$ is a constant, ∇_s denotes the surface gradient, and μ_c is the equilibrium surface chemical potential. Following Herring [12, 13] and Mullins [24], we have $\mu_c = -\gamma H$, where $\gamma > 0$ is the constant surface tension and H the mean curvature of film surface. Linearizing both the surface gradient ∇_s and the mean curvature H , we obtain

$$\mathbf{j}_{SD} = K_s \gamma \nabla \Delta h. \quad (1.7)$$

To determine \mathbf{j}_{ES} , we recall the argument in Johnson *et al.* [15] and Siegert & Plischke [32]. For simplicity, consider the step-flow growth of a thin film with an average step width l . Let $m = |\nabla h|$ be the macroscopic surface slope and take the lattice parameter to be the unity. Then, $m = 1/l$. Denote also by σ the adatom diffusion distance. Assume temporarily an infinite Ehrlich–Schwoebel barrier. For small m for which $\sigma < l$, only the atoms that land on a terrace within distance σ of the step edge shared by the adjacent upper terrace will make it to the edge. The rest will attach to islands on the terrace, and will not contribute to the net current. In this case, the total current should be given by the number of atoms which land in strips of width σ near an advancing step edge shared by the adjacent upper terrace, $F\sigma$, multiplied by the number of such strips per unit length, σ/l . Since $m = |\nabla h| = 1/l$, we have that $\mathbf{j}_{ES} = F\sigma^2 \nabla h$ for small m . For large m for which $\sigma > l$, assume that the current has the form $\mathbf{j}_{ES} = F\sigma^2 f(\sigma m) \nabla h$ for some function f . Since in this case all atoms land on terraces will stick to step edges, the current should not depend upon the diffusion distance σ . Thus, $f(s) \sim 1/s^2$ for large values of s . To the leading order, this scaling is found to agree with experiments [15]. Consequently, $\mathbf{j}_{ES} \sim (F/m^2) \nabla h$ for large m . Assume now a finite Ehrlich–Schwoebel barrier B_c . As proposed in [15], the corresponding surface current is an interpolation of the two values for small and large m , i.e.

$$\mathbf{j}_{ES} = \frac{FB_c \sigma^2}{1 + \alpha \sigma^2 |\nabla h|^2} \nabla h, \quad (1.8)$$

where α is a positive constant independent of σ . Finally, we obtain (1.1) from (1.5)–(1.8) with suitable scaling.

We remark that the energy functional $E_2(h)$ and the related equation (1.2) are also derived in Ortiz *et al.* [25] based on a series expansion of flux in powers of the profile gradient, together with the symmetry principle and the enforcement of Onsager's reciprocity relations from statistical mechanics.

In §2, we show a nonlinear morphological instability in epitaxial growth on rough surfaces. In §3, we prove the well-posedness and solution regularity for the initial-boundary-value problem. In §4, we prove various kinds of bounds and error estimates for Galerkin spectral approximations. In §5, we present numerical results. Finally, in §6, we draw conclusions.

2 Nonlinear morphological instability

An interesting experiment on unstable growth of thin films on rough surfaces is reported in Gyure *et al.* [11]. In this experiment, the molecular-beam epitaxy of InAs buffer layers is performed on InAs(001) substrates that initially exhibit small wavelength oscillations. Such oscillations remain when the thickness of buffer layers reaches 600Å. They almost disappear when the thickness reaches 1500Å. Much later, when the thickness reaches 2µm, new, large wavelength oscillations appear. Kinetic Monte Carlo simulations strongly suggest that this morphological instability in the rough-smooth-rough pattern is due to the Ehrlich–Schwoebel effect [11].

Following Coleman *et al.* [6], we now show by a high-order perturbation analysis that such a morphological instability is due to nonlinear interaction of different modes in perturbation, and is captured by the Ehrlich–Schwoebel effect included in both of the growth equations (1.1) and (1.2).

Perturb a constant height function and set

$$h(x, t) = h_0 + \epsilon h_1(x, t) + \epsilon^2 h_2(x, t) + \epsilon^3 h_3(x, t) + \cdots \quad (2.1)$$

with the initial condition

$$h(x, 0) = h_0 + \epsilon \sum_{j=1}^N a_j \exp\{i(k_j \cdot x + \phi_j)\}, \quad (2.2)$$

where h_0 is a complex constant, ϵ is a parameter small in magnitude, h_1 , h_2 , and h_3 are complex-valued functions of x and t , $N \geq 2$ is an integer, all a_j ($1 \leq j \leq N$) are complex constants, ϕ_j ($1 \leq j \leq N$) are real constants, and k_j ($1 \leq j \leq N$) are real, two-dimensional, constant vectors – the wave-vectors.

Inserting (2.1) into (1.1) or (1.2) and comparing orders of ϵ , also using (2.2), we obtain the following equations and initial conditions for h_1 , h_2 , and h_3 , the same for both equations (1.1) and (1.2):

$$\epsilon: \quad \partial_t h_1 = -\Delta h_1 - \delta \Delta^2 h_1, \quad (2.3)$$

$$h_1(x, 0) = \sum_{j=1}^N a_j \exp\{i(k_j \cdot x + \phi_j)\}, \quad (2.4)$$

$$\epsilon^2: \quad \partial_t h_2 = -\Delta h_2 - \delta \Delta^2 h_2, \quad (2.5)$$

$$h_2(x, 0) = 0, \quad (2.6)$$

FIGURE 2. Typical dispersion relation.

$$\epsilon^3 : \quad \partial_t h_3 = \nabla \cdot (|\nabla h_1|^2 \nabla h_1) - \Delta h_3 - \delta \Delta^2 h_3, \tag{2.7}$$

$$h_3(x, 0) = 0. \tag{2.8}$$

The h_1 equation (2.3) is the linearized equation around the steady-state solution $h(x, t) = h_0$. Solving the initial-value problem (2.3) and (2.4), we obtain that

$$h_1(x, t) = \sum_{j=1}^N a_j \exp\{\omega(k_j)t + i(k_j \cdot x + \phi_j)\}, \tag{2.9}$$

where $\omega(k)$ is the growth rate for wave-vector k , determined by the dispersion relation

$$\omega(k) = |k|^2 - \delta |k|^4.$$

See Figure 2 for a plot of a typical such dispersion relation. There exists a critical value, k_c , of the modulus of wave-vector,

$$k_c = \sqrt{\frac{1}{\delta}} \quad \text{such that} \quad \begin{array}{ll} \omega(k) > 0 & \text{if } |k| < k_c, \\ \omega(k) < 0 & \text{if } |k| > k_c. \end{array} \tag{2.10}$$

The maximum growth rate $\omega_m = 1/(4\delta)$ occurs at any wave-vector with modulus $\sqrt{1/(2\delta)}$.

From (2.5) and (2.6), we immediately have that $h_2(x, t) = 0$ identically.

The h_3 equation (2.7) is still linear, but it has a nonlinear source term $\nabla \cdot (|\nabla h_1|^2 \nabla h_1)$ which comes from the Ehrlich–Schwoebel effect. By (2.9), we have

$$\begin{aligned} g(x, t) &\equiv \nabla \cdot [|\nabla h_1(x, t)|^2 \nabla h_1(x, t)] \\ &= - \sum_{l,m,n=1}^N a_l a_m a_n (k_l \cdot k_m) [k_n \cdot (k_l - k_m + k_n)] \\ &\quad \times \exp\{[\omega(k_l) + \omega(k_m) + \omega(k_n)]t + i[(k_l - k_m + k_n) \cdot x + \phi_l - \phi_m + \phi_n]\}. \end{aligned}$$

Applying the Fourier transform to both sides of (2.7) and (2.8), we obtain for each variable ξ of Fourier transformed functions and each time t that

$$\begin{aligned}\partial_t \widehat{h}_3(\xi, t) - \omega(\xi) \widehat{h}_3(\xi, t) &= \widehat{g}(\xi, t), \\ \widehat{h}_3(\xi, 0) &= 0,\end{aligned}$$

where

$$\widehat{u}(\xi) = \mathcal{F}(u)(\xi) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}^2} u(x) e^{-i\xi \cdot x} dx$$

is the Fourier transform of a function $u = u(x)$. Solving this initial-value problem for each ξ , we get

$$\widehat{h}_3(\xi, t) = \int_0^t e^{\omega(\xi)(t-\tau)} \widehat{g}(\xi, \tau) d\tau.$$

Consequently, by the inverse Fourier transform, defined for a function $U = U(\xi)$ by

$$\check{U}(x) = \mathcal{F}^{-1}(U)(x) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}^2} U(\xi) e^{ix \cdot \xi} d\xi,$$

we obtain

$$h_3(x, t) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}^2} \left[\int_0^t e^{\omega(\xi)(t-\tau)} \widehat{g}(\xi, \tau) d\tau \right] e^{ix \cdot \xi} d\xi = \int_0^t \mathcal{F}^{-1} \left(e^{\omega(\xi)(t-\tau)} \widehat{g}(\xi, \tau) \right) d\tau.$$

After a series of calculations, we obtain an explicit expression of $h_3(x, t)$, which, together with (2.1), (2.9), and the fact that $h_2(x, t) = 0$, in turn yields

$$\begin{aligned}h(x, t) &= h_0 + \epsilon \sum_{j=1}^N a_j \exp\{\omega(k_j)t + i(k_j \cdot x + \phi_j)\} \\ &\quad - \epsilon^3 \sum_{l,m,n=1}^N \frac{a_l a_m a_n (k_l \cdot k_m) [k_n \cdot (k_l - k_m + k_n)]}{\omega(k_l) + \omega(k_m) + \omega(k_n) - \omega(k_l - k_m + k_n)} \\ &\quad \cdot (\exp\{[\omega(k_l) + \omega(k_m) + \omega(k_n)]t\} - \exp\{\omega(k_l - k_m + k_n)t\}) \\ &\quad \cdot \exp\{i[(k_l - k_m + k_n) \cdot x + \phi_l - \phi_m + \phi_n]\} + O(\epsilon^4),\end{aligned}\tag{2.11}$$

provided that

$$\omega(k_l) + \omega(k_m) + \omega(k_n) - \omega(k_l - k_m + k_n) \neq 0 \quad \forall l, m, n : 1 \leq l, m, n \leq N.\tag{2.12}$$

Suppose that all the wave-vectors k_j ($1 \leq j \leq N$) in the initial condition (2.2) satisfy (2.12) and

$$|k_j| > k_c \quad \forall j : 1 \leq j \leq N.\tag{2.13}$$

Then, all $\omega(k_j) < 0$ ($1 \leq j \leq N$) by (2.10). Consequently, all the ϵ terms in (2.11) decay exponentially. However, a careful look at the expression (2.11) finds that in fact all the ϵ^3

terms in (2.11) also decay exponentially except those with indices $l, m,$ and n satisfying

$$0 < |k_l - k_m + k_n| < k_c. \tag{2.14}$$

If this holds for some indices $l, m,$ and $n,$ then a new, unstable mode with the wavenumber $k_l - k_m + k_n$ will be generated. Since ϵ^3 is much smaller than $\epsilon,$ it takes a relatively long period of ‘buffering’ time – during which the surface appears to be smooth – for the new oscillation to be observed.

This nonlinear morphological instability, characterized by the rough-smooth-rough growth pattern, models accurately the experimentally observed transient in early stage of thin film epitaxy on rough surface as described above. It is clear from our analysis that this instability is due to the nonlinear interaction of different modes in the perturbation and that the nonlinearity originates from the Ehrlich–Schwoebel effect. If an initial perturbation contains modes with both large and small wavenumbers, then the small wavenumber component of the perturbation will grow quickly and the new, unstable modes generated by the nonlinear interaction of those modes with large wavenumbers will also grow exponentially but at a much later time. Therefore, both kinds of unstable modes, old and new, will develop but in different temporal scales.

Figure 3 shows a sequence of snapshots of the surface height at different time from our numerical simulation of the initial-boundary-value problem of the one-dimensional growth equation with slope selection

$$\begin{aligned} h_t &= ((h_x)^3 - h_x - h_{xxx})_x & \forall (x, t) \in (0, 12) \times (0, T], \\ h(\cdot, t) &\text{ is 12-periodic} & \forall t \in [0, T], \\ h(x, 0) &= 0.1 \left(\sin \frac{\pi x}{2} + \sin \frac{2\pi x}{3} + \sin \pi x \right) & \forall x \in [0, 12], \end{aligned}$$

where a subscript t or x denotes a corresponding partial derivative and $T > 0$ is a constant. In all the plots, the horizontal axis is the x axis. We see that the initial oscillation is damped immediately at $t = 1.$ After a relatively long period of “buffering” time, from $t = 1$ to $t = 15,$ a new kind of oscillation appears, and then exponentially increases. Notice that all the wavenumbers $k_1, k_2,$ and k_3 in the initial condition used in the simulation satisfy (2.12) and (2.13) for $N = 3$ with the critical wavenumber $k_c = 1.$ Moreover, only one ordered index triple (l, m, n) with $1 \leq l, m, n \leq N$ satisfies (2.14). This is why the new oscillation consists of one sinusoid profile. In the last two plots for $t = 60$ and $t = 240,$ the height different from that of the others. It is clear that a steady-state is reached at around $t = 60.$

Define the roughness (or the interface width [4]) for the height function at time t by

$$w(t) = \sqrt{\frac{1}{L} \int_0^L [h(x, t) - \bar{h}(t)]^2 dx}, \quad \text{where } \bar{h}(t) = \frac{1}{L} \int_0^L h(x, t) dx$$

with $L = 12.$ The two plots in Figure 4 show in different scales the evolution of film surface roughness, in particular, the rough-smooth-rough pattern. The flat part at long time in the right plot shows that a steady-state solution is reached.

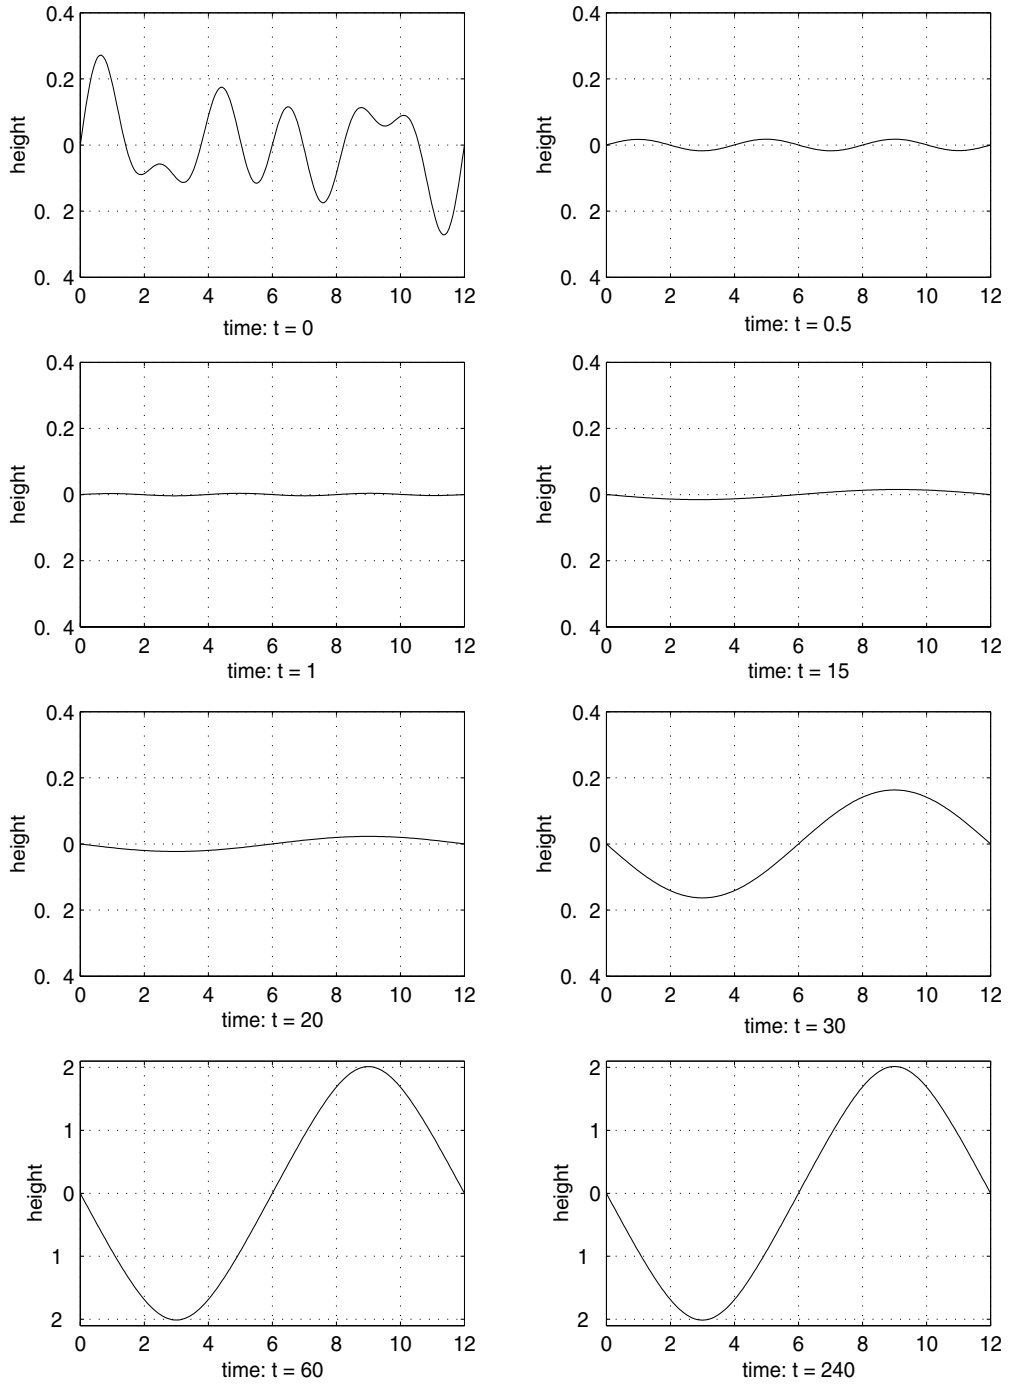

FIGURE 3. Morphological instability due to nonlinear interaction.

FIGURE 4. Evolution of the surface roughness.

3 The initial-boundary-value problem

Consider the initial-boundary-value problem for the d -dimensional ‘growth’ equation

$$\partial_t h = -\nabla \cdot [(1 - G(|\nabla h|^2))\nabla h + \delta \nabla \Delta h] \quad \text{in } \Omega \times (0, T], \tag{3.1}$$

$$h(\cdot, t) \text{ is } L\text{-periodic for all } t \in [0, T], \tag{3.2}$$

$$h(x, 0) = h_0(x) \quad \forall x \in \Omega, \tag{3.3}$$

where $h : \bar{\Omega} \times [0, T] \rightarrow \mathbb{R}$ is a d -dimensional ‘height’ function in a co-moving frame, $\Omega = \prod_{j=1}^d (0, L_j) \subset \mathbb{R}^d$, $d = 1, 2$, or 3 , \mathbb{R} denotes the set of all real numbers, $L = (L_1, \dots, L_d)$, all L_1, \dots, L_d , δ , and T are positive constants, $h_0 : \Omega \rightarrow \mathbb{R}$ is a given function, and

$$G(s) = \begin{cases} G_1(s) = \frac{s}{1+s} & \text{without slope selection,} \\ G_2(s) = s & \text{with slope selection.} \end{cases}$$

Here, we rearrange the second-order term in (1.1), and use $G(\cdot)$ to unify notation.

Let $C_{per}^\infty(\bar{\Omega})$ be the set of all restrictions onto $\bar{\Omega}$ of all real-valued, L -periodic, C^∞ -functions on \mathbb{R}^d . For any integer $m \geq 0$ and any extended real number $p \in [1, \infty]$, let $W_{per}^{m,p}(\Omega)$ be the closure of $C_{per}^\infty(\bar{\Omega})$ in the usual Sobolev space $W^{m,p}(\Omega)$. Note that $W_{per}^{0,p}(\Omega) = L^p(\Omega)$, if $p \neq \infty$. For $m \geq 1$ and $p = 2$, we write $H_{per}^m(\Omega)$ instead of $W_{per}^{m,2}(\Omega)$, and denote by $H_{per}^{-m}(\Omega)$ the dual space of $H_{per}^m(\Omega)$. Throughout the paper, we denote by $\|\cdot\|$ the $L^2(\Omega)$ -norm. We also write a function $u : \Omega \times [0, T] \rightarrow \mathbb{R}$ which is in a function space X for each t as a mapping $u = u(t) : [0, T] \rightarrow X$.

Definition 3.1 (Weak solution) *A function $h : \Omega \times [0, T] \rightarrow \mathbb{R}$ is called a weak solution of the initial-boundary-value problem (3.1)–(3.3), if*

$$(1) \ h \in L^2(0, T; H_{per}^2(\Omega)) \text{ and } \partial_t h \in L^2(0, T; H_{per}^{-2}(\Omega));$$

(2) for any $\phi \in H_{per}^2(\Omega)$,

$$\langle \phi, \partial_t h \rangle + \langle \nabla \phi, (G(|\nabla h|^2) - 1)\nabla h \rangle + \delta \langle \Delta \phi, \Delta h \rangle = 0 \quad a.e. t \in (0, T), \quad (3.4)$$

where, without confusion, $\langle \cdot, \cdot \rangle$ denotes the action of a distribution on a test function or the inner product of $L^2(\Omega)$;

(3) $h(x, 0) = h_0(x)$ for a.e. $x \in \Omega$.

Theorem 3.1 (Existence, uniqueness, and energy identity) *Let $h_0 \in H_{per}^2(\Omega)$. Then, the initial-boundary-value problem (3.1)–(3.3) has a unique weak solution $h : \Omega \times [0, T] \rightarrow \mathbb{R}$ that satisfies the following energy identities:*

$$\begin{aligned} \frac{d}{dt} \|h\|^2 + 4E_1(h) + 2 \int_{\Omega} \left[\frac{1}{1 + |\nabla h|^2} + \ln(1 + |\nabla h|^2) \right] dx &= 2|\Omega| \quad a.e. t \in (0, T), \\ \frac{d}{dt} E_1(h) + \|\partial_t h\|^2 &= 0 \quad a.e. t \in (0, T), \end{aligned}$$

and

$$\begin{aligned} \frac{d}{dt} \|h\|^2 + 4E_2(h) + \|\nabla h\|_{L^4(\Omega)}^4 &= |\Omega| \quad a.e. t \in (0, T), \\ \frac{d}{dt} E_2(h) + \|\partial_t h\|^2 &= 0 \quad a.e. t \in (0, T), \end{aligned}$$

for (1.1) and (1.2), respectively, where $E_1(h)$, $E_2(h)$ are given in (1.3), (1.4), and $|\Omega|$ is the measure of Ω .

Theorem 3.2 (Stability) *Let $g_0, h_0 \in H_{per}^2(\Omega)$. Let g, h be the weak solutions of (3.1) and (3.2) with $g(\cdot, 0) = g_0$ and $h(\cdot, 0) = h_0$ a.e. Ω , respectively. Then,*

$$\|g - h\|_{L^\infty(0, T; L^2(\Omega))} + \|g - h\|_{L^2(0, T; H^2(\Omega))} \leq C \|g_0 - h_0\|_{L^2(\Omega)},$$

where $C = C(\delta) > 0$ is a constant.

Theorem 3.3 (Regularity) *Let $h_0 \in H_{per}^m(\Omega)$ for some integer $m \geq 2$. Then, the weak solution $h : \Omega \times [0, T] \rightarrow \mathbb{R}$ of the initial-boundary-value problem (3.1)–(3.3) satisfies*

$$h \in L^\infty(0, T; H^m(\Omega)) \cap L^2(0, T; H^{m+2}(\Omega)) \quad \text{and} \quad \partial_t h \in L^2(0, T; H^{m-2}(\Omega)).$$

For $d \geq 4$, we still have the existence, uniqueness, energy identities, and stability for the two equations. But for (1.2) (with slope selection), both the definition of a weak solution and the assumption on initial data must be modified: in addition, we need to assume in the definition of a weak solution that $\nabla h \in L^4(0, T; L^4(\Omega))$ and that the test function ϕ is such that $\nabla \phi \in L^4(0, T; L^4(\Omega))$. We need also to assume that the initial data $h_0 \in H_{per}^{r(d)}(\Omega)$, where $r(d)$ is the smallest integer that greater than or equal to $1 + d/4$. Note that $H_{per}^{r(d)}(\Omega) \hookrightarrow W^{1,4}(\Omega)$.

Slightly changing the definition of a weak solution by requiring that $\partial_t h \in L^1(0, T; H_{per}^{-2}(\Omega))$ instead of $\partial_t h \in L^2(0, T; H_{per}^{-2}(\Omega))$, we can prove the existence of a weak solution with a much weaker assumption: $h_0 \in L^2(\Omega)$. The proof will need a refined compactness result that is obtained, for example, in Simon [33].

To prove the above and other theorems, we need some preparation. First, we recall the following elementary result.

Lemma 3.1 *We have for any $\phi \in H^2_{per}(\Omega)$ that*

$$\begin{aligned} \|\nabla\phi\|^2 &\leq \|\phi\|\|\Delta\phi\| \leq \frac{1}{2}\|\phi\|^2 + \frac{1}{2}\|\Delta\phi\|^2, \\ \sum_{j,k=1}^d \|\partial_{x_j x_k} \phi\|^2 &= \|\Delta\phi\|^2. \end{aligned}$$

Now denote for each integer $N \geq 1$

$$H_N = \text{span}\{1, \cos(2\pi k \cdot x/L), \sin(2\pi k \cdot x/L) : 0 < |k| \leq N\},$$

where $k = (k_1, \dots, k_d) \in \mathbb{Z}^d$ with $k_j \geq 0$ ($1 \leq j \leq d$), \mathbb{Z} is the set of all integers, x/L denotes the vector $(x_1/L_1, \dots, x_d/L_d)$, and $|k| = \sum_{j=1}^d k_j$. Notice that $H_N \subset C^\infty_{per}(\bar{\Omega})$. Denote also by $\mathcal{P}_N : L^2(\Omega) \rightarrow H_N$ the $L^2(\Omega)$ -projection onto H_N , which is defined for any $u \in L^2(\Omega)$ by $\mathcal{P}_N u \in H_N$ and

$$\langle \mathcal{P}_N u - u, \phi \rangle = 0 \quad \forall \phi \in H_N.$$

Lemma 3.2 *We have for any integer $m \geq 0$ that*

$$\begin{aligned} \|\mathcal{P}_N u\|_{H^m(\Omega)} &\leq \|u\|_{H^m(\Omega)} \quad \forall u \in H^m_{per}(\Omega), \quad \forall N \geq 1, \\ \lim_{N \rightarrow \infty} \|\mathcal{P}_N u - u\|_{H^m(\Omega)} &= 0 \quad \forall u \in H^m_{per}(\Omega). \end{aligned}$$

Proof The case $m = 0$ is trivial. For $m \geq 1$, these results follow from the fact that any derivative of a function in H_N is still in H_N and that $\mathcal{P}_N \hat{\partial} = \hat{\partial} \mathcal{P}_N$ for any derivative $\hat{\partial}$. □

The following lemma treats the nonlinearity in (1.1) and (1.2). It can be proved by direct verification.

Lemma 3.3 *We have for any vectors $a, b \in \mathbb{R}^d$ that*

$$\begin{aligned} &2(a - b) \cdot \left(\frac{|a|^2 a}{1 + |a|^2} - \frac{|b|^2 b}{1 + |b|^2} \right) \\ &= \frac{(|a|^2 - |b|^2)^2}{(1 + |a|^2)(1 + |b|^2)} + |a - b|^2 \left(\frac{|a|^2}{1 + |a|^2} + \frac{|b|^2}{1 + |b|^2} \right), \\ &(a - b) \cdot (|a|^2 a - |b|^2 b) = |a|^2 |b|^2 - (a \cdot b)^2 \\ &\quad + ((a - b) \cdot a)^2 + ((a - b) \cdot b)^2 + ((a - b) \cdot a)((a - b) \cdot b), \end{aligned}$$

and, in particular, that

$$(a - b) \cdot (G(a)a - G(b)b) \geq 0.$$

Given any integer $k \geq 1$, we denote $|\nabla^k u| = \sum_{|\gamma|=k} |\partial^\gamma u|$ for any smooth function u . For each integer j with $1 \leq j \leq k$, we also denote by $A_{k,j}$ the set of all pairs (α, β) with $\alpha = \{\alpha_i\}$ and $\beta = \{\beta_i\}$ two finite sequences of integers such that $1 \leq \alpha_i \leq k+1-j$ for all $i \geq 1$ and $\sum_{i \geq 1} \alpha_i \beta_i = k$, and denote $A_k = \cup_{j=1}^k A_{k,j}$.

Lemma 3.4 *Given any integer $k \geq 1$, there exists a constant $C_k > 0$ such that*

$$|\nabla^k G_2(u(x))| \leq C_k \sum_{(\{\alpha_i\}, \{\beta_i\}) \in A_k} \prod_{i \geq 1} |\nabla^{\alpha_i} u(x)|^{\beta_i} \quad \forall x \in \Omega, \forall u \in C^k(\Omega).$$

Proof Fix $u \in C^k(\bar{\Omega})$ and $x \in \Omega$. Denote by ∂^k any partial derivative of order k . We have by induction that

$$\partial^k [G_2(u(x))] = \sum_{j=1}^k \sum_{(\{\alpha_i\}, \{\beta_i\}) \in A_{k,j}} C_{k,j,\{\alpha_i\},\{\beta_i\}} G^{(j)}(u(x)) \prod_{i \geq 1} (\nabla^{\alpha_i} u(x))^{\beta_i},$$

where $C_{k,j,\{\alpha_i\},\{\beta_i\}}$ are all constants independent of u . This, together with the fact that $|G_2^{(j)}(s)| \leq 1$ for any integer $j \geq 1$ and any $s \geq 0$, implies the desired inequality. \square

We now proceed to prove Theorems 3.1–3.3. Our proofs rely heavily on the *a priori* bounds on spectral approximations of weak solutions. Such bounds will be fully established in the next section. Throughout the paper, we denote by C a generic, positive constant that can in general depend on d, L_j ($1 \leq j \leq d$), T, δ , and h_0 , but not on N .

Proof of Theorem 3.1 It follows from Theorem 4.1 that there exist a sequence of functions $\{h_N\}_{N=1}^\infty \subset L^\infty(0, T; H_{per}^2(\Omega))$ with $\{\partial_t h_N\} \subset L^2(0, T; L^2(\Omega))$ such that for each $N \geq 1$ $h_N(\cdot, 0) = h_0$; for any $\psi_N \in H_N$

$$\langle \psi_N, \partial_t h_N \rangle + \langle \nabla \psi_N, [G(|\nabla h_N|^2) - 1] \nabla h_N \rangle + \delta \langle \Delta \psi_N, \Delta h_N \rangle = 0 \quad \text{a.e. } t \in (0, T); \quad (3.5)$$

and

$$\|h_N\|_{L^\infty(0, T; H^2(\Omega))} + \|\partial_t h_N\|_{L^2(0, T; L^2(\Omega))} \leq C. \quad (3.6)$$

Consequently, there exists $h \in L^\infty(0, T; H_{per}^2(\Omega))$ with $\partial_t h \in L^2(0, T; L^2(\Omega))$ such that

$$h_N \overset{*}{\rightharpoonup} h \quad \text{in } L^\infty(0, T; H^2(\Omega)), \quad (3.7)$$

$$\partial_t h_N \rightharpoonup \partial_t h \quad \text{in } L^2(0, T; L^2(\Omega)), \quad (3.8)$$

$$h_N \rightarrow h \quad \text{in } L^2(0, T; H^1(\Omega)), \quad (3.9)$$

where the strong convergence (3.9) follows from (3.8), the weak convergence $h_N \rightharpoonup h$ in $L^2(0, T; H^2(\Omega))$ which follows from (3.7), and a usual compactness result (cf. [34, Theorem 2.1, Chapter III]). So, Part (1) of Definition 3.1 is satisfied.

Let $\phi \in H^2_{per}(\Omega)$ and $\eta \in C[0, T]$. For each $N \geq 1$, set $\psi_N = \mathcal{P}_N\phi$ in (3.5), multiply both sides of the resulting identity by $\eta(t)$, and integrate against t to yield

$$\begin{aligned} & \int_0^T \langle \eta(t)\mathcal{P}_N\phi, \partial_t h_N(\cdot, t) \rangle dt + \int_0^T \langle \eta(t)\nabla\mathcal{P}_N\phi, G(|\nabla h_N(\cdot, t)|^2)\nabla h_N(\cdot, t) \rangle dt \\ & - \int_0^T \langle \eta(t)\nabla\mathcal{P}_N\phi, \nabla h_N(\cdot, t) \rangle dt + \delta \int_0^T \langle \eta(t)\Delta\mathcal{P}_N\phi, \Delta h_N(\cdot, t) \rangle dt = 0. \end{aligned} \tag{3.10}$$

It directly follows from Lemma 3.2, (3.7), and (3.9) that

$$\int_0^T \langle \eta(t)\mathcal{P}_N\phi, \partial_t h_N(\cdot, t) \rangle dt \rightarrow \int_0^T \langle \eta(t)\phi, \partial_t h(\cdot, t) \rangle dt \quad \text{as } N \rightarrow \infty, \tag{3.11}$$

$$\int_0^T \langle \eta(t)\nabla\mathcal{P}_N\phi, \nabla h_N(\cdot, t) \rangle dt \rightarrow \int_0^T \langle \eta(t)\nabla\phi, \nabla h(\cdot, t) \rangle dt \quad \text{as } N \rightarrow \infty, \tag{3.12}$$

$$\int_0^T \langle \eta(t)\Delta\mathcal{P}_N\phi, \Delta h_N(\cdot, t) \rangle dt \rightarrow \int_0^T \langle \eta(t)\Delta\phi, \Delta h(\cdot, t) \rangle dt \quad \text{as } N \rightarrow \infty. \tag{3.13}$$

By the Hölder inequality, the Sobolev embedding $H^2(\Omega) \hookrightarrow W^{1,4}(\Omega)$, Lemma 3.2, (3.6)–(3.9), and the fact that $G(s) \leq s$ for all $s \geq 0$, we deduce that

$$\begin{aligned} & \left| \int_0^T \langle \eta(t)\nabla\mathcal{P}_N\phi, G(|\nabla h_N(\cdot, t)|^2)\nabla h_N(\cdot, t) \rangle dt - \int_0^T \langle \eta(t)\nabla\phi, G(|\nabla h(\cdot, t)|^2)\nabla h(\cdot, t) \rangle dt \right| \\ & \leq \left| \int_0^T \langle \eta(t) [\nabla\mathcal{P}_N\phi - \nabla\phi], G(|\nabla h_N(\cdot, t)|^2)\nabla h_N(\cdot, t) \rangle dt \right| \\ & \quad + \left| \int_0^T \langle \eta(t)\nabla\phi, G(|\nabla h_N(\cdot, t)|^2) [\nabla h_N(\cdot, t) - \nabla h(\cdot, t)] \rangle dt \right| \\ & \quad + \left| \int_0^T \langle \eta(t)\nabla\phi, [G(|\nabla h_N(\cdot, t)|^2) - G(|\nabla h(\cdot, t)|^2)]\nabla h(\cdot, t) \rangle dt \right| \tag{3.14} \\ & \leq \|\eta\|_{L^\infty(0,T)} \|\mathcal{P}_N\phi - \phi\|_{W^{1,4}(\Omega)} \int_0^T \|\nabla h_N\|_{L^4(\Omega)}^3 dt \\ & \quad + \|\eta\|_{L^\infty(0,T)} \|\phi\|_{W^{1,\infty}(\Omega)} \|\nabla h_N\|_{L^4(0,T;L^4(\Omega))}^2 \|\nabla h_N - \nabla h\|_{L^2(0,T;L^2(\Omega))} \\ & \quad + \|\eta\|_{L^\infty(0,T)} \|\phi\|_{W^{1,\infty}(\Omega)} \left(\|\nabla h_N\|_{L^4(0,T;L^4(\Omega))}^2 + \|\nabla h\|_{L^4(0,T;L^4(\Omega))}^2 \right) \|h_N - h\|_{L^2(0,T;H^1(\Omega))} \\ & \leq C \|\mathcal{P}_N\phi - \phi\|_{H^2(\Omega)} + C \|h_N - h\|_{L^2(0,T;H^1(\Omega))} \\ & \rightarrow 0 \quad \text{as } N \rightarrow \infty. \end{aligned}$$

Letting $N \rightarrow \infty$ in (3.10), we get from (3.11)–(3.14) that

$$\begin{aligned} & \int_0^T \eta(t) \{ \langle \phi, \partial_t h(\cdot, t) \rangle + \langle \nabla\phi, [G(|\nabla h(\cdot, t)|^2) - 1] \nabla h(\cdot, t) \rangle \\ & \quad + \delta \langle \Delta\phi, \Delta h(\cdot, t) \rangle \} dt = 0. \end{aligned} \tag{3.15}$$

Since $\eta \in C[0, T]$ is arbitrary, this implies (3.4). Part (2) of Definition 3.1 is satisfied.

Notice that, after a possible modification of h on a set of measure zero, we have $h \in C([0, T]; L^2(\Omega))$. Moreover, $h(t) = h(s) + \int_s^t h'(\tau) d\tau$ for any $s, t \in [0, T]$, where

$h(t) = h(\cdot, t) \in L^2(\Omega)$ and $h'(t) = \partial_t h(\cdot, t)$, (cf. [8, Theorem 2, Section 5.9]). Replace $\eta(t)$ in (3.15) by $\eta_T(t) = -t/T + 1$ and integrate by parts against t for the first term to get

$$\begin{aligned} & \int_0^T \frac{1}{T} \langle \phi, h(\cdot, t) \rangle dt + \int_0^T \eta_T(t) \{ \langle \nabla \phi, [G(|\nabla h(\cdot, t)|^2) - 1] \nabla h(\cdot, t) \rangle + \delta \langle \Delta \phi, \Delta h(\cdot, t) \rangle \} dt \\ & = \langle \phi, h(\cdot, 0) \rangle. \end{aligned} \quad (3.16)$$

Repeat the same argument using (3.5) with $\psi_N = \mathcal{P}_N \phi$ to deduce with ϕ replaced by $\mathcal{P}_N \phi$ and use Part (3) of Theorem 4.1 to deduce

$$\begin{aligned} & \int_0^T \frac{1}{T} \langle \mathcal{P}_N \phi, h_N(\cdot, t) \rangle dt + \int_0^T \eta_T(t) \{ \langle \nabla \mathcal{P}_N \phi, [G(|\nabla h_N(\cdot, t)|^2) - 1] \nabla h_N(\cdot, t) \rangle \\ & \quad + \delta \langle \Delta \mathcal{P}_N \phi, \Delta h_N(\cdot, t) \rangle \} dt = \langle \mathcal{P}_N \phi, h_0 \rangle. \end{aligned}$$

Thus, taking the limit $N \rightarrow \infty$, we deduce from (3.7), (3.9), and (3.12)–(3.14) that

$$\begin{aligned} & \int_0^T \frac{1}{T} \langle \phi, h(\cdot, t) \rangle dt + \int_0^T \eta_T(t) \{ \langle \nabla \phi, [G(|\nabla h(\cdot, t)|^2) - 1] \nabla h(\cdot, t) \rangle + \delta \langle \Delta \phi, \Delta h(\cdot, t) \rangle \} dt \\ & = \langle \phi, h_0 \rangle. \end{aligned} \quad (3.17)$$

Now, a comparison of (3.16) and (3.17), together with the arbitrariness of $\phi \in H_{per}^2(\Omega)$, shows that Part (3) in Definition 3.1 is also satisfied. Thus, h is a weak solution.

The uniqueness follows from the stability established in Theorem 3.2. The energy identities can be obtained by setting $\phi = h(\cdot, t)$ and $\phi = \partial_t h(\cdot, t)$ for each $t \in (0, T]$ in (3.4), respectively, and using the definition of $E_1(h)$ and $E_2(h)$. \square

Proof of Theorem 3.2 Let $w = g - h$. Since g and h are two weak solutions, we have for any $\phi \in H_{per}^2(\Omega)$ and a.e. $t \in (0, T)$ that

$$\langle \phi, \partial_t w \rangle + \langle \nabla \phi, (G(|\nabla g|^2) \nabla g - G(|\nabla h|^2) \nabla h) \rangle - \langle \nabla \phi, \nabla w \rangle + \delta \langle \Delta \phi, \Delta w \rangle = 0.$$

Since $w \in L^2(0, T; H_{per}^2(\Omega))$ and $\partial_t w \in L^2(0, T; L^2(\Omega))$, $\frac{d}{dt} \langle w, w \rangle = 2 \langle w, \partial_t w \rangle$ (cf. [8, Theorem 2, Section 5.9]). Setting $\phi = w(\cdot, t)$ for each $t \in (0, T]$ and applying Lemma 3.3 with $a = \nabla g$ and $b = \nabla h$, we deduce that

$$\frac{1}{2} \frac{d}{dt} \|w\|^2 - \|\nabla w\|^2 + \delta \|\Delta w\|^2 \leq 0, \quad \text{a.e. } t \in (0, T).$$

But, by integration by parts, the Cauchy–Schwarz inequality, and Young’s inequality,

$$\|\nabla w\|^2 = -\langle w, \Delta w \rangle \leq \|w\| \|\Delta w\| \leq \frac{1}{2\delta} \|w\|^2 + \frac{\delta}{2} \|\Delta w\|^2.$$

This implies that

$$\frac{d}{dt} \|w\|^2 - \frac{1}{2\delta} \|w\|^2 + \frac{\delta}{2} \|\Delta w\|^2 \leq 0 \quad \text{a.e. } t \in (0, T).$$

The desired inequality now follows from the Gronwall inequality. \square

Proof of Theorem 3.3 Since the unique weak solution is a weak limit of finite-dimensional approximations whose bounds are established in Theorems 4.1 and 4.2, the assertion of theorem follows. □

4 Galerkin spectral approximations

In this section, we define Galerkin spectral approximations, and prove bounds and error estimates for such approximations.

Theorem 4.1 (Galerkin spectral approximations) *Let $h_0 \in H_{per}^2(\Omega)$. For each integer $N \geq 1$, there exists a unique $h_N : \Omega \times [0, T] \rightarrow \mathbb{R}$ such that*

- (1) $h_N \in C^\infty(\bar{\Omega} \times [0, T])$ and $h_N(\cdot, t) \in H_N$ for any $t \in [0, T]$;
- (2) for any $\phi \in H_N$ and any $t \in (0, T]$,

$$\langle \phi, \partial_t h_N \rangle + \langle \nabla \phi, (G(|\nabla h_N|^2) - 1) \nabla h_N \rangle + \delta \langle \Delta \phi, \Delta h_N \rangle = 0; \tag{4.1}$$

- (3) $h_N(\cdot, 0) = \mathcal{P}_N h_0$;
- (4)

$$\|h_N\|_{L^\infty(0,T;H^2(\Omega))} + \|\partial_t h_N\|_{L^2(0,T;L^2(\Omega))} \leq C. \tag{4.2}$$

We shall call $h_N : [0, T] \rightarrow H_N$ for each $N \geq 1$ the (semi-discrete) Galerkin spectral approximation of the weak solution $h : \Omega \times [0, T] \rightarrow \mathbb{R}$ of the initial-boundary-value problem (3.1)–(3.2).

Theorem 4.2 (Bounds for Galerkin spectral approximations) *Let $h_0 \in H_{per}^m(\Omega)$ for some integer $m \geq 2$. For each integer $N \geq 1$, let $h_N : [0, T] \rightarrow H_N$ be the Galerkin spectral approximation of the weak solution $h : \Omega \times [0, T] \rightarrow \mathbb{R}$ of the initial-boundary-value problem (3.1)–(3.2). Then,*

$$\|h_N\|_{L^\infty(0,T;H^m(\Omega))} + \|h_N\|_{L^2(0,T;H^{m+2}(\Omega))} + \|\partial_t h_N\|_{L^2(0,T;H^{m-2}(\Omega))} \leq C. \tag{4.3}$$

Theorem 4.3 (Error estimates) *Let $m \geq 4$ be an integer and $h \in L^\infty(0, T; H^m(\Omega))$ be a weak solution of the initial-boundary-value problem (3.1)–(3.3). For each integer $N \geq 1$, let $h_N : [0, T] \rightarrow H_N$ be the Galerkin spectral approximation of h . Then, we have*

$$\|h - h_N\|_{L^\infty(0,T;L^2(\Omega))} + \|h - h_N\|_{L^2(0,T;H^2(\Omega))} \leq CN^{-m},$$

where the constant C can depend upon the solution h .

Proof of Theorem 4.1 Let $s(N) = \dim(H_N)$ and $\{\phi_j\}_{j=1}^{s(N)}$ be an orthonormal basis of H_N with respect to the $L^2(\Omega)$ inner product. Consider

$$h_N(x, t) = \sum_{j=1}^{s(N)} a_j(t) \phi_j(x)$$

with some functions $a_j = a_j(t)$ ($1 \leq j \leq s(N)$) to be determined. Set $\phi = \phi_j$ in (4.1) for each j ($1 \leq j \leq s(N)$) and use the orthogonality of $\{\phi_j\}_{j=1}^{s(N)}$ to obtain

$$a'_j(t) = f_j(a_1(t), \dots, a_{s(N)}(t)), \quad j = 1, \dots, s(N), \quad (4.4)$$

where all $f_j: \mathbb{R}^{s(N)} \rightarrow \mathbb{R}$ ($1 \leq j \leq s(N)$) are smooth and locally Lipschitz. Set

$$a_j(0) = \langle h_0, \phi_j \rangle, \quad j = 1, \dots, s(N), \quad (4.5)$$

which is equivalent to Part (3). It follows from the theory for initial-value problems of ordinary differential equations that there exists $T_N > 0$ such that the initial-value problem, (4.4) and (4.5), has a unique smooth solution $(a_1(t), \dots, a_{s(N)}(t))$ for $t \in [0, T_N]$.

For each $t \in [0, T_N]$, set $\phi = h_N(\cdot, t) \in H_N$ in (4.1) and use Lemma 3.1 together with Young's inequality to get

$$\frac{1}{2} \frac{d}{dt} \|h_N\|^2 + \int_{\Omega} |\nabla h_N|^2 G(|\nabla h_N|^2) dx + \delta \|\Delta h_N\|^2 = \|\nabla h_N\|^2 \leq \frac{C}{2} \|h_N\|^2 + \frac{\delta}{2} \|\Delta h_N\|^2.$$

Multiply both sides of the inequality by $2e^{-Ct}$ and integrate against t to deduce that

$$\|h_N(\cdot, t)\|^2 + \int_0^t \int_{\Omega} |\nabla h_N|^2 G(|\nabla h_N|^2) dx + \|\Delta h_N\|_{L^2(0,T;L^2(\Omega))}^2 \leq C(1 + e^{CT}) \quad (4.6)$$

for all $t \in [0, T_N]$. This, together with the orthogonality of $\{\phi_j\}_{j=1}^{s(N)}$, implies that

$$\sum_{j=1}^{s(N)} [a_j(t)]^2 = \|h_N(\cdot, t)\|^2 \leq C(1 + e^{CT}) \quad \forall t \in [0, T_N].$$

The solution $(a_1(t), \dots, a_{s(N)}(t))$ of the initial-value problem, (4.4) and (4.5), is thus bounded on $[0, T_N]$, and hence can be uniquely extended to a smooth solution over $[0, \infty)$. Parts (1)–(3) are proved.

Replacing T_N by T in (4.6) and applying Lemma 3.1, we then obtain that

$$\|h_N\|_{L^\infty(0,T;L^2(\Omega))} + \|h_N\|_{L^2(0,T;H^2(\Omega))} \leq C. \quad (4.7)$$

Set now $\phi = \partial_t h_N(\cdot, t)$ in (4.1) to get for any $t \in [0, T]$ that

$$\|\partial_t h_N\|^2 + \frac{d}{dt} E(h(\cdot, t)) = 0,$$

where $E(h) = E_1(h)$ for Eq. (1.1) (without slope selection) and $E(h) = E_2(h)$ for Eq. (1.2) (with slope selection). Integrating against t , noting that $\ln(1+s) \leq s$ for all $s \geq 0$, and using Lemma 3.1, (4.7), and Young's inequality, we obtain that

$$\|\partial_t h\|_{L^2(0,T;L^2(\Omega))}^2 + \|h_N\|_{L^\infty(0,T;H^2(\Omega))}^2 \leq C.$$

This and (4.7) imply (4.2). Part (4) is proved. \square

Proof of Theorem 4.2 We proceed by induction on $m \geq 2$. Assume $m = 2$. Denote by ∂ any first-order spatial partial derivative. Set $\phi = \partial^2 h_N(\cdot, t) \in H_N$ in (4.1) for each $t \in (0, T]$ and integrate by parts to get

$$\frac{1}{2} \frac{d}{dt} \|\partial h_N\|^2 + \int_{\Omega} \nabla \partial h_N \cdot \partial [G(|\nabla h_N|^2) \nabla h_N] dx - \|\nabla \partial h_N\|^2 + \delta \|\Delta \partial h_N\|^2 = 0.$$

Since

$$\nabla \partial h_N \cdot \partial [G(|\nabla h_N|^2) \nabla h_N] = |\nabla \partial h_N|^2 G(|\nabla h_N|^2) + 2 (\nabla \partial h_N \cdot \nabla \partial h_N)^2 G'(|\nabla h_N|^2) \geq 0,$$

we obtain by integrating over $t \in [0, T]$ and using Lemmas 3.1, 3.2, and (4.2) that

$$\|h_N\|_{L^2(0,T;H^3(\Omega))} \leq C. \tag{4.8}$$

Similarly, using $\phi = \Delta^2 h_N(\cdot, t) \in H_N$ for $t \in (0, T)$, we get by Lemma 3.2, (4.2), (4.8), the generalized Hölder inequality, and the Sobolev embedding $H^1(\Omega) \hookrightarrow L^6(\Omega)$ that

$$\begin{aligned} \delta \int_0^T \|\Delta^2 h_N\|^2 dt &\leq C + \int_0^T \int_{\Omega} |\Delta^2 h_N \nabla \cdot (G(|\nabla h_N|^2) \nabla h_N)| dx dt \\ &\leq C + C \int_0^T \int_{\Omega} |\Delta^2 h_N| |\nabla h_N|^2 |\nabla^2 h_N| dx dt \\ &\leq C + C \int_0^T \|\Delta^2 h_N\| \|h_N\|_{W^{1,6}(\Omega)}^2 \|h_N\|_{W^{2,6}(\Omega)} dt \\ &\leq C + C \int_0^T \|\Delta^2 h_N\| \|h_N\|_{H^2(\Omega)}^2 \|h_N\|_{H^3(\Omega)} dt \\ &\leq C + \frac{\delta}{2} \int_0^T \|\Delta^2 h_N\|^2 dt + C \|h_N\|_{L^2(0,T;H^3(\Omega))}^2. \end{aligned} \tag{4.9}$$

The estimate (4.3) for $m = 2$ now follows from Lemma 3.1, (4.9), and (4.2).

We now prove (4.3) for $m \geq 3$ under the assumption that $h_0 \in H_{per}^m(\Omega)$ and

$$\|h_N\|_{L^\infty(0,T;H^{m-1}(\Omega))} + \|h_N\|_{L^2(0,T;H^{m+1}(\Omega))} + \|\partial_t h_N\|_{L^2(0,T;H^{m-3}(\Omega))} \leq C. \tag{4.10}$$

Setting $\phi = (\partial^m)^2 h_N(\cdot, t) \in H_N$ in (4.1) for each $t \in (0, T]$, integrating by parts in space, and integrating over $[0, T]$ in time, we have by Lemmas 3.1, 3.2, and (4.10) that

$$\begin{aligned} &\|h_N\|_{L^\infty(0,T;H^m(\Omega))}^2 + \|h_N\|_{L^2(0,T;H^{m+2}(\Omega))}^2 \\ &\leq C + C \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-1} [G(|\nabla h_N|^2) \nabla h_N]| dx dt \\ &\leq C + C \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^m h_N| |G(|\nabla h_N|^2)| dx dt \\ &\quad + C \sum_{l=1}^{m-1} \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-l} h_N| |\nabla^l [G(|\nabla h_N|^2)]| dx dt. \end{aligned} \tag{4.11}$$

It follows from the generalized Hölder inequality, the Sobolev embedding $H^{m+1}(\Omega) \hookrightarrow W^{m+1,6}(\Omega)$, and the assumption (4.10) that

$$\begin{aligned} & \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^m h_N| |G(|\nabla h_N|^2)| \, dx \, dt \\ & \leq C \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^m h_N| |\nabla h_N|^2 \, dx \, dt \\ & \leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \|h_N\|_{W^{m,6}(\Omega)} \|h_N\|_{W^{1,6}(\Omega)}^2 \, dt \\ & \leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \|h_N\|_{H^{m+1}(\Omega)} \|h_N\|_{H^m(\Omega)}^2 \, dt \\ & \leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \|h_N\|_{H^{m+1}(\Omega)} \, dt. \end{aligned}$$

This, together with (4.10), (4.11), and Young's inequality, leads to

$$\begin{aligned} & \|h_N\|_{L^\infty(0,T;H^m(\Omega))}^2 + \|h_N\|_{L^2(0,T;H^{m+2}(\Omega))}^2 \\ & \leq C \sum_{l=1}^{m-1} \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-l} h_N| |\nabla^l [G(|\nabla h_N|^2)]| \, dx \, dt. \end{aligned} \quad (4.12)$$

Assume first that $m = 3$. Since $d/(d+3) \in (0, 1/2)$, we can use the Gagliardo–Nirenberg inequality [22, Theorem 1, Section 1.4.8] and the Sobolev embedding to get

$$\|h_N\|_{W^{2,6}(\Omega)} \leq C \|h_N\|_{W^{3,6}(\Omega)}^{d/(d+3)} \|h_N\|_{H^2(\Omega)}^{3/(d+3)} \leq C \|h_N\|_{H^4(\Omega)}^{1/2} \|h_N\|_{H^2(\Omega)}^{3/(d+3)}.$$

Consequently, direct calculations, the generalized Hölder inequality, the Sobolev embedding, and the assumption (4.10) imply that

$$\begin{aligned} & \sum_{l=1}^{m-1} \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-l} [G(|\nabla h_N|^2) \nabla h_N]| \, dx \, dt \\ & \leq C \int_0^T \int_{\Omega} (|\nabla^5 h_N| |\nabla^2 h_N|^2 |\nabla h_N| + |\nabla^5 h_N| |\nabla^3 h_N| |\nabla h_N|^2) \, dx \, dt \\ & \leq C \int_0^T \|h_N\|_{H^5(\Omega)} \left(\|h_N\|_{W^{2,6}(\Omega)}^2 \|h\|_{W^{1,6}(\Omega)} + \|h\|_{W^{3,6}(\Omega)} \|h\|_{W^{1,6}(\Omega)}^2 \right) \, dt \quad (4.13) \\ & \leq C \int_0^T \|h_N\|_{H^5(\Omega)} \|h_N\|_{H^4(\Omega)} \left(\|h\|_{H^2(\Omega)}^{(d+9)/(d+3)} + \|h\|_{H^2(\Omega)}^2 \right) \, dt \\ & \leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \|h_N\|_{H^{m+1}(\Omega)} \, dt \end{aligned}$$

Now assume that $m \geq 4$. Notice from (4.10) and the Sobolev embedding $H^2(\Omega) \hookrightarrow L^\infty(\Omega)$ that $|\nabla^k h_N(x)| \leq C$ if $k \leq m - 3$. Thus, since the highest order of derivatives in

$\partial^l[G(|\nabla h_N|^2)]$ is $l + 1$, all $|\nabla^l[G(|\nabla h_N|^2)]| \leq C$ with $l \leq m - 4$. Consequently,

$$\begin{aligned} & \sum_{l=1}^{m-1} \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-l} h_N| |\nabla^l[G(|\nabla h_N|^2)]| dx dt \\ & \leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \|h_N\|_{H^{m+1}(\Omega)} dt \\ & \quad + C \sum_{l=m-3}^{m-1} \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-l} h_N| |\nabla^l[G(|\nabla h_N|^2)]| dt, \end{aligned}$$

which, together with (4.12), leads to

$$\begin{aligned} & \|h_N\|_{L^\infty(0,T;H^m(\Omega))}^2 + \|h_N\|_{L^2(0,T;H^{m+2}(\Omega))}^2 \\ & \leq C \sum_{l=m-3}^{m-1} \int_0^T \int_{\Omega} |\nabla^{m+2} h_N| |\nabla^{m-l} h_N| |\nabla^l[G(|\nabla h_N|^2)]| dx dt. \end{aligned} \tag{4.14}$$

Applying Lemma 3.4 and repeatedly using the fact that $|\nabla^k h_N| \leq C$ for $k \leq m - 3$, we obtain by a series of calculations that

$$\begin{aligned} |\nabla^{m-3}[G(|\nabla h_N|^2)]| & \leq C |\nabla^{m-3}(|\nabla h_N|^2)| \leq C \sum_{j=2}^{m-2} |\nabla^j h_N|, \\ |\nabla^{m-2}[G(|\nabla h_N|^2)]| & \leq C |\nabla^{m-2}(|\nabla h_N|^2)| + C |\nabla^{m-3}(|\nabla h_N|^2)| |\nabla(|\nabla h_N|^2)| \\ & \leq C \left(\sum_{j=2}^{m-2} |\nabla^j h_N| \right) |\nabla^2 h_N| + \sum_{j=3}^{m-1} |\nabla^j h_N|, \\ |\nabla^{m-1}[G(|\nabla h_N|^2)]| & \leq C |\nabla^{m-1}(|\nabla h_N|^2)| + C |\nabla^{m-2}(|\nabla h_N|^2)| |\nabla(|\nabla h_N|^2)| \\ & \quad + C |\nabla^{m-3}(|\nabla h_N|^2)| [|\nabla(|\nabla h_N|^2)|^2 + |\nabla^2(|\nabla h_N|^2)|] \\ & \leq C \sum_{j=4}^m |\nabla^j h_N| + C \left(\sum_{j=3}^{m-1} |\nabla^j h_N| \right) |\nabla^2 h_N| \\ & \quad + C \left(\sum_{j=2}^{m-2} |\nabla^j h_N| \right) (|\nabla^2 h_N|^2 + |\nabla^3 h_N|). \end{aligned}$$

It thus follows from (4.14), the generalized Hölder inequality, the Sobolev embedding, and (4.10) that

$$\begin{aligned} & \|h_N\|_{L^\infty(0,T;H^m(\Omega))}^2 + \|h_N\|_{L^2(0,T;H^{m+2}(\Omega))}^2 \\ & \leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} (\|h_N\|_{W^{m-1,4}(\Omega)} \|h_N\|_{W^{m-2,4}(\Omega)} \\ & \quad + \|h_N\|_{W^{m-2,6}(\Omega)} \|h_N\|_{W^{m-2,6}(\Omega)} \|h_N\|_{H^m(\Omega)}) dt \end{aligned}$$

$$\begin{aligned} &\leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \left(\|h_N\|_{H^m(\Omega)} \|h_N\|_{H^{m-1}(\Omega)} + \|h_N\|_{H^{m-1}(\Omega)}^2 \|h_N\|_{W^{m-1,6}(\Omega)} \right) dt \\ &\leq C \int_0^T \|h_N\|_{H^{m+2}(\Omega)} \|h_N\|_{H^{m+1}(\Omega)} dt. \end{aligned}$$

This, together with (4.12), (4.13), Young's inequality, and (4.10), implies that

$$\|h_N\|_{L^\infty(0,T;H^m(\Omega))} + \|h_N\|_{L^2(0,T;H^{m+2}(\Omega))} \leq C. \quad (4.15)$$

Finally, setting $\phi = (\partial^{m-2})^2 \partial_t h_N(\cdot, t) \in H_N$ in (4.1) for each $t \in (0, T]$ and then integrating against t , we have by integration by parts and using (4.10), (4.15), and Lemma 3.2 that

$$\|\partial_t h_N\|_{L^2(0,T;H^{m-2}(\Omega))}^2 \leq C + C \int_0^T \int_\Omega |\nabla^{m-2} \partial_t h_N| |\nabla^{m-1} [G(|\nabla h_N|^2) \nabla h_N]| dx dt.$$

Comparing this with (4.11), we obtain by the same argument used above that

$$\|\partial_t h\|_{L^2(0,T;H^{m-2}(\Omega))} \leq C.$$

which, together with (4.15) imply (4.3) for $m \geq 3$. \square

Proof of Theorem 4.3 Fix $N \geq 1$. A direct calculation using Fourier expansion implies that

$$\|h - \mathcal{P}_N h\|_{L^2(\Omega)} \leq CN^{-m} \|h\|_{H^m(\Omega)} \quad \text{a.e. } t \in (0, T). \quad (4.16)$$

By the definition of $\mathcal{P}_N : L^2(\Omega) \rightarrow H_N$ and (3.4), we have for any $\phi \in H_N$ that

$$\begin{aligned} &\langle \phi, \partial_t \mathcal{P}_N h \rangle + \langle \nabla \phi, G(|\nabla \mathcal{P}_N h|^2) \nabla \mathcal{P}_N h \rangle - \langle \nabla \phi, \nabla \mathcal{P}_N h \rangle + \delta \langle \Delta \phi, \Delta \mathcal{P}_N h \rangle \\ &= \langle \nabla \phi, G(|\nabla \mathcal{P}_N h|^2) \nabla \mathcal{P}_N h - G(|\nabla h|^2) \nabla h \rangle \quad \text{a.e. } t \in (0, T). \end{aligned}$$

With $w_N = \mathcal{P}_N h(\cdot, t) - h_N(\cdot, t) \in H_N$ for $t \in (0, T)$, this, together with (4.1), leads to

$$\begin{aligned} &\langle \phi, \partial_t w_N \rangle + \langle \nabla \phi, G(|\nabla \mathcal{P}_N h|^2) \nabla \mathcal{P}_N h - G(|\nabla h_N|^2) \nabla h_N \rangle - \langle \nabla \phi, \nabla w_N \rangle + \delta \langle \Delta \phi, \Delta w_N \rangle \\ &= \langle \nabla \phi, G(|\nabla \mathcal{P}_N h|^2) \nabla \mathcal{P}_N h - G(|\nabla h|^2) \nabla h \rangle \quad \text{a.e. } t \in (0, T). \end{aligned}$$

Setting $\phi = w_N \in H_N$, applying Lemma 3.3 with $a = \nabla \mathcal{P}_N h$ and $b = \nabla h_N$, the Cauchy-Schwarz inequality, the Sobolev embedding $H^4(\Omega) \hookrightarrow W^{2,\infty}(\Omega)$, and Lemma 3.2, we have

$$\begin{aligned} &\frac{1}{2} \frac{d}{dt} \|w_N\|^2 - \|\nabla w_N\|^2 + \delta \|\Delta w_N\|^2 \\ &\leq |\langle \nabla w_N, [G(|\nabla \mathcal{P}_N h|^2) - G(|\nabla h|^2)] \nabla \mathcal{P}_N h \rangle| + |\langle \nabla w_N, G(|\nabla h|^2) \nabla (\mathcal{P}_N h - h) \rangle| \\ &= |\langle (\nabla w_N \cdot \nabla \mathcal{P}_N h), G(|\nabla \mathcal{P}_N h|^2) - G(|\nabla h|^2) \rangle| + |G(|\nabla h|^2) \nabla w_N, \nabla (\mathcal{P}_N h - h)| \\ &= |\langle \nabla \cdot [(\nabla w_N \cdot \nabla \mathcal{P}_N h) \mathcal{Q}_N], \mathcal{P}_N h - h \rangle| + |\nabla \cdot [G(|\nabla h|^2) \nabla w_N], \mathcal{P}_N h - h|, \end{aligned}$$

where

$$Q_N = \begin{cases} \frac{\nabla \mathcal{P}_N h + \nabla h}{(1 + |\nabla \mathcal{P}_N|^2)(1 + |\nabla h|^2)} & \text{if } G = G_1, \\ \nabla \mathcal{P}_N + \nabla h & \text{if } G = G_2. \end{cases}$$

Therefore,

$$\begin{aligned} & \frac{1}{2} \frac{d}{dt} \|w_N\|^2 - \|\nabla w_N\|^2 + \delta \|\Delta w_N\|^2 \\ & \leq C \left(\|h\|_{W^{2,\infty}(\Omega)}^2 + \|\mathcal{P}_N h\|_{W^{2,\infty}(\Omega)}^2 \right) \|\mathcal{P}_N h - h\| (\|\nabla w_N\| + \|\Delta w_N\|) \\ & \leq C \|\mathcal{P}_N h - h\| \|\nabla w_N\| + C \|\mathcal{P}_N h - h\| \|\Delta w_N\| \\ & \leq C \|\mathcal{P}_N h - h\|^2 + C \|\nabla w_N\|^2 + \frac{\delta}{2} \|\Delta w_N\|^2 \quad \text{a.e. } t \in (0, T). \end{aligned}$$

This, together with Lemma 3.1 and Young’s inequality, implies that

$$\begin{aligned} \frac{d}{dt} \|w_N\|^2 & \leq C \|\mathcal{P}_N h - h\|^2 + C \|\nabla w_N\|^2 - \delta \|\Delta w_N\|^2 \\ & \leq C \|\mathcal{P}_N h - h\|^2 + C \|w_N\|^2 - \frac{\delta}{2} \|\Delta w_N\|^2, \end{aligned}$$

The desired error estimate now follows from the Gronwall inequality, the fact that $w_N(0) = 0$, and the estimate (4.16). □

5 Numerical simulation

To simulate the growth dynamics numerically, we have developed the following spectral method for the initial-boundary-value problem (3.1)–(3.3).

Step 1: splitting. Rewrite the underlying equation as

$$\left(\partial_t + \frac{\delta}{2} \Delta^2 + \Delta \right) h = A(\nabla h) - \frac{\delta}{2} \Delta^2 h,$$

where $A(\nabla h) = \nabla \cdot [G(|\nabla h|^2)\nabla h]$.

Step 2: spectral approximation. Perform the Fourier transform to get

$$\left(\frac{d}{dt} + \frac{\delta}{2} |k|^4 - |k|^2 \right) \hat{h}_k(t) = \hat{A}_k(t) - \frac{\delta}{2} |k|^4 \hat{h}_k(t) \quad \forall k : |k| \leq \frac{N}{2},$$

where $\hat{h}_k(t)$ and $\hat{A}_k(t)$ with $|k| \leq N/2$ are the Fourier modes at time t of the solution $h(\cdot, t)$ and the nonlinear term $A(\nabla h(\cdot, t))$, respectively, and $N \geq 1$ is a fixed integer.

Step 3: reformulation with integrating factor. Rearrange the ordinary differential equation with an integration factor to get

$$e^{-\left(\frac{\delta}{2}|k|^4 - |k|^2\right)t} \frac{d}{dt} \left[e^{\left(\frac{\delta}{2}|k|^4 - |k|^2\right)t} \hat{h}_k(t) \right] = \hat{A}_k(t) - \frac{\delta}{2} |k|^4 \hat{h}_k(t) \quad \forall k : |k| \leq \frac{N}{2}. \tag{5.1}$$

Step 4: Crank–Nicolson and Adam–Bashforth discretization. Use the Crank–Nicolson and Adam–Bashforth schemes to discretize the surface diffusion and nonlinear terms, respectively, to get

$$\begin{aligned} & e^{-\left(\frac{\delta}{2}|k|^4 - |k|^2\right)t_{n+1/2}} \frac{\left[e^{\left(\frac{\delta}{2}|k|^4 - |k|^2\right)t_{n+1}} \hat{h}_k^{n+1}(t) - e^{\left(\frac{\delta}{2}|k|^4 - |k|^2\right)t_n} \hat{h}_k^n(t) \right]}{\Delta t} \\ &= \frac{3\hat{A}_k^n - \hat{A}_k^{n-1}}{2} - \frac{\delta}{2}|k|^4 \frac{\hat{h}_k^n + \hat{h}_k^{n+1}}{2} \quad \forall k : |k| \leq \frac{N}{2}, \end{aligned}$$

where \hat{h}_k^n and \hat{A}_k^n approximate $\hat{h}_k(t_n)$ and $\hat{A}_k(t_n)$, respectively, t_n is the n -th time step, and Δt is the time stepping. This can be simplified to

$$\begin{aligned} & \frac{e^{\left(\frac{\delta}{2}|k|^4 - |k|^2\right)\frac{\Delta t}{2}} \hat{h}_k^{n+1} - e^{-\left(\frac{\delta}{2}|k|^4 - |k|^2\right)\frac{\Delta t}{2}} \hat{h}_k^n}{\Delta t} \\ &= \frac{3\hat{A}_k^n - \hat{A}_k^{n-1}}{2} - \frac{\delta |k|^4}{4} \left(\hat{h}_k^n + \hat{h}_k^{n+1} \right) \quad \forall k : |k| \leq \frac{N}{2}. \end{aligned}$$

Step 5: solve the system and perform the inverse Fourier transform. This will give the numerical solution at different time steps.

Using this numerical method, we solve the initial-boundary-value problem (3.1)–(3.3) with the parameter $\delta = 0.1$, the space dimension $d = 2$, the domain $\Omega = (0, 2\pi) \times (0, 2\pi)$, and the initial data

$$h_0(x) = 0.1(\sin 3x_1 \sin 2x_2 + \sin 5x_1 \sin 5x_2) \quad x \in \Omega.$$

In this case, the critical modulus of wavevector is $k_c = \sqrt{10}$ (cf. 2.10), and the most unstable modes are those with wavevectors k such that $|k| = \sqrt{5}$. The initial data h_0 consists of only two linearly stable modes $k_1 = (3, 2)$ and $k_2 = (5, 5)$. However, their interaction generates an unstable mode $k_2 - 2k_1 = (-1, 1)$ (2.14).

For a height profile $h = h(x, t)$, we denote its energy by $E(t) = E(h(t))$, where $E(h) = E_1(h)$ in the case without slope selection and $E(h) = E_2(h)$ in the case with slope selection, cf. (1.3) and (1.4). We also define its interface width or roughness by

$$w(t) = \sqrt{\frac{1}{|\Omega|} \int_{\Omega} [h(x, t) - \bar{h}(t)]^2 dx}, \quad \text{where } \bar{h}(t) = \frac{1}{|\Omega|} \int_{\Omega} h(x, t) dx.$$

In our contour plots below, we use the coordinate (x, y) instead of (x_1, x_2) .

5.1 The growth dynamics with slope selection

Figures 5 and 6 show the decay of energy $E(t)$ and the development of profile roughness $w(t)$, respectively. We observe that initially both the energy and roughness decay rapidly. However, after a relatively long period of time, the roughness starts to grow. This is exactly the morphological instability in the rough-smooth-rough pattern that is analyzed

FIGURE 5. The decay of energy for the growth with slope selection.

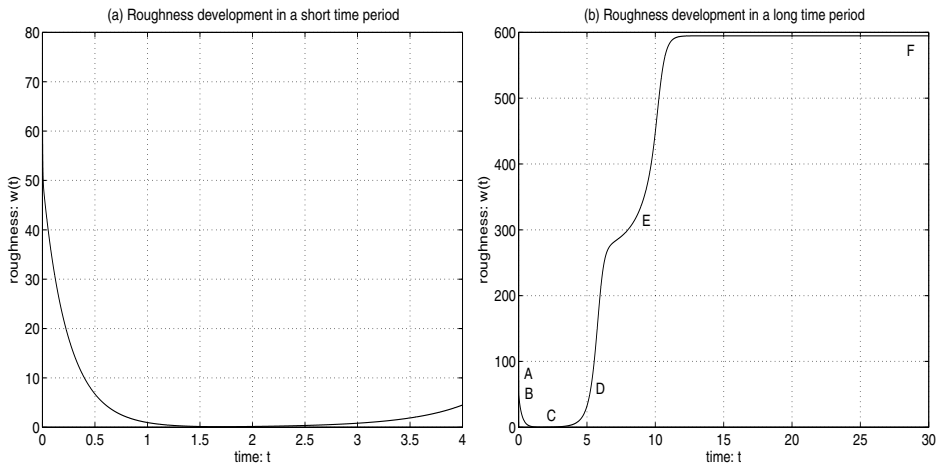

FIGURE 6. The development of roughness for the growth with slope selection.

in §2. Notice that the flat tail in Figures 5(b) and 6(b) indicate that a steady-state solution is reached. The letters A, B, C, D, E and F marked on Figures 5(b) and 6(b) indicate different coarsening stages at time $t = 0, 0.05, 2.5, 5.5, 8,$ and 30 , respectively. There is a structural transition from each stage to the immediate next one.

Figure 7 shows contour plots in grey scale of the height profile h corresponding to the four stages A, B, C, D, E, and F as marked in Figures 5(b) and 6(b). At Stage B, the initial mode $(5, 5)$ has disappeared but $(3, 2)$ still exists. Note that mound or pyramid base boundaries are straightened locally. At Stage C, both of these initially linearly stable modes are gone. However, the mode $(-1, 1)$ which is generated from

FIGURE 7. Contour plots of height profiles for the growth with slope selection.

these modes appears. Observe that at Stage D a new mode (1,2) appears due to further interaction of different modes in the profile. Notice that (1,2) is one of the most unstable modes. But this mode almost disappears at Stage E. Finally, Figure 7(f) shows a steady-state profile which consists mainly of only one mode (1,1). Comparing Figure 7 with

FIGURE 8. Contour plots of gradients for the growth with slope selection.

Figures 5 and 6, we observe that, after the initial preparation, the coarsening dynamics is characterized by a fast structural transition and a very slow motion in between such transitions.

Figure 8 shows contour plots of the profile gradient $|\nabla h|$ at those marked stages.

FIGURE 9. Decay of energy for the growth without slope selection.

FIGURE 10. Development of roughness for the growth without slope selection.

5.2 The growth dynamics without slope selection

Figures 9 and 10 show the decay of energy $E(t)$ and the development of profile roughness $w(t)$, respectively. They are similar to those for the growth dynamics with slope selection. In particular, the initial rough-smooth-rough pattern is the same. But, in this case, the energy becomes negative. The letters A, B, C, D, E, and F marked on Figures 9(b) and 10(b) correspond to different coarsening stages at time $t = 0, 0.05, 2.5, 5.5, 8,$ and 30 , respectively. For the purpose of comparison, we have chosen them to be the same as for the case with slope selection.

Figures 11 and 12 show contour plots of the height profile h and the magnitude of its gradient $|\nabla h|$ at the different stages marked on Figures 11(b) and 12(b). With regards to

FIGURE 11. Contour plots of height profiles for the growth without slope selection.

structural transition in the coarsening, they are similar to those plots in Figures 9 and 10 for the growth dynamics with slope selection. However, from the corresponding grey scale bars, we see clearly that the profile gradient for the growth without slope selection is much larger in magnitude than that for the growth with slope selection.

FIGURE 12. Contour plots of gradients for the growth without slope selection.

6 Conclusions

We have rigorously proved that the initial-boundary-value problem of the growth equation (1.1) or (1.2) is well-posed. Both of our weakly nonlinear analysis and numerical simulation reveal a nonlinear morphological instability in the rough-smooth-rough pattern at an early

stage of growth, agreeing with reported experiments on thin film epitaxy on rough surfaces. In this early stage, linearly stable modes are damped immediately. But their nonlinear interaction possibly generates new unstable modes. Mound or pyramid base boundaries are immediately straightened locally. This is different from phase boundaries in the Cahn–Hilliard coarsening. We have also developed a spectral numerical method for simulating the coarsening dynamics governed by the underlying equations, with or without slope selection. Our numerical results clearly distinguish different stages of coarsening such as the initial preparation and the alternating rapid structural transition and slow motion. They also display a large mound slope that characterizes the coarsening dynamics without slope selection. More simulations with various kinds of initial data with or without noise are required to predict the exact roughness component for both of the growth laws.
